Purpose: The pathological mechanisms of abnormal collagen type IV predisposing to macular hole formation in Alport syndrome are hypothesized to be related to a weakened internal limiting membrane. However, deviant collagen type IV might also predispose to macular hole formation in these patients due to vitreous cortex abnormalities. We aim to describe the posterior vitreous structures visible on optical coherence tomography (OCT) imaging in a case series of patients with collagen type IV mutations.

Methods: An observational case series of OCT-findings in three patients with collagen type IV abnormalities.

Results: In two patients diagnosed with Alport syndrome and in one patient with a possibly pathogenic genetic variant in COL4A3 we observed a remarkable posterior vitreous cortex with a vitreoschisis-like appearance on OCT. One of these patients developed a rhegmatogenous retinal detachment and one patients developed a macular hole.

Conclusions: These vitreous cortex findings are possibly related to abnormal collagen type IV and might additionally be associated with pathological mechanisms of macular hole formation in Alport syndrome. Future studies might confirm the presence of abnormal collagen type IV in the vitreous cortex in macular hole patients with Alport syndrome.

ABSTRACT BODY:

Purpose: CLN2 type Batten Disease is a fatal neurodegenerative condition of childhood that is associated with retinal dystrophy and blindness. Intracerebroventricular infusion of Cerliponase alfa (rhTPP1) greatly slows the rate of neurodegenerative decline but not retinopathy. In 2020 intravitreal administration of rhTPP1 was shown to slow retinal degeneration in a canine model of CLN2. We report on the first-in-man use of intravitreal rhTPP1 for the treatment of CLN2 type Batten Disease associated retinal dystrophy.

Methods: 8 children (4 female) aged 5-9 with genetically and clinically confirmed CLN2 Batten Disease were prospectively enrolled. Patients were selected if they were currently in the retinal degenerative phase of the condition. Enrolled children are undergoing 8-weekly intravitreal injections of rhTPP1 (0.2mg in 0.05ml) into the right eye for a total of 12 to 18 months. The left eye is untreated and acts as a paired control.

The primary outcome is safety based on the clinical detection of intraocular complications and in particular uveitis. A secondary outcome is central foveal thickness (CFT) and paracentral macular thickness (PMT) measured by spectral domain OCT (Heidelberg Spectralis Flex).

Results: Participants have had between 2 and 4 intravitreal injections and 4-6 months of followup so far. No adverse reactions (uveitis, raised IOP or media opacity) have been detected. The mean baseline CFT was 81µm (right), 87µm (left). The CFT has reduced by 16% in right eyes and 20% in left eyes. The mean baseline PMT was 213µm (right), 213µm (left). The PMT has reduced by 4% (right) and 7% (left).

A paired t-test showed that the difference between the rate of foveal and paracentral retinal thinning between left and right eyes was not statistically significant (p= <0.05) at this early stage in the trial.

A statistically significant difference between the PMT over time (but not CFT) was found for both right (p=0.046) and left (p=0.015) eyes (paired t-test).

Conclusions: Intravitreal rhTPP1 appears safe with no evidence of uveitis detected. Rapid retinal thinning is seen in untreated eyes, confirming that patients are in the degenerative phase of the condition. A slower rate of retinal thinning is seen in treated eyes, although a statistically significant difference is not seen at this early stage in the trial.

ABSTRACT BODY:

Purpose: To examine the distribution of nonperfusion areas (NPAs) and its clinical relevance in diabetic retinopathy (DR) of different severities using widefield optical coherence tomography angiography (OCTA).

Methods: One hundred and forty-two eyes in 113 patients with diabetes (27 eyes with no DR [NDR], 71 with nonproliferative DR [NPDR], and 44 eyes with proliferative DR [PDR]) were prospectively participated. We obtained nominal 20 × 23mm (1614 × 1856 pixels) OCTA images using Xephilio OCT-S1. We evaluated NPAs within the 20mm-diameter circle centered on the fovea. After automatic detection of vessel edges using an ImageJ plug-in (Canny edge detection), the image was divided into regions of interest (ROIs) of 10 × 10 pixels, and ROIs without the edges were defined as NPAs. The frequency of the NPAs were calculated for each ROI. The ROIs with greater differences in the frequency than the third quartile were defined as significant areas. We evaluated area under the receiver operating characteristic curve (AUC) for DR severity discrimination using the NPA rates.

Results: The differences in the NPA rates between NDR and NPDR in each ROI were 1.4% (interquartile range [IQR], 0.0-2.7). Within central 10 mm, 34.5%, 13.8%, 7.1%, and 5.2% in temporal, superior, nasal, and inferior quadrants corresponded to the significant areas. The percentages outside it were 36.2%, 27.2%, 27.2%, and 30.3% in individual quadrants. The AUCs of NPA rates in total or significant areas to discriminate NPDR from NDR were 0.772 (95% confidence interval [CI], 0.687-0.856) and 1.000 (95% CI, 1.000-1.000), respectively. Further comparative study revealed that the differences in the NPA rate between NPDR and PDR in each ROI were 5.8 % (IQR, 1.9-10.2). The percentage of significant area was 0.0% in the quadrants other than the temporal subfield within central 10mm, while the percentages of significant area outside it were 39.1%, 36.5%, 19.8%, and 38.7%, respectively. The AUCs of NPA rate was 0.887 (95% CI, 0.828-0.946) and 0.946 (95% CI, 0.906-0.986) in the total and significant areas, respectively.

Conclusions: Clinically significant NPAs on widefield OCTA images might be useful in diagnosing NPDR and PDR as well as suggest the processes of vasoregression in DR.

TITLE: The prevalence of binocular vision dysfunctions in Taiwanese non-presbyopia adults

SESSION TITLE: Visual Function: perception, adaptation, spatial, visual acuity and binocular vision

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Chen, Department of Optometry, Da-Yeh University, Dacun, Changhua, TAIWAN|

Commercial Relationships Disclosure: Yayu Chen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Refractive error is associated with binocular vision dysfunctions. Although the myopia rate of young adults in Taiwan has already reached nearly 90%[1], the prevalence of binocular vision dysfunctions in Taiwan is still unclear. Thus, the purpose of this study is to investigate the prevalence of binocular vision dysfunctions in non-presbyopia adults in Taiwan.

Methods: A total of 107 healthy non-presbyopia adults aged between 20 to 40 years old were included in this study. All participants were corrected refractive errors and examined accommodative tests and binocular vision tests. The collected data were analyzed and categorized into 7 types of vergence dysfunctions and 2 types of accommodative dysfunctions by using the diagnostic criteria of Ma et el.[2]

Results: The results showed that 48.6% of all participants were normal binocular vision and 51.4% were abnormal binocular vision (including vergence dysfunctions and accommodative dysfunctions). In the vergence dysfunctions, there were 15.0% were basic exophoria (BXO), 8.4% were convergence insufficiency (CI), 5.6% were divergence insufficiency (DI), 3.7% were fusional vergence dysfunction (FVD), 2.8% were basic esophoria (BSO), 1.9% were convergence excess (CE), and 1.9% were divergence excess (DE). In the accommodative dysfunctions, there were 8.4% were accommodative insufficiency (AI) and 3.7% were accommodative infacility (AIF).

Conclusions: In conclusions, this study indicated that 39.3% of the participants were vergence dysfunctions and 12.1% were accommodative dysfunctions. BXO and AI is the most common type in vergence dysfunctions and accommodative dysfunctions, respectively.

ABSTRACT BODY:

Purpose: Reliable mild photocoagulation and selective retina therapy (SRT) selectively damaging the retinal pigment epithelium (RPE) while sparing the neuroretina, the photoreceptors as well as the choroid are highly demanded. However, due to the inter- and intraindividual variability of RPE and choroidal absorption, optical microsurgery requires reliable real-time laser dosing to prevent unwanted overexposure and extended damage of the neuroretina. In this experiment optical coherence tomography (OCT) was implemented to detect minimal damage, and a laser feedback control algorithm was used for real-time dosing. For the first time in-vivo experiments on rabbits were performed with microsecond laser pulses of varying duration.

Methods: Pigment rabbit eyes (n=6) were exposed to laser pulses of 4, 8, 12, and 20 µs in duration (wavelength, 532 nm; ramp-mode, maximum 15 pulses; repetition rate, 100 Hz). Therefore, a system with a scanning laser ophthalmoscope and spectral-domain OCT (Heidelberg Engineering) extended with a prototype laser (Meridian Medical) was used. For each laser lesion, the increasing ramp's end energy was individually controlled in real-time using OCT dosimetry (central wavelength, 870 nm; scan rate, 80 kHz). Within 1 hour after irradiation, retinal changes were assessed with fluorescein angiography (FA), indocyanine green angiography (ICGA), color fundus photography (CFP) and OCT.

Results: OCT dosimetry utilizing the control algorithm can interrupt the ramp-mode in real-time for each lesion individually. The preconditioned algorithm enabled treatment with a clearly visible breakdown of the blood-retinal barrier (BRB) according to FA and ICGA imaging and barely visible treatment lesions according to CFP. OCT B-scans through the treated areas provided a first indication of the morphological tissue impact. Preliminary evaluation shows that the algorithm stopped the laser at 4 µs at a ramp end energy of 53 µJ (corresponds to 13/15 pulses), at 8 µs at 68 µJ (5/15 pulses), at 12 µs at 74 µJ (7/15 pulses), and at 20 µs at 100 µJ (1/15 pulses).

Conclusions: The novel system with OCT based laser dosing proved to induce minimal visible damage and BRB breakdown in a wide range of pulse durations. The new irradiation scheme and algorithm are being optimized and tested in multiple subjects to further limit unwanted damage and enable pure RPE selective laser microsurgery in real-time.

ABSTRACT BODY:

Purpose: Evidence from literature demonstrates that exogenous administration of hydrogen sulfide (H_2S) decreases inflammation in retinal pigment epithelial cells exposed to homocysteine (Ravi et al. 2021, EER 212:108759). Since lipopolysaccharide (LPS) has been reported to induce inflammation in cultured human iris-ciliary body (ICB) explants (Brito et al. 2004, EER 79:203), we investigated the pharmacological actions of H_2S-releasing compounds on LPS-induced inflammation in cultured porcine ICB explants (using Tumor Necrosis Factor-alpha, TNFα, as a marker).

Methods: Freshly isolated porcine ICB explants were cut into quadrants and cultured in Roswell Park Memorial Institute (RPMI) 1640 medium containing 1% penicillin-streptomycin. Explants were then exposed to different concentrations of LPS for 20 h. When used, H_2S-releasing compounds, sodium hydrosulfide (NaHS) and GYY4137 were added to media 15 mins and 30 mins, respectively, before the end of the incubation period. Concentrations of TNFα in culture supernatants were measured using ELISA kit purchased from Sigma-Aldrich.

Results: Different concentration of LPS tested elicited increases in TNFα production in cultured ICB explants over basal levels (7.21 ± 0.29 ng/g; n = 6). For instance, LPS 10 ng/ml, 25 ng/ml, and 50 ng/ml enhanced TNFα production up to 10.36 ± 0.23 ng/g (n = 6), 12.32 ± 0.40 ng/g (n = 5) and 11.80 ± 1.11 ng/g (n = 5), respectively. In the presence of LPS (25 ng/ml), a fast-releasing H_2S compound, NaHS (5 μM and 50 μM) caused significant ($p < 0.001$) decreases in LPS-induced TNFα production by 22.7 % ± 3.6 % (n = 6) and 26.5 % ± 5.3 % (n = 5), respectively. Likewise, the slow-releasing H_2S compound, GYY4137 (1 μM and 10 μM) evoked significant ($p < 0.001$) reductions of LPS-induced TNFα production by 25.0 % ± 3.7 % (n =5) and 19.9% ± 1.8 % (n = 4), respectively.

Conclusions: We conclude that LPS can induce an inflammatory response in the cultured porcine ICB explants. Both fast- and slow-releasing H_2S compounds reduced LPS-induced TNFα production in the ICB explants suggesting an anti-inflammatory action of this gas in the anterior uvea.

ABSTRACT BODY:

Purpose: Various carriers for the Boston Keratoprosthesis (KPro) have been proposed, however the optimal parameters of these grafts remain to be elucidated. One important parameter is the thickness of the carrier grafts. We examine the impact of corneal thickness on aqueous leak after KPro implantation in Life4C-preserved fresh corneal grafts.

Methods: Using a femtosecond laser, corneal donor buttons were mounted on an artificial anterior chamber and cut to various thicknesses. Anterior segment OCT was used to measure the thickness before and after the cut creation. A dermatologic punch was used to make a central hole and the KPro was assembled in the standard fashion. The assembled corneal construct was mounted onto the anterior chamber which was attached to a phacoemulsification machine with the intraocular pressure (IOP) set at the lowest setting of 20 mmHg. The IOP was gradually increased and a fluorescein strip was used to check Seidel positivity.

Results: The thicknesses of the tested corneal grafts were measured to be 79 µm, 242 µm, 389 µm, 414 µm, 435 µm, and 702 µm. When connected to the phacoemulsification machine, the fresh corneas of 79 µm and 242 µm were Seidel positive at 20 mmHg, while the remaining fresh corneas remained Seidel negative even at maximal IOP (80 mmHg).

Conclusions: A minimal corneal carrier graft thickness between 242 µm and 435 µm is required to avoid intraoperative leak during KPro implantation using fresh corneas. This is thinner than our previously reported range for ethanol-preserved corneas. Additional experiments are needed to further narrow down this range and compare to preserved carrier grafts.

TITLE: Structural Organization of the Sclera in Chicks after Deprivation Myopia Measured Using Second Harmonic Generation Microscopy

SESSION TITLE: Mechanisms of Refractive Error and Eye Development

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.M. Bueno, R. Martinez-Ojeda, E.J. Fernandez, P. Artal, Universidad de Murcia, Murcia, Murcia, SPAIN|M.P. Feldkaemper, Universitatsklinikum Tubingen Forschungsinstitut fur Augenheilkunde, Tubingen, Baden-Württemberg, GERMANY|

Commercial Relationships Disclosure: Juan Bueno: Commercial Relationship: Code N (No Commercial Relationship) | Rosa Martinez-Ojeda: Commercial Relationship: Code N (No Commercial Relationship) | Enrique Fernandez: Commercial Relationship: Code N (No Commercial Relationship) | Marita Feldkaemper: Commercial Relationship: Code N (No Commercial Relationship) | Pablo Artal: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The outer layer of the sclera is a dense connective tissue mainly composed of collagen fibers. Abnormal eye growth during myopia progression is associated with extracellular matrix (ECM) restructuring and scleral thinning. Second Harmonic Generation (SHG) microscopy allows visualizing collagen-based tissues without the use of markers. In this work, we obtained SHG images from scleral tissues to objectively quantify possible changes in collagen organization as a function of different amounts of induced deprivation myopia in chicks.

Methods: A SHG microscope operating in backscattering-mode was used to image chick scleral tissues in 26 eyes from areas close to the optic nerve head. Unstained scleral punches of both control and deprived (mean refraction=-8D) eyes were used in the experiment. Myopia was induced by placing a translucent diffuser in one of the chickens' eyes for one week. Two SHG imaging modalities were employed: Tomographic (XZ or YZ), and regular XY images. The former allowed direct estimation of the scleral thickness, while the latter were used to characterize the collagen fiber structural dispersion by means of Fourier and Radon transforms.

Results: Scleral collagen fibers provided strong SHG signals for analysis. We did not find differences in scleral thickness as a function of ocular refraction. On the opposite, fiber structural dispersion significant increased with refraction (R=0.48, p=0.01) and decreased with axial length (R=0.67, p=0.0002). The structure of scleral collagen fibers ranged between a non-organized and a quasi-aligned (with a dominant direction of the fibers) distribution.

Conclusions: SHG microscopy imaging provided a high-resolution visualization of individual collagen fibers of the chicken sclera with different levels of induced myopia. A significant decrease in fiber structural dispersion was associated to a higher myopic refraction. Nevertheless, the thickness of the control sclerae and that of deprived eyes were similar. This technique allows quantifying alterations during myopia induction, providing a useful tool for a better understanding of the emmetropization processes.

ABSTRACT BODY:

Purpose: The role of glial cell line-derived neurotrophic factor (GDNF) in pathogenesis of primary open-angle glaucoma (POAG) is not clear. The aim of the study was to measure the content of GDNF in the aqueous humor, lacrimal fluid, and blood serum in patients with POAG and age-related cataract.

Methods: We examined 30 patients (30 eyes) with POAG and age-related cataract. Forty-seven previously examined patients of similar age and sex with age-related cataract (47 eyes) served as a control (Shpak AA, et al. IOVS 2021, 62; ARVO e-abstract 718). Collection of stimulated lacrimal fluid was performed by a pipette on the day preceding surgery; the aqueous humor of the anterior chamber and the blood were sampled during the phacoemulsification of a cataract. The concentration of GDNF was measured using an enzyme immunoassay RayBio® Human GDNF ELISA Kit (RayBiotech, USA) on a ChemWell 2910 automatic analyzer (Awareness Technology Inc., USA).

Results: Compared to controls, at the earlier stages of POAG (stages 1-2 according to classification by Mills et al., 2006), GDNF concentration (median [interquartile range]) was significantly decreased ($P<0.05$ – $P<0.001$) in all studied biological fluids: in aqueous humor (46 [14-57] vs. 83 [59-119]), lacrimal fluid (176 [96-238] vs. 314 [244-422]) and serum (163 [128-202] vs. 196 [174-239]) pg/mL. In later stages 3-4, the GDNF levels increased, however, in the aqueous humor and lacrimal fluid remained significantly reduced in comparison with controls. An inverse correlation with the perimetric index VFI was found for the content of GDNF in lacrimal fluid ($r=-0.47$; $P=0.01$) and serum ($r=-0.40$; $P=0.03$); a direct correlation was found between the GDNF levels in serum and aqueous humor ($r=0.47$; $P=0.01$).

Conclusions: In patients with POAG, GDNF level in the aqueous humor, lacrimal fluid, and blood serum is significantly decreased, especially in the earlier stages of the disease. In subsequent stages, reduction of GDNF level in the aqueous humor and lacrimal fluid is less pronounced, however the level of GDNF in these media remains significantly reduced compared to patients without glaucoma. An inverse correlation with the perimetric index VFI was found for the content of GDNF in lacrimal fluid and blood serum, as well as a direct correlation of GDNF levels in the blood serum and aqueous humor.

ABSTRACT BODY:

Purpose: Leber's hereditary optic neuropathy (LHON) has been considered a prototypical mitochondriopathy and a textbook example for maternal inherited disease. However, recently, an autosomal recessive form of LHON (arLHON) has been described, caused by disease-causing variants in the nuclear encoded gene DNAJC30. We performed a retrospective screening of DNAJC30 in a large series of genetically unsolved patients clinically diagnosed with LHON patients or other forms of inherited optic atrophy (OA). We compiled and compared the prevalence, patients' demography and clinical findings with those linked to mtDNA variants.

Methods: 1202 patients (1197 index patients and 5 affected family members, male: female ratio 1.8:1) were retrospectively selected for DNAJC30 screening, including 800 patients with a clinical diagnosis of LHON and 402 patients with OA. Genomic DNA samples of patients were used for screening of the coding sequence of DNAJC30 gene and its flanking untranslated regions by PCR amplification and subsequent Sanger sequencing. Pathogenicity of variants was assessed by in silico software prediction, allele frequency, and segregation analysis. Microsatellite marker analysis was performed to analyze the founder effect for the variant c.152A>G;p.(Tyr51Cys). Clinical examinations include visual acuity measurement, slit lamp examination, perimetry, indirect ophthalmoscopy, optical coherence tomography and color vision (Ishihara plates and Farnsworth-Munsell Dichotomous D-15 test).

Results: We identified likely pathogenic variants in 2.9% (35/1202) patients. The missense variant c.152A>G;p.(Tyr51Cys) accounted for 90% of disease-associated alleles in our cohort. Marker analysis provided strong evidence for a founder effect and a common origin of this mutation. Furthermore, we identified two novel pathogenic variants in DNAJC30: the nonsense variant c.610G>T;p.(Glu204*) and the in-frame deletion c.230_232del;p.(His77del). Clinical investigation of the patients with arLHON revealed a younger age of onset, a more frequent bilateral onset and an increased clinically relevant recovery compared to LHON associated with disease-causing variants in the mitochondrial DNA (mtLHON).

Conclusions: This study expands previous findings on arLHON and emphasizes the importance of DNAJC30 in the genetic diagnostics of LHON and OA in European patients.

ABSTRACT BODY:

Purpose: Laser speckle contrast imaging (LSCI) is a promising technique for measuring the retinal hemodynamics because LSCI is capable of imaging large field of retinal blood flow in just a few seconds. This study aims to evaluate retinal hemodynamics abnormalities in Alzheimer's disease (AD) through our custom-built LSCI.

Methods: 83 Patients with AD and 75 healthy age and sex-matched subjects were recruited in the study. All subjects underwent medical history, blood pressure measurement, the Montreal Cognitive Assessment (MOCA), best-corrected visual acuity, intraocular pressure (IOP), and custom-built LSCI. Based on the laser speckle phenomenon, the LSCI was used to measure the retinal blood flow. A laser diode at 850 nm wavelength was used for LSCI. An annular fiber bundle was adopted for uniform retinal illumination. The retinal speckle pattern images were captured by the CMOS camera (M3ST507M-H, DO3THINK, GuangDong, China) with 1224 pixels X 1024 pixels at a frame rate of 80 fps for a 5-second measured period. Then, LSCI algorithm was proposed to calculate the laser speckle contrast (LSC) value to represent the blood velocity. The relative blood flow of the optic nerve head area was chosen to obtain the retinal blood flow pulsatility curve (Fig. 1). According to the pulse-waveform analysis, the quantitative parameters can be calculated, such as flow acceleration index (FAI). The eye with better corrected visual acuity was selected for the LSCI.

Results: There was no significant difference between the groups for systolic blood pressure, diastolic blood pressure, mean blood pressure, IOP, and ocular perfusion pressure. No difference in patients with diabetes mellitus, and hypertension was observed between two groups. Compared to controls, the parameters corrected visual acuity (0.86±0.19 vs 0.93±0.19, p=0.05), MOCA scores (15.9±7.0 vs 28.1±1.5, p<0.01)), and FAI (1.17±0.39 versus 1.33±0.54, p=0.05) were significantly lower in AD (Fig. 2).

Conclusions: The present study demonstrates significant differences in retinal hemodynamics between AD patients and healthy subjects through LSCI. FAI may be a useful indicator for early detection of AD.

ABSTRACT BODY:

Purpose: There is a lack of clinically usable biomarkers for the diagnosis and prognosis of age-related macular degeneration (AMD). Visualizing the effect of healthy and pathological aging on the retina may aid the discovery of novel imaging biomarkers for AMD. To this end, we explore the use of deep learning to synthesize counterfactual OCT images that reflect hypothetical scenarios in which age, sex or disease stage of the scanned subject are changed while the subject's identity remains fixed.

Methods: We developed a counterfactual generative adversarial network (GAN) that alters existing OCT images to visualize the retina at a different, operator-selectable age, sex or AMD disease stage. Two datasets, which have been curated for the PINNACLE study, were used for GAN training and validation: 175,869 OCT images of predominantly healthy participants in the UK Biobank population study and 57,875 images of AMD patients undergoing treatment at Southampton Eye Unit. The visual quality of the counterfactuals was quantified by conducting a Turing Test, in which five expert ophthalmologists were asked to distinguish between real and artificially generated OCT images. Additionally, we measured whether the generated images faithfully depict the counterfactual age and sex and preserve the subject identity by predicting these demographics using independently trained ResNet-50 neural networks.

Results: The generated counterfactuals were indistinguishable from real OCT images in most cases (Turing Test accuracy: 76.6%±18.4%). The GAN realistically modified image features associated with subject age and sex (correlation between counterfactual and predicted age: Pearson's R of 0.86±0.02; agreement between counterfactual and predicted sex: 79.7%±5.8%), while preserving subject identity in 88.8%±6.4% of counterfactuals. Several observed retinal changes were linked to plausible biomarkers, such as thinning of retinal layers with aging or increase in drusen size with progressing AMD.

Conclusions: We have demonstrated the ability of GANs to generate realistic counterfactual OCT images, which can be used to visualize the individual course of retinal changes caused by healthy or pathological aging.

ABSTRACT BODY:

Purpose: Atoh7 plays a major role in the development of retinal ganglion cells and the optic nerve and mutations in ATOH7 have been associated with multiple ocular disease traits in humans. In zebrafish, atoh7 mutants fail to generate retinal ganglion cells during embryogenesis, until 6 days post fertilization. Here we characterized adult atoh7 mutants to explore the consequences of missing retinal output on retinal and tectal structure, as well as visually-mediated behaviors.

Methods: We raised atoh7 mutants to adulthood under adjusted feeding and holding conditions and systematically characterized their phenotype at 10 to 12 months of age. The histological structure of retina and tectum was monitored using histology and immunohistochemistry. We performed measurements of retinal thickness and analysis of blood vessel distribution using optical coherence tomography. Further, visually-mediated behavior was assessed using a dark-light place preference test, a social preference test, and the optokinetic response assay. The influence of vision on shoaling behavior was analyzed using the idTracker software.

Results: Adult atoh7 mutants display a darker body pigmentation and significantly reduced body size. Likewise, their retina is significantly thinner (more than 10 %) as they lack all retinal ganglion cells, and therefore, neither possess a nerve fiber layer, nor form an optic nerve. In addition, the distribution of retinal blood vessels is altered in atoh7 mutants. The optic tectum of atoh7 mutants is reduced in size by 25 % and contains less white matter, as well as exhibits a disrupted layering. Applied behavioral assays confirm that adult atoh7 mutants are blind, and show changes in their social behavior.

Conclusions: We find that retinal ganglion cells are still lacking at the adult stage of zebrafish atoh7 mutants resulting in the absence of the optic nerve and a failure of the optokinetic response. Moreover, we conclude that missing innervations of the optic tectum and the associated lack of visual input are the likely cause of structural changes of the optic tectum and subsequent alterations in social interactions.

ABSTRACT BODY:

Purpose: Neovascular diseases of the retina represent a significant disease burden with diabetic retinopathy being the leading cause of blindness in the western world. The development of anti-VEGF drugs revolutionized the treatment of these diseases and significantly improved outcomes. In recent studies, bevacizumab has been proven to be noninferior to Ranibizumab, making anti-VEGF more accessible to patients. New biosimilar molecules to bevacizumab have been approved for use in cancer patients but have yet to be approved in the eye. The goal of this study is to demonstrate that these molecules are safe and effective at reducing neovascularization in the eye.

Methods: Mouse and rabbit models were used to investigate efficacy and safety, respectively, of two novel anti-VEGF biosimilars. Animals were randomized to receive either bevacizumab, Mvasi or Zirabev in one eye; contralateral eyes served as saline or no treatment controls. For the efficacy arm of the study, adult C57BL/6J mice received four laser burns per eye to induce choroidal neovascularization (CNV). Intravitreal anti-VEGF treatments were administered 4,10, and 14 days post-injury followed by fundus fluorescein angiography (FA) and OCT weekly. For the safety study, adult New Zealand White rabbits received a single intravitreal anti-VEGF treatment. Animals were followed weekly with both photopic and scotopic ERG in addition to OCT at endpoint.

Results: CNV was observed in all groups indicated by fluorescein leakage at each laser-induced lesion. No difference was observed in the change of overall area or mean gray value between injury and endpoint among biosimilar treatments. Further, no difference was observed in the change of area and depth of lesions post biosimilar treatment. Regarding safety, no significant changes were seen in A or B wave amplitude over the 4 weeks across all groups. When compared with the contralateral eye controls (saline only), none of the eyes treated with anti-VEGF showed a decrease in amplitude in either photopic or scotopic ERG.

Conclusions: To date, we have seen no difference in the efficacy of bevacizumab, Zirabev and Mvasi. Further, there have been no adverse structural changes and no changes in retinal function. We conclude that these drugs may be suitable alternatives to bevacizumab but will need to be further investigated through a clinical trial.

ABSTRACT BODY:

Purpose: To assess for retinal alterations immediately following membrane peeling procedures with the Finesse Sharkskin ILM Forceps (Alcon, Ft Worth, TX) using intraoperative optical coherence tomography (iOCT).

Methods: A post-hoc analysis of the IRB-approved prospective DISCOVER iOCT study was performed to evaluate iOCT findings in eyes that underwent membrane peeling procedures with the Finesse Sharkskin Forceps, an FDA-cleared handheld membrane peeling device. The forceps were utilized as part of the standard-of-care surgical procedure. In the DISCOVER study, a standardized imaging iOCT protocol is utilized with imaging obtained at various pre-determined time points in the surgery. Pre-peel and post-peel iOCT video and images were evaluated for each eye to assess for post-peel anatomic alterations. Surgical video/iOCT correlation was conducted to evaluate the etiology of anatomic alterations, such as instrument-tissue interaction vs indirect peeling forces.

Results: Thirty-two eyes were included in the analysis with a primary diagnosis of either epiretinal membrane for 22 eyes (69%) and full thickness macular hole for 10 (31%). Ten eyes (31%) underwent complete membrane peeling with Sharkskin Forceps, and 22 eyes (69%) underwent combined peeling with membrane loop-induced edge initiation with peel completion performed with the Sharkskin Forceps. Three eyes (9%) had focal retinal alterations identified on iOCT following tissue-instrument interaction with Sharkskin Forceps demonstrating focal full thickness retinal elevations. Two eyes (6%) had focal inner retinal elevations and one eye (3%) had a full-thickness retinal elevation that were not related to direct tissue-instrument interaction but rather indirect peeling forces. All of these alterations were subclinical (i.e., not visible without iOCT). No intraoperative adverse events occurred.

Conclusions: iOCT-identified architectural alterations related to direct-tissue instrument interaction was relatively infrequent (<10%) with similar frequency to previously reported alterations with other surgical instruments. Further longitudinal comparative research is needed to better understand clinical impact of various peeling methods.

ABSTRACT BODY:

Purpose: The aim of this study was to develop a new rabbit model of chronic intraocular hypertension produced by Gold Nanoparticles (GNP) with characteristics similar to human chronic glaucoma and to evaluate different inflammation and oxidative stress biomarkers related with glaucoma.

Methods: Six rabbit were used to the animal model development, n=3 for study group and n=3 for control group. The ocular hypertension model was developed by making multiple intraocular injections of 100 µl of PBS +GNP (80nM concentration) in study group and only PBS in the control group. Increasing intraocular pression (IOP) protocol was developed during a period of 4 weeks by series of four intra-anterior chamber weekly injections. After intracameral injection period, another 4 weeks were stablished without treatment before to measure IOP recovery. IOP was measured weekly by TonoVet tonometer. For biomarkers evaluation, Six rabbit were used to the animal model development, n=3 for study group and n=3 for control group. Following the animal model developed with GNP, it was extracted 100µl of aqueous humor before to inject the PBS+ GNP solution (study group) or only PBS (control group). Osteopontin and diadenosine tetraphosphate were analyzed by HPLC. Data are represented as mean ± SD and p value<0.05 were consider statistically significant.

Results: The IOP was increased in the study group from 12,4 ± 1.1 mmHg at the baseline to 18,2 ±1,3 mmHg after 4 weeks of injections, being the trend statistically significant (p<0.05). The increasing was constant, being around 2 mmHg each week.

However, no differences were found in control group for any measurement, keeping in similar values during all experiment. The IOP recovery in the study group was completed after 4 weeks without GNP injections. Regarding biomarkers evaluation, it was found a significant increasing of Osteopontin after 4 weeks of GNP injections, from 0.0042 ± 0.03 nM to 0.07 ± 0.04 nM (p<0.05). No changes were found in the control group. For Diadenosine tetraphosphate , no differences were found between groups.

Conclusions: The ocular hypertension animal model with GNP seems to be a great option to study the different potential biomarkers of Glaucoma. New long term studies to analyze the effect of GNPs in the ganglion cells density are needed to convert this hypertension model to a glaucoma model.

SUBMITTER (NAME ONLY): Ana Isabel Jimenez

TITLE: Phase I of SYL1801, a new siRNA delivered in eye drops for age-related macular degeneration

SESSION TITLE: AMD: Clinical and translational research/AMD therapies (excluding anti-VEGF)

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Jimenez, R&D, Sylentis, SPAIN|V. Ruz, B. Vargas, Regulatory, Sylentis, SPAIN|A. Bleau, Clinical Operations, Sylentis, SPAIN|

Commercial Relationships Disclosure: Ana Isabel Jimenez: Commercial Relationship(s);Code E (Employment):Sylentis | Veronica Ruz: Commercial Relationship(s);Code E (Employment):Sylentis | Beatriz Vargas: Commercial Relationship(s);Code E (Employment):Sylentis | Anne Marie Bleau: Commercial Relationship(s);Code E (Employment):Sylentis

ABSTRACT BODY:

Purpose: The objective of this study is to determine safety, tolerability and pharmacokinetic (PK) profile of different doses of SYL1801 ophthalmic solution in healthy volunteers. SYL1801 is a small interfering ribonucleic acid (siRNA) inhibitor of NRARP (Notch-Regulated Ankyrin Repeat Protein) synthesis, a key regulator of choroidal neovascularization.

Methods: This is an observer-masked, parallel groups, time-lagged study comprised of two treatment intervals: single ascending dose (SAD) and multiple ascending dose (MAD). Four different dose levels of SYL1801 were evaluated: 10 mg/mL q.d. (once daily), 25mg/mL q.d., 50 mg/mL q.d. and b.i.d. (twice daily). SAD intervals included three subjects per cohort and consisted of one treatment day, while MAD intervals had six subjects per cohort treated for 7 consecutive days. Administration in eye drops at Day 1 (through Day 7 for MAD interval) was conducted in one randomly chosen eye. Follow up visits were performed 24 and 72 hours after last administration.

Primary outcomes were ocular tolerability at the site of administration (cornea and conjunctiva) 72 hours after last instillation of SYL1801 and primary PK parameters determination. Secondary outcomes included ocular tolerability at 1 and 24 hours, electrocardiography, laboratory parameters, secondary PK parameters and adverse event (AE) occurrence. PK samples were collected 2, 15, 30 minutes, 1, 4 and 24 hours after last administration (LLOQ: 1 ng/mL).

Results: A total of 36 healthy volunteers were allocated into one of the different administration schedules and completed the study. Preliminary reports after study close-out showed that 4 possibly related AEs (blepharitis in 2 subjects; queratitis, hyperemia and ocular irritation, in 1 subject each) were reported; all of them were mild and resolved in less than 72 hours. PK parameters could not be determined given SYL1801 was only detected in one study sample. No cumulative effect was observed

Conclusions: This study provides evidence that SYL1801, a new siRNA administered in eye drops for retinal diseases, is safe and well tolerated. Few related AEs occurrence together with limited systemic bioavailability supports good safety profile. This, together with in vitro and in vivo efficacy data, further supports clinical development of SYL1801.

ABSTRACT BODY:

Purpose: To gain insight into the genomic organization and transcript composition of inherited retinal disease (IRDs) genes using publicly available RNA-Seq datasets obtained from the human retina.

Methods: We retrieved from publicly available expression databases 177 bulk RNA-Seq human retina data from non-visually impaired post-mortem donors (Pinelli et al., PMID:27235414 and Ratnapriya et al., PMID:30742112). After quality control analysis, we retained only 161 of them. We then re-analyzed the whole datasets using an ad-hoc designed pipeline. RNA-Seq alignments were assembled at a single sample level and merged to generate an Observed Transcriptome that allowed us to create a single set of assembled transcripts. Transcript expression levels were quantified by scaling TPM (Transcript Per Million) abundance estimates per sample (scaled TPM), and transcripts with less than one median TPM were filtered out. We selected a subset of newly identified candidate transcripts for independent validation by Reverse Transcriptase (RT-)PCR. cDNAs were obtained from RNA extracted from human retina and blood samples. Obtained RT-PCR products were sequenced to assess their identity.

Results: We focused our analysis on 219 IRD genes and identified a total of 3367 putative novel transcripts. The latter were the results of a) partial intron retentions, b) exon skipping and extension, and, in fewer cases, c) novel exon additions and d) connections with other transcriptional units. RT-PCR analysis carried out on a selected subset of putative novel transcripts revealed an overall 50% rate of experimental validation.

Conclusions: This is, to the best of our knowledge, the most comprehensive and extended meta-analysis of IRD genes carried out on RNA-Seq data. Our work provides a reliable expression quantification of IRD transcripts in the human retina, including the identification of novel ones, and paves the way towards a better understanding of the organization of their transcriptional units and, possibly, of the molecular mechanisms underlying inherited retinal diseases.

TITLE: Single cell RNA sequencing reveals heterogeneity of Müller glia-derived progenitors and partial recapitulation of the developmental retinogenesis program in the light injured zebrafish retina

SESSION TITLE: Retina Development and Regeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Celotto, F. Rost, S. Hans, M. Brand, Center for Regenerative Therapies Dresden, Zentrum fur Regenerative Therapien Dresden, Dresden, Sachsen, DE, academic/medres, GERMANY|

Commercial Relationships Disclosure: Laura Celotto: Commercial Relationship: Code N (No Commercial Relationship) | Fabian Rost: Commercial Relationship: Code N (No Commercial Relationship) | Stefan Hans: Commercial Relationship: Code N (No Commercial Relationship) | Michael Brand: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In zebrafish, retinal progenitors (RP) derive from Müller glia (MG) and restore the entire retinal architecture upon lesion. Detailed information on the underlying genes orchestrating this process is missing. Here, we profile the transcriptome of RPs and MGs and track their differentiation in the early regenerating zebrafish retina.

Methods: Adult zebrafish expressing mCherry in MG and GFP in all proliferating cells were used. Retinae of either untreated controls or light lesioned animals were dissociated at 44 hours post lesion (hpl), 4 and 6 days post lesion (dpl). Subsequently, mCherry as well as mCherry/GFP double-positive cells were isolated via Fluorescence Activated Cell Sorting and single cell RNA sequencing (scRNAseq) was performed using 10x Genomics. To validate the results of the scRNAseq, we applied immunohistochemistry and in situ hybridization.

Results: Bioinformatic analysis of 11690 cells identified 15 different cell clusters. Four clusters represent MG. Two clusters contain resting, gfap-positive MG, which are found at all four time points. The others contain reactive, proliferating and reactive, non-proliferating MG obtained at 44 hpl and 4 dpl, respectively. Heterogeneous RP clusters appear at 4 and 6 dpl. Multipotency markers, like pax6a, pax6b, rx1 and vsx2, are expressed in early RPs and resting or reactive MG. Both, early RPs and reactive MG upregulate proliferative, Notch-related and inflammatory markers, like pcna, her4.1 and hmgb2b. A second cluster of RPs is proliferative and expresses early neurogenic markers like atoh7 and pou2f2a. A third RP cluster upregulates markers of several neuronal lineages, like onecut1, onecut2 (horizontal cells), otx5 (photoreceptors) and neurod4 (amacrine cells). Retinal ganglion cells, horizontal cell RPs (pcna, lhx1a, prox1) and photoreceptor RPs (pcna, nr23, thrb) branch from neurogenic RPs already at 4 dpl. Red and blue cones derive from photoreceptor RPs as well as amacrine and bipolar cells from neurogenic RPs at 6 dpl. Rods were not present in the sampled progeny.

Conclusions: MG and early RPs have highly similar transcriptomes, whereas neurogenic and fate restricted RPs initiate markers of retinogenesis in the regenerating retina. Regenerated progeny arises following the developmental retinogenic order.

TITLE: The Effect of Intracameral Cefuroxime after Routine Cataract Surgery on Macular Thickness and Perfusion Status

SESSION TITLE: OCT Angiography Clinical Applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Wang, Y. Peng, Ophthalmology, Taipei Tzu Chi Hospital, New Taipei City, TAIWAN|C. Cheng, National Taiwan University College of Medicine, Taipei, TAIWAN|

Commercial Relationships Disclosure: Chia-Yu Wang: Commercial Relationship: Code N (No Commercial Relationship) | Chun-Yao Cheng: Commercial Relationship: Code N (No Commercial Relationship) | Yi-Jie Peng: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess the safety of intracameral cefuroxime (ICI) 1mg/0.1ml at the end of routine phacoemulsification procedure, we designed a retrospective observational study to evaluate the early changes in retinal thickness (MRT), superficial capillary plexus (SCP) and deep capillary plexus (DCP) by optical coherence tomography (OCT) and optical coherence tomography angiography (OCTA) after uncomplicated phacoemulsification.

Methods: 27 eyes of 27 Asian adults were included: 13 eyes with ICI cefuroxime (CEF group) (67.5±12.7 years old); 14 eyes without ICI cefuroxime (Control) (69.93±8.32 years old). All subjects underwent a complete examination including best-corrected visual acuity (BCVA), slit lamp, fundoscope, OCT and OCTA scan before surgery (T0), 1 day (T1), 7 days (T7) and 30 days (T30) after surgery. The retinal thickness was defined as the average thickness in the central, inner and outer circle of the ETDRS grid. We exported OCTA images into ImageJ software (Figure 1). After subtracting the fovea avascular zone (FAZ), we made a 3mm diameter circle centered on the fovea to analyze vessel density (VD) and skeleton density (SD) of SCP and DCP respectively. Independent t test was used to compare parameters between two groups.

Results: (Table 1) Before surgery, there was no significant difference of the mean VD and SD both in SCP and DCP between two groups. (Figure 2) At T1, the mean VD and SD in DCP increased significantly in CEF group compared to controls (29.63±3.24 % vs 25.93±2.30 %; P=0.003 and 8.15±0.91 % vs 7.40±0.64 %; P=0.025, respectively). At T30, the mean VD and SD in DCP elevated again in CEF group (29.89±2.99 % vs 27.73±2.56 %; P=0.054 and 8.11±0.75 % vs 7.52±0.54 %; P=0.026, respectively). Otherwise, there was no difference of mean BCVA, MRT and VD/SD in SCP between groups.

Conclusions: This study elucidates that VD and SD in DCP increase significantly at postoperative day 1 and day 30 in eyes with ICI cefuroxime after cataract surgery. Although the safety of prophylactic ICI cefuroxime is widely accepted nowadays, cefuroxime may still induce subclinical macular perfusion changes without affecting the postoperative visual acuity and macular thickness.

TITLE: Characterizing extremely negative reviews of ophthalmologists on yelp.com

SESSION TITLE: Eyecare delivery and economics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.F. Smith, M. Qureshi, O. Adeleye, H. Luong, Mayo Clinic School of Medicine - Scottsdale Campus, Scottsdale, Arizona, UNITED STATES|J. Shen, Ophthalmology, Mayo Clinic Arizona, Scottsdale, Arizona, UNITED STATES|

Commercial Relationships Disclosure: Jacob Smith: Commercial Relationship: Code N (No Commercial Relationship) | Muhammad Qureshi: Commercial Relationship: Code N (No Commercial Relationship) | Olufunmilola Adeleye: Commercial Relationship: Code N (No Commercial Relationship) | Hanna Luong: Commercial Relationship: Code N (No Commercial Relationship) | Joanne Shen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Patient satisfaction with the care experience is a critical element of overall high quality healthcare delivery, and patients increasingly utilize online crowd-sourced physician rating tools to evaluate and select a physician. We performed a retrospective characterization of one-star reviews on yelp.com. We hypothesized that most reviews would be nonclinical in nature and that complaints referencing a procedural episode would be largely clinical in nature.

Methods: A search was performed for reviews on yelp.com using the keyword “ophthalmologist” for the top 8 most population-dense metropolitan areas in the United States. One-star reviews were classified as procedural or nonprocedural. Complaints were analyzed and categorized as clinical or nonclinical.

Results: 5,532 reviews were assessed, of which 477 (8.6%) were one-star reviews to be analyzed. These reviews amounted to 1,120 distinct complaints, 287 (25.6%) were clinical in nature and 833 (74.4%) were nonclinical. The most common clinical complaints were technical incompetence/error (50; 17.4%), unsatisfactory result (46; 16.0%), and complication (43; 15.0%). The most common nonclinical complaints were office staff interpersonal (182; 21.8%), wait time (174; 20.9%), and physician interpersonal (141; 16.9%). Patients reporting an ophthalmologic procedure (surgery, injection, etc.) wrote 64 reviews resulting in 193 (17.2%) complaints. Nonprocedural patients wrote 413 reviews resulting in 927 (82.8%) complaints. Compared with nonprocedural reviews, procedural reviews were more likely to relate a clinical complaint (93.8% procedural vs. 28.6% nonprocedural, $P < 0.001$).

Conclusions: The majority of one-star reviews of ophthalmologists in highly populated urban areas included in this study focused on nonclinical complaints unrelated to a procedure performed by the clinician being reviewed, confirming our hypothesis. Procedural complaints were more likely to include a clinical component to the review. These findings can help clinicians identify and address unique healthcare delivery challenges in the field of ophthalmology.

ABSTRACT BODY:

Purpose: Information on the structure and direction of the scleral collagen and retinal nerves might be helpful in the diagnosis and monitoring of glaucoma, age-related macular degeneration (AMD) and high myopia. In this pilot study, polarization sensitive-OCT (PS-OCT) is used to image the orientation and birefringence of these fiber structures in the eye in these patient groups.

Methods: A depth-multiplexed fiber-based PS-OCT system will be used to extract quantitative and local information on optic axis, birefringence, and depolarization from the retina and peripapillary sclera. The setup contains a swept-source laser centered at 1060 nm with a repetition rate of 200 kHz. Data of glaucoma, wAMD and high myopia patients will be obtained.

Results: By segmentation of the RNFL, Henle's fiber layer and the first 180 µm of sclera, orientation en face images of the different structures can be created (Fig. 1). As the orientation of the retinal nerves is known to be radially from the optic nerve head, absolute orientations of Henle's fiber layer and the sclera could be extracted, as shown in Fig 1. d) and f). The first layer of sclera collagen fibers is oriented approximately parallel to the retinal nerves. A ring structure can be recognized around the optic nerve head, where the orientation of the collagen fibers is circular.

Conclusions: PS-OCT has been used to successfully extract optic axis orientation of the retinal nerves, Henle's fiber layer and the sclera locally in 3D in vivo. The PS-OCT system will be used to detect pathological changes in fiber structures associated with disease. PS-OCT imaging of myopia, wAMD and glaucoma can improve our understanding of retinal biomechanics and structural alterations in different disease stages.

ABSTRACT BODY:

Purpose: Proteins associated with the innate immune system alongside essential and non-essential trace metals are associated with age-related macular degeneration (AMD) onset. Determining the location of innate immune receptors thought to be involved in disease pathogenesis is important when assessing how best to target these receptors. Non-specificity of antibody staining is a challenge for certain immune receptors, e.g. NLRP3. Here mass spectrometry imaging (MSI) has been used to identify and spatially characterise both proteomic and metallomic species within ocular tissue.

Methods: Proteomic data was acquired from mouse ocular tissue prepared on a HTX M3+, trypsin was applied at 25 $\mu l min^{-1}$. 5 $mg ml^{-1}$ of CHCA matrix was applied with variable flow rates. Analysis was conducted using SELECT SERIES MRT and SYNAPT MALDI-MS instruments (Waters Corporation, Manchester, UK) within the mass range 700 to 2000Da. Metallomic analysis was conducted on the same ocular tissue using a NexION 350X ICP-MS (PerkinElmer, Manchester, UK) coupled to an UP-213 laser ablation (LA) system (New Wave Research, Freemont, CA, USA). The ICP-MS was run in Kinetic Energy Discriminatory (KED) mode utilising a variable laser spot size (6 & 40µm), 46% laser energy and a repetition rate of 22Hz.

Results: Investigations are currently underway to interpret the spatial distribution of key biomarkers associated with AMD pathology within mouse ocular tissues. MALDI-MS has exhibited the distribution of NLRP3 and associated proteins in mouse retinal tissue. Current preliminary data suggests the presence of peptides of interest including tentative identifications of peptides associated with the NLRP3 inflammasome. Additionally, LA-ICP-MS has been used to characterize accumulation of both essential and non-essential metals within mouse ocular tissues, utilizing high resolution mass spectrometry to identify determine spatial distribution of key trace metals within the mouse chorio-retinal microanatomy.

Conclusions: This study exhibits the capabilities of multimodal MSI, and how when utilised in an interdisciplinary manner, MALDI-MSI and LA-ICP-MSI have potential to inform on unknown biological mechanisms of retinal degeneration.

ABSTRACT BODY:

Purpose: Achromatopsia (ACHM) is an inherited retinal disease marked by total cone photoreceptor dysfunction. Tübingen University Hospital completed a Phase I/II clinical trial evaluating the safety and efficacy of an AAV-based, subetinal gene therapy (GT) in adults affected by ACHM due to mutations in CNGA3. One year after GT for ACHM, patients demonstrated a significant, yet not clinically relevant, improvement of best-corrected visual acuity (BCVA) and contrast sensitivity (CS). Because ACHM patients are affected from birth, we hypothesized, that beyond retinal restitution of CNGA3 bioactivity, neural plasticity of the visual system could be a limiting factor in treatment response. To test this hypothesis, patients underwent diffusion tensor imaging (DTI), an established surrogate for white matter (WM) integrity and organization, prior to, and one year after GT.

Methods: Nine patients were examined by a single operator, using a Siemens PRISMA 3T MRI device and a 64-channel head coil. Data processing relied on FSL and SPM12. Using DTI, we measured fractioned anisotropy (FA), a scalar value between 0 and 1, which denotes the directionality of diffusion, and mean diffusivity (MD), the mean speed of diffusion along all tensors. DTI, BCVA and CS measurements were taken prior to, and 1 year after GT. We then performed a voxel-wise regression analysis for ΔFA and ΔMD vs. ΔBCVA and ΔCS along the visual system, with a significance threshold of $p<0.05$, and rejection of small clusters (<25 voxels).

Results: DTI imaging revealed multiple clusters (n=12) along the visual system, in which WM changes [ΔFA, ΔMD] and clinical treatment response [ΔBCVA, ΔCS] one year after GT displayed a moderate to strong (R^2=0.47-0.74), and significant ($p<0.05$) correlation. This was the case for both BCVA (vs. FA R^2=0.48-0.56, n=4 vs. MD R^2=0.47-0.72, n=4), and CS (vs. FA R^2=0.48-0.74, n=3, vs. MD R^2=0.66, n=1).

Conclusions: Despite a low effect size in adult ACHM patients, DTI revealed a significant correlation between the degree of BCVA and CS improvement, and the degree of WM plasticity in key areas of the visual system, one year after GT. This supports the notion, that neural plasticity might indeed be a limiting factor in the treatment response of adult ACHM patients. Based on these results, it seems sensible to treat younger patients, which harbor greater potential for a remodeling of the visual system.

ABSTRACT BODY:

Purpose: Evaluate the GS030 optogenetic therapy in subjects with end-stage non-syndromic retinitis pigmentosa.

Methods: The GS030 optogenetic therapy combines an intravitreal injection of gene therapy with the use of a medical device. The GS030 gene therapy vector expresses channelrhodopsin ChrimsonR-tdTomato in retinal ganglion cells. The light-stimulating goggles encode the visual scene and project corresponding light pulses to activate the retinal ganglion cells. PIONEER is an international open-label dose-escalation clinical study of GS030 for the treatment of late-stage retinitis pigmentosa.

Results: 9 patients were injected with increasing doses of gene therapy: 3 received 5E10 viral genomes (vg)/eye, 3 received 1.5E11 vg/eye, and 3 received 5E11 vg/eye. Started 8 weeks after injection, the use of light-stimulating goggles was well tolerated. The main ocular adverse event related to gene therapy was mild intraocular inflammation responsive to corticosteroid treatment. Following systematic visual training with the goggles, two patients were able to locate and touch small objects on a table. One of these 2 patients underwent EEG recording during a visual test, which showed vision-related cortical activity.

Conclusions: GS030 demonstrates a good safety profile up to 2.5 years after vector administration, and preliminary efficacy assessment shows partial functional recovery in two patients.

ABSTRACT BODY:

Purpose: Form-deprivation and lens-induced myopia are two well-established models for experimental myopia research. Although both paradigms induce axial myopia, form-deprivation myopia is induced by the absence of clear vision and the axial elongation can progress continuously with large inter-subject variability (open-loop); whereas lens-induced myopia by imposing hyperopic defocus stops when eyes receive a clear focal image (closed-loop). This pilot study investigated whether the refractive development in both eyes was independent of each other under the bilateral form-deprivation condition.

Methods: At day 5 post-hatching (P5), White Leghorn chicks were randomly assigned to receive either unilateral (UFD, n=5) or bilateral form deprivation (BFD, n=5) by covering one (right eye) or both eyes with translucent diffusers. At the onset and over the 9-day treatment period, refractive state and ocular axial dimensions were measured longitudinally (P5, P7, P10, P12, and P14) using a modified Hartinger refractometer and a high-resolution A-scan ultrasonographer, respectively. Two-way repeated measures ANOVA was used for statistical analysis. All parameters were expressed as mean±SD.

Results: Both treatment and duration showed significant main effects on spherical-equivalent refractive error (SE) development (Treatment effect: $F(3,16)= 4.19$, $p<0.05$; Duration effect: $F(1,19)= 36$, $p<0.001$). Regardless of the treatment received, form-deprived eyes showed a rapid myopic shift in refractive state and vitreous chamber elongation (Fig 1A&B). Interestingly, the high myopia induced by BFD paradigm was highly synchronized in both eyes: the interocular difference in SE and vitreous chamber depth (VCD) were: P10: SE= 0.97±2.61D, VCD= −29.21±37.03μm; P12: SE= −0.08±1.84D, VCD= 7.78±83.87μm; P14: SE= 2.19±0.83D, VCD= 43.29±51.74μm (Fig 2A&B).

Conclusions: Refractive development in both eyes was synchronized under bilateral form deprivation in chickens. Further studies are warranted to understand the mechanism of inter-ocular synchronization and its potential role in form deprivation myopia.

ABSTRACT BODY:

Purpose: To compare the detection rate of retinal NVs in eyes with PDR between UWF-FA and WF-OCTA systems.

Methods: In this ongoing prospective study patients with NV at the disc (NVD) or elsewhere (NVE) detected on UWF-FA (California, Optos) were recruited from our outpatient clinic. Single-capture 65° (18x18 mm) WF-OCTA-imaging was performed using a Zeiss PLEX Elite prototype (Carl Zeiss Meditec GmbH) at an A-scan rate of 1.7 mHZ; and an axial and lateral resolution of 9 µm and 20 µm, respectively. Angiograms were visually enhanced using a deep learning-based algorithm for denoising. WF-OCTA B-scans were examined for blood flow signals above the internal limiting membrane by two retina specialists.

Results: 38 eyes of 26 patients with PDR detected on UWF-FA were included until December 2021. 36 eyes (94.7%) had at least one NV within the 18x18mm WF-OCTA. A total of 141 NVEs were detected on UWF-FA of which 41 (29.1%), 50 (35.5%), 28 (19.9%), and 22 (15.6%) were located superotemporal, inferotemporal, superonasal, and inferonasal, respectively. Significantly more NVEs occurred in the temporal compared to the nasal quadrants ($p < 0.05$). 87 NVEs (61.7% of all NVEs) were detected using single-capture WF-OCTA. Compared to UWF-FA the number of NVEs detected on WF-OCTA in the superotemporal, inferotemporal, superonasal, and inferonasal quadrants was 35 (85.4%), 40 (80%), 5 (17.9%), and 7 (31.8%), respectively.

Conclusions: Single-capture WF-OCTA allows correct classification of PDR in 95% of individuals by detecting at least one NV within the observed field. On UWF-FA NVEs were most prevalent in the temporal fields with a majority of them detected on WF-OCTA scans. Quick and non-invasive WF-OCTA imaging has the potential to replace FA as a single diagnostic tool in clinical routine in the evaluation of PDR activity.

ABSTRACT BODY:

Purpose: Mitochondrial dysfunction is highly implicated in various acute, chronic and genetic disorders of the visual system, owing to the high demand of energy supply of ocular cells and their constant exposure to oxidative stress. Recently, Mitochondrial transplantation (MitoPlant) has emerged as a novel therapeutic modality for the treatment of ischemia/reperfusion insults. It was previously shown that MitoPlant temporarily protects retinal ganglion cells from cell death during ocular ischemia. Here, we characterized MitoPlant dynamics in retinal ganglion precursor-like cells, by evaluating uptake and survival of mitochondria in recipient cells under oxidative stress.

Methods: We developed a new method for detection of transplanted mitochondria using qPCR, based on a difference in the mtDNA sequence of C57BL/6 and BALB/c mouse strains. We applied this approach together with flow cytometry and imaging techniques to evaluate mitochonrial transplantation dynamics in 661W cells in steady state conditions and under oxidative stress.

Results: We demonstrate that exogenous mitochondria are substantially internalized as early as three hours after transplantation, and that the levels of exogenous mitochondria decline in recipient cells after twenty four hours. Interestingly, exposure of the target cells to moderate oxidative stress prior to MitoPlant dramatically enhanced mitochondrial uptake and extended the survival of mitochondria in recipient cells by more than three fold.

Conclusions: We developed a new research tool that enables following exogenous mitochondrial survival within recipient cells and demonstrate that oxidative stress significantly enhances exogenous mitochondria uptake and survival in retinal ganglion precursor-like cells. These results may promote delineating MitoPlant mechanism and the development of tools to prolong mitochondrial survival, thereby offering novel opportunities for the use of MitoPlant as a promising therapy for chronic and genetic mitochondrial diseases.

TITLE: Characterization of subconjunctival murine fibroblasts and human Tenon fibroblasts

SESSION TITLE: Surgery & Wound Healing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Luedtke, E. Molinski, M. Binter, C. Framme, R. Meister, J. Tode, H. Fuchs, Ophthalmology, Medizinische Hochschule Hannover, Hannover, Niedersachsen, GERMANY|

Commercial Relationships Disclosure: Philipp Luedtke: Commercial Relationship: Code N (No Commercial Relationship) | Esther Molinski: Commercial Relationship: Code N (No Commercial Relationship) | Maximilian Binter: Commercial Relationship: Code N (No Commercial Relationship) | Carsten Framme: Commercial Relationship(s);Code R (Recipient):Bayer, Novartis, MedUpdate | Roland Meister: Commercial Relationship: Code N (No Commercial Relationship) | Jan Tode: Commercial Relationship(s);Code R (Recipient):Bayer, Novartis, Atheneum Consulting | Heiko Fuchs: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Excessive wound healing after glaucoma filtration surgery (GFS) is primarily caused by the transformation of subconjunctival Tenon fibroblasts into increased extracellular matrix-producing myofibroblasts. The extracellular matrix forms a barrier that causes inadequate absorption of excess aqueous humor by the conjunctiva and increases intraocular pressure. To test future fibrosis inhibitors in vivo after GFS in a mouse model, murine subconjunctival fibroblasts (mSCFs) were isolated and compared to human Tenon fibroblasts (hTFs).

Methods: Methods:

(1) Tissue samples were taken from the subconjunctival space of C57BL/6 mouse eyes (n=3) or tenon from humans undergoing trabeculectomy surgery (n=3). Both cell types were compared morphologically, by immunocytochemistry (ICC) and Western blot analysis. An outgrowth of cells from both tissues was observed 5 to 7 days after initial culture and could be successfully expanded until passages 5-7.

(2) ICC staining of Vimentin, α-SMA, Collagen I (Col1), and Collagen VI (Col6) was performed with both cell types after 5 days of treatment without or with TGF-beta (10 ng/ml) to induce fibrosis or with the TGFBR2-inhibitor SB431542 (10 ng/ml) to block fibrosis induction.

(3) Western blots of α-SMA (with and without TGF-beta treatment for 5 days) and Col1 (without treatment) were performed.

Results: The ICC analysis revealed that Col1 was present in every cell line in the perinuclear region's cytoplasm in mouse and human cultures. Extracellular Col1 could not be detected. Col6 could also be seen in the perinuclear area, and structures of Col6 connecting neighboring cells could be detected in all analyzed cell types. Vimentin showed a filamentous distribution in mSCFs and hTFs. As expected, the number of α-SMA-positive cells was increased in both cell types after 5 days of TGF-beta exposure. Western blots analysis showed higher α -SMA protein expression in TGF-beta treated mSCFs and hTFs compared to untreated or SB431542-treated cells.

Conclusions: MSCFs and hTFs have a filamentous distribution of Vimentin. Both show Col1 and Col6 expressions in the perinuclear region. Both cell types share the origin and ability to transform into myofibroblasts as TGF-beta treatment for 5 days induced α-SMA protein compared to untreated or SB431542-treated cells. The similarities between mSCFs and hTFs are essential for conducting trabeculectomy or subconjunctival scarring studies.

ABSTRACT BODY:

Purpose: To evaluate the safety and efficacy of netilmicin/dexamethasone fixed combination in the treatment of meibomian gland dysfunction (MGD)-associated posterior blepharitis.

Methods: In this observational and controlled study were enrolled 40 patients with MGD and symptoms of dry eye disease. Two groups were established: 20 patients (group 1) received netilmicin 3 mg/ml and dexamethasone 1 mg/ml eye gel two times daily, whereas in group 2 (20 patients) received vehicle two times daily for 15 days. Patients underwent at baseline, and after 15 and 45 days Symptom Assessment in Dry Eye (SANDE) questionnaire, Visual Analogue Rating Scale (VARS) for dry eye symptoms, Keratograph 5M (Oculus, Germany) was used to assess non-invasive tear film breakup time (NIBUT), tear meniscus height (TMH), ocular redness and meibography score. Moreover, fluorescein tear-film breakup time (T-BUT), fluorescein ocular surface staining, lid margin evaluation including hyperemia, edema and meibum expressibility and quality examinations were carried out. Furthermore, intraocular pressure (IOP) and best-corrected visual acuity (BCVA) were considered as safety parameters

Results: In group 1, at 15 and 45 days there were statistically significant changes in VARS and SANDE score ($p < 0.0001$) as well as lid margin parameters, T-BUT and fluorescein ocular surface staining ($p < 0.0001$). No significant changes in BCVA and IOP were noted at the end of the study. Comparing the two groups, a significant improvement of SANDE was observed at 15 days in group 1 as well as lid margin parameters, BUT and fluorescein ocular surface staining at 15 and 45 days (all $p < 0.0001$).

Conclusions: Netilmicin/dexamethasone combination is effective and safe to treat MGD-associated posterior blepharitis improving both symptoms, and ocular surface signs.

ABSTRACT BODY:

Purpose: Retinal vascular diseases represent one of the most common causes for vision loss in the western world. To study angiogenic processes and identify novel therapeutic targets, researchers utilize a variety of in vitro angiogenesis assays in either 2D or 3D settings. Interestingly, research results from 2D and 3D in vitro assays do not necessarily align. In this study, we compare transcriptomic and immunocytochemical changes in vascular endothelial cells from common 2D and 3D in vitro angiogenesis assays to unravel advantages and disadvantages and, based on this, the preferred use of the respective assay.

Methods: The 2D Migration Assay and 3D Spheroid Sprouting Assay were both performed using human umbilical vein endothelial cells (HUVEC). Human VEGF165 was used to stimulate the endothelial cell migration and sprouting. We applied RNA Seq analysis to assess the transcriptomic modulations in HUVECs following stimulation with hVEGF165 in the respective 2D and 3D setting. Immunocytochemistry was used to characterize differences at the protein level in the assays performed.

Results: In both 2D and 3D assays, genes related to angiogenesis, migration and vascular development were enriched after stimulation with hVEGF165. Interestingly, in the 3D setting vascular endothelial cells showed a clearer transcriptomic shift in response to hVEGF165 treatment (foldchange: 3.96, differentially expressed genes (DEG): 763) than in the 2D setting (foldchange: 1.34, DEG: 167). Upregulation of common proangiogenic genes including KDR and VCAM1 was comparable in both assays. In contrast, transcriptomic changes related to cell-matrix interaction and glycolysis were both significantly increased only in the 3D setting. Immunocytochemical stainings revealed that exclusively in the 3D setting, vascular endothelial cells were able to generate an in vivo like tip cell behavior visualized by localized CD34 expression in the spheroid sprouts.

Conclusions: Our data underline that the transcriptomic profile of vascular endothelial cells and their responsiveness to VEGF and most likely other test substances is influenced by the assay microenvironment. For scientific questions regarding matrix interactions or glycolytic switches researchers should consider the 3D setting. For high throughput screening experiments and investigations of main angiogenic pathways the 2D setting may be sufficient.

ABSTRACT BODY:

Purpose: Changes in lipid metabolism, chronic inflammation and increased oxidative stress have been discussed as patho-etiogenetic drivers in age-related macular degeneration (AMD). Systemic medication, such as lipid-lowering drugs (LLD) and anti-diabetic drugs, affect these pathways and may therefore also play a role in AMD pathogenesis. We aimed to investigate associations of commonly used systemic drugs with AMD prevalence in the European population.

Methods: We included 38,694 adults from 14 population-based studies from the European Eye Epidemiology (E3) consortium. We performed multivariable logistic regression modelling to examine medication use association with prevalence of AMD as well as late AMD. Analyses were carried out separately by study and results pooled using random effects meta-analysis. We conducted these analyses separately for LLD, anti-diabetic drugs, non-steroidal anti-inflammatory drugs (NSAID), and L-Dopa.

Results: Between studies, mean age ranged from 61.5 ± 7.1 to 82.6 ± 3.8 years and prevalence ranged from 12.1% to 64.5% and from 0.5% to 35.5% for any and any late AMD, respectively. In the meta-analysis of our multivariable models, LLD and anti-diabetic drugs were associated with lower AMD prevalence (OR 0.85, 95% confidence interval

(CI)=0.79 - 0.91 and OR 0.78, 95% CI=0.66 - 0.91). We found no association with late AMD or with any other medication.

Conclusions: Our study shows an association of LLD and anti-diabetic drug use with lower AMD prevalence across multiple European cohorts. Our findings support the importance of metabolic processes in the complex etiology of AMD.

ABSTRACT BODY:

Purpose: Angiogenesis in the normally avascular cornea underlies common corneal diseases. Corneal sensory nerves, derived from the trigeminal ganglion (TG), are master regulators of ocular surface homeostasis. Here we seek to determine whether corneal nerves directly modulate angiogenesis and investigate the role of neuropeptide alpha-Melanocyte-Stimulating Hormone (α-MSH).

Methods: TG neurons were isolated from C57BL/6 mice and cultured in Neurobasal A medium. A co-culture system was set up by placing TG neurons in in the top chamber of a transwell and vascular endothelial cells (VEC, MILE SVEN1 cell line) in the bottom chamber. VEC proliferation, migration, and tube formation were determined with and without TG neurons. In vivo corneal angiogenesis was induced by placing intrastromal sutures in BALB/C mouse corneas.

Results: Presence of TG neurons in co-culture decreased VEC proliferation by 35% (P=0.008) and migration by 20% (P=0.046). Similarly, conditioned media (CM) of TG neurons reduced VEC proliferation (P<0.0001), migration (p=0.017), and the number of junctions (P=0.004) and length of tubes (P=0.001) formed by VEC. Topical application of neuron CM led to a 76% reduction in suture induced-corneal angiogenesis in vivo (P=0.025). More than 80% of TG neurons and 90% of subbasal corneal nerves express α-MSH. α-MSH (100nM) reduced VEC proliferation, migration, and tube formation in vitro and subconjunctival injection of α-MSH reduced corneal angiogenesis by 56% (P=0.008) in vivo. Antagonizing α-MSH signaling with Agouti-signaling protein or siRNA knock-down in TG neurons reversed the inhibitory effects of neuron CM on VEC proliferation, migration, and tube formation.

Conclusions: TG neurons and corneal nerves express anti-angiogenic neuropeptide α-MSH, which plays a critical role in the direct modulation of corneal angiogenesis by peripheral sensory nerves.

TITLE: The use of ocular coherence tomography (OCT) for early glaucoma screening in patients with diabetes

SESSION TITLE: Glaucoma epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Johnson, P. Gupta, T. Lee, J. Rosdahl, Department of Ophthalmology, Duke University School of Medicine, Durham, North Carolina, UNITED STATES|

Commercial Relationships Disclosure: Nicholas Johnson: Commercial Relationship: Code N (No Commercial Relationship) | Priya Gupta: Commercial Relationship: Code N (No Commercial Relationship) | Terry Lee: Commercial Relationship: Code N (No Commercial Relationship) | Jullia Rosdahl: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Though there are no population-based screening recommendations for glaucoma, screening in at-risk populations has proven beneficial. Ocular coherence tomography (OCT) is a popular tool for assessing structural damage from glaucoma. The purpose of this study is to determine the utility of OCT for glaucoma screening in a population of diabetic patients. These results may inform future screening practices for early detection of glaucoma.

Methods: In this prospective study, patients with diabetes were screened for diabetic eye disease at a Duke primary care clinic over six months. The current study is a post-hoc analysis of OCT data collected from these patients. Glaucoma suspects (GS) were identified based on abnormal retinal nerve fiber layer (RNFL) thickness on OCT. Two-dimensional fundus photos of GS were graded by two independent raters for cup-to-disc ratio (CDR), image quality, and presence of optic disc notching, rim thinning, or disc hemorrhage.

Results: Of the 807 subjects that were screened, 50 patients (6.2%) were identified as GS due to abnormal RNFL thickness in at least one eye. The cohort of GS was 44% female and 70% white. Mean RNFL thickness for GS was significantly lower than mean RNFL in the total screening population ($p<0.001$). Median CDR for GS was 0.44. Twenty-eight eyes of 17 GS were marked as having optic disc notching or rim thinning by at least one grader, while 13 eyes of 7 GS were marked by both graders. Racial differences showed that mean CDR was significantly higher in non-whites than whites ($p<0.001$). Patient age was negatively correlated with RNFL ($r=-0.29$, $p=0.004$).

Conclusions: The aim of this study was to determine the percentage of diabetic patients categorized as GS by OCT and elicit how many suspects also showed clinical signs of glaucomatous damage. Results of this study suggest that in a sample of diabetic patients, a small but clinically significant minority may be flagged as GS based on OCT. Nearly one-fifth of these suspects demonstrated clinical signs of glaucoma on fundus evaluation. The construction of screening guidelines for glaucoma remains an important discussion in primary prevention of the disease. These results suggest that screening with OCT may be warranted in certain populations to allow for earlier diagnosis and treatment, particularly in older, non-white patients with diabetes.

TITLE: Novel PKM2 activators for photoreceptor neuroprotection: identifying potential clinical candidates

SESSION TITLE: New drugs, mechanisms of action and ocular toxicology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Chaudhury, E. Weh, H. HAGER, T.J. Wubben, C.G. Besirli, Ophthalmology and Visual Sciences,, University of Michigan Michigan Medicine, Ann Arbor, Michigan, UNITED STATES|J. RECH, B. WATCH, INTERNAL MEDICINE, University of Michigan, ANN ARBOR, Michigan, UNITED STATES|

Commercial Relationships Disclosure: Sraboni Chaudhury: Commercial Relationship: Code N (No Commercial Relationship) | JASON RECH: Commercial Relationship: Code N (No Commercial Relationship) | BRENNAN WATCH: Commercial Relationship: Code N (No Commercial Relationship) | Eric Weh: Commercial Relationship: Code N (No Commercial Relationship) | HEATHER HAGER: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Wubben: Commercial Relationship: Code N (No Commercial Relationship) | Cagri Besirli: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: There is a lack of successful treatment options that prevent photoreceptor cell death. We have shown that reprogramming photoreceptor metabolism via activation of PKM2 is a novel therapeutic strategy for neuroprotection. The low aqueous solubility and structural features of current PKM2 activators limit their ability to be translated to the bedside. The goal of this study was to develop the next generation of small molecule PKM2 activators, with improved solubility and in vivo potency for ocular delivery.

Methods: To address the structural limitations of current PKM2 activators, medicinal chemistry efforts focused on a pyridazinoindolone heterocyclic core with a range of functional groups. 49 novel analogues were developed, and solubility of the compounds was tested at pH 7.4. The ability to activate PKM2 was tested with human recombinant PKM2 enzyme, in vitro in 661W cells, and in vivo in rat retina via intravitreal (IVT) injection, oral gavage, or intraperitoneal injection (IP), using a continuous, enzyme-coupled assay that measures the depletion of NADH via absorbance at 340 nm.

Results: All compounds showed nanomolar potency with recombinant PKM2 and in vitro in 661W cells. MCTI-566 was identified as a highly soluble PKM2 activator with aqueous solubility of 385 µg/mL and an AC_{50} = 83 ± 9 nM. When injected intravitreally, MCTI-566 retained PKM activation as compared to tool compound and known selective PKM2 activator, ML-265. Interestingly, a single oral dose of ML-265 (50 mg/kg) produces similar PKM activation in the retina as a single intravitreal injection of ML-265 (1 mM) and retains 100% increased PKM activation after 1 week. Likewise, a single IP dose (50 mg/kg) of MCTI-566 produced similar PKM activation in the retina as compared to a single IVT injection of ML-265 (1 mM) and retained 100% increased PKM activation in the retina after 1 week.

Conclusions: This study developed the next generation of PKM2 activators with improved aqueous solubility while maintaining nanomolar potency. Successful commercial development of MCTI-566 would be transformative for ophthalmology, as a novel PKM2 activator could potentially be the first therapeutic to stop photoreceptor death and improve vision in currently untreatable eye conditions. Future studies will assess ocular and systemic toxicity and in vivo efficacy.

ABSTRACT BODY:

Purpose: To compare the clinical characteristics and high-resolution optical coherence tomography (HR-OCT) findings between corneal squamous metaplasia and ocular surface squamous neoplasia (OSSN).

Methods: A retrospective case control study of eight patients, four with histologically confirmed squamous metaplasia and four with histologically confirmed OSSN, that presented to the Miami Veterans Administration Medical Center and Bascom Palmer Eye Institute between 2016 and 2020, was performed. Clinical characteristics, HR-OCT findings, and pathology were evaluated and compared.

Results: Four patients with squamous metaplasia and four with OSSN were evaluated. In the metaplasia group, 75% were male, two were white, and two were black. In the OSSN group, all four were white males. All lesions were opalescent and occurred at the limbus; however, the borders were more smooth and rounded in the metaplastic lesions compared to OSSN. HR-OCT findings were indistinguishable between the two groups. The attached figure compares the slit lamp photograph, HR-OCT, and pathology between a case with squamous metaplasia (top row) and a case with OSSN (bottom row).

Conclusions: There is overlap in clinical characteristics and HR-OCT findings between corneal squamous metaplasia and OSSN, highlighting one limitation of HR-OCT. As such, if a corneal opacity has some but not all HR-OCT findings of OSSN, squamous metaplasia should also be considered. A biopsy may be indicated to further evaluate and guide treatment.

ABSTRACT BODY:

Purpose: To investigate the link between aqueous cytokine expression and quantitative leakage phenotypes on ultra-widefield fluorescein angiography (UWFA) in diabetic retinopathy (DR).

Methods: Patients with DR enrolled in the prospective randomized PRIME trial were included in this study. Baseline aqueous samples were analyzed for cytokine expression using a multi-plex ELISA assay for 54 cytokines. UWFA scans from the same visit were utilized for automated machine learning-enhanced quantitative analysis to obtain perivascular leakage index (PLI) and general leakage index (GLI) with manual correction, as needed. Perivascular leakage was denoted by hyperfluorescence within 5 pixels of the segmented vascular tree. Generalized leakage was all other leakage beyond the specified distance from the vessel. Pearson's correlation was used to study the correlation between leakage metrics obtained from UWFA and 16 high expression cytokines found in >80% of the samples.

Results: Thirty-seven DR eyes without edema were included in this study. Significant correlations of panretinal PLI with ANGPTL4 (r=0.36, p=0.028) and angiostatin (r=0.37, p=0.025) were identified. Additionally, panretinal GLI significantly correlated with ANGPTL4 (r=0.40, p=0.015), IFNg (r=0.35, p=0.035), and CXCL16 (r=0.33, p=0.047). Foveal PLI significantly correlated with TNFa (r=0.40, p=0.015). Foveal GLI significantly correlated with VEGF-D (r=0.33, p=0.043), IL12p70 (r=0.34, p=0.039), and IL-17 (r=0.43, p=0.007). PlGF correlated significantly with foveal PLI/GLI ratio (r=0.48, p=0.002) and ANG-2 correlated significantly with panretinal PLI/GLI ratio (r=0.58, p=0.002). Additional correlation trends were identified with panretinal PLI with HB-EGF (r=0.32, p=0.051) and follistatin (r=0.28, p=0.097). Panretinal GLI trended towards significant correlation with VEGF-A (r=0.28, p=0.091), HGF (r=0.28, p=0.097), IL-17 (r=0.28, p=0.090), and TNFb (r=0.28, p=0.092. Foveal PLI/GLI ratio showed correlation trend for ANG-2 (r=0.28, p=0.097).

Conclusions: In this analysis, PLI and GLI on UWFA demonstrate differential significant correlations with aqueous cytokine expression in eyes with DR. Further investigation with larger datasets is warranted to substantiate these associations and evaluate the potential role for these signals for treatment response.

ABSTRACT BODY:

Purpose: Müller glia (MG) in several zebrafish models of chronic photoreceptor degeneration fail to re-enter the cell cycle and regenerate lost cells. Our goals were to determine the transcriptional and cellular responses to chronic degeneration and to identify mechanisms that prevent regeneration in cep290 and bbs2 mutant zebrafish.

Methods: RNA-seq, single-cell RNA-seq, and qRT-PCR were used to assess gene expression changes. Immunohistochemistry was performed on retinal cryosections to monitor retinal cell types. Acute injury was generated by exposing animals to high intensity light. Dexamethasone and irf8 mutant zebrafish were used for temporary and chronic immune suppression, respectively. The gamma-secretase inhibitor RO4929097A was used to inhibit Notch signaling. A minimum of 6 animals per group were tested. Data was quantified and analyzed using ANOVA with post hoc comparisons.

Results: Zebrafish cep290 and bbs2 mutants exhibit progressive photoreceptor degeneration beginning at 3 months of age. Degeneration leads to an immune response with accumulation of 4C4+/L-plastin+ cells in the outer nuclear layer (ONL) and subretinal space and the upregulation of inflammatory signaling pathways. Both mutants exhibit increased numbers of PCNA+ cells in the ONL but only a 2-fold increase in the number of proliferating Müller glia. At 1 month of recovery following acute light damage, the density of regenerated photoreceptors in cep290 or bbs2 mutants at all ages remained significantly lower than that of wild-type animals. In irf8;cep290 double mutants, which possessed significantly fewer microglia, there was reduced inflammation and cone degeneration was rescued. Finally, single-cell RNA-sequencing revealed sustained notch3 expression in MG of cep290 mutants and inhibition of Notch signaling induced MG to re-enter the cell cycle in both mutants.

Conclusions: Zebrafish cep290 and bbs2 mutants progressively lose cones beginning by 3 months of age. Regeneration of lost cones occurs only following acute damage, suggesting that the mutants retain the ability to stimulate reprogramming and proliferation of Müller glia. Finally, we show that inhibition of Notch signaling releases that constraint. Our results indicate that therapies to suppress microglia function may prolong photoreceptor survival and that triggering regeneration requires more than inflammation alone.

ABSTRACT BODY:

Purpose: To evaluate the treatment response to topical steroidal eye drops in peripapillary pachychoroid syndrome (PPS)

Methods: In an observational study we examined 15 patients (21 eyes) with a diagnosis of PPS. Patients were followed for 2-10 years prior to topical steroidal treatment without any signs of reduction of the cysts, even upon the more classical treatments like photodynamic therapy or oral acetolozamide. All included patients received topical Pred Forte 10mg/ml (PF) 3-times daily for four weeks. Upon a good response (absence of cysts) the topical steroids were tapered off by one drop a month.

Results: Of the included 21 eyes, baseline visual acuity (VA) was 20/30. The median choroidal thickness was 202um at 3mm nasal of the fovea, 369um 1.5 nasal of the fovea, and 430um subfoveal. All patients showed a good anatomical response to topical steroids on OCT. Six patients experienced prolonged reduction of cysts even when dosage was reduced to once daily. On tapering of PF, 3 patients (4 eyes) had recurrence of cysts that subsequently disappeared when dosage was increased. The VA improved in 9 eyes, remained unchanged in 5 and decreased in 3 eyes. Seven eyes experienced elevated IOP (range 26-32mmHg), for which in 2 eyes PF was discontinued upon which cysts recurred.

Conclusions: In this observational study for recalcitrant cystic changes secondary to PPS we saw a favorable response to topical steroids in all 15 cases (21 eyes). During tapering off of the steroidal drug recurrence of the cysts was seen that disappeared again upon increasing the topical drugs. The disappearance of the cysts resulted in better reading vision and better contrast but only mildly improved VA. Topical steroids may be a viable treatment option in PPS.

TITLE: Customized Epi-On Crosslinking Algorithms for Automated Keratoconus Treatment Planning
SESSION TITLE: Keratoconus and corneal biomechanics
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: D.C. Adler, M. Smirnov, B. Tavakol, Z. Hill, D. Usher, Glaukos Corp, Burlington, Massachusetts, UNITED STATES|
Commercial Relationships Disclosure: Desmond Adler: Commercial Relationship(s);Code E (Employment):Glaukos Corp.;Code I (Personal Financial Interest):Glaukos Corp. | Mikhail Smirnov: Commercial Relationship(s);Code E (Employment):Glaukos Corp.;Code I (Personal Financial Interest):Glaukos Corp. | Behrouz Tavakol: Commercial Relationship(s);Code E (Employment):Glaukos Corp.;Code I (Personal Financial Interest):Glaukos Corp. | Zachary Hill: Commercial Relationship(s);Code E (Employment):Glaukos Corp. | David Usher: Commercial Relationship(s);Code E (Employment):Glaukos Corp.;Code I (Personal Financial Interest):Glaukos Corp.

ABSTRACT BODY:

Purpose: Customized crosslinking treatments for keratoconus enhance visual and keratometric outcomes compared to non-customized treatments by tailoring the ultraviolet (UV) light pattern to the corneal geometry of the individual patient. Currently, physicians manually customize UV patterns using heuristics. Here, we assess 12 automated epi-on treatment planning algorithms in an in silico study to identify which have the greatest potential for aberration reduction and corneal flattening while eliminating user subjectivity.

Methods: 20 digital corneas were created using 3D tomography from keratoconic subjects. 12 planning algorithms were applied to each cornea representing 4 input maps (anterior tangential curvature, pachymetry, anterior and posterior elevation) and 3 scaling parameters (small, medium, and large UV zones). Each algorithm automatically detected and segmented the keratoconic defect and created stacked UV dose patterns of 11, 13, and 15 J/cm^2 fit to the individual corneas.

A photochemical-biomechanical model simulated epi-on treatment effects and predicted post-op corneal shapes. Outputs included change in max corneal curvature (Kmax), cone location and magnitude index, keratoconus severity index, vertical coma (VC), astigmatism, and spherical and higher-order aberrations. Comparisons were made to non-customized 9mm UV spots and manually-customized treatments.

Results: In silico analysis showed a spectrum of corneal flattening and aberration reduction tradeoffs. Pachymetry-based algorithms generated UV patterns that were central, circular, and gave the largest predicted change in Kmax (-2.4D). Elevation algorithms were peripheral, elliptical, and gave the largest predicted change in VC (-0.6um). Tangential curvature algorithms gave a balance between Kmax (-2.3D) and VC (-0.5um). All algorithms outperformed a 9mm spot (-0.2D Kmax, -0.1um VC) and manual customization (-1.7D Kmax, -0.3um VC).

Conclusions: Automated UV treatment plans may outperform non-customized and manually-customized crosslinking treatments for keratoconus while eliminating subjectivity.

ABSTRACT BODY:

Purpose: The purpose of the study was to evaluate the ability of OK-101, a novel chemerin receptor agonist, to improve neuropathic corneal pain (NCP). We investigated the efficacy of lipidated (L) and non-lipidated (NL) OK-101 in an NCP mouse model of ciliary nerve ligation.

Methods: NCP was induced by ligation of the ciliary nerve and confirmed by stimulation with 5M hyperosmolar saline (HS) and eye wiping response (counts/30 sec) on day 3. The integrity of the corneal epithelium was revealed by corneal fluorescein staining (CFS, Grade 0-3 in 5 regions on a 0-15 severity scale). Mice were divided into groups and given either L- or NL-OK-101 with a frequency of either 6/6 or 3/6 times/day or balanced salt solution (BSS) vehicle control. Gabapentin (100mg/kg i.p.) given on days 4, 7, 10 and 14 after surgery was used as a positive control. Treatment duration was for a total 11 days and efficacy measured by 5M HS and eye wiping. Safety measures included blink reflex due to mechanical stimulation by Cochet-Bonnet esthesiometer and CFS performed at 7, 10 and 14 days post surgery.

Results: NCP was established as demonstrated by increased eye wipes after ligation compared to naïve mice (36.65±6.45 vs. 13.74±3.18 counts/30 sec; $p<0.0001$) with no difference in CFS ($p>0.05$). Both compounds at either frequency did show an analgesic effect by inhibiting the hypersensitivity to 5M HS compared to BSS at day 14 (L-OK-101 at 3/6 17.5±0.78 and 6/6 15.4±0.73; NL-OK-101 at 3/6 16.8±0.88 and 6/6 14.6±0.75 vs. BSS 27.2±0.68 counts/30 sec; $p<0.0001$). Additionally, L- and NL-OK-101 at 6/6 and NL-OK-101at 3/6 times per day inhibited corneal nociceptor sensitization similar to gabapentin at day 14 (14.6±0.75, 15.4±0.73 and 16.8±0.88 vs 13.2±0.80 counts/30 sec, respectively). Both L- and NL-OK-101 at either frequency showed statistically significant ($p <0.05$) recovery of mechanical sensitivity threshold on par with gabapentin and significantly better than vehicle control ($p <0.01$) at days 7 and 10. Both the compounds showed no effect on corneal epithelial integrity compared to gabapentin or BSS (0.56±0.45 vs. 0.78±0.60 or 0.66±0.50 on the severity scale).

Conclusions: Topically administered OK-101 was effective in reducing NCP in a ciliary nerve ligation mouse model suggesting OK-101 could be a potential therapeutic target for the treatment of neuropathic corneal pain.

ABSTRACT BODY:

Purpose: Retinal artery occlusion (RAO) is an emergency that can lead to poor visual outcomes and is associated with an increased risk of cerebral stroke and cardiovascular events. Fluorescein angiography is the traditional diagnostic tool for RAO; however, wide-field swept-source optical coherence tomography angiography (WF SS-OCTA) is able to provide quick and non-invasive angiographic information with a wide field of view. In this study, we looked for associations between OCT-A vascular metrics and visual acuity (VA) in patients with prior diagnosis of RAO.

Methods: Patients with diagnoses of central or branched RAO were included. A 6 x 6mm Angio and a 15 x 15mm AngioPlex Montage OCT-A image were obtained for both eyes in each patient using the Zeiss Plex Elite 9000 WF SS-OCTA device. Each 6 x 6mm image was divided into nine Early Treatment Diabetic Retinopathy Study (ETDRS) subfields. The average measurement of the central foveal subfield, inner ring, and outer ring was calculated for each parameter. Non-perfusion area (NPA) was manually measured using 15 x 15mm Montage images. A linear regression model was utilized to identify a correlation between the imaging metrics and VA. A P-value less than 0.05 was considered to be statistically significant.

Results: 25 subjects were included in the study. For RAO eyes, there was a statistically significant negative correlation between VA and retinal thickness as well as superficial capillary plexus vessel density (VD). A negative correlation was found between VA and deep capillary plexus VD without statistical significance. There was a positive correlation between VA and choroidal thickness as well as choroidal volume without statistical significance. No significant correlation was found between VA and the above metrics in contralateral eyes. For NPA measurements, no significant correlation was found.

Conclusions: This is the first study to investigate the utility of WF SS-OCTA in RAO and to demonstrate correlations between various retinal vascular imaging metrics and visual outcomes. Further investigations should explore the associations between these imaging findings and cardiovascular risk as RAO patients are at elevated risk for symptomatic stroke. The results of this study provide a basis to understand the structural changes involved in visual outcomes in RAO. Furthermore, they may help guide management of RAO and prevention of cerebral stroke and cardiovascular accidents in patients with RAO.

ABSTRACT BODY:

Purpose: Rhodopsin-associated autosomal dominant retinitis pigmentosa (RHO-adRP) is an inherited retinal disease that results in blindness due to photoreceptor degeneration. Over 150 mutations in the RHO gene are known to cause RHO-adRP. Using a dual AAV system, Editas Medicine is exploring potential therapy with a highly efficient CRISPR/Cas9 to knockout aberrant endogenous rhodopsin and replace it with an exogenous functional rhodopsin (KO&R).

Methods: The specificity of a human and non-human primate (NHP) cross-reactive Cas9 guide was tested using human retina explants transduced with the KO&R. Pharmacokinetics and pharmacodynamics of the KO&R were assessed in humanized mRho$^{hRHO/+}$ mice. Efficacy was measured in NHPs by comparing knockout (KO) only and KO&R versions of the dual AAV system delivered via subretinal injection. A miniRHO promoter was used to drive Cas9 as well as RHO expression while restricting editing and replacement of RHO expression to the rod photoreceptors. On- and off-target editing was assessed using Next Generation Sequencing. Endogenous and replacement RHO levels were quantified using NanoString and tandem mass spectrometry. Morphological and functional readouts were assessed by histopathology and electroretinography.

Results: No off-target editing was observed in human retina explants after transduction with the KO&R. The KO&R achieved maximal levels approximately 6 weeks post-dose and remained stable for at least 13 weeks post-dose in mRho$^{hRHO/+}$ mice. The KO&R levels displayed a dose response reaching a plateau at a dose of 6E12 vg/ml. Studies in NHP demonstrated nearly 100% knockout of endogenous RHO, and replacement RHO produced over 30% of normal RHO protein. The KO&R-injected eyes showed restoration of RHO expression in the outer segments and retention of normal photoreceptor structure and function (ERG analysis) compared to the KO-injected eye.

Conclusions: Editas characterized and demonstrated high efficacy of a CRISPR/Cas9-based KO&R therapeutic strategy for RHO-adRP. The experimental therapy is mutation-agnostic and could be a potential one-time treatment to permanently suppress the toxic gain of function associated with mutated RHO. The efficacy of our KO&R gene editing therapy in NHP supports continued advancement of this approach toward treating patients.

ABSTRACT BODY:

Purpose: Next generation sequencing (NGS), that is, short-read sequencing (SRS), has been widely used in identifying pathogenic mutations in inherited eye diseases (IEDs). However, the approximate diagnosis rate using SRS is around 52%, which is probably due to novel genes, or variants that may be missed by SRS approaches, such as structural variants (SVs) and variants in introns or regulatory regions. In this study, we performed long-read sequencing (LRS) to re-evaluate the disease-causing mutations of IED patient whose genetic etiology remained unclear after SRS.

Methods: Long read sequencing around 30X genome coverage using the PacBio Sequel II system was performed on a Chinese family with a proband diagnosed with syndromic optic atrophy. Comprehensive bioinformatic analysis was then conducted, followed by trio-based segregation analysis and pathogenicity analysis.

Results: Genome-wide SV calling yielded a total of 130520 SVs, with de novo SVs of 12188. Among them, we determined a novel 1447-bp de novo heterozygous deletion located in the NR2F1 gene which was segregated with the phenotype of optic atrophy and epilepsy. The de novo deletion spans the 5’ UTR and the first exon along with partial intron 1, resulting in haploinsufficiency of NR2F1,which has been reported to be the etiology of autosomal dominant Bosch-Boonstra-Schaaf optic atrophy syndrome (BBSOAS).

Conclusions: The genetic etiology of the family with syndromic optic atrophy was successfully identified using LRS and we reported a novel SV associated with BBSOAS. Overall, this study has shown that SVs may contribute to the genetic etiology of syndromic optic atrophy, and that SV analyses should be included in the genetic workflow of IED. It also demonstrates the potential value of long-read sequencing in identifying SVs in patients with IEDs.

ABSTRACT BODY:

Purpose: To determine whether tumor necrosis factor, alpha-induced protein 3 (TNFAIP3) regulated toll-like receptor 4 (TLR4) actions on the NOD-like receptor protein 3 (NLRP3) inflammasome.

Methods: Western blotting was done on retinal lysates from TLR4 floxed and endothelial cell specific TLR4 knockout mice for TNFAIP3, TLR4, and NLRP3 pathway proteins. Retinal endothelial cells (REC) were grown in normal and high glucose and treated with TNFAIP3 siRNA, followed by Western blotting for TLR4 and NLRP3 pathway proteins.

Results: Loss of TLR4 in endothelial cells increased TNFAIP3 levels, while decreasing NLRP3 pathway proteins. High glucose culturing conditions increased TLR4 and NLRP3 proteins, which were increased by TNFAIP3 siRNA.

Conclusions: Data demonstrate that TLR4 regulates NLRP3 pathway proteins. TNFAIP3 can regulate TLR4 and the NLRP3 pathway. TNFAIP3 may offer a new target for therapeutic development against retinal inflammation

ABSTRACT BODY:

Purpose: ABCA4 c.5461-10T>C is the third most common Stargardt disease type 1 (STGD1)-causing variant, for which no treatment is available. It leads to exclusion of exons 39 and 40, resulting in out-of-frame ABCA4 transcripts and a severely reduced production of wildtype ABCA4 protein. Here, we investigated the restoration of wildtype splicing by QR-1011, an antisense oligonucleotide (AON), as a therapeutic approach using in vitro cell models.

Methods: The effect of target-specific AONs was investigated by transfection (n=3) of HEK293 cells using a splice-predictive midigene model carrying the mutation. Isoform-specific digital PCR (dPCR) was used for absolute quantification of correct transcript as a percentage of all measured ABCA4 transcripts. Subsequently, QR-1011, the best performing AON, was studied in 3 dimensional CRISPR-Cas9 edited or patient-derived human retinal organoids (ROs), both homozygous for c.5461-10T>C. ROs (n=6 or 8 per group) were treated once with either QR-1011 or a control AON and harvested after 8 weeks. The quantification of transcripts by dPCR was accompanied by immunohistochemistry (IHC) and Western Blot (WB) analysis to identify rescue of wildtype ABCA4 protein expression post-AON treatment. Statistical analysis was performed with either two-tailed Student’s t-test or one-way ANOVA with Dunnett’s multiple comparisons test.

Results: In midigene-transfected cells, QR-1011 achieved 51,8±2,4% (mean±SEM; p<0,0001 vs. control) of correct transcript and was selected as best splice-modulating AON. In CRISPR-Cas9 edited ROs, QR-1011 corrected 37,9±2,1% (p<0,0001) of the full-length ABCA4 isoform after 8-weeks, while patient-derived ROs contained 46,04±7,1% (p<0,0001) of wildtype transcript after similar treatment. By contrast, in both control groups, only 3% of wildtype ABCA4 transcripts were detected. Furthermore, IHC and WB analysis of treated ROs revealed rescue of wildtype ABCA4 protein, which was localized in outer segments of photoreceptor cells, as opposed to control samples where no protein was observed.

Conclusions: QR-1011 treatment resulted in splice correction in both midigene and organoid models. Moreover, when administered to ROs, QR-1011 restored the production of ABCA4 protein. These results show the ability of QR-1011 to correct aberrant splicing caused by the c.5461-10T>C mutation in ABCA4 and highlight its therapeutic potential for STGD1.

ABSTRACT BODY:

Purpose: Purpose: New treatment strategies are needed to improve the disease management for patients who respond poorly to anti-VEGF treatments. Microfibrillar-associated protein 4 (MFAP4) is an extracellular matrix protein and a ligand for avb3 and avb5 integrins. We previously showed that anti-MFAP4 antibodies (anti-MFAP4) effectively block pathological angiogenesis and inflammation in a mouse model of laser-induced choroidal neovascularization and in a rat model of diabetic retinopathy. Here, we report the efficacy of anti-MFAP4 in a rabbit model of CNV.

Methods: CNV lesions were induced in 18 brown HyD rabbits by subretinal injection of 50µl of MatriGel containing 100ng FGF2 and 100ng LPS. Bruch's membrane was perforated with a 30G micro-lancet to ensure a small subretinal hemorrhage from the choroidal vessels. The growth of lesions was observed using optic and fluorescein angiogram (FA) modules of a Heidelberg Spectralis. Once CNV growth had reached measurable size after one month, animals received 50µl intravitreal injections of anti-MFAP4 (2mg), ranibizumab (Lucentis 0.5mg) or remained as untreated controls. Lesions were then measured one and two months after the treatments using FA. Three of the control animals and one of the ranibizumab animals were lost to imaging due to cloudiness.

Results: The vascular area of the CNV lesions were significantly reduced after 1 month ($p<0.05$), 2 months ($p<0.001$) and were sustained for 6 months after intravitreal injection with 2mg anti-MFAP4 (n = 12 of 6 rabbits). The 0.5mg Lucentis-treated (n = 10 of 5 rabbits) group had reduced lesion size only after 4 and 6 months compared with initial measurement. (2-way ANOVA with post hoc Tukey test). At each time point the anti-MFAP lesion size was smaller than anti-VEGF lesion size ($p<0.001$, two way ANOVA)

Conclusions: We demonstrated a single intravitreal injection of anti-MFAP4 effectively reduced the CNV lesion size in the rabbit model. Using MFAP4 as alternative target to VEGF could be used as novel strategy, particularly in patients who respond poorly to anti-VEGF treatments.

ABSTRACT BODY:

Purpose: So far, the natural course of geographic atrophy (GA) progression in age-related macular degeneration (AMD) has primarily been investigated by fundus photography and fundus autofluorescence (FAF) imaging. The aim of this long-term retrospective, observational clinical study was to show the enlargement rate (ER) of GA, defined as complete retinal pigment epithelium and outer retinal atrophy (cRORA) and to find predictors of progression.

Methods: All patients available in the database of Vista Eye Clinic Binningen, Switzerland, with follow-up of at least 24 months and existing GA in at least one eye, regardless of neovascular AMD (nAMD) being present initially or in the course of disease, were included. SD-OCT and FAF evaluations were performed according to a standardized protocol. The cRORA area ER (mm2/yr), the cRORA square root area ER (mm/yr), the FAF GA area and the condition of the outer retina (inner-/outer segment line (IS/OS) and external limiting membrane (ELM) disruption scores) were determined.

Results: 210 eyes of 133 patient (65% females) were included. Mean follow-up time was 4.0±2.3 (range 2-10) years. 109 (52%) eyes were classified as primary or secondary nAMD, 101 (48%) as exclusively dry AMD. The primary lesion was unifocal in 151 (72%) and multifocal in 59 (28%) eyes. A strong correlation was observed between the area of cRORA (SD-OCT) and the FAF GA area ($r= 0.925$; $p<0.001$). Mean ER was 1.44±1.6 mm2/yr and mean square root ER 0.29±0.19 mm/yr. There was no significant difference in mean ER between eyes without (dry AMD) and with intravitreal anti-VEGF injections (nAMD) (0.3±0.19 mm/yr vs. 0.28±0.20 mm/yr; $p=0.466$). Eyes with a multifocal GA pattern at baseline had a significantly higher mean ER compared to eyes with a unifocal pattern (0.34±0.19 mm/yr vs. 0.27±1.19 mm/yr; $p=0.008$). There were moderate significant correlations between ELM and IS/OS disruption scores and visual acuity at baseline, 5 and 7 years (all r values ca. -0.5; $p<0.001$). In multivariate regression analysis, a scattered cRORA pattern at baseline ($p=0.022$) and a smaller baseline lesion size ($p=0.036$) were associated with a higher mean ER.

Conclusions: SD-OCT evaluated cRORA area might serve as a GA parameter comparable to traditional FAF measurement. The dispersion pattern and baseline lesion size might be predictors of ER, whereas anti-VEGF treatment seems not to be associated with ER.

ABSTRACT BODY:

Purpose: The lamina cribrosa (LC) is hypothesized to be the site of initial axonal damage in glaucoma with the peripapillary retinal nerve fiber layer (RNFL) thickness is widely used as a standard metric for quantifying this damage. The purpose of this study was to determine in vivo changes in the microstructure of the LC in eyes of non-human primates (NHP) with naturally occurring RNFL thinning.

Methods: Spectral-domain OCT scans (Leica, Chicago, IL) of the optic nerve head (ONH) were acquired in vivo from a colony of 50 adult rhesus monkeys, suspected of having high prevalence of naturally occurring glaucoma. The circumpapillary global and quadrant RNFL thickness was analyzed using a custom automated segmentation software. From the set of 100 eyes, the 10 eyes with the thinnest global RNFL values were selected as the study group, while 10 eyes with RNFL values around the 50^{th} percentile were used as the control group. A previously described automated segmentation algorithm was used for LC microstructure analysis. The LC microstructure was analyzed globally and in the following volumetric sectors: quadrants, central and peripheral lamina, and 3 depth slabs (anterior, middle, posterior; Figure). Beam thickness/pore diameter ratio (BPR) and connective tissue volume fraction (CTVF: beam volume/total volume) were calculated globally and in sectors.

Results: 20 eyes (15 animals) were analyzed (Table 1). While no significant difference was detected between groups for age, weight or disc size, the study group had significantly thinner RNFL than the control group ($p<0.01$). The study group had significantly larger BPR and CTVF compared with the control group (Table 2). Significant sectoral differences between study and control group RNFL thickness were noted for BPR and CTVF in the nasal and temporal quadrants, central LC, and in LC depth. Across eyes, the global RNFL thickness was moderately negatively correlated only with the global CTVF (lower RNFL thickness associated with higher CTVF; $r^2=0.63$, $p=0.045$).

Conclusions: Eyes with thinner circumpapillary RNFL had thicker LC BPR and CTVF globally and in various sectors when compared to eyes with normal RNFL thickness. Whether these LC changes are the cause of RNFL damage or the result of remodeling of the LC requires further investigation.

ABSTRACT BODY:

Purpose: Due to advances in optics, electronics and computation, morphological changes of the photoreceptor mosaic can be made visible by adaptive optics ophthalmoscopy (AOO). Retinitis pigmentosa (RP) is a degenerative retinal disease that affects primarily the rod photoreceptors followed by the loss of cone receptors. This paper aims to present typical findings in RP with the adaptive optics flood illumination retinal camera rtx1.

Methods: 174 patients with syndromic or non-syndromic RP were examined with the commercially available adaptive optics flood illumination retinal camera rtx1 and spectral domain optical coherence tomography (OCT) and fundus autofluorescence (FAF) imaging at the Center for Ophthalmology, University of Tuebingen. AOO patterns were studied in the context of multimodal retinal imaging.

Results: Five different patterns in RP could be observed: 1) unspecific atrophy, 2) central visibility of cones, 3) “puffy” cones, 4) the “cheetah” pattern, and 5) atrophic pigment clumping. These patterns in AOO correlated with findings on OCT and FAF imaging. We hypothesize that these patterns represent specific stages of photoreceptor degeneration in RP.

Conclusions: AOO provides an additional dimension to high-resolution retinal imaging in RP, enabling to determine patterns of retinal degeneration. Future evaluation of cone photoreceptor mosaic using AOO imaging is warranted to determine changes on an even more microscopical level, e.g. photoreceptor integrity.

ABSTRACT BODY:

Purpose: The retinal pigment epithelium (RPE) serves as an outer blood retinal barrier during Klebsiella pneumoniae (KP) infection in endogenous endophthalmitis. Nevertheless, the pathogen-associated molecular patterns and the specific adhesion molecules used of RPE cells upon interaction with KP are yet been reported. In this study, we investigate the changes of diabetic ocular environment facilitate the development of KP invasion to the eye.

Methods: In this study, we investigated the ability of KP to invade human RPE cells (ARPE-19) in in vitro diabetic condition (in 27.5mM and 17.5mM glucose culture medium). Adhesion and invasion assays were undertaken to investigate roles of tight junction proteins, adhesion molecules, acute inflammatory molecules (IL-1, IL-6, IL8) and molecules involved in the pathogen-associated molecular patterns via ELISA and western blot studies. The results were validated via RNA sequencing on ARPE-19 cells.

Results: We concluded that KP adhesion and invasion to RPE were increased in hyperglycemic condition via breaking down specific tight junction pathway proteins and enhancing specific adhesion molecules including vascular cell adhesion protein 1 (VCAM-1) and activated leukocyte cell adhesion molecule (ALCAM). Furthermore, toll-like receptor 4 (TLR4) was enhanced for pattern recognition and NF-kB and MAPK pathway were involved during KP infection.

Conclusions: This is the first study to highlight the pattern recognition, adhesion molecules engaged, and signal transduction pathway during KP invasion to the eye in diabetic ocular condition in vitro. The results suggest a strong rationale for between endogenous endophthalmitis and systemic KP infection for individuals with diabetes mellitus.

ABSTRACT BODY:

Purpose: Facial trauma can have a variety of sequelae, including orbital floor fractures and traumatic optic neuropathy. Although these injuries are common, their management is controversial. Our goal was to summarize management practices at international high-volume eye trauma centers and identify areas of alignment and discrepancy.

Methods: An online survey was conducted from August 2020 to January 2021 to obtain a census of management paradigms for orbital floor fractures and traumatic optic neuropathy at high-volume eye trauma centers globally. Trauma experts responded on behalf of general practices at their institutions.

Results: Response rate was 85.7% (36/42); 3 of the responding centers were excluded from analysis due to low case volume. Of the responding institutions, 54.5% (n=18/33) routinely administered systemic antibiotics for orbital floor fractures, with oral amoxicillin and clavulanic acid (n=13/18, 72.2%) and oral cefalexin (n=4/18, 22.2%) being most common. Only 27.3% (n=9/33) of respondents administered systemic steroids, most of whom utilized oral steroids (n=7/9, 77.8%). Respondents considered the optimal timing for surgical repair of orbital floor fractures to be on average 11.46 ± 8.46 days from presentation, with oculoplastic surgeons participating in performing the repair at 72.7% (n=24/33) of responding institutions and oral and maxillofacial surgeons at 57.6% (n=19/33) of centers. Most experts did not routinely admit patients with isolated orbital fractures on presentation (n=26/33, 78.8%); however, 48.5% (n=16/33) of respondents admitted patients after the repair for an average of 3.50 ± 1.96 days. For cases of traumatic optic neuropathy, 63.6% (n=21/33) of respondents routinely administered systemic steroids, with 57.1% (n=12/21) preferring intravenous administration. High dose steroids (methylprednisolone 1gm daily) were used by 36.4% (n=12/33) of responding centers and moderate doses (prednisone 1 mg/kg daily) were preferred by 21.2% (n=7/33).

Conclusions: While experts largely agreed on administering antibiotics for orbital floor fractures and steroids for traumatic optic neuropathy, responding trauma experts differed on many aspects of optimal management paradigms. Further investigations are needed into best treatment regimens to institute evidence-based care in ophthalmic trauma.

TITLE: Synthetic Nuclease Resistant Enhanced Hammerhead Ribozymes for Nucleic Acid Ocular Therapeutics

SESSION TITLE: Gene Therapy and Gene Editing for Ocular Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Myers, J.M. Sullivan, Ophthalmology (Ross Eye Institute), University at Buffalo, Buffalo, New York, UNITED STATES|J. Myers, J.M. Sullivan, Research Service, VA Western New York Healthcare System, Buffalo, New York, UNITED STATES|

Commercial Relationships Disclosure: Jason Myers: Commercial Relationship(s);Code P (Patent):Research Foundation of SUNY, Veterans Administration | Jack Sullivan: Commercial Relationship(s);Code P (Patent):Research Foundation of SUNY, Veterans Administration (8,252,527 and 8,450,473)

ABSTRACT BODY:

Purpose: We are investigating enhanced hammerhead ribozymes (EhhRzs) that exceed the turnover rate of historical minimal hhRzs (mhhRzs). Small synthetic nuclease resistant EhhRzs are great candidates for intraocular therapeutics. The inner limiting membrane (ILM) which provides a structural boundary between the vitreous and retina allows diffusional entry of small nucleic acids for retinal therapies.

Methods: Substrate RHO-266 RNA is 15 nt long with a 5' FAM and 3' BHQ1 (IDT); cleavage at CUC 266 results in liberation of quenched fluorescence which is quantified optically in real time. Synthetic EhhRzs are generated by IDT. Cleavage reactions are initiated by mixing EhhRz with substrate RNA in assay buffer (10 mM Tris-HCl, pH 7.5 with 0.5 mM Mg^{2+}) and optically measured at 37°C in a qRT/PCR machine. Nuclease assays are performed in 10% Normal Human Serum (NHS) or recombinant RNase A (100nM) at 37°C. Data are analyzed in Origin.

Results: Chemical modifications (2'-O-Methyl, 2OMe) throughout the EhhRz (except for core nucleotides: G5,G8,G12, A9,A15.1), provides nuclease resistance at 24hrs, but catalytic activity is abolished (1/min vs unmodified 283/min, p=7.30E-12). Locked nucleic acid (LNA) residues incorporated at the 5 and 3' ends with 2OMe occupied residues in the EhhRz (except for U4, G5,8,12, A9, A15.1, and stem) resulted in catalytic activity (382/min) but lacked nuclease resistance (p=1.11E-6). Antisense oligos designed to protect regions of the EhhRz core demonstrated nuclease protection and provided evidence of susceptibility at U4. An EhhRz incorporating 2OMe, LNA, 2'-Fluor C in the stem, and 2'-Amino U4, maintained strong catalytic activity (112/min) and nuclease resistance at 24hrs.

Conclusions: Chemically-modified EhhRzs that provide nuclease protection while retaining enhanced catalytic activity contribute a useful tool for synthetic nucleic acid ocular therapeutics. These studies incentivize novel chemical biological approaches to further enhance catalytic activity while preserving nuclease insensitivity and extended tissue and cellular half-lives. Synthetic EhhRzs with increased catalytic activity support function under Michaelis-Menten conditions ([S] >> [E]) that allow for robust target mRNA knockdown at lower levels of therapeutic delivery (and toxicity).

ABSTRACT BODY:

Purpose: As glaucoma occurs from multifactorial causes, studying glaucoma causative mutation leading to a monogenic form of glaucoma would help better understand glaucoma development. Here, we tested if glaucoma may sensitize cells to death induced by cell stressors.

Methods: Gene editing

CRISPR/Cas9-mediated deletion of genes was performed by electroporation of Cas9 RNP in 661w.

OPTN E50K cell line generation

To generate cell lines harboring Optn-WT and Optn-E50K, PhiC31 integrase system was adapted following the manufacturer's protocol.

Ischemia-reperfusion injury model

The needle was connected to a 0.9 % NaCl reservoir and hung it up to sustain the pressure of the mice eye. After 45 minutes of ischemia induction by pressure.

Results: Optn-KO and Optn-E50K sensitize cells to TNFα-dependent necroptosis.

Optn-KO and Optn-E50K are more susceptible to necroptosis stimuli TBE (TNFα, BV6, Emricasan) and TTaE (TNFα, Takinib, Emricasan) confirmed by lactate dehydrogenase (LDH) release. GNE684, a small molecule Ripk1 inhibitor, suppressed LDH release. WB analysis confirmed that the phosphorylation of Ripk1, Ripk3, and Mlkl, the core axis of necroptosis, were induced more prominently in Optn-KO and Optn-E50K under necroptosis stimuli also in the glaucoma experimental mice model. Only necroptosis conferred this susceptibility of Optn-KO and Optn-E50K but not apoptosis such as doxorubicin or staurosporine. Thus, we confirmed that Optn can protect cells against TNFα-mediated necroptosis, and Optn-E50K is a loss-of-function mutation in the cell death context.

mRNA levels of TNFα and RIPK3 are elevated in the retina from glaucoma patients.

TNFα and RIPK3 showed a well correlated transcript-to-translation ratio. The transcript level of TNFα and RIPK3, a critical component of necroptosis, are upregulated in the glaucomatous retina compared to the non-glaucomatous retina. These data could underline the connection to necroptotic cell death in glaucoma pathogenesis.

Conclusions: Here, we showed that the Optn-E50K variant, a glaucoma causative mutation in an autosomal dominant pattern sensitizes cells to TNFα-mediated necroptosis. This study may suggest implications of TNFα in glaucoma pathogenesis in both subtypes, intraocular pressure (IOP) –related and non-IOP-related glaucoma, and inform possible future therapy for neuropathies in the retina.

ABSTRACT BODY:

Purpose: To evaluate visual outcomes of 103 consecutive Toric intra-ocular lens (IOL) placement procedures from 2017-2019 at a single center using an FDA-approved Toric IOL with non-frosted haptics.

Methods: We conducted a retrospective chart review of consecutive monofocal Toric IOL's from a single manufacturer, performed at a single surgery center by a single surgeon. All patients underwent femtosecond laser capsulotomy with placement of 2 marks on the anterior capsule 180 degrees apart on the target axis. Iris registration technology aided identification of the steep corneal axis at the capsular plane for alignment and accounted for head positioning during laser. IOL powers were planned with Barrett Toric calculator. Pre- and post-operative data points were recorded and analyzed. Patients with reduced best-corrected-visual-acuity (BCVA) due to pre-existing retinal (epiretinal membrane) and corneal (keratoconus or Fuch's dystrophy) conditions were excluded from the final analysis. Four eyes were excluded due to lack of follow up, and 18 eyes were that were targeted for near were excluded as well.

Results: 103 consecutive surgeries were evaluated. The mean cohort age was 72 years old and 56% female and 44% male. 67% of patients identified as non-Hispanic white, 26% identified as Hispanic and 7% did not report. After application of all exclusion criteria, our final cohort included 74 eyes, of which 58 eyes (78.4%) achieved our goal of 20/30 or better uncorrected visual acuity (UCVA). Of the 16 eyes (21.6%) that did not achieve the goal of 20/30 UCVA or better, 9 of 16 (56%) had >0.75D residual astigmatism, and 12 of 16 (75%) had >0.50D of myopic spherical equivalent. 5 eyes (6.8%) underwent post-operative IOL rotation for axis correction, and 5 eyes (6.8%) underwent laser vision correction adjustments. No patients underwent IOL exchange.

Conclusions: While Toric IOLs with unfrosted haptics have potential to provide excellent UCVA for patients undergoing cataract surgery, the 6.8% rate of return to the OR for repositioning the toric IOL to the correct axis in our study population is high. Frosted haptics potentially improve visual outcomes by increasing rotational stability through a textured surface creating more friction between the haptic and the capsular bag. Our future goal is to evaluate outcomes in a matched cohort of eyes with monofocal toric IOLs that have frosted haptics.

ABSTRACT BODY:

Purpose: High levels of proinflammatory cytokines in the aqueous humor (AqH) have been associated with corneal graft failure (CGF) and endothelial cell loss after corneal transplant. Pyroptosis is a recently described caspase-1-dependent proinflammatory programed cell death mechanism. Pyroptosis is triggered upon inflammasome activation, which is a multiprotein complex comprised by the protein apoptosis-associated speck-like protein containing a caspase recruitment domain (ASC); a nucleotide oligomerization domain-like receptor (NLRs); and procaspase-1. In the present study, we assessed caspase-1 levels in primary human corneal endothelial cells (PhCEC) following exposure to the AqH of patients with CGF and from healthy patients.

Methods: PhCEC were incubated in vitro for 60 minutes with the AqH of patients with CGF (n=4) who underwent corneal transplantation and healthy patients who underwent cataract surgery (n=4). The levels of caspase-1 in PhCEC were determined by ELISA 24 hours following exposure. A specific caspase-1 inhibitor (Ac-YVAD-cmk) was used to assess downregulation in these cells.

Results: Protein levels of caspase-1 were significantly higher in PhCEC incubated with the AqH of patients with CGF than those incubated with the AqH of healthy eyes ($p<0.0043$), and with the group with no AqH exposure ($p<0.0008$). The last two groups did not show differences between them ($p=0.58$). Additionally, levels of caspase-1 were significantly downregulated by the caspase-1 inhibitor Ac-YVAD-cmk in PhCEC exposed to the AqH of patients with CGF ($p<0.0017$) but showed no differences in other groups.

Conclusions: AqH of patients with CGF induced inflammasome activation in corneal endothelial cells and was downregulated by Ac-YVAD-cmk, suggesting that pyroptosis may play an essential role in the pathogenesis of endothelial cell death that leads to CGF. These findings reassert the importance of further studies of this pathway for therapeutic purposes.

ABSTRACT BODY:
Purpose: This study aimed to analyze the effect of binocular blindness in critical periods on visual white matter pathways.
Methods: We have previously reported that diffusion MRI measurements along early visual white matter pathways (the optic tract; OT and optic radiation; OR) acquired from patients of adult-onset eye diseases (glaucoma, leber hereditary optic neuropathy, and cone-rod dystrophy) differ from those acquired from healthy controls (Ogawa et al., 2014; Takemura et al., 2019). However, few studies have analyzed how early blindness affects tissue properties of visual white matter pathways. Here, we acquired diffusion MRI from a male in their 40s with congenital glaucoma (CG) who went binocular blind around 7 to 8 years old using 3T MRI (SIEMENS Trio Tim). We compared his diffusion measurements along OT and OR with age matched healthy controls (n=25, female=11) and glaucoma groups (n=10, female=4). Datasets obtained from healthy controls and glaucoma subjects were already analyzed in a previous study (Ogawa et al., 2021).
We applied probabilistic tractography to identify the OT and OR (Sherbondy et al., 2008). We then estimated fractional anisotropy (FA) along the OT and OR in all subjects, and then compared FA of CG from that of other groups.
Results: The diffusion measurements in the OT and the OR of CG were significantly different from those of the other two groups. In both OT and OR, CG showed significantly smaller FA compared with those in the glaucoma group (OT: $d' = 3.75$, $p = 0.03$; OR: $d' = 5.40$, $p = 0.001$) and the healthy controls (OT: $d' = 5.26$, $p = 0.005$; OR: $d' = 7.68$, $p < 0.001$).
Conclusions: Our preliminary analysis suggests that white matter tissue changes occurring in CG is significantly bigger than those in the glaucoma group. The results raise a possibility that the complete loss of binocular visual input occurred during the visual critical period may cause bigger changes in the microstructure of visual pathways.

ABSTRACT BODY:

Purpose: Doctors find it challenging to address lifestyle changes in patients with age-related macular degeneration (AMD) despite the current insight that a healthy lifestyle can reduce risk of progression by half. We developed an easy to use lifestyle scoring form for patients with intermediate or unilateral late AMD who are still at risk for severe visual loss.

.

Methods: Scoring forms were created based on risk estimates for lifestyle factors from validated studies. Patients ascertained from the clinic and patient organizations received scores for smoking, Mediterranean diet, exercise, and BMI. Each healthy outcome received a point; the maximum score was 13 points. We determined tertiles of total genetic risk by genotyping the 52 known common risk variants.

Results: In an ongoing AMD lifestyle study, we analyzed the scores from the first 38 AMD patients with intermediate or unilateral late AMD. Of these, 16 (42%) had a total lifestyle score ≤ 6; only 2 (6%) scored ≥ 10. Low scores were mainly driven by non-adherence to the Mediterranean diet, with low vegetable and fish intake being most prominent. The majority (56%) of patients had a genetic risk in the highest tertile.

Conclusions: This lifestyle form provides an easy tool to gain insight about the lifestyle of AMD patients, and can help motivate them to improve their daily habits to reduce the impact of their genetic risk.

ABSTRACT BODY:

Purpose: Controversy exist regarding the effects of treatment of neovascular (NV) age-related macular degeneration (AMD) with anti-vascular endothelial growth factor (VEGF) on choroidal thickness (CT). We performed a cross sectional study to investigate the possible differences in choroidal thickness (CT) between the treated NV eyes and the untreated non-NV (NNV) eyes of patients with unilateral NV AMD.

Methods: A total of 164 eyes of 82 consecutive patients were selected from an ongoing prospective cohort study of patients with unilateral NV AMD. Patients had a mean age of 74.5 years (standard deviation [SD] 7.7) and 51/82 were female. Patients had to have unilateral NV AMD for which they received anti-VEGF treatment (currently or in the past). Two researchers (FT and FC) independently measured CT on spectral domain enhanced-depth imaging optical coherence tomography images using the calliper function in Heidelberg Eye Explorer (version 2.6.4.0, Heidelberg Engineering, Heidelberg, Germany). CT was measured at the fovea as well as 1500 µm and 3000 µm from the fovea in both the temporal and nasal direction. Interclass correlation coefficients (ICC) and Bland-Altman plots were calculated to check for intergrader reliability. The average value of the two measurements was then used. Differences between CT in NV and NNV eyes were assessed using a paired-samples T-test. Associations of CT with variables of interest were assessed through Pearson’s correlation coefficient analysis.

Results: ICC was above 0.941 across all measurement points. Bland-Altman plots revealed no intergrader bias. Average CT (SD) was 223.4 (107.8)µm and 233.4 (109.4)µm for NNV and NV eyes, respectively (P = .16). Age was significantly but weakly correlated with subfoveal thickness with a correlation coefficient of -.258 (P =.019). The amount of injections was not associated with CT (correlation coefficient - 0.01, P =.957).

Conclusions: In this cohort of unilateral AMD patients there appears to be no difference in choroidal thicknesses of NV eyes treated with anti-VEGF compared to the fellow NNV eye.

Commercial Relationships Disclosure: Oliver Gardiner: Commercial Relationship(s);Code E (Employment):Ufonia Limited | Mohita Chowdhury: Commercial Relationship(s);Code E (Employment):Ufonia Limited | Ernest Lim: Commercial Relationship(s);Code F (Financial Support):Ufonia Limited;Code E (Employment):Ufonia Limited | Aisling Higham: Commercial Relationship(s);Code E (Employment):Ufonia Limited;Code F (Financial Support):Ufonia Limited | Nick de Pennington: Commercial Relationship(s);Code E (Employment):Ufonia Limited;Code O (Owner):Ufonia Limited

ABSTRACT BODY:

Purpose: As cataract surgery numbers rise, follow up demands place further strains on hospital services. This study uses data collected using an automated telephone platform Dora, which asks patients symptom-based questions to elicit postoperative concerns. We compare the ability of different machine learning techniques to understand patients' descriptions of their symptoms during a cataract surgery follow up with Dora.

Methods:

The training and test datasets were collected from two non-overlapping patient populations who used Dora as part of ethically approved research studies across 3 diverse UK hospitals. The training dataset was augmented with members of the public using the Dora platform. All participants consented to their data being used and the data was fully anonymised. The datasets consist of transcribed utterances of patients describing their symptoms in response to questions like "is your eye red?". Each utterance was labelled with an intent, for example, "gritty" or " red eye" from a total of 24 different intents. Two ophthalmologists independently labelled the dataset and resolved conflicts to establish ground truth labels.

We compared 5 different deep learning and traditional machine learning models; the optimal hyperparameters for each were determined using a grid search and 4-fold cross-validation on the training set. The models were then trained on the entire training dataset and their performance evaluated on the test set.

Results: The training dataset included 1558 unique utterances from 191 patients and 254 members of the public. The test dataset had 255 unique utterances from 142 patients. The best performing model was the Dual Intent and Entity Transformer (DIET) classifier using word embeddings from BERT as presented in Table 1.

Conclusions: Deep learning models have the potential to accurately classify patient intents as part of a natural language conversation, with the DIET classifier performing best. Particularly in this low-data domain, the models benefit greatly from pretrained language models such as BERT. These models can thus be used to deliver autonomous clinical conversations for cataract surgery follow up.

ABSTRACT BODY:

Purpose: Alzheimer's Disease (AD) is a common neurological disorder affecting millions of individuals worldwide. We performed an experimental model and attempted to identify retinal biomarkers that can be used for a noninvasive diagnosis of this brain disorder.

Methods: Cryosections of brains and retinas from cadavers were analyzed. 2 cadavers without a history of neurodegenerative disease (1 male, 1 female) and 4 cadavers affected by AD (2 males, 2 females) were used. The structures of the brain specifically focused on were the prefrontal cortex (PFC), hippocampus, temporal lobe, visual cortex. Each tissue section was immunostained with antibodies against total tau (TT), phospho-tau 181 (PT181), phospho-tau 205 (PT205), and beta-amyloid (BA). Every stained section was then microscopically analyzed to compare and contrast each marker using optical density (OD) measurements.

Results: Retina samples of AD cadavers expressed a statistical significance increase in OD of the TT marker when compared to normal cadavers (AD = 0.37 OD ± 0.179, Normal = 0.01 OD ± 0.0049). In regards to the brain structures, only the TT markers in PFC were found to have statistical significant increases in OD value (AD = 0.28 OD ± 0.0621, Normal = 0.04 OD ± 0.0423). TT, PT181, PT205, and BA also expressed slight increases in OD in several brain structures of the AD cadavers but were not found to be statistically significant.

Conclusions: There is a significant increase in the TT marker in the retina with similar findings in the PFC. This suggests that using TT as a marker in the PFC and retina has the highest potential to aid in diagnosing AD, with a possibility of studying the progression of AD through TT in different areas of the brain in future research.

ABSTRACT BODY:

Purpose: Central geographic subendothelial deposits in the form of a fibrillar layer (FL) are formed in advanced stages of Fuchs endothelial corneal dystrophy (FECD). Previous studies demonstrated a decrease in corneal endothelial cell (CEC) density and an increase in corneal backscatter in the FL area. The present study investigated the association of clinical FL detection with alterations in corneal thickness.

Methods: Analysis of patients (n=96) presenting for Descemet membrane endothelial keratoplasty (DMEK) for advanced FECD at the Department of Ophthalmology, University Hospital of Cologne, Germany. Slit lamp biomicroscopy with FECD grading was followed by Scheimpflug imaging with en face backscatter analysis and tomography / pachymetric analysis. FL dimensions were measured and correlation with tomographic / pachymetric values was performed. Formal approval to conduct this study was obtained from the Ethics Committee of the University of Cologne (No. 16.424). The research adhered to tenets of the Declaration of Helsinki.

Results: A FL was detected in 74% of all eyes (n=71). FL dimension measures (mean + SD) were for area 9.97+-5.13 mm^2, for maximum caliper diameter 4.38+-1.07 mm, for maximum vertical caliper diameter 3.50+-0.93 mm, and for maximum horizontal caliper diameter 4.09+-1.10 mm. Pachymetric values in FL-positive versus FL-negative eyes were for central corneal thickness (CCT) 614.59+-51.82 µm and 575.12+-48.38 µm (p=0.001), for corneal thickness at the apex (ACT) 613.97+-51.57 µm and 575.20+-46.15 µm, for peripheral corneal thickness at 1mm (PCT_{1mm}) 615,73+-49,95 µm and 580,20+-44.21 µm (p=0.002), for PCT_{2mm} 625.15+-47.63 µm and 599.07+-40.85 µm (p=0.017), for PCT_{3mm} 651.04+-46.32 µm and 635.04+-39.86 µm (p=0.128) and for PCT_{4mm} 695.07+-51.75 µm and 686.00+-43.20 µm (p=0.435), respectively. Correlation analysis indicated a weak correlation for the FL maximum vertical caliper diameter with ACT and PCT_{1mm} values.

Conclusions: Scheimpflug en face backscatter detection of a FL is associated with increased corneal thickness within the central 2 mm of advanced FECD eyes. Combined with our previous studies showing reduced CEC count and increased light scattering in the FL area this provides further evidence that the detection of a FL may qualify as a criterion for intervention in FECD patients in the future.

ABSTRACT BODY:

Purpose: Vision loss in many open-angle glaucoma (OAG) patients continues despite successful treatment lowering intraocular pressure (IOP). The reasons remain elusive. Here, we show that mathematical modeling and machine learning (ML) can help identify subgroups of OAG patients whose disease process entails different relative contributions of IOP and blood pressure (BP).

Methods: 115 OAG patients were assessed every 6 months over a 7-year period for IOP, systolic and diastolic blood pressures (SBP, DBP), heart rate (HR), structural and hemodynamic evaluations via ocular coherence tomography (OCT), Heidelberg Retinal Tomography (HRT), Heidelberg Retinal Flowmetry (HRF), and Color Doppler Imaging (CDI). Fuzzy c-means (FCM) clustering was applied to the dataset comprising: (i) IOP, SBP, DBP, HR measured at the first visit for each patient in the IGPS study; and (ii) individualized estimates of vascular pressures and resistances obtained via a validated mathematical model (Guidoboni et al, IOVS, 2014). FCM is part of ML and the mathematical model is based on physiology, leading to physiology-informed ML. Follow-up visits and data from OCT, HRT, HRF and CDI were not used for clustering.

Results: While the data for IOP and mean arterial pressure (MAP) for the first visit of each IGPS patient do not exhibit any particular pattern (Fig.1a), the physiology-informed ML method revealed 3 distinct clusters. The slanted lines separating the clusters result from the nonlinear interplay that IOP and BP have on ocular hemodynamics captured by the mathematical model. Fig. 2 shows that the cluster membership based on the first visit is associated with different clinical outcomes after 4 years (p values obtained with the 2-sample paired Wilcoxon signed rank test for medians; p <= 0.05 in bold). Cluster 1 shows minimal progression, whereas Cluster 2 shows marked structural progression accompanied by significant hemodynamic changes. Cluster 3 exhibits significant changes only in HRT and HRF markers, but not in OCT and CDI.

Conclusions: This study suggests that the proposed physiology-informed ML approach can identify and quantify the relative contributions of IOP and BP on the OAG risk for patient subgroups. Thus, this approach may enable precision medical approaches of IOP and BP management in OAG.

ABSTRACT BODY:

Purpose: Retinopathy of prematurity (ROP) is a major cause of vision loss and blindness in children. In ROP, the onset of neovascularization (NV) is at around 32-weeks gestational age, regardless of gestational age at birth, which coincides with the development of rod outer segments and full rod function. Photoreceptors may play an important role in ROP pathogenesis. Yet, the molecular and cellular mechanisms through which photoreceptors control retinal NV in ROP are largely unknown. We aim to investigate the role of photoreceptors in controlling retinal angiogenesis via suppressor of cytokine signaling 3 (SOCS3).

Methods: The Cre/LoxP system was used to generate rod photoreceptor specific Socs3 knockout mice (Socs3 cKO) by crossing Socs3 flox/flox mice with Rhodopsin improved Cre mice (Rho-iCre) and Socs3 overexpression mice (Socs3 cOE) by crossing Socs3 OE flox/flox mice with Rho-iCre mice. The oxygen induced retinopathy (OIR) mouse model was used as a ROP preclinical model. Mice were exposed to 75% oxygen from postnatal day (P)7 to P12 and returned to room air from P12 to P17. Retinas were enucleated, fixed, and stained with endothelial cell marker isolectin B4 at P17 for phenotypical analysis. NV and vaso-obliteration (VO) was quantified using Image J. Real-time PCR and western blot were used to validate the efficacy of Socs3 overexpression and knockout. Immunohistochemistry was used to determine protein localization in the retina. Results are reported as mean ± SEM, and statistical analyses were performed with GraphPad Prism (v8.0).

Results: In the OIR model, SOCS3 expression was highly induced in the photoreceptor layer. The efficacy of photoreceptor Socs3 overexpression and knockout was validated. Cre recombination of Socs3 in the outer nuclear layer of the retina was confirmed using Rho-iCre driven mTmG reporter mice. In the OIR model, SOCS3 deficiency in rod photoreceptors significantly increased NV by 25% ($p<0.01$, n=18-20) without influencing VO ($p>0.05$) compared to controls. Conversely, SOCS3 overexpression significantly decreased NV by 28% ($p<0.01$, n=17-20) but not VO ($p>0.05$) compared to littermate controls. Pharmacologic treatment with SOCS3 activator naringenin suppressed retinal neovascularization.

Conclusions: Our data strongly suggests that rod photoreceptor SOCS3 mediates neovascularization in the OIR model. Activation of photoreceptor SOCS3 may be a potential therapeutic for treating retinal angiogenesis.

ABSTRACT BODY:

Purpose: Different species block varying amounts of wavelengths in the ultraviolet (UV) spectrum to protect the retina. However, evolution of UV vision in some mammalian species is thought to aid in environmental navigation, communication, and foraging behavior. Specifically, dogs and cats are suspected to have UV vision although the percent transmission (%T) of UV light reaching the retina is not clearly defined. The aim of this study is to assess the transmission of the UV spectrum (200-400 nm) through enucleated globes of different species (dogs, cats, rabbits, pigs, and humans) using spectrophotometry.

Methods: Globes (n=6-10 per species) from animal models were analyzed within 24 hours of death. Human globes (n=2) were acquired from an eye bank. For spectrophotometry, a 5-10 mm circular area of sclera and choroid from the posterior aspect of the globe was removed under a surgical microscope. The retina remained intact to mimic the path of light through the living eye. The %T of wavelengths from 200-800 nm were measured through the ocular media (cornea, aqueous humor, lens, and vitreous humor) and retina of dogs, cats, pigs, rabbits, and humans. The %T within the UV range (200-400 nm) and UV-Visible range (200-800 nm) were compared between species. Data was analyzed using area under the curve and ANOVA with significance set at $p<0.05$.

Results: Compared to other species, there was a significantly larger amount of UV %T in globes of dogs and cats ($p<0.0001$). Cats transmitted the highest percentage of UV light with over 59% transmission at 400 nm whereas dogs transmitted 27% of light at 400 nm. At 350 nm, cats transmitted 30% of light and dogs transmitted 9%. There was also a significantly larger amount of UV %T in globes of rabbits compared to pigs ($p=0.0021$) and humans ($p=0.0150$). Rabbits transmitted 27% of light at 400nm and less than 1% at 350 nm. Humans and pigs did not differ significantly in the amount of UV %T ($p=0.9985$) and transmitted less than 1% of light below 400nm.

Conclusions: Dogs and cats have significantly higher transmission of wavelengths below 400 nm through their ocular media and retina compared to rabbits, pigs, and humans. This suggests that these crepuscular species can take advantage of UV light both in nature and under artificial lighting conditions. Results from this study will support further vision research in cats and dogs. These results may be used to train companion, working, and service animals.

ABSTRACT BODY:

Purpose: In normally-sighted individuals, visual acuity benefits from binocular summation. However, this effect is weakened in amblyopic individuals, especially for high spatial frequency (SF) stimuli (Pardhan and Gilchrist, 1992). To clarify the underlying disorder, we examined the function of thick and thin stripes in human V2 (and V3) during monocular and binocular perception. In normally sighted individuals, these stripes respond differentially to low- vs. high-SF components (Tootell and Nasr, 2017).

Methods: Six strabismic and five anisometropic (best-corrected visual acuity in the amblyopic eye 20/60 to 20/300) individuals, aged 19-55 years old, participated in this study. Using high-resolution fMRI (7T; voxel size = 1 mm isotropic), we localized thin and thick stripes across V2/V3 (Figure 1A). Then, we measured the activity within these stripes as subjects were presented with high (99%) and low (5%) contrast gratings of 0.1–5.8 cycle/deg., either monocularly or binocularly.

Results: For monocularly presented high-contrast stimuli, thin and thick stripes showed a preference for high-SF (Figure 1B) and low-SF (Figure 1C), respectively. This preference did not vary based on the stimulated eye. When presented binocularly, low-SF (but not high-SF) gratings evoked a significantly stronger response, compared to when the same stimuli were presented monocularly ($p<0.01$). When normalized relative to the averaged response, this effect was significantly stronger in thin compared to thick stripes ($p<0.05$).

For low-contrast stimuli, high-SF gratings evoked a stronger response when presented to fellow- compared to amblyopic-eye (Figure 1D-E). However, only the response to low-SF gratings benefited from binocular summation.

Conclusions: In amblyopic individuals, the impact of binocular summation is limited to the response to low-SF gratings and appeared to be stronger in V2/V3 thin (relative to thick) stripes.

ABSTRACT BODY:

Purpose: To develop a clinically applicable approach to assess the robustness of an individual optic nerve head (ONH) from a standard 3D optical coherence tomography (OCT) scan by predicting how it would deform under a hypothetical acute change in intraocular pressure (IOP).

Methods: 316 subjects had their ONHs imaged non-invasively with 3D optical coherence tomography (OCT) before and after acute IOP elevation through ophtalmo-dynanometry – a method to raise IOP via globe indentation. We then categorized each ONH as robust or compliant. To do so, a 3D digital volume correlation algorithm was applied to both OCT volumes of each ONH to extract an IOP-induced average effective strain in the lamina cribrosa region (E_{eff}). 169 subjects were considered to exhibit robust ONHs ($E_{eff} < 4\%$) and 147 were classified as compliant ($E_{eff} > 4\%$). Learning from these biomechanical data, we compared three algorithms to assess ONH robustness strictly from a baseline (undeformed) OCT volume: (1) a point cloud classification network, (2) a decision tree ensemble, and (3) an autoencoder in combination with a fully connected binary classification network. For each method, 253 subjects were used for training and 63 for testing. To evaluate the performance of our algorithms in predicting ONH robustness, we used the area under the receiver operating characteristic curve (AUC).

Results: All three methods were able to assess ONH robustness from 3D structural information alone. The point cloud classification network (AUC: 0.77) performed slightly better than the decision tree ensemble (AUC: 0.69) and the autoencoder (AUC: 0.68).

Conclusions: We introduce a novel machine learning based method to assess ONH robustness strictly from a standard 3D OCT scan. Our proposed approach may have wide clinical interest because it does not require new hardware (it can be combined with any existing OCT device) and can assess ONH robustness without the need of performing complex biomechanical tests. Longitudinal studies should establish if ONH robustness estimated by the herein presented technique helps to predict and better understand the development and progression of glaucoma. Our method will soon be improved by incorporating a larger biomechanical dataset.

ABSTRACT BODY:

Purpose: We have previously shown that aged C57BL/6J (B6) mice have increased cathepsin S in tears, lacrimal gland lysates, and spleen. High cathepsin levels have been linked to the generation of autoreactive T cells. This study investigated the effects of cathepsin S inhibition on age-related dry eye disease in B6 mice.

Methods: Female B6 mice aged 15.5 to 17 months were randomized (n=16/group) to receive either a medicated diet formulated by mixing the cathepsin S inhibitor (R05461111, 262.5mg/kg chow, Roche, Switzerland) or standard diet (placebo) for 12 consecutive weeks. Eye draining lymph nodes and lacrimal glands (LGs) were excised and prepared for either histology or assayed by flow cytometry to quantify infiltrating T cells. The number of inflammatory foci (>50 cells) was counted under a 10X microscope lens. Image analysis of scanned H&E-stained LGs was used to calculate focus score/4mm^2 and foci area (μm^2). Eyes and adnexae were collected and processed for histology. Goblet cell density was investigated in PAS-stained sections. Expression of Tnf, Ifn, Il12, and Cxcl10 was investigated by real-time PCR in LG and conjunctiva.

Results: Compared to the standard diet, mice subjected to cathepsin S inhibition showed a decrease in CD4$^+$IFN-γ$^+$ (49.6±9 vs. 35±7.5%) and an increase in CD4$^+$Foxp3$^+$ (9.2±4 vs. 19.4±5 %) cells in the LGs (n=5/group, P<0.05 or lower). A similar non-statistically significant trend was observed in ocular draining nodes. The frequency of total CD45$^+$IL-12$^+$ cells was decreased in cathepsin S-inhibitor diet LGs, accompanied by a decrease in frequency and activation (CD86 expression) in CD45$^+$CD11c$^-$MHC II$^+$CD11b$^+$F4/80$^+$ cells. While there was no change in focus score between the treatment groups (2.2±0.7 vs. 2.62±0.7 focus score/4mm^2), a significant increase in conjunctival goblet cell density was observed in the inhibitor-treated animals (45±5.5 vs. 30±7.8 goblet cells/mm, P <0.01) compared to the standard diet. Significant lower levels of Ifn, Tnf, Il12 (range 25-40% decrease) were observed in LG, while low levels of Ifn, Il12, and Cxcl10 (range 40-70% decrease) were present in the conjunctiva in the inhibitor-treated mice.

Conclusions: Altogether our results indicate that therapies aimed at reducing cathepsin S can improve age-related dry eye disease. Further studies with a longer duration are needed to evaluate the role of cathepsin S in the formation of inflammatory foci in the aged lacrimal gland.

ABSTRACT BODY:

Purpose: Idiopathic serous epithelial detachments (SPEDs) are part of the spectrum of central serous chorioretinopathy (CSCR). This study presents imaging characteristics of those with idiopathic SPED compared to those without in UK Biobank (UKBB), a prospective cohort study.

Methods: UKBB is a biomedical database with over 500,000 UK participants aged 40-69 years. Of these, colour and optical coherence tomography (OCT) gradable images were obtained using spectral domain OCT (Topcon- 1000, Topcon, Japan) in 68517 participants. The images were graded masked by trained and certified graders.

Idiopathic SPED cases were selected for detailed grading; number of SPEDs, height, base diameter and location of the largest SPED, sub-foveal choroidal thickness (SFCT), maximum choroidal thickness (MCT), and greatest (vertical) choroidal vessel diameter (CVD) on the foveal scan.

A control-group of an equal number of pathology free UKBB eyes were graded using the same method. T-tests were used for comparisons, using SPSS v26.

Results: Of the 68517 available retinal images, 109 eyes (85 patients) had at least one idiopathic SPED, 12 patients had bilateral SPEDs. 76% of eyes had one SPED, 17% had two SPEDs, 4% three, 2% four and 2% over 5. Mean SPED height was 100.2μm (range 23-501) and mean base diameter 483.97μm (119-1961).

Extra-foveal SPEDs were present in 73%, 19% were juxta-foveal and 8% sub-foveal (geometric centre of the fovea). There was a slight predilection for superior and nasal presentation but this was not significant.

There was a significant difference in mean SFCT between groups, 355μm (141-567) for those with SPED and 265 μm (111-443) for those without ($p<0.001$). With SPED the mean MCT was 414 μm (190-567), 320 μm (176-458) for those without ($p<0.001$). CVD was also significantly different; 191 μm (108-439) for SPED eyes and 165 μm (93-267) for non-SPEDs ($p<0.001$).

Conclusions: SFCT and MCT were significantly higher in those with SPEDs than those without. Additionally CVD of the largest gradable vessel (foveal scan) was significantly greater in those with SPEDs, signifying choroidal vascular changes in those with SPED. The weakness of the study was that no enhanced depth imaging was available for this cohort, however we demonstrated the feasibility of using this image set for SPED analysis.

ABSTRACT BODY:

Purpose: Electrical stimulation (ES) employing a low-intensity electric current with minimal tissue heating presents a potential therapeutic modality that can be applied noninvasively to the eye. However, the cellular level effects of the ES on several retinal cell types are largely unexplored. In this study, we evaluated the effects of ES on microglia (MG) and human retinal endothelial cells (HREC) in vitro.

Methods: Primary brain MG was isolated from adult C57BL/6 mice. The resulting cultures were subjected to ES (biphasic, 300 μA, 20 Hz) for 1 hour. The activation profile of MG was studied by immunostaining, RT-PCR, and cytokine arrays. Calcium flux in response to ATP 10^{-7} M stimulation (120 sec) was measured by Fura-2. MG cells oxygen consumption and mitochondria activity were studied through high-resolution respirometry (Seahorse XF24, Agilent), JC-1 mitochondria membrane potential assay, and cellular ATP content quantification. The effect of ES on primary human endothelial cells (HREC) angiogenic activity was investigated using migration and tube formation assays combined with a measure of VEGFA expression. Findings were validated using the choroidal explant sprouting assay.

Results: ES reduced the expression of proinflammatory cytokines, including IL-6, TNFα, COX-2, and ATP-induced Ca2+ flux in the MG cells ($p<0.05$). Seahorse XF24 analysis of ES MG cells indicated reduced basal ($p<0.05$) and maximal ($p<0.05$) respiration and ATP production ($p<0.01$). Proton leak was not significantly affected compared to control cultures ($p>0.05$), suggestive of a lack of mitochondria damage. The results were confirmed by reduced cellular ATP content ($p<0.01$) and reduced JC-1 mitochondrial potential in the ES MG cells. In HREC, endothelial cells migration ($p<0.01$) and tube formation ($p<0.01$) were suppressed by ES, vascular outgrowth from choroidal explants was also reduced ($p<0.05$). Western blotting and immunostaining analysis of ES HREC further confirmed reduced VEGFa expression.

Conclusions: ES inhibits MG activity by reversibly depolarising mitochondrial potential and ATP production. The lack of ATP reduces Ca^{2+} flux in response to proinflammatory stimuli due to depletion of endoplasmic reticulum (ER) Ca2+ depo. ES also reduces the angiogenic potential of HREC by suppressing VEGF expression and choroidal vessels ex-vivo. These data suggest the therapeutic potential of biphasic ES in inflammatory and neovascular diseases of the eye.

ABSTRACT BODY:

Purpose: Celf1 encodes an RNA-binding protein (RBP) that post-transcriptionally regulates gene expression by distinct mechanisms, including alternative splicing. Germline knockout (KO) or lens-specific conditional knockout (cKO) Celf1 mice develop lens defects and early-onset cataract. We sought to identify RNA targets of CELF1 protein in the lens, particularly those regulated at the level of alternative splicing, and whose mis-regulation upon CELF1-deficiency may contribute to lens defects and cataract.

Methods: We performed integrative analysis using multiple omics-based approaches to identify Celf1-regulated downstream RNA targets in the lens. Individual-nucleotide resolution UV crosslinking and immunoprecipitation (iCLIP) followed by high-throughput RNA-sequencing (iCLIP-seq) identified CELF1 protein-RNA binding sites in adult mouse wild-type (WT) lens. This data was analyzed in the context of RNA-seq data on Celf1 KO or Celf1 cKO and control mouse lenses, which identified mis-regulated candidate genes with alternative splicing events.

Results: Integrative analysis of iCLIP-seq and RNA-seq data allowed the prioritization of 22 RNAs whose splicing pattern is likely directly controlled by CELF1 protein in the lens. Of these, seven RNAs that encode proteins linked to cytoskeleton (e.g. ABLIM1, ANK2, CLTA, CTNNA2, SPTBN1, SEPTIN8, YWHAE) were validated by RT-PCR to have mis-expressed alternative splice isoforms in Celf1 KO lens. Normal lens fiber cell differentiation involves cytoskeleton modifications that are necessary for their characteristic morphology and organization, which is found to be perturbed in Celf1-deficient lens. Thus, abnormal splicing of these cytoskeletal protein-encoding RNAs may contribute to the cataract pathology in Celf1 KO lenses.

Conclusions: Integrative analysis using iCLIP-seq data generated on WT lens (for identifying RNA binding sites of CELF1 protein) and RNA-seq data generated on Celf1 KO and Celf1 cKO lens (for identifying genes with mis-regulated alternative splicing event) led to prioritization of targets that are linked to the cytoskeleton and whose altered expression may explain distinct aspects of the lens pathology and cataract resulting from Celf1 deficiency.

ABSTRACT BODY:

Purpose: Disease and damage in the posterior segment of the eye are a major global cause of blindness. Topical eye-drop treatments are less effective because therapeutic molecules penetrate ocular tissue barriers poorly. We investigated penetration enhancement of the most commonly used anti-inflammatory drug, dexamethasone sodium phosphate (DSP), after topical delivery with three penetration enhancing agents (PEAs) — an in-house synthesized novel helical polymer and two commonly used cell penetrating peptides (CPPs), TAT and Penetratin.

Methods: Trans-corneal penetration of the three PEAs and DSP formulations with PEAs were assayed ex-vivo in a rapid and cost-effective screening model of excised porcine cornea and quantified using UV & fluorescence spectroscopy for PEAs and by high performance liquid chromatography (HPLC) for DSP. Immunostaining of corneal sections with tight junction markers, ZO-1 and Claudin-5, assessed the integrity of tight junctions and also provided a reference for visualizing the internalized PEA in corneal epithelium by confocal microscopy. Trans-epithelial electrical resistance (TEER) measurements for the corneal epithelium before and 60 minutes after application were used to determine the integrity of corneal barriers and barrier function. Furthermore, in-vitro cytotoxicity of PEAs was performed by the MTT assay in ARPE-19 and HCE-2 cells, whilst immunocytochemistry (ICC) was used in assays involving adult rat primary retinal cultures.

Results: All three PEAs effectively crossed the cornea individually. There was almost 15-fold enhancement of DSP trans-corneal permeation after topical application with PEAs. Confocal microscopy after immunostaining showed retention and epithelial internalization of PEAs on corneal epithelial surfaces while also revealing intact tight junctions. TEER measurements confirmed that there was no damage to the integrity of barrier function after PEA/DSP application. Finally, MTT assays and ICC showed no toxicity in ARPE-19, HCE-2 cells, or primary rat retinal cells, respectively.

Conclusions: Topically applied novel polymers, TAT and Penetratin all increased trans-corneal penetration efficiency of DSP without causing any damage to the corneal barrier integrity or in-vitro toxicity. This can potentially increase the bioavailability of DSP in the posterior segment tissues.

TITLE: Retinal and Choroidal Thickness at Different Eccentricities in the Myopic Eye

SESSION TITLE: Myopia: Structural Changes from Retina to Sclera

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J. Villa-Carpes, D. Orenes, J. Marin-Sanchez, Ophthalmology, Hospital Clinico Universitario Virgen de la Arrixaca, El Palmar, Murcia, SPAIN|J. Villa-Carpes, E.J. Fernandez, D. Orenes, R. Martinez-Ojeda, J.M. Bueno, Laboratorio de Óptica, Universidad de Murcia, Murcia, Murcia, SPAIN|F. Avila, Departamento de Física Aplicada, Universidad de Zaragoza, Zaragoza, Aragón, SPAIN|

ABSTRACT BODY:

Purpose: Myopia progression might alter the morphology of the posterior eye, particularly the neural retina and the choroid. In this work we investigated whether, and eventually to what extent, the amplitude of myopia correlates with both retinal and choroidal thickness measured with a commercial swept-source optical coherence tomography (OCT) instrument.

Methods: Retinal OCT images from 42 myopes (25 females and 17 males; mean age: 27.1±4.0 years) were acquired around the fovea. Subjects were distributed into three groups according to their objective refraction: low myopia (>-1D), moderate myopia (-1D to -4,5D] and high myopia [-4,5D to -12D]. The OCT images were digitally processed, correcting geometrical distortions and curvature, with a custom MATLAB^{TM} software adopting the Bruch membrane as the reference plane for intra-retinal distances. From the so-processed images, retinal and choroidal thicknesses were semi-manually obtained at four different eccentricities along the horizonal meridian (fovea, 2.25mm nasal; 2.25 and 3.38mm temporal from fovea) using ImageJ^{TM}. Three measurements were obtained from each location.

Results: Thicknesses of both retina and choroid followed a normal distribution (Shapiro-Wilk test). Foveal retinal thickness did not correlate with refraction in any group. On the opposite, certain linear correlation (R=0.45) appeared for sub-foveal choroidal thickness. When the groups were considered, the mean sub-foveal choroidal thickness was statistically different in the high myopia group (ANOVA test). Nasal and temporal retinal thickness exhibited a moderate association with refraction, with significant differences between low-moderate myopia and high myopia groups. Neither nasal nor temporal at 3.38 mm choroidal thickness correlated with ocular refraction. Nevertheless, significant differences between low and high myopia groups were found at 2.25-mm temporal location.

Conclusions: A significant decrease in sub-foveal choroidal thickness was found in the high myopia group with no variations in foveal thickness between groups. Retinal thickness correlated with refraction at 2.25mm eccentricity, nasal and temporal locations, with high myopes exhibiting lowest values. Retinal and choroidal thicknesses show differences as a function of refraction and eccentricity, which might be a marker for myopia evolution, also serving to evaluate current treatments.

ABSTRACT BODY:

Purpose: Autosomal dominant Retinitis Pigmentosa (adRP) is an inherited retinal degenerative disease that initially affects rod photoreceptors function and survival. The first gene identified to cause adRP was RHO, which encodes for rhodopsin, a G-protein coupled receptor involved in the detection of low level light and the consequent activation of rods phototransduction cascade. We focused our attention on a common UK pathogenic rhodopsin amino acid substitution, RHO^{M39R}. Here we have investigated the effect of light on retinal function and degeneration in both RHO^{M39R} and Rho^{M39R} models.

Methods: To investigate the role of light in retinal degeneration, we used two different models: Rho^{M39R} knock-in (KI) mice and $RHO^{M39R/+}$ human iPSC-derived retinal organoids (hROs). Different levels of light exposure were investigated as a modifier of disease. Optic Coherence Tomography (OCT) and Electroretinogram (ERG) were performed on mice to characterise mouse retina thickness and activity, respectively. Electron microscopy was performed to characterise the ultrastructure of the retina. Rhodopsin protein levels were analysed by western blotting. RNAseq was performed to evaluate changes in the retinal transcriptome, while immunohistochemistry was used to analyse rhodopsin localization and retina degeneration in both mouse retina and hROs.

Results: 3 weeks old $Rho^{M39R/+}$ KI mice reared in ambient light had impaired retinal function by ERG, while the thickness of the outer nuclear layer (ONL) was comparable to control $Rho^{+/+}$. By contrast, rearing in reduced ambient light exposure, protected the ERG function of $Rho^{M39R/+}$ animals. Exposure to bright light (max intensity: 30 $cd*s/m^2$) through repeated ERG, caused a progressive decrease in ONL thickness and in retinal activity. 3 week old $Rho^{M39R/M39R}$ KI mice raised in ambient light showed severely compromised retinal function, reduced ONL thickness and altered outer segment (OS) morphology. Moreover, a single exposure to bright light significantly decreased the ONL thickness of $Rho^{M39R/M39R}$ KI retina within 24h, while inducing the expression of apoptotic genes by 3h. 170-200 days old $RHO^{M39R/+}$ hROs showed signs of retinal degeneration and mistrafficking of rhodopsin compared to control $RHO^{+/+}$ hROs.

Conclusions: The combined study in both KI mice and human ROs can provide insights into the role of light in sector RP in mammalian models and the ability to develop new therapies to treat RP patients.

ABSTRACT BODY:
Purpose: This study aimed to investigate the association between circulating drug levels and anti-drug antibodies (ADAs), clinical response, and concurrent immunomodulatory treatment (IMT) in patients with non-infectious uveitis treated with TNF-α inhibitors.
Methods: A retrospective study was conducted at the National Eye Institute. Patients who underwent anti-adalimumab or anti-infliximab immunoassay testing for the presence of ADAs were included. Chart review was performed for demographic and laboratory data.
Results: Forty-two adalimumab and 12 infliximab patients were included. In the adalimumab group, mean duration since diagnosis and duration of therapy of 84.2 and 30.6 months, respectively. In the infliximab group, mean duration since diagnosis and duration of therapy was 92.5 and 20.9 months, respectively. 35.8% of all adalimumab patients had ADAs with a mean antibody level (MAL) of 97.3 AU/mL. No infliximab patients developed ADAs.

When divided based on clinical response, 54.8% of adalimumab patients were complete responders with a mean drug level (MDL) of 11.4 mcg/mL, 14.3% were partial responders with MDL 9.7 mcg/mL, and 30.9% were non-responders with MDL 6.8 mcg/mL. ADAs were present in 21.7% of complete responders (MDL 4.1 mcg/mL and MAL 73.4 AU/mL), 50% of partial responders (MDL 2.1 mcg/ML and MAL 250.2 AU/mL), and 53.8% of non-responders (MDL 2.2 mcg/mL and MAL 35.3 AU/mL). In the infliximab group, MDL was 27.2 mcg/mL.

MDL and MAL were also analyzed based on use of concurrent IMTs. ADAs were present in 20.0% of patients on mycophenolate mofetil, 38.5% on methotrexate, and 53.8% on monotherapy. MDL and MAL were 12.57 mcg/mL and 50.33 AU/mL for the mycophenolate group, 9.02mcg/mL and 42.8 AU/mL for methotrexate, and 6.78mcg/mL and 147.34 AU/mL for monotherapy, respectively.
Conclusions: ADAs were observed in 35.8% of adalimumab and 0% of infliximab patients. In the adalimumab cohort, complete responders had a higher MDL and lower ADA compared to partial and non-responders. Notably, when antibodies were present, MDL was lower regardless of clinical response, suggesting that a complete clinical response is associated with higher drug levels even when ADAs are present. Lastly, patients who used IMTs concurrently had a higher MDL and lower frequency of ADA in the adalimumab group, suggesting a benefit over monotherapy. Additional research is required to better understand the impact of ADAs in non-infectious uveitis.

ABSTRACT BODY:

Purpose: To evaluate the effect of amniotic membrane transplantation (AMT) on trabeculectomy in patients with pseudoexfoliation glaucoma (PXG)

Methods: We reviewed the medical records of patients with PXG who underwent fornix-based trabeculectomy with Mitomycin C with or without AMT. Kaplan-Meier survival curves were compared with log-rank test in AMT group and control group. All patients had follow-up of at least 12 months. Surgical success was defined by following 4 criteria. (1) Criteria A: intraocular pressure (IOP) ≤ 18 mmHg and IOP reduction 20% without medication; (2) Criteria B: IOP ≤ 15 mmHg and IOP reduction 25% without medication; (3) Criteria C: IOP ≤ 18 mmHg and IOP reduction 20% with or without medications; (4) Criteria D: IOP ≤ 15 mmHg and IOP reduction 25% with or without medications. Kaplan-Meier survival curves were compared with log-rank test in AMT group and control group. Cox proportional hazard models were used to estimate the influence of AMT on surgical success accounting for confounding variables.

Results: 52 eyes with AMT (AMT group) and 33 eyes without AMT (control group) were included in this retrospective study. Cumulative success rates were 86.5% at 12 months and 83.8% at 24 months for AMT group, and 63.6% and 56.3% for control group by criterion A. Complete success rates were significantly greater for AMT group than for control group by criteria A and B (P = 0.017, P = 0.005, respectively). Cumulative success rates were 92.1% at 12 months and 89.0% at 24 months for AMT group, and 75.1% and 62.8% for control group by criterion C. Qualified success rates were significantly greater for AMT group than for control group by criteria C and D (P = 0.047, P = 0.021, respectively). On multivariable Cox regression analyses, AMT was associated with higher success rate with all criteria for complete and qualified success (P ≤ 0.04 for all). Avascular bleb developed in 7 eyes (21.2%) of control group while there were no eyes with avascular bleb in AMT group (P = 0.004).

Conclusions: In patients with PXG, trabeculectomy with AMT for target IOP ≤ 18 mmHg or ≤ 15 mmHg was more successful than trabeculectomy without AMT. Avascular bleb was found only after trabeculectomy without AMT.

ABSTRACT BODY:

Purpose: Age is a critical risk factor for ocular hypertension in glaucoma. But, how age affects the regulation of conventional outflow is unclear. The aim of this study was to determine the effect of age on outflow in the presence or absence of pilocarpine (PILO).

Methods: C57BL/6J mice (1-30 month-old) were used for the study. Green fluorescence beads (0.1um) were perfused intracamerally at pressures 15, 20, 25 and 30 mmHg for 10 min at each pressure in live mice. Pressure was set by a column of fluid connected to a cannulation needle, and outflow (OF) was calculated at each pressure level by the volume leaving the column during 10 min intervals. For PILO studies, 1% PILO was applied topically to one eye just before pressure steps. After perfusions, mice were immediately euthanized. Anterior segment flat mounts were imaged by confocal microscopy.

Results: Regardless of age, the inferior quadrant displayed the least amount of tracer in the majority of the eyes. Overall fluorescence intensity decreased in an age dependent manner, with a greater percentage of low flow regions found in eyes of older mice. Eyes treated with PILO showed increased fluorescence intensity in inferior quadrants, especially in aged eyes. However, age did not significantly change averaged OF across all pressures measured in vivo. As expected, PILO significantly increased mean OF in both young and aged eyes (young: 0.36±0.09 vs 0.52±0.14 ul/min, p=0.02, n=7-33; aged: 0.4±0.12 vs. 0.57±0.14 ul/min, p=0.03, n=6-27). Interestingly, PILO effects in young mice was rapid, increasing OF during the first 10 min by 79% at 15 mmHg (0.45±0.17 vs. 0.80±0.37 ul/min, p=0.04) and by 57% during the next 10 min at 20 mmHg (0.34±0.14 vs. 0.53±0.27 ul/min, p=0.11). In contrast, we observed no increase in OF in old mice for the first 20 min of PILO at IOP 15 or 20 mmHg. The last 20 min of PILO perfusion was different in old mice, significantly increasing OF by 67-69% (25 mmHg=0.39±0.15 vs 0.66±0.16 ul/min, p=0.006; 30 mmHg=0.41±0.11 vs. 0.69±0.17 ul/min, p=0.009). By comparison, PILO had no significant effects in young mice over the last 20 min.

Conclusions: Labeled high flow regions were reduced with age, which is consistent with the lower outflow detected in aged human eyes. In addition, age also impacted the effects of PILO on outflow tissues, where young mice showed a rapid response and aged mice had a slower and more constant response.

TITLE: The nuclear receptor REV-ERBα regulates retinal vessel regeneration in a mouse model of oxygen-induced retinopathy

SESSION TITLE: Vascular Biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.K. Blomfield, F. Yemanyi, C. Liu, S. Huang, K. Bora, M. Maurya, J. Chen, Department of Ophthalmology, Boston Children's Hospital, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Alexandra Blomfield: Commercial Relationship: Code N (No Commercial Relationship) | Felix Yemanyi: Commercial Relationship: Code N (No Commercial Relationship) | Chi-Hsiu Liu: Commercial Relationship: Code N (No Commercial Relationship) | Shuo Huang: Commercial Relationship: Code N (No Commercial Relationship) | Kiran Bora: Commercial Relationship: Code N (No Commercial Relationship) | Meenakshi Maurya: Commercial Relationship: Code N (No Commercial Relationship) | Jing Chen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Ischemic proliferative retinopathies, like retinopathy of prematurity and diabetic retinopathy, are often blinding and treatment options are limited. Current treatments focus primarily on reducing pathological neovascularization (NV) in the second phase of disease without addressing vessel loss in the first phase. We aimed to investigate the latter by assessing the role of REV-ERBα, a nuclear receptor and transcriptional repressor with a cellular cytoprotective effect, in promoting vessel regeneration in a mouse model of oxygen-induced ischemic retinopathy (OIR).

Methods: Wild-type (WT) and systemic REV-ERBα knockout (KO) mice were analyzed for developmental retinal angiogenesis at post-natal day (P) 5 and P10 for superficial and deep vessel network. In OIR, mice were kept in 75% oxygen from P7-P12 and returned to room air until P17. Vascular morphology was assessed in retinal flat mounts with isolectin (endothelium marker) staining. The effects of REV-ERBα on angiogenesis and endothelial cell (EC) function were analyzed in sprouting assays of aortic rings isolated from REV-ERBα KO mice and in human retinal microvascular endothelial cells (HRMECs) treated with REV-ERBα agonists (SR9009 and SR9011). Expression levels of potential REV-ERBα target genes involved in angiogenesis and antioxidant defense were analyzed in HRMECs and mouse retinal tissue.

Results: REV-ERBα KO retinas displayed normal developmental angiogenesis when compared to WT, with no significant difference observed in superficial vascular area at P5 or in deep layer vessel morphology at P10. In the OIR model, REV-ERBα KO mice showed a substantially greater area of retinal vaso-obliteration at both P12 and P17, as well as a substantially greater area of pathological NV at P17. REV-ERBα KO aortic ring explants had significantly reduced sprouting when compared to WT. Treatment with REV-ERBα agonists increased vascular tube formation in HRMECs in both normal and H_2O_2-treated conditions. Expression of Nrf2, a master regulator of antioxidant response, was significantly decreased in REV-ERBα KO retinas, while in HRMECs treated with REV-ERBα agonists, Nrf2 expression was increased.

Conclusions: Our results suggest that genetic deficiency of REV-ERBα may impede vascular regeneration in retinopathy, without impacting developmental angiogenesis, possibly through dysregulation of EC oxidative stress response.

ABSTRACT BODY:

Purpose: To track retinal fibrosis (RF) growth in a group of treatment naïve eyes with neovascular age related macular degeneration (nAMD) over a follow up period of one year using a polarization sensitive optical coherence tomography prototype (PS-OCT).

Methods: In this prospective observational study, patients with treatment naïve nAMD were included and treated according to a treat and extend regimen with intravitreal aflibercept.

At baseline and month 12 each patient underwent

PS-OCT & color fundus photography (CFP) imaging.

PS-OCT technology depicts retinal fibrosis based on its birefringence, where fibrotic lesions appear as columns of uniform axis-orientation.

A new algorithm was used to automatically detect retinal fibrosis in single B-scans and subsequently calculate the area of the fibrosis within the image.

Results: We analyzed 54 eyes with treatment naïve MNV due to AMD.

The mean age was 76.9 years, 62.5% of patients were diagnosed with type 1, 20.83% with type 2 and 16.67 with type 3 MNV, respectively.

At baseline only 1 eye showed retinal fibrosis, in this eye fibrosis size increased from 2.4mm^2 to 3.1 mm^2 (increase by 30%).

At year 1, fibrotic tissue was detected in 5 more eyes, within those eyes

mean fibrosis area increased significantly from 0 to 4.51 ± 1.15mm^2 ($p<0.05$).

Four out of 6 eyes with fibrosis were diagnosed with type 2 MNV.

Conclusions: In our study cohort around 10% of patients developed retinal fibrosis within one year.

Retinal fibrosis occurred more likely in type 2 MNV than in different MNV types.

This PS-OCT prototype combined with the new algorithm offers a precise and objective method to detect, measure and track fibrosis growth in nAMD.

ABSTRACT BODY:

Purpose: Changes in refractive errors are common among diabetics with an increased prevalence of both hyperopia and myopia. However, it is unknown whether refractive errors are associated with changes in eye health or comorbid conditions. The purpose of this retrospective study was to characterize the refractive error changes among diabetic subjects in an urban setting and investigate the relationship between refractive error and eye health or comorbid conditions.

Methods: Medical records from 300 subjects were reviewed over an average time span of 9 years at Brooklyn Veteran's Affairs Hospital. Subjects were chosen with eye visits in 2021 with a 3-year minimum eye visit history and were excluded if they had previous cataract surgery. Spherical equivalents for baseline and last refractive errors were collected as well as cup-to-disk (C/D) ratios, glaucoma status, body mass index (BMI), and presence of hypertension, hyperlipidemia, coronary artery disease, chronic kidney disease. Chi-square t-test, multiple linear regression, and logistic regression were used for statistical analysis.

Results: Diabetics mean baseline refraction was -0.12 (1.68) right eye (OD) and -0.21 (1.79) left eye (OS) and mean last refraction was 0.13 (1.91) OD and 0.05 (1.88) OS. Non-diabetic subjects mean baseline refraction was -0.16 (2.11) OD and -0.22 (2.22) OS and mean last refraction was 0.08 (2.42) OD and 0.03 (1.12) OS. Refractive error changes among diabetic subjects were 0.25 (0.81) OD and 0.26 (0.88) OS and among non-diabetic subjects 0.24 (1.12) OD and 0.25 (0.86) OS. Using multiple regression, there was a statistically significant negative association between C/D ratio OD and OD refractive change ($\beta = -0.7$; $p = 0.05$) and between BMI and OS refractive change ($\beta = -0.03$; $p = 0.007$). Further analysis showed 1 unit increase in baseline OD/OS refraction was associated with a 0.33 ($p = 0.04$) and 0.31 ($p = 0.07$) decrease in BMI respectively. There were no statistically significant associations between refractive error differences and the remaining covariates.

Conclusions: In our study population, a refractive error shift was observed from myopia to hyperopia and refraction error difference was negatively associated with C/D ratio and obesity. No difference was found between refraction error difference among diabetic vs non-diabetic subjects and there was no statistically significantly association with other comorbidities.

ABSTRACT BODY:

Purpose: To assess a new modification of a previously published photographic four-step severity grading scale (S1-S4) for trachomatous scarring (TS).

Methods: A cross-sectional study was conducted of adult women in Kongwa, Tanzania. Images of the everted eyelids were taken and graded for the presence and severity of TS. The previously published severity scale for TS defines S3 as ‘conjunctival scarring occupying at least one third but less than 90% of the upper eyelid’. In the new modification, S3 was subdivided into two categories: 1) S3A - scarring covering at least one third but less than 50% of the upper eyelid conjunctiva, and 2) S3B - scarring covering at least 50% but less than 90% of the upper eyelid conjunctiva. The feasibility, reliability, and ease of use of this new grading modification were evaluated. This new categorization was then applied to images taken of the same women 3 years prior as part of a longitudinal study, to evaluate whether it could help detect prior undetected progression.

Results: A total of 5397 eyes of 2712 subjects were included in this study. We report on a subset of these eyes, 4412 eyes of 2217 subjects. Of the eyes graded, 761 (17.5%) were graded as S3. 87 of the S3 eyes were re-graded using the modified grading scheme; 29 (33.3%) were S3A, and 58 (66.7%) were S3B. 64 eyes were noted to also have been graded as S3 3 years prior. To evaluate whether splitting the S3 category might help detect more progression, these eyes were re-graded using the modified grading scheme; 22% of the eyes were noted to have progressed from S3A to S3B. Interobserver agreement using the modified grading system on a set of 36 images was an unweighted kappa of 0.60.

Conclusions: The modified photographic TS grading system is both easy to implement and reliable; it is also able to help detect more progression of scarring. This more nuanced modified TS grading system will be beneficial for future studies analyzing trachomatous scarring in photographs.

SUBMITTER (NAME ONLY): Raghavi Sudharsan

TITLE: Disease-driven Prolactin Isoform Expression in Canine Inherited Retinopathies

SESSION TITLE: Modeling inherited retinal degeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Sudharsan, G.D. Aguirre, W.A. Beltran, Clinical Sciences & Advanced Medicine, University of Pennsylvania, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Raghavi Sudharsan: Commercial Relationship: Code N (No Commercial Relationship) | Gustavo Aguirre: Commercial Relationship: Code N (No Commercial Relationship) | William Beltran: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We recently identified a novel Prolactin transcript lacking the first exon (PRLΔE1) that is highly upregulated in photoreceptors (PR) in two non-allelic canine early-onset retinal degenerations (RD): PDE6β-RCD1 and RPGR-XLPRA2. Expression of PRLΔE1 in the two models correlated with the onset of cell death and increased steadily as retinal degeneration progressed. This short PRL isoform was also identified in human retinas. We have now expanded our study of expression of PRLΔE1 to other canine retinopathies, including RPGR-XLPRA1, NPHP5-LCA, RHO-ADRP, CNGB3-ACHM3, and in RPGR retinas post gene augmentation therapy.

Methods: Retinal PRL expression was probed by RNA in situ hybridization (RNA-ISH, RNAscope, ACDBio) performed on OCT embedded normal and mutant retinal sections. RPGR immunolabeling was performed following PRL RNA-ISH in RPGR -XLPRA1 and -XLPRA2 retinas that had received AAV-RPGR gene therapy.

Results: PR-specific expression of PRLΔE1 was observed in the following canine models of progressive inherited retinal degeneration (IRD): RPGR-XLPRA1 and NPHP5-LCA. In RPGR-XLPRA2 carrier retinas that undergo random X-inactivation, patches of PRLΔE1 expression correlated with patches of PR degeneration. However, we did not observe expression of PRLΔE1 24 hrs and 2 wks after light exposure that triggers acute rod loss in the canine RHO-T4R model of adRP. No PRLΔE1 expression was seen either in the CNGB3-ACHM3 retina that undergoes extremely slow cone degeneration. In RPGR-XLPRA1 and RPGR-XLPRA2 dogs subretinally-injected with an AAV-RPGR vector, PRLΔE1 was completely absent in treated PRs while robust expression was seen in diseased/untreated areas.

Conclusions: PRLΔE1 expression has now been found in 4 different canine models of IRD with a protracted loss of PRs. PRLΔE1 expression correlates with the onset of retinal degeneration and is sustained as PR cell death progresses. Corrective gene therapy in RPGR mutant dogs that prevented further retinal degeneration and PR cell loss also completely ceased PRLΔE1 expression in these retinas. Additional studies are underway to characterize the function of PRLΔE1 in IRD.

ABSTRACT BODY:

Purpose: The P23H mutation in the rhodopsin (RHO) gene represents the most common form of adRP in North America. We previously showed successful gene editing using the ARCUS nuclease, RHO 1-2, a meganuclease, in a TgP23HhRHO pig model of adRP when treatment began at postnatal days, P3-7. This time-point corresponds to mid-stage human adRP, where many rod photoreceptors are present. However, from birth, untreated TgP23H pigs have no rod isolated ffERG response. To determine how late in adRP Rho1-2 gene editing continues to be successful, we evaluated its therapeutic efficacy when treatment began at P18 or P30 when fewer rods remain.

Methods: RHO 1-2 mRNA was packaged in a self-complementary AAV5 vector with a GRK1 promoter and was delivered subretinally (40 µl) to both eyes of TgP23H pigs at P18 and P30. Eyes from untreated animals served as control. The efficacy of $2x10^{10}$vg (n:eyes=8, P18; n=6 P30) and $6x10^{10}$vg (n=2 eyes, P30) on retinal structure and function were assessed at regular post injection intervals through 20 weeks post-injection (wpi). Fundus imaging, clinical exams, and OCTs assessed RHO 1-2 tolerability and retinal structure. Full-field ERGs assessed retinal function. At final time-point, the animals were euthanized and the retinal sections were processed for immunohistochemistry/confocal microscopy to assess the photoreceptor morphology.

Results: Treatment with RHO 1-2 was well tolerated, with no signs of an immune response. Treatment with both concentrations of RHO 1-2 (2 or $6x10^{10}$vg) rejuvenated a rod isolated ffERG b-wave response as early as 8wpi (~9uV). Mean b-wave amplitudes increased until 17wpi (~13-20uV) and were maintained through 20wpi. There is a strong correlation between rod isolated function and rod morphology. RHO 1-2 treated Tg P23H rods, have elongated inner and outer segments (IS/OS) and correctly localized rhodopsin. In contrast, untreated areas in the same retina or untreated Tg retinas have almost no rods and those that remain have no IS/OS and mislocalized rhodopsin.

Conclusions: Our results show that ARCUS nuclease RHO1-2 gene editing of the P23H hRHO allele rejuvenated rods even in late-stage disease. This approach arrested rod degeneration and rejuvenated rod structure and function in TgP23HhRHO pig model of adRP. These findings expand the therapeutic window for RHO 1-2 to retina late-stage adRP.

ABSTRACT BODY:

Purpose: Von Hippel-Lindau (VHL) disease is caused by a mutation of the VHL gene and characterized by the development of retinal hemangioblastomas (RH). Current pathophysiologic mechanisms of RH development and progression are still insufficient to predict RH behavior. VHL gene is involved in the cellular response to hypoxia and in many intracellular signaling pathways expressed both in angiogenesis and inflammation. Optical coherence tomography (OCT) allows to identify hyper-reflective retinal foci (HRF) known as aggregates of activated microglial cells as possible in vivo biomarker of local inflammation. The aim of the present study was to investigate the presence of HRF in patients with genetically confirmed VHL disease.

Methods: In this cross-sectional study, patients with VHL underwent complete ophthalmological examination and OCT with HRA + OCT Spectralis. HRF were manually identified and calculated in inner (IR), outer (OR) and full retina. Age-matched healthy subjects were enrolled as controls.

Results: 113 eyes of 63 VHL patients and 56 eyes of 28 healthy subjects were evaluated. HRF number was significantly higher in VHL than in controls in IR (28.06 ± 7.50 vs 25.25 ± 6.64, p=0.042). No difference was observed in OR and in full retina (OR: 7.73 ± 2.59 vs 7.95 ± 2.51, p = 0.599; full retina: 35.79 ± 8.77 vs 33.20 ± 7.47, p = 0.093).

Conclusions: Retinal microglial activation, documented by the increase of HRF, characterizes VHL eyes. The role of activated microglia in the retina of VHL eyes needs to be better investigated, mainly considering local VHL disease manifestations.

ABSTRACT BODY:

Purpose: Cross-sectional assessment of extraocular muscles (EOM) and adnexa by high-resolution surface coil orbital magnetic resonance imaging {(MRI), 1.5T Seimens Symphony} was performed in symptomatic Indian geriatric subjects with small-angle horizontal diplopia at distance, diagnosed as having age-related distance esotropia (ARDE). These MRI parameters was compared with similar image derivations in age matched asymptomatic and younger subjects.

Methods: 9 ARDE subjects (18 orbits) of average age 77.2±3.6 years (8 males) were imaged fixating at a central target. 2mm thick contiguous quasi-coronal image planes perpendicular to the orbital axis were analysed for EOM pulley locations, EOM cross sections and LR-SR band length while quasi-sagittal and axial planes were used to measure rectus EOM length, all by Image J software as per published norms. A comprehensive ophthalmic and neurological evaluation was performed in all subjects. The comparative control groups comprised 10 age matched asymptomatic subjects (20 orbits) of average age 67±4.7 years (7 males)–Group 1; 13 middle-aged subjects (26 orbits) of average age 48±4.7 years (7 males)–Group 2 and 12 young subjects (24 orbits) of average age 26±7.8 years (6 males)–Group 3.

Results: The average LR-SR band length in Group 1, 2 and 3 respectively were 12.8±3.2mm, 10.3±1.7mm and 8.7±1.8mm as compared to 14.4±2.8mm in the ARDE group (p=0.06, ≤0.0001, ≤0.00001). The angulation of the long axis of the lateral rectus (LR) muscle to the globe vertical axis was 23 ± 7.4^{o} (Group 1), 7.5 ± 8.8^{o} (Group 2) and 1.2 ± 7.9^{o} (Group 3) as compared to 22.4 ± 11.3^{o} in the ARDE group (p=0.8, ≤0.0001, ≤0.00001). The rectus EOM length was similar in all groups. Unilateral LR-SR band rupture was observed in one ARDE subject (Figure 1A-E).

Conclusions: The significant rectus EOM elongation and characteristic LR-SR band rupture observed in $2/3^{rd}$ cases of ARDE patients in the Caucasian population was not observed in a similar symptomatic geriatric Indian cohort. However, age-related progressive LR-SR band lengthening and increased angulation of the LR muscle to the globe probably accounted for the loss of LR functioning as an abductor at distance and consequent ARDE (Figure 2A-E).

ABSTRACT BODY:

Purpose: Deep learning approaches have been successfully applied to estimate visual field (VF) information from optical coherence tomography (OCT) scans. We retrospectively assessed the potential of pointwise VF estimation from opposing macular OCT B-scan pairs using a 2D convolutional neural network (CNN).

Methods: Data were retrospectively collected from two European glaucoma clinics (C1 and C2). Inclusion criteria consisted of paired SPECTRALIS® macular OCT volume scans (61 B-scans) and Humphrey Field Analyzer (HFA) 24-2 SITA Standard VF exams. C1 consisted of 1516 OCT-VF pairs from 850 eyes of 485 individuals while C2 encompassed 35 OCT-VF pairs from the same number of eyes. OCT-VF pairs of C1 were split as 60% training, 20% validation, and 20% testing, while the data from C2 was used as an external test set. The validation and test sets were filtered on HFA reliability indices.

Macular B-scans were assigned from 0 (most inferior scan) to 60 (most superior scan), with B-scan 30 intersecting the fovea (Figure 1). Four opposing B-scan pairings were used as model input to a custom ResNet-50 CNN that was adapted to the prediction of 52 continuous values. The four experiments were named after their B-scan pairing: 00-60, 10-50, 20-40, and 30-30. Individual models were ensembled through prediction averaging. Model performance was evaluated using Pearson’s r, as well as the percentage decrease in mean absolute error from baseline (MAEdecr). The latter was defined as the MAE when the mean value per VF point would be predicted.

Results: Baseline MAE for the test sets in C1 and C2 were 7.57dB and 9.38dB, respectively. For C1, the 10-50 B-scan pair performed the best [r=0.71(0.65-0.76), MAEdecr=33%], although the difference with 00-60 and 20-40 setups was not significant. The CNN trained with 30-30 B-scan pairs performed significantly worse [r=0.65(0.58-0.71), MAEdecr=29%]. Prediction averaging yielded the best performance [r=0.73(0.68-0.78), MAEdecr=35%]. Performance on the 32 OCT-VF data points of C2 was significantly lower.

Conclusions: Opposite macular B-Scan pairs performed similar in the task of 52 HFA 24-2 SS threshold value estimation using a custom 2D CNN. The middle B-Scan that intersects the fovea performed significantly worse. Future experiments should investigate the added-value of including all B-Scans using a 3D CNN for automated VF estimation.

ABSTRACT BODY:

Purpose: To confirm, in a larger population, results from a study of conjunctival epithelial cells gene expression associated to contact lens (CL) wear (CLW) and discomfort (CLD).

Methods: Thirty-six subjects were recruited in this new study in order to complete the data from the 24 ones enrolled in a previous study done by our group (López-de la Rosa et al., Ocul Immunol Inflamm, 2019). Therefore, a total of 60 subjects were included in this analysis: 40 CLWs, further divided into 20 asymptomatic CLW (ACLW) and 20 symptomatic CLW (SCLW) according to the CLDEQ-short form, and 20 non-CLWs. The exclusion criteria were extended or continuous CL wear (overnight use) and the presence of dry eye disease. CL wearers had to be CL users for at least 6 months before being included in the study. Conjunctival impression cytology was used to collect bulbar conjunctival epithelial cells. Expression of 84 genes related to neuropathic and inflammatory pain was analysed by RT-PCR using a commercial PCR array. The effect of CL wear and discomfort between non-CL and CL-wearers and between ACLW and SCLW was analysed. Additionally, a gene set enrichment analysis was performed in order to assign biological meaning to the genes differentially expressed.

Results: 6 genes were found to be significantly upregulated in the CL wearers compared to the non-wearers: CD200, EDN1, PTGS1 and TNF, involved in modulation of pain responses, P2RX7 related to pain conduction, and GRIN1, involved in synaptic transmission. Regarding CLD, 11 genes were found to be significantly downregulated in SCLW subjects compared to ASCLW: BDKRB1, DBH, PDYN, PTGS1 and TNF, related to pain responses modulation, CACNA1B, GRIN1, GRM1 and HTR1A, related to synaptic transmission, and ADORA1 and P2RX3, involved in pain conduction.

Conclusions: The present study confirms previous findings of the increased expression of CACNA1NB and PTGS1 genes in conjunctival epithelium associated with CLW, and also includes the finding of EDN1, P2RX7 and TNF upregulated genes. Additionally, this study also confirms the previously reported alteration in ADORA1, BDKRB1, CACNA1B, HTR1A, PTGS1, and PYDYN genes associated with CLD. Additionally, DBH, GRIN1, GRM1 and TNF genes have been also found to be significantly altered in CLD. CL wear and CLD might be responsible for, or related to, changes in several pain-related gene expression in conjunctival epithelial cells.

TITLE: Botulinum Toxin A for Horizontal Concomitant Strabismus in Chinese Children: A Pilot Study

SESSION TITLE: Strabismus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Jiang, L. Li, Department of Ophthalmology, Beijing Children's Hospital, CHINA|

Commercial Relationships Disclosure: Jingjing Jiang: Commercial Relationship: Code N (No Commercial Relationship) | Li Li: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: For childhood strabismus, early surgical intervention improves both motor and sensory outcomes. Botulinum toxin type A (BTA) injection is an alternative to incisional surgery that is fast, less invasive, and preserves a more normal biomechanical construct. This study was undertaken to assess recruitment potential for a randomized controlled trial to assess the safety and effectiveness of BTX-A for horizontal concomitant strabismus in children in our institution.

Methods: Records of all children, all less than age 18 years, treated with BTX-A for horizontal concomitant strabismus at Beijing Children's Hospital between December 2014 and December 2020 were reviewed retrospectively. Bilateral injections of BTX-A (Henli, 2.5u/0.1ml) were made into the medial or lateral rectus muscles under general anesthesia. Reinjection was permitted if initial alignment was not satisfactory. Patients were followed at least 12months after the last injection. Success was defined as a final misalignment <10 PD, or a final misalignment < 20 PD if there was evidence of binocular single vision.

Results: 71 patients were included. Mean age at initial treatment was 52.15 ± 39.31months. 52 had esotropia and 19 had exotropia. The mean follow-up period was 25.82±14.76 months. The mean number of botulinum toxin injection per patient was 1.27 ± 0.48. A total of 53 patients (74.65%) received one injection, 17 patients (23.94%) two injections, one patient (1.41%) three injections. 51 patients (71.83%) showed successful alignment at the last visit after the final injection. The mean amount of esodeviation before injection was 46.35 ± 20.7 PD at distance and 46.73 ± 20.53 PD at near. At the final follow-up, the mean esodeviation was 11.56 ± 14.88 PD at distance and 12.31 ± 14.47 PD at near ($p < 0.001$). The mean amount of exodeviation before injection was 44.21 ± 16.52 PD at distance and 46.84 ± 14.45 PD at near. At the final follow-up, the mean exodeviation was 16.32 ± 20.40 PD at distance and 17.42 ± 20.01 PD at near ($p < 0.001$). 20 patients (28.17%) developed transient ptosis after injections, vertical deviations were seen in 3 patients (4.23%), Subconjunctival haemorrhage was seen in 5 patients (7.04%). All these adverse events had resolved in all cases within 3 months.

Conclusions: BTA is an effective treatment for management of horizontal strabismus in children. Additional study of this unique cohort is warranted.

ABSTRACT BODY:

Purpose: To investigate how a novel vascular endothelial growth-factor A (VEGF-A) and angiopoietin-2 (Ang-2) bispecific protein (surrobody), RO-634, inhibits human umbilical vein endothelial cell (HUVECs) migration by assessing wound closure post exposure to VEGF-A in laboratory models.

Methods: HUVEC cells were purchased and grown in a 5% CO_2 humidified incubator at 37°C. Endothelial Cell Medium was used for optimal proliferation. Culture-inserts were used to evaluate HUVEC migration potential. Thirty-five thousand HUVEC cells were seeded into a bifurcated chamber and incubated overnight. Eighteen hours after initial seeding, the culture inserts were removed and cells were washed 3x with 1x PBS. After washing, media containing 40 ng of VEGF-A was added along with either bevacizumab, aflibercept, or RO-634. Cells were incubated with the desired medium for 12 hours. The percent change in wound closure was calculated using an image of the same area over the two designated timepoints. This process was repeated in triplicate.

Results: At 12 hours, HUVEC cells exposed to 40 ng of VEGF-A and aflibercept demonstrated a 70% reduction in VEGF-induced HUVEC migration compared to no treatment. HUVEC cells exposed to 40 ng of VEGF-A and bevacizumab demonstrated a 22% reduction in VEGF-induced HUVEC migration compared to no treatment. HUVEC cells exposed to 40 ng of VEGF-A and RO-634 demonstrated a 68% reduction in VEGF-induced HUVEC migration compared to no treatment. The difference in reduction in VEGF-induced HUVEC migration between aflibercept and RO-634 was insignificant ($p=0.93$). The results are shown in figure 1.

Conclusions: This data suggests that novel bispecific protein (surrobody), RO-634, is effective at preventing HUVEC migration post exposure to VEGF-A and is superior at preventing cell migration when compared with bevacizumab in this experiment. There is no statistically significant difference between aflibercept and RO-634 in preventing cell migration of endothelial cells.

TITLE: In Vitro Evaluation of REMOGEN® OMEGA for HLA-DRA and MMP-9 Modulation and Cytotoxicity to Human Ocular Surface Cells

SESSION TITLE: Immunobiology: Ocular Surface, Glaucoma and Retinal Degeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E.G. Romanowski, N.A. Stella, R.M. Shanks, The Charles T. Campbell Ophthalmic Microbiology Laboratory, Department of Ophthalmology, University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Eric Romanowski: Commercial Relationship(s);Code F (Financial Support):TRB Chemedica | Nicholas Stella: Commercial Relationship(s);Code F (Financial Support):TRB Chemedica | Robert Shanks: Commercial Relationship(s);Code F (Financial Support):TRB Chemedica

ABSTRACT BODY:

Purpose: REMOGEN® OMEGA (REM) (TRB Chemedica) is a topical, preservative-free emulsion of essential fatty acids (eicosapentaenoic acid and docosahexanoic acid), vitamin E, glycerol, polyacrylic acid, and polymers that is used for treating symptoms and signs of dry eye and/or ocular surface damage, due to diseases such as superficial keratitis, Sjögren syndrome or primary dry eye syndrome. The goals of the current study were to determine whether pretreatment with REM affects the production of HLA Class II histocompatibility antigen (HLA-DRA) and matrix metalloproteinase 9 (MMP-9) by human corneal limbal epithelial (HCLE) cells after stimulation with lipopolysaccharide (LPS) as well as the overall cytotoxicity to HCLE cells. HLA-DRA and MMP-9 have been implicated as biomarkers of ocular inflammation in dry eye disease.

Methods: For the cytotoxicity assays, HCLE cells were incubated for 6 h with a 2-fold dilution series of REM (50%-0.1953%) or a mock solution. Cells were assessed for cytotoxicity using Presto Blue (Invitrogen). For the ELISA assays, HCLE cells were pretreated for 24 h with 50% REM or a mock solution, washed, then treated with or without LPS (10 mg/ml). ELISA assays for HLA-DRA (MyBiosource.com) and MMP-9 (Life Technologies-ThermoFisher) were carried out using the manufacturers' instructions. Statistical analysis (ANOVA with Dunnett's and Tukey's Post-test) was performed with GraphPad Prism.

Results: No significant differences in cytotoxicity were demonstrated among the mock treated and the REM concentrations at 6 h ($n=4$ for each concentration, $p>0.05$). REM pretreatment of HCLE cells stimulated with LPS significantly reduced MMP-9 production (85.1%; $n=4$, $p<0.01$) and HLA-DRA production (52.5%; $n=5$, $p<0.001$) compared to mock-pretreated cells.

Conclusions: After 24 h of pretreatment, REM significantly reduced MMP-9 and HLA-DRA production by the ocular surface HCLE cell line. Despite a high concentration up to 50% and extended exposure, there was no statistically significant loss of ocular surface cell viability caused by REM. REM appears to be nontoxic and anti-inflammatory to HCLE cells in vitro.

ABSTRACT BODY:

Purpose: In clinical practice, topical ophthalmic antibiotics are commonly prescribed for numerous indications such as bacterial conjunctivitis, keratitis, blepharitis, dacryocystitis and also as prophylactic treatment after ocular surgeries. Due to the anatomical connection through the nasolacrimal duct it is possible that antibiotic eye drops also have an effect on the nasal and pharyngeal bacterial composition. This was investigated in the present study.

Methods: Twenty healthy volunteers were randomized into four treatment groups to receive different antibiotic eye drops or topical lubricants as control. Five subjects received gentamicin eye drops, 5 received ciprofloxacin eye drops, 5 received povidone eye drops unpreserved and 5 received povidone eye drops preserved with benzalkonium chloride (BAC). Subjects self-administered the assigned eye drops 4 times daily for one week. Nasal and pharyngeal swabs were taken before the first administration and after the last dose. Illumina next-generation sequencing (NGS) based 16S rRNA analysis was performed on all samples to gain information about the nasal and pharyngeal bacterial microbiome. Bacterial richness data were provided as operational taxonomic units (OTUs).

Results: None of the administered eye drops had a relevant effect on the pharyngeal microbiome. In contrast, a numerical increase in bacterial richness in nasal swabs was found after antibiotic treatment. In particular, nasal bacterial richness increased from 163 ± 30 to 243 ± 100 OTUs with gentamicin treatment ($p = 0.06$) and from 114 ± 17 to 144 ± 45 OTUs with ciprofloxacin treatment ($p = 0.31$). In the povidone group, nasal bacterial richness only changed from 177 ± 41 to 186 ± 63 OTUs ($p = 0.88$) while in the povidone + BAC group, it almost remained identical (148 ± 50 vs. 148 ± 39 OTUs, $p= 1.0$).

Conclusions: Although not statistically significant, the results of the present study point towards a potential effect of topical antibiotics on the nasal bacterial flora, while no effect on the pharyngeal microbiome was found. To confirm these results, larger studies including more subjects are needed.

TITLE: Bilateral Sequential and Simultaneous Rhegmatogenous Retinal Detachments: Analysis of the Anatomical and Functional Outcomes

SESSION TITLE: Vitreoretinal surgery/VR Interface/PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Doukkali, M. Hébert, E. You, M. Ghasempourabadi, S. Bourgault, M. Caissie, É. Tourville, A. Dirani, Centre universitaire d'ophtalmologie - Université Laval, Hopital du Saint-Sacrement, Quebec, Quebec, CANADA|

Commercial Relationships Disclosure: Sihame Doukkali: Commercial Relationship: Code N (No Commercial Relationship) | Mélanie Hébert: Commercial Relationship: Code N (No Commercial Relationship) | Eunice You: Commercial Relationship: Code N (No Commercial Relationship) | Mohammadhossein Ghasempourabadi: Commercial Relationship: Code N (No Commercial Relationship) | Serge Bourgault: Commercial Relationship: Code N (No Commercial Relationship) | Mathieu Caissie: Commercial Relationship: Code N (No Commercial Relationship) | Éric Tourville: Commercial Relationship: Code N (No Commercial Relationship) | Ali Dirani: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: There are few reports regarding outcomes in sequential and simultaneous bilateral rhegmatogenous retinal detachment (BRRD) repair. We performed this retrospective cohort study to assess the anatomical and functional outcomes in BRRD repair.

Methods: Patients diagnosed with BRRD between 2014 and 2020 at the CHU de Québec – Université Laval were reviewed. We excluded patients with other etiologies (e.g., diabetic retinopathy, tractional retinal detachment (RD), exudative RD) and patients with previous vitreoretinal surgeries. There were 218 eyes of 109 patients. Of these, 86 (79%) were male and median [Q1, Q3] age at presentation for the first eye was 60 [54, 66] years. Data include patient demographics, preoperative characteristics, intraoperative management, single surgery anatomic success (SSAS), complications, and final pinhole visual acuity (PHVA) in logarithm of the minimal angle of resolution (logMAR).

Results: Of the 109 patients included, 92% (n=100) had sequential BRRD and 8% (n=9) simultaneous BRRD. Simultaneous BRRD patients were more likely to have high myopia (simultaneous: 78% vs. sequential: 23%; $p<0.001$) and half of them (n=5, 56%) had unilateral symptoms only. Between first and second eye RD, median [Q1, Q3] duration of symptoms was shorter for the second eye compared to the first (first: 7 [3, 15] days vs. second: 4 [2, 10] days; p=0.028). Second eyes also had less retinal tears (first: 2.94 ± 2.76 tears vs. second: 2.38 ± 1.79 tears; p=0.031) and better median [Q1, Q3] PHVA at presentation (first: 0.46 [0.14, 2.30] vs. second: 0.24 [0.06, 0.95]; p=0.012). SSAS was 92% (n=100) and 93% (n=101) for the first and second eye, respectively (p=1.00). Both eyes improved visual acuity with comparable PHVA at 3 months (first: 0.30 [0.14, 0.48] vs. second: 0.34 [0.13, 0.70]; p=0.36). Final PHVA was however better for the first eye (first: 0.14 [0.04, 0.30] vs. second: 0.20 [0.04, 0.43]; p=0.010). Complication rates were similar between both eyes (first: n=1, 1% vs. second: n=2, 1.8%).

Conclusions: In this BRRD cohort, SSAS was similar for both eyes. The subsequent eye was more likely to be treated earlier with less advanced presentations, but at 3 months, PHVA was not significantly different between eyes. Difference in final PHVA may be attributable to longer follow-up in first eyes.

TITLE: Dacryocystitis: an update on microbiology and drug susceptibility

SESSION TITLE: Antimicrobial Resistance, Epidemiology and New Antimicrobials

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Chiu, C. Lin, Ophthalmology, Kaohsiung Medical University Chung Ho Memorial Hospital, Kaohsiung, TAIWAN|T. Chiu, Kaohsiung Medical University School of Medicine, Kaohsiung, TAIWAN|C. Lin, Kaohsiung Municipal Siaogang Hospital, Kaohsiung, TAIWAN|

Commercial Relationships Disclosure: Tzu-yu Chiu: Commercial Relationship: Code N (No Commercial Relationship) | Chia-Ching Lin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: More accessible medical environments may change the microbiology of dacryocystitis. The aim of our study was to identify the changing trends in microorganisms in lacrimal sac infections and examine their susceptibilities against currently recommended antibiotics.

Methods: Patients who admitted under diagnosis of dacryocystitis between 2011 and 2021 at Kaohsiung Medical University Hospital, a tertiary medical center, were retrospectively reviewed. The pus cultures collected from these patients were then evaluated to determine the types of microorganisms and their antimicrobial susceptibilities.

Results: In this study, a total of 67 patients hospitalized with dacryocystitis were evaluated, which was more common in females than in males (83.58% vs 16.41%).

From 65 pus samples, 64 microorganisms were isolated. The rate of positive culture was 87.7% and mix culture was 10.76%. The proportion of gram positive and negative isolates was nearly equal (51.56% vs 46.88%). The three most frequently isolated microorganisms were Staphylococcus aureus (23.43%) followed by Pseudomonas aeruginosa (20.31%), Staphylococcus epidermidis (7.81%) and Escherichia Coli (7.81%). An incidence of oxacillin-resistance Staphylococcus species in was 65.21%. Sensitivity of common antibiotics for aerobic bacteria is 34.10% in ampicillin-sulbactum, 50% in cefazolin, 29.63% in erythromycin and 48.14% in tetracycline.

Conclusions: Staphylococcus species, especially S. aureus, is the major pathologic microorganism in dacryocystitis. Vancomycin, cefoperazone-sulbactum and imipenum are the most sensitive antibiotics against most common isolated microorganisms in our study. The high prevalence of oxacillin-resistance and increasing isolation of Pseudomonas aeruginosa, could provide us a reference for empirical antibiotics selection.

ABSTRACT BODY:

Purpose: Loss of vision in severe dry age-related macular degeneration (AMD) is secondary to retinal pigment epithelium and photoreceptor damage. The CCN family of matricellular proteins are key signaling molecules involved in many vital biological functions, including cell proliferation, angiogenesis, fibrosis, and wound healing. Recently, it has been shown that CCN5 (WISP-2) is efficacious in a laser induced choroidal neovascularization model. This is the first study assessing the efficacy of CCN5 gene delivery in a rat sodium-iodate challenge model.

Methods: Brown-Norway rats received a single 5 µL intravitreal or subretinal of either AAV2-GFP ($5*10^{10}$ vg/eye) or AAV2-CCN5 in two doses ($1*10^{10}$ or $5*10^{10}$ vg/eye). Naïve animals and intravitreally-delivered Met12 peptide (50 µg/eye) served as control. Sodium-iodate ($NaIO_3$) was injected intravenously 3 weeks following AAV injections. Electroretinography (ERG), fundus imaging, autofluorescence, and optical coherence tomography (OCT) was used to evaluate the condition of the injected eyes for up to 4 weeks after sodium-iodate challenge. At the conclusion of the study, eyes were collected for histology. Data were expressed as means ± SEM and analyzed using one-way ANOVA.

Results: No significant changes, other than the uniform expression of GFP across the retina in the AAV2-GFP group, was observed between AAV injection and $NaIO_3$ challenge. After $NaIO_3$ administration, lesions appeared on fundus images and on OCT in a week, and increasingly worsened till the end of the study in the AAV2-GFP group and ERG amplitudes gradually decreased for up to 50% of naive animals by day 28. In contrast, the high dose AAV2-CCN5 group performed just as well as naïve. The low dose AAV2-CCN5 group performed slightly but not significantly worse than the high dose group. Results with subretinally- or intravitreally-delivered AAV2-CCN5 were not significantly different in any applicable groups.

Conclusions: $NaIO_3$ challenge can reaibly induce RPE and photoreceptor loss and is considered to model these dry-AMD symptoms. Our study demonstrated that AAV-mediated delivery of CCN5 to the retina was tolerable and equally beneficial for protecting against damage induced by $NaIO_3$. These results pave the way to begin to utilize intravitreally- or subretinally-delivered CCN5 therapy for the treatment of severe dry-AMD and geographic atrophy.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is a leading cause of vision loss in the elderly, and its prevalence is growing rapidly due to the increasingly aging global population. Choroidal neovascularization (CNV) is the aberrant growth of blood vessels beneath the retina that characterizes the most severe form of AMD. Mechanisms underlying the improper vascularization of the choroid are not entirely understood. A handful of microRNAs become dysregulated in ocular tissue during the progression of AMD and of these miR-34a may play a significant role due to its involvement in many gene pathways relating to inflammation, angiogenesis, and cellular senescence. Although a positive correlation has been previously established between miR-34a and CNV in the ocular tissue of patients suffering from wet AMD, there has yet to be a causal link made between the two. Therefore, we hypothesized that the upregulation of miR-34a in ocular tissue with age promotes CNV.

Methods: To investigate the role of miR-34a in CNV, we used an experimental mouse model of laser-induced CNV. Further analysis using bulk-RNA sequencing analysis of choroidal cell lysates revealed downstream targets of miR-34a likely to be implicated in the progression of CNV.

Results: Using whole-body miR-34a$^{-/-}$ mice we found that CNV lesions were significantly decreased in the absence of miR-34a compared to wild-type controls. Additionally, preliminary RNA-seq analysis revealed genes that are potential downstream targets of miR-34a in the context of laser-induced CNV.

Conclusions: Ultimately, we found that miR-34a may promote CNV by downregulating key genes that regulate angiogenesis in the choroid. Investigating the underlying mechanisms of miR-34a in promoting CNV will lead to an improved understanding of AMD pathogenesis and may provide novel treatment strategies for this debilitating disease.

ABSTRACT BODY:

Purpose: People with ultra-low vision (ULV) use echolocation and white cane for navigation and wayfinding. There is very little information about how their limited vision can be useful in efficient and safe navigation in unfamiliar settings and environments. The purpose of this study was to develop and calibrate a virtual reality tool for assessing visual wayfinding in people with ULV.

Methods: 15 participants with ULV completed wayfinding tasks in three settings – a street crossing, a cafeteria, and a metro station in virtual reality. Each of these scenarios were presented under different levels of visual clutter to present a range of visual demands and cognitive loads. Task completion times and number of collisions were recorded. Habitual cane users (n=7) were tested with and without cane. Visual acuity was estimated for all participants using the Berkeley Rudimentary Vision Test.

Results: The mean number of collisions ranged from 0.7 to 5.3 among participants across different scenes. The number of collisions increased with increasing clutter and there was a significant association between the number of collisions and estimated visual acuity (R^2 = 0.6, $p<0.05$). Mean task completion times ranged from 25.6 to 87.2s across different scenes and was significantly associated with estimated visual acuities (R^2 = 0.75, $p< 0.005$). We did not observe a speed vs. accuracy trade-off probably because participants were asked to walk at their normal walking speeds. Participants had more total number of collisions without cane (80) than with cane (54) which was statistically significant ($p<0.05$). Similarly, the mean task completion times were higher for without cane (478.2s) compared to with cane (342.9 s) which was also statistically significant ($p<0.05$).

Conclusions: Overall, we found that performance in the wayfinding test presented in virtual reality was consistent with visual acuity of our participants with ULV and could be used as a reliable functional mobility assessment for ULV once calibrated. This test could also be used as a rehabilitation tool to improve wayfinding in people with ULV by training to reduce the number of collisions in the safety of virtual environment. Even though there were no real obstacles to detect, we found that using a cane provided an advantage for habitual users.

ABSTRACT BODY:

Purpose: To investigate the efficacy of monthly or every-other-month (EOM) intravitreal pegcetacoplan compared with sham in patients with GA secondary to age-related macular degeneration.

Methods: OAKS (NCT03525613) and DERBY (NCT03525600) are phase 3, randomized, double-masked, sham-controlled studies. Enrolled patients were ≥60 years old, with best-corrected visual acuity ≥24 letters, and GA area between 2.5 and 17.5 mm^2, including foveal and extrafoveal lesions. The primary endpoint for both studies was change in GA lesion size from baseline to Month 12 measured by fundus autofluorescence. Safety measures included incidences of ocular and systemic adverse events.

Results: OAKS and DERBY enrolled 637 and 621 patients, respectively. OAKS showed statistically significant reductions in GA lesion growth vs sham in the monthly and EOM arms by 22% (p=0.0003) and 16% (p=0.0052), respectively. The results of DERBY did not reach statistical significance: pegcetacoplan decreased GA lesion growth vs sham by 12% (p=0.0528) and 11% (p=0.0750) in the monthly and EOM arms, respectively. In a prespecified pooled analysis, reductions were 17% (p<0.0001; nominal) and 14% (p=0.0012; nominal) in monthly and EOM arms vs sham. In a prespecified analysis of extrafoveal GA lesions, growth was reduced by 35% (p<0.0001; nominal) and 21% (p=0.0159; nominal) in OAKS and by 16% (p=0.0712; nominal) and 25% (p=0.0028; nominal) in DERBY in the monthly and EOM arms, respectively, compared with sham. In a prespecified analysis of foveal GA lesions, growth was reduced by 16% (p=0.0324; nominal) and 16% (p=0.0179; nominal) in OAKS and by 7% (p=0.3611; nominal) and increased by 1% (p=0.8993; nominal) in DERBY in the monthly and EOM arms, respectively, compared with sham.

Conclusions: Monthly and EOM pegcetacoplan met the primary endpoint in OAKS, with positive trends also observed in DERBY. Pegcetacoplan demonstrated greater efficacy in patients with extrafoveal lesions at baseline. Taken together with the positive results from the well-controlled phase 2 FILLY study, these findings support the efficacy of pegcetacoplan in slowing the progression of GA lesions.

ABSTRACT BODY:

Purpose: There is growing evidence of a direct association between Pentosan polysulfate (PPS) (the only FDA approved oral medication for the treatment of interstitial cystitis) therapy and the development of macular changes. Using multimodal retinal imaging, we describe an expanded spectrum of findings among PPS users.

Methods: Thirty-nine participants who were current or recent users of PPS underwent a brief eye exam answered a comprehensive medical and ophthalmic questionnaire, including dosage and duration of PPS exposure. Multimodal imaging including color fundus photography, fundus autofluorescence (FAF) and spectral domain optical coherence tomography (SD-OCT) was obtained. Images were evaluated by expert graders at the Wisconsin Reading Center. Abnormalities were categorized as definitive toxicity (DT) if seen on both FAF and SD-OCT and questionable toxicity (QT) if seen on either FAF or SD-OCT.

Results: The mean PPS daily dose of the study cohort was 282mg (88-400mg), while the mean cumulative dose was 915g (19-3650g) over a mean period of 8.8 years (2 months-25 years). DT was identified in 24 (31%) of eyes and QT in 8 (10%) of eyes. A total of 16 (41%) participants had at least one eye graded as DT, while bilateral DT was seen in 8 (20.5%) participants. Retinal pigment epithelium (RPE) abnormalities (thickening and/or thinning) were present in all DT eyes. RPE atrophy was seen in 7 (18.0%) eyes, predominantly outside the central subfield. SD-OCT features include the presence of a flying-saucer sign and consistent interdigitation zone abnormalities ranging from thickening to disruption. FAF abnormalities were seen in 22 (91.6%) eyes, and in 18 (75%) eyes these were found outside the central subfield and extending beyond the arcades. Predominant hypoautofluorescence was present in 13 (54.1 %) eyes, compared to 3 (12%) eyes with predominant hyperautofluorescence and 5 (20.8%) eyes with a predominant mixed appearance.

Conclusions: A PPS retinopathy prevalence of 41% is higher than previously reported and suggests a wider phenotypic spectrum of structural abnormalities among PPS users. The RPE and outer retina are the most common areas of macular changes, with a constellation of findings often seen outside the macula. The subtle and atypical findings in this cohort should prompt clinicians to consider lowering the threshold for diagnosing PPS retinopathy.

ABSTRACT BODY:

Purpose: Bacillary detachment (BD) is a unique optical coherence tomography (OCT) signature that has been traditionally described primarily in inflammatory disorders. A previous analysis identified BD in neovascular age-related macular degeneration (nAMD) in the Phase 2 OSPREY study. The goal of this analysis was to evaluate BD incidence, clinical features, and response to anti-vascular endothelial growth factor (VEGF) therapy in a large Phase 3 nAMD study.

Methods: This was a post hoc analysis of the spectral domain (SD)-OCT images collected during the 48-week anti-VEGF treatment period from the randomized clinical trial HAWK in participants with nAMD. BD was defined on SD-OCT as a hyporeflective space above a hyperreflective linear structure continuous with the ellipsoid zone (EZ) band (Figure 1). Characterization of compartmental parameters, including retinal metrics and retinal fluid volumes, was performed using a machine-learning-augmented feature extraction platform. Fluid contained within the BD was identified as subretinal fluid for this analysis. This hypothesis-generating analysis did not adjust for multiple comparisons and was treatment agnostic.

Results: A total of 72/656 eyes (11%) had BD at baseline on SD-OCT. Compared to eyes without BD at baseline, BD eyes demonstrated significantly higher mean central subfield thickness (CST, 498 µm vs 366 µm; $p<0.001$), total retinal fluid volume (1.14 mm^3 vs 0.53 mm^3; $p<0.001$), subretinal fluid volume (1.01 mm^3 vs 0.37 mm^3; $p<0.001$), macular total retinal fluid index (TRFI, 0.09% vs 0.05%; $p<0.001$), and lower EZ-retinal pigment epithelium (RPE) CST (2.42 mm^3 vs 4.64 mm^3; $p<0.001$), respectively. After a single anti-VEGF injection, resolution of BD was noted in 94.4% of eyes at Week 4.

Conclusions: BD was identified in a significant proportion of nAMD eyes and was associated with higher baseline fluid volumes and CST. Anti-VEGF therapy resulted in a rapid and dramatic resolution of BD lesions in nearly 95% of eyes with a single injection.

TITLE: Archetypal Longitudinal Visual Field Analysis of Optic Neuritis and Idiopathic Intracranial Hypertension in a “Real World” Clinical Setting

SESSION TITLE: Machine Learning and Augmented Virtual reality

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Branco, E. Solli, M.J. Kupersmith, Neurology, Icahn School of Medicine at Mount Sinai, New York, New York, UNITED STATES|T. Elze, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|L.R. Pasquale, M.J. Kupersmith, Ophthalmology, Icahn School of Medicine at Mount Sinai, New York, New York, UNITED STATES|W. Jui-Kai, R.H. Kardon, Ophthalmology, The University of Iowa Hospitals and Clinics, Iowa City, Iowa, UNITED STATES|

ABSTRACT BODY:

Purpose: We recently used archetypal analysis (AA), a form of unsupervised machine learning, to derive quantifiable patterns, or archetypes (AT), of visual field (VF) loss from the optic neuritis treatment trial (ONTT) and idiopathic intracranial hypertension treatment trial (IIHTT) datasets. Our purpose was to derive new AT models for VFs from clinic-based ON and IIH cases. For both ON and IIH, we hypothesized: 1. The new AT model would resemble our prior AT model; 2. Baseline AT1 (normal VF pattern) weight would be associated with outcome VF mean deviation (MD); 3. AA would reveal residual patterns of VF defects in eyes with MD≥-2.00 dB at outcome.

Methods: We derived two AT models: one based on 446 VFs from 142 patients with acute ON, and the other based on 798 VFs from 120 patients with IIH and VF loss (Fig. 1). We compared these ATs to the ONTT and IIHTT-derived ATs. We compared outcome MD values between patients with baseline AT1 weights above and below the mean using the Mann-Whitney U test. We assessed change in MD over time in each group using the Wilcoxon signed rank test. We determined the number of VFs with abnormal AT weights in eyes with MD≥-2.00 dB at outcome.

Results: For ON, the two ATs of greatest relative weight (RW; 52.7%, 6.32%) resembled those derived from the ONTT (40.2%, 9.43%). For IIH, the three ATs of greatest RW (51.8%, 8.50%, 7.11%) resembled those derived from the IIHTT (30.9%, 23.9%, 5.89%). For ON VFs with baseline AT1 weights < the mean, the improvement in MD (12.9 dB, $p<0.001$) was greater than for those with baseline AT1 weights > the mean (2.61 dB, $p<0.001$). Outcome AT1 weight and MD did not differ between the two groups. For IIH VFs with baseline AT1 weights < the mean, the improvement in MD (2.01 dB, $p<0.001$) was greater than for those with baseline AT1 weights > the mean (0.77 dB, $p<0.001$). On average, VFs with baseline AT1 weights > the mean reached better MD values (-1.26 dB vs. -3.69, $p<0.001$) at outcome than those with baseline AT1 weights < the mean (Fig. 2). For VFs with MD≥-2.00 dB at outcome, 19/45 ON and 44/88 IIH VFs had an abnormal AT.

Conclusions: AA identified reproducible and quantifiable patterns from “real world” IIH and ON VFs. Baseline AT1 weight is associated with VF outcome. AA can indicate residual defects in VFs at outcome.

ABSTRACT BODY:

Purpose: We performed a retrospective study to identify demographic and ocular characteristics associated with six identifiable optic disc phenotypes in Primary Open Angle Glaucoma (POAG) patients.

Methods: Records of patients from the UCLA Stein Glaucoma Division between 1997 and 2019 were reviewed; included were those with a diagnosis of POAG, one disc photo within two years of a visual field (VF), ≥ 2 VFs with Mean Deviation (MD) > -10dB, Pattern Standard Deviation (PSD) probability <0.05, and a Cirrus Optical Coherence Tomography (OCT) with optic disc area between 1.14 and 3mm^2. Poor quality images were excluded. The photos were classified independently by three masked glaucoma specialists into disc phenotypic subgroups, according to standard reference photographs: 1) Concentric rim thinning, 2) Focal rim thinning, 3) Acquired pit of the optic nerve (APON), 4) Tilted (with or without peripapillary atrophy (PPA)), 5) Extensive PPA, and 6) Broad rim thinning. Covariates included age, race/ethnicity, sex, family history of glaucoma, smoking status, hypertension, cardiovascular disease, diabetes, visual acuity (LogMAR), IOP, refractive error, number of medications, central corneal thickness (CCT), visual field MD and PSD, disc area and RNFL thickness. Multinomial Logistic Regression analysis included all covariates.

Results: In 420 eyes of 420 patients, phenotypes included 127 Concentric thinning (30%), 117 Focal thinning (28%), 95 Broad thinning (23%), 45 Tilted (11%), 22 Extensive PPA (5%) and 14 APON (3%). Variables with statistically significant differences ($p < 0.05$) between phenotypes included sex, race, age, refraction, mean PSD, disc area, RNFL. Phenotype traits of interest included 1) Females were more likely to have Focal Thinning, APON and Broad Thinning; 2) Asians were more frequently tilted; 3) African descent were more likely to have Concentric thinning; and 4) APON was less likely to have cardiovascular disease and diabetes.

Conclusions: This study reports six phenotypic classifications of POAG patients, with emergence of different and ocular and systemic differences between phenotypes. Future refinement of phenotypes should allow improved individualization of patient care and enhance genetic associations.

ABSTRACT BODY:

Purpose: Identifying eyes without current hydroxychloroquine (HCQ) retinal toxicity that are at high-risk to progress to toxicity could facilitate clinician intervention for HCQ dosing modifications. The purpose of the current study is to analyze predictive capability of a machine learning (ML)-based model for identifying eyes that progressed to HCQ toxicity by using a combination of quantitative higher-order SD-OCT features and baseline clinical variables.

Methods: This was an IRB-approved retrospective cohort study of 371 subjects on HCQ without evidence of toxicity where data was collected at baseline and final screening visits. OCTs from all timepoints were analyzed with an automated multi-layer compartmental segmentation system to provide quantitative outer retinal parameters. A selection of baseline clinical features (i.e., cumulative HCQ dose, duration of therapy) and quantitative SD-OCT biomarkers (e.g., volumetric ellipsoid zone (EZ) integrity and compartmental measurements) were compared between eyes that progressed to toxicity (progressors) and eyes that did not progress (nonprogressors). A random forest classifier with 10-fold cross validation was trained using baseline features selected based on univariate analysis.

Results: This analysis includes 371 subjects on HCQ with 21 progressing to hydroxychloroquine retinopathy. Baseline features showed highly statistically significant differences in means between progressors and non-progressors: partial EZ attenuation percentage (9.4±8.7% vs 5.6±3.7 %; $p<0.0001$, panmacular ONL volume (3.4±0.6 mm3 vs 4.0±0.5 mm3 ; $p<0.0001$), panmacular EZ volume (1.0±0.2 mm3 vs 1.2±0.2 mm3 ; $p<0.0001$), ONL-RPE thickness 1 mm nasal to fovea (116.4±21.2 µm vs 128.6±17.8 µm; $p<0.0045$), and daily HCQ dose (5.3±1.4 mg/kg vs 4.8±1.5 mg/kg; $p=0.02$). The random forest classifier demonstrated a mean area under curve of 0.89 (0.77-0.94) with sensitivity and specificity of 90% and 80% respectively in identifying progressors.

Conclusions: Combining targeted quantitative SD-OCT biomarkers with HCQ dose enabled the development of a highly discriminating ML-based classification model for the prediction of progression to HCQ toxicity. Future research will be focused on analyzing this model in external datasets and prospective studies.

ABSTRACT BODY:

Purpose: Inherited retinal degenerative diseases, such as Retinitis Pigmentosa (RP), show progressive loss of rods and cones until the individual becomes blind. While rods are lost, downstream neurons are still functional and undergo remodeling as degeneration progresses. While individual cell types have been studied in retinal degenerative models, it remains unclear how the whole retina is affected. To better understand retinal plasticity during degeneration/regeneration (deg/reg), we generated and characterized a transgenic zebrafish (Zf) model expressing the P23H rhodopsin mutation. We hypothesize single cell analysis of P23H Zf will allow us to assess how each cell type is affected during the progression of RP.

Methods: Single cell RNA sequencing analysis was performed separately on WT and P23H retinas. TSNE clusters were generated through Seurat. Cytoscape, and String pathway analysis tools were used to identify pathways for each cell type.

Results: All cell types are found across WT and P23H TSNEs, however, P23H retinas display distinct differences in gene expression. Rods in the P23H retinas show higher levels of oxidative stress genes and markers involved in the misfolded protein pathway. Since Zf regenerate retinal neurons, P23H retinas maintain ~40% of rods compared to WT. Cones in the P23H model don’t undergo cell death, but express increased levels of stress. Retinal neurons downstream of photoreceptors show evidence of remodeling. Rod BPCs increases in genes involved in dendritic self-avoidance and decreases in genes involved in axon targeting. Horizontal cells (HCs) show increases in genes involved in axon remodeling. RGCs from P23H retinas show upregulation of genes involved with postsynaptic glutamatergic receptors. Surprisingly, cones in P23H retinas also have increased expression of genes regulating circadian rhythm.

Conclusions: Photoreceptor deg/reg impacts predominant functions of downstream retinal cell types. While rods are continuously deg/reg, downstream neurons display synapse remodeling activity. Rod BPCs and HCs undergo rewiring, implying a constant state of forming new synapses with newly formed rods. RGCs seem to upregulate their glutamatergic receptors so that there is increased sensitivity in the retinal circuitry. Overall, the retinal environment adjusts so that living photoreceptors may be utilized to maintain rod photoreceptor signal transduction.

ABSTRACT BODY:

Purpose: A potential strategy to treat inherited diseases that are associated with protein misfolding is to correct folding, restore the three-dimensional structure and enhance traffic. Here we investigate the plasma membrane localisation of ABCA4 protein using an in vitro cell model, which could be used as a screen for drugs that positively affect folding.

Methods: The trafficking of the ABCA4 was investigated at 37^0C in vitro by transient transfection of HEK293 and CHO cells using plasmids encoding for the wild-type (WT)-ABCA4 protein and four missense variants, provided by Professor Molday, UBC, Canada. The expression levels of the proteins was assessed by Western Blot (WB) and the cell surface expression was evaluated by immunocytochemistry (ICC) using an antibody against an extracellular epitope. In order to determine whether the traffic and folding were temperature-sensitive, the same experiments were performed at reduced temperature (30^0C). A quantitative assay was developed to monitor the membrane protein plasma membrane traffic. Statistical analysis was performed with two-tailed Student's t-test.

Results: At 37^0C the expression level of the WT-ABCA4 assessed by WB did not show a significant difference to the missense variants. Plasma membrane staining was observed only in few cells expressing WT-ABCA4. When cells were grown at 30^0C, the steady-state protein levels and the plasma membrane signal of the WT and the missense variants were increased. The plasma membrane specificity of the quantitative assay and the ability to detect pharmacological rescue of protein folding was confirmed using WT rhodopsin (RHO) and the misfolding P23H-RHO variant. In this assay WT-ABCA4 showed an increase in plasma membrane signal compared to all the missense variants, except A1038V, suggesting it is not associated with mistrafficking.

Conclusions: Reduced growth temperature can enhance the plasma membrane traffic of WT and missense variants of ABCA4 in cultured cells, suggesting that some of these variants are temperature sensitive misfolding variants that might be amenable to pharmacological rescue. The assay we developed is able to quickly and robustly detect plasma membrane localization, which could be used as a surrogate marker for correct folding and trafficking, and has potential use for high-throughput screening of small molecules able to restore ABCA4 folding.

ABSTRACT BODY:

Purpose: To analyze short-term changes of mean photoreceptor thickness (PRT) on the ETDRS-Grid after vitrectomy and membrane peeling in patients with epiretinal membrane (ERM) using deep-learning.

Methods: Forty-eight patients with idiopathic ERM were included in this prospective study. Healthy fellow eyes served as control. Study examinations comprised best-corrected visual acuity (BCVA) and spectral-domain optical coherence tomography before surgery, 1 week, 1 month and 3 months after surgery. Mean PRT was assessed using an automated algorithm and correlated with BCVA and central retinal thickness (CRT).

Results: Regarding PRT, a significant decrease from baseline to week 1 in the central 1mm (38.23µm±6.88µm to 32.13µm±5.61µm, $p<0.001$), 3mm (34.52µm±4.09µm to 29.78µm±4.24µm, $p<0.001$) and 6mm (32.40µm±3.69µm to 28.17µm±3.72µm, $p<0.001$) disc area as well as a significant increase at month 3 in the 6mm (32.40µm±3.69µm to 32.99µm±2.60µm, $p=0.031$) disc area of the study eye compared to the fellow eye (at baseline 40.82µm±5.62µm, 36.29µm±4.61µm and 33.46µm±4.68µm in the 1mm, 3mm and 6mm disc area, respectively; at week 1 40.35µm±4.91µm, 36.79µm±3.63µm and 33.97µm±4.12µm in the 1mm, 3mm and 6mm disc area, respectively; at month 3 33.07µm±4.15µm in the 6mm disc area) were observed. Changes in PRT in the central 1mm, 3mm and 6mm disc area after 1 week correlated negatively with the change in BCVA (0.30±0.24 logMar to 0.25±0.17 logMar; $rs=-0.350$, $p=0.034$; $rs=-0.337$, $p=0.041$ and $rs=-0.343$, $p=0.038$, respectively) and CRT (449.90µm±78.97µm to 462.20µm±52.53µm; $rs=-0.604$, $p<0.001$; $rs=-0.399$, $p=0.013$ and $rs=-0.344$, $p=0.034$, respectively). Visual acuity increased significantly from baseline (0.30±0.24 logMar) to month 3 (0.15±0.16 logMar, $p<0.001$).

Conclusions: Application of an automated algorithm across a 6mm grid with different sections allows for a comprehensive evaluation of the photoreceptor layer in the macula. Early changes of PRT allow prediction about postoperative functional and even morphological outcomes.

ABSTRACT BODY:

Purpose: Mutations in the heme transporter FLVCR2 cause Fowler syndrome, a prenatal lethal disease characterized by proliferative vasculopathy leading to glomeruloid bodies in the brain and retina. We hypothesize that intracellular heme content represents a completely novel regulator of angiogenesis regulating endothelial tip to stalk differentiation.

Methods: Primary culture of retinal endothelial cells (BREC) were used to test the effect of siRNA to FLVCR2. Cell proliferation was assessed by EdU incorporation or ki67 immunostaining. Tube formation was determined by Matrigel assay in vitro and in retinal explants ex vivo. Heme synthesis was inhibited by using succinylacetone (SA) and induced by 5-Aminolevulinic acid (5ALA). VEGF signaling and cleaved NOTCH product were determined by Western blot. Endothelial-specific knockout of FLVCR2 was achieved by Cdh5-Cre recombination in mice.

Results: Knockdown of FLVCR2 in BREC led to increased proliferation and tube formation, coincident with a 50% decrease in intracellular heme content. Inhibiting heme biosynthesis with SA was able to mimic the effects of FLVCR2 knockdown. Conversely, adding back the heme precursor 5ALA or membrane soluble hemin reversed the effects of FLVCR2 knockdown and SA, respectively. Decreasing intracellular heme levels by either FLVCR2 knockdown or SA did not alter VEGF signaling, nor did it alter mitochondrial function as measured by Seahorse. NOTCH signaling pathway was increased by FLVCR2 knockdown and blocking NOTCH cleavage with gamma-secretase inhibitor DAPT was able to completely prevent the increase in cell proliferation and tube formation. In retinal explants decreased intracellular heme levels promoted increased sprout length but only when provided after tip cell formation and initiation of angiogenesis. In a similar manner, inducing endothelial-specific FLVCR2 knockout at post-natal day 7 led to the formation of glomeruloid structures and hypoxia in the superficial capillary plexus of the retina. Additionally, systemic administration of SA lead to an underdevelopment of the deep capillary plexus in the retinas of wild-type mice.

Conclusions: Together, these results suggest that low levels of intracellular heme in retinal endothelial cells promote the stalk cell phenotype increasing proliferation and tube formation and reveal heme as a novel regulator of retinal angiogenesis.

ABSTRACT BODY:

Purpose: Fungal keratitis (FK) is an infectious disease of the cornea that is increasing in prevalence worldwide. To combat increasing prevalence and improve current therapies, broad-spectrum antifungal agents and models that reliably assess efficacy of topical applied drugs are needed. Current models such as in vitro minimum inhibitory concentration assays can be challenging to interpret due to the lack of established drug breakpoints for many fungal species. These in vitro methods may also fail to correlate well with in vivo application. The purpose of this research is to compare an ex vivo corneal model for antifungal drug efficacy to recent results from a gold-standard MIC assay, with the hypothesis that this method will provide an accurate evaluation of therapeutic efficacy that is better representative of fungal colonization and corneal infection.

Methods: Archived isolates of Aspergillus flavus, A. fumigatus, Fusarium falciforme, and F. keratoplasticum, sourced from equine FK patients at North Carolina State University, were used for this study. Disinfected porcine cadaver globes were inoculated via intrastromal injection with approximately 500,000 conidia of A. flavus, A. fumigatus, F. keratoplasticum, or F. falciforme. Corneas were excised and incubated in Dulbecco's Modified Eagle Cell Culture Medium (DMEM) with either amphotericin B (AMB), luliconazole (LUL), natamycin (NAT), or voriconazole (VOR) at a concentration equivalent to 0.0X, 0.25X, 1.0X or 2.0X of the previously reported MIC. Radial fungal growth was monitored by imaging corneas and measuring area of colonization by pixel count every 12 hours for 72 hours total.

Results: All antifungal drugs examined significantly inhibited growth of A. fumigatus and F. keratoplasticum at or below the MIC at all time points. With few exceptions, all drugs inhibited growth of A. flavus below the MIC at all time points. AMB did not inhibit growth of F. falciforme, while all other drugs inhibited growth at or below the MIC for all time points except for LUL at 24 hours.

Conclusions: Inhibition of radial fungal growth in corneas injected with conidia and incubated in AMB, LUL, NAT, or VOR corresponded well with in vitro MICs in each isolate. With few exceptions, ex vivo fungal growth was significantly inhibited at one-half of the established MIC.

ABSTRACT BODY:

Purpose: The ABCA4 gene, implicated in Stargardt disease (STGD1), has a high percentage of splicing altering pathogenic variants, some of which leading to complex defects. Antisense oligonucleotides (AONs) have shown promising results in targeting splicing altering variants. Here, we selected two regions in ABCA4, containing four variants, leading to complex splicing defects on which we performed AON-based rescue studies.

Methods: Three variants were selected in intron 13, i.e. c.1938-619A>G and c.1938-621G>A that lead to inclusion of a pseudoexon (PE2) on their own or together with a second PE (PE1), located upstream, and c.1938-514A>G that results in the inclusion of PE3 or PE3 and PE1 together (Figure 1). Three novel AONs were designed to target PE2 and PE3, while PE1 was targeted using a previously tested AON1 with adjustments in the sugar moieties (Sangermano et al. Genet Med. 21:1751-1760; 2019). Variant c.6148-84A>T in intron 44 was selected as it resulted in either inclusion of a short PE (PE4) or of a longer PE (PE5) together with exon 44 skipping. All AONs had a phosphorothioate backbone and a 2'-O-methoxyethyl sugar modification. AON efficacy was assessed using in vitro splice assays in HEK293T cells using midigene constructs containing the variants of interest. (Figure 1: Schematic representation of variants in intron 13 (a) and intron 44 (b) causing complex splicing defects. The blue squares represent the PE inclusions. In green, the positions targeted by the AONs used in the study are shown).

Results: Treatment with AON1 for all intron 13 variants successfully promoted PE1 exclusion. AON2 and AON3 efficiently corrected the splicing defects caused by variants c.1938-619A>G and c.1938-621G>A, including the PE1 insertion, while AON4 showed no effect. Aberrant splicing due to c.1938-514A>G was completely corrected by AON3 and partially (~80%) by AON4. Surprisingly, AON2, not targeting PE3 directly, was also able to partially correct PE3 insertion. For intron 44 splicing defects, AON5 showed a partial effect while AON6 was able to completely restore normal splicing.

Conclusions: AON-based splicing modulation is a promising approach to target complex splicing defects in ABCA4. Different variants localized in specific regions can be efficiently targeted by a single AON when the related PEs share part of their sequence.

ABSTRACT BODY:

Purpose: Study the anatomic and functional outcomes of surgery in uveitic non-exudative retinal detachment (NERD).

Methods: Retrospective case series of consecutive eyes with uveitic NERD undergoing surgery between January 2012 and December 2019.

Results: 75 eyes of 70 patients were included. The etiology of intraocular inflammation causing NERD was infectious in 73.3% of cases, immune in 9.3% of cases, tumoral in 2.7% of cases and idiopathic in 14.7% of cases. Posterior and panuveitis accounted for 96.4% of included eyes. Proliferative vitreoretinopathy (PVR) was present in 28.2% of eyes at baseline. The first surgery consisted in vitrectomy alone, scleral buckling alone (SB) or both in respectively 88%, 4% and 8% of cases. Reattachment rate was 75 % after 1 surgery (100% in case of SB) and 89.3% after ≥ 2 surgeries. The mean best corrected visual acuity (BCVA) was 1.5±0.8 logMAR at presentation improving to 1.1±0.9 logMAR at the last follow up (36.6±23.5 months). At the last follow up, 66,6% of eyes reached a countable BCVA (≥20/400 Snellen). After multivariate analysis, the predictive factors of final BCVA≥20/400 were: having baseline BCVA≥20/400(OR=6.1,p=0.01), inactivity of baseline ocular inflammation (OR=0.2 for active inflammation, p=0.015) and absence of retinal detachment (RD) relapse during the follow up (OR=0.1 for RD relapse, p=0.001). The predictive factors of final retinal reattachment were: having baseline BCVA≥20/400(OR=11.3, p=0.05), and absence of relapse within the first 6 weeks of surgery (OR=0.1 for RD relapse, p=0.03).

Conclusions: When managed properly, uveitic NERD has a good anatomic outcome especially when SB is used. For the first time, presence of active inflammation at the time of RD seems to cause the poorest visual outcomes. This should urge physicians adopt the most adequate perioperative anti-inflammatory strategy.

ABSTRACT BODY:

Purpose: Roughly 425 million people are diagnosed with diabetes, which is the leading cause of adult-onset blindness. Despite the prevalence of diabetic retinopathy, 70% of adult diabetic patients develop visually debilitating corneal complications, including impaired wound healing. Unfortunately, treatment for diabetes-induced corneal damage remains limited. The current project seeks to begin investigating a peptide-based combination therapy, thymosin β4 and vasoactive intestinal peptide (Tβ4/VIP), to restore high glucose-induced damage to the corneal epithelium.

Methods: The electric cell-substrate impedance sensing (ECIS®) system was used for real-time monitoring of barrier function and wound healing of human telomerase-immortalized corneal epithelial cells (HUCLs). HUCLs were seeded (60,000 cells/well) in DMEM/F12 media supplemented with 10% FBS, 1% pen/strep in a 96-well array plate. Upon confluency, cells were serum starved for 12-16 h before treatment with normal glucose (5mM; NG) or high glucose (25mM; HG) + Tβ4 (0.1%) and VIP (5nM). Total resistance of the HUCL monolayer across a range of frequencies (250-64,000 Hz) was measured over time to assess barrier integrity. For the wound healing assay, a precise electrical wound (250 μm diameter) was induced. Cell migration was monitored by recording the time required to reform a monolayer. To confirm these findings, Western blot was used to assess protein levels of select markers (ZO-1, occludin and claudin-1) associated with the corneal epithelial tight junction complex.

Results: Barrier integrity was significantly impaired under HG conditions and restored with Tβ4/VIP treatment; whereas, Tβ4 and VIP monotherapies were not effective. This was further supported by reduced levels of tight junction proteins after HG exposure compared to NG, which were enhanced with Tβ4/VIP treatment. Likewise, wound healing was significantly impaired under HG conditions as evidenced by reduced migration velocity. Remarkably, Tβ4/VIP significantly improved cell migration velocity despite HG conditions and restored barrier function similar to that observed under NG conditions.

Conclusions: These results support the premise that Tβ4 works synergistically with VIP to enhance the therapeutic activity with potential for significant impact regarding the treatment of diabetes-induced complications of the cornea.

ABSTRACT BODY:

Purpose: Visual stimuli influence myopic axial elongation via a retina-to-sclera signaling cascade, ultimately triggering scleral remodeling and influencing biomechanics; however, it is still unclear which signaling molecules relay myopigenic cues across the posterior eye wall. Here, we show that ocular outcomes between mice exposed to FD and those treated with oral atRA are highly comparable, suggesting a role for atRA in myopigenic retinoscleral signaling.

Methods: Male C57 Bl/6J mice (4 wks of age) were subjected to unilateral FD (n=15), leaving the contralateral eye untreated (Contra; n=15). Additional mice received daily delivery of icing sugar pellets (Ctrl, 2.5 g/kg, n=11) or sugar+atRA (RA, 25 mg atRA/kg, n=17) via a voluntary feeding paradigm. Refractive error (RE) was measured prior to and at the conclusion of treatment (FD: 3 wks, RA: 2 wks). After sacrifice, sclerae were isolated and used to quantify either tensile stiffness (unconfined compression and biphasic modeling; Brown et al., J Royal Soc Int, 2020) or glycosaminoglycan (GAG) and DNA content (dimethylmethylene blue and picogreen assays).

Results: Contra and Ctrl eyes were not significantly different on any outcome measure, and all animals had comparable RE at baseline. Both FD and oral atRA caused relative myopia to develop vs. controls (FD: -4.3D, $p<0.001$; RA: -5.6D, $p<0.001$). The changes in RE were accompanied by significantly decreased scleral tensile stiffness (34% and 32% lower in the FD and RA groups vs controls, respectively, FD: $p<0.001$, RA: $p<0.001$). Neither the degree of myopia ($p=0.29$) nor decrease in stiffness ($p=0.92$) differed between atRA vs. FD. Neither scleral GAG nor DNA content significantly differed between any group.

Conclusions: FD, a myopigenic visual cue, and oral atRA both induce myopia and comparably alter scleral properties in mice. The unchanged scleral DNA content suggests oral atRA is not influencing biomechanics via altered cellular proliferation; thus, the decreased stiffness may be due to scleral remodeling. GAGs were hypothesized as a biomechanically relevant remodeling target that may overlap between the two treatments; however, GAG content of the entire sclera was not measurably affected by either treatment. Work is ongoing to better characterize scleral GAGs via immunohistochemistry and to measure atRA concentrations in FD-treated eyes.

ABSTRACT BODY:

Purpose: Use of a combination corticosteroid and antibiotic product is common in ocular inflammatory conditions for which corticosteroid therapy is indicated and there exists a risk of superficial bacterial infection. Combination loteprednol etabonate 0.5% and tobramycin 0.3% (LE/T) has been evaluated for blepharokeratoconjunctivitis in two trials, but there has been limited reporting on real-world use of this combination product. We report on the use of LE/T in our practices including prescribing patterns and outcomes.

Methods: This was a retrospective chart review conducted at 3 optometric practices in the USA. Data were collected from cases in which LE/T was used and data was recorded for the period commencing with therapy with a minimum of one follow-up visit (within 2 months). Data abstracted included patient demographics, diagnosis, LE/T dosing regimen, pre- and post-treatment ocular signs, and symptoms, intraocular (IOP) pressure measurements, adverse event (AE) reports, and visual acuity, and any notations as to resolution of baseline condition. Primary outcomes included IOP elevations and AEs.

Results: A total of 98 patient charts were extracted, and data from 87 patient charts (115 LE/T treated eyes) were included in the analysis. Mean (SD) years of age was 45.6 (19.7), most patients were white (83.9%), and just over half were female (58.6). Most eyes (94 of 115) had data for only one related follow-up visit; 20 had data for two. Common baseline conditions were conjunctival injury/corneal abrasion (25.3%), keratitis (19.5%), viral conjunctivitis (16.1%), and blepharitis/MGD (11.5%). The most common LE/T dosing regimen was one drop four times daily. Mean IOP (SD) at baseline was 15.1 (4.3) mm Hg and 15.8 (4.1) mm Hg at the first follow up visit. No adverse events were recorded, and there were no changes in visual acuity with treatment. Where recorded, most patients (88.2%) were noted as having their condition resolved or resolving at the first follow up visit.

Conclusions: LE/T appears to have been well-tolerated when used for the management of various ocular inflammatory conditions encountered in optometric practice. Most patient charts reflected the resolution of the baseline condition with the use of LE/T.

TITLE: Characterisation of three novel animal models of geographic atrophy

SESSION TITLE: Animal Models of Age Related Macular Degeneration

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: N. Hudson, J. O'Callaghan, C. Delaney, A. Reddy, K. Byrne, S. Doyle, M. Campbell, The University of Dublin Trinity College, Dublin, IRELAND|

Commercial Relationships Disclosure: Natalie Hudson: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey O'Callaghan: Commercial Relationship: Code N (No Commercial Relationship) | Conor Delaney: Commercial Relationship: Code N (No Commercial Relationship) | Avril Reddy: Commercial Relationship: Code N (No Commercial Relationship) | Kieva Byrne: Commercial Relationship: Code N (No Commercial Relationship) | Sarah Doyle: Commercial Relationship: Code N (No Commercial Relationship) | Matthew Campbell: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Recently, we have been developing novel approaches to elucidate the early initiating factors that may underlie retinal degeneration in the pathology of dry age-related macular degeneration (AMD), and specifically its end-stage Geographic Atrophy (GA). We have discovered that altered expression of a key tight junction component, claudin-5, found at the inner blood-retinal barrier (iBRB) can lead to an atrophy-like appearance in the retinal pigment epithelium (RPE). Here, we sought to further develop novel animal models with varying claudin-5 expression levels, and iBRB integrity, to assess the damage observed and downstream changes that lead to RPE atrophy.

Methods: We have developed three novel animal models that vary in the expression levels of claudin-5 and induce retinal degeneration within different time frames. These animal models are: 1) RNAi based inducible claudin-5 knockdown mice, 2) Cldn5+/- mice and 3) C57BL6/J mice sub-retinally injected with adeno-associated virus (AAV) vectors expressing shRNA targeting claudin-5. Each model has been characterised to determine the effect of constant claudin-5 suppression on retinal and RPE integrity at different time points in retinal degeneration. In-life imaging of mice was carried out by optical coherence tomography (OCT) to examine retinal and RPE integrity and fundus fluorescein angiography (FFA) to assess retinal blood vessel integrity. In addition, electroretinography (ERG) has been carried out to determine electrophysiological activity. Immunohistochemical, histopathological, protein and transcript analysis was undertaken following sacrifice to further characterise these models.

Results: Assessment of these three mouse models shows that RPE atrophy progression varies depending on the level and length of time of claudin-5 expression at the iBRB and is exacerbated when addition of high cholesterol chow was provided.

Conclusions: Each of the three models developed provide unique characteristics that enable us to determine changes that are arising at the varying stages of disease progression, which may aid us in understanding GA pathology in humans. Targeting the inner retinal vasculature by stabilising and regulating claudin-5 expression may have therapeutic potential for preventing GA onset and development.

ABSTRACT BODY:

Purpose: Gene expression dysregulation is emerging as a dominant model in complex diseases. However, accessing the transcriptome profiles in large disease and non-disease cohorts are challenging, which present significant limitation in identifying genes and pathways involved in the disease process using existing methods such as differential gene expression analysis. The purpose of this study was to apply machine learning methods to uncover gene expression signatures associated with Age-related Macular Degeneration (AMD).

Methods: RNAseq data from 453 donor retina belonging to normal and AMD patients were used to establish and test the model for AMD classification. We investigated three feature selection methods and tested seven machine learning models using 10 folds cross-validation to find the best model. To train the models, the data was randomly split into 70% training data and 30% test data. The training data was then further split for a 10 times cross validation repeated 5 times. Sensitivity, specificity, accuracy, and Matthews Correlation Coefficient (MCC) were used to compare the performance of the machine learning models. We used a combination of pathways analysis, co-expression regulation networks, and recursive feature selection methods to identify the candidate with higher discriminative power.

Results: Most classifiers performed well achieving 70-80% accuracy. Among seven machine learning models used, eXtreme Gradient Boosting (xgb) linear yielded the highest accuracy (82%) in differentiating the advanced AMD from controls based on 555 genes/features. The sensitivity and specificity for gene expression predictions to differentiate AMD from non-AMD was 80% and 82% respectively with an MCC score of 0.63. These features were enriched for genes in immune response, complement and extracellular matrix and connected to known AMD genes through co-expression networks and gene expression correlation.

Conclusions: Our work demonstrates the merits of machine learning approaches for disease classification and suggests the key role of gene expression changes in AMD despite a small patient population. Gene regulatory networks are sufficiently interconnected with individual genes having a small impact on the disease outcome. Thus, our method provides an opportunity to regain the holistic view of the AMD that is lost in experimentally tested reductionist approaches.

ABSTRACT BODY:

Purpose: Orbital fibroblasts are targets of the immune response in thyroid eye disease (TED). In vitro work has shown that in response to immune activation, orbital fibroblasts produce cytokines and undergo adipogenesis. In this study, we use single nuclear RNA sequencing (snRNA-Seq) to characterize and compare gene expression and cell types present in orbital fat isolated from control patients and those with TED.

Methods: We performed nRNA-Seq on retrobulbar fat from three control patients undergoing resection of prolapsed orbital fat and three patients with TED undergoing orbital decompression. TED patients had clinical activity scores ranging from 0-3.

Results: We identified multiple cell types in control patients and those with TED using snRNA-Seq, including fibroblasts and adipocytes (Figure 1a). TED patients have a higher proportion of adipocytes than controls (Figure1b), and TED-specific adipocytes expressed higher levels of adipocyte-enriched/specific genes, FKBP5 and PLIN5 (Figure 1c). TED patients show a reduced proportion of fibroblasts (Figure 1a) and reduced expression in fibroblast-enriched genes (Figure 2a). In addition, we identified fibroblast subtypes that express markers that we have described previously during adipogenic differentiation in vitro, such as PPARG and PDE3B (Figure 2b). In addition, gene expression changes in orbital fibroblasts undergoing adipogenesis match closely to our previous observations in vitro.

Conclusions: We demonstrate evidence of hyperplasia within orbital adipocytes and fibroblasts in TED patients. We identify in vivo changes in gene expression in TED orbital fibroblasts that are consistent with our current in vitro model of orbital adipogenesis.

ABSTRACT BODY:

Purpose: Augmentation of oxidative stress-induced inflammation due to deterioration of antioxidant defense with advancing age is suggested to be associated with aging-related blinding diseases. The multifunctional antioxidant protein Peroxiredoxin 6 (Prdx6) provides cytoprotection and delays lens opacity by regulating reactive oxygen species (ROS) homeostasis. Herein, we showed, for the first time, that Prdx6-deficiency in mouse (m) lens epithelial cells (mLECs) causes ROS-induced Nlrp3 inflammasome activation-mediated inflammatory cell death.

Methods: $Prdx6^{-/-}$ (a model for aging) and $Prdx6^{+/+}$ LECs-derived from Prdx6-deficient and wild-type of 12 months old mice lenses were treated or untreated with N-acetylcysteine (NAC) or Prdx6, and then exposed to H_2O_2 (0-100μM) for different periods. ROS levels were quantified by H2-DCF-DA dye and cell death was evaluated by LDH (a marker for pyroptotic cell death) and MTS assays. Western blot or ELISA and real-time PCR were used to monitor expression or activation of Prdx6, NF-κB, IκBα, Nlrp3 inflammasome (Nlrp3, ASC, caspase-1) activation, IL-1β, and gasdermin-D in $Prdx6^{+/+}$ and $Prdx6^{-/-}$ LECs lysates or cell culture supernatant. SN50, a NF-κB inhibitor was used to block NF-κB activation. Two-tailed Student's t-test and one–way ANOVA were used for statistical analysis.

Results: Compared to $Prdx6^{+/+}$, $Prdx6^{-/-}$ LECs bearing elevated ROS showed markedly increased expression and activation of Nlrp3 and inflammatory proteins; caspase-1, IL-1β, ASC, NF-κB and gasdermin-D with elevated caspase-1 activity, IL-1β secretion and gasdermin-D cleavage involved in cell death/pyroptosis. These factors and cell death were further increased in $Prdx6^{-/-}$ LECs in response to H_2O_2. Under these conditions, a supply of Prdx6 or NAC or SN50 to $Prdx6^{-/-}$ LECs attenuated ROS-driven aberrant activation of Nlrp3, the inflammatory factors, and therapeutically reduced caspase-1 activation, release of IL-1β and LDH, and suppressed cell death ($p<0.001$). Coupled with a significantly the lower vulnerability of $Prdx6^{+/+}$ LECs, these results revealed that Prdx6-deficiency caused ROS-dependent activation of Nlrp3 inflammasome assembly and pyroptosis in LECs.

Conclusions: Our findings underscore the importance of Prdx6 in the redox-signaling network of Nlrp3 inflammasome activation regulating LECs homeostasis as its deficiency is associated with ROS/Nlrp3 inflammasome activation-dependent pyroptotic cell death.

TITLE: A novel HIF1α inhibitor KC7F2 attenuates oxygen-induced retinal neovascularization

SESSION TITLE: Retinal Vascular Diseases excluding Diabetic Retinopathy

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: X. Tang, K. Cui, P. Wu, Y. Xu, X. Liang, Sun Yat-Sen University Zhongshan Ophthalmic Center State Key Laboratory of Ophthalmology, Guangzhou, Guangdong, CHINA|

Commercial Relationships Disclosure: Xiaoyu Tang: Commercial Relationship: Code N (No Commercial Relationship) | Kaixuan Cui: Commercial Relationship: Code N (No Commercial Relationship) | Peiqi Wu: Commercial Relationship: Code N (No Commercial Relationship) | Yue Xu: Commercial Relationship: Code N (No Commercial Relationship) | Xiaoling Liang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: KC7F2 is a novel molecule compound that can inhibit the translation of hypoxia-inducible factor 1α (HIF1α). The purpose of the present study was to investigate whether KC7F2 played a role in oxygen-induced retinal neovascularization (RNV).

Methods: Oxygen-induced retinopathy (OIR) models in C57BL/6J mice and Sprague-Dawley rats were used for in vivo study. After intraperitoneal injections of KC7F2, RNV was detected by immunofluorescence and hematoxylin-eosin staining. Retinal inflammation was explored by immunofluorescence. EdU incorporation assay, cell counting kit-8 assay, scratch test, transwell assay and matrigel assay were used to evaluate the effect of KC7F2 on the proliferation, migration and tube formation of human umbilical vein endothelial cell (HUVEC) induced by vascular endothelial growth factor (VEGF) in vitro. Protein expression was examined by Western blot.

Results: KC7F2 treatment (10 mg/kg/d) in OIR mice significantly attenuated pathological neovascularization ($p=0.0005$), and decreased the number of preretinal neovascular cell nuclei ($p=0.0071$), without changing avascular area ($p=0.3583$), which showed the same trends in OIR rats. Consistently, after the KC7F2 intervention (10 μM), cell proliferation was inhibited in VEGF-induced HUVEC ($p=0.0172$), which was in agreement with the trend observed in retinas of OIR mice ($p<0.0001$). Meanwhile, KC7F2 suppressed VEGF-induced HUVEC migration ($p=0.0003$) and tube formation ($p=0.0135$), and decreased the density of leukocytes ($p=0.0027$) and microglia ($p=0.0001$) co-localizing neovascular areas in the retinas. Moreover, HIF1α-VEGF pathway activated in retinas of OIR mice and hypoxia-induced HUVEC, was suppressed by KC7F2 treatment.

Conclusions: The current study showed the anti-angiogenic effect of KC7F2 via HIF1α-VEGF pathway, suggesting that it might be an effective drug for RNV treatment.

TITLE: Developing a Zebrafish Model of Dominant Optic Atrophy

SESSION TITLE: Molecular Mechanisms Underlying Inherited Ocular Disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Strachan, B.N. Kennedy, N. O'Sullivan, SBBS, University College Dublin, Dublin, IRELAND|

Commercial Relationships Disclosure: Elin Strachan: Commercial Relationship: Code N (No Commercial Relationship) | Breandan Kennedy: Commercial Relationship: Code N (No Commercial Relationship) | Niamh O'Sullivan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Optic Atrophy (OA) is a hereditary neurodegenerative disease characterised by progressive sight loss. This is associated with the irreversible degeneration of retinal ganglion cells. Most cases are associated with dominant mutations in the gene OPA1 (optic atrophy 1), a protein essential for mitochondrial fission – many OA patient fibroblasts have previously been noted to have varying mitochondrial dysfunction. It is unclear why mitochondrial dysfunction leads to retinal ganglion cell death, and there is currently no treatment for OA. I aim to create a zebrafish model of optic atrophy in order to understand the pathogenic mechanisms leading to sight loss in this condition.

Methods: I have designed pairs CRISPR guides to target commonly mutated regions of the zebrafish Opa1 gene, to create a large deletion. This deletion is predicted to cause a loss of function in the resulting protein. These guides were injected into 1-4 cell stage zebrafish embryos, and I subsequently performed optokinetic response assays to determine the presence of a visual defect in the resulting crispants.

Results: I was able to validate the presence of the predicted deletion through PCR and sequencing. Optokinetic response assays revealed a significant reduction in visual acuity in 5dpf crispants compared to siblings without deletion events. I am in the process of raising a subset of the crispants to produce a stable heterozygous line to repeat and validate these experiments.

Conclusions:

I have designed and validated CRISPR guides to create a large deletion in the Opa1 gene. Crispants injected with these guides display a reduction in visual acuity consistent with sight loss seen in patients with loss of OPA1 function. This is a positive early indication this model could be used to study the pathogenicity of loss of function Opa1 mutations. The visual phenotype could additionally be used to screen for modulators of Opa1 function in future.

ABSTRACT BODY:

Purpose: The endothelin system has been shown to be a contributor to neurodegeneration in rodent models of glaucoma. The purpose of this study was to determine if the endothelin receptor antagonist, macitentan, could promote neuroprotection by blocking endothelin-1 (ET-1) mediated vasoconstrictive changes as well as reduce RGC loss and axonal injury during ocular hypertension.

Methods: Adult retired breeder male and female Brown Norway rats were either untreated or treated with macitentan (5 mg/kg body wt) in dietary gels three days per week. Following the treatments, the rats were intravitreally injected in one eye with 4 ml of 500 mM ET-1 and the retinal vasculature was imaged in a Micron IV retinal imaging system. In a parallel set of experiments IOP was elevated in one eye of Brown Norway rats and the animals were treated with macitentan for 4 weeks in dietary gels. Pattern ERG analysis, RGC counts and PPD staining of optic nerve sections were carried out.

Results: ET-1 administration produced rapid vasoconstrictive effects in retinal arteries that occurred 5 min after intravitreal administration and recovery began to occur 20 minutes post-injection. Rats treated with macitentan in the diet abrogated the ET-1 mediated vasoconstrictive effects or delayed its onset. Following IOP elevation in rats, untreated rats exhibited a significant 32% loss of RGCs, compared to naïve rats. Dietary administration of macitentan (5 mg/kg) significantly ($p<0.01$) enhanced the survival of RGCs (5% RGC loss), significantly ($p<0.01$) protected against optic nerve axonal injury and a trend towards preservation of PERG amplitude (not significant).

Conclusions: Blocking both ET_A and ET_B receptors by oral administration of the endothelin receptor antagonist, macitentan, may protect from hypoxic injury as well as promote RGC survival during ocular hypertension. Endothelin receptor antagonists could potentially act through both vascular and cellular mechanisms to promote neuroprotection in glaucoma.

ABSTRACT BODY:

Purpose: Triamcinolone acetonide injectable suspension for suprachoroidal use (SCS-TA) provides targeted steroid delivery to the choroid/retina while minimizing exposure in nontarget tissues. The PEACHTREE Study evaluated SCS-TA for macular edema (ME) secondary to noninfectious uveitis (NIU). In these post-hoc analyses, we evaluated the efficacy and safety of SCS-TA in subjects from PEACHTREE categorized by discreet anatomic subtype of uveitis.

Methods: In PEACHTREE, 160 NIU subjects with ME were randomized 3:2 to SCS-TA or sham procedure at baseline and week 12 and were followed for 24 weeks. Subjects diagnosed with NIU of any anatomic subtype, including anterior-, intermediate-, posterior-, and pan-uveitis, were included. Herein, efficacy endpoints, including changes in best corrected visual acuity (BCVA), central subfield retinal thickness (CST), and safety endpoints, including adverse event (AE) reports and intraocular pressure (IOP), were evaluated in subjects diagnosed with NIU in a single anatomic location.

Results: Of subjects in the SCS-TA and control arm, 13 vs 7 had anterior uveitis, 21 vs 15 had intermediate uveitis, 20 vs 11 had posterior uveitis, and 30 vs 24 had panuveitis. Across NIU subtypes, at week 24, SCS-TA-treated subjects showed significant improvements from baseline in BCVA ranging from 12.1 to 15.9 letters, while control subjects showed changes ranging from -1.6 to 9.1 letters, with significant between-treatment differences among subjects diagnosed with posterior- or pan-uveitis ($P \leq 0.024$). Similarly, changes in CST ranging from -120.1 to -189.0 µm were observed in SCS-TA-treated subjects vs -20.3 to 10.2 µm in control subjects, with significant between-treatment differences among intermediate-, posterior- and pan-uveitis subtypes ($P \leq 0.014$). Reports of AEs appeared similar between treatments by anatomic subtype. At week 24, SCS-TA-treated subjects showed IOP changes of 0.5 to 3.1 mm Hg compared to -1.2 to 1.7 mm Hg in control subjects.

Conclusions: Treatment with SCS-TA resulted in significant BCVA improvements from baseline in all anatomic NIU subtypes and was significantly better vs control in posterior- and pan-uveitis. Significant improvements in CST from baseline were observed vs both baseline and control for most anatomic NIU locations. Safety findings were comparable across discreet NIU subtypes.

TITLE: Assessing Off-Target Interactions Between Schlemm's Canal-Targeted Nanocarriers and the Cornea Endothelium

SESSION TITLE: Pharmacology/cellular mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Scott, M. Vincent, M. Johnson, Northwestern University, Evanston, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Evan Scott: Commercial Relationship: Code N (No Commercial Relationship) | Michael Vincent: Commercial Relationship: Code N (No Commercial Relationship) | Mark Johnson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Nanoscale drug carriers (i.e. nanocarriers) can be designed to both target as well as avoid specific cell types during therapy. With a goal of developing an IOP-lowering agent with minimal off-target effects, we designed FLT4-targeted latrunculin A-laden nanocarriers (t-LatA-NCs) that bind specifically to Schlemm's canal cells. This targeted glaucoma therapeutic enhances uptake compared to non-targeted nanocarriers (nt-LatA-NCs) and significantly lowers IOP in mice via intracellularly delivered LatA, a known cell-softening agent that decreases outflow resistance in the eye[1]. Here, we examine the toxicity and non-specific binding of these nanocarriers to corneal endothelial cells in vitro and in situ.

Methods: An immortalized bovine cornea endothelial cell line (BCE C/D-1b, ATCC, Manassas, VA) was exposed to t-LatA-NCs or free drug (effective LatA concentrations up to 2.5 mM) for 24 hours. Cytotoxicity was examined using the MTT (3-(4,5-dimethylthiazolyl-2)-2,5-diphenyltetrazolium bromide) assay. Nine human corneoscleral rims from six donors were obtained from Eversight (Chicago, IL). Corneas were isolated from rims and were incubated with dye-loaded nt-NCs or t-NCs (18 µg LatA /ml), or PBS for 2 hours. Afterwards, single cell suspensions were prepared and analyzed by flow cytometry to examine whether the FLT4-binding peptide modulates the extent of micelle internalization by the cornea endothelium. NC uptake was quantified by determining the percentage of CD325 (N-Cadherin) positive cells that internalized the dye-loaded micelles.

Results: LatA was non-toxic to bovine corneal endothelial cells in vitro. The t-LatA-NCs consistently enhanced corneal endothelial cell viability above the free drug treatment group ($p<0.05$). Human corneal endothelial cells showed minimal uptake of NCs, and there was no significant difference between t-LatA-NCs and nt-LatA-NCs (see Fig., 2.3 ± 0.8% vs 1.7 ± 0.5%, respectively, $p>0.3$).

Conclusions: Our results demonstrate that our optimized cell softening glaucoma nanotherapy is non-toxic to bovine cornea endothelial cells in vitro. Furthermore, FLT4 targeting ligands did not enhance uptake by the human cornea endothelium in situ.

ABSTRACT BODY:

Purpose: To investigate if the production of PHEMA (poly(2-hydroxyethyl methacrylate)), a biomaterial previously used in artificial corneas, with biomacromolecules enhances viability and integration of human corneal keratocytes (HCK).

Methods: Several varieties of PHEMA-based hydrogels were prepared with 0.05% collagen (COL-I), 0.1% COL-I, 0.2% COL-I, or 0.1% COL-I in combination with 0.025% hyaluronic acid (HA). Samples were individually sterilized by beta-irradiation prior to use in vitro. HCK were seeded at a density of $2x10^4$ cells/cm^2 onto the top surface of hydrogel discs of different compositions. Viability at 5 days post-seeding was measured by quantifying ATP released from metabolically viable cells. Infiltration of cells into the porous biomaterial was quantified by counting the number of DAPI-stained nuclei in horizontal cryosections of HCK-seeded hydrogel buttons. To determine whether corneal cells exposed to the various hydrogels alter their secreted MMP profile, conditioned media was collected 6 days post-seeding for semi-quantification of MMPs using an antibody array dot blot approach.

Results: Only PHEMA-based hydrogels prepared in the presence of 0.1% COL-I alone supported statistically significant enhanced viability of HCK across three independent assays ($p<0.05$) when compared to viability on unmodified PHEMA hydrogels (n=6 samples per hydrogel, per assay; One-way ANOVA, with Dunnett's multiple comparison test). Preliminary data suggested that collagen-only modified PHEMA hydrogels (0.1% or 0.2% COL-I) encouraged deeper infiltration of cells into the biomaterial. MMP levels secreted from HCK grown on modified hydrogels were expressed as fold-change compared to levels observed from cells grown on unmodified samples ($p<0.01$, one-way ANOVA, with Tukey's multiple comparison test). MMP 1 and MMP 3 levels were significantly increased in all modified hydrogels samples, whereas MMP8, MMP10, and MMP13 remained constant across all samples. COL-I-only hydrogels elicited a significant decrease in MMP2 levels, whereas MMP9 levels were only significantly reduced when HCKs were cultured on hydrogels containing both HA and COL-I.

Conclusions: By supporting enhanced survival of HCK in vitro, PHEMA hydrogels containing 0.1% COL-I may allow for improved biointegration of hydrogel-based keratoprosthesis in diseased eyes.

ABSTRACT BODY:
Purpose: Amblyopia is a common cause of visual impairment that results from unequal visual inputs during development. The imbalance is known to manifest through synaptic alterations in visual cortex that shift ocular dominance. Understanding the effects of amblyogenic drivers and their reversal with synaptic plasticity could enable improvements in amblyopia treatment efficacy. This study uses a specific model of activity-dependent neural plasticity, the Bienenstock, Cooper, and Munro (BCM) model, to compare the dynamics of amblyopia recovery at the neuronal level under several treatment protocols, including optical correction, patching, atropine penalization, and binocular therapies.
Methods: We use a model of the single cortical cell receiving natural scene stimuli from two channels representing each eye. Thalamocortical synaptic modification obeys the BCM learning rule where competition between the two eyes drives changes in ocular dominance. Anisometropic amblyopia is modeled by blurring input to the affected eye, and the fix (with glasses) rebalances the structure of inputs. Patching is modeled with unstructured activity (noise) in the fellow eye, and atropine penalization uses both noise and blurred input to the fellow eye. Binocular therapies involving contrast modification and dichoptic masks are modeled with established input filters.
Results: Imbalanced structure of inputs produce a long-lasting ocular dominance shift in favor of the fellow eye that recovers partially when input is re-balanced. We can drive recovery by shifting the difference between inputs in favor of the affected eye, and the rate of recovery increases with greater input disparity. The rate of recovery is greater with patch and atropine treatment models as compared to contrast disparity alone. Addition of dichoptic masks enhances the rate of recovery with the binocular treatment model, comparable to traditional therapies. The efficacy of binocular therapy is directly dependent on the size of the dichoptic masks and level of contrast disparity.
Conclusions: The BCM principles of activity-dependent synaptic plasticity are sufficient to model the ocular dominance shifts underlying the development of and recovery from amblyopia. The importance of the dichoptic masks and contrast disparity levels on the efficacy of the binocular therapy model suggests that these parameters require precise refinement to optimize amblyopia recovery.

ABSTRACT BODY:

Purpose: There is no precise method of individualized risk assessment and automated screening for macular retinopathy due to hydroxychloroquine (HCQ) induced retinal toxicity. We propose the explorative analysis of deep learning methods on spectral-domain optical coherence tomography (SD-OCT) to detect retinopathy before topographical fundus damage and further predict individualized SD-OCT-based risk assessment for HCQ toxicity.

Methods: Clinical Data from 73 patients on HCQ treatment, including SD-OCT, multifocal electroretinogram (mfERG), and autofluorescence (FAF) images, were collected and classified as normal vs. abnormal according to overall clinical assessment and mfERG results (as per Figure 1).

For detection of HCQ induced retinopathy, an Inception-v3 model was trained on augmented images from corresponding “normal” and “abnormal” SD-OCT images using transfer learning on ImageNet pre-trained weights. Performance improvement on Image preprocessing techniques such as Contrast Limited Adaptive Histogram Equalization (CLAHE) and Block Matching and 3-D (BM3D) Filtering were also analyzed.

For prediction of risk of HCQ toxicity, a Long Short Term Memory-based Classifier is proposed with the same structured data as shown below in Figure 2.

Results: For detection, on preprocessed images augmented from 228 “abnormal” SD-OCTs and 128 “normal” SD-OCTs with a 80-20 train-test split, the Inception-v3 model gave a precision of 0.72, recall of 0.92, F1 score of 0.81 and an Accuracy of 0.81 for detecting “abnormal” conditions.

Contrast Limited Adaptive Histogram Equalization (CLAHE) significantly improved the performance. However, Block Matching and 3D Filtering (BM3D) was too slow to be performed on an augmented dataset. For prediction, we had only three patients with advanced “bull’s eye” maculopathy presented over a period of time; thus, prediction analysis could not be performed.

Conclusions: Explorative analysis of deep-learning methods on SD-OCT shows that effective screening methods could be developed for early macular retinopathy detection due to HCQ toxicity with proper Image preprocessing. DL-based HCQ toxicity risk predictors require a larger dataset, and further analysis is required for this task.

ABSTRACT BODY:

Purpose: Exogenous endophthalmitis (EE) is the most serious complication of penetrating eye surgeries and open globe trauma (OGT). It is crucial to know the associated factors that will determine the final visual prognosis. The aim of the present study was to describe the epidemiological, clinical profile and visual outcomes (VO) predictors in patients with EE in a referral ophthalmology center.

Methods: Retrospective, observational clinical study. Patients diagnosed with EE between January 2018 to September 2021 were included. Data collected included demographic characteristics, endophthalmitis origin, culture samples, microbiological diagnosis, initial and final best corrected visual acuity (BCVA), and treatment received. Major outcome was change in BCVA after endophthalmitis treatment and associated factors. T-test and Fisher's exact test for statistical analysis were used.

Results: Seventy-three patients with EE were included. Surgery associated (SA) was the most common cause responsible for 39 cases (53.4%), followed by keratitis associated 18 cases (24.6%) and trauma associated (TA) 16 cases (21.9%). Gram-positive bacteria predominated in positive cultures (n= 35 [54.3%]). There was a statistically significant difference at mean age between TA group 41.1 ±18.7 years and SA group 59.9 ±20.9 years (p= 0.002).

Final logMAR BCVA in the TA group was 4 ±0.9 (Snellen, light perception [LP]) and in the SA group was 2.7 ±1.7 (Snellen, Hand Motion [HM]). Fourteen (35.8%) patients in the SA group had a final BCVA ≥ 20/400; whereas in the TA group all patients had a final BCVA ≤ CF.

Risk factors for non-improving BCVA after EE included OGT (p= 0.007) and initial BCVA of LP or worse (p <0.0001) in the SA group. There was no statistical difference in the final VO in patients that were treated with intravitreal injection (II) and those treated with vitrectomy (VTM) (p =0.40). Although 6 patients (75%) treated with VTM had an improvement in final BCVA compared with 12 (57.1%) of the patients just treated with II, this could be due to the sample number. We observed a tendency of diminishing cases of TA endophthalmitis after covid era, this could be associated with the isolation measures recommended.

Conclusions: Surgery associated EE had a better visual prognosis than those with trauma associated EE. The initial BCVA is a meaningful indicator for final VO, being favorable when is better than HM.

ABSTRACT BODY:

Purpose: Polypyrimidine tract binding protein (PTB) is an alternative splicing factor that can alter splice site selection. Knockdown of PTB can convert cultured fibroblasts to neurons and glial-like cells into neurons in the cortex and dentate gyrus of adult mice. In the retina, knockdown of PTB was proposed to convert Müller glia (MG) into retinal ganglion cells, but this has been questioned due to apparent nonspecific uptake of AAV vectors. We sought to determine the effect of knockdown of PTB after intravitreal injection into zebrafish.

Methods: We injected antisense oligonucleotides (ASOs) targeting PTB into 1016tuba1a:GFP transgenic fish that express GFP in dedifferentiated MG and proliferating progenitor cells during retina regeneration. We then immunostained retinal sections with antibodies against GFP, against Lcp1, a marker of leukocytes and macrophages, and also antibodies against Proliferating Cell Nuclear Antigen (PCNA), and/or co-injection of EdU to detect proliferation.

Results: Intravitreal injection of antisense oligonucleotides (ASOs) targeting PTB in zebrafish produced a robust proliferative response 72 hours post injection. However, few, if any, of the proliferating cells detected after injection of ASOs targeting PTB co-localized with GFP in 1016tuba1a:GFP fish. At 1 week post PTB ASO treatment we detected co-labeling of Lcp1 and EdU in 31 of the 69 EdU^+ cells compared to just 1 of 5 EdU^+ cells in PBS treated retinas ($p=0.026$) or 3 of 8 EdU^+ cells in GFP ASO treated retinas ($p=0.049$).

Conclusions: In response to PTB knockdown, there is activation of immune type cells, which may include microglia and/or type 1 or 2 macrophages. Activation of the immune system aligns with previous work showing that PTB regulates inflammatory responses in mammals. Further experiments are needed to precisely identify the proliferating cells observed after ASO targeting of PTB, but our results support a role for inflammation in response to decreased levels of PTB.

ABSTRACT BODY:

Purpose: Multizone soft contact lenses (SCL) have been shown effective to control myopia progression in young eyes due to proposed introduction of myopic defocus. This project investigated the myopic defocus introduced and how this varied as a function of lens geometry.

Methods: Ten healthy young adult, myopic subjects were binocularly fitted with each of 4 contact lenses in a random order. Lenses included single vision (SV), concentric-ring dual-focus (DF), center-distance multifocal (MF), and a new multi-zone optical design with RingBoost^{TM} (RB) technology. A Shack-Hartmann aberrometer was modified to allow open field binocular viewing and capture full natural pupil wavefront aberrations of right eyes at 4 target vergences (TVs) between -0.25 and -4.00 D. Wavefront data were processed using a custom MATLAB program. Eye plus lens defocus was quantified as the difference between the measured refractive state (RS) and target vergence (TV) based on the average of all lenslet samples within each zone of the multizone designs throughout the entire pupil and compared to equivalent (theoretical) zone areas of SV. Defocus measures of all samples throughout the natural pupil were then used to calculate the percentage of the pupil that contained myopic defocused light for each lens. Myopia was defined as -0.50 D or more myopia, and hyperopia +0.75 D or more hyperopia.

Results: At -0.25 D TV on average only 11.44% of the pupil was myopic with SV, whereas 62.44%, 84.23%, and 50.39% of the pupil was myopic for the DF, MF, and RB designs, respectively. At -4 D TV, all lenses exhibited a systematic decrease in the percentage of pupil area with myopic defocus (SV: 2.81%; DF: 18.05%; MF: 5.32% and RB: 26.33%), but more of the pupil remained myopic with the multizone lenses compared to SV.

Conclusions: Multizone lenses introduced significant amounts of myopic defocus at all viewing distances, however, the magnitude and proportion of defocus was influenced by the lens zone geometry along with viewing distance dependent changes in pupil sizes. Lens with the RingBoost^{TM} (RB) technology retained relatively higher levels of myopic defocus at near viewing.

TITLE: The role of retinal BDNF on the development of the dorsolateral geniculate nucleus

SESSION TITLE: Retinal and central processing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Bierlein, M.J. Van Hook, Dept of Ophthalmology & Visual Sciences, University of Nebraska Medical Center, Omaha, Nebraska, UNITED STATES|

Commercial Relationships Disclosure: Elizabeth Bierlein: Commercial Relationship: Code N (No Commercial Relationship) | Matthew Van Hook: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Brain-derived neurotrophic factor (BDNF) is a key regulator of nervous system plasticity with important roles in the development and maintenance. Within the visual system, the role of retinal BDNF transported to the dorsolateral geniculate nucleus (dLGN), the visual relay center of the thalamus, has not been characterized. Therefore, our goal was to determine whether retinal BDNF influences the development of the dLGN by selectively deleting retinal BDNF using Cre-lox technology.

Methods: We used a mouse line with Cre expression specific to the retina (Chx10-Cre) crossed with BDNFfl/fl mice to selectively delete BDNF from the retina. To test for visual system function differences between Chx10-Cre;BDNFfl/fl (cKO) and control (C57Bl/6J or BDNFfl/fl mice) of both sexes, we analyzed eye tracking abilities in an optomotor (OMR) task using stimuli of varying spatial frequency (n=46) or contrast sensitivity (n=31) and recorded electroretinograms (ERGs) to analyze any retinal differences (n=26 eyes). We also analyzed mEPSCs (n=41) as well as sholl analysis (n=21) in neurobiotin-filled dLGN thalamocortical (TC) neurons. Additionally, we analyzed binocular segregation using intravitreally-injected cholera toxin b (CTb) traces in young mice (n=10).

Results: Results from OMR showed that cKO mice spent less time tracking than controls (spatial frequency: p=0.02; cKO n = 24, ctr n = 22 mice, unpaired t-test; contrast sensitivity: p=0.02; cKO n = 18, ctr n = 13 mice, unpaired t-test), however, there were no differences in outer retinal light responses (p=0.7 A wave, p=0.9 B wave; cKO n = 10 eyes, ctr n = 16 eyes, unpaired t-test). cKO TC neurons had a higher frequency (p=0.02) and lower area in cKO mEPSCs (p=0.046), (cKO n = 19 cells, 9 mice; ctr n = 22 cells, 12 mice, nested t-test nested t-test). Sholl analysis of TC neurons indicated that cKO TC neurons were significantly less complex than control neurons (p=0.03, -7.183 ± 3.066 SEM; cKO n = 11 cells, 6 mice; ctr n = 10 cells, 4 mice). Additionally, CTb analysis suggested no significant differences in binocular segregation (p=0.97; cKO n = 5 mice; ctr n = 5 mice, unpaired t-test).

Conclusions: These results suggest that retinal BDNF plays a role in the structure and function of the dLGN. These results further our understanding of both developmental and neurodegenerative processes in the visual system.

TITLE: Field of View Measurements in Low Vision Telescopes

SESSION TITLE: Assistive Devices, Visual Function Assessment, and Vision Restoration Therapies

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F. Spors, N. Ghazaryan, B. McAllister, College of Optometry, Western University of Health Sciences, Pomona, California, UNITED STATES|

Commercial Relationships Disclosure: Frank Spors: Commercial Relationship: Code N (No Commercial Relationship) | Nane Ghazaryan: Commercial Relationship: Code N (No Commercial Relationship) | Bennett McAllister: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The aim of this study was to determine the accuracy of the visual field of view claims by low vision telescope manufacturers for commonly prescribed telescopes in a setting that can be easily duplicated in a clinical Low Vision practice.

Methods: The useful visual fields of 20 telescopes were determined based on measurements in one observer which had an intact visual field. The visual fields were measured by the investigator as dynamic visual fields using a tangent screen set up at 2, 4, and 6 meters and a standardized Goldmann target size of 2mm. To avoid experimental bias, the manufacturer-stated fields of view were not known by the investigators prior to concluding all measurements. Statistical analysis was conducted using repeated-measures ANOVA with Dunnett's multiple comparisons test and a P value of < .05 was considered statistically significant. A difference of more than 1 degree was considered clinically meaningful.

Results: Statistically significant differences were found between the manufacturer-stated visual field angles and the measured field angles for measuring distances of 2 m (P = .0.0004) and 4 m (P = 0.0.0183), but not for 6 m (P = 0.1431).

At 2 m, the measured visual field angles (mean 13.12 degrees, SD 3.802) were substantially larger than the manufacturer-stated visual field angles (mean 11.08 degrees, SD 3.163). This difference was clinically meaningful.

At 4 m, the measured visual field angles (mean 12.41 degrees, SD 3.766) were substantially larger than the manufacturer-stated visual field angles (mean 11.08 degrees, SD 3.163). This difference was clinically meaningful.

At 6 m, the measured visual field angles (mean 11.88 degrees, SD 3.449) were slightly larger than the average of the manufacturer-stated visual field angles (11.08 degrees, SD 3.163). This difference was considered clinically not relevant.

Conclusions: For the 20 measured telescopes, the manufacturer-stated field angles are appropriate for a distance of 6 m. At shorter distances of 2 m and 4 m, the manufacturer-stated visual field angles underestimate the measured visual field angles. Since telescopes are inherently designed for seeing distant objects, the manufacturer-stated visual field angles are reliable.

TITLE: Tight Adherent Feature on Optical Coherence Tomography may Predict Postoperative Visual Outcome in Epiretinal Membrane Eyes

SESSION TITLE: Imaging of posterior segment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Peng, Ophthalmology, Taipei Tzu Chi Hospital, Taipei, TAIWAN|T. Lai, Ophthalmology, En Chu Kong Hospital, New Taipei City, TAIWAN|

Commercial Relationships Disclosure: Yi-Jie Peng: Commercial Relationship: Code N (No Commercial Relationship) | Tzu-Ting Lai: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the predictive parameter among preoperative measurements that best predicts postoperative visual outcome in the epiretinal membrane (ERM) surgery.

Methods: Thirty-three consecutive patients with idiopathic unilateral ERM patients between 2015 and 2018 were enrolled. Moreover, age-matched healthy eyes were selected as the control group. Based on preoperative optical coherence tomography (OCT), we further divided the patients with ERM into two groups: type 1, loosely attached ERM, and type 2, tight adherent ERM. We documented the vision and thickness of various retinal layers: nerve fiber layer, ganglion cell layer, inner plexiform layer (GCL+IPL), inner nuclear layer (INL), outer retinal layer (ORL), and retinal pigment epithelium/Bruch complex layer before and after the surgery. We analyzed the eyes that underwent combined ERM and cataract surgery or ERM surgery with subsequent cataract surgery. The association between postoperative visual acuity and these variables was analyzed using multiple linear regression analysis.

Results: We identified 11 eyes with type 1 adhesion and 22 eyes with type 2 adhesions. Both groups demonstrated significantly thicker GCL+ IPL thicknesses than the controls. The postoperative best-corrected visual acuity (BCVA) in type II patients was worse than type I pateints ($p=0.026$). The preoperative GCL + IPL and INL layers were significantly thicker in type II patients ($p=0.005$ and $p= 0.033$, respectively) than in type I patients. Multiple linear regression analysis showed that GCL+IPL thickness was an independent predictor of postoperative visual acuity (VA).

Conclusions: Idiopathic ERM demonstrated significantly thicker inner retinal layers (GCL + IPL and INL). However, the ORL thickness was similar between the normal eyes and ERM eyes. The preoperative GCL + IPL and INL layers were significantly thicker in patients with type II ERM than that in patients with type I ERM. Preoperative GCL + IPL thickness is an independent prognostic factor for the ERM surgery.

ABSTRACT BODY:

Purpose: To assess the role of sex hormones in male and female patients with central serous chorioretinopathy (CSC), a disease with a pronounced male predilection.

Methods: A total of 206 chronic CSC patients (183 males, 23 females) and 59 healthy controls (29 males, 30 females) were enrolled. Serum testosterone, estradiol, albumin, and sex hormone-binding globulin levels were determined using immunoassays. The free fraction of testosterone and the free testosterone/estradiol-ratio were calculated.

Results: No differences in the levels of total testosterone and estradiol were observed between CSC patients and healthy controls. Albumin levels were found to be lower in male CSC patients compared to controls (controls 47.8 g/L, patients 46.0 g/L, adj. p = 0.006). Only in females with CSC, sex hormone-binding globulin levels were found to be lower (controls 94.2 nmol/L, patients 50.4 nmol/L, adj. p = 0.001), together with a higher free testosterone/estradiol-ratio (controls 0.06, patients 0.18, adj. p = 0.018).

Conclusions: In this study, we did not find evidence for a disturbance in sex hormone levels in males with CSC. The lower levels of sex hormone-binding globulin in females with CSC, leading to a disturbed free testosterone/estradiol-ratio, warrants further investigation into the role of androgens in females with CSC.

ABSTRACT BODY:

Purpose: There is marked attenuation in the amplitudes of N1 and P1 in the mfERG responses of eyes with a history of severe (i.e., treated) ROP; N1 and P1 in eyes with a history of mild (i.e., untreated) or no ROP differ little from term-born controls (Altschwager et al., 2017). We aimed to determine the cellular origins of these previously reported deficits.

Methods: We measured the moment-by-moment association of response amplitude and the volume of retinal layers in the respective retinal regions stimulated by the standard 103 scaled hexagonal mfERG elements. Adolescent and adult subjects (N=45) participated. Each element was aligned to its corresponding area on the OCT; stimuli falling on the fovea and on the optic nerve head were excluded. The OCT volumes were segmented into “photoreceptor,” “postreceptor,” and “inner” retinal layers. Linear mixed-effects modeling was used to derive estimated coefficients (voltage/volume) for each layer throughout the full 80-ms standard epoch in subjects with (a) no history of ROP (N=26), (b) a history of ROP too mild to require treatment (N=15), and (c) severe ROP treated with laser photoablation (N=4).

Results: Overall, volume of the photoreceptor layer was attenuated while the inner layer was enlarged in the severe retinae. The modeling revealed no marked differences in the mfERG-to-OCT relationships among subjects with no history of ROP or a history of mild ROP. However, it suggested that the marked attenuation in the amplitudes of N1 and P1 in the mfERG responses of severe ROP subjects results mostly from a combination of decreased cornea-negative postreceptor potentials and a latency shift in cornea-positive postreceptor potentials that flatten P1 (but do not much change its implicit time). Also, because the contribution of the inner retina was most significant in the interval between the prominent troughs/peaks of the intact response, it did not rescue N1 and P1 amplitudes. Across all groups, photoreceptor retinal responses differed little.

Conclusions: Model results were in good overall agreement with previous interpretations of the origins of the mfERG. The marked mfERG abnormalities in eyes with severe ROP are probably mediated in large part by changes in bipolar cell function. There was no evidence of dysfunction in the macular cones.

TITLE: Prevalence and clinical characteristics of neurotrophic keratopathy in a Hispanic population in northeastern Mexico.

SESSION TITLE: Corneal Imaging and Corneal Nerves

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Castillo, J.E. Valdez, D. Loya-Garcia, R.E. Ruiz, J.E. Arreola, Instituto de Oftalmologia y Ciencias Visuales, Instituto Tecnologico y de Estudios Superiores de Monterrey, Monterrey, Nuevo Leon, MEXICO|

Commercial Relationships Disclosure: Alberto Castillo: Commercial Relationship: Code N (No Commercial Relationship) | Jorge Valdez: Commercial Relationship: Code N (No Commercial Relationship) | Denise Loya-Garcia: Commercial Relationship: Code N (No Commercial Relationship) | Raul Ruiz: Commercial Relationship: Code N (No Commercial Relationship) | Jesus Arreola: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the prevalence and clinical characteristics of neurotrophic keratopathy (NK) in northeastern Mexico.

Methods: Cross-sectional study in which NK patients admitted to our ophthalmology clinic between 2015-2021 were consecutively enrolled. Data regarding demographics, clinical characteristics, and comorbidities were collected at the time diagnosis of NK was made. General descriptive analyzes were performed using measures of central tendency and comparative analysis using Student's T test for quantitative data and Fisher's test or chi-square distribution for qualitative data. $P < 0.05$ was considered statistically significant.

Results: Results: In the period from 2015 to 2021, a total of 74,056 patients were treated and of these 42 had a diagnosis of neurotrophic keratitis. The prevalence found was 5.67 [CI95 3.95 ~ 7.38] in 10,000 cases. The mean age observed was 59 ± 17.21 years (Table 1), occurring more frequently in males in 59% and with corneal epithelial defects in 66.7% (Table 1). The most frequent antecedents were the use of topical medications in 90% (Table 1), the presence of diabetes mellitus 2 in 40.5% (Table 1) and systemic arterial hypertension in 26.2% (Table 1). The associated clinical characteristics that were observed more frequently were visual acuity deficiency in 81% (Table 1) followed by foreign body sensation in 50% (Table 1). A greater association of developing corneal ulceration was found in females while males only presented corneal epithelial alterations (Table 2). Furthermore, no association was observed with the use of contact lenses (Table 2). Among the clinical characteristics, the absence of ocular pain, redness and constant tearing were associated with the progress of the disease (Table 2).

Conclusions: Neurotrophic keratitis is an underdiagnosed disease with a broad clinical spectrum. The antecedents that were contracted corroborate what was reported in the literature as risk factors. The prevalence of the disease in this geographical area was not reported, so it is expected to increase over time when searching for it intentionally.

ABSTRACT BODY:

Purpose: ZO-1 binds to Claudins at the apical junctional complex as an intracellular scaffold protein. Thus, it manifests contiguously at the cellular periphery in the endothelium with an intact barrier function. However, stressful stimuli, such as hypothermia, oxidative stress, and allograft rejection, break down the perijunctional actomyosin ring (PAMR) concomitant with the destruction of ZO-1 organization (insets in Fig.). This study aims to quantify such disruptions of ZO-1 through combined immunocytochemistry, confocal microscopy, and automatic image skeletonization.

Methods: Porcine eyes were subjected to hypothermia (4 °C; 3-7 days) or oxidative stress (100 μM; H_2O_2 for 60 min). Next, images of PAMR and ZO-1 were registered by immunocytochemistry combined with confocal microscopy at the focal plane of ZO-1. The images were then subjected to automatic segmentation by (U-Net)-based deep learning workflow to delineate ZO-1 distribution at the cellular periphery. Finally, the segmented images were skeletonized using the scikit-image (python) implementation of the Zha84 method, and the corresponding outputs were analyzed for estimating the distribution of branch lengths.

Results: In untreated cells, ZO-1 was contiguous with tricellular junctions. At moderate hypothermic stress, the linear edges were disrupted along with the loss of tricellular links. The linear edges broke down into smaller pieces and punctate blobs at severe stress levels. The severity of the impact on ZO-1 generally paralled those on PAMR. The U-Net led to reliable segmentation with an F1 score of 82%, IoU of 77%, and an accuracy of 94%. Subsequent skeletonization and determination of branch lengths showed a skewed distribution profile compared to those for untreated cells (Fig.) with the frequency of appearance of small segments increasing significantly with higher stress levels.

Conclusions: We have developed a workflow to quantify the ZO-1 disruption patterns in response to hypothermia and oxidative stress in the corneal endothelium.

TITLE: Single-cell recordings reveal modulation of ON and OFF retinal signals in the myopic murine eye

SESSION TITLE: Retinal and central processing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Mazade, M.T. Pardue, Department of Biomedical Engineering, Georgia Institute of Technology, Atlanta, Georgia, UNITED STATES|R. Mazade, M.T. Pardue, Atlanta VA Center for Visual & Neurocognitive Rehabilitation, Decatur, Georgia, UNITED STATES|

Commercial Relationships Disclosure: Reece Mazade: Commercial Relationship: Code N (No Commercial Relationship) | Machelle Pardue: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Visual pathways that signal luminance increments (ON pathway) and decrements (OFF pathway) have been suggested to differentially influence myopia progression and are more weakly driven by defocused stimuli. However, inner retinal signals (including those from ON and OFF pathways) have not been directly studied electrophysiologically in myopic eyes. Here, we investigate how responses from single inner retinal neurons are modulated in myopia.

Methods: Lens-induced myopia (LIM) in C57BL/6J mice was generated unilaterally by placing a -10D lens over the OD eye, leaving the OS eye as a contralateral control (LIM, n=29). Refractive errors (RE) were measured in animals before lens placement and at the end of the treatment period (>2 weeks). A subset of mice were left untreated as naïve controls (Ctrl, n=9). Retinas were collected and prepared for whole-cell voltage clamp recordings. A white OLED screen (max luminance: ~2,000 cd/m^2) was used to generate full-field, 500 ms duration flash stimuli. Light-evoked ON and OFF excitatory and inhibitory responses were measured from single dark-adapted bipolar (BC) and amacrine cells (AC), identified via fluorescent labeling.

Results: All LIM mice developed a myopic shift (ΔRE OD - OS) after 2 weeks (-2.7±0.2 D, $p<0.001$) whereas Ctrl mice did not. The average ON and OFF excitatory response across all recorded cells was ~50% weaker in myopic (n=14 cells) than non-myopic eyes (Ctrl + LIM OS eyes, n=12 cells; $p=0.034$). Interestingly, myopia affected ON- and OFF-driven inhibition in opposite directions. Combining all recorded cells, ON inhibition decreased ~28% and OFF inhibition increased ~42% in myopic (ON n=23, OFF n=20 cells) compared to non-myopic eyes (ON n=14, OFF n=12 cells; $p<0.001$). In myopic eyes, ACs, cone BCs, and rod BCs primarily contributed to reduced ON inhibition while ACs and OFF cone BCs primarily contributed to increased OFF inhibition.

Conclusions: Our results provide direct electrophysiological evidence suggesting modulation of inner retinal ON and OFF responses in myopic eyes. On average, LIM led to weaker ON and OFF excitatory drive, weaker ON-driven inhibition, and stronger OFF-driven inhibition to inner retinal neurons. Our preliminary findings suggest that retinal dysfunction in myopia includes altered ON/OFF retinal balance and supports our ongoing investigation of the effects of myopia on visual signaling in all retinal cell types.

ABSTRACT BODY:

Purpose: The Andhra Pradesh Eye Disease Study III (APEDS III) represents a 15 year follow up of a cohort of participants who were initially evaluated in APEDS I from 1996-2000. It included the surviving participants from all age groups (n=5395; 83.6%) belonging to three rural areas of APEDS I. The present study was aimed to assess the incidence, visual impairment (VI) and blindness due to Retinitis Pigmentosa (RP) in this rural Southern Indian cohort.

Methods: Following a detailed interview, all the participants underwent a comprehensive eye examination including fundus photography and diagnostic tests. Visual acuity (VA) was measured using a standard logarithm of minimum angle of resolution (logMAR) chart at a distance of three meters. Unaided, presenting, pinhole and best-corrected VA were also recorded. All participants with RP of APEDS I were followed up until APEDS III. Descriptive statistics using mean ± standard deviation with inter-quartile range (IQR) were calculated. Main outcome measures were RP incidence, VI and blindness as per World Health Organization criteria.

Results: At baseline (APEDS I), 7771 participants residing in three rural areas were examined. There were 9 cases of RP with mean age at baseline of 47.33 ± 10.89 years (IQR 39-55). There was a male preponderance (6:3) and the mean best-corrected visual acuity (BCVA) of 18 eyes from nine participants was 1.2 ± 0.72log MAR (IQR 0.7-1.6). Over a mean follow-up duration of 15 years, 5395/7771 (69.4%) were reexamined, which included 7 RP participants from APEDS I. Additionally, 2 new cases of RP were identified that provided an overall incidence of 370/million in 15 years (24.7/million per year). The mean BCVA of 14 eyes of seven patients who were reexamined in APEDS III was 2.17±0.56log MAR (IQR 1.8-2.6) and 5 of these 7 patients developed incident blindness during the follow-up period.

Conclusions: The overall incidence of RP was relatively high in the Southern Indian population and this information would be valuable in planning for future eye care strategies to address and prevent this condition.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is the primary cause of irreversible blindness in the elderly. The current paradigm for wet AMD treatment is monthly intravitreal injection of anti-VEGF antibodies, which poses a significant economic burden to the patients. Continuous blocking of VEGF may have adverse effect in choroid capillaries and the ciliary body. We propose a gene therapy approach to drive inducible and reversible VEGF repression using a CRISPR-based system, which could avoid repetitive intravitreal injection while achieving controllable VEGF repression.

Methods: ARPE-19 and mouse RPE cell lines were engineered to express Cas9-Krab reversibly as controlled by doxycycline (Dox), which was confirmed by Western blot analysis and immunostaining. A series of guide RNA pairs targeting human (mouse) VEGF promoter were used in screening to identify guide RNAs that can repress VEGF expression. constitutively expressed. Real-time PCR and ELISA were employed to quantify the VEGF expression before and after Dox treatment in the system. Laser injury model is being used to evaluate the efficacy of the approach in vivo.

Results: Induction and dosage-response of Cas9-Krab expression were confirmed by Western blot analysis and immunostaining. In addition, Cas9-Krab can be reinduced in the same cells within 12 hours 7 days after the first induction. Guide RNAs have been screened to target VEGF promoter RPE cells. Up to 90% reduction of VEGF mRNA and protein expression has been achieved in the system.

Conclusions: We have established a CRISPR-based reversible VEGF repression system, which could be used to treating retinal diseases including AMD and diabetic retinopathy. (This research has been supported by a grant from BrightFocus Foundation)

ABSTRACT BODY:

Purpose: Ocular graft versus host disease (oGVHD) affects 40-60% of patients who have undergone allogeneic hematopoietic stem cell transplant resulting in debilitating eye disease characterized by decreased vision, pain, and dry eye disease (DED). The mechanisms underpinning inflammation in oGVHD are not completely understood. Granzyme B (GzmB) is a serine protease associated with granule mediated perforin dependent pathway leading to apoptosis. GzmB is thought to be involved in multiple autoimmune diseases such as Systemic Lupus Erythematous, scleroderma, which share similarities to GvHD. We hypothesize that the production of GzmB increases the severity of oGvHD, playing a critical role in oGVHD pathogenesis via perforin dependent and independent mechanisms.
Methods: We conducted an allogeneic hematopoietic stem cell transplant using a mouse model. This study included four groups; T and B cell depleted Bone Marrow (TBCD-BM) only, TBCD-BM+Splenocytes (BM+Spl), TBCD-BM+Splenocytes+IL-2c (BM+Spl+IL2), and TBCD-BM+Splenocytes(-CD8depl)+IL-2c (BM+Spl-CD8+IL2). CD8depl is a group in which CD8 T cells were depleted from the spleen prior to transplantation. IL-2c is a complex of murine IL-2 cytokine and IL-2 monoclonal antibody which activate T-cells. GvHD and oGvHD was scored for the duration of the experiment to determine the progression of GvHD and oGvHD. The individual scores for cornea staining, eyelid, eyelid fur, and cornea haze are used to determine the overall oGvHD score by combining the values and then taking the average within the groups at each time point. Grade 1 refers to the least severe and Grade 4 refers to the most severe. In addition, we collected tissue from the cornea, eyelid, conjunctiva, and lacrimal gland from the mice and quantified the gene expressions of GzmB, Arg-1, TNFα, and IFNγR using RT-qPCR.
Results: BM+Spl-CD8+IL2 group showed a significant increase (75%, p=0.013) in oGvHD severity compared to BM+Spl. In fact, the BM+Spl+IL2 group showed a 7.5% increase in oGvHD compared to BM+Spl though this was not significant. BM+Spl+IL2 showed an increase in GzmB, IFNγR, Arg-1 expression in the conjunctiva (36, 3, and 3-fold), the eyelid (42, 7, and 2-fold), and the cornea (38, 33, 1.2-fold) compared to TBCD-BM only.
Conclusions: The presence of IL-2c which promotes GzmB production of T cells increases the severity of oGvHD. Further investigation of GzmB in oGvHD is warranted as a potential target for therapy.

ABSTRACT BODY:

Purpose: The differential responses of S, M, and L cones to short, medium, and long wavelengths of light produce human color vision. Objective methods have been developed to examine cone spectral responses but remain limited. Previously, we developed an adaptive optics optical coherence tomography (AO-OCT) method that used the cone optoretinogram to identify spectral types of individual human cones with unprecedented sensitivity, accuracy, and efficiency [1]. Here, we extend this approach to measuring cone sensitivities across the visible spectrum by controlling the wavelength and strength of stimulation with a supercontinuum laser.

Methods: AO-OCT volumes of 1°×0.8° at 3.8° temporal retina were acquired repeatedly over 5s at 10 Hz for one color normal subject. AO-OCT cone optoretinograms were observed 2.5s after stimulation with flashes of 450, 480, 520, 545, 570, 600, and 635 nm light. Flashes consisting of 5-8 power levels (0.23-31μW) were generated by a supercontinuum laser and controlled by an acousto-optic tunable filter, both spectrally (<1.8 nm bandwidth) and temporally (60 ms flash duration except at 450 and 480 nm that needed longer exposures). Cone spectral types were classified and the mean cone response following stimulus was obtained for the different flash strengths and wavelengths. After compensating for lenticular and macular absorption, the mean cone response as a function of flash strength was fit to a power law from which cone spectral sensitivities were extracted.

Results: Twenty spectral sensitivity measurements were acquired in total. We compared our measurements to Stockman & Sharpe's well-recognized psychophysical cone fundamentals using an iterative function to find the offset producing the minimum total difference between our sensitivity measurements and that of the normalized psychophysical data. Our measurements produced a least-squared error for S, M, and L cones of 0.00, 0.017, and 0.022, respectively, using all seven wavelengths with the exception of 480 nm for S cones. To date we have determined confidence intervals (CIs) for L and M cones of <0.083 and <0.074, respectively, for 545, 570, and 600 nm and for L cones of ±0.034 at 635 nm.

Conclusions: We have developed an objective method that provides highly specific and sensitive measurements of cone sensitivity across the visible spectrum.

ABSTRACT BODY:

Purpose: To assess the efficacy and safety of NOV03 (100% perfluorohexyloctane; F6H8) an investigational, novel, water-free, preservative-free sterile eye drop dosed four times a day (QID) compared to hypotonic saline eye drops for the treatment of the signs and symptoms of dry eye disease (DED) associated with Meibomian gland dysfunction (MGD).

Methods: Mojave was a Phase 3, multicenter, randomized, comparator-controlled, double-masked study conducted in subjects ≥18 years with DED associated with MGD. Eligible subjects were randomized 1:1 to NOV03 or hypotonic saline and instilled 1 drop QID into both eyes for approximately 57 days. Efficacy was assessed at Day 15, Day 29, and Day 57. Primary efficacy endpoints were the change from baseline (CFB) in total corneal fluorescein staining (tCFS; primary sign) and in VAS dryness score (primary symptom) at Day 57. The study eye was the eye with the worse tCFS score at baseline. Safety endpoints included adverse events (AEs), visual acuity, biomicroscopy, fundoscopy and intraocular pressure.

Results: A total of 620 subjects were randomized and treated (n=311 NOV03; n=309 saline). Mean age was 53.6 years, and the majority of subjects were female (78.7%). On Day 57, mean (SD) CFB in tCFS (–2.3 [2.8] NOV03 group vs –1.1 [2.9] saline group) and eye dryness VAS score (–29.5 [28.6] NOV03 group vs –19.0 [27.2] saline group) were statistically significantly different in favor of NOV03 ($P<0.001$ for both). Few subjects experienced ocular AEs in the study eye (9.6% NOV03 group, 9.7% saline group). Blepharitis, mostly mild, was the only AE that occurred in a >1% higher proportion of subjects treated with NOV03 vs saline (1.6% vs 0.3%). Other safety assessments were unremarkable.

Conclusions: In this Phase 3 study of subjects with DED associated with MGD, NOV03 eye drops demonstrated statistically significant improvements over hypotonic saline eye drops in both the primary sign (tCFS) and the primary symptom (VAS dryness) endpoints. NOV03 appeared well tolerated in this population. Efficacy and safety findings were consistent with those reported in a previous Phase 3 study (Gobi).

ABSTRACT BODY:

Purpose: To evaluate the current management of RPE65-IRD in Europe since market authorization of Voretigene Neparvovec (VN, Luxturna™) in 2018. To date, over 200 patients have been treated outside the USA, of which about 90% in Europe. We conducted among all EVICR.net centers and ERN-EYE health care providers (HCPs) the second multinational survey on management of IRDs in Europe with a special focus on RPE65-IRD.

Methods: An electronic survey questionnaire with 48 questions specifically addressing RPE65-IRD (2019 survey [1]) was developed and sent to 126 EVICR.net centers and ERN-EYE HCPs. Statistical analysis was performed with Excel and R.

Results: The overall response rate was 44%; 26 sites follow RPE65-IRD patients. Table 1 compares data with the 2019 survey[1]. By June 2021, 8/26 centers have treated 57 RPE65-IRD cases (1 – 19/site, median 6), and 43 await treatment (range 0 - 10/site, median 5). The overall age range was 3 – 52 years, and 172 patients do not (yet) qualify for treatment (2 - 60/site, median 15). Main reasons were too advanced (54% on average) or mild disease (18% on average). Only 38% of centers participate in the PERCEIVE registry (EUPAS31153, http://www.encepp.eu/encepp/viewResource.htm?id=37005). Table 2 summarizes objective and subjective outcomes for 12 items. Quality of life and full field stimulus test (FST) improvements had the highest scores.

Conclusions: This second multinational survey on management of RPE65-IRD of EVICR.net sites and ERN-EYE HCPs in Europe indicates that RPE65-IRD is diagnosed more reliably in 2021 compared to 2019. By June 2021, 8/26 sites reported detailed results. Main reasons for non-treatment were too advanced or mild disease. Patient satisfaction

with treatment was 40%. Detailed results were not available in 50 to 80% of the 12 outcome items.

ABSTRACT BODY:

Purpose: Hyperosmolarity of the precorneal tear film plays a key role in the underlying pathobiology of dry eye disease (DED). The insulin-like growth factor binding protein-3 (IGFBP-3) is a pleiotropic protein present in the precorneal tear film and is downregulated in response to hyperosmolar stress (H-stress) in corneal epithelial cells (CECs). The purpose of this study was to evaluate the role of IGFBP-3 in mitochondrial morphology and metabolic activity in CECs and corneal epithelium exposed to H-stress.

Methods: Telomerase-immortalized human corneal epithelial (hTCEpi) cells were cultured in isotonic keratinocyte basal media (KBM, 330 mOsm) or KBM with osmolarity values up to 450 mOsm, with or without recombinant human (rh)IGFBP-3 for 2 or 24 hours. Mitochondrial respiration, morphology, and dynamics were analyzed using a seahorse metabolic flux analyzer, real-time PCR, and transmission electron microscopy. Expression and localization of IGFBP-3 and type I IGF-receptor (IGF-1R) were analyzed using subcellular fractionation/immunoblotting. Protein translation was quantified with a SUnSET assay. Injection of 20 mU of botulinum toxin B into the exorbital lacrimal gland of C57BL6/N mice was used to induce DED. DED was confirmed using a phenol red thread test and by corneal staining using fluorescein. After 21 days of DED, mice were treated topically with balanced salt solution with or without rhIGFBP-3. IGFBP-3 expression in the corneal epithelium was assessed using an IGFBP-3 ELISA and immunofluorescence.

Results: H-stress decreased IGFBP-3 expression in vitro and in vivo. Intra- and extracellular levels of IGFBP-3 parallel mitochondrial respiration in CECs under H-stress. At 2 hours of H-stress, IGFBP-3 induced mitochondrial translocation of IGF-1R. At 24 hours, there was a stress-mediated decrease in oxidative phosphorylation that was blocked by the addition of exogenous IGFBP-3. Treatment with IGFBP-3 also promoted IGFBP-3 nuclear localization, mitochondrial hyperfusion, and protein translation. In vivo, exogenous IGFBP-3 restored CEC health.

Conclusions: These data show that IGFBP-3 mediates mitochondrial structure and function through an early and late biphasic response. These findings could pave the way for novel therapeutics for diseases in ocular tissues, such as DED, with underlying mitochondrial and metabolic dysfunction.

ABSTRACT BODY:

Purpose: Elevated intraocular pressure (IOP) is the primary risk factor for glaucoma, a leading cause of irreversible blindness consequent to retinal ganglion cell (RGC) degeneration. Elevated IOP induces biomechanical aberrations within ocular tissues – including the transmission of stretch through the lamina cribrosa (LC) region of the optic nerve head (ONH), the initial site of RGC damage. ONH astrocytes (ONHA), a primary cell type of the LC, respond to stretch in a manner that promotes pathological extracellular matrix (ECM) remodeling (fibrosis) and mechanical damage of RGC axons within the ONH. A complex set of molecular mechanisms regulate ECM remodeling. Part of this regulation may involve microRNAs (miRNAs), small molecules that inhibit protein expression by binding to and silencing mRNA. In this study, we examined miRNA expression profiles of ONHA exposed to cyclic stretch. We hypothesized that cyclic stretch would increase expression of miRNAs that silence anti-fibrotic protein translation and decrease expression of miRNAs that silence pro-fibrotic protein translation, promoting a net-fibrotic molecular signaling environment.

Methods: Primary human normal ONHA cell strains (n=3) were exposed to 0-12% cyclic stretch for 24 hours; controls were exposed to 0% stretch. RNA samples were collected from stretched and control cells. miRNA PCR arrays were used to determine expression changes for miRNAs associated with fibrosis. Expression fold changes were normalized to SNORD68. The bioinformatics tool TargetScan was used to predict mRNA targets for dysregulated miRNAs. Western blotting of conditioned medium was used to compare TGFβ2, fibronectin, and transglutaminase 2 expression between control and stretched ONHA.

Results: miR-146b-5p was upregulated by +5.97-fold (P = 0.029) in stretched ONHA. Predicted mRNA targets for miR-146b-5p are involved in fibrosis and cell survival, among other functions. Preliminary data indicates the upregulation of secreted proteins associated with fibrosis (TGFβ2, fibronectin, transglutaminase 2) by stretched ONHA.

Conclusions: Stretch modulates miRNA expression in cultured human ONHA, miR-146b may mediate ECM alterations and other pathological changes at the LC. Future experimental directions will include assessing co-expression of other miR-146 family miRNAs, validating putative mRNA targets and elucidating the mechanisms by which specific miRNAs and their targets modulate ECM remodeling.

ABSTRACT BODY:

Purpose: A growing number of studies show that homeostasis of the ocular surface is impacted by the intestinal microbiome, and several 16S sequencing studies have demonstrated dysbiosis of the intestinal microbiota in Sjögren Syndrome (SS) patients. In this study, we utilized metagenomic sequencing to perform a deeper analysis of the intestinal microbiome to identify differential bacterial species using stools collected from sex- and age-matched subjects.

Methods: Age-matched healthy (n = 20), dry eye (n = 4) and SS (n = 7) female patients were enrolled at the BCM Alkek Eye Center. Ocular disease severity was scored following International Dry Eye Workshop guidelines. Patients were supplied with stool collection kits and submitted samples within 24 hours post-collection. High quality DNA was prepared for metagenomics sequencing from stool aliquots using DNEasy Powersoil Pro kits. Sequencing, annotation, and initial analysis were performed by Diversigen with their BoosterShot Shotgun Sequencing service. We further analyzed the data using the vegan and randomForest packages in R statistical software.

Results: Shannon alpha diversity and observed operational taxonomic units (OTUs) were significantly decreased in SS ($P<0.05$). Observed OTUs inversely correlated with ocular severity score (Spearman's $r=-0.37$, $P<0.05$). Using Bray-Curtis beta diversity analysis, we found significant separation between healthy and SS groups (PERMANOVA $R^2=0.08$, $P<0.05$), but not between healthy and dry eye groups. We investigated taxonomic differences using the Random Forest machine learning algorithm. At the phylum level, Bacteroidetes ($P<0.05$) and Actinobacteria ($P<0.01$) contributed the most to community differences. At the species level, SS patients were distinguished by significant increases in Bacteroides caecimuris, Mediterranea masilliensis, Bacteroides coprophilus and Clostridium_sp_7_3_54FAA and a significant decrease in Bifidobacterium bifidum compared to healthy controls (all $P<0.01$), and these species changes correlated with disease severity.

Conclusions: Our metagenomic data confirm that the SS gut microbiome is less diverse, and that reduced diversity correlates with increased ocular disease severity. In addition, we have identified specific bacterial species that are either depleted or enriched in SS patients and correlate with ocular surface disease severity.

TITLE: Longitudinal characterization of foveal RA signaling in human Retinal Organoids

SESSION TITLE: Retina Development and Regeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: I. Khandaker, Ophthalmology, University of Pittsburgh, Pittsburgh, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Irona Khandaker: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Induced pluripotent stem cells (iPSCs) derived human retinal organoids (hRetOrg) have emerged as a powerful system for studying retinal diseases while formation of a fovea has not been yet achieved in current methods. We hypothesize that foveated-hRetOrg can be generated if in vivo developmental molecular programs underlying fovea formation, namely Retinoic Acid (RA) signaling, are recapitulated in this in vitro system. We therefore settled to longitudinally characterize RA signaling in hRetOrg during retinogenesis period.

Methods: We established a hRetOrg culture system generated from a human control iPSC line, IMR(90)-4, based on Zhong et al. 2014 and Cowan et al. 2020 methods. We collected hRetOrg from the beginning of retinogenesis at week (W) 5 up to fully differentiated stages at W21 for gene expression analysis by qRT-PCR, in situ hybridization and immunohistochemistry. We also employed electroporation technique to perform localized transfections in defined hRetOrg domains using customized electrodes and chambers.

Results: We confirmed recapitulation of in vivo retina developmental key points in our hRetOrg cultures, such as formation of eye-field at day (D) 7, optic vesicle –like configurations at D16 and optic cup-like structures at D25. Around W5, neural retinal cells spontaneously began to differentiate following in vivo birth dating orders. Immunohistochemistry analysis of W21 hRetOrg showed Rhodopsin, SW, and M/LW cone expressions in outer segment-like structures confirming full differentiation of photoreceptors in our cultures. Regarding RA signaling analysis, we found that RA synthesizing enzymes ALDH1A1 (dorsally expressed in vivo) and ALDH1A3 (ventrally expressed in vivo) are expressed in non-overlapping domains with slightly different dynamics. Expression of RA degradative enzymes is more complex and highly variable among organoids. Additionally, we also developed an efficient gene transfection method of hRetOrg via electroporation for precise spatiotemporal regulation of expression of any gene of interest.

Conclusions: This study thoroughly characterizes RA signaling in current hRetOrg cultures during retinogenesis period, constituting a reference where upon genes of interest can be manipulated in order to recapitulate in vivo patterns of foveal molecular mechanisms, which ultimately can lead to the formation of foveated-hRetOrgs.

ABSTRACT BODY:

Purpose: The International Classification of Retinopathy of Prematurity (ICROP) defines the classification of ROP for clinical trials and treatment guidelines, however ICROP has historically been predominantly influenced by ROP pathology in the US and Europe. Since ROP phenotypes can vary especially in low-and-middle-income countries (LMIC), there is a gap in knowledge as to how applicable ICROP classifications are to treatment in LMIC. In this study, we evaluate the ICROP classifications of all babies treated for ROP at the Aravind Eye Hospital (AEH) in South India.

Methods: A retrospective study was performed on all treatment-requiring (TR) ROP at AEH between April 2019 and November 2020. As part of routine tele-ROP screening, disease was documented by Retcam Shuttle and graders recorded the level of disease by ICROP criteria using a web-based data management system iTeleGENx (Chicago, IL, USA). Diagnosis of TR-ROP and any treatment received were recorded.

Results: A total of 204 eyes of 104 babies were diagnosed with TR-ROP out of 2700 babies (3.9%) screened for ROP during the time interval. The mean ± standard deviation (SD) gestational age was 30 ± 2 wks and average birth weight was 1270 ± 285 g. Using ICROP criteria and current treatment guidelines, 184 eyes of 94 babies (89.5%) were treated according to guidelines with either zone 1, with plus (37.2%), zone 2, stage 3, with plus (42.6%) or zone 1, stage 3 (4.3%). 20 eyes of 10 babies (9.6%) who received treatment had Type 2 ROP ICROP characteristics, presenting with zone 2 stage 3, pre-plus ROP (80%).

Conclusions: We found that approximately 90% of babies were treated according to guidelines established by the ICROP and Early Treatment for ROP (ETROP) study, suggesting that despite demographic and phenotypic differences, the ICROP informs clinical diagnosis and management in LMIC.

ABSTRACT BODY:

Purpose: Safety and efficacy of triamcinolone acetonide injectable suspension, for suprachoroidal use (SCS-TA) in the treatment of macular edema (ME) associated with noninfectious uveitis (NIU) was previously demonstrated in the Phase 3 PEACHTREE study. This post-hoc analysis evaluated the impact of age on treatment outcomes from that study.

Methods: Subjects with ME secondary to NIU (N=160) were randomized 3:2 to receive a suprachoroidal injection of SCS-TA (4 mg) or a sham procedure in the study eye at baseline and Week 12 and were followed for 24 weeks. Subjects received rescue therapy based on preestablished criteria. Anatomical and visual outcomes, incidence of adverse events, and intraocular pressure (IOP) elevations were evaluated at each visit. A post-hoc analysis was performed to stratify best corrected visual acuity (BCVA, ETDRS letters), central subfield thickness (CST, μm), need for rescue and incidences of IOP and cataract by subject age (≤50 and >50 years).

Results: In the SCS-TA vs control arms, 46 vs 33 subjects were ≤50 years and 50 vs 31 subjects were >50 years of age. Similar proportions of subjects had persistent NIU (>3 month duration) in both age groups, while time since ME diagnosis was shorter in the younger age group (50.5 vs 90.0 weeks in the SCS-TA arm). Change from baseline (CFB) in BCVA was greater with SCS-TA vs control in both age groups at all visits. At Week 24, in subjects ≤50 and >50 years of age, respectively, the CFB in BCVA was 15.2 and 12.5 ($P<0.001$ for both) and between treatment differences were 9.4 and 12.5 ($P\leq0.014$ for both). In both age groups, CFB in CST was greater with SCS-TA vs control at all visits; between treatment differences were -148.3 and -120.2 in subjects ≤50 and >50 years of age ($P\leq0.008$ for both). The rescue rate for SCS-TA vs control was 8.7 vs 66.7% and 18.0 vs 77.4% in subjects ≤50 and >50 years of age, respectively. Incidences of IOP elevation ≥10 mm Hg from baseline at any post-baseline visit in the SCS-TA vs control arms were 15.2 vs 18.2% and 16.3 vs 16.1% in the ≤50 and >50 year age groups, respectively. Cataract rates in the SCS-TA vs control arms were 8.7 vs 9.1% and 6.0 vs 3.2% in subjects ≤50 and >50 years of age, respectively.

Conclusions: These data suggest that SCS-TA is effective and well tolerated in the treatment of ME associated with NIU irrespective of patient age.

ABSTRACT BODY:

Purpose: Epigenome editing utilizing the CRISPR (clustered, regularly interspaced, short palindromic repeats)-Cas9 platform has emerged as a promising alternative to cleavage-dependent gene editing, providing a novel approach for targeted control of gene expression. Previous work has shown that fusing several transcriptional regulators to dCas9 in tandem can achieve a synergistic increase in activity, although the additional payload of an epigenetic effector molecule limits AAV-based delivery strategies.

Methods: We developed a novel 105-aa MeCp2 repressor effector comprised of the MeCp2 transcriptional repressor domain (TRD). We first designed gRNAs to target the epigenome editor systems with both S. aureus (Sa) and C. jejuni (Cj) Cas9 proteins to a HEK293 cell line harboring a proline-glutamate-serine-threonine-rich (PEST) destabilized-GFP (dGFP) sequence and measured dGFP expression by fluorescence spectroscopy. To validate our epigenetic editor using a clinically relevant target, we next employed a dual luciferase (Firefly-Renilla) assay system to screen gRNAs against neural retina leucine zipper (NRL), a transcription factor dictating a rod cell phenotype in photoreceptors. Oligonucleotides encoding the relevant sequence were cloned into a reporter construct, and then co-transfected into HEK-293T cells with plasmids expressing the dSaCas9-repressor and relevant gRNA sequence to NRL.

Results: At 48-hour and 96-hour timepoints, we observed a ~20% reduction in dGFP expression with the dSaCas9 bipartite KRAB-MeCp2 repressor, in comparison to no detectable dGFP knockdown with a non-targeting gRNA control. Following in silico design and screening in a dual luciferase assay, significant knockdown was observed against NRL across 5 of 6 tested repressor effector combinations, with the best gRNA achieving 57.6% luciferase knockdown

Conclusions: Our results confirm the development and in vitro validation of a novel bipartite repressor effector that can be packaged all-in-one in AAV. No discernible epigenetic repression was detected with the CjCas9 protein. To facilitate in vivo epigenetic editing, we generated AAV8 for both dSaCas9-KRAB and dSaCas9-KRAB-MeCp2 repressor systems. Future studies will evaluate the utility of Cas9-mediated repressors in retinal organoids and in an Nrl.EGFP mouse model.

TITLE: Effects of normal aging on the mouse retina assessed by full-field flash and flicker electroretinography.

SESSION TITLE: Electroretinography: basic mechanisms and disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: O. Persidina, J. Park, T. Nguyen, J. McAnany, Illinois Eye and Ear Infirmary, Department of Ophthalmology and Visual Sciences, University of Illinois at Chicago College of Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Oksana Persidina: Commercial Relationship: Code N (No Commercial Relationship) | Jason Park: Commercial Relationship: Code N (No Commercial Relationship) | Tara Nguyen: Commercial Relationship: Code N (No Commercial Relationship) | J Jason McAnany: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate changes in the electroretinogram (ERG) that accompany normal aging in mice. Previous studies have shown that the flash ERG a- and b-wave amplitudes decrease with increasing age in mice. By contrast, the effect of age on the flicker ERG has not been reported in mice, despite its utility for assessing cone pathway function. This study compared the effects of normal aging on single flash and flicker ERGs in C57BL/6J mice.

Methods: ERGs were recorded from a single cohort of wild type C57BL/6J mice at 5, 10, and 30 weeks of age (9 to 10 mice per age group) using conventional techniques. Dark-adapted flash ERGs were recorded across a broad range of luminance (-3.0 to 2.0 log $cd*s*m^{-2}$); a- and b-wave amplitude and implicit time (IT) were calculated from these responses. In addition, the light adapted flicker ERG elicited by sinusoidally modulated light was measured across a range of temporal frequencies (2 to 31 Hz). Fourier analysis was applied to extract amplitudes and phases from the flicker responses. Analysis of variance was used for statistical comparisons of amplitude and timing among age groups.

Results: There were significant differences in the a-wave amplitude ($F = 73.31$, $p < 0.001$) and b-wave amplitude ($F = 134.72$, $p < 0.001$) for the three age groups. From week 5 to week 30, the amplitudes of both components decreased by a factor of approximately 1.8. There were no significant age-related differences in the implicit time of these components (both $F < 2.29$, $p > 0.10$). There were significant differences in the fundamental amplitude of the flicker ERG ($F = 46.85.00$, $p < 0.001$) and in the second harmonic amplitude ($F = 9.79$, $p < 0.001$) for the three age groups. From week 5 to week 30, the amplitudes of both components decreased by a factor of approximately 1.8. There were no significant age-related differences in the phases of these components (both $F < 2.64$, $p > 0.08$).

Conclusions: Age scales the single flash and flicker ERG similarly, reducing response amplitude by nearly half from 5 to 30 weeks without affecting response timing. Although similar declines in rod and cone photoreceptor function could explain these findings, changes in ocular resistance with age may provide an alternative explanation. Age-related loss of ERG amplitude should be considered in studies that involve mice of different ages.

ABSTRACT BODY:

Purpose: To explore the understanding and adoption of artificial intelligence (AI) applications within clinical ophthalmology.

Methods: For this exploratory pilot study, semi-structured one-on-one interviews (N=18) were conducted with ophthalmologists, ophthalmology residents, fellows, and medical professionals involved in the diagnosis and treatment of eye diseases. An interview guide informed by prior research of an interdisciplinary team and clinical expertise steered the question-asking process. Virtual interviews lasted approximately 30 minutes and were analyzed with a qualitative content analysis approach.

Results: The majority of participants were white (56%), male (61%), and aged 25-44 years (Mean=32.3). 78% were affiliated with academia and 38% were attending physicians with 1-11 years of practice. Analysis revealed all participants believed that AI informed practice was vital in ophthalmology, with many participants describing it as the “future of the profession.” While all participants were able to discuss specific applications of AI to the field, such as diagnosing diabetic retinopathy and glaucoma, very few participants had used AI in their own practice. A balance between the ‘computer and the clinician’ was noted. Identified disadvantages of an AI-integrated practice include: machine learning techniques can be subject to human data collection bias, a lack of ‘big data’ to help inform AI models, lack of buy-in from the profession, and a perceived lack of access to AI in rural areas. Participants envision integrating AI into future practice as a tool to help guide decision making and to save time. No substantial differences or patterns in responses were noted across participant demographics.

Conclusions: Participants exhibited foundational knowledge of AI in clinical ophthalmology practice and how AI can be leveraged in their future work. However barriers to adoption and integration of AI to practice were widely noted. Looking forward, additional training on specific AI driven models to increase clinician knowledge and adoption are recommended for actualization of AI improvements in clinical practice.

ABSTRACT BODY:

Purpose: Precision genome editing could advance greatly the treatment of inherited retinal diseases (IRDs), as shown by the reversion of IRD-causing mutations by CRISPR/Cas9 and restoration of visual function in animal models. However, before broader human application, it is imperative to improve the safety profile of vectors for genome editor delivery to minimize deleterious off-target and bystander effects, which can occur when they are expressed over prolonged periods of time. As genomic DNA edits are permanent, a one-time treatment with transiently delivered genome editors should be sufficient to correct an IRD mutation. One such promising method is the administration of genome editors as preformed proteins and ribonucleoproteins encapsulated within virus-like particles (VLPs).

Methods: All animal procedures were approved by the IACUC at UC Irvine and conformed to the recommendations of the American Veterinary Medical Association Panel on Euthanasia and ARVO.

We developed engineered VLPs (eVLPs), an improved VLP platform for packaging and delivering genome editor proteins and RNPs. eVLP possess many of the same advantages as viral vectors, including cell-type tropism and large cargo capacity, but offer significant safety advantages over lentiviral and AAV vectors, such as decreased off-target and bystander editing, and no risk of genomic integration. We exploited the property of Moloney murine leukemia virus which accommodates C-terminal fusion of proteins to its gag structural protein to ensure proper and controlled packaging of genome editors within the eVLPs.

Results: We produced eVLP constructs carrying Cre recombinase or adenine base editors (ABEs). eVLPs efficiently delivered their cargoes to cell lines in vitro. When injected subretinally, eVLPs effected genomic changes in the RPE, such as loxP recombination and A to G nucleotide changes, as assessed by imaging and ERG. Importantly, these eVLPs correct mutations with similar on-target and substantially lower bystander and off-target editing compared to virally delivered ABEs.

Conclusions: By iteratively modifying the surface glycoprotein of eVLPs, we will screen for eVLPs which facilitate the delivery of genome editors to photoreceptors, which historically have been difficult to target with enveloped viruses. We hope the adaptation of this technology will enable the broader application of genome editors to the mouse and human eye.

ABSTRACT BODY:

Purpose: Vascular endothelial cells (VEC) are essential for retinal homeostasis and their dysfunction underlies pathogenesis in diabetic retinopathy (DR) and exudative age-related macular degeneration (AMD). Studies have shown that recombinant adeno-associated virus (rAAV) vectors can deliver the gene to neural cells of the retina, yet targeting VECs remains extremely challenging. In this study, we developed rAAV capsid mutant vectors with improved tropism to target retinal VEC through the incorporation of endothelial targeting peptides into the viral capsid.

Methods: rAAV2/2, 2/2[QuadYF-TV], and rAAV2/9 serotype vectors (n=10, capsid mutants per serotype) expressing GFP were generated by inserting heptameric peptides (7AA) designed to increase endothelial targeting at positions 588 (2/2 and 2/2[QuadYF-TV] or 589 (2/9) of the virus protein (VP1-3). The packaging and transduction efficiency of the VEC targeting vectors was assessed on HEK293T cells to confirm infectivity. Subsequently, each vector (MOI=75000) was administered to ex vivo primary bovine VECs. After 72 hours, cells were labeled with CD31, and transduction efficiency was quantified using flow cytometry. Following identification of a mutant (EC5) with improved endothelial tropism, AAVs vectors were administered intra-ocularly and intravenously in C57Bl/6j mice under isoflurane anesthesia. After 4-months, cSLO imaging was performed to assess tropism before the eyes and organs (heart, liver, lungs, and brain) were collected for post-mortem histology.

Results: All capsid mutant rAAV vectors generated were found to transduce HEK293T cells leading to expression of GFP, indicating insertions did not adversely affect packaging. The EC5 mutant demonstrated increased transduction of CD31+ primary bovine VECs in all serotypes, with a fold change of 1.7, 2.7- and 3.6-times higher transduction efficiency when incorporated in the rAAV2/9, 2/2, and 2/2[QuadYF-TV] capsids, respectively. cSLO imaging demonstrated visible expression of GFP in the retinal vasculature following intravenous administration for EC5 mutant vectors versus unmodified controls.

Conclusions: The generation of rAAV vectors targeting retinal VECs could improve gene therapy treatment for DR and AMD. Our findings suggest that incorporating endothelial targeting peptide into rAAV capsid could improve tropism and allow delivery of therapeutic transgenes efficiently to the retinal VECs.

TITLE: Herpes Simplex Virus Type 1 Does Not Stimulate Parthanatos During Infection of ARPE-19 Cells

SESSION TITLE: Infection and Immunity

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Oh, R.D. Dix, Biology, Georgia State University, Atlanta, Georgia, UNITED STATES|R.D. Dix, Ophthalmology, Emory University School of Medicine, Atlanta, Georgia, UNITED STATES|

Commercial Relationships Disclosure: Jay Oh: Commercial Relationship: Code N (No Commercial Relationship) | Richard Dix: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Parthanatos is a caspase-independent cell death pathway whose contribution to retinal disease during the pathogenesis of acute retinal necrosis (ARN) or progressive outer retinal necrosis (PORN) caused by herpes simplex virus type 1 (HSV1) remains unclear. Grady et al (2012) showed that parthanatos is simulated during HSV1 infection of primary human fibroblasts. Our laboratory also has shown that key parthanatos proteins are stimulated within retinitis-susceptible eyes of mice with retrovirus-induced immunosuppression (MAIDS) after murine cytomegalovirus infection (Oh et al, 2019). These observations prompted us to investigate the possibility that parthanatos might also operate during HSV1 infection of human retinal cells. We, therefore, performed a pilot study to test the hypothesis that parthanatos-associated PARP-1 and PAR proteins are stimulated during HSV1 infection of ARPE-19 cells.

Methods: Monolayers of ARPE-19 cells were inoculated with either HSV1 [KOS] (moi = 10) or maintenance medium (negative control) and harvested at 1, 2, and 3 days postinfection. Monolayers of uninfected ARPE-19 cells were treated with hydrogen peroxide (H_2O_2) (500 uM) for stimulation of parthanatos (positive control) and harvested at 2 hrs after treatment. HSV1-infected, mock-infected, and H_2O_2-treated cells were lysed and subjected to western blot analysis for detection of PARP-1 and PAR proteins.

Results: H_2O_2-treated ARPE-19 cells showed stimulation of PARP-1 and especially PAR that is essential for the operation of parthanatos. Whereas PARP-1 protein was stimulated in both mock-infected and HSV1-infected ARPE-19 cells at relatively equal amounts at all times investigated, stimulation of PAR protein was not detected in either mock-infected or HSV1-infected ARPE-19 cells at all times investigated.

Conclusions: Although parthanatos can operate in ARPE-19 cells as suggested by stimulation of PARP-1 and PAR following H_2O_2-treatment, we provide new evidence that HSV1 infection may inhibit the operation of parthanatos in ARPE-19 cells, possibly through virus-encoded suppressors as seen during apoptosis and necroptosis (Guo et al, 2015). Our findings also suggest that stimulation of parthanatos during HSV1 infection is cell-type specific. Our pilot study provides proof-of-principle for further investigations to determine the role of parthanatos during the pathogenesis of HSV1-induced ARN and PORN.

TITLE: Precise quantification of episcleral venous flow rates in human subjects before and after netarsudil 0.02%

SESSION TITLE: Biomechanics and ocular blood flow

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S. Kim, University of Maryland at College Park, College Park, Maryland, UNITED STATES|V. Chen, J. Pottenburgh, O. Saeedi, University of Maryland School of Medicine, Baltimore, Maryland, UNITED STATES|M. Cruz, University of Miami School of Medicine, Miami, Florida, UNITED STATES|

Commercial Relationships Disclosure: Sarah Kim: Commercial Relationship: Code N (No Commercial Relationship) | Victoria Chen: Commercial Relationship: Code N (No Commercial Relationship) | Marvin Cruz: Commercial Relationship: Code N (No Commercial Relationship) | Jessica Pottenburgh: Commercial Relationship: Code N (No Commercial Relationship) | Osamah Saeedi: Commercial Relationship(s);Code F (Financial Support):Aerie Pharmaceuticals, Heidelberg Engineering, Vasoptic Medical Inc.

ABSTRACT BODY:

Purpose: Netarsudil, a Rho-kinase inhibitor and norepinephrine transporter inhibitor, is known to lower episcleral venous pressure, however, its precise effect on flow rates has not been studied. We have recently developed erythrocyte mediated angiography, EMA, a technique in which autologous fluorescently labeled erythrocytes are reinjected into a human subject permitting the observation and precise quantification of flow rates. The purpose of this study was to quantify the short- and long-term effects of netarsudil on episcleral venous flow rates in treatment-naïve ocular hypertensive and glaucoma suspect subjects using EMA.

Methods: This prospective study enrolled treatment-naive ocular hypertensive and glaucoma suspect patients. All subjects underwent anterior segment EMA, conventional indocyanine green angiography, and applanation tonometry at baseline, 1 hour after drop instillation, and 1-2 weeks after once daily topical netarsudil use. A MATLAB program we developed was used to track erythrocytes on EMA angiograms. Vessel diameter was measured using the Automated Retinal Image Analyzer program. Changes in erythrocyte velocity, vessel diameter, estimated blood flow, and IOP were assessed using two-sample unpaired t-tests.

Results: Twelve episcleral vessels of nine eyes of seven patients were analyzed. IOP was reduced from 15.6±3.4 to 10.7±4.1mmHg at 1-hour (p=0.017) and 11.1±4.3mmHg at 1-2 week(s) after therapy initiation (p=0.007). Mean erythrocyte velocities did not differ significantly in this sample from baseline (2.2±1.0 mm/s), at one hour (3.1±1.4mm/s, p=0.063), or at 1-2 weeks (1.8±1.4 mm/s, p=0.219). However, vessel diameter increased from 62.7±14.5um to 100.2±32.3um (p=0.003) after one hour and 85.8±30.9um (p=0.008) after 1-2 weeks. Episcleral blood flow increased significantly from 0.45±0.28μL/min to 1 hour post eyedrop (2.06±02.41μL/min, p=0.033), but not after 1-2 weeks (0.74±0.94μL/min, p=0.121).

Conclusions: We found that netarsudil 0.02% resulted in significant IOP reduction and associated increase in episcleral venous flow rates in treatment-naïve glaucoma suspect patients. This is the first study to our knowledge that quantified the change in episcleral venous blood flow in vivo after a pharmacologic intervention, which can be assessed using EMA. This technology has the potential to offer novel biomarkers for treatments that target the conventional outflow pathway.

ABSTRACT BODY:

Purpose: An imbalance of pro and anti-angiogenic factors contributes to the pathology of neovascular AMD (nAMD). Thrombospondin-1 (TSP-1) is a potent inhibitor of angiogenesis induced by pro-angiogenic factors such as vascular endothelial growth factor (VEGF). Granzyme B (GrB) is a serine protease whose extracellular activity is increased in the outer retina and choroid of human eyes with choroidal neovascularization (CNV) from nAMD. This study determines the effects of GrB on TSP-1 in silico, and in cell-free cleavage assays, human eyes, RPE culture, and an explant choroid sprouting assay (CSA).

Methods: Mapping of human TSP-1 protein sequences for potential GrB cleavage sites was performed with GraBCas while the prediction of cleavage product size was done with the Compute pI/Mw tool from ExPASy. To confirm predictions, cell-free cleavage assays were done by digesting rhTSP-1 with rhGrB in 50 mM Tris, pH 7.5 for 2 hours at 37^{O}C. Electrophoresis was performed on the digestion products, followed by Coomassie Brilliant Blue staining and imaging. CNV donor eye tissue sections were probed by immunohistochemistry for GrB and TSP-1. RPE cells were stimulated with GrB. CSA using RPE-choroid-sclera explants from 3-month-old C57BL/6J mice was established and cultured with rhTSP-1 (1 µg) or rhGrB (100nM) treatments. Images of CSA explants were captured and sprouting morphometry was quantified Western blot (WB) was used to assess TSP-1 expression in RPE cell culture and CSA supernatant.

Results: In silico analysis predicted six potential GrB cleavage sites in the N- and C-termini and within type III repeats of TSP-1. Cell-free cleavage assays shows that GrB cleaves TSP-1 with double fragments ranging ~100kDa and triple fragments between 63-75kDa. An inverse relationship of GrB and TSP-1 was confirmed in RPE and choroid of CNV eyes, with higher GrB and lower TSP-1 immunolabelling. WB showed significantly reduced expression of TSP-1 in GrB-treated RPE cell culture ($p<0.05$) and CSA supernatant ($p<0.05$) compared with controls. Vascular sprouting area was significantly reduced in TSP-1 treated CSA ($p<0.05$) compared with controls.

Conclusions: GrB cleavage of antiangiogenic factors such as TSP-1 may contribute to CNV development in nAMD via pro-angiogenesis. Future studies are required to investigate whether the pharmacological inhibition of extracellular GrB could mitigate CNV in nAMD by conserving intact TSP-1.

TITLE: Late-Onset Orbital Infection Following Blowout Fracture Repair with a Medpor Titan Implant: A Case Report

SESSION TITLE: Oculoplastics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Gutermuth, Wayne State University School of Medicine, Detroit, Michigan, UNITED STATES|R. Beaulieu, Ophthalmalology, Kresge Eye Institute, Detroit, Michigan, UNITED STATES|R. Beaulieu, Consultants in Ophthalmic and Facial Plastic Surgery, Southfield, Michigan, UNITED STATES|

Commercial Relationships Disclosure: Brian Gutermuth: Commercial Relationship: Code N (No Commercial Relationship) | Robert Beaulieu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To report a case of late orbital infection with aspergillus and multiple bacteria species nine months after orbital floor fracture repair using the Titan Medpor implant.

Methods: Observational case report

Results: A 40 year-old male with a non-contributory past medical and ocular history presented with diplopia and right-sided enophthalmos after sustaining trauma to the orbit. Examination was relevant for moderate limitation in downgaze and exophthalmometry readings of 19.5 mm on the right and 22 mm on the left. His exam was otherwise unremarkable. CT imaging revealed a right orbital floor fracture with herniation of orbital contents into the maxillary sinus. Surgical repair achieved proper coverage of the fracture edges by a Medpor Titan orbital implant, which is a sheet of titanium mesh embedded within a porous polyethylene matrix with a solid barrier surface facing the orbital contents. Post-operatively, he had full extraocular motility, resolution of his diplopia and enophthalmos, and equal exophthalmometry measurements at one day, one week, and two months. He returned to clinic on post-operative month nine with complaints of right eye gaze-evoked amaurosis on upgaze, intermittent diplopia, and a pressure sensation on upgaze. Exam revealed full extraocular motility, 1 mm of hyperglobus on the right, and exophthalmometry readings of 22.5 mm on the right and 22 mm on the left. CT imaging of the orbits with and without contrast demonstrated a malpositioned orbital implant with a peri-implant capsule and fluid collection. He underwent orbital implant removal with drainage of the fluid collection. Cultures revealed the presence of non-fumigatus Aspergillus, along with rare Staphylococcus epidermidis and Neisseria sicca.

Conclusions: Our case presents two uncommon orbital pathologies. The first being the occurrence of late orbital infection in an immunocompetent patient with an otherwise uncomplicated recovery. The second is a culture-proven orbital infection with Aspergillus spp. after an orbital floor repair with a porous polyethylene comprised implant. Post-operative orbital infection with Aspergillus sp. has no clearly defined incidence, with only a few case reports describing the complication. We use this case to bring awareness to these rare occurrences and the need to have high suspicion of late-onset implant infection in patients with orbital signs after fracture repair.

ABSTRACT BODY:

Purpose: To determine the incidence of and risk factors for progression in patients with Posner Schlossman Syndrome (PSS) by assessing time to progression (TTP).

Methods: This retrospective multi-centre study reviewed long-term follow-up data of PSS patients across five Australian institutions between 1990 and 2020. Initial presentation clinical data, demographics, frequency of PSS relapse without progression, antiviral usage and anterior chamber (AC) tap results were recorded. Progression was defined as development of chronic secondary glaucoma, chronic uveitis or permanent corneal or endothelial failure. Relapse without these features was not counted as progression. TTP was taken as the time from initial presentation to the first detection of progression. Cox proportional hazards regression and Kaplan-Meier analysis were used to estimate the risk of disease progression and compare progression free survival among different groups.

Results: 102 consecutive patients (68 men and 34 women) met the inclusion criteria. Follow-up ranged from 0-31 years with a mean of 5.0 years. 47 of 102 patients met the criteria for progression with development of chronic glaucoma (n=39), chronic inflammation (n=22) or permanent endothelial failure (n=4). TTP varied from 0–11 years with a median of 0.8 years. 46 of 102 patients underwent an AC tap of which 28 were positive (viral DNA identified) and 18 negative. Median progression free survival in tap-positive patients was 2.6 years compared to 5.3 years in the tap-negative group.

On univariate analysis, higher age at presentation was associated with increased risk of progression (HR 1.03 per year of increased age, $p<0.0001$), whilst immunocompetence (HR 0.36, $p=0.037$) and white ethnicity showed a reduced risk of progression (HR 0.36). On multivariate analysis increased age at presentation (HR 1.03 per year, $p=0.002$) and a positive AC tap (HR 2.8, $p=0.001$) showed increased risk of progression while white ethnicity (HR 0.27, $p=0.02$) was protective.

Conclusions: The long-term prognosis of PSS is reasonable. The majority of patients do not progress by 5.0 years. Increasing age at presentation and a positive AC tap are associated with increased risk of progression and white ethnicity is associated with reduced risk. This information might be used to guide management of patients with PSS.

CONTROL ID: 3710517

TITLE: Effect of Prostaglandin Analogues on Corneal Hysteresis in Treatment Naïve Racially Diverse Patients

SESSION TITLE: Pharmacology/cellular mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: V. Barquet-Piza, M. Giovingo, Ophthalmology, John H Stroger Hospital of Cook County, Chicago, Illinois, UNITED STATES|J. Nelson, Des Moines University, Des Moines, Iowa, UNITED STATES|

Commercial Relationships Disclosure: Viviana Barquet-Piza: Commercial Relationship: Code N (No Commercial Relationship) | Joshua Nelson: Commercial Relationship: Code N (No Commercial Relationship) | Michael Giovingo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Corneal hysteresis (CH) has been shown to be an independent risk factor for the development and progression of glaucoma. Topical Prostaglandin Analogues (PGA) are a common first-line treatment for open-angle glaucomas. Previous studies have found that high CH values are associated with a lower rate of visual field loss, while low CH have been identified as an independent risk factor for development and progression of glaucoma. PGA's have been demonstrated to increase CH through several mechanisms including reduced central corneal thickness, increased keratocyte density, and lower intraocular pressure. The aim of this study is to investigate if starting PGA treatment alters corneal hysteresis in a treatment naïve, racially diverse group of patients.

Methods: A total of 38 eyes from 19 patients were analyzed. Patients with a diagnosis of either primary open angle glaucoma, ocular hypertension, normal tension glaucoma, or anatomically narrow angle who were treatment naïve were included. CH measurements were taken with the Ocular Response Analyzer (ORA) prior to PGA use and after PGA use. CH measurements with waveform score lower than 3.5 were excluded. Demographic data for the patients was also obtained.

Results: Paired T-Test were completed to examine variance between untreated and treated CH values for each patient. Significant increases in CH were observed after PGA use in both right eye (OD) ($p=0.02$) and left eyes (OS) ($p=0.002$). There was an average CH increase of 1.08 (SD=+1.70) OD and 1.13 (SD=+1.28) OS. 57.89% of the study population identified as African American/Black, 26.32% Hispanic, 10.53% White, and 5.26% Asian.

Conclusions: These findings demonstrated a significant increase in CH after starting PGA use in a predominantly Black and Hispanic population. This increase in CH could lead to a reduction in glaucoma progression, as well as identify a possible modifiable risk factor for glaucoma that was previously not considered, particularly in populations that are already at higher risk, and identify a new therapeutic effect of PGA. Further studies are necessary to determine if the effects of PGA on CH persist long term.

TITLE: Depth-dependent structural responses of mouse lens fiber cells during whole lens shape changes
SESSION TITLE: Lens Biology
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: M.H. Shihan, J. Parreno, V.M. Fowler, University of Delaware, Newark, Delaware, UNITED STATES|S.K. Biswas, W. Lo, Morehouse School of Medicine, Georgia, UNITED STATES|
Commercial Relationships Disclosure: Mahbubul Shihan: Commercial Relationship: Code N (No Commercial Relationship) | Justin Parreno: Commercial Relationship: Code N (No Commercial Relationship) | Sondip Biswas: Commercial Relationship: Code N (No Commercial Relationship) | Woo-Kuen Lo: Commercial Relationship: Code N (No Commercial Relationship) | Velia Fowler: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Two common age-related lens pathologies, cataracts, and presbyopia are linked to age-dependent increases in lens stiffness. The mouse lens has dramatic alterations in fiber cell shapes and organization with lens age, along with increased lens stiffness. However, little is known about the relationship between observed depth-dependent cellular structures, and lens biomechanical properties. We aimed to determine lens fiber cell macro-to-nanoscale structural deformation during and after lens compression as a function of radial depth.

Methods: Freshly dissected 8-week-old mouse lenses were compressed by application of 10 glass coverslips (CS). Images of lenses were taken with an Olympus SZ11 dissecting microscope with a digital camera, followed by fixation for scanning electron microscopy (SEM). Images of mouse fiber cells under compression and after recovery were captured by a JEOL 820 scanning electron microscope. Image analysis was performed using ImageJ.

Results: Morphometrics analysis revealed that at 10 CS load (29% axial strain), lens axial diameter, aspect ratio, and volume decreased compared to controls while equatorial diameter increased, as expected. Upon release of load, equatorial diameter and aspect ratio recovered completely, while axial diameter and volume recovered partially. SEM revealed that cortical fiber bundle curvature increased under compression (10CS), compared to controls and recovered lenses, while nuclear fiber bundle curvature was unaffected. The paddles and protrusions of outer cortical fibers were severely distorted by compression, with a near absence of paddle-associated protrusions in the compressed lens compared to controls, while this phenomenon was rescued in the recovered lens. Notably, in SEM images of the inner cortex, the nanostructures of fiber cells were unaffected by compression, resembling the morphology of controls and recovered lenses.

Conclusions: Our study reveals that gross lens shape change caused by mechanical strain results in ultrastructural-level changes of the lens fiber cells in a depth-dependent fashion such that the nanostructures of fiber cells are deformed in the outer cortex, but little to no deformation in the inner cortex and nucleus of the lens. This provides critical information to expand current biomechanical models of lens shape changes in terms of presbyopia and cataracts.

ABSTRACT BODY:

Purpose: Excessive neutrophil activation and secretion of their effector molecules result in tissue damage during ocular inflammation. Previously, our study demonstrated that mast cells initiate neutrophil recruitment to the ocular surface following injury. Here, we investigated whether mast cells promote activation of neutrophils to secrete tissue-damaging effector molecule.

Methods: Bone marrow cells were harvested from femurs and tibias of Balb/c mice and cultured for 3-4 weeks in the presence of IL-3 (10 ng/ml) and SCF (50 ng/ml) to generate mast cells. Neutrophils were magnetically sorted from the bone marrow cells of Balb/c mice using a neutrophil isolation kit (>95% purity). Mast cells were co-cultured with neutrophils at 1:1 ratio for 3 hours. Thereafter, neutrophils were harvested to evaluate the expression of their activation markers, CD11b and Ly6G, using flow cytometry. Supernatants of the co-cultures were collected to assess the activity of myeloperoxidase (MPO), an enzyme involved in neutrophil-mediated collateral tissue damage, using a colorimetric assay kit.

Results: Neutrophils co-cultured with mast cells expressed a significantly higher level of maturation marker CD11b (5-fold increase) ($P=0.0002$), compared to neutrophils cultured in medium alone. Similarly, a significant 48% increase in the expression of Ly6G by neutrophils was observed in the presence of mast cells compared to neutrophils cultured alone ($p=0.008$). In addition, a significant 50% increase in MPO activity was observed in neutrophils when cultured in the presence of mast cells, compared to control neutrophil cultures ($p=0.03$).

Conclusions: Our data demonstrate that mast cells amplify neutrophil activation and promote the secretion of tissue damaging myeloperoxidase enzyme.

ABSTRACT BODY:

Purpose: With increasing use of axial length to monitor myopia progression, the ratio of refractive error (RE) change to axial elongation (AE) has important clinical implications. However, the true value of the ratio and how age and axial length affect it remain uncertain. We conducted a systematic review and meta-analysis to model the ratio.
Methods: A systematic search was performed using Ovid Medline, EMBASE, and Cochrane Central Register of Controlled Trials. The following combined terms were used: “myopia” or “myopic” and “child” or “children” and “progression” or “longitudinal” or “follow-up” or “shift” and “axial”. Studies containing simultaneous RE change and AE in untreated eyes were identified. Other data collected were mean baseline age, standard deviation (SD) of AE, SD of RE change, sample size and proportion of Asian subjects in the study population. Due to desired statistical properties, the natural logarithm of the magnitude of mean refractive error change versus mean axial elongation was analyzed with a weighted multivariable linear mixed effects meta-analysis model, including three levels of random effects to account for all variability. The standard inverse variance method was used for weighting. Baseline values for mean RE and mean AE were included in the model as covariates.
Results: A total of 67 studies with 86 different subpopulations and 167 evaluations contained complete data sets. The model is plotted in the Figure and covariates summarized in the Table. The overall weighted mean ratio was 2.04 [95%CI: 1.96, 2.12] D/mm. No covariates were statistically significant. Prediction intervals were relatively large, potentially reflecting variability in refractive error.
Conclusions: This work sets a benchmark for clinical expectations with respect to the ratio between RE change and AE in myopic children. The lack of apparent impact of age on the ratio may reflect counterbalance between physiologic growth observed in younger children and a decreased ratio, anticipated from optical calculations, in longer eyes of older children. Interpretation should take into account limitations of using aggregated rather than individual subject data.

ABSTRACT BODY:

Purpose: When patients with macular edema due to pathologies like neovascular age-related macular degeneration (nAMD) and diabetic retinopathy (DR) fail to show significant improvement within the first 3 to 6 months of initiating anti vascular endothelial growth factor (anti-VEGF) treatment, they are often switched to a different anti-VEGF agent. However, the benefits of such a switch were not well established. We examined the effectiveness of anti-VEGF agent switching in eyes with retinal pathologies that show poor response to Bevacizumab Intra-vitreal injections.

Methods: We retrospectively compared the results of the central macular thickness (CMT) and visual acuity (VA) between eyes with sub-optimal response to at least three Bevacizumab injections that continued retreatment with Bevacizumab versus those that switched to Aflibercept or Ranibizumab injections. 59 eyes were investigated: 21 eyes with Diabetic retinopathy (DR)- group A, 28 eyes with neovascular age-related macular degeneration (nAMD)- group B. Group C composed of group A and group B and 10 more eyes with either retinal vein occlusion or pseudophakic cystoid macular edema. Groups were divided into subgroups- groups A1 (8 eyes), B1(14 eyes), and C1 (25 eyes) continued to be treated with Bevacizumab. Groups A2, B2, C2 consisted of patients that switched to aflibercept or Ranibizumab injections and included 13, 14, and 34 eyes respectively.

Results: In all eyes where treatment has been switched to either Aflibercept or Ranibizumab, a decrease of CMT was seen; 38.5 (SD 46.2); 92.6 (SD 106.8), and 82.1 (SD 115.6) microns in groups A2, B2, and C2 respectively. However,a mean increase of 1.63 microns (SD 87.3) was found in the CMT of eyes in group A1; and a mean decrease in CMT of 5.71 (SD 111.7) and 2.12 (SD 94.9) microns was found in group B1 and C1 respectively. The difference in CMT was statistically significance between groups B1 versus B2 and between C1 versus C2 groups ($p=0.025$, $p=0.004$, respectively). A similar trend was seen between groups A1 versus A2 but statistical significance was not achieved. Analysis of the visual acuity revealed no significant difference between all groups.

Conclusions: Our results may indicate that switching between anti-VEGF agents is indeed an effective strategy to treat eyes with sub-optimal response to Bevacizumab injections.

ABSTRACT BODY:

Purpose: Both high and low blood pressure (BP), together with intraocular pressure (IOP), are risk factors for glaucoma. The underlying physiological mechanisms for both high and low BP as a risk factor remain elusive. Here a novel physiology-informed machine learning (ML) approach combines physiology-based mathematical modeling and unsupervised clustering to discern the impact that abnormal BP may have on glaucoma.

Methods: 115 open angle glaucoma (OAG) patients were assessed for: IOP, systolic and diastolic BP (SBP, DBP), heart rate (HR), and color Doppler imaging (CDI) of peak-systolic and end-diastolic velocity (PSV, EDV) of the ophthalmic artery (OA) and central retinal artery (CRA). For each patient, IOP, SBP, DBP, and HR were fed to a validated mathematical model (Guidoboni et al, IOVS, 2014) which estimates hemodynamic variables unavailable from instrumentation. The enhanced dataset and the model-estimated variables are fed to a Fuzzy c-means (FCM) clustering algorithm to identify patient clusters with similar ocular hemodynamics.

Results: The FCM clustering algorithm revealed 3 clusters plotted in the IOP-MAP plane in Fig.1 (left) (MAP=mean arterial pressure = 2/3DBP+1/3SBP). Fig.1 (right) shows that ocular perfusion pressure (OPP = 2/3MAP-IOP) is high in cluster 2 and low in cluster 3. The PSV medians in the CRA are similar for all clusters (<10%), while the PSV median in the OA of cluster 2 was ~22% higher than in clusters 1 and 3 (see Fig.2 (top)). On the other hand, cluster 3 exhibits higher vascular resistance in the venules and central retinal vein (Fig.2 (bottom)).

Conclusions: High and low BP may contribute to glaucoma in different ways, depending also on the IOP level. The bigger discrepancy in PSV medians in OA with respect to CRA may indicate that patients in cluster 2 need a stronger autoregulation engagement to maintain homeostasis, thereby limiting their capacity to accommodate physiological BP fluctuations. High venous resistance in cluster 3 might render those vessels susceptible to venous collapse. The technology for measuring venous resistances is currently unavailable and our results indicate that its development might be an important goal for the study of glaucoma.

ABSTRACT BODY:

Purpose:

To introduce a model called FundusNet which learns visual representations of Fundus images that can be employed in other downstream tasks of ophthalmic imaging applications to further improve the generalization performance.

Methods:

We employ a self-supervised learning approach formulated as a contrastive learning framework by incorporating a broad family of data augmentation. This could potentially lessen the sensitivity of the model to domain-specific information in the data and therefore improve upon the generalization of learned features that can be used across different domains. In the contrastive learning framework, the representations are learned by maximizing the agreement between the two augmented views of the same data input. This framework consists of four main components, augmented views, base encoder, projection head, and contrastive loss.

We evaluate the quality of the learned representation for a downstream task of glaucoma detection and compare our method to a fully supervised method and transfer learning method using a pre-trained network on non-medical images, ImageNet and CIFAR. We employ a subset of the I-ODA dataset for unsupervised pre-training which learns the base encoder model. I-ODA is a real-world multi-domain ophthalmic imaging dataset from which we isolated 14k fundus photos with 6000 glaucoma and 8000 non-glaucoma images.

Results:

Our method archives the performance accuracy of 84.87% outperforming the strongest supervised baseline by ~2% and self-supervised baseline by ~4.6%. Among the supervised baselines, the custom-designed method achieves a better result over off-the-shelf ResNet. This shows that specifically designed networks are usually very important to the success of supervised methods which could limit their generalization capacity, especially for real-world clinical applications. The superior performance of FundusNet over transfer learning that uses pre-trained networks on ImageNet shows that transfer learning performs the best when the nature of target data is similar to the one used for pretraining.

Conclusions:

FundusNet addresses the limitation of transfer learning with non-medical images for ophthalmic imaging applications that face a shortage of labeled data. Self-supervised learning is able to achieve a more general representation and hence improve the generalization performance as opposed to fully supervised methods.

ABSTRACT BODY:

Purpose: The Alabama Screening and Intervention for Glaucoma and eye Health through Telemedicine (AL-SIGHT) program provided evidence-based eye health education tailored for patients at-risk for glaucoma in rural primary care clinics. The education program was based on the InCHARGE eye health education program designed for African Americans and materials from Prevent Blindness and NEI's National Eye Health Education Program. This study investigated the impact of the first year of AL-SIGHT's eye health education on at-risk patients' knowledge about glaucoma and attitudes about eye care.

Methods: Three federally qualified health centers in rural, underserved communities in Alabama enrolled participants with one or more risk factors: Black or Hispanic ≥ 40 years, White ≥ 50 years, diabetes, a pre-existing glaucoma diagnosis, and/or a family history of glaucoma. Participants were administered a 7-question survey to assess their knowledge and attitudes on glaucoma and eye care prior to delivery of the education program and ocular imaging. Follow-up surveys were administered 6 weeks and 6 months after the initial visit by telephone call or web-based survey. Participant changes of survey responses from baseline to 6-week and 6-month follow-ups were compared using McNemar's test.

Results: 209 participants completed the 6-week follow-up survey. Overall, there was a 56% improvement in knowledge but only a 9% improvement in attitude from baseline. 87 participants complete the 6-month follow-up survey. There was a 68% improvement in knowledge and a 13% improvement in attitude from baseline. Tables 1 and 2 describe the change in knowledge about glaucoma and attitudes about eye care at the 2 time points for each question.

Conclusions: AL-SIGHT's eye health education program improved knowledge about glaucoma at both the 6-week and 6-month timepoints. The program also had a slight improvement in attitudes about eye care, but these questions had a high percentage correct at baseline. It is encouraging that the 6-month results showed that the improved knowledge was maintained, although the sample size was smaller. Efforts will be made to stress to participants that a complete glaucoma exam consists of much more than just measuring eye pressure.

TITLE: Indications Cited when Initiating Scatter Laser Photocoagulation in Proliferative Sickle Cell Retinopathy

SESSION TITLE: Macular diseases/Macular edema/Functional testing/evaluation/Laser

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.T. Griffin, Drexel University College of Medicine, Philadelphia, Pennsylvania, UNITED STATES|M.T. Griffin, R. Mahmoudzadeh, D. Xu, J. Light, Retina, Wills Eye Hospital, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Matthew Griffin: Commercial Relationship: Code N (No Commercial Relationship) | Raziyeh Mahmoudzadeh: Commercial Relationship: Code N (No Commercial Relationship) | David Xu: Commercial Relationship: Code N (No Commercial Relationship) | Jacob Light: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Sickle cell disease (SCD) is the most common inherited blood disorder, affecting 100,000 people in the United States and 3.2 million people globally. In proliferative sickle cell retinopathy (PSR) retinal capillary non-perfusion (CNP) leads to retinal neovascularization (NVE) that may progress to vitreous hemorrhage (VH) or tractional retinal detachment (TRD) and vision loss. Scatter laser photocoagulation is the gold standard for managing PSR but published guidelines predate the use of ultra-widefield imaging (UWFI) which allows for earlier detection of peripheral CNP and NVE. Little to no data exists on current practice patterns in PSR. We compiled data on laser photocoagulation in PSR to examine practice patterns at Wills Eye Hospital from 2014 to 2021.

Methods: Clinical charts from the Wills Eye Hospital Retina Service/Mid Atlantic Retina Group from 2014 to 2021 were retrospectively reviewed. Patients with SCR were identified using ICD-10 codes for SCD (H57.1), other non-diabetic proliferative retinopathy (H35.20, H35.21, H35.22, H35.23), and retinal disorders in diseases classified elsewhere (H36). Charts were reviewed to confirm the diagnosis of SCR and at least one documented laser treatment of at least one eye (CPT codes 67145, 67227, 67228). Exclusion criteria included comorbid diabetic or hypertensive retinopathy as well as uveitis and retinal vasculitic disease. Clinical data including VA, IOP, imaging/exam findings, prior laser status, length of follow-up, genotype, and patient demographics were recorded. The indications for initiating laser as documented by retina specialists were reported as our primary outcome.

Results: 97 scatter laser procedures performed by 30 retina specialists on 79 eyes (N = 79) (40 OD, 39 OS) in 55 patients (mean age 43.3) were identified. Primary indications for laser among all eyes were NVE/CNP (68.4%), VH (21.5%), and TRD (10.1%). Indications cited among treatment naïve eyes (n = 64) were NVE/CNP (67.2%), VH (20.3%), and TRD (12.5%). Patient characteristics are reported in Figure 1.

Conclusions: Retina specialists frequently elect to perform scatter laser photocoagulation in PSR based on peripheral NVE and CNP. Current practice patterns guided by UWFI may lead to earlier initiation of laser in PSR. Further study is warranted to evaluate the effectiveness of these treatment decisions and identify best practices for preventing vision loss in PSR.

ABSTRACT BODY:

Purpose: Currently, the causal and temporal relationships between the degeneration in retinal vasculature and glaucoma remain ill-defined. This study evaluated the early rate of changes in optical coherence tomography angiography (OCTA) metrics in a cohort of normal tension glaucoma (NTG) eyes, and their relationships to the subsequent risk of glaucoma progression.

Methods: Three hundred and thirty-four eyes from 167 NTG patients with a follow-up period of ≥24 months were included. A swept-source OCT was used to acquire OCTA images of the peripapillary region with a scan area of 3mm x 3mm centered on the optic disc. An automated customized program was used for quantitative analysis to compute the circumpapillary vessel density (cpVD) after the removal of retinal arterioles and venules from the raw OCTA images. Early longitudinal changes of OCTA metrics from baseline to 1 year were determined for each eye. The relationship between the rate of OCTA metrics decay determined from 3 time points (0, 6, and 12 months) in the first year of follow-up to the subsequent risk of glaucoma progression was evaluated. We further attempted to define cut-off values of rate of OCTA decay in the early follow-up phase that would stratify eyes into high risk of glaucoma progression in the subsequent follow-up period.

Results: Twenty-seven eyes (8.08%) developed visual field deterioration over a mean follow-up period of 35.58 ± 5.56 months. Each 1% elevation of the annual rate of cpVD decay in the first year of follow-up was associated with more than 40% risk of glaucoma progression (RR [CI], Temporal cpVD: 1.46 [1.02-2.09]; Nasal cpVD: 1.64 [1.21-2.21]; Global cpVD: 1.48 [1.09, 2.01]) (Table). The Kaplen-Meier curves illustrate that NTG eyes with faster rates of cpVD decay the were associated with significantly higher risk of glaucoma progression, compared to eyes with slower rates of cpVD decay.

Conclusions: This study demonstrated the significant associations between early changes in cpVD as measured by OCTA and the subsequent risk of NTG progression. The findings provided evidence to support the prognostic value of retinal vasculature analysis and a novel perspective for such interpretation in the clinical settings.

TITLE: An experimental mouse model of AIDS-related progressive outer retinal necrosis (PORN) shows evidence for subclinical herpesvirus encephalitis

SESSION TITLE: Infection and Immunity

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R.D. Dix, J. Oh, Biology, Georgia State University, Atlanta, Georgia, UNITED STATES| R.D. Dix, Ophthalmology, Emory University School of Medicine, Atlanta, Georgia, UNITED STATES|

Commercial Relationships Disclosure: Richard Dix: Commercial Relationship: Code N (No Commercial Relationship) | Jay Oh: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Progressive outer retinal necrosis (PORN) in AIDS patients is a variant of acute retinal necrosis (ARN) in immunocompetent patients. ARN caused by herpes simplex virus type 1 (HSV1) has been associated with subclinical herpes simplex encephalitis (HSE). We therefore sought to develop a new animal model of HSV1 retinal necrosis in mice with retrovirus-induced immunosuppression (MAIDS) that mimics AIDS-related PORN and investigate the possible development and pathogenesis of subclinical HSE during HSV1 PORN as seen during HSV1 ARN.

Methods: Following anterior chamber inoculation of right eyes of groups of C57BL/6 mice with MAIDS with 10^4 PFU of either HSV1 [KOS] or HSV1 [H299] (ARN-associated clinical isolate), the inoculated right eyes, right brain halves, left brain halves, and uninoculated left eyes were collected at 3, 5, 7, or 10 days postinfection (pi) and subjected to standard plaque assay or histopathologic analysis.

Results: Histopathologic analysis of HSV1 [KOS]- or HSV1 [H299]-infected right eyes of mice with MAIDS at 10 days pi revealed retinal disease reminiscent of AIDS-related PORN in ~80% of inoculated animals whereas all uninoculated left eyes showed normal retinal architecture. Although HSV1 [KOS]- or HSV1 [H299]-infected right eyes of MAIDS mice showed consistently high amounts of infectious virus ranging from 10^3 to 10^5 PFU, right brain halves in comparison showed little ($<10^2$ PFU) to no detectable infectious virus. Significantly, none (0%) of the HSV1 [KOS] or HSV1 [H299] uniocular-infected animals showed evidence for acute HSE.

Conclusions: We have successfully developed a clinically relevant mouse model for AIDS-related HSV1 PORN using mice with MAIDS that also shows evidence for subclinical HSE. The mouse model is not virus strain dependent. Studies are ongoing to define with greater clarity the development of subclinical HSE during MAIDS-related HSV1 PORN and identify those factors of innate immunity that prevent or minimize virus spread from retina to brain and protect against acute HSE development with focus on macrophages and related cytokines/chemokines as well as programmed cell death pathways.

ABSTRACT BODY:

Purpose: Birdshot retinochoroidopathy (BSRC) is characterized by multifocal choroidal lesions, retinal vasculitis, and macular edema. However, some patients may present with HLA-A29-associated retinal vasculitis without choroidal lesions. We aim to test the hypothesis that these patients may share clinical features with birdshot retinochoroiditis, including the need for systemic immunosuppressive therapy.

Methods: A retrospective medical chart review of patients who were HLA-A29 positive and had retinal vasculitis, yet no birdshot lesions was performed. Demographic, clinical, and therapeutic data were entered into a new database for analysis.

Results: Five patients who had HLA-A29-associated retinal vasculitis without choroidal lesions were identified. The median age at presentation was 52 years (range 14 - 71); 60% were female. At presentation, four patients had a visual acuity of 20/50 or better in both eyes. All eyes had mild vitritis, while 3 eyes (30%) had cystoid macular edema. One patient presented with bilateral optic nerve swelling. All patients required treatment with systemic steroids and immunosuppressive therapy.

Conclusions: HLA-A29-associated retinal vasculitis without choroidal lesions appears to share many clinical features with birdshot chorioretinitis, including the need for systemic immunosuppressive therapy. Whether this entity represents an early form of birdshot retinochoroiditis or a more localized variant of the disease is a topic for further studies.

Commercial Relationships Disclosure: Signe Jeppesen: Commercial Relationship: Code N (No Commercial Relationship) | Toke Bek: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate regional distribution and total blood flow in retinal vessels within two months after branch retinal vein occlusion (BRVO).

Methods: Retinal blood flow was studied in the four main arcade arterioles and venules in 40 normal persons (18 males and 22 females) aged (mean±SD, range) 34.5±7.7, 24-57 years and in thirteen patients with BRVO (6 males and 7 females) aged (mean±SD, range) 54.3±7.0, 41-62 years at the time of referral and after one and two months using Doppler OCT (Medical University, Vienna, Austria).

Results: The total blood flow in the four arcades showed no significant differences among arterioles and venules and no significant difference among the normal and BRVO patients (two-way ANOVA, $p>0.39$), and in the BRVO patients the total blood flow showed no significant changes over time ($p>0.44$). At referral and after one month there was no significant difference between the blood flow in the affected and the non-affected temporal arcade vessels ($p>0.20$ for all comparisons), but after two months the blood flow difference between the non-affected and the affected temporal venule in BRVO patients had increased significantly ($p=0.04$). During the same period, there was no significant changes in central retinal thickness, best corrected visual acuity or in the oxygen saturation in the affected vessels ($p>0.15$ for all comparisons).

Conclusions: Restitution of the retina until two months after referral for BRVO can be accompanied with changes in the distribution of but not in total retinal blood flow.

ABSTRACT BODY:

Purpose: Macular schisis is commonly observed in individuals with X-linked retinoschisis (XLRS) and enhanced S-cone syndrome (ESCS). The schisis can occur in several retinal layers in XLRS, perhaps most commonly in the inner nuclear layer (INL), whereas the schisis location in ESCS is less documented. The present study quantified retinal layer thickness as an approach to infer the location of macular schisis in XLRS and ESCS.

Methods: Horizontal macular B-scans (9 mm width) were acquired from 22 control subjects (25 to 50 yo, 14 males), 9 subjects with XLRS (18 to 50 yo; all genetically confirmed), and 6 subjects with ESCS (16 to 48 yo; 3 males; 5 genetically confirmed). The thickness of the INL, outer nuclear layer plus outer plexiform layer (OPL+ONL), and outer segments of the photoreceptors (OS+) was calculated from the scans using a semi-automated approach. For each layer, thickness was averaged throughout the scan and ANOVA on ranks was used to compare mean thickness for the three subject groups.

Results: Eight of 9 XLRS subjects and 5 of 6 ESCS subjects had macular schisis by OCT imaging. The INL was abnormally thick for all XLRS subjects, and ranged from normal to abnormally thin for all but one ESCS subject. As a group, the INL was significantly thicker than normal for the XLRS subjects ($Q = 3.85$, $p < 0.05$), but not significantly different from normal for the ESCS subjects ($Q = 1.75$, $p > 0.05$). Conversely, the OPL+ONL was abnormally thick for all ESCS subjects and abnormally thin for all XLRS subjects. The mean OPL+ONL was significantly thicker than normal for the ESCS subjects ($Q = 3.62$, $p < 0.05$) and significantly thinner than normal for the XLRS subjects ($Q = 2.81$, $p < 0.05$). The OS+ was abnormally thin for all but one XLRS subject, and ranged from borderline-thin to thick for the ESCS subjects. As a group, the OS+ was significantly thinner than normal for the XLRS subjects ($Q = 3.85$, $p < 0.05$), but not significantly different from normal for the ESCS subjects ($Q = 0.16$, $p > 0.05$).

Conclusions: In this sample of subjects, macular schisis was predominately located in the INL of XLRS subjects and in the OPL+ONL of ESCS subjects. Additionally, photoreceptor thinning appears to be a common characteristic of XLRS that is less apparent in ESCS. These data may provide an additional objective approach to differentiate between XLRS and ESCS.

ABSTRACT BODY:

Purpose: Introduction: A pivotal RCT study was conducted to evaluate the safety and efficacy of a novel treatment for amblyopia using the CureSight, a binocular- eye-tracking- based device compared with the golden standard of amblyopia treatment-patching.

Methods: 103 participants children aged 4-9 with anisometropic, strabismic or mixed amblyopia watched an internet content of their choice on the CureSight screen five times a week for 90 minutes vs. 7 days a week of 120 minutes of patching over 16 weeks . An eye tracker with a sampling rate of 90 Hz was used to identify the gaze position of each eye. During the treatment, patients wore anaglyph glasses over their habitual correction spectacles. Binocular stimulation movies using any internet or educational content were presented with the images of both eyes superimposed and the foveal area of the non-amblyopic eye blurred to a visual acuity of two lines below the acuity of the non-amblyopic eye. Best-corrected visual acuity (BCVA) at near and distance, stereo acuity, contrast sensitivity and reading performance were assessed. Primary efficacy endpointof the study was the mean change in distance BCVA of the amblyopic eye from baseline after binocular CureSight treatment, compared to that of patching. The secondary efficacy endpoint was the change from baseline to week 16 in in both study groups: stereo acuity test score, binocular distance and near BCVA and the amblyopic eye near VA.

Results: Interim analysis of the pivotal study was conducted after approximately 90% of the evaluable cohort subjects completed the 16-week follow-up visit. The primary outcome results were defined as “favorable” according to the statistical analysis plan (CP ≥ 90%) for the pre-planned analysis with 87 completed subjects.

Conclusions: The full study results are expected during February 2022 and will be presented at the conference.

ABSTRACT BODY:

Purpose: PEGDA drug delivery devices (PDDD) have potential for the treatment of chronic vitreoretinal diseases, surpassing the ocular barriers, and sustaining the drug release. In vivo models are the most used to analyze the potential of PDDD. However, there are cellular biomarkers that can be analyzed in vitro to prevent non desired effects in preclinical studies. Here, we analyzed the acute cell response in vitro in terms of cell viability, cytotoxicity, apoptosis, and necrosis in cells exposed to PDDD.

Methods: PDDD were 3D bioprinted at Lawrence Livermore National Laboratory. Endothelial cells SVEC 4-10 (ATTC®) were used in three groups: control (non-treated), negative control (treated with 15% DMSO), and treated (exposed to PDDD). For the cytotoxicity test, a second negative control was used (treated with 5% DMSO). SVEC 4-10 cells (5,000/100mL per well) were incubated in a 96-well plate with or without a ~2.4 mg piece of PDDD for 24h to determine cell viability (with Cell Titer Blue, Promega) and cytotoxicity (with LDH assay kit, Pierce). For apoptosis analysis (with Annexin V kit, ThermoFisher Scientific), 200,000 cells/well in a 12-well plate were used. The results were analyzed using GraphPad Prism 8.01 software.

Results: The viability of cells exposed to PDDD was 70.9%, with significant difference when compared to the control ($p = 0.0383$). The cytotoxicity measured by LDH activity was 2.17% ($p = 0.0123$). The early apoptosis was 24.1% in the treated cells and 15.9% in the control, while the late apoptosis was 3.4% and 2.7% respectively. There was no difference in the necrosis analysis (0.1% in treated and non-treated cells).

Conclusions: The exposure to PDDD decreased the cell viability and increased the cytotoxicity near to the acceptable treshold. The apoptotic activity increased in 10% in the treated cells, however, the viability decrease is not attributed to necrotic events. This in vitro biocompatibility panel allows the adjudgment making in the composition of the PDDD before using it in preclinical models. Additionally, this panel can be complemented with the analysis of oxidative stress, genotoxicity, and inflammatory markers.

ABSTRACT BODY:

Purpose: Tropomyosin receptor kinase B (TrkB) is an effective target for neuroprotection in experimental glaucoma models. Supplying agonist ligands, such as brain-derived neurotrophic factor (BDNF) and neurotrophin-4 (NT4), by protein or gene therapy in glaucoma models has been shown to protect retinal ganglion cells (RGCs). However, long-term protection is hindered by TrkB down-regulation and truncated TrkB isoforms. Previous experiments have demonstrated when both TrkB and BDNF are expressed and given to the eye before optic nerve injury, RGC death is delayed. For this experiment, we are using a two-vector approach to confirm the necessity of both the receptor and ligand for the long-term neuroprotection of RGCs.

Methods: Adeno-associated viruses (AAVs) were made by our Viral Vector Technologies AAV Production Core. For in vitro protein quantification, HEK-293 cells were transduced with AAVs. Supernatant and lysate were collected three days afterward for ELISAs. Adult C57BL/6J mice or adult Sprague Dawley rats were used. The eyes were intravitreally injected with AAV2 vectors expressing TrkB, proBDNF, NT4, or a combination of AAVs. Three weeks after AAV injection, optic nerve injury was performed. Two or four weeks after injury, animals were sacrificed, eyes were collected, retinas were dissected, immunofluorescently stained for Brn3a and flat-mounted to count the RGC number.

Results: In vitro transduction of HEK-293 cells after 3 days of AAV treatment shows increased expression of TrkB, BDNF, or NT4. In vivo treatment of the combination of AAV2-TrkB with either AAV2-proBDNF or AAV2-NT4 significantly increases the survival of RGCs up to 78% two or four weeks after severe optic nerve injury compared to up to 46% in single AAV in both mice and rats.

Conclusions: Intravitreal administration of the combination of separate vectors encoding AAV2-TrkB and either AAV2-BDNF or AAV2-NT4 shows a significant neuroprotective effect after optic nerve injury in mice and rats, greater than achieved with ligand- or receptor-providing vectors alone.

ABSTRACT BODY:

Purpose: The visual signal entering the mouse retina is distributed across ~14 different bipolar cell (BC) types and then across ~40 different retinal ganglion cell (RGC) types. Each of these cell types are specialized to perform a specific computation for extracting relevant features of the visual world. To understand how these computations are implemented in neural circuits, we need to measure neural population activity in distinct BC and RGC types. Existing technologies are limited in scope in measuring population neural activity across synaptic tiers.

Methods: We have developed a single-photon light-sheet imaging system for measuring large-scale population activity of retinal cells. We used retinas from transgenic mice: Ai148;PVCre and Ai148;PCP2Cre expressing GCaMP6f in RGCs and BCs respectively. Cone photoreceptors expressing S-opsin were targeted for UV pattered and full-field stimulation. A semi-automated algorithm was used to characterize functionally distinct RGCs and BCs based on their spatiotemporal calcium footprints.

Results: The performance of the system was optimized by imaging fluorescent beads and axonal varicosities of individual RGCs. Axial resolution was obtained as ~20-30um, indicating clear laminar separation between the excitation light-sheet and the photoreceptor layer on which the visual stimulus was focused. We routinely imaged somatic activity of 200-300 RGCs (n=5 mice), and ~20-50 BCs (n=2 mice). Using different stimuli, we were able to drive different patterns of calcium activity, that allowed us to classify RGCs into 8-10 types in this mouse line, in agreement with previous anatomical findings. We further imaged visual stimulus evoked calcium activity in the synaptic terminals of multiple BCs simultaneously, and were able to distinguish different BC types from their inter-terminal and intra-terminal activity patterns.

Conclusions: Our platform provides a low-cost high-throughput solution for imaging calcium fluorescence dynamics in large populations of retinal cells at somatic and synaptic resolutions and classifying them based on their response characteristics. These findings have potential implications for revealing how visual signals are transformed at the synapses of functionally distinct BCs and RGCs.

ABSTRACT BODY:

Purpose: Prior research has not described the relationship between physical activity at home and the home environment in persons with visual impairment. Here we investigate the association between (1) the number and frequency of fall-related home hazards and (2) poor lighting with home physical activity in patients with glaucoma.

Methods: In this cross-sectional study, participants were 57 years or older at recruitment and diagnosed with primary glaucoma or were glaucoma suspects. Seven areas of participants' homes were evaluated (bedroom, bathroom, living room, kitchen, dining room, hallway, and indoor stairs) for fall hazards using the Home Environment Assessment for Visually Impaired (HEAVI). Based on these data, the total number of hazards, frequency of hazards, and average home lighting were calculated. Physical activity at home (average daily: steps, moderate to vigorous (MV) activity minutes, and peak cadence) was estimated from 7 days of GPS data (to confirm home location) and accelerometer data (to gauge activity). Negative binomial regression models were used to evaluate the relationship between each measure of home PA with metrics of the home environment. Models controlled for age, race, gender, integrated visual field sensitivity, comorbidities, and polypharmacy.

Results: One hundred fifty-three participants were included in the analysis with a mean age of 71 years (SD=7.8); half were male and about a third were Black. For every 0.1 log unit increase in average home lighting, significant increases of 3% in average daily peak cadence ($p=0.008$) and a 12% increase in MV activity ($p=0.03$) were observed. Furthermore, the average number of steps taken at home daily increased in homes with more home hazards (22% more steps/10 additional home hazards, $p=0.04$) and it was not associated with average home lighting ($p>0.05$). The frequency of hazards was not associated with any activity metric ($p>0.05$ for all)

Conclusions: The home environment, in particular lighting at home, may influence home physical activity in those with glaucoma. Further research is needed to better understand this relationship and how we may improve the PA at home using home modifications to improve home safety.

ABSTRACT BODY:

Purpose: Hexagonal-shaped corneal endothelial cells (CECs) are essential in maintaining corneal transparency for clear vision. In glaucoma patients, abnormal CEC function caused by high intraocular pressure (IOP) can contribute to vision loss. We developed a multi-scale imaging workflow to determine whether we could identify morphological and structural variations at at the nanoscopic level using a mouse model of high IOP induced by anterior chamber cannulation

Methods: We cannulated the left eyes of wild-type (WT) mice using anterior chamber puncture, and controlled the IOP to be 40 mmHg by adjusting the height of the syringe; right eyes served as controls. We first used a custom visible-light optical coherence tomography (vis-OCT) to monitor the overall corneal damage in real-time. After one hour of hypertension treatment, we sacrificed the mice, isolated their corneas, and processed one half for single-molecule localization microscopy (SMLM) and the other half for scanning electron microscopy (SEM)

Results: The vis-OCT images of control corneas showed a typical normal stroma (Fig. 1A). Increased corneal thickness was observed (Fig. 1B) with typical edematous appearance after maintaining 40 mmHg IOP for one hour. SMLM images showed the typical hexagonal structures of CECs in controls (Fig. 1C). However, after hypertension treatment, the intercellular tight junction structures labeled by ZO-1 became distorted dramatically, showing variations including extended filaments (Fig. 1E) or discontinuous and thinner junctional structures (Fig. 1D) between CECs. Using SEM, we identified similar hexagonal structures of CECs as showed in SMLM (Fig. 1F). Meanwhile, we observed the junctional structural variations on the surface level of CECs in hypertensive corneas, validating SMLM imaging results (Fig. 1G)

Conclusions: We imaged corneal flat-mounts to reveal nanoscopic variations in CECs in hypertension mouse models using vis-OCT, SMLM, and SEM. Such disruptions of the intercellular junctional structure of CECs in corneas may contribute to the loss of transparency and vision damage in glaucoma patients with high IOP

TITLE: Spatial summation is altered throughout the macula in juvenile X-linked retinoschisis

SESSION TITLE: Fundamental and Applied Psychophysics and Color Vision

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. McAnany, J.C. Park, R.A. Hyde, Illinois Eye and Ear Infirmary, Department of Ophthalmology and Visual Sciences, University of Illinois at Chicago, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: J Jason McAnany: Commercial Relationship: Code N (No Commercial Relationship) | Jason Park: Commercial Relationship: Code N (No Commercial Relationship) | Robert Hyde: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Previous studies suggest that the fovea of individuals with juvenile X-linked retinoschisis (XLRS) may be functionally similar to that of the normal periphery. We evaluated this hypothesis by determining the relationship between contrast threshold and stimulus size across the visual field in XLRS subjects.

Methods: Nine subjects with XLRS and 10 age-similar, visually-normal individuals participated. Thresholds were measured at 15 locations along the horizontal meridian of the visual field using a commercially available Octopus visual field perimeter. The field locations were grouped into four regions based on eccentricity from fixation: peripheral (10^{o}-60^{o}), perifoveal (5^{o}-10^{o}), parafoveal (2^{o}) and foveal. Stimulus area ranged from 0.01 deg^{2} to 2.32 deg^{2} (Goldmann sizes I to V). Thresholds for the control and XLRS groups were compared statistically by analysis of variance with Bonferroni-corrected pairwise comparisons. The relationship between threshold and stimulus size was described using a spatial summation model to quantify the critical area of spatial summation beyond which threshold is independent of stimulus size.

Results: For measurements in the periphery and perifovea, thresholds were modestly elevated for the XLRS group (less than 2.5x). Threshold differences between groups were significant in the periphery and perifovea for the size I to IV stimuli ($p < 0.02$), but not for the size V stimulus ($p > 0.06$). Threshold elevations were larger in the parafovea (4.7x) and fovea (8.4x) for the XLRS group, and pairwise comparisons indicated significant differences for all stimulus sizes ($p < 0.001$). XLRS thresholds measured in the fovea, parafovea, and perifovea did not differ significantly from those measured from the peripheral field of the control group ($p > 0.09$). The critical area for spatial summation was significantly larger for all field regions for the XLRS group compared to the control group ($p < 0.002$).

Conclusions: Spatial summation characteristics of the XLRS fovea, parafovea, and perifovea are similar to those of the normal periphery, suggesting abnormally large receptive field sizes in XLRS. The data indicate that scaling stimulus size can equate thresholds for the XLRS and controls subjects throughout all areas of the visual field.

ABSTRACT BODY:

Purpose: Corneal neovascularization (CNV) is a consequence of a variety of ocular pathologies including infectious and autoimmune etiologies. RhoA and its downstream effector ROCK play an important role in the development of neovascularization. Previous research has shown promise in treating CNV using both RhoA and ROCK inhibitors. We tested the hypothesis that Netarsudil treatment in an alkali burn injury mouse model will decrease CNV.

Methods: Wild type mice of age 3-6 months were divided into treatment and control groups. Alkali burn injury was performed on the right eye to induce CNV. One week after burn, anterior segment photography was done to ensure similar levels of baseline CNV between treatment and control groups. The treatment group was treated with the rho-kinase inhibitor, Netarsudil solution (0.02%; 0.02 mg/mL), brand name Rhopressa, at a frequency of once-a-day for 4 weeks. The control group was treated with balanced saline solution (BSS) in a similar manner. At the end of treatment, mice were euthanized for final anterior segment photography and corneal immunostaining was performed using CD31 to quantify CNV.

Results: A total of 5 mice have been treated thus far (3 in treatment group, 2 in control group). Anterior segment photos shortly after alkali burn show similar levels of baseline CNV (Figure 1). Immunostaining results at this stage indicate no significant difference in percent CNV between the treatment and control groups at four weeks (Figure 2). There was a large range in percent corneal neovascularization in the mice treated with Netarsudil.

Conclusions: This study is designed to evaluate whether inhibition of rho-kinase can regress established CNV in an alkali burn injury mouse model. Our experiment at this stage indicates no significant difference in CNV in the mice treated with Netarsudil versus BSS. A treatment goal of 30 mice is currently underway as a larger sample size of mice is needed to power conclusions. Final results have the potential to impact future research directions for treatment of CNV.

TITLE: The Ciliary Transition Zone Protein Tectonic1 Forms a Membrane Ciliary Barrier in Mouse Rod Outer Segments

SESSION TITLE: Biochemistry and Molecular Biology of the Retina/RPE

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Truong, J.R. Willer, J. Martinez-Marquez, A. Travis, J.N. Pearring, Ophthalmology, University of Michigan Michigan Medicine, Ann Arbor, Michigan, UNITED STATES|

Commercial Relationships Disclosure: Hanh Truong: Commercial Relationship: Code N (No Commercial Relationship) | Jason Willer: Commercial Relationship: Code N (No Commercial Relationship) | Jorge Martinez-Marquez: Commercial Relationship: Code N (No Commercial Relationship) | Amanda Travis: Commercial Relationship: Code N (No Commercial Relationship) | Jillian Pearring: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Light is detected by the outer segment compartment of retinal photoreceptors. The outer segment is an adapted primary cilium, which are thin microtubule-based organelles that relay extracellular signals to the cell through receptors enriched in the ciliary membrane. The distinct protein composition of the cilium is maintained by a membrane diffusional barrier, formed by transition zone proteins. While previous work has shown that membrane proteins utilize ciliary transport carriers (such as TULP, IFT, and BBSome) to enter and exit the cilium, the molecular components of the diffusion barrier remain unknown. Tectonic1 (Tctn1), an extracellular protein, forms a large complex with other ciliary proteins at the transition zone and has been shown to regulate ciliary membrane composition in primary cilia. We hypothesize that Tctn1 forms a diffusion barrier that maintains the unique membrane-associated protein composition of the photoreceptor outer segment.

Methods: To study Tctn1 in rod photoreceptors, a conditional Tctn1floxed mouse was generated through CRISPR gene targeting. This $Tctn1^{flox/flox}$ mouse was then crossed to an iCre75 mouse, which specifically expresses Cre recombinase in rod photoreceptors, to then generate our rod-specific Tctn1 knock-out mouse ($iCre;Tctn1^{f/f}$).

Results: We found that ciliary outer segment formation is normal in the absence of Tctn1; however, proteins typically excluded from the outer segment are now accumulating within the outer segment of $iCre;Tctn1^{f/f}$ rods. Mislocalization of these proteins in the outer segment is detrimental to rod health as photoreceptor degeneration occurs by 6 months. Interestingly, we show that the abundance and localization of ciliary transport carriers are not affected by the loss of Tctn1 which would suggest that Tctn1 acts as a physical gate at the transition zone.

Conclusions: Together, our results show that Tctn1 is part of the membrane ciliary gate. We are now testing whether the loss of Tctn1 impacts the diffusional rate of membrane proteins through the transition zone, allowing them to sneak by the exit machinery. Ultimately, my work has helped to understand how the transition zone functions as a membrane gate within photoreceptors and primary cilia in general.

ABSTRACT BODY:

Purpose: Electroretinography (ERG) plays a vital role in the diagnosis of various eye diseases. The International Society for Clinical Electrophysiology of Vision (ICSEV) has published guidelines standardizing the acquisition of ERG. However, repeatability of ERG measurements has not been clearly elucidated. In this study, we aim to assess the repeatability of ERG measurements as performed using ICSEV guidelines.

Methods: 98 consecutive patients with various ocular conditions and a recent ERG were included in our study. Full-field ERG (Diagnosys, LLC) was performed by a single examiner, with repeat measurements recorded as per ICSEV guidelines. The magnitudes of the A and B waves, along with their respective latencies, under each testing condition were collected. Statistical tests of repeatability including coefficient of variation and intraclass correlation coefficient (ICC) were employed. Statistical analysis was performed using MedCalc software.

Results: Using the coefficient of variation, A and B wave latencies and magnitudes had very good repeatability (<10) under the Scotopic 3 and 10 conditions. A wave latency, B wave latency and B wave magnitude measurements under Scotopic 0.01 conditions also had very good repeatability. A wave latency and B wave magnitude under both photopic conditions had good repeatability (10-20). A wave magnitude under both photopic conditions and the A wave magnitude under Scotopic 0.01 had poor repeatability (>30). Using the ICC, the scotopic 3 and 10 measurements had the best repeatability, with multiple measures demonstrating excellent repeatability. Measurements under scotopic 0.01 conditions also had good to excellent repeatability. The photopic measurements had varied repeatability scores, with the A wave magnitude and latency under photopic 3 conditions demonstrating poor reliability.

Conclusions: ERG measurements had variable repeatability using the standard protocol, with those under scotopic 3 and 10 conditions demonstrating the highest degree of repeatability. Further studies are required to elucidate this and explore the repeatability of ERG measurements in different patient populations.

ABSTRACT BODY:

Purpose: Choroidal neovascularization (CNV) and consequent sub-retinal fibrosis remain sight-threatening conditions with a significant percentage of patients being resistant to anti-VEGF-based treatments or presenting frequent recurrences. MicroRNA-21-5p (miR-21) is a non-coding RNA with pro-angiogenic and pro-fibrotic abilities that our group and others have previously studied for its pathogenic implications in diabetic and oxygen-induced retinopathy. Here, we have investigated the effects of blocking miR-21 in an experimental model of CNV.

Methods: CNV was induced in C57Bl/6J mice by laser injury of Bruch's membrane and analyzed at different time points. MiR-21 inhibition was achieved by intraorbital injection of miR-21 Locked Nucleic Acid (LNA) inhibitor. As control, we used mice subjected to CNV that were injected with scramble antagomir or age-matched normal mice. Immunohistochemistry was performed to visualize retinal histopathological changes (hematoxilin/eosin staining) and to assess vascular density and distribution (isolectin B4), fibrotic progression (collagen I), and reactivity to alpha smooth muscle actin (alpha SMA) antibodies suggesting epithelial to mesenchymal transition (EMT). Quantitative RT-PCR was used to assess miR-21 levels in the different experimental groups.

Results: In untreated CNV mice neovascularization was observed to peak around day 14 post-injury before mildly regressing at day 21. Collagen I (Col1) staining showed that in CNV mice fibrosis progressed further beyond 14 days. In CNV mice treated with miR-21 inhibitor (a.miR-21), Col1 and Isolectin B4 stained areas were noticeably smaller beyond the 7-day post-injury time point as compared to untreated CNV mice or mice treated with scramble antagomir. Quantification of the fibrosed area through measurement of the Col1 stained areas in maximum projection images confirmed these findings. Expression of fibrosis and EMT markers (alpha SMA) were significantly downregulated in a.miR-21 injected mice. SD-OCT-based analysis also evidenced that a.miR-21 rescued retinal thickness and decreased neovascular lesions in CNV mice. Lastly, H&E staining confirmed improved retinal architecture in a.miR-21 treated CNV mice.

Conclusions: Our data indicate miR-21 as a novel player in CNV induction and progression and suggest its inhibition as a new therapeutic strategy for this potentially blinding condition.

TITLE: Optical coherence tomography angiography (OCTA) demonstrates displacements of large disc and peripapillary vessels during horizontal duction

SESSION TITLE: Pediatric ophthalmology and imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Lim, J.L. Demer, Jules Stein Eye Institute, Los Angeles, California, UNITED STATES| S. Lim, A. Tran, J.L. Demer, University of California Los Angeles, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Seongjin Lim: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Tran: Commercial Relationship: Code N (No Commercial Relationship) | Joseph Demer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: It has been proposed that eye-movement related deformation of optic nerves could induce mechanical stress in the optic disc from which the retinal vasculature emerges. To study this phenomenon quantitatively we used OCTA for high-resolution 3D imaging of larger disc and peripapillary vessels during horizontal duction.

Methods: Eight eyes of 5 normal adults were imaged in the 3×3 mm^2 region centered on the disc using the Heidelberg Spectralis scanner in central gaze, and in 35° ab- and adduction. Deep learning was employed for automatic identification of blood vessels and Bruch's membrane. Furthermore, we applied 3D scale-invariant feature transformation (SIFT) to extract feature points for the blood vessels. Among paired feature points in different gaze positions, we filtered for points with a distance <100 µm from large vessels. We registered vascular feature points to compute their displacements relative to the center of Bruch's membrane opening (BMO). We reconstructed the plane of Bruch's membrane whose normal vector defines the Z-axis (anterior-posterior). The X-axis (temporal-nasal) was defined by a line from BMO center to the fovea, and the Y-axis was perpendicular to X and Z.

Results: In adduction, feature points in nasal disc and peripapillary region were displaced farther temporally by 10±9 µm (mean±SD), significantly more than 2±11 µm in the temporal region (p=0.0011, n=8 eyes); this indicates horizontal compression of the vascular arbor from the nasal side. Adduction also resulted 13±15 µm anterior displacement in nasal region that was significantly larger than 5±13 µm in the temporal region (p=0.0157), indicating tilting of the vascular arbor. However, in abduction temporal and anterior displacements were similar in the nasal and temporal regions, indicating absence of both horizonal compression and tilting of the vascular arbor.

Conclusions: OCTA demonstrates that both ab- and adduction induce 3-dimensional deformations of major blood vessels emerging from the optic disc, but only in adduction is the vascular arbor tilted and horizontally compressed. These findings are consistent with optic nerve tethering in adduction but not abduction.

ABSTRACT BODY:

Purpose: Dual inhibition of angiopoietin-2 and vascular endothelial growth factor-A with faricimab, a bispecific antibody designed for intraocular use, may promote vascular stability and durable efficacy in patients with neovascular age-related macular degeneration (nAMD). Here we report updated week 48 results of the phase 3 TENAYA (NCT03823287) and LUCERNE (NCT03823300) trials, comparing efficacy, safety, and durability of faricimab with aflibercept in patients with nAMD.

Methods: Patients with nAMD (pooled N = 1329) were randomized 1:1 to faricimab up to every 16 weeks (Q16W; n = 665) or aflibercept every 8 weeks (Q8W; n = 664). After 4 initial doses every 4 weeks (Q4W), faricimab-treated patients were treated Q8W, every 12 weeks (Q12W), or Q16W based on prespecified central subfield thickness (CST) and best-corrected visual acuity (BCVA) criteria at weeks 20 or 24. The primary endpoint was mean change from baseline in BCVA averaged over weeks 40, 44, and 48. Secondary efficacy endpoints, including visual and anatomic outcomes and safety, were assessed Q4W through week 48.

Results: Faricimab up to Q16W treatment resulted in comparable visual acuity outcomes compared to aflibercept Q8W, including noninferior BCVA gains averaged over weeks 40–48 (+6.2 and +5.9 Early Treatment Diabetic Study letters, respectively). Anatomical outcomes were also comparable between treatment arms, including mean reductions in CST from baseline averaged over weeks 40–48. Regarding durability, at week 48, 45.3% of faricimab-treated patients were on Q16W dosing and 78.7% were on Q12W dosing or longer. Representative cases of patients achieving Q16W dosing and associated retinal images will be presented. Faricimab was well tolerated, with low rates of intraocular inflammation and no vasculitis or occlusive retinitis events reported.

Conclusions: Pooled data from TENAYA/LUCERNE demonstrate that through week 48, faricimab up to Q16W offered durable vision gains and meaningful anatomic improvements that were comparable with aflibercept Q8W and was well tolerated.

ABSTRACT BODY:

Purpose: Intraretinal hyperreflective foci (IHF) on optical coherence tomography (OCT) in eyes with intermediate age-related macular degeneration (AMD) are associated with a higher risk for progression to advanced AMD. This study evaluates the impact of IHF on cone- and rod-mediated vision in patients with intermediate AMD using mesopic and scotopic microperimetry and correlate the findings with retinal structures revealed by multimodal imaging including adaptive optics scanning laser ophthalmoscopy (AOSLO).

Methods: In a retrospective study involving 225 eyes of 141 subjects with AMD, IHF were identified on spectral domain OCT B-scans in 123 eyes of 69 subjects, aged 77.3 ± 7.3 years old. Lesions associated with AMD such as drusen and subretinal drusenoid deposits (SDD) were assessed by color fundus photographs, infrared reflectance, blue-light autofluorescence, and OCT. Cone photoreceptor structure was examined by AOSLO. Cone- and rod-mediated sensitivity was tested using a microperimeter (MP1-S, Nidek) under mesopic and scotopic conditions in 16 eyes of 16 subjects with intermediate AMD (grades 5 to 8 in the AREDS 9-step severity scale). Mesopic and scotopic light sensitivity tested in the retinal areas with and without IHF but with a similar SDD/drusen load were compared in the same eye.

Results: Retinal areas with IHF exhibited significantly reduced mesopic (16.92 ± 5.59 dB vs. 18.62 ± 4.73 dB, $p = 0.0003$) and scotopic (8.31 ± 5.72 dB vs. 9.70 ± 5.63 dB, $p = 0.0087$) light sensitivity, in comparison to those without IHF. AOSLO revealed disrupted cone photoreceptor structure in areas with IHF and the photoreceptor mosaic was largely not visible in regions with IHF (Figure).

Conclusions: IHF are associated with significant loss of visual function and photoreceptor degeneration in eyes with intermediate AMD. Larger prospective longitudinal studies are required to investigate the pathogenesis and sequence of events leading to the development of IHF and associated photoreceptor loss.

TITLE: Analysis of 1-month-old MOTS-c in H2O; Using High Resolution Mass Spectrometry

SESSION TITLE: AMD - Biochemical and molecular disease mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Z. Mohtashami, M. Ozgul, M. Kenney, Ophthalmology, University of California Irvine, Irvine, California, UNITED STATES|B. Katz, Chemistry, University of California Irvine, Irvine, California, UNITED STATES|

Commercial Relationships Disclosure: Zahra Mohtashami: Commercial Relationship: Code N (No Commercial Relationship) | Mustafa Ozgul: Commercial Relationship: Code N (No Commercial Relationship) | Ben Katz: Commercial Relationship: Code N (No Commercial Relationship) | M.Cristina Kenney: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: MOTS-c peptide is one of the mitochondrial derived peptides which represent a new class of biologically active molecules with potential to protect retinal cells from oxidative stress associated with retinal pathology. State-of-the-art techniques can be used to analyze stability of intact MOTS-c peptide and identify MOTS-c fragments for possible use in future therapeutic investigation of age-related macular degeneration.

Methods: Stability analyses was done by High-Resolution Mass Spectrometry (HRMS). During this process the MOTS-c solutions with a concentration of 12.5 µg/ml were stored at 4°C and 37°C for 30 days.

Mass spectrometric analysis was performed using Xevo G2-XS Quadrupole Time-of-Flight mass spectrometer (HRMS) coupled to UPLC. The UPLC method used 30 minutes linear gradient at 0.3 mL/min from 97% A to 97% B where A is 0.1% Formic Acid in water and B is 100% Acetonitrile. For HRMS analysis, positive electrospray ionization mode was utilized. A capillary transfer temperature of 300°C and a spray voltage of 3.0 kV were used to accomplish ionization. A resolution of 30,000 Full Width at Half Maximum was used for a full scan experiment within a range of 100–2000 m/z as well as 15,000 FWHM with an isolation window adjusted to 2.0 m/z for. Leucine Enkephalin was used as a lock mass for nominal mass correction, and a CsNaI ladder was used to calibrate the detector.

Results: In MOTS-c peptide with molecular weight of 2173.11g/mol, the main ions of +5, +4 and +3 were formed at 435.84, 544.54 and 725.72 m/z (Figure 1). In MOTS-c, oxidation of methionine remained constant upon incubation of MOTS-C in water for 30 days at 37^{O}C. Intact MOTS-c peptides without oxidation were detected at the highest intensities. HRMS spectrums of MOTS-c stability in HPLC water are presented in Figures.

Conclusions: It is the first time that 1-month stability properties of MOTS-c peptide and its oxidation and degradation products have been analyzed in detail using advanced HRMS technologies. The data suggest that intact MOTS-c peptides in HPLC water represent a more stable form than Humanin-G peptides in water. The results may help researchers design better in vitro and in vivo experimental parameters to further understand the critical role of MOTS-c in physiological conditions and human diseases.

ABSTRACT BODY:

Purpose: Birdshot chorioretinitis (BSCR) is a chronic uveitis that can lead to a progressive loss of visual acuity and field over time. The aim of this study was to assess the manifestations of the disease in patients >80 years old.

Methods:

Among the patients with BSCR prospectively followed in our cohort (ClinicalTrials.gov Identifier: NCT05153057), we focused our analyses on those examined at age >80 years. Patients were assessed in a standardized manner including visual symptoms, best-corrected visual acuity (BCVA), dilated ophthalmic examination, visual field testing (Humphrey 30-2), fundus autofluorescence (FAF), fluorescein angiography and SD-OCT. When multiple visits occurred after age 80, data from the most recent visit were used. Active inflammation was defined by the presence of macular edema and/or vitritis and/or vasculitis and/or papillitis. Confluent atrophy was defined as hypoautofluorescent spots on FAF.

Results:

As of October 2021, 37 of 442 patients (8.8%, 74 affected eyes) were >80 years old at the most recent clinical visit. Mean age was 84.0 ± 3.7 years (range 80-93 years) and 24 (64.9%) patients were female. The mean disease duration was 22.4 years. Mean LogMAR BCVA was 0.53 ± 0.77 (range 0 – 2.3) in affected eyes, with 32 patients (86.5%) having 20/40 or better vision in at least one eye. Thirty-two patients (86.5%) received treatment during follow up. Systemic corticosteroids, immunosuppressants, and corticosteroid injections [intravitreal or sub-tenon] were previously prescribed in 24 (64.9%), 16 (43.2%) and 21 (56.8%) patients respectively. Thirty-three patients (89.2%) were receiving no treatment and 57 eyes (81.4%) in 30 patients (85.7%) had no active inflammation at the most recent visit. Confluent atrophy in the posterior pole was observed in 30 (42.8%) eyes in 17 patients (48.6%). Patients with confluent atrophy had significantly worse mean BCVA (LogMAR 1.0±0.94 vs 0.13±0.15, $p<0.0001$), longer mean disease duration (26.9±9.8 vs 17.6±9.0 years, $p=0.0005$), thinner mean central macular thickness on SD-OCT (245.6±117.2 vs 268.0±48.8 µm, $p=0.002$) and worse visual field mean deviation (-15.1±7.7 vs -6.8±6.0 dB, $p=0.0003$).

Conclusions: The majority of patients with BSCR aged >80 have preserved BCVA of 20/40 or better in at least one eye over several decades of disease duration. Confluent atrophy in the posterior pole was correlated with worse visual function in these patients.

ABSTRACT BODY:

Purpose: Tissue biopsy of Rb can cause tumor spread, so it is contraindicated. We demonstrated that aqueous humor (AH), an ocular fluid, is a high-yield liquid biopsy source enabling in vivo detection of tumor-derived cell-free DNA (cfDNA), thus overcoming the contraindication to biopsy. In ~13% of Rb patients, tumor progression is driven by epigenetic deregulation of tumor-promoting pathways without detectable genomic alterations. However, epigenetic studies have been done only on primary tumors from surgically removed eyes. The frequency and effect of epigenomic regulation in eyes that have been saved with therapy are unclear due to a complete lack of access to in vivo tumor tissue. Therefore, epigenetic analysis of AH cfDNA is highly desired to understand the broader spectrum of Rb tumorigenesis and prognosis.

Methods: We included 16 AH samples and 4 Rb tumors from 12 patients with 14 Rb eyes in the study. We conducted global DNA methylation profiling of tumor tissues from surgically removed Rb eyes and AH samples collected from different clinical stages and treatment outcomes using the Illumina Infinium EPIC DNA methylation BeadArray platform. Publicly-available DNA methylation data of normal retina, Rb eyes, and Rb patients were obtained from Gene Expression Omnibus (GEO, GSE57362) for cell-type DNA methylation comparisons.

Results: Our preliminary studies revealed a high degree of concordance in genome-wide differential DNA methylation patterns between paired AH and tumor samples. Integrating our data with large public datasets, we identified reliable Rb DNA methylation signatures in AH cfDNA that have potential diagnostic and prognostic applications. We also identified DNA hypermethylation of the RB1 promoter, which may serve as an efficacious target of DNA methylation inhibitors. By integrating DNA methylation data with gene expression data, we identified over 300 differentially expressed genes potentially directly regulated by DNA methylation in Rb tumorigenesis.

Conclusions: Our findings set the stage for exploring epigenetic markers using AH cfDNA specimens, including identifying potential prognostic markers and therapeutic targets to ultimately improve the clinical management of Rb patients.

ABSTRACT BODY:

Purpose: To evaluate the change in the area of reticular pseudodrusen (RPD) over a two year period in eyes with age-related macular degeneration (AMD).

Methods: AMD eyes with RPD enrolled in the Amish Eye Study (AES) with baseline and two year follow-up infrared reflectance (IR) images were eligible for this analysis. Eyes were excluded for poor quality images, extension of RPD beyond the margins of the image, or if they developed geographic atrophy at the month 24 visit. Thirty-degree IR images and volume OCTs (6x6mm, 512x97, ART=9, fovea-centered) were obtained using the Spectralis HRA+OCT. Using the instrument software, a certified grader delineated the RPD area (mm^2) on the IR image using the free hand tool, and measured the choroidal thickness on the OCT at the foveal center as well as at 3500 µm superior and inferior to the foveal center. Measurements were performed on both baseline and Month 24 images. 30% of eyes were randomly selected for reproducibility analysis by a second masked grader. The change over two years was assessed using paired t tests.

Results: Of 1332 eyes (666 subjects) enrolled in the AMISH eye study, a total of 108 eyes (from 54 subjects) were noted to have RPD and from these 35 eyes of 22 subjects were included in the final analysis (32 eyes were excluded due to extension of RPD to the image border, 19 due to poor image quality, and 22 due to development of GA). The mean age of included subjects was 72.7 ± 9.1 (range: 3.5 – 84) years and 13 were female (37%). Mean subfoveal choroidal thickness at baseline was 194.58 ± 79.2 µm. RPD area was increased significantly ($p < 0.001$) at month 24 (17.67 ± 9.59 mm^2) compared to baseline (11.44 ± 7.96 mm^2) with a mean increase of 6.23 ± 4.64 mm^2. There was no significant change at 2 years, however, in choroidal thickness in any of the regions: superior ($p = 0.09$), subfoveal ($p = 0.26$) and inferior ($p = 0.52$). Intraclass correlation (ICC) for RPD area between the two graders was 0.997 with a mean difference of 0.49 mm^2.

Conclusions: In this longitudinal natural history analysis, we observed an increase in RPD area of >6mm^2 over two years despite no significant change in choroidal thickness. These findings may provide new insight into the evolution and lifecycle of RPD.

TITLE: Demographic Factors Associated with Differential Access to Treatment in Keratoconus Patients at a U.S. Urban Safety Net Hospital

SESSION TITLE: Keratoconus and corneal biomechanics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: O. Ihionu, M. Arsiwala, N. Sanayei, H.J. Lee, Boston University School of Medicine, Boston University School of Medicine, Boston, MA, US, academic/medsch, Massachusetts, UNITED STATES|J. Samra, Biostatistics, Boston University School of Public Health, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Oluchi Ihionu: Commercial Relationship: Code N (No Commercial Relationship) | Jasmeet Samra: Commercial Relationship: Code N (No Commercial Relationship) | Mohsin Arsiwala: Commercial Relationship: Code N (No Commercial Relationship) | Nedda Sanayei: Commercial Relationship: Code N (No Commercial Relationship) | Hyunjoo Lee: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: There is limited information regarding the influence of demographic factors on keratoconus outcomes. The purpose of this study is to examine the effects of race/ethnicity, primary patient language, health insurance, and area deprivation index (ADI) on rates at which patients receive two different keratoconus interventions: corneal collagen crosslinking (CXL) and medical contact lenses (CL). Our primary hypothesis was that patients who live in more impoverished areas, as determined by ADI, have lower access rates to CXL and CL, and that other demographic factors could influence this access to treatment as well.

Methods: Electronic medical records of keratoconus patients at Boston Medical Center from 2012-2020 were retrospectively examined to obtain CXL and CL treatment records, race/ethnicity, primary language, insurance (private, public, or none), and home address. National ADI quintile was determined by address, and patients were categorized as 1st, 2nd, or 3rd quintiles and above (most disadvantaged). Logistic regression models were used to calculate odds ratios for keratoconus treatment adjusted for age, ADI, insurance, race/ethnicity, and language. Chi-square likelihood ratios were used to test for associations between demographic factors and odds of treatment. Post-hoc analyses were performed using Tukey's method at a 5% family-wise error rate.

Results: 572 charts were reviewed, and 32 patients were excluded due to incomplete records. Of 540 remaining KCN patients, 42 received CXL and 213 received and/or had a history of CL. There was no significant association between ADI and CXL treatment (p=0.688) or CL access (p=0.912). Multivariate analyses showed that patients whose primary language was not English were less likely to have CL access relative to patients whose primary language was English (ORadj=0.65, 95% CI 0.45-0.93, p=0.021). Insurance status (p=0.002) and race/ethnicity (p=0.003) had significant associations with CXL treatment in multivariate models. When adjusted for all other factors, including insurance status, White patients were more likely to receive CXL relative to Black patients (ORadj=8.54, 95% CI 2.82-27.09) and patients with private insurance were more likely to receive CXL than those without insurance (ORadj=10.00, 95% CI 2.59-66.22).

Conclusions: Our data demonstrate disparities in keratoconus treatment access for disadvantaged groups.

ABSTRACT BODY:

Purpose: About 20 patients develop ocular complications per 1 million smallpox immunizations, usually through autoinoculation, in which the patient transfers Vaccinia from the immunization site to the eye. We observed central corneal steepening (CCS) that occurred in the setting of Vaccinia virus-associated nummular keratitis.

Methods: A 40-year-old healthy male with no significant past ocular or medical history who was vaccinated against smallpox in 2003 was examined. Within 2 weeks of vaccination, he developed a diffuse skin rash and bilateral eye redness. He later experienced progressive decline in his corrected distance visual acuity. After undergoing an eye exam, he was informed that the blurry vision was associated with smallpox vaccination. He also developed significant nearsightedness and astigmatism.

Results: Recently, his vision with corrective glasses of OD=-6.50- 2.50 x 140; 20/30, and -5.00- 2.50 x 130; 20/60. Pupils, ocular motility, confrontation visual field, external exam, lids, and conjunctiva were unremarkable. There were no symblepharon, tear film, or function abnormalities. Bilateral, fine peripheral corneal neovascularization and multiple peripheral coin shape opacities (subepithelial/anterior stroma) that spared the central corneas were noted. Some of these opacities coalesced. Pentacam tomography revealed significant CCS similar to central keratoconus in each eye (Fig. 1). Anterior segment optical coherence tomography demonstrated subepithelial and anterior stromal lesions that were confined to superficial peripheral corneal layers without involvement of deeper corneal layers and the visual axis (Fig. 2). A plausible explanation for the patient's stable myopic shift and astigmatism is that inflammation caused structural changes in the corneal mid-periphery. This process may be similar to the myopic refractive changes seen in conductive keratoplasty, in which heat-induced shrinking of peripheral collagen lamellae causes CCS.

Conclusions: Significant CCS can occur in the setting of mid-peripheral nummular keratitis, which presumably mimics the conductive keratoplasty biomechanical changes in the corneal mid-periphery that led to the CCS.

ABSTRACT BODY:

Purpose: Proliferative vitreoretinopathy (PVR) represents the greatest risk of failure of retinal detachment repair surgery. No pharmacotherapies have prevented the formation of PVR, so a significant unmet need exists. The epithelial-to-mesenchymal transition (EMT) of retinal pigment epithelial (RPE) cells is critical in PVR pathogenesis. Increased glycolysis is a hallmark of RPE EMT. Pyruvate kinase M2 (PKM2) is a key regulator of glycolysis that exists in different oligomeric states, dimer and tetramer, and has been implicated in glycolytic reprogramming of cells. Small molecule modulators of PKM2, like ML-265, induce tetramerization reducing glycolytic reprogramming. We assessed the therapeutic potential of pharmacologically inducing PKM2 tetramerization in preventing PVR.

Methods: To mimic the loss of cell contact observed in the PVR process and stimulate EMT, primary human fetal RPE (hfRPE) were seeded at 10% density. Expression of EMT markers, PKM2, and mediators of glycolytic reprogramming and proliferation were assessed. A continuous, enzyme-coupled assay that measures the depletion of NADH measured PK activity. Targeted metabolomics assessed the impact of ML-265 on the metabolic profile of hfRPE. The therapeutic potential of ML-265 in attenuating RPE EMT and PVR was evaluated in in vitro assays. ML-265 toxicity was assessed via transepithelial electrical resistance (TEER) and cell death markers.

Results: Low seeding density of hfRPE demonstrated a fibroblastic-like PVR phenotype (hfRPE EMT) with induction of EMT markers α-SMA and NCAD. PKM2 but not PKM1 expression was increased. Yet, overall PK activity was decreased and the phosphoenolpyruvate (PEP) to pyruvate ratio was increased in hfRPE EMT suggesting PKM2 is in the low activity, dimeric state. ML-265 treatment increased PK activity >3-fold in hfRPE EMT. ML-265 induced a decrease in glycolytic intermediates and the expression of HIF1A, GLUT1, and PDK1in hfRPE EMT. ML-265 decreased the proliferation of EMT hfRPE cells and the expression of MYC and CCND1 as well as inhibited EMT hfRPE-mediated gel contraction with a reduction in α-SMA expression. Exposure to ML-265 did not reduce TEER or increase annexin or PI staining in differentiated hfRPE.

Conclusions: This study suggests that pharmacologically inducing PKM2 tetramerization may be an innovative therapeutic strategy for PVR.

ABSTRACT BODY:

Purpose: To evaluate the association between multiple sclerosis (MS) and retinal fractal dimension (FD), a retinal vascular geometric index of complexity.

Methods: A retrospective cohort study with data from 96,992 patients, of which 250 had multiple sclerosis seen at a tertiary ophthalmic institution in London, United Kingdom. Retinal fractal dimension was extracted from macular-centered colour fundus photographs using the Vascular Assessment and Measurement Platform for Images of the Retina. Multivariable linear regression evaluated the association between retinal FD and multiple sclerosis adjusting for age, sex, hypertension and diabetes mellitus.

Results: Patients with multiple sclerosis were younger (61.6 +/- 12.8 years of age versus 68.2 +/-12.5, $p<0.001$) and more likely to be female (72.4% versus 50.9%, $p<0.001$) but less likely to be diabetic (32.4% versus 47.5%, $p<0.001$) or hypertensive (73.6% versus 80.1%, $p<0.001$). Retinal FD was similar regardless of MS status (non-MS: 1.511+/-0.032 versus MS: 1.514 +/- 0.032, $p=0.23$). After adjustment for age, sex, hypertension and diabetes mellitus, retinal fractal dimension was reduced in patients with MS (b -0.0043, 95% confidence interval: -0.008, -0.0006, $p=0.024$).

Conclusions: Retinal FD is reduced in people with MS. It remains unclear whether FD may be related to disease severity and therapeutics and further work should characterize its role in dynamic disease modelling.

ABSTRACT BODY:

Purpose: To evaluate the relationship between characteristics of geographic atrophy (GA) lesions at baseline and Month 6, on the growth rate of atrophy over 12 months.

Methods: A total of 82 eyes of 82 subjects with geographic atrophy (GA) and 12 months of follow-up data at the Doheny Image Reading Center were included in this retrospective analysis. All subjects had undergone blue light fundus autofluorescence (FAF) imaging at baseline, Month 6, and Month 12. To be included in this analysis, the total GA lesion area was required to be between 2.54 and 17.78 mm^2, and in multifocal cases, at least one of the lesions was required to be larger than 1.27 mm^2. Areas of definite decreased autofluorescence (at all visits) corresponding to GA were manually segmented using planimetric reading center software. Lesion location (subfoveal vs nonfoveal), number, morphology (multifocal, horseshoe, ring, single), perimeter, and circularity index were measured at baseline and at month 6. Development of new/distinct lesions, as well as merger of two or more lesions at Month 6, were also assessed. These lesion characteristics at baseline and month 6 were correlated with the month 12 GA growth rate by linear regression analysis.

Results: Of 82 eyes included in this analysis, 50 were multifocal. Baseline GA area and annual growth rate of GA were 8.06 ± 4.06 mm^2 and 2.02 ± 1.13 mm^2 respectively. The average number of atrophic lesions at baseline was 3.8 ± 3.7 and this decreased to 3.5 ± 3.5 at month 12 ($p = 0.58$). The average perimeter of the lesions at baseline was 20.61 ± 10.90 mm and this increased to 20.74 ± 10.42 mm at month 6, but the difference was not significant ($p = 0.94$). In addition, the increase in CI from 0.34 ± 0.21 at baseline to 0.37 ± 0.21 at month 6 was also not statistically significant ($p = 0.41$). Figure 1 illustrates the Descriptive Regression Coefficients for GA area growth at month 12. Factors associated with a faster enlargement of GA are shown in Figure 2.

Conclusions: Although many baseline lesion characteristics can influence the enlargement rate of GA, their predictive value is small compared to the prior growth rate. This suggests that a “run-in” period prior to randomization may be useful for standardizing treatment arms in interventional trials.

TITLE: GABAergic but not Glutamatergic Modulators Microinjected into the Suprachiasmatic Nucleus Elevate IOP

SESSION TITLE: Glaucoma: biochemistry, biomechanics and omics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. DeCarlo, B.C. Samuels, Ophthalmology, The University of Alabama at Birmingham Department of Medicine, Birmingham, Alabama, UNITED STATES|

Commercial Relationships Disclosure: Arthur DeCarlo: Commercial Relationship: Code N (No Commercial Relationship) | Brian Samuels: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Glaucoma is a leading cause of blindness in adults. Elevations and fluctuations in intraocular pressure (IOP) are thought to be risk factors for development and progression of glaucoma. This research targets the hypothalamic suprachiasmatic nucleus (SCN) in an attempt to identify new pharmacological targets for regulating IOP. The SCN lies above the pituitary gland at the base of the brain. It makes direct neural connections to the retina and to other more caudal nuclei, such as the dorsomedial hypothalamic and perifornical areas, which our lab has identified as playing a potential role in IOP regulation. The SCN is the primary modulator of circadian rhythms and is well situated to modulate IOP diurnal rhythms, thus it is of significant interest.

Methods: Male Sprague-Dawley rats (n=35) were placed under mild isoflurane anesthesia at midday. Using a stereotactic surgical approach, a 75 nL injectate of a chemical neurotransmitter agonist, antagonist, or control solution was delivered to the SCN while recording IOP, heart rate (HR), blood pressure (MAP), and intracranial pressure (ICP).

Results: The net increase of IOP in response to the $GABA_A$ antagonist bicuculline methiodide (BMI) injected into the SCN was similar (+6.8 +/- 1.2 mm Hg, n=8) to previously reported responses by the dorsomedial hypothalamus (+7.1 +/- 1.9, n=9) or by the raphe pallidus (+7.4 +/- 1.4, n=8) to BMI injection. The IOP response of the SCN to the glutamate receptor agonist, NMDA, was low (+4.7 +/- 0.8 mm Hg, n=8), and the response to the glutamate receptor antagonist, MK 801, was also low (+5.0 +/- 0.5, n=5). However, IOP was markedly raised (+14.3 +/- 2.4 mm Hg, n=5) by injecting a standard PBS solution of 0.1M phosphate buffer with added 154 mM NaCl (579 mM calculated osmolarity), though there was an absence of corresponding increases in ICP, HR, or MAP. Further investigation using a 0.9% NaCl injectate (308 mM calculated osmolarity) did not show IOP stimulation (+4.0 +/- 1.1 mm Hg, n=4), nor did injection of an artificial CSF solution (311 mM calculated osmolarity) raise the IOP (+5.4 +/- 1.3, n=5).

Conclusions: IOP regulation appears to be mediated by GABAergic and not glutamatergic neuronal pathways in the SCN, but neural conductivity associated with extracellular hyperosmolarity may play a significant role in SCN IOP regulatory activity.

ABSTRACT BODY:

Purpose: Keratic precipitates (KPs) are a feature of ocular inflammation. KP morphology has been described as a vital diagnostic clue for different forms of inflammatory disease, yet there is no agreed morphology classification system. We aimed to undertake a rapid review to identify the most commonly used descriptors for KP morphology, and to describe the degree of consensus around slit-lamp based descriptions of KP morphology amongst a group of paediatric uveitis specialists.

Methods: Rapid literature review (search term: “keratic precipitates”) to identify the descriptive terms used for KPs, and frequency of use, in the published literature. REDCap image based electronic survey of KP morphology undertaken by members of the United Kingdom’s Paediatric Ocular Inflammation Group (POIG), who were asked to indicate KPs type present in each image. Degree of consensus for each of the 29 images in the survey was analysed for each KP morphological parameter with a threshold set at 80% agreement.

Results: The rapid review identified 469 papers, of which 259 used descriptive terms for keratic precipitates. The most commonly used descriptors (total 76 terms identified) were ‘mutton-fat’ (n=93 papers), ‘fine’ (n=76), ‘stellate’ (n=40), ‘large’ (n=33) and ‘medium’ (n=32).

The response rate for the survey was 26/32 (81.%). Consensus was met for the descriptive terms ‘large’ (consensus reached for 25/29 images, median consensus 91%, range 58 – 100%), mutton-fat (23/29, median 91%, range 54 – 100%), stellate (25/29, 90%, 57 – 100%), but not for the terms fine/dust (12/27, 74%, 50 – 96%) or medium (11/27, 73%).

Conclusions: This survey reveals an absence of clinical consensus around the classification of KPs using size (fine V medium), although there is evidence of good consensus on the appearance of large, stellate and mutton-fat KP. Harmonisation of clinical nomenclature is a key foundation for multi-centre research such as the currently underway POIG supported UNICORN (UK Uveitis in Childhood Prospective National Cohort study). These findings work will support future attempts to create consensus based nomenclature for this important diagnostic sign.

ABSTRACT BODY:

Purpose: A subset of defects in the DHDDS gene, which is required for protein glycosylation, cause retinitis pigmentosa 59 (RP59). We previously generated a knock-in model of the most prevalent DHDDS mutation, K42E. Here, we describe new findings obtained by ultrastructural and light level analyses to assess the fine structure of the mutant mouse retina and RPE.

Methods: Eyes from 6 homozygous K42E and 3 WT mice at 18 mo were used in this study. Histological analysis was performed using semithin sections stained with toluidine blue. Transmission electron microscopy (TEM) was performed on ultrathin (80-100 nm) sections prepared from mixed aldehyde-fixed, epoxy-embedded tissues using standard conditions. TUNEL staining was performed using paraffin-embedded tissue sections to assess cell death.

Results: Histological analysis revealed that the K42E retina was comparable to WT retina in all layers except the OPL, where patchy invasion by rod nuclei was observed and processes of second-order neurons were reduced, especially in the periphery. Pyknotic nuclei were observed in the ONL and INL, and TUNEL staining revealed several dying cells in the mutant retina compared to WT. At the TEM level, most rod and cone terminals showed normal presynaptic ultrastructure, with synaptic ribbons decorated with synaptic vesicles anchored to the plasma membrane and contacted post-synaptic processes from horizontal and bipolar cells. However, some photoreceptor cell bodies and terminals displayed darkened cellular material, consistent with impending cell death. Basal infoldings on the RPE adjacent to Bruch’s membrane were frequently disorganized and severely degenerated RPE was occasionally observed in K42E mice.

Conclusions: Perturbations in the RPE and OPL and cell loss in the Dhdds K42E mouse retina are consistent with previously described ERG deficits in this RP59 model. These results suggest that defective RPE function and signal transmission between photoreceptors and inner retinal neurons may be major contributors to the etiology of RP59.

ABSTRACT BODY:

Purpose: Glial and neuronal responses to acoustic blast overpressure (ABO) exposure have been studied extensively in the brain and retina, but remain relatively uncharacterized in the optic nerve. We examined the expression and distribution patterns of GFAP, synemin, nestin and neurofilament-M (NF-M) in rat optic nerve following ABO relative to unexposed controls, to ascertain basal and post-blast distribution of these major intermediate filament (IF) cytoskeletal components.

Methods: Anesthetized adult male Long-Evans rats were subjected to ABO exposure, with the blast directed at the right side of the head (Allen et al., 2018, 2021). Optic nerves were harvested at 1 wk post-ABO alongside non-exposed, age/sex-matched controls, and fixed in PBS-buffered PFA. Transverse cryosections (O.C.T. embedment) were prepared, subjected to antigen retrieval, and processed for confocal microscopy immunofluorescence histochemistry (IHC) using polyclonal antibodies (Abs) against GFAP, nestin, and NF-M, and monoclonal antibodies against synemin (clone A8), with suitable fluor-conjugated secondary Abs. Local thickness mapping and particle analysis of synemin immunolabeling through z-stacks was performed in FIJI ImageJ™. Statistical analysis: Student's t-test, significance threshold $p<0.05$ (N=3/group).

Results: GFAP, nestin and synemin were robustly expressed in control optic nerve astrocytes, with overlapping distribution through the IF cytoskeleton. Astrocytes were evenly distributed through control transverse optic nerve sections. Synemin partially co-localized with GFAP and nestin IF and appeared to form fine cytoskeletal structures along the astrocytic cell processes. At 1 wk post-ABO, astrocytes appeared heterogeneous, with a sub-population exhibiting hypertrophic cell processes, and were re-distributed more centrally in the optic nerve. Co-labeling for axons using anti-NF-M identified distinct axonal bundles that appeared ordered and regularly spaced in control optic nerves. At 1 wk post-ABO, peripheral disturbance to the axon bundles was observed. Local thickness analysis revealed a ~1.5-fold increase in particle size of cytoskeletal synemin through the astrocytic processes.

Conclusions: Astrocytes undergo morphological and distribution changes in the rat optic nerve following ABO, accompanied by altered synemin localization through the IF cytoskeleton.

ABSTRACT BODY:

Purpose: Changes in optic nerve head swelling (papilledema) are delayed following intracranial pressure (ICP) changes in IIH. Retinal vascular changes may occur more quickly and are therefore a potential non-invasive, quantitative biomarker for ICP changes in IIH. The purpose of this study is to characterize retinal vessel tortuosity in a cohort of untreated IIH subjects.

Methods: Peripapillary arteriolar and venular tortuosity indices (aVTI, vVTI) were measured for 4 arterioles and 4 venules in a region of interest 4.5-6.4mm centered on the optic nerve on retinal photographs centered on the optic nerve from the baseline visit (prior to treatment) of study eyes in subjects who completed IIHTT follow up (n=126). VTI was measured using custom software that uses a clustering algorithm to identify center lines of each selected vessel. Curve magnitudes were then calculated by the ratio of vessel segment length to straight length between inflection points which establish a dimensionless VTI. For each subject, VTI was averaged for each vessel type and compared with other baseline parameters from the IIHTT (demographics, IOP, ICP, BP, other photographic parameters) using Pearson correlation and linear regression(LR).

Results: VTI measurements for ≥3 arterioles and/or venules were successful for 101 eyes. aVTI was 0.14 +/- 0.05 and vVTI was 0.12 +/ -0.07. vVTI was associated with gender(r=0.23,p= 0.02 LR), IOP(r=0.28,p=0.005 LR), ICP(r=0.17,p=0.08 LR), optic nerve elevation area(r=0.18,p=0.087 LR) and average venule diameter(r=0.27,p=0.006 LR). aVTI was associated with average arteriole diameter(r=0.19,p=0.06 LR). All other comparisons had slopes with p>0.1.

Conclusions: vVTI and aVTI could be measured on the majority of photographs of untreated papilledema. Cross sectional analysis showed weak correlations with other markers of IIH and local pressures. Analysis of association between VTI change and IIH treatment response are needed to assess the potential of retinal VTI as a marker of disease treatment.

SUBMITTER (NAME ONLY): Navita Lopez

TITLE: Microglia utilize both CR3 and Mertk receptor pathways to eliminate RGCs in the embryonic retina

SESSION TITLE: Retina Development and Regeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Lopez, S.R. Anderson, M.L. Vetter, Neurobiology, University of Utah Health, Salt Lake City, Utah, UNITED STATES|

Commercial Relationships Disclosure: Navita Lopez: Commercial Relationship: Code N (No Commercial Relationship) | Sarah Anderson: Commercial Relationship: Code N (No Commercial Relationship) | Monica Vetter: Commercial Relationship(s);Code C (Consultant/Contractor):Roche

ABSTRACT BODY:

Purpose: Microglia are the resident myeloid cells of the CNS that serve multiple roles during development. We previously showed that these phagocytes are responsible for the elimination of a subset of newborn retinal ganglion cells (RGCs) in the embryonic retina. This is partly dependent on microglial recognition of RGCs by complement receptor 3 (CR3); however, we hypothesize that additional receptor pathways are involved. Here we investigate the role of the TAM receptor tyrosine kinases, which are known to facilitate phagocytosis. Embryonic retinal microglia express two members of this family, Mertk and Axl. Microglial-mediated phagocytosis of excess neurons is a pivotal process in neural development, and we hypothesize that embryonic retinal microglia utilize both CR3 and TAM receptors to recognize and eliminate a subset of viable newborn RGCs in the developing retina and regulate RGC density.

Methods: We used B6. Mertk$^{-/-}$, Axl$^{-/-}$ and Mertk$^{-/-}$Axl$^{-/-}$ mice to assess the role of TAM receptors in embryonic RGC elimination. Retinal whole mounts were collected at P0, when excess RGCs would persist, and we performed RBPMS immunostaining and confocal imaging then quantified RGC density. To determine if multiple receptor pathways cooperate to contribute to embryonic RGC elimination, we used Mertk$^{-/-}$, CD11b$^{-/-}$ (CR3) and Mertk$^{-/-}$ CD11b$^{-/-}$ mice and analyzed RGC number at P0 in whole mount retinas.

Results: We find that genetic ablation of Mertk resulted in an increase in RGC density at birth compared to wildtype controls. Mertk$^{-/-}$ mice showed an 8.95% increase in RGC density at P0 (n=12; p=0.005). Mice deficient in both Mertk and Axl, resulted in a 11.81% increase in RGC density (n=12; p<0.0001), similar to Mertk$^{-/-}$ alone, suggesting that Mertk is primarily responsible. We show that with knockout of both Mertk and CD11b, there is an additive effect, with a 19.78% increase in RGC density (n=4; p<0.0001).

Conclusions: Shortly after RGCs are generated, a non-apoptotic subset is eliminated by phagocytic microglia. We show that multiple microglial receptor pathways contribute to the embryonic elimination of RGCs, and we establish that Mertk and CR3 cooperate in this process. Future studies will define the properties of RGCs targeted for elimination.

ABSTRACT BODY:

Purpose: To assess the visual impact and reasons for treatment delay during the COVID-19 pandemic lockdown in neovascular age-related macular degeneration (nAMD) patients in ongoing anti-VEGF therapy.

Methods: Retrospective, national, multicentre, observational study in nAMD patients treated with anti-VEGF therapy and registered in the Fight Retinal Blindness (FRB) Spain platform prior to lockdown. Study cohort was divided in timely treated patients (TTP) and delayed treatment patients (DTP). Mean change in best corrected visual acuity (BCVA, in ETDRS letters) from the last follow-up visit (FUV) before lockdown (BLD) (baseline [BL] visit) to the first FUV after lockdown (ALD) was assessed. A specific questionnaire was distributed to the participant centers to investigate further the reasons for treatment delay in all individual cases.

Results: A total of 245 eyes fulfilled the eligibility criteria, from which 39.6% were TTP (n=97) and 60.4% were DTP (n=148). TTP presented greater baseline and final BCVA compared to DTP (64.1 vs 58.7 letters, p=0.023, and 63.6 vs 57.1, p=0.004). BCVA loss was significantly greater for DTP vs TTP (-2.0 vs -0.6 letters, p=0.016). For DTP cohort, the primary reason for visit delay was patient decision (48.2%) followed by limited hospital clinic capacity (42.7%). When patients decided not to attend scheduled visits, the main reason was fear to Covid-19 infection (49.4%).

Conclusions: This study provides relevant data about the impact on visual outcomes of Covid-19 pandemic lockdown on nAMD patients and specifically provides new additional information regarding the main reasons for treatment and visits delay from both patients and healthcare service delivery perspectives.

ABSTRACT BODY:

Purpose: A small molecule activator of TrkB, HIOC, has been shown to protect against vision loss following ocular blast injury (Dhakal et al, J Neurotrauma 2021;38:2896). In this study, we assessed the protective effects of a fluoropyridine analog of HIOC.

Methods: Using HIOC as a lead structure, an analog (HIFN) containing fluorine substituted pyridine was synthesized. Adult male C57BL/6J mice were subjected to blast overpressure injury at ~20psi. Within 30 minutes of blast, animals were administered intraperitoneally either vehicle, HIFN or HIOC (40mg/kg). The treatment was continued for another 6 days. Contrast sensitivity at a spatial frequency of 0.064c/d and visual acuity (spatial frequency threshold) were measured using the optomotor response. Scotopic electroretinogram (ERG) and pattern ERG (spatial frequency of 0.155 c/d, 2.1 contrast reversal/sec and mean luminance of 50cd/m^2) were recorded. TrkB activation was assessed by western blot analysis of TrkB phosphorylation. Animals were administered with TrkB specific inhibitor, ANA-12 (0.5mg/kg), 2.5 h prior to treatment with compound.

Results: HIOC and HIFN both reduced the visual acuity ($p \leq 0.05$ vs Blast-Veh) and contrast sensitivity deficits after blast ($p \leq 0.05$ vs Blast-Veh). The protection of contrast sensitivity afforded by HIFN was better than that by HIOC at 7-week post blast ($p \leq 0.05$). No effects of blast, HIFN, or HIOC were observed in the scotopic ERG a-wave or b-wave amplitudes. At 8-week post blast there was a significant decline in P1 and N2 wave amplitude of pERG in Blast-Veh group ($p \leq 0.001$). HIFN and HIOC treatment reduced the decline in P1 amplitude ($p \leq 0.05$ vs Blast-Veh). HIFN and HIOC showed a trend to increase the N2 amplitude compared to vehicle, but the effects were not statistically significant ($p=0.06$ vs Blast-Veh). HIFN activated TrkB at a concentration of 10 nM in NIH/3T3 cells expressing human TrkB. The TrkB inhibitor, ANA-12, blocked the protective effects exhibited by HIFN and HIOC in blast animals.

Conclusions: HIFN protects against blast-induced vision loss and retinal ganglion cell damage, as assessed by pERG. HIFN appears to preserve contrast sensitivity better than HIOC, although this needs to be assessed at different drug doses. The protective effects of HIFN are due to activation of TrkB receptor.

TITLE: Effect of N0651 on ocular inflammation in endotoxin-induced uveitis and autoimmune uveitis in the rat.

SESSION TITLE: Anti inflammatory agents, antibiotics and antivirals

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Burgoyne, E. DeBruin, N. Hatfield, J. Langlands, Naegis Pharmaceuticals Inc., British Columbia, CANADA|

Commercial Relationships Disclosure: David Burgoyne: Commercial Relationship(s);Code O (Owner):Naegis Pharmaceuticals Inc.;Code E (Employment):Naegis Pharmaceuticals Inc. | Erin DeBruin: Commercial Relationship(s);Code E (Employment):Naegis Pharmaceuticals Inc. | Nicolas Hatfield: Commercial Relationship(s);Code E (Employment):Naegis Pharmaceuticals Inc. | John Langlands: Commercial Relationship(s);Code E (Employment):Naegis Pharmaceuticals Inc.;Code O (Owner):Naegis Pharmaceuticals Inc.

ABSTRACT BODY:

Purpose: Uveitis is a common cause of visual disability and blindness. Experimental models of uveitis have been developed in rats by injection of endotoxin (endotoxin induced uveitis; EIU) or immunization with ocular antigens (experimental autoimmune uveitis; EAU). N0651 is a novel compound inhibiting the production of leukotrienes C4 and B4 (LTC4/B4) with greater potency than zileuton. Studies were undertaken to evaluate the effect of N0651 on measures of inflammation in EIU and EAU in the rat.

Methods: EIU was induced in Lewis rats by injection of 75 µg LPS into the hind paw. Levels of inflammation in the eye were assessed after 24 hrs by clinical score and histologically. N0651 (30 mg/kg) and prednisolone (2 mg/kg) were administered orally at the time of LPS challenge and 6 hrs post challenge.

EAU was induced in Lewis rats by injection of R16 peptide (30 µg) in 200 µL of complete Freund's adjuvant in the base of the tail. Clinical signs of disease were evident 6 days after immunization. Animals were treated with N0651 topically 4 times daily (10 µL/eye; 0.5% solution) plus a single daily oral dose (30 mg/kg) after ocular clinical signs of uveitis were observed.

Results: In the EIU model, N0651 (30 mg/Kg) reduced the clinical scores from 7 to 4 (max possible score 7), and histological examination of eyes showed N0651 reduced cell content and fibrin content in the aqueous humor and cornea. The effect on clinical score was comparable to that seen with prednisolone, however, the effect on both cell content and fibrin deposition in the cornea were minimal.

In the EAU model, clinical scores were reduced after topical + oral N0651 compared to control (median 1.25 vs 2.75; maximum possible score 4). Histological scoring of the posterior segment demonstrated lower disease severity (median 2 vs 3.75; maximum possible score 4), and reduced retinal thickness in N0651 treated animals compared to untreated (139.5 vs 185.5 nm).

Conclusions: N0615 affords protection against development of uveitis in both the EIU and EAU models,demonstrating effects at both the anterior and posterior segments in each model, respectively.

TITLE: High axial resolution optical coherence tomography images show important features in patients with age-related macular degeneration

SESSION TITLE: OCT Clinical Applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Dolz-Marco, R. Gallego Pinazo, Unit of Macula, Oftalvist, Valencia, Valencia, SPAIN|

Commercial Relationships Disclosure: Rosa Dolz-Marco: Commercial Relationship(s);Code C (Consultant/Contractor):Heidelberg Engineering, Novartis, Roche;Code F (Financial Support):Novartis, Roche, IveriBIO, Celltrion | Roberto Gallego Pinazo: Commercial Relationship(s);Code C (Consultant/Contractor):Novartis, Roche, ORA clinical, Carl Zeiss Meditec;Code F (Financial Support):Novartis, Roche, IvericBIO, Celltrion

ABSTRACT BODY:

Purpose: To evaluate the clinical benefit of high axial resolution optical coherence tomography (OCT) images in patients diagnosed with age-related macular degeneration (AMD) using a research OCT prototype (High-Res OCT, Heidelberg Engineering, Germany) with 3 µm optical resolution.

Methods: Patients diagnosed with AMD undergoing routine macular evaluation were scheduled for High-Res OCT imaging. The examination included OCT, OCT angiography, fundus autofluorescence, and multispectral images acquired with commercially available OCT device (SPECTRALIS) and High-Res OCT images acquired using the research prototype. Findings observed on the High-Res OCT images were compared and correlated with the conventional OCT and multimodal approach.

Results: One-hundred eleven eyes of 63 patients were included. A better delineation of retinal layers was achieved with increased contrast between layers in the High-Res OCT images. The status of the outer retinal bands (external limiting membrane, photoreceptors ellipsoid and interdigitation zones) and the content of the retinal pigment epithelium (RPE) detachment both in neovascular and non-neovascular cases were better assessed in High-Res images when compared to conventional OCT. A significant split between the RPE layer and Bruch's membrane was observed in the majority of cases (84%) in the foveal area and also extending throughout the macula and was not evident on conventional OCT.

Conclusions: High-Res OCT images provided a detailed representation of structures in the retina not seen with conventional OCT axial resolution (about 7 µm). A better delimitation between layers was observed, and better assessment of important biomarkers in AMD cases was achieved, which might be beneficial in the improvement of segmentation algorithms and clinical evaluation of these cases.

TITLE: Elucidating strain-dependent responses of Shroom3 in lens epithelial cell proliferation

SESSION TITLE: Lens Biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.M. George, H.L. Chandler, T.F. Plageman, The Ohio State University College of Optometry, Columbus, Ohio, UNITED STATES|H.L. Chandler, The Ohio State University College of Veterinary Medicine, Columbus, Ohio, UNITED STATES|

Commercial Relationships Disclosure: Stephanie George: Commercial Relationship: Code N (No Commercial Relationship) | Heather Chandler: Commercial Relationship: Code N (No Commercial Relationship) | Timothy Plageman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The mechanisms underlying an increased lens size due to lens epithelial cell proliferation in presbyopia remain unknown. Biomechanical strain is hypothesized to be a contributor, as the zonules attach to the lens germinative zone. Shroom3, a cytoskeletal protein, is necessary for ocular development and facilitates lens placode invagination. Preliminary studies demonstrate that Shroom3 mutants lack ventral optic cup closure, illustrating the significance of Shroom3 in epithelial folding, fusion, and potentially, proliferation. We hypothesize inducing intercellular strain through Shroom3 overexpression increases proliferation in vitro.

Methods: Model epithelia, Madin-Darby canine kidney (MDCK) cells, were transfected with Shroom3 to create a stable line (pTre3-Shroom3-mCherry) inducible with doxycycline with dual selection hygromycin/G418. Once cells reached confluence on glass coverslips, EdU was incorporated into cells for 18 hours and fixed with paraformaldehyde. Cells were imaged throughout the coverslip centrally and peripherally (n=5) using Zeiss Axio Observer (N=3). MDCK wildtype (wt) cells were used to control for the effect of doxycycline. The number of nuclei and EdU^{+} cells were counted using ImageJ. Statistical analysis was performed using two-tailed Student's t-test.

Results: SHROOM3 overexpression resulted in significantly reduced mitosis, as shown through nuclei counts ($p \leq 0.001$) and percentage of EdU^{+} cells ($p \leq 0.001$). The addition of doxycycline affected proliferation differently depending on the location of cells on the coverslip. Peripheral $doxycycline^{+}$ wt cells showed decreased proliferation ($p \leq 0.05$) compared to pTre3g-Shroom3-mCherry $doxycycline^{-}$ cells, but not compared to peripheral $doxycycline^{-}$ wt cells. Central $doxycycline^{+}$ wt cells showed decreased proliferation ($p \leq 0.05$) compared to $doxycycline^{-}$ wt cells but not to pTre3g-Shroom3-mCherry $doxycycline^{-}$ cells.

Conclusions: Our results contradict our hypothesis and instead show that Shroom3 decreases proliferation. Although doxycycline affected proliferation both centrally and peripherally, results were not consistent between cells with/without doxycycline; our results can be attributed to SHROOM3 expression levels. Future experiments will apply these methods to in vivo models.

ABSTRACT BODY:

Purpose: Complement factor H (CFH) inhibits the alternate pathway of the complement system. Compromised CFH expression causes immune system imbalance and complement-mediated damage to healthy cells. CFH expression and activity changes are associated with increased risk of age-related macular degeneration (AMD), but the relative contributions of CFH from the retinal pigmented epithelium (RPE) and the choroid are not known. Here we aim to study the effects of CFH in choroid versus RPE using CFH knockout (KO) iPSCs and the 3D bioprinting technique.

Methods: iPSC line from a healthy donor (wildtype, WT-iPSC) was genetically modified to generate a CFH-KO-iPSC using CRISPR/Cas9 technology. Both WT- and CFH-KO-iPSC lines were differentiated into RPE, endothelial cells (EC), pericytes, and fibroblasts and validated by immunophenotyping. Capillary formations by iPSC-derived cells were assessed by a hydrogel tubulogenesis assay combining ECs, pericytes, and fibroblasts matured for 3 weeks. 3D-bioprinting was performed on a biodegradable PLGA scaffold for choroid formation and the RPE monolayer seeded on the other side of the scaffolds. Live images of GFP expression from ECs were documented for capillary formation and maturation for 5 weeks after 3D-bioprinting.

Results: All differentiated cell components from WT- and CFH-KO-iPSC were cryopreserved and thawed successfully prior to functional validation and 3D bioprinting. CD31+ EC was verified by acetylated-Dil-LDL uptake, hydrogel tubulogenesis, and expression of CD146 and vWF, ETV2, PLVAP, CA4, and RGCC. Pericytes were differentiated from CD31- cells with TGF-b3 and PDGF-bb and confirmed the expression of PDGFR-b, NG2, CD44, and a-SMA. Fibroblasts were differentiated from pericytes and expressed vimentin, connexin43, and collagen-I. EC, pericytes, and fibroblasts were assembled into capillary-like structures in 3D hydrogel tubulogenesis assay up to 3 weeks. Bruch's membrane formation in bioprinted tissues was confirmed by the expression of fibronectin, collagen-I, laminin, and elastin.

Conclusions: Our results show that all four cell components (RPE, EC, pericytes, and fibroblasts) were differentiated from WT- and CFH-KO-iPSC with compatible protein expressions. Using these cell components we generated 3D-bioprinted ex-vivo choroid-RPE system that provides as a tool to investigate the disease mechanism and the role of anaphylatoxins in RPE versus the choroid.

TITLE: Ocular Pulse Amplitude (OPA) in Canine ADAMTS10-Open-Angle Glaucoma (ADAMTS10-OAG)

SESSION TITLE: Animal models of human ocular disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: V. Raphtis, D. Sharma, A. Anderson, C. Harman, A.M. Komaromy, Michigan State University, East Lansing, Michigan, UNITED STATES|

Commercial Relationships Disclosure: Vanessa Raphtis: Commercial Relationship: Code N (No Commercial Relationship) | Dhruv Sharma: Commercial Relationship: Code N (No Commercial Relationship) | Amanda Anderson: Commercial Relationship: Code N (No Commercial Relationship) | Christine Harman: Commercial Relationship: Code N (No Commercial Relationship) | Andras Komaromy: Commercial Relationship(s);Code F (Financial Support):Reichert Technologies

ABSTRACT BODY:

Purpose: To evaluate the effect of the G661R missense mutation in the ADAMTS10 gene on ocular pulse amplitude (OPA) in dogs.

Methods: Animals studied included 39 glaucomatous and 14 unaffected control male and female dogs between the ages of 6 months and 12 years (median: 3.2 years). Dogs were sedated with butorphanol and midazolam and average of both right and left eye were measured. Intraocular pressure (IOP) was measured with the Icare® Tonovet rebound tonometer. The Reichert Model 30™ Pneumotonometer was used to measure OPA, deviation index, and pulsation rate. During each session, measurements were taken twice, once for acclimation to the probe and noise of the pneumotonometer, and a second time for actual data collection. Central corneal thickness (CCT) measurements were taken via Accutome® PachPen, and A-scan biometry assessed with DGH Technology Scanmate. Data analysis was conducted with ANOVA, ANCOVA and regression models.

Results: Mutant dogs had a significantly lower OPA of 4.24 +/- 2.05 mmHg (mean +/- SD) compared to 6.54 +/- 2.83 mmHg of normal dogs (p=0.002). There was no significant age effect, and OPA was not correlated with any other parameters, including CCT. As expected, mutant dogs displayed a greater mean IOP of 25.04 +/- 8.04 mmHg compared to 15.25 +/- 3.59 mmHg of normal dogs.

Conclusions: The lower OPA in ADAMTS10-mutant dogs corresponds to previously documented weaker and biochemically distinct posterior sclera. OPA measurement could be a valuable in vivo clinical tool to assess individuals' scleral biomechanics, and therefore their susceptibility to IOP elevation.

ABSTRACT BODY:

Purpose: Elevated intraocular pressure (IOP) is a major risk factor for open angle glaucoma (OAG). During each heartbeat, IOP exhibits pulsations described as ocular pulse amplitude (OPA). OPA has been shown to be relevant in glaucoma as IOP and OPA are affected by several factors, including systolic and diastolic blood pressure (SBP, DBP), tissue biomechanics, and aqueous humor (AH) flow. Here, we use a mathematical model to investigate how IOP and OPA are influenced by variations in SBP, DBP, and model parameters characterizing tissue biomechanics and AH flow in comparison with clinical data.

Methods: The model calculates IOP and OPA from the balance between AH inflow and outflow, the pulsatile BP inputs, and the deformability of ocular tissues. Two simulation scenarios are considered (health and disease), with the latter characterized by an outflow facility reduced by 70% with respect to baseline. In both scenarios, physiological variations are included in SBP and DBP as normal distributions [SBP~ N (124.1, 11.1) and DBP ~ N (77.5, 7.1)]. Variations in all other model parameters were assumed to follow a uniform distribution [± 15% with respect to published baseline values (Szopos et al 2016, Stefanoni et al 2018)].

Results: The table in Fig.1 compares model predictions for IOP and OPA with clinical data on 90 healthy subjects (Cheng et al, 2017) and 115 glaucoma patients. In both health and disease, model results are within the same range of clinical data. Fig. 2 shows the scatterplots of OPA versus pulse pressure (PP=SBP-DBP) as computed by the model (a) and measured clinically (b) on glaucoma patients. When fitted with a linear regression, both computed and measured data had a positive slope of 0.0265 and 0.0122, respectively.

Conclusions: The model proved capable of simulating IOP and OPA in health and disease. OPA was predicted to increase with PP as evidenced by clinical data on glaucoma patients. These data suggest mathematical modeling approaches may help clinicians confirm and/or discriminate OAG disease.

TITLE: Factors influencing chorioretinal biomechanical responses to IOP

SESSION TITLE: Glaucoma: biochemistry, biomechanics and omics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Pan, S. Kwok, J. Liu, Department of Biomedical Engineering, The Ohio State University, Columbus, Ohio, UNITED STATES|J. Liu, Department of Ophthalmology and Visual Sciences, The Ohio State University, Columbus, Ohio, UNITED STATES|

Commercial Relationships Disclosure: Manqi Pan: Commercial Relationship: Code N (No Commercial Relationship) | Sunny Kwok: Commercial Relationship: Code N (No Commercial Relationship) | Jun Liu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A positive intraocular pressure (IOP) stretches the ocular shell and its inner lining: the chorioretinal tissue. Interestingly, chorioretinal folds occur under certain conditions despite the stretch created by IOP. In this study, we developed a computation model to determine which biomechanical factors most influenced chorioretinal stresses and strains and the implications for chorioretinal folds.

Methods: A computational model of the eye with two layers, the sclera and the chorioretina, was developed (Fig. 1A). Seven input factors including scleral/chorioretinal thickness, scleral/chorioretinal Poisson's ratio, scleral/chorioretinal modulus, and IOP were independently varied within the reported ranges in the human eye (Fig. 1B). The mean in-plane stress and strain of the chorioretina were quantified as outcome measures. Input factors were ranked based on their relative influence on the outcome measures.

Results: Under all simulated conditions, the chorioretinal tissue experienced a positive in-plane strain but a negative in-plane stress (Fig. 1C, D). The 3 inputs that had largest influence on chorioretinal stress were, ranked in order, IOP, scleral modulus, and chorioretinal Poisson's ratio (Fig. 2). The 3 inputs that had largest influence on chorioretinal strain were, ranked in order, scleral modulus, IOP, and chorioretinal Poisson's ratio (Fig. 2). The mean in-plane stress within the chorioretina during IOP change from 10 to 30 mmHg was -1.15 to -3.46 kPa. The mean in-plane strain within the chorioretina was 1.13% to 0.14% when sclera modulus changed from 1 to 9 MPa.

Conclusions: The chorioretinal tissue experiences a negative in-plane stress which may underlie localized folding. This stress is strongly dependent on IOP, while sclera modulus has the largest effect on the in-plane strain. Changes in either may induce chorioretinal folds, consistent with clinical observations. These results provide new biomechanical insights into chorioretinal folds.

L. Gore & Associates, Deerfield, Trinity Partners, Kala Pharmaceuticals, Acucela, Ionis Pharmaceuticals.;Code F (Financial Support):Bayer

ABSTRACT BODY:

Purpose: Cataract surgery is commonly performed in patients with retinitis pigmentosa (RP), but concern exists regarding the possibly heightened risk of postoperative cystoid macular edema (CME). We evaluated the association between RP and postoperative CME after cataract extraction (CE).

Methods: We analyzed eight years of longitudinal data from the IBM MarketScan® database (2010 – 2018) and included patients aged 18 to 65 years who underwent single-phase CE. We excluded CME and diabetic macular edema cases at baseline. Incident postoperative CME in the same eye that underwent CE was assessed. A mixed-effects Cox model estimated the hazard ratio (HR) and 95% confidence intervals (CI) for the association between CME and RP, controlling for sex, age, diabetes, hypertension, epiretinal membrane (ERM), and retinal vein occlusion. Johns Hopkins University Institutional Review Board approved this project.

Results: The cohort included 468,123 subjects and 615,645 eyes: 124 with RP and 615,521 without RP. Median follow-up was 9.06 months (95% CI, 9.06 – 9.09). Postoperative CME was reported in 4,933 eyes (0.8%). Subjects with RP had 4.83 times the risk of CME (95% CI, 2.13 – 10.92; P<0.001) than those without RP but with similar characteristics. On average, RP cases developed CME 3.9 weeks later than those without RP (95% CI, 2.04 – 6.5; P<0.001). In the cohort, baseline ERM was associated with higher risk of postoperative CME (HR, 4.30, 95% CI, 3.12 – 5.93; P<0.001). Age was inversely associated with CME; subjects aged 55 to 65 had 52% lower risk of postoperative CME (95% CI, 39% – 62%; P<0.001) than those aged 18 to 34. However, when stratified by RP status, neither baseline ERM nor age had the same effect in RP eyes. In these subjects, ERM had a protective effect (HR, 0.12; 95% CI= 0.48 – 0.97; P=0.004), and age did not significantly influence the risk, although it had a bimodal distribution.

Conclusions: Postoperative CME among RP patients may be significantly higher than candidates without RP but otherwise similar characteristics. In addition, CME in RP patients may have a delayed presentation, necessitating longer follow-up. Understanding this risk will facilitate clinician-patient communication regarding treatment recommendations and vision-impacting complications. Future research should focus on interventions to reduce CME risk in RP patients.

TITLE: Indications and Outcomes of Surgery for High Myopia: STAAR Intraocular Collamer Lens (ICL) vs. LASIK

SESSION TITLE: Refractive and non-refractive corneal surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C.S. Bouchard, K. Kirk, Ophthalmology, Loyola University Health System, Maywood, Illinois, UNITED STATES|Y. Ren, Rosalind Franklin University of Medicine and Science Chicago Medical School, North Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Charles Bouchard: Commercial Relationship: Code N (No Commercial Relationship) | Kent Kirk: Commercial Relationship: Code N (No Commercial Relationship) | Yanhan Ren: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Although the ICL is more invasive than laser-assisted in situ keratomileusis (LASIK), it is indicated for patients with very high myopia, commonly over -7D. ICL is associated with certain risks including cataract and glaucoma which may develop years after surgery requiring additional procedures. In this study, we examined the outcome and safety profile of ICL vs. LASIK at 1 week, 1 month, and 1 year postoperatively.

Methods: In this retrospective study, we examined records from a single surgeon (KK) as well as 2 patients with post ICL complications requiring ICL removal. An important aim of this study was to use the 1 year follow up data since this is one of the standard ICL follow up visits. We hypothesized that the FDA approved ICL (2005) would have a comparable target refractive outcome and safety profile when compared to LASIK.

Results: There were a total of 45 ICL eyes and 65 LASIK eyes. Preoperatively, ICL patients had a significantly higher manifest refraction spherical equivalent (MRSE) and cycloplegic refraction spherical equivalent (CRSE) than LASIK patients ($p<0.05$). For patients who received the ICL implants, the average MRSE at 1-week, 1-month, 1-year post-op was -0.37D±(0.13), -0.29D±(0.09), -0.53D±(0.15); and -1.60D±(0.16), -0.36D±(0.15), -0.36D±(0.07) for patients who received LASIK. The differences in post-op MRSE between ICL and LASIK were not statistically significant ($p>0.05$). The only significant differences were 1 month LogMAR best corrected visual acuity and 1 year LogMAR distance uncorrected visual acuity ($p<0.05$), in which LASIK had better visual acuity. Common postoperative findings in both groups were refractive target deviations and punctate keratitis. Reoperation rates in the ICL and LASIK groups were 21.4% and 10.8% respectively, which was not statistically significant ($p>0.05$). 42.6% of ICL patients underwent the procedure during the COVID-19 pandemic compared to 26.2% of LASIK.

Conclusions: Our results demonstrate that ICL is safe and effective for patients with high myopia. Although ICL patients had a significantly higher preoperative MRSE compared to the LASIK group, the ICL patients were able to achieve similar refractive targets. There were no cases of glaucoma or cataract at 1 year in the ICL group. In conclusion, ICL surgery is as safe and effective as LASIK surgery in correcting patients with high myopia, regardless of pre-operative refractive error.

TITLE: Insulin promotes RGC dendrite regeneration through ribosomal protein S6 kinase activation leading to restoration of neuronal function in glaucoma

SESSION TITLE: Neuroprotection and neuroregeneration

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S. El Hajji, N.A. Belforte, Y. Shiga, F. Dotigny, A. Di Polo, Department of Neuroscience, Universite de Montreal, Montreal, Quebec, CANADA|S. El Hajji, N.A. Belforte, Y. Shiga, F. Dotigny, A. Di Polo, Centre Hospitalier de l'Universite de Montreal, Montreal, Quebec, CANADA|

Commercial Relationships Disclosure: Sana El Hajji: Commercial Relationship: Code N (No Commercial Relationship) | Nicolas Belforte: Commercial Relationship: Code N (No Commercial Relationship) | Yukihiro Shiga: Commercial Relationship: Code N (No Commercial Relationship) | Florence Dotigny: Commercial Relationship: Code N (No Commercial Relationship) | Adriana Di Polo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We previously demonstrated that insulin promotes RGC dendrite regeneration through activation of the mTOR pathway. However, the precise mechanisms of insulin-mediated regeneration and the effect of insulin on vision restoration are not well understood. Here, we asked: 1) what are the mTOR downstream effectors responsible for insulin-induced dendritic regrowth? 2) does insulin restore RGC function and visual responses in glaucoma?

Methods: Ocular hypertension (OHT) was induced by injection of magnetic microbeads in Thy1-YFP mice. Daily insulin or saline eye drops started at 2-weeks after OHT induction, when there is marked dendritic retraction, and dendrites were imaged and reconstructed 1 or 4 weeks later. The role of the mTORC1 downstream effectors, S6K and 4EBP1, was assessed by loss of function using targeted siRNAs. RGC survival and function were evaluated using complementary methods: i) quantification of RBPMS-positive neurons, ii) single-RGC calcium dynamics using two-photon microscopy live imaging in transgenic mice carrying the calcium indicator GCaMP6f, and iii) optomotor reflex assays.

Results: Insulin promoted a substantial increase in RGC dendritic length and complexity in glaucomatous eyes (n=6 mice/group, ANOVA, $p<0.001$). siRNA-based knockdown of S6K impaired insulin-mediated RGC dendrite regeneration, while 4EBP1 silencing had no effect. Intriguingly, S6K increased mTORC2 activity through phosphorylation of mSIN1 enhancing RGC dendrite regeneration. Insulin promoted robust RGC survival at 3 and 6 weeks of OHT induction relative to saline (OHT-3wks, insulin: 2057±34 RGC/mm^2, vehicle: 1679±66 RGC/mm^2, N=3-6 mice/group, ANOVA, $p<0.001$). Importantly, insulin restored light-evoked RGC calcium dynamics (n=6 mice/group, $p<0.01$) and improved visual acuity (N=5-8 mice/group, ANOVA, $p<0.01$) in glaucoma

Conclusions: Our data show that S6K is a key signaling component required for insulin-mediated RGC dendrite regeneration, an effect that is enhanced by cross-talk with mTORC2 through mSIN1 activation. Importantly, insulin prevents RGC loss while restoring light-evoked responses and visual acuity. These findings support a critical role for insulin as a pro-regenerative therapy and identify downstream targets to restore RGC connectivity and function in glaucoma

ABSTRACT BODY:

Purpose: To develop high speed and high resolution retinal imaging for precise measurement of the flow dynamics in the smallest to largest vessels in the living human retina.

Methods: An adaptive optics (AO) enhanced line scan imaging system employing a low coherent superluminescent near-infrared diode (λ=795 nm) as the imaging light source and a high speed line camera was designed to image the retina in a near-confocal mode. An anamorphic imaging mechanism was adopted to increase light collecting efficiency and ensure adequate digitization of optical resolution. To image the blood flow in vessels with a diameter < 10 μm, retinal images were acquired with a full 2D raster scanning mode of 512 lines/frame. Blood velocity was measured by the spatiotemporal traces of the red blood cells. To image blood flow in vessels with a diameter > 10 μm, the scanner was programmed to stop across the vessel in a frame thereby directly generating the spatiotemporal traces of the red blood cells within the vessel in this frame. The blood velocity profile across vessel lumen was measured by the slope of the spatiotemporal traces at different radial positions.

Results: With the full 2D raster scanning mode, the instrument produced retinal images with cellular level resolution at a frame rate of 400 frames/second (FPS) with a digitization of 512×512 pixels over a field of view of 1.2 deg ×1.2 deg. This mode allows for the red blood cells flowing the capillaries directly imaged. Blood velocity in vessels with a diameter up to 200 μm can be measured with the partial 2D mode.

Conclusions: The continuous velocity of the erythrocytes measured by high spatiotemporal resolution retinal imaging renders the fine profile of the erythrocyte movement. In-vivo study of high order hemodynamics that reflects the overall mechanical property of retinal vasculature is underway.

ABSTRACT BODY:

Purpose: Measurements of the pattern electroretinogram (pERG) and of the photopic negative response (PhNR) have been used to evaluate inner-retinal function in humans and in animal models of disease. The purpose of this study was to determine the correlation between these two electrophysiological measures using a commercially-available electrophysiology system.

Methods: 6-month-old, wild-type C57BL/6J female mice were tested (N = 9). Stimuli were generated by a Celeris rodent ERG system (Diagnosys, LLC, MA, USA), which was also used to record the ERG signals. The PhNR was elicited by a 20-cd-s-m^{-2} white flash presented against a 40 cd/m^2 green adapting field. The flashes were presented at a rate of 2 Hz and 200 response were averaged for analysis. The PhNR was calculated as the amplitude of the trough following the b-wave divided by the b-wave amplitude (PhNR/b). The pERG was elicited by a contrast reversing bar stimulus (bar width: 0.06 cycles/degree; mean luminance: 50 cd/m^2; reversal rate: 2.1/sec); 400 sweeps were averaged for analysis. The pERG waveform was characterized by a positive peak (P) followed by a negative trough (N). pERG amplitude was defined in two ways: 1) baseline to N (“N”); 2) P-to-N.

Results: The PhNR amplitude ranged from 2.6 to 11.3 μV and the latency ranged from 91.1 to 182.5 ms. The PhNR/b amplitude ratio ranged from 0.08 to 0.20. The pERG N ranged from 0.8 to 3.7 μV, whereas the pERG P-to-N ranged from 2.0 to 8.2 μV. The coefficient of variation (standard deviation/mean) was 0.30, 0.49, and 0.44 for the PhNR/b, P-N, and N amplitudes, respectively. The PhNR/b ratio was not correlated with pERG P-to-N ($r = 0.25$, $p = 0.52$), but was correlated significantly with pERG N ($r = 0.70$, $p = 0.04$).

Conclusions: The significant correlation between the PhNR/b ratio and the pERG N component suggests that these measures may share a common retinal source. Although the variability among measures is similar, PhNR measurement may have practical advantages over pERG recordings in rodent models.

ABSTRACT BODY:

Purpose: Frequent home-based visual field (VF) testing using portable perimetry devices, such as the tablet-based Melbourne Rapid Fields (MRF, M&S Technologies, Niles, IL, USA), has been proposed to improve earlier detection of glaucoma progression. This pilot observational study evaluated MRF in terms of test reproducibility.

Methods: Subjects who were either glaucoma suspects or who had a glaucoma diagnosis were recruited during regular clinic visits. After a training session in the office with MRF, subjects were loaned tablets with pre-installed MRF software and instructed to take VF tests at home daily for one week as a training period, then weekly thereafter for three months. To assess a learning effect during the first week, longitudinal analysis with a fixed effects model was used to calculate the change of the group mean over time for test performance as measured by mean deviation (MD) and pattern standard deviation (PSD), and an asymptotic regression model was fit to the first five tests.

Results: Fifty-two subjects with a mean age of 62 years (range 30-79) are included in this analysis. There was a significant learning effect between the first and second test, as evidenced by a significant difference in MD (0.63 dB, CI = [0.06, 1.21], P = 0.031) and PSD (-0.58 dB, CI = [-1.05, -0.12] P = 0.013). The average MD and PSD of the second and third tests was similar to that of subsequent tests during the first week. Similarly, in an asymptotic regression model, 99.5% of the asymptote was reached for MD and PSD already after the second test, which indicates that nearly all learning had been completed prior to the second test.

Conclusions: Preliminary results show a strong learning effect from the first MRF test done independently by subjects. As we look to operationalize the use of new VF devices for at home monitoring, these data suggest that an average of the second and third MRF tests can be used as a baseline measure. Participants seem to reach a performance “steady state” starting with their second test.

ABSTRACT BODY:

Purpose: To investigate the ability of macular and circumpapillary retinal nerve fiber (cpRNFL) change rates and clinical/demographic factors to predict development of glaucoma from glaucoma suspects (GS) through elastic net regression (ENR) and machine learning (ML) models.

Methods: 162 eyes of 146 patients with GS were included. The eyes were required to have characteristic glaucomatous optic nerve changes without visual field (VF) defects. Development of glaucoma was defined as having VF glaucoma hemifield test outside normal limit and pattern standard deviation 5% in 3 consecutive exams. Global and sectoral rates of change of macular ganglion cell/inner plexiform layer (GCIPL) and cpRNFL OCT were calculated with linear mixed-effect models. The ENR and ML models, gradient boost model (GBM), support vector machine (SVM) and Naïve Bayes (NB) were fit for structural rates of change and clinical/demographic parameters in order to predict the development of glaucoma in GS. Parameter tuning with Grid Search Method and 5-fold cross validation were applied for each ML model.

Results: 47 eyes developed glaucoma based on the study criteria. The average follow-up time was 2.3 and 2.1 years for glaucoma and GS eyes, respectively. The rates of average GCIPL were significantly faster in the eyes that converted to glaucoma (= –0.10, P<0.001) and the average cpRNFL rates was not significant (= –0.15, P=0.152). Predictive factors that were selected by ENR were average, minimum, superior and temporal superior GCIPL change rates and average intraocular pressure (IOP) during follow-up (AUC (95% confidence interval (CI)=0.71 (0.62, 0.80)). Parameters with highest relative importance from GBM were average GCIPL rates, average IOP during follow-up, age, axial length temporal superior and temporal inferior GCIPL and temporal cpRNFL change rates (Figure 1). The AUC (95% CI) for prediction of glaucoma development was 0.91 (0.86, 0.97), 0.87 (0.81, 0.92) and 0.82 (0.75, 0.89) for GBM, SVM and NB, respectively (Figure 2).

Conclusions: Development of glaucoma in glaucoma suspect eyes can be predicted from longitudinal macular and cpRNFL OCT data and average IOP during follow-up with clinically relevant accuracy. The proposed models may assist clinicians to predict better the development of glaucoma.

ABSTRACT BODY:

Purpose: We have previously shown a correlation between Treg dysfunction and enhanced APC maturation in the graft site of recipients at high-risk (HR) of rejection, at early stages after corneal transplantation. Herein, we investigated graft site environment-induced function changes of Treg in HR recipients.

Methods: High risk (HR) and low risk (LR) allogeneic corneal transplantations were performed using C57BL/6 mice as donors and BALB/c as hosts. On days 3 and 7, post-transplantation $CD4^{+}CD25^{+}FoxP3^{+}$ Tregs and prototypical phenotypic maturation markers on $CD11b^{+}MHC\text{-}II^{high}$ APCs were assessed. Bone marrow GM-CSF-generated $CD11b^{+}$ APCs were preconditioned with Tregs FACS-sorted from the graft-site of HR or LR in the presence of LPS (100ng/ml) and IL-2 (10ng/ml) and sonicated allogenic splenocytes (1:20:21) for 48 hours. Then, Tregs were removed, and $CD4^{+}CD25^{-}$ naïve T cells were added for 5 days. Next, MACS-sorted naïve Tregs from naïve mice were cultured with IL-6, with or without anti-IL-6R antibody for 12 hours, and co-cultured as above. Tregs from LR recipients were injected in newly HR host, and vice versa. Readouts included flow cytometry, ELISA, RT-PCR, and clinical follow-up.

Results: Treg frequencies and their expression levels of FoxP3 were significantly lower in HR compared to LR ($p<0.01$). The frequency of $FoxP3^{+}$ Treg expressing alpha E integrin (CD103) was significantly lower in HR vs. LR ($p<0.001$) as well as the expression of IL-6R ($p<0.001$). Frequencies of $MHC\text{-}II^{high}$, CD80, CD86, and CCR7 in $CD11b^{+}$APC, as well as IFN-g production by CD4+ T cells, $^{+}$ T cells were found significantly higher when APCs were preconditioned with Treg from HR recipients vs. LR ($p<0.001$). This was recapitulated when APCs were preconditioned with naïve Treg pretreated with IL-6. Finally, adoptive transfer of Treg from LR to HR recipient mice suppressed the expression of maturation markers in the grafted cornea ($p<0.001$) and led to 55% allograft survival ($p<0.0001$); while adoptive transfer of HR Treg to LR host increased the expression of those markers ($p<0.001$) and led to 100% allograft survival ($p<0.0001$).

Conclusions: These results demonstrate that the transplant environment alters the regulatory function of the graft site’s early infiltrated Treg, and suggest that highly functional Treg could be a potential therapeutic approach to improve survival in HR corneal transplants.

ABSTRACT BODY:

Purpose: In mammals, loss of retinal cells due to disease or trauma is an irreversible process which leads to blindness. Interestingly, regeneration of retinal neurons is a well-established process in some non-mammalian vertebrates and is driven by the Muller glia (MG) which are able to re-enter the cell cycle and reprogram into neurogenic progenitors upon retinal injury or disease. Progress has been made to “translate” this mechanism to mammals to promote retinal regeneration. A breakthrough in the field was the demonstration that MG can generate new neurons in vivo in the adult mouse retina after the overexpression of the pro-neuronal transcription factor Ascl1. In this study, we show that the same strategy could be applied to regenerate retinal neurogenic progenitors using human MG in vitro.

Methods: In human fetal development, MG appear following a temporal central to periphery gradient in the retina and, can first be identified at Day 73 in the center and later (D100) in the periphery. We have developed protocols for obtaining in vitro 2D cultures of MG dissociated from stem cell-derived organoids over 150 days of age. MG cultures were characterized with immunostaining and single cell RNA sequencing (scRNA-seq). We used lentivirus mediated gene delivery for over-expression of ASCL1 (CMV-ASCL1-GFP). The addition of EdU to the culture combined with GFP allowed us to track newly generated cells to control for any surviving neurons from the initial dissociation of the organoids. To determine whether ASCL1 induces neurogenesis in human MG, we used scRNA-seq analysis and Immunolabeling (IHC) for neuro-specific antibodies and EdU.

Results: IHC analysis showed that MG are present in retinal organoids around Day 180. MG derived from organoids can be grown and passaged in 2D cultures, are of good purity and contain only few surviving neurons. MG can also be frozen for cell banking. When infected with a lentivirus driving ASCL1-GFP, the human MG can be reprogrammed to a neurogenic state as assessed with IHC, and by using scRNA-seq. Our study demonstrates for the first time that Ascl1 can reprogram human MG into neurogenic progenitor cells in vitro.

Conclusions: Our work demonstrates the first evidence of regenerative capacity of MG in human.

ABSTRACT BODY:

Purpose: Dehydrodolichyl diphosphate synthase (DHDDS) catalyzes the committed step for dolichol synthesis, required for protein N-glycosylation. Its mutations underlie RP59 (OMIM# 613861). Here, we describe development of novel RP59 mouse models, using Bestrophin1 (BEST1)- and cone-rod homeobox (CRX) Cre-driven Dhdds ablation.

Methods: Dhdds$^{flx/flx}$ mice were bred against BEST1-Cre or CRX-Cre mice and against ZsGreen reporter mice to achieve Dhdds ablation in RPE/Müller glia cells or photoreceptor (PR)/bipolar (BP) cell progenitors, respectively. Controls: wildtype (WT) C57BL/6J mice, and CRX-Cre and BEST1-Cre mice bred against ZsGreen reporter mice. Western blot (WB) ±PNGase-F was performed on retinas from PN 4-wk old Dhdds KO vs. WT mice, probing with anti-RHO (1D4). Ectopic Cre expression was monitored using a blue light box. Immunohistochemistry (IHC) against RHO, GFAP, and GLUL, and ERG analysis was performed on all mouse lines (N=3/group). Statistical analysis: Student's t-test, $P<0.05$ (significance threshold).

Results: CRX-Cre mice expressed Cre in PR and BP cells. BEST1-Cre-ZsGreen mice showed Cre activity in RPE/Müller cells, with "leaky" expression in BP cells. Whole body green fluorescence revealed ectopic expression. Dhdds ablation using the ectopic BEST1-Cre line led to panretinal degeneration. ERG outcomes were a function of Cre expression in individual lines. BEST1-Cre Dhdds$^{flx/flx}$ mice exhibited significantly decreased ERG responses, vs. controls.. Remnant retinal cells in leaky Best1-Cre Dhdds$^{flx/flx}$ mice were mostly ZsGreen-negative. Dhdds deletion in PR/BP progenitor cells caused early-onset retinal degeneration with null ERG responses at PN 4-wk. IHC and TUNEL analysis of PN 4-wk KO retinas revealed >90% loss of PR and BP cells. However, WB (RHO+) results were comparable for mutant vs. WT retinas, indicating no protein N-glycosylation defect.

Conclusions: Use of a ZsGreen reporter background afforded confirmation of targeted vs. ectopic Dhdds, highlighting the importance of including a fluorescent reporter background in studies involving Cre-LoxP system-dependent, spatially restricted ablation of target genes. Retinal degeneration, rather than dysplasia, was observed, despite initiation of early-onset Dhdds ablation. These findings suggest that PR and BP cells are highly sensitive to loss of CPT activity.

ABSTRACT BODY:

Purpose: Accumulating evidence suggests an involvement of adaptive immune responses in the pathophysiology of glaucoma. The purpose of this study was to determine if differences in the T-cell populations exist between patients with primary open angle glaucoma (POAG) and age-matched controls.

Methods: Peripheral blood mononuclear cells (PBMC) were obtained from POAG patients (n=60) and age matched controls (n=40). T-cells were then profiled by fluorescence assisted cell sorting (FACS) using a panel of 29 cell surface markers. In a second experiment, PBMC were stimulated with phorbol myristate acetate (PMA) and ionomycin and analyzed using a panel of 18 cytokine markers. Data were collected on a Cytek® Aurora equipped with five lasers and 64 detectors and analyzed with SpectroFlo and FlowJo software. Data are given as frequencies of total cell number in each sample.

Results: Few differences between POAG and control samples were detected among unstimulated T cell populations. However, there is a significant increase of naïve CD4 T cells in POAG patients (POAG: 4114%; controls: 3415%; P=0.036). However, upon ex vivo stimulation several significant differences in CD4 cell populations are apparent. These include increased frequencies in POAG samples of CD4 T cells expressing CD154 (POAG: 6511%; controls: 537%; P=0.017), naïve CD4 T cells numbers expressing IFN (POAG:10.5%; controls: 0.40.1%; P=0.001), and TNF (POAG: 136%; controls: 73%; P=0.003). Likewise, there was a significant increase in IL-17A expressing central memory cells (POAG: 0.6 controls 0.4 P=0.049). In contrast, a significant decrease in IL-21 (POAG:2 ctrls:5P=0.0002) and IL-17 (POAG: 0.2 controls: 0.4P=0.011) effector memory cells was detected in the POAG cohort. No differences in the CD8 T cells population between POAG and control samples were observed.

Conclusions: Our data suggest that trafficking of central memory cells and/or effector CD4 memory cells is altered in POAG patients. Additionally, the T cell activation threshold is reduced in POAG patients. These findings indicate that T cells in POAG patients are more likely to actively contribute to pro-inflammatory signaling than those of controls.

ABSTRACT BODY:

Purpose: Fibrosis is a glaucoma filtration surgery (GFS) problem that often demands reoperation. At present, different antifibrotic drugs are used to inhibit fibrosis with unsatisfactory results. Only a few GFS mouse models for drug research exist. These are difficult to perform and complicated by the big murine lens, which can easily be damaged while penetrating the anterior chamber. We designed the first GFS mouse model without anterior chamber penetration, leaving the lens safely untouched.

Methods: Baseline intraocular pressure (IOP) was measured under inhalation anesthesia. Then, surgery was performed in six C57BL/6J mice under general anesthesia. A 27G needle was inserted into the conjunctiva and slid forward subconjunctivally close to the limbus. The sclera was penetrated, and a fistula was created between the posterior chamber and subconjunctival space. Afterwards, clinical examination and IOP-measurement under inhalation anesthesia followed every two days for two weeks.

Results: Postoperatively, a filtering bleb was seen in every mouse (n=6). Mean IOP decreased from 14.2 mmHg (±3.0 SD) at baseline to 8.33 mmHg (±0.9) on day two after surgery. The conjunctiva was elevated until day two in every mouse. Between days four and eight, pigment and stronger conjunctival injection were seen at the fistula, as well as a significant IOP rise. From day eight onwards, IOP stayed at baseline values; the GFS bleb was flat again.
Mean IOP values (±SD) during follow-ups were: 11.5 mmHg (± 3.7) at day 4, 13.0 mmHg (±2.7) at day 6, 9.6 mmHg (±2.0) at day 8, 13.2 mmHg (±1.2) at day 10, 14.4 mmHg (±0.2) at day 12, and 15.2 mmHg (±2.8) at day 14. No infectious complications were seen.

Conclusions: We developed a new, inexpensive, easy to perform, reproducible GFS mouse model, which can be used for fibrosis research or antifibrotic drug screening in vivo. It works without penetration of the anterior chamber, leaving the large murine lens untouched and thereby minimizing complications.

ABSTRACT BODY:
Purpose: To maintain vision throughout a lifetime, photoreceptors must remain viable despite chronic stress, including oxidative stress. Photoreceptors may have specialized stress adaptations, such as maintaining healthy pools of mitochondria, to remain robust and functional. We exposed zebrafish to systemic or cone-specific stressors and evaluated the impact on cone mitochondria.
Methods: We generated transgenic zebrafish with fluorophores targeted to cone mitochondria (Tg(gnat2:Su9-mKate2); Tg(gnat2:Su9-TagBFP)). Zebrafish larvae were exposed to cold stress (16°C), cone-specific oxidative stress (using the transgenic line Tg(gnat2:Su9-KillerRed)), or 1.2 mM chloramphenicol starting at 3 or 4dpf. At 6dpf, larvae were imaged live using confocal microscopy.

To assess cone mitochondria localization, we used a triple transgenic fish expressing a cone mitochondrial marker, a Müller glia marker (Tg(GFAP:TdTomato)) and a cone cytosol marker (Tg(gnat2:EGFP)).

To assess mitophagy, we used larvae co-expressing the BFP mitochondria marker and an autophagosome marker fluorescently tagged under the Müller glia promotor (Tg(GFAP:EGFP-mCherry-LC3)). Results reported as mean ± SEM.
Results: Cone mitochondria were rarely seen outside the ellipsoid region, but this was increased post all stressors. 23.6% ± 1.6% (n = 44 zebrafish) of mislocalized cone mitochondria co-localized with Müller glia after cold stress. This occurred to a lesser extent in unstressed conditions (14.0% ± 3.7%; n = 38 zebrafish). Of the mislocalized mitochondria in Müller glia, 4.5% ± 3.0% co-localized with unacidified LC3, 33.2% ± 5.7% co-localized with acidified LC3, and 48.4% ± 9.0% were proximal to LC3 post cold stress (n = 10 zebrafish).
Conclusions: Photoreceptor mitochondria adapt to chronic stress by migrating away from the dense mitochondrial cluster in the ellipsoid region. These mitochondria can leave the cell and be taken up by Müller glia cells. Some cone mitochondria are likely undergoing mitophagy since they are associated with autophagosomes in Müller glia.

ABSTRACT BODY:

Purpose: The purpose of this study was to evaluate the functional and clinical effect of intravitreally injected anti-IL-6 antibody for the treatment of experimental autoimmune uveitis (EAU) in mice.

Methods: EAU was induced in 17 female B10.RIII mice by Inter-Photoreceptor-Binding-Protein (IRBP) in complete Freund's adjuvant, boosted by Pertussis toxin. Anti-IL-6 antibody was intravitreally injected on day 10, 13 and 16 after EAU induction (day 0) into the randomized treatment eye and isotype antibody likewise into the fellow control eye. Visual acuity testing via Optodrum and clinical scoring via fundus imaging (6 EAU grades) was done single-blinded on day 0, 10, 13, 16 and 18.

Results: Uveitis developed in all 17 mice. Visual acuity was significantly higher in treated eyes compared to the fellow control eyes on day 13, 16 and 18. The greatest effect was seen on day 16 and 18 ($p < 0.001$, t-test). Clinical uveitis score was significantly reduced in treated eyes compared to the fellow control eyes on day 13, 16 and 18 with greatest effect on day 18 ($p = 0.003$, Wilcoxon-test).

Conclusions: Intravitreal anti-IL-6 treatment significantly attenuates experimental autoimmune uveitis in mice. The effect was seen clinically and functionally. Further studies are needed to evaluate intravitreal anti-IL-6 application as a therapy concept for the treatment of non-infectious uveitis in humans.

ABSTRACT BODY:

Purpose: Limbal stem cell deficiency (LSCD) occurs as a result of limbal stem cell damage and/or sclerocorneal limbal niche destruction. Our research group has recently demonstrated that transplantation of both bone marrow- and adipose tissue-derived mesenchymal stem cells (BM-MSCs and AT-MSCs) in a LSCD rabbit model reduces the development of corneal opacity, and partially restores the tissue structure of the damaged ocular surface. The aim of this work was to study the effect of BM-MSC and AT-MSC transplantation on the corneal and limbal epithelial phenotype of a rabbit model of ocular surface failure due to LSCD.

Methods: A total LSCD model was developed in 15 New Zealand white rabbits through 360 surgical limbal peritomy after N-heptanol-based denudation of the corneal surface. Three weeks after the injury, 10 rabbits were transplanted with 250,000 human MSCs on amniotic membrane (5 with BM-MSCs; 5 with AT-MSCs) and 5 non-transplanted animals formed the untreated group. At the end of the follow-up (11 weeks), immunofluorescence studies in ocular surface tissue sections were done to analyze the expression of corneal (CK3, E-cadherin) and limbal (CK15, p63) epithelial cell specific markers. Fluorescence intensity was measured using ImageJ software in 2 tissue sections per rabbit.

Results: E-cadherin expression was similar in untreated LSCD eyes and healthy control eyes, but it significantly increased in LSCD eyes after BM-MSC transplantation. The expression of CK3, CK15 and p63 was significantly reduced in untreated LSCD eyes compared to healthy control eyes, but transplantation of both BM-MSCs and AT-MSCs in LSCD eyes induced a partial (CK15) or an almost full (CK3 and p63) recovery of their expression levels. Nevertheless, the expression levels achieved were in general higher in the eyes treated with BM-MSCs than in those treated with AT-MSCs.

Conclusions: Although the effect of BM-MSC transplantation seems slightly superior, transplantation of both BM-MSCs and AT-MSCs in a LSCD rabbit model partially restores corneal and limbal epithelial phenotype. Therefore, both types of MSCs seem valid alternatives for the treatment of LSCD.

ABSTRACT BODY:

Purpose: To assess rod-mediated ERG responses to full-field stimuli in pediatric patients with biallelic variants in ABCA4. Typically, the conspicuous clinical feature in ABCA4 retinal disease is maculopathy.

Methods: Of our 44 patients with biallelic variants in ABCA4, 40 had at least one ERG test. The age at ERG test was 1.26–22.12 (median: 11.09) years, except for one patient who was tested at age 58 years. The variants in ABCA4 ranged from double nulls (producing no protein) to less severe. We calculated the amplitude and sensitivity of the rod photoresponse (R_{rod} and S_{rod}) from the a-wave and the postreceptor activity (V_{max}, $1/\sigma$) from the b-wave.

Results: Among those with double null variants, nearly all (92.5%) had R_{rod} values below the 95% prediction limit for normal (PLN), and 67.5% had S_{rod} values below the PLN. By contrast, among those with mild mutations, the rod photoresponse deficits were uncommon. As for the postreceptor response parameters, even in the case of the double nulls, deficits in V_{max} were less frequent. All values of the postreceptor response parameters (V_{max}, $1/\sigma$) were normal in those with mild variants in ABCA4.

Conclusions: Significant deficits in rod-mediated ERG responses to full-field stimuli are common, even though the obvious clinical feature is maculopathy. The frequent deficits in rod photoreceptor activity are likely indicators of the pathobiology of ABCA4 retinal disease. ABCA4 is expressed in both rods and cones.

ABSTRACT BODY:

Purpose: To characterize the incidence rate of iscahemic stroke in patients following a new diagnosis of proliferative diabetic retinopathy (PDR) at a regional ophthalmic institution in London, United Kingdom.

Methods: Methods: A historical cohort study of all patients >= 40 years of age and newly diagnosed with proliferative diabetic retinopathy between January 1st 2008 and March 31st 2018 linked with national data on hospital admissions using the Hospital Episode Statistics database. Ischaemic stroke was defined as code I63/I64 using the International Classification of Diseases 10th Revision. Incidence rates with 95% confidence intervals were calculated using the Poisson distribution and adjusted hazard ratios (HR) modelling incidence of stroke against fixed covariates of age, sex, ethnicity and socioeconomic deprivation was through Cox proportional hazard modelling and Fine-Gray competing risks regression.

Results: Results: A total of 2537 patients (1544 male, 61.9%) with a mean age of 60.5 +/- 10.6 were newly diagnosed with PDR during the eligible period. Among the cohort, 72 had an incident iscahemic stroke with a crude rate of 1123.3 (883.4-1403.1) per 100,000 person-years at risk. Men (59.6 +/- 10.6 years) were younger at diagnosis than women (62.0 +/- 10.5, p <0.001); those with greater socioeconomic deprivation were also diagnosed at a younger age (most deprived decile 58.8 +/- 10.6 versus least deprived decile 62.2 +/- 11.8, p<0.001). On adjusted analysis, age alone was associated with greater hazards of incident stroke (HR 1.05, 1.03-1.08).

Conclusions: Discussion: Greater socioeconomic deprivation and male sex are associated with a younger age of PDR diagnosis. Following diagnosis, incidence of iscahemic stroke is higher with greater age but does not appear to be associated with ethnicity, sex or socioeconomic deprivation.

ABSTRACT BODY:

Purpose: To assess the pointwise relationship between macular function and structure in healthy and glaucomatous eyes for inner and outer segmentations assessed by OCT.

Methods: 72 eyes were included and divided into two groups: control group made up of 27 eyes and a primary open-angle glaucoma (POAG) group of 45 eyes. All eyes underwent retinal sensitivity assessment with microperimetry MP-1 and the structure was studied with OCT (Spectralis). The following automatic segmentations were considered: outer retinal layer, ganglion cell layer (GCL), inner plexiform layer (IPL), GCL+IPL and ganglion cell complex (mRNGL+GCL+IPL). Microperimetry maps were exactly superimposed over OCT maps considering anatomical references by using Overlay2 software. Punctual thicknesses for each considered segmentation were obtained in correspondence with every point of assessed macular sensitivity. The displacement of the ganglion cells of the retina were considered for inner retinal segmentations. Structure-function associations were calculated by using Spearman correlation. Significant correlation maps were plotted.

Results: Healthy group did not show significant correlations in any of the considered segmentations. In contrast, we found positive significant correlations for inner retinal layers but not for outer retinal layer. This significant correlations followed different patterns: peripheral for mRNFL, paracentral in temporal area for GCL, IPL and GCL+IPL and combined for mRNGL+GCL+IPL. The highest number of significant correlations were obtained for mRNGL+GCL+IPL.

Conclusions: There are specific patterns of significant pointwise structure-function correlation in macula for inner retinal layers in POAG.

ABSTRACT BODY:

Purpose: To dissect oxidative stress-related cell death pathways in RPE and retina using the $NaIO_3$ mouse degeneration model.

Methods: Three-month-old C57BL/6J mice received a single tail vein injection of 10 mg/Kg $NaIO_3$; the DJ-1 KO mice were also analyzed as a model of increased sensitivity to oxidative stress. This concentration of $NaIO_3$ induces degeneration only in the DJ-1 KO mice. Parallel groups of mice were injected with PBS. Retina and RPE were isolated, lysed, and analyzed by LC-MS/MS. Panther analysis tool and Ingenuity Pathway Analysis were used to analyze the proteomics data. Main observations were further assayed by Western blotting, immunohistochemistry, confocal microscopy, and histology in mice injected with increasing concentrations of $NaIO_3$ (10-30 mg/Kg).

Results: Proteomics data analyses suggested cell death and survival as one of the top modulated molecular and cellular functions in RPE and retina of C57BL/6J and DJ-1 KO mice injected with 10 mg/Kg $NaIO_3$ compared to PBS injected equivalent. Apoptosis and necroptosis pathways were analyzed using active caspase-3 (acas3) and p-MLKL immunostaining. In PBS-injected mice, we observed increased acas3 reactivity in the DJ-1 KO mice compared to C57BL/6J mice; p-MLKL was observed in both mice strains in the photoreceptor inner segments and GCL. With 10 mg/Kg $NaIO_3$, acas3 was observed only in the photoreceptor inner segment of C57BL/6J retinas, whereas it was observed in RPE and photoreceptors with 20 mg/Kg $NaIO_3$. In DJ-1 KO mice, acas3 was expressed in RPE and photoreceptor degenerating cells and OPL and INL at both concentrations of $NaIO_3$. In C57BL/6J retinas, p-MLKL staining was observed only in GCL with 10 mg/Kg $NaIO_3$, whereas its expression was observed in RPE, ONL, and GCL with 20 mg/Kg $NaIO_3$. In DJ-1 KO mice, p-MLKL was localized in ONL and GCL with 10 and 20mg/Kg $NaIO_3$. Injection of the pan-caspase inhibitor, Z-VAD-Fmk, after 10 mg/Kg $NaIO_3$ injection in DJ-1 KO mice completely inhibited RPE degeneration in DJ-1 KO, thereby, confirming the role of caspase-mediated apoptosis of RPE in the initiation of the degeneration in this mouse model.

Conclusions: Oxidative stress-induced RPE and retinal cell death involve activation of both apoptosis and necroptosis.

ABSTRACT BODY:

Purpose: SGMS2 (sphingomyelin synthase 2 (SMS2)) pathogenic variants cause a rare autosomal dominant skeletal disorder with characteristic skull lesions known as Calvarial Doughnut Lesions with Bone Fragility (CDL) (MIM 12655). A recurrent nonsense mutation (c.148 C>T,p.Arg50*) has been found in 4 of 6 reported families and interestingly, affected members of one of these families also exhibit congenital glaucoma with variable expressivity. In this study we report on a large Filipino family with characteristic skull lesions and juvenile onset open angle glaucoma (JOAG).

Methods: Eighteen members of a 4-generation family were recruited. All subjects underwent a comprehensive eye exam and skull radiography, and DNA samples were obtained. Whole exome sequencing (WES) was performed in 5 family members with JOAG. An in-house WES pipeline was used to align sequence reads and complete variant calling and annotation. After confirming the absence of mutations in genes known to cause early-onset glaucoma WES data was filtered to retain rare variants (minor allele frequency <1%) that were protein altering and predicted to be pathogenic. Sanger sequencing was done to confirm segregation of candidate variants.

Results: Six family members were diagnosed with JOAG and presented with a mean age at diagnosis of 25.5 years, 83% blind in at least one eye, mean intraocular pressure of 29.4 mmHg, and glaucomatous optic nerves. No mutations were found in known disease-causing genes and after variant filtering, a known recurrent heterozygous stop gain mutation, SGMS2 c.148C>T(p.Arg50*), was identified in all subjects with JOAG. Ten family members had abnormal skull radiographs, including all 6 JOAG subjects. The SGMS2 p.Arg50* variant was present in all family members with skull abnormalities.

Conclusions: Here we report on the first Filipino family with CDL and confirm segregation of a recurrent SGMS2 variant found in other families with European Caucasian ancestry. Our study also identifies a second CDL family with early-onset glaucoma raising the possibility that SGMS2 genetic variation can contribute to glaucoma pathogenesis. SGMS2 impacts metabolism of ceramide, sphingomyelin and diacyglycerol, all of which could contribute to trabecular meshwork dysfunction and/or retinal ganglion cell degeneration in glaucoma. Further work is needed to confirm a role for SGMS2 in glaucoma development.

TITLE: Visual, build-up and motor activity of superior colliculus neurons is correlated with visual suppression and fixation preference in strabismic non-human primates (NHP)

SESSION TITLE: Retina imaging and pupillometry

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Ramachandran, V.E. Das, Physiological Optics/Vision Science, University of Houston College of Optometry, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure: Santoshi Ramachandran: Commercial Relationship: Code N (No Commercial Relationship) | Vallabh Das: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Strabismic humans and NHPs often develop the ability to saccade to a target with either eye depending on the targets' spatial location. Fixation preference in strabismus could possibly be accounted for in a competitive decision framework wherein the brain chooses between two retinal errors (since eyes are pointing in different directions) to prepare a saccade. We tested this framework by recording from visuo-motor neurons in the superior colliculus (SC) of strabismic NHPs, a structure critical in target selection and saccade generation.

Methods: Neural recordings from the intermediate/deep SC were obtained while two head-fixed strabismic (~30° XT) NHPs performed a delayed saccade task under binocular viewing conditions. In Exp. 1 (2-target condition), visual targets were presented at two locations corresponding to the neuronal receptive field of either the viewing or deviated eye, and resulted in fixation-switch or no fixation-switch saccades whose amplitude and direction were matched. In Exp 2. (1-target condition), a visual target was placed at a location (single neuronal receptive field) where the animal switched fixation on some trials and did not on other trials. Paired t-tests were performed to compare firing rates of visual, buildup and saccade related response in fixation-switch and no fixation-switch trials.

Results: Exp. 1 (n=25): Robust visual sensory responses were observed when targets were presented at receptive field locations of either the viewing or deviated eye with evidence of only small interocular suppression in both NHPs. Motor responses for fixation-switch and no-fixation switch trials were not significantly different (saccade matched). Mean build-up responses showed no difference in these trials since the cell response corresponds to the 'winning' saccade. Exp. 2 (n=21): Both peak visual and mean build-up responses were reduced for trials in which the cell response did not correspond to the 'winning' eye, suggesting the presence of suppression and that the build-up activity may be used to facilitate eye choice. Data analysis from second NHP is ongoing.

Conclusions: Analysis of neural data from SC visuo-motor cells suggests that this structure plays an important role in eye choice for visual stimuli in strabismus and provides important insight on how visual suppression influences eye choice behavior.

Commercial Relationships Disclosure: Paul Kayne: Commercial Relationship(s);Code E (Employment):Palatin Technologies, Inc | Priyanka Dhingra: Commercial Relationship(s);Code E (Employment):Palatin Technologies, Inc. | Alison Obr: Commercial Relationship(s);Code F (Financial Support):Palatin Technologies, Inc. | John Dodd: Commercial Relationship(s);Code E (Employment):Palatin Technologies, Inc. | Carl Spana: Commercial Relationship(s);Code E (Employment):Palatin Technologies, Inc.

ABSTRACT BODY:

Purpose: Anti-inflammatory benefits of the melanocortin system suggest that melanocortin receptor (MCr) agonists have promise in the treatment of inflammatory diseases. The selective MC1r agonist, PL8177 and the MC1r/MC3r/MC4r/MC5r pan-agonist PL9654, were investigated in a streptozotocin (STZ) rat model of DR and their effects on ocular inflammation, retinal cell population composition, and gene and protein expression were determined. The objective was to determine the effectiveness of PL8177 and PL9654 in this model and to characterize its mechanism of action.

Methods: Effect of PL8177 and PL9654 on vision was investigated in a 114-day study. STZ-rats were randomly assigned to 5 separate study arms. On days 4–113, rats received BID subcutaneous administration of vehicle (0.9% NaCl); PL9654 0.05mg/kg, 0.1mg/kg, or 0.5mg/kg; or PL8177 1mg/kg. Visual function was measured by optokinetic tracking every 2 wks from day 43 to day 113. Cataract images were acquired after each optokinetic session. Rats were euthanized on day 114. Right-eye retinas were dissected and snap-frozen; left eyes were enucleated and fixed for histology. Retinal thickness and photoreceptor degeneration/loss were measured.

Results: PL9654 doses of 0.05–0.5mg/kg and PL8177 at 1mg/kg showed significant efficacy in reducing vision loss in STZ-treated rats compared to vehicle. PL9654 0.1 and 0.5mg/kg significantly reduced loss of both visual acuity and contrast vision. At 0.05mg/kg, PL9654 significantly reduced loss of contrast vision. PL8177 1mg/kg significantly reduced loss of visual acuity. Histopathology showed that there was significantly less photoreceptor degeneration with PL9654 0.1mg/kg vs vehicle($P<0.05$). Retinal thickness was also significantly improved for the PL9654($P<0.05$) and PL8177($P<0.05$) groups vs vehicle. There were no adverse events resulting from administration of either PL9654 or PL8177. Changes in the cellular population compositions, gene expression changes and protein level data will be presented and discussed at the conference.

Conclusions: SC BID administration of the melanocortin agonists PL9654 and PL8177 show promise in the treatment of DR by reducing vision loss and photoreceptor degeneration in the STZ-rat model of DR. Single nuclei RNAseq and proteomic data will be interpreted in the context of disease change to identify alterations in immune and cellular states of the rat retinas.

ABSTRACT BODY:

Purpose: Conventional adaptive optics (AO) ophthalmic imaging is largely limited to cooperative adults who are able to sit upright and fixate for extended periods. Our handheld AO optical coherence tomography (HAOOCT) probe enables 3D visualization of photoreceptor cells in upright and recumbent subjects, further extending AO-OCT into clinical settings.

Methods: OpticStudio and SolidWorks were used to design custom optics and mechanics, respectively, for the compact wavefront sensor and lens-based spectral domain HAOOCT system. HAOOCT was designed to achieve 2.26 μm lateral resolution and 4.01 μm axial resolution. The final form factor of HAOOCT is approximately 22 x 18 x 5.2 cm with a total weight of 630 g (Fig. 1). HAOOCT volumes with 1° FOV were acquired with a volume rate of 2.3 Hz. Volumes with overlapping FOVs were registered and averaged. Consented healthy adult volunteers were imaged in both upright and recumbent postures at the Duke Eye Center.

Results: The photoreceptor mosaic was visualized in all volunteers under different experimental setups. The imaging results from two of these subjects are shown in Fig. 2. Subject A was imaged while seated and stabilized with a chin/forehead rest, with HAOOCT mounted on an ophthalmic translation stage. An averaged B-scan (linear scale) and en face maximum intensity projection (MIP) show the photoreceptor mosaic 3-5° from fovea (Fig. 2a-b). Subject B was directed to lay in a fully recumbent position on a reclined chair and imaged with HAOOCT in handheld operation. A single B-scan and en face MIP from an un-registered volume reveal the photoreceptor mosaic (Fig. 2c-d).

Conclusions: We achieved cone photoreceptor visualization in adult volunteers using HAOOCT in both stabilized and handheld configurations. This is the first demonstration of a handheld WFS-based AO ophthalmic system and the first attempt to collect AO-OCT volumes using a handheld system.

ABSTRACT BODY:

Purpose: This study evaluated the performance of a semi-automated algorithm to populate a research database with electronic health record (EHR) data, while reducing manual burden and flagging errors.

Methods: We developed a semi-automated algorithm to extract data from structured fields of the University of Michigan EHR for participants enrolled in the Michigan Screening and Intervention for Glaucoma and Eye Health through Telemedicine (MI-SIGHT) Program. Data collected included 76 elements from the technician eye exam such as medical history, visual acuity and refraction, and 196 elements from the physicians' screening results such as assessment of the external and fundus photographs. A randomly selected sample of participants were identified. Data was extracted from the EHR through 1) the semi-automated algorithm, 2) manual extraction, and 3) gold standard double data entry. The algorithm performance and manual data extraction were compared to double data entry and error rates were calculated. Algorithm non-completion rate, or proportion of data elements that still required manual data entry, was measured. Algorithm training continued iteratively until pattern errors could no longer be identified.

Results: Fifty participants and their progress notes from the technician exam and physician screening results were randomly selected for evaluation from the 1288 participants enrolled. Manual data entry took approximately 12 hours, and the semi-automated algorithm took 2 hours for the 50 participants. For technician exams, the algorithm flagged 15.8% of the data (n=585/3700) for manual entry. Reasons for manual entry included typographic errors and non-conventional entries. Of the remaining entries that were entered automatically, the error rate was 0.5% (n=15) for manual extraction errors and 0.1% (n=3) for algorithm errors (p=0.005, McNemar's test). For the physician screening results, 7.0% of data (n=686/9800) was flagged for manual entry. Of the remaining data, the error rate was 0.1% (n=9) for manual extraction errors and 0% for algorithm errors (p=0.003, McNemar's test).

Conclusions: The algorithm showed strong performance in automatic data extraction and substantially reduced manual data entry burden. This type of process could improve both rigor and reproducibility in studies with large samples and numerous data elements. Next steps involve testing the algorithm in a new sample.

ABSTRACT BODY:

Purpose: The systemic transport of dietary vitamin A/all-trans retinol/ROL bound to RBP4 into peripheral tissues for storage is an important process that continuously provides chromophore precursors to the retina under fasting conditions, which is necessary for visual function. While the blood transport of the lipophilic vitamin A into the eye is facilitated by the membrane receptor STRA6, the systemic transporter for dietary vitamin A remained elusive. Using a mammalian model, we recently identified retinol binding protein receptor 2 (RBPR2), which has high affinity binding for RBP4 and is critical for systemic ROL uptake and transport to the eye.

Methods: A whole body rbpr2$^{-/-}$ null mouse line was generated and maintained with vitamin A sufficient and deficient diets. Morphological, immunohistological, HPLC, and electron microscopy studies were performed on rbpr2$^{-/-}$ mice from 2-8 months of age to evaluate the effects of RBPR2 loss on ocular retinoid content, retinal pathology, and opsin content in photoreceptors. Electroretinography (ERG) analysis was performed to evaluate visual function in rbpr2$^{-/-}$ and control mice. Spectral optical coherence tomography (OCT) analysis was performed to evaluate the retinal layer thickness.

Results: Rbpr2 knockout mice were viable on both vitamin A sufficient and replete diets. Rbpr2 mice on vitamin A sufficient diets, showed lower ocular retinoid levels, but no significant retinal phenotypes. However, when these mice were placed on vitamin A replete diets, they displayed significantly lower ocular retinoid content, decreased opsins, and significant retinal phenotypes. ERG analysis showed significant decreased visual function in rbpr2$^{-/-}$ mice on vitamin A sufficient and replete diets.

Conclusions: Our studies of RBPR2 null mice established the importance of the RBPR2 protein for the systemic availability of dietary vitamin A for proper ocular retinoid homeostasis. Under conditions of vitamin A excess and deficiency, our analyses revealed that RBPR2-mediated systemic vitamin A homeostasis is a regulated process that is important for vitamin A transport to the eye when RBP4-ROL constitutes the only transport mode in the fasting condition/vitamin A deficiency. Our findings identifying RBPR2 as a systemic vitamin A transporter have important implications for disease states associated with impaired blood vitamin A homeostasis and visual function.

ABSTRACT BODY:

Purpose: Individuals who meet certain criteria are eligible for a Certificate of Visual Impairment (CVI) in England and Wales. We explored monthly certifications from Jan 2017 to Dec 2021 to investigate any effects of the COVID-19 pandemic.

Methods: CVI forms are sent to the Certifications Office at Moorfields Eye Hospital. Numbers of CVI forms received per month from January 2017 to December 2021 were analysed. Means and standard deviations as well as maximum and minimum numbers of monthly certification forms were calculated for each calendar year. The average for the years 2017, 2018 and 2019 for each calendar month was calculated, and numbers for each calendar month of 2020 and 2021 were expressed as a proportion of this average.

Results: Mean (SD) monthly certification forms received were 2115 (208), 2229 (386), 2245 (187) for the years 2017, 2018 and 2019 respectively. In 2020, the mean (SD) was 1624 (741) certifications; in 2021, the mean (SD) was 2012 (277) certifications. Monthly certifications were consistently greater than 1800 in the years 2017 to 2019, but in 2020, certifications fell drastically in April, May and June (607, 509 and 539 certifications respectively). Monthly certifications were below 1800 also in July and August of 2020 (1231 and 1267 certifications respectively) and in Jan and Feb of 2021 (1580 and 1579 certifications respectively). When expressed as a proportion of the average of the same calendar month in 2017-2019, monthly certifications were below 30% in April, May and June of 2020. For all other months in 2020 and 2021, the proportion remained above 75% of the average for 2017-2019.

Conclusions: We found a marked (>70%) reduction in certification forms received in April, May and June of 2020, coinciding with the first national lockdown. As certifications can enable access to support, this is another manifestation of the consequences of the pandemic for patients with vision loss. A similar magnitude reduction was not seen for subsequent lockdowns.

ABSTRACT BODY:

Purpose: Kjer's dominant optic atrophy (DOA) is an autosomal dominant disorder caused by mutation in the OPA1 gene in chromosome 3. The mutation results in retinal ganglion cell (RGC) degeneration and optic atrophy. The affected patients have varying degrees of visual deficits, including decreased best corrected visual acuity (BCVA), visual field defects, cataracts, and nystagmus. These visual deficits pose challenges to clinical testing. Subjective assessments such as BCVA and visual field tests do not accurately reflect the disease severity due to floor effect. Similarly, the retinal nerve fiber layer (RNFL) thickness, which reflects the structural changes of the retina, also plateaus as the disease progresses.

Photopic negative response (PhNR), recorded via the electroretinogram, can be used to assess the RGC dysfunction in the absence of reliable patient fixation or clear ocular media. The purpose of this study was to validate the use of PhNR as an objective measurement to assess visual function in patients with DOA.
Methods: Data were collected at the University of Ottawa Eye Institute. Ganglion cell complex analysis was performed by Cirrus HD-OCT (Carl Zeiss Meditec). Mean deviations were analyzed by Humphrey Field Analyzer 3 (Carl Zeiss Meditec). PhNR data of control subjects and DOA patients were recorded on Espion E3 (v.6, Diagnosys LLC). Briefly, full field PhNRs were recorded using red (640 nm) flashes on blue (470 nm) rod saturating background. PhNR was performed using three stimulus intensities: 1, 5, and 7 cd•s/m^2. Statistical analysis was performed using SigmaPlot (v.14.5).
Results: Clinical data from 14 eyes of 7 DOA patients with BCVA varying between 20/40 to counting fingers at 2 ft, were compared to control data (n=28). All DOA patients showed visual field mean deviations outside of normal limits, and abnormally reduced RGC layer, inner plexiform layer, and RNFL thickness. PhNR data demonstrated reduced amplitudes across all three stimulus intensities compared to controls (-8.8 ± 6.2 µV vs -32.6 ± 2.2 µV @ 1 cd•s/m^2; -5.1 ± 4.6 µV vs -34.2 ± 2.5 µV @ 5 cd•s/m^2; and -7.5 ± 4.7 µV vs -40.2 ± 3.4 µV @ 7 cd•s/m^2; p = < 0.001).
Conclusions: In combination with the other standard clinical measurements, such as BCVA, visual field and RNFL thickness, the PhNR tests can provide objective measurement of the RGC layer integrity and serve as a biomarker for disease and therapy management.

ABSTRACT BODY:

Purpose: Traditional office-based automated visual field (VF) testing requires expensive machines and poses logistical challenges that limit its use. Novel VF devices could change the paradigm of glaucoma monitoring and dramatically improve access to care if patients can reliably use these devices at home. A positive user experience is crucial for uptake and ongoing use of novel portable VF devices. We compare the patient experience using the IMOvifa virtual reality (VR) VF test (CREWT Medical Systems, Inc., Tokyo, Japan) and tablet-based Melbourne Rapid Fields (MRF) VF test (M&S Technologies, Niles, IL, USA) to that when using the Humphrey Field Analyzer (HFA).

Methods: As part of a pilot observational study, subjects who were either glaucoma suspects or had a prior glaucoma diagnosis performed VF tests on IMOvifa, MRF, and HFA in a random testing order. All subjects were reliable, experienced HFA testers. Participants were trained to use IMOvifa and MRF, then surveyed after completing their first test on each device. The survey used 5-point Likert questions to assess subjects' experiences with the novel devices, how frequently they would be willing to use each one, and to compare each device to the HFA.

Results: We surveyed 56 research subjects with mean age of 62 years (range 30-79). A "very good" overall experience was reported by 75% and 96% of subjects for IMOvifa and MRF, respectively. 68% (95% CI = [56%, 80%]) and 66% (95% CI = [54%, 78%]) of subjects preferred IMOvifa and MRF over HFA, respectively (Table 1). Subjects primarily cited ease of use and comfort as reasons for their preference. Specifically, participants preferred the MRF's portability and IMOvifa's capability to allow both eyes to remain open during testing. 71% (95% CI = [60%, 83%]) and 79% (95% CI = [68%, 89%]) of subjects stated that they would be willing to take IMOvifa and MRF at least once per week, respectively (Table 2).

Conclusions: There was a strong preference for novel VR and tablet-based VF tests over HFA 24-2 SITA Standard, and overall participant experience using these devices was positive. Further research is needed to determine the role of these devices in clinical care.

ABSTRACT BODY:

Purpose: To evaluate the conjunctival vessel density (CVD), as a sign of inflammation, before and after treatment with a solution of Sodium Hyaluronate, Xanthan gum and osmoprotectants (HX) in mild-moderate dry eye disease (DED), and to compare it with clinical parameters: matrix metalloprotease 9 (MMP9) test, break-up time (BUT), corneo-conjunctival vital staining, Schirmer test I (STI).

Methods: Images were acquired by Keratograph 5m (OCULUS Optikgeräte GmbH, Wetzlar, Germany) using the R-scan for automatic classification of bulbar redness (BR) and vessel-enhanced images to perform CVD analysis (Fig 1A).

Data collected before (V0) and 4 months-after treatment (V1) with HX artificial tears q.i.d.

Images were exported in TIFF format and loaded in ImageJ software. Images were normalized in terms of grayscale distribution. In order to work in the same conjunctival area, the same ovaloid area was used (Fig 1B). Then, images were binarized by using Otsu threshold. Finally, the ratio of the white pixels, corresponding to conjunctival vessels, with respect to the black pixels of the images, to obtain the CVD (Fig. 1C).

Clinical MMP9 test, BUT, SICCA score, STI were performed.

Adverse events data (burning, blurred vision) were collected.

Continuous variables (mean±standard deviation) were analyzed by using two-tailed T test and chi-square test. Statistical significance was set to $p<0.05$.

Results: We collected data from 12 eyes of 12 patients. None presented adverse events.

MMP9 positivity was 66.7% at V0 and 16.7% at V1 ($p=0.03$); BUT was 4.6±1.4 at V0 and 5±1.3 at V1 ($p=0.0001$); V0 SICCA score was 2.8±1.4, and 1.2±1.1 at V1 ($p<0.0001$); STI was 10.7±6.9 at V0 and 12.9±7.2 at V1 ($p=0.01$). BR score was 0.9±0.3 at V0 and 1±0.5 at V1 ($p=0.001$). CVD was 0.07±0.03 at V0, resulting 0.05±0.02 at V1 ($p<0.0001$) (Figure 2).

Conclusions: The HX formula was effective in improving the anatomical and functional parameters.

CVD seems to offer a more reliable method than BR in evaluating inflammation. In fact, BR score is linked to the area explored, that vary in accordance to ocular discomfort and, for this reason, resulted higher at V1. This bias is overcome calculating CVD in a fixed area. In conclusion, HX formula is effective in treating ocular surface; CVD seems promising as inflammatory marker.

SUBMITTER (NAME ONLY): Christina Wentz

TITLE: The Effect of Ophthalmic Blue Blocker Lenses and Anti-Reflective Coats on Digital Reading Efficiency and Comfort

SESSION TITLE: Vision Impairment, Visual Function, and Quality of Life

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Wentz, J. Winters, Illinois College of Optometry, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Christina Wentz: Commercial Relationship: Code N (No Commercial Relationship) | Janis Winters: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: With increasing time spent on devices, there is rising interest in the use of blue light blocking (BB) lenses to reduce symptoms of digital eye strain. Current research is conflicted about the benefits use of these lenses might have and on what components of eye strain these may be. We conducted an experiment to compare the effects, if any, commercially available BB and/or antireflective (AR) coatings may have relative to a coating-free control on eye movements, reading rate, and subjective assessments of digital eye strain symptoms.

Methods: Twenty-eight emmetropic or contact lens corrected subjects (ages 22-31 years old; 10 male, 18 female) completed pursuit, saccade, and fixation assessments via the RightEye Dynamic Vision test while wearing clear, un-tinted BB, AR, BB/AR, and control (coating-free) lenses in a randomized order. They then completed a 20-minute reading task while wearing each of the lenses and filled out a questionnaire regarding their eye strain symptoms. Analysis of variance tests were used for statistical analysis and a p value of 0.05 was considered significant.

Results: Pursuits, saccades, and fixations were not significantly different between the control and any of the treatment lens options ($p_{pursuits} = 0.39$, $p_{saccades} = 0.91$, and $p_{fixations} = 0.89$). Similarly, there was no significant percent change in the reading rate for any of the treatments relative to the control ($p_{reading} = 0.44$). The subjective eye strain symptom survey found statistically insignificant differences in score for all of the questioned symptoms. These included blurred vision while viewing the text ($p = 0.45$), blurred vision at distance after the task ($p = 0.49$), difficulty/slowness refocusing eyes after the task ($p = 0.96$), irritated or burning eyes ($p = 0.71$), dry eyes ($p = 0.78$), eye strain ($p = 0.94$), headache ($p = 0.65$), tired eyes ($p = 0.56$), sensitivity to bright lights ($p = 0.65$), and discomfort in the eyes ($p = 0.74$).

Conclusions: We find no statistical evidence to support claims that BB lenses with or without AR coat or AR coats alone will improve digital eye strain symptoms. This finding is consistent with other studies using the same symptom questionnaire. Additionally, we find no support for these lenses and coatings to alter eye movements or change reading rate significantly.

ABSTRACT BODY:

Purpose: Glaucoma is a leading cause of vision loss characterized by the progressive degeneration of retinal ganglion cells (RGCs). Among many underlying causes of the disease, autophagy dysfunction has been associated with the onset of RGC deficits. Here, we hypothesized that an imbalance between autophagy and mTOR signaling resulted in the neurodegeneration of RGCs. Using human pluripotent stem cells (hPSCs), we characterized how a mutation in the autophagy receptor Optineurin (OPTN) contributes to autophagy dysfunction resulting in RGC neurodegeneration through the repression of mTOR, and validated these changes in a mouse glaucoma model.

Methods: hPSCs with an OPTN(E50K) gene mutation and corresponding isogenic controls were differentiated to RGCs following established methods. Changes to autophagic flux as well as mTOR signaling were characterized in hPSC-derived RGCs. To further validate these findings, ocular hypertension was induced in mice by intracameral injection of magnetic microbeads. Retinal protein lysates and cross sections were analyzed at 2 weeks of glaucoma induction.

Results: OPTN(E50K) RGCs exhibited a higher number of OPTN puncta and impaired autophagic-lysosomal degradation. By characterizing the key autophagy modulator mTOR, OPTN(E50K) RGCs demonstrated decreased expression of the mTORC1 effector phospho-S6 and increased expression of the upstream stress sensor AMPK. Pharmacological inhibition of mTOR in otherwise healthy RGCs resulted in neurite retraction similar to RGCs with the OPTN(E50K) mutation, while enhancement of mTOR signaling in OPTN(E50K) RGCs rescued RGC neurodegeneration. In agreement with our findings in hPSC-RGCs, an increase in the expression of autophagy-associated proteins was associated with a decrease in mTOR signaling in the microbead occlusion mouse model.

Conclusions: Our study demonstrates a connection between autophagy disruption and mTORC1 inactivation, which can contribute to neurodegeneration in glaucoma. The delicate balance between autophagy and mTOR signaling demonstrates that RGC neurodegeneration may result from the disruption of multiple signaling pathways. In future studies, an emphasis should be placed upon the targeting of autophagy induction while maintaining cellular homeostasis via mTOR signaling, leading to the investigation of new protective strategies to prevent glaucoma-associated neurodegeneration.

ABSTRACT BODY:

Purpose: To characterize rod-, cone- and melanopsin-mediated pupil responses (PLR) for small focal chromatic light stimuli presented in peripheral and central retinal locations in optic neuritis patients.

Methods: Ten acute optic neuritis (ON) patients (mean age ± standard deviation: 32.3 ± 9.29 years) 7 females and 3 males, and 26 age-similar healthy controls (35.4 ± 12.4 years) 15 females and 11 males, were enrolled. The pupil light responses (PLR) for small (0.43°) red and blue light stimuli (peak 485 nm and 625 nm, respectively) presented at 54 locations of a 24-2 visual field were recorded. In addition, the melanopsin-mediated sustained pupil responses (pupil response, recovery, PRP) were evaluated at central and peripheral VF locations. All patients underwent Optical Coherence Tomography imaging, standard perimetry (Humphrey SITA Standard protocol), and their best corrected visual acuity was determined.

Results: Attenuated melanopsin-mediated PLR was recorded in the peripheral VF in ON eyes compared to controls, with ROC AUC = 91.1% (p=0.001). The rod and cone-mediated percentage of pupil contraction (PPC) were lower by more than 2 standard errors (SEs) from the mean of controls in the majority of visual field test targets (mean ± SE: 60% ± 12 % and 55% ± 10 %, respectively) in optic neuritis eyes, even in patients with normal visual acuity. Furthermore, even though normal visual acuity and VEP P100 were recorded in the fellow eyes, substantially lower rod- and cone-mediated PPC values (lower than 2SEs from the mean of controls) were identified in the fellow eyes of all patients (mean ± SE: 33% ± 9 % and 30%± 7 % of test targets, respectively). Peripapillary OCT of both eyes was within normal limits.

Conclusions: Substantially lower rod-, cone- and melanopsin-mediated PLR are recorded in ON and fellow eyes of patients, even in eyes with normal VA. The melanopsin-mediated pupil response to blue light at the peripheral retina may present a novel, highly sensitive surrogate functional biomarker for detection of ON.

TITLE: Pregabalin, an IOP-reducing CACNA2D1 antagonist, may also preserve optic nerve health by binding to CACNA2D2.

SESSION TITLE: Neuroprotection and Neuroregeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.J. Kim, T. Hollingsworth, W. Edwards, M.M. Jablonski, The University of Tennessee Health Science Center, Memphis, Tennessee, UNITED STATES|

Commercial Relationships Disclosure: Minjae Kim: Commercial Relationship: Code N (No Commercial Relationship) | TJ Hollingsworth: Commercial Relationship: Code N (No Commercial Relationship) | Will Edwards: Commercial Relationship: Code N (No Commercial Relationship) | Monica Jablonski: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: CACNA2D1 is an L-type calcium channel subunit that is expressed by several structures in the eye. Previously, we showed that a topically applied CACNA2D1 antagonist—pregabalin (PRG)—lowered IOP in mice, and that the amplitude of response varied between mice carrying the B and D haplotypes of the gene, originating from C57BL/6 mice (B6) and DBA/2J (D2) mice, respectively. In this study, we aim to show that CACNA2D2, an isoform of CACNA2D1, is expressed in the eye and may be targeted using PRG to modulate optic nerve health.

Methods: Whole eyes from B6 and D2 mice at 1 month of age were immunostained and imaged for CACNA2D1 and CACNA2D2. Systems genetics methods were used to analyze the relationship between optic nerve health and the haplotype of Cacna2d2 using estimates of the number of live axons per optic nerve across the BXD family of mice. Because there is no published crystal structure of CACNA2D2, we used the human N-type voltage gated calcium channel (PDB:7VFU) for homology modeling of both B and D haplotypes of CACNA2D2 (sequence identity: 56%). Molecular docking was performed using Prime software (Schrödinger, Inc., USA).

Results: Immunohistochemical analysis revealed that both CACNA2D1 and CACNA2D2 are expressed in the eye, with CACNA2D2 having its highest expression in the optic nerve. Systems genetics analyses demonstrated a significant reduction in number of live axons per optic nerve in mice with the D haplotype, compared to those with the B haplotype. Finally, molecular docking of PRG to the B haplotype of CACNA2D2 revealed a binding site with a docking score of –10.820 kcal/mol, while that of the D haplotype yielded –5.794 kcal/mol.

Conclusions: Through this study, we confirmed the expression of CACNA2D2 in mouse eyes and using systems genetics analyses demonstrated that it may play a role in modulating optic nerve health. Furthermore, molecular docking of CACNA2D2 revealed PRG's potential binding site and affinity, which differed between the B and D haplotypes. Together, our findings offer promising evidence to support the exploration of PRG being used therapeutically to not only lower IOP, but also to preserve healthy axons in the eye.

ABSTRACT BODY:

Purpose: Emerging evidence indicates that high-fat diet (HFD)-induced gut dysbiosis exacerbates choroidal neovascularization (CNV), the hallmark lesion of neovascular AMD (nAMD). Previous studies describe the pathogenic effects of short-term (ST) HFD-induced gut dysbiosis on the evolution of nAMD however the impact of long-term (LT) HFD consumption remains unknown. We aim to evaluate and compare the consequences of ST and LT HFD on gut microbiome composition as well as CNV features.

Methods: Seven weeks old male C57BL/6J were fed 23% HFD for 8 weeks (ST-HFD) and 21 weeks (LT-HFD) while control groups were maintained on a regular diet (young-ND and aged-ND, respectively) and then underwent laser induction of CNV. Choroidal flatmounts were immunostained with IB4 isolectin for CNV and IBA-1 for microglia infiltration. 16S rRNA sequencing of fecal DNA from these groups was done on the Illumina MiSeq platform and analyzed by QIIME2.

Results: LT-HFD induced a more prominent effect on gut dysbiosis, reflected by severely suppressed microbial diversity in contrast to the ST-HFD group. Specifically, protective microbes from the phylum (p.) Bacteroidetes/order (o.) Bacteroidales and p.Actinobacteria (o.Bifidobacteriaceae) were further decreased by LT-HFD, while, pathogenic p.Firmicutes (o.Clostridiales) were more prominently increased in the LT-HFD group compared to ST-HFD. The Bacteroidetes to Firmicutes ratio was most affected in the ST-HFD group but somewhat begins to recover in the LT-HFD, as shown in the previous aging-related gut-microbial studies.

LT-HFD caused a larger increase in CNV size compared with the aged ST-ND fed mice (1.62 fold-change, p=0.0049), while the ST-HFD intake compared to ND resulted in a smaller influence on CNV size (1.42fold-increase, p=0.0048). LT-HFD was associated with significantly increased IBA1 activated microglial infiltration within and outside CNV lesion (p=0.003 and p=0.013, respectively), but this was not noted with ST-HFD.

Conclusions: LT-HFD had a more robust effect on gut dysbiosis as well as CNV size and microglial infiltration. Our data indicate that the duration of unhealthy diet intake may influence gut microbial shifts that correlate with nAMD pathogenesis.

ABSTRACT BODY:

Purpose: Topical eyedrops remain the primary treatment option of anterior ocular conditions but have been demonstrated have poor efficacy in many cases since less than 5% remains bioavailable after administration. Drug eluting gels applied to the inferior fornix have been developed as alternatives to conventional eyedrops. However, due the high shearing forces and significant globe movement, the retention of these gels is often difficult. To overcome this, degradable thermo-gels with tunable muco-adhesive properties were developed for sustained release of cysteamine for the treatment of ocular cystinosis.

Methods: N-isopropylacrylamide co-polymers were synthetized with varying concentrations of the disulfide co-monomer polydisulfide ethyl ether methacrylate. The polymers were then crosslinked with chitosan (MW 80-200 kDa, DDA = 70%). The muco-adhesive properties of the gels were evaluated by rheologic synergism. The viscosity of the gels (n=3) at 10% (wt/v) was measured either in PBS or 3% (wt/wt) mucin suspensions.

The safety of the cysteamine conjugated thermo-gels was evaluated using 19-week-old female Brown Norway Rats (n=4). Thermo-gels were applied every day for one week. At days 1, 2, 3, and 7 the cornea was assessed utilizing optical coherence tomography imaging system as well as by fluorescence staining to measure corneal disruption. After 7 days, the eyes were harvested, and corneal health was assessed by histology.

Results: By inclusion of varying concentrations of the muco-adhesive disulfide monomer as well as crosslinking with muco-adhesive chitosan, the rheological synergism of the system was found to be highly tuneable from 0.01 to 10 (Pa*s). Importantly, it was found that the inclusion of both components resulted in greater synergy than either component alone. The in vivo histological analysis of corneal morphology and thickness, as shown in Figure 1, demonstrated that the produced thermo-gels did not lead to statistically significant corneal thickening after one week compared to PBS treated rats ($p>0.05$).

Conclusions: The results show that we can produce a wide range of muco-adhesive properties by incorporating different concentrations of muco-adhesive components into the thermo-gels. The cysteamine thermo-gels have been shown to be well tolerated in a rat model, supporting their potential for use as alternatives to conventional, acidic, cysteamine eyedrops which require frequent reapplication on a daily basis.

ABSTRACT BODY:

Purpose: To evaluate the impact of anti-VEGF therapy and changes in optical coherence tomography (OCT) metrics on the refractive error (RE) in diabetic macular edema (DME).

Methods: A post-hoc analysis of DRCR protocol T. The RE in diopters (D) was measured using standard protocol refraction. Spherical equivalent (SE) data was calculated for study and fellow eyes at baseline, one-year, and two-year visits. The SE change of the eyes with persistent edema was compared to those with resolved edema stratified by lens status. The correlation between RE changes and OCT metrics like baseline fluid and central subfield thickness (CST) was evaluated.

Results: Among 543 patients, a small hyperopic shift was found from baseline to the 1-year follow up in the study eye [0.06 (0.67), p= p=0.015] and the fellow eye [0.07 (0.75), p=0.013]. A small hyperopic shift was also observed from baseline to the 2-year follow-up in the study eye [0.04 (0.82), p=0.022] and the fellow eye [0.12 (0.84), p= 0.001]. There was no significant difference between the SE change of the study and fellow eyes at 1-year and 2-year visits (p= 0.89 and 0.23, respectively). No significant difference in SE shift was found between eyes with and without edema at two years in phakic (0.12 D and 0.08, p=0.87) and pseudophakic eyes (-0.24 and -0.08, p=0.30). In phakic patients, SE change was significantly different in eyes with no edema at 1-year and 2-year visits and baseline (IRF+/SRF-) vs. eyes with baseline (IRF+/SRF+), both at one year [0.19 (0.63) vs. -0.03 (0.85), respectively, p=0.003] and two years follow up [0.16 (0.74) vs. -0.14 (0.98), respectively, p= 0.039]. In pseudophakic patients, no significant difference was noted between SE change of eyes with no edema at 1-year and 2-year visits and baseline (IRF+/SRF-) compared to eyes with baseline (IRF+/SRF+) at one year [-0.01 (0.53) vs. 0.03 (0.55), respectively, p=0.93] and two years [-0.09 (0.63) vs. -0.08 (0.51) , respectively, p=0.77]. The SE shift was not correlated with CST change at the end of the first (r=0.013, p=0.77) nor the second year (r=0.02, p=0.62).

Conclusions: DME patients receiving anti-VEGF therapy have minimal changes in RE. Appropriate refraction may be considered at any point regardless of edema.

Commercial Relationships Disclosure: Patrick Herbert: Commercial Relationship: Code N (No Commercial Relationship) | Kaihua Hou: Commercial Relationship: Code N (No Commercial Relationship) | Chris Bradley: Commercial Relationship: Code N (No Commercial Relationship) | Michael Boland: Commercial Relationship(s);Code C (Consultant/Contractor):Zeiss | Pradeep Ramulu: Commercial Relationship(s);Code C (Consultant/Contractor):Heru Inc. | Mathias Unberath: Commercial Relationship: Code N (No Commercial Relationship) | Jithin Yohannan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We assess whether we can forecast future rapid visual field (VF) worsening using deep learning models (DLM) trained on baseline VF, OCT, and clinical data. Additionally, we study the impact of adding additional VF data (beyond baseline) on model performance.

Methods: We included eyes that met the following: 1) followed for glaucoma or suspect status 2) had at least five reliable VFs over time (VF_1, VF_2, VF_3, VF_4, VF_5) 3) had one reliable baseline OCT scan (OCT_1) and one set of baseline clinical measurement: age, gender, BCVA, IOP ($Clinical_1$) at the time of VF_1.

We designed a DLM to detect eyes at risk for future rapid VF worsening (mean deviation (MD) slope <-1 dB/yr across all five VFs). The input to the DLM consisted of spatially oriented total deviation values from VF_1 (+/- VF_2 and VF_3 in some models) and spatially oriented RNFL thickness values from OCT_1 (Figure 1A). We input this VF/OCT stack into a vision transformer feature extractor. The output of the feature extractor was concatenated with $Clinical_1$ and put through a dense linear classifier to make a final prediction for that eyes' risk of future rapid VF worsening (Figure 1B). We used 80% of data for training, 10% for validation, and 10% for testing.

We compared the performance of models with differing inputs by computing area under receiver operating curve (AUC) in the test set. Specifically, we trained models with following inputs: Model (1) VF_1; (2) VF_1 + $Clinical_1$; (3) VF_1 + OCT_1; (4) VF_1 + $Clinical_1$ + OCT_1; (5) VF_1 + VF_2 + $Clinical_1$ + OCT_1; (6) VF_1 + VF_2 + VF_3, + $Clinical_1$ + OCT_1

Results: We included a total of 4,537 unique eyes from 2,963 patients. Mean and (SD) for: age | VF MD at baseline | MD slope, was: 65.9 years (12.4) | -3.4 dB (4.3) | -0.21 dB/yr (1.0). 518 (11.4%) of eyes underwent rapid VF worsening. Model 6 most accurately forecasted rapid worsening with an AUC (95% CI) of 0.85 (0.78, 0.93). Remaining models in descending order of performance and their respective AUC [95% CI] were: Model 5 (0.81 [0.73 to 0.89]), Model 4 (0.75 [0.66, 0.83]), Model 2 [0.75 [0.66, 0.83], Model 3 (0.71 [0.62, 0.80]), Model 1 (0.68 [0.59, 0.77]).

Conclusions: DLMs trained on multimodal data from early visits can forecast future rapid worsening with AUC >0.8. Deployment of such models in clinical practice may allow us to stratify high from low-risk glaucoma patients early in the disease course.

TITLE: Subcellular patterning of focal adhesions regulates stiffness-dependent differences in myofibroblast differentiation of corneal keratocytes.

SESSION TITLE: Corneal stromal biology, wound healing modulators and regeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Maruri, K. Iyer, D. Schmidtke, V. Varner, The Department of Bioengineering, The University of Texas at Dallas, Richardson, Texas, UNITED STATES|M. Petroll, The Department of Ophthalmology, The University of Texas Southwestern Medical Center, Dallas, Texas, UNITED STATES|

Commercial Relationships Disclosure: Daniel Maruri: Commercial Relationship: Code N (No Commercial Relationship) | Krithika Iyer: Commercial Relationship: Code N (No Commercial Relationship) | David Schmidtke: Commercial Relationship: Code N (No Commercial Relationship) | Matthew Petroll: Commercial Relationship: Code N (No Commercial Relationship) | Victor Varner: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Following surgery or traumatic injury, corneal wound healing can cause a scarring response that impairs ocular function. This fibrosis is caused in part by myofibroblast differentiation of corneal keratocytes in response to transforming growth factor beta 1 (TGF-β1). Previous studies have shown that the changes in extracellular matrix (ECM) stiffness of can regulate this process, but it remains unclear how keratocytes sense changes in their physical microenvironment. Here, we used a polyacrylamide (PA) gel system to show that the subcellular patterning (and activation of signaling downstream) of focal adhesions underlies stiffness-dependent differences in myofibroblastdifferentiation of corneal keratocytes.

Methods: Soft (1 kPa) and stiff (10 kPa) polyacrylamide (PA) hydrogels were fabricated on glass coverslips, functionalized with type I collagen, plated with primary corneal keratocytes (NRKs), and cultured in defined serum free media with or without exogenous TGF-β1. In some experiments, an inhibitor of focal adhesion kinase (PF-228) was also added to the media. Cells were fixed and stained for F-actin, as well as markers for myofibroblast activation (α-SMA), contractility (pMLC), or focal adhesions (vinculin). We also used traction force microscopy (TFM) to quantify NRK traction stresses.

Results: Treatment with TGF-β1 elicited stiffness-dependent differences in the number, size, and subcellular distribution of FAs in cultured NRKs. On stiff substrata, cells exhibited large FAs distributed throughout the entire cell body, while on soft gels, the FAs were smaller and fewer in number, localized primarily to the distal tips of thin cellular extensions. Larger and increased numbers of FAs correlated with elevated cellular traction stresses. Inhibition of focal adhesion kinase (FAK) disrupted stiffness-dependent differences in contractility and myofibroblast differentiation of cultured NRKs. Further, in the presence of the inhibitor, we no longer observed stiffness-dependent differences in the subcellular patterning of FAs.

Conclusions: Taken together, these data suggest that changes in the subcellular patterning of FAs, as well as the activation of FAK, have important implications for stiffness-dependent myofibroblast differentiation of corneal keratocytes during wound healing.

TITLE: The Most Influential Articles on Artificial Intelligence in Ophthalmology
SESSION TITLE: Machine Learning and Big Data
SESSION TYPE: Paper Session
AUTHORS/INSTITUTIONS: M. Joly-Chevrier, I. Hardy, Department of Ophthalmology, Universite de Montreal, Montreal, Quebec, CANADA|A. Nguyen, Faculty of Medicine, McGill University, Montreal, Quebec, CANADA|
Commercial Relationships Disclosure: Maxine Joly-Chevrier: Commercial Relationship: Code N (No Commercial Relationship) | Anne Xuan-Lan Nguyen: Commercial Relationship: Code N (No Commercial Relationship) | Isabelle Hardy: Commercial Relationship: Code N (No Commercial Relationship)
ABSTRACT BODY:
Purpose: Significant advances in artificial intelligence (AI) has led to promising applications in ophthalmology. This study highlights the 100 most cited ophthalmology research papers on AI.
Methods: Ophthalmology research papers published between 1990 and October 2021, were extracted from the Institute for Scientific Information Web of Knowledge platform, using the keywords AI, machine learning (ML), and deep learning (DL). Papers were assessed for eligibility based on title/abstract review, followed by full-text review. The primary outcome measure was the number of times cited. Secondary outcome measures were: publication year, author attributes, journal name, study design and characteristics (ophthalmology subspecialties, pathology examined, AI branches, algorithms, databases, and imaging modalities used).
Results: The 100 publications were cited between 27 and 399 times, with a median of 46 [IQR: 32-74]. All papers were published between 1994 and 2020, with 64% of them published in 2017-2019. They were written by 1 to 30 authors, with a median of 7 [4-9] authors per paper. 482 unique authors wrote between 1 and 13 papers. 46% of corresponding authors were based in the USA and 23% in Europe. The top three journals were: Investigative Ophthalmology & Visual Science (26%), Ophthalmology (14%) and JAMA Ophthalmology (8%). 67 studies were retrospective, 21 prospective and 4 ambidirectional. Out of the 100 publications, 46 focused on retina, 35 on glaucoma and 10 on cornea and external disease. Studies mainly examined glaucoma (37%), age-related macular edema (28%), and diabetic retinopathy (27%). The most used imaging modalities were: fundus photography (42%), optical coherence tomography (OCT, 42%), and visual fields (VFs, 14%). 78 studies were geared towards the development and evaluation of a diagnostic technology. Among the 86 studies specifying their ML algorithms, 78% used supervised learning, 11% unsupervised learning and 12% used a mix of both techniques. 78 studies focused on DL. Among the 95 studies specifying their algorithm approach, convolutional NNs were the most used (51%). Among the 51 studies specifying their database, 65% used private databases and 51% used public databases.
Conclusions: This is the first study to analyze the characteristics of the 100 most-cited ophthalmology papers on AI. The use of AI was predominantly for image recognition to develop and evaluate a new diagnostic technology.

TITLE: Influence of Census Tract Poverty Indicator on Survival in Cases of Conjunctival and Uveal Melanoma diagnosed within the State of Texas

SESSION TITLE: Public Health II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Erapuram, F. Dihowm, Internal Medicine, Texas Tech University Health Sciences Center El Paso, El Paso, Texas, UNITED STATES|Z.S. Hussain, University of Medicine & Health Sciences, Basseterre, SAINT KITTS AND NEVIS|

Commercial Relationships Disclosure: Jenson Erapuram: Commercial Relationship: Code N (No Commercial Relationship) | Zain Hussain: Commercial Relationship: Code N (No Commercial Relationship) | Fatma Dihowm: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In 2019, the CDC released the National Health Statistics Report highlighting the ultimate impact of poverty on healthcare utilization. Additionally, prior studies have highlighted differential incidences of melanoma stratified by poverty classification within Texas. This retrospective cohort analysis is the first of its kind in characterizing novel survival trends within the class of orbital melanomas in the state of Texas.

Methods: The Texas Cancer Registry (TCR) acted as provision for state-level standardized cancer statistics. 2,585 cases of conjunctival and uveal melanomas diagnosed between January 1, 1995 and December 31, 2018, a 23-year time interval, were extracted. All cases with unknown or arbitrary values of cause of death were eliminated from analysis. Cox proportional hazards modeling was performed to yield hazard ratios (HR) with 95% Confidence Intervals (CI). Kaplan-Meier (KM) curves were curated to visualize survival trends. Statistical significance was achieved at $p<0.05$. All statistical analyses were performed with IBM SPSS Version 26.

Results: N=1966 (79.1%), N=403 (16.2%), and N=116 (4.7%) cases were diagnosed with choroidal, ciliary body, and conjunctival melanomas, respectively. N=606 (24.4%) cases died of cancer-related causes and N=510 (20.5%) cases died due to causes unrelated to cancer. Patients residing in neighborhoods with poverty indices of 10-19.9% and 20-100% demonstrated 24.7%, 43.6%, and 33.0% increased hazards of multi-variable cause-specific, other-cause, and all-cause death, respectively, as compared to patients residing in neighborhoods with poverty indices of 0-5% and 5-9.9%. Within patients residing in poverty indices of 10-19.9% and 20-100%, female patients experienced increased hazards of other-cause death and former tobacco users experienced decreased hazards of cause-specific death as compared to current users (HR=0.619, p=0.019).

Conclusions: To the authors' knowledge, this investigation is the first to characterize the influence of psychosocial parameters, including poverty, gender, and tobacco use on survival in patients diagnosed with conjunctival, choroidal, and ciliary body melanomas within the state of Texas. Reconciliation of poverty and subsequent lack of healthcare utilization and psychological well-being are likely important thought processes when delivering care to those afflicted by ophthalmic cancers.

TITLE: Peripheral image quality in model pseudophakic eyes measured by a double pass system

SESSION TITLE: IOLs and Presbyopia

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Christaras, S. Tsoukalas, H.S. Ginis, Department of Research, Athens Eye Hospital, Glyfada, Attiki, GREECE|D. Christaras, H.S. Ginis, Diestia Systems, Athens, Attiki, GREECE|P. Artal, Laboratorio de Optica, Universidad de Murcia, Murcia, Murcia, SPAIN|

Commercial Relationships Disclosure: Dimitrios Christaras: Commercial Relationship: Code N (No Commercial Relationship) | Spyridon Tsoukalas: Commercial Relationship: Code N (No Commercial Relationship) | Pablo Artal: Commercial Relationship(s);Code I (Personal Financial Interest):Voptica SL;Code P (Patent):Voptica SL | Harilaos Ginis: Commercial Relationship(s);Code C (Consultant/Contractor):Voptica SL;Code P (Patent):Voptica SL

ABSTRACT BODY:

Purpose: The pseudophakic eye has generally higher peripheral astigmatism compared to the natural eye, leading to worse peripheral image quality. In this work, peripheral astigmatism of the pseudophakic eye is assessed in vitro using an anatomically equivalent eye model with two different types of intraocular lenses (IOL), by using an instrument based on the double pass principle. The purpose of this work is twofold: to measure peripheral astigmatism in the pseudophakic eye and to evaluate the capability of the double pass instrument to assess peripheral image quality in pseudophakic eyes.

Methods: A water-filled artificial eye was used, including a custom meniscus lens acting as cornea, and a black cardboard acting as fundus, which could pivot around a fixed axis, allowing measuring at field angles of up to 30 degrees. The IOL was supported by its haptics in a receptacle behind a diaphragm. Two IOLs were used in this study: a biconvex hydrophobic acrylic IOL with 20D power (Acrysof SA60AT, Alcon) and an inverted meniscus type hydrophobic acrylic IOL with 22D power (ArtIOL, Art55, Voptica) that reportedly has reduced peripheral astigmatism. Peripheral astigmatism was measured using a custom-made double pass instrument featuring a 780nm laser source, a tunable lens (EL-16-40-TC, Optotune) and a retinal camera (DMM37UX273-ML, The Imaging Source). The instrument can record through focus images of the point spread function. By applying the appropriate processing, defocus and astigmatism at each eccentricity can be calculated.

Results: The fundus' position of the artificial eye was set at best focus, i.e. the through focus scan using the double pass system returned 0D for both IOLs. Since defocus depends on retinal curvature, which can vary in the population, only peripheral astigmatism was assessed in this study. At 15 degrees astigmatism was measured to be 1.5D and 0D for the Acrysof IOL and the ArtIOL respectively. At 30 degrees astigmatism was found to be 5.65D and 3.5D for the Acrysof IOL and ArtIOL respectively. In all measurements the axis of astigmatism was at 0 degrees when measuring at horizontal field angles.

Conclusions: A novel double pass instrument for the measurement of peripheral image quality was used to measure peripheral astigmatism at 15 and 30 degrees in two IOLs of different type: a biconvex and an inverted meniscus lens. The meniscus lens produced lower astigmatism at all peripheral locations.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is a degenerative disorder of the macula, the region of the central retina responsible for the greatest visual acuity. Oxidative stress and aging of retinal pigment epithelial (RPE) cells are the major reason for AMD. 4-Hydroxynonenal (4-HNE) is a major product of lipid peroxidation, which is accumulated in aging cells and could be related to several age-related diseases. The mechanism of RPE cell death under oxidative stress is still controversial. The goal of the current study is to determine RPE cell death mechanisms using 4-HNE and RSL3 treatment models.

Methods: ARPE-19 or human primary RPE cells were treated with 4-HNE or RSL3, cell viability was tested 24 hours later. The effect of apoptosis, necroptosis, pyroptosis, and ferroptosis pathways on cell survival was tested using specific inhibitors. Cellular ATP and ROS levels were measured. PYCARD and RIPK3 expression were used to visualize inflammasomes and necrosomes. Lipid ROS, a ferroptosis marker, was tested using BODIPY reagent. RIPK1 and MLKL knockdown RPE cell lines were established using CRISPR/Cas9 to confirm the roles of the two genes.

Results: 1. 4-HNE-induced RPE cell death can be rescued by ferroptosis inhibitors (Lip-1 and Fer-1) and both upstream and downstream necroptosis inhibitors (RIPK1 inhibitor Nec-1 and MLKL inhibitor NSA, respectively); 2. RSL3-induced RPE ferroptosis can be rescued by Nec-1 but not NSA; 3. Both 4-HNE and RSL3 induce RIPK3 activation in RPE cells which can be inhibited by Lip-1, Fer-1, and Nec-1; 4. Both 4-HNE and RSL3 induce lipid ROS accumulation in RPE cells which can be inhibited by Lip-1, Fer-1, Nec-1 but not NSA; 5. RIPK1 and MLKL knockdown can prevent 4-HNE induced RPE cell death while RIPK1 but not MLKL knockdown can prevent RPE ferroptosis; 6. MCC950, an inflammasome (pyroptosis marker) inhibitor, couldn’t prevent RSL3 induced RPE ferroptosis alone, but the combination of NSA and MCC950 could partially rescue the cells.

Conclusions: Both RSL3 and 4-HNE can induce RPE ferroptosis. Ferroptosis is associated with RIPK3 activation, therefore representing one type of necroptosis. However, 4-HNE but not RSL3-induced RPE cell death can be inhibited by MLKL inhibition. Nec-1 is likely a better inhibitor for RPE ferroptosis compared to NSA, possibly because RIPK1/3 activation can induce inflammasome activation when MLKL is inhibited.

ABSTRACT BODY:

Purpose: Angiogenesis is a major cause of vision loss and blindness in numerous ocular diseases, including in the cornea, macular degeneration, and diabetes. To treat angiogenesis, laser photocoagulation, photodynamic therapy, and anti-vascular endothelial growth factor therapy such as bevacizumab (BEV) are often utilized, but these treatments can damage adjacent healthy tissue or require frequent administration and can carry a risk of infection. To improve the treatment efficiency, increase the treatment duration, and reduce these side-effects, the current study describes a novel treatment of ocular angiogenesis using miniature biodegradable silicon nanoneedles (SiNNs) fabricated on a tear-soluble contact lens.

Methods: The SiNNs were encapsulated with BEV (BEV@SiNNs) and used as drug carriers for long-term, sustained drug delivery. The potential treatment effects of BEV@SiNNs were evaluated on a rabbit corneal neovascularization (CNV) model (n = 24) after approval from the University of Michigan IACUC. To generate CNV, a suture was placed on the animal cornea and allowed for CNV development up to one month. BEV@SiNNs were applied on the cornea and monitored by optical coherence tomography (OCT), color photography, and red-free imaging. The treatment outcome was followed up for one-month post-treatment.

Results: The tear-soluble contact lens dissolved within 1 minute. CNV was rapidly reduced within 7 days post-treatment that persisted to at least 28 days (Figure) whereas no CNV reduction occurred with control. Vessel density was 2.9 ± 2.0% for BEV@SiNNs versus 85.8 ± 0.9% for control. SiNNs did not cause cytotoxicity. Histological images showed normal corneal morphology without evidence of cell death or damage to the corneal endothelium cells, corneal thickness, and limbal stem cells.

Conclusions: The SiNNs are an efficient drug delivery vehicle for treatment of ocular angiogenesis.

ABSTRACT BODY:

Purpose: CEP290 (centrosomal protein 290), a large multi-domain containing protein, is a key component of the transition zone in many primary and motile cilia. Mutations in Cep290 cause several ciliopathies, including Meckel Syndrome (MKS) and retinal specific disorders such as Leber Congenital Amaurosis (LCA). The CEP290 protein has been proposed as a component of the “Y-links” structures, which span from the axoneme microtubule doublets to the ciliary membrane in the connecting cilium (CC) of photoreceptor cells. Our goal is to determine the location of CEP290 protein and the structural effects of CEP290 defects at the nanometer scale.

Methods: We use a number of advanced microscopies, including transmission electron microscopy and immuno-electron microscopy, super-resolution and expansion fluorescence microscopy, and cryo-electron microscopy to examine ciliary ultrastructure in WT mice and two Cep290 mutant mouse lines with early-onset retinal degeneration. One is virtually devoid of functional CEP290 (near-null, nn), and the other is a complete knockout (KO).

Results: At post-natal day 10 in both CEP290 mutants, we observe formation of CC, less or no outer segment (OS) discs, and presence of Y-links. Immunogold TEM reveals the ultrastructural location of CEP290 in the area between the microtubules and the ciliary membrane, but not on the Y-links. Immunogold TEM and expansion microscopy also reveal a spiral periodicity in CEP290 staining around the CC. Each mutant displays multiple ciliary protein mislocalization from the CC at P10, preceding photoreceptor degeneration. Each mutant shows slightly different pathogenesis, with extracellular vesicles present instead of OS discs, and more ciliogenesis defects present in the KO.

Conclusions: These results suggest that CEP290 is not required as a structural component of Y-links in the CC. Its location, the formation of EV’s instead of OS discs, and the mislocalization of multiple ciliary proteins, may facilitate a proposed function as a "gate-keeper" for protein trafficking through the CC. CEP290’s localization throughout the length of the CC, an observation unique to photoreceptors and not ubiquitous to all ciliary transition zone proteins, may help explain the retina-specific symptoms of several CEP290 mutations. The additional photoreceptor phenotypes present in the KO mutants hint at the difference between loss of CEP290 vs presence of mutated CEP290 within photoreceptors.

ABSTRACT BODY:

Purpose: Identifying patients who are at high risk for development of subfoveal geographic atrophy (sfGA) in dry age-related macular degeneration (AMD) will be critical to personalized treatment management and potential clinical trial enrichment for eyes at greatest risk. In this study, the role of shape and texture-based radiomic features within the sub-retinal pigment epithelium (subRPE, i.e., space bounded by RPE and Bruch's membrane) on baseline SD-OCT scans is evaluated as potential biomarkers to discriminate between eyes that are at highest risk of sfGA progression.

Methods: This was an IRB-approved retrospective image analysis study of subjects with dry AMD without sfGA with 5-year clinical and SD-OCT follow-up. Based on sfGA status at year five, eyes were categorized as Progressors and Non-progressors. A total of 26 shape-based fractal dimension (FD) and 364 texture-based radiomics features were extracted from the subRPE compartment of the baseline SD-OCT scans. Minimum Redundancy Maximum Relevance (MRMR) feature selection method was employed to identify features from the training set (N=96) and evaluated with 3 different machine-learning classifiers over 500 iterations of 3-fold cross validation. Classifier performance was validated on the test set (N=41).

Results: Random Forest classifier yielded a cross-validated area under the Receiver Operating Characteristics curve (AUC) of 0.89±0.09 and 0.76±0.06 using isolated shape-based FD and isolated texture-based radiomics features, respectively. Mean fractal entropy was identified as the most significant shape-based biomarker with higher values of entropy being associated with greater shape disorder and risk for sfGA progression. The Laws texture features were identified as the most discriminating features with the Progressors having higher feature expression. This suggests higher degree of heterogeneity within the subRPE compartment texture for the Progressors. A combination of shape and texture features yielded a significant improvement in the classifier performance with AUC=0.92±0.02.

Conclusions: In this study, radiomics-based characterization of the subRPE compartment in dry AMD identified multiple potential imaging biomarkers. Future works will involve prospective multi-institutional validation of the fractal and texture features for clinical trial enrichment and assessments for therapeutic response in dry AMD patients.

ABSTRACT BODY:

Purpose: Artificial intelligence (AI) algorithms can learn and perpetuate racial biases from patterns in medical images if those images contain information relevant to self reported race or ethnicity. Recent studies have shown that convolutional neural networks (CNNs) can be trained to classify images as being from black or white patients from medical images that were not previously thought to contain information relevant to the classification of self-reported race. Herein, we evaluate whether grayscale retinal vessel maps (RVMs) of patients screened for retinopathy of prematurity (ROP) similarly contain the potential for racial bias.

Methods: 4095 retinal fundus images (RFIs) were collected from 245 Black and White infants (as labeled by self-report from parents). A U-Net generated RVMs from RFIs, which were subsequently thresholded, binarized, or skeletonized (Figure). CNNs were then trained to predict self-reported race from color RFIs, raw RVMs, and thresholded, binarized, or skeletonized RVMs. Area under the precision-recall curve (AUC-PR) was evaluated.

Results: CNNs predicted self-reported race from RFIs near perfectly (image-level AUC-PR: 0.999, subject-level AUC-PR: 1.000). Raw RVMs were almost as informative as color RFIs (image-level AUC-PR: 0.938, subject-level AUC-PR: 0.995). Ultimately, CNNs were able to detect whether RFIs or RVMs were from self-reported Black or White babies, regardless of whether images contained color, vessel segmentation brightness differences were nullified, or vessel segmentation widths were normalized.

Conclusions: Both Color RFIs and black and white RVMs contain information relevant to the race of patients. These results suggest that biomarker-based strategies to remove information relevant to race or ethnicity (such as skin or fundus pigmentation) may not be effective, and that the potential for racial bias exists even in images that do not appear to contain relevant information.

ABSTRACT BODY:

Purpose: Macrophages are integral to maintenance of choroidal function. This study aims to investigate the role of senescent macrophages in inducing advanced wet age-related macular degeneration (AMD) characterized by choriocapillaris neovascularization and functional atrophy of the retinal pigment epithelium (RPE). Utilizing a 3D bioprinted “choroid” with a confluent capillary network, fibroblasts, primary macrophages and polarized RPE monolayer, we aim to model and investigate the mechanisms behind AMD initiation and progression in this 3D Outer Blood Retinal Barrier (3D-OBRB) system.

Methods: Endothelial cells, choroidal fibroblasts, ocular pericytes, and primary macrophages mixed with a collagen-derived gel were 3D-printed on a degradable scaffold to facilitate development of microvascular networks. iPSC-derived RPEs were seeded on the opposite side of the scaffold 7 days after bioprinting. Primary polarized M1, M2, and mixed ratios of M1+M2 macrophages were included in the hydrogel. Confocal microscopy, trans-epithelial electrical resistance measurements (TER), were used to analyze RPE health and structural integrity of choroidal vasculature.

Results: Single (M1 or M2 only) macrophage treatments resulted in increased capillary growth in the choroid space compared to the non macrophage treated control but, didn’t cause any noticeable pathological effect. Mixed macrophage treatments caused increased vascular growth into the 3D-OBRB sub-RPE space, similar in phenotype of type-I CNV, after 5 weeks, with the 2:1 M1:M2 ratio causing the most severe increase. The RPE monolayer also saw decreased TER at the same time point, with 1:2 M1:M2 macrophage treatment causing the biggest decrease. In all cases, macrophages take on “bloated” foam-cell like morphologies, similar to what is seen in patients with advanced AMD. While our bloated macrophages are ki67-/p16+, we are also investigating said macrophages using gene expression analysis to further demonstrate their senesent state.

Conclusions: While healthy macrophages proved to be beneficial during the initial developmental period, development of senescent macrophages coincides with compromised 3D-OBRB physiology. This 3D tissue model allows for the study of ocular immune populations, and their role in ocular health, via a reductionist in-vitro system.

ABSTRACT BODY:

Purpose: Humans are unable to regenerate retinal neurons leading to blinding diseases, in contrast zebrafish exhibit remarkable capacity for regenerating lost neurons throughout life. Multiple studies have defined transcriptomic shifts driving zebrafish retinal regeneration following the death of multiple cells types, but to identify disease-relevant therapeutic strategies it is critical to look at the zebrafish response to loss of discrete retinal cell types. Here, we profiled regeneration-associated transcriptomic shifts over a long time course in zebrafish in response to loss of either rod photoreceptors or bipolar interneurons.

Methods: The primary method used was bulk-tissue (whole eyes) microarrays conducted on larval zebrafish samples. Our lab has developed transgenic retinal ablation models to kill specific retinal cells and induce a regenerative response. Groups of larvae were collected following the induced ablation (or non-ablated samples for control) of rods or bipolar cells at multiple timepoints throughout regeneration including 0, 8, 16, 24, 32, 40, 48, 60, 72, 96, 144, and 240 hours into induced regeneration. Pathway analysis tools were used to identify patterns characterizing transcriptomic changes at each timepoint along with a particular interest in comparing differentially expressed genes and pathways between the different cell type patterns.

Results: Throughout our time course we found more cell-type specific transcriptomic changes rather than those shared between the two models. Of the changes that were shared, there was more similarity earlier on following induced cell death (~24h) rather than later (~72h and on). Numerous well-defined pathways were found to be differentially regulated in one model while absent from the other (example: p53 signaling changes more prominent in bipolar cells). We then used the literature to help characterize pathway changes associated with different phases of retinal regeneration including stem cell activation, proliferation, differentiation, and more.

Conclusions: We successfully identified both shared and cell-type specific regeneration patterns, with the majority leaning toward the latter. This supports the theory that further defining these cell-type specific (fate-biased) responses will be critical in developing more therapeutic strategies to induce regeneration in the mammalian retina.

ABSTRACT BODY:

Purpose: Nerve growth factor (NGF), brain-derived neurotrophic factor (BDNF), neurotrophin3 (NT-3) bind to tyrosine kinase (Trk) receptors, TrkA, TrkB, and TrkC, respectively. This study investigated the efficacy of novel molecule agonists of Trk receptors in an in vivo model of dry eye disease.

Methods: Small molecule agonists for TrkC (C1) or pan-Trk (pan) were synthesized based on structural formula and β-turns. C57BL/6J mice were subjected to desiccating stress (DS) and received bilateral eye drops of C1, pan or vehicle (2x/day). The corneal barrier function was assessed by uptake of a fluorescent dye (n=11-18/ group). The conjunctival goblet cell (GC) density was measured in paraffin-embedded, PAS-stained sections (n=10-14/group). Corneal epithelial lysates were collected for either western blot or RNA extraction. Extracted total RNAs were used for NanoString analysis. Immunofluorescent staining was performed on wholemount corneas using anti-A20 and anti-PTGER4 antibodies.

Results: Compared to naïve mice, desiccated mice treated with vehicle showed corneal barrier disruption (55±11 vs 97.8±38.4 gray levels, $P<0.01$) and goblet cell loss (50±11 vs 37±11 goblet cells/mm, $P<0.01$). Compared to treatment with vehicle, pan and C1- treated mice showed an improvement in corneal barrier function (98±38 vs 59±17 and 72±18 gray levels, respectively, $P<0.01$), and higher conjunctival GC density (37±11 vs 46±10 and 52±13 GC/mm, respectively, $P<0.05$). NanoString results revealed upregulation of specific mRNA transcripts (Ptger4, Tnfaip3 [encoding A20], Il1a and Ptger4, Tlr3, Osal1, respectively) in Pan and C1-treated corneas compared to vehicle-treated corneas (all P-adj<0.05). Western blot results showed that treatment with pan and C1 decreased vehicle-induced NFkB nuclear translocation after DS for one day and increased PTGER4 and A20 protein levels after 5 days of DS in corneal epithelium lysates. These results were confirmed by immunostaining using antibodies for A20 and PTGER4 in wholemount corneas.

Conclusions: Small molecule agonists of Trk receptors improve dry eye disease by decreasing NFkB activation and increasing protein expression of anti-inflammatory molecules A20 and PTGER4. Further studies are needed to investigate whether pan and C1 analogs modulate other pathways involved in dry eye.

TITLE: Glaucomatous stressors drive Schlemm's canal cell pathobiology via elevated YAP activity

SESSION TITLE: Glaucoma: molecular, biochemical and biomechanical mechanisms

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S. Herberg, H. Li, P.S. Ganapathy, Ophthalmology and Visual Sciences, SUNY Upstate Medical University, Syracuse, New York, UNITED STATES|M. Kuhn, W.D. Stamer, Ophthalmology, Duke University, Durham, North Carolina, UNITED STATES|

Commercial Relationships Disclosure: Samuel Herberg: Commercial Relationship: Code N (No Commercial Relationship) | Haiyan Li: Commercial Relationship: Code N (No Commercial Relationship) | Megan Kuhn: Commercial Relationship: Code N (No Commercial Relationship) | William Stamer: Commercial Relationship: Code N (No Commercial Relationship) | Preethi Ganapathy: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Dysfunction of the Schlemm's canal (SC) inner wall endothelium and trabecular meshwork is the principal cause of decreased outflow facility in glaucoma. Extracellular matrix (ECM) stiffening and increased transforming growth factor beta2 (TGFβ2) in the aqueous humor are strongly associated with outflow tissue dysfunction. Yes-associated protein (YAP) has emerged as key contributor to glaucoma pathogenesis; YAP1 was recently identified as potential genetic risk factor. However, the precise role of SC cell YAP signaling in response to known glaucomatous stressors is poorly understood. Here, we investigate how ECM stiffness/composition and TGFβ2 regulate YAP activity in human SC cells using biomimetic hydrogels, and whether pharmacologic YAP inhibition increases ex vivo outflow facility.

Methods: ECM hydrogels were fabricated by photocrosslinking functionalized collagen type I, elastin-like polypeptide, and hyaluronic acid. Bioinert alginate was added to facilitate Ca^{2+}-mediated hydrogel stiffening (~3-fold) and alginate lyase-mediated softening. Fibronectin (FN) was used to coat ECM hydrogels (10 μg/cm^2). Donor-derived SC cells were plated on hydrogels and stimulated with TGFβ2 (2.5 ng/ml), Y27632 (10 μM), or latrunculin B (Lat B; 2 μM). Verteporfin (VP; 0.5 μM) was used for YAP inhibition. YAP transcriptional activity, cytoskeletal organization, fibrotic marker levels, and ECM remodeling were quantified. Outflow facility with perfusion of VP (10 μM) was measured in enucleated eyes from C57BL/6J mice using iPerfusion.

Results: ECM stiffening increased YAP activity and F-actin levels in SC cells ($p<0.001$). Nuclear YAP completely translocated to the cytoplasm within 3 h after ECM softening; F-actin levels reached baseline after 24 h ($p<0.0001$). FN coating enhanced SC cell YAP activity and F-actin/ECM remodeling. TGFβ2 increased nuclear YAP ($p<0.001$) contingent on cytoskeletal integrity; Y27632 or Lat B co-treatment interrupted aberrant YAP signaling. VP treatment fully blocked TGFβ2-driven YAP activation in SC cells ($p<0.0001$) and largely restored FN, TGM2, F-actin, αSMA, and pMLC levels ($p<0.001$). Importantly, 6/10 mouse eyes displayed ~15-80% increased outflow facility with VP perfusion.

Conclusions: Our data suggest that YAP modulates SC cell dysfunction in response to known glaucomatous stressors, and that pharmacologic YAP inhibition has promising potential to improve outflow tissue dysfunction.

TITLE: Ultrastructure of bipolar cell dendritic trees and rod convergence in the simplex retina of L. erinacea

SESSION TITLE: Retinal and central processing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Wagh, J.G. Fathi, M. Ramon, Y. Yusuf, A. Alazzeh, I. Anastassov, Cell and Molecular Biology (CMB), San Francisco State University, San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure: Abhiniti Wagh: Commercial Relationship: Code N (No Commercial Relationship) | Jessamyn Fathi: Commercial Relationship: Code N (No Commercial Relationship) | Marta Ramon: Commercial Relationship: Code N (No Commercial Relationship) | Yaqoub Yusuf: Commercial Relationship: Code N (No Commercial Relationship) | Aya Alazzeh: Commercial Relationship: Code N (No Commercial Relationship) | Ivan Anastassov: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Visual information processing under scotopic and photopic conditions is generally divided between the rod and cone systems, which transmit information to dedicated bipolar pathways. However, the simplex retina of L. erinacea utilizes rods across the full range of illumination. We know little about what functional and anatomical features of rod pathways in mixed rod-cone retinas are present in skate. Here, we use SB-3DEM to examine the convergence ratio of rods to postsynaptic partners (identified as putative bipolar cells), as well as the dendritic tree architecture of putative bipolar cell types.

Methods: Retinal pieces were embedded in resin blocks, and serial block-face scanning electron microscopy (SB-3DEM) was performed on individual samples from the tapetal retinal region of adult animals. The dataset analyzed here was from the entire cross section of the retina with a width of 82µm, height of 314 µm, and depth of 29 µm. Section thickness was 65nm, and pixel size was 7nm x 7nm.; the dataset has 452 sections. 3-D representations of dendritic processes and synaptic ribbons were obtained through segmentation in Reconstruct software; quantifications were done in Amira 3D software.

Results: We quantified a total of 97 dendritic processes, or tips, in the initial putative bipolar cell examined. In mouse retina, rod bipolar cell dendritic tips are likely sites of contacts with rods and appose a rod synaptic ribbon ~84% of the time (Anastassov et al., 2019). We have so far determined that ~1/5 of the 97 tips identified are likely apposed to a ribbon. Additional measurements on the rest of the dendritic tips, as well as reconstructions of other putative bipolar cells in the dataset, are ongoing. Preliminary observations show that individual bipolar cell processes may be capable of making both invaginating and basal contacts with the same rod terminal.

Conclusions: We show the rod-only skate retina likely has the same high rod-to-bipolar-cell convergence ratio found in mixed rod-cone retinas, supporting prior electrophysiological evidence of high sensitivity. Invaginating putative bipolar cell dendritic tips are likely sites of contact with individual rods, although exact contact probability is yet to be determined. Finally, putative bipolar cells may posses invaginating (normally ON) and basal (normally OFF) contacts within the same cell, suggesting a hybrid dendritic architecture.

ABSTRACT BODY:

Purpose: A previous small case series identified a 50% proton pump inhibitor (PPI)/histamine (H2) blocker usage rate in patients with toxoplasma retinochoroiditis, higher than the rate of 20% described in the general population. A primary defense against T. gondii tachyzoites is acidification of phagolysosomes within an acidic environment. Usage of PPI/H2 blockers can increase gastric pH and weaken host defenses, which we hypothesize may increase susceptibility to infection. Therefore, we conducted a case control study of medical claims data from a national database to determine if PPI/H2 blocker usage is associated with the development of ocular toxoplasmosis.

Methods: A retrospective, matched case control study using data from a medical claims database was performed from 2000-2020. Cases of ocular toxoplasmosis were identified using ICD 9/10 codes. The index date for cases was considered the earliest date of diagnosis of ocular toxoplasmosis. Controls were matched up to 5:1 for age, gender, race, with eligibility date within 3 months from index date of matched cases. Exclusion occurred for being < 18 years old, having congenital toxoplasmosis, having <2 years in the insurance plan prior to the index date and not having at least one visit to an eyecare provider prior to the index date. The primary outcome was defined as having a prescription for PPI or H2 blocker, or a disease that was likely to lead to PPI/H2 blocker use prior to the index date. Multivariate conditional logistic regression analyses were performed controlling for demographic and systemic health variables.

Results: 4069 cases and 19177 controls met our eligibility criteria. 24.3% (989/4069) of ocular toxoplasmosis cases were on PPI/H2 blockers compared to 19.2% (3673/19177) of controls. An adjusted logistic regression model demonstrated a 28% increase in the odds of PPI/H2 blocker use in ocular toxoplasmosis cases compared to matched controls (95% CI: 1.17-1.40, $p < 0.001$).

Conclusions: PPI/H2 blocker exposure was associated with ocular toxoplasmosis, corroborating findings from prior case series suggesting an association between the two. Further research studying the mechanisms of PPI/H2 blocker use, gastric acid suppression and T gondii infectivity may help reduce risk of ocular infection.

TITLE: Probing the Contribution of Retinal Pigment Epithelium to Eyecup Metabolism

SESSION TITLE: Retinal metabolism and physiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Chiu, D. Hass, J.B. Hurley, Biochemistry, University of Washington, Seattle, Washington, UNITED STATES|

Commercial Relationships Disclosure: Collin Chiu: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Hass: Commercial Relationship: Code N (No Commercial Relationship) | James Hurley: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The eyecup consists of retinal pigment epithelium (RPE), choroid, and sclera. RPE metabolism is assumed to be dominant in eyecup preparations, but this has yet to be proven rigorously. In this study we probe the contribution of retinal pigment epithelial cells to eyecup metabolism. We approach this question by determining metabolic flux in eyecup tissue from control and mice injected with the selective RPE cell toxin sodium iodate ($NaIO_3$).

Methods: We injected C57BL/6J mice with a single intraperitoneal dose of saline or 50 mg/kg $NaIO_3$. Seven days later we sacrificed mice via cervical dislocation and dissected eyecup tissue into Krebs-ringer bicarbonate buffer supplemented with either labeled or unlabeled 5 mM glucose. We quantified extracellular flux of glucose and lactate using spectrophotometric assays and intracellular flux of 1,2-$^{13}C_2$-glucose using gas chromatography-mass spectrometry. We compared glucose flux in saline-injected control eyecups to eyecups from NaIO3-injected mice.

Results: $NaIO_3$ treated eyecups released 42% less lactate from media than controls ($p<0.05$), despite negligible glucose consumption. Surprisingly most glycolytic and TCA cycle metabolite levels were unchanged by $NaIO_3$ injection. $NaIO_3$ treatment did however significantly decrease levels of lactate and the TCA cycle metabolites malate and fumarate. ^{13}C flux from 1,2-$^{13}C_2$-glucose to lactate and malate was also decreased by $NaIO_3$ treatment.

Conclusions: Our results suggest that glycolytic flux and lactate export in the eyecup is partly due to retinal pigment epithelium metabolism. However, metabolite levels and flux were partly maintained, implying that RPE metabolism may not be dominant in the eyecup. The remaining glucose metabolism could be due to contributions from endothelial cells, or microglial cells recruited to the eyecup after $NaIO_3$ treatment. Further analysis is required to fully understand the role of RPE metabolism in the eyecup.

ABSTRACT BODY:

Purpose: Proteoglycan 4 (PRG4, or lubricin) is a mucin-like glycoprotein present on the ocular surface and in tears, with both lubricating and anti-inflammatory properties. Biological processes occur in solution; therefore, studying proteins' biophysical properties in solution contribute to understanding their function. Here, we biophysically characterize recombinant human PRG4 (rhPRG4), previously shown to be clinically effective in reducing signs and symptoms of dry eye, and determine the effect of the cation Mg^{2+} and high pH on rhPRG4 size in solution.

Methods: rhPRG4 (Lubris BioPharma) at pH7, and in some cases native human PRG4, was assessed in solution for hydrodynamic diameter (Dh, by dynamic light scattering), charge (zeta potential), structure (circular dichroism, CD), density (analytic ultracentrifugation, AUC), and molecular fingerprint (raman spectroscopy). The kinetics of rhPRG4 binding to type 1 Collagen (Col1) was assessed (quartz crystal microbalance). Finally, the effects of 1-5mM $MgCl_2$ or pH9-10 on Dh was assessed.

Results: rhPRG4 had a main (~85%) peak at Dh=~170nm (with a minor at ~30nm, z-avg Dh=~110nm) and a -21mV zeta potential. Native PRG4 Dh and charge were similar to rhPRG4. CD indicated rhPRG4 had a main extended structure peak ~202nm and no discernible tryptophan peak at ~290nm. AUC indicated a dominant species at ~4S. Raman spectroscopy showed the ratio of normalized (to 891cm-1, C-C) peaks at $980cm^{-1}$ and at $550cm^{-1}$, associated with β-sheets and disulfide bonds respectively, was ~2.9. rhPRG4 rapidly bound to Col1, with a t~8sec. $MgCl_2$ caused a decrease of the main Dh peak in a dose dependent manner, reducing to ~140nm at 5mM. Finally, pH9 caused a decrease in the main peak and an emergence of an intermediate peak at ~120nm, and pH10 even more so.

Conclusions: The clinically effective rhPRG4 assessed here had similar size and charge to native PRG4, and quickly adhered to Col1 (which is present on the ocular surface). The size, charge, and density for rhPRG4 are larger than those published for a different version of recombinant human lubricin (ECF843: Dh=~60nm, ~0mV, and a more compact 6.5S major peak), which recently did not produce supportive data in a dry eye clinical trial. Reduced Dh of rhPRG4 caused by Mg^{2+} and pH9-10 may be due to osmotic deswelling of the mucin domain and disulfide bond

reshuffling, respectively, which are likely to affect function as well.

ABSTRACT BODY:

Purpose: An increasing number of eye disorders are associated with protein misfolding, oxidative stress, inflammation, and apoptosis. It is hypothesized that a cell-penetrable, protease-resistant amphiphilic mini chaperone peptide (CPPRAMC) having the core αA-crystallin chaperone region sequence can help treat such disorders. We have tested our hypothesis using cell culture and Caenorhabditis elegans (C. elegans) model systems.

Methods: The CPPRAMC, having all D- amino acids, and the control peptides were synthesized (>95% pure) by GenScript. The anti-aggregation activity of the CPPRAMC was confirmed in vitro by testing the suppression of $A\beta_{1-42}$ (25 μM) oligomerization and fibrillization under TEM. The suppression of mutant myocilin (DsRed-MYOC-Y437H) accumulation in TM cells was confirmed by fluorescence imaging. The ability of CPPRAMC to protect ARPE-19 cells from $A\beta_{1-42}$-induced cytotoxicity was evaluated by performing an EarlyTox cell integrity assay on treated cells. The anti-oxidative property of CPPRAMC was demonstrated in ARPE-19 cells challenged with 7.5 mM sodium iodate for 24 hr. The cellular ROS activity was measured with 2′,7′-Dichloro-fluorescein diacetate. The therapeutic efficacy of the CPPRAMC was also evaluated in C. elegans wild-type (N2) worms subjected to stress and in transgenic (CL4176) worms expressing human $A\beta_{1-42}$. The anti-inflammatory property of CPPRAMC was tested using HEK293 IL-6 reporter cells (Invivogen).

Results: CPPRAMC treatment (5 μM) reduced the accumulation of DsRed-MYOC-Y437H protein in TM cells. Aβ peptide-treated (5 μM) ARPE-19 cells showed 25% apoptosis while cells treated with CPPRAMC (5 μM) + Aβ peptide showed 10% apoptotic cells. Doubling the molar concentration of CPPRAMC reduced the number of dead cells to 5%. CPPRAMC (5 μM) completely suppressed the NaIO3-induced ROS production. CPPRAMC ablates the LPS-induced release of IL-6 in mouse macrophages (Raw264.7) and blocks IL-6 signaling (50 pM) completely in HEK-Blue IL-6 reporter cells when used at 1 μM. CPPRAMC feeding augments the lifespan (46%) and increases the thermotolerance (51%) of wild-type C. elegans. CPPRAMC treatment delays β-amyloid induced paralysis and increases survival (18%) in transgenic CL4176 worms.

Conclusions: The results suggest the beneficial effects of CPPRAMC in treating diseases associated with protein misfolding, oxidative stress, inflammation, and apoptosis that affect vision.

ABSTRACT BODY:

Purpose: Purpose: Proliferative vitreoretinopathy (PVR) is still the most common cause of failure after retinal reattachment surgery due to secondary growth and contraction of cellular membranes within the hyaloid and retina. The epiretinal membrane is a thin sheet of fibrous tissue that develops on the macula. The treatment of choice to date is either surveillance when no retinal detachment has yet occurred or vitreoretinal surgery and removal of those PVR membranes to prevent or treat further complications, such as recurrent retinal detachment. Identification of factors that may interfere with the formation and regulation of PVR membranes could facilitate the development of novel therapeutics. Various groups have shown that the ROCK pathway is involved in PVR pathogenesis; however, the presence of rho-kinase in human PVR membranes has not yet been demonstrated. To compare the ROCK-signaling in two different types of human ocular fibrotic membranes, we aim to study in addition the ROCK pathway in human ERM.

Methods: Methods: Membranes were obtained in the course of vitreoretinal surgery from 6 patient eyes with proliferative vitreoretinopathy (PVR) and 12 eyes with epiretinal membranes (ERM). To show that the Rho/ROCK signalling pathway is involved in these vitreoretinal diseases, immunohistochemistry staining for hematoxylin and eosin, collagen-1, alpha-smooth muscle actin (a-SMA) and Rho-kinase isoforms (ROCK1 and ROCK2) of surgically excised human PVR and ERM membranes were performed. In addition, the human ocular fibrotic membranes were analysed with rtPCR to screen for the Rho-kinase related gene expression levels, expression differences and RNA content.

Results: Results: Different fibrotic markers, such as collagen 1 and a-SMA were detected together with ROCK1 and ROCK2 in PVR and ERM membranes.

Conclusions: Conclusions: The current results indicate that Rho-kinase is expressed in human ocular fibrotic membranes, such as PVR and ERM, and might play a role in its formation.

ABSTRACT BODY:

Purpose: Dry age-related macular degeneration is closely related with retinal pigment epithelial (RPE) cell dysfunction and photoreceptor degeneration. Sodium iodate ($NaIO_3$), a chemical oxidizing agent, induces patchy retinal & RPE cell loss in multiple mammalian species. $NaIO_3$ model has been used to test drug candidates for treating retina & RPE degeneration. Neuroprotective effect of ciliary neurotrophic factor (CNTF) has been well demonstrated in retinal ganglion cell and photoreceptor cell damage models. In this study, we evaluated the protective effect of intravitreal (IVT) administration of recombinant human CNTF (rHCNTF) in $NaIO_3$ model in mice.

Methods: 20mg/kg $NaIO_3$ was injected intraperitoneally in 8-10 week old C57BL/6J mice. Mice received IVT injections of 1ml rHCNTF (1.5mg or 2.0mg) or control (buffer or water) in the left eye one day prior and after $NaIO_3$ injection. Optical Coherence Tomography (OCT) and electroretinogram (ERG) were performed at baseline and one-week post $NaIO_3$ injection to evaluate the retinal structural and functional changes. One-week post $NaIO_3$, animals were euthanized. RPE/choroid flat mount was stained with phalloidin to evaluate the damage.

Results: Seven days after $NaIO_3$ injection, subretinal changes and retinal thickness loss (>50um) were observed in both eyes of the control groups (buffer, water) by OCT imaging. In contrast, there were minimal subretinal and retina thickness changes (<10um loss) in rHCNTF injected eyes. ERG showed significant protection of a, b and c wave amplitudes in rHCNTF injected eyes. Interestingly, in the contralateral noninjected eyes of rHCNTF group, there was also less retinal damage by OCT and ERG evaluation. Consistent with the in vivo observations, RPE/choroid flat mounts showed more RPE cell survival, and close to normal morphology in CNTF treated eyes. Contrarily, severe damage and loss of RPE cells were found in the control eyes.

Conclusions: Intravitreal injections of rHCNTF prevented $NaIO_3$ induced structural & functional damages in RPE & retina. These findings demonstrate a protective role of CNTF in RPE and photoreceptor cells after oxidative stress challenge, and support CNTF as a potential therapeutic agent for the treatment of RPE and photoreceptor loss in disease.

ABSTRACT BODY:

Purpose: To assess the feasibility of machine learning enhanced volumetric fluid characterization in diabetic macular edema (DME) and compare the longitudinal fluid dynamics between the treatment groups in the Phase III VISTA DME clinical trial.

Methods: In the Phase III VISTA clinical trial, patients were randomly assigned to receive either 2mg IAI every 4 weeks (2q4), 2mg IAI every 8 weeks following 5 initial monthly doses (2q8), or laser photocoagulation (rescue with IAI was allowed beginning at week 24). Utilizing a machine learning-enhanced fluid feature extraction platform, OCT images taken monthly for each patient were analyzed from Baseline to Week 24, at Week 52, and at Week 100. For each visit, intraretinal fluid (IRF) and subretinal fluid (SRF) metrics were extracted through automated fluid segmentation with manual correction, as needed. IRF/SRF total macular volume, central subfield volume (CSV), and central subfield fluid indices (i.e. percentage of retina occupied by fluid) were analyzed.

Results: Four hundred forty-three patients were included in the study with successful OCT feature extraction, with 148 in the 2q4 group, 148 in the 2q8 group, and 147 in the laser group. At baseline, all groups demonstrated similar IRF and SRF volumetric parameters ($p>0.05$). At Week 100, the pooled IAI group showed significantly less mean panmacular IRF volume than the laser group $0.135\pm0.39mm^3$ vs $0.275\pm0.47mm^3$; $p=0.006$, respectively) and lower CSV IRF fluid index ($0.06\pm0.13\%$ vs $0.12\pm0.18\%$; $p=0.002$), despite 41% of laser patients receiving IAI between weeks 24 and 100. Laser and pooled IAI showed significant improvement in SRF from Baseline to Week 100 (both $p<0.01$).

The 2q4 group showed significantly greater mean change in all IRF parameters at week 100 compared to 2q8, including panmacular IRF volume ($-0.137\pm0.34mm^3$ vs $-0.064\pm0.16mm^3$; $p=0.034$), IRF CSV ($-0.012\pm0.034mm^3$ vs $-0.003\pm0.02mm^3$ respectively; $p=0.006$), and CSV IRF index ($-0.04\pm0.09\%$ vs $-0.01\pm0.07\%$; $p=0.0019$).

Conclusions: Utilizing a machine learning-enhanced extraction platform, longitudinal volumetric fluid assessment was feasible and demonstrated greater reduction in IRF with IAI at week 100 compared to laser photocoagulation. The 2q4 group demonstrated a greater reduction in IRF at week 100 compared to the 2q8 group.

TITLE: Optical quality evaluation and vision simulation of a binocular diffractive multifocal intraocular lens system vs. a conventional diffractive multifocal intraocular lens

SESSION TITLE: IOLs and Presbyopia

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Naujokaitis, G. Labuz, G. Auffarth, Dept. of Ophthalmology, Ruprecht Karls Universitat Heidelberg, Heidelberg, Baden-Württemberg, GERMANY|

Commercial Relationships Disclosure: Tadas Naujokaitis: Commercial Relationship: Code N (No Commercial Relationship) | Grzegorz Labuz: Commercial Relationship: Code N (No Commercial Relationship) | Gerd U Auffarth: Commercial Relationship(s);Code C (Consultant/Contractor):Alcon;Code F (Financial Support):Alcon;Code R (Recipient):Alcon;Code R (Recipient):Cristalens Industrie

ABSTRACT BODY:

Purpose: In the binocular diffractive multifocal intraocular lens (IOL) system Artis Symbiose (Cristalens Industrie, France), in addition to the distance focus, one lens features an extended depth of focus profile for intermediate vision (Artis MID) and the other lens for near vision (Artis PLUS). We performed a laboratory study to evaluate the optical quality of the Artis Symbiose IOL system in comparison with a conventional diffractive multifocal IOL AcrySof IQ PanOptix (Alcon, TX, USA), and to simulate binocular vision with the study IOLs.

Methods: The Artis MID and Artis PLUS IOLs were compared with the AcrySof IQ PanOptix IOL using an optical bench setup. Modulation transfer function and phase transfer function were obtained within the defocus range of +0.75D to -4.0D at spectacle plane in polychromatic light at the aperture of 3 mm using a model cornea with positive spherical aberration. Simulated visual acuity (VA) values were derived from the optical transfer function weighted by the neural contrast sensitivity. The United States Air Force (USAF) resolution chart images were acquired and processed to simulate binocular vision.

Results: All the studied IOLs had a predicted VA of 0.2 logMAR or better throughout the range of +1D to -3D. At distance focus, their simulated VA was minimally better than 0.0 logMAR (range -0.03 to -0.01 logMAR). The peak simulated VA values of the Artis MID were at 0D of defocus (-0.02 logMAR) and at -1.5D (0.00 logMAR); of the Artis PLUS, they were at 0D of defocus (-0.01 logMAR) and at -2.5D (0.01 logMAR). The AcrySof IQ PanOptix demonstrated three peaks: at 0D of defocus (-0.02 logMAR), at -1.75D (0.03 logMAR) and at -2.5D (0.02 logMAR). The binocular summation of the USAF chart images in the simulated binocular system indicated comparable results to those of AcrySof IQ PanOptix. However, at a defocus of 1.0D and -1.5D, the combination of Artis MID and Artis PLUS produced a slightly better image quality.

Conclusions: The binocular multifocal IOL system may yield better intermediate VA and wider defocus range in binocular vision compared to monocular implantation of the conventional multifocal IOL. However, more research is needed to better understand the effect of binocular summation in the binocular multifocal IOL system and in bilateral conventional multifocal IOL implantation.

ABSTRACT BODY:

Purpose: To evaluate the relationship between contrast sensitivity and lower extremity physical function in a population of high-functioning older adults.

Methods: Cross-sectional analysis of 190 older adults in B-NET who completed baseline contrast sensitivity function, corrected distance visual acuity testing, and lower extremity function using the expanded short physical performance battery (eSPPB).

Results: Participant mean age was 76.4 (range 70.3 – 90.7) years with 56% identifying as female. Presenting corrected logMAR visual acuity was good overall with a mean 0.092 +/- 0.10 and median of 0.097 (range 0 – 0.602), which translates to a mean and median Snellen acuity of approximately 20/25 (range 20/20 – 20/80). Mean eSPPB was 2.0 (Range 0.48, 3.26). Log contrast sensitivity accounted for approximately 6.2% of the variance in baseline eSPPB ($p<0.001$) and remained significantly associated with eSPPB after adjusting for age, sex, and presenting visual acuity ($p=0.009$). A 1-standard deviation lower log contrast sensitivity score was associated with a -0.10 adjusted difference in eSPPB. Similarly, participants with a log contrast sensitivity less than 1.55 had a significantly lower eSPPB score than those with better log contrast sensitivity in both unadjusted (Beta = -0.270, 95% CI (-0.45, -0.09), $p=0.003$) and adjusted models (Beta = -0.216, 95% CI (-0.39, -0.038), $p=0.018$).

Conclusions: Impairment in contrast sensitivity is associated with worse performance on tests of lower extremity physical function, independent of corrected distance visual acuity. These findings suggest there may be a subgroup of older adults with poor contrast sensitivity who may be at risk of decline in physical function despite having good visual acuity and who may benefit from targeted screening protocols and interventions to prevent disability.

ABSTRACT BODY:

Purpose: Changes in expression of several enzymes have been reported in age-related and degenerative ocular diseases. However, the current ‘omics approaches (transcriptomics, proteomics) only determine abundance changes, which does not provide true enzyme functionality (e.g., in the case of propeptide processing or the presence of inhibitors). Chemoproteomics (e.g., activity-based protein profiling [ABPP]) is a versatile tool to broadly probe enzyme class activity and is a technique that has not been fully utilized in vision research. Employing ABPP, we performed an unbiased characterization of active serine hydrolases in mouse eyes and primary ocular cultures.

Methods: Neural retina (NR), RPE, and liver from WT C57BL/6 mice were homogenized and probed with a TAMARA-tagged fluorophosphonate (FP) probe that specifically and covalently labels the active-site of functional serine hydrolases. Samples were analyzed by fluorescent imaging after SDS-PAGE. NR, RPE, liver, and serum were also procured from fibulin-3 knockout (F3 KO) mice (a model that we speculated may have a different serine hydrolase activity landscape) and processed similarly. Lastly, samples (apical, basal, and lysates) from primary porcine RPE cells established on transwells were harvested by ABPP after 1 and 6 mo in culture.

Results: ABPP of serine hydrolases with the TAMARA FP probe revealed a number of differential activities between ocular tissues as well as liver in WT animals. Lower amounts of active serine hydrolases were detected in F3 KO animals in all of the tissues compared to WT littermates. Moreover, TAMARA FP probe was able to detect changes in serine hydrolase activity in polarized RPE cultures, highlighting that serine hydrolase activity is concentrated in the apical fraction, with little activity detected basally or in cell lysates.

Conclusions: Our data demonstrate the ability of ABPP to detect tissue-level differences in activity of serine hydrolases. We also identified polarity-specific differences in serine hydrolase activity of RPE cells and changes therein with culture age. We speculate that ABPPs for additional enzyme classes such as MMPs and cysteine proteases will yield important ocular pathobiology information and may serve as potential biomarkers for impending ocular diseases, enabling researchers to identify and monitor the active location of these enzymes, providing an additional dimension to conventional ‘omics approaches.

ABSTRACT BODY:

Purpose: Activating Protein-2 beta (AP-2β), encoded by Tfap2b, is a transcription factor expressed in the periocular mesenchyme (POM), which gives rise to the developing corneal stroma. We have previously shown that conditional knock out of AP-2β (AP-2β NCC KO) in the POM of mice causes an anterior segment phenotype that includes a closed iridocorneal angle, absent corneal endothelium and reduced corneal epithelial stratification. Our earlier studies have shown that the mutant corneal epithelium lacks Keratin-12 (K12), a corneal epithelial marker, and instead expresses Keratin-15 (K15), a marker of conjunctival and limbal epithelia. The purpose of this study was to expand our investigation and determine if the AP-2β NCC KO corneal epithelium has shifted to a conjunctival cell fate.

Methods: To generate the AP-2β NCC KO model, male mice heterozygous for Tfap2b, Tfap2b$^{+/-}$, and the wnt1-cre transgene, Wnt1Cre$^{+/-}$, were bred with female mice in which the Tfap2b gene was floxed, Tfap2b$^{lox/lox}$. AP-2β expressing offspring from this breeding scheme were used as age-matched controls. Eyes were enucleated from euthanized 6-month-old mice and processed before being embedded in paraffin. H&E staining along with immunohistochemistry for Muc5AC (Abcam), a goblet cell specific marker, were performed.

Results: Similar to our previous findings for 2-3 month old mutants, the corneal epithelium of 6 month old AP-2β NCC KO mice exhibits significantly reduced stratification. Unlike earlier stages, at this later stage the mutant has numerous vesicles in the superficial layer of the corneal epithelium. With respect to Muc5AC staining, the mutants exhibited regions of positive staining along the epithelium that was not observed in the controls.

Conclusions: The present findings of aberrant expression of Muc5AC in the mutant corneal epithelium, along with earlier data showing phenotypic changes in keratin expression, strongly suggest a shift towards conjunctival cell fate. Thus, expression of AP-2β in the developing POM is critical for regulating corneal epithelial cell fate. Further investigation of the corneal epithelial phenotype in AP-2β NCC KO mutants will contribute to our understanding of epithelial cell fate determination and stratification, and the pathogenesis of diseases marked by corneal thinning, neovascularization and opacification.

TITLE: Lower Income Affordable Care Act Marketplace Subscribers Face Lower Trabecular Bypass Device Surgery Rates Despite Cost Protection

SESSION TITLE: Public Health II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Hatcher, J. Lindsey, J. Mattingly, Ophthalmology, Vanderbilt University Medical Center, Nashville, Tennessee, UNITED STATES|G. Lin, P. Karnam, Vanderbilt University School of Medicine, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure: Jeremy Hatcher: Commercial Relationship: Code N (No Commercial Relationship) | George Lin: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Lindsey: Commercial Relationship: Code N (No Commercial Relationship) | Preethi Karnam: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Mattingly: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Social determinants of health, especially insurance status, socioeconomic status, and race, have been linked to poor outcomes in patients with glaucoma. The Affordable Care Act (ACA) was passed to address such disparities in access to care, but there is a paucity of literature assessing its efficacy in facilitating access to ophthalmologic care. We evaluated demographic and cost differences between ACA patients who were eligible for trabecular bypass device (TBD) surgery and did or did not receive it.

Methods: This is a retrospective, claims-based cohort study using a novel 2017 to 2019 claims dataset of Affordable Care Act (ACA) marketplace plan subscribers containing deidentified data about medical conditions, procedures, and associated cost (yearly mean n= 3,560,440). Socioeconomic status was inferred from eligibility for cost-sharing reduction subsidies based on the federal poverty limit. ICD-10 and CPT codes identified patients who underwent cataract surgery and were eligible for TBD surgery (n=653) as well as those who went on to receive TBD surgery (n=249).

Results: A statistically significant difference was found in TBD surgery rates between lower income ACA marketplace subscribers with subsidies and higher income patients who were subsidy ineligible (27.6% vs 43.0%, p=0.0035, multiple logistic regression). Lower income patients paid less out-of-pocket TBD cost due to subsidies ($324 vs $2494, p<0.001, Mann-Whitney U test) compared to higher income patients. Actual out-of-pocket costs for TBD surgery were similar to expected costs as advertised on the ACA website.

Conclusions: This investigation of novel ACA claims data highlights a potential disparity in access to TBD surgery for lower income ACA patients. Despite paying much less out-of-pocket, lower income patients receive TBD surgery at lower rates than their higher income peers. Our study design precludes analysis of the individual decisions that contribute to this difference in rates and the role of race. Our investigation examines health equity using a novel ACA dataset and, to our knowledge, is the first to assess eye surgical referral rates and cost experience among the ACA population.

ABSTRACT BODY:

Purpose: Recent advancements in treatments for ocular diseases have led to many novel, anterior interfacing medical devices and surgical procedures. This necessitates new methods for visualizing device-tissue interaction and assessing the preclinical performance of these medical devices. One valuable method for visualizing the internal, anterior surface of the eye is the 2004 Miyake-Apple technique. The purpose of this study was to modernize this method using current camera technology.

Methods: Whole human cadaver eyes (LionsGift) were obtained within 72 hours of donor death. A 25-gauge valved Alcon port was inserted to allow for infusion and intraocular illumination of the eye. Rather than slicing the eye in half as previously done in the Miyake-Apple technique, a 8.2mm temporary keratoprosthesis (TKP) was sutured to the posterior of the eye providing an opening for anterior visualization. A custom designed, 3D printed, fixture (Figure 1) held both the eye and a 4K USB web camera utilizing a Sony IMX317 sensor and 20-degree manual focus lens. The eye was secured to the fixture by holding the optic nerve with an alligator clip. A High-Resolution Volk Wide Field Lens was placed into the channel below the sutured TKP. The camera was aligned with the wide field lens and manually focused. Videos and images were then captured utilizing the camera application on a laptop with the USB camera connected.

Results: This custom setup provided high resolution still and video imaging of the intraocular anterior surface of the eye (Figure 2). The wide field lens allowed for visualization from the apex of the cornea to approximately 13mm from the limbus. Anatomic features such as the pupil, intraocular lens, ciliary bodies, pars plana, and choroidal vasculature were clearly visible.

Conclusions: This updated Miyake-Apple technique provides a useful tool for visualizing the anterior surface of the eye. As the globe remains almost fully intact, tissue connectivity is undisturbed which provides a robust anatomic model with visualization for surgical testing. In the future, this model could be used for preclinical assessment of placement and fixation of intraocular lens and drug eluding implants in addition to visualization of intravitreal or suprachoroidal injections and suprachoroidal cannulation.

TITLE: Effect of cycloplegia on contrast sensitivity measured by the Ohio Contrast Cards

SESSION TITLE: Fundamental and Applied Psychophysics and Color Vision

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Takoo, A. Toole, A. Brown, College of Optometry, The Ohio State University, Columbus, Ohio, UNITED STATES|

Commercial Relationships Disclosure: Shihij Takoo: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Toole: Commercial Relationship: Code N (No Commercial Relationship) | Angela Brown: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To measure the repeatability of contrast sensitivity measured using the Ohio Contrast Cards (OCC), before and after cycloplegia, in a general pediatric optometric population. The OCC (Precision-Vision, Woodstock IL) present 0.15 cy/deg horizontal square-wave gratings of variable contrast (stepsize=0.15 Log10 units) on cards similar to the Teller Acuity Cards.

Methods: We used the OCC to measure monocular contrast sensitivity (CS) on 41 non-amblyopic children (ages 4-11, mean=7.8, SD=2.1). Each child's CS was measured twice, by different examiners, before their routine, dilated, cycloplegic eye exam. After the exam, when the eyes were still cyclopleged (Tropicamide, Cyclopentolate, or both), CS was measured again. Children who wore glasses were tested with their glasses on before and after the exam, and again after the exam, without their glasses. Refractive errors were obtained by wet retinoscopy. The study was powered to reveal a test-retest difference of one card at corrected $p<0.05$ with power=0.90. We compared the results of the first test, which was pre-cycloplegia and pre-exam, to the results of the post-cycloplegia, post-exam test. For children who wore glasses, we compared the pre- and post- tests with glasses on; otherwise we compared tests with glasses off.

Results: The pre-exam and post-exam results were similar (mean LogCS=2.07, SD=0.14; mean LogCS difference=0.01, SD=0.12). The 95% limits of agreement (±1.96 x SD[difference]) were ±0.24 Log units, and weighted Cohen's K=0.59, 95% CI=0.38–0.80. Under cycloplegia, the uncorrected blur for horizontal gratings at the test distance was +0.08 D to +5.27 D (mean=1.71 D, SD=1.08 D), and uncorrected CS under cycloplegia was not associated with blur (r= -0.01, p=0.94). Mean LogCS, measured across the two pre-exam tests was 2.07 (SD=0.15), and those were also closely similar (mean difference=0.02 Log units, SD=0.12) and highly correlated (r=0.73, $p<0.0001$), and the intra-examiner repeatability was high (weighted K=0.70, 95% CI=0.53–0.87).

Conclusions: The Ohio Contrast Cards show good repeatability in this population when pre-exam pre- cycloplegia tests are compared to post-exam post-cycloplegia tests, indicating that the cards can be used without regard to cycloplegia. There is no significant effect of refractive error on the measurements, showing that the Ohio Contrast Cards is an effective near test used under cycloplegia on a range of refractive errors.

ABSTRACT BODY:

Purpose: Highly polarized and compartmentalized neurons respond rapidly and precisely to surrounding stimuli at long distances. This capacity has been linked in part to specific RNA localization and local translation. 3' untranslated regions (3'UTRs) regulate RNA localization. In this study, we explored RNA translation and dependence on 3'UTRs in axonal growth cones of hippocampal neurons expressing axonal targeting 3'UTR, dendrite targeting 3'UTR and no 3'UTR in vitro, to explore mechanisms involved in regional growth cone translation.

Methods: We generated constructs carrying photoswitchable fluorescent reporter Dendra^{myr} with axonal targeting GAP43-3'UTR, dendrite targeting Nrgn-3'UTR, and no 3'UTR. Dendra signals in growth cones were recorded in primary hippocampal neuron cultures before and after photoswitching to observe local translation-dependent recovery of Dendra signal, with and without protein synthesis inhibitors. Growth cone protein synthesis was also studied in response to treatment with brain-derived neurotrophic factor (BDNF), forskolin, and KCl-induced depolarization and repolarization.

Results: Neurons expressing axonal targeting Dendra^{myr} 3'GAP43 showed recovery of Dendra signal in distal growth cones 40 minutes after photoswitching; treatment with anisomycin disrupted recovery, demonstrating that recovery was due to local new protein synthesis. No significant recovery was observed in neurons with the expression of Dendra^{myr} 3'Nrgn or Dendra^{myr} controls. Axon-targeted Dendra translation increased with 2 hours treatment with BDNF and was even greater with combination treatment with BDNF and forskolin. KCl-induced depolarization for 2 hours increased local translation, whereas 20 hours of KCl decreased of local Dendra signal after photoswitching. The disruption of local Dendra translation in growth cones after 20 hours incubation with KCl was restored after washing out KCl.

Conclusions: BDNF/TrkB activation increases local translation of axon-targeted mRNA in distal growth cones; cellular repolorization restores long-term depolarization induced disruption of local protein synthesis of reporter Dendra in distal growth cones. Live cell recording distal growth cones in primary neurons expressing axon-targeting Dendra^{myr} 3'GAP43 is a promising platform for screening of candidates that support local translation and promote axon growth.

ABSTRACT BODY:

Purpose: Non-mydriatic digital retinal imaging can improve patient access to diabetic retinal screening exams. We performed a retrospective review to determine if digital retinal imaging could be utilized in the Christiana Care Health System (CCHS) primary care setting to identify pathology and assist those needing follow-up. This technology could be crucial in maintaining patients' health in a cost-effective way.

Methods: Diabetic patients aged 18 years and older who participated in the Intelligent Retinal Imaging System (IRIS, Pensacola, FL) retinal screening initiative at four primary care clinics in the Christiana Care Health System (Wilmington, DE) from September 2018 to November 2020 were included. Photos were taken by clinic staff using the Volk Pictor Plus Fundus camera. Retinal images were interpreted by CCHS-affiliated ophthalmologists using a modified ICDR system and the results communicated to the primary care clinic via IRIS. IRIS data and the electronic medical record (EMR) was utilized to record the screening result and follow-up recommendations. Outcomes of interest included number of interpretable images, the pathology identified, documentation of referral, and number of patients who completed a follow-up exam.

Results: 613 patients (1226 eyes) underwent the screening exam but there was no documentation of an exam result in the EMR for 50 (8.1%) patients. Of the 411 patients (73%) who had bilateral interpretable images, 323 (78.6%) of patients had no pathology in either eye. 88 patients had a referrable diagnosis which included 53 with diabetic retinopathy ((60.2%) (35 mild, 12 moderate, 2 severe, 4 proliferative), and a mixture of other suspected diseases. For the 238 patients (42.3%) uninterpretable or diseased patients for whom follow-up was recommended, 165 patients (69.3%) had referrals generated by the primary care physician. Of these, 65 (39.4% and 27.3% of the original 238) had a follow-up exam with an optometrist or ophthalmologist documented in the EMR.

Conclusions: Utilizing the IRIS protocol, the majority of patients were able to complete a diabetic screening. However, taking quality photographs remains a limitation. The majority of patients who needed a follow-up referral received one, yet a minority of patients followed through with the exam. We have found several areas to improve: importing IRIS exams into the EMR, generating referrals, and patient follow-up. Our next step is to address these issues.

ABSTRACT BODY:

Purpose: Ischemic retinal injuries are a major cause of blindness with limited treatment options. Endothelial caspase-9 (EC Casp9) loss was previously reported to decrease retinal edema and neuronal death in a mouse model of Retinal Vein Occlusion (RVO). But its role on modulating the astroglial response and visual function remained unknown. This study tested the hypothesis that the endothelium and astrocytes share caspase-9 signaling that contributes to contrast sensitivity decline in retinal vein occlusion (RVO).

Methods: We performed RVO in inducible EC-Casp9 (iEC Casp9 WT/KO) and astroglia caspase-9 (iAstro Casp9 WT/KO) adult male and female mice by tail vein injection of Rose Bengal and photocoagulation of major retinal veins. Contrast sensitivity was tested pre RVO and 1-day post-RVO (P-RVO) using Striatech's OptoDrum System at visual acuity ranges 0.05, 0.15, and 0.25 cycles/°. Retinas were collected 1- and 2-days post RVO (P-RVO). Immunohistochemistry against cl-caspase-9, cl-caspase-6, GFAP, Nestin and AQP-4 was followed by blind quantification using thresholding analysis in FIJI. Data was evaluated in injured iEC/iAstro Casp9 WT (n=6-8), iEC/iAstro Casp9 KO (n=4-9), and uninjured groups (iEC/iAstro Casp9 WT, n=3-6, iEC/iAstro Casp9 KO, n=3-6). One-way ANOVA followed by Fisher's LSD test was used for statistical analysis.

Results: Loss of EC-Casp9 led to a decrease in astroglial cl-caspase-9 and a significant decline in downstream effector cl-caspase-6 1- and 2-days P-RVO compared to injured iEC-Casp9 WT ($p=0.02$, $p=0.004$). Injured EC-Casp9 WT/KO did not show differences in GFAP, but a significant decline in AQP-4 expression was noted 1 day P-RVO when compared to uninjured controls ($p=0.01$). Nestin increased significantly at 2 days P-RVO in injured EC-Casp9 WT compared to uninjured controls ($p=0.008$) and injured EC-Casp9 KO ($p=0.02$). Astroglial caspase-9 loss led to a significant decrease in cl-caspase-6 ($p=0.02$) and no changes in GFAP. Knockout of caspase-9 in the endothelium or astrocytes significantly rescued contrast sensitivity decline after vascular injury compared to iEC/iAstro Casp9 WT at low acuity values ($p=0.02$).

Conclusions: Our results demonstrate that EC Caspase-9 contributes to astroglial caspase-6 and Nestin expression after injury. Moreover, that endothelial-astroglial caspase-9 signaling is relevant for contrast sensitivity decline in RVO.

ABSTRACT BODY:

Purpose: Coronavirus-19 (COVID-19) has been associated with ophthalmic manifestations. The relationship between tear film SARS-CoV-2 RNA, timing of illness and eye disease are unknown. We evaluated hospitalized COVID-19 inpatients for retinopathy and tear film viral RNA.

Methods: Hospitalized COVID-19 inpatients were offered enrollment from January-June 2021. Full dilated ophthalmic examination and conjunctival swabs were taken for triplex RT-PCR for SARS-CoV-2 RNA targeting N2, E and RNAse P. Demographic, clinical outcomes and laboratory data were collected. Univariate and multivariate analyses of systemic disease and laboratory risk factors for retinopathy and SARS-CoV-2 RNA detection were assessed.

Results: Sixty patients were prospectively enrolled in this cross-sectional, observational study. The mean age was 58.8 years (Standard deviation [SD] 15.2 years) and 29 (48%) were female. Retinopathy associated with COVID-19 in 12 of 60 patients (20%). Univariate analyses revealed that younger age, greater body mass index (BMI) and extracorporeal membrane (ECMO) requirement were associated with increased odds of COVID-19 retinopathy. The mean age (SD) of patients with COVID-19 retinopathy was 49.0. (11.6) compared to 61.2 (15.1) years in individuals without retinopathy (p=0.01). The mean BMI was 38.8 (9.8) in patients with retinopathy compared to 31.8 (9.0) in those without retinal disease findings (p=0.04). ECMO requirement was observed in 33% of patients with retinopathy compared to 8% in those without retinopathy (p=0.04). Multivariate analyses trended towards increased risk of retinopathy with younger age (aOR 0.95 (95% CI 0.90-1.01, p=0.095) and with increased BMI (aOR. 1.08, 95% CI 1.00-1.18, p=0.056). Fifteen of 60 patients (25%) tested positive in their tear film for SARS-CoV-2 RNA with a trend towards a shorter length of illness and hospitalization in patients who were positive. The N2 gene was particularly sensitive with 18 of 19 eyes (94.7%) showing N2-positivity (with or without E gene detection), including 2 patients in whom the B.117 / B.1.525 alpha or “United Kingdom” variant was detected.

Conclusions: A 20% rate of retinopathy was observed and SARS-CoV-2 RNA within tear film was detected in 25% of hospitalized COVID-19 patients. Continued infection control precautions are required given the risk of viral RNA in tear film, which may also be sensitive for the detection of COVID-19 variants.

ABSTRACT BODY:

Purpose: To evaluate and compare cellular and structural abnormalities in the cornea between patients who develop definite oGVHD after hematopoietic stem cell transplantation (HSCT) and patients who do not develop oGVHD.

Methods: Patients who received HSCT were evaluated in the University of Illinois at Chicago (UIC) Dry Eye and oGVHD Clinic and classified as having definite oGVHD or none oGVHD using the international consensus classification system based on symptom analysis, corneal staining, Schirmer's I test, and conjunctival redness. In vivo confocal microscopy (IVCM) was performed using HRT3 RCM (Heidelberg Engineering, Franklin, MA) to evaluate the corneal epithelium, nerve plexus, and stroma. Abnormalities detected were compared between groups.

Results: Patients with definite oGVHD (n= 100 eyes) had significantly greater abnormalities in the epithelium (21% vs 4.7%; $p < 0.05$) as compared to none oGVHD (n=86 eyes). Epithelial abnormalities included loss of hexagonal shaped cells in a honeycomb pattern with homogenous cell border reflectivity. The number of patients with complete loss of sub basal nerve plexus was significantly greater in definite oGVHD as compared to none oGVHD (20% vs 2%; $p < 0.05$). Sub basal nerve plexus in definite oGVHD patients also showed increased beading of nerves and presence of spindle shaped cells in the nerve plexus area as compared to none oGVHD. The corneal stroma in definite oGVHD and none oGVHD did not show significant differences other than increased reflectivity in definite oGVHD patients.

Conclusions: Patients with definite OGVHD have significant cellular and structural abnormalities in the cornea that may include abnormal epithelium morphology, loss of corneal nerves, and presence of presumed inflammatory cells in the nerve plexus area.

ABSTRACT BODY:

Purpose: Cellular differentiation is marked by temporally and spatially coordinated gene expression regulated at multiple levels, including chromatin landscape dynamics. DNA methylation represents a universal mechanism to control chromatin organization, compaction and its accessibility.Cytosine methylation of CpG dinucleotides regulates binding of methylation-sensitive DNA-binding transcription factors. Earlier studies in mouse lens examined function of DNA methyltransferases Dnmt1, Dnmt3a and Dnmt3b; however, analysis of DNA methylation during lens fiber cell differentiation remains to be determined.

Methods: Using whole genome bisulfite sequencing (WGBS), we investigated dynamics of DNA methylation changes during mouse lens fiber cell and epithelium differentiation between embryos (E14.5) and newborns (P0.5) using microdissected lenses. Embryonic stem (ES) cells and neural progenitor cells (NPCs) data were used for comparisons. To link these data with general chromatin structure and gene expression, our earlier ATAC- and RNA-seq datasets were included. Role of CpG methylation on Pax6 binding was analyzed using lens ChIP-seq data and in vitroanalyses using a set of methylated and unmethylated prototypic Pax6-binding sites.

Results: Major differences in DNA methylation between lens, ES and NPC cells were found. For example, both Pax6and Prox1loci show low and unmethylated regions in lens cells compared to both ES and NPC cells. Within the microdissected lens cells, we identified DNA methylation and “open” chromatin changes by defining differentially methylated and/or accessible regions during mouse lens fiber cell (Path1: epi/E14.5-fib/E14.5-fib/P0.5) and epithelium (Path2: epi/E14.5-epi/P0.5) differentiation. For example, ATAC- and RNA-seq data demonstrate that reduced methylation is directly linked with increased expression of fiber cell abundant genes, including crystallins, intermediate filament proteins Bfsp1 and Bfsp2, and gap junction proteins Gja1 and Gja8. Both in vivoand in vitrodata show that CpG methylation is not detrimental for Pax6 binding to DNA.

Conclusions: Our study has generated the first data on DNA methylation changes between two different mouse lens developmental points and linked these data with chromatin accessibility domains and gene expression. Our data support the model that between E14.5 and P0.5, DNA demethylation modulates gene expression of critical genes required for lens morphogenesis.

ABSTRACT BODY:

Purpose: The goal of this study was to identify the neurons that make synapses onto intrinsically-photosensitive retinal ganglion cells (ipRGCs) with somas located in the inner nuclear layer (INL), also known as the “displaced” type. The working hypothesis was that there were two distinct types of displaced ipRGCs, including one with input from OFF bipolar cells.

Methods: Three pieces of central macaque retina were fixed and stained en bloc with heavy metals. Sets of horizontal sections were acquired using scanning block-face serial electron microscopy. The ipRGCs were readily identified by the large diameters of their somas relative to others in the INL and by the lipofuscin granules they contained. They were analyzed using the Viking Annotation System and SBFSEM-tools. The presynaptic cells were also analyzed and identified morphologically.

Results: The volumes located about 2 mm temporal and 1.25 mm nasal to the center of the fovea each contained one ipRGC with its soma in the INL. Their dendrites had a large diameter and formed very sparse arbors confined entirely to the outermost stratum (S1) of the inner plexiform layer (IPL), and their axons were varicose. The volume located about 1.5 mm inferior to the center of the fovea contained somas of two ipRGCs, one similar to those in the other volumes and one smaller type with distal dendrites that gradually descended into the inner half of the IPL. All four ipRGCs received the majority of their inputs from amacrine cells. These likely included axons of dopaminergic amacrine cells with somas located outside the volumes. The smaller displaced ipRGC received virtually all of its excitatory input from five types of ON bipolar cells, mainly via the distal dendrites. The three larger displaced ipRGCs each received input from three types of OFF bipolar cells: DB1, DB2 and OFF midget (see figure). These would generate robust OFF responses in the larger displaced ipRGCs under a wide variety of conditions.

Conclusions: The larger type of displaced ipRGCs are likely the source of OFF responses recorded recently from human ipRGCs using microelectrode arrays. Input from the OFF pathway may account for the “paradoxical” pupillary responses seen in some patients with congenital stationary night blindness.

ABSTRACT BODY:

Purpose: High-power laser models of murine injury have been used to create clinically visible lesions, the study of which has illuminated angiogenesis targets for wet age-related macular degeneration (wet-AMD). We developed a laser injury model featuring subclinical lesions in one quadrant of the retina to elicit retinal gliosis. We also exploited a genetic model of retinal degeneration (JR5558 mouse line), investigating gliosis and the peptidyl arginine deiminase-4 (PAD4)-citrullination axis in both these models.

Methods: A cluster low-power laser protocol (CLPLP) was established where C57Bl6 mice received 9 consecutive pulses of 50 mW for 5 seconds each applying 5 such burns in a cluster to one quadrant of the retina. The conventional laser protocol (CLP; 250 mW 100 msec) was also employed. Non-injured mice and laser injured cohorts were sacrificed along a 7 to 30 day post-injury time course. JR5558 mice were sacrificed at 30 and 60 days of age. Eyes were cryosectioned, antibody stained for glial fibrillary acidic protein (GFAP), citrullination (F95), citrullinated-GFAP and PAD4, then analyzed by epifluorescence microscopy.

Results: In the CLP, fundus imaging reveals bright autofluorescence of the lesion sites at time of injury, remaining visible for extended time periods. In the CLPLP, cluster injury is barely noticeable and rapidly resolved, suggesting the CLPLP models subclinical levels of injury. When retinas from CLPLP were co-stained for GFAP and F95, Muller cell-specific expression was observed at the lesion. PAD4 expression was also observed, however with reduced expression compared to CLP. In the JR5558 mouse line spontaneous lesions revealed striking upregulation of GFAP in Muller cell processes spanning the retina. Remarkably, GFAP citrullination along Muller cell processes starting at the endfeet was observed along with PAD4 expression.

Conclusions: We previously reported that retinal gliosis and hypercitrullination initiates in the endfeet following the CLP, and citrullinated GFAP is also seen in human wet-AMD maculae. We extend this study showing sub-clinical features of retinal pathology created with CLPLP also feature these biomarkers. Furthermore, as the PAD4-hypercitrullination axis is also engaged in the endfeet of JR5558 mice, we propose that Muller glial endfeet are a ‘citrullination bunker’ that initiates and sustains citrullination in retinal degeneration.

ABSTRACT BODY:

Purpose: Neovascular age-related macular degeneration (nvAMD) is a major cause of vision loss. Although very effective treatments exist for nvAMD, these require intervention after the rupture of Bruch's membrane, require multiple treatments, and may be associated with increased risk of atrophy after prolonged treatments. Discovering how neovascular endothelial cells from human eyes differ from non-neovascular cells at the transcriptional level will provide new knowledge about the process of pathologic angiogenesis and may offer opportunities for prevention.

Methods: Three frozen sections were collected from a macula with an extensive type I neovascular membrane (death to freezing interval < 5 hours) and two frozen sections were collected from an age-matched control eye. The spatial transcriptome of each section was evaluated using the Visium platform. Gene expression profiles from each spot were integrated with an independent collection of single-cell expression data comparing the choroid of nvAMD maculas (n = 2), non-neovascular, early AMD maculas (n = 9), and control maculas (n = 9).

Results: Spatial transcriptomics identified three retinal layers, with distinct ganglion cell, interneurons/glia, and photoreceptor cell-associated genes in spots corresponding to ganglion cell layer, inner nuclear layer, and outer nuclear layer, respectively (Figure 1). Twenty four genes were identified with a log fold change of >0.2 between both (a) spots overlapping with neovascular membranes and those in the choroid outside of neovascular membranes and (b) nvAMD single-cells vs controls . These include genes involved in cytoskeleton (TUBA1A, TUBA1B), extracellular matrix (FN1) and stress responses (SOD2, GADD45B).

Conclusions: Spatial transcriptomic analysis of the macula reliably maps transcripts to their cellular sources. Cells from neovascular membranes have altered transcriptomes compared to both the peripheral choroid outside of the CNV lesion and from non-AMD maculas. These two experiments identify several genes enriched in neovascular AMD that may offer insight into pathogenic angiogenesis.

ABSTRACT BODY:

Purpose: Digital Eye Strain Diseases are rapid increasing disorders linked to the growing and more prolonged use of video terminals. To date, the only way to mitigate these disorders is using tear substitute or reducing the exposure to the electronic devices. Focus of our research was the development of an eye drop (MDV 2101) based on a specific peptide (MDV PEPTIDE) able to relieve strain of the ocular muscles. Well demonstrated pharmacological activity of the peptide (MDV PEPTIDE) comprises the attenuation of the eye muscle contraction regulating the release of Acetylcholine and so the binding between the neurotransmitter and their receptors in the muscle.

Methods: MDV 2101 is an isosmotic aqueous solution containing 50 ppm of MDV PEPTIDE in a new and patented Hyaluronic Acid drug delivery system. The stability of the formulation has been executed by means HPLC analysis, Osmolarity and pH changes. The safety of MDV2101 was evaluated by cellular viability using in vitro human corneal cells model (HCE-SkinEthic), through MMT assay.

Results: We found out that the MDV PEPTIDE in the formulation was stable after 24 months at 25°C, pH and osmolality did not exhibit any variation too. The MMT results after 30 min (irritation test) and 24h (cytotoxicity test) of MDV2101 contact time suggested absence of direct toxicity and no epithelial surface damage (viability >98% versus negative control - PBS).

Conclusions: MDV2101, safe and stable under our experimental conditions, thanks to the peculiar mechanism of action of MDV PEPTIDE, may be a helpful candidate to relieve Digital Eye Strain Syndrome symptoms.

ABSTRACT BODY:

Purpose: The health inequalities that exist between Indigenous and non-Indigenous Canadians begin in childhood and diverge further from this foundational developmental period. Indigenous children are at high risk for visual impairment (VI) due to limited access to vision care services with a risk of blindness six times greater than non-Indigenous children. These communities consist of a large youth demographic with 28% under the age of fourteen. This study provides data on prevalence and causes of VI in Indigenous children living in remote northern Ontario, Canada.

Methods: This cross-sectional study included 259 Indigenous children aged 8 months to 18 years living in remote northern communities along James Bay, Ontario served by the Weeneebayko Area Health Authority. All children underwent at least one complete eye examination between November 2020 and November 2021, including cycloplegic refraction.

Results: Of the 259 children examined (age range 0.67 to 18 years, mean 10.3, median 9.0 years) the main cause of treatable or avoidable VI was uncorrected refractive error. Of the examined children, 203 (78%) had refractive errors, of which, 156 (77%) did not use correction. Visual acuity (VA) was measured in 518 eyes of 259 subjects and ranged from 20/15 to counting fingers (CF). Of the 203 children with refractive error, 69 (34%) experienced mild VI, (VA worse than 20/40 up to 20/60 in the better-seeing eye), 55 (27%) experienced moderate VI, (VA worse than 20/60 up to 20/200 in the better-seeing eye) and 12 (6%) children experienced severe VI, (VA worse than 20/200 in the better seeing-eye). The overall prevalence of myopia was 33% (85) (range -0.5DS up to -7.0DS of eyes examined, mean -2.3DS, median -2.0DS) and of hyperopia was 29% (76) (range +0.5DS up to +7.0DS of eyes examined, mean +1.8DS, median +1.5DS). Astigmatism was evident in 66% (171) (range -0.5DC up to -5.5DC of eyes examined, mean -2.0DC, median -1.8DC). Of the 259 children, 107 (41%) had never previously received an eye examination.

Conclusions: These findings suggest high rates of uncorrected refractive error, particularly astigmatism, resulting in poor vision among Indigenous children. There is an urgent need to address the gap in the delivery of eye care to Indigenous Canadians.

ABSTRACT BODY:

Purpose: TMEM97 is an important endoplasmic reticular protein involved in cell migration, cancer, cholesterol processing, and neurodegenerative diseases. Histatins are a family of endogenous antimicrobial peptides that have numerous effects in multiple biological systems. Histatin-1 (Hst1) has roles in epithelial wound healing and migration. We recently showed, using biophysical and biological methods including co-immunoprecipitation, and surface plasmon resonance (SPR) that Hst1 is an endogenous ligand for TMEM97. We also determined that presence of TMEM97 was necessary for Hst1 to exert pro-migratory effects in corneal epithelia. Given the growing understanding that TMEM97 is important to ophthalmic biology, we sought to generate a method to scalably produce TMEM97 in an E. coli for future experiments. Commercially sourced TMEM97 is costly and is produced in eukaryotic systems. We validated the function of the E. coli expressed protein utilizing previously tested methods as well as a new orthogonal method [isothermal titration calorimetry (ITC)].

Methods: BL21DE3 cell culture pellets containing His-TEV-TMEM97 was processed and lysate underwent HisTrap affinity and SEC 16/600 SD200 purification. TMEM97 (108-176) was prepared in 10 mM Tris, pH 7.4, 150 mM NaCl, 0.05% Tween-20. All ITC experiments were performed while stirring at 395 rpm using a VP-ITC titration microcalorimeter from MicroCal™, LLC (Northampton, MA). TMEM97 purchased from OriGene and His-TEV-TMEM97 in E.coli were prepared in HBS buffer containing 10 mM HEPES, pH 7.4, 150 mM NaCl, and 0.05% n-dodecyl-β-D-maltoside (DDM). The CM5 sensor surface was first activated by 1-ethyl-3-(3-dimethylaminopropyl) carbodiimide hydrochloride (EDC)/N-hydroxy succinimide (NHS) mixture using a Biacore T200 or Biacore 8K instrument (GE Healthcare).

Results: We confirmed that Hst1 bound both commercially sourced and E. coli expressed TMEM97 utilizing. ITC was also performed as an orthogonal analytical method. Utilizing ITC we found that Hst1 bound TMEM97 with high affinity.

Conclusions: This study establishes a scalable research grade method for production of TMEM97, which demonstrates high-affinity binding to Hst1. Furthermore, we were able to demonstrate the binding between Hst1 and TMEM97 using a previously unreported method, ITC. This method will allow future research studies requiring large quantities of TMEM97 to better understand the importance of this protein to ophthalmic cellular function.

TITLE: Defining the phenotype and distribution of resident immune cells surrounding meibomian gland orifices in mice

SESSION TITLE: Modulation of ocular surface immunity during health and disease

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: C. Wu, L.E. Downie, H.R. Chinnery, Optometry and Vision Sciences, The University of Melbourne Faculty of Medicine Dentistry and Health Sciences, Melbourne, Victoria, AUSTRALIA|C. Wu, C. Maldonado-codina, P. Morgan, The University of Manchester, Manchester, Manchester, UNITED KINGDOM|

Commercial Relationships Disclosure: Ching Yi Wu: Commercial Relationship: Code N (No Commercial Relationship) | Laura Downie: Commercial Relationship: Code N (No Commercial Relationship) | Carole Maldonado-codina: Commercial Relationship: Code N (No Commercial Relationship) | Philip Morgan: Commercial Relationship: Code N (No Commercial Relationship) | Holly Chinnery: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Inflammation and keratinisation of the meibomian glands (MGs) and MG orifices (MGOs) are pathophysiological mechanisms involved in MG dysfunction (MGD). However, the normal immune cell (IC) profile of MGOs, which act as an interface between the external environment and internal glandular duct, has not been clearly defined. The aim of this study was to determine the presence, phenotype and distribution of MG orifice-associated immune cells (MOICs) in healthy young and aged mice.

Methods: Flatmounts of the superior and inferior eyelids of young (i.e. 12-15-week old; n=9-12/group) and older (i.e. 21-29-week old; n=5-6/group) $CD11c^{eYFP}$ and Cx3cr1-deficient $Cx3Cr1^{GFP/GFP}$ mice were used. $CD11c^{+}$ dendritic cells (DCs) and $Cx3cr1^{+}$ ICs surrounding MGOs were visualized using four-colour immunofluorescent confocal microscopy. Eyelids were incubated with antibodies targeting MHC-II^{+} ICs, and F-actin to visualise MGOs. MOIC density (cells/mm^2) within a normalized peri-orifice area, relative to the MGO area, were quantified. Two adjacent MGOs in the nasal, central and temporal regions of both superior and inferior eyelids were analysed.

Results: In descending order of average density, $CD11c^{+}$ DCs (abundant), MHC-II^{+} and $Cx3cr1^{+}$ (scarce) ICs were identified at MGOs. More MOICs expressed $CD11c^{+}$ nasally than temporally in young mice (nasal 942±391 vs temporal 680±348 cells/mm^2, p=0.0199), but not in older mice (nasal 932±592 vs temporal 611±446 cells/mm^2 p>0.05). On average, there were more $Cx3cr1^{+}$ IC nasally compared with temporally in older mice (nasal 93±43 cells/mm^2 vs temporal 5±0.2 cells/mm^2, p=0.048). In young mice, there were no regional differences in MHC-II^{+} IC density along the eyelid, but fewer MOICs expressed MHC-II^{+} in young Cx3cr1-deficient mice (186±248 cells/mm^2) compared to $CD11c^{eYFP}$ mice (350±280 cells/mm^2; p=0.0048).

Conclusions: Immune cells that surround mice MGOs are mostly $CD11c^{+}$ and MHC-II^{+}, with few expressing $Cx3cr1^{+}$. There are more $CD11c^{+}$ DCs in MGOs at the nasal eyelid, relative to the temporal region, in young mice. The Cx3cr1 receptor may have a partial role in the presence of MHC-II^{+} ICs around MGOs, as fewer MOICs expressed MHC-II^{+} in young $Cx3Cr1^{GFP/GFP}$ mice. These novel findings provide a basis for further investigations of MOICs and their role in MGD.

ABSTRACT BODY:

Purpose: LCA10 is a severe, degenerative inherited retinal disease resulting in childhood blindness, which has no treatment. Sepofarsen, an RNA antisense oligonucleotide designed for LCA10 due to the frequent c.2991+1655A>G variant in the CEP290 gene, produced clinically meaningful improvements in visual acuity in a Phase 1b/2 trial. The aim of the phase 3 trial (ILLUMINATE) was to assess the efficacy and safety of sepofarsen compared to sham in

c.2991+1655A>G-LCA10 participants.
Methods: ILLUMINATE (NCT03913143) was a double-masked, randomized, sham-controlled study performed across 14 sites in Europe, North America and Latin America. Eligible participants were aged ≥ 8 years, carried at least one c.2991+1655A>G in the CEP290 gene and had best-corrected visual acuity (BCVA) ranging from 0.4 (20/50 Snellen equivalent) to 3.0 logMAR (Hand Motion). Participants were randomly assigned (1:1:1) to receive intravitreal injection of sepofarsen 160/80 µg (maintenance dose of 80 µg every 6 months, starting 3 months after the loading dose of 160 µg), 80/40 µg (same regimen but doses of 40µg and 80µg respectively), or sham. The primary endpoint was mean change from baseline in BCVA, in the treatment eye (worse seeing eye), compared with sham at Month 12. Secondary endpoints included full-field stimulus testing threshold (FST; red, blue, white), a mobility course composite score, and safety. Trial recruitment was completed in January 2021.
Results: Between March 29, 2019 and January 6, 2021, 52 participants were screened, of whom 36 were randomized (group allocation masked at the time of abstract submission). At baseline, the mean age was 29.0 (SD 14.5) years, including 12 (SD 33.3%) participants aged 8 to 18 and 24 (66.7%) participants aged >18 years. Sixteen (44.4%) of the participants were homozygous for the target variant whereas 20 (55.6%) were compound heterozygous. Mean baseline BCVA in the treatment eye was 1.25 logMAR (SD 0.66) and mean baseline BCVA in the fellow eye was 1.01 logMAR (SD 0.27).
Conclusions: Sepofarsen, an innovative RNA antisense oligonucleotide, is the most advanced program in development for the treatment of LCA10. Learning from recruitment suggested the commonality of the c.2991+1655A>G variant in LCA10. Updated results will be included as available.

ABSTRACT BODY:

Purpose: Autosomal recessive CEP290-LCA (LCA10) is a severe inherited retinal disease resulting in early vision loss and currently has no treatment. Sepofarsen is an RNA antisense oligonucleotide targeting the most common c.2991+1655A>G disease-causing variant in the CEP290 gene. Long-term safety and efficacy of sepofarsen in the first eye treated (FE) and safety and efficacy in the second eye treated (SE) in this extension trial (Insight; NCT03913130) were evaluated.

Methods: Subjects who completed the Ph1b/2 sepofarsen trial could enroll in the extension trial for continued dosing in the FE and initiation in the SE with the 160/80µg loading/maintenance dose. Frequency and severity of adverse events, and change in best-corrected visual acuity (BCVA) and full-field stimulus testing (FST) threshold were assessed. Baseline was defined as the value measured within the same month of – or last measurement prior to – the first dosing for each eye. Due to covid-19, some participants have missed scheduled injections. As such data up to – or available measurement prior to – 6 months after the last dosing have been included in the analysis for each eye.

Results: At data cut-off in mid-October 2021, 9 subjects (of 11 from the Ph1b/2 trial) aged 15–45 years were followed up to 46 months, 5 of them received at least one intravitreal injection of sepofarsen in the SE. Three subjects developed cataracts in the FE and 2 in the SE, of which 2 recovered following cataract surgery. Time to onset since initial dose was 13 months or later. Between 35-46 months after the 1st injection, long term BCVA improvement was reported in 4/6 FE ranging from -0.20 to -0.54 logMAR and 5/5 FE improved in either blue FST, red FST or both ranging from -0.21 to -2.06 log cd/m2. The SE showed a similar trend as the FE in BCVA (3/5 SE showed a change ranging from -0.06 to -2.50 logMAR) and in blue and red FST (4/4 SE showed improvement ranging from -0.27 to -4.57 log cd/m2).

Conclusions: The longer-term sepofarsen safety profile is consistent with that observed in the Ph1b/2. Meaningful BCVA and FST improvements observed in the Ph1b/2 continued up to 46 months. The responses in the SE were similar to the responses seen in the FE in both visual acuity and retinal sensitivity improvements. A Phase 2/3 (ILLUMINATE; NCT03913143), multiple dose, double-masked, randomized, sham-controlled trial is ongoing.

TITLE: Hyaluronic Acid based Therapeutic Bandage Contact Lenses for Corneal Wound Healing

SESSION TITLE: Corneal epithelial biology and repair mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.J. Tian, L. Liu, M. Ross, H. Sheardown, McMaster University, Hamilton, Ontario, CANADA|

Commercial Relationships Disclosure: Jennifer Tian: Commercial Relationship: Code N (No Commercial Relationship) | Lina Liu: Commercial Relationship: Code N (No Commercial Relationship) | Mitchell Ross: Commercial Relationship: Code N (No Commercial Relationship) | Heather Sheardown: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Corneal scarring resulting from improper healing of the cornea is the third most common cause of blindness worldwide. Current methods for aiding corneal wound healing can be expensive, difficult to source, or have low bioavailability. Plano lenses have been used as bandage contact lenses (BCLs) to reduce pain and prevent the corneal surface from further damage after injury, but they have limited therapeutic effects. By conjugating hyaluronic acid (HA) onto the surface of the contact lens, it is thought that a BCL capable of improving corneal wound healing and minimizing scarring can be produced.

Methods: Model pHEMA-co-TRIS lenses were synthesized using free radical polymerization. Surface acrylation was done in the presence of the catalyst diisopropylethylamine (DIPEA). The small molecules diethylamino ethanethiol (DEAET) and dimethylamino ethanethiol (DMAET) were tethered using a thiol-ene "click" reaction. The successful acrylation and conjugation of the small molecules were confirmed through FTIR. Quantification of HA was performed using radiolabelled HA and subsequent gamma counting. In vitro cell studies using human corneal epithelial cells (HCECs) were conducted to determine cytotoxicity using MTT and LIVE/DEAD.

Results: FTIR showed the successful acrylation and conjugation on the lens surface. DMAET and DEAET modified lenses showed significantly higher ($p < 0.001$) HA binding compared to model pHEMA-co-TRIS controls at all time points shown in Figure 1. The modified lenses improved release kinetics preventing an initial burst release and showed consistent release when unloaded and reloaded with HA. The contact angle was significantly decreased ($p < 0.05$) for the modified model lenses with HA without affecting the equilibrium water content and optical transparency. Finally, the modified model lenses did not exhibit any cytotoxicity in vitro with HCECs.

Conclusions: Our results show that we were able to produce a lens capable of surface binding HA. The lens was able to bind more HA compared to unmodified controls while providing a sustained release of HA and excellent rebinding kinetics. The lenses were well tolerated based on in vitro cell studies.

ABSTRACT BODY:

Purpose: Porcine eyes are commonly used for training and testing of vitreoretinal surgeries but present limitations due to anatomical differences. While human cadaver eyes work well for exterior work, pupillary visualization is typically too cloudy for vitreoretinal surgery. Our purpose is to describe a method for the preparation of human cadaver eyes that preserves retinal adhesion and allows for clear visualization of the fundus.

Methods: Human eyes that are not eligible for corneal transplants are procured from a partner eye bank. Tissue is stored in Optisol or Life4C storage media. Vials are shipped on ice and refrigerated once received. The globe is placed in a 3D-printed fixture that replicates eye rotation and fixed in position by clamping the optic nerve. A port is inserted and connected to an infusion line which pressurizes the eye with BSS (balanced salt solution) to ~30mmHg. A corneal trephine blade is used to remove the central cornea. Once removed, 0.12 forceps are used to remove the iris and replicate visualization of a dilated eye. Next, the lens is removed through the corneal opening. Finally, a temporary keratoprothesis (TKP) is sutured onto the sclera. The process is summarized in Figure 1.

Results: Eyes prepared by this method allow a clear view of the fundus, with sufficient resolution to identify blood vessels and distinguish the microneedles used in subretinal injections. Our team has performed hundreds of subretinal injections using this model. Figure 2 shows representative visualization through the TKP with a subretinal bleb in the top left quadrant.

Conclusions: Conclusions: A more realistic ex vivo model for vitreoretinal surgery can be achieved with human cadaver eyes by removing the cornea, iris, and crystalline lens, then suturing a TKP to maintain pressure. By shipping eyes in corneal storage media on ice and storing under refrigeration, the retina can remain attached for up to a week post-mortem. This technique can facilitate practice and testing of vitreoretinal surgeries in human eyes.

ABSTRACT BODY:

Purpose: SPVN06 is a proposed gene therapy for patients experiencing vision loss due to rod-cone dystrophy (RCD), regardless of the causative mutation. In all RCD, photoreceptor degeneration is first observed in rods, and subsequently in cones, in large part due to a lack of trophic support. SPVN06 encodes, in a single AAV, the cDNAs for trophic factor Rod-derived Cone Viability Factor (RdCVF) and thioredoxin enzyme RdCVF-Long (RdCVFL), both isoforms of the NXNL1 gene. RdCVF, secreted by rods, protects cones from degeneration by stimulating aerobic glycolysis. RdCVFL is a potent antioxidant protecting cones from oxidative stress. SPVN06 early nonclinical development included several pharmacology studies in rd10 mice, a fast-progressing model of RCD.

Methods: rd10 mice were born and raised in darkness until transferred to regular cyclic light on postnatal day (P) 31 up to study termination at P48. At P15 or P18, the animals received a bilateral subretinal administration of 1 µL of vehicle or SVPN06 at 1E8 vg/eye. Effect of SPVN06 on retinal function and structure were evaluated by optokinetic (OKT), ffERG, optical coherence tomography (OCT) and histology.

Results: A highly significant protection of the visual function (OKT) was noted at P32 ($p<0.0001$) when the animals received SPVN06 1E8 vg/eye at P18. The level of visual function in SPVN06-treated eyes was similar to wild-type (WT) level versus only ~50% of WT in vehicle-injected eyes. At the later timepoints (P38 and P45), the difference between the 2 groups remained significant, although visual loss continued in both vehicle and SPVN06 treated eyes. H&E staining of the retina at P48 didn't reveal a protection of the ONL, whereas PNA staining at the same timepoint revealed greater density of the cone outer segments and/or their membrane remnants in SPVN06-treated eyes. When injection was conducted at PN15, no protection of the visual function was noted suggesting an optimal timing (P18) for treatment in this model. There were no significant SPVN06-related changes in ffERG or OCT parameters.

Conclusions: SPVN06 dramatically protects retinal degeneration in rd10 mice, a fast-progressing model of RCD, supporting clinical development.

ABSTRACT BODY:

Purpose: Insurance coverage (IC) eligibility for functional eyelid surgery requires visual field (VF) exams demonstrating constriction of superior field of vision with improvement after taping the upper eyelids to simulate surgery. Limited access to standard automated perimetry (SAP) machines and the need for a skilled technician produce a bottleneck effect which slows clinic flow. We compared the results of a Superior-64 VF test between a virtual reality (VR) device and SAP in patients with ptosis, brow ptosis, and dermatochalasis.

Methods: Patients undergoing non cosmetic eyelid surgery evaluation had the eyelids in their natural state (unT) and taped (T) assessed by a Superior-64 VF test strategy using VR and SAP in random order. The percentage of grid seen was calculated for both eyelid positions using the devices. Fulfillment of IC criteria for blepharoplasty, defined as a 30% or 12-degree increase in grid seen from unT to T, was assessed for agreement between VR and SAP.

Results: 39 eyes (20 OD, 19 OS) from 20 (15 female, 5 male) patients were tested using SAP and VR (Figure 1). There was significant improvement in the percentage of grid seen from the unT to T state using VR (36% to 75%; $t(38)=-8.94$, $p<0.001$) and SAP (34% to 64%; $t(38)=-7.16$, $p<0.001$). SAP and VR IC results agreed in 29 (74%) eyes (Table 1). A diagnosis of dermatochalasis was significantly associated with meeting IC qualification using SAP ($X2(1, N=39)=4.18$, $p=0.041$) and approached significance using VR ($X2(1, N=39)=3.39$, $p=0.066$). However, this association did not exist for subjects diagnosed with ptosis or brow ptosis. Of subjects with disagreement, there was no association between order of test administration and fulfillment of IC criteria ($X2(1, N=10)=0.28$, $p=0.598$).

Conclusions: VR Superior-64 VF test showed reliable agreement with SAP in meeting IC criteria and may offer a more accessible alternative to SAP in eyelid functional VF evaluation. Patients diagnosed with dermatochalasis have greater ability to demonstrate improvement in VF exam from the unT to T state on both devices than those with ptosis or brow ptosis. Further studies should focus on understanding test-retest variability of superior VF testing and the cause of disagreement between SAP and VR.

ABSTRACT BODY:

Purpose: Retinal progenitor cells undergo a transition between transcriptionally distinct early- and late-stage specific states during the course of neurogenesis, which control their ability to generate specific postmitotic cell types. Using integrated scRNA- and scATAC-Seq, we identified NR2F1 and NR2F2 as transcription factors that are strong candidates for maintaining early-stage identity in retina progenitors. In this study, we investigate the effects of misexpressing NR2F1 and NR2F2 in late-stage retinal progenitors.

Methods: We generated single cell RNA sequencing libraries from retinas electroporated ex vivo at P0 with 100ug of either a control GFP-expressing plasmid or individual or a combination of plasmids overexpressing NR2F1 and NR2F2. We then isolated and profiled electroporated cells from 10-15 retinas using scRNA-Seq. We collected between 4500 and 7000 cells per sample and then utilizing the Seurat R package processed the data. We then analyzed expression of known marker genes and conducted differential gene expression analysis to elucidate how NR2F1/2 overexpression impacted cell type population dynamics and gene regulatory networks.

Results: Within these datasets, we identified cell clusters with marker gene expression representing primary RPC, neurogenic RPC, G2/M phase RPC, microglia, amacrine, starburst amacrine, and photoreceptor cells. NR2F1/2 combined overexpression at P0 led to an increased fraction of RPC and amacrine clusters alongside a decrease in the overall fraction of primary RPCs. In addition, we observed ectopic expression of RGC-enriched markers (Ebf3, Elavl3) within the amacrine and neurogenic RPC populations as well as a loss of RPC markers (Pax6). [SB1] Similar effects of NR2F1/2 overexpression were observed at P2 and P5 individually, with additional RGC-specific markers (Rbpms, Calb2, Snca) detected at this age.

Conclusions: Our observation that NR2F1/2 overexpression leads to induction of expression of RGC-specific markers implies that these transcription factors may control temporal patterning of retinal progenitors, and render them competent to generate RGCs. These findings also imply that NR2F1/2 promote the transition from primary to neurogenic progenitors and may promote neurogenic competence.

TITLE: Incidence and Risk of Retinopathy in Patients With and Without Interstitial Cystitis and Pentosan Polysulfate Sodium Use

SESSION TITLE: New drugs, mechanisms of action and ocular toxicology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Desjarlais, V. Medic, J.E. Kim, Department of Ophthalmology and Visual Sciences, Medical College of Wisconsin, Milwaukee, Wisconsin, UNITED STATES|

Commercial Relationships Disclosure: Eric Desjarlais: Commercial Relationship: Code N (No Commercial Relationship) | Velinka Medic: Commercial Relationship: Code N (No Commercial Relationship) | Judy Kim: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Pentosan polysulfate sodium (PPS) is an oral medication used for the management of interstitial cystitis (IC). Recent studies have demonstrated an association between prolonged use and pigmentary maculopathy. However, to our knowledge, no studies have investigated or controlled for the potential association between IC and retinopathy. The aim of this study was to investigate the incidence and risk of retinopathy in patients with and without IC and PPS use.

Methods: Data for this retrospective cohort study was sourced from TriNetX, a nationwide, multicenter database. Adult, female patients with IC were matched to non-IC controls with a 1:4 ratio on age, sex, race, and ethnicity. Index dates for patients with IC and their matched controls were determined by the first recorded IC diagnosis. Patients could not have a retinopathy diagnosis before their index date. The IC cohort was subdivided according to duration of PPS use: never, less than five years, at least five years. The outcome measure was any one of six retinopathy diagnoses: exudative or nonexudative age-related macular degeneration, drusen, hereditary retinal dystrophy, toxic maculopathy, or unspecified macular degeneration. Univariate and multivariable Cox proportional hazards models were fitted. The multivariable model adjusted for age, race, ethnicity, smoking, and medical comorbidities. Hazard ratios (HRs) were estimated with the non-IC cohort as the reference category.

Results: The study included 110,300 adult, female patients. There were 22,060 and 88,240 patients with and without IC, respectively. With an average age of 53.92 (SD 16.22) years, 96,110 (87.14%) patients were non-Hispanic white, 8,835 (8.01%) were non-Hispanic black, and 5,355 (4.85%) were Hispanic. Incidence per 100,000 person-years was 173.88 (95% CI 162.96 - 185.53) for patients without IC, 226.63 (95% CI 198.63 - 258.56) for IC without PPS use, 293.02 (95% CI 234.02 - 366.89) for IC with less than five years of PPS use, and 558.91 (409.97- 761.95) for IC with at least five years of PPS use. Adjusted HRs were 1.31 (95% CI 1.13-1.51) for IC without PPS use, 1.70 (95% CI 1.35-2.15) for IC with less than five years of PPS use, and 3.10 (95% CI 2.26-4.27) for IC with at least five years of PPS use.

Conclusions: Patients with IC had greater incidence and risk of retinopathy. Prolonged PPS use further increased incidence and risk of retinopathy.

ABSTRACT BODY:

Purpose: Glaucoma patients suffer from visual field defects and ultimately blindness due to progressive loss of retinal nerve fibers. It is one of the leading causes of visual impairment in developed countries. The aim of this study is to determine the relationship between glaucoma and vision-related quality of life (VRQoL) and to explore associated factors of VRQoL in participants with glaucoma.

Methods: Participants in the population-based prospective observational cohort study (Gutenberg Health Study) underwent an ophthalmological examination including optic nerve head photography, intraocular pressure (IOP) measurement and a screening visual field exam between 2007-2012. Optic nerve head photographs were graded and classified according to the modified “International Society of Geographical and Environmental Ophthalmology” (ISGEO) glaucoma classification including adjustment for optic disc size. History of glaucoma or ocular hypertension (OHT) was defined as an ongoing prescription of IOP lowering medication or a history of glaucoma surgery. VRQoL was quantified using the German version of the Visual Function Questionnaire-25 and the Rasch-transformed visual functioning scale (VFS) was computed. A priori defined multivariable quantile regression models were carried out to analyze relationships.

Results: A total of 10,075 enrolled participants had both glaucoma grading and VRQoL investigation and were included in the study. Of these, 108 (1.1%) had glaucoma based on the ISGEO classification and 226 (2.2%) had a history of glaucoma or OHT. Glaucoma was associated with a significantly reduced VFS in both, participants with treatment (-8.14 [95% CI, -11.00 - -2,79]; P=0.005) and without treatment (-5.53 [95% CI, -8.31- -2.80]; P <0.001) compared to participants without glaucoma. IOP treatment without an ISGEO glaucoma diagnosis, such as in OHT, was also associated with a reduction on the VFS (-2.71 [95% CI, -5.39 - -0.01]; P=0.046).

Within participants with glaucoma impaired visual acuity of the better seeing eye (-5.62 [95% CI, -9.16 - -3.63] per each 0.1 on the logMAR chart; P=0.020) was associated with lower VFS, whereas history of glaucoma surgery, glaucoma medication use, IOP, size of the visual field defect, and family history of glaucoma were not associated with VFS.

Conclusions: Glaucoma is a common eye disease that reduces VRQoL.

ABSTRACT BODY:

Purpose: The macaque retina conveys visual information to the brain via ~20 anatomically distinct retinal ganglion cell (RGC) types. Yet only the most common LGN-projecting types have been characterized physiologically. Many of the remaining RGCs project to the superior colliculus (SC), an evolutionarily ancient region implicated in eye movements and, most recently, perceptual decision making. Here we catalog SC-projecting RGC types in the macaque retina and develop an approach to anatomically identify and physiologically characterize them in the living eye.

Methods: Injections of the retrograde tracer rhodamine dextran were aimed at the foveal SC in two macaques. Two stereotaxic-coordinate based injections were made in one macaque, and one MRI-guided injection was made in the second. Rhodamine expression was mapped with a fundus camera, then imaged in detail with adaptive optics scanning light ophthalmoscopy (AOSLO). The second macaque also expressed the genetically-encoded, calcium indicator GCaMP6s in the ganglion cell layer (Fig. 1). In the first macaque, post-mortem ex vivo imaging with a confocal microscope supplemented the in vivo imaging of rhodamine expression.

Results: Each injection labeled a sparse population of SC-projecting RGCs, consistent with earlier reports. We imaged the rhodamine-labeled RGCs in vivo with AOSLO, and some could be coaligned with GCaMP6s-expressing RGCs. The calcium responses of RGCs in rhodamine-labeled regions did not differ from areas without rhodamine expression. We traced the dendritic fields of 64 rhodamine-labeled RGCs that were imaged ex vivo with a confocal microscope, identifying parasol, smooth monostratified, large sparse, broad thorny and narrow thorny RGCs.

Conclusions: A complete account of the retinal input to the SC has been elusive since the rarity of many SC-projecting RGC types makes them difficult to target for physiological investigation. The anatomical approach developed here could address this gap in knowledge, laying the foundation for subsequent in vivo measurements of the response properties of these rare and understudied RGC types.

ABSTRACT BODY:

Purpose: Recently we showed that the inactivation of cathepsin K (CTSK), a secretory lysosomal protease, increased the ECM deposition and actin-bundling in the trabecular meshwork (TM) and elevated the intraocular pressure. In this study, we explored the loss-of-function effect of CTSK on the human TM proteome.

Methods: Normal primary human TM (HTM) cells (n=4) in vitro were transfected with either siRNA against CTSK (siCTSK) or scrambled siRNA (siScr) as control. 72h post-transfection, the protein was collected, and mass spectrometry-based quantitative proteomics was performed. Changes in protein levels were screened using criteria- $p \leq 0.05$ and mean $\pm 2\sigma$ of log2 as confidence fold change limits. MetaCore^{TM} was used for the functional pathway enrichment analysis.

Results: We found an increase and decrease in 398 and 132 proteins in TM respectively due to siCTSK. The upregulated proteins were related to– a) TM cell contractility and cell adhesion proteins- actin scaffolding protein tensin 1 (p=0.03), paxillin (p=0.01), docking protein involved in tyrosine kinase-based signaling related to cell adhesion BCAR1/p130cas (p=0.04), tyrosine-phosphorylated growth factor receptor adaptor protein NCK1 (0.04) and NCK2 (p=0.03), serine/threonine-protein kinase D1 (PRKD1) (p=0.001), and Guanine nucleotide exchange factor Vav2 (p=0.04), intracellular signal transducer and transcriptional modulator activated by TGFβ SMAD3 (p=0.04); b) sphingosine kinase 2 (SPHK2) (p=0.0001), which is involved in phosphorylation of the lysosphingolipid sphingosine-1-phosphate; and c) apoptosis-related proteins including caspase 1 (p=0.03), which cleaves and activates caspase 3 (p=0.02), caspase 7 (p=0.01), nuclear factorκB (NFkB) p105 subunit (p=0.05), and a critical apoptosis regulator receptor-interacting serine/threonine-protein kinase 1 (RIPK1) (p=0.03). Interestingly there was a significant decrease in the levels of actin depolymerizing protein phosphatase SSH1 (p=0.03), cell survival or anti-apoptotic protein tank binding kinase 1 (TBK1) (p=0.03), TBK1 adaptor protein 5-azacytidine-induced protein 2 (AZI2) (p=0.01), and as expected CTSK (p=0.04).

Conclusions: These unbiased observations establish the functionality of CTSK in regulating the TM actin cytoskeleton and the maintenance of TM cellularity. We propose that dysregulation of CTSK in TM can cause increased contractility and cell loss leading to elevated IOP and glaucoma.

TITLE: Title: A Novel Test of Low Contrast Reading in Non-Advanced Age-Related Macular Degeneration: A Potential Functional Endpoint for Clinical Trials.

SESSION TITLE: AMD: Clinical and translational research/AMD therapies (excluding anti-VEGF)

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Dusharm, E. bensinger, K. Dieter, J.D. Rodriguez, M.B. Abelson, G. Wallstrom, R&D, Ora Inc, Andover, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Mathew Dusharm: Commercial Relationship(s);Code E (Employment):ORA INC | Ethan bensinger: Commercial Relationship(s);Code E (Employment):ORA INC | Kevin Dieter: Commercial Relationship: Code N (No Commercial Relationship) | John Rodriguez: Commercial Relationship(s);Code E (Employment):ORA INC | Mark Abelson: Commercial Relationship(s);Code O (Owner):ORA INC | Garrick Wallstrom: Commercial Relationship(s);Code C (Consultant/Contractor):ORA INC

ABSTRACT BODY:

Purpose: Purpose: The development of effective therapies for nonadvanced age-related macular degeneration (AMD) has been hindered by a lack of sensitive, reversible endpoints to be used in clinical trials. Many clinical reading tests (e.g., MNREAD) use a relatively small number of words (10-20) and yield highly variable estimates of a patient's reading rate (1). Our group developed a novel reading test, Ora Reading Passages™ test, that assessed patients' reading efficiency algorithm under mesopic vision conditions, for naturalistic reading at low and high contrast. This study reports results from a third longitudinal visit for a cohort of non-advanced AMD patients tested in 2017.

Methods: Methods: Nine non-advanced AMD patients with visual acuity of 20/25 or better from the original cohort (2017) and 16 matched controls returned for the third visit. During a single study visit, all participants completed a battery of visual function tests including the Ora Reading Passages™ test. In the Ora Reading Passages™ test, patients viewed four naturalistic reading passages from National Geographic Education (5^{th}-7^{th}) grade-reading levels, presented at low and high contrast levels. Patients were asked to read aloud a passage of text at a comfortable reading pace.

Results: Results: Patients with non-advanced AMD had significant algorithmic efficiency differences for the passages in 'Reading Artifact 05' at both low and high contrast background levels ($p < 0.0077$). 'Reading Silk Road 08' ($p = 0.057$) and Reading Coral 14($p = 0.0611$). Results showed consistent patterns of observable data across our longitudinal study (1).

Conclusions: Conclusions: The Ora Reading Passages™ test, which assesses the algorithmic efficiency of reading in contrast levels (low - high) for mesopic vision conditions, demonstrated significant differences between non-advanced AMD patients and matched controls. These differences have remained relatively consistent over a 3-year longitudinal period. Our results suggest a repeatable test that can serve as a reliable and reversible functional endpoint in future clinical trials for therapies aimed at treating nonadvanced AMD.

TITLE: Zone 1 Trauma: Wound Dehiscence Compared to Primary Trauma

SESSION TITLE: Anterior Segment and Trauma Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Seery, M. Dastjerdi, Rutgers New Jersey Medical School, Newark, New Jersey, UNITED STATES|

Commercial Relationships Disclosure: Christopher Seery: Commercial Relationship: Code N (No Commercial Relationship) | Mohammad Dastjerdi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Ocular trauma is a significant cause of visual loss. Zone 1 injury is considered favorable prognostically compared to more posterior injuries, however, the same favorable prognosis may not be true for dehiscenced corneal wounds. The goal is to determine if this paradigm holds true for all situations, including wound dehiscence, or just primary traumatic injuries.

Methods: Retrospective chart review of all patients who underwent open globe repair based on CPT codes at University Hospital, Newark, NJ from 1/1/2019 to 12/1/2020. Those with Zone 1 injuries were identified and presenting vision, final visual outcomes, associated ocular pathology, long term complications, and need for further surgeries were reviewed. Zone 1 injuries were defined as all injuries limited to the cornea from limbus to limbus.

Results: 58 eyes were identified- 38 primary trauma and 20 dehisced wounds (11 PKP, 5 clear corneal incisions, 1 laceration, 1 ECCE, 1 RK, 1 tectonic graft). All dehisced wounds were blunt trauma and all primary traumas were projectiles or sharp penetrating injuries. Dehisced wounds had more posterior segment pathology i.e. hemorrhagic choroidal, vitreous hemorrhage, retinal detachment, choroidal effusion (all 20% v 2.63%, 5.26%, 5.26%, and 0% respectively), vitreous prolapse (20% v 2.63%) and uveal prolpase (80% v 36.84%). Dehisced wounds had more traumatic aphakia (40% v 0%) and dislocated lenses (15% v 0%). Primary trauma was more likely to have traumatic cataracts (55.26% v 10%) or no lens changes (44.74% v 25%). 2 dehisced wounds required enucleation, while no primary traumas were enucleated. Cataract/secondary intraocular lens surgery was performed in 34% of the primary traumas (10% in dehisced wounds). Primary traumas achieved 20/40 vision or better 44.74% (10% dehisced wounds). 7.89% patients with wound dehiscence ended NLP (none in primary trauma).

Conclusions: Dehisced wound patients had poorer visual outcomes as well as a higher rate of posterior segment pathology and expulsion of intraocular contents (lens, vitreous, and uvea). More important than the zone of injury is the mechanism. Ruptured globe as defined by Birmingham Eye Trauma Terminology likely portends poorer prognosis while penetrating and lacerating injuries by the same classification system likely a better prognosis, and as such, we believe that the traditional classification of zone of injury being a predictive factor of visual outcome is outdated.

ABSTRACT BODY:

Purpose: To identify the aqueous humor (AH) profile of lipid mediators in primary open angle glaucoma (POAG) eyes compared to those without glaucoma

Methods: AH samples from eyes with and without glaucoma underwent lipidomic analyses using liquid chromatography-mass spectrometry (LC-MS). Glaucoma samples were obtained from 60-80-year-old POAG patients undergoing a glaucoma surgery with or without cataract surgery. Matched control samples were obtained from patients undergoing routine cataract surgery. Patients with diabetes mellitus, systemic inflammatory disease, uveitis, retinopathy and age-related macular degeneration and those on Aspirin were excluded. From each eye, 100 mL of AH was collected using a 30 Gauge needle mounted on a 1-mL syringe, introduced into the anterior chamber anterior to the limbus, prior to any surgical intraocular entry. The samples were immediately snap frozen on dry ice and stored at -80C until assessment by lipidomic analyses of a panel of 40 polyunsaturated fatty acids (PUFA), metabolites and lipid mediators. All participants signed an informed consent. This study was approved by the University Health Network and Kensington Eye Institute Research and Ethics Boards.

Results: AH was collected from 16 and 18 eyes with and without glaucoma, respectively. The mean age was 68.7±6.4 years for the glaucoma group and 71.0±4.7 years for the control group (p=0.25). The mean preoperative intraocular pressure 14.1±3.1 and 15.2±1.6 mmHg for the glaucoma and control groups, respectively (p=0.24). The cup-to-disc ratios were 0.9±0.1 and 0.3±0.1 for the glaucoma and control groups, respectively (p<0.001). All 16 glaucoma eyes received prostaglandin analogue eye drops prior to surgery; 15 were on beta-blocker eye drops. There were statistically significant differences between glaucomatous and control eyes for arachidonic acid (1328.0±322.0 vs 643.1±130.6, p=0.001), lipoxin A_4 (0.79±0.14 vs 0.32±0.10, p=0.01) and 12-hydoxyeicosapentanoic acid (0.35±0.17 vs undetected, p=0.04). Substantial levels, but no significant differences, were identified for docosahexanoic acid (212.0±46.33 vs 131.1±22.36, p=0.11), eicosapentanoic acid (6.21±1.40 vs 3.76±0.32, p=0.08), prostaglandin E_2 (2.83±1.92 vs undetected, p=0.13) and prostaglandin D_2 (2.43±1.49 vs 0, p=0.09).

Conclusions: Increased levels of lipid mediators are present in glaucomatous eyes. Arachidonic acid metabolites may play a role in glaucoma pathogenesis.

ABSTRACT BODY:

Purpose: To assess photic effects caused by interaction between light from off-axis glare source and the edge of various commercially available intraocular lenses.

Methods: An experimental bench was developed to study the effects of off-axis glare source on various intraocular lens edge designs. The lenses were placed in a wet cell behind a model cornea. The lens fixture was designed to suspend the edge of the optic in isolation, so that scattering from edges of the wet cell or the model cornea does not confound the experimental results. A camera was placed behind the cornea and the intraocular lens. The bench setup allows the camera to move axially and be positioned at different angles to the optical axis of the system of the cornea and intraocular lens.

Results: A few commercially available intraocular lenses were tested. Results showed that intraocular lenses with sharp edges have the potential to cause severe glare effects close to the optical axis. Results suggest that even though the sharp edges of the IOL have been shown to reduce posterior capsular opacification (PCO) rates, optimization of lens edge design to reduce light scatter can benefit the patient by reducing PCO and also reduce scattering of light close to the optical axis. Even though there is a high likelihood that the stray light from glare sources will be blocked by the iris, decentered IOL or posterior positioning of the IOL can potentially expose the edge of an IOL to off-axis light entering the cornea.

Conclusions: Intraocular lenses such as enVista and PreVue (Yellow) IOLs (Bausch & Lomb, Inc.) have relatively lower glare, suggesting that these IOLs have an optimal edge geometry leading to low PCO[1], and at the same time reduce off-axis light scattering when compared to other IOLs, such as Alcon's Acrysof IOLs.

ABSTRACT BODY:

Purpose: The tear film is a protein-rich multilayer fluid that coats the corneal and conjunctival epithelia. Dry eye disease (DED), a multifactorial inflammatory disease of the ocular surface, is characterized by tear film instability. DED diagnostic methods are limited, and there is an urgent need for objective biomarkers. We analyzed human tear fluid to identify potential proteomic biomarkers associated with DED.

Methods: Tear samples were collected via Schirmer strips from 41 DED patients and 41 healthy controls. Proteomic analysis was performed using liquid chromatography-tandem mass spectrometry (LC-MS/MS). To ensure proteomic changes did not derive from confounding factors, multivariate regression analysis was performed, adjusting for age, sex, and race. Targeted parallel reaction monitoring (PRM) analysis was used to confirm the changes of 15 selected proteins.

Results: A total of 3288 unique proteins were identified in 82 tear samples. 89 of the 500 proteins detected in at least 50% of the samples were significantly altered in DED patients. 76 of the altered proteins were extracellular exosome proteins, and 28 were glycoproteins. The altered proteins are implicated in retinal homeostasis, cell-cell adhesion, proteolysis, receptor-mediated endocytosis, innate immune response, antibacterial humoral response, phagocytosis, and the complement pathway. The levels of lipocalin-1 (LCN1: 0.12-fold), lactoperoxidase (LPO: 0.15-fold), mesothelin (MSLN: 0.16-fold), heparan sulfate proteoglycan (HSPG2: 0.19-fold), nucleobindin-2 (NUCB2: 0.22-fold), zinc-alpha-2-glycoprotein (AZGP1: 0.33-fold), cystatin-C (CST3: 0.39-fold), polymeric immunoglobulin receptor (PIGR: 0.41-fold), and antileukoproteinase (SLP1: 0.43-fold) were decreased in DED patients, while the levels of serpin B5 (SERPINB5: 3.29-fold), calpain-2 catalytic subunit (CAPN2: 3.27-fold), complement factor H (CFH: 3.18-fold), protein S100-A8 (S100A8: 3.14-fold), and ubiquitin-like modifier-activating enzyme 1 (UBA1: 2.90-fold) were increased.

Conclusions: Using a shotgun approach, we found that the levels of 89 tear proteins were altered in DED patients. Targeted PRM analysis of 15 selected proteins confirmed the changes of 14 proteins in DED patients (9 decreased and 5 increased). These findings demonstrate the potential of tear protein levels as biomarkers for DED, and the pathways involving these proteins may further our understanding of the mechanisms underlying DED.

ABSTRACT BODY:

Purpose: To develop a cost-effective and scalable 3D printing method and novel bioinks to fabricate contact lenses.

Methods: The bioink formulations consisted of GelMA (gelatin methacrylate), LAP (Lithium phenyl-2,4,6-trimethylbenzoylphosphinate), and a yellow food-grade dye. The dye minimizes unwanted light leakage during the photopolymerization process. A commercial mSLA (masked stereolithography) printer, the Photon Mono X (AnyCubic, Shenzhen), was retrofitted with a custom temperature and humidity control kit. The printing process was performed at 40 ^{O}C and 90% humidity to ensure that the GelMA remained at a liquid state and to prevent the bioink from drying out, respectively. A set of matrix cubes of varying sizes with holes was used as a standard control. Images of the cubes were taken with a camera, top-down and side-review, analyzed with the ImageJ software and compared with the original CAD designs to derive an overall print quality score. Two print variables, exposure time (5 s to 40 s) and yellow dye concentration (1 – 7%), were analyzed in this study.

Results: The best resolution with the highest print scores were obtained at either 5% yellow dye concentration and 30 seconds exposure time, or 3% yellow dye concentration and 20 seconds exposure time. There was an overall optimal range for both print times (20 - 30 s) and yellow dye concentration (3 - 5%). Values above or below this critical value resulted in lower print quality scores of the standard cubes. A prototype contact lens with a 200 μm thickness was able to be 3D printed using the developed print methods and parameters, with a total print time of approximately 20 minutes. Approximately 28 contact lenses can be printed at the same time using the 3D printer. However, the surface and edges of the 3D printed contact lens were still visually very rough.

Conclusions: The current study demonstrated that a low-cost commercial 3D mSLA printer can be used to fabricate model contact lenses using a hydrogel material. Still, further work is necessary to improve the print quality for fabricating ultra-thin devices such as contact lenses. Future work will use this 3D printing method to fabricate contact lenses for drug delivery.

ABSTRACT BODY:

Purpose: The American Academy of Ophthalmology (AAO) and the National Heart, Lung, and Blood Institute (NHLBI) suggest sickle cell patients undergo dilated funduscopic exams (DFE) every 1-2 years to screen for sickle cell retinopathy, but there is a paucity of research reporting whether such guidelines are followed in the sickle cell disease (SCD) population. A retrospective study was performed to assess whether adults with SCD at our institution are adhering to the recommendations.

Methods: This study is a chart review of 842 adult patients with sickle cell diagnosis, seen from 3/17 – 3/21 by internists in the Montefiore healthcare system. Data was collected through the Electronic Medical Record (EMR) of patients with a DFE categorized as normal (Retinopathy -, n = 216) or with retinopathy (Retinopathy +, n = 199). A regular DFE was defined as at least one DFE every 2 years. Screening rates were calculated by removing patients with retinopathic disease noted in EMR from total SCD patients. Yearly DFE rates were calculated from March to March, since COVID-19 was declared a global pandemic in March 2020. Two-tailed Student's t-test was used for statistical analysis of continuous data, Fisher's exact test for categorical data, and two-sample proportion test for comparison of yearly exam rates.

Results: The Retinopathy - group was younger ($p<0.001$) and contained less SC genotype ($p<0.001$) compared to Retinopathy +. 40.3% of the Retinopathy - patients were screened regularly (n = 87), whereas 59.7% had irregular screening (n = 129). There was a significant decrease in the total rate of all patients with DFEs, comparing the average rate of 29.8% pre-COVID (3/17-3/20) to 13.6% during COVID (3/20-3/21) ($p<0.001$). Similarly, the screening rate for non-retinopathic patients decreased from an average rate of 18.6% pre-COVID to 6.7% during COVID ($p<0.001$).

Conclusions: The results demonstrate that our rate of routine dilated fundoscopic examination for SCD patients is very low. These low rates were even more adversely affected by the onset of the COVID-19 pandemic, as clinics closed and access to physicians decreased. Screening rates need to be increased by patient involvement and education, easier access to ophthalmologists and novel ways of screening for retinopathy (e.g. annual screening fluorescein angiograms) to reduce risk of blindness in these patients.

Commercial Relationships Disclosure: Sirin Triwutpipatkul: Commercial Relationship: Code N (No Commercial Relationship) | Rath Itthipanichpong: Commercial Relationship: Code N (No Commercial Relationship) | Bharkbhum Khambhiphant: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To develop a mixed reality (MR) headset with the customized obstacle detection software and voice guided navigation (CU glasses) for avoiding indoor obstacles using a spatial mapping technique and compare its performance with a white cane.

Methods: Ten normal sighted people aged 29-65 years were recruited into this pilot, cross-sectional study. The experiment room was set up with ten soft non-harmful obstacles including 4 face-level, 3 trunk-level and 3 knee-level obstacles. All subjects were blindfolded and trained to use both the CU glasses (CUG) and a white cane (WC) before entering the experiment room. All subjects were randomly assigned to 2 groups (CUG or WC) and walked through the 10 obstacles from entrance (point A) to exit (point B) one by one. After that all subjects were switched the group and walk through the 10 obstacles once again from point B to point A. The number of bumping into obstacles and time from entrance to exit were recorded.

Results: The CUG group had lower number of obstacles hit compared with the WC group

The mean (SD) number of obstacles hit of the CUG group, and the WC group was 0.7 (+/- 0.48) and 1.4 (+/-0.84) respectively. The mean difference (95% CI) of number of obstacles hit between 2 groups was 0.7 (0.12, 1.27), p=0.016. The total time (SD) from start to finish of the CUG group and the WC group was 5.18 (+/-3.42) and 3.21 (+/-2.78) minutes respectively. The mean difference (95% CI) was 1.97 (-4.39, 0.45), p=0.111. All subjects completed the test without any falls or injuries.

Conclusions: The CU glasses can decrease the number of obstacles hit compared with white cane in our indoor experimental environment. Further studies in the blind subjects are needed to assess its full potential as an assistive device for improving orientation and mobility for the blind.

ABSTRACT BODY:

Purpose: During corneal wound healing, keratocytes located within the stroma are activated into a repair phenotype by the release of soluble growth factors, such as transforming growth factor-beta 1 (TGF-β1) and platelet-derived growth factor-BB (PDGF-BB). This process is often accompanied by an increase in tissue stiffness. Previous studies have shown that the TGF-β1-mediated myofibroblastic differentiation of corneal keratocytes is regulated by changes in stiffness, but it is unclear if the keratocyte response to other growth factors, such as PDGF-BB, is stiffness-dependent. Here, we used a polyacrylamide (PA) gel system to determine if changes in substratum stiffness modulate the proliferation and motility of primary corneal keratocytes cultured in the presence of PDGF-BB. We also investigated how the stiffness-dependent myofibroblastic differentiation of cultured keratocytes is influenced by treatment with both TGF- β1 and PDGF-BB.

Methods: PA substrata with an elastic modulus of either 1 kPa (soft) or 10 kPa (stiff) were fabricated to mimic the mechanical properties of either normal or fibrotic corneal tissue, functionalized with type I collagen, plated with primary rabbit corneal keratocytes (NRKs), and cultured in defined serum-free media in either the presence or absence of TGF- β1 and/or PDGF-BB.

Results: When treated with PDGF-BB, NRKs exhibited a more elongated morphology and a higher rate of proliferation on stiff, as opposed to soft, PA substrata. Using a freeze-injury assay, however, we did not observe stiffness-dependent differences in the PDGF-BB-driven motility of these cells. In the presence of TGF-β1, NRKs cultured on soft PA substrata exhibited low levels of myofibroblastic differentiation, as measured by alpha-SMA immunofluorescence and cellular traction forces. When treated with both TGF-β1 and PDGF-BB, however, increased levels of alpha-SMA immunofluorescence were observed on the soft PA substrata, and we no longer observed stiffness-dependent differences in myofibroblastic differentiation, suggestive of mechanotransductive cross-talk between the signaling pathways downstream of TGF-β1 and PDGF-BB.

Conclusions: Taken together, these data highlight the importance of the combined biochemical and biophysical microenvironment on keratocyte behavior during corneal wound healing.

TITLE: Assessing resident cataract surgical outcomes using electronic health record data
SESSION TITLE: Vision care training and education
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: G. Xiao, Johns Hopkins University School of Medicine, Baltimore, Maryland, UNITED STATES|M. Boland, Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|D. Srikumaran, S. Sikder, F. Woreta, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|
Commercial Relationships Disclosure: Grace Xiao: Commercial Relationship: Code N (No Commercial Relationship) | Divya Srikumaran: Commercial Relationship: Code N (No Commercial Relationship) | Shameema Sikder: Commercial Relationship: Code N (No Commercial Relationship) | Fasika Woreta: Commercial Relationship: Code N (No Commercial Relationship) | Michael Boland: Commercial Relationship: Code N (No Commercial Relationship)
ABSTRACT BODY:
Purpose: To use electronic health record (EHR) data to investigate the relationship between resident experience and cataract surgery outcome measures, including visual acuity and unplanned return to the operating room.
Methods: EHR data were collected from cataract surgeries performed at the Johns Hopkins Wilmer Eye Institute from July 1, 2016 to March 1, 2020, and cases were categorized into resident or attending as primary surgeon. Pre-operative and post-operative visual acuity (VA) were recorded for each surgery, and data on unplanned return to OR were collected.
Results: This study analyzed 14537 cataract surgery cases from July 1, 2016 to March 1, 2020. Out of 337 surgeries that could be attributed to residents with both pre-operative and post-operative VA data, 248 resident cases (73.6%) had better post-operative VA and 170 cases (50.5%) had more than 2 lines improvement in VA. There was no statistical difference in the proportion of cases with better post-operative VA or more than 2 lines improvement between resident and attending cases. The rate of unplanned return to the operating room within 90 days of cataract surgery was not statistically different between resident (1.8%) and attending (1.2%) surgeons.

Attending surgeons had a statistically greater proportion of cases with post-operative VA better than 20/40 but this finding has to be considered in the context that, on average, resident cases started out with poorer baseline visual acuity. Multivariable regression models of VA outcomes versus resident experience that controlled for pre-operative VA, patient age, American Society of Anesthesiologists (ASA) score, and estimated income showed that only pre-operative VA was statistically related to VA outcome.
Conclusions: Resident experience was not related to VA outcomes but pre-operative VA, ASA classification, and attending/resident status were important in predicting post-operative VA. Given the impact of pre-operative VA on post-operative outcomes, VA cutoffs may not provide a high-quality metric to assess resident competency and experience. The use of EHR data can provide an ongoing way to evaluate and monitor resident cataract outcomes.

ABSTRACT BODY:

Purpose: Familial dysautonomia (FD) is an autosomal recessive neurodegenerative disease caused by a splicing mutation in the gene encoding Elongator complex protein 1 (ELP1, also known as IKBKAP). A T-to-C base change in the 5' splice site of ELP1 exon 20 results in exon 20 skipping with tissue specific reduction of ELP1 protein predominantly in the central and peripheral nervous system. In addition to a complex neurological phenotype, FD patients exhibit progressive retinal degeneration that severely affects their quality of life. To rescue retinal degeneration in FD, we have developed a novel splicing-targeted therapeutic approach based on Exon specific U1 small nuclear RNA (ExspeU1 snRNA)). Using a phenotypic mouse model, TgFD9; $Ikbkap^{D20/flox}$, we have tested the therapeutic efficacy of ExspeU1 to correct ELP1 mis-splicing and rescue of retinal degeneration.

Methods: Adeno Associated Vector expressing ExspeU1 was delivered to the retina (AAV2- ExspeU1) by Intravitreal injection. RT-PCR analysis was performed to analyze ELP1 splicing in the retina. Optical Coherence Tomography (OCT) analysis was used to evaluate the thickness of the retinal layers. Retinal whole-mount staining was performed to count the number of retinal ganglion cells (RGCs), and immunohistochemical staining was performed to detect the transduction of AAV2- ExspeU1 in the retina.

Results: To restore ELP1 splicing defect and prevent RGC loss in FD, we have designed a novel splice targeted therapy using ExSpeU1s that permits targeted binding to intronic sequences downstream of the mutant 5' splice site enhancing recruitment of the spliceosomal machinery. In vivo delivery of AAV2- ExspeU1 to the retina showed broader transduction throughout the retina, predominantly in RGCs. Our findings indicated a significant improvement in ELP1 splicing correction in the retina in AAV2- ExspeU1 injected mice (n=6) compared to sham injected mice ($p<0.001$) and support the therapeutic potential of an AAV2- ExspeU1 based treatment to rescue RGC loss in FD.

Conclusions: Our findings demonstrate that delivery of AAV2- ExspeU1 to the retina in FD mice by intravitreal injection corrected the ELP1 splicing defect and therfore it has the potential to rescue the retinal degeneration observed in FD patients. These findings highlight the therapeutic value of AAV2- ExspeU1 delivery to treat retinal degeneration in FD.

TITLE: Y-like behavioral responses to contrast-modulated patterns as a specific test of the magnocellular pathway

SESSION TITLE: Visual Function: perception, adaptation, spatial, visual acuity and binocular vision

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Ramirez, C. Baker, Ophthalmology, McGill University, Montreal, Quebec, CANADA|L.W. Thompson, A. Rosenberg, Neuroscience, University of Wisconsin-Madison, Madison, Wisconsin, UNITED STATES|

Commercial Relationships Disclosure: Ana Ramirez: Commercial Relationship(s);Code P (Patent):Based on these findings the technology transfer office for UW-Madison (WARF) has filed a patent application (pending) with Ari Rosenberg, Curtis Baker and Ana Ramirez listed as inventors. | Lowell Thompson: Commercial Relationship: Code N (No Commercial Relationship) | Ari Rosenberg: Commercial Relationship(s);Code P (Patent):As for first author | Curtis Baker: Commercial Relationship(s);Code P (Patent):As for first author

ABSTRACT BODY:

Purpose: The primate magnocellular pathway originates in parasol retinal ganglion cells, which like Y-cells of the cat, respond nonlinearly to high spatial frequencies (SFs) and temporal frequencies (TFs). However, the contribution of Y-like cells to human visual perception are not well understood.

The contrast-modulated (CM) stimuli used here were composed of high SF contrast-reversing grating carriers that were contrast modulated by a low SF drifting sinewave envelope. Since CM carrier-tuned responses in visual cortex are mediated by Y-cell inputs, we hypothesized that human psychophysical performance for CM stimuli might reflect properties of nonlinear Y-like cells, rather than linear responses to conventional gratings.

Methods: Healthy subjects (N=6) reported the direction of motion of CM envelopes or luminance-modulated (LM) gratings from 2.1-8.5 degrees of eccentricity. SF (for LMs) or carrier SF (for CMs) was varied for different values of TF (LMs) or carrier TF (CMs).

Results: LM performance was low-pass with SF, with the cut-off systematically decreasing with TF. CM performance was bandpass with carrier SF, with best performance at high carrier SFs (1.5-3.0cpd) and TFs (15-20Hz). These observations were confirmed with an ANOVA, showing a significant effect of carrier SF, $p<0.05$, but not carrier TF, $p=0.1$, or their interaction, $p=0.75$. The eccentricity-dependence also differed for LM and CM stimuli. At the highest TF (20Hz), the low-pass LM performance decreased systematically with eccentricity, while CM performance was bandpass with carrier SF, and rather independent of eccentricity. An ANOVA showed a significant main effect for the carrier-SF, $p=<0.05$, but not eccentricity $F(3,2)=0.8$, $p=0.48$, or their interaction, $p=0.56$.

Conclusions: Since nonlinear subunits of Y-like cells respond better at higher TFs than linear mechanisms respond to gratings, the psychophysical performance for CMs is consistent with Y-like cells. The good performance for CM stimuli at carrier SFs that are high for peripheral vision and the relative independence of eccentricity are also consistent with responses of small Y-like nonlinear subunits. These results suggest that our CM behavioral task provides a specific indicator of the functioning of Y-like cells in human vision. This might be relevant to assessing pathologies related to damage in the magnocellular pathway, including glaucoma.

TITLE: Classification and automated detection of retinal arteriovenous crossing morphology in systemic arterial hypertension using infrared scanning laser ophthalmoscopy

SESSION TITLE: Machine Learning: Segmentation and Classification

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Iafe, H. Hosseini, J. Choi, C. Hoeferlin, I. Chehaibou, S.D. Schwartz, Retina Division, Jules Stein Eye Institute, Los Angeles, California, UNITED STATES|A. Hatamizadeh, Computer Science Department, University of California Los Angeles Henry Samueli School of Engineering, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Nicholas Iafe: Commercial Relationship: Code N (No Commercial Relationship) | Hamid Hosseini: Commercial Relationship: Code N (No Commercial Relationship) | Ali Hatamizadeh: Commercial Relationship: Code N (No Commercial Relationship) | Jinseo Choi: Commercial Relationship: Code N (No Commercial Relationship) | Cory Hoeferlin: Commercial Relationship: Code N (No Commercial Relationship) | Ismael Chehaibou: Commercial Relationship: Code N (No Commercial Relationship) | Steven Schwartz: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate whether retinal vascular analysis of arteriovenous (AV) crossings in Infrared Scanning Laser Ophthalmoscope (IR-SLO) images using convolutional neural networks (CNN) may contribute to classification and risk stratification of patients with systemic hypertension.

Methods: Medical records and IR-SLO images were reviewed for 152 consecutive patients. Healthy control group images were used to assess normal vasculature. The morphologic characteristics of AV crossings were compared between patients with and without hypertension, evaluating continuity of the central venous light reflex and the presence of venous narrowing. Retinal specialists manually categorized all images by the severity of change; a subset of 99 images was analyzed using a CNN model.

Results: Sixty-three patients (51%) had systemic hypertension. Venous changes at AV crossings were more common in hypertensive patients (44/63, 70%) compared to normotensive patients (19/61, 32%; $P < 0.0001$). Moderate changes were seen in 25 (40%) hypertensive patients compared to 15 (25%) normotensive patients (P=0.002). Severe changes were noted in 19 (30%) hypertensive patients compared to 4 (7%) normotensive patients (P=0.001). Output predictions of the CNN model had a mean Average Precision (mAP) of 81% for image classification.

Conclusions: The presence of morphological changes at AV crossings is correlated with hypertension in this series of patients. The authors propose that IR imaging may be used in the clinical setting to evaluate hypertensive retinal vasculature changes and provide a framework for automated classification and risk stratification.

Commercial Relationships Disclosure: Rachel Fehrman: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Lipinski: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Recombinant adeno-associated virus (rAAV) vectors have become promising tools for mediating gene transfer to retinal neurons for the treatment of monogenic inherited retinal diseases. Unfortunately, due to the limited 4.8 kb coding capacity of rAAV and the large size of many therapeutic transgene cassettes, numerous retinal diseases cannot currently be treated using rAAV-mediated gene therapy. To circumvent this limitation, transduction with two or more vectors, each containing separate gene fragments, has been utilized. Although these studies have shown success, in vivo efficiencies remain around 10%. Due to this fact, our study aims to investigate the cellular transduction efficacy when multiple reporter transgenes are delivered to the murine retina.

Methods: Female C57BL/6J mice (N=9) received bilateral intravitreal injections of one, two, or three recombinant AAV (rAAV) vectors packaging a ubiquitously expressing mCherry, green fluorescent protein (GFP), and/or blue fluorescent protein (BFP) transgene cassettes respectively (N=3/group). Dual fluorescence confocal scanning laser ophthalmoscopy (cSLO) was performed 4 weeks post-injection to assess transgene expression in vivo. Retinae were harvested and dissociated allowing quantification of transduction efficiency via flow cytometry.

Results: cSLO imaging revealed dual injection of rAAV2/2[MAX].CBA.GFP and rAAV2/2[MAX].CBA.mCherry (N=6 eyes) resulted in widespread retinal transduction centered on the optic near head. The pattern of GFP and mChery expression was observed to substantial overlap, indicating efficient co-transduction following delivery of multiple vectors. Preliminary flow cytometry analysis of dissociated retinae revealed that up to 62.0% (±9.2%) of GFP+ve cells also co-expressed mCherry, indicating that co-transduction with multiple vectors is only partially efficient. Analysis of triple injected eyes in ongoing.

Conclusions: This study indicates that the ability of multiple rAAV vectors to transduce individual retinal neurons following administration via a single injection is substantially higher than the recombination efficiencies previously reported, suggesting that co-transduction with rAAV vectors containing multiple fragments is not a limiting factor.

ABSTRACT BODY:

Purpose: To quantify the morphology of astrocytes, connective tissue beams, and axonal compartments in post mortem human optic nerve heads (ONH), comparing control to glaucoma, central to peripheral ONH, and by degree of optic nerve damage.

Methods: Serial cross-sections of 16 glaucoma ONH (from 12 donors, median age=79) and 9 control ONH (from 6 donors with no glaucoma history and normal optic nerves, median age=83) were immunolabelled for confocal and second harmonic generation imaging as described in Ling et al. 2019. 63 structural features of lamina cribrosa (LC) were measured, including astrocytic glial fibrillary acidic protein (GFAP) area fraction, actin area fraction, median axonal compartment area, average collagen beam width, and nuclei density. Global and regional differences were compared between controls and glaucoma, and among glaucoma severity groups judged by masked grading of axon loss in nerve cross-sections by two observers.

Results: The area fraction of GFAP and actin in the LC pores was significantly decreased in glaucoma eyes ($P = 0.014$, 0.009, respectively) and these measures declined consistently with increased glaucoma damage (Figure 1). However, the mean area of LC pores was not significantly different in glaucoma eyes. Median axonal compartment area was significantly lower in glaucoma ($P = 0.015$). GFAP area fraction in pores was higher in periphery than center LC in both control and glaucoma ($P = 0.057$, $P = 0.025$, respectively). While in controls the mean collagen beam width was similar in central and peripheral regions, in glaucoma the beam width was significantly lower in peripheral than in central regions ($P = 0.007$).

Conclusions: This cross-sectional, quantitative analysis of LC structure suggests that loss of axons in glaucoma is associated with reductions in astrocyte cytoskeletal components and axonal compartments, as well as progressive beam thinning.

ABSTRACT BODY:

Purpose: Mutations in the SLC4A11 gene are associated with Fuchs endothelial corneal dystrophy (FECD). SLC4A11 is expressed by corneal endothelial cells (CECs) and regulates corneal fluid balance and ion homeostasis. SLC4A11 mutations can cause disease through protein misfolding and an unfolded protein response. Prior studies showed that correcting mutant SLC4A11 misfolding can restore CEC functional activity. Thus, a safe and effective chemical corrector for SLC4A11 mutations related to FECD may be identified through an advanced research pipeline consisting of cell-based assays, CRISPR screens, and high content imaging (HCI) technologies. The purpose of this study is to develop a cell-based system for our research pipeline.

Methods: Plasmids suitable for HCI were generated to express doxycycline-inducible (Tet-on) GFP-SLC4A11 wild-type or mutant (G709E) fusion proteins. The plasmids were stably transfected into a HEK293T dCas9-KRAB cell line to allow for CRISPR genetic screens. Confocal microscopy was used to assess the cellular localization of GFP-tagged $SLC4A11^{WT}$ and $SLC4A11^{G709E}$ in the absence or presence of doxycycline and glafenine (positive control compound). The cell culture assay was then miniaturized to 384-well plate format and optimized for high throughput phenotypic screens (HTS). A screening Z' score was determined as a statistical parameter for predicting the success of HTS campaigns.

Results: Confocal microscopy showed that expression of both proteins was doxycycline inducible, but the WT protein was properly trafficked to the plasma membrane while the G709E mutant was retained in puncta. Addition of glafenine partially restored normal trafficking of $SLC4A11^{G709E}$. The doxycycline concentration (2 µg/mL), assay volume (20 µL), treatment time (48 hrs) and number of cells/well (3,000 cells) were successfully optimized. Dose-response curves identified the concentration required for maximal activity (40 µM) and confirmed that the negative control (DMSO) had no measurable effect on fluorescence or cell viability. The calculated Z' score for 40 µM glafenine was 0.32.

Conclusions: We have developed a cell-based assay that is ready for HCI and CRISPR genetic screens for discovering correctors for FECD-associated mutations. More broadly, this assay and workflow can be readily adapted for use in other genetic causes of FECD and other ocular disorders.

ABSTRACT BODY:

Purpose: We have previously shown that in the diabetic retina histone deacetylase 6 (HDAC6) is one of the initiating factors promoting stress-induced premature senescence (SIPS) in the retinal vasculature. This is a key pathogenic process involved in the onset and progression of diabetic retinal microangiopathy and diabetic retinopathy (DR). Anti-aging and senolytic drugs are thought to be beneficial for neurodegeneration and cardiovascular disease including diabetes. Silymarin (SIL) is a flavone that has been shown to halt senescence in a number of cell types including endothelial cells. Here we have investigated the effects of SIL on retinal vascular SIPS in an experimental model of DR also determining its inhibitory ability towards HDAC6.

Methods: Morphological and biochemical analyses were performed comparing streptozotocin-induced diabetic rats (STZ) with age-matched normoglycemic rats (control) and with STZ-rats that received SIL (200 mg/Kg/day p.o.) starting 2 weeks after the onset of hyperglycemia and continued for all the duration of diabetes (8 weeks). SIPS was shown by immunostaining for S-A-beta GAL and by immunoblotting for p16ink4a and p21waf. HDAC6 expression and activity were measured by immunoblotting and fluorescence enzymatic assay, respectively. Docking studies were done to elucidate at molecular level SIL and HDAC6 interaction.

Results: Our analyses showed that SIL preserved retina cells survival while down-regulating the expression of pro-inflammatory and pro-oxidant factors. SIL also reduced the expression of senescence markers and downregulated the expression and activity of HDAC6. Docking studies-based predictions revealed SIL potential interaction with both the catalytic and zinc-finger ubiquitin-binding domains of HDAC6 demonstrating strong inhibitory activity of SIL towards this deacetylase.

Conclusions: Overall, our studies demonstrate SIL beneficial effects in the diabetic retina by preventing diabetes-induced retinal vascular SISP through its inhibitory activity towards HDAC6. These results also warrant further studies to assess SIL senolytic activity and set the stage to clinical studies evaluating the use of this flavone as potential adjuvant therapy for DR.

TITLE: Risk factors for vision loss among nursing home residents: a cross-sectional analysis

SESSION TITLE: Vision Impairment, Visual Function, and Quality of Life

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W. Monaco, H. Meng, A. Arif, S. Aggarwal, School of Aging Studies, University of South Florida, Tampa, Florida, UNITED STATES|R. Qureshi, Ophthalmology, University of Colorado Denver School of Medicine, Aurora, Colorado, UNITED STATES|

Commercial Relationships Disclosure: William Monaco: Commercial Relationship: Code N (No Commercial Relationship) | Riaz Qureshi: Commercial Relationship: Code N (No Commercial Relationship) | Hongdao Meng: Commercial Relationship: Code N (No Commercial Relationship) | Areeb Arif: Commercial Relationship: Code N (No Commercial Relationship) | Sulbh Aggarwal: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Approximately two percent of older adults currently live in nursing homes and this institutionalized population is at substantial risk for vision loss. It is important that the risks for vision loss be characterized to ensure appropriate vision care is provided for nursing home patients. Our objective was to evaluate the association of age-related eye diseases (AREDs) and multi-morbidities with vision impairment (VI).

Methods: This is a cross-sectional analysis of comprehensive eye examination records for 7927 residents of 74 North Carolina nursing homes who were ≥65 years at time of the initial patient visit. Complete data on outcomes, associated factors, and covariates were included from the standardized Centers for Medicare and Medicaid Services eye exam. We defined VI and blindness respectively as best-corrected visual acuity between 20/40 and 20/200, and 20/200 or worse. Clinical diagnoses of AREDs were defined by the attending clinician. Data were extracted from electronic health records and al analyses were conducted in SAS version 9.4. We used descriptive statistics to summarize the resident characteristics and AREDs and logistic regression analysis to examine independent risk factors for VI.

Results: A total of 7927 initial eye exam records (mean age 83 (SD = 8.5), 68% female) with complete data were included in the analysis. Overall, 34% of the residents had normal vision, 43% had VI, and 23% were blind. The prevalence of vision impaired/blind among participants with AREDs including untreated cataracts, macular degeneration, glaucoma, and diabetic retinopathy were respectively 71%, 76%, 69%, and 63%. Among patients with AREDs, prevalence of blindness ranged from 53% for patients with cataracts to 23% for patients with diabetic retinopathy.

Conclusions: Comprehensive eye examinations showed vision impairment and blindness affected 66% of nursing home residents, overall. This study substantiates the positive impact of comprehensive eye examinations to promote visual, systemic and cognitive health and wellbeing and the need that eye care service be used to inform policy and practice to improve patient functioning and independence. Further analyses are being performed to determine whether or not correction of refractive error could reduce vision impairment or blindness.

ABSTRACT BODY:

Purpose: A prospective observational clinical study was performed to evaluate ocular symptoms related to dry eye disease (DED) in patients infected with COVID-19.

Methods: The staff of an University Hospital in Londrina city, Brazil, who presented respiratory symptoms and underwent nasal swab PCR test for SARS-CoV-2 detection at the outpatient unit during November to December 2020 was assessed by electronic messages and separated in two groups (PCR test negative or control group – CG, and PCR test positive or COVID-19 group - COVG). Sociodemographic data, presence of ocular and systemic comorbidities, place of treatment (home, infirmary or intensive care unit), and the Ocular Surface Disease Index (OSDI) questionnaire, translated and validated to Portuguese for DED evaluation were performed. OSDI contains 3 subsections including visual-related function (category A), ocular symptoms (category B) and environmental triggers (category C). Scores range from 0 to 100 with 0 to 12 representing normal, 13 to 22 mild DED, 23 to 32 moderate DED and 33 severe DED. The data was submitted to statistical analysis.

Results: From 450 electronic messages sent, 113 patients were included. 62(54,85%) had laboratory-confirmed (RT-PCR) Covid-19. The mean age was 36 years, ranging from 21 to 60 years. 83 (73.4%) patients were female. The main systemic comorbidity was smoking (23%), followed by obesity (3.5%) and hypertension (1.76%). The mean OSDI score was 13.85 in the COVG and 5.37 in the CG (p=0.002). The COVG had a mean score of 3.50 related to category A, 1.05 to category B and 2.13 to category C while the CG presented a mean score of 1.41, 0.39 and 0.80 respectively (p = 0.003; p=0.04; p=0.01). Patients who required hospitalization for treatment presented OSDI score proportionally greater than those who were treated at home (25.67) (p=0.052).

Conclusions: OSDI score was higher in the COVG and among patients who required hospitalization for treatment. These results suggest association of COVID infection and DED; and increase of DED according to the severity of respiratory symptoms.

ABSTRACT BODY:

Purpose: To investigate the factors associated with choroidal microvasculature dropout (MvD) enlargement detected by optical coherence tomography angiography (OCT-A) in glaucoma eyes.

Methods: Ninety-one eyes of 68 primary open angle glaucoma (POAG) patients were enrolled. Only eyes with 4 good quality OCT-A and OCT scans of the optic nerve head with 2 years follow-up were included. Area of MvD were analyzed on en-face images at each visit (see Figure). Univariable and multivariable mixed effects models were constructed to identify the factors contributing to MvD area over time.

Results: Peripapillary MvD was detected in 53 (58.2%) eyes at baseline and in an additional 17 (18.7%) eyes during follow-up, whereas MvD was not detected in 21 (23.1 %) eyes during the entire follow-up period. In eyes with MVD at baseline, mean baseline MVD area was 0.15 (0.09, 0.22) mm^2. In eyes with MvD at baseline, mean (95% CI) of rate enlargement of MVD area was 0.05 (0.04, 0.06) mm^2/year. In the univariable model, worse baseline VF MD (coefficient ß =0.27, 95%CI: 0.10, 0.44, P=0.002), greater intraocular pressure (IOP) fluctuations (ß=0.86, 95% CI: 0.24, 1.48, P=0.007), higher peak IOP (ß=0.17, 95% CI: -0.01, 0.35, P=0.067) and greater number of IOP lowering medications (ß =1.36, 95% CI: 0.67, 2.05, P<0.001) were associated with faster MvD area enlargement (Table 1). In the multivariable model, worse baseline VF MD, greater IOP fluctuations, higher peak IOP and greater number of IOP lowering medications remained significantly associated with faster MvD area enlargement (Table 1). No associations were found between mean IOP during follow-up and MvD changes over time. In the 17 eyes that developed MvD during follow-up, long-term IOP fluctuation [95% CI], defined as the standard deviation of IOP measurements during follow-up, was significantly greater (3.5 [2.3, 4.7] mmHg) in eyes with MvD compared to eyes that did not develop MvD (1.9 [1.5, 2.3] mmHg, P=0.012).

Conclusions: IOP fluctuation was associated with MvD enlargement and development. Other factors, including peak IOP, worse baseline VF MD and number of glaucoma medications were significantly associated with MvD area enlargement in glaucomatous eyes. The identification of factors associated with MvD enlargement may improve our understanding of the role of choroidal microvasculature in glaucoma.

ABSTRACT BODY:

Purpose: The visual system requires stable encoding of environmental illuminance across a wide dynamic range. Illuminance is encoded within the retina by the M1 subclass of intrinsically photosensitive retinal ganglion cells (M1 ipRGCs). M1 ipRGCs integrate extrinsic signals from photoreceptors with their own intrinsic light responses to drive non-image-forming (NIF) behaviors such as the pupillary light reflex (PLR) and circadian photoentrainment. This integration is vital for illuminance encoding and downstream NIF behaviors; however, it is unknown whether the M1 ipRGC circuit can compensate for perturbations to its synaptic input. In perturbed circuits, homeostatic plasticity can restore neural activity and preserve functional stability. However, it is unclear how and to what extent homeostatic plasticity can restore activity in the highly specialized M1 ipRGC circuit and preserve NIF behaviors at the level of the entire organism.

Methods: To address this question, we used mice in which the type 6 bipolar cell (B6), which provides ~90% of the synaptic input to M1 ipRGCs, was genetically deleted through targeted expression of diphtheria toxin (DTA; B6-DTA mice). We recorded the PLR and circadian rhythms of B6-DTA and control mice under different illuminance regimes to analyze the extent, if any, of homeostatic compensation. Additionally, we performed immunohistochemical assays to confirm B6 deletion and electrophysiological experiments to investigate the B6 to M1 ipRGC synapse.

Results: First, we expand upon previous structural evidence to show that type 6 bipolar (B6) cells functionally provide extrinsic photoreceptor-derived input to M1 ipRGCs. We find preserved PLR magnitude, sensitivity, and kinetics in B6-DTA mice. Using a novel stimulus paradigm to isolate the extrinsic component of the PLR, we found only subtle changes in pupil responses for B6-DTA mice. Furthermore, B6-DTA mice were able to successfully photoentrain their circadian rhythms across a broad range of light levels.

Conclusions: We demonstrate that homeostatic plasticity preserves NIF vision via compensatory rewiring of non-canonical synaptic input to M1 ipRGCs. The mechanisms by which this plasticity is accomplished could reveal fresh insights into both the biology of retinal illuminance-detection circuits as well as novel strategies to preserve visual behaviors after injury.

TITLE: A Comparative Analysis of Alternative Calcium Chelators for the Treatment of Calcific Band Keratopathy

SESSION TITLE: Refractive and non-refractive corneal surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Z. Guo, R.K. Henry, M. Dastjerdi, Institute of Ophthalmology and Visual Science, Rutgers New Jersey Medical School, Newark, New Jersey, UNITED STATES|R.K. Henry, Rutgers Robert Wood Johnson Medical School New Brunswick, New Brunswick, New Jersey, UNITED STATES|

ABSTRACT BODY:

Purpose: K_3EDTA and K_2EDTA are readily available alternatives to Na_2EDTA, the traditional calcium chelator used to treat calcific band keratopathy. In this study we compare clinically relevant biochemical properties of each chelator in terms of pH, osmolarity, and calcium chelation potential.

Methods: 0.2 M Solutions of K_2EDTA (BD) and K_3EDTA (BD, obtained from vacutainer tubes) and Na_2EDTA (0.2M, Sigma Aldrich) were made. The pH of each solution was first measured (Mettler Toledo pH meter) and the theoretical osmolarity calculated with the assumption of full disassociation of EDTA salts. Next, we calculated the calcium chelation potential of each EDTA salt by titrating with 10 µmol of calcium hydroxyapatite or 10 µmol $CaCl_2$ containing Patton-Reeder colorimetric indicator (endpoint indicated by color shift from pink to blue). All titrations were repeated three times to obtain an average and standard deviation. Statistical significance was analyzed using Analysis of Variance (ANOVA) calculations.

Results: The 0.2 M solutions of Na_2EDTA, K_2EDTA, and K_3EDTA have pH values of 4.43, 5.71 and 9.191 and theoretical osmolarities of 600, 600, and 800 mOsm/L, respectively. Calcium chelation ability was similar among all 3 solutions: 0.94-0.98 mol of EDTA was needed to fully chelate 1 mol calcium ions of $CaCl_2$ (P=0.296), 0.100-0.108 mol of EDTA was needed to fully chelate 1 mol calcium ions of the hydroxyapatite aqueous suspension (P=0.296), and 0.992-0.996 mol was needed to chelate 1 mol calcium ions of hydroxyapatite in acidic solution (P=0.178, Table). Compared to the clinical standard 3% Na_2EDTA, approximately 3.3% K_2EDTA and 3.6% K_3EDTA is needed to chelate an equivalent amount of calcium.

Conclusions: Herein we provide clinically relevant biochemical properties of two alternatives to disodium EDTA and demonstrate comparable calcium chelation ability among all 3 solutions. In situations where sterile sources of Na_2EDTA is unavailable, salts of potassium EDTA may provide a convenient and equally effective method of treatment for band keratopathy.

ABSTRACT BODY:

Purpose: Investigate the relationship between quantitative biomarkers obtained with optical coherence tomography (OCT) and a deep learning analysis and disease recurrence and management.

Methods: A single-medical center retrospective analysis was designed. This study obtained scans of swept-source OCT at a medical center. Thirty-three eyes of 17 patients (7 females, 10 males) with Vogt-Koyanagi-Harada disease (VKH) or sympathetic ophthalmitis (SO) were imaged consecutively between October 2012 and January 2021. Choroidal vessel structure was segmented and visualized in 3D, after which quantitative vessel volume maps are generated. Region-based choroidal vessel volume (CV), choroidal stroma volume (SV), and vessel index (VI) were analyzed for disease severity.

Results: OCT-based CV volume maps disclose regional CV changes in patients with VKH or SO. Two metrics in recurrence VKH, (i) choroidal volume at 1-, 3- and 6-month (p=0.01, 0.04 and 0.03), (ii) CV volume at one months (p=0.03), were higher than well treated VKH.

Conclusions: The deep-learning analysis of OCT images described here provides a 3D visualization of how the choroid may reflect disease severity in VKH patients. Moreover, CV or SV before treatment may become the biomarker for recurrence of VKH.

ABSTRACT BODY:

Purpose: Docosahexaenoic acid (DHA) is essential for photoreceptor function and health, therefore retinal DHA depletion is associated with many retinal degenerative diseases such as age-related macular degeneration. However, the multiple cis-double bonds in natural DHA (H-DHA) in the metabolically active retina are highly prone to free radical peroxidation that generates deleterious lipid metabolites that contribute to age-related retinal pathologies. We hypothesize bis-allylic deuterated docosahexaenoic acid DHA (D-DHA) will be more resistant to lipid peroxidation, inhibit light-induced radical lipid peroxidation, and attenuate light-induced retinal degeneration. We therefore determined the protective effect of D-DHA against light-induced oxidative stress in the retina.

Methods: Sprague-Dawley rats were raised on regular lab chow under 25-lux light conditions until 8 weeks of age. The rats were then switched to experimental diets of H-DHA or D-DHA until retinal DHA levels were ~50% or 75%. To determine the protective effect of D-DHA against light stress, we exposed the rats to cool white fluorescent bright light stress (2700-lux for 6 h) and returned them to their normal housing conditions for 1 week after which we determined retinal function by electroretinography (ERG). We examined preservation of retinal structure by H&E staining and further performed immunostaining on retinal sections using 4-Hydroxynonenal (4-HHE) and Carboxyethylpyrrole (CEP) formed from H-DHA under oxidative stress.

Results: We showed that D-DHA replaced H-DHA in the retina in time dependent manner and had no effect on retinal function under no light stress conditions. After light stress, we observed preservation of retinal function as determined by ERG a-wave and b-wave amplitudes in D-DHA fed rats compared to H-DHA fed rats. Histological analyses revealed significant loss of photoreceptor outer nuclear layer in light exposed H-DHA fed rats compared to D-DHA fed rats 1 week after light stress. Our immunohistological data showed high levels of 4-HHE and CEP in H-DHA under oxidative stress compared to D-DHA fed rats.

Conclusions: Deuterium-reinforced DHA preserved retinal structure and function against light-induced retinal degeneration most likely by inhibiting lipid peroxidation. Taken together, our results suggest the dietary D-DHA may be beneficial in attenuating oxidative stress-induced retinal pathologies.

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) is the major vascular complication of diabetes and is the main cause of blindless worldwide. The development of DR is associated with chronic inflammation of diabetic patients. Neutrophils are inflammatory cells able to release structures formed by extracellular DNA decorated with proteolytic enzymes and proteins with posttranslational modifications such as citrullinated histone 3 (H3Citr) named neutrophil extracellular traps (NETs). The aim of this study is to determine the association between the serum levels of H3Citr and the DR in different clinical stages.

Methods: This is a cross-sectional study. Diabetic (DMT2) patients with and without different stages of RD were included as well as control subjects. Once the informed consent was signed, clinical, ophthalmological, and metabolic evaluations were performed, and a peripheral blood sample was obtained. Activation of Peripheral blood neutrophils (PBN) was achieved by means of flow cytometry, while H3Citr serum levels were evaluated by ELISA. H3Citr and metabolic status correlations were also performed. Finally, PBN-H3Citr was measured by means of western blot and compared among groups.

Results: CD66b is an activation marker for neutrophils. PBN-CD66b+ cells were significantly higher ($p \leq 0.05$) only in the Proliferative DR (PDR) group when compared between the other groups. We observed an increased concentration of H3Citr levels in DMT2 without DR [DMT2-non-DR], respect to the other groups. Regarding the association of H3Citr with the clinical and metabolic conditions, we found a significative positive correlation ($p \leq 0.05$) between serum concentration of H3Citr levels with their clinical and metabolic values such as Body Mass Index (BMI), glycosylated hemoglobin (HgA1b), fasting glucose, cholesterol, Low-Density Lipoproteins (LDL) and triglycerides (TG). Finally, H3Citr expression from PBN obtained from PRD and activated with ionomycin was significantly higher when compared with the other groups.

Conclusions: Taking together these results, suggest that PBN from PRD patients are more prone to be activated and this might reinforce the inflammatory hypothesis of the RD. Interestingly, serum H3Citr is able to predict a systemic inflammatory state among DMT2. This post translationally modified protein is of interest to study DMT2 and its main microvascular complication, the DR.

TITLE: Role of Fibroblast Growth Factor Receptor 2 (FGFR2) in Corneal Stromal Thinning.

SESSION TITLE: Corneal stromal biology, wound healing modulators and regeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Joseph, A.K. Boateng, O.P. Srivastava, School of Optometry and Vision Science, University of Alabama at Birmingham, Birmingham, Alabama, UNITED STATES|

Commercial Relationships Disclosure: Roy Joseph: Commercial Relationship: Code N (No Commercial Relationship) | Akosua Boateng: Commercial Relationship: Code N (No Commercial Relationship) | Om Srivastava: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The Fibroblast Growth Factor Receptor 2 (FGFR2) is a membrane-spanning tyrosine kinase that mediates signaling of fibroblast growth factors (FGFs). It regulates embryogenesis, angiogenesis, tissue homeostasis and wound repair. It also plays an important role in cell functions such as proliferation, differentiation, apoptosis and migration. Our earlier results showed that FGFR2 was significantly down-regulated in keratocytes of human keratoconus corneal stroma. To determine the functional and mechanistic roles of FGFR2-mediated signaling in keratocytes during corneal development, a stromal specific FGFR2 knockout (KO) mouse was developed.

Methods: FGFR2 KO mouse model was generated by the following methodology: FGFR2 flox mice (Jackson Labs) were crossed with inducible keratocyte specific-Cre mice (Kera-rtTA/tet-O-Cre, Dr. Winston Kao, University of Cincinnati). The pregnant females were fed doxycycline chow (600 mg/kg) to induce corneal stromal-specific FGFR2 KO pups. The flox-, Cre-, and wild-type (wt) mice were used as controls. Corneal thickness were determined using an ultra-high resolution spectral domain optical coherence tomography instrument (SDOCT, Bioptigen). Both males and female mouse were analyzed by OCT at different ages. The topography and pachymetry maps were obtained using an OCT based method. Tunel assay and immunohistochemical analysis were performed to determine the apoptotic cells and collagen 1 expression in KO corneas relative to controls, respectively.

Results: Gene-expression analysis showed that among the two isoforms of FGFR2 (FGFR2-iiib [epithelial-specific] and FGFR2-iiic [mesenchymal specific]), FGFR2-iiic was expressed in the normal corneal stroma. OCT-based analysis of the FGFR2 KO mice (n=20) corneas showed localized stromal thinning compared to control mice (n=20). Some of the mice even developed anterior synechia (iris attached to the anterior cornea), which has been reported in human keratoconus. Immunohistochemical analysis showed relatively lower expression in collagen1 and more apoptotic cells in the FGFR2 KO corneal stroma compared to control mice stroma.

Conclusions: The FGFR2 KO mice showed localized stromal thinning similar to that seen in human keratoconus cornea. This suggested that the stromal-specific conditional FGFR2 KO mouse model would elucidate functional and mechanistic roles of FGFR2 in stromal keratocytes and also serve as a keratoconus animal model

TITLE: Full-thickness eyelid laceration repair: human cadaver versus cadaveric pig head as a model for teaching ophthalmology residents

SESSION TITLE: Vision care training and education

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Carlisle, S. Patel, C. Weller, Ophthalmology, Penn State Health Milton S Hershey Medical Center, Hershey, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Grant Carlisle: Commercial Relationship: Code N (No Commercial Relationship) | Saager Patel: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Weller: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The purpose of this study was to investigate the efficacy of human cadaver and cadaveric pig head as a model to educate ophthalmology residents with the understanding and ability to perform full-thickness eyelid laceration repair at a single institution.

Methods: Ophthalmology residents at Penn State Health Milton S. Hershey Medical Center were anonymously surveyed using a Likert questionnaire inquiring about their comfort and ability to perform a full-thickness eyelid laceration repair. Answers included options 1 (“Incomplete understanding”) - 5 (“Mastery”). The survey was administered pre-intervention (n=9), post-human cadaveric model (n=9), and post-pig cadaveric model (n=8). Prior to working with the model, residents were given a 20-minute tutorial introducing clinical approach to laceration repair as well as a detailed explanation on how to approach the procedure. Wet-labs with either model included one 2-hour session. Survey results were compared using two-tailed Student’s t-test.

Results: Pre-curriculum survey results for full-thickness eyelid laceration repair included the following: “Mean Score Knowledge” PGY2(2.0), PGY3(2.0), PGY4(3.0) and “Mean Score Performance” PGY-2(1.7), PGY-3(2.0), PGY-4(3.3). Thirty-three percent of residents were comfortable with being the primary surgeon during repair. Post-survey results after using a human cadaver model: “Mean Score Knowledge” PGY2(2.7), PGY3(4.3), PGY4(3.3) and “Mean Score Performance” PGY-2(2.0), PGY-3(4.3), PGY-4(3.7). Seventy-eight percent of residents were comfortable being the primary surgeon for repair after training on the human cadaver model. Cadaveric pig head model post-survey results are pending. All training years reported in improvement in knowledge and ability to perform eyelid-laceration repairs after training with a human cadaver.

Conclusions: Human cadavers significantly improved ophthalmology resident’s knowledge and ability to perform full-thickness eyelid laceration. Cadaveric pig heads may be a useful and more affordable model for educating ophthalmology residents with the understanding and ability to perform eyelid-margin involving laceration repair.

TITLE: Evaluation of effect of modified housing on fogging of reusable wide angle panoramic contact lens during vitreoretinal surgery
SESSION TITLE: Vitreoretinal surgery/VR Interface/PVR
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: K. Chalam, S. Gupta, Ophthalmology, Loma Linda University, Loma Linda, California, UNITED STATES|
Commercial Relationships Disclosure: K V Chalam: Commercial Relationship: Code N (No Commercial Relationship) | Shailesh Gupta: Commercial Relationship: Code N (No Commercial Relationship)
ABSTRACT BODY:
Purpose: To evaluate the effectiveness of modified housing on fogging of reusable wide angle contact lens during vitreoretinal surgery
Methods: Wide angle contact lens provides panoramic view of retina and enables successful vitreoretinal surgery in complex retinal detachments through improved visualization of vitreoretinal periphery upto and beyond ora serrata. However frequent steam sterilization erodes the glue that holds lens elements, allows fogging due to migration of steam in between lens elements and result in poor visualization of the fundus.

In this study, we altered the housing and evaluated its effectiveness. Modified housing has two modes; open mode during sterilization and closed mode after completion of sterilization (Figs 1&2).

The lens system has two lens groups. The first group has a concave posterior surface [Radius of curvature (ROC) = 7.8 mm], for placement on the patient's cornea. This group acts to direct light rays originating from the posterior chamber towards the second lens group II for focusing. The group I lens system collimates the light rays. Group II is located in a spaced–apart relationship with respect to first lens group I. This allows an air space between them. The group II focuses the light rays and provides panoramic visualization of retina.

Housing that holds the two lens systems has a rotational window that is open during steam sterilization and closed during surgery
Results: The lens system provided real and inverted panoramic image of the fundus. The lens system is configured to minimize chromatic aberration and provide improved image as compared to the other lens systems. It provides 160 degrees of fundus view during static viewing and 170 degrees during dynamic view with excellent depth of focus.

Modified housing has facilitated fog free visualization of retina during surgery while allowing effective steam sterilization compliant with standard operating room regulations.
Conclusions: This modified wide angle contact lens provides a real inverted panoramic fog free view of the retina and allow repeated usage without deterioration of image and prolonged the life of wide angle contact lens system. It has added significance in covid era, as stringent sterilization is essential for prevention of disease

ABSTRACT BODY:

Purpose: Previously we identified that the miR-183/96/182 cluster (miR-183C) regulates corneal resident immune cells (CRICs) and nerves. This study is to uncover its roles in shaping the cellular landscape of the cornea, with a focus on CRICs.

Methods: Corneas anterior to the limbus of naïve, adult, female miR-183C knockout mice (ko) and their wild-type littermates (wt) were dissociated into single cells. Dead cells were removed using a Dead Cell Removal kit and Magnetic Activated Cell Sorting (MACS). To enrich CRIC, CD45+ cells were enriched by MACS. scRNA libraries of total corneal cells or enriched CRICs were prepared using the Next GEM Single Cell 3' Reagent kits v3.1 (10xGENOMICS) before sequencing on an Illumina NovaSeq, followed by alignment and tabulation with Cell Ranger. Analysis were performed in R using Seurat and SingleR packages.

Results: We obtained sc transcriptomes of 8,163 and 7316 total corneal cells of 2-3 months old (mo), and 8,783 and 6,211 corneal cells of 6-8 mo wt and ko mice, respectively; 1,981 (wt) and 2915 (ko) MACS-enriched CRICs of 6-8 mo mice.

In total corneal cells, 11 populations (clusters) were identified, including 4 stromal-keratocyte and/or endothelial, 6 epithelial clusters and 1 CRIC cluster. Mononuclear phagocyte system (MPS), including monocytes, macrophages (Mf) and dendritic cells, were increased in ko vs wt mice, consistent with our previous observation by immunostaining and flow cytometry. Multiple populations changed their representations at both ages and/or at the younger vs the older ages in ko vs wt mice.

In CRICs, 13 clusters were uncovered, 6 of which were CRICs for further analysis. Preliminary data suggest that the number of resident MPS cells and the expression of both classical M1 and M2 signature genes in resident Mf are simultaneously increased of ko vs wt mice. Small subpopulations of CRICs, positive to microglial or T-cell or IL-17 or proliferative cell markers, were also increased in the ko mice.

Further analyses on differentially expressed genes and functional annotation in various cell types between the ko vs wt mice are ongoing to uncover cell type-specific targets and molecular pathways regulated by miR-183C.

Conclusions: scRNA seq provides unprecedented molecular insights into the roles of miR-183C regulating the cellular composition and properties of the cornea.

ABSTRACT BODY:

Purpose: A new silicone hydrogel (SiHy) material, lehfilcon A (TOTAL30®) with surface modification of a 2-methacryloyloxyethyl phosphorylcholine (MPC) polymer, was recently developed. This study was designed to evaluate the in vitro surface biological interactions as well as their impact on tear film stability on the surface of lehfilcon A and other reusable SiHy materials.

Methods: The surface structures of lehfilcon A, comfilcon A, senofilcon A, senofilcon C, and samfilcon A contact lenses were imaged using Atomic Force Microscopy (AFM). After fouling in an artificial tear lipid solution, the distributions of fluorescently labeled non-polar lipids on the entire lenses as well as the cross-sections of these SiHy materials were visualized and quantified in three-dimensional (3D) via confocal laser scanning microscopy (CLSM). The in vitro tear film stability on the fouled lens surface was further assessed using a modified multifunctional topographer method.

Results: Lehfilcon A contact lenses exhibited distinctive surface features and topographies resulting from its densely packed MPC polymer units, which was not seen on other reusable SiHy materials. Fluorescent intensity measurements of 3D CLSM images (Figure 1) showed that lipid deposition on the lens surface was significantly less for lehfilcon A compared to the other reusable SiHy materials ($p<0.05$ for all). Furthermore, lehfilcon A demonstrated a significantly longer surface moisture break up time than other tested contact lenses in the in vitro topography videos (19 s vs. <5 s, $p<0.05$ for all).

Conclusions: The hydrophilic nature of the MPC polymer layer provided an antifouling surface feature for lehfilcon A contact lenses, which delivered greater in vitro tear film stability than other reusable SiHy contact lenses. These exceptional characteristics may help achieve outstanding on-eye performance for this new SiHy contact lens.

ABSTRACT BODY:

Purpose: To identify longitudinal SD-OCT biomarkers associated with successful treatment discontinuation and visual outcomes in eyes with central or branch retinal vein occlusion (RVO) and macular edema.

Methods: We retrospectively reviewed 66 eyes with treatment-naïve RVO and ME with 24-month follow-up, and assessed SD-OCT biomarkers including central subfield thickness (CST), intraretinal cyst size, number of intraretinal hyperreflective foci (HF), disorganization of retinal inner layers (DRIL), and outer retinal layer disruptions of the external limiting membrane (ELM), ellipsoid zone (EZ), or interdigitation zone (IZ) at presentation, 3 months, or 6 months after treatment initiation. We employed multivariate regression analyses to identify biomarkers associated with (1) successful treatment discontinuation for at least 6 months without fluid recurrence and (2) visual acuity (VA) at 24-months.

Results: Among 43 eyes with CRVO/HRVO and 23 with BRVO, 47% and 49% of eyes successfully stopped therapy over the 2 years, respectively, with a median time to discontinuation of 5 months (95% CI 2-8) for the CRVO/HRVO group and 5 months (95% CI 3-8) for the BRVO group. SD-OCT biomarkers including CST, cyst size, DRIL, and ELM/EZ/EZ disruptions all improved at 3 months, and remained stable at 6 months. On multivariate regression, lower CST at 6 months ($P = 0.03$) was associated with successful treatment discontinuation, while better BCVA at 6 months ($P = 0.04$) and %DRIL improvement at 3 months ($P = 0.02$) predicted better visual outcomes at 24 months.

Conclusions: Early anatomic response at 6 months is associated with successful treatment discontinuation of RVO with macular edema within 2 years, while early visual gains and DRIL improvements are linked to long-term visual outcomes.

TITLE: Crib-Related Ocular Injuries in Children Ages 0 to 23 Months
SESSION TITLE: Anterior Segment and Trauma Epidemiology
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: S. Uppuluri, A. Uppuluri, M.A. Zarbin, N. Bhagat, Department of Ophthalmology & Visual Science, Rutgers New Jersey Medical School, Newark, New Jersey, UNITED STATES|
Commercial Relationships Disclosure: Siri Uppuluri: Commercial Relationship: Code N (No Commercial Relationship) | Aditya Uppuluri: Commercial Relationship: Code N (No Commercial Relationship) | Marco Zarbin: Commercial Relationship: Code N (No Commercial Relationship) | Neelakshi Bhagat: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The objective of this retrospective, cross-sectional study was to describe the demographics and types of crib-related ocular injuries in children under 2 years of age that occurred between 2000 and 2019, as documented by the National Electronic Injury Surveillance System (NEISS) database.

Methods: The NEISS database was used to identify cases of crib-related ocular injuries in children between the ages of 0 and 23 months from 2000 to 2019. The NEISS reports information on emergency department (ED) visits involving a consumer product from a nationally representative sample of U.S. hospitals. Statistical analysis was performed using IBM SPSS 23.

Results: In total, 551 weighted cases of crib-related ocular injuries were identified. By sex, age, and race, the majority of cases occurred in boys (73.2%), and the plurality of cases occurred at 9 months of age (21.9%) and in Whites (30.8%). There was no significant difference in age by sex ($p = 0.227$). The vast majority of cases were treated and released, rather than admitted (99.1% vs 0.9%), and occurred at home (71.7%). Documented ocular injury types included corneal abrasion (58.4%), foreign body (1.8%), contusion (5.9%), unspecified eye injury (15.1%), subconjunctival hemorrhage (16.1%), and open globe injury (3.6%). When types of ocular injury were stratified by sex, significant differences in prevalence of contusion and subconjunctival hemorrhage were identified, with contusion occurring more commonly in girls (0% vs. 21.9%; $p < 0.001$), and subconjunctival hemorrhage occurring more commonly in boys (22.0% vs 0%; $p < 0.001$). Furthermore, when ocular injury types were stratified by age, with cases divided into either 0-11 months or 12-23 months, contusion (4.8% vs. 7.4%; $p = 0.022$) and corneal abrasion (58.0% vs. 59.0%; $p < 0.001$) were more prevalent in the older age group, while subconjunctival hemorrhage (27.4% vs. 0%; $p < 0.001$) and open globe injury (6.2% vs. 0%; $p < 0.001$) were more common in the younger age group.

Conclusions: In children under 2 years of age, between 2000 to 2019 over 500 cases of crib-related ocular injuries presented to emergency departments in the United States. The majority of injuries occurred in boys, those less than 12 months of age, and at home. The most common ocular injury was corneal abrasion, and the rate of severe ocular injury, open globe injury, was low at 3.6%. The vast majority of cases were triaged in the ED and discharged home.

TITLE: Sensitivity of tele-ophthalmic diagnosis of diabetic retinopathy when performed by resident physicians

SESSION TITLE: Telehealth

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Agi, R.K. Henry, M. Shah, B. Szirth, N. Bhagat, Ophthalmology, Rutgers The State University of New Jersey, Newark, New Jersey, UNITED STATES|

Commercial Relationships Disclosure: Nathan Agi: Commercial Relationship: Code N (No Commercial Relationship) | Roger Henry: Commercial Relationship: Code N (No Commercial Relationship) | Megh Shah: Commercial Relationship: Code N (No Commercial Relationship) | Bernard Szirth: Commercial Relationship: Code N (No Commercial Relationship) | Neelakshi Bhagat: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: During the Covid-19 era, understanding the benefits and limitations of tele-ophthalmology has become increasingly important. In this study, we aim to assess the accuracy of tele-ophthalmic diagnosis of diabetic retinopathy (DR) and diabetic macular edema (DME) when performed by resident physicians.

Methods: Retrospective study on 16 patients (32 eyes; 28 DR and 4 controls) who presented to a retina clinic at an academic medical center. Automated OCT-B images with 3D topographic maps and fundus photographs of the posterior pole using a Topcon Maestro 3D OCT-1 unit were taken. Images were transmitted remotely to a resident physician who assessed the severity of the DR and DME on the basis of the fundus photographs and OCT. The same images were transmitted to a retina specialist for grading. Primary outcomes included DR and DME grade as defined by the International Clinical Diabetic Retinopathy classification scale. We then tested the concordance between diagnoses rendered via tele-OCT by the resident compared to the retina attending's remote diagnosis and the gold standard retina specialist's clinical examination using Cohen's Kappa statistic (κ).

Results: Agreement between ophthalmology residents and attendings on tele-OCT diagnosis of DR was substantial (78% concordance on presence and 75% on severity), while agreement on identifying and grading edema was moderate (60% concordance on DME presence and 52% concordance on overall DME severity). Detection of DR by residents via tele-retinal imaging is highly sensitive (100% sensitivity), while detection of DME is highly specific (79-95% specificity). Discordance between residents and attendings on DME grading may owe to differences in opinion regarding what constitutes mild edema versus no edema; however, both concordance and predictive accuracy increase when identifying patients with moderate to severe DME.

Conclusions: This study provides proof of principle for the sensitivity and specificity for remote diagnosis of DR via tele-OCT fundus and OCT-B images. This technology may be useful in identifying patients at risk of severe vision loss and enable early detection of patients who need referral for prompt treatment. These findings may be particularly relevant to training programs looking to implement tele-retinal diabetic screening or using tele-OCT where prompt access to a retina specialist may not be possible.

ABSTRACT BODY:

Purpose: The eye is a uniquely accessible organ with very sophisticated imaging systems for evaluation of it's anatomy and vasculature in particular. The tight junction protein claudin-5 which is richly expressed at the inner blood retinal barrier (iBRB) is also expressed at the level of the blood brain barrier(BBB). Developing software which could use ocular vasculature as an indicator of BBB integrity has applications in a number of neurodegenerative disorders and neurological insults. We sought to evaluate the integrity of the in neurological disorders (CSF1R mutation and Visual Snow) using FOVAS (Fluorescent Ocular Vascular Analysis Software), a novel quantitative analysis software tool for FFA studies.

Methods: 3 subjects were recruited, 1 with adult onset leukoencephalopathy with axonal spheroids (ALSP) – (an autosomal dominant CSF1R mutation) and 2 with visual snow syndrome. Fundus fluorescein Angiography (FFA), Optical Coherence Tomography (OCT) and fundal autofluorescence were performed using the Heidelberg SPECTRALIS. Sodium fluorescein (1 mg/mL) was administered and images obtained at 1 minute, 2 minutes, 4 minutes and 5 minutes post injection. FFA and OCT images were obtained with a 30 degree angle of view and 73 line cuts were acquired. Heidleberg Eye Explorer (HEYEX) was used to capture images. FFA analysis and quantification was conducted using FOVAS against a threshold determined from the fluorescein signal of n = 33 normal healthy controls (aged 18 -30).

Results: In the subject with a CSF1R mutation, FFA images showed a significantly increased fluorescein signal in the peri- and para-foveal regions of the macula. In both subjects with visual snow, FFA images showed a significantly increased fluorescein signal in the foveal, peri, para and extra foveal regions suggesting an increased iBRB permeability in this disorder. FOVAS analysis suggests a potential pathology involving tight junctional proteins of the endothelium.

Conclusions: We report increased permeability of the iBRB in a single case of an individual with a condition in involving a dominant acting mutation in the gene CSF1R and in a small case series of patients with Visual Snow syndrome following FOVAS analysis. We conclude that with the development of FOVAS and a robust dataset demonstrating 'normal' inner retinal vascular integrity, we can potentially expedite the study of blood tissue barrier disruption in neurodegenerative diseases.

Song: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The optimal protocols for using optical coherence tomography angiography (OCTA) for glaucoma patient care is under investigation. We conducted a prospective observational imaging study of glaucoma patients and suspects to determine the OCTA's intrasession repeatability for 4.5x4.5mm and 6x6 image scans.

.

Methods: For 46 consecutive patients, two peripapillary 4.5mm and 6mm OCTA scans were obtained on the same day. Images with a signal strength >6, and minimal decentration were analyzed. Inclusion was further determined by 2 graders using a custom quality scale (1-7) for each characteristic: motion artifact, floaters, fadedness, missing data. Vessel Area Density (VAD) and Flux of the annulus around the optic nerve head were obtained using Zeiss quantification software (Cirrus 11.0, Zeiss). Images were evaluated for intrasession repeatability of OCTA metrics using intraclass correlation coefficient (ICC).

Results: From the initial 46 patients, 30 were eligible for inclusion. Their mean age was 47.4±14.6 years with 12 males and 18 females. A total of 180 images from 45 eyes were analyzed.

The mean signal strength of 4.5mm images was 9.7 ± 0.6 and the mean total quality score was 26.4 ± 1.6 (n=180) based on the 2 graders' scores. (Table 1) The ICC for VAD of the annulus was 0.94 (95% CI 0.90-0.97) and 0.95 (95% CI 0.91-0.97) for Flux for the 4.5 mm scans (Table 2). When comparing the ICC for glaucoma patients to glaucoma suspects, for VAD it was 0.94 (95% CI 0.83-0.98) vs 0.89 (95% CI 0.79-0.95), respectively. The ICC for Flux for glaucoma patients and suspects were 0.95 (95% CI 0.85-0.98) vs 0.88 (95% CI 0.77-0.94), respectively.

The mean signal strength of 6mm images was 9.4 ± 0.8 and the mean total quality score was 26.2 ± 1.8 (n=180) based on the 2 graders' scores. The ICC for VAD was 0.94 (95% CI 0.90-0.97) and the ICC for Flux was 0.96 (95% CI 0.93-0.98). For 6mm scans, when comparing glaucoma patients to suspects, the ICC for VAD was 0.96 (95% CI 0.87-0.99) vs 0.89 (95% CI 0.79-0.95), and the ICC for Flux was 0.98 (95% CI 0.93-0.99) vs 0.90 (95% CI 0.80-0.95), respectively.

Conclusions: OCTA 4.5mm and 6mm scans for the same patient taken on the same date demonstrated high repeatability based on ICC for VAD and for Flux. 4.5mm and 6mm images have high repeatability for both glaucoma patients and suspects.

TITLE: Disease in a Dish Model of Human Glaucomatous Retinal Ganglion Cell Degeneration

SESSION TITLE: Retinal ganglion cells

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: I. Ahmad, M. Subramani, Ophthalmology and Visual Sciences, University of Nebraska Medical Center, Omaha, Nebraska, UNITED STATES|

Commercial Relationships Disclosure: Iqbal Ahmad: Commercial Relationship: Code N (No Commercial Relationship) | Murali Subramani: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Glaucoma is a group of multifactorial diseases with a unifying pathology retinal ganglion cells (RGCs) degeneration, leading to irreversible blindness. To test the hypothesis that human RGCs are intrinsically vulnerable in glaucoma we have developed an in vitro disease model using the primary open angle glaucoma (POAG) patient-specific induced pluripotent stem cells (iPSCs) for generating functional RGCs. We have previously demonstrated that RGCs derived from a POAG patient-specific iPSCs with the risk allele of a developmentally relevant gene, SIX6 display developmental and functional abnormalities. Here we have examined the developmental susceptibility of RGCs derived from a POAG patient-specific iPSCs containing mutation in a non-developmental gene, MYOC.

Methods: The model was created using the iPSC technology. Briefly, peripheral blood mononuclear cells (PBMCs) were harvested from patients' and age matched controls' blood samples. PBMCs were reprogrammed using the transduction of Sendai virus, expressing Yamanaka factors (Oct4, Klf4, Sox2, and c-Myc). Multiple MYOC and control iPS clones were generated for the characterization of pluripotency. RGCs were generated by a chemical induction protocol, using small molecules, that recapitulates the mechanism of normal RGC genesis.

Results: A modification of neural induction protocol to generate retinal progenitor cells (RPCs) led to the generation of Rx^+ and Pax^+ cells from both MYOC patient-specific and control iPSCs, however there was a significant decrease in the number of Rx^+ and $Pax6^+$ RPCs in the former versus latter. The neural rosettes (NRs) containing the Rx^+ and $Pax6^+$ RPCs appeared less compact in MYOC patient-specific versus control groups. Examination of select gene expression in RGCs derived from patient-specific RPCs suggested developmental abnormalities. For example, the levels of transcripts of RGC regulators (Atoh7, Brn3b, Isl1), markers (SCNG, Thy1), axon growth and guidance regulators (GAP43, DCC, EPHB3) were significantly decreased in MYOC patient-specific RGCs, compared to controls. The complexity of neurites and length of axons ($SM132^+$ and $Tau1^+$) were also observed decreased in MYOC patient-specific RGCs versus controls.

Conclusions: Our preliminary results suggest that the mutation in MYOC gene may make human RGCs susceptible to developmental abnormalities.

TITLE: Ophthalmologic findings in children with embryonal tumor with multilayered rosettes (ETMR)

SESSION TITLE: Oculoplastics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Guo, M.S. Borchert, M. Chang, University of Southern California Keck School of Medicine, Los Angeles, California, UNITED STATES|M.S. Borchert, M. Chang, Ophthalmology, Children's Hospital Los Angeles Medical Group, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Sarah Guo: Commercial Relationship: Code N (No Commercial Relationship) | Mark Borchert: Commercial Relationship: Code N (No Commercial Relationship) | Melinda Chang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Embryonal tumor with multilayered rosettes (ETMR) is a rare, newly classified WHO grade IV, highly malignant variant of the primitive neuroectodermal tumor. Ophthalmologic findings associated with this tumor have not been previously described.

Methods: We performed a retrospective, observational review of children diagnosed and treated with ETMR at our tertiary care children’s hospital over the past six years. A total of five patients were identified. Three children had suspected ocular abnormalities and were referred for ophthalmologic evaluation. We reviewed the charts of these three patients and describe the ophthalmologic findings.

Results: Patient 1 was a 2-year-old girl with a tumor located in the right pons extending along the cerebral peduncle who presented with ataxia and esotropia. She was found to have a right abducens palsy and amblyopia of the right eye, and amblyopia treatment was initiated. Patient 2 was a 2-year-old girl with a primary tumor in the right midbrain and pons with extensive leptomeningeal dissemination who presented with right facial weakness, imbalance, intermittent emesis, and nystagmus. She was found to have gaze-evoked right beating and upbeat nystagmus, leading to a preference for left gaze and downgaze. Her therapists were advised not to inhibit the face turn that she adopted to minimize oscillopsia. Patient 3 was diagnosed at 2 weeks old with a posterior fossa tumor involving the roof of the 4th ventricle, superior medullary velum, and surrounding vermis after prenatal testing revealed hydrocephalus. She developed abducens palsy after tumor resection and ventriculoperitoneal shunt placement. Outpatient ophthalmology evaluation was recommended, but the patient did not follow up. The abducens palsy remained persistent at 3 year follow up with oncology despite disease remission.

Conclusions: This case series suggests that ophthalmologic findings are common in children with ETMR and may require treatment and/or inform systemic therapies. It is important for clinicians to assess vision and ocular motility and consider ophthalmology referral in children with ETMR.

ABSTRACT BODY:

Purpose: Tumor biopsy can identify prognostic biomarkers for metastatic uveal melanoma (UM). Aqueous humor (AH) biopsy is less invasive and repeatable, and thus facilitates longitudinal monitoring of disease. We investigated if the AH of UM eyes had sufficient tumor-derived cell free DNA (cfDNA) to perform genetic analysis of the tumor.

Methods: A case series of 37 AH samples from 12 choroidal and 8 ciliary body (CB) tumor patients were studied. From 12 choroidal tumor patients, there were 9 paired pre- and post-radiation, 2 post-radiation only and 1 at enucleation AH samples. One CB tumor biopsy wash sample was collected. AH was analyzed for nucleic acids (Qubit Assay Kits). Whole-genome sequencing was done on DNA samples isolated from the AH samples and cells from tumor wash via 150bp paired-end Illumina sequencing to detect somatic copy number alterations (SCNAs). Hybridization-based capturing and targeted sequencing were subsequently done using a custom gene panel that covers all exonic regions of the BAP1 and GNAQ genes.

Results: Comparing paired pre- and post-radiation AH samples revealed significantly higher nucleic acid concentrations post-radiation. Most significant increases within choroidal and CB groups respectively were seen in miRNA (n=9 pairs, P=0.016 and n=8 pairs, P=0.008). Among post-radiation AH samples, there was a significantly higher concentration of dsDNA (P=0.033), ssDNA (P=0.033) and RNA (P=0.018) in CB compared to choroidal. Highly recurrent UM SCNAs were identified in 0/11 post- choroidal and 5/8 (62.5%) post- CB samples. Of those 5 SCNA-containing post- AH samples that underwent targeted resequencing, BAP1 or GNAQ somatic mutations were detected in 3/5 (60%). The DNA profile of the only available tumor sample was highly concordant with its corresponding post-AH sample (r=0.978).

Conclusions: AH is a source of cfDNA in UM eyes, with a higher yield of nucleic acids post-radiation. This is the first-time that UM SCNAs and mutations were identified in cfDNA isolated from the AH. This suggests that AH can serve as a liquid biopsy for UM.

TITLE: A zebrafish model system for studying the ANGPT/TIE2 pathway and glaucoma

SESSION TITLE: Glaucoma Genetics

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S. Rong, A. Larson, J.L. Wiggs, Ophthalmology, Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Shi Song Rong: Commercial Relationship: Code N (No Commercial Relationship) | Anna Larson: Commercial Relationship: Code N (No Commercial Relationship) | Janey Wiggs: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Rodent-based studies have shown that ANGPT1 is indispensable for the development and maintenance of the ocular lymphatic network, which is essential for normal aqueous humor drainage. In humans, ANGPT1 loss-of-function mutations cause primary congenital glaucoma with variable expressivity. In this work, we characterized an angpt1 knock-out zebrafish model allowing for high throughput characterization of potential disease-causing variants as well as investigation of novel gene-based therapeutics targeting the ANGPT/TIE2 signaling pathway.

Methods: Using ABTL zebrafish embryos, angpt1 was disrupted by injection of a splice-site morpholino before 4 cell stage. Microangiography, ocular histology, and visual motor responses (VMR) were compared between morphants and controls at day 5 post-fertilization (5dpf). Phenotype recovery using wild type and mutant human mRNA was also evaluated in the morphants. An adult fish knock-out line was created using CRISPR/Cas9, generating an 11 bp deletion in exon 5 of angpt1. The phenotypic features of the crispant embryos with different genotypes (WT/WT, WT/del, and del/del) were compared.

Results: Morpholino-induced skipping of exon 3 and the exon 5 11bp deletion in crispants was confirmed by next-generation sequencing. Phenotypic characterization of morphants showed abnormal ocular and trunk vasculature compared with controls at 5dpf ($P<0.05$). Additionally, the ventral limbal structures, which anatomically correspond to the aqueous humor outflow pathway in adult zebrafish, the ventral canalicular network, were abnormal in morphants ($P<0.05$). The VMR test showed reduced sensitivity to light in morphants compared to controls ($P_{t\text{-}test}<0.001$). Compared with wild type crispant embryos, homozygous 11bp deletion carriers (crispants) also showed malformation of the vasculature ($P<0.05$), ventral limbal structures ($P=0.019$), and VMR reduction ($P=0.005$). Furthermore, human mRNAs containing c.A62G (p.N21S) and c.C239T (p.S80F), two rare ANGPT1 variants found in human glaucoma cases, failed to rescue the VMR phenotype compared with wild type mRNA ($P<0.05$), suggesting deleterious variant effects.

Conclusions: Loss of angpt1 in zebrafish embryos recapitulates several essential ocular and functional phenotypes from existing animal models. Further work offers opportunities for high throughput evaluation of human ANGPT1 variants as well as exploring novel gene-based therapeutic approaches.

ABSTRACT BODY:

Purpose: To characterize stimulus-driven intrinsic optical signal imaging (R-IOI) in the rat retina, as compared with other, previously studied species (cat, monkey, human, mouse, etc). It is further hypothesized that imaged signals from an albino strain of rat would be larger than those found in a pigmented strain.

Methods: Intrinsic optical signals of anesthetized (K/X) adult rat retina were recorded and imaged in vivo with a cooled CCD camera attached to a custom optical rig with a front-end endoscope/otoscope -- a setup previously used for R-IOI of mice (Begum et al, 2020). Retinal images under near-infrared (700-900nm) illumination were collected at 2Hz for 10-20secs while a brief (300msec) visible (505nm) LED stimulus was delivered to the retina.

Results: Stimulus-driven intrinsic signals were observed in the rat retina, similar to those previously describe in other species (cat, monkey, human, mouse). In comparison to R-IOI of (pigmented) adult C57BL/6J wild-type mouse retina performed under the same stimulated and recording conditions using the same equipment, imaged signals from pigmented Long-Evans adult rats were preliminarily similar in time course, but larger in amplitude (0.24% vs 0.060%). However R-IOI under the same conditions recorded in albino Sprague-Dawley adult rats revealed signals greater in amplitude (0.58% +- 0.16% vs 0.24% +- 0.067%). One major difference is that the retinal return, the amount of NIR illumination reflected back into the camera was also substantially greater in the albino vs pigmented rat -- typically 6-7 times greater.

While the larger retinal return likely contributed to the observed greater signal amplitude in the albino rat, another hypothesis is that a greater contribution of the choriocapillaris is observed in the albino rat. This may be expected due to our previous work demonstrating a dominant hemodynamic component of the R-IOI signal that is driven by rod activity. For comparison, the cat has exhibited the largest signal (1-2%) while the macaque monkey is at 0.25%.

Conclusions: These findings confirm the expectation that R-IOI reveals imaged signals similar to those observed in other species.

Furthermore, the greater signal amplitudes observed in the albino rat coincide with previous evidence of a significant component of the observed R-IOI signal originating from outer retinal sources (rod photoreceptors).

Commercial Relationships Disclosure: Emmanuel Issa Nassrallah: Commercial Relationship: Code N (No Commercial Relationship) | Georges Nassrallah: Commercial Relationship: Code N (No Commercial Relationship) | Christina Mastromonaco: Commercial Relationship: Code N (No Commercial Relationship) | Ana Dias: Commercial Relationship: Code N (No Commercial Relationship) | Jose Mansure: Commercial Relationship: Code N (No Commercial Relationship) | Nabil Saheb: Commercial Relationship: Code N (No Commercial Relationship) | Miguel Burnier: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Anterior capsular contraction syndrome (ACCS) is characterized by excessive contraction and fibrosis of the anterior lens capsule after phacoemulsification and intraocular lens (IOL) implantation, leading to phimosis of the anterior capsulotomy. Epithelial-to-mesenchymal transition (EMT) of lens epithelial cells and extracellular matrix remodelling (ECMR) are associated with ACCS. Zonular instability (ZI) is correlated with ACCS but it is unclear if zonulopathy (ZP) is caused by lens epithelial changes or if it is an independent risk factor. The aim of this cross-sectional study is to assess the associations of EMT, ECMR, and ZP with progressively smaller capsulorhexis diameter (CD) in post-mortem eyes.

Methods: A total of 104 post-mortem pseudophakic human eyes from the MUHC-McGill University Ocular Pathology & Translational Research Laboratory were examined. Images of the eyes in Miyake-Apple view and region of interest analysis were done using ImageJ to measure capsule area (CA), ciliary ring area (CRA), and CD. Zonular stability was measured using CA over CRA ratio (CCR) and capsule-ciliary ring decentration (CCD). Capsular bags with IOLs were extracted, and EMT and ECMR were quantified via automated immunohistochemistry with anti-SMA (smooth muscle actin) and anti-FN (fibronectin), respectively. Slides were digitized and analyzed via the Positive Pixel Count v9 algorithm. Correlation was assessed via simple linear regression, one-way ANOVA, and two-sample t-test.

Results: There was a statistically significant positive correlation between CCR and CD ($p=0.0106$, $N=104$) but not between CCD and CD ($p=0.44842$, $N=104$). No significant correlation between CD and FN ($p=0.14213$, $N=75$) or SMA ($p=0.41087$, $N=75$) was found. However, when comparing samples with the largest CD with samples of CD <2 standard deviations from the mean, FN staining was reduced in samples with a smaller CD ($p=0.01171$). There was no correlation between CCR or CCD with FN or SMA staining. Cataract-to-death time did not correlate with CCR ($p=0.73958$), CCD ($p=0.14405$), or FN ($p=0.11619$), but did have a positive correlation with SMA ($p<0.0001$).

Conclusions: ZI, as indicated by a low CCR, had the strongest correlation with small CD in post-mortem pseudophakic eyes. Moreover, the degree of ZI does not seem to correlate with EMT or ECMR, suggesting that it may be an independent risk factor for smaller CD and, perhaps, the development of ACCS.

ABSTRACT BODY:

Purpose: NPHP5 gene augmentation successfully rescues photoreceptor structure, function, and vision for up to 6 months when delivered at early-stage disease in the canine NPHP5 model of LCA, a severe form of inherited childhood blindness (Aguirre et al. Mol Ther 2021). We now report on the long-term (up to 5.4 years) follow-up of 20 mutant dogs treated unilaterally at more advanced stages of disease including: early/mid (n=3), mid (n=4), late (n=9) and very late (n=4) stages.

Methods: Dogs were subretinally-injected (0.1-0.15 mL) with a scAAV2/5 or scAAV2/8$_{(C\&G+T494V)}$ vector construct (4.74×10^{12} vg/mL) carrying full-length canine or human NPHP5 cDNA under control of a GRK1 promoter. Throughout the course of the study, photoreceptor structure and function were assessed by SD-OCT and ERG. Rod- and cone-mediated visual behavior was evaluated in an obstacle avoidance course under scotopic and photopic illumination.

Results: While progressive ONL thinning was seen by OCT over time, ONL rescue was still detectable in the treated retinal area at the latest post injection (PI) time-point (up to ~ 5 years in early/mid, and mid stage groups; and up to ~ 3 years in the late-stage group). No ONL preservation was seen in untreated areas of injected eyes, nor in BSS or uninjected contralateral eyes beyond the visual streak. ERG showed restoration of both rod- and cone-mediated function in all AAV-NPHP5 injected eyes, with the exception of dogs from the very late-stage group in which only cone-mediated ERG was restored. Vision testing performed in a subset (n=13) of dogs showed persistent recovery in the early/mid- (3 out of 3), mid- (2 out of 2), late- (4 out of 4), and very late- (1 out of 2) stage groups. Vision restoration was independently documented in the single dog from the very late-stage group that refused to enter the obstacle course by using a modification of the protocol.

Conclusions: These results show long-term (3 - 5.4 years) restoration of photoreceptor function and preservation of structure as well as visually-guided behavior following subretinal NPHP5 gene augmentation therapy delivered at patient-relevant advanced stages of disease. A treatment effect was detectable by ERG as early as 4-8 weeks PI. In addition, these results show that cones are receptive to very late-stage intervention even when most rod photoreceptors are lost.

ABSTRACT BODY:

Purpose: Non-human primates offer a significant advantage in the study of the pathogenesis and therapeutics for corneal disease because of their ocular similarity to humans. This study aims to define the range of normal central corneal thickness (CCT) and corneal endothelial cell density (ECD) in rhesus macaques (Macaca mulatta) and to determine the effect of age, body weight, and sex on these parameters.

Methods: Ophthalmic examination was performed in 144 rhesus macaques without corneal or anterior chamber lesions. The range of age of the primates examined was 0.2-29.4 years (mean 13.7 ± 7.1 years); 98 were females and 46 were male. The ECD was semi-automatically counted and manually counted using in vivo specular microscopy while CCT was measured via ultrasound pachymetry (USP). Linear regression model and mixed effects linear regression were used to evaluate the main effects of age, body weight, sex, intraocular pressure (IOP) and axial length of the globe (AXL) and refractive error on CCT and ECD. A concordance correlation coefficient (CCC) was calculated to estimate the reliability of semiautomatic versus manual counts. Linear regression with mixed effects linear regression were used to evaluate the main effects of an individual's body weight, age and sex on corneal thickness and corneal endothelial cell density.

Results: Mean ECD was 2717 ± 423 cells/mm^2, similar to the reported range for humans in early adulthood at approximately 2500 cells/mm^2. Mean CCT was 483 ± 39 µm, which was similar to that documented for humans at 534.8 ± 34.7 µm. IOP and sex were statistically significantly associated with CCT, while body weight, age, and AXL were associated with ECD ($p < 0.05$). There was good reliability between semiautomatic and manual ECD counts (CCC=0.79). There was no significant correlation between CCT and ECD (p=0.89).

Conclusions: The rhesus macaque has similar corneal characteristics when compared to humans and can thus serve as an ideal model to study corneal endothelial cell disorders and corneal diseases. This study suggests a normal range of ECD from 2294-3140 cells/mm^2 and 444-522 µm for CCT in rhesus macaques (Macaca mulatta).

TITLE: Impact of Neurofibromatosis type 1 (NF1) heterozygosity on RGC death after optic nerve injury

SESSION TITLE: Retinal ganglion cells

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: X. Xia, C. Sun, Z. Luo, K. Russano, J.L. Goldberg, Spencer Center for Vision Research, Byers Eye Institute, Stanford University, California, UNITED STATES|S. Shyamsundar, Geisinger Commonwealth School of Medicine, Scranton, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Xin Xia: Commercial Relationship: Code N (No Commercial Relationship) | Catalina Sun: Commercial Relationship: Code N (No Commercial Relationship) | Ziming Luo: Commercial Relationship: Code N (No Commercial Relationship) | Saishravan Shyamsundar: Commercial Relationship: Code N (No Commercial Relationship) | Kristina Russano: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Goldberg: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Neurofibromatosis type 1 (NF1) due to loss of heterozygosity at the neurofibromin/NF1 locus is associated with optic glioma, degeneration of retinal ganglion cells (RGCs), and vision loss. Understanding the impact of heterozygosity at the NF1 locus remains a major goal when considering neuroprotective or restorative therapies. Previous studies using optic nerve crush injury revealed increased RGC death in NF1-heterozygote mice, illustrating a neurofibromin-dependent intracellular signaling pathway responsible for neuronal survival. But there are several types of neurons and glial cells in the retina and optic nerve. Here we asked whether RGC-specific Nf1 heterozygosity increases RGC death after optic nerve injury.

Methods: Nf1 flox/wt mice aged 4-6 weeks under isoflurane anesthesia were injected intravitreally with AAV2-cre to carry out RGC-specific Nf1 one allele deletion, or AAV2-GFP control viral vectors. Two weeks later, mice underwent optic nerve crush conducted by cross-action forceps 2mm posterior to the globe under direct visualization. Two weeks after optic nerve crush, eyes were harvested and post-fixed with 4% PFA for 1h at room temperature. Retinas were isolated, permeabilized with 2% Triton-X-100 in PBS and stained with an RGC-specific anti-RBPMS antibody, followed by mounting on slides and imaging by confocal laser scanning microscopy. Eight images of each retina were imaged and quantified to measure RGC density. Results are presented as cells/mm^2 for each retina. All experiments were masked.

Results: The survival of RGCs in AAV2-cre-injected eyes was significantly less than that in AAV2-GFP-injected eyes after optic nerve crush (Fig 1.).

Conclusions: RGC-specific Nf1 one allele deletion may exacerbate RGC death after optic nerve injury. Our next step is going to see if astrocyte specific Nf1 heterozygosity using AAV5-GFAP-cre will worsen RGC death after optic nerve injury.

TITLE: Reprogramming adult Müller glia in a light-damage model of photoreceptor degeneration.

SESSION TITLE: Retinal and central processing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Pavlou, T. Reh, Biological Structure, University of Washington, Seattle, Washington, UNITED STATES|

Commercial Relationships Disclosure: Marina Pavlou: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Reh: Commercial Relationship(s);Code P (Patent):PCT/US2020/030407

ABSTRACT BODY:

Purpose: Patients with degenerative retinal dystrophies suffer from various degrees of blindness as a result of acute or gradual photoreceptor cell death. While gene supplementation therapies attempt to treat affected individuals with monogenic disorders at an early disease stage, there is a clinical demand for universal treatment that can halt or even reverse the effects of degeneration at later stages. We have shown that NMDA-induced ablation of retinal ganglion cells and amacrine cells, together with Ascl1 overexpression in murine Müller glia (MG) induces the MG to generate neurons. This work investigates the potential for glia-to-neuron reprogramming in retinas that suffered photoreceptor ablation, which better mimics the pathology of patients with late-stage retinal degeneration.

Methods: To induce photoreceptor degeneration, adult mice homozygous or heterozygous for the Rpe65 Leu450 were subjected to light-damage by exposing them to ~20,000 lux of white light for 6 hours. To test glia-to-neuron conversion, transgenic mice were used with inducible MG-specific expression of the proneural transcription factor Ascl1 (Glast-CreER/LNL-tTA/TetO-Ascl1-GFP) or Ascl1 in combination with other transcription factors. One week after light-damage, when most photoreceptors in the central retina were ablated, the transgenic mice were injected with tamoxifen to induce the expression of neurogenic factors in MG followed by intravitreal injection of Trichostatin-A (TSA) alone or with γ-secretase inhibitor DAPT. Four weeks later, the number and types of glial-derived neurons was assessed.

Results: Light-damaged retinas showed uniform recombination, confirming that GLAST-controlled gene expression in MG was effective during and after photoreceptor cell death After 4 weeks of Ascl1 expression in MG, approximately 30% of the recombined MG expressed the bipolar/photoreceptor marker Otx2+, similar to the effects previously reported with NMDA-induced retinal injury. The proportions of GFP+Chx10+ (~40%), GFP+Otx2+ (~30%) and GFP+Sox2+ (~65%) populations were similar between eyes that received TSA or TSA+DAPT, suggesting that Notch pathway inhibition with DAPT in this context did not improve the reprogramming outcome.

Conclusions: This work sets the stage for understanding how reprogramming paradigms could translate in models of photoreceptor degeneration, with the aim of regenerating the retina at late disease stages.

TITLE: Clinical Characteristics and Treatment Outcomes for Patients with Exudative Age-Related Macular Degeneration with Visual Acuity of 20/40 or Better

SESSION TITLE: AMD: Clinical and translational research/AMD therapies (excluding anti-VEGF)

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Nawash, J. Ong, J. Chhablani, Department of Ophthalmology, University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Baraa Nawash: Commercial Relationship: Code N (No Commercial Relationship) | Joshua Ong: Commercial Relationship: Code N (No Commercial Relationship) | Jay Chhablani: Commercial Relationship(s);Code C (Consultant/Contractor):Novartis;Code C (Consultant/Contractor):Abbvie;Code C (Consultant/Contractor):Salutaris

ABSTRACT BODY:

Purpose: Exudative Age-Related Macular Degeneration (eAMD) is the leading cause of vision loss in the western world. Most of the clinical studies in eAMD include eyes with 20/40 or worse visual acuity (VA). However, a small subset of patients may also present with good VA. Literature lacks knowledge about the clinical characteristics, treatment protocols, and long-term outcomes in this subset. The aim of this study was to describe clinical characteristics and treatment outcomes of anti-VEGF monotherapy in this subset of wet AMD patients with good VA (20/40 or better).

Methods: This was a retrospective chart review study that included patients who had a diagnosis of naive exudative AMD with good VA presenting between 2011 and 2021. Patient charts were from a single hospital system. Eyes with a history of anti-VEGF injections; less than one-year follow-up; history of vitrectomy, and/or any associated ocular disease were excluded. Clinical data were collected for both the eye of interest and the fellow eye including ocular and systemic history, BCVA, imaging findings, and anti-VEGF therapy details.

Results: Fifty-one eyes of 49 patients were included in this study per inclusion criteria. Average age at presentation was 75 ± 8.23 years with 33 (64%) female eyes and 18 (36%) male eyes. All eyes were treated as needed after loading-dose. Average LogMAR at baseline was 0.176 ± 0.11 (Snellen's equivalent 20/30) with a VA at 1 year follow-up of 0.185 ± 0.19 (Snellen's equivalent 20/31) ($p = 0.78$). 3 (6%) patients lost more than 3 Snellen lines after one year. Of the 51 eyes analyzed, 11 fellow eyes concurrently had a confirmed diagnosis of wet AMD with an average LogMAR of 0.181 ± 0.27 (Snellen's equivalent 20/30). An average of 6.14 ± 2.72 injections were administered per patient during the first year of diagnosis with an average maximum treatment-free interval of 3.77 ± 3.03 months

Conclusions: Eyes with good visual acuity with active wet AMD maintained good visual acuity throughout the first year of anti-VEGF monotherapy with a treatment-free interval of approximately 4 months. Further analyses are underway to assess changes in VA and other parameters for area under the curve (AUC) analysis.

ABSTRACT BODY:

Purpose: Artificial intelligence (AI) has the potential to augment the clinical utility of ophthalmic imaging. Input data used in training these AI algorithms are often required to meet strict inclusion criteria to maximize accuracy on high quality images. However, in clinical settings, an AI trained on pristine images without ocular co-morbidities may have limited utility. This study aims to evaluate the accuracy of an artificial intelligence algorithm applied to color fundus photos (CFPs) with simulated cataracts in detecting diabetic retinopathy (DR).

Methods: A database of 3662 CFPs (from the Asia Pacific Tele-Ophthalmology Society (APTOS) 2019 data) was used, with 80% of images used for training and 20% for testing. Using transfer learning, a convolutional neural network (Inception-ResNet-v2) was trained to classify the training images as either DR or non-DR. The CNN was then applied to classify the testing images four times, once each with mild simulated cataract, moderate simulated cataract, severe simulated cataract, and no simulated cataract. Cataracts were simulated by applying varying degrees of gaussian blur corresponding with distorting an image to appear as it would to an eye that is 20/40 (mild), 20/100 (moderate) and 20/200 (severe). Accuracy was compared by confusion matrix, including sensitivity (Sn) and specificity (Sp), and receiver operator curves (ROC).

Results: The CNN was able to classify the dataset without any simulated cataract with an accuracy of 97.0%, Sn 95.7%, Sp 98.3%. On the mild cataract dataset, the CNN had an accuracy of 93.1%, Sn 91.8%, Sp 94.3%. For moderate cataract, accuracy was 62.8%, Sn 31.4%, Sp 95.2%. For severe cataract, accuracy was 53.5%, Sn 11.8%, Sp 96.5%.

Conclusions: Artificial intelligence algorithms are often trained on pristine datasets, where variability is controlled to allow for optimum performance. However, real world data often has significant noise. This study shows that the accuracy of an AI algorithm trained to detect DR is significantly diminished when a simulated cataract is superimposed on the image. To prepare AI for clinical use, cataract and other real-world clinical challenges causing poor image quality must be accounted for.

TITLE: Area of Schlemm's canal in healthy and glaucoma eyes imaged using swept-source optical coherence tomography

SESSION TITLE: Aqueous humor dynamics and Trabecular Meshwork

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Z. Nafar, T. Callan, Carl Zeiss Meditec, Inc., Dublin, California, UNITED STATES|

Commercial Relationships Disclosure: Zahra Nafar: Commercial Relationship(s);Code E (Employment):Carl Zeiss Meditec, Inc. | Thomas Callan: Commercial Relationship(s);Code E (Employment):Carl Zeiss Meditec, Inc.

ABSTRACT BODY:

Purpose: Optical coherence tomography (OCT) of the anterior segment (AS) can provide visualization of small features such as the trabecular meshwork and Schlemm's canal (SC) and become an important tool for diagnosis and treatment of glaucomatous patients. In this study, we evaluate the capability of an AS add-on lens module in visualizing Schlemm's canal and its diagnostic potential by evaluating the cross-sectional area in healthy and glaucomatous eyes.

Methods: A swept-source OCT instrument, PLEX® Elite 9000 (ZEISS, Dublin, CA) with prototype software, was equipped with an AS add-on module. The limbal area was scanned with a High-Definition (HD) Cross scan. An external fixation target was used to perpendicularly scan the limbal region.

HD Cross = 6 mm cross pattern, 5 B-scans with 0.125 mm separation, 1024 A-scans/B-scan and 1536 pixels in depth (3 mm depth) at 100 kHz, with 5 repetitions averaged.

Both eyes of 2 healthy and 2 glaucomatous patients (8 eyes) with ages ranging from 32-67 years old were scanned. Acquisition was done by an expert operator to confirm the presence and consistency of the SC and its location in the scanned area. The area of the SC was then visually evaluated by an expert.

Results: Schlemm's canal was successfully observed in all 8 cases, although it is generally easier to visualize SC in healthy and younger subjects. Consistently the cross-sectional area appears to be smaller in older and glaucomatous eyes (figure 1). However, more data is needed for a clinically significant comparison of cross-sectional area.

Conclusions: PLEX Elite 9000 with AS add-on module provides good quality visualization of Schlemm's canal in both healthy and glaucoma patients. Thus, it has the potential to be used as a diagnostic tool for glaucoma.

TITLE: Outcomes in recurrent rhegmatogenous retinal detachment repair: does initial surgery impact results?

SESSION TITLE: Vitreoretinal surgery/VR Interface/PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Hébert, J. Garneau, E. You, S. Bourgault, M. Caissie, É. Tourville, A. Dirani, Ophthalmology, Hopital du Saint-Sacrement, Quebec, Quebec, CANADA|

Commercial Relationships Disclosure: Mélanie Hébert: Commercial Relationship: Code N (No Commercial Relationship) | Jerome Garneau: Commercial Relationship: Code N (No Commercial Relationship) | Eunice You: Commercial Relationship: Code N (No Commercial Relationship) | Serge Bourgault: Commercial Relationship: Code N (No Commercial Relationship) | Mathieu Caissie: Commercial Relationship: Code N (No Commercial Relationship) | Éric Tourville: Commercial Relationship: Code N (No Commercial Relationship) | Ali Dirani: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: More studies now guide the management of primary rhegmatogenous retinal detachment (RRD), but less is known on managing recurrent RRD (re-RRD). We analyzed outcomes in re-RRD repair using pars plana vitrectomy (PPV) only or PPV with scleral buckle (PPVSB) in a retrospective cohort study.

Methods: Patients operated for re-RRD at the Centre hospitalier universitaire de Québec – Université Laval between 2014 and 2018 were included. Exclusion criteria included: non-RRD etiologies of initial detachment (e.g., traumatic, tractional), initial RRD with proliferative vitreoretinopathy (PVR) grade ≥C2, and patients with silicone oil during first surgery. Procedure choice at first and second surgery was at the surgeon's discretion. Patients were categorized based on surgery sequence of first and second surgery: PPV then PPV (PPV-PPV), PPV then PPVSB (PPV-PPVSB), or PPVSB then PPV (PPVSB-PPV). Primary outcome was recurrent surgery success rate (re-SSR) and secondary outcome was final pinhole visual acuity (PHVA) in logarithm of the minimum angle of resolution (logMAR).

Results: There were 139 patients included. Twelve (9%) underwent PPV-PPV, 51 (37%) underwent PPV-PPVSB, and 76 (55%) underwent PPVSB-PPV. Median [Q1, Q3] age at initial presentation was 64 [59, 72] years. There were 85 (61%) men, 63 (45%) pseudophakic patients, and 24/114 (21%) high myopic patients. Baseline PHVA in logMAR was 0.88 [0.18, 2.30].

Surgery sequence did not significantly alter re-SSR (PPV-PPV: 9, 75% vs. PPV-PPVSB: 38, 75% vs. PPVSB-PPV: 57, 75%; p=1.00). It also did not change the use of silicone oil at second surgery (PPV-PPV: 5, 42% vs. PPV-PPVSB: 18, 35% vs. PPVSB-PPV: 36, 47%; p=0.40). At final follow-up, PHVA was 0.60 [0.18, 1.00] and did not significantly differ by sequence (p=0.16). In multiple regression analyses, main factors influencing re-SSR were pseudophakia (odds ratio (OR) 3.356, p=0.012) and initial macula-off status (OR 0.368, p=0.048), while surgery sequence did not alter re-SSR (p>0.05).

Conclusions: Following re-RRD repair, there were no significant differences in re-SSR and final PHVA based on sequence of surgery. Pseudophakia increased re-SSR, and macula-off status decreased re-SSR. This is likely because pseudophakia allows a closer shave of the vitreous base to reduce the incidence of postoperative PVR and recurrent tears, while macula-off status suggests a more extensive initial detachment.

ABSTRACT BODY:

Purpose: There is variability in the amount and direction of cyclotorsion induced when a person moves from sitting to supine position. For laser vision correction, alignment is measured in the sitting position and surgery is performed in the supine position. In this retrospective study, we examine the amount and direction of cyclotorsion in sitting versus supine position in patients undergoing laser vision correction.

Methods: A retrospective chart review was done at Northwestern Medicine Department of Ophthalmology, Chicago, Illinois, USA of 893 eyes in 515 consecutive patients who underwent LASIK/PRK with successful iris registration. Amount and direction of cyclotorsion between sitting position versus supine position were analyzed. The amount and direction of cyclotorsion of each eye were quantified, and in patients undergoing bilateral procedures, concordance of cyclotorsion between right and left eye was assessed.

Results: 881 (98.6%) of the 893 eyes were found to have cyclotorsion with a mean of 2.88 degrees. 605 (67.8%) excyclotorted and 276 (30.9%) incyclotorted ($p < 0.001$). For a breakdown of degrees of cyclotorsion, see Figure 1. Average cyclotorsion in the right eye was 3.12 degrees and 2.52 in the left ($p < 0.001$). 361 patients underwent bilateral surgeries. 185 (51.2%) had concordant cyclotorsion (eyes rotate in same direction), while 166 (45.9%) had discordant cyclotorsion (eyes rotate in opposite directions).18 patients underwent subsequent retreatment with 14 (77.8%) demonstrating cyclotorsion in the same direction on both surgery days and 4 (22.2%) with cyclotorsion in different directions ($p= 0.001$).

Conclusions: Average cyclotorsion was less than 3 degrees, and when torsion was present about two-thirds of the eyes had excylotorsion. Amount and direction of cyclotorsion in one eye did not always correlate with the same amount and direction of cyclotorsion in the contralateral eye. Understanding that there is variability in cyclotorsion is important in surgeries such as wavefront guided LASIK/PRK where identification of and correction for cyclotorsion can impact visual results.

ABSTRACT BODY:

Purpose: Our research focuses on the development of a robust software-based algorithm to overcome the motion artifacts from the patient's involuntary eye movements on OCT and OCTA retinal images. Acquiring multiple volumes from the same retinal location followed by precise registration and averaging reduces the effects of motion artifacts and improves the contrast, resulting in better visualization of distinctive features and facilitation of retinal diseases diagnosis in clinics.

Methods: In our 3D registration method, prior to the registration, the motion artifacts are detected and eliminated. Following the motion artifact removal, a B-scan-based registration is applied to align the spatial coordinates of all the volumes to the coordinates of a reference volume with minimum motion artifacts. B-scan-based registration is followed by an en face affine registration to correct the rotation angle difference between each volume and the reference volume.

Results: The accuracy and robustness of our proposed method are evaluated on datasets with 3 different field-of-views (FOVs) acquired from 4 custom-built OCT systems. Figure 1 illustrates a small FOV OCT dataset (>100 volumes) obtained using a 1060 nm swept-source OCT system. The final averaged result is a motion-free volume with an increased signal-to-noise ratio (79.43% improvement), allowing for better visualization of retinal capillary, photoreceptor mosaic, and RPE layers. Figure 2 shows a middle FOV OCTA dataset (> 20 volumes) acquired using an 800 nm spectral-domain OCT system. The final OCTA volume data shows a more distinct vasculature network without noticeable motion artifacts in superficial and deep capillary plexus.

Conclusions: We have developed a novel 3D volume registration algorithm that can be utilized for various OCT/OCTA volumes with different spatial resolutions and FOVs. This registration algorithm can be utilized across different OCT platforms to overcome the motion artifacts.

ABSTRACT BODY:

Purpose: Correction of single base mutations in messenger RNA is a potential therapeutic approach for inherited retinal disease. A Cas13 enzyme fused to an adenosine deaminase acting on RNA deaminase domain ($ADAR_{DD}$) can be directed by a guide RNA (gRNA) for the targeted correction of G>A mutations. Here, we compare Cas13 RNA editing tools and the length and design of gRNAs for the correction of premature termination codons (TAG > TGG) in an USH2A gene fragment in a luciferase assay. As USH2A, like many photoreceptor genes, is poorly expressed in common cell lines, the luciferase assay was designed for facile in vitro screening.

Methods: A dual luciferase reporter assay expressing the target mutations was used in HEK293T cells in a 96-well format. Cells were triple transfected with constructs expressing the reporter assay, Cas13-$ADAR_{DD}$ effectors and gRNAs. dPspCas13b, dPspCas13b-Δ984-1090, and the minimal dCas13-bt1, -bt3 and -bt5 orthologues were tested, $ADAR_{DD}$ with E488Q and E488Q/T375G mutations were compared, and 30nt and 50nt gRNAs with a range of distances between a A-C mismatch at the target adenosine and the gRNA scaffold were screened for activity. On-target RNA editing rates were analysed by restoration of firefly luciferase activity and trace decomposition of Sanger sequencing reads of cDNA.

Results: Using dPspCas13b, a screen of 50nt gRNAs with mismatch distances of 18-42nt between the A-C mismatch and the gRNA scaffold demonstrated editing rates of 2-49%. No loss of activity of the best performing guides was seen with the truncated dPspCas13b-Δ984-1090. The minimal dCas13bt orthologues demonstrated lower editing rates of 1-22% with 50nt guides. dPspCas13b constructs with the specific $ADAR_{DD}$(E488Q/T375G) mutation demonstrated a 60% loss of on-target activity relative to constructs with the $ADAR_{DD}$(E488Q) mutation, but off-target editing was undetectable. For both dCas13bt and dPspCas13, 30nt guides were significantly less efficient. Sanger sequencing of corrected transcripts found significantly higher on-target correction than detected by luciferase restoration.

Conclusions: RNA editing with Cas13 efficiently corrects G>A mutations in USH2A gene fragments in vitro. The described luciferase assay allowed efficient comparison of a range of constructs and gRNAs for editing optimisation.

ABSTRACT BODY:

Purpose: Fluorescence lifetime ophthalmoscopy (FLIO) can distinguish lifetime variations across the normal and diseased fundus, yet the role of individual fluorophores is unclear. Adaptive optics (AO) FLIO enables cellular-scale resolution of unique cell types in distinct retinal layers. Here, we apply in vivo AOFLIO to compare the lifetimes of cellular-scale structures throughout the healthy macaque retina to those of specific retinal fluorophores.

Methods: In 2 male macaques, AOFLIO was performed using two-photon excited fluorescence (730 nm, ~55 fs, 80 MHz, 7 mW) in a scanning light ophthalmoscope (19 1.1x1.3° regions, 5-18° ecc.). The nerve fiber (NF), ganglion cell (GC), and photoreceptor (PR) layers were imaged. At each pixel, phasor analysis, where the cos and sin Fourier transform of the decay trace is computed at the laser pulse rate, yielded a Cartesian coordinate (g,s). Clusters from in vivo data were compared to a phasor fingerprint of common retinal fluorophores NADH, FAD, elastin, all-trans-retinol (ROL), and all-trans-retinal (RAL) in solution measured in the same system.

Results: In the phasor fingerprint, each fluorophore had a unique position. Phasor plots of in vivo data suggested contributions from several fluorophores. The artery wall phasor showed a dominance of elastin not seen in veins (Fig 1). Phasors of NF and GC, dominated by metabolites, oriented along the free/bound NADH axis. Consistent with previous work, the PR phasors separated into rods, M/L cones, and S cones. Rods and M/L cones laid on a ROL/RAL axis (Fig 2); M/L cones had a 48±12% mean relative contribution from ROL, significantly higher than in rods (30±16%) possibly due to increased photopigment bleach (paired t-test, p=.02). After a 2 min 730 nm exposure, the S cone lifetime became longer, which may be indicative of oxidative stress. The optic disc edge clustered separately from PR closer to bound NADH, FAD, and elastin (Fig 2).

Conclusions: The axial and lateral resolution of AOFLIO allows identification of multiple origins of fluorescence in distinct retinal cells and layers. We demonstrated the first in vivo AOFLIO assessment in the inner retina and further characterized the outer retina. Comparing phasor signatures throughout the retina to those of known fluorophores establishes a basis for assessing subcellular molecular pathways that are expected to shift in disease.

ABSTRACT BODY:

Purpose: To investigate the mechanism for developing dry eye disease in the Pinkie mouse strain with a loss of function RXRα mutation.

Methods: Measures of dry eye disease were assessed in the cornea and conjunctiva. Expression profiling by single-cell RNA sequencing (scRNA-seq) was performed to compare gene expression in conjunctival immune cells. Conjunctival immune cells were immunophenotyped by flow cytometry and confocal microscopy. Activity of RXRα ligand 9-cis retinoic acid (RA) was evaluated in cultured monocytes and γδT cells.

Results: Compared to wild type (WT) C57BL/6, Pinkie has increased signs of dry eye disease, including corneal barrier disruption, conjunctival cornification and goblet cell loss, and corneal vascularization, opacification, and ulceration with aging. scRNA-seq of conjunctival immune cells identified γδT cells as the predominant IL-17 expressing population in both strains and there is a 4-fold increased percentage of γδT cells in Pinkie. Compared to WT, significantly increased expression of IL-17a and IL-17f in conventional T cells and IL-17f in γδT cells was found in Pinkie. Flow cytometry and immunostaining revealed an increased number of IL-17^{+} γδT cells in Pinkie. Tear concentration of the IL-17 inducer IL-23 is significantly higher in Pinkie. 9-cis RA treatment suppresses stimulated IL-17 production by γδT and stimulatory activity of monocyte supernatant on γδT cell IL-17 production. Compared to WT bone marrow chimeras, Pinkie chimeras have increased IL-17^{+} γδT cells in the conjunctiva after desiccating stress and anti-IL-17 treatment suppresses dry eye induced corneal MMP-9 production/activity and conjunctival goblet cell loss.

Conclusions: These findings indicate that RXRα suppresses generation of dry eye disease inducing γδT17 cells in the conjunctiva and identifies RXRα as a potential therapeutic target in dry eye.

ABSTRACT BODY:

Purpose: To determine whether an association between functional and structural tests of the tear film can be found and to describe if a significant difference between preoperative and postoperative parameters is present.

Methods: We studied 34 eyes of 17 patients undergoing LASIK surgery. OCT tear film (TF) analysis consisted of structural parameters such as tear meniscus height, depth, and area (RTVue-100 Fourier-domain OCT) and functional tests such as Schirmer, Non-Invasive Tear Breakup Time (NIBUT) (Keratograph 5M), and Ocular Surface Discomfort Index (OSDI). Measurements were performed before and 1 month after the procedure. Wilcoxon test was used to compare basal vs postoperative structural and functional TF parameters. Correlation analysis and linear regression were also implemented to model the association between these variables. A p-value of less than .05 was considered of statistical significance.

Results: No significant changes between basal and postoperative measurements were observed in the structural and functional TF variables. The analysis yielded a negative correlation (Rho= -0.349, p= 0.043) between basal tear meniscus height and basal NIBUT. A negative correlation between basal tear meniscus height and 1-month postoperative NIBUT (Rho= -0.409, p=.016) and 1-month postoperative Schirmer test (Rho= -0.360, p= .036) was observed. The linear regression model yielded no significant correlation. Change (delta) in basal vs 1-month postoperative NIBUT was associated with age and spherical equivalent (β=.547, p=.028, and β=-.522, p=.016).

Conclusions: Our analysis did not demonstrate a significant difference between basal vs 1-month measurements in neither structural or functional tests. However, results suggest that Dry Eye Disease can manifest with normal structural TF parameters while yielding altered results in the functional evaluation. More studies are needed in order to determine the presence of significant differences in basal vs longer-term measurements.

ABSTRACT BODY:

Purpose: Motivational Interviewing (MI) has improved medication adherence rates for patients with chronic illnesses. The Support, Educate, Empower (SEE) program, a 7-month MI-based personalized glaucoma coaching program, has previously shown to improve medication adherence by 21-percentage points in a sample of non-adherent glaucoma patients. The goal of this study was to assess adherence in the 12-months following the conclusion of the SEE program intervention.

Methods: Glaucoma patients ≥40 years, taking ≥1 medication, self-reporting poor medication adherence were recruited from the University of Michigan for the SEE pilot study. Participants' medication adherence rates were monitored electronically (AdhereTech, New York, NY) during a 3-month pre-intervention phase (pre-counselling adherence), 7-month intervention phase while they received personalized coaching sessions (counselling adherence), and for an additional 12-months following the conclusion of their coaching sessions (post-counselling adherence). Adherence was summarized with descriptive statistics and compared using paired t-tests.

Results: Medication adherence data were available for 39 participants. Post-counselling adherence rates were censored for 18 participants (56%); 3 participants received glaucoma laser or incisional surgery, 3 had changes made to their glaucoma medication regiment, and 12 stopped using their electronic medication monitors before the full 12-month follow-up period. Average follow-up was 284 days (standard deviation, SD=110, range=41 to 365). The average post-counselling adherence was 66.5% (SD=22.5%), significantly less than the average counselling adherence rate of 81.3% (SD=17.6%, $p<0.0001$) but significantly more than pre-counselling adherence rate of 59.9% (SD=18.5%, $p=0.04$). The decrease in adherence post-counseling was mostly observed in the first 4 months (mean decrease=17.4%, SD=19.5%, $p<0.0001$).

Conclusions: Medication adherence rates significantly decreased among SEE program participants in the 12 months following their last counselling session, although they were still significantly higher than pre-counselling adherence rates. These results suggest that glaucoma patients may need additional counselling sessions to see continued benefit from the program. We suggest that patients should be seen every 3-month for a "booster" counselling session.

ABSTRACT BODY:

Purpose: Retinal ischemia-reperfusion injury (I/R) is a general cause of vision loss, and no effective treatment is available for retinal I/R. Pemafibrate, a peroxisome proliferator-activated receptor α (PPARα) modulator, was suggested as a promising therapeutic in ischemic retinopathies. However, its roles have not been clearly unraveled in retinal I/R. In this study, we investigated therapeutic effects of pemafibrate against retinal dysfunction in an experimental model of retinal I/R by transient elevation of intraocular pressure (IOP).

Methods: Adult male mice (5–7 weeks old; C57BL/6) were orally given to pemafibrate (0.5 mg/kg) for 4 days, followed by retinal I/R (IOP: 90–99 mmHg; 40 minutes). Mice were continuously given to pemafibrate (0.5 mg/kg) once every day until the end of experiments, 5 days after retinal I/R. Retinal functional changes were measured using electroretinography (ERG). Then, the retina, liver, and serum samples were used for western blotting (WB), qPCR, immunohistochemistry (IHC, sagittal-sectioning, and flat-mounting), or ELISA analysis.

Results: Retinal dysfunction and retinal ganglion cell (RGC) loss stained by NeuN were prevented by pemafibrate administration (ERG, a-wave and b-wave: 1.7-fold and 1.5-fold increase, $p < 0.05$; IHC, RGC: 1.7-fold increase, $p < 0.001$). Pemafibrate administration increased hepatic PPARα target gene expressions (qPCR, $p < 0.05$) and serum levels of fibroblast growth factor 21 (FGF21; ELISA, 20.3-fold increase, $p < 0.01$), one of the neuroprotective molecules in the eye. Retinal inflammation stained by Isolectin GS-IB4 and pathological gliosis stained by GFAP were reduced by pemafibrate administration (IHC, GS-IB4: 0.26-fold decrease, $p < 0.01$; GFAP: 0.76-fold decrease, $p < 0.05$). Furthermore, pemafibrate administration altered expressions in hypoxia-response genes (qPCR, $p < 0.05$) via hypoxia-inducible factor-1α (HIF-1α; WB, 0.70-fold decrease, $p < 0.01$) pathway and pro-apoptotic and anti-apoptotic genes such as c-Jun, Nrf2, and Ho-1 (qPCR, $p < 0.05$) in the ischemic retina.

Conclusions: Our data suggest possibilities of therapeutic effects of pemafibrate on ischemic retinal degeneration via multiple protective pathways.

ABSTRACT BODY:

Purpose: To evaluate the therapeutic effect of near infrared (810 nm) photobiomodulation (PBM) on retinal neovascularization in a mouse model of oxygen-induced retinopathy (OIR).

Methods: Sixteen mouse pups (C57BL/6J) were placed in hyperoxia (75% oxygen) from P7 to P12. Following the switch to normoxia, the pups were treated with 810 nm whole body photobiomodulation (6 J/cm^2) daily for 6 min from P13 to P17. At P17, fluorescein angiography (FA), confocal scanning laser ophthalmoscopy (cSLO) and OCT imaging was performed. Post in-vivo imaging, retinal flatmounts were stained with isolectin GS-IB4-Alexa Fluor-568 and imaged with a Zeiss Axiophot fluorescent microscope. A machine learning based algorithm was used for calculating vascular tufts in isolectin stained flatmount images. The cSLO and volumetric OCT images were evaluated for retinal avascular area in the central 55^o retina. Statistical comparisons were made using non-parametric one tailed t-test with significance at $P < 0.05$, 95% CI.

Results: Photobiomodulation resulted in significantly decreased retinal neovascularization, as observed in flatmount images. FA images were analyzed and quantified for retinal avascular area using central 55^o retina with optic nerve head in center. The avascular area in PBM treated group was decreased compared with OIR non treated controls. The body weight of pups at P17, an indicator of overall health, was significantly increased in PBM treated group compared with control group.

Conclusions: The single wavelength PBM treatment of oxygen-induced retinopathy mouse shows decreased neovascularization and increased body weight. The results suggest PBM as a promising therapeutic for ROP.

ABSTRACT BODY:

Purpose: The cornea is crucial for visual acuity as it allow light refraction to the retina and constitutes the first ocular barrier. It ruptures frequently cause infection and in severe cases, lead to the complete loss of vision. In North America, corneal wounds accounts for 37% of visual deficiency. Normal homeostasis of the corneal epithelium is ensured by corneal epithelial stem cells. According to the severity of the trauma, stem cell integrity can be compromised and a corneal transplantation may be required. In order to reduce the need for donor corneas, understanding of corneal wound healing and development of an tissue-engineered human cornea (hTECs) is of prime importance. For transplantation purposes or to conduct research studies, the human corneal epithelial cells (hCECs) used in the hTECs production must be of the highest possible quality. The present study was intended to evaluate the impact of the post-mortem interval (PMI) on the properties of hCECs in vitro.

Methods: hCECs were isolated from the limbal area of donor corneas at different PMI (from 0 to 19 days) and grown as monolayers or on hTECs. The gene expression pattern was determined in ten populations. Growth rate measurements and colony-forming efficiency assays were conducted to evaluate the hCECs proliferative potential whereas the histological integrity of the hTECs was analysed by immunofluorescence. The stem cell population from cultured hCECs with different PMI was evaluated by p63 staining and the PMI impact on the wound closure dynamic studied on both hCECs and hTECs.

Results: Short PMI hCECs have a gene expression pattern distinct from that of long PMI hCECs grown as monolayers, and also displayed an increased number of daily doublings and generated more colonies per seeded cell compared with long PMI hCECs. Immunofluorescence analyses revealed that components of the basement membrane and extracellular matrix were deposited similarly in all hTECs, irrespective of the hCECs PMI. Interestingly, short PMI hCECs have more stem cells than the long PMI cells, which significantly accelerated wound closure in the short PMI group (in both hCECs and hTECs).

Conclusions: These results suggest that hTECs reconstructed using short PMI hCECs have a higher number of limbal stem cells and exhibit a more efficient wound healing response in vitro, making them the best candidates to produce substitutes for clinical studies.

TITLE: Multi-meridian wave-based corneal optical coherence elastography in normal and keratoconic patients

SESSION TITLE: Keratoconus and corneal biomechanics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F. Zvietcovich, J. Birkenfeld, A. Varea, A.M. Gonzalez, A. Curatolo, S. Marcos, Institute of Optics, Consejo Superior de Investigaciones Cientificas, Madrid, Madrid, SPAIN|A. Curatolo, International Centre for Translational Eye Research, Polska Akademia Nauk, Warszawa, Mazowieckie, POLAND|S. Marcos, The Center for Visual Science, University of Rochester, Rochester, New York, UNITED STATES|

Commercial Relationships Disclosure: Fernando Zvietcovich: Commercial Relationship: Code N (No Commercial Relationship) | Judith Birkenfeld: Commercial Relationship: Code N (No Commercial Relationship) | Alejandra Varea: Commercial Relationship: Code N (No Commercial Relationship) | Ana Gonzalez: Commercial Relationship: Code N (No Commercial Relationship) | Andrea Curatolo: Commercial Relationship: Code N (No Commercial Relationship) | Susana Marcos: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The detection of pre-clinical keratoconus remains a challenging task. We propose to use wave-based optical coherence elastography to measure full spatial-dependent elasticity of normal and keratoconic corneas. We hypothesize that both advanced and pre-clinical keratoconus corneas can be identified as outliers from a baseline metric.

Methods: A 500 kHz ultrasonic air-coupled transducer co-focused with an optical coherence tomography system was used to generate quasi-harmonic mechanical perturbation at the corneal apex. Lamb wave propagation speed and average thickness were measured within 16 corneal meridians covering 360 degrees during 1s of acquisition. Measurements were conducted in thirty-one human healthy subjects (control group, N = 62 corneas; age: 20-50 yo; corneal astigmatism <2 diopters) and three keratoconic patients (N = 5 corneas; age: 14-50 yo). All measurements were fully non-contact, and followed the approved research protocol adhered to the tenets of the Declaration of Helsinki. Spatial anisotropy of wave speed (SAWS) was calculated from the meridional-dependent wave speed of each cornea. Speed and thickness for each corneal meridian were projected in a thickness-speed map (TSM) for further statistical analysis.

Results: SAWS was statistically significantly higher in advanced (0.353, $p = 1\times10^{-11}$, N = 3) and pre-clinical (0.249, p = 0.04, N = 2) keratoconus corneas when compared to the baseline. Moreover, we found a linear correlation between meridional speed and thickness (RMSE = 0.738, $p = 5.4\times10^{-98}$) in normal corneas when measurements were projected into the TSM (Fig. 1). A 95% confidence level was used as a baseline metric to separate normal (stiffer) from abnormal (softer) corneal elasticity. We found abnormal elasticity in at least 10 out of 16 meridians in advanced keratoconus corneas ($p = 1\times10^{-10}$, N = 3), and in at least in 4 out of 16 meridians in pre-clinical keratoconus corneas ($p = 1.5\times10^{-5}$, N = 2).

Conclusions: Our results show important biomechanical differences in SAWS and TSM between normal and keratoconus corneas, suggesting those as potential biomarkers for progression and severity of keratoconus, following sensitivity and specificity studies on a larger sample of keratoconic (and their contralateral) eyes.

ABSTRACT BODY:

Purpose: Late-onset retinal degeneration (L-ORD) is an autosomal dominant disorder caused by mutations in the C1q-tumor necrosis factor-5 (CTRP5/C1QTNF5) gene. The purpose of this study was to understand the pathology of L-ORD by analysis of the proteome of the Retinal Pigment Epithelium-Choroid (RPE-Ch) tissue in mouse models carrying the S163R Ctrp5 mutation. The current study mainly focuses on components of the complement pathway as a function of age.

Methods: The proteomes of the RPE-Ch, which include Bruch's membrane (BrM), were analyzed in wild-type (WT), heterozygous S163R Ctrp5 mutation knock-in (Ki/WT), and homozygous knock-in (Ki/Ki) mice of approximately 5 and 18 months (m) of age. The mass spectral data were analyzed using MaxQuant software for the identification and quantification of the levels of peptides in the RPE-Ch. The proteins identified in the analysis were further experimentally validated in the RPE-Ch tissue of 5 and 18 m old mutant and WT mice by immunohistochemistry (IHC) and western blotting.

Results: Components of the three complement pathways were present in the WT and mutant mouse proteome of RPE-Ch. Five components of the classical pathway were observed to increase over 2 fold ($p<.05$) in WT and mutant mice with age. C4b was increased 2.7 and 3.9 fold with age in WT and Ki/WT, respectively. Both C1qb and C1qc were increased 2 and 3 fold with age in WT and Ki/WT, respectively. CFH, which is involved in the alternative pathway increased 1.4 fold ($p<.05$) with age in the WT mice and was higher in the Ki/WT but it did not reach significance. IHC was used to assess the levels of the components of the alternative complement pathway CFB, CFH, and C3, specifically in BrM. At 18 m of age, the levels of each protein were higher in mutant compared to WT mice. These observations were further validated using western blot analysis. CFB showed an increase by 2.1 fold in Ki/WT and 2.9 fold in Ki/Ki compared to WT. CFH increased by 1.35 fold in Ki/WT and 1.5 fold in Ki/Ki.

Conclusions: Proteome analysis of RPE-Ch revealed an increase in members of the classical complement pathway with age in the WT and L-ORD mouse models. The levels of components of the alternative pathway (CFB, CFH, and C3) were increased in BrM-Ch of mutant mice at 18 m. This study provides insight and support for the potential role of the complement system in L-ORD pathology.

ABSTRACT BODY:

Purpose: To investigate the effect of smoking on the rates of progressive visual field damage over time in glaucoma.

Methods: In this longitudinal study, 354 primary open-angle glaucoma (POAG) patients with a minimum of 3 years follow-up and 5 visual fields (VF) tests were enrolled from the Diagnostic Innovations in Glaucoma Study (DIGS) and the African Descent and Glaucoma Evaluation Study (ADAGES). Univariable and multivariable linear mixed models were used to investigate the effects of smoking on the rates of 24-2 VF mean deviation loss after adjusting for confounding factors such as alcohol consumption and Body Mass Index. VF progression was defined using pointwise linear regression (three test locations having a significant regression slope ($p<0.01$) of ≤-1dB per year). Logistic regression was used to identify whether different levels of smoking intensity were associated with VF progression. Kaplan-Meier curve and the log-rank test were used to compare the cumulative risk ratio of progression between different smoking intensity categories.

Results: A total of 511 eyes of 354 patients with glaucoma followed from multicenter glaucoma registries were included over the mean follow-up of 12.4 years. Mean baseline age was 62.3 years; 124 (35%) were African ethnicity. Of the 354 patients, 168 (59.8%) and 149 (42.1%) had reported a history of smoking or alcohol consumption, respectively. 39 (11%) were heavy smokers. In a multivariable model, higher smoking intensity was associated with faster VF loss (coefficient -0.05 (-0.08,-0.01)dB/year per 10 pack-years, P=0.01). Developing VF progression in eyes of heavy smokers (>20 pack-years) was 2.2 times greater than in eyes of non-smokers after adjusting for confounding factors (OR=2.21; 95% CI: 1.02,4.76; P=0.04), Figure 1. A significantly higher proportion of progressing eyes were found in heavy smokers compared to non-smokers by Kaplan-Meier analysis (log-rank test, $P<0.01$), Figure 2.

Conclusions: Heavy smokers are more likely to have VF loss in eyes with glaucoma. The prospective longitudinal design of this study supports the hypothesis that levels of smoking may be associated with glaucoma progression. Additionally, this information can be used for clinically relevant tobacco prevention and intervention messages.

TITLE: Deep Learning to distinguish Best vitelliform macular dystrophy (BVMD) from adult vitelliform macular degeneration (AVMD)

SESSION TITLE: Machine Learning and Image Processing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Crincoli, Z. Zhao, J. Estrada Walker, C. Mehanna, S. Halouani, A. Miere, Centre Hospitalier Intercommunal de Creteil, Creteil, Île-de-France, FRANCE|

Commercial Relationships Disclosure: Emanuele Crincoli: Commercial Relationship: Code N (No Commercial Relationship) | Zhanlin Zhao: Commercial Relationship: Code N (No Commercial Relationship) | Juliana Estrada Walker: Commercial Relationship: Code N (No Commercial Relationship) | Carl Joe Mehanna: Commercial Relationship: Code N (No Commercial Relationship) | Safa Halouani: Commercial Relationship: Code N (No Commercial Relationship) | Alexandra Miere: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To automatically classify, using a deep learning model, spectral-domain optical coherence tomography (SD-OCT) and blue fundus autofluorescence (FAF) images of Best vitelliform macular dystrophy (BVMD) and adult vitelliform macular degeneration (AVMD).

Methods: Fifty-two BVMD eyes (SD-OCT images and FAF images) and 43 AVMD eyes (SD-OCT images and FAF images) were included. The contrast-based auto local threshold was used to preprocess FAF images. SD-OCT B-scans were binarized and processed using a mean-based auto local thresholding. MatLab deep learning toolbox was used as a framework for the deep learning process. Images were classified using Inception-ResNet-v2 convolutional neural network(CNN). Transfer learning using the ImageNet dataset was performed. Established augmentation techniques were used. Seventy (70)% of the images were used to train the network while 10% was used for validation and 20% for testing. Accuracy, sensitivity, and specificity were assessed using confusion matrices. The area under the receiver operating characteristics (AUROC) curves was determined to evaluate the model performances. The deep learning model's confidence was assessed using binomial logistic regression on the test set.

Results: The accuracy of the classification using FAF images was 96.8%. The model showed a 98.0% sensitivity and 95.4% specificity for the diagnosis of BVMD with an AUROC of 0.980 (CI 0.949 – 1.000). The accuracy of the classification using SD-OCT images was 0.936. The model showed a sensitivity of 94.2%, a specificity of 93.0%, and an AUROC of 0.942 (CI 0.890 – 0.994) for the diagnosis of BVMD. Binomial logistic regression revealed a 92% of correct classification probability.

Conclusions: The study shows good performances of CNN-based automated classification in differentiating the vitelliform stage of BVMD lesions from AVMD based on preprocessed FAF and SD-OCT images. With further developments, this model may help evaluate and distinguish the two clinical entities.

TITLE: Outcomes of a Microstent Procedure Combined With Cataract Extraction in Mild/Moderate versus Severe Open Angle Glaucoma

SESSION TITLE: Surgery & Wound Healing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Badar, R. Enzor, Ophthalmology, Indiana University School of Medicine, Indianapolis, Indiana, UNITED STATES|Y. Catoira-Boyle, Ophthalmology, Richard L Roudebush VA Medical Center, Indianapolis, Indiana, UNITED STATES|

Commercial Relationships Disclosure: Ayesha Badar: Commercial Relationship: Code N (No Commercial Relationship) | Rikki Enzor: Commercial Relationship: Code N (No Commercial Relationship) | Yara Catoira-Boyle: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The Hydrus microstent (Ivantis, Irvine, CA) is a minimally invasive glaucoma surgery (MIGS) that spans approximately 90 degrees of the Schlemm's canal to improve trabecular outflow. Hydrus is FDA-approved to be performed in combination with cataract surgery in patients with mild to moderate open angle glaucoma. We performed this study to evaluate the safety and efficacy of phaco-Hydrus in patients stratified by severity of open angle glaucoma.

Methods: We completed a retrospective chart review of Hydrus microstent combined with phacoemulsification cataract extraction with intraocular lens implantation (phaco-Hydrus) performed in 22 eyes of 21 patients with mild/moderate (n=11) or severe (n=11) primary open angle glaucoma or normal tension glaucoma at a single academic site from 7/2020 to 7/2021. Mean age was 73.29 ± 7.27 years, 62% patients were Caucasian and 29% African American, and 95% were male. The average follow up was 5.95 ± 3.15 months (range 3-12 months). Surgical technique included insertion of the Hydrus microstent into the Schlemm's canal nasally. Data is reported as mean ± standard deviation, and comparisons were made of pre-operative and three-month data using paired Student's t-tests.

Results: At three months postoperatively, the average IOP reduction for all open angle glaucoma patients receiving phaco-Hydrus was -2.55 ± 3.77 mmHg (-24.02 ± 39.00%) (P = 0.0047). The average drop reduction was -0.50 ± 0.91 (P = 0.018). Average IOP reduction for mild to moderate open angle glaucoma was 1.0 ± 3.2 (P = 0.33) and average drop reduction was 0.64 ± 0.81 (P = 0.026). Average IOP reduction for severe open angle glaucoma was 4.09 ± 3.76 (P = 0.0048) and average drop reduction was 0.36 ± 1.03 (P = 0.27). Phaco-Hydrus in patients with severe open angle glaucoma resulted in greater IOP reduction than in mild to moderate glaucoma (P = 0.052). None of the patients required an additional glaucoma surgery during the follow-up period.

Conclusions: The combination of the Hydrus microstent with phacoemulsification cataract surgery results in significant IOP reduction for patients with all stages of open angle glaucoma, including severe. Greater IOP reduction was observed in patients with severe stage compared to mild to moderate stage open angle glaucoma. Phaco-Hydrus may be an effective option for patients with severe open angle glaucoma.

TITLE: APE1/Ref-1 is overexpressed and colocalizes with neovascular tufts and hypoxic regions in the oxygen-induced retinopathy mouse model

SESSION TITLE: Vascular Biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G.D. Hartman, A. Muniyandi, M.R. Kelley, T.W. Corson, Indiana University School of Medicine, Indianapolis, Indiana, UNITED STATES|

Commercial Relationships Disclosure: Gabriella Hartman: Commercial Relationship: Code N (No Commercial Relationship) | Anbukkarasi Muniyandi: Commercial Relationship: Code N (No Commercial Relationship) | Mark Kelley: Commercial Relationship(s);Code P (Patent):US 16/968,009;Code C (Consultant/Contractor):Ocuphire Pharma;Code C (Consultant/Contractor):Apexian Pharmaceutical | Timothy Corson: Commercial Relationship(s);Code P (Patent):US 16/968,009

ABSTRACT BODY:

Purpose: Current treatments for retinal neovascularization as seen in proliferative diabetic retinopathy (PDR) and retinopathy of prematurity (ROP) include intravitreal injections of anti-vascular endothelial growth factor (VEGF) biologics. However, anti-VEGF biologics are accompanied by tachyphylaxis, high treatment burden, and complications, corroborating an unmet need for novel therapeutic targets. A promising therapeutic target for treatment of PDR and ROP is the redox transcriptional regulatory function of the protein apurinic/apyrimidinic endonuclease 1/reduction-oxidation factor 1 (APE1/Ref-1). Ref-1 activity has been implicated in multiple relevant pathways involved in retinal neovascularization including angiogenesis, inflammation, and stress response. First-generation Ref-1 redox inhibitor APX3330 is already in phase II clinical trials for DR and diabetic macular edema (DME). However, the expression of Ref-1 has yet to be fully characterized in retinal neovascular disease. We aimed to assess Ref-1 expression in the murine oxygen-induced retinopathy (OIR) model to increase understanding of Ref-1's role in retinal neovascularization.

Methods: Neonatal mice and dams were exposed to hyperoxia (75% O_2) or room air for 5 days (P7-P12). Mice were injected with pimonidazole for visualization of hypoxic regions two hours before euthanasia and enucleation at P12, P15, and P17. Retinal flatmounts were coimmunostained for Ref-1, vasculature (isolectin B4), and hypoxia (Hypoxyprobe). Spatial and temporal expression of Ref-1 was analyzed by confocal microscopy.

Results: Ref-1 colocalized with vasculature and hypoxic regions in the OIR model. Mean fluorescent intensity (MFI) of Ref-1 in OIR eyes was higher compared to normoxia control eyes at each time point ($p<0.0001$, two-way ANOVA, Tukey's post hoc test). Ref-1 colocalized with neovascular tufts, and Ref-1 expression was absent in vaso-obliterated areas of the retina.

Conclusions: Previous data revealed that Ref-1 inhibition blocks laser-induced choroidal neovascularization (L-CNV). Here, we revealed that Ref-1 is highly expressed in pathological angiogenic tufts in the murine OIR retina, suggesting that Ref-1 is likewise important for retinal neovascularization, thus providing context for new potential therapeutic use in PDR and/or ROP.

ABSTRACT BODY:

Purpose: Retinitis Pigmentosa (RP) is a group of inherited disorders with loss of rod photoreceptors followed later by cone photoreceptors. The most common point mutation of RP in the United States is a proline to histidine amino acid change at position 23 (P23H). Our previous studies indicated that misfolded P23H rhodopsin activates the inositol-requiring enzyme 1 (IRE1) pathway of the unfolded protein response (UPR) and undergoes endoplasmic reticulum associated degradation (ERAD) by unclear mechanisms. Here, we investigate the role of lysine ubiquitination in P23H and wild-type (WT) rhodopsin protein turnover.

Methods: HEK293FT cells were transfected with a pcDNA3.1 plasmid vector expressing WT or P23H human rhodopsin from a cytomegalovirus (CMV) promoter (Invitrogen). A PrimeStar Mutagenesis site-directed primers using in-frame modifications of 5'-AAG-3' to 5'-AGG-3' were used to convert all 11 lysines on human WT and P23H rhodopsin to arginines (K-null). Immunoprecipitation and immunoblots were performed to measure protein levels of rhodopsin and ubiquitin. A cycloheximide chase assay determined $t_{1/2}$ of P23H and K-null P23H rhodopsin. RT-qPCR was performed to measure E3 ubiquitin ligase expression in P23H homozygous ($Rho^{P23H/P23H}$) mouse retinas. HEK293T cells containing I642G mutant allele were treated with DMF or 1NM-PP1 to artificially activate IRE1.

Results: P23H K-null was significantly less ubiquitylated than intact P23H rhodopsin. P23H K-null had significantly increased protein half-life compared to intact P23H rhodopsin in cycloheximide chase assays. Single lysine-to-arginine point mutations did not significantly change P23H rhodopsin ubiquitination. Additionally, a K-null WT rhodopsin also showed reduced ubiquitination of WT rhodopsin. Lastly, we identified 18 E3 ubiquitin ligase genes expressed in HEK293T cells, regardless of IRE1 activation status with 13 genes upregulated in $Rho^{P23H/P23H}$ mouse retinas.

Conclusions: Our findings support that lysine ubiquitylation is an important post-translational modification for WT and P23H rhodopsin protein degradation. Multiple lysine residues are likely ubiquitinylated during rhodopsin protein degradation. Strategies to ubiquitinylate P23H rhodopsin could enhance its clearance by autophagy or proteasome degradation and potentially benefit retinitis pigmentosa patients carrying these mutations.

ABSTRACT BODY:

Purpose: Anterior uveitis (AU) is the most common form of uveitis and an important condition encountered both in primary care unit and specialist uveitis clinics. There are several known and many possible etiologies for AU, and clinical characteristics in AU differ depending on the cause. In this study, we focused on AU and investigated the detailed epidemiological profile and the clinical finding-related differences.

Methods: Clinical charts of consecutive 275 patients with 335 eyes (mean age 52.5 ±19.1 years, male/female = 124/151) who made a first visit at National Defense Medical College Hospital between January 2010 and March 2020 were retrospectively reviewed. Visual acuity, intraocular pressure (IOP), unilateral/bilateral uveitis at first visit, and diagnosis, were collected from clinical charts. In eyes suspected infectious uveitis, multiplex polymerase chain reaction tests (PCR) using anterior aqueous humor were performed as previous reports, and diagnosed.

Results: Epidemiologically, acute AU was the most frequent (21.8%), followed by viral AU (20.7%) consisting of varicella zoster virus (VZV) at 9.1%, herpes simplex virus (HSV) at 8.0%, and cytomegalovirus (CMV) at 3.6%, scleritis (13.5%), diabetic iritis (7.6%), and Posner-Schlossman (P-S) syndrome (5.5%), although unexplained cases were 17.1%. Unilateral AU was 78.2% of the total, of which 86.7% of acute AU, 96.5% of viral AU (VZV 100%, HSV 100%, and CMV 80%), 75.7% of scleritis, 57.1% of diabetic iritis, and 100% of P-S syndrome. One hundred eleven AU patients (40.4%) were more than 60 years old, which were composed of viral AU at 34.2% (VZV 14.4%, HSV 12.6%, and CMV 7.2%), scleritis at 14.4%, acute AU at 13.3%, P-S syndrome at 6.3%, and diabetic iritis at 4.5%. AU patients with visual disturbance less than 20/30 accounted for 36% of the total, which consisted of 46.7% of acute AU, 50.9% of viral AU (VZV 48%, HSV 54.5%, and CMV 50%), 16.2% of scleritis, 47.6% of diabetic iritis, and 55.6% of Fuchs' uveitis. Comparing acute AU and viral AU, viral AU patients were significantly older and had higher intraocular pressure than acute AU patients.

Conclusions: AU is predominantly unilateral, and the etiology was identified in about 80%. The most frequent disease was acute AU, followed by viral AU, and visual acuity was equally impaired in them. However, it was suggested that viral AU patients were older and had higher IOP than acute AU patients.

ABSTRACT BODY:

Purpose: Traditional perimetry is bulky, time-consuming, expensive, requires careful disinfection, and is impractical for use outside the standard outpatient office. The aim of this proof-of-concept prospective study is to demonstrate the feasibility of use of a portable Virtual Reality Visual Field (VRVF) device[1] for hospital-based ophthalmology consultations. Secondary aims are to investigate the clinical utility of the device and to quantitatively compare results to in-office gold standard Humphrey Visual Field (HVF) testing.

Methods: In this ongoing study, all ophthalmology consultations at a single site over the course of a 5-month study period will be included. Patients undergo VRVF testing (BOLT strategy, Stim III) only if the ophthalmology service has been consulted for: blurry vision, unexplained vision loss, rule out papilledema, baseline examination prior to medication initiation or surgical intervention, or suspected neurologic/neuro-ophthalmologic disease. Data collected include patients' attitudes towards testing experience, management decisions made based on testing, diagnoses, and VRVF and HVF parameters.

Results: Of the 45 consultations made over the initial one-month period, 4 patients were eligible for VRVF testing (mean age 57.5 +/- 18.0 years). Average patient usability rating was 5.75 (scale of 1-hardest to 10-easiest), with all participants indicating they would do the test again and none reporting adverse outcomes. 50% of exams were to establish visual field baseline prior to neurosurgical intervention and the remaining were for the workup of PION. In no case did results change management. Follow up HVF was available for 2 participants (4 eyes). Strong correlation between VRVF and HVF was noted for point-by-point comparison ($r=0.93$, $p<0.0001$), mean deviation ($r=0.99$, $p=0.0025$), but not pattern standard deviation ($r=0.31$, $p>0.05$).

Conclusions: Prior VRVF studies have focused on its utility for outpatient glaucoma monitoring. This is the first known study to look at the use of VRVF for hospital-based ophthalmic consultations. Based on our preliminary data, VRVF can be used in the hospital setting in a quick, easy, safe, and reliable manner. However, <10% of total ophthalmic consultations qualified for study participation, suggesting that the technology might be most effectively applied in conjunction with neurology and neurosurgery services. 1. ABSTRACT BODY:

Purpose: Pentosan Polysulfate Sodium (PPS) is prescribed to treat bladder pain or discomfort. Pearce et al. [2018] reported adults taking this medication presenting with a maculopathy suggestive of a primary retinal pigmented epithelium (RPE) injury. We previously presented that prolonged intraperitoneal injections of PPS cause retinal dysfunction in mice. Here we report observations from a new mouse model.

Methods: 10 male and 10 female age-matched 129S2/SvPasCrl mice were given ad libitum mouse chow, either standard or supplemented with PPS. The daily dosage of PPS from the food was initially 500 mg/kg, later increased to 1000 mg/kg, then finally 2000 mg/kg over 14 months. Mice regularly had retinal function assessed by electroretinography (ERG). Mice were sacrificed after being maintained for 7 months on the highest PPS dose. One eye was fixed by freeze substitution for sagittal paraffin sectioning and histology. The contralateral eye was fixed in Z-Fix for RPE-flatmounting. Flatmounts were imaged using confocal microscopy and images were analyzed using a custom pipeline in CellProfiler.

Results: After 10 months, we observed diminution of mean c-wave amplitudes (10 cd.s/m2 scotopic flash, $p<0.04$, unpaired t-test). By 11 months, we also observed a main drug effect showing diminution of mean scotopic a- and b-wave amplitudes (5 flashes, $p<0.01$ for b-waves, $p<0.03$ for a-waves, two-way repeated measures ANOVA). Post-mortem histology measures showed decreased outer segment thickness superior to the optic nerve head ($p<0.05$, mixed effects analysis). Analysis of the RPE flatmounts revealed increased mean cell area in PPS-treated mice ($p<0.005$, unpaired t-test).

Conclusions: That oral ingestion of PPS results in ERG amplitude reduction, confirms our previous findings from experiments in which delivery was by IP injection, and possibly more closely models the clinical findings. This loss may be related to the decreased outer segment length observed in PPS-treated mice. Increased RPE cell size is known to occur in PPS retinopathy. These observations seem to corroborate the clinical observations suggesting a primary RPE injury.

ABSTRACT BODY:

Purpose: The clear corneal epithelium is crucial for vision and regenerates from limbal stem cells (LSCs) whose differentiation in homeostasis has been resolved transcriptionally by recent single cell RNA sequencing (scRNAseq) studies. Yet, it remains poorly understood how LSC differentiation becomes co-opted after injury to promote wound healing or whether differentiation is perturbed in aging, diabetes, and dry eye disease (DED). In the present work, we evaluate--at the single cell level--corneal epithelium in animal models of these conditions that could impact LSC regeneration of the ocular surface.

Methods: Using scRNAseq, we profiled mouse corneal epithelium in homeostasis, in aging, in streptozotocin-induced diabetes, following debridement of the central cornea, and in aqueous tear-deficient DED resulting from lacrimal gland excision.

Results: In homeostasis, we captured the full sequence of corneal epithelial differentiation from LSC to superficial squamous cell, as well as identify candidate genes and gene networks that characterize key stages of differentiation. In models of aging or diabetes, we found that there were only mild transcriptional changes, with ≤10 dysregulated genes in total across all cell types (adjusted p-value < 0.05, $|\log_2[\text{fold-change}]| \geq 1.5$). However, epithelial debridement or DED induced more dramatic changes to aid the regeneration of the injured ocular surface. First, there was expanded expression of some putative LSC markers to other non-LSC cell types, such as Krt14 and Ifitm3 with $\log_2[\text{fold-change}]$ ranging from 1.5-2.5 (adjusted p-value < 0.05). Second, there was upregulation of epidermal wound healing-associated genes Fabp5 and Rbp1 with $\log_2[\text{fold-change}]$ ranging from 1.5-2.5 (adjusted p-value < 0.05). Finally, we provide markers for new corneal epithelial cell states that appeared after epithelial debridement or in DED. These wound healing-elicited cell states were not apparent in homeostasis (1.7% of cells in control eye vs. 27% after debridement; 0.5% of cells in control eye vs. 11% in DED).

Conclusions: This transcriptional dissection uncovers dramatic reconfiguration of the corneal epithelial stem cell compartment in injury and DED, providing a framework and atlas for future study of these ocular surface stem cells in health and disease.

ABSTRACT BODY:

Purpose: Aging is associated with declining vision and increased risk of age-related ocular diseases. In addition to genetics, extrinsic factors such as dietary habits have been linked to risk of retinal neurodegeneration, as shown by the AREDS1/2 clinical trials. We previously illustrated epigenetic changes as drivers of molecular aging in mouse rod photoreceptors and identified mitochondrial energy metabolism as a key process. However, the precise molecular networks through which aging and diet (nutrients) interact with retinal health remain poorly understood. We hypothesize that aging and lifestyle influence retinal homeostasis through epigenomic changes and altered cellular metabolism. This study employed a multi-omics strategy to characterize the role of nutrition in retinal aging.

Methods: A cohort of 12-month-old male and female C57BL6/J mice were fed (ad libitum) control chow (NIH-31) or one of four special diets: high-fat diet; Mediterranean diet; a custom diet with AREDS2 supplements; or supplementation of vitamins B6, B9 and B12. Supplements were tailored to mimic human allowance. After six-months, each group was subjected to electroretinography (ERG). The retinas were then isolated for Seahorse assays to determine metabolic status or for preparing RNA or DNA for transcriptome or whole genome methylation analyses, respectively.

Results: The control, AREDS and vitamin B groups showed a stable body weight over the treatment course. However, the high-fat and Mediterranean diets displayed remarkable weight gain, with prominent lead by female mice. ERG analysis revealed high variance, in both scotopic and photopic measures, among some of the groups, probably as a result of the ad libitum environment. No significant differences in ERG were detected between the treatments. Retinal extracellular acidification rate (glycolytic activity) and oxygen consumption rate (mitochondrial respiration) were impacted with age but the responses of diet groups and gender remain to be clarified conclusively. Transcriptome and methylation analyses are in progress.

Conclusions: Our study shows that nutritional habits can exert varying responses even in a controlled isogeneic setting. We predict that diet primes the retinal molecular/cellular landscape during aging either in favor or against disease development, with the final outcome being determined by divergent factors. Understanding the nexus between diet, aging, and retinal health is vital for preserving healthy vision.

ABSTRACT BODY:

Purpose: Reactive Müller glial cells in humans do not display the regenerative characteristics of those in zebrafish. We performed the first single-nucleus RNA sequencing of retina from patients with primary open-angle glaucoma (POAG) and controls to characterize the human Müller glial response to injury.

Methods: Nuclei were isolated from trephene punches of the macula taken from postmortem eyes and sequenced. Data was integrated and analyzed after quality control with Seurat v3. Sequencing findings were confirmed by RNAscope and standard immunofluorescence. Human retinal explants were cultured with and without N3B1P3C, an inhibitor of Lats kinase in the Hippo/Yap pathway. Proliferation was measured using AlexaFluor nuclear localization of EdU indicating synthetic nucleotide uptake.

Results: After quality control and data integration, 17,401 nuclei were isolated from 26,471 original droplets, derived from macular samples of 4 patients without retinal disease and 3 patients with POAG. The proportion of retinal ganglion cells in glaucomatous retina was significantly lower than that in healthy retina ($p=0.024$). An activated subpopulation of Müller glia was identified in both healthy and glaucomatous retina by cell clustering. Cross-species analysis comparing zebrafish and humans identified YAP1 activation as a differentiator between zebrafish and human glial activation. Human retinal explants cultured with N3B1P3C demonstrated significant proliferation of GS+ Muller cells ($p=0.044$).

Conclusions: Our data, including the first single-nucleus RNA sequencing of glaucomatous retina in humans, identify an activated subpopulation of human MGCs with transcriptomic signature similar to regenerative MGCs in other species, but limited by molecular brakes such as Hippo/Yap pathway factors. By inhibiting these brakes with a small molecule (N3B1P3C), we induced proliferation of Müller glia in human retinal explants for the first time. Further manipulation of endogenous activation pathways may allow for recruitment of a quiescent stem cell population and vision-restoring therapies.

ABSTRACT BODY:

Purpose: Although keratoconus has a significant heritable component, the genetic basis of the disease remains poorly understood. Epidemiological evidence suggests a relationship between keratoconus, corneal biophysical parameters, and anthropomorphic measures. To identify potential molecular factors underlying keratoconus, we analyzed genetic correlations between corneal biophysical parameters and anthropomorphic traits.

Methods: We assembled genome-wide association study summary statistics from European-derived participants in the UK Biobank including biophysical parameters (central corneal thickness [CCT], corneal hysteresis [CH], corneal resistance factor [CRF], and 3mm index of keratometry result [3mmK]), and anthropomorphic traits (body mass index [BMI], weight, and height). We calculated global and focal genetic correlations (r_g) between traits using linkage disequilibrium (LD) score regression, applying Bonferroni's correction for multiple hypothesis testing. Finally, we identified genes located within significantly correlated regions and identified patterns of tissue expression and pathway enrichment using gene set enrichment analysis.

Results: We observed significant genetic correlations between height and corneal biophysical parameters, but not keratometry. Global LD score regression revealed significant negative correlations between height and both CH (r_g = -0.12; p = 2.0×10^{-7}) and CRF (r_g = -0.11; p = 6.9×10^{-7}). Focal analysis revealed 68 genomic regions exhibiting significant local genetic covariance between CRF and height, containing 763 protein-coding genes, including 15 with known keratoconus associations in DisGeNet (Table). Gene set enrichment analysis on the list of genes in regions with significant focal r_g revealed enrichment among metabolic pathways with known keratoconus associations, including oxytocin signaling and transient receptor potential (TRP) channel regulation ($p < 0.001$; Figure).

Conclusions: These results suggest that interrogating the shared genetic heritability between CH, CRF and height may inform the genetic architecture for ectatic corneal disease and possibly provide new disease insights for keratoconus.

ABSTRACT BODY:

Purpose: Patients with Stickler syndrome are at increased risk of retinal detachment (RD). The vast majority of Stickler syndrome is due to mutations in COL2A1 and COL11A1, which are responsible for type 1 and type 2 Stickler syndrome, respectively. Few studies have examined patients that had RD prior to presentation, or incident RD, in COL11A1 patients.

Methods: Descriptive retrospective case series of patients with mutations in COL2A1 and COL11A1 presenting to the University of Utah without an incident RD from 2010 to 2020.

Results: 3 of 10 COL2A1 patients who received bilateral prophylactic laser or cryotherapy developed RD. Of these 3 COL2A1 patients with post-prophylaxis RD, all 3 received 360 cryotherapy and developed RD 2 weeks, 3 months, and 2 years after prophylaxis. 2 of 8 COL2A1 patients who did not initially receive prophylaxis developed RD. 0 of 6 COL11A1 subjects who received prophylaxis developed RD and 0 of 5 COL11A1 subjects who did not initially receive prophylaxis developed RD. The average length of follow-up was 5.7 +/- 5.3 years for COL2A1 patients and 7.1 +/- 4.1 years for COL11A1 patients.

Conclusions: In our sample, despite prophylactic treatment, incidence of RD in patients with COL2A1 mutations was higher compared to patients with COL11A1 mutations. We also noted a high rate of RD occurring soon after 360 cryotherapy prophylaxis.

ABSTRACT BODY:

Purpose: To study the relationship between retinal vessel caliber and tortuosity and the 5-year incidence of hypertension.

Methods: The community-based longitudinal Tongren Cohort Study included individuals undergoing routine health examinations. Using a proved deep learning model called vessel-constraint network, the retinal vessel calibers and tortuosity within a region of 0.5 to1.5 disc diameters from the disc margin were automatically segmented, based on color fundus images.

Results: A total of 9230 individuals(age: 43.6±13.9years) were enrolled, with the 5-year cumulative incidence of hypertension to be 18.8% and severe hypertension to be 7.0%. Narrower retinal arteriolar (odds ratio(OR):0.98; 95%CI:0.97,0.99; P<0.001), wider venular (OR:1.006; 95%CI:1.002,1.01;P=0.005), and smaller arteriole-to-venule caliber ratio (OR:0.72;95%CI:0.63,0.82;P<0.001) were associated with increased hypertension incidence after multivariable adjustment. Compared with individuals with the 5% widest arteriolar or the 5% narrowest venular, those with the 5% narrowest arteriolar or the 5% widest venular had a 17.1-fold or 2.3-fold increased risk for developing hypertension within 5 years. The receiver operating curves(ROC) for retinal vessel calibers to predict hypertension and severe hypertension was 0.79 (95%CI:0.78,0.80) and 0.84 (95%CI:0.82,0.86), respectively. The ROC was higher for women than men(0.81v.s.0.73 for hypertension; 0.87v.s.0.78 for severe hypertension; both P<0.001), and for younger than older participants (0.77v.s.0.72 for hypertension; 0.82v.s.0.76 for severe hypertension; both P<0.05). Baseline venular tortuosity was positively associated with baseline hypertension prevalence (OR:1.57; P=0.01) but not with incident hypertension (P=0.449). Baseline arteriolar tortuosity was associated with neither prevalence nor incidence of hypertension.

Conclusions: Automatically assessed narrower arterioles and wider venules on conventional fundus images indicate an increased risk for incident hypertension within 5 years. Assessment of retinal vessels may help to screen individuals with risk of developing hypertension.

ABSTRACT BODY:

Purpose: To compare post-operative outcomes up to 1 year in patients after blepharoplasty with and without glucocorticoid use within 1 year prior to surgery.

Methods: A retrospective cohort study was performed using TriNetX (Cambridge, MA, USA): a federated electronic health record database comprised of US healthcare organizations. Patients with upper or lower eyelid blepharoplasty were identified by CPT code and stratified into two cohorts based on glucocorticoid use 1 year prior to surgery. Glucocorticoids included cortisone, prednisone, prednisolone, methylprednisolone, dexamethasone, betamethasone, and hydrocortisone. 1:1 propensity score matching separated two cohorts while controlling for baseline characteristic and comorbidities: age, BMI, gender, primary hypertension, diabetes mellitus, chronic lower respiratory disease, nicotine dependence, heart failure, and alcohol related disorders. Patients with ocular comorbidities were screened out. Primary post-operative outcomes included dry eye syndrome, lagophthalmos, conjunctival edema, dacryoadenitis, orbital and periorbital cellulitis, strabismus, diplopia, orbital hemorrhage, and acute conjunctivitis. 1-year relative risk of post-operative outcomes were compared between the groups; those with a p-value less than 0.05 being statistically significant.

Results: 17,804 patients were included in the analysis with 8,902 patients in each of the blepharoplasty with and without glucocorticoid use cohorts. The cohort receiving glucocorticoids in the past year had a statistically significant increased risk of post-operative dry eye syndrome (RR, 1.25; 95% CI, 1.16-1.36), lagophthalmos (RR, 1.55; 95% CI, 1.13-2.13), and conjunctival edema (RR, 3.9; 95% CI, 1.95-7.81). No significant difference in risk was attributable to either cohort regarding dacryoadenitis, orbital and periorbital cellulitis, strabismus, diplopia, orbital hemorrhage, and acute conjunctivitis.

Conclusions: Pre-surgical glucocorticoid use up to one year may impact post-operative course following blepharoplasty. Patients receiving glucocorticoids up to one year prior were more likely to develop post-operative dry eye syndrome, lagophthalmos, and conjunctival edema. Appropriate patients should be counselled on such risk both before and after blepharoplasty.

ABSTRACT BODY:

Purpose: ARIS is a 5-year, multicenter, international, prospective, observational cohort study of participants with early AMD or reticular pseudodrusen (RPD) to identify novel biomarkers of disease progression. The purpose of this abstract is to describe the detailed imaging characteristics of the initially enrolled participants.

Methods: Baseline and 12-month follow up images were evaluated for four cohorts: early AMD, RPD only, RPD and large drusen, and healthy controls. Optical coherence tomography (OCT) images were graded for drusen structure and RPD characteristics. Fundus autofluorescence (FAF) images were graded for hypo and hyperautofluorescence and background pattern. Color fundus photography (CFP) images were graded for drusen size and area, pigmentary changes, RPD, and AMD severity scale.

Results: The cohorts comprised 38 eyes with early AMD, 18 eyes with RPD only, 10 eyes with RPD and large drusen, and 36 healthy control eyes.

In baseline evaluation of the early AMD cohort, OCT showed that drusen were predominantly dome shaped (52.8%) with hyperreflective cores (66.7%). Confluent drusen were observed in 47.2% of eyes. Abnormal FAF was seen in 50% of eyes in this cohort, all with areas of abnormality less than 2 disc areas. There was no significant hypo or hyper FAF in any eyes. CFP findings showed predominantly medium drusen (92.1%) and increased pigmentation in 5.3%. There were no eyes with depigmentation. Baseline AMD severity scale was level 2–4 in 63.2% of eyes. Progression of ≥ 1 step on the AMD scale over 12 months was seen in 17 (44.7%) eyes in the early AMD cohort.

Baseline assessment of the combined RPD cohorts showed global RPD distribution in 88.9% of eyes and superior distribution in 7.4%. Peripapillary RPD was seen in 25.9%. OCT-based staging showed stage 4 RPD in 63%. Baseline AMD scale was level 6 in 32.1% eyes and level 7 in 42.9%. Progression of ≥ 1 steps on the AMD scale over 12 months was seen in 2 (7.1%) eyes in the RPD cohort, with one eye progressing to late AMD. In the RPD subset with large drusen, drusen area ≥ 1 disc area was seen in 70% of eyes at baseline, with no eyes progressing ≥ 1 step on the AMD severity scale.

Conclusions: The 5-year ARIS introduces reproducible methods for detailed documentation of AMD phenotypes. This systematic evaluation will offer insight into the development of outcome variables in future studies of potential AMD treatments.

TITLE: Deep Binary Descriptor-based Identification of Retinal Lesions for Diabetic retinopathy

SESSION TITLE: Retinal vascular diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Lian, School of Intelligence Engineering, Shandong Management University, Jinan, Shandong, CHINA|X. Yang, Shandong Normal University, Jinan, Shandong, CHINA|

Commercial Relationships Disclosure: Jian Lian: Commercial Relationship: Code N (No Commercial Relationship) | Xinbo Yang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The detection and classification of retinal lesions play a vital role in screening diabetic retinopathy, one primary cause of visual impairment globally. Extensive research on deep learning has shown their good performance in this area. However, these methods suffer from the image samples' scarcity and diversity of morphological characteristics. This study aims to establish a binary descriptor-based classification instrument for discriminating the retinopathy slices by leveraging deep backbone models capable of resolving complex cases.

Methods: 4 datasets of retinal slices were collected in this study. In total, there are three types of retinal images used as the input for the proposed deep learning-based pipeline, which consists of 3 phases (as shown in Fig. 1):
We added affine transformations to the raw samples.
What fed the original and deformed retinal images into one backbone model.
The generated feature for each slice was fed into a non-linear classifier to discriminate three categories of diabetic cases.
Note that three constraints, including affine transformation in variation, even distributed, and quantization loss minimization was imposed on the features rendered as a binary descriptor. The structure of the proposed approach is shown in Figure 1.

Results: The proposed framework is superior to the state-of-the-art algorithms in accuracy, sensitivity, and precision. The ten-fold cross-validation accuracy of the presented approach on the samples is 98.35%.

Conclusions: The findings indicate that the proposed approach is a potentially helpful instrument for retinal lesion identification. By constraining the output features extracted from the input images it not only can increase the generalization of the deep learning models but also guarantee accuracy.

ABSTRACT BODY:

Purpose: A novel topical ointment AZR-MD-001, containing selenium disulphide designed to treat meibomian gland hyperkeratinisation, has been shown to improve symptoms and signs of meibomian gland dysfunction (MGD). This study evaluated the effect of biweekly dosing on tear film parameters in a double-masked, vehicle-controlled, randomized, parallel group clinical trial in individuals with MGD.

Methods: Participants with evidence of MGD (Meibomian Gland Secretion score [MGS] ≤12 for 15 glands of the lower lid), and signs and symptoms of dry eye (fluorescein tear break-up time [FBUT] <10 seconds and Ocular Surface Disease Index [OSDI] score >12) in both eyes were enrolled. Participants were randomly assigned to receive either the test AZR-MD-001 1% or control ointment to the lower eyelid margin (NCT04314362). Tear evaporation rate (TER), lipid layer thickness (LLT), non-invasive keratograph tear break-up time (NIKBUT), tear meniscus height (TMH) and FBUT were measured at baseline and after 2, 4, 6 weeks and 3 months of treatment. Differences between active and vehicle were analyzed relative to baseline using ANCOVA.

Results: Twenty-two participants (7 males and 15 females, aged 44.8 ± 17.7 years, average baseline OSDI 37.1 ± 14.2) completed the study. Compared with the vehicle group, a significantly greater improvement (reduction) in TER was observed in the active treatment group at the 2-week visit (mean treatment difference ± standard error: -30.2 ± 14.8$gm^{-2}h$, p=0.044). A corresponding reduction (worsening) in FBUT was also observed in the vehicle group at the 2-week visit compared to the treatment group (1.3 ± 0.6 sec, p=0.037). The number of meibomian glands yielding liquid secretion was significantly higher in the active group at 3 months (1.8 ± 0.9, p = 0.043), whereas the improvement in MGS score didn't quite reach statistical significance (5.6 ± 2.9, p = 0.056). No differences were observed for change from baseline between the two groups for OSDI score, LLT, NIKBUT or TMH at any visit.

Conclusions: Measurable improvements in tear film stability were observed with use of the novel topical ointment containing selenium disulphide. Further work to understand the potential longer-term benefits of the ointment, including any changes to meibomian gland morphology associated with functional improvements, is warranted.

TITLE: Risk Factors for Enucleation Following Open Globe Injury: A 17-Year Experience

SESSION TITLE: Anterior Segment and Trauma Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Toiv, University of Michigan Medical School, Ann Arbor, Michigan, UNITED STATES|A.F. Durrani, Y. Zhou, P.Y. Zhao, D.C. Musch, M. Huvard, D.N. Zacks, Department of Ophthalmology and Visual Sciences, W K Kellogg Eye Center, Ann Arbor, Michigan, UNITED STATES|

Commercial Relationships Disclosure: Avi Toiv: Commercial Relationship: Code N (No Commercial Relationship) | Asad Durrani: Commercial Relationship: Code N (No Commercial Relationship) | Yunshu Zhou: Commercial Relationship: Code N (No Commercial Relationship) | Peter Zhao: Commercial Relationship: Code N (No Commercial Relationship) | David Musch: Commercial Relationship: Code N (No Commercial Relationship) | Michael Huvard: Commercial Relationship: Code N (No Commercial Relationship) | David Zacks: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: At the time of open globe injury, it may be difficult for clinicians to predict which eyes are at highest risk for ultimately requiring enucleation. We performed a 17-year retrospective cohort study to report outcomes and risk factors for enucleation following open globe injury (OGI) to better aid clinicians counseling patients at OGI diagnosis.

Methods: A retrospective cohort study of all patients who presented to the University of Michigan with open globe injury (OGI) and were surgically managed between January 2000 and July 2017 was conducted. At least 30 days of follow-up was required. All eyes that ultimately underwent enucleation following OGI were identified and their clinical course analyzed. The main outcome measured was the rate of enucleation after OGI.

Results: There were 588 eyes meeting inclusion criteria. The mean patient age was 40.75 ± 25.1 (range 1 – 91) and 441/585 (75.2%) patients were male. Average follow up time was 1079.8 ± 1895.7 days. 117/588 eyes (19.9%) required enucleation after OGI, with 95/117 (81.2%) undergoing enucleation less than 30 days from injury. For all eyes, the average presenting logMAR vision was 2.11 ± 1.01 (Snellen equivalent between counting fingers and hand motion). In eyes that underwent enucleation, the mean presenting logMAR vision was 2.91 ± 0.470 (Snellen equivalent between hand motion and light perception). The most common mechanism of injury requiring enucleation was globe rupture, 89/117 (76.1%), with 14/117 (12.0%) eyes having penetrating injuries and 14/117 eyes (12.0%) having perforating injuries. The mean age of patients that underwent enucleation was 45.6 ± 22.5 (range 3 – 91).

Conclusions: Open globe injuries (OGI) are often visually devastating and in a significant number of cases ultimately require enucleation. Despite emergent closure within 24 hours, 19.9% of eyes diagnosed with OGI require enucleation. 81.2% of these eyes required enucleation within 30 days of injury. Eyes that underwent enucleation tended to have worse presenting visual acuity, with mean presenting logMAR vision of 2.91 ± 0.470 (Snellen equivalent between hand motion and light perception), compared to a mean presenting logMAR vision of 2.11 ± 1.01, in all eyes with OGI.

Ali Khan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: This study compared clinical outcomes of combined pars plana vitrectomy (PPV) and secondary scleral fixation of an intraocular lens (IOL) using Gore-Tex suture versus the Yamane technique.

Methods: This study was a single-center, retrospective, consecutive case series conducted at Wills Eye Hospital (Philadelphia, PA, USA) between 12/01/2017 and 12/01/2021. Eyes that underwent scleral fixation of a Bausch and Lomb Akreos AO70 or enVista MX60E IOL using Gore-Tex suture or a Tecnis ZA9003 or Zeiss CT LUCIA 602 IOL using the Yamane technique were included. Primary outcome measures were change in visual acuity (VA) and occurrence of intraoperative and postoperative complications with minimum follow-up of 120 days.

Results: Sixty-eight eyes of 64 patients (47% male, mean(± SD) age 72(±12) years) with the main surgical indication of dislocated IOL or retained lens material were included. Mean follow-up was 501 days (median 366 days, range 132-1254 days). Fifty-two eyes (76.5%) underwent Gore-Tex suture fixation and 16 eyes (23.5%) underwent Yamane fixation. Across all eyes, VA improved from 1.34±0.74 (20/437) preoperatively to 0.36±0.37 (20/46) at 3 months and 0.32±0.36 (20/42) at final follow-up ($p<0.001$ for both timepoints). VA improved in statistically significant fashion for each secondary IOL technique (Table 1). No intraoperative complications were noted. Postoperative complications are included in Table 2, and there was no statistically significant difference between groups. In the Gore-Tex group, 2/52 eyes (3.8%) required reoperation for conjunctival erosion with exposed suture (n=1) and for IOL decentration (n=1). In the Yamane group, 2/16 (12.5%) eyes required reoperation for epiretinal membrane formation (n=1) and for retinal detachment (n=1). There were no cases of postoperative endophthalmitis, suture breakage, or haptic breakage in the post-operative follow-up period.

Conclusions: Scleral fixation of IOLs with Gore-Tex suture and intrascleral haptic fixation (Yamane technique) resulted in improvement of VA. No significant difference in post-operative complication profiles was noted. Both techniques appear to be safe and effective for secondary IOL surgery in combination with PPV.

ABSTRACT BODY:

Purpose: The development of small gauge vitrectomy has improved rates of self-sealing sclerotomies and decreased post-operative pain and inflammation. However, concerns regarding vitrector bending with smaller gauge sizes remains an area of concern. Therefore, the purpose of this study was to investigate the mechanical properties and stiffness of 23-, 25- and 27-gauge vitrectomy vitrectors across three different vitrectomy systems to inform surgical techniques.

Methods: Nine vitrectors (3 each of 23-, 25-, and 27 gauge) from Alcon, DORC and Bausch and Lomb (B/L) were measured. The force required to vertically displace each vitrector by 1mm at the tip and 15mm from the tip was measured using an electronic force gauge (Electroforce 5500 Thermal Analysis Instruments, USA). Measurements were recorded in gramforce (gf). Five measurements were performed at each location and fully elastic deformation was ensured. One way ANOVA and Post-Hoc Tukey analysis were performed to evaluate statistical significance.

Results: Across brands, B/L demonstrated the least stiffness at both the tip and at 15mm for 23-gauge (8.0±0.3 gf, 67.3±1.0 gf), 25-gauge (6.8±0.3 gf, 60.5±0.4 gf) and 27-gauge (3.3±0.1 gf, 33.9±0.5 gf) vitrectors. Within each brand, the 25 gauge vitrector was less stiff than the 23 gauge vitrector and the 27 gauge vitrector was less stiff than the 25 gauge vitrector at both tip and 15mm. These differences were statistically significant for Alcon ($P<0.001$, $P<0.001$), DORC($P<0.001$, $P<0.001$) as well as B/L ($P<0.001$, $P<0.001$).

Conclusions: Based on this study, 25-gauge vitrectors, although larger than 27-gauge vitrectors and less stiff than 23-gauge vitrectors, may offer favorable compromise between stiffness and gauge size. However, surgeon experience, preference, and expertise should be paramount. Knowledge of these mechanical properties may aid surgeons in choosing between gauge size and vitrectomy system to optimize their comfort and efficiency.

TITLE: Exfoliation syndrome (XFS): Production of extracellular aggregates in a human capsulorhexis culture model

SESSION TITLE: Pharmacology / Cellular mechanisms

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: T. Borras, D. Fleischman, Ophthalmology, University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, North Carolina, UNITED STATES|

Commercial Relationships Disclosure: Terete Borras: Commercial Relationship: Code N (No Commercial Relationship) | David Fleischman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: XFS in the eye causes the formation of deposits on anterior segment tissues that can lead to the development of exfoliation glaucoma. Clinically, deposits are seen on the lens surface. Our goal was to define human capsulorhexis cultures as an XFS model by determining if lens exfoliation material (XFM) was produced by lens epithelial cells (LE) or deposited externally. To analyze local distribution of XFM components LOXL1, ELN and FBN1 in XFS & normal capsulorhexis tissues and to investigate LOXL1's role in the formation of XFS aggregates.

Methods: Lens-capsules (LC) were harvested in tissue culture (TC) media during capsulorhexis surgery (IRB approved). Four h post-surgery, specimens were stained with trypan blue, transferred to a 2-chamber dish with coverglass bottom (4.2 cm^2), washed, and incubated floating in media overnight. Curled LCs were flattened with craft brushes (LE layer down), incubated with media drops 2 days for attachment, and fed normally for 2-4 weeks. IHC was performed in the same dish with LOXL1, ELN, FBN1, Collagen IV and DDK antibodies. Images were acquired through the chamber coverglass (unmounted) by fluorescence microscopy and analyzed with CellSens. LOXL1 overexpression was achieved by infection with DDK-tagged Ad.LOXL1 (variant G-G).

Results: 83 LCs were processed. LOXL1, ELN, and FBN1 are abundantly secreted by LEs and can raise to the surface through the 14 nm capsule membrane. LCs from XFS patients show patches of aggregates which stain heavily with LOXL1, ELN and FBN1. The XFS cells' morphology exhibit an extracellular ring reminiscence of a pericellular matrix. Interestingly, a similar extracellular ring is observed in LEs transduced with Ad.LOXL1. ELN shows a globular conformation in the aggregate and a fiber shape away from it. Overexpression/secretion of LOXL1 induces LOXL1/FBN1 and LOXL1/ELN deposit-like aggregates. FBN1 forms microfibril bundles in most transduced LCs.

Conclusions: Lens organotypic cultures from capsulorhexis of normal- and XFS- cataractous lenses represent a unique model to identify mechanistic differences between normal and XFS cells. Morphological and functional similarities between XFS- and LOXL1-transduced cells reaffirm the functional relevance of LOXL1 and the prospect of using this gene to manage the disease. This model could also be used to search for potential treatments to disassociate and/or prevent XFM aggregates.

ABSTRACT BODY:

Purpose: Convergence and divergence eye movements become asymmetrical movements of both eyes when they are included in saccadic eye movements. The deviation of the fixation point with respect to the fixation target at the time of convergence and divergence eye movements can be quantified using eye tracking. In this study, we aimed to investigate the difference between fixation target and fixation point resulting from the difference in the moving speed of the fixation target.

Methods: We recruited nine university students without abnormalities as our subjects. For the measurement, we used a novel eye tracking device (nac Image Technology, Tokyo, Japan). As the subjects looked into this device with both eyes, the fixation target moved closer and farther from it in a pseudo manner. The subjects repeated convergence and divergence eye movements for 20 s by looking at the fixation target that moved between 0.3 m and 1 m. The sampling rate of the device was 30 Hz, and the movement speeds of the fixation target were 2, 4, 6, 8, and 10 deg/s. We measured the fixation point and calculated the difference from the fixation target. The difference between the fixation point and fixation target at each movement speed of the fixation target was tested using the Friedman test. P-value <0.05 was considered statistically significant.

Results: The differences between the fixation point and fixation target (median [25th–75th percentiles]) were 119.2 [70.6–191.7], 135.8 [101.2–147.6], 147.2 [135.1–173.7], 179.6 [175.4–209.0], and 203.3 [198.7–216.8] mm at 2, 4, 6, 8, and 10 deg/s, respectively. Friedman test revealed that the difference between the fixation point and the fixation target increased as the movement speed of the fixation target increased ($P < 0.001$).

Conclusions: As the movement speed of the fixation target increased, differences between the fixation point and the fixation target in the convergence and divergence eye movements increased, suggesting that the asymmetry of both eyes increased.

ABSTRACT BODY:

Purpose: Many studies measure aqueous VEGF concentration as a proxy for vitreous VEGF concentration. Usually, underlying these studies is the assumption that aqueous VEGF is merely the result of diffusion from the vitreous compartment. Here, we examine the validity of this assumption by implementing it into a mathematical model and assessing how well it fits real data compared to models which implement additional potential mechanisms of intraocular VEGF production and transport.

Methods: This study consists of a meta-analysis of prior studies followed by the generation and fitting of mathematical models to pooled study data. More specifically, a search of studies that simultaneously report both aqueous VEGF and vitreous VEGF concentrations was conducted, and the data was compiled to determine the relationship between the two concentrations and how their corresponding ratio varies with increasing concentration. Several mathematical models, each representing a different potential mechanism of VEGF production or transport, were then generated and fit to the data, and the resulting coefficients of determination (R^2 values) were compared.

Results: As Fig 1 shows, the base model, which only considers the production and subsequent diffusion of vitreous VEGF to the aqueous compartment, where it undergoes clearance, fit the meta-analysis data poorly (average R^2 = 0.162). Models which implemented additional mechanisms on top of the base model performed better (average R^2 values ranging from 0.463 to 0.707), with a model exhibiting supplementary VEGF production in the aqueous compartment or by the ciliary body performing best (average R^2 = 0.707).

Conclusions: The base model is insufficient to explain the relationship between aqueous and vitreous VEGF concentrations. Other mechanisms of VEGF production and/or transport must be present, with a strong candidate being the addition of VEGF production in the aqueous compartment or by the ciliary body.

ABSTRACT BODY:

Purpose: Telemedicine for remote grading of images has been effective in retinopathy of prematurity (ROP) screening in resource-limited settings. Ultra widefield fundus imaging systems can be cost-prohibitive for widespread use. Smartphone-based digital fundus imaging has been described as a low-cost alternative, however the relative effectiveness of this approach has not been fully evaluated. The purpose of this study is to compare ROP diagnosis between the Retcam (Natus Medical Incorporated, Pleasanton CA, USA) and a smart-phone based approach using the MII (Make in India) Retcam adapter.

Methods: 100 paired exams from 95 infants imaged on both the Retcam and MII were acquired during routine image-based ROP screening via telemedicine between August-September 2021 at Aravind Eye Hospital. Images were uploaded to a web-based data management system (iTeleGENx, Chicago, IL, USA) which enabled randomization and matching. A single grader was presented with demographics including birthweight and gestational age, and determined the ROP diagnosis according to the International Classification of Retinopathy of Prematurity. Exams were anonymized and presented in two time periods in random order to prevent recall bias. Sensitivity and specificity calculations were made for TR-ROP, Type 2 or worse, and pre-plus or worse in at least one eye.

Results: Using the Retcam as the gold standard, the sensitivity for type 2 or worse in either eye was 78.6% and specificity was 97.6%. For TR-ROP, the sensitivity was 100% and specificity was 98.9%. The sensitivity for Type 2 or worse on the Retcam and pre-plus or worse on the MII was 85.7% specificity was 90.6%. Table 1 summarizes the diagnosis of ROP on both devices with regards to zone, stage, presence or absence of plus disease, and category of disease.

Conclusions: The MII Retcam demonstrated high sensitivity and specificity for TR-ROP, though did not capture all eyes with type 2 ROP. This may be due to limitations in field of view, image quality, learning curve, or other factors. Our analysis suggests that if pre-plus can be clinically recognized using the MII Retcam, it could be used as a surrogate for the presence of Type 2 or worse disease. Referral criteria using lower field of view cameras should be evaluated, including potential applications of artificial intelligence to these cameras to evaluate vascular severity.

ABSTRACT BODY:

Purpose: While socioeconomic disparities impact clinical care and patient outcomes, their impact on the anatomic and visual outcomes of retinal detachment in patients with viral retinitis is unstudied.

Methods: This case series included 19 eyes in 19 patients from a single academic institution between January 1, 2008 and December 31, 2018. Patient characteristics including age, sex, race, ethnicity, insurance, immunosuppression, viral retinitis, retinal detachment, retinal detachment repair, visual and anatomic outcomes, missed appointments, and Area Deprivation Index [ADI] were collected.

Results: The low-ADI group, indicating less socioeconomic disadvantage, was comprised of twelve patients with national ADIs less than 38, and the high-ADI group of six patients with national ADIs greater than 38. High-ADI patients tended to be younger (average age 38.0 versus 51.3; P=0.056), of female sex (P=0.034), and had more missed appointments (median 11.0 vs 0; P=0.002). A similar number of patients in both the high-ADI and low-ADI groups underwent pars plana vitrectomy alone or pars plana vitrectomy with scleral buckle. Visual acuity was similar in the high-ADI group than in the low-ADI group at baseline, but worse at the final follow-up visit (P=0.004). Post-operative and final visit ocular hypotony were more common in the high-ADI group (P=0.022).

Conclusions: In our series, socioeconomic disadvantage negatively affects the visual outcomes in patients with viral retinitis associated-retinal detachments. These factors should be considered by ophthalmologists when treating these patients.

ABSTRACT BODY:

Purpose: Oxidative stress and inflammation are common phenomena in Dry Eye Disease (DED). However, their roles in the pathogenesis of DED need to be clarified. In our study, we illustrated the relationship between oxidative stress and DED in vitro, with a mitochondria-targeted antioxidant, SkQ1.

Methods: Tert-butyl hydroperoxide (TBHP) was added in cultured human corneal epithelial cell (HCEC) for oxidant damage model. 4 hydroxynonenal (4-HNE) and Malondialdehyde (MDA) were determined as indicated biomarker of oxidant damage. The antioxidant effect of SkQ1 was evaluated. Two dry eye in vitro models were set up by culturing HCEC in hypertonic medium or media with 0.0002% benzalkonium chloride (BAK). Cell statuses were monitored by viability assay (MTT), Reactive Oxygen Species (ROS) assay (FACS and fluorescent staining) and apoptosis assay (FACS), cytokines and matrix metalloproteases were quantified with ELISA.

Results: ROS, 4-HNE and MDA level were increased in TBHP model. SkQ1 effectively eliminated ROS, associated with reduced apoptosis and IL-6, MMP3 production. The relationship between oxidant damage and DED was explored using hyperosmolarity and BAK-induced in vitro models. Excessive mitochondrial ROS was found in both models and happened earlier than cell apoptosis and viability loss. SkQ1 significantly reduced level of mitochondrial ROS, followed by decreased cell apoptosis and reversed cell viability. Upregulation of inflammatory factors production was determined in each model (IL-6, MMP3, MMP9 in hyperosmotic model; IL-1α, IL-6, MMP9 in BAK model), while SkQ1 effectively down-regulates the protein level of these DED-associated cytokines and matrixes.

Conclusions: Our finding indicates that increased mitochondrial ROS level widely occurs in DED models which orchestrates cell apoptotic and inflammatory responses. Antioxidant SkQ1 reverts these cell damages, offering an universal therapeutic potential. 4-HNE and MDA, as widely accepted biomarkers in DED, were significantly upregulated in dry eye patients' tears, suggesting a perspective clinical application of antioxidant agent for DED.

TITLE: Rate of Children Treated for Strabismus and Amblyopia Strongly Correlates with the Prevalence of Pediatric Ophthalmologists in US States

SESSION TITLE: Pediatric Ophthalmology Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Paul, T. Frempong, Department of Medical Education, Icahn School of Medicine at Mount Sinai, New York, New York, UNITED STATES|T. Frempong, Department of Ophthalmology, New York Eye and Ear Infirmary of Mount Sinai, New York, New York, UNITED STATES|

Commercial Relationships Disclosure: Megan Paul: Commercial Relationship: Code N (No Commercial Relationship) | Tamiesha Frempong: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Strabismus and amblyopia occur in approximately 3% of US children by age three and, if treated early, can be corrected with excellent results. However, pediatric ophthalmologists (POs) are currently in high demand across the US. Therefore, this ecological study seeks to determine whether the prevalence of POs is associated with the rate of children treated for strabismus and amblyopia in the US.

Methods: The Vision and Eye Health Surveillance System was used to determine each state's rate of treated strabismus and amblyopia. The number of POs by state was determined using the American Association for Pediatric Ophthalmology website while population was taken from the US Census Bureau. A bivariate linear regression compared the prevalence of POs by state to the rate of children treated for strabismus and amblyopia. This was repeated but controlled for health insurance and race by state. A final linear regression compared the economic cost of pediatric vision issues using the Vision Health Initiative and the prevalence of POs in states.

Results: The highest prevalence of POs was in Maryland while the lowest were in Vermont and Wyoming. In the bivariate regression, there was a positive association between the rate of children treated for strabismus and amblyopia and the prevalence of POs ($\beta=2.97$, $p<0.01$). After controlling for health insurance and race, the rate of treated children was still positively associated with the prevalence of POs in each state ($\beta=2.58$, $p<0.01$). Notably, while the prevalence of POs and economic burden of vision issues were not statistically associated ($p=0.196$), Vermont had the highest economic burden of vision issues in children among all states.

Conclusions: This study indicates that the prevalence of POs in a given state is strongly tied to the rate of children being treated for strabismus and amblyopia, even after controlling for health insurance and race. In states where there is a lower prevalence of POs, there are potentially children who are not treated for eye conditions. This is substantiated by the fact that Vermont had one of the lowest rates of POs but the highest economic burden. While more physicians should be encouraged to enter this field, other strategies like telehealth and training technicians in underserved areas may help to mitigate these disparities.

ABSTRACT BODY:

Purpose: The Wwtr1 gene encodes the transcriptional co-activator with PDZ-binding motif (TAZ), which is a mechanotransducer that can be activated via Rho GTPase activity and actin cytoskeletal tension. Mice deficient in TAZ demonstrate a softer Descemet's membrane (DM) and decreased corneal endothelial cell (CEnC) density. The purpose of this study was to evaluate the impact of Rho-associated protein kinase (ROCK) inhibition on CEnCs and DM in wildtype (WT) and heterozygous TAZ ($Wwtr1^{+/-}$) knockout mice.

Methods: Beginning at 6 months of age, 12 WT and 12 $Wwtr1^{+/-}$ mice were treated with topical netarsudil 0.02% ophthalmic solution (Rhopressa©) or vehicle control twice daily for 6 months. Endothelial cell density (ECD) was monitored using in vivo confocal microscopy. To compare the degree of age-related CEnC loss over time, % ECD change from baseline values were calculated. Following 6 months of treatment, all mice were euthanized and eyes were collected. For the right eyes, elastic modulus of Descemet's membrane (DM) was measured with atomic force microscopy. The left eyes were used for immunofluorescence staining of actin-phalloidin on corneal endothelial wholemounts.

Results: The $Wwtr1^{+/-}$ mice had softer DM than WT mice in control groups; however, treatment with topical netarsudil significantly stiffened DM of $Wwtr1^{+/-}$ mice compared with treated control ($Wwtr1^{+/+}$) mice. There were no statistical differences in % ECD change between netarsudil-treated versus control groups at each timepoint in both WT and $Wwtr1^{+/-}$ mice. While ECD was mildly lower in $Wwtr1^{+/-}$ versus WT mice at baseline, no differences were observed between groups at study termination. Distinct actin-phalloidin staining pattern such as bleb-like appearance was observed in netarsudil-treated groups of both WT and $Wwtr1^{+/-}$ mice consistent with cytoskeletal rearrangement by topical ROCK inhibition.

Conclusions: Topical netarsudil increased DM stiffness in $Wwtr1^{+/-}$ mice to approximate that of WT control mice, suggesting that ROCK inhibition modulates CEnC-matrix interactions. The lack of ECD change is likely due to the mild phenotype displayed by this cohort of $Wwtr1^{+/-}$ mice. Further study with $Wwtr1^{-/-}$ mice with more severe ECD loss is warranted to determine the impact of long-term ROCK inhibition on CEnC loss.

TITLE: Five-year effects of selective laser trabeculoplasty
SESSION TITLE: IOP and laser therapy
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: D.L. Swain, B. Eliassi-Rad, Ophthalmology, Boston University School of Medicine, Boston, Massachusetts, UNITED STATES|D.L. Swain, Anatomy and Neurobiology, Boston University School of Medicine, Boston, Massachusetts, UNITED STATES|
Commercial Relationships Disclosure: David Swain: Commercial Relationship: Code N (No Commercial Relationship) | Babak Eliassi-Rad: Commercial Relationship: Code N (No Commercial Relationship)
ABSTRACT BODY:
Purpose: Studies have shown the efficacy of selective laser trabeculoplasty (SLT) to lower intraocular pressure (IOP) as adjuvant therapy during short-term follow-up; however, few studies have assessed the long-term efficacy of SLT on preventing worsening visual fields and thinning of retinal nerve fiber layer (RNFL) with continued medical therapy. We examined IOP, visual field parameters, and RNFL thickness at 3- and 5-yrs post-SLT.
Methods: A retrospective chart review was performed of 51 eyes of 39 patients with glaucoma treated with SLT at Boston Medical Center between 2012 – 2016 with subsequent follow-up with Humphrey visual field (HVF) and optical coherence tomography (OCT) exams. Outcome measures included IOP, visual acuity, number of glaucoma medications, number of months to subsequent surgical intervention. HVF outcomes included mean deviation (MD) and pattern standard deviation (PSD). OCT outcomes included RNFL mean thickness, and superior and inferior quadrant thickness.
Results: Twenty-five eyes required subsequent surgical intervention to control IOP (mean time to intervention = 33.6 ± 20.0 months) within the follow-up period. In 26 of 51 eyes, IOP was controlled at 5-yrs after SLT. In this group, mean IOP was significantly decreased by 3 mmHg and 3.5 mmHg at 3- and 5-yrs after SLT, respectively. Mean number of glaucoma medications was significantly increased at 5-yrs (2.8 ± 1.6; P = 0.02), compared to pre-SLT (2.1 ± 1.1). Mean HVF MD was significantly higher at 5-yrs (-8.07 ± 7.15 dB) compared to pre-SLT (-5.85 ± 4.04 dB). Mean PSD significantly increased at 3-yrs (5.38 ± 2.94 dB) and 5-yrs (6.76 ± 2.79 dB), compared to pre-SLT (4.78 ± 2.93 dB; P = 0.04 and ≤ 0.01, respectively). Inferior quadrant RFNL thickness decreased significantly at 5-yrs (91.1 ± 20.8 µm), compared to pre-SLT (95.4 ± 23.0 µm).
Conclusions: Overall, 51% of eyes had IOP controlled at 5-yr post-SLT with continued medical therapy; however, mean number of glaucoma medications was significantly higher. Also, there was progression of MD and PSD on HVF and inferior quadrant thinning on OCT at 5-yr follow-up. Our findings suggest that SLT may have some long-term benefit in controlling IOP with continued medical therapy. However, a significant number of patients required subsequent laser/surgical procedure to lower IOP, prevent worsening visual fields, and thinning of RFNL.

ABSTRACT BODY:

Purpose: Direct reprogramming of glia into neurons is a potentially promising approach for the replacement of neurons lost to injury or neurodegenerative disorders. Knockdown of the polypyrimidine tract-binding protein Ptbp1 has been recently reported to induce efficient conversion of retinal Muller glia into functional neurons. However, several major concerns remain to be addressed. First, none of these approaches convincingly demonstrated a reduction of Ptbp1 expression in glial cells in situ. Second, lineage relationships between glia and neurons were inferred through the use of GFAP promoter-based AAV constructs or transgene, which are known to show neuronal expression in some contexts. Third, convincing evidence for direct glia-to-neuron conversion using reliable genetic lineage analysis and/or single-cell RNA-Sequencing (scRNA-Seq)-based trajectory analysis is missing. These concerns need to be addressed before the Ptbp1 knockdown approach can further advance toward clinical applications.

Methods: Here, we use a combination of genetic lineage tracing, scRNA-Seq, and electroretinogram analysis to show that specific deletion of Ptbp1 in adult retinal Muller glia does not lead to any detectable level of neuronal conversion.

Results: Only a few changes in gene expression are observed in Muller glia following Ptbp1 deletion, and glial identity is maintained. These findings highlight the importance of using genetic manipulation and lineage tracing methods in studying cell type conversion.

Conclusions: Our data indicate that the Muller glia-to-neuron conversion reported in previous studies following Ptbp1 knockdown does not reflect the effects of Ptbp1 loss of function.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is a blinding disease characterised by dysfunction of the retinal pigmented epithelium (RPE) which culminates in disruption or loss of the neurosensory retina. Genome-wide association studies have identified >60 genetic risk factors for AMD, however the expression profile and functional role of many of these genes remain elusive in human RPE. Development of a simple-to-use in vitro RPE model would help us study the complex genetics and pathogenesis of AMD.

Methods: To facilitate functional studies of AMD-associated genes, we developed a human RPE model with integrated CRISPR interference (CRISPRi) for gene repression by generating a stable ARPE19 cell line expressing dCas9-KRAB. To demonstrate the potential of this CRISPRi RPE system, we performed transcriptomic analysis of the human retina to prioritise AMD-associated genes and selected TMEM97 as a candidate gene for further knockdown study. Following CRISPRi-mediated knockdown of TMEM97, we analysed cell viability and oxidative stress levels to determine its functional role in ARPE19.

Results: Characterisation of CRISPRi ARPE19 show that the cell line retains stable expression of dCas9-KRAB for at least 2 months. Moreover, the CRISPRi ARPE19 cell line expresses RPE marker ZO-1 and retains the ability to form a polarised monolayer with hexagonal RPE morphology following nicotinamide treatment, supporting the quality of the derived cell line. Our results show that CRISPRi enables significant knockdown of TMEM97 in ARPE19 using specific sgRNAs. In particular, knockdown of TMEM97 in ARPE19 reduces reactive oxygen species (ROS) levels and exerts a protective effect against oxidative stress-induced cell death. This work provides the first functional study of TMEM97 in RPE and supports a potential role of TMEM97 in AMD pathobiology.

Conclusions: Our study demonstrates the potential for using CRISPRi to study AMD-associated genes in RPE, and the CRISPRi RPE platform generated here provide a useful in vitro tool for functional studies of AMD-associated genes.

ABSTRACT BODY:

Purpose: Recently, we (PNAS 2020) and other groups have successfully generated human retinoblastoma (Rb) organoids from pluripotent stem cells with specific mutations of RB1 gene. This study was aimed to establish Rb organoids derived from patient-specific induced pluripotent stem cells (iPSCs) for disease modeling and tumorigenesis study.

Methods: First, we generate iPSCs from an Rb patient with defined heterozygous mutation in RB1 ($RB1^{m1/wt}$). The second allelic mutation was constructed by CRISPR/Cas9 gene editing ($RB1^{m1/m2}$). Established iPSCs were developed into well-layered retinal organoids (ROs) through step-wise differentiation. Live imaging, RNA-Seq and immunostaining were carried out to analyze the Rb organoids.

Results: The $RB1^{m1/m2}$ iPSC-derived ROs displayed apparent tumorigenesis and biological features, consistent with Rb in patients. High-resolution X-ray computer tomography (microCT) scanning confirmed the rosette-like structure and more pores in Rb organoids. The gene enrichment of Rb organoids found by RNA-Seq analysis were highly related to cell cycle. Compared with $RB1^{m1/wt}$ and $RB1^{wt/wt}$ derived ROs, tumor-related markers including SYK, $p16^{INK4a}$, DEK were highly expressed in both the solid tumor and the adjacent tissues in $RB1^{m1/m2}$ derived ROs. We also found the highly expression of photoreceptor precursor markers, CRX and OTX2, in $RB1^{m1/m2}$ derived ROs, in line with Rb derivation from cone-committed cells. Besides, immunostaining showed that ARR3 positive maturing cone precursors are co-localized with proliferative markers Ki67 or PCNA, indicating Rb is originated from maturing cone precursors.

Conclusions: Combined with CRISPR/Cas9 technology and 3D retinal organoids differentiation, we successfully generated Rb organoids and observed tumorigenesis in vitro which derived from $RB1^{m1/m2}$ iPSCs with patient-specific genetic background. Rb organoids generated from iPSC with RB1 compound heterozygous mutation resemble real Rb in structural and molecular aspects.

TITLE: Prevalence of ocular involvement from comorbid autoimmune disease in patients with Type 1 Diabetes

SESSION TITLE: Diabetic retinopathy epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Shin, T. Winter, S. Orsdemir, Loma Linda University School of Medicine, Loma Linda, California, UNITED STATES|

Commercial Relationships Disclosure: Matthew Shin: Commercial Relationship: Code N (No Commercial Relationship) | Timothy Winter: Commercial Relationship: Code N (No Commercial Relationship) | Sena Orsdemir: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Type 1 Diabetes (T1D) is an autoimmune disease associated with Hashimoto's thyroiditis (HT), Celiac disease (CD) and several other autoimmune diseases, but there is no report exploring the prevalence of eye disease in those with comorbid autoimmunity. This study investigates the frequency of ocular involvement (OI) in patients with T1D and one or more autoimmune diseases.

Methods: Retrospective chart review of patients with T1D, ages 1-100, with one or more autoimmune conditions that may affect the eyes at a tertiary referral center. Co-existing autoimmune diseases involving the eye were specified to include Hashimoto's Thyroiditis, Celiac disease, Systemic Lupus Erythematosus, Graves disease, Multiple Sclerosis, Juvenile Idiopathic Arthritis, Sjogren's syndrome, Ankylosing Spondylitis, Sarcoidosis, and Reactive Arthritis.

Results: 3,880 patients (mean age 36.9 years (median 29), 57.4% female, 47.3% Caucasian) with T1D were identified, of which 331 (8.53%) had one or more comorbid autoimmune condition(s) and OI was present in 13 (3.9%). Similar to other reports in the literature, 186 (4.8%) had HT and 98 (2.5%) had CD. Two autoimmune conditions were present in 302 patients with 8 (2.65%) having OI, 26 patients had three autoimmune conditions with 3 (11.5%) having OI and 3 patients had four autoimmune conditions with 2 (66.7%) having OI. The autoimmune diseases thought to affect the eye included Lupus with uveitis in 1/25 (4%), Graves disease with OI in 3/22 (13.6%), Multiple Sclerosis with OI in 2/9 (22.2%), Juvenile Idiopathic Arthritis with uveitis in 1/7 (14.3%), Sjogrens with OI in 5/6 (88.3%), Ankylosing Spondylitis with OI in 0/5 (0%), Sarcoidosis with OI in 1/3 (33.3%) and Reactive Arthritis with OI in 0/2 (0%).

Conclusions: Ocular involvement from one or more comorbid autoimmune diseases in patients with T1D is uncommon, but becomes more likely with increasing number of comorbid autoimmune diseases. Further clinical studies and reviews will be needed to understand the pathophysiology of this finding.

ABSTRACT BODY:

Purpose: A training exercise was performed using en face optical coherence tomography (OCT) images to study the ability of graders to reliably identify persistent choroidal hyper-transmission defects (hyperTDs), also known as complete retinal pigment epithelium and outer retinal atrophy (cRORA).

Methods: Formal training on how to identify persistent hyperTDs on en face OCT images was provided to 11 graders. Persistent hyperTDs were defined as bright, well-delineated lesions having a greatest linear dimension (GLD) of at least 250 µm. Training consisted of a tutorial session followed by the grading of three pretest exercises, each consisting of three cases. After all the graders scored 100% on the pretest exercises, they evaluated a final test set consisting of 30 en face OCT images from 29 eyes with non-exudative age-related macular degeneration (AMD). These images contained 107 hyperTDs, as determined by a senior author (P.J.R.) and represented a variety of AMD-related atrophic lesions.

Results: A total of 1177 hyperTDs from 30 en face OCT images were reviewed by the graders. The mean sensitivity, PPV, and modified accuracy for all the graders were 99.0%, 99.2%, and 98.2%, respectively. There was a 97% agreement observed between all the graders (AC_1 = 0.97). Internal graders from the Bascom Palmer Eye Institute had a slightly higher agreement compared with the external graders (AC_1 = 0.98 vs. 0.96). The hyperTDs most often incorrectly identified included the following features: (1) hyperTDs containing a hypo-transmission defect (hypoTD) core, (2) single hyperTDs that were incorrectly graded as two separate lesions, and (3) hyperTDs with a borderline GLD close to 250 µm.

Conclusions: The accurate detection of persistent hyperTDs on en face OCT images by graders demonstrates the feasibility of using this OCT biomarker to identify disease progression in eyes with non-exudative AMD. Thus, hyperTDs can represent a clinical trial endpoint in studies designed to test new therapies that may slow disease progression from intermediate AMD to cRORA.

ABSTRACT BODY:

Purpose: Positron emission tomography (PET) is a well-established imaging modality to assess tissue metabolism while magnetic resonance imaging (MRI) and computed tomography (CT) are used to provide anatomical information. Combining PET with MRI or CT imaging may provide unique insight into the in vivo pathophysiology of extraocular motility (EOM) in numerous disease processes. The aim of the study was to use 18F-fluorodeoxyglucose (18F-FDG) PET MRI/CT to characterize the structure-function relationships of EOM disorders.

Methods: 18F-FDG PET MRI and CT scans were performed in patients with EOM disorders. The maximum standardized uptake value (SUVmax), a marker of glucose metabolism, was calculated for the lateral, medial, superior, and inferior rectus muscles, as well as the cerebellum. These were compared to SUVmax values of the same structures from control patients without EOM dysfunction.

Results: In our preliminary observations, three orbits with hypoactive motility disorders were compared to five orbits without EOM disorders on 18F-FDG PET MRI and CT imaging. The SUVmax of extraocular muscles in hypoactive motility disorders was significantly less than that of control extraocular muscles, including the superior rectus (mean 2.8 ± SD 1.18 and 6.3 ± 1.20, $p = 0.008$), inferior rectus (3.83 ± 0.91 and 12.73 ± 0.98, $p < 0.00001$), medial rectus (3.37 ± 0.78 and 10.8 ± 2.09, p 0.002) and lateral rectus muscles (3.03 ± 0.55 and 7.98 ± 2.27, $p = 0.015$). There was no significant difference in SUVmax of the cerebellum in both groups (12.33 ± 0.80 and 10.725 ± 0.97, $p = 0.069$) demonstrating equivalent metabolite uptake.

Conclusions: 18F-FDG PET MRI and CT has the ability to illustrate differences in metabolic functioning in hypoactive EOM disorders. The high clinical potential of combining high resolution anatomic structural detail with the metabolic profile of the extraocular muscle will enable improved analysis of extraocular motility and identification of new pathologies.

ABSTRACT BODY:

Purpose: The impact of diet and gut dysbiosis on the pathogenesis of retinal disorders has recently been described, but the precise mechanism remains unclear. Previously, our team profiled the retinal transcriptome in the context of high fat diet (HFD) induced gut dysbiosis. Yet, the effect of gut microbial imbalance on the retinal pigment epithelium (RPE) and choroid, key players in retinal diseases, is unknown. Through multi-omics analysis, the purpose of this study is to identify how the RPE/choroid transcriptome is modulated by HFD-induced gut dysbiosis and microbiome-transcriptome associations.

Methods: RPE-choroidal tissue was dissected from C57BL/6 mice on normal diet or fed 23% HFD for 8 weeks (4 mice/group). RNA-seq was performed on NovaSEQ6000. Limma and LYNX were used for functional enrichment analysis of differentially expressed genes (DEGs). 16S rRNA-seq was performed on fecal DNA, and taxonomical microbiome composition was analyzed with QIIME2. Taxonomy was associated with retinal and RPE/choroidal transcriptomic data via Pearson correlation at the genus level within matched mice. The correlation matrix was filtered to contain only significant genera ($p<0.05$) with at least one DEG to highlight relevant host-microbiome associations.

Results: We identified 60 potential DEGs related to HFD ($p<0.05$, $logFC>1$, $logFC<-1$) in the RPE/choroid transcriptome including Serpine1 and Fabp7, players in angiogenesis and fatty acid homeostasis, respectively. Enrichment analysis further highlights a number of key regulatory pathways in angiogenesis and signal transduction. In the choroid, Ppargc1a, a coactivator in angiogenesis and oxidative stress regulation, was found to be tightly correlated with the HFD-associated phylum Firmicutes. Meanwhile, fibronectin and matrix metalloproteinases, both ECM components involved in debris deposition and retinal disease, were strongly associated with the class Clostridia in the retina.

Conclusions: Our study reveals a number of RPE-choroidal genes and pathways modulated by HFD-induced gut dysbiosis. In addition, the genes' implications in various retinal pathologies shed insight into the role of the gut-retina axis in diseases such as AMD. Finally, the strong correlation between specific chorioretinal genes and microbial populations may provide better understanding of the interplay in microbiome-chorioretinal pathways.

TITLE: Melatonin Reduces Optic Nerve Crush-Induced Retinal Ganglion Cells Senescence Via the SIRT1-dependent Pathway

SESSION TITLE: Pharmacology/cellular mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Shi, Y. Xu, J. Huang, Sun Yat-Sen University Zhongshan Ophthalmic Center State Key Laboratory of Ophthalmology, Guangzhou, Guangdong, CHINA|

Commercial Relationships Disclosure: Yuxun Shi: Commercial Relationship: Code N (No Commercial Relationship) | Yue Xu: Commercial Relationship: Code N (No Commercial Relationship) | Jingjing Huang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Melatonin, a hormone mainly secreted by pineal gland, is believed to be involved in exerting the protective effects in the aged-related and neurodegenerative diseases through silent information regulator type 1 (SIRT1)-dependent pathway. However，the effect of melatonin on retinal ganglion cells (RGCs) senescence was unknown. Thus, in this study, we aimed to examine the effect of melatonin on RGCs senescence following optic nerve crush (ONC) and explore whether SIRT1 was involved in this process.

Methods: ONC model was established in this study. EX527, an inhibitor of SIRT1, was injected intraperitoneally into mice 30 minutes before ONC and melatonin was administrated abdominally into mice after ONC every day. The immunofluorescence and western blot were used to evaluate the expression of SIRT1, p16 and p53. β-gal staining was employed to detected senescence cells. Hematoxylin & eosin (HE) staining, retina flat-mounts and optical coherence tomography (OCT) were used to evaluate the loss of retina tissue. Pattern electroretinogram (p-ERG) was performed to evaluate the visual function of retina.

Results: Melatonin stimulated the expression of SIRT1 in RGCs 3 days after ONC, which was normally expressed in RGCs of normal C57BL/6J mice and decreased after ONC. Meanwhile, the melatonin therapy restored the decreased RGCs numbers and ganglion cell complex (GCC) thickness ($p<0.001$, 0.01, respectively) 14 days after ONC. Moreover, the treatment of melatonin suppressed the ONC-induced senescence index at day 3 by decreasing the expression of p16, p53 and β-gal positive cells ($p<0.05$). Furthermore, the p-ERG showed that melatonin improved the amplitude of P50 and N95 ($p<0.05$). Besides, administration of EX527 decreased the protective effect of melatonin after ONC, which revealed that SIRT1 was involved in the process of melatonin regulating RGCs senescence after ONC.

Conclusions: Our data suggested that melatonin ameliorated the RGCs senescence via the SIRT1-dependent pathway following ONC, which may provide an important insight for the treatment of RGC senescence.

ABSTRACT BODY:

Purpose: Excessive formation and residence of myofibroblasts in stroma following ocular trauma/injury leads to loss of corneal transparency and vision impairment. This study sought to determine if corneal myofibroblasts could be de-differentiated into precursor fibroblasts/keratocytes via epigenetic reprogramming using an established in vitro model.

Methods: Primary human corneal stromal fibroblasts (hCSFs) generated from healthy donor corneas were used to generate human corneal myofibroblasts (hCMFs) by exposing cultures to transforming growth factor beta1 (TGFβ1; 5 µg/mL) for 72 h. Sodium Butyrate (NaB), an epigenetic modifier and histone deacetylase inhibitor, was used to induce epigenetic reprogramming by growing hCMFs in +/- NaB for 72 h. Trypan blue exclusion assay and phage-contrast microscopy were used to examine cytotoxicity and morphologic changes. Quantitative reverse transcription PCR (qRT-PCR) and immunofluorescence were used to study the expression of α-smooth muscle actin (α-SMA), collagen type 3 (Col 3), and fibroblast-specific protein 1 (FSP1). The DNA methylation was quantified by measuring the 5-methylcytosine (5-mC) levels with a commercial assay kit.

Results: TGFβ1 treatment converted >95% hCSFs to hCMFs with significant upregulation of α-SMA protein and gene expression. A dose-dependent cytotoxicity assay with NaB (0-100 mM) in CMFs showed IC_{50} of NaB 20.38 mM. CMFs treated with NaB for 72 h led to the disappearance of typical myofibroblastic morphology and demonstrated a significant reduction in α-SMA, and Col 3, and increase in FSP1 expression compared to control untreated CMFs ($p < 0.05$). A significantly increased DNA methylation was observed in NaB-treated CMFs compared to the control untreated CMFs ($p < 0.05$).

Conclusions: Dedifferentiation of corneal myofibroblasts to precursor fibroblasts seems possible via epigenetic reprogramming with NaB. Further studies are warranted.

ABSTRACT BODY:

Purpose: It is not known whether Dual Energy-Computed Tomography (DE-CT) might be able to detect differences in the crystalline lens that could be related to physiologic differences in lens opacity or incidental cataract formation. This study investigated whether there is a relationship between possible demographic and clinical risk factors for cataract and x-ray attenuation of the crystalline lens on DE-CT of the head.

Methods: Retrospective review of 198 eyes in 103 adult subjects who underwent DE-CT exams of the head. Regions of interest spanning 3-5 mm^2 were placed over the center of the native crystalline lens and the x-ray attenuation of each lens was recorded in Hounsfield Units (HU) at 3 DE-CT energy levels: 40 keV, 70 keV, and 190 keV. Demographic and environmental risk factors for cataract were collected from the medical record. Generalized estimating equations were used to assess the relationship between these risk factors and relative density of the lens at each energy level.

Results: The mean age in the older vs. younger cohort was 81.4 5.7 yrs vs. 22.66 2.93 yrs. 46.6% of subjects were female, 38.8% non-Hispanic white, 22.3% diabetic, and 37.9% never smokers. The mean HU attenuation values were significantly lower for the older vs. younger group (GEE $p=0.022$) at 40 keV, but there was no significant difference at higher energy levels (70 or 190 keV; all $p>0.05$). Mean HU attenuation values were significantly higher for females vs. males (40 keV: 76.4±13.3 vs. 70.7±1.3; 70 keV: 79.0±7.4 vs. 74.2±7.6; 190 keV: 80±7.9 vs. 75.8±9; all $p<=0.01$) and non-whites vs. non-Hispanic whites (40 keV: 77.6±13.1 vs. 70.5±13.2; 70 keV: 80±7.9 vs. 74.1±7.0; 190 keV: 81.0±8.1 vs. 75.5±8.5; all $p<=0.001$) at all 3 energy levels. However, there was no significant association between lens attenuation and either diabetes or smoking status (all $p>0.05$). In multivariable analysis, both female sex (all $p<0.01$) and nonwhite race (all $p<0.01$) but not age-group ($p>0.05$) remained significant independent predictors of lens attenuation at all 3 energy levels.

Conclusions: The crystalline lens of females and non-white subjects had significantly higher attenuation on DE-CT, which may suggest higher density or increased concentration of materials like calcium. These groups may be at greater risk for cataracts independent of other well-known risk factors such as age, diabetes, or smoking status.

ABSTRACT BODY:

Purpose: Congress passed the CARES Act (Coronavirus Aid, Relief, and Economic Security) Provider Relief Fund to help healthcare providers recoup lost revenue during the pandemic. We aimed to determine how much of this federal aid was provided to ophthalmology and optometry practices, and whether the amount of aid received varied based on practice size.

Methods: We used the Centers for Medicare and Medicaid Services (CMS) Physician Compare National Database to identify medical practices that provide eye care. We used practice names to link this database to the Health and Human Services (HHS) Provider Relief Fund (PRF) database to determine how much aid each practice received through the CARES Act.

Results: We identified 2,625 optometry or ophthalmology practices that received funding through the CARES Act Provider Relief Fund that were not hospital-owned or affiliated with multi-specialty practices. Large practices with more than 10 clinicians accounted for only 268 of the 2,625 practices in our sample, but received nearly half of all funding ($182 million). Per-practitioner funding varied based on practice size (p=0.047), but differences in per-practitioner funds were not significant after adjusting for practice specialty (ophthalmology, optometry, or both).
We also found that retina specific practices tended to receive more than their counterparts.

Conclusions: This study demonstrates a relatively uniform distribution of per capita funds when adjusted for ophthalmologists, optometrists, and mixed-practices regardless of practice size. This policy demonstrates how federal aid is distributed to independent ophthalmology practices, and
that smaller practices which are at higher risk may need larger per capita payments to remain viable during times of economic stress.

ABSTRACT BODY:

Purpose: To characterize the morphology and functional aspects of an unusual incidental finding in two treatment-naïve cynomolgus macaques.

Methods: Animal #1 was a 2.8 kg, 2.67-year old male of Cambodian origin. Animal #2 was a 3.9 kg, 7.75-year old female of Chinese origin. Both animals underwent clinical ophthalmoscopic examination, color fundus photography, spectral domain optical coherence tomography (OCT), blue (BAF) and infrared (IRFA) fundus autofluorescence, fluorescein angiography (FA), full field electroretinography (ERG), and flash visually evoked potentials (fVEP). Animal #1 also had genomic analysis conducted to assess for known molecular mutations.

Results: Both animals had normal anterior segments including corneas, lenses and vitreous. No cell or flare was noted. Animal #1 had numerous prominent white spots in the macula (Figure 1) and extending peripherally to about 2 disc diameters beyond the nasal margin of the optic disc and the arcade vessels in both eyes. The peripheral retina was unremarkable. FA showed the spots to be window defects, i.e., early hyperfluorescence with late fading but no leakage. The spots were hyper-BAF, hypo-IRAF. OCT showed thickening at the interdigitation zone (IZ) (Figure 2). Animal #2 had fainter spots, but the size and distribution were similar to Animal #1. Except for the fundus findings, both animals were otherwise healthy. Scotopic and photopic ffERG and fVEP were normal. Whole genome sequence analysis of Animal #1 was negative for EFEMP1 (Doyne's), RDH5 (albipunctatus) and RLBP1 (retinitis pigmentosa).

Conclusions: We have not observed similar white spots in the thousands of cynomolgus macaques examined over the past two decades. Thus, the finding is rare in our cohort of animals. There is no obvious human correlate to these spots. They appear to be functionally benign and are not associated with inflammation. The spots were fainter in the older animal, which could indicate fading over time or just be individual variation. Yiu, et al (Sci Rep 2017;7:1513) reported drusenoid lesions in rhesus macaques but the OCT thickening in our animals is in the IZ, not at Bruch's membrane. These findings illustrate the importance of baseline ocular examinations in preclinical toxicity studies.

ABSTRACT BODY:

Purpose: Retinopathy of Prematurity (ROP) screening criteria vary around the world based on the population at risk. Screening criteria based on birthweight (BW) and gestational age (GA) can be more broad in low- and middle-income countries like India, where ROP can be more commonly seen in less premature babies than in the US. The purpose of this project was to evaluate the effect of various screening criteria on a large population of premature babies in South India.

Methods: We analyzed two years of data from the Aravind Eye Hospital ROP telescreening program (1/1/19-12/31/20). During that period, participating neonatal care units referred babies for screening who were less than 36 weeks postmenstrual age (PMA), or less than 2000 grams, or who had other risk factors for ROP. We evaluated 3 different screening criteria for sensitivity and specificity for detecting treatment-requiring (TR) ROP: US screening criteria (<31 weeks[w] PMA or < 1500 grams[g] BW), Indian criteria (<36w or <2000g), and intermediate criteria (<34w or <1750g).

Results: The sensitivity / specificity of the 3 sets of guidelines (India, Intermediate, and US) were 100% / 13%, 100% / 40%, and 85% / 67%, respectively, as seen in the table. Of the entire screened population (N = 2714 babies), use of intermediate criteria would reduce screening burden by 38% without missing a case of TR-ROP in this population.

Conclusions: ROP screening criteria evolve as demographics and practices in a region change. Current Indian screening criteria are 100% sensitive, but nonspecific, and US screening criteria are insufficiently sensitive for implementation in this Indian population. An intermediate cutoff produced 100% sensitivity with 38% reduced screening burden and can be considered in the future if 100% sensitivity can be ensured.

ABSTRACT BODY:

Purpose: There is discrepancy in reported studies on correlations between in vivo confocal microscopy (IVCM) findings in the cornea and clinical parameters of dry eye disease (DED). The purpose of our study is to evaluate this correlation in our patients.

Methods: This cross-sectional study included 80 eyes of 40 patients with DED which was defined as symptoms of DED plus abnormal tear breakup time (TBUT) or Schirmer test. Patients with previous ocular surgery or contact lens use were excluded. All patients underwent a comprehensive ocular surface evaluation which included Ocular Surface Disease Index (OSDI) questionnaire, corneal fluorescein staining (CFS, NEI grading, 0-15), conjunctival lissamine green staining (LGS, NEI grading, 0-18), TBUT, Schirmer test with anesthesia, and tear osmolarity. In addition, IVCM was performed in the central cornea of both eyes. Three IVCM images of subbasal area were used to measure subbasal nerve fiber length (SNFL) and dendritic cell (DC) density by two independent masked observers. The average values of both observers were used for analysis. Correlations between IVCM parameters and clinical parameters were then investigated.

Results: There were 35 women and 5 men, with a mean age of 61.4±15.1 years (range, 26-86 years). The average values were 53.15 ± 25.4 for OSDI, 6.1 ± 4.3 for CFS, 3.5 ± 3.9 for LGS, 4.9 ± 2.5 seconds for TBUT, 10.6 ± 6.5 mm for Schirmer, and 300.6 ± 27.7 for tear osmolarity. The mean SNFL was 14.69 ± 6.15 mm/mm^2 and mean subbasal DC density was 114.4 ± 64.3 cells/mm^2. Correlation analysis showed that OSDI had significant correlation with CFS (P=0.001, r= 0.60) and Schirmer (P=0.017, r= -0.46). CFS also had significant correlations with LGS (P=0.001, r=0.58), TBUT (P=0.002, r= -0.57), and Schirmer ((P=0.003, r= -0.55). There was also a significant negative correlation between SNFL and age (P=0.028, r= -0.42). However, there were no statistically significant correlations between SNFL or DC density and other clinical parameters. Osmolarity also showed no correlations with any IVCM or clinical parameters.

Conclusions: There are no significant correlations between IVCM parameters and clinical signs or symptoms of DED. Caution should be exercised in clinical use of IVCM for DED evaluation.

ABSTRACT BODY:

Purpose: PReferentially expressed Antigen in MElanoma (PRAME) immunohistochemistry (IHC) is a valuable diagnostic tool and prognostic marker in the evaluation of cutaneous melanomas. Recently, strong nuclear PRAME IHC labeling was found to help distinguish malignant from benign conjunctival melanocytic lesions (CMLs) (PMIDs: 20805128, 34268800, 34089198). To corroborate these findings, we performed a retrospective study of PRAME IHC staining patterns in previously biopsied CMLs at our institution.

Methods: CMLs were obtained from 16 patients who underwent biopsy of conjunctival lesions. IHC was performed to evaluate for melanocytic differentiation (MelanA, HMB-45, or SOX-10) and nuclear PRAME expression. Patient demographics, lesion characteristics, and PRAME status by IHC were included in the retrospective cohort analysis.

Results: The cohort of 16 patients included 11 females and 5 males, with an average age of 48.8 years (range 3 to 86 years). At the time of the study, all patients were alive and without evidence of metastatic disease. CML diagnoses were categorized as either benign melanosis (5/16), benign nevus (8/16), or malignant melanoma (3/16). Nuclear PRAME immunolabeling was detected in 2 of 3 patients with malignant melanoma (66%) and 0 of 13 histologically benign CMLs. Of the 3 malignant melanoma cases, PRAME nuclear expression was not detected by IHC on both the biopsy and subsequent excision of an invasive melanoma that involved the superior nasal and temporal conjunctiva of an 86-year-old male, harboring BRAF V600E, MSH2 R406X, and TERT promoter mutations.

Conclusions: Our current study is consistent with prior reports, which contend that PRAME IHC can be used as an ancillary marker to help distinguish malignant versus benign CMLs. However, our analysis revealed one patient with a PRAME-negative invasive conjunctival melanoma. Although the findings are promising, additional large-scale studies are needed to determine the specificity and sensitivity of PRAME IHC in the evaluation of suspected conjunctival melanomas.

ABSTRACT BODY:

Purpose: Biomechanical factors may contribute to the pathogenesis of keratoconus (KC). We aimed to determine the protein expression alterations of primary human corneal fibroblasts (HCF) and KC fibroblasts (HKC) in response to cyclic mechanical stretch (CMS) to mimic the physiological condition in human corneas.

Methods: HCF (n=3) and HKC (n=3) cells were cultured in 6-well plates with or without of 15% CMS (1 cycle/s for 24-hours) using a computer-controlled Flexcell FX-6000T Tension system. Extracted cellular protein (30µg) was digested with trypsin followed with liquid chromatography-mass spectrometry-based comparative proteomics using label-free spectral counting method. After protein database search, we normalized the peptide spectra matches (PSM) of each protein to the total PSM of each sample expressed as a percentage before comparison to compensate for possible variation due to sample loading. We performed the following comparisons: HKC-CMS vs HKC-no-CMS, HCF-CMS vs HCF-no-CMS, HKC-CMS vs HCF-CMS, and HKC-no-CMS vs HCF-no-CMS. We used two-tailed Student's t-test to identify differentially expressed proteins (DEP) ($p<0.05$). Gene ontology (GO) enrichment analysis was done using the WebGestalt 2013 version.

Results: We identified a total of 5370 proteins in all the samples. On average, 1717 proteins were identified per sample, of which 1241 proteins were detected in ≥6 samples and 696 proteins in all 12 samples. Differential analysis identified 74 and 65 CMS-responsive proteins in HCF and HKC cells respectively. 12 and 6 proteins were induced by CMS in HCF and HKC cells respectively. We identified 79 DEP in HKC-no-CMS vs HCF-no-CMS and 67 DEP in HKC-CMS vs HCF-CMS. GO analysis indicated the involvement of cell cycle regulation and interferon-mediated signaling in HCF response to CMS while HKC responds to CMS with the involvement of DNA damage response, insulin receptor binding, and oxidoreductase activity. KC-specific GO includes protein complex assembly/disassembly, hydrolase activity, and mitochondrial proteins without CMS, but includes wound healing and DNA damage response with CMS.

Conclusions: For the first time, our biomechanical study has identified a differential response of HKC cells to CMS with proteins involved in wound healing, DNA damage response, and oxidoreductase activity, suggesting the potential role of biomechanical stretch in KC development.

ABSTRACT BODY:

Purpose: Variants in the retinitis pigmentosa GTPase regulator gene (RPGR) and, specifically, in its retinal isoform opening reading frame-15 ($RPGR^{ORF15}$) have been associated with rod-cone (RCD), cone and cone-rod dystrophies (CD and CRD). While RPGR-related RCD is well understood, the characteristics and progression of RPGR-related CD/CRD were less frequently investigated. Here, we report the genotyping and genotype-phenotype correlation of a large cohort of patients with RPGR-related CD/CRD.

Methods: 34 index patients and 2 affected relatives were recruited at the “Quinze-Vingts” Hospital, Paris, France. Genetic screening was performed through direct Sanger sequencing of the $RPGR^{ORF15}$. Phenotypic data were collected retrospectively.

Results: 29 distinct variants in $RPGR^{ORF15}$ were identified, of which 27 were frameshift or nonsense and 24 were located towards the 3’ end of the $RPGR^{ORF15}$ transcript. 20 variants are novel sequence alterations. 15 subjects were affected by CD and 19 were diagnosed with CRD. Mean age at last examination was 43,97 ± 11,24 years. Best corrected visual acuity (BCVA) was 0.97 ± 0.71 LogMAR (20/200 Snellen equivalent). The most important predictors of BCVA seem related to morphologic data, with a significant correlation found for the central retinal thickness (β coeff. -0.523, p=0.003), autofluorescence (β coeff. 0.353, p=0.044) and peripapillary sparing (β coeff. -0.376, p=0.031). When analyzing longitudinal data, progressive decline of BCVA was noted, with more than 60% of the patients reaching a BCVA ≥ 1 LogMar in the best eye during their sixth decade of life.

Conclusions: We confirmed that $RPGR^{ORF15}$ variants associated with CD/CRD phenotypes are mostly located within the 3' end of the transcript (C-terminal part of the protein). Several imaging parameters may be useful as prognostic factors in these patients, although prospective longitudinal studies will be needed to confirm these results. The longitudinal data showed a rapidly progressive disease, possibly locating an optimal window of intervention for future therapies in younger ages.

Commercial Relationships Disclosure: Zachary Harbin: Commercial Relationship: Code N (No Commercial Relationship) | Luis Vasquez: Commercial Relationship: Code N (No Commercial Relationship) | Zachary Brooke: Commercial Relationship: Code N (No Commercial Relationship) | Jihad Isteitiya: Commercial Relationship: Code N (No Commercial Relationship) | Celina Villanueva: Commercial Relationship: Code N (No Commercial Relationship) | Ahmad Kheirkhah: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Patients' perspectives on their disease can significantly affect the disease course and outcome. However, limited data are available on patients' perceptions of their dry eye disease (DED). It also remains unknown whether patient's language plays any role in such perceptions. This study aims to compare patients' perception of DED and the effectiveness of its treatment between Spanish- and English-speaking patients.

Methods: This cross-sectional study included 62 patients with DED in San Antonio, Texas. All patients completed a questionnaire to evaluate their perspectives on their DED including their satisfaction with understanding DED, their opinion on easiness of following doctors' advice, their opinion on the effectiveness of the treatment, their satisfaction with the eye care, and their general outlook on DED. English version was used for English-speaking patients, and Spanish version was used for Spanish-speaking patients. All patients also had a comprehensive ocular surface examination as well as Ocular Surface Disease Index (OSDI) questionnaire. We then compared the patients' perspectives on DED between English- and Spanish-speaking patients.

Results: There were 44 women and 18 men, with an average age of 60.8±13.8 years (range, 27-87 year). There were 18 Spanish-speaking patients and 44 English or bilingual speaking patients. The average OSDI score was 53.4±19.7. Among all, 57% were satisfied with their understanding of DED, 81% found it easy to follow their doctors' advice for DED management, 61% thought that the DED treatment had been helpful, 69% were satisfied with their eye care for DED, and 61% expressed optimism regarding the long-term prospects of their DED. Comparisons between Spanish- and English-speaking patients did not yield significant demographic or clinical differences. However, Spanish-only speaking patients reported a lower understanding of DED compared to English-speaking patients (33.3% vs 65.9%, respectively, P=0.006). There were no significant differences in other DED perspectives between these two groups.

Conclusions: Our data suggests patients speaking only Spanish experience a gap in understanding of their DED. By understanding the ethnic differences in patients' perceptions of their DED, proper measures can be implemented to help guide treatment of this common condition.

TITLE: Optical Coherence Tomography (OCT) Risk Markers for Progression of Intermediate Age-Related Macular Degeneration (AMD) to Late AMD

SESSION TITLE: Imaging of posterior segment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.W. Pak, K. Taylor, S. Whittier, A. Dieu, R. Voland, B.A. Blodi, A. Domalpally, Ophthalmology and Visual Sciences, University of Wisconsin-Madison, Madison, Wisconsin, UNITED STATES|

Commercial Relationships Disclosure: Jeong Pak: Commercial Relationship: Code N (No Commercial Relationship) | Kenneth Taylor: Commercial Relationship: Code N (No Commercial Relationship) | Samuel Whittier: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Dieu: Commercial Relationship: Code N (No Commercial Relationship) | Rick Voland: Commercial Relationship: Code N (No Commercial Relationship) | Barbara Blodi: Commercial Relationship: Code N (No Commercial Relationship) | Amitha Domalpally: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Early detection of geographic atrophy (GA) is key in preventing progression from intermediate to late AMD. OCT biomarkers provide a novel means of identifying early GA. We aimed to identify the frequency and the predictive role of OCT biomarkers for AMD progression.

Methods: This is a retrospective cohort study performed at the Wisconsin Reading Center. We evaluated OCT and fundus photographs (FP) of 102 eyes of 65 participants at baseline and at 5-years. At baseline, multimodal assessment excluded Complete Retinal Pigment Epithelial Outer Retinal Atrophy (cRORA), late AMD and ungradable images, and 73 eyes of 45 participants with intermediate AMD were evaluated using OCT for presence/number of hyperreflective foci (HRF), largest drusen size, drusen volume, drusen with hyporeflective core, reticular pseudodrusen (RPD) and Incomplete Retinal Pigment Epithelial Outer Retinal Atrophy (iRORA). AMD severity level was graded from FP. At 5-years, cRORA and CNV were assessed from multimodal imaging as a measure of progression to late AMD.

Results: At baseline, HRF were seen in 40 eyes (55%) with a mean of 4 (SD 6.0) per eye. The mean largest drusen size in horizontal width was 0.64 (SD 0.44) mm and the mean drusen volume was 1.06 (SD 0.24) mm^3. Hyporeflective drusen were found in 40 eyes (55%). RPD was present in 20 eyes (27%) with a mean RPD area of 4.1 (SD 10.8) mm^2. iRORA was identified in 24 eyes (33%). Thirteen eyes were the AMD severity levels 1-5 (18%), while 60 eyes were the levels 6-8 (82%). At 5-years, 13% of eyes developed CNV and 37% cRORA. In a multivariate model, iRORA and all drusen characteristics were associated with development of cRORA with an adjusted odds ratio of 4.4 (95% CI 1.2,18).

Conclusions: OCT features of intermediate AMD can be reproducibly graded and serve as precursors for development of endpoints such as cRORA. iRORA and all drusen characteristics are associated with increasing AMD severity and are strong predictors of cRORA. It remains to be studied if some OCT-related features of iRORA may be more predictive of progression than others. Long term studies with larger sample size are required to understand these important harbingers to advance new therapies for AMD.

ABSTRACT BODY:

Purpose: The effects of intraocular pressure (IOP) reduction on retinal vessel density (VD) in glaucoma patients undergoing treatment are not fully understood. The purpose of this study is to determine if detectable changes in VD, as measured by optical coherence tomography angiography (OCTA), occur as result of IOP lowering therapy from either a prostaglandin analogue (PGA) or trabeculectomy surgery.

Methods: 6x6mm Spectral Domain OCTA images of the superficial macula and the radial peripapillary capillaries were obtained (Zeiss, Dublin, CA, Cirrus 11.0.0.23113). Images were quality graded then quantified using prototype software. OCTA images of primary open angle glaucoma patients who experienced >20% IOP reduction 3-6 months after treatment with a PGA or trabeculectomy were included. The Wilcoxon Signed Rank Test was used to compare VD change before and after treatment initiation. VD change was compared to the within eye coefficient of repeatability (CRw).

Results: 42 surgically treated eyes (37 patients) and 66 PGA treated eyes (35 patients) underwent OCTA imaging at baseline. After exclusion for image quality and follow-up, 18 surgically treated eyes (17 patients) and 12 PGA eyes (9 patients) were included in the final analysis. The median change in peripapillary VD was -0.0084 (min: -0.0660, max: 0.0578) among trabeculectomy eyes (p=0.958) and -0.0073 (-0.0409, 0.0736) for the PGA eyes (p=0.885) after 3-6 months. Change in macular VD was 0.0121 (-0.0174, 0.0254) for trabeculectomy eyes (p=.230) and -0.0018 (-0.0193, 0.0320) for PGA eyes (p=0.493) during the study period. See Table 1. Based on our prior studies (Lee et al 2021, Vorperian et al 2022 in submission), CRw is 0.087 for peripapillary VD and 0.018 for macular VD.

Conclusions: No significant change in peripapillary and macular VD was seen for either group 3-6 months after IOP reduction. The median differences when compared to the CRw per region are lower, suggesting that the observed differences may be attributable to intersession variability. Further study is needed to determine the utility of macular and peripapillary VD on OCTA as a biomarker for monitoring disease progression and therapeutic efficacy after intervention.

Nagy, Ophthalmology, Semmelweis Egyetem, Budapest, Budapest, HUNGARY|

Commercial Relationships Disclosure: Eric Mikula: Commercial Relationship(s);Code E (Employment):ViaLase, Inc. ;Code P (Patent):ViaLase, Inc. | Gagik Djotyan: Commercial Relationship(s);Code C (Consultant/Contractor):ViaLase, Inc. | Kinga Kranitz: Commercial Relationship: Code N (No Commercial Relationship) | Zoltán Nagy: Commercial Relationship: Code N (No Commercial Relationship) | Tibor Juhasz: Commercial Relationship(s);Code E (Employment):ViaLase, Inc. ;Code P (Patent):ViaLase, Inc.

ABSTRACT BODY:

Purpose: FLT is an innovative, non-invasive glaucoma procedure which aims to reduce intraocular pressure (IOP) via the creation of aqueous humor (AH) drainage channels through the trabecular meshwork (TM) and into Schlemm's canal (SC). As of this writing, the optimal physical treatment parameters of drainage channel(s) for FLT are not known. The purpose of this study was to develop a finite element model (FEM) to help predict the optimal drainage channel size (cross-sectional area) for IOP reduction.

Methods: The 3D finite element model of the human eye and the conventional AH outflow pathway used data published in the literature to inform the geometry of the anterior chamber (AC), TM, SC, and collector channels (CC). The major boundary conditions consisted of an AH inflow rate source term (2.5 uL/min) and the episcleral venous pressure, which comprised a pressure condition on the distal boundary of the CC's (9 mmHg). The TM and CC's were modeled as porous material, with given permeabilities, to approximate the resistance to AH outflow found in these tissues in-vivo. The permeability of the TM and CC's was estimated by comparing iterative FEM simulations with IOP data collected from ex-vivo experiments as well as unpublished preliminary clinical data. FLT was modelled by applying a block-like channel of connecting the anterior chamber to SC.

Results: Table 1 shows the finite element model predictions for IOP values following FLT using drainage channels of varying cross-sectional dimension. A channel size of 100 μm x 100 μm was found to achieve approximately (±2%) the maximal achievable IOP reduction (pressure within SC). Beyond this size, no appreciable increase in IOP reduction was achieved. This is in relative agreement with experimental laboratory as well as clinical results which demonstrated similar IOP reduction with channels measuring 200 μm x 500 μm.

Conclusions: The finite element model of FLT developed in this study demonstrates initial predictive power regarding drainage channel geometry and subsequent IOP reduction. Furthermore, the model shows the potential for reducing drainage channel size significantly, thus reducing procured time and overall tissue alteration, without sacrificing IOP performance. Importantly, the model suggests that drainage channel geometry may be chosen to fine-tune IOP reduction, thus optimizing the FLT procedure for a particular patient.

ABSTRACT BODY:

Purpose: To evaluate global visual field prediction using a gradient-boosted approach based on optical coherence tomography (OCT) structural measures in primary open angle glaucoma (POAG).

Methods: 721 glaucoma eyes from 506 Asian Chinese participants from a study site in Singapore and 111 glaucoma eyes from 63 Caucasian participants from Bucharest were included in the study. All participants underwent the same study protocol, including OCT imaging and 24-2 visual field testing using standard automated perimetry. Retinal nerve fiber layer (RNFL) thickness measurements and global visual field mean deviation (MD) values were extracted for each study eye. Data from the Singapore site was split using stratified sampling based on glaucoma severity into a training dataset and internal testing dataset using a 80/20 ratio, while an external test dataset was constructed with the Bucharest data. A gradient boosted ensemble tree (GBT) model was trained using 5-fold cross validation with the training data, and evaluated on the internal and external test datasets using mean average errors (MAE). Predictions were compared with a baseline MAE which predicted the mean MD, and with multi-variate linear regression (LR), using Pearson correlation analysis and Wilcoxon signed rank testing. 95% confidence intervals were generated using bootstrapping with 5000 samples.

Results: Participants in the internal dataset had an average age of 66.7±8.1 years and MD of -5.85±5.05 dB, while those in the external dataset had an average age of 63.6±11.7 years and MD of -4.79±5.79 dB. Differences in the mean MD were not significant (P=0.118). Baseline MAE on the internal and external test datasets was 3.80 dB and 4.09 dB respectively. The gradient boosted approach achieved a MAE of 3.01 dB (95%CI: 2.58-3.49) and Pearson correlation of 0.59 (0.47-0.70) on the internal test dataset, and a MAE of 3.04 dB (95% CI: 2.52-3.68) and Pearson correlation of 0.66 (95%CI: 0.44-0.82) on the external test dataset. Results obtained with GBT were significantly better than LR (P<.001) on both datasets.

Conclusions: Global visual field prediction using gradient boosted trees performed better than baseline and linear regression on independent internal and external datasets. The results motivate further evaluation of the approach and its applicability in structure-function studies.

US11029540, US10898407;Code C (Consultant/Contractor):HOYA Lens Thailand Ltd.;Code F (Financial Support):HOYA Lens Thailand Ltd.

ABSTRACT BODY:

Purpose: To investigate the effect of blue-light filtering lens on refractive changes in myopic schoolchildren over 2 years. The current study reports the 1-year interim findings.

Methods: 148 myopic Chinese schoolchildren aged 8-13 years were recruited in a 2-year randomized clinical trial (ClinicalTrials.gov identifier: NCT03538002) and were randomly assigned into blue-light filtering (BF) or single vision (SV) lenses treatment groups. The study outcomes were cycloplegic spherical equivalent (SE) and axial length (AL) measured by open-field auto-refractor and non-contact optical biometer, respectively. Baseline measurements were collected before the lens wear, and subjects were followed-up at a 6-month interval. Only the data of the right eyes were used for analysis. Mixed repeated measures analysis of covariance was applied to compare the within-subject time effect and between-subject treatment effect on SE and AL, controlled with age.

Results: A total of 135 children completed 6- and 12-month follow-ups (65 in BF group vs. 70 in SV group). Subjects in both groups had similar baseline age (mean ±SD; BF vs. SV; 10.0±1.5 vs. 10.2±1.5years), SE (BF vs. SV; -2.70±1.05D vs. -2.62±0.99D), and AL (BF vs. SV; 24.61±0.77mm vs. 24.62±0.77mm). Both SE and AL progressed significantly across time ($p<0.001$), and the interactions with age were both significant ($p<0.001$), in which older children tended to progress slower. The progressions in SE and AL were comparable between BF and SV groups (SE: $p=0.73$; AL: $p=0.73$).

Conclusions: Our findings demonstrated that the 12-month effect of BF lens on myopic progression in schoolchildren was insignificant, which could be due to the partial filtering of blue light. Thus, the contribution of wavelength on myopia development shall not be excluded, and a longer study period is warranted.

ABSTRACT BODY:

Purpose: This study characterizes the association of gender, race, and insurance status on burdensome aspects of repeated IVI using a validated patient survey to quantitatively measure patient burden.

Methods: QUALITII is a 50-item validated survey of patients receiving repeated IVI for retinal diseases (McClard et al 2021). The survey introduced the treatment burden score (TBS) composed of 9 items which examines the most salient aspects of burden. In this study, results from the multicenter QUALITII survey were analyzed using multivariate regression to understand how gender, race, and insurance status influenced patient-perceived burden.

Results: Of 1,416 patients surveyed from 4 large urban retinal clinics, 55% were women, 15% were non-White, and 32% had public health insurance only. Women reported more frequent eye pain (53%) and higher mean level of discomfort (2.01) than men (46%, 1.68) (p= 0.009; p=<0.001 respectively). Women reported mean anxiety level of 4.01 and men reported mean anxiety level of 4.51 during treatment (0=very anxious; p=<0.001). Non-White patients reported higher mean anxiety level (3.89) than reported by White patients during treatment (4.30) (p=0.017). A greater proportion of non-White patients reported spending >3 hours for clinic visits (18.9%) compared to proportion of White patients spending >3 hours (6.7%) (p=<0.001). A similar percentage of White and non-White patients required an escort to attend appointments, but non-White patients reported a lower convenience score (3.43) than reported by White patients (4.00) (p=0.002). No significant difference was reported by patients with public insurance compared to private insurance in terms of pain, anxiety, and inconvenience. Median TBS for private insurance (17) and public insurance (15) were equivocal (p=0.11). Median TBS was higher for women (17) than men (14) (p=<0.001) and higher for non-White (17) than White (15) patients (p=0.03).

Conclusions: There are gender and race disparities in perceived treatment burden associated with IVIs. TBS was highest in women and non-White patients. Moreover, the TBS was dictated by higher pain and anxiety score in women while the TBS in non-White patients was driven by higher anxiety and inconvenience of treatment. Insurance status did not have a significant effect on perception of burden.

ABSTRACT BODY:

Purpose: Several recent studies have demonstrated poor sleep quality in myopes. A recent study found that young myopes have significantly delayed melatonin circadian timing, delayed sleep onset, greater sleep onset latency, and shorter sleep duration compared to emmetropes (Chakraborty et al, PMID: 33030546). To better understand these sleep characteristics in myopes, this study examined the differences in the pattern of night-time light exposure before sleep in myopes and emmetropes.

Methods: 14 emmetropes (mean refractive error, −0.09 ± 0.13 dioptres) and 17 myopes (−4.99 ± 2.18 dioptres) with a mean age of 22.07 ± 2.38 years had objective measures of ambient light exposure collected over 7 days, using a wrist-worn actigraphy device (Actiwatch 2). Measures of visible light illuminance were captured every 30 seconds, 24 hours a day over this period. The average daily light exposure, and light exposure for 1 hour (120 epochs), 3 hours (360 epochs) and 5 hours (600 epochs) before sleep onset, as determined by Actiwatch, were calculated. A linear regression was performed to examine the association between night-time light exposure and sleep onset, sleep latency and the total sleep duration reported in our recent publication (PMID: 33030546). All results are reported as average ± standard error mean.

Results: Compared to emmetropes (507.24 ± 106.65 lux), the average daily light exposure was significantly less in myopes (261.79 ± 52.99 lux, Mann–Whitney rank sum test, p=0.021). The average night-time light exposure across the five-hour duration before sleep was significantly greater in myopes (52.24 ± 8.28 lux) than in emmetropes (25.21 ± 9.47 lux, two-way ANOVA, p=0.014). The average light illuminance between the two groups wasn't significantly different for 1 hour (myopes, 20.81 ± 8.28 lux; emmetropes, 9.31 ± 9.47 lux) and 3 hours (myopes, 45.52 ± 8.28 lux; emmetropes, 29.14 ± 9.86 lux) before sleep onset (both p>0.05). The night-time light exposure was positively associated with delayed sleep onset (r^2 = 0.22, p=0.009), but not with sleep onset latency and sleep duration.

Conclusions: Young adult myopes had greater night-time light exposure compared to emmetropes, which was particularly evident 3 – 5 hours before sleep onset and may contribute to delayed sleep and circadian timing in myopes. These findings in myopes may be related to greater screen time or academic work at night and require further investigation.

ABSTRACT BODY:

Purpose: To characterize if and how ophthalmologists communicate with patients electronically.

Methods: A survey regarding ophthalmologists' electronic communication habits with patients was distributed online through an electronic mail (e-mail) listserv. Univariate analysis was performed to examine associations between demographic factors and communication with patients though phone calls and email.

Results: Of 92 respondents, the average age was 55.2 years old (range: 32-86). Respondents were predominantly male (70.7%) with >10 years of attending experience (81%). Overall, 37% of respondents choose not to provide any contact information to patients, 13% provide e-mail, 22.8% provide a phone number, and 27.2% provide both modes of contact. Reasons for sharing contact information include checking on post-operative patients (63%) or patients with complications (52.2%). Although most respondents (55.4%) do not discuss guidelines for using their personal e-mail or phone number with patients, the majority express little or no regret sharing their contact information (87%). The majority of respondents (75.2%) endorse reimbursement for extra time talking with patients outside of clinic appointments, however only 6.4% bill their calls. Furthermore, documentation habits for communication encounters in the electronic medical record (EMR) are variable, with 44.6% of physicians documenting most of the time and 30.4% rarely documenting. Among physicians with social media accounts, most allow patients to follow their professional (57.6%), but not personal accounts (14.3%).

Conclusions: Over one-third of attending ophthalmologists do not share email address or phone numbers with patients. Ophthalmologists may share their personal information more frequently for postoperative patients and those with complications. There is widespread support for reimbursements for time spent communicating with patients outside of clinic visits, however, billing and documentation of such encounters are inconsistent.

TITLE: Dedicated Chalazion Excision Clinic as a Tool for Early Surgical Autonomy in Ophthalmology Residency

SESSION TITLE: Vision care training and education

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L.Y. Lin, G.W. Armstrong, P. Yadav, Ophthalmology, Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Lisa Lin: Commercial Relationship: Code N (No Commercial Relationship) | Grayson Armstrong: Commercial Relationship(s);Code O (Owner):Ocular Technologies Inc;Code C (Consultant/Contractor):McKinsey & Company;Code C (Consultant/Contractor):Xenon-VR;Code C (Consultant/Contractor):Opthalytics;Code C (Consultant/Contractor):Kriya Therapeutics;Code S (non-remunerative):American Medical Association | Prashant Yadav: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Ophthalmology residency programs aim to improve resident surgical teaching through increased surgical exposure and primary case numbers over a three-year period. Resident run surgical clinics across various surgical specialties have been founded to help develop surgical autonomy and earlier resident surgical experiences. We present the first demonstration of a resident run chalazion clinic in ophthalmology residency with the goal of increasing exposure to orbital procedures for junior residents or post-graduate year 2s (PGY2s).

Methods: The resident run chalazion clinic was founded in July 2020. Retrospective review of ACGME case logs of all residents per academic year before and after establishment of the chalazion clinic was performed in order to assess the number of chalazion excisions performed.

Results: A resident of any class year performed an average of 4.9 excisions prior to the founding of the clinic (91 total), and 14.4 excisions after the founding of the clinic (202 total). The average number of chalazion excision and drainages for each resident increased by 211.1% within the first year of the clinic. Among PGY2s, the average increased from 4.7 excisions per year to 22.3 excisions per year, a 374.5% increase. All juniors residents logged a minimum of 9 cases compared to only 87.5% residents logging a minimum of 3 cases.

Conclusions: To the best of our knowledge, this is the first description of a dedicated chalazion clinic or a resident run minor procedure clinic in ophthalmology. On average, all residents and PGY2s in particular, experienced an increase in the average number of chalazion excisions. While chalazion excisions have low complication rates and are not technically challenging, increased early exposure to and volume of ophthalmic procedures could help improve junior resident’s skills. This model is also beneficial as it offloads other outpatient ophthalmology and oculoplastics clinics, where chalazion excision and drainage may be difficult to add to the schedule or a lower priority for procedural scheduling. This clinic provides a proof of concept of a dedicated minor procedure clinic run by ophthalmology residents. Future directions include integrated future interns (PGY1s) into the clinic to further develop early procedural skills.

ABSTRACT BODY:

Purpose: All Lowe oculocerebrorenal syndrome (OCRL) patients develop dense bilateral congenital cataracts, but only 50% develop glaucoma. Carriers of OCRL are at risk for early onset cataracts in the 3rd to 4th decade, but show no increased risk of glaucoma. The cause of the variable glaucoma phenotype in OCRL is unknown, and contrasts sharply with the highly penetrant cataract phenotype. No studies detail the subclinical structural variations in the anterior segment between glaucomatous and non-glaucomatous pediatric OCRL patients. Quantitating these differences may inform why half of OCRL patients develop glaucoma. Ultrasound biomicroscopy (UBM) is a high-resolution imaging technique for noninvasive in-vivo imaging of these anterior segment structures. This prospective case-series compares structural features in UBM images between a pediatric OCRL patient with glaucoma and an OCRL patient without glaucoma.

Methods: We obtained quantitative UBM images of a 1.2-month boy with OCRL who developed glaucoma (diagnosed at age 2 months) to UBM images of a 0.9-month boy with OCRL who did not develop glaucoma after 5 years of follow up (4 eyes, 2 subjects). Iris, lens, angle, and corneal parameters were extracted from images and compared using box plots.

Results: In the setting of OCRL, increased lens reflectivity, steeper corneal curvature (CRC), increased angle opening distance (AOD), thinner central cornea (CCT), and a deeper anterior chamber (ACD) were noted in two eyes of the subject who later developed glaucoma compared to the subject without glaucoma. Mean differences were CRC= -0.95 mm, AOD=+0.49 mm, CCT=-0.04 mm, ACD=+0.32 mm. Angle to angle distance and lens thickness were similar between the subject with glaucoma compared to the subject without glaucoma.

Conclusions: Anterior segment evaluation using quantitative UBM for individuals with OCRL may identify structural risk factors for glaucoma. Future studies will be needed to determine the sensitivity and specificity of UBM features for prediction of glaucoma.

TITLE: The Monitoring of Neovascular Age-related Macular Degeneration with Choroidal Neovascular Membrane using Optical Coherence Tomography Angiography Scan

SESSION TITLE: Imaging of posterior segment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Mok, W. Lam, Department of Ophthalmology, The University of Hong Kong, Hong Kong, HONG KONG|

Commercial Relationships Disclosure: Janice Hoi Man Mok: Commercial Relationship: Code N (No Commercial Relationship) | Wai-Ching Lam: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: This study investigates the application of Optical Coherence Tomography Angiography (OCTA) in monitoring treatment response of choroidal neovascularization (CNV) in neovascular age-related macular degeneration (nAMD) following intravitreal anti-vascular endothelial growth factor (VEGF) injection.

Methods: In this prospective study, nAMD patients with fluorescein angiographic confirmed CNV who require anti-VEGF injection were included. Subjects received two OCTA scans, namely before and 4-6 weeks after the injection. 34 eyes from 32 subjects were studied between August 2020 and Dec 2021 at Grantham Hospital, Hong Kong. Correlation analysis between the interval changes on the consecutive OCTA scans, including the CNV classification type, vessel area, vessel density, morphology, border, and treatment outcome, including visual acuity (VA), central subretinal thickness (CST), is performed using SPSS Statistics.

Results: The subjects were of mean age 75.7 (63 - 92), a male to female ratio 1:28 to 1, and have a mean visual acuity of 0.232 (0.02 - 0.7). There were 4 eyes with Type 1 CNV, 14 with Type 2, and 7 with Type 4 CNV. CNV was unidentifiable in 9 eyes.

Eyes with type 2 CNV has significantly larger CNV area in outer and choriocapillaris layer, and lower density in choriocapillaris layer. The CNV area (before treatment 3.94 mm2, after treatment 2.76 mm2, P=0.03) and density (before treatment 0.53, after treatment 0.40, P=0.02) in choriocapillaris was significantly reduced in the repeated scan. Statistical analysis revealed significant correlations between the reduction in CNV vessel density in choriocapillaris layer and decreased CST (P=0.001); CNV vessel area in choriocapillaris layer were also significantly correlated to the improvement of VA (P=0.038).

Conclusions: With treatment, the reduction in CST corresponds to reduction in CNV density. This can be attributed to effective anti-angiogenesis and anti-permeability actions by the anti-VEGF treatment. Reduction of CNV area with treatment corresponds to the improvement of visual acuity.

A positive correlation between CNV area and density on OCTA scans and patient's treatment outcome hints at the potential use of OCTA scans to monitor disease progression.

TITLE: Outcomes of infants with retinopathy of prematurity treated with intravitreal bevacizumab with or without laser ablation

SESSION TITLE: Retinopathy of prematurity

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Patrick, Y. He, A. Wang, Ophthalmology, The University of Texas Southwestern Medical Center, Dallas, Texas, UNITED STATES|

Commercial Relationships Disclosure: Hank Patrick: Commercial Relationship: Code N (No Commercial Relationship) | Yu-Guang He: Commercial Relationship: Code N (No Commercial Relationship) | Angeline Wang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinopathy of prematurity (ROP) is a leading cause of blindness in children in the US. It involves development of neovascularization in premature infants and can lead to retinal detachment and blindness. Treatment involves prevention of retinal detachment and has evolved from full-thickness cryotherapy to laser ablation. More recently, physicians have employed anti-VEGF agents, such as intravitreal bevacizumab (IVB), based on the pathophysiology of the disease and evidence from the BEAT-ROP and RAINBOW studies. However, there is a need for data on how these treatments influence the timing of the disease and monitoring recommendations in patients with ROP. This study investigates the outcomes of infants with ROP treated with IVB, including average time to complete revascularization and to subsequent laser therapy.

Methods: A retrospective, hospital-based study. Infants who met threshold for treatment and received IVB between 2018 and 2021 were included (n=20). Patients were monitored from their first ROP screening exam until complete revascularization or laser therapy. Age, weight, and risk factors for treatment were also analyzed.

Results: Patients had an average birth weight of 702 grams and average gestational age at birth of 24.8 weeks. Patients received IVB at an average post-menstrual age (PMA) of 37.1 weeks. 30% (n=6) of patients had disease regression and subsequent complete vascularization and did not require laser treatment. 35% (n=7) required laser for recurrence of ROP. 35% (n=7) required laser treatment for persistent avascular retina. Of those who fully vascularized without laser treatment, close monitoring was stopped at an average PMA of 51.2 weeks, or 18.9 weeks after IVB. Disease recurrence occurred at average PMA of 49.5 weeks, or 13.4 weeks after IVB. Laser for avascular retina occurred at average PMA of 60.9 weeks, or 25.6 weeks after IVB.

Conclusions: This study offers insight into the timing and management of ROP after IVB. Approximately one third of patients will develop recurrence of ROP following injection, and patients need to be followed up to PMA of 60 weeks to monitor for recurrence and to decide on need for laser treatment.

ABSTRACT BODY:

Purpose: To determine the effect of three amniotic scaffolds (Biovance3L Ocular (Biovance3L), AMBIO2®, AmnioGraft®) on human ocular epithelial cell adhesion and proliferation.

Methods: Human corneal epithelial cells (HCEC) and human conjunctival epithelial cells (HConEpiC) were seeded into wells. Adhesion and proliferation were measured at days 1, 4 and 7 on the scaffolds. Extracted conditioned media was used for growth assays.

Results: Biovance3L showed significantly higher epithelial cell viability ($P < 0.001$) and significantly greater epithelial cell adhesion ($P \leq 0.011$) vs other scaffolds. Epithelial cell proliferation rate was
significantly greater on Biovance3L than AmnioGraft® ($P < 0.001$). HCEC migration from cells cultured on Biovance3L and AMBIO2® were comparable ($P = 0.885$) and significantly greater than AmnioGraft® ($P \leq 0.006$). The different scaffolds did not affect the migration of HConEpiC.

Conclusions: Biovance3L had a significant effect on human epithelial cells by supporting greater viability, adhesion, and proliferation compared with other scaffolds. Further research is needed to assess the clinical impact of these findings.

TITLE: Lubricating effect of three different eyedrops on contact lenses

SESSION TITLE: Contact lens

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Iwashita, T. Itokawa, Y. Okajima, T. Suzuki, Y. Hori, Ophthalmology, Toho Daigaku, Ota-ku, Tokyo, JAPAN|

Commercial Relationships Disclosure: Hiroko Iwashita: Commercial Relationship: Code N (No Commercial Relationship) | Takashi Itokawa: Commercial Relationship: Code N (No Commercial Relationship) | Yukinobu Okajima: Commercial Relationship: Code N (No Commercial Relationship) | Takashi Suzuki: Commercial Relationship: Code N (No Commercial Relationship) | Yuichi Hori: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Many Soft Contact lens (SCL) users medicate several eyedrops to improve discomforts. Friction of both SCL and ocular surface is one of important factor for CL discomfort. This study aimed to detect lubricating effect of three different eyedrops (artificial tears, low surface tension artificial tears, 0.1% hyaluronic acid) by measuring coefficient of friction (CoF).

Methods: The CoF was measured by using developed pendulum friction tester. The weight of the load was set at 17.2 g and estimated the pressure on the CL surface as 1.1 kPa. The maximal sliding velocity was set to 90.0 mm/s. Three daily disposable conventional hydrogel lenses (etafilcon A+ polyvinylpyrrolidone, nelfilcon A, and omafilcon A containing 2-methacryloyloxyethyl phosphorylcholine [MPC]) and four silicone hydrogel lenses (narafilcon A, senofilcon A, delefilcon A, and stenfilcon A) were measured under three different types of lubricants, artificial tears, lubricants containing 2-MPC (MPC solution) and 0.1% hyaluronic acid.

Results: The mean ± SD of CoF of conventional hydrogel were Artificial tear; 0.038 ± 0.01, MPC solution; 0.036 ± 0.005, and 0.1% hyaluronic acid; 0.035 ± 0.005. Those of silicone hydrogel lenses were Artificial tear; 0.036 ± 0.004, MPC solution; 0.035 ± 0.003, and 0.1% hyaluronic acid; 0.036 ± 0.003. There were no significant differences of CoF among three lubricants and there was no significant difference of CoF between hydrogel and silicone hydrogel lenses. ($P > 0.05$).

Conclusions: Conclusions: Low surface tension artificial tears denotes high wettability on SCLs showed similar lubricate effect on SCLs as artificial tear and 0.1% hyaluronic acid. Three different eye drops showed similar lubricant effect on both conventional hydrogel and silicone hydrogel lenses. It was suggested that surface tension and viscosity of 0.1% HA on SCLs would not affect to CoF.

TITLE: Corneal nerve changes in hyperglycemic mice: association with diabetic neuropathy

SESSION TITLE: Corneal Imaging and Corneal Nerves

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Zhou, A. Lee, J.J. Kwok, A.C. Lo, Ophthalmology, The University of Hong Kong, Hong Kong, HONG KONG|

Commercial Relationships Disclosure: Ting Zhou: Commercial Relationship: Code N (No Commercial Relationship) | Allie Lee: Commercial Relationship: Code N (No Commercial Relationship) | Jeremy Kwok: Commercial Relationship: Code N (No Commercial Relationship) | Amy Lo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Diabetic neuropathy represents the third most prevalent neurological disorder. Recent studies demonstrated that diabetic corneal nerve alternations may be a potential surrogate marker to reveal the peripheral nerve status of diabetic patients. Therefore, it is of great importance to investigate the dynamic changes of corneal nerves and its association with intraepidermal nerve damage upon hyperglycemia, which is helpful for further studies on the underlying pathophysiological mechanisms and therapeutic targets of diabetic neuropathy. We tested whether dynamic loss of corneal nerve occurred in the early stage of diabetic neuropathy using in vivo microscopy in a diabetic mouse model.

Methods: 8-week-old Thy-1/YFP mice were injected with 50 mg/kg streptozotocin (STZ) for 5 consecutive days for hyperglycemia induction. Bodyweight and blood glucose levels were recorded weekly. Corneal sensitivity was tested with Cochet-Bonnet esthesiometer weekly. At 4, 8, 12, 16, 20, and 24 weeks after STZ injection, corneal nerves and epidermal nerves from the hind paw and leg skin were visualized with in vivo microscopy. Meanwhile, corneal and epidermal nerve analyses were performed on corneal flat mount and skin from the hind paw and leg, respectively using Imaris and Neuron J software.

Results: Hyperglycemia was successfully induced and led to a loss of corneal nerve fiber. At 4 weeks after STZ injection, the total number of nerve fibers in the central cornea showed a significant loss (23.6±3.7%) while subbasal nerve plexus in the central cornea showed a loss in corneal nerve fiber density (CNFD), corneal nerve fiber length (CNFL) and corneal nerve branch density (CNBD). At 16 weeks after STZ injection, the total number of nerve fibers in the peripheral cornea was significantly decreased (46.2±4.6%). Subbasal nerve plexus in peripheral cornea showed a loss in CNFD, CNFL, and CNBD. At 24 weeks after STZ injection, corneal nerve fibers could be detected except the ones in the stroma. More importantly, these pathological features occurred earlier than changes in epidermal nerve fibers and earlier than cornea functionality (corneal sensitivity test).

Conclusions: Our results show that in vivo microscopy, a non-invasive tool for longitudinal nerve fiber detection, revealed dynamic changes in corneal nerves upon hyperglycemia, suggesting that monitoring of corneal nerve fiber may lead to earlier diagnosis of diabetic neuropathy.

ABSTRACT BODY:

Purpose: Accurate and precise as well as efficient measurements of choroidal neovascularization (CNV) lesions are important in the laser-induced CNV mouse model, one of the major animal models used in developing therapeutic agents for various neovascular retinal diseases. We present the utility of FIJI-assisted automatic quantification of the total volume of CNV.

Methods: Laser-induced CNV was induced in C57BL/6J mice according to the established protocol. Following CNV induction, mice were treated with intravitreal injection of either PBS (n=6-7) or aflibercept (Eylea®) (n=11). One week after treatment, RPE/choroid flat mounts were stained with rhodamine-conjugated Griffonia simplicifolia lectin B4 (GSA). Z-stacks of the entire CNV lesion obtained using laser confocal microscopy were converted to binary stacks using FIJI. Thresholded voxels were quantified using the Voxel-Counter Plugin. Data from volumetric analysis and multiple area analyses from blindly selected, mean, and a maximum of measured areas using FIJI were compared.

Results: FIJI-assisted automatic quantitative volumetric analysis of CNV was useful in detecting experimental outliers in laser-induced CNV genesis and provided accurate and precise measurements of total areas of CNV with a lower coefficient of variance (63%) than in multiple area analyses, including blindly selected, mean, and a maximum of measured areas (76%, 69%, and 67% respectively). A lower coefficient of variance resulted in increased statistical significance (p-value) when comparing CNV lesions in PBS and Eylea treated groups (Figure).

Conclusions: FIJI-assisted automatic quantitative volumetric analysis can be useful for accurate, precise and efficient measurements of total areas of CNV. Further, this approach can be advantageous in determining the efficacy of therapeutic agents in the laser-induced CNV mouse model.

ABSTRACT BODY:

Purpose: This study aims to establish a correlation of serum inflammatory markers with aqueous samples in patients without diabetic retinopathy. Several cytokines are elevated in the aqueous and vitreous of patients with advanced diabetic retinopathy(DR) and may be future targets for therapy to prevent DR progression. However, the correlation of these ocular inflammatory markers with serum inflammatory markers is unknown. Currently the only serum marker for Diabetes is HbA1c which does not directly reflect the current DR stage.

Methods: This cohort was a cross-sectional study of patients with no diabetic retinopathy who underwent vitrectomy surgery for non-inflammatory conditions. Demographic and clinical data was obtained from chart review. Aqueous humor and serum samples were obtained from all patients concurrently and analyzed for 24 different inflammatory markers. The correlation between serum and ocular cytokines were evaluated using Pearsons correlation.

Results: A total of 70 patients were included in this analysis. 51.4% of the patients were female and 91.4% were Caucasian. 60% of patients were pseudophakic. One patient was treated with Imatinib for metastatic GI Stromal cancer and 4 patients were treated with Latanoprost for elevated IOP. No other patients were on systemic or topical anti-inflammatory medications. 40% of patients underwent surgery for vitreous floaters, 23% for ERM, 20% for Macular Hole, and other non-diabetic indications for vitrectomy. Of the 24 markers evaluated, a total of 6 cytokines were found to have a statistically significant correlation between the aqueous and serum. The following markers had a positive correlation coefficient FIT 3L ($R=0.3017$, $p=0.01$), MCP 3 ($R=0.4072$, $p< 0.001$), MDC ($R=0.3025$, $p=0.01$), IL4 ($R=0.554$, $p=<0.001$). A negative correlation was seen in VEGF ($R=-0.257$, $p=0.032$) and sCD40L ($R=-0.2708$, $p=0.02$).

Conclusions: This study documents the correlation of ocular to serum inflammatory markers in normal eyes. Subsequent longitudinal analyses from this clinical trial studies will evaluate the association between serum and ocular cytokines in various stages of diabetic retinopathy. The data in this study will be invaluable as a baseline for future analysis to evaluate cytokines in diabetic retinopathy.

ABSTRACT BODY:

Purpose: To evaluate the changes in refraction and axial length for a period of 6 years in children who completed the two-year clinical trial of Defocus Incorporated Multiple Segment (DIMS) lenses.

Methods: Myopic children who had completed the 2-year randomized clinical trial of DIMS lens were included in this follow-up study. Their cycloplegic refraction and axial length (AL) were measured up to 6 years. Children who changed to other myopia control methods were excluded. Participants were divided into 4 groups - Group 1: wore DIMS spectacles for a total of 6 years (include first two years in RCT); Group 2 wore DIMS spectacles in the first 3.5 years and changed to wear SV spectacles afterward; Group 3: wore SV spectacles in the first 2 years of RCT and switched to wear DIMS spectacles afterward; Group 4: wore SV spectacles in the first 2 years of RCT and switched to wear DIMS spectacles in the 3rd year and then switched to wear SV spectacles lens till end of the 6^{th} year. Changes in spherical equivalent refraction (SER) and AL over the 6 years were analyzed and compared.

Results: 90 children completed the data collection at for a period of 6 years. The children in Group 1 (n=36) wore DIMS lenses throughout the study had -0.92 ± 1.15D of myopia progression and 0.60 ± 0.49mm of axial elongation. The mean annual changes were 0.15D and 0.10mm. Group 2 (n=14) stopped DIMS lens wear after the first 3.5 year and showed more myopia progression (mean differences: 0.2D) and axial elongation (0.07mm) than those in Group 1 between year 3.5 to year 6. Children in both Group 3 (n=22) and Group 4 (n=18) who wore the SV spectacles in the first two years and then switched to wear DIMS lens. Their rate of myopia progression and axial elongation decreased after switching to DIMS lens wear. Children in Group 4 exhibited faster myopic progression when they stopped the DIMS lens wear from year 3.5 to year 6.

Conclusions: DIMS lens maintained the effect on slowing myopia progression and axial growth in myopic children over a period of 6 years. When children stopped DIMS lens wear and wore single vision lenses, their myopia progression was faster than the children who continued with DIMS lens wear.

ABSTRACT BODY:

Purpose: Primary congenital glaucoma (PCG) is an autosomal recessive disease that occurs due to developmental defects in the anterior chamber angle and trabecular meshwork. The resulting resistance to aqueous humor outflow raises the intraocular pressure and damages the optic nerve. PCG exhibits considerable genetic heterogeneity, and the known mutation spectrum does not explain the entire genetic basis of this disease. As anterior segment dysgenesis (ASD) and PCG share overlapping phenotypes, we determined the involvement of ASD-associated genes in PCG pathogenesis.

Methods: A large cohort of PCG cases (n=586) and ethnically matched controls (n=1758) were screened by deep sequencing with a customized gene panel comprising of known ASD-associated genes using the Ion Ampliseq chemistry. A combination of GATK and Haploview softwares was used for variant analysis. The identified variants were validated by Sanger sequencing. Pathogenicity of the variants was determined through SIFT, PolyPhen2 and Mutation Taster scores. Ingenuity Pathway Analysis (IPA) was used for network and pathway analyses.

Results: We identified 71 novel and rare pathogenic variants in 123 (20.9%) PCG cases across the ASD genes: FBN1, HMX1, LMX1B, MAF, PITX3, PRDM5, RAX, SIX1, SIX6, SLC4A11, SOX2, TRIM44, VAX1 and WT1. The affected amino-acid residues were conserved across multiple species and the variants were either absent or rarely observed in our controls and global databases. We also identified 52 significantly associated polymorphisms conferring risk to PCG. These genes shared similar molecular functions and were involved in the regulation of Wnt and Hedgehog signaling and cell growth and survival pathways (Akt/PI3K/NfkB). Moreover, we detected co-occurrence of pathogenic variants between ASD and PCG candidate genes in 63 cases (10.75%) indicating potential multi allele interactions and possible dysregulation of multiple pathways in PCG.

Conclusions: Our results expand the mutation spectrum of PCG with the identification of pathogenic variants in ASD genes and suggest their potential involvement in PCG. Our observations on the co-occurrences of pathogenic variants in ASD and PCG candidate genes suggest gene-gene interactions in PCG pathogenesis.

TITLE: Comparison of serum autoantibody against aldehyde dehydrogenase 2 and thyrotropin receptor antibody in patients with Grave's ophthalmopathy

SESSION TITLE: Clinical Uveitis & Orbital Inflammation: Etiology, Epidemiology & Clinical Assessment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Lin, ophthalmology, Kaohsiung Medical University Chung Ho Memorial Hospital, Kaohsiung, TAIWAN|

Commercial Relationships Disclosure: Chia Ching Lin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Grave's ophthalmopathy (GO) is an autoimmune disorder characterized by orbital inflammation and is associated with Grave's hyperthyroidism. Thyrotropin receptor autoantibody (TRAb) was first identified to be related to Grave's hyperthyroidism and have been demonstrated to be associated with the clinical activity score (CAS) of GO in some studies, while in others its correlation with the severity of GO was controversial. Our previous study has identified an autoantibody against aldehyde dehydrogenase 2 (ALDH2) which has strong correlation with CAS in patients with GO. With the previous literatures that showed TRAb are correlated with the CAS of GO patients, we would expect their titers to be correlated with the titers of anti-ALDH2 antibody. The purpose of this study is to compare the serum titers of anti-ALDH2 antibody and TRAb in patients with GO.

Methods: Fifty patients with active GO were enrolled in this study. The patients' thyroid function status, medical history, surgical history, and serum anti-ALDH2 antibody and TRAb titers were collected. All patients were examined by the same ophthalmologist to determine the levels of the CAS. The correlation coefficients between serum anti-ALDH2 antibody, TRAb, and thyroid function, and the CAS were calculated by Pearson's and Spearman's rho correlation analysis.

Results: There was significant correlation between the titers of anti-ALDH2 antibody and the CAS ($r=0.301$, $p<0.05$) (Figure 1), but not between the titers of anti-ALDH2 antibody and TRAb ($r=0.014$, $P=0.921$). The TRAb level was significantly correlated with T3 and TSH levels ($r=0.406$ and -0.32, $p<0.05$, respectively), but had no significant correlation with the CAS ($r=0.021$, $p=0.884$) (Table 1).

Conclusions: The level of anti-ALDH2 antibody was significantly correlated with the CAS but not the TRAb level and thyroid function, suggesting that it might be more specific to orbital tissue and the disease activity of GO. The TRAb level was significantly associated with thyroid function instead of the clinical activity of GO, indicating its role in Grave's hyperthyroidism rather than ophthalmopathy.

TITLE: Recovery of Vision in Open Globe Injury Patients with Initial No Light Perception Vision

SESSION TITLE: Endophthalmitis & Trauma

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: K.M. Wai, N.A. Sherif, M. Tieger, G.W. Armstrong, Ophthalmology, Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Karen Wai: Commercial Relationship: Code N (No Commercial Relationship) | Noha Sherif: Commercial Relationship: Code N (No Commercial Relationship) | Marisa Tieger: Commercial Relationship: Code N (No Commercial Relationship) | Grayson Armstrong: Commercial Relationship(s);Code O (Owner):Ocular Technologies Inc;Code C (Consultant/Contractor):McKinsey & Company;Code C (Consultant/Contractor):Xenon-VR;Code C (Consultant/Contractor):Ophthalytics;Code C (Consultant/Contractor):Kriya Therapeutics;Code S (non-remunerative):American Medical Association

ABSTRACT BODY:

Purpose: The recovery of vision in open globe injuries (OGI) in patients who present with no light perception (NLP) vision is poorly understood. These patients often undergo primary enucleation or evisceration to mitigate the risk of sympathetic ophthalmia. We conducted a retrospective chart review to identify patient characteristics, OGI features, and surgical events that may predict the recovery of any vision in patients initially presenting with NLP vision to inform clinical management.

Methods: The Massachusetts Eye and Ear (MEE) OGI Database was used to identify patients with NLP vision at presentation from January 1999 to December 2019. The medical records of these patients were analyzed to identify demographic characteristics; zone of injury; time from injury to surgical repair; need for vitrectomy; presence of retinal detachment, vitreous hemorrhage, intraocular foreign body (IOFB), hyphema, amongst 17 other features; and visual acuity (VA) at last follow-up appointment. Logistic regression was used to analyze the relationship between regained vision at the most recent follow-up visit and the above dependent variables (Python 3.10.1). Patients without a documented VA at most recent follow-up were excluded.

Results: A total of 294 OGI cases with NLP at presentation that met inclusion criteria were identified, of which, 119 cases (35.95%) regained better than NLP vision at most recent follow-up. Regained vision ranged from VAs of 20/70 (3.36%) to LP (35.29%). Nine (3.06%%) Zone I, 52 (17.69%) Zone II, 118 (40.14%) Zone III, and 115 (29.12%) Zone unknown injuries were documented. Vitrectomy was positively associated with regained vision (B=2.2, p=0.002), while previous intraocular surgery was negatively associated with regained vision (B=-0.9, p=0.03). Both the presence of an IOFB and OGI repair within ten hours of injury approached statistical significance for association with regained vision (B=-1.5, p=0.08 and B=0.9, p=0.09, respectively).

Conclusions: While OGIs cause severe ocular morbidity, a significant proportion of OGIs with initial NLP vision regained some vision during follow-up care. Previous intraocular surgery was negatively associated with return of vision, while vitrectomy was positively associated. These findings argue for primary closure of OGIs given potential for return of vision rather than primary enucleation, even in the presence of NLP vision at initial presentation.

ABSTRACT BODY:

Purpose: To compare the binocular and accommodative function of Spatio-Temporal Optical Phase (S.T.O.P®) contact lenses (CL) against MiSight® (MS) in myopic young adults. S.T.O.P CL feature rotationally asymmetric power maps, designed with meridionally and azimuthally varying power distributions, combined with a peripheral carrier configured with rotation assisting features The resulting dynamic optical signal on the retina may decelerate the rate of myopia progression and minimise the decay of treatment effect found in options which provide a relatively static optical signal.

Methods: Prospective, randomized, single-masked (participant), cross-over trial where participants aged 18-39 years wore MS and two S.T.O.P designs (F2 and DT), each for a minimum of 5 days at 6 hours/day, daily wear, with CLEARCARE disinfection. Assessments occurred while wearing each design at the end of the wearing cycle. Binocular function assessments comprised phoria at 3m and 40cm (Modified Thorington). Accommodative function measurements comprised monocular accommodative facility (MAF) at 40cm (±2.00D, left eye occluded), and dynamic accommodative response (AR) at 6m, 70cm, and 40cm. Dynamic AR was calculated from autorefraction measurements (Grand Seiko WAM5500, high speed mode: 6 measurements/s) on the left eye (not wearing a CL and occluded under black cardboard placed on the tilted hot mirror), while the right eye (wearing a CL) viewed each target. Customized hardware was used to coordinate measurements, which were recorded for 8s at each distance (144 measurements in total).

Differences between designs were assessed using linear mixed model, a Bonferroni correction was applied where applicable, and significance was set at 5%.

Results: While wearing F2 compared to MS, MAF was higher (12.2±5.9 vs. 10.5±5.3, p=0.007) and AR was lower at 70cm (0.75±0.36 vs 0.95±0.37, p<0.001) and 40cm (1.58±0.55 vs 1.74±0.50, p=0.007). The SD of AR measurements was also lower with F2 compared to MS at 70cm and 40cm (p<0.001), suggesting accommodation was more consistent with F2. There were no differences between designs for phoria at either 3m or 40cm (p>0.2), nor were there any differences between DT and MS for any measurement (p>0.06).

Conclusions: Both S.T.O.P designs were comparable to MS for binocular function. DT was comparable to MS for accommodative function. F2 was better for MAF and required less accommodation compared to MS.

ABSTRACT BODY:

Purpose: Recent preclinical data and post hoc analysis of clinical data suggest the importance of new approaches that inhibit the generation of pathological levels of VEGF while maintaining physiological levels of VEGF in ocular neovascular disease (NV). Here, we investigated the novel function of a fully human monoclonal IgG anti-c-kit antibody (NN2101) in inhibiting hypoxia and pathological angiogenesis while maintaining trophic factor homeostasis.

Methods: HRMEC, RPE, MIO-M1, and Y79 cells were used in vitro to demonstrate the inhibitory effect of NN2101. Proteomic secretome profiling was performed to identify angiogenesis- and inflammation-related proteins in hypoxia-conditioned media. Also, db/db mice were treated every 2 weeks with NN2101 via intravitreal injection for 16 weeks.

Results: Hypoxia-induced expression of c-kit, HIF, and VEGF in Muller glial, photoreceptor, and RPE cells was reduced by NN2101. Interestingly, NN2101 reduced HIF-1α protein stability via the ubiquitin-proteasome pathway. In addition, NN2101 decreased tube formation, migration, and proliferation of hypoxic endothelial cells. Consistently, in vivo Matrigel plug assay showed NN2101 inhibits neovascularization. HRMEC/RPE co-culture exhibited that HIF-1α inhibition by NN2101 effectively blocks VEGF secretion from RPE, similar to Eylea. Also, secretome analysis under hypoxia showed proangiogenic factors, including HIF target genes related to AMD, RVO, and DR were up-regulated, an effect significantly reduced by NN2101 vs Eylea. In muller glial and photoreceptor cells, NN2101 treatment maintained VEGF at basal levels even under the hypoxic conditions, whereas Eylea reduced VEGF to 10% of basal levels. In db/db mice, NN2101 rescued apoptosis in the ganglion cell layer, whereas Eylea-treated mice showed increased apoptotic cell death compared to vehicle control. Analysis of ERG waveforms and immunofluorescence staining demonstrated that the function of photoreceptors, amacrine, and Muller glial cells were significantly improved by NN2101 in the db/db mouse. Also, the number of degenerative capillaries was significantly decreased by NN2101 treatment compared to control.

Conclusions: We demonstrated that c-kit inhibition with NN2101 efficiently suppresses pathological vessels by reducing expression of multiple angiogenic cytokines via destabilization of HIF in the retina.

ABSTRACT BODY:

Purpose: To investigate the efficacy of a deep learning regression method to predict macula ganglion cell-inner plexiform layer (GCIPL) and optic nerve head (ONH) retinal nerve fiber layer (RNFL) thickness for use in glaucoma neuroprotection clinical trials.

Methods: Glaucoma patients with good quality macula and ONH scans were enrolled in two longitudinal studies, the African Descent and Glaucoma Evaluation Study (ADAGES) and the Diagnostic Innovations in Glaucoma Study (DIGS). Spectralis macula posterior pole scans and optic nerve head (ONH) circle scans on 3327 pairs of GCIPL/RNFL scans from 1096 eyes (550 patients) were included. Participants were randomly distributed into training (502 participants) and test (48 participants) sets. Networks had access to GCIPL and RNFL data from one hemiretina of the probe eye and all data from the fellow eye. The models were then trained to predict the GCIPL or RNFL thickness of the remaining probe eye hemiretina (see Figure). Mean absolute error (MAE) and r^2, calculated using each individual bin (“global”) or averaged over the entire hemifield (“mean”), were used to evaluate model performance.

Results: The deep learning model was able to predict superior and inferior GCIPL thicknesses with a global r^2 values of 0.90 and 0.86, r^2 of mean of 0.90 and 0.86, and mean MAE of 3.7 μm and 4.2 μm, respectively (see Table). For superior and inferior RNFL thickness predictions, model performance was slightly lower, with a global r^2 of 0.75 and 0.84, r^2 of mean of 0.81 and 0.82, and mean MAE of 9.3 μm and 8.5 μm, respectively. There was only a modest decrease in model performance when predicting GCIPL and RNFL in more severe disease. Using our predictions, we

estimate that we can reduce patient numbers by 11-fold compared to a conventional trial.
Conclusions: Our deep learning models were able to accurately estimate both macula GCIPL and ONH RNFL hemiretinal thickness. These model predictions may help reduce clinical trial sample size requirements and/or trial duration and facilitate the development of neuroprotective glaucoma therapies.

ABSTRACT BODY:

Purpose: A national audit of Australian optometry practices estimated the appropriateness of glaucoma primary care against evidence-derived clinical indicators. Benchmarking is a quality improvement activity; however, benchmarks for glaucoma primary care delivery do not exist. We developed benchmarks for glaucoma primary care delivery.

Methods: Normative and realistic benchmarks were developed as more than one comparator improves feedback credibility. A systematic review identified 11 glaucoma audit studies for inclusion. Compliance score averages were extracted to provide normative benchmark ranges. Realistic benchmarks were separately derived from the pre-existing nationally representative dataset using the Achievable Benchmarks of Care (ABC) method. A Bayesian adjustment was used to limit effect of small numbers of eligible patient encounters on practice appropriateness scores. ABCs were calculated from the top ten percent of Bayesian adjusted appropriateness scores. The appropriateness scores for each practice were compared to the developed benchmarks to explore distribution of practices that were at or above benchmarks.

Results: Normative benchmarks were established for 17 clinical indicators. The normative benchmarks for 8 (of 17) indicators were met by more than 80% of practices. Realistic benchmarks were calculated for 34 clinical indicators with 26 indicators having realistic benchmarks set at or above 90% appropriateness. The realistic benchmarks for 14 (of 34) clinical indicators were met by more than 80% of practices. There were 10 clinical indicators where most (>80%) of the optometry practices did not meet either benchmark (Fig). These indicators related to the identification of glaucoma risk factors (migraine history, steroid use, high and low blood pressure status), side effects of glaucoma medication, and physical examinations (applanation tonometry, gonioscopy or van Herick angle assessment, size of optic disc, pattern of neuroretinal rim, visual field assessment).

Conclusions: This study established normative and realistic benchmarks for glaucoma primary care clinical indicators. Most Australian optometry practices provided care at or above the benchmarks. Pockets of sub-optimal care delivery identified should be targeted for quality improvement. The developed benchmarks may be used to provide feedback and monitor the success of such programs.

ABSTRACT BODY:

Purpose:

Screening of food materials for myopia suppressive factors measuring expression of early growth response 1 (Egr-1), a myopia suppressive gene, demonstrated that ginkgo biloba extracts (GBEs) increase Egr-1 activity in a previous study. This study was aimed to assess the suppressive effects of GBEs on myopia using a lens-induced myopia model in mice.

Methods: 3-week-old male C57B6/ J mice were randomly assigned to three groups: mice fed with normal chow and equipped with 0 diopter (D) lenses to their both eyes (control group), mice fed with normal chow and equipped with -30 D lenses to their both eyes (myopia-induced group), and mice fed with 0.0667% GBEs and equipped with -30 D lenses to their both eyes (GBEs group) (n = 8 in each group). Refraction, axial length, and choroidal thickness were measured with an infrared photorefractor and an SD-OCT system before and 3 weeks after feeding.

Results: Compared with the control group, refraction ($p < 0.001$), axial length ($p < 0.05$), and choroidal thickness ($p < 0.001$) showed myopic shifts in the myopia-induced group three weeks after normal feeding. In the GBEs group, change in refraction was significantly suppressed compared with the myopia-induced group (-1.59 ± 3.90 D vs. -9.92 ± 2.49 D, $p < 0.001$). Change in axial length was significantly suppressed compared with the myopia-induced group (0.19 ± 0.04 mm vs. 0.22 ± 0.02 mm, $p<0.05$). Change in choroidal thickness in the GBEs group was significantly suppressed compared with the myopia-induced group (-0.27 ± 0.47 um vs. -1.32 ± 0.56 um, $p < 0.01$).

Conclusions: GBEs showed suppressive effects on myopia in mice.

ABSTRACT BODY:

Purpose: Mammals sense light primarily with rods, cones, and intrinsically photosensitive retinal ganglion cells (ipRGCs). IpRGCs support a variety of visual processes, one of the most important being synchronization of the circadian clock with the solar day. These neurons provide practically all retinal input to the master clock, the suprachiasmatic nucleus (SCN; located in the hypothalamus). The clock responds to irradiance, the overall intensity of illumination, rather than image detail. We hypothesized that ipRGCs send an effective representation of irradiance to the master clock.

Methods: To preserve natural ipRGC responses and obtain a high level of experimental control, we used an ex vivo, acute brain slice that contained most of the SCN and retained intact connectivity with both retinas (Wong, Graham, and Berson 2007 J Biol Rhythms). We made these explants from adult mice in which ipRGC axons and presynaptic terminals expressed an optical reporter of activity. We imaged this reporter with multiphoton microscopy while delivering visual stimuli to the retinas.

Results: The signals conveyed from ipRGCs to the SCN are complex and dynamic. IpRGC terminals are differentially tuned to light intensity, with distinct subsets activated across the environmental range. The most common terminal is silent when the intensity is below or above its preferred range. Terminals also vary in their response kinetics, with some remaining activated long after the period of illumination. Terminals with different tunings and response kinetics are intermingled within the volume of the SCN. Finally, the retina-SCN explant is robust, with light responses remaining for at least 24 hours after preparation.

Conclusions: IpRGC signals within the SCN appear to support an effective representation of irradiance. By preferring different irradiance ranges, each ipRGC encodes its range at high resolution and the population of ipRGCs collectively encodes a broad range. By silencing outside of their preferred ranges, ipRGCs potentially save energy. By producing persistent responses, ipRGCS smooth temporal contrast to favor the representation of ambient illumination rather than image detail. Moreover, the full spectrum of ipRGC signals appears to be repeated throughout the SCN and is thus broadly available to postsynaptic neurons.

ABSTRACT BODY:

Purpose: Patients on systemic immunomodulatory therapy (IMT) for uveitis are at higher risk of infection and infectious complications. While other medical specialties have studied the safety of IMT in non-ocular, autoimmune conditions vis-à-vis coronavirus disease 2019 (COVID-19), little is known about the effects of these drugs in uveitis patients specifically. The objective of this study was to determine if uveitis patients with COVID-19 were at higher risk of hospitalization for this pandemic illness and whether systemic IMT affected this risk.

Methods: Retrospective cohort study of uveitis patients in 2020 in the United States. The Symphony health insurance claims dataset was used. Inclusion criteria were an ICD10 code for COVID-19, a code for any form of non-infectious uveitis or scleritis, and age 18 or greater. Drugs studied included methotrexate, mycophenolate, azathioprine, tacrolimus, cyclosporine, adalimumab, infliximab, tocilizumab, rituximab, and JAK, IL-17, and IL-12/23 inhibitors. The main outcome measure was adjusted odds of hospitalization for COVID-19. Multivariable logistic regression was used to adjust for major risk factors for severe COVID-19 disease, including age, biological sex, cardiac, pulmonary, hepatic, and renal disease, obesity, organ transplant, stroke, and certain cancers.

Results: 3,974,272 patients in the dataset were diagnosed with COVID-19 in 2020. Of these, 6389 (0.16%) had established diagnoses of uveitis or scleritis. Within the uveitis group, mean age was 54 years (SD 16), and 62% were female. 708 (11.1%) of the uveitis patients were hospitalized for COVID-19, significantly greater than the 7.3% rate amongst all adult, COVID-19-positive patients in the dataset ($p < 0.001$) and the CDC estimate of 7.5% for the US population in 2020 ($p < 0.001$). No agent showed a statistically significant effect on hospitalization. The higher rate of hospitalization in uveitis patients was partly, though not completely, explained by higher rates in uveitis-associated autoimmune conditions in the dataset as a whole.

Conclusions: Uveitis patients have a greater risk of hospitalization for COVID-19 compared with the general population. As a whole, conventional IMT and biologics do not increase the risk of COVID-19 hospitalization amongst uveitis patients infected with the virus.

ABSTRACT BODY:

Purpose: Ethambutol (EMB) is used in the treatment of tuberculosis (TB) or mycobacterium avium complex infections. A devastating adverse effect of EMB is toxic optic atrophy, which occurs in 1–2.5% of patients. To date, the pathophysiology of EMB-induced optic atrophy is incompletely understood.

Methods: Human iPSC-derived retinal ganglion cells (iPSC-RGC) or retinal organoids were treated with 2, 20, 200, or 2,000 µg/ml EMB. Time and dose-dependent EMB induced changes were observed by confocal microscopy and gene expression changes by RT-PCR. Mitochondrial function in iPSC-RGC was measured using the Seahorse XFe analyzer.

Results: Treatment of retinal organoids with EMB resulted in a time and dose-dependent loss of RGC, but not other retinal neurons. 24 hours of EMB treatment induced the dose-dependent formation of bubbles in the cytosol of iPSC-derived RGC concordant with increased NOS3 synthesis ($P=0.0001$). At higher concentrations significantly elevated expression of the apoptotic mediators BAX, APAF1, CASP3, CASP8, and CASP7 was detected (1.5 to 3-fold). We also detected increased expression of MIEF1 (1.8-fold, $P<0.0001$), suggesting impaired maintenance of mitochondrial DNA. Mitochondrial staining demonstrated decreased mitochondrial length in EMB treated iPSC-RGC (112.1±41.6 µm vs. 212.9±76.3 µm in untreated controls, $P<0.0001$), indicating mitochondrial fragmentation. Functional mitochondrial measurements demonstrated that spare respiratory capacity in iPSC-RGC is increased by 21%, 20% and 27% treated with 2, 20, or 200 µg/ml EMB, respectively ($P<0.05$). Furthermore, cells treated with 200 ug/mL EMB displayed a 24% increase in non-mitochondrial respiration ($P=0.005$).

Conclusions: Our findings suggest that Ethambutol-induced optic atrophy may be caused by nitric oxide stress and dysregulation of mitochondrial dynamics in favor of mitochondrial fission. This, in turn, causes an increase in energy demand that may lead to RGC dysfunction and, eventually, apoptotic cell death.

ABSTRACT BODY:

Purpose: Accurate segmentation of the fovea and the arteriovenous vein in the optic disc centre plays a vital role in the diagnostic system for diabetic retinopathy. In recent years, deep learning has shown its powerful performance in medical image analysis. Accordingly, this study presents a fundus image segmentation method based on self-attention and mixed-loss adversarial networks. Extensive experiments were performed on the fovea and the optic disc's central fine arteriovenous vein in two public datasets.

Methods: As shown in Fig. 1, the fundus images were preprocessed by using data augmentation operations such as rotation and symmetry and sent to the generator based on the separable convolutional U-Net. It adopts a self-attention mechanism to adjust the feature weights between the sampling points to guarantee the detection accuracy. Second, we leverage the separable convolutional U-Net to implement the segmentation by adding the adversarial training framework. The generator's outcome is improved by the output of the judge and the loss return.

Results: The proposed method outperforms the state-of-the-art algorithms in accuracy and execution efficiency. In general, the average sensitivity is 95.56%, and the detection performance is 97.21% over the data samples.

Conclusions: The proposed method has low computational complexity while achieving promising accuracy. The segmentation results obtained are close to manual delineation. It is therefore a potential instrument in clinical applications.

ABSTRACT BODY:

Purpose: Develop and validate a questionnaire that quantitatively determines spectacle independence following bilateral implantation with presbyopia-correcting intraocular lenses.

Methods: The content of the PRSIQ was based on literature reviews as well as clinician and patient input. Draft items were assessed/revised in debriefing interviews for qualitative validation. Two quantitative validation studies were conducted with the initial PRSIQ, and two quantitative validation studies were conducted with the final PRSIQ. Confirmatory factor analyses, including IRT calibration, were performed, as well as reliability estimates and validity analyses of the resulting scores. To estimate effect size, Generalized Estimating Equations (GEEs) were used to account for repeated measures.

Results: Over 50 patients provided direct input in the development of the PRSIQ. Qualitative research demonstrated that patients often considered themselves spectacle independent. Yet, when probed, it was determined some actually wore correction for certain activities.

Quantitative assessments conducted across 4 studies (n=3,208) demonstrated evidence of validity. A higher proportion of patients who achieved spectacle independence had 20/20 or better binocular uncorrected intermediate vision and lower magnitude of residual refraction. Those classified as spectacle independent had higher satisfaction with overall uncorrected vision at all distances. GEE models (n=272) demonstrated a consistent large effect size resulting in significantly greater proportion of participants achieving spectacle independence in the treatment vs. control arm. Test-retest reliability was high (>0.84) overall and in the refractory stable population.

Conclusions: The PRSIQ is a patient-reported measure assessing spectacle independence following cataract surgery. All quantitative analyses conform to predictions and support the use of the PRSIQ as a measure of spectacle independence.

ABSTRACT BODY:

Purpose: Nonsense mutation in the terminal exon of the RP1 gene is a common cause of autosomal dominant retinitis pigmentosa. Production of truncated RP1 proteins has yet to be demonstrated in RP1 patients due to the lack of patient-derived retinal tissue and appropriate antibodies. TO enable detection of truncated RP1 proteins in patient-derived retinal tissues we modified the mutant RP1 locus in patient-derived induced pluripotent stem cells (iPSCs) with the luminescent HiBiT tag.

Methods: Paired nickase CRISPR/Cas9 gene editing was used to insert the HiBiT luminescent tag into iPSCs from an 85-year old female donor with RP1 p.E700X. HiBiT tagged iPSCs were characterised and differentiated into retinal organoids. Retinal organoids were treated with the translational readthrough inducing drug PTC124 and HiBiT-tagged RP1 protein detected by luminescence assays and western blotting.

Results: High efficiency insertion of the HiBiT tag into the RP1 locus was demonstrated in RP1 patient-derived iPSC. Western blotting demonstrated expression of full-length RP1 protein (198kDa) as well as a novel 47kDa band in RP1-HiBiT retinal organoids and adult human retinal tissues. HiBiT blotting of RP1-HiBiT retinal organoids revealed four luminescent bands (22kDa, 47kDa, 90kDa and 100kDa). Treatment with PTC124 reduced expression of the 22kDa and 90kDa bands, increased 47kDa expression and induced expression of a new 120kDa band.

Conclusions: We demonstrate the first direct evidence for production of truncated RP1 protein in retinal cells derived from an RP1 patient. Treatment of patient-derived retinal organoids with PTC124 induced limited translational readthrough of mutant RP1 mRNA, but did not result in production of full-length PR1 protein. We also report but detection of a novel 48kDa RP1 protein isoform in HiBiT retinal organoids and adult human retina.

ABSTRACT BODY:

Purpose: Intracameral bimatoprost implant slowly releases bimatoprost to lower intraocular pressure (IOP). Previously reported phase 3 studies of the implant (ARTEMIS) evaluated IOP lowering post single administration only through 15 weeks, because 2 additional implants were administered at 16-week intervals. This analysis used data from a phase 3b clinical trial to evaluate the longevity of IOP control after single administration of the 10-µg bimatoprost implant.

Methods: Ongoing, open-label, multicenter, phase 3b study (NCT03850782) evaluating bimatoprost implant pro re nata in patients with open-angle glaucoma or ocular hypertension inadequately managed with topical IOP-lowering medication for reasons other than efficacy (eg, intolerance or nonadherence). Retreatment criteria were based on clinically meaningful IOP increase (investigator judgement), time from last administration, residual implant size assessment, and safety evaluation. Rescue treatment (IOP-lowering medication or procedure) was allowed. Analysis included Kaplan-Meier estimates of time to rescue/retreatment after the day 1 implant administration in the study eye, and IOP in those participants not rescued/retreated. Data available as of October 20, 2021 were analyzed.

Results: A total of 203 participants administered a 10-µg bimatoprost implant were included in the analysis. Baseline mean (SD) IOP was 25.6 (2.97) mmHg. Mean (SD) IOP and mean (SD) change from baseline (mmHg) in those not rescued/retreated were 17.6 (3.77) and −7.9 (3.90) at week 12 (n=175); 18.3 (4.40) and −6.6 (4.12) at month 6 (n=114); 18.5 (4.17) and −6.1 (4.05) at month 8 (n=74); and 18.5 (3.52) and −5.9 (3.81) at month 12 (n=47). The Kaplan-Meier estimate (95% CI) of the probability of not requiring rescue/retreatment after a single administration of the bimatoprost implant was 97.4% (93.8%, 98.9%) at week 12; 74.6% (67.0%, 80.8%) at month 6; 65.1% (56.5%, 72.4%) at month 8; and 55.5% (46.1%, 63.9%) at month 12.

Conclusions: Based on the available data, the estimated probability of IOP control after a single bimatoprost implant administration was 75% at 6 months and 56% at 12 months. The duration of IOP control is consistent with results of a previous phase 1/2 study (Craven et al. Drugs. 2020;80:167-79). Not all participants included in the present analysis had reached the month 12 visit, and the study is still enrolling. Safety outcomes will be reported at study completion.

SUBMITTER (NAME ONLY): Grayson Armstrong

TITLE: Physician-to-Physician eConsultations to Ophthalmologists at an Academic Medical Center

SESSION TITLE: Using Technology for Care Delivery and Improvement

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: G.W. Armstrong, N.A. Sherif, A.C. Lorch, Ophthalmology, Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|G.W. Armstrong, A.C. Lorch, Ophthalmology, Harvard Medical School, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Grayson Armstrong: Commercial Relationship(s);Code O (Owner):Ocular Technologies Inc;Code C (Consultant/Contractor):McKinsey & Company;Code C (Consultant/Contractor):Xenon-VR;Code C (Consultant/Contractor):Ophthalytics;Code C (Consultant/Contractor):Kriya Therapeutics | Noha Sherif: Commercial Relationship: Code N (No Commercial Relationship) | Alice Lorch: Commercial Relationship(s);Code C (Consultant/Contractor):Regeneron

ABSTRACT BODY:

Purpose: Despite the known advantages of electronic consultation (eConsult) to patients, providers, and healthcare systems, including increased timely access to specialist consultation, decreased resource waste, and improved care coordination, the role of eConsults in ophthalmology has yet to be explored. We conducted a retrospective chart review to evaluate the feasibility and diagnostic accuracy of a physician-to-physician eConsults ophthalmology program and characterize the types of clinical questions and ophthalmic learning needs of healthcare providers.

Methods: Ophthalmology eConsults were reviewed to identify submission-to-response time, primary diagnoses made by eConsultants, and referral outcomes including symptom resolution, completion of follow-up appointments, and presentation to an emergency department (ED). eConsults underwent thematic review and categorized based on the type of clinical question asked, urgency, and ophthalmic condition addressed. Demographic data on patients and referring providers were also collected.

Results: One hundred ophthalmology eConsults were placed, and 100% were responded to by an ophthalmologist. An average of 1.6 days and a standard deviation (SD) of ±1.9 elapsed from the time an eConsult order was placed to the time the consultation was completed. Of the eConsults, 62% (n=62) were recommended for an in-person evaluation; of these, 48.4% (n=30) presented to an ophthalmologist. For patients who had an in-person follow-up, concordance of diagnoses between eConsultant and in-person evaluation was observed in 93% (n=28) of cases. On average, in person evaluations occurred within 28.9 (SD ±27.4) days of the eConsult response. The most common clinical inquiries were related to appropriate triage and referral (24.4%), management (22%), and diagnosis (19.7%). All eConsults were nonurgent. The most common ophthalmic condition addressed was chalazia/hordeola (14%). Only 5% of patients presented to an ED for the same ophthalmic concern addressed by eConsult.

Conclusions: Ophthalmology eConsultants can diagnose, triage, and manage nonurgent ocular conditions with high accuracy through electronic medical record review. eConsult programs can also facilitate timely access to specialty care.

TITLE: Benzoic acid-mediated inhibition of retinal necroptosis involves ciliary neurotrophic factor

SESSION TITLE: Animal models of human ocular disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Jin, C. Lu, S. Li, Neuroscience Center of Excellence, LSU Health New Orleans, New Orleans, Louisiana, UNITED STATES|M. Jin, Department of Ophthalmology, School of Medicine, LSU Health New Orleans, New Orleans, Louisiana, UNITED STATES|

Commercial Relationships Disclosure: Minghao Jin: Commercial Relationship: Code N (No Commercial Relationship) | Chunfeng Lu: Commercial Relationship: Code N (No Commercial Relationship) | Songhua Li: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We have previously showed that ciliary neurotrophic factor (CNTF) suppresses expressions of rod and cone opsins as well as visual cycle enzymes (RPE65 isomerase and lecithin:retinol acyl transferase), thereby reducing the formation of the light sensitive visual pigments that mediate normal vision and photodamage-induced retinal degeneration. The purpose of this study was to test whether benzoic acid, which has been shown to promote CNTF expression in cell culture, and CNTF-deficiency can protect photoreceptors from light damage-induced necroptosis.

Methods: Dark adapted wild-type (129S2/Sv strain) and $Cntf^{-/-}$ mice treated with different doses of sodium benzoate (NaB) were exposed to 15000 lux light to induce retinal photodamage. Expression of the necrosome proteins such as receptor interacting protein kinase 1 (RIPK1), RIPK3, and mixed lineage kinase domain-like protein (MLKL) in the retinas were analyzed by immunoblot and immunohistochemical analyses. Interaction of these necrosome proteins were determined by double-immunostaining and immunoprecipitation assays. Activation of the necrosomes was assessed by detecting phosphorylation of MLKL. Photoreceptor degeneration was evaluated by immunohistochemistry and immunoblot analysis of opsins and cone arrestin.

Results: Intense light exposure induced a significant upregulation of both RIPK expression and MLKL phosphorylation in the WT mouse retinas. Interactions of the necrosome proteins were also enhanced in the WT retinas exposed intense light. Under the same light conditions, NaB treatment inhibited the RIPK upregulation and MLKL activation in a dose-dependent manner in WT retinas. Immunoblot and immunohistochemical analyses showed that intense light exposure caused degeneration of rods and cones in WT mice and NaB-treatment alleviated the light-induced degeneration of photoreceptors in WT. The same intense light exposure induced more greater activation of the necrosomes in the $Cntf^{-/-}$ retinas, as compared to WT mice. NaB-treatment, however, did not significantly inhibit RIPK3 upregulation, MLKL phosphorylation and retinal degeneration in the $Cntf^{-/-}$ mice exposed to the intense light.

Conclusions: 1) activation of the necrosomes contributes to light-induced retinal degeneration in both WT and $Cntf^{-/-}$ mice; 2) NaB inhibited photodamage-induced necrosome activation in the WT, but not in $Cntf^{-/-}$, retinas.

TITLE: Disease modelling and functional characterisation using iPSC derived RPE in RCBTB1-associated retinopathy

SESSION TITLE: Stem cells and disease modeling in vitro

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Z. Huang, S. McLenachan, D. Zhang, Centre for Ophthalmology and Visual Science, The University of Western Australia, Perth, Western Australia, AUSTRALIA|Z. Huang, S. McLenachan, D. Zhang, F.K. Chen, Lions Eye Institute, Nedlands, Western Australia, AUSTRALIA|F.K. Chen, Department of Ophthalmology, Royal Perth Hospital, Perth, Western Australia, AUSTRALIA|

Commercial Relationships Disclosure: Zhiqin Huang: Commercial Relationship: Code N (No Commercial Relationship) | Samuel McLenachan: Commercial Relationship: Code N (No Commercial Relationship) | Dan Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Fred Chen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: RCBTB1 has been hypothesized to be involved in biological processes associated with the ubiquitin proteasome system (UPS) and oxidative stress pathways in retinal cells. We sought to expand our understanding of the physiological and pathological role RCBTB1 in retinal cells using an iPSC derived RPE cellular model of RCBTB1-associated retinopathy.

Methods: Expression of RCBTB1 was quantified via qRT-PCR and western blotting in patient derived iPSC-RPE cells (c.[170delG];[707delA]) compared to healthy controls. Co-immunoprecipitation (Co-IP) was conducted in health control iPSC-RPE cells to characterize interactions between RCBTB1 and other proteins including CUL3, UBE2E3 and NFE2L2. Human ubiquitin array analysis in these cells using an R&D Systems Proteome Profiler Human Ubiquitin Array Kit (ARY027, R&D Systems) was performed to measure the ubiquitination level of 49 different proteins. Furthermore, mitochondrial integrity and structure in iPSC-RPE were investigated using transmission electron microscopy.

Results: Reduced RCBTB1 expression level was confirmed in patient derived iPSC-RPE cells compared to healthy controls. Co-IP experiment demonstrated that RCBTB1 interacts with CUL3 and UBE2E3 but not NFE2L2 in iPSC-RPE cells. Analysis of ubiquitin array identified two protein with significant change of ubiquitination level, including PDGFR β (platelet derived growth factor receptor β) and p53. Ultrastructural analysis not only showed a thinner RPE cell layer displaying shorter microvilli, but also showed disrupted cristae formation and architecture of mitochondria in patient derived RPE compared to control, indicating mitochondrial dysfunction and consequent excessive ROS production may play a role in cellular damage in RCBTB1 deficient RPE cells.

Conclusions: We identified RCBTB1 deficiency and its effect on UPS and mitochondria ultrastructure using an iPSC derived RPE cellular model. Furthermore, we identified two potential RCBTB1 interacting proteins, CUL3 and UBE2E3. Our findings shed light on the physiological role RCBTB1 plays in human RPE cells.

Thanuja: Commercial Relationship: Code N (No Commercial Relationship) | Joseph Bonanno: Commercial Relationship: Code N (No Commercial Relationship) | Sangly Srinivas: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Local hotspots of elevated osmolarity of the tear film, predicted in the tear breakup domains, are implicated in dry eye disease (DED). We have prepared osmosensitive nanoliposomes and characterized for sensing local osmolarity of the tear film by noninvasive fluorescence imaging.

Methods: Nanoliposomes, loaded with fluorescent dyes, calcein (susceptible to self-quenching) and sulforhodamine 101 (SR101), were produced by the thin-film hydration method followed by ultrasonication and repeated extrusion.

Results: Nanoliposomes were spherical, unilamellar, uniform in size and negatively charged (117.9 ± 6.4 nm; polydispersity index [PDI] of 0.15 ± 0.02, -23.7 ± 1.5 mV). They showed negligible dye leakage during storage over 3 days, and underwent minimal changes in size, PDI, and charge. Deliberate swelling and shrinkage of nanoliposomes by exposure to hyposmotic and hyperosmotic media led to rapid de-quenching and quenching of calcein fluorescence. Thus, the ratio of green fluorescence of calcein (F_{Green}) to the red fluorescence of SR101 (F_{Red}) decreased with increasing osmolarity and vice versa; F_{Green}/F_{Red} vs. osmolarity obeyed Boyle-Van't Hoff's law. When nanoliposomes were dispersed in a gelatin film and sucrose solution was introduced at the center, local F_{Green}/F_{Red} altered with osmolarity in response to sucrose gradients. When instilled on contact lenses or ex vivo porcine corneas, nanoliposomes suspension dispersed evenly and showed a decrease in F_{Green}/F_{Red} vs. time when exposed to room air.

Conclusions: Fluorescent nanoliposomes of high osmosensitivity and suitable for sensing local osmolarity on the corneal surface have been prepared and characterized. The measurements of local osmolarity will advance our current understanding of the pathophysiology of DED and possibly establish novel diagnostics to assess the severity of the disease.

ABSTRACT BODY:

Purpose: Many retinal diseases differentially affect arteries and veins. We sought to develop a tool to non-invasively analyze arteriolar and venular connectivity of capillary plexuses in the healthy macula using optical coherence tomography angiography (OCTA), and examined clinical applications in eyes with neovascular pathology.

Methods: 20 eyes of 20 healthy controls (age 25.3 ± 2.2 years) were imaged with OCTA, and 3D volumes of the full retinal slab segmented into superficial (SCP), middle (MCP), and deep capillary plexuses (DCP). Large SCP vessels were classified as arterioles or venules by 2 graders. We implemented a custom watershed algorithm to identify arteriolar- and venular-connected capillaries by using the large SCP vessels as seed points for flooding the rest of the vascular network. We calculated A/V ratios of arteriolar- to venular-connected vessels and adjusted flow indices (AFI) for the SCP, MCP, and DCP.

We also analyzed 2 eyes of a patient with proliferative diabetic retinopathy (PDR) and 1 eye of a patient with macular telangiectasia (MacTel) to evaluate utility of this method in visualizing vascular connectivity to pathological neovascularization (NV).

Results: In healthy eyes, MCP A/V ratio was significantly higher than the SCP and the DCP, indicating a higher proportion of arteriolar-connected vessels (all $p < 0.001$). Arteriolar-connected vessel AFIs were higher than venular-connected AFIs in the SCP, but this pattern reversed in the MCP and DCP, which had higher venular-connected AFIs than arteriolar (all $p < 0.001$).

In the PDR eyes, preretinal NV originated from venules, while intra-retinal microvascular abnormalities appeared as dilated capillary loops within the MCP connecting an arteriole and venule. In MacTel, diving SCP venules formed the epicenter of outer retinal NV.

Conclusions: We developed an algorithm for assigning arteriolar and venular connectivity of retinal vessels. Healthy eyes showed increased MCP arteriolar connections but relatively slower arteriolar vs. venular flow velocity in the MCP and DCP, which may contribute to the unique vulnerability of these layers to ischemia in conditions like paracentral acute middle maculopathy (PAMM). In eyes with neovascular pathology, our findings were consistent with histopathologic studies. Further studies are needed to investigate utility of this method in PAMM and other vascular diseases.

ABSTRACT BODY:

Purpose: Primary open-angle glaucoma (POAG) manifests as distinct visual field (VF) loss patterns localizing to the nerve fiber layer. We used an autonomous algorithm to classify incident visual field VF loss patterns in POAG and evaluated whether a plant-based low carb diet and other risk factors may be differently associated for POAG with paracentral VF loss versus POAG with peripheral VF loss.

Methods: Participants (n=79,906) from the Nurses' Health Study (NHS), aged ≥40 years and free of glaucoma, were followed from 1980 to 2018. Information on diet, body mass index, smoking, diabetes and other covariates were assessed on biennial questionnaires. Deciles of a plant-based low-carbohydrate-diet (LCD) adherence score were calculated to represent adherence to diets lower in carbohydrate and higher in protein and fat from plant sources. Incident POAG cases with reproducible Humphrey VF loss were confirmed with medical records. The total deviation information of the earliest reliable VF for each eye with POAG was extracted, and a statistical learning method was used to identify optimal solutions for regional vision loss patterns. Each POAG eye was assigned the VF pattern ("archetype") based on the highest weighting coefficient. Multivariable-adjusted hazard ratios (HRs) for POAG of various archetypes and 95% confidence intervals (CIs) were estimated using per-eye Cox proportional hazards models.

Results: We identified 14 archetypes; of these, 9 archetypes represented early loss. For comparison, we combined 2 archetypes showing paracentral VF loss (n=165 eyes with incident POAG) and combined 7 archetypes showing peripheral VF (n=1145 eyes with incident POAG). The associations for body mass index (BMI; kg/m2), cigarette smoking, and diabetes for the two outcomes were not significantly different ($p_{contrast}$≥0.11). However, the association with higher adherence to a plant-based LCD score was stronger for paracentral VF loss (HR=0.79, 95%CI= 0.66, 0.96 per 1 SD increase in diet score) versus peripheral VF loss (HR=1.00, 95%CI=0.98, 1.01), with $p_{contrast}$=0.03.

Conclusions: Compared to POAG with peripheral VF loss, POAG with early paracentral VF loss may have common as well as distinct determinants; higher adherence to a plant-based LCD diet was inversely associated only with paracentral VF loss.

ABSTRACT BODY:

Purpose: Human iPS cell (hiPSC)-derived retinal organoids would not ordinarily contain microglia because the hiPSC are driven down a neuroectodermal pathway and microglia are derived from yolk sac. In normal development, however, microglia migrate into the retina where the neural environment is essential for the development and maintenance of their mature functional properties. Since microglia are known to play critical roles in maintaining the normal retinal environment, as well as retinal disease, we set out to develop a new 3D in vitro model by co-culturing hiPSC-derived retinal organoids and hiPSC-derived microglia.

Methods: Retinal organoids and microglial progenitor cells were differentiated from a common line of hiPSCs and co-cultured at various numbers of weeks in culture. The localization, morphology, and properties of microglia in the retinal organoids were evaluated by immunostaining and qPCR.

Results: We co-cultured microglial precursor cells with retinal organoids between 20 to 35 weeks old. We observed IBA1-positive microglia in the retina from 2 weeks after the start of co-culture, reaching maximal numbers at 4 to 6 weeks. The mean number of microglia in the retina was 6.0±2.1/mm. At 6 weeks of co-culture, microglia were observed in the outer and inner plexiform, as well as ganglion, cell layers where retinal microglia cells physiologically locate in vivo. While in the retinal organoids, microglia morphology matured from uniformly spherical to small cell bodies with long branching processes. The expression of mature cell type specific microglia markers Tmem119 and P2ry12 was also increased at 6 weeks of co-culture.

Conclusions: We optimized the timing and parameters for successful integration of microglia into retinal organoids. The hiPSC-derived microglial precursor cells co-cultured with hiPSC-derived retinal organoids migrated to their proper anatomical locations and developed a morphological maturity comparable to that observed in vivo. Our results suggested that this co-culture system may be useful for understanding the pathogenesis of retinal diseases involving pathological activity of retinal microglia and for drug discovery.

ABSTRACT BODY:

Purpose: Neuroinflammation is closely associated with neurodegeneration, and is a major cause of vision impairment in blinding diseases such as diabetic retinopathy (DR). Spermine oxidase (SMOX) is a major enzyme in the polyamine oxidation pathway. Previous findings from our laboratory have shown that treatment with MDL 72527, a selective inhibitor for SMOX, reduced microglial activation and upregulated antioxidant signaling in a mouse model of retinal excitotoxicity. In the present study, using the same model, we investigated the impact of SMOX inhibition on the status of inflammatory cells, cytokine levels, and oxidative damage.

Methods: Mice (8-10 weeks old) received 20 nmoles of NMDA (N-Methyl-D-aspartate) or NMLA (N-Methyl-L-aspartate, control) intravitreally. 40 mg/kg/day of MDL 72527 or vehicle (normal saline) was given to mice through intraperitoneal injections. Retinal cryostat sections were prepared for immunostaining and fresh frozen retinal samples were used for Western blotting or qRT-PCR studies. C8-B4 cells were used for studying the impact of conjugated acrolein in vitro on microglia cells.

Results: Immunostaining of retinal sections showed a significant increase in the number of inflammatory cells of M1 phenotype, positive for CD (Cluster Differentiation) 68 and CD16/32 in excitotoxicity-induced retinas, while MDL 72527 treatment markedly reduced these changes ($N=3-5$, $P<0.05$). SMOX inhibition with MDL 72527 upregulated the number of M2 phenotype cells stained with arginase1 and CD206 ($N=4-6$, $P<0.05$). While retinal excitotoxicity upregulated the level of several inflammatory cytokines, MDL 72527 treatment significantly reduced many of these molecules including IL-1β, TNF-α, CCL3, and IL-21 ($N = 6-8$, $P< 0.05$). Excitotoxicity-induced upregulation in protein-conjugated acrolein (an indicator of SMOX activation and oxidative damage) was also reduced in response to SMOX inhibition ($N=5-6$, $P<0.05$). In-vitro studies using C8-B4 microglia cells showed changes in cellular morphology and an increase in reactive oxygen species formation in response to conjugated acrolein treatment.

Conclusions: Our findings indicate that the inhibition SMOX pathway reduced neuroinflammation and oxidative damage, and suggests its potential as a therapeutic target to treat neurodegenerative diseases of the eye.

ABSTRACT BODY:

Purpose: Non-penetrating injuries to the cornea and ocular surface, including non-healing persistent epithelial defects, are a significant cause of combat-related visual loss and morbidity. Mesenchymal Stromal Cells (MSCs) play an important role in tissue repair and maintenance and have been used as a cell-therapy in numerous clinical studies. The purpose of this study was to evaluate the safety and dosing of allogeneic bone marrow-derived MSCs for promoting corneal epithelial repair.

Methods: In the first cohort of our single center, Phase 1, 3 + 3 conventional cohort expansion dose-escalation study, participants with stage 2 or 3 non-healing corneal epithelial defects received a single subconjunctival injection of freshly thawed bone marrow-derived MSCs. Participants met eligibility criteria for clinical trial ID #NCT04626583 and agreed to participate in an IRB approved protocol for Investigational New Drug #18400 (FDA/CBER). MSCs were produced at the University of Illinois Hospital Clinical Stem Cell Laboratory following Good Manufacturing Practice protocols and were stored in cryogenic conditions. Patients received a single subconjunctival injection of 1.0×10^6 (50ul) MSCs along with their standard of care. Primary outcome measures included safety, defined as incidence of treatment emergent adverse events (TAEs) assessed at 28 days, and efficacy, defined as proportion of participants with epithelial defect closure assessed via slit lamp fluorescein staining exam.

Results: The initial cohort of n=3 participants were enrolled. At 28 days no TAEs occurred and all participants had improvement in size of corneal epithelial defects. Complete resolution was seen in one participant by 14 days, and between 28 and 56 days in another participant. The third participant, who is still being followed, had 80% improvement in epithelial defect size at 28 days.

Conclusions: These early results support the safety of locally delivered MSCs for non-healing corneal epithelial defects, while providing some signs of efficacy. Additional cohorts of this dose-escalation study, followed by further double masked, placebo controlled studies of larger size and longer duration are warranted in determining the efficacy of MSC as a treatment modality for corneal epithelial defects.

ABSTRACT BODY:

Purpose: Collecting medical data for clinical research studies needs tremendous perseverance. Yet, patients post a lot of their own personal health data on social media and share their experiences through international virtual support groups. Recurrent epithelial erosion (RCE) induces recurrent pain while reducing patients' quality of life. We report data of RCE patients who belong to an international English-speaking support group hosted by a social network. We aimed at better defining patients' symptomatology and the subjective efficacy of proposed treatments, and subsequently compared our results with literature.

Methods: We designed a 24-question questionnaire consisting in three parts: demographics, clinical data and therapies. The treatments' efficacy to prevent RCE was scored through a semi-quantitative 4-gradescale (from "no effect" to "very efficient"). In May 2021, we posted a 6-month ephemeral hyperlink on the RCE support group forum (Facebook, Meta®) pointing at our questionnaire

Results: The RCE group included 1856 members. We harvested 257 complete responses (13.8%; 222 women and 35 men; average age =42+/-12 y). Responders were mostly North Americans (n=152; 59.1%), and Caucasian (n=214; 83.3%). Fewer than one-third of RCEs were attested by a corneal subspecialist MD (n=70; 27.2%), whereas 91.8% were referred to a health care professional (n=236). The predominant symptom was acute awakening pain (n=198; 77.0%). RCE significantly impaired patients' quality of life (n=176; 68.4%). Daily wearing of an anti-Covid-19 surgical mask may have increased the frequency of episodes (n=41; 16.0%). Among surgical procedures, manual debridement was the most performed (n=56; 21.8%), effective in a third of patients (n=17; 30.3%). PTK was performed in one-fifth of patients (n=52; 20.2%), effective in two-thirds (n=31; 59.6%). 176 patients (68.4%) were treated with hypertonic gel, which, according to the patients was the most efficient medical treatment d (n=103; 58.5%; $p<0.0001$).

Conclusions: To our knowledge, this is the first real-life study involving patients with RCE, and the second collecting data through a social network in ophthalmology. Our results are consistent with previous retrospective or prospective reports based on medical records despite responder selection bias. The use of social networks to collect real life data seems to be promisingly reliable as a medical evaluation tool.

ABSTRACT BODY:
Purpose:
There are 350,000 eHealth apps.[1] There were 218 Billion app downloads in 2020.[2] Amblyopia is the most common cause of vision impairment in children and young adults, affecting 99.2M worldwide.[3] Amblyopic patients and family members fall into the demographic of mobile app users. What do free apps for amblyopia offer to our patients?
Methods:
We used the search terms “lazy eye,” “amblyopia,” “improve vision,” and “eye exercises” in the Google Play and Apple App stores to compile a list of top 10 free apps. iOS apps do not provide download information.

Inclusion criteria: Free, English language, ≥100,000 downloads in Google Play Store, ≥40 reviews in Apple App Store.
Exclusion criteria: Foreign language, paid apps.
Results: Top 10 apps (most downloads to least) in Google Play Store, Figure 1.
Top 10 apps (most reviews to least) in Apple App Store, Figure 2.

For all Android and iOS apps, vision: 7/20; color vision: 7/20; “fix and follow”: 8/20; OKN stripes: 4/20; color contrast: 5/20; vision games: 6/20; Gabor patch: 4/20; definition/education of amblyopia: 0/20; “dichoptic training: 0/20; AAO reference: 0/20. Amblyopia Va improvement exercises are more common in Android versus iOS apps. Only 1 iOS app has a visual acuity test, versus 6 Android apps. Only 2/10 iOS apps had reviews ≥100.
Conclusions: The free amblyopia apps add to the treatment armamentarium of amblyopia patients. However, additional educational features would be helpful for our amblyopic patients in the future. Eye MDs can continue to play a health education role in digital health solutions.

ABSTRACT BODY:

Purpose: To determine if binocular dichoptic and monocular occlusive therapies with or without the use of electronic devices are effective for the management of amblyopia in children.

Methods: A prospective randomized doble blinded study was conducted in our institution with 37 amblyopic children, aged from 4 to 10 years. The inclusion criteria were diagnosis of amblyopia anisometropic, strabismic and mixed (both). The exclusion criteria were amblyopia due to deprivation, previous amblyopia treatment, intraocular surgery, neurologic conditions or psychomotor retardation and uncooperative patients for visual acuity assessment. Participants were assigned into 3 groups: the first(1^{st}) group: patch on the fellow eye with near vision activities, the second(2^{nd}) group: patch on the fellow eye with the use of electronic devices and the third(3^{rd}) group: with binocular red-green glasses and electronic devices. The treatment was prescribed for 4 months with 2 consecutive hours daily. Study follow-up visits were scheduled every month during treatment and 2 months after to evaluate amblyopia relapse. With assessment of the best corrected visual acuity (BCVA) using the ETDRS chart and stereopsis using the Titmus test. Friedman test and McNemar test were used for statistical analysis.

Results: A total of 37 amblyopic children (18 boys and 19 girls) were recruited, 18 (47%) with anisometropic, 13 (35%) with strabismic and 6 (16%) with mixed amblyopia; 27 (73%) were classified as moderate and 10 (27%) with severe amblyopia. In the 1^{st} and 2^{nd} group were assigned 13 patients each, and 3^{rd} one 11 patients. A statistically significant improvement was obtained in the BCVA in all three groups (1st one from 0.69 to 0.45 logMAR p=0.024, 2nd one from 0.67 to 0.50 logMAR p=0.050 and 3rd one from 0.63 to 0.40 logMAR p=0.032) compared from baseline up to 16 weeks of treatment, with stabilization of the visual acuity after cessation of the treatment. No improvement in stereopsis was observed in any of the 3 groups.

Conclusions: The binocular red-green glasses group demonstrated improvement of BCVA in the amblyopic eye as well as in the other groups of treatment.

ABSTRACT BODY:

Purpose: Descemet Membrane Endothelial Keratoplasty (DMEK) provides excellent visual acuity and decreased tissue rejection compared to other forms of corneal transplantation. However, the thinness and fragility of DMEK tissue makes it more technically challenging with increased risks of failure with poor handling. This study was performed to determine the effect the learning curve has on DMEK outcomes.

Methods: A single-center, retrospective review of 232 DMEK surgeries for Fuchs' Dystrophy completed from start to finish by three corneal fellows was conducted. Using a standardized surgical technique and pre-loaded DMEK tissue, the learning curve for each individual fellow was analyzed by comparing the surgical outcomes from the beginning and the end of fellowship. Consecutive surgeries in groups of 10 were compared to the last 20 consecutive surgeries of the fellowship for tissue unscroll time, rebubble rate, and 6-month endothelial cell loss (ECL). A novice DMEK surgeon was considered proficient when the average outcomes for a group of 10 consecutive surgeries was not statistically different than the last 20 surgeries. Students t-test, Mann-Whitney U test, and a Fisher's exact test was used for statistical analysis.

Results: Fellow 1 (n=83 total DMEKs) had no statistical difference between the first 10 DMEK surgeries and the last 20 DMEK surgeries for rebubble rate (0% vs 15%, P=0.53) tissue unscroll time (5.5 vs 4.5 min, P=0.067), and 6-month ECL (32.2% vs 32.2%, P=0.53). Fellow 2 (n=65) did not have a statistically different rebubble rate (20% vs 10%, P=0.85) or 6-month ECL (22.9% vs 18.4%, P=0.31), however the unscroll time was significantly longer in the first 10 (4.7 vs 2.7 min, P=0.035). The difference resolved by the second 10 DMEKs. Fellow 3 (n=84) had similar 6-month ECLs (29.3% vs 28.1%, P=0.66) in the first 10 DMEKs, however significantly higher rebubble rates (30% vs 0%, P=0.030) and unscroll time (4.1 vs 1.9 min P=0.004). This difference was no longer significant by the second 10 DMEKs in all 3 categories.

Conclusions: By the second 10 surgeries, all three fellows achieved a similar rebubble rate, 6 month ECL, and tissue unscroll time as at the end of their 1 year training. 6 month ECL was the same in all three fellows at the beginning and the end of their training. With adequate supervision and training, DMEK surgery can be taught safely to fellows without significant compromise in patient outcomes.

ABSTRACT BODY:

Purpose: To investigate the predictive value of retinal nerve fiber layer defects (RNFLDs) as a risk factor for an incident stroke in 5 years.

Methods: The Kailuan Cohort Study is a community-based study, performed in Tangshan, China. A total of 14,441 participants (male: 9835 (68.1%); mean age: 53 ± 13 years (range: 21 - 108 years)) have been enrolled since the baseline in 2015,. They underwent a series of ophthalmic and systematic examinations. Using fundus photographs a localized RNFLD was defined as a wedge-shape, not spindle-shaped, defect in the retinal nerve fiber layer, running in direction to and not necessarily reaching the optic disc border. Incident cerebrovascular events including stroke were recorded till December 2019. Cox proportional hazards models were used to assess the relationship between the RNFLD prevalence at baseline and the incidence of stroke in a multivariable model.

Results: Within a follow-up of 5 years (mean: 44 ± 12 months), 291 participants developed a cerebral stroke (2.0% ± 0.1%). After excluding those individuals with glaucoma, optic neuropathy, diffuse RNFL loss, and those with unevaluable fundus photographs, 215 participants with incident stroke were compared with a randomly selected control group (n = 2147). Incident stroke occurred in the 22nd month as mean (95% confidence interval (CI): 20 - 24 months) after enrollment. The RNFLD prevalence at baseline was significantly more frequently observed in the group with incident stroke than in the control group (83/215 (38.6% ± 3.3%) versus 296/2147 (13.8% ± 0.7%); Odds ratio: 3.93; $P < 0.001$). Cox proportional hazards model demonstrated a statistically increased risk of stroke in participants with RNFLDs ($P < 0.001$), with a hazards ratio (HR) of 3.87 (95% CI: 2.45 - 6.13), after controlling of age, sex, and comorbidity of diabetes or hypertension.

Conclusions: This study demonstrated the presence of RNFLDs as a biomarker for an increased risk of future cerebral strokes.

ABSTRACT BODY:

Purpose: Subretinal fibrosis ccurs in multiple retinal diseases, including wet Age-related macular degeneration (AMD) and proliferative vitreoretinopathy (PVR). We have reported that miR-24 inhibits choroidal neovascularization (CNV) by regulating actin cytoskeleton remodeling. We aim to define the function of miR-24 in subretinal fibrosis. We hypothesize that miR-24 overexpression can repress epithelial-mesenchymal transition (EMT) and endothelial-mesenchymal transition (EndMT), therefore inhibiting fibrosis in AMD and PVR diseases.

Methods: MiR-24 overexpression in RPE and ECs was quantified by RT-qPCR. Fibrosis-related gene expression was measured by Western blot and immunostaining. Novel miR-24 target gene expression was tested by Western blot and confirmed by luciferase assays. Lentiviral-mediated knockdown or overexpression of target genes was used to mimic or rescue this phenotype. The effect of miR-24 on stress fiber formation was visualized by Phalloidin staining and quantified by ratio of G-actin/F-actin. Nuclear translocation of MRTF-A was tested in TGF-β2 treated cells after miR-24 overexpression. In PVR model, miR-24 overexpressing TGF-β2 treated RPE cells were delivered into mouse eye intravitreally. Fundus photography, histologic analysis and a PVR grading scheme were used to monitor PVR progression. Student’s t-test was used for statistical analysis.

Results: MiR-24 overexpression repressed EMT, EndMT-associated gene expression in both RPE and ECs as shown by Western blot and immunostaining. SMAD3, a major protein critical for fibrosis by mediating TGF-β signaling, was identified as a miR-24 target gene and was downregulated by miR-24 overexpression. Knockdown or overexpression of miR-24 target genes partially mimicked or rescued miR-24 overexpression phenotypes. miR-24 also repressed stress fiber formation and increased ratio of G-actin/F-actin, consistent with downregulation of its verified target protein. Overexpression of miR-24 inhibited nuclear translocation of MRTF-A in TGF-β2 treated cells. In the in vivo PVR model, miR-24 overexpression suppressed PVR formation, suggesting that miR-24 could repress fibrosis in vivo.

Conclusions: MiR24 overexpression prevents EMT, EndMT and fibrosis in RPE and EC cells through targeting TGF/SMAD3 and LIMK2/PAK4 pathways. MiR-24 will be investigated as a therapeutic agent for subretinal fibrosis in vivo.

ABSTRACT BODY:

Purpose: To assess the unmet needs of inflammatory eye disease patients and their caregivers, with a goal towards developing a patient-centered smartphone application (app) for learning about and managing uveitis.

Methods: Prospective cross-sectional survey of uveitis patients and their caregivers. The data collected included: demographic information, time since diagnosis, educational level, smartphone ownership/use, smartphone type, use of health apps, interest in a uveitis app, current modalities for learning about uveitis, understanding and desired information about uveitis, challenges of being a uveitis patient/caregiver, current challenges in disease management, and the relative importance of a variety of possible app features.

Results: 79 completed surveys were collected from 74 patients and 5 caregivers. Among the respondents, 60% were female, 44.7% were Black or African American, and a majority (80%) of patients were aged between 30-74 years. 66% were uveitis patients or caregivers for less than 5 years, 92% used a smartphone regularly, and 97% expressed interest in a smartphone app for uveitis patients. While 60% of respondents reported having health-related apps on their phones, 58% did not use them regularly, and 85% did not currently use any smartphone apps to manage or learn about uveitis. Important features of a potential smartphone app for patients and caregivers included educational materials about uveitis (96%), accessibility considerations such as text size and text-to-voice features (95%), as well as reminders for appointments (67%), medications (89%) and lab work/blood tests (94%). Challenges faced by patients and caregivers included those related to ocular symptoms, understanding of the disease process, transportation, and the associated psychiatric burden. Patients and caregivers generally reported a moderate understanding of the disease process (55%) but a good understanding of uveitis treatment (81%) and the importance of follow-up testing (90%).

Conclusions: There is an unmet need for a patient-centered smartphone app for uveitis, featuring understandable educational content, reminders for appointments and medications, and a customizable interface to accommodate vision changes. Patients and caregivers who are motivated to seek information about uveitis, including newer patients or those with lower understanding about the disease, could especially benefit from a dedicated uveitis app.

ABSTRACT BODY:

Purpose: To determine the efficacy of tumor necrosis factor (TNF) inhibitor agents in establishing scleritis quiescence and having a systemic corticosteroid sparing effect within the first year of TNF inhibitor therapy.

Methods: We conducted a multicenter retrospective chart review of patients with scleritis treated with a TNF inhibitor (adalimumab, infliximab, etanercept, golimumab, certolizumab) for at least six months between May 2016 and May 2021. Data on demographics, concurrent systemic diseases, prior therapeutic history, concurrent treatment with systemic corticosteroids, clinician assessment of scleritis activity and reason(s) for TNF inhibitor discontinuation was collected at pre-specified time points. We evaluated for scleritis quiescence and concurrent doses of systemic corticosteroids at 6 and 12 months.

Results: We identified 46 patients (56.5% female) treated for scleritis with TNF inhibitors. Mean ± SD age was 56 ± 13.5 years (range 15-87) when starting a TNF inhibitor. Underlying systemic autoimmune disease was present in 74% of subjects; rheumatoid arthritis was most common. Most patients had received prior immunosuppressive therapy (91%). 43 patients had active scleritis at time of initiation of TNF inhibitor therapy (33 adalimumab, 6 infliximab, 3 certolizumab, 1 etanercept). At 6 months 79% (34/43) of subjects obtained scleritis quiescence with TNF inhibition. At 12 months 77% (30/39) of subjects remained quiescent. Baseline daily corticosteroid use (22.5 ± 21.6 mg) decreased to 5.4 ± 8.4 mg by 6 months ($p<0.001$) and to 2.6 ± 5.9 mg by 12 months ($p<.0001$) of anti-TNF therapy.

Conclusions: TNF inhibitors are an effective scleritis therapy and provide significant systemic corticosteroid sparing effect.

ABSTRACT BODY:

Purpose: Visual acuity (VA) measurement obtained from a letter acuity chart is assumed to predict the ability to resolve the visual details of objects in real life. Conversely, a person's ability to see object details in daily life could be used to estimate the person's visual acuity. The goal of our project is to determine if a person's Yes/No answers to a series of questions about their vision in daily life can be used to estimate their visual acuity.

Methods: 333 participants from four different testing sites responded to a set of 100 yes/no questions designed to assess people’s acuity for recognizing familiar objects at typical viewing distances. The questions were selected to evaluate acuities ranging from normal to ultra-low vision. A sample question is: "Are you able to count the individual tines on a fork that is sitting on the table in front of you?". Measured VA values were available from all participants and converted to logMAR units. The yes/no responses to the 100 questions were analyzed by a two-parameter (2PL) model based on Item Response Theory. The 2PL model estimated each participant's visual ability (θ) to answer the set of questions and the difficulty and discriminability of each question.

Results: The mean age and VA of the sample were 56.66 years (18 to 93, SD = 20.72) and 0.58 logMAR (-0.3 to 2.0 logMAR, SD = 0.45). The three largest diagnostic categories were glaucoma (17%), macular degeneration (13%), and cataract (9%). The percentage of yes responses answered by each participant was significantly correlated with their VAs ($r = -0.71$, $p < .001$). A strong relationship was also found between each participant's visual ability estimate (θ) from the 2PL model and their VA ($r = -0.72$, $p < .001$). Each participant's VA was predicted by their estimated theta based on the linear relationship between the two variables. The average prediction error, calculated by the absolute difference between the predicted VA and actual VA, was 0.23 logMAR (SD = 0.18). The same linear function was used to infer the acuity limit required for each question. For example, the VA limit of the question above about forks was 0.83 logMAR.

Conclusions: Our results show that a questionnaire can be used for estimating visual acuity worse than 20/40. The item responses provide insights into the real-world visual capabilities of people across a range of acuities and may be a potentially useful tool in telehealth.

ABSTRACT BODY:

Purpose: The mechanism by which repeated intravitreal injections of the anti-VEGF drug beviczimab can produce chronically elevated intraocular pressure (IOP) is poorly understood. Here we describe a novel method for rat TM dissection, RNA isolation, and preliminary findings of TM gene expression after serial beviczimab injections.

Methods: Twelve Brown Norway male retired breeder rats were randomly assigned to receive 3 uniocular, pars plana intravitreal injections of either 0.20 µL bevacizumab (0.005 mg, n=6) or 0.20 µL balanced salt solution plus (BSS+ control, n=6) once per week under isoflurane anesthesia. Fellow eyes were untreated. Awake IOP (10 measurements per eye) was monitored three times per week prior to the start of injections and until the animals were sacrificed. One week after the third injection, animals were sacrificed, followed by immediate enucleation of both experimental and uninjected eyes. Anterior segments were first cut into quarters, and the iris and ciliary body removed with fine jewelers forceps to expose the TM. Using these same forceps, the TM was gently pealed off, revealing the outer wall of Schlemm's canal. TM tissue was placed in Trizol with the aid of a bent 30g needle and RNA was isolated using glycogen as a carrier. After pre-amplification, RT^2 Profiler PCR Arrays (Qiagen) were used to quantitate extracellular matrix and adhesion molecule-related gene expression.

Results: Linear regression indicated that IOP did not change in the experimental (P=.47) or control eyes (P=.48) over the 4 week experiment. We were successfully able to extract RNA from rat TM (n=24) obtained with the above technique (mean=77.6 ng/ml ± 38.1). In PCR arrays, Mmp11 was signficiantly downregulated in the TMs of beviczimab-injected eyes compared to fellow eyes (-2.97 fold, p = 0.046), but not in BSS+-injected eyes. Spp1 was significantly down-regulated in BSS+ eyes (-1.59 fold, p=0.031), but one of the fellow eye samples was unusable.

Conclusions: We can successfully isolate sufficient RNA from rat TM tissue for gene expression analysis. Mmp11 degrades α1-antitrypsin and IGFBP1, but has limited proteolytic activity on classical extracellular matrix molecules. Further work is needed over longer time periods to understand better the chronic effects of anti-VEGF injections on TM gene expression and IOP in this promising model.

Commercial Relationships Disclosure: MILAN RAI: Commercial Relationship: Code N (No Commercial Relationship) | Yamunadevi LAKSHMANAN: Commercial Relationship: Code N (No Commercial Relationship) | Henry Chan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Flicker-induced retinal stimulation has been found to increase the retinal blood flow in response to increased metabolic demands of activated retinal neurons, but the influence of flickering light exposure on full-field electroretinogram (ffERG) is still unclear. The purpose of this study was to investigate the physiological changes of retinal response by ffERG after brief flickering light stimulation.

Methods: Nine anaesthetized C57BL/6J mice (10 week-old) were light adapted at 1 cd/m^2 for 10 minutes. After light adaptation, baseline ffERG (pre-flickering) was recorded and then was followed by 60 seconds of resting period to eliminate the aftereffect of light flashes. After resting period, the tested eye was stimulated by 8-Hz flickering light with 0.20 cd.s/m^2 for 60 seconds that was immediately followed by post-flickering ffERG recording. Amplitudes and implicit times of ERG responses measured before and after flickering light stimulation were compared by paired t-test.

Results: Retinal flickering light stimulation induced a significant increase in b-wave amplitude (pre-flickering amplitude=170.50±11.38μV; post-flickering amplitude=187.79±12.37μV; percentage change=10.42%±5.71%, $p<0.001$). However, there was no significant change in b-wave implicit time (pre-flickering implicit time=55.76±3.14ms; post-flickering implicit time=54.33±3.23ms; percentage change=-2.50%±7.18%, $p>0.05$), a-wave amplitude (pre-flickering amplitude=-43.50±7.07μV; post-flickering amplitude=-36.95±6.51μV; percentage change=-11.91%±56.37%, $p>0.05$) and a-wave implicit time (pre-flickering implicit time=22.08±1.11ms; post-flickering implicit time=21.87±1.21ms; percentage change=-1.12%±6.13%, $p>0.05$).

Conclusions: Flickering light stimulation on retina led to a significant increase in ERG responses originating from middle retinal layer, primarily from bipolar cells but did not have significant effect on responses originating from photoreceptors. Further studies are required to understand the mechanism underlying enhanced ERG responses related to flicker-induced hyperemia.

ABSTRACT BODY:

Purpose: To report results from a retrospective analysis of clinical data, evaluating disease progression of patients with GA in 1 eye and either GA or choroidal neovascularization (CNV) in the other eye, over 3 years.

Methods: Patients (125,743) with GA in ≥1 eye were identified from the American Academy of Ophthalmology IRIS® Registry (Intelligent Research in Sight) from January 2016 to March 2017. Patients were excluded if they had a history of CNV or active CNV in the study eye, a history of any other retinal condition, or <36 months of follow-up. Patients were grouped by fellow eye status: Cohort 1, GA:GA; Cohort 2, GA:CNV (study eye GA, fellow eye CNV). Subgroups were classified by lesion location: nonsubfoveal (NSF) or subfoveal. Main outcomes were study and fellow eye disease progression including visual acuity (VA) over 3 years.

Results: Patients (36,817) met the inclusion criteria: Cohort 1: 21,789 (59.27%); Cohort 2: 14,976 (40.73%). In the GA:GA Cohort, NSF study eyes had a better mean VA at baseline (67.37 letters) than subfoveal eyes (62.33 letters). Mean 3-year VA changes from baseline were comparable for NSF (−10.38) and subfoveal (−9.31 letters) study eyes. Similar trends were observed in the GA:CNV Cohort: NSF study eyes had a better mean VA at baseline (65.80 letters) than subfoveal eyes (46.80 letters). Mean 3-year VA changes from baseline were similar for NSF (−8.53 letters) and subfoveal (−8.26 letters) study eyes. In GA:GA and GA:CNV Cohorts, NSF study eyes with a baseline VA of ≥20/40 lost a mean of −10.33 and −8.19 letters and subfoveal eyes lost a mean of −8.59 and −9.96 letters over 3 years, respectively (Figure). NSF study eyes with a baseline VA of <20/40 and ≥20/100 in GA:GA and GA:CNV Cohorts lost a mean of −12.09 and −11.44 letters vs −13.57 and −12.89 letters, respectively in subfoveal eyes over 3 years (Figure).

Conclusions: GA caused substantial disease burden in this retrospective study of a large real-world database. Eyes with GA lost significant vision over a 3-year period, consistent with trends in the previously reported 2-year analysis. The rate of vision loss was numerically similar regardless of whether lesions were NSF or subfoveal at baseline. Eyes with good vision at baseline lost more letters over 3 years compared to eyes with poor vision.

Commercial Relationships Disclosure: Seen Hang Chan: Commercial Relationship: Code N (No Commercial Relationship) | Kai Yip Choi: Commercial Relationship: Code N (No Commercial Relationship) | Henry Chan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: This cross-sectional study aimed to investigate the refractive error in Hong Kong preschool children and its association with near work (including digital device usage) among these children.

Methods: A total of 336 preschool children aged between 3 and 7 years from 6 local kindergartens were examined. Eye examinations including habitual visual acuity, photorefraction, and ocular biometric measurements were carried out. Parental questionnaires on environmental and behavioural factors including near work habits were collected. Refractive error, expressed as spherical equivalent power (SE), and axial length (AL) were the main outcome measures. Only data on right eye was presented. SE and AL were compared among groups with different time spent on near work, including reading, drawing, doing homework and using digital devices, including mobile phones and handheld electronic devices.

Results: In total, 9.82% of the children had an SE of at least -0.50 D while 24.70% of the children had an SE more than +0.50 D. The overall mean SE was +0.21±0.73 D, ranging from -4.00 D to +2.50 D. The mean AL was 22.41±0.72 mm, ranging from 20.03 mm to 24.69 mm. SE was negatively correlated with age ($r=-0.13$, $p=0.02$) but no significant difference was found between gender ($p=0.69$). AL was positively correlated with age ($r=0.40$, $p<0.001$) but no significant difference was found between gender ($p=0.23$). AL was also significantly correlated with height after age adjustment ($r=0.14$, $p=0.02$), but not weight ($p=0.90$). Children with less than 2 hours of non-digital near work per day had significantly more hyperopic SE than those with 2 hours or more (+0.29±0.60 vs +0.11±0.84, $p=0.03$), but no significant difference in AL was found ($p=0.09$). Children using digital devices for less than 2 hours per day also had significantly shorter AL than those with 2 hours or more (22.32±0.68 vs 22.50±0.79, $p=0.04$), but no significant difference was found in SE ($p=0.34$).

Conclusions: Longer time spent on near work, including doing homework, reading books and drawing, and on digital devices including mobile phone and handheld electronic devices were associated with more myopic refractive power in Hong Kong preschool children.

TITLE: Angle kappa measurement with swept-source optical coherence tomography using a vertical cavity surface emitting laser

SESSION TITLE: New improvements in imaging and development of biomarkers

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Yogo, N. Takeno, S. Masegi, Advanced Technology Development Dept., Eye Care Div., Kabushiki Kaisha Nidek, Gamagori, Aichi, JAPAN|

Commercial Relationships Disclosure: Hirofumi Yogo: Commercial Relationship(s);Code E (Employment):NIDEK CO., LTD. | Naoki Takeno: Commercial Relationship(s);Code E (Employment):NIDEK CO., LTD. | Seiji Masegi: Commercial Relationship(s);Code E (Employment):NIDEK CO., LTD.

ABSTRACT BODY:

Purpose: Measurement of angle kappa (κ) is clinically important because a large κ can cause decentrations during intraocular lens (IOL) implantation, leading to decreased vision. However, it is difficult to directly measure κ in clinical practice. Hence, this angle is estimated from the magnitude of displacement of the light reflected from the cornea from the pupil center to the nasal aspect. However, there may be accurate methods to determine κ using optical coherence tomography (OCT). In this investigation, we report the κ measurements from a prototype swept-source (SS) OCT device that simultaneously captures images of the anterior segment and the fundus.

Methods: We captured low-resolution and high-resolution images of healthy eyes with the wavelength sweep frequencies at low-speed and high-speed modes with a SS-OCT. This prototype uses vertical cavity surface emitting laser (VCSEL) technology that can change the wavelength sweep frequency. In low-speed mode, the anterior segment and the fundus were captured in one shot to image the cornea, iris, anterior chamber angle, and fovea. This image serves as a reference image for aligning each segment when constructing the whole eye OCT image. In high-speed mode, the OCT images of the anterior segment and the fundus are captured separately. During anterior segment image capture, we measured the corneal curvature and anterior chamber width as references for calculation of the magnitude of distortion in OCT images captured at low-speed mode. The whole eye OCT image was constructed by aligning the image captured in high-speed mode with the reference image captured in low-speed mode. The whole eye OCT image was used to geometrically establish the pupillary axis (PA). The visual axis (VA) was estimated from the whole eye OCT image considering that the central OCT beam and the ray from the internal fixation lamp to the fundus are coaxial. The angle formed by PA and VA was used to calculate κ.

Results: The κ calculated from the whole eye OCT image was 4.78 deg.

Conclusions: We have developed a SS-OCT that simultaneously acquires images of the anterior segment and fundus and κ measurements. This method for measuring κ is expected to contribute to improving the accuracy of intraocular lens surgery.

ABSTRACT BODY:

Purpose: Retinitis Pigmentosa (RP) and Leber Congenital Amaurosis (LCA) are rare inherited retinal degenerative disorders. There is no RP/LCA-specific measure of visual impairments and impacts on vision-dependent activities of daily living (ADL). The Visual Symptom and Impact Outcomes patient-reported outcome (ViSIO-PRO) and observer-reported outcome (ViSIO-ObsRO) measures were developed through qualitative research with RP/LCA patients, caregivers of child patients and expert clinicians. This study evaluated the psychometric properties of the instruments.

Methods: The 49-item ViSIO-PRO and 27-item ViSIO-ObsRO instruments were completed by 83 adult and adolescent patients and 22 caregivers of child patients aged 3-11 years with RP/LCA, respectively, at baseline and 12-16-day follow-up. Concurrent measures were also administered at BL. Psychometric analyses assessed item (question) properties, dimensionality, scoring, reliability, validity, and score interpretation.

Results: Responses to the ViSIO-PRO and ViSIO-ObsRO items were mainly evenly distributed across response options. Inter-item correlations were mostly moderate-to-strong (>0.30) at baseline within hypothesized domains. Item properties, qualitative data and clinical input supported retention of 35 ViSIO-PRO items and 25 ViSIO-ObsRO items. Confirmatory factor analysis supported a four-factor model (visual function symptoms, mobility, vision-dependent ADL and broader health-related quality of life). A bi-factor model supported calculation of total scores and domain scores. Internal consistency was high for all domain and total scores (Cronbach's alpha>0.70). Test-retest reliability for the total scores was strong between BL and 12-16-day follow-up (Intraclass Correlation Coefficients=0.66-0.98). Convergent validity was supported by strong correlations in a logical pattern with concurrent measures at baseline. There were statistically significant differences in mean ViSIO-PRO and ViSIO-ObsRO scores between known-groups

defined by global impression items at baseline. Distribution-based methods provide initial insights to guide interpretation of scores.
Conclusions: Findings supported item reduction, established the scoring of the ViSIO-PRO and ViSIO-ObsRO instruments, and provided evidence of reliability and validity as outcome measures in RP/LCA.

ABSTRACT BODY:

Purpose: There is an unmet need for sustained drug delivery for glaucoma pharmacotherapy. We describe a miniaturized injectable delivery system (MIDS) based on biodegradable polymers engineered for zero-order release of timolol maleate for a minimum of 8 weeks, injected into the intracameral (IC) or intravitreal (IV) space

Methods: MIDS device is a cylindrical implant (unique thin-film semi-permeable polymeric membrane encapsulating a pharmaceutical core) that provides zero-order drug delivery, and fabricated for use with a 23-gauge needle. In vitro pharmacokinetics studies were performed in temperature- and pH-controlled fluid chambers over 20 weeks. MIDS devices were injected into the IC and IV space of New Zealand rabbits. Eyes were examined weekly, with intraocular pressures (IOP) measurements (Tono-Vet, iCare). At sacrifice at 8 weeks post-injection, eyes were enucleated and dissected, and ocular compartment drug concentrations were determined by lipid chromatography-tandem mass spectrometry. Two tailed student’s t-test was used for statistical analysis.

Results: In vitro studies of MIDS devices demonstrated approximate zero-order drug release over 1 to 5 months. Ocular safety was acceptable, without significant intraocular inflammation. At 8-week post injection, in vivo studies demonstrated that IOP in experimental eyes was lowered by 11.1±6.5% (N = 5, p = 0.019) for IC devices and 14.6±3.9% (N = 5, p = 0.020) for IV devices. Analysis of ocular tissues revealed different concentration profiles for IC vs. IV at 8 weeks (in ng/g; except for aqueous in ng/mL): aqueous 28.45±5.44 vs 4.50±2.15, iris 36.67±9.73 vs 32.52±25.30, vitreous 0.28±0.26 vs 37.17±19.03, and ciliary body 14.39±3.59 vs 50.93±18.64. Blood concentration of drug was below the quantitation limit (< 0.4ng/ml) at 8 weeks for both groups

Conclusions: MIDS devices achieved zero-order release of timolol maleate in vitro. Over 8 weeks, implanted eyes' mean IOPs were lowered compared to controls at each weekly timepoint with similar levels of reduction between IC and IV. Target tissue drug concentrations at the ciliary body at 8 weeks exceeded therapeutic levels. Compared to IC, IV injection appeared to result in 4-5 times higher drug levels in the ciliary body. The technology has the potential to be provide continuous IOP-lowering therapy to overcome issues of patient compliance with daily eye drops

Commercial Relationships Disclosure: Carlo Galang: Commercial Relationship: Code N (No Commercial Relationship) | Dirk-Uwe G Bartsch: Commercial Relationship: Code N (No Commercial Relationship) | Alexandra Warter: Commercial Relationship: Code N (No Commercial Relationship) | Fritz Gerald Kalaw: Commercial Relationship: Code N (No Commercial Relationship) | Lingyun Cheng: Commercial Relationship: Code N (No Commercial Relationship) | William Freeman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We wanted to assess the quality of images of photoreceptors and cone density in parafoveal region using the High Magnification Module of Heidelberg Spectralis in patients with age-related macular degeneration.

Methods: We captured 8x8-degree area on primary gaze using the high magnification lens of the Heidelberg Spectralis in high-resolution mode. 10 eyes of 6 subjects with age-related macular degeneration were imaged. A 2mm pupil diameter was achieved by illuminating the fellow eye with a flashlight to eliminate the diffraction from astigmatic errors. We analyzed 200 x 200 μm within 5 degrees from the fixation. Using the image J, we estimated for the cone density and computed for the proportion to the number of cones/mm^2.

Results: Astigmatic errors can be reduced by taking the scans through a pupil of less than 3mm. The mean cone density in our study was 10992 cones/mm^2 (±1460.07) in 6 patients (mean age of 80 years) compared to 14,988 cones/mm2 (±1403.15) in non-AMD eyes (Mendonça et al.) in 8 patients (mean age of 33 years). Our patient population is significantly older, and as expected, analysis of regions in each macula shows more photoreceptor loss in areas of drusen in younger and non-AMD eyes (Mendonça).

Conclusions: We found that elderly patients have reduced number of cone count compared to younger patients. Areas adjoining drusen have particularly lower cone counts. Drusen and age are associated with reduced global and focal macular density. The high magnification SLO using narrow aperture does permit study of regional and focal cone density without adaptive optics.

ABSTRACT BODY:

Purpose: To identify different retinal cell types from patterns of transcriptome data and to evaluate the model based on data from different batches.

Methods: We developed a deep domain adaptation model to identify retinal cells based on single-cell RNA sequencing (scRNA-seq) data (Fig. 1). The dataset included 44,808 single cells from 39 retinal cell types with 24,658 genes collected from mice in seven different batches (B1 to B7). Our unsupervised model included source classification, adversarial, and target virtual adversarial loss functions in the learning process along with domain adaptation strategy based on conditional maximum mean discrepancy (CMMD) loss function to align the source and target distributions to reduce misclassification error and maximize robustness. We evaluated the proposed model using classification accuracy and confusion matrix based on data from different batches.

Results: The number of cells in each batch ranged from 3226 to 8336 (Fig. 2-B). The accuracy of the model based on different pairs of batches is shown in Fig. 2-C to 2-H. The mean accuracy of the model for correctly classifying 39 different retinal cell types was ~92%. Across seven different batches, the identification accuracies of the model ranged from 74% to nearly 100%. Our results outperformed several state-of-the-art models.

Conclusions: We integrated multiple loss functions to a deep learning-based domain adaptation model to identify retinal cell types from scRNA-seq data and achieved a high level of accuracy in detecting correct retinal cell types. The model was relatively resistant to batch effect and could be used in single-cell studies to detect various cell types from different tissues.

ABSTRACT BODY:

Purpose: To compare the visual performance of Spatio-Temporal Optical Phase (S.T.O.P®) contact lenses (CL) against MiSight® (MS) in myopic young adults. S.T.O.P CL feature rotationally asymmetric power maps, designed with meridionally and azimuthally varying power distributions, combined with a peripheral carrier configured with rotation assisting features. The resulting dynamic optical signal on the retina may decelerate the rate of myopia progression and minimise the decay of treatment effect found in options which provide a relatively static optical signal.
Methods: Prospective, randomized, single-masked (participant), cross-over trial where participants aged 18-39 years wore MS and two S.T.O.P designs (F2 and DT), each for a minimum of 5 days at 6 hours/day, daily wear, with CLEARCARE disinfection. Following CL wear, visual performance was assessed with subjective questionnaire (0-100 scale) for clarity of vision and ghosting (distance, intermediate, near), driving vision, overall vision satisfaction and comfort. Willingness to purchase was assessed with a binary Yes/No response. High and low contrast visual acuity (HCVA/LCVA) were measured monocularly and binocularly at 6m. HCVA was also measured binocularly at 70, 50 and 40cm. Differences between designs were assessed using linear mixed model, a Bonferroni correction was applied where applicable, and significance was set at 5%.
Results: F2 was better than MS for clarity of vision at intermediate (71±18 vs. 61±24, $p<0.001$) and near (78±16 vs. 64±28, $p<0.001$) while MS was better than DT at near (64±28 vs. 56±26, $p<0.001$). F2 was better for ghosting than MS (79±24 vs. 64±30, $p<0.001$), and the difference was independent of distance ($p=0.13$). There were no differences between designs for driving vision, comfort, overall vision satisfaction, or willingness to purchase ($p>0.06$).
MS was better than F2 and DT for monocular and binocular HCVA at 6m (mean difference [MD]≤ 2 letters; $p\leq0.001$ and ≤0.002, respectively) and binocular HCVA at 50cm (MD≤2 letters, $p\leq0.02$). There was no difference between designs for LCVA ($p>0.07$).
Conclusions: Though MS was significantly better than both S.T.O.P designs for HCVA, the MD was only 2 letters. Overall, both S.T.O.P designs were comparable to MS for visual performance, with F2 outperforming MS in some aspects of subjective visual performance.

ABSTRACT BODY:

Purpose: AAV gene therapy in the age of CRISPR-based gene targeting has emerged as a potentially disruptive technology for previously incurable ocular diseases, but its applications are so far limited to monogenic diseases. The capability to perform multiplexed targeting of endogenous genes would open the field of ocular gene therapy to new applications, including polygenic diseases. Recent discovery of alternative CRISPR systems beyond the widely used SpCas9 has expanded the toolkit for genetic manipulation. CRISPR-Cas12a systems enable simultaneous targeting of multiple genomic loci by processing numerous crRNAs from a single transcript, but this capability had not yet been demonstrated in vivo, in part due to relatively low efficiency of Cas12a systems.

Methods: We used structure-guided protein engineering to develop an improved LbCas12a variant, and we tested its in vivo function through AAV-based delivery to retinal ganglion cells as well as subretinal delivery by electroporation in postnatal mice.

Results: Compared to wildtype Cas12a, our improved dCas12a variant has significantly greater efficacy in gene activation, especially at low CRISPR-RNA (crRNA) conditions. It also achieves improved gene repression and gene editing. Additionally, it has similar off-targeting effects compared to its wildtype equivalent. This new Cas12a variant achieved improved AAV-based gene editing in retinal ganglion cells in vivo. Additionally, delivery of the improved dCas12a-activator with a single crRNA array simultaneously activated multiple endogenous targets and directed the differentiation of retinal progenitor cells in retina of postnatal mice.

Conclusions: Our system enables simultaneous modulation at multiple genomic loci, thus paving the way for CRISPR-based modulation of multiple pathways or synergistic targets, such as in the case of non-monogenic diseases which consist of a large proportion of human diseases.

ABSTRACT BODY:

Purpose: Thyroid Eye Disease (TED) is an autoimmune disease that affects 20-25% of patients with Grave's disease. In the course of TED, the eyelids, orbital fat, orbital adnexa, ocular surface and extra ocular muscles have the potential to be affected. TED can be detrimental to patients both physiologically and psychologically, thus severely affecting a patients quality of life. Ocular surface irritation is a common complaint for patients with TED, and it can be multifactorial. One of the lesser studied causes of this discomfort is superior limbic keratoconjunctivitis (SLK). The focus of this study was on understanding SLK incidence in patients diagnosed with TED and what factors may contribute to SLK manifestation.

Methods: Consecutive patients presented to a TED clinic over a 2 year period. A complete thyroid related history and examination was performed following the VISA template. The presence of SLK was determined by the staining of lissamine green of the superior limbus. Other TED markers, such as changes to eyelid position, proptosis and strabismus were recorded. Ocular surface factors were also recorded. All data was extracted and stored in a TED related database. The incidence of SLK was calculated and binary and multivariate statistics were performed to determine potential associated factors.

Results: Sample consisted of 268 patients. The SLK incidence in this cohort was found to be 5%. Bivariate statistical analysis showed no relationship/difference between various demographics, thyroid bloodwork, eyelid position and signs of corneal disease.

Conclusions: Typical demographic, clinical and serum values of TED were not predictive of SLK. A clear relationship between SLK incidence and severity of TED or characteristics of TED was not found. SLK remains an idiosyncratic reaction affecting approximately 5% of patients with TED.

ABSTRACT BODY:

Purpose: 24-2C SITA Standard is a prototype visual field (VF) test using the 24-2C test pattern, which added 10 new test locations to the 24-2. In this clinical study, we explored the diagnostic efficacy of global summary indices derived from 24-2C SITA Standard in a preliminary cohort of normal and glaucomatous eyes.

Methods: 24-2C SITA Standard (SS-C) and 24-2C SITA Faster (SFR-C) VFs were acquired on an HFA3 perimeter (ZEISS, Dublin, CA) at each of two visits on one eye of a group of 32 normal and 34 glaucomatous subjects. 24-2 SITA Standard (SS) and 24-2 SITA Faster (SFR) VFs were extracted from 24-2C VFs. The last qualified test for each VF was used for data analyses. The diagnostic performance for the VF global indices of Mean Deviation (MD), Visual Field Index (VFI) and Pattern Standard Deviation (PSD) was assessed using the area under the receiver operator characteristic curve (AROC) and sensitivity. AROCs were compared to those of SS and SS-C.

Results: Mean age was 58.1 (standard deviation, SD: 7.6; range: 44 to 75) years for normal subjects and 71.6 (SD: 9.2; range 53 to 98) years for glaucoma patients. Mean MD_{SS-C} was 0.35 (SD: 1.02; range: -1.63 to 2.45) dB and -8.57 (SD: 8.15; range: -25.29 to 1.39) dB in normal and glaucomatous eyes ($P<0.001$), respectively (see Table 1). The AROC of MD_{SS-C} was 0.95. Compared to MD_{SS-C}, the AROCs for MD_{SS}, MD_{SFR}, and MD_{SFR-C} were 0.94 ($P=0.120$), 0.94 ($P=0.563$), and 0.95 ($P=0.889$), as shown in Table 2. The sensitivities at 95% specificity were 82.0% (MD_{SS}), 71.0% (MD_{SFR}), 85.0% (MD_{SS-C}), and 76.0% (MD_{SFR-C}), respectively. The AROC of VFI_{SS-C} was 0.97. Compared to VFI_{SS-C}, the AROCs for VFI_{SS}, VFI_{SFR}, and VFI_{SFR-C} were 0.96 ($P=0.799$), 0.96 ($P=0.881$), and 0.96 ($P=0.873$), as shown in Table 2. The sensitivities at 95% specificity were 88.0% (VFI_{SS}), 88.0% (VFI_{SFR}), 88.0% (VFI_{SS-C}), and 85.0% (VFI_{SFR-C}), respectively. Similar results were observed for PSD.

Conclusions: The findings in this preliminary cohort suggest that the new 24-2C SITA Standard global summary indices may have similar (non-inferior) diagnostic performance to those of the existing 24-2 and 24-2C SITA strategies. In terms of global summary indices, 24-2C SITA Standard may provide a reasonable clinical alternative to current clinical threshold strategies for the diagnosis of glaucoma.

ABSTRACT BODY:

Purpose: Non-invasive brain stimulation can induce an acute, transient change in neural excitability when applied to the visual cortex. If sustained, brain stimulation-induced changes in visual cortex excitability could have important implications for the treatment of amblyopia and other brain-based vision disorders. Using a double-blinded study design we investigated whether multiple daily sessions of visual cortex transcranial random noise stimulation (tRNS), a type of non-invasive brain stimulation, have cumulative and lasting effects on visual cortex excitability.

Methods: 53 participants (26 ± 5 years) with normal vision were enrolled. In a preliminary baseline session, phosphene thresholds (the minimum intensity of visual cortex single-pulse transcranial magnetic stimulation required to induce a phosphene percept) were measured. Lower phosphene thresholds indicate greater visual cortex excitability. 34 of 53 adults could reliably detect phosphenes and continued with the study. The participants were then randomly assigned to the treatment (tRNS) or control (sham stimulation) group and completed five consecutive daily tRNS/sham sessions. High-frequency tRNS (1mA, 100-640 Hz) or sham stimulation was applied to the primary visual cortex for 40 mins. Phosphene thresholds were measured pre- and post-tRNS/sham stimulation on each stimulation day, and then every 24h for 3 days after the final stimulation day.

Results: A repeated-measures general linear model conducted on the phosphene threshold data revealed a significant interaction ($p < 0.001$) between Stimulation Type (tRNS vs. sham) and Time (baseline, 5 x stimulation days [post stimulation thresholds], 3 x post-stimulation sessions). tRNS induced a cumulative, daily reduction in phosphene threshold indicating a sustained enhancement of visual cortex excitability. Sham stimulation had no effect. In the tRNS group, phosphene threshold was reduced by 15 ± 3% from baseline on stimulation day 5, an effect that was still statistically significant 24h (9 ± 3.5%, $p < 0.001$) and 48h (4 ± 2%, $p = 0.003$) later. The effect waned when remeasured 72h post-stimulation.

Conclusions: Our results provide the first evidence of a sustained increase in cortical excitability following multi-day non-invasive brain stimulation. This finding warrants further study into the potential of tRNS as a tool to enhance vision rehabilitation in amblyopia and other brain-based visual disorders.

ABSTRACT BODY:

Purpose: We recently showed that a refined sequential detection pattern for multi-offset adaptive optics scanning light ophthalmoscopy (AOSLO) can increase the contrast of weakly scattering inner retinal structures, including presumed microglial cells. However, sequential detection was still time-consuming, preventing dynamics from being monitored over short intervals (< 3 mins). Here we show that fiber-bundle (FB) detection AOSLO overcomes this limitation to reveal microglia and immune cell dynamics in healthy and diseased retinas.

Methods: We designed and implemented a custom 7-fiber optical FB in AOSLO that allows for simultaneous confocal and multi-offset detection. We imaged the nerve fiber layer at several locations at multiple timepoints (from minutes to weeks) in 5 healthy participants and in 3 patients with ocular syphilis or uveitis. Microglia and immune cells were manually segmented for quantification.

Results: Fiber-bundle detection reduced single acquisition time to 10-20 sec, permitting improved imaging over larger areas and monitoring of dynamics over short intervals. Microglia in healthy retinas ranged in size from 7 to 19 μm (mean:13 μm) and appeared in two distinct morphologies including rounded cells and elongated cells with visible processes. Microglia moved slowly in healthy eyes (0.05 μm/sec on average), but their motility was increased in patients with active infections or inflammation up to 0.34 μm/sec. Macrophage-like cells containing granular internal structures were seen in an eye with acute syphilitic posterior placoid chorioretinitis. Images were acquired at multiple time points during treatment, decreases in the quantity and motility of microglia were correlated with improvements of vision and other biomarkers. Microglia activity was apparent in an eye affected by acute retinal vasculitis but absent in another patient’s eye affected by a chronic course of retinal vasculitis that was quiescent at the time of imaging.

Conclusions: FB-AOSLO has revealed the fine-scale structure and dynamics of microglia in the retina during active infection and inflammation in the living eye for the first time. FB-AOSLO offers promise as a powerful tool for detecting and monitoring retinal inflammation and infection in the living eye over short timescales. FB-AOSLO may be useful for distinguishing cases of active infection/inflammation and for evaluating response to treatment.

ABSTRACT BODY:

Purpose: To investigate the function of endoplasmic reticulum stress in the development of fibrotic cataract and its underlying mechanisms.

Methods: C57BL/6 mice were punctuated with a 26-gauge needle in the central lens capsule as the fibrotic cataract model. Primary rabbit lens epithelial cells (LEC) were exposed to TGF-β2. eIF2α inhibitor ISRIB was used to treat LEC both in vivo and in vitro, ER stress inhibitor 4-PBA, inducer thapsigargin and tunicamycin, IRE1α inhibitor 4μ8C were used to treat LEC in vitro. LECs were transfected with siRNA to knockdown ATF4. Western blot assays and immunofluorescence staining were carried out to measure changes in protein expression such as BIP, eIF2α, IRE1α, LC3-II, p62, FN, α-SMA, etc. mRNA expression was investigated by RT-PCR. Autophagosome was observed by electron microscopy (TEM). Immunostaining and mRFP-GFP-LC3 reporter were applied to indicate autophagy flux. Clinical parameters were measured using slit-lamp bio-microscopy.

Results: ER stress was triggered during fibrotic cataract and TGFβ2-induced EMT of LEC, which in turn enhanced the EMT process. PERK/eIF2α/ATF4 branch of unfolded protein response is selectively required for EMT. Anterior chamber injection of ISRIB in fibrotic cataract mouse model showed significantly improved clinical parameters and limited capsular opacities. Interestingly, we found ISRIB decreased LC3-II, along with impaired the turnover of p62 in a time-dependent manner. Besides, TEM showed abnormally autophagic vacuoles under TGFβ2 stimulation, which was largely abolished by the cotreatment with ISRIB. To further investigate the crosstalk between ER stress and autophagy during fibrotic cataract, autophagic inducer rapamycin and lysosomal inhibitor chloroquine was used. Our results indicated that the suppression of ISRIB on mesenchymal gene expression was attenuated by rapamycin, but augmented by CQ, indicating that the regulation of autophagic flux by ISRIB is implied in the anti-fibrotic process.

Conclusions: Our research for the first time suggests that the activation of ER stress in fibrotic cataract both in vivo and in vitro. PERK/eIF2α/ATF4 branch selectively regulates EMT process in LEC through autophagy. eIF2α inhibitor, ISRIB, is highly effective at suppressing the development of lens subcapsular plaque and keeping the transparency of lens. Thus, ISRIB may be a potential therapeutic target to reduce EMT and fibrotic diseases.

ABSTRACT BODY:

Purpose: To determine differences in one year postoperative complications following pars plana vitrectomy (PPV) in patients who are on statin therapy.

Methods: A retrospective cohort study was done with data collected from TriNetX (Cambridge, USA), a federated electronic health records network. Patients who underwent PPV were identified by CPT code and separated between those on statin therapy for one-year preceding PPV and those without statin use. This study used propensity score matching to match the two cohorts for age, sex, and other systemic comorbidities. The primary outcomes measured after one year in the postoperative period included: vitreous hemorrhage, choroidal hemorrhage, retinal detachment or break, retinal edema, cystoid macular degeneration, macula puckering, intraoperative complications and disorders of the eye, ischemic optic neuropathy, cataracts, glaucoma, strabismus, corneal edema, dry eye syndrome, central retinal vein and artery occlusion, vitreous opacities, ptosis, lens dislocation, endophthalmitis, and retinal vascular occlusions.

Results: A total of 54,159 patients were identified to have undergone PPV and stratified into statin vs. non-statin use cohorts with 13,592 patients in each cohort after propensity matching. The cohort with prior history of statin therapy had a significantly higher risk of developing vitreous hemorrhage (RR, 1.15; 95% CI 1-1.33), retinal edema (RR, 1.15; 95% CI, 1.02-1.3), macula puckering (RR, 1.21; 95% CI 1.1-1.33), intraoperative complications of the eye (RR, 1.47; 95% CI 1.13-1.91), glaucoma (RR, 1.12; 95% CI 1.02-1.23), vitreous opacities (RR 1.42; 95% CI, 1.19-1.69) and ptosis (RR, 1.42; 95%; CI 1.13-1.79). The statin group had significantly lower risks of developing retinal vascular occlusions (RR, 0.7; 95% CI 0.56-0.89) and lens dislocation (RR, 0.75; 95% CI 0.66-0.86). No other significant differences were found between the cohorts.

Conclusions: Statin is one of the most prescribed medications. This study found an association between statin use with increased risk of developing vitreous hemorrhage, retinal edema and vitreous opacities in the long term post-operative period. This is possibly due to statin's biphasic effect on angiogenesis. Statin use was also associated with lower risks of retinal vascular occlusions and lens dislocation. This study highlights various associations of statin therapy on outcomes after PPV.

ABSTRACT BODY:

Purpose: To identify the molecular basis for autosomal dominant retinitis pigmentosa (adRP) with reduced penetrance in an Israeli Muslim Arab family.

Methods: Patients underwent a detailed ophthalmic evaluation, including funduscopic examination, visual field testing, spectral-domain optical coherence tomography, fundus autofluorescence imaging and electroretinography. Genetic analysis was performed by a combination of whole exome sequencing and Sanger sequencing. Pathogenicity of the identified intronic variant was evaluated in silico using several web-based tools; in vitro, using a minigene-based assay; and in vivo, using reverse transcription-PCR analysis of lymphocyte-derived RNA.

Results: Affected individuals had childhood onset of night blindness followed by concentric restriction of the visual field. Ophthalmoscopic findings included narrowed retinal blood vessels and mid-peripheral bone spicule pigmentation. Full-field electroretinography was non-measurable in the third decade of life. In affected individuals we identified a novel heterozygous intronic variant, located at position +5 of PRPF31 intron 11 (c.1146+5G>T). The same variant was also detected in an unaffected family member. The variant was predicted to alter splicing of intron 11 by in silico analysis. In vitro splicing assay and reverse transcription-PCR analysis of lymphocyte-derived RNA revealed that the wt allele yielded both the expected product, harboring exon 11, and a shorter product in which exon 11 was skipped. The mutant allele yielded mainly the shorter product. Skipping of exon 11 is expected to cause a frameshift which yields an aberrant truncated protein (p.Tyr359Serfs*29). These results suggest that some degree of alternative splicing of exon 11 may occur normally, and that the c.1146+5G>T allele further weakens intron 11 donor splice-site and enhances the skipping of intron 11.

Conclusions: We report a novel intronic mutation in PRPF31 underlying adRP. This report expands the spectrum of pathogenic mutations in PRPF31 and further demonstrates the importance of intronic mutations. Moreover, it demonstrates the phenomena of reduced penetrance, previously associated with PRPF31 mutations.

ABSTRACT BODY:

Purpose: To evaluate the status of the internal limiting (ILM) flap following various ILM flap techniques for macular holes (MH).

Methods: Retrospective case series including eyes that underwent pars plana vitrectomy (PPV) and ILM flap for MH. The FLAP techniques included conventional ILM flap (C-ILM), temporal ILM flap (T-ILM), superior wide-base ILM flap transposition (SWIFT), and pedicle ILM flap (P-ILM). Postoperative imaging included ICG fluorescence imaging (ICG-FI) (Spectralis, Heidelberg Engineering Inc., Heidelberg, Germany) and optical coherence tomography (OCT).

Results: 49 eyes of 40 patients, mean age 68.3 years, with mean follow-up of 10.3 months were included in the study. Ten (20%) eyes were highly myopic, 22 (45%) eyes had chronic MH, and 7 (14%) eyes had history of prior MH surgery. The ILM flap technique included C-ILM / T-ILM (22 eyes), SWIFT (25 eyes), and P-ILM (2 eyes).

The MH closed in 46 (94%) eyes. ICG fluorescence attributable to ILM flap was detected in all eyes, however, in 3 eyes the flap borders were not discernable. The ILM flap covered the MH completely in 36 (75%) eyes, partially in 7 (15%) eyes, and provided no coverage in 5 (10%) eyes. In 1 eye it was not possible to ascertain coverage on ICG-FI or OCT. In the 2 eyes with P-ILM the ICG-FI showed a displaced flap with no coverage of the MH.

In cases with closed MH, OCT demonstrated intraretinal ILM fragments in 5 (23%) eye in I-ILM /T-ILM groups, and in none of the eyes in SWIFT or P-ILM group. Imaging with ICG-FI / OCT showed folding of the ILM flap in 14 (64%) eyes in I-ILM / T-ILM group, in 6 (24%) eyes in SWIFT /P-ILM group, and in 1 eye in P-ILM group.

Conclusions: ILM flap techniques are associated with a high MH closure rate and are useful in the management of MHs with high-risk characteristics. Postoperative multimodal imaging including ICG-FI and OCT indicates good coverage of the MH by the ILM flap in the majority of the cases.

ABSTRACT BODY:

Purpose: Patients with aniridia associated PAX6 mutations develop corneal and anterior segment defects. This study aims to understand the mechanisms of PAX6 regulation at the limbus and its effects on cornea-specific gene targets.

Methods: Multiple ocular cell lines, primary limbal cultures, human corneo-scleral tissues and hiPSC-derived ocular tissues were evaluated for differential expression of PAX6 variants and their spatial distribution by qRT-PCR, Sanger sequencing, luciferase reporter assays, ChIP-PCR, Immunocytochemistry (ICC), Immunohistochemistry (IHC) and RNA-FISH assays. Statistical analysis was performed using Student's t test.

Results: We report the identification of four novel splice variants of PAX6 in human ocular tissues and are generated by alternative splicing at two major splicing hotspots near Exon 5-6-7 and Exon 12-13 splice junctions. These variants carry in-frame deletions, possibly affecting either the N-terminal paired domain-mediated DNA binding or C-terminal PST domain-mediated transactivation functions. qRT-PCR evaluations revealed that these novel splice variants are driven by the PAX6 pA promoter in all ocular tissues and was highly expressed in the limbal and corneal epithelium. Activation of canonical Wnt signals in limbal cultures induced the expression of novel splice variants. Luciferase reporter assays using recombinant PAX6 isoforms has confirmed negative auto-feedback regulation on PAX6 pA promoter. While PAX6A could activate K3 promoter, it had no effect on K12, TAp63 and dNp63 promoters. However, a paired domain truncated isoform significantly activated the dNp63, K12 and K3 promoters. In situ localization studies using RNA-FISH combined with ICC/IHC has confirmed that the novel variants are co-expressed along with PAX6A transcripts in a sub-set of cells that are predominantly located at the basal and suprabasal layers of limbal and corneal epithelium. These cells are identified as $PAX6^{Low}$, $p63\alpha^{High}$, $BrdU^{+}$ and $K3/K12^{-}$ proliferating and migrating TACs.

Conclusions: The novel PAX6 splice variants alter the relative stoichiometry of wild type transcripts and ensure low levels of PAX6 expression in basal cells. This enables the self-renewal of activated LSC and expansion of TACs, while preventing pre-mature differentiation, thus promoting optimal epithelial stratification during normal corneal development and wound healing.

TITLE: Agreement of macular thickness map in low-cost OCT
SESSION TITLE: OCT Clinical Applications
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: K. Romero, H. Bagherinia, S.A. Bello, Carl Zeiss Meditec, Inc., Dublin, California, UNITED STATES|
Commercial Relationships Disclosure: Kique Romero: Commercial Relationship(s);Code E (Employment):Carl Zeiss Meditec, Inc. | Homayoun Bagherinia: Commercial Relationship(s);Code E (Employment):Carl Zeiss Meditec, Inc. | Simon Bello: Commercial Relationship(s);Code E (Employment):Carl Zeiss Meditec, Inc.

ABSTRACT BODY:

Purpose: Macular Thickness Analysis (MTA) is an important tool for diagnosing and monitoring patients with retinal disease. The robustness of MTA can be limited in low-cost devices due to the quality of the optical coherence tomography (OCT) data. In this study we evaluate the agreement of MTA between repeat scans of the same eye using a low-cost OCT prototype.

Methods: A low-cost OCT prototype system (ZEISS, Dublin, CA) was used to image 42 subjects with a range of ocular pathologies, including age-related macular degeneration (AMD). One eye of each subject was scanned three times. The inner limiting membrane (ILM) and the retinal pigment epithelium (RPE) of each OCT volume were segmented using a prototype segmentation algorithm. Macular thickness (MT) map with 512x512 pixels over an area of 5.78x5.78 mm was created by measuring the difference between the ILM and RPE. Two MT maps (out of the three) were selected based on the segmentation quality determined with a prototype segmentation quality algorithm for this study.

The two MT maps were registered to each other and the ETDRS grid with 9 sectors was placed at the center of each map. The ETDRS grid consists of three concentric circles with radiuses of 0.5, 1.5 and 2.89 mm (Fig 1). Each ETDRS sector value was calculated by averaging the MT values within the sector. Linear regression and Bland-Altman analysis were used to compare the MT maps.

Results: Fig 2 shows the statistical comparison between the ETDRS sectors generated using two MT maps per subject. All sectors show an absolute mean difference less than 2 microns. The 95% lower and higher limits of agreement varied between -18 and 19 microns. R-squared values varied between 0.85 and 0.99.

Conclusions: This study demonstrated the agreement between two MT maps generated from two scans per eye using the low-cost OCT prototype. Our results show good correlation and agreement between two MT maps which is important for diagnosing and monitoring patients using macular thickness analysis.

ABSTRACT BODY:

Purpose: The dysfunction of Müller cells can induce photoreceptor degeneration. We have previously identified a link between Müller cells and photoreceptors through which inhibition of MAPK signalling in Müller cells upregulated the expression of Interphotoreceptor Retinoid-Binding Protein (IRBP), which is a photoreceptor-specific protein, and prevented photoreceptor degeneration. However, the exact signalling transduction remains unclear. We aim to explore the signalling between Müller cells and photoreceptors in response to stresses.

Methods: Retinal tissues from four human eye donors were cultured for 24 hours with PD98059, the ERK1/2 inhibitor, or the same concentration of DMSO as controls. Total RNA was extracted, and its quality was assessed. Next-generation sequencing was performed to explore the transcriptional changes after ERK1/2 inhibition. We then performed QIAGEN Ingenuity Pathway Analysis (IPA) on all the differentially expressed genes ($P<0.05$) to identify canonical pathways that significantly changed after inhibition of MAPK signalling. We also validated the changes of identified signalling pathways after PD98059 treatment in human retinal explants by Western blot. We further treated the human retinal explants with the specific inhibitors of the identified signalling pathway and evaluated the downstream changes compared with the upstream inhibition of MAPK signalling by Western blot.

Results: IPA analysis found JAK/STAT3 signalling pathway, NF-κB Signaling pathway and Interleukin-6 Signaling pathway were significantly inhibited after the inhibition of MAPK in human retinal explants ($P<0.05$). Western blotting further validated that the treatment of PD98059 significantly inhibited the phosphorylation levels of STAT3 (the ratio of phosphorylated STAT3 to total STAT3). The treatment of 5,15-DPP, STAT3 specific inhibitor, on human retinal explants significantly increased the expression of neuroprotective IRBP protein by photoreceptors.

Conclusions: Our findings suggest that JAK/STAT3 pathway is involved in the signalling between Müller cells and photoreceptors in response to stresses. The inhibition of JAK/STAT3 pathway activity may have neuroprotective effects on the retina.

Commercial Relationships Disclosure: Youngyoon Amy Seo: Commercial Relationship: Code N (No Commercial Relationship) | Gabriella Rogers: Commercial Relationship: Code N (No Commercial Relationship) | David Myung: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Millions of people suffer from corneal diseases, but less than 2% of patients have access to corneal transplantation due to the shortage of cadaveric donor corneal tissue. Moreover, rapid and complete epithelial wound healing is critical to prevent infection and scarring that can lead to blindness. Biomaterial matrices have been investigated as a way to fill corneal defects and support epithelialization. Loading growth factors into defect-filling hydrogels is a promising approach toward enhancing corneal epithelialization. Here, we incorporate epidermal growth factor (EGF) into in situ-forming collagen gels to study the effect of their controlled release from within defect-stabilizing matrices on epithelial cell adhesion and proliferation.

Methods: EGF was added to a neutralized collagen solution and crosslinked either via N-hydroxysuccinimide chemistry using 8-arm PEG or via UV light using riboflavin as a photosensitizer. We compared the gels' degradation as well as the proliferation, migration, and phenotype of corneal epithelial cells (CECs) seeded on these gels and the epithelial wound healing response in ex vivo organ culture model. Cell viability and cytotoxicity were measured using colorimetric assays. We also executed an in vitro scratch assay which mimics cell migration during wound healing in vivo. The presence of biomarkers that promote epithelial healing were compared across three groups: cells without treatment, collagen gels alone, and EGF encapsulated within PEG- or UV-crosslinked collagen hydrogels.

Results: Encapsulated EGF accelerated in vitro corneal epithelial cell proliferation and migration. Gels loaded with EGF also exhibited a lower degradation rate and accelerated corneal wound healing in our organ culture studies. Immunohistochemical analysis exhibited expression of 4-hydroxynonenal within the epithelium and alpha-smooth muscle actin within the surrounding stroma for 8-arm PEG collagen and UV riboflavin gels with EGF. Immunohistochemical studies demonstrated that both types of EGF-loaded collagen gels fostered tight junction formation and maintained normal epithelial phenotype.

Conclusions: Our study suggests that collagen gels with encapsulated EGF can fill corneal defects and enhance corneal epithelial regeneration. Further work to investigate the effects of EGF-loaded collagen gels in vivo are merited.

ABSTRACT BODY:

Purpose: Many eyes with neovascular AMD have poor outcomes because they develop subretinal fibrosis which is neither preventable nor treatable. Metabolic reprogramming in the retina is reported as one critical pathogenic process in retinal fibrosis. The JR5558 mouse develops subretinal neovascularization, resulting in local gliosis and photoreceptor death. The subretinal lesions in these mice have several key molecular and pathological features of subretinal fibrosis. The de novo serine/glycine synthesis plays an essential role in the formation of fibrotic scars. We aim to explore the changes of this metabolic pathway in a mouse model of subretinal fibrosis in this study.

Methods: The subretinal lesions in the JR5558 mouse expanded between 4 and 8 weeks of age and became established in size and location around 12 weeks. The changes of four key enzymes in the de novo serine/glycine synthesis (phosphoglycerate dehydrogenase (PHGDH), hydroxymethyltransferase 2 (SHMT2), phosphoserine phosphatase and phosphoserine aminotransferase 1) were evaluated during the time course for the development of subretinal fibrosis. We explored the distribution pattern of these enzymes by immunofluorescent staining in the retina of JR5558 mice compared with the controls, costained with cellular retinaldehyde-binding protein (CRALBP, a Müller cell and retinal pigment epithelium (RPE) marker). We also quantified protein levels of key enzymes in the JR5558 mouse retinas by Western Blot. The C57BL/6 mouse retina was used as a control to compare the expression level of these enzymes in fibrosis mouse retinas.

Results: We found that PHGDH, a key rate-limiting enzyme of de novo serine synthesis, was expressed by Müller cells and RPE in the JR5558 mouse retina. It was strongly expressed in the subretinal lesions. SHMT2, a key mitochondrial enzyme that converts serine to glycine, was expressed by the Müller cells and extensively expressed in the retinal fibrotic lesions. The protein level of PHGDH was significantly upregulated in the JR5558 mouse retinas at 8 weeks of age, the peak stage of the development of subretinal fibrosis, compared with the age-matched C57BL/6 wild type controls.

Conclusions: Our findings suggest that the de novo serine/glycine biosynthesis is activated during the development of the subretinal fibrotic lesions in the JR5558 mouse model, perhaps representing a novel therapeutic target for subretinal fibrosis.

ABSTRACT BODY:
Purpose: To describe the microscopic characteristics of known lesions associated with intermediate age-related macular degeneration (AMD) on adaptive optics ophthalmoscopy (AOO) imaging and their correlation to other multimodal imaging methods.
Methods: Patients with intermediate AMD were enrolled in an observational longitudinal multicenter cohort to decipher the natural history of the disease. Participants underwent spectral-domain optical coherence tomography (SD-OCT), infrared scanning laser ophthalmoscopy (IR-SLO), and fundus autofluorescence (FAF) imaging using the Spectralis device (Heidelberg Engineering, Germany). Flood-illumination AOO images were acquired using the commercially available rtx1 camera (Imagine Eyes, France). AO image mosaics were constructed using the montage function on the i2k Retina AO software (DualAlign LLC, USA). En face and/or cross-sectional images across modalities were manually aligned to perform intra- and inter-modality comparisons of retinal lesions.
Results: Heterogeneity of drusen characteristics was observed on AOO. Typical large drusen were characterized by a hyper-reflective rim with central iso-reflectivity. The visibility of the cone photoreceptor mosaic was largely obliterated around and on top of these drusen. On the contrary, cone photoreceptors were visualised in another group of patients with smaller drusen that manifested on AO images as a hyper-reflective rim with internal hypo-reflectivity. Cone visibility on AO correlated with the presence of interdigitation zone on OCT B-scans. Subretinal drusenoid deposits (SDD) typically displayed hypo-reflective circles surrounding areas of iso-reflectivity on AO images. Early stages of the SDD appeared as an ill-defined area of hypo-reflectivity. Several distinct phenotypes of retinal pigment epithelium and outer retinal atrophy were identified on AOO. Variability in the focusing depth can significantly alter the appearance and interpretation of AO images.
Conclusions: We describe various phenotypes of intermediate AMD on adaptive optics ophthalmoscopy, showing distinct patterns, which correlate with known morphologic presentations on multimodal imaging. The significance of the described changes is yet to be determined in large longitudinal cohort studies.

TITLE: Involvement of purines and prostaglandins in hypoxia-induced dilatation of larger and smaller porcine retinal vessels ex vivo

SESSION TITLE: Retinal metabolism and physiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Ernst, T. Bek, Department of Ophthalmology, Aarhus Universitetshospital, DK-8200 Aarhus N, Mid Jutland Region, DENMARK|

Commercial Relationships Disclosure: Charlotte Ernst: Commercial Relationship: Code N (No Commercial Relationship) | Toke Bek: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The metabolic pathways leading from hypoxia to retinal vasodilatation involve effects of both purines and prostaglandins, but the interaction between these compounds in the response has not been studied in detail. Therefore, the purpose of the present study was to investigate how effects of purinergic and prostaglandin receptors interact to result in hypoxia-induced dilatation of porcine retinal arterioles, pre-capillary arterioles and capillaries in vitro.

Methods: Porcine superior hemiretinas (n=40) were mounted in a specially designed perfusion chamber, and the diameter of retinal arterioles, pre-capillary arterioles and capillaries were studied during hypoxia with and without the presence of the EP1 receptor antagonist SC-19220, the EP4 receptor antagonist L-161-982, the prostaglandin synthesis inhibitor ibuprofen, and ibuprofen combined with the ecto-nucleotidase inhibitor AOPCP or ATP.

Results: Hypoxia induced vasodilatation of all vascular branching levels ($p<0.01$ for all comparisons). The dilatation of arterioles was inhibited by ibuprofen alone and in combination with the ecto-nucleotidase inhibitor, and by blocking of the EP4 receptor ($p\leq0.04$ for all comparisons). The response in pre-capillary arterioles differed from that of the arterioles by a lack of blocking of the hypoxia-induced dilatation by the EP4 receptor antagonist ($p=0.49$). The response in capillaries differed from that of the pre-capillary arterioles by a blocking effect by all the studied prostaglandin antagonists ($p<0.01$ for all comparisons) on the hypoxia-induced dilatation.

Conclusions: Hypoxia-induced dilatation of retinal vessels is regulated differentially in arterioles, pre-capillary arterioles and capillaries. This may provide the foundation for selective interventions on the diameter of retinal vessels at different branching levels.

TITLE: Longitudinal Changes in Outer Nuclear Layer and Choroidal Thickness in Patients using Hydroxychloroquine before Development of Retinopathy

SESSION TITLE: Macular diseases/Macular edema/Functional testing/evaluation/Laser

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Min, J. Lee, Y. Yoon, Ophthalmology, Asan Medical Center, Seoul, KOREA (THE REPUBLIC OF)|

Commercial Relationships Disclosure: Chan Hong Min: Commercial Relationship: Code N (No Commercial Relationship) | Joo Yong Lee: Commercial Relationship: Code N (No Commercial Relationship) | Young Hee Yoon: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Early detection of hydroxychloroquine(HCQ) retinopathy is important. Prior studies have suggested that HCQ primarily damages photoreceptors, with subsequent disruption of retinal pigment epithelium and choroidal thinning. The aim of this study was to determine whether changes of outer retinal layer(ONL) thickness and choroidal thickness might signal impending toxic effects of HCQ before development of retinopathy.

Methods: We included patients who were screened for HCQ retinopathy, and followed for ≥ 12 months. Based on visual field, optical coherence tomography(OCT) and autofluorescence, patients with no retinopathy were collected. During follow-up period, HCQ was continued in 121 patients (continued group), and stopped in 25 patients due to non-retinotoxicity reasons (discontinued group).

Using OCT images, ONL thickness was obtained from fovea, inner ring and outer ring of the Early Treatment of Diabetic Retinopathy Study(ETDRS) grid. Subfoveal choroidal thickness(SFChT) was measured from EDI-OCT. The thicknesses were measured at baseline, and repeated at least 1 year apart. Comparison was made between the baseline OCT and the last OCT available in each group.

Results: At baseline, mean dose/kg were 3.90mg/kg, 4.70mg/kg, and duration of medication 154.2months, 90.5months, in ‘continued’ and ‘discontinued’ group, respectively. There were no significant differences in thicknesses between ‘continued’ and ‘discontinued’; mean ONL thicknesses of foveal(87.9, 88.1um), inner ring(66.5, 64.5um), outer ring(54.2, 51.6um) and mean SFChT(246.6, 229.9um).

Over the follow-up period, 'continued’ group(mean of 37.4months) showed a progressive ONL thinning in outer ETDRS ring(54.2 to 53.0um, p=0.000), and progressive decrease in SFChT(246.6 to 218.7um, p=0.000). ‘Discontinued’ group(mean of 33.3months) also showed a significant ONL thinning in outer ETDRS ring(51.6 to 50.1um, p=0.001), but, interestingly, showed a significant increase in SFChT(229.9 to 239.2um, p=0.024) after cessation of HCQ medication.

Conclusions: ONL thinning was observed progressively in patients taking HCQ prior to development of retinopathy. Although choroidal thickness also decreased while HCQ treatment, thinning was partially recovered following early discontinuation of HCQ. We suggest the measurements of ONL and choroidal thickness might be used for early detection of HCQ retinal toxicity.

ABSTRACT BODY:

Purpose: Excessive microglia activation is considered as a pathological factor that leads to neuroinflammation and neurodegeneration. Baicalein (Ba), a natural occurring flavonoid, displays a wide spectrum of bioactivities including anti-inflammation. In this study, we investigated the effects of Ba on the lipopolysaccharide (LPS)-induced microglia activation in mouse BV2 microglia cell line. We also evaluated the anti-inflammatory and neuroprotective effects of Ba using a retinal ischemia/reperfusion (I/R) mouse model.

Methods: Activation of BV2 cells was induced by 1μg/ml LPS for 6 hours prior to the addition of PBS, vehicle or Ba (10μM). After a total 48-hour incubation, pro-inflammatory cytokine protein and mRNA levels were quantified by cytokine array assays and quantitative polymerase chain reaction (qPCR), respectively. For in vivo studies involving I/R injury, the morphological and transcriptome changes of mouse microglia and retinas were evaluated, either in the presence or absence of Ba (100μM) treatment.

Results: As expected, upregulation of pro-inflammatory cytokines was detected in LPS-primed BV2 cells. Ba effectively suppressed the expression of most cytokines including IL-6, IL-1β, and TNF-α, as compared to the vehicle-treated group which showed a similar expression profile as LPS-stimulated control. Concurrently, Ba significantly suppressed the mRNA expression of Il-6, Il-1β and Tnf-α in LPS-stimulated BV2 cells. After 1 week of I/R injury, mouse retinas displayed an increased population of IBA-1+ microglia/macrophages along with enlarged IBA-1+ cell body and shortened cellular processes, as well as an increased expression of activated microglia markers (e.g. Iba-1, Cox2) and pro-inflammatory cytokines (e.g. Il-1β, Il-1α). Weekly intravitreal administration of Ba retained the morphological and transcriptional features of resting microglia. Ba also effectively reduced the retinal ganglion cells (RGCs) loss by 80% at 4 weeks after I/R injury.

Conclusions: Our results suggest that Ba acts as a negative regulator of activated microglia and immune responses both in vitro and in vivo, effectively alleviating neurodegeneration in retinal I/R injury. This finding indicates that Ba could be a potential therapeutic agent to neurodegenerative retinal diseases.

ABSTRACT BODY:

Purpose: Visual impairment is a serious adverse effect in children with a brain tumor. To date, visual impairment is often underestimated and unrecognized, while early detection of visual impairment is important to potentially preserve the visual function. Our aim was to assess the prevalence and type of abnormal ophthalmological findings in children with a newly diagnosed brain tumor and to identify potential oncological and clinical risk factors.

Methods: In this prospective nationwide cohort study, we included children, aged 0-18 years, with a newly diagnosed brain tumor in the Netherlands between May 2019 and August 2021. A comprehensive ophthalmological examination (including orthoptic evaluation, visual acuity, visual fields and fundoscopy) was performed at diagnosis. Multivariable logistic regression analyses were performed to estimate the odds ratio (OR) and 95% confidence interval (CI) of the risk factors.

Results: In total, 170 children were included (43.5% female; median age [interquartile range], 8.3 [3.9 – 13.0] years; 48.2% infratentorial tumors, 35.3% midline tumors and 16.5% cerebral hemispheres tumors). Overall, 101 children (59.4%) presented with visual symptoms at diagnosis. The most common findings on ophthalmological examination were papilledema (50.6%), gaze deficits (31.8%), visual field defects (29.4%), nystagmus (23.5%), strabismus (18.8%) and decreased visual acuity (10.5%). The risk of papilledema was associated with older age in years (OR 1.2, 95% CI 1.1 – 1.3) and hydrocephalus (OR 15.8, 95% CI 5.7 – 43.4). Visual field defects were detected more frequently in children with a tumor located in the cerebral hemisphere (OR 5.3, 95% CI 1.5 – 19.1) or midline (OR 6.0, 95% CI 2.0 - 18.1).

Conclusions: We found a high prevalence of abnormal ophthalmological findings in an unselected cohort of children at brain tumor diagnosis. These findings emphasize the need of standardized ophthalmological surveillance and of awareness of health care providers for ophthalmological abnormalities in this patient group.

ABSTRACT BODY:

Purpose: Pax6 is a master regulator governing development of both brain and eye. Our previous studies have shown that SUMO1-mediated sumoylation is an indispensable step towards activation of p32 Pax-6 (Yan et al. 2010. PNAS). However, how does the sumoylated Pax6 regulate lens development is largely unknown. Here, we present evidence to show how sumoylated Pax6 regulates lens stalk regression during lens development.

Methods: CRISPR/Cas9 technology is used to create the mouse model where the conserved amino acid, 90E was deleted so that the conserved sumoylation site was altered. RNAseq analysis was used to analyze the transcriptional activity of the mutated Pax6. In situ hybridization and QRT-PCR were used to confirm mRNA expression of Pax6 and other downstream genes in both wild type and mutant mice. Cycloheximide and MG132 treatments were used to determine the half life of wild type and mutant Pax6 protein. H.E. staining was used to record the lens morphology.

Results: Deletion of the conserved 90E amino acid caused significant changes in the sumoylation pattern of the mutant Pax6, which changes the stability of Pax6. The mutated pax6 displays fundamental changes in regulating expression of the downstream genes. The expression patterns of over 20 genes involved in control of apoptosis in the embryonic lens were altered, leading to inhibition of apoptosis in the lens stalk region of the mutant mouse. As a result, lens stalk regression was halted, causing microphthalmia.

Conclusions: Sumoylated Pax6 regulates apoptotic genes to control lens stalk regression. Supported by National Natural Science Foundation of China (Grants #81970787, #82000876, #81770910) and Natural Science Foundation of Guangdong Province and Guangdong City Joint Program of China (Grant # 2019B1515120014) , and the Fundamental Funds, 3030901010110 of the State Key Laboratory of Ophthalmology of Zhongshan Ophthalmic Center.

ABSTRACT BODY:

Purpose: The damages in photoreceptor-retinal pigment epithelium (RPE) complex are clinically known in DME. We therefore investigated the effects of extracellular microvesicles containing mitochondria on such pathological changes in this translational research.

Methods: 661W cells (mouse cone photoreceptor cell line) were cultured in DMEM containing DME sera, and the cell culture supernatants were applied to a two-step centrifugation in order to obtain extracellular microvesicles as pellets. We performed flow cytometry after staining with Mitobright and PCR was applied to characterize microvesicles derived from 661W cells. The microvesicles were administered to ARPE19 cells (human RPE cell line) and cell death was evaluated by LIVE / DEAD assay. Seven days after the subretinal injection of the microvesicles in C57BL / 6 mice, the RPE flatmount was prepared and immunostained with ZO-1 antibody.

Results: Electron microscopic analyses demonstrated mitochondria with a cristae structure in the vitreous humor of patients with diabetic retinopathy. Flow cytometry revealed mitochondria positive staining in most extracellular microvesicles, and PCR showed a significant increase in mitochondrial DNA in such microvesicles ($P<0.05$). Administration of the microvesicles induced cell death of ARPE19 and 661W cells in a concentration-dependent manner ($P<0.001$ at any concentration), but cell death was significantly suppressed by the single-stranded oligo DNAs C151 and A151 ($P<0.001$ in both comparisons). The aggregation, deformation and enlargement in RPE cells were observed in the RPE flatmounts of the mice administrated with the microvesicles, whereas these changes were reversed by oligo DNAs.

Conclusions: These data suggest that microvesicles containing mitochondrial DNA are involved in photoreceptor-RPE damage in DME.

ABSTRACT BODY:

Purpose: To describe the corneal and refractive properties of patients with congenital nystagmus syndrome compared to healthy subjects.

Methods: In this comparative cross-sectional observational study, a scheimpflug imaging tomography was conducted on eyes of congenital nystagmus syndrome patients and compared with those of healthy individuals (control group). Corneal astigmatism prevalence, corneal astigmatic power, maximal keratometry, mean keratometry and pachymetry values were obtained and compared between the groups.

Results: 32 eyes of 16 congenital nystagmus syndrome patients and 32 eyes of 16 healthy individuals were included in the study. All nystagmus patients (100%) had astigmatism of at least 1 diopter compared to 11 subjects (34.375%) in the control group ($P<0.001$). The average astigmatic power in the patient's group was 3.383 ± 1.135 diopters compared to 0.8281 ± 0.58.54 diopters in the control group ($P<0.001$). The maximal keratometric power in the patient's group was 44.16 ± 2.444 diopters compared to 42.88 ± 2.052 diopters in the control group ($P=0.027$). The mean keratometric power in the patient's group was 41.98 ± 2.129 diopters compared to 41.40 ± 5.121 diopters in the control group ($P=0.560$). The mean pachymetric value in the patient's group was 557.1 ± 47.15 μm compared to 544.2 ± 29.32 μm in the control group ($P=0.1945$).

Conclusions: All patients with congenital nystagmus syndrome have visually significant astigmatism. Corneal tomography can be used to asses and grade the corneal astigmatism in these patients.

ABSTRACT BODY:

Purpose: Cold storage of donor corneas is inevitable before endothelial transplantation or preparation of cultured cells for “cell injection therapy”. Here we have examined the effects of hypothermia on endothelial tight junctions (TJs) and its principal regulator, the perijunctional actomyosin ring (PAMR).

Methods: Ex vivo porcine corneas were exposed to hypothermia (HYPO: 4 °C; 1 to 7 days) in Cornisol™ medium with and without pretreatment with a microtubule-stabilizing agent (epothilone B, EpoB; 100 nM), p38 MAP kinase inhibitor (SB-203580, SB; 20 μM), antioxidants (quercetin; 100 μM, or Vitamin E; 1 mM), or iron chelator (deferoxamine; 10 mM) and examined subsequently with and without rewarming (37 °C for 3 h). The damage to microtubules, PAMR, and ZO-1 (a marker of TJs) in the endothelium was assessed by immunocytochemistry. In addition, we imaged paracellular flux of FITC-avidin across endothelial cells grown on biotinylated gelatin to evaluate the functional integrity of TJs.

Results: Exposure to HYPO led to disassembly of microtubules, disruption of PAMR (Figs. A,B), and loss of contiguous distribution of ZO-1 at the cellular periphery (Fig. E,F). These responses were slightly augmented by rewarming after HYPO. However, the damage to PAMR and ZO-1 could be abated by pretreatment with EpoB, SB, antioxidants, or the iron chelator (Figs. C,G). Deliberate oxidative stress to endothelium by exposure to H2O2 and t-butyl hydroperoxide (tBHP) also led to widespread damage to the organization of PAMR and ZO-1 (Figs. D,H) in a p38 MAP kinase-dependent manner. Furthermore, photodynamic treatment with riboflavin or tryptophan + UV-A also caused damage to PAMR and ZO-1, which could be abolished by cotreatment with catalase. In cultured cells, both HYPO and oxidative stress caused a significant increase in the flux of FITC-avidin, indicating a loss in barrier integrity.

Conclusions: Prolonged cold storage of corneas induces destruction of the cytoskeleton in the endothelium via activation of oxidative stress, leading to a breakdown of the barrier function. Thus, the inclusion of microtubule stabilizers, antioxidants, and iron chelators in the storage medium has the potential to overcome the endothelial barrier failure during cold storage of donor corneas.

ABSTRACT BODY:

Purpose: Equipping the human retinal organoids (hROs) with neuro-immune cells (retinal microglia) to make hROs more representative of real retinas.

Methods: An efficient and simplified method was established to generate high-purity microglia from human pluripotent stem cells (hPSCs), then co-culturing the microglia with hROs to induce the differentiation of retinal microglia. The retinal microglia were characterized by the flow cytometry, ELISA, immunofluorescence staining and RNA sequencing.

Results: We established a simplified approach to differentiate hPSCs into high purity (>90%) microglia (PSC-MG). PSC-MG express microglia-specific markers, release cytokines upon stimulation, and are capable of phagocytizing bacteria. When co-cultured with three-dimensional hROs, PSC-MG migrated into the hROs, tended to differentiate into resident retinal microglia, and simultaneously induced apoptosis in some neural cells and promoted the migration of the photoreceptor precursors.

Conclusions: We developed a simplified and efficient method to generate microglia from human pluripotent stem cells, and we reported the first derivation of retina-resident microglia in vitro, providing a new source of human retinal microglia for developmental and disease studies and regenerative therapeutics.

ABSTRACT BODY:

Purpose: There is no unifying postulate that explains how and why two eyes within the same environment and identical genetic influences develop asymmetrically and produce different refractive errors, sometimes leading to amblyopia and loss of binocularity. This unique pilot study analysed extraocular muscle (EOM) characteristics of the more emmetropic globe acting as an intrinsic control for the more myopic globe in subjects with non-strabismic myopic anisometropia (anisomyopia) of 1D or more by high resolution fast spin echo T2 weighted (T2FSE) surface coil orbital magnetic resonance imaging {(MRI), 3T Siemens Skyra}.

Methods: 5 subjects (10 orbits) of average age 20±7.2 years (3 males) with anisomyopia were imaged with the subject fixating at a central target. 2mm thick contiguous quasi-coronal image planes perpendicular to the orbital axis were analysed for EOM pulley locations, EOM cross sections and LR-SR band length while quasi-sagittal and axial planes were used to measure rectus EOM and optic nerve (ON) length, all by Image J software as per published norms (Figure 1A-E). A comprehensive ophthalmic evaluation was performed in all subjects.

Results: The average refractive error and axial length (AL) in the more myopic eye was -7±3.6D, 26.1±0.4mm versus -1.5±2.4D,24.1±1.7mm in the more emmetropic eye (p=0.02, 0.04).None of the subjects were amblyopic in either eye. The average stereopsis was 520±455 arcseconds (TNO test). 2 subjects with moderate anisomyopia of 2D demonstrated 100 arcseconds stereopsis. There was marked effacement and lengthening of the LR-SR band in the more myopic eye (10.4±0.8mm) versus the more emmetropic eye (8.6±0.6mm, p=0.003). The antero-posterior extent of the LR-SR band was seen in 1.4±0.5 slices in the more myopic eye versus 3.2±0.4 slices in the more emmetropic eye (p=0.0004). The rectus EOM and ON length was similar in both eyes.

Conclusions: Anisomyopia provides a unique biological control to evaluate structural and biomechanical ocular and adnexal differences in the same individual.

ABSTRACT BODY:

Purpose: Childhood-onset Stargardt Disease (STGD1) is characterized by accumulation of bisretinoids which cause progressive retinal atrophy leading to rapid visual loss. Because bisretinoid toxins are derived from circulating retinol, reduction of retinol delivery to the eye, via antagonism of serum retinol binding protein 4 (RPB4), has been explored as a means to slow disease progression in STGD1. Tinlarebant, an orally administered, potent and specific non-retinoid antagonist of RPB4, has been developed to determine whether reduction of circulating RPB4-retinol is a safe and effective treatment approach for STGD1.

Methods: The Phase 1b/2 study is a multicenter, single arm, open-label study followed by a 2-year extension to evaluate safety and tolerability and efficacy of Tinlarebant. Eleven subjects aged 12-18 years received oral Tinlarebant (5 mg) daily for a 28-day treatment period. Treatment emergent adverse events (TEAEs), PK/PD, and visual function outcomes were evaluated.

Results: A total of 28 TEAEs were reported and were mild in severity. Seven TEAEs reported by 6 subjects (54.5%) were non-ophthalmic and considered to be non-drug-related; 21 TEAEs reported by 10 subjects (90.9%) were ophthalmic. Delayed dark adaptation (DDA) and xanthopsia (both mild and reversible), reported by 7 subjects (63.6%), were attributed to drug. DDA and xanthopsia were noticed principally on waking and resolved within 10 minutes. All subjects tolerated these AEs. Tinlarebant plasma concentration and RBP4 suppression appeared to be correlated. RBP4 levels declined rapidly within 4 hours of treatment on Day 1. Mean RBP4 level reached 20% of mean baseline on Day 8 of treatment. Suppression was maintained throughout the study. Mean RBP4 level returned to 92.3% of baseline values following 14 days of drug cessation. Visual acuity (VA) was available for all time points in 8 subjects, 7 improved with 3 subjects experiencing a 5-, 10-, and 24-letter improvement, in at least one eye. Where quantitative autofluorescence (qAF) was available qAF was correlated with VA improvements.

Conclusions: Tinlarebant has an acceptable safety profile in adolescent STGD1 subjects. There was a trend for VA improvement. The observed AEs were anticipated based on mode of action. STGD1 subjects from the Phase 1b study are now participating in the 2-year Phase 2 extension study.

ABSTRACT BODY:

Purpose: A reliable animal model providing chronic ocular hypertension (COH) and characteristic neurodegeneration is essential to recapitulate human glaucoma and understand molecular mechanisms. This study aims to develop an experimental glaucoma model induced by a novel in situ-crosslinked hydrogel and thoroughly evaluate the effectiveness of this model.

Methods: We designed and developed a novel method of inducing persistent IOP elevation in C57BL/6J mice using an injectable hydrogel formulated by hyperbranched macromolecular poly(ethylene glycol) (HB-PEG) and thiolated hyaluronic acid (HA-SH). The hydrogel's characteristics were first assessed to determine its mechanical strength, swelling profile and cytocompatibility. Retinal whole-mount immunostaining was used to determine retinal ganglion cell (RGC) loss and hematoxylin-eosin (HE) staining was used to measure ganglion cell complex (GCC) thickness. All experimental data were analyzed using GraphPad Prism (v9.0; GraphPad Software, CA, USA) and were presented as the mean ± standard error of the mean (SEM). A P value less than 0.05 was regarded as statistically significant.

Results: An appropriate hydrogel formulation was determined to induce chronic IOP elevation and the effectiveness of our model was thoroughly evaluated. We determined that the HB-PEG/HA-SH hydrogel generated under physiological conditions was suitable for intracameral injection. When the concentration ratio of HB-PEG and HA-SH was 1:1 (10 mg/ml each), the highest storage modulus (68 Pa) was observed (Fig. 1A) while minimal swelling (Fig. 1B) and degradation profile (Fig. 1C) was observed. Besides, HTMCs maintained high viability after co-culture with HB-PEG/HA-SH hydrogel (Fig. 1D), indicating the good cytocompatibility of the hydrogel. Injection of the hydrogel (Fig. 2A-B) induced a persistent IOP elevation over 50% above baseline (Fig. 2C), which led to progressive RGC loss (37.12 ± 2.61% and 41.62 ± 4.94% on day 28 in the central and peripheral retinal regions, mean ± SEM, $P<0.001$) (Fig. 2D-E) and GCC thickness reduction (10.03 ± 3.25%, mean ± SEM, $P = 0.0093$) (Fig. 2F-G).

Conclusions: The in-situ forming HB-PEG/HA-SH hydrogel system could be an appropriate strategy for developing a reliable experimental glaucoma model without any confounding factors. We expected this model would be conducive to the development of neuroprotective and neuroregenerative therapies.

TITLE: JTE-013 alleviates demyelination and preserves visual function after ischemia/reperfusion by inhibiting sphingosine-1-phosphate receptor 2 (S1PR2)

SESSION TITLE: Neuroprotection and Neuroregeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Xue, J. Lin, Z. Liu, Q. Zhang, Y. Li, Y. Zhuo, Sun Yat-Sen University Zhongshan Ophthalmic Center State Key Laboratory of Ophthalmology, Guangzhou, Guangdong, CHINA|

Commercial Relationships Disclosure: Jingfei Xue: Commercial Relationship: Code N (No Commercial Relationship) | Jicheng Lin: Commercial Relationship: Code N (No Commercial Relationship) | Zhe Liu: Commercial Relationship: Code N (No Commercial Relationship) | Qi Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Yiqing Li: Commercial Relationship: Code N (No Commercial Relationship) | Yehong Zhuo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Myelin sheaths play an important role in neurodegenerative diseases; the conduction of the action potential is impaired without normal myelin sheaths, which could cause visual dysfunction and cognitive impairment. Sphingosine-1-phosphate receptor 2 (S1PR2), a G-protein coupled receptor, was previously reported to be associated with demyelination. We hypothesize that decreased S1PR2 by JTE-013 could reverse the demyelination and protect the survival of retinal ganglion cells (RGCs) and axonal regeneration.

Methods: Adult wild-type male C57Bl/6J mice (5-8 weeks) were purchased to establish the retinal ischemia/reperfusion (I/R) model. The right eye was perfused with sterile 0.9% saline solution for 1 hour to hold the IOP at 70 mmHg. The mice were randomly categorized into three groups in our experiments: blank control group, injured group, and treatment group. The eyes in the treatment group (N=3-7) were intravitreally injected with 3μl JTE-013 immediately after reperfusion, and the eyes in the injured group (N=3-7) with 3μl PBS. The optic nerves were perfusion-fixed and sectioned for immunofluorescent staining. We could detect the change of S1PR2 in the three groups. Then we measured the fluorescence intensity of myelin basic protein (MBP) and SMI32 to evaluate demyelination and axonal degeneration. The retinas were stained with βIII-tubulin and RBPMS to calculate the number of RGCs. Finally, we could observe the myelin sheaths and axons of the optic nerve by transmission electron microscope. One-way ANOVA and unpaired t test was used for statistical analysis.

Results: The expression of S1PR2 significantly increased in the injured ($p<0.05$) groups and the JTE-013 could inhibit the increase of S1PR2 (Figure 1A). The fluorescence intensity of MBP was significantly decreased in the injured ($p<0.01$) group, and JTE-013 could alleviate demyelination ($p<0.001$) (Figure 1B). Meanwhile, inhibiting S1PR2 could increase the number of RGCs ($p<0.001$) and reduce axonal degeneration ($p<0.05$) compared to the injured group (Figure 2). Quantification of G-ration and axons in electron micrographs also showed that JTE-013 could decrease myelin loss and increase the number of axons.

Conclusions: JTE-013 could relieve demyelination by inhibiting S1PR2, protecting RGCs and axons.

ABSTRACT BODY:

Purpose: Myopic progression is commonly caused by axial elongation in an eye resulting in the thinning and reduced stiffness of the sclera. There exist limited studies on the stiffness of the posterior eyewall in myopic eyes. Our goal is to examine whether myopic eyes had greater deformability in the posterior eye of a cohort of adults in Singapore.

Methods: Fifty-eight myopic eyes of 29 subjects (ages 37-87) were enrolled.

Ultrasound (US, Quantel Aviso, 20 MHz) B-mode scans were performed in primary gaze across 100 frames to study the posterior of each eye. Manual compression by a handheld ophthalmodynamometer was used at specified intervals to capture the displacement over time and assess the degree of deformability, or strain, of the tissues of the retina-choroid-sclera (RCS) layer in the posterior eye wall.

For each frame, strain elastography was used to measure the relative stiffness (RS) of several regions of interest (ROI) in RCS layer, with orbital fat as the baseline. Softer tissues experience more strain and are expected to be less stiff than harder tissues.

Results: Average RS across 100 frames was compared across eyes for ROIs in RCS layer. At an interval of before-and-after compression, paired t-test showed significant difference between the change in average RS for a ROI ($p=0.01$) and across 2 different ROIs ($p=0.01$ and $p<0.01$) when compared against the baseline orbital fat. Average RS at 2 different intervals of before-and-after compression showed significant difference for an ROI ($p=0.01$) and of 2 different ROIs ($p=0.01$ and $p=0.04$) for paired t-test.

Axial length (AL, measured by IOLMaster) ranged 22.59 to 30.72 mm and spherical error (SE) ranged from 0.7 to -15.7 D. Increase in AL (per 1 mm) showed a decrease in average RS for an RCS layer ROI during compression of -0.283 ($R^2=0.40$, $p<0.01$) and no compression of -0.0139 ($R^2=0.19$, $p=0.04$). During compression, increase in SE (per 1 D) showed an increase in average RS of 0.00783 ($R^2=0.23$, $p=0.02$) for an RCS layer ROI.

Conclusions: Our qualitative and semiquantitative measure of posterior eye wall strain shows promise as an imaging biomarker identifying regions in myopic eyes that are less stiff and more susceptible to deformability that, when combined with other metrics (AL, SE) may help assess at an early stage, the risk of progression of a stable high myopia eye to PM with staphyloma.

ABSTRACT BODY:

Purpose: The gene GUCY2D encodes the photoreceptor guanylate cyclase a key phototransduction enzyme involved in the restoration of cytoplasmic cGMP and return to the dark state of the photoreceptor. GUCY2D is associated with inherited retinal diseases including autosomal dominant cone-rod dystrophy (CRD). We performed a retrospective, observational cohort study to describe the natural history and progression of GUCY2D-associated CRD. In addition, the study aimed to investigate structural and functional biomarkers and their correlation with GUCY2D-associated CRD.

Methods: Retrospective analysis was conducted on data from 16 patients with GUCY2D-associated CRD across two sites. Assessments included central macular thickness (CMT) and length of disruption to the ellipsoid zone (EZ) via optical coherence tomography (OCT), electroretinography (ERG) parameters, best corrected visual acuity (BCVA), and fundus autofluorescence.

Results: At first visit, with a mean age of 30 years (range 5 – 70 years), 11 patients had a BCVA below the medical standards for holding an Australian Driver's licence (LogMAR > 0.3 in both eyes), and 1 patient met the Australian definition of legal blindness (LogMAR ≥ 1 in both eyes). Analysis over the observation period (mean = 7 years, range 0 – 17 years) demonstrated a deterioration of LogMAR by -0.019 per year (SE = 0.003, $p < 0.0001$), during which 3 patients crossed the threshold of legal blindness. This study also demonstrated a significant reduction in CMT of -1.3 µm per year (standard error (SE) = 0.4 µm; p = 0.005) and lengthened disruption of the EZ by 42 µm per year (SE = 5 µm, p = <0.0001). Similarly, cone function as measured by ERG was shown to decrease with increasing age; b-wave amplitude of both the light-adapted 30 Hz flicker and fused flicker decreased by 0.83 µV (SE = 0.30 µV, p = 0.005) and 0.21 µV (SE = 0.09 µV, p = 0.02) per year, respectively. Reduction in CMT and increased EZ disruption on OCT were significantly associated with functional changes including poorer BCVA and decreased cone function on ERG.

Conclusions: We have described the natural long-term decline in vision and cone function associated with mutations in GUCY2D. We have also identified a set of functional and structural biomarkers that may be useful as outcome parameters for future therapeutic clinical trials.

ABSTRACT BODY:

Purpose: Profound losses in stereoacuity have been documented earlier in bilaterally asymmetric keratoconus. This study determined whether 1) these losses can be explained by imbalances in retinal image contrast between the two eyes, arising from the underlying interocular differences in disease severity (Experiment 1) and 2) correction of the contrast imbalance restores stereoacuity in these subjects to the level of healthy controls (Experiment 2).

Methods: In Experiment 1, the magnitude of contrast imbalance of 50 cases with bilaterally asymmetric keratoconus (11 to 31yrs) with spectacles was determined from the symmetry of interocular rivalry switches of dichoptically-presented orthogonal Gabor patches with 5cpd and 1.5cpd carrier spatial frequency. The stimulus contrast attenuation required in the stronger eye (as judged by greater value of D-index), relative to 100% contrast in the weaker eye, to achieve this symmetry was considered a measure of this contrast imbalance. In Experiment 2, random dot stereoacuity of 40 cases with bilaterally asymmetric keratoconus (16 to 32yrs) was measured at baseline, at the contrast balance point and at 20% below and above the contrast balance point using standard adaptive staircases.

Results: The magnitude of contrast imbalance was positively correlated with increasing interocular difference in D-index ($r=0.74$, $p<0.001$). The magnitude of contrast imbalance was significantly greater for 5cpd than for 1.5cpd stimulus ($p<0.001$). Stereoacuity was positively correlated with the extent of contrast imbalance in these cases ($r=0.47$, $p<0.002$). Contrast balancing improved stereoacuity by a median value of 34.6% (19.0-65.1%), independent of baseline stereoacuity (261.3-1257.3arc sec) or contrast imbalance levels ($r<0.2$, $p>0.26$ for both). Contrast bias towards the weaker eye (239.6-1707.6arc sec) produced a greater loss of stereoacuity than bias toward the stronger eye (181.9-1161.4arc sec) ($p=0.001$).

Conclusions: Contrast imbalance scales with the magnitude of interocular difference in keratoconus severity, more so for higher than lower spatial frequencies. Stereoacuity partially improves with contrast balancing in keratoconus. Results of the contrast biasing experiment indicate that cyclopean viewing may be weighted more towards the input from the stronger eye in keratoconus, independent of its contrast strength.

ABSTRACT BODY:

Purpose: CREB is a transcription factor and its most prominent function is to control the synaptic plasticity associated with long-term memory. In our recent studies, we demonstrated that CREB regulates oxidative stress-induced apoptosis and aging in lens by inhibiting αB-crystallin expression but promoting P300-P53-Bak/Bax signaling axis (Wang L et al. 2021. Aging Cell). Whether CREB is capable to regulate lens differentiation remains largely unknown. Here, in the present study, we demonstrate that CREB directly regulates Pax6 and other genes to control differentiation of mouse lens.

Methods: CRISPR/Cas9 Technology was used to create mouse model CREB-S133A. RNAseq analysis was used to compare the transcriptional activity of wild type and mutant CREB-S133A.Gel mobility shifting assays were used to determine binding of CREB to Pax6 gene promoter. ChIP assays were used to confirm the binding of CREB to the Pax6 gene promoter. Reporter gene constructs driven by different promoter and enhancer regions of the Pax6 gene were generated and used to assay the relative strength of different Pax6 gene promoter regions. QRT-PCR and Wes were used to analyze mRNA and protein expression levels.

Results: RNAseq analysis revealed the reverse relationship between CREB and Pax6. EMSA assays demonstrate that CREB directly binds to the promoter region of Pax6. ChIP assay results confirmed that CREB binds to Pax6 promoter in vivo. In mouse lens epithelial cell, overexpression WT-CREB resulted in downregulation of Pax6. Silence of CREB upregulates Pax6. RNAseq analysis also revealed that CREB can regulate a panel of differentiation-related genes.

Conclusions: Through direct control of Pax6 and other downstream differentiation-related genes, CREB regulates lens differentiation. Supported by National Natural Science Foundation of China (Grants #82000842, #81970787, #82000876, #81770910) and Natural Science Foundation of Guangdong Province and Guangdong City Joint Program of China (2019B1515120014) , and the Fundamental Funds, 3030901010110 of the State Key Laboratory of Ophthalmology of Zhongshan Ophthalmic Center.

ABSTRACT BODY:

Purpose: To develop and validate a deep learning model for detecting keratoconus based on corneal maps from CASIA and Pentacam instruments.

Methods: We collected 3428 corneal maps from CASIA optical coherence tomography (OCT)-based imaging instrument (SS-1000, Tomey, Japan) at Jichi Medical University, Japan, and collected 217 corneal maps from Pentacam Scheimpflug-based imaging instrument (Oculus Optikgerate GmbH) at Al-Amal eye clinic in Baghdad, Iraq. We developed a deep learning framework based on AlexNet architecture to detect keratoconus based on anterior elevation maps in CASIA dataset only. We then evaluated the developed model based on corneal maps in the Pentacam dataset using accuracy, specificity, sensitivity, and area under the receiver operating characteristic curve (AUC) (Fig.1)

Results: The CASIA dataset included corneal maps from 1845 normal eyes and 1583 eyes with keratoconus (annotated based on the CASIA built-in Ectasia Screening Index;ESI). The Pentacam dataset included 114 normal eyes and 103 eyes with keratoconus (annotated based on clinical evaluations through two specialists). The accuracy and AUC of the proposed deep learning model in detecting keratoconus from anterior elevation maps tested on Pentacam dataset was 86.7% and 0.93, respectively (Fig.2). The sensitivity, specificity, and F-score of the model were 0.74, 0.98, and 0.88, respectively.

Conclusions: We developed a device-agnostic deep learning model to detect keratoconus and evaluated it based on corneal maps collected from two different cohorts (Japan and Iraq) based on two different instruments (CASIA and Pentacam). The accuracy of the proposed model in detecting keratoconus from two different instruments was reasonable. This novel approach demonstrates the generalization of the developed deep learning model. This model may augment clinical evaluations of keratoconus in day-to-day ophthalmological care.

ABSTRACT BODY:

Purpose: Ophthalmic surgeons are at an increased risk for musculoskeletal disorders resulting in chronic back and neck pain, which has been linked to disability, productivity loss, and early retirement. Prior studies have correlated these outcomes to work-related routines and equipment specific to ophthalmic exams and surgeries, which may be exacerbated by poor posture. The purpose of this study was to observe the effect that a commercially available posture trainer, Upright Go, can have on the improvement of posture of ophthalmic surgeons.

Methods: Five ophthalmologists-in-training were studied over a period of four weeks during their surgical rotations between September 2020 and June 2021. Participants underwent an “observation” period consisting of two surgical days during which their postural data was tracked via the posture training device and recorded through an associated phone application. The trainees then entered a two-week “training” period, during which the device was calibrated and programmed to vibrate anytime the user slouched past a certain degree specific to the calibration of each user. The final “testing” period consisted of another two surgical days with the vibration setting turned back off while user posture was again tracked. The percentage of time users spent upright intraoperatively pre- and post- training was evaluated.

Results: All five participants demonstrated an increase in the percentage of time spent upright after the training period. Across all participants, the total average percentage spent upright in the observation period was 64.2%, while in the testing period was 89.3%, resulting in an average improvement of 25.1% of time spent in an upright position after the completion of the training period ($p<0.002$). The range of improvement of time spent upright was 16.0% to 33.5%.

Conclusions: This cohort study utilized the Upright Go device to help determine the effect that its training could have on improvement of posture in ophthalmic surgeons. The results indicated a significant increase in the average proportion of time spent with upright posture compared after the training period.

ABSTRACT BODY:

Purpose: To evaluate the accuracy of different deep learning models for detecting glaucoma from fundus photographs.

Methods: We used a dataset with 1707 fundus photographs from 919 normal eyes and 788 eyes with glaucoma. We developed five different deep learning architectures in Google Colaboratory to detect glaucoma based on fundus photographs. We randomly selected 80% of the fundus photographs for development of models and 20% of the fundus photographs for final testing and evaluation of models. We developed a customized convolutional neural network (CNN) with 13 layers and compared it against four of the existing CNN architectures including AlexNet, VGG16, DensNet121, and ResNet50. We used different accuracy metrics to compare the performance of developed models based on the testing subset (Table 1).

Results: Table 1 shows the accuracy of different models in detecting glaucoma based on different CNN architectures using development and testing subsets. The customized CNN architecture achieved an accuracy of 87.2% and 92.6% on testing and development subsets, respectively. Figure 1 shows the receiver operating characteristics (ROC) curves of all CNN architectures. The area under the receiver operating characteristic curve (AUC) of the customized CNN was 81.8% and 96.5% based on testing and development subsets, respectively.

Conclusions: We performed a pilot study to show that it is feasible to detect glaucoma from fundus photographs based on different deep learning architectures. However, two factors are critical in robustly evaluating deep learning models. The datasets would need to be representative of underlying decease characteristics. The model would need to be generalizable. Validating the customized CNN architecture based on larger and independent datasets is desirable and may augment clinical practice in glaucoma assessment.

TITLE: Investigation of visual functions in adult anisometropic amblyopia
SESSION TITLE: Amblyopia
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: A. Rakshit, K.L. Schmid, A.L. Webber, School of Optometry and Vision Sciences, Faculty of Health, Queensland University of Technology, Brisbane, Queensland, AUSTRALIA|A.L. Webber, School of Optometry and Vision Science, University of New South Wales, Sydney, New South Wales, AUSTRALIA|D. Majhi, Pediatric Ophthalmology, LV Prasad Eye Institute Bhubaneswar Campus, Bhubaneswar, Orissa, INDIA|
Commercial Relationships Disclosure: Archayeeta Rakshit: Commercial Relationship: Code N (No Commercial Relationship) | Katrina Schmid: Commercial Relationship: Code N (No Commercial Relationship) | Ann Webber: Commercial Relationship: Code N (No Commercial Relationship) | Debasmita Majhi: Commercial Relationship: Code N (No Commercial Relationship)
ABSTRACT BODY:
Purpose: The purpose was to assess visual acuity, binocular vision, higher order executive function (selective and divided attention), and functional ability (fine motor skills and reading speed) in participants with and without anisometropic amblyopia. In addition, to determine if visual acuity and binocular function influence the functional outcome measures. The hypothesise was that as for amblyopic children, adults will also exhibit reduced performance on visual attention and visual search tasks.
Methods: 20 adults with anisometropic amblyopia (mean age= 22±3.9 yr) and 10 adults with normal visual development (26.8±4.4 years; controls) participated. Vision assessment included refraction, visual acuity (monocular and binocular) and binocular function (BF) (Worth 4 Dot and Randot Preschool Stereo test). Fine motor skills and reading speed were tested by Bruninks-Oseretsky Test of Motor Proficiency (BOTMP) and International Reading Speed Texts (IReST) respectively. Visual attention and processing speeds were assessed using the three subtests of the Useful Field of View (UFOV): central processing, divided attention, and selective attention. Visuo-cognitive search proficiency was measured using static and dynamic presentations of the Trail Making Tests (TMTs), parts A and B, with increasing levels of executive function demand. All participants performed these functional tasks binocularly.
Results: Amblyopes showed a mean VA of 0.51(0.25) logMAR in the amblyopic eye. They exhibited slower reading performance (124±40 wpm) and slower completion time in TMT searches (Trail A - 58±24secs, Trail B- 73±28secs) as compared to controls (reading speed:159±34 wpm; TMT: Trail A- 43±4sec, Trail B- 53±8sec) ($p<0.05$). They also performed significantly poorer than control subjects on the fine motor skills subitems (for example, making dots in a circle, transferring pennies and sorting cards) ($p<0.01$). VA in the amblyopic eye was a significant predictor of UFOV performance ($F(2,17)= 2.82$, $p=0.03$). Both VA and BF score were significant predictors of TMT [VA: ($F(2,17)=3.559$, VA: $p=0.048$, BF score: $p=0.03$].
Conclusions: Adults with anisometropic amblyopia exhibited reduced performance on fine motor skills, reading speed, visual attention and visual search compared to control participants. These findings have implications for understanding the impact of amblyopia on everyday function in adults.

TITLE: Long-term efficacy and safety of idebenone in patients with LHON in the chronic phase: Results from the LEROS study

SESSION TITLE: Neuro-ophthalmology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: X. Llòria, L. Tomasso, Chiesi Farmaceutici SpA, Parma, Emilia-Romagna, ITALY|T. Klopstock, Department of Neurology, Ludwig-Maximilians-Universitat Munchen, Munchen, GERMANY|

Commercial Relationships Disclosure: Xavier Llòria: Commercial Relationship(s);Code E (Employment):CHIESI FARMACEUTICI S.p.A.;Code E (Employment):Santhera Pharmaceuticals | Livia Tomasso: Commercial Relationship(s);Code E (Employment):CHIESI FARMACEUTICI S.p.A. | Thomas Klopstock: Commercial Relationship(s);Code C (Consultant/Contractor):CHIESI FARMACEUTICI S.p.A.;Code C (Consultant/Contractor):GenSight Biologics;Code F (Financial Support):CHIESI FARMACEUTICI S.p.A.;Code F (Financial Support):GenSight Biologics

ABSTRACT BODY:

Purpose: Leber's hereditary optic neuropathy (LHON) is a rare mitochondrial disorder resulting in severe, bilateral vision loss. Idebenone is approved in Europe for the treatment of LHON, but data in chronic patients is relatively sparse. Here, we report results from LEROS, a Phase 4, externally controlled, open-label interventional study (ClinicalTrials.gov NCT02774005), which included chronic patients (1 to ≤5 years since onset) with LHON treated with idebenone for up to 24 months.

Methods: LEROS included patients with LHON ≥12 years old and with a disease onset ≤5 years prior. Overall, 199 patients were enrolled, 181 of which formed the mITT population (excluded patients without a confirmed primary causative mtDNA mutation). NH data were available from 372 patients. Patients were divided into 2 groups for analysis based on time since onset in the most recent eye: subacute/dynamic (≤1 year) and chronic (>1 year). Outcomes in the idebenone-treated group were compared to retrospective data from the NH cohort, matched based on time since disease onset. Outcome measures (from baseline) were clinically relevant recovery (CRR): improvement from 'off-chart' VA to at least 1.6 logMAR, or a ≥0.2 logMAR improvement if already 'on-chart'; clinically relevant stabilization (CRS): maintenance of VA <1.0 logMAR; and clinically relevant benefit (CRB): reaching a CRR, a CRS, or both.

Results: LEROS met its primary endpoint, showing a significant increase in the proportion of subacute/dynamic eyes with a CRB from baseline following 12 months of treatment, compared to the matched external NH cohort. A secondary endpoint, identical to the primary but in chronic patients, was also successfully met; CRB was observed in 50.3% (72/143) of treated, chronic eyes versus 37.9% (59/153) from the NH cohort (p = 0.0087). CRB was largely driven by CRR, observed in 32.9% (47/143) of treated eyes versus 19.0% (29/153) in the NH cohort (p=0.058). In treated chronic patients, the median best VA at baseline was 1.48 logMAR (n=87) and showed an improvement over the study duration to 1.32 (n= 81), 1.23 (n=70), 1.26 (n=66) and 1.16 (n=55) logMAR at 6, 12, 18 and 24 months, respectively.

Conclusions: LEROS provides evidence of a significant therapeutic benefit of idebenone treatment in patients with LHON in the chronic stage, a group for whom viable treatment options are otherwise severely limited.

ABSTRACT BODY:

Purpose: Glaucoma diagnosis is still based on ophthalmic examination and visual field interpretation. Several structural parameters from the optic nerve and the macular area measured by optical coherence tomography (OCT), and the combination of some of them, have shown noteworthy diagnostic performance. We aimed to validate the discriminative ability of two OCT-based diagnostic calculators (RETICs) and to compare it with that of isolated OCT parameters

Methods: We revised the charts of 76 primary open-angle glaucoma (A), 107 glaucoma suspects (B), and 67 healthy control cases (C). Demographics, visual field, and high-quality OCT disc and macular parameters were included. The reference diagnosis (clinical examination) was compared against the probability of having glaucoma obtained from the two RETICs glaucoma diagnosis calculators (GDC). Both GDC1 and 2 derived from multivariate logistic regressions using either only the numeric (quantitative) data from peripapillary retinal nerve fiber layer (pRNFL), optic disc, and ganglion cell-inner plexiform layer (GCIPL) (GDC2) or along with qualitative data (color scoring of the quantitative data according to a normative database) (GDC1). The sensitivity and specificity of all parameters were analyzed. The Area Under the Receiver Operating Characteristic Curves (AUROCC) were compared in glaucoma suspects and glaucoma patients, for both calculators, and the best OCT parameters

Results: The three best OCT parameters in terms of AUROCC for both A and B were inferior pRNFL (0.931; 0.760), average pRNFL (0.925; 0.745), and minimum GCIPL (0.919; 0.735), showing no statistically significant differences among them. The AUROCC from both GDC1 and 2 were high (0.949 & 0.943, p=0.61) and moderate (0.739 & 0.73, p=0.56) for glaucomatous eyes and glaucoma suspects, respectively; compared to the OCT-derived parameters, the discriminative ability was modestly superior and non-inferior for both calculators in A and B groups, respectively. GDC2 was able to correctly classify 46.9% and 14.7% more cases compared to GDC1

Conclusions: The combination of OCT parameters provided by the RETICs calculators had the highest diagnostic ability to discriminate glaucoma vs control eyes, although it was not as good in glaucoma suspects. GDC2 had the best results, suggesting that adding qualitative structural information does not improve glaucoma diagnosis performance

ABSTRACT BODY:

Purpose: Subretinal hyperreflective material (SHRM) in eyes with exudative neovascular age-related macular degeneration (AMD) treated with anti-vascular endothelial growth factor (VEGF) may gradually turn from macular neovascularization (MNV) type 2 into type 1 appearance on OCT. We here aimed to study the impact of this transformation on functional and morphological outcomes.

Methods: Data for this post-hoc sub-analysis emerged from a 12-month, randomized, open label, multicenter study comparing the efficacy of Ranibizumab pro re nata versus Aflibercept bimonthly intravitreal injections in treatment-naïve patients newly diagnosed with exudative neovascular AMD (SALT). Imaging comprised fluorescein angiography, color fundus photography and autofluorescence at baseline and month 12, and monthly SDOCT (Spectralis SDOCT, Cirrus HDOCT). 203 eyes of 203 study patients with SHRM on SDOCT at baseline were included. Two certified graders blinded to functional data assigned each eye to one of the following 4 categories: (A) SHRM remains present with type 2 appearance, (B) SHRM partially transformed into type 1 appearance, (C) SHRM completely transformed into type 1 appearance, (D) SHRM disappeared. The area of decreased autofluorescence was additionally evaluated at baseline and month 12.

Results: Analyses of variances (ANOVAs) found a significant effect of the factor SHRM CATEGORY (levels A (n=136), B (n=18), C (n=23), D (n=26)) on the change of BCVA at 3 months compared to baseline ($F[3,196]=6.86;p<0.001$): Post-hoc t-tests were significant ($p<0.05$) for comparisons of SHRM Category A (mean 3.8 ETDRS letters) with B (9.9), C (10.7) and D(10.8). At 12 months ($F[3,196]=4,85;p=0.003$) post-hoc t-tests found a significant difference between SHRM Category A (4.6) only versus C (15.1) and D (10.6), but not B (8.4). For the area of decreased autofluorescence at 12 months, we also found a significant effect ($F[3,170]=4.41;p=0.005$): Post-hoc t-tests showed significant differences between Category A (mean area 1.076 mm^2) versus B (0.079) and C (0.077) but not D (0.385).

Conclusions: Eyes with transformation of SHRM from type 2 into type 1 appearance on the course of therapy had a significantly higher mean improvement of visual acuity 3 and 12 months after initiation of therapy and showed a smaller area of decreased auto-fluorescence after 12 months.

ABSTRACT BODY:

Purpose: Glaucoma is an eye disease with widespread involvement of the brain. Since visual cortex (VC) may possess lower choline levels in glaucoma, and basal forebrain (BF) has cholinergic projections to VC for modulating cerebral blood flow and visual processing, we postulate that the vascular functions of the VC and BF are involved in glaucoma (PMID: 31242454). Recently, we used a novel whole-brain relative cerebrovascular reactivity (rCVR) mapping technique via resting-state functional MRI (rsfMRI) without gas challenge, and observed rCVR decrease in VC and rCVR increase in BF in patients with increasing glaucoma severity (PMID: 34892116). However, the underlying mechanisms remain to be elucidated. Here, we applied a hydrogel-induced glaucoma mouse model to elevate intraocular pressure (IOP) (PMID: 31176841), mapped whole-brain rCVR using rsfMRI, and measured optomotor responses (OMR). We hypothesize that chronic IOP elevation can lead to rCVR changes in the glaucomatous brain along with visual impairments.

Methods: For the glaucoma model, C57BL/6J mice (male, 15-weeks, n=15) received intracameral injection of cross-linking hydrogel to the right eye to obstruct aqueous outflow and induce chronic IOP elevation. Controls (male, 15-weeks, n=13) were untreated. IOP was measured in both eyes 2-3 times per week for 3 weeks, followed by OMR and rsfMRI experiments at 7 Tesla (Fig. 1A).

Results: Sustained IOP elevation was confirmed in the right eyes of the glaucoma model (Fig. 1B). Over 90% of mouse optic nerve fibers are known to project to the contralateral visual brain; rCVR decreased in the left but not right VC, whereas rCVR increased in the right BF in the glaucoma model but not the controls (Fig. 2A). These rCVR changes were inversely coupled (Fig. 2B). In addition, IOP of the injected eye was inversely correlated with rCVR in the left VC, while positively correlated with rCVR in the right BF (Fig. 2C). OMR revealed a decrease in visual acuity and an increase in visual contrast threshold for the injected eye (Fig. 2D) indicating visual impairment. The decrease in visual acuity was inversely correlated with rCVR in the BF (Fig. 2E).

Conclusions: Mouse rCVR mapping using rsfMRI detects widespread brain changes induced by chronic IOP elevation, and demonstrates vascular involvement in glaucoma both within and beyond the primary visual pathways.

ABSTRACT BODY:

Purpose: Retinal degeneration is a leading cause of disability in the industrialized world. Many retinopathies are marked by an irreversible photoreceptor loss, thus photoreceptor transplantation has emerged as a potential treatment strategy. However, conditions allowing donor photoreceptor incorporation and maturation are largely unknown. This study thus aimed to elucidate the regenerative potential of transplanted human photoreceptors in a cone-degeneration only host.

Methods: A hiPSC cone (iPSC-mARR3-GFP) and a hiPSC rod and cone (iPSC-Crx-mCherry) reporter line were used to produce retinal organoids. Reporter-positive photoreceptors at day 200 of differentiation were FAC sorted and transplanted into the subretinal space of adult Cpfl1 (cone photoreceptor function loss 1) mice with vitreal immune suppression. After 3, 10, or 26 weeks, grafts were examined using immunohistochemistry, electron microscopy, next generation sequencing, and multi-electrode array recordings (MEA).

Results: With increased post transplantation time, photoreceptor clusters from both cell lines showed extensive incorporation into the host neural retina, accompanied by considerable interaction with host inner retinal cells. Rod and cone bipolar cells extended neurites into the transplants and Müller glia processes were present throughout grafts, frequently forming a common outer limiting membrane in line with the human cells. Interestingly, increased donor-host interaction correlated with improved graft polarization and maturation. Especially after 26 weeks, properly oriented inner and in several cases well stacked outer segments were observed. Putative synapses between donor cells and host bipolars were detected, while graft function was confirmed by MEA recordings. Transcriptome comparison to age matched retinal organoids further indicated improved human photoreceptor maturation within the murine environment versus the in vitro setting.

Conclusions: This study shows that human photoreceptors can incorporate extensively into the murine host retina and that interaction with host Müller glia and/or bipolars benefits their maturation, polarization and ultimately function. Deciphering the cellular and molecular factors essential for proper donor photoreceptor integration will be of utmost importance to optimize photoreceptor replacement therapy towards clinical application.

ABSTRACT BODY:

Purpose: To develop functional visual tests to better understand the potential advantages of a full sphero-cylindrical toric correction for contact lenses (CL) neophytes with low values of astigmatism.

Methods: We used a custom set of video cameras and thin film pressure sensors to monitor and automatically quantified several daily functional activities in terms of time and performance. These activities include i) pouring a liquid into a recipient up to a certain marked level, ii) inserting a key in a lock and turning it, and iii) finding three (digital) files in a computer desktop placed among other files and attach them into an email. Currently, we have tested the procedures in nineteen first year university students. All of them were contact lens neophytes with no previous experience of CL fitting. Subjects were split into two homogenous groups matched by age and refractive error with no statistically significant differences within these variables. Subjects in group one (N=10) had a cylinder value of -0.9 ± 0.3 D and were monocularly fitted with a spherical CL (Precision1, Alcon Laboratories, Inc, Fort Worth, TX). Subjects in group two (N=9) had a similar cylinder, -1.0 ± 0.4 D, and were fitted with a toric CL (Precision1 for Astigmatism). All subjects performed three trials of tasks i) and ii) and a single email test. Data was averaged correspondingly.

Results: On average, subjects in the toric group were able to complete all tasks faster than subjects in the spherical lens group. Pouring the liquid, opening the lock and sending the attachments by email was respectively 28%, 3% and 10% faster in the toric group compared to the spherical group. However, for this pilot study, we only reached statistically significant differences for the first task (pouring the liquid up to a certain level; $p = 0.02$). Interestingly, for those tests with repeated trials (pouring and key lock), subjects in the toric group performed more consistently across trials than subjects in the spherical group. On average, data dispersion was two times smaller in both tests for the toric group.

Conclusions: Toric CL fitting tended to improve some aspects of functional vision compared to a spherical CL fitting in CL neophytes even with low levels of astigmatism. Further studies in a larger population are required to confirm these functional benefits.

ABSTRACT BODY:

Purpose: Leber's hereditary optic neuropathy (LHON) is a rare mitochondrial disorder resulting in severe, bilateral vision loss. Idebenone is approved in Europe for the treatment of LHON, but controlled data beyond a 6-month treatment duration is lacking. Here, we report results from LEROS, a Phase 4, externally controlled, open-label interventional study (ClinicalTrials.gov NCT02774005), in which visual acuity (VA) outcomes following 24 months of idebenone treatment were compared to an external, matched, natural history (NH) cohort.

Methods: LEROS included patients with LHON ≥12 years old and with a disease onset ≤5 years prior. Overall, 199 patients were enrolled, 181 of which formed the mITT population (excluded patients without a confirmed primary causative mtDNA mutation). NH data were available from 372 patients. Patients were divided into 2 groups for analysis based on time since onset in the most recent eye: subacute/dynamic (≤1 year) and chronic (>1 year). Outcomes in the idebenone-treated group were compared to retrospective data from the NH cohort, matched based on time since disease onset. Outcome measures (from baseline) were clinically relevant recovery (CRR): improvement from 'off-chart' VA to at least 1.6 logMAR, or a ≥0.2 logMAR improvement if already 'on-chart'; clinically relevant stabilization (CRS): maintenance of VA <1.0 logMAR; and clinically relevant benefit (CRB): reaching a CRR, a CRS, or both.

Results: The primary endpoint, the proportion of subacute/dynamic eyes with a CRB from baseline following 12 months of treatment, compared to the matched external NH cohort, was successfully met. CRB was observed in 42.3% (60/142) of treated eyes versus 20.7% (40/193) from the NH cohort (p=0.002). At 24 months, this significant difference was maintained, at 52.9% (64/121) versus 36.0% (27/75) (p=0.0297). In treated subacute/dynamic patients, the median best VA at baseline was 1.28 logMAR (n=109) and showed an initial worsening at 6 months to 1.41 logMAR (n=90). A recovery was then observed to 1.30 (n= 81), 1.20 (n=75) and 1.07 (n=70) logMAR at 12, 18 and 24 months, respectively. No new safety signals were observed for idebenone.

Conclusions: LEROS corroborates the outcomes of previous studies, demonstrating that long-term treatment with idebenone results in prolonged clinical benefit in patients with LHON in the subacute/dynamic phase.

ABSTRACT BODY:

Purpose: Fundus autofluorescence (FAF) imaging is often used in diagnosis for dry age-related macular degeneration (dAMD). The purpose of this study is to detect the retinal pigment epithelium (RPE) damage using FAF imaging in an animal model and validate the correlation between FAF and other functional evaluation items.

Methods: Thirty or 35 mg/kg sodium iodate ($NaIO_3$) was injected intravenously into Brown Norway rats to induce RPE degeneration. FAF images were obtained on 2, 5, and 8 days after $NaIO_3$ treatment and the RPE degeneration area was quantified. The a, b, and c-wave amplitude of electroretinogram (ERG) were recorded for at least 1 hour after the onset of dark-adaption. In vitreous fluorophotometry (VFP) evaluation, fluorescein was injected intravenously and, after circulating for 2 hours, the fluorescein concentration of vitreous humor was measured by Fluorotron Master to evaluate the outer blood-retinal barrier (BRB) function. The retinal sample was histopathologically observed with hematoxylin and eosin (HE) staining and immunostaining of ZO-1 and RPE65. To examine its effects on the $NaIO_3$ rat model, N-acetyl cysteine (NAC) was administrated intravitreally 30 minutes prior to $NaIO_3$ injection.

Results: Compared to normal rats, $NaIO_3$ rats showed numerous dark spots in the FAF image, indicative of RPE damage. The RPE degeneration area was correlated with reduction of each ERG wave amplitude, dysfunction of outer BRB, and retinal structure changes. In addition, RPE protection by NAC on $NaIO_3$-induced RPE degeneration rat model was confirmed by the quantification of damaged RPE area in the FAF image, and it was consistent with the results of ERG and VFP measurements.

Conclusions: This study demonstrates that FAF is useful to observe the RPE and evaluate the efficacy of RPE protection in vivo rat eye. Using FAF imaging, RPE function of the same sample can be evaluated at several time points. This is an advantage compared to invasive methods such as histopathological examination which is generally used in non-clincial studies.

ABSTRACT BODY:

Purpose: To investigate predictors of retinal nerve fiber layer (RNFL) thinning over time and their association with patient race.

Methods: From Mass. Eye and Ear glaucoma service, all patients with at least four reliable (signal strength ≥ 6) Cirrus spectral-domain optical coherence tomography (OCT) peripapillary scans over a minimum period of 2.5 years and an electronically available, questionnaire based self-reported race as either Asian, Black, or White were selected. Patient race, age and sector-specific circumpapillary RNFL thickness (cpRNFLT) at first visit were investigated by multivariable linear regression to predict the slope of cpRNFLT over time. To determine the best parameter combination to predict cpRNFLT slopes, the Akaike Information Criterion (AIC) was applied. A race specific sub-analysis was performed to reveal possible specific race-related impacts.

Results: 3,689 eyes of 1,959 patients (57.3% female) were selected. 159 patients identified as Asian, 395 as Black and 1,408 as White. On average, patients were followed up (mean±std) with 4.99±1.24 visits over 5.15±1.62 years with a mean follow-up interval of 1.32±0.35 years. Entire population results: Fig. 1A compares models to predict cpRNFLT slope over time from baseline. Baseline thickness was the best predictor in all sectors. Race outperformed age except for the temporal sector. In all sectors, the best model over all parameter combinations was the model with all parameters, where higher baseline age and lower baseline thickness were related to faster RNFL thinning over time. Race specific sub-analyses: With the exception of the temporal RNFLT slope (not shown on figures), there was a significant (ANOVA, $p<0.01$) main association between race and all parameters. Black patients are younger at first visit and have thicker baseline RNFL (Fig. 1B,C), but are nevertheless subject to faster RNFL thinning than the other races (Fig.2).

Conclusions: While models based on the entire population identified higher baseline age and thinner baseline RNFL as predictors for faster future RNFL thinning, the race-specific sub-analysis revealed an opposite effect for the group of Black patients alone, who presented at significantly younger ages and with thicker RNFL at their first visits but where still subject to faster RNFL thinning compared to the other races.

ABSTRACT BODY:

Purpose: To investigate the therapeutic potential of mesenchymal stem cell (MSC)-conditioned media on NM-mediated corneal damage.

Methods: Nitrogen mustard treatment on cells (human corneal epithelial primary cells, human corneal limbal epithelial cells) and mouse eyes after 2mm-diameter epithelial wound.

Cells and mouse eye were used for LDH toxicity assay, ROS measurements, JC-1 immunostaining, ATP measurement.

Cells are treated and measured metabolic gene changes after nitrogen mustard with or without MSC-CM.

Porcine eye and mouse eye are used for corneal epithelial wound healing.

Results: MSC-CM helps to restore mitochondrial function, resulting in leading cell survival after following NM exposure. MSC-CM decreased intracellular ROS generation after NM exposure and functioned as antioxidant capacity. Moreover, MSC-CM helps epithelial cells migration and proliferation to heal a wound after NM-mediated cell injury. In parallel experiments, both in vivo and ex vivo experiments confirmed that NM exposure on murine and porcine eyes showed that (i) induced apoptosis, (ii) increased corneal epithelial thickness by unpacking cornea structure, and (iii) delayed wound healing. Especially, NM injury of the porcine eye produced extensive damage on the loss of membrane integrity of the surface epithelium and the loss of corneal stromal matrix and it is possibly induced corneal and stromal inflammation and apoptosis. Whereas, MSC-CM enhanced the wound healing process and protected corneal structure compared to the NM exposure group. Moreover, MSC-CM enhanced epithelial cell barrier formation after NM exposure.

Conclusions: Taken together, these studies identified NM-induced corneal injuries damaged on the corneal epithelium, resulting in the loss of epithelium and unpacking cornea structure by disrupting epithelial cell barrier function. However, MSC-CM enhanced epithelial cell barrier formation to protect epithelium-stroma structure after NM exposure. These results suggest that MSC-CM has a therapeutic potential to protect against possible chemical eye injury and it could be helpful in the development of targeted therapies.

ABSTRACT BODY:

Purpose: To uncover the underlying molecular causes of inherited retinal disease (IRD) in 105 unrelated families of Iranian descent, an integrated approach consisting of whole exome sequencing (WES) and autozygosity mapping was used.

Methods: WES was performed in 105 Iranian IRD families, predominantly originating from a consanguineous background (77%). Data-analysis was performed using the in-house Seqplorer tool. Variants were confirmed using Sanger sequencing and families underwent segregation analysis. Copy number variants (CNVs) were assessed via the ExomeDepth algorithm and validated using qPCR. Variants were classified based on ACMG/ACGS guidelines. The AutoMap tool was used to determine runs of homozygosity (ROHs) in unsolved patients. ROHs were inspected for variants in novel candidate genes using Seqplorer and QCI Interpret Translational.

Results: By interrogating known IRD genes (n=290) using a WES-based analysis, we were able to obtain a molecular diagnosis for 85% of the IRD cohort. In total, 103 (likely) disease-associated variants were identified in 42 genes, 58 of which are novel variants (56%). ABCA4, EYS, AIPL1 and CRB1 were the four most implicated genes. Not surprisingly, the majority of causal variants were present homozygously (81%) while compound heterozygous and heterozygous/hemizygous variants were found in 14.5% and 4.5% of solved cases respectively. In addition, the importance of structural variation (SV) in IRD was demonstrated, with CNVs identified in 8% of the cohort, including novel CNVs in CDHR1, CHM and RD3. Homozygous nonsense and missense deleterious variants were found in novel retina-expressed candidate IRD genes, specifically OGDHL, PFKFB2 and QRFPR.

Conclusions: This integrated study using WES and an in-depth analysis of the variants provided insight into the genetic architecture of IRD in Iran, an understudied population. We provided 85% of patients with a molecular diagnosis and expand the molecular spectrum of IRD in Iran by the identification of novel variants in known IRD genes in the majority of patients, emphasizing the power of WES as a first-tier genetic test in consanguineous IRD cohorts. Autozygome-guided exome sequencing revealed several novel candidate genes for IRD in unsolved cases. In the remaining patients, whole genome sequencing has the potential to uncover non-coding variation and complex structural variation.

TITLE: Complementarity of sensitivity and just noticeable difference in the study of Retinitis Pigmentosa and Stargardt disease

SESSION TITLE: Fundamental and Applied Psychophysics and Color Vision

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Fars, J.J. Kremers, C. Huchzermeyer, Ophthalmology, Universitatsklinikum Erlangen, Erlangen, Bayern, GERMANY|

Commercial Relationships Disclosure: Julien Fars: Commercial Relationship: Code N (No Commercial Relationship) | Jan Kremers: Commercial Relationship: Code N (No Commercial Relationship) | Cord Huchzermeyer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate if sensitivity and just noticeable difference thresholds were modified in patients with retinitis pigmentosa (RP) and Stargardt disease (STGD1).

Methods: We examined 29 normal observers (29±10 years), 19 RP (43±15 years) and 14 STGD1 (43±14 years) using a temporal contrast sensitivity procedure based on the silent substitution paradigm. L-, M-, S-cone and Rod isolating sine-wave modulations were tested with a dedicated LED stimulator at frequencies that stimulate single retino-geniculate pathway in the perifovea without intrusion by other pathways. L- and M-cones at low (parvocellular) and high frequencies (magnocellular), S-cones at low frequencies (koniocellular) and Rods at medium frequencies (rod driven pathway) were analysed. From the temporal contrast sensitivity procedure, two measures were extracted: the sensitivity and the just noticeable differences (JND). The first corresponds to the inverse of the absolute threshold i.e. the contrast at 50% probability of detection. The JND is the difference threshold and is calculated by subtracting the contrast at 75% probability of detection from the contrast at 25%. Then two Bayesian mixed models were produced to detect the influence of subject group (normal subjects and the two patient groups), of the post receptoral pathway and of the age of the observers on either the sensitivity or the JND thresholds.

Results: Sensitivities of RP patients were close to normal. STGD1 patients displayed a large sensitivity decrease for most measurements. JND values of STGD1 patients were close to normal while RP patients had larger values than normal observers, specifically parvocellular and rod mediated pathways.

Conclusions: The two studied perception parameters (sensitivity and JND values) display opposite differences in RP or STGD1 patients. The decreased sensitivity in STGD1 patients can be related to the macular degeneration. RP patients may display a larger uncertainty in stimulus detection because a larger retinal area is affected even though the retinal degeneration is subjacent to the stimulus in the perifovea. The use of JND may allow us to describe early effects of vision loss. Our results exhibit a potential complementarity of the sensitivity and JND methods to describe and follow the development of retinal diseases.

ABSTRACT BODY:

Purpose: We have been developing the Kyoto University Substance (KUS) 121 which is an inhibitor of valosin-containing protein ATPase. It has a protective effect on retinal cells in vitro and in animal models of ocular diseases, including retinitis pigmentosa, retinal artery occlusion, and glaucoma. To examine the safety and efficacy of KUS121, we conducted an investigator-initiated clinical trial on patients with central retinal artery occlusion (CRAO).

Methods: Nine patients with CRAO with symptoms lasting between 3 and 48 hours were recruited for the clinical trial (phase 1/2, UMIN000023979). KUS121 was intravitreally injected daily for 3 days. We assessed the safety of the drug and the patients' visual function (visual acuity and visual field) outcomes for 3 months.

Results: Between November 2016 and December 2017, 11 patients with non-arteritic CRAO were assessed, and nine patients were recruited for the study. All the nine patients completed the follow-up. No serious adverse events or side effects were observed. The final best corrected visual acuity (BCVA) was improved compared with that at baseline in all the patients. Seven out of nine (78%) patients showed BCVA equal to or better than 0.05. The average visual field area and scores were also improved.

Conclusions: We confirmed the efficacy and safety of KUS121 in preserving the visual function of patients with CRAO. We are currently preparing for the next phase of clinical trials. Additionally, KUS121 is being developed as a therapeutic agent for other retinal diseases such as age-related macular degeneration.

ABSTRACT BODY:

Purpose: Usher Syndrome is a leading cause of deaf-blindness, with variants in USH2A being the most prevalent cause. With growing interest in this condition, and potential therapeutics going to trial, further understanding of how structure and function change through the disease course is required. OCT and microperimetry may provide more sensitive markers of progression and need to be further investigated.

Methods: Patients with molecularly confirmed biallelic USH2A variants were recruited at Moorfields Eye Hospital. Subjects were monitored at two time points (12.8 +/- 2 months apart). Heidelberg Spectralis OCT images were acquired. Novel OCT segmentation was developed using UNET with EfficientNet Backbone, based on 2770 double graded images. Micropermetry was performed using MAIA Expert Exam. Custom analysis was developed in Matlab, to evaluate visual sensitivity volume across the macular and by ring (fixation, 2°, 6°, 10°). Comparison between visits used Wilcox Signed Rank test, between devices used Mann-Whitney.

Results: Thirty-five patients were recruited (44 eyes of 23 patients included). Macular sensitivity loss was not significant between visits (p=0.08). Analysis of the individual ring sensitivity was also not significant between exams. Analysis of EZ area showed 5.02% (range:0.02-0.12%) loss across timepoints. EZ thickness compared to MP volume were significantly correlated (fixation- p=0.03; 2°- p=0.04, 6°- p=0.01, 10°- p=0.003). ONL thickness compared to MP volume were significantly correlated 2°- p=0.03, 6°- p=0.01, 10°- p=0.01).

Conclusions: Novel OCT analysis showed better sensitivity for progression than manual measures, or functional analysis. Therefore, more robust analysis should be used, included deep learning trained segmentation models, for future analysis. There was a significant relationship in ONL and EZ thickness with MP sensitivities when compared over specific regions.

ABSTRACT BODY:

Purpose: Corneal scarring is a major cause of blindness worldwide and an important indication for corneal transplantation. With the limitations of corneal grafting, there is a need to explore alternative therapies for corneal scarring. We have previously reported on the optimal dosing frequency and safety of topical delivery of MSC-derived extracellular vesicles (EV) in normal rat corneas. In this study, we investigated the potential therapeutic effects of MSC-EV in a rat corneal scarring model.

Methods: Conditioned media of human embryonic stem cells (ESC)-derived MSC was concentrated and fractionated to obtain enriched EV fractions (80-150nm). Irregular phototherapeutic keratectomy (irr-PTK) was used to induce corneal scarring in Sprague Dawley rats. Topical EV or saline were applied to the injured rat corneas for 6 days or until the epithelium was healed, whichever was earlier. Corneal clarity was assessed using slit-lamp imaging and in-vivo confocal microscopy (IVCM). Stromal reflectivity was quantitatively analyzed. Immunohistochemistry of the excised corneas was performed.

Results: Following irr-PTK, corneas that received topical EV treatment were relatively clearer (with a significantly lower mean corneal haze score) throughout the follow-up period compared to the corneas in the control group with saline treatment ($p=0.002$). Stromal reflectivity imaged using IVCM also showed a significant reduction of haze intensity ($p=0.004$). Corneal vascularisation, quantified by the area of vascularized quadrant, vessel length and diameter, was also significantly lower in EV-treated corneas. Lower expression of CD31 (vascular endothelial marker), LYVE1 (lymphatic marker), fibronectin and Col3a1 (fibrosis markers) were detected in EV treated corneas. EV-treated corneas also displayed a regenerative immune phenotype characterised by a higher infiltration of regenerative M2 over M1 macrophages.

Conclusions: Our findings demonstrated that ESC-derived MSC EV are potential regenerative therapies for corneal injuries, effected through anti-angiogenesis, anti-fibrosis, and immunomodulation.

ABSTRACT BODY:

Purpose: The high-resolution optical coherence tomography (HighRes-OCT) is an improvement of the routinely used spectral-domain OCT (SD-OCT) with increased axial resolution in tissue from 7 to 3 µm and may provide new informations about ultrastructural changes in age related macular degeneration (AMD), especially in iRORA and cRORA (incomplete, complete retinal pigment epithelial, outer retinal atrophy). The aim of this study is to show how increased axial resolution in a novel HighRes-OCT can distinguish structures not detected with conventional OCT in AMD

Methods: The prospective observational pilot study is performed on 50 patients at different AMD stages. An OCT of the macula is performed with the SD-OCT (SPECTRALIS ©, Heidelberg Engineering, Heidelberg, Germany) and the investigational HighRes-OCT (SPECTRALIS ©, Heidelberg Engineering, Heidelberg, Germany). The scan patterns used are 20° x 20° volume scan with 49 sections and 25 ART frames (512 A-scans per B-scan). Two different retina specialists then qualitatively compare the images. The presence of iRORA and cRORA was evaluated according to the consensus definition for atrophy associated with AMD on OCT. The main parameters assessed were the presence or absence of choroidal hypertransmission, zone of attenuation and/or disruption of the retinal pigment epithelium. Furthermore, the hyperreflective foci 94+and the thinning of the outer plexiform layer above atrophy were also investigated.

Results: Our results show that increased axial resolution in HighRes-OCT reveals several features such as better visualization of the Bruch’s membrane complex and the photoreceptor inner segments as well as a better delimitation of the inner plexiform layer than in a SD-OCT image. In geographic atrophy, the hyperreflective foci are clearer and there is a striking thinning of the outer plexiform layer above atrophy compared with conventional OCT in both forms of RORA.

Conclusions: Increased axial resolution OCT provides a higher resolution and yields more information about anatomical features in patients with both, iRORA and cRORA. This new technology can improve the diagnosis precision and will reserve us exciting data.

ABSTRACT BODY:

Purpose: The effect of the timing and cumulative exposure of repeated anti-vascular endothelial growth factor (VEGF) injections for treatment of diabetic macular edema (DME) on the subsequent risk of proliferative diabetic retinopathy (PDR) is unclear. We report associations for PDR development on patients receiving anti-VEGF treatment for DME at point of care and evaluated the application of the novel weighted cumulative exposure (WCE) method to such data.

Methods: Retrospective multicenter electronic medical records-based study from 27 centers across the United Kingdom. We implemented (1) a multivariable Cox model ignoring anti-VEGF exposures as baseline (M_{Cox}), and modelled the complex time-varying nature of repeated anti-VEGF injections using 3 more models as: (2) a time-dependent unweighted cumulative sum of exposures (M_{tdcCox}), (3) as the average anti-VEGF injections over the most recent 6 months (M_{6moCox}), and (4) as a the weighted cumulative sum of past exposures (M_{WCE}). Primary outcome measure was PDR development. All models allowed for baseline diabetic retinopathy (DR) grade, age, sex, ethnicity, type of diabetes and index of multiple deprivation. Model goodness of fit was quantified by Akaike information criterion (AIC).

Results: We included 4439 patients. The unweighted time-dependent multivariable Cox regression (M_{tdcCox} AIC=3454; M_{6moCox} AIC=3452) provided a better model fit than the baseline model (M_{Cox} AIC=3488), and the M_{WCE} had the best fit overall (AIC=3364). Table 1 shows hazard ratios for all models. Severe NPDR showed a more than 5-fold increase in hazards of PDR when compared to mild NPDR ($p<0.0001$) in all models. Every 5-year rise in age was associated with decreased hazards of PDR in all models ($p<0.001$). In M_{WCE}, patients with type 1 diabetes had a 2.02-fold increase in PDR hazards ($p=0.0001$), when compared with type 2 diabetes. The least deprived patients showed a 38 to 42% reduction in PDR hazards when compared to the most deprived patients in all models ($p<0.048$).

Conclusions: Baseline DR features remain the most important predictor for clinical outcomes but, our model highlighted the importance of adjusting for anti-VEGF injection number and timing that is achievable in this novel application of the WCE model to ophthalmology data. WCE models can enhance our interpretation of complex time series data.

ABSTRACT BODY:

Purpose: Type 1 CNV is associated with a late hyperfluorescent plaque (LPHP) that does not increase with time, seen on ICGA (indocyanine angiography). Missing in literature to date, this study evaluates the frequency of LPHP in type 1 CNV in CSCR and AMD and its prognostic value in visual acuity and response to anti-VEGF.

Methods: We retrospectively reviewed the images and medical records of patients from Jules Gonin Eye Hospital in Lausanne, Ophtalmopole Hopital Cochin and Centre Ophtalmologique de l'Odéon in Paris between 2012 and 2021. Inclusion criteria were: type 1 CNV secondary to CSCR and AMD, late ICG cliché (>20mins) and visualisation of CNV on OCTA. Quantitative and qualitative parameters on OCT and best corrected visual acuity were recorded at baseline and after 3 monthly VEGF injections.

Results: 83 eyes of 83 patients were included in the study 35 with CSCR and 48 with AMD. Compared to the AMD group, patients in the CSCR group were younger (61.3 ± 10.4 vs. 80.2 ± 6.8 years, p<0,001), predominantly male (68,6% vs 35,4%; p=0,003) and with a thicker choroid (379 ± 93,3 4 vs 204,2 ± 93,2µm; p<0,001). Type 1 CNV in CSCR showed significantly less LPHP (31,4%) compared to eyes with AMD (77,1%; p<0,001). Patients with LPHP at baseline (n=48) were older (76,1 ± 10,8 years vs. 67 ± 13,2, p=0,002), had a worse baseline BCVA (0,37 ± 0,22 vs 0,27 ± 0,28 LogMAR, p=0,03), compared to eyes without LPHP (n=35). SFCT was higher in the CSCR subgroup (n=35) for eyes with LPHP (n=11) compared to eyes without LPHP (n=24) (434 ± 92,2 vs 346,1 ± 86,4µm respectively; p=0,006). BCVA at baseline did not differ significantly between CNV in CSCR or AMD (0.29 ± 0.28 vs. 0.36 ± 0.23 Logmar, p=0,14). Eyes without LPHP had a significant better BCVA than eyes with LPHP (0,37 ± 0,22 vs 0,27 ± 0,28 LogMAR, p=0,03).

Conclusions: LPHP was significantly less present in chronic CSCR complicated by CNV than in AMD. BCVA was higher in eyes without LPHP at baseline. This shows that leakage of macromolecules from CNV and its accumulation in the RPE imaged by the LPHP differs in eyes with CSCR and AMD. LPHP associated with worse BCVA at baseline in both diseases might suggest a suffering of the RPE. LPHP should not only be considered as a hallmark for choroidal neovascularization but also a sign of RPE dysfunction. Its long-term prognostic value still remains to be explored in larger cohorts.

ABSTRACT BODY:

Purpose: Earlier studies have suggested that poor manual control could detrimentally affect learning in children. The purpose in this study was to investigate the relationship between manual control and common eye problems in children.

Methods: This cross-sectional study included 173 (87 males) children and adolescents aged 6 to 16 years (mean ± SD 10.5 ± 3.4) who participated in a school vision program offered to children in 2nd, 5th and 10th grade in Kongsberg municipality, Norway. Refractive error, visual acuity, binocular vision, ocular biometry measurements and a medical history were obtained for all children. Children who failed (according to predetermined criteria) one or more of these measures were considered to have an uncorrected eye or vision problem and were referred to the university eye clinic. All children completed the Leeds Clinical Kinematic Assessment Tool (CKAT, Flatters et al. 2014;9(2):e88692) — a manual control task where the child made a series of aiming movements and traced two abstract shapes with a handheld stylus on a digital tablet. Welch t-test was used for statistical analysis.

Results: Forty-three (25%) children were classified to have a common uncorrected eye or vision problem. This group had significantly poorer performance in aiming (movement time mean ± SD 1.44 ± 0.26 seconds) compared to those with normal eye and vision status (1.33 ± 0.25 seconds, p=0.018). There was no group difference for tracing (penalised Path Accuracy (pPA) Shape A: 1.37 ± 0.49 vs. 1.51 ± 0.4, p=0.10 and Shape B: 1.32 ± 0.53 vs. 1.39 ± 0.42, p=0.48).

Conclusions: The results suggest that common uncorrected eye and vision problems could affect manual control in children. Because learning benefits from good manual control, uncorrected eye and vision problems may pose an implicit disadvantage for learning.

ABSTRACT BODY:

Purpose: The choriocapillaris fulfills many functions essential to retinal homeostasis. It supports the delivery of metabolism substrates to the photoreceptors, clears metabolic waste products from the subretinal space and may passively regulate the temperature of the back of the eye. Previous experimental and theoretical work have shown that the choriocapillaris comprises diffusion-limited regions, where the passive transport of material is dominantly diffusive. We sought to characterize the salient features of mass transport within these regions and to identify the structural and functional parameters determining their physical characteristics.

Methods: This analysis relied on three-dimensional mathematical models of the choriocapillaris informed by the angioarchitecture of the human choroid as observed through whole mounts stained with Ulex Europaeus Agglutinin I. Blood was modelled as a Newtonian fluid, and analytical and numerical solutions for the blood flow were obtained by solving the Navier-Stokes equation. Mass was modeled as a passive scalar, and its concentration field was determined by solving the advection-diffusion equation. Transfers to the retina were simulated by imposing a Dirichlet boundary condition on the upper surface of the choriocapillaris and studying spatial variations of the Nusselt number.

Results: Diffusion-limited regions represent areas of reduced exchange with the outer retina. Their number is equal to the number of arteries and vein connected to the choriocapillaris, which makes them ubiquitous. The width of these regions is solute-specific and increases with molecular diffusivity. It is mainly determined by the relative arrangement of arteriolar and venular insertions into the choriocapillaris, arterial flow rate and the vascular volume fraction of this capillary bed.

Conclusions: Exchange between the choriocapillaris and outer retina is markedly reduced over diffusion-limited regions. The location and surface area of these regions is determined by both structural and functional parameters, some of them quantifiable using imaging techniques. Their existence and characteristics may partly explain the spatial selectivity of several pathologies associated with degenerative diseases of the retina.

ABSTRACT BODY:

Purpose: Oxidative stress (OS) caused by hypoxia/hyperoxia environment results in progressive loss of trabecular meshwork (TM) cells in primary open angle glaucoma (POAG). Our previous report demonstrated; a hybrid nitric oxide (NO) donor-antioxidant molecule SA-2 protect primary human (h) TM cells against t-butyl hydrogen peroxide (TBHP) induced cell death and increased superoxide dismutase enzyme level. Here we investigated the effect of SA-2 on mitochondrial energy metabolism by measuring the respiration status, glycolysis rate and energy production.

Methods: Primary hTM cells obtained from human donor eyes (IRB approved at UNTHSC) were seeded in 24-well culture plates (Seahorse XFe 24 Cell Mito Stress kit, Agilent), and starved for 24h before treatment with SA-2 (1 μM,10μM,100μM, and 1mM). In a separate experiment, the cells were pretreated with TBHP (150μM) for 30 minutes, followed by the addition of SA-2 (10μM,100μM). After 24h, the mitochondrial complex inhibitors and uncoupling reagents (oligomycin, FCCP, rotenone/antimycin A) were added. The plate was analyzed for changes in oxygen consumption rate (OCR) and extracellular acidification rate (ECAR) using the Seahorse XFe24 analyzer following the manufacturer instructions.

Results: The mean OCR was significantly decreased (>70%) followed by increase in the mean ECAR (~3-fold) after treatment with TBHP compared to oligo/FCCP/rot treated cells, hereafter called as negative control. Treatment with SA-2 at 1 μM,10μM,100μM and 1mM concentrations increased both oligomycin/FCCP induced decrease in ATP production and maximal mitochondrial respiration followed by an increase in the mean ECAR compared to negative control. The mean OCR was higher in SA-2 (100μM) +TBHP treated cells followed by an increase in ECAR in SA-2 (10μM or 100μM) +TBHP treated cells than TBHP and negative control treated cells. N =2-3.

Conclusions: Mitochondrial respiration was impaired after TBHP treatment to hTM cells following cell death. While most of the mitochondrial targeting anti-oxidant compounds increase OCR but not ECAR, we found the hybrid NO donor-anti-oxidant compound SA-2 increases ATP production, maximal mitochondrial respiration and increases glycolytic energy production in hTM cells. This finding provides a novel direction for further investigation into the effect of SA-2 and mitochondrial bioenergetics during OS-induced cell death.

ABSTRACT BODY:

Purpose: An acquired vitelliform lesion (AVL) is a retinal abnormality characterized by the accumulation of yellowish hyperfluorescent material in the subretinal space, but its impact on photoreceptor anatomy is incompletely understood. This study aimed to examine cone photoreceptor structure in eyes with AVL using multi-modal imaging including adaptive optics scanning laser ophthalmoscopy (AOSLO).

Methods: This was a retrospective study of subjects with AVL associated with age-related macular degeneration and adult-onset foveomacular vitelliform dystrophy. Subjects underwent color fundus photography (CFP), en-face infrared reflectance (IR), blue-light reflectance (BR) and autofluorescence (AF) imaging, and spectral-domain volume optical coherence tomography (SD-OCT) of the central macular. AVL was diagnosed based on the characteristic hyper-reflective subretinal material, anterior to the retinal pigment epithelium, with en face and cross-sectional OCT. Photoreceptor structure near the AVL was examined by AOSLO.

Results: AVL was found in a total of 28 eyes of 27 subjects, aged 77.7 ± 6.5 years. All subjects were white non-Hispanic and 14 were female, with mean Snellen visual acuity of 0.25 ± 0.37 (LogMAR, Snellen equivalent:). AOSLO revealed the cone mosaic disruption with apparently decreased cell density and lost or altered (hyper or hypo) reflectivity in the AVL affected areas. (Figure)

Conclusions: AOSLO imaging of cone photoreceptors near AVLs indicate that photoreceptor degeneration may be associated with AVL development. Because AVL represents a high-risk marker for atrophic or neovascular events that lead to significant vision loss, in vivo characterization of photoreceptor status in areas affected by AVL is important for a better understanding of disease pathophysiology and for the development of interventional trials.

ABSTRACT BODY:

Purpose: This meta-analysis can substantiate the relationship between microvascular changes in retina and severity of diabetic retinopathy (DR) to the risk of progression to end stage renal disease (ESRD) in diabetic kidney disease (DKD) patients.

Methods: Systematic search on PubMed & Embase for articles studying association between DR & chronic kidney disease progression yielded a total of 18,725 articles. Joanna Briggs Institute critical appraisal checklist for cohort studies was used to assess the quality of the selected articles. Higgins & Thompson's I^2 statistic was used to see the degree of heterogeneity. Based on degree of heterogeneity, fixed or random effects model was used to estimate pooled effect using inverse variance method. Results were expressed as hazard ratios and odds ratios with 95% CIs.

Results: After scrutinizing 18017 articles, data from 10 relevant studies (7 prospective and 3 retrospective) were extracted and total of 14,355 patients are included. DR was significantly associated with ESRD with pooled HR of 2.42 (95% CI: 1.70-3.45) [Fig1] and pooled OR of 2.61 (95% CI: 1.76-3.87) [Fig2]. Sensitivity analysis done with biopsy proven DKD and prospective studies yielded similar results with pooled HR 2.76 (1.26-6.04) and OR of 1.79 (1.04-3.09). There was significant association of severity of DR and risk of progression to ESRD with pooled OR for non-proliferative DR: 2.13 (1.82–2.50) and for proliferative DR OR of 3.56 (2.93–4.33).

Conclusions: While association of DR and presence of DKD is already clearly established, this novel meta-analysis substantiates that presence of DR is associated with risk of progression to ESRD. The substantial burden of kidney disease fosters interest in new ways of screening for early disease diagnosis especially via non-invasive imaging. Such an association in clinical workflows can be utilized by an ophthalmologist for early recommendation to patients for possible DKD diagnosis. Since fundoscopy is less invasive and more convenient for the patients than a kidney biopsy, the stage of DR could be useful for prognosticating the clinical course of diabetic nephropathy. Pooled HR of 2.42 & pooled OR of 2.61 with p-value < 0.0001 indicates that presence of DR is predictive of progression of DKD patients to ESRD.

TITLE: Piezo2-positive mechanosensory nerve terminals are present in the chamber angle of the human eye

SESSION TITLE: Aqueous humor dynamics and Trabecular Meshwork

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Naghibi, E. Tamm, University of Regensburg, Institute of Anatomy, Regensburg, Bavaria, GERMANY|

Commercial Relationships Disclosure: Gholamreza Naghibi: Commercial Relationship: Code N (No Commercial Relationship) | Ernst R. Tamm: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Because of the lack of a specific molecular marker, the question has not been answered conclusively if there are specific proprioceptive sensory nerve endings in the human chamber angle that serve as mechanoreceptors. Piezo2 has been identified as a mechanosensitive ion channel that plays a role in rapidly adapting mechanically activated currents in somatosensory neurons. To clearly identify proprioceptive nerve endings in the human chamber angle, we investigated anterior segments of human eyes for the presence of Piezo2-containing nerve endings.

Methods: Human autopsy eyes (age >80 years) without any obvious ocular pathology were investigated. The anterior eye segment was dissected in quadrants. From each quadrant, wedge-shaped specimens with 1.6 mm width on average, and containing trabecular meshwork and ciliary muscle were cut. The specimens were fixed in 2 % paraformaldehyde for immunohistochemistry or Karnovsky's solution for transmission electron microscopy (TEM). Serial tangential 12-20 µm cryosections were cut and immunostained with antibodies against Piezo2. To distinguish axons from terminal nerve endings, double immunohistochemistry was performed combining Piezo2 antibodies with antibodies against synaptophysin that specifically stains synaptic vesicles in nerve terminals.

Results: Piezo2 immunoreactive axons were identified in iris and ciliary muscle. Piezo2/synaptophysin immunoreactivity was detected almost exclusively in club- or bulb-shaped nerve terminals in the scleral spur (75 %) or, more inwardly, at the apex of the longitudinal portion of the ciliary muscle. The nerve endings were considerably larger (17.7 µm on average) than sympathetic or parasympathetic terminals and resembled Ruffini-like sensory nerve endings as present e.g., in the carotid sinus. TEM confirmed that the nerve endings were identical with putative mechanosensory nerve endings previously identified based on ultrastructural criteria (Tamm et al., IOVS 1994).

Conclusions: We conclusively confirm the presence of mechanosensory nerve terminals that measure stress or strain of the scleral spur extracellular matrix. Such changes are likely induced by ciliary muscle contraction and/or changes in intraocular pressure.

ABSTRACT BODY:

Purpose: Targeted RNA editing utilizing the ubiquitous human adenosine deaminase acting on RNA (ADAR) enzyme is a possible new genetic therapeutic approach for the treatment of inherited retinal diseases (IRDs). Utilizing guideRNA (gRNA) to recruit the endogenously expressed ADAR enzyme to a mutated RNA and facilitating the deaminization of a specific adenosine to inosine (read as a guanine by the ribosome), allows for the correction of mRNA transcripts in a transient and tunable manner. According to our recent analyses, 40% of single nucleotide variants (SNVs)-causing IRDs are candidates for ADAR-directed editing. Our aim is to design and test gRNAs that induce targeted ADAR editing for 3 common Israeli mutations causing IRDs: TRPM1- p.K294*, FAM161A- p.R523*, and KIZ- p.R76*.

Methods: After determining Israeli IRD candidate mutations, we used a yeast model to identify candidate gRNAs for these mutations by measuring yeast survival and percent editing in next generation sequencing (NGS). Effective gRNA sequences were then assessed for appropriate chemical modifications and produced as single-stranded RNAs. We developed a fluorescence-expressing plasmid reporter system for ADAR editing by inserting a gene cassette harboring a nonsense mutation in between mCherry and EGFP, and subsequently transfected these plasmids into HeLa cells to test the candidate gRNAs. Successful editing of target gene RNA fragments produced by the reporter plasmid is measured through fluorescent microscopy, Sanger sequencing, and NGS.

Results: Our yeast model identified three possible gRNAs, one for each candidate mutation previously mentioned. In this yeast model, the gRNAs targeting mutations in TRPM1, FAM161A, and KIZ showed 9%, 1%, and 0.2% editing respectively of a relevant nucleotide flanking each mutation. Using our reporter system in HeLa cells, we found that the gRNA complementary to the target TRPM1 mutation induced RNA editing levels in our system of up to 55% in Sanger sequencing, 40% in NGS, and the treated cells expressed both mCherry and EGFP. Experiments utilizing the FAM161A and KIZ appropriate gRNAs are in progress.

Conclusions: Targeted RNA editing utilizing the ADAR enzyme could be the next frontier of genetic therapy for IRDs due to its ability to edit SNVs in a tunable manner. Next steps include applying this genetic therapy to the appropriate knock-in mouse models and retinal organoids.

ABSTRACT BODY:

Purpose: A relative peripheral hyperopia has been suggested as a trigger on myopization in children. However, this is not fully validated yet, due to the lack of longitudinal results following the development process. To address the gap, our aim was to measure high-resolution two-dimensional peripheral refraction maps during two years of myopia progression in a group of children.

Methods: Peripheral refraction maps were measured using a peripheral sensor device (VPR, Voptica SL, Murcia, Spain) in a group of Chinese children (age 9-16 years) under cycloplegia. The maps cover a field from nasal 30° to temporal 30° of every 1°, and from superior 20° to inferior 16° of every 4°. After the study was closed, 214 children's data were available after one year and 152 children's data were available after two years. The participants were classified into three refraction progression groups based on their refractive change for hyperopic, emmetropic, and myopic subjects, separately. The difference of baseline peripheral defocus pattern was compared between each group by using ANOVA test. Central myopia progression as a function of peripheral defocus was investigated by simple linear regression.

Results: After the first year, a significantly different from the baseline refraction pattern was found between the various progression group in emmetropes. Baseline peripheral defocus in the central vertical field (horizontally, within ± 15°) at baseline was found to be significantly correlated with central myopic shift, especially in the superior retina [(S8°-S12°) X (N5°-T5°)]. Emmetropic subjects with more myopic defocus in the superior retina had more myopic progression (for refractive change, $r=0.32$, $p<0.001$; for axial change, $r=0.42$, $p<0.001$) (Figures a&b). In contrast, no obvious difference in baseline refraction pattern was found in the groups of hyperopes and myopes. The same tendency was confirmed after 2 years.

Conclusions: Children having the greater progression of myopia in central refraction over a two-year- period presented an initial relative myopic defocus in the superior retina. This type of relative refraction in the superior retina could be used as a predictor of central myopia. In relation, devices for keeping the superior retina emmetropic in children might be a myopia control strategy.

ABSTRACT BODY:

Purpose: To investigate associations between diabetic retinopathy (DR) and chronic kidney disease (CKD) in type 2 diabetes patients.

Methods: In the cross-sectional, community-based Tongren Health Care Study, individuals who attended regular health care check-up examinations from January 2014 to December 2019 were consecutively enrolled. Type 2 diabetes was diagnosed based on fasting plasma glucose concentration of ≥7.0 mmol/L or a medical history, after excluding patients with type 1 diabetes and gestational diabetes. DR was assessed using color fundus photograph. CKD was defined by a reduced estimated glomerular filtration rate (eGFR) of <60ml/min/1.73mm^2 and/or albuminuria.

Results: Out of 62,217 study participants, 5103 (8.2%) had diabetes. Within the diabetic group, the prevalences of DR, reduced eGFR, albuminuria and CKD was 12.8% (95% confidence interval:11.8,13.7), 4.6% (95%CI:4.2,5.1%), 10.1% (95%CI:9.3,10.9%) and 13.3% (95%CI:12.4,14.3%), respectively. DR was present in 21.0% of the individuals with CKD, and CKD was detectable in 20.9% of the DR patients. Reduced eGFR or albuminuria were concurrent with DR in 3.9% and 18.8% of the participants with DR, respectively. The presence of DR and DR severity were significantly associated with the combined occurrence of CKD and albuminuria (P<0.05), but not with reduced eGFR. Factors independently associated (multivariable analysis) with the presence of CKD instead of DR were older age (P<0.001, OR=1.05), a higher body mass index (P<0.001, OR=1.14), a higher serum concentration of triglycerides (P<0.001, OR=1.26), and a lower blood glucose (P<0.001, OR=0.93). Having both diabetes and arterial hypertension was a significant risk factor for the presence of a reduced eGFR as compared with DR (P=0.005, OR=4.47).

Conclusions: Around 1/5 of CKD patients had concurrent DR, and 1/5 of DR patients had concurrent CKD, in this type 2 diabetes population. Those with older age, higher body mass index, combining with hypertension and dyslipidemia had a higher chance of being affected by CKD than by DR, while those with a higher fasting glucose level had a higher chance of being affected by DR than by CKD.

ABSTRACT BODY:

Purpose: Stargardt disease (STGD1) is the most frequent inherited macular degeneration affecting ~1 in 10,000 persons. STGD1 is caused by bi-allelic pathogenic variants in ABCA4. Due to a complex mechanism in which the combined severity and penetrance of variants determines whether a person is affected by STGD1 and how severely a person is affected, the risks for individuals with STGD1 to pass on STGD1 to the offspring are currently unknown when no genetic data from the other genetic parent of the (future) offspring is available. Knowing the recurrence risks is crucial for individuals with STGD1 who have a desire to have children.

Methods: In this study, based on genetic data from 5,579 published bi-allelic STGD1 patients, we first categorized all known ABCA4 variants into mild, moderately severe or severe categories. This was based on i) existing data from functional and clinical studies, ii) null allele predictions, iii) comparison of variant frequency data in STGD1 individuals versus general population variant data from gnomAD, iv) observed versus expected homozygous variant occurrence in STGD1 individuals and v) the ratio in which variants occur with known mild and severe variants in trans in STGD1 individuals compared to the same ratio of known severe variants. Based on the sum allele frequencies of the variants in the resulting categories, Hardy-Weinberg equations and the STGD1 genotype-phenotype model described previously (Maugeri et al. 1999; PMID 10090887), we estimated the recurrence risks for STGD1 and early onset STGD1. These risk calculations are based on the severity of the variants of the individual with STGD1 when the genetic data of the unaffected partner is unknown.

Results: The recurrence risks for any form of STGD1 for offspring of STGD1 patients range from 0.68-3.1%. The recurrence risks for early onset STGD1 in the offspring range from 0.34-0.79%. The recurrence risks are the highest for STGD1 patients who carry two severe alleles (2.8-3.1%) and are the lowest for STGD1 patients who carry two moderately severe alleles (0.68-0.79%).

Conclusions: These personalized recurrence risk calculations will be of help in the genetic counseling of individuals with STGD1 who have a desire to have children.

ABSTRACT BODY:

Purpose: Defects in corneal limbal epithelium can lead to persistent corneal epithelial defects (PECD), marked by chronic inflammation, neovascularization, scarring and conjunctivalization. A simple, reproducible and sustainable method for generation of animal models with PECD is necessary for assessing the new therapeutic modalities. The purpose of the study is to develop an animal model with PECD and to study epithelial regeneration potential of allogeneic simple limbal epithelial transplantation (allo-SLET) and conjunctival limbal allograft (CLAL).

Methods: Complete corneal and limbal epithelium of the New Zealand White Rabbit (n=10) was mechanically debrided using the Alger brush-II 1.0-mm round-ended burr after 360° Limbal peritomy. Rabbits were observed for corneal haziness, vascularization and epithelial defect using clinical photograph, slit lamp, fluorescein staining and anterior segment optical coherence tomography (AS-OCT) post debridement. At 4-8 week post debridement, allo-SLET without human amniotic membrane (n=5) and CLAL (n=5) was performed in the rabbit eyes with a donor graft obtained from the Dutch-Belted rabbit. The extent of epithelialization was assessed by change in the central corneal epithelial thickness (CCET) using AS-OCT.

Results: All eyes showed epithelial defect up to 4 weeks as evident by the fluorescein staining. In 70% (7/10) of the eyes superficial neovascularization was observed after 4 weeks of which 42% reached the central cornea. Epithelial defect was observed even after 5 weeks of debridement in 70% (7/10) of the eyes. Epithelial migration was observed from the transplanted grafts for up to 3 weeks in both the cases and graft were stable up to 3 months with no sign of epithelial rejection. Allo-SLET treated eye showed significant increase in CCET ($P = 0.0255$, n=5) as compared to CLAL ($P > 0.5$, n=5) at 3 month of transplantation.

Conclusions: Mechanical debridement using alger brush-II 1.0-mm round-ended burr is an effective method for the establishment of persistent corneal epithelial defect in New Zealand white rabbits. Limbal allograft transplantation lead to significant corneal epithelialization in PECD especially in allo-SLET.

ABSTRACT BODY:

Purpose: To determine the 10-year morphological outcomes and progression to exudative AMD in the fellow eyes (FE) of patients with naïve exudative AMD.

Methods: Data from 52 patients with naïve exudative AMD in one eye and at least 10 years of follow-up were retrospectively reviewed. Baseline optical coherence tomography (OCT) features as presence and type of drusen and non-foveal atrophy, central retinal thickness, subfoveal choroidal thickness and presence of intraretinal hyperreflective foci (iHRF) were acquired in the FEs; macular neovascularization (MNV) type was also assessed in the exudative AMD eye. Choroidal vascularity index of the FE was calculated in a region of 1500 µm centered at the fovea. Time and rate of progression of the FEs into exudative AMD were examined by Kaplan-Meier analysis and Cox regression.

Results: Twenty-eight FEs (53.8%) developed exudative AMD within the 10-year follow-up. An earlier progression to exudative AMD was associated with the presence of iHRF (47.625 vs 108.647 months, p=0.014), Subretinal Drusenoid Deposits (SDD) and Cuticular drusen (43.0 and 47.6 vs 90.2 months respectively, p<0.001) at baseline. Cuticular drusen were furthermore associated with a higher risk of developing an exudative MNV (Hazard Ratio [HR] 9.137; 95% confidence interval [CI] 1.643 – 50.818, p=0.023). Type 3 MNVs in the exudative AMD eye significantly associated with early MNV development in the FE (40.51 months; 95% CI 10.921 – 70.222, p=0.041). No other significant associations emerged between baseline features in FE and progression to exudative AMD.

Conclusions: Type 3 MNV in the exudative AMD eye and presence of iHRF, SDD and Cuticular drusen in FEs of patients with exudative AMD may identify eyes at high risk of progression to MNV throughout a 10-year period. Further studies with larger sample sizes will be needed to confirm these findings.

ABSTRACT BODY:

Purpose: Drivers with visual field loss (VFL) such as glaucoma have higher risk of motor vehicle accidents and poorer driving performance when compared to age-matched drivers with no visual field loss. To date, conventional visual field tests have strong limitations in predicting on-road driving performance of VFL drivers. We developed a new screening-test (Driving Visual Field Attentional Test) for drivers with peripheral VFL such as individuals with glaucoma.
The aim of this study was to assess whether or not the Driving Visual Field Attentional Test is able to predict the outcome of an on-road driving test in drivers with VFL.

Methods: Twelve drivers with binocular VFL, aged 65.2 ±9.7, and twenty-four control drivers (matched for age and sex) aged 61.3±11,5, all holders of a driving license and active drivers, were recruited. They were asked to fill in a questionnaire about medical history, driving habits and motor vehicle collisions. They subsequently underwent an ophthalmologic examination including a battery of perimetric tests: Goldmann II-4 and III-1 and Esterman. Finally, they completed the Driving Visual Field Attentional Test, a UFOV test, a MMSE, and performed a practical on-road test under the supervision of expert evaluators. Driving evaluators were not aware of drivers' visual status. The receiver operating characteristic (ROC) curve was used to investigate the ability of the different tests to discriminate between safe and unsafe drivers.

Results: Drivers with VFL detected fewer peripheral targets (p=.002) compared to the control drivers group. Four drivers with VFL failed the driving test. Three drivers with VFL and five controls were found to be "questionable". ROC analysis revealed that the Driving Visual Field Attentional Test was an excellent predictor of failing the road test with an area-under-the-curve (AUC) value of 0.86 (CI: 0.58-1.0, p=0.01). UFOV also reached acceptable predictive power (AUC= 0.72, CI: 0.49-0.95, p=0.06). A cut-off score set at 28 non-responses provided 75% sensitivity (i.e., 75% of people who failed the road test were correctly identified) with a 100% specificity.

Conclusions: Preliminary analyses indicate that Driving Visual Field Attentional Test is a reliable predictor of at-risk driving for patients with visual field loss. Further testing with more subjects will be done to confirm these preliminary results.

ABSTRACT BODY:

Purpose: Intraocular inflammation in the anterior chamber can occur in ocular infectious, autoimmune conditions and following ocular surgery. In most cases, anterior segment inflammation is assessed through slit lamp examination of the aqueous humor (AH). This technique entails limitations in terms of interobserver agreement, accuracy and precision. The purpose of our study is to present an Artificial Intelligence based Anterior-Segment Optical Tomography (AI-OCT) model for intraocular inflammation assessment and validate it by flow cytometry (FC) analysis of the AH and slit lamp examination

Methods: 16 B-scan AS-OCT imaging (CASIA 2, Tomey Corporation, Nagoya, Japan) and slit lamp examination by Standardization of Uveitis Nomenclature (SUN) were performed immediately before an intraocular surgical procedure in 95 eyes of 70 patients. As the first step of the surgical procedure, >30 µl of AH were aspirated through a paracentesis using a 27G canula. Samples underwent FC analysis within 5 hours after extraction. A cocktail of CD markers (CD3, CD4, CD8, CD16, CD19, CD33, CD45), together with forward and side scatter characteristics, were used to determine the immunologic cellular profile in the AH samples. A gate was constructed to filter out pigmentary cells. OCT radial scans were analysed by the AI-OCT model in five configurations of 1, 2, 4, 8 and 16 radial images. Pearson's R and Spearman's ρ was subsequently calculated to measure FC acquisition correlation with the AI-OCT model and SUN score, respectively

Results: Spearman's ρ rank correlation ($p = 0.0379$, $\rho = 0.2523$) between FC acquisition of AH and the inflammatory score of SUN classification was measured. Pearson's r correlation was measured for each constellation revealing single image scans ($p < 0.001$, $r = 0.7103$, $\sigma = 0.04179$) as the most optimal. Spearman's ρ rank correlation was calculated between inflammatory score of SUN classification and all five AI-OCT system collection-of-image configurations. Sixteen slice configuration achieved the highest Spearman's ρ rank correlation ($p = 0.107$, $\rho = 0.3078$, $\sigma = 0.03639$) of all five collection-of-image configurations

Conclusions: AI-OCT based particle detection shows correlation with FC analysis of AH. These findings suggest that AI-OCT models could represent a quantifiable and objective alternative to slit lamp based examination in patients with intraocular inflammation

ABSTRACT BODY:

Purpose: To examine the laser technique and bovine tissue status for optimal adhesion of a novel laser-activated thin-film chitosan-based corneal adhesive.

Methods: Central penetrating corneal linear incisions of 2 mm or 4 mm were created in an ex vivo bovine eye model. Disc-shaped adhesives with an area of 50.2 mm^2 were used and infrared laser of 810 nm, 125 mW, and 1 mm spot diameter was delivered using a manual fiber optic probe to the adhesive. There were 4 test groups; group 1, incisions were closed using either a grid-like (n=20) or concentric (n=20) lasering technique. Group 2, incisions were closed with epithelium-on (n=20) or epithelium-off (n=20). Group 3, using 4 mm incisions, ocular surface temperature was varied to 5.7 °C (n=10), 21.9 °C (n=10) or 33.2 °C (n=10). Group 4, postmortem duration of the bovine tissue was varied to less than 6 hours (n=20) or between 24 to 30 hours (n=20) to close both 2 mm and 4 mm incisions. A custom burst pressure testing chamber was used to assess adhesion strength which was compared using the highest tolerable fluid pressure to cause a wound leak. Data were analyzed using unpaired t-test or one-way ANOVA with statistical significance at $p<0.05$.

Results: The burst pressure of 4 mm incisions was higher when closed using a concentric (205.1 (±16.7) mmHg) technique than the grid-like (86.3 (±14.0) mmHg) lasering technique, $p<0.05$. The burst pressure was higher in 2 mm and 4 mm incisions with the epithelium-on group (224.3 (±20.7) and 205.1 (±65.4) mmHg, respectively) than epithelium-off group (51.7 (±6.5) and 9.8 (±1.5) mmHg, respectively), both $p<0.05$. Burst pressure did not demonstrate any significant difference in groups 3 and 4.

Conclusions: Strongest adhesion was achieved using a concentric lasering technique and with an intact corneal epithelium. Variation of ocular surface temperature and postmortem duration up to 30 hours did not affect adhesion strength.

ABSTRACT BODY:

Purpose: Foveal hypoplasia (FH) is characterised by the continuation of inner retinal layers posterior to the foveola. Varying degrees of FH represent different stages of arrested foveal development. The Leicester Grading System for FH divides typical FH into four grades and an additional grade for atypical FH. The grading system has been applied to various disorders including albinism, idiopathic infantile nystagmus (with or without FRMD7 variants), and PAX6, SLC38A8 and AHR variants. The grading system is used as a diagnostic and prognostic tool. To date, it is unclear whether variants of certain genes are associated with worse foveal morphology and prognosis. Thus, we aimed to perform a comparative multi-centre study to characterise the genotypic and phenotypic spectrum of FH in the aforementioned aetiologies.

Methods: Patients with known genetic associations with FH and nystagmus (n=575) were identified from 10 centres from 8 countries (75.6%), as part of FDIG, or extracted from publicly available datasets from previously reported literature (24.4%). Genetic diagnosis was achieved using targeted panel-based sequencing or exome sequencing. Due to the rarity of AHR variants, we only included cases reported in the literature (n=2). Optical coherence tomography of the fovea was obtained in all subjects.

Results: The most common genetic aetiology for typical FH was albinism (66.1%), followed by PAX6 (22.8%) and SLC38A8 variants (7.1%). FRMD7 (3.7%) and AHR variants (0.4%) were rare causes of FH. All grades of FH were seen in albinism and PAX6 variants. All SLC38A8 cases demonstrated grade 3 or 4 FH. In AHR variants, only grade 3 FH has been reported. In cases of FH and FRMD7 variants only grade 1 FH was observed.

Conclusions: We characterised the phenotypic and genotypic spectrum of FH. Our data suggests that arrested retinal development occurs earlier in SLC38A8 and AHR variants and much later in FRMD7 variants. The defined time-period of foveal developmental arrest for albinism and PAX6 variants appears to demonstrate more variability. Our findings provide mechanistic insight into disorders associated with FH and have significant prognostic and diagnostic value.

ABSTRACT BODY:

Purpose: The assessment of visual field sensitivities in young children continues to be a challenge. Children often do not sit still, fail to fixate stimuli for longer durations, and have limited verbal capacity to report visibility. We investigated the use of a head-mounted VR display, gaze-contingent flicker pupil perimetry (gcFPP), and three fixation stimulus conditions to determine best practices for optimal fixation and pupil response quality.

Methods: A total of twenty healthy children aged 3-11 years old (mean age and SD 7.2 ± 2.4, 14 male) passively fixated a dot, counted the repeated appearance of an animated character, and watched an animated movie in separate trials of 80s each. We presented large flickering patches at different eccentricities and angles in the periphery to evoke pupillary oscillations (20 locations, 4s per location).

Results: The results showed that gaze precision and accuracy did not differ significantly across the fixation conditions but pupil amplitudes were strongest for the fixation dot ($p < .01$) and count task ($p < .05$) when compared to the animated movie condition. A query revealed that 18 out of 20 children favored the counting task condition.

Conclusions: We recommend the use of the counting task as fixation condition for pupil perimetry because children enjoyed it the most and it achieved strongest pupil responses. The VR set-up appears to be an ideal apparatus for children to allow free range of movement, an engaging visual task, and reliable eye measurements.

TITLE: Choroidal Changes in Non-ocular Sarcoidosis

SESSION TITLE: Imaging of posterior segment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Han, J. Lee, Ophthalmology, Asan Medical Center, Songpa-gu, Seoul, KOREA (THE REPUBLIC OF)|

Commercial Relationships Disclosure: Ye Eun Han: Commercial Relationship: Code N (No Commercial Relationship) | Junyeop Lee: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate choroidal features associated with non-ocular sarcoidosis using optical coherence tomography.

Methods: In this retrospective case-control study, twenty eyes with non-ocular sarcoidosis and 20 age and spherical equivalent-matched healthy controls were evaluated. The subfoveal thickness, area ratio, and choroidal vascularity index (CVI) of the choroid were analyzed. Factors correlated with the choroidal thickness were investigated.

Results: Sattler's layer was significantly thicker in eyes with non-ocular sarcoidosis than in healthy controls, while there were no differences in Haller's layer and total choroid between groups. The area ratio (Sattler's to Haller's layer) was also larger in eyes with non-ocular sarcoidosis than in control. There were no differences in terms of the CVIs of all sublayers between groups. Age was significantly associated with the thickness of Sattler's layer.

Conclusions: A disproportionate enlargement of subfoveal Sattler's layer without vascular or total choroidal thickness changes may be subclinical manifestations of non-ocular sarcoidosis.

ABSTRACT BODY:

Purpose: To use machine learning to identify gut microbiota associations with age-related macular degeneration.

Methods: Macular OCT scans (Optovue iVue 100, Freemont, CA) taken between 2014-20120 from participants of the TwinsUK cohort were graded for signs of age-related macular degeneration according to the E3 OCT grading system.

Stool samples from TwinsUK participants were collected and DNA extracted and sequenced on an Illumina MiSeq platform. 16S sequences were demultiplexed in QIIME. Amplicon sequence variants (ASVs) were generated using the DADA2 package in R. Chimeras were removed and taxonomy assigned using SILVA 1.3.2. Samples with a sequencing depth of less than 10,000 reads were excluded.

Two different random forest analyses were conducted to select the most important microbiome features that predicted AMD status. The first ordered the microbiome variables based on the Gini classification index and the second used a frequency-corrected ranking approach.

Results: A total of 404 stool samples from 321 AMD participants (mean age ±SD 67.6±7.8, 90% female) and 1,736 stool samples from 1,355 controls (mean age ±SD 61.3±7.6, 91% female) were included in the analysis. Our machine learning analyses identified three microbiota taxa that were likely significant predictors of AMD phenotypic status. Our results indicate that the phylum Firmicutes (RF permutational p-value=0.008) and additionally, two genera: Ruminococcus (RF permutational p-value=0.0005) and Prevotellaceae-NK3B31 are associated with AMD (RF permutational p-value=$1x10^{-05}$).

Conclusions: With the assistance of machine learning, this study suggests that an increased abundance of certain gut microbiome taxa may be associated with an increased probability of having AMD. Further validation is required from other cohorts and further studies are needed to explore any causal relationships between the gut microbiome and AMD.

ABSTRACT BODY:

Purpose: Machine Learning (ML) models have shown above-human performance in the classification of ophthalmic imaging. However, this is often only achieved in limited ways and in unrealistic environments. In addition, many methods use Artificial Neural Networks (ANNs), the workings of which are uninterpretable to human users. These 'black box' models can lead to unintended consequences, including misdiagnosis. As ML models find use in the clinical environment, these errors could be perpetuated at scale and jeopardise patient safety. There is an urgent need for interpretable models, since this will enable users to identify biases, train more accurate models and even find use in machine teaching. Using a new method, counterfactual visual explanations (CVEs), we explore a novel way to allow humans to understand model outputs. This allows clinicians to answer 'What if?' questions like 'How would this OCT showing AMD need to change in order for it to be classified as a healthy scan?'.

Methods: Generative Adversarial Networks (GANs) are a gold standard ML framework for producing synthetic images. We train a state-of-the-art model, StyleGAN, using 1,000 central B-scans from patients with no pathology, and with AMD. In addition, we use a cyclical GAN, cycleGAN, that takes in a healthy scan and outputs a new image with signs of AMD. In an exploratory qualitative investigation, we show our output images to several consultant ophthalmologists for review.

Results: After training, we are able to produce synthetic OCT B-scans at native resolution. We show for the first time that it is possible to create synthetic optical coherence tomography scans of sufficient quality that world leading retinal experts are unable to differentiate between real images and our synthetic ones. We also successfully demonstrate the first example of counterfactual image generation using GANs and provide a framework for further exploration of this method in the literature.

Conclusions: GANs can be used to generate realistic OCT B-scans and generate counterfactual examples. Along with improved interpretability, synthetic images can be produced at scale to help with augmenting datasets and in addition obviate many of the ethical hurdles that currently exist around distributing medical data.

ABSTRACT BODY:

Purpose: To design, build and validate a new optical instrument to measure ocular refraction and aberrations rapidly in a two-dimensional (2D) wide field. Existing peripheral refractors are constrained to limited meridians, therefore requiring several visual fixations at different points to complete an actual 2D map, making them impractical for clinical use.

Methods: The instrument combined the scanning of 850-nm laser beam with a Hartmann-Shack (H-S) wavefront sensor. A multielement eyepiece was designed for wide field operation. A steering mirror scanned the beam generating a flying spot on the subject's retina. The light backscattered from the retina was de-scanned by the steering mirror and redirected to the H-S relay for optical measurements. The visual fixation stimulus was generated by rotating the steering mirror, forming a flickering disc of 0.5 deg diameter. The stimulus was intermittently presented for 150 ms every 300 ms. During the time off, the beam was sequentially scanned on the retina, and refraction/aberrations were estimated at 98 Hz. Trial lenses were measured at different eccentricities for prior calibration. Accordingly, residual field aberrations of the apparatus were computationally compensated. A group of 10 young normal subjects participated in the first series of measurements.

Results: The instrument estimated the magnitude and orientation of trial lenses within a precision of 5 %. The basic operation mode in real subjects obtained the refraction in 50x50 deg field (88 sampled points, 5 deg step), with a single fixation point, in 3 sec. With 2 fixation points at ±15 deg horizontal, refraction distribution in 80x50 deg field could be obtained. Other protocols included high density, 1 deg step, at any selected meridians. Retinal sampling can be customized and adapted to virtually any clinical need. 2D refraction and aberration maps were obtained in the group of subjects.

Conclusions: The new scanning peripheral refractor permitted the accurate, programmable, and rapid measurements of peripheral optical parameters of the eye. A single fixation point provided data in a field of 50x50 deg in 3 sec. The enhanced capabilities of this instrument, such as wide angle and speed would allow its use in the clinic for the characterization of peripheral optics as a clinical tool in myopia management.

ABSTRACT BODY:

Purpose: Patients with chronic central serous chorioretinopathy (cCSC) may have spontaneous subretinal fluid (SRF) resolution, but little is known about clinical characteristics that can help to predict which patients will have such a spontaneous resolution. We performed a retrospective clinical study to learn about factors that may predict spontaneous SRF resolution in cCSC patients.

Methods: This retrospective cohort study included 38 treatment-naive cCSC patients in whom spontaneous SRF resolution on optical coherence tomography (OCT) occurred, and 38 gender- and age-matched cCSC patients from the multicenter randomized controlled trials PLACE and SPECTRA, who received treatment after baseline visit. In both groups, clinical characteristics and findings on multimodal imaging were assessed at first presentation. Most importantly, the OCT scan was analyzed for the presence of the Fuji sign, a novel morphological feature on OCT in which SRF has a triangular shape resembling the Japanese Mount Fuji. In addition, the number of focal leakage points on fluorescein angiography (FA) and presence of SRF on OCT in the fellow eye were assessed.

Results: The Fuji sign on OCT occurred significantly more often in the study group compared to the control group (16/38 (42.1%) vs 5/38 (13.2%), respectively; p=0.005). The number of focal leakage points on FA was 0.83 ± 0.72 in the study group and 1.71 ± 1.64 in the control group (p<0.001). SRF on OCT was also present in the fellow eye at baseline visit in 5/38 (13.2%) patients in the study group and in 9/38 (23.7%) patients in the control group.

Conclusions: The Fuji sign on OCT and number of focal leakage points on FA can help to identify which cCSC patients with foveal SRF have a higher chance of spontaneous SRF resolution without treatment.

ABSTRACT BODY:

Purpose: To compare the dose-response rate and treatment efficiency between occlusion therapy and dichoptic video gaming using VR goggles in children with amblyopia.

Methods: In this prospective Randomized Clinical Trial (NCT 03767985) newly diagnosed children with amblyopia were recruited. Visual Acuity (VA) was measured using the crowded tumbling E-chart. After informed consent they were randomized to patching therapy: 2 hrs/day; compliance was monitored electronically using the Occlusion Dose Monitor; or dichoptic video game therapy using VR goggles: 1 hr/wk under direct supervision. The dose-response rate and treatment efficiency were calculated for both groups using VA gains and objectively monitored treatment hours. Mann-Whitney U test was used to investigate differences in dose-response and treatment efficiency between the two treatment groups.

Results: Ninety-four children were recruited; 29 subjects refused and 2 were excluded. After refractive adaptation period, 23 subjects (24%) attained interocular VA <0.2 logMAR rendering them ineligible for the RCT; another 7 dropped out. Thirty-three children were included; median age was 5.4 (IQR 4.5-6.7) years. Mean compliance with occlusion therapy was 81±42%. Nine (56%) dropped out of the gaming group compared to 3 (18%) in the occlusion group. Reasons for drop-out in the gaming group were primarily due to young age (i.e. difficulties comprehending the game settings and the game itself) and logistic problems. After 24 weeks of treatment the median dose-response relationship for occlusion therapy was 71.78h/0.1 logMAR VA gain. For the gaming group this was 8.00h/0.1 logMAR VA gain. Median treatment efficiency was 0.08 (-0.19 – 0.68) VA gain/100 h in the occlusion group and 1.25 (0.42 – 2.08) VA gain/100 h in the gaming group ($p<0.001$).

Conclusions: Treatment efficiency and dose-response were significantly more favorable with gaming therapy compared to occlusion therapy after 24 weeks of treatment. However, more than half of the children from the gaming group failed to complete the treatment. Dichoptic video gaming using VR goggles seems to be most applicable in children older than 5.5 years of age with anisometropic amblyopia in whom the amblyopia persists after refractive adaptation.

ABSTRACT BODY:

Purpose: Cone photoreceptors drive both central and peripheral vision in most lighting conditions encountered during daily activities. Panretinal cone-driven responses can be measured using the light-adapted flicker electroretinogram (ERG). We analysed flicker ERG peak times recorded from over 1600 healthy adult twins to explore the distribution, association with age and heritability.

Methods: Participants were recruited from the TwinsUK cohort and underwent undilated photopic 28.3 Hz flicker ERG recordings (RETeval system with Sensor Strip skin electrodes, LKC technologies, Gaithersburg, MD). The device measured pupil diameter and adjusted stimulus strength to provide retinal illuminance (85 Td s white flicker; 850 Td white background) equivalent to the international standard. ERG peak times were averaged from both eyes. The distribution of responses and relationships with age were explored. Coefficients of intrapair correlation were calculated for monozygotic (MZ) and dizygotic (DZ) pairs as well as formal estimation of heritability by structural equation modelling.

Results: Recordings were obtained from 1594 participants (mean (SD) age 53.2 (16.5) years; 84% female). Mean (SD) peak time was 25.7 (1.3) ms (median 25.4 ms). The distribution deviated significantly from normality (Kolmogorov-Smirnov test $p<0.0001$). Following subtraction of a constant from each peak time, the reciprocal yielded a normal distribution (Kolmogorov-Smirnov $p=1$). Peak times showed significant positive correlation with age (Spearman correlation coefficient 0.54, $p<0.0001$). The increase with age was not linear; an expression by which the rate of change with age increased for older ages described the data mor closely than a simple linear fit. The participants included 675 full twin pairs (444 MZ and 231 DZ pairs). Coefficients of intra-pair correlation were 0.81 and 0.44 for MZ and DZ pairs respectively. Our estimate of heritability was 0.75 (95% CI, 0.70-0.78).

Conclusions: Peak times were not normally distributed, but their transformation to a normal distribution after taking the reciprocal (following subtraction of a constant time) might be consistent with some rate of signal processing being normally distributed. The relationship with age was not linear but showed a greater slope for older age groups. Approximately 75% of the variance in peak times could be attributable to genetic factors.

ABSTRACT BODY:

Purpose: Splicing is essential for most basic cellular processes. It is not known why mutations in the largest and most conserved component of the spliceosome (PRPF8) cause Retinitis Pigmentosa (RP13). We hypothesised that mis-splicing affects those processes critical for vision such as retinal development and cilia function[ML1] . This study investigates using iPSCs derived from four affected individuals and isogenic controls generated using CRISPR/Cas9. Retinal and non-retinal tissues were differentiated and analysed to make clear the tissue specific phenotype and identify similarities to other types of PRPF-linked RP.

Methods: Fibroblasts from one de novo and three familial patients with RP13 were reprogrammed to iPSCs via RNA-based transduction. The missense mutation in PRPF8 was then edited using CRISPR/Cas9 to generate paired isogenic control lines (n = 8). All lines were differentiated in parallel to retinal pigment epithelium (RPE), retinal organoids (RO) and kidney organoids using published protocols. Isogenic pairs were cultured, collected, and processed in parallel for a range of experiments including qPCR, immunofluorescence microscopy, and electron microscopy. Statistical analysis was performed using two-tailed paired t test, results shown as mean ± SEM.

Results: Expression of the mutant PRPF8 transcript was detected by qPCR in RP13 cells but not the RP13-Cas9 controls ($p < .001$ for all cell types). We investigated whether the mutation affects localisation to intranuclear domains enriched with splicing factors, known as nuclear speckles. The colocalization of PRPF8 and nuclear speckle marker SC35 was reduced in RP13 iPSCs, RPE and photoreceptors ($p < 0.05$ for all cell types). In addition, cilia of RP13 RPE were 10% longer ($p < 0.05$) and a fraction of these had swollen axonemes, but cilia frequency was unaffected. To gain insight into possible effects on tissue function we carried out a quantitative ultrastructural analysis. A significantly reduced number of mitochondria were found in RP13 RPE (10 ± 1 vs 17 ± 1, $p < 0.01$) and photoreceptors (57 ± 13 vs 107 ± 11, $p < 0.05$).

Conclusions: These results suggest that retinal and non-retinal tissues exhibit a splicing phenotype in RP13. Retinal cells exhibit ciliary defects and a possible metabolic shift that warrant further investigation. The combined splicing and ciliary phenotype presented resembles that caused by PRPF31 mutations.

SUBMITTER (NAME ONLY): Sandra Wagner

TITLE: Does reading text with inverted contrast affect the ciliary muscle structure of emmetropic and myopic eyes?

SESSION TITLE: Refractive Error: Myopia, Hyperopia, vision and models

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Wagner, T. Strasser, Institute for Ophthalmic Research Tuebingen, Eberhard Karls University Tuebingen, Tuebingen, GERMANY|T. Strasser, University Eye Hospital Tuebingen, Tuebingen, GERMANY|

Commercial Relationships Disclosure: Sandra Wagner: Commercial Relationship: Code N (No Commercial Relationship) | Torsten Strasser: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Previous research found that reading white text on black background increased the choroidal thickness in young adults, possibly inhibiting myopia (Aleman et al., 2018). We have already shown that prolonged reading of conventional text (black-on-white) leads to a thinning of the ciliary muscle (CM) in both emmetropes and myopes (Wagner et al., 2019). We aim to assess whether the contrast polarity of the reading material affects the CM structure and whether this differs between emmetropic and myopic eyes.

Methods: Optical coherence tomography (OCT) is used to image the subjects' CM at baseline and after having read binocularly white text on black background on an ebook reader for a continuous 30-min period at 25cm distance. Before and after the nearwork task, a minimum of 3 OCT images of the right eye's CM is taken while subjects first fixate a far (0D), then a near target (4D) with their left eye, respectively. OCT images are analyzed using custom-developed software to achieve CM thickness (CMT) profiles and selective CMT readings.

Results: Preliminary results with 6 adults (3 myopic, 3 emmetropic; age 19-43) showed that the CMT profiles of myopic eyes decreased after the 30-min reading period, while CMT profiles of emmetropes were rather thicker afterwards, especially for the 4D condition. Analysis of CMT changes (pre-post) likewise showed a thinning in myopic, but a CMT increase in emmetropic eyes in both target conditions (median emm/ my: 0D: -35.29µm/ 38.28µm; 4D: -12.70µm/ 57.19µm; Fig.).

Conclusions: Stimulating predominantly retinal ON pathways by presenting white-on-black text was previously found to produce a thickening of the choroid (Aleman et al., 2018). Our preliminary data suggests that the CM is also affected by the text's contrast polarity, however differing depending on the eye's refractive error. Emmetropic CM becomes rather thicker after reading white-on-black text, being in line with the previous finding of increased choroidal thickness. In contrast, the CM structure of myopic eyes, being thinner after the near task, seems to be unaffected by the contrast polarity, since post-task thinning has equally been measured for black-on-white text previously (Wagner et al., 2019). We further intend to increase the sample size to consolidate the preliminary outcome. A longitudinal dataset would allow to test whether the text polarity only affects the CM prior to myopia onset.

ABSTRACT BODY:

Purpose: To examine the distribution and interocular symmetry of foveal avascular zone (FAZ) parameters after correction for lateral magnification, in a large cohort of healthy, young adults.

Methods: Participants underwent a comprehensive ophthalmic examination including axial length measurement and optical coherence tomography angiography (OCTA) imaging of the macula. OCTA images of combined superficial and deep retinal vessel plexuses were processed via a custom software to extract foveal avascular zone area (FAZA) and vessel density in a 300-µm annulus surrounding the foveal avascular zone (FD-300), with and without correction for lateral magnification. Bland-Altman analyses were performed to examine the effect of lateral magnification on FAZA and FD-300, as well as to evaluate the interocular agreement in both parameters.

Results: OCTA images were acquired in 504 adults (261 females [51.8%], 243 males [48.2%]; average [standard deviation] age: 28.2 [0.7]). The mean (SD) of laterally corrected FAZA and FD-300 were 0.22 (0.10) mm^2 and 51.9 (3.2) %, respectively. Relative to raw, uncorrected data, 55.6% of corrected FAZA showed a relative change greater than 5% while all FD-300 changes were within 5%. There was good interocular symmetry (mean OD-OS difference, 95% limits of agreement) in both FAZA (0.006, -0.077 to 0.118 mm^2) and FD-300 (-0.05, -5.39 to 5.30 %).

Conclusions: Clinicians should strongly consider accounting for lateral magnification when evaluating FAZA. If working with a 5% error margin, correcting for lateral magnification is not necessary when evaluating FD-300. Good interocular agreement in FAZA and FD-300 suggests the contralateral eye can be used as control data.

ABSTRACT BODY:

Purpose: Glaucoma is characterized by progressive retinal ganglion cell loss and optic nerve degeneration, and is a leading cause of blindness worldwide. While pharmacological approaches aimed at lowering intraocular pressure (IOP) are effective at preventing vision loss, patient compliance is extremely poor. As such, there is a need for the development of a long-acting IOP-lowering gene therapy for glaucoma. Herein, we assess the tolerability and tropism of three recombinant adeno-associated virus (rAAV) vectors when injected intracamerally in a non-human primate (NHP) model.

Methods: Six sero-negative African Green Monkeys underwent ophthalmic examinations, including optical coherence tomography (OCT), confocal scanning laser ophthalmoscopy (cSLO), tonometry, pachymetry and slit lamp imaging, to establish pre-injection baseline values. Eyes (N=12) were randomized and injected intracamerally with either a high ($1x10^{12}$vg) or low ($1x10^{11}$vg) dose of rAAV2/2[MAX], 2/6 or 2/9 packaging a ubiquitously expressing green fluorescent protein (GFP) reporter, with the contralateral eye left uninjected as a control. Assessments were repeated 1, 3, 7, 14, 21, 28, 35, 42 and 49 days post-injection at which point eyes were enucleated for histology.

Results: Transient increase in IOP was observed in all rAAV treated eyes immediately following vector injection, with pressures returning to normal by day 7. Slit lamp bimicroscopy revealed increased inflammation as evident by increased cell counts immediately following injection, as well as a secondary phase of inflammation 14-21 days after injection, which both resolved spontaneously without pharmacological intervention. No permanent alteration in retinal volume or appearance was observed in any rAAV treatment eyes via OCT or SLO. Corneal thickness remained constant in 11/12 injected eyes. Specular microscopy at day 42 indicated in all injected groups there were no changes in endothelial health. cSLO imaging at D42 revealed fluorescence signal in several eyes indicative of GFP expression; histology confirmed signal in the lens capsule, iris, and iridocorneal angle.

Conclusions: Together the results indicate that intracameral administration of rAAV appears to be well tolerated in naïve NHPs, leading to transduction of anterior chamber structures and may be relevant for the treatment of glaucoma.

ABSTRACT BODY:

Purpose: Many inherited retinal degenerations (IRD) present with nyctalopia and peripheral vision loss. Despite this, spatial assessments of scotopic visual function are limited. Scotopic microperimetry combines scotopic two-colour (cyan and red stimuli) perimetry with fundus-controlled microperimetry. By analysing the cyan minus red stimuli sensitivity differences, it enables scotopic central retinal sensitivity mapping and spatial identification of photoreceptor dysfunction. Mesopic microperimetry has become a prominent outcome measure in IRD clinical trials. However, the use of scotopic microperimetry in IRDs is less well established, we sought to determine more about the usefulness of this test.

Methods: Participants underwent 20 minutes dark adaptation before two-colour scotopic microperimetry, on one eye, using the Macular Integrity Assessment System (MAIA; CenterVue, Padova, Italy), 37-point, ultra-wide radial grid, with cyan and red stimuli, respectively. Five participants underwent repeat scotopic testing. The reliability indices and repeatability were analysed.

Results: Thirteen participants with genetically confirmed IRD diagnoses (CHM = 10, USH2A =2 and RHO =1) and good visual acuity (mean VA 83 [SD±5] ETDRS letters) completed microperimetry. Three participants were excluded due to >20% fixation losses. The remaining 10 participants showed good fixation stability with a mean 95% bivariate contour ellipse fixation area of 1.57 (SD±1.71) and 2.56 (SD±3.62) degrees^2 for cyan and red stimuli, respectively. Mean cyan sensitivity (dB) was 5.36 (SD±6.9), mean red sensitivity was 8.41 (SD±7.7), cyan minus red sensitivity was -3.19 (SD±4.9). The individual test point repeatability for cyan stimuli was ±6.42dB, ±4.67dB for red stimuli and ±7.57dB for cyan minus red. Cyan minus red sensitivity plots showed both choroideremia and USH2A-associated retinitis pigmentosa (RP) participants had mixed rod/cone photoreceptor dysfunction. Whereas the Rho-associated RP participant showed diffuse rod specific dysfunction.

Conclusions: Scotopic microperimetry appears a reliable and repeatable marker of scotopic central macular sensitivity. However, to more accurately model the patterns of photoreceptor dysfunction in different IRDs, it may be necessary to consider specific pointwise test-retest variability values when categorising between rod versus cone retinal dysfunction.

TITLE: Clinical outcome of a modified treat-and-extend protocol in the treatment of neovascular age-related macular degeneration.

SESSION TITLE: AMD and Anti-VEGF

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: B.N. Vofo, Y. Cnaany, I. Chowers, Hadassah Medical Center Department of Ophthalmology, Jerusalem, Jerusalem, ISRAEL|

Commercial Relationships Disclosure: Brice Vofo: Commercial Relationship: Code N (No Commercial Relationship) | Yaacov Cnaany: Commercial Relationship: Code N (No Commercial Relationship) | Itay Chowers: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To compare the outcomes of neovascular age-related macular degeneration (nvAMD) patients treated with a modified treat and extend protocol (MTAE) to that of those treated with a conventional treat and extend protocol (TAE).

Methods: A retrospective analysis of two consecutive groups of treatment naive nvAMD patients was conducted. The first group began anti-vascular endothelial growth factor (VEGF) therapy between January 2006 and December 2011, and were treated using the conventional TAE protocol. The second group began anti-VEGF treatment between January 2016 and December 2017 and was treated using a MTAE. In the MTAE protocol, visual acuity and dilated fundus exams were performed once in 3 visits, while during the other 2 visits, an OCT assessment was used to guide retreatment. The time spent per encounter, and the visual and anatomical outcomes were compared between the two groups after 36 months of follow-up.

Results: The TAE and MTAE cohorts included 135 eyes (116 patients, 41.4% female, mean age: 76.9±7.8 years) and 119 eyes (94 patients, 55.3% female, mean age 79.8±6.8 years), respectively. Both groups had similar baseline characteristics. At 36 months, the number of injections administered, (7.9±2.9 vs 8.1±2.3 injections, respectively, p=0.55), the number of eyes that gained ≥15 Early Treatment for Diabetic Retinopathy Study (ETDRS) letters 31 (23%) vs 30 (25.2%), respectively (p=0.39) and lost ≥15 EDTRS letters 29 (21.5%) vs 21 (17.7%), respectively, were similar in both groups (p=0.43). Anatomical outcomes per OCT were also similar in both groups. Both waiting time and service time were reduced during OCT-only assessments compared to full assessments (32±20 minutes vs 56±40 minutes, and 9±4 minutes vs 26±10 minutes, respectively, p<0.001 in each case). Saving an average of 41 minutes for each patient encounter.

Conclusions: MTAE and TAE protocols yielded comparable visual and anatomical outcomes. Applying MTAE leads to reduced number of full assessment visits which is associated with shorter time spent in the clinic during the OCT-only assessment visits. MTAE may further streamline anti-VEGF therapy, thereby, reducing patient, caregivers, and staff time allocated to treatment.

ABSTRACT BODY:

Purpose: Age is a major risk factor for many retinal diseases which, together, are estimated to severely impact on the visual function of >1.8 billion people by 2050. The precise pathobiology underpinning age-associated retinal degeneration remains ill-defined although there is broad recognition that low-grade chronic inflammation plays an important role. Regulatory T cells (Treg) have recently emerged as key players in tissue homeostasis, due to their capacity to regulate local immune responses and limit inflammation, as well as their role in metabolic regulation, regeneration, and neuroprotection. However, the role of Treg in retinal homeostasis and age-associated retinal neurodegeneration is yet to be investigated.

Methods: Treg depletion was induced by intraperitoneal diphtheria toxin (DT) administration to Foxp3-DTR mice over 17 days (3 consecutive DT injections and then one DT injection every 4 days). The retinal neurovascular unit was assessed in young (3-4m) and aged (16-23m) Foxp3-DTR mice receiving DT, its vehicle (PBS) and C57BL/6 WT mice receiving DT. Gliosis (GFAP, Iba-1, CD68) and changes in neuronal populations (PKCα/secretagogin, rod/cone bipolar cells; Brn3a, retinal ganglion cells; Cone-arrestin, cone-photoreceptors) were assessed by immunohistochemistry.

Results: We observed a significant decrease Cone-arrestin^{+} and DAPI^{+} cells in the ONL in Treg-depleted aged but not young Foxp3-DTR mice, along with an alteration in the typical laminarity of cone and rod bipolar cells in the INL, further indicating retinal neurodegeneration. Aged Foxp3-DTR mice treated with DT also showed enhanced Müller cell gliosis, especially in the ONL. Interestingly, an increase in Iba-1^{+} cells was found in the ONL of aged Foxp3-DTR treated with DT as well as in the subretinal space of both aged and young Foxp3-DTR, together with RPE dysmorphology. Considering the differences observed between young and aged Treg-depleted mice, we analysed changes in expression in between young and aged Treg. When compared with young Treg, aged Treg showed an upregulation of genes linked to gene ontology terms related to neuronal processes, suggesting that with aging Treg may acquire a neuroprotective role.

Conclusions: Depletion of Foxp3^{+} Tregs exacerbates retinal neurodegeneration, Muller gliosis and microglia infiltration in aged animals compared to young controls. Hence, Treg have a key role in regulating immune homeostasis in age-related retinal pathology.

ABSTRACT BODY:

Purpose: Open globe injuries (OGI) are an important cause of visual impairment worldwide. This retrospective cohort analysis evaluates incidence and risk factors associated with open globe repairs (OGR) and visual acuity (VA) outcomes after surgery in the American Academy of Ophthalmology IRIS Registry.

Methods: Patients with OGR were identified by Current Procedural Terminology codes (65275, 65280, 65285, 65286, 65235, 65260, 65265) from 2014 to 2018 in the IRIS Registry. Annual and 5-year incidence rates per 100,000 persons were calculated. Factors associated with OGR and VA <20/40 and VA <20/200 at final follow up (3 to 12 months post OGR) were evaluated using multivariable logistic regression models adjusting for sex, race, ethnicity, US region, concurrent and subsequent surgeries, and baseline VA. Statistical analyses were performed in R.

Results: 15,316 OGR's were identified during the study period; 5-year incidence was 30.1/100,000. Annual incidence ranged from 10.9 to 12.7/100,000. OGR was positively associated with older v younger ages <21 yrs, e.g. > 80 yrs (OR, 4.9 [CI: 4.1-6.0]); male v female (OR, 3.1 [CI: 2.7-3.6]); Black v White race (OR, 1.7 [CI, 1.5-2.1]); Hispanic v Non Hispanic ethnicity (OR, 1.4 [CI, 1.2-1.7]); living in the South (OR, 1.40 [CI, 1.33-1.47]) and West (OR- 1.29 [CI, 1.21-1.36]) (v Midwest) regions and inversely associated with Asian v White race (OR- 0.5 [CI, 0.3-0.8]). Vision impairment final follow up was associated with VA <20/200 at presentation (20/200 v better than 20/40 - OR, 11.6 [CI, 8.0-155.6]); older age e.g. 80+ y (v < 21 y) (OR, 5.8 [CI, 3.2-10.7]); and Black race (v White) (OR, 1.8 [CI, 1.3-2.5]). Risk factors were similar for VA < 20/200 post OGR. Among all OGR patients presenting with VA 20/200 or worse, VA improved to 20/40 or better at follow up in 19% (331/1748) of patients; VA improved to better than 20/40 in only 10% (20/ 192) of Black OSR patients.

Conclusions: Our findings support previously established risk factors associated with OGR of older age and male sex and bring to light racial disparities in risk of OGI and poor visual outcomes that warrant further exploration.

ABSTRACT BODY:

Purpose: To explore the association of the genetic risk score (GRS) for the onset of Age-Related Macular Degeneration (AMD) with the adherence to the Mediterranean diet (MedDiet) – the Coimbra Eye Study (CES).

Methods: 612 subjects (161cases/451 controls) who completed a validated lifestyle and food frequency questionnaire were genotyped in collaboration with the European Eye Epidemiology Consortium. Cases were participants staged 2, 3 or 4 and controls were participants staged 0 (> 60 years-old) or 1 (> 70 years-old), Rotterdam Classification. The adherence to the MedDiet was calculated with mediSCORE (range 0-9) calculated by the sum of nine food group: vegetables, legumes, fruits, cereals, fish, meat, dairy products, fats and alcohol. High adherence to the MedDiet was defined as a mediSCORE equal or >6 (range: 6–9). A GRS was calculated using the 52 single nucleotide polymorphism identified by the International AMD Genomics Consortium. GRS was considered missing if at least one genotype of the major risk variants (CFH rs570618, CFH rs10922109, C2/CFB/SKIV2L rs429608, ARMS2 rs3750846 or C3 rs2230199) was missing. High GRS was classified as greater than or equal to the median. A multivariate logistic regression model with generalized estimating equations for 1216 individual eyes was used to examine the association of AMD, GRS and mediSCORE, controlled by age, sex, smoking and physical exercise.

Results: A higher adherence to the MedDiet was significantly associated with a decreased risk of AMD (OR=0.61, 95%CI 0.39-0.94, p=0.024) and a higher GRS was significantly associated with an increased risk of AMD (OR=2.44, 95%CI 1.66-3.58, p<0.0001). However, no statistical significant interaction was found between the GRS and MedDiet (p=0.284). Despite this, the adherence to the MedDiet was found to be protective for AMD in people with low GRS (OR=0.44, 95%CI 0.21-0.94, p=0.034), while no benefit was observed for people whose GRS was high (OR=0.70, 95%CI 0.40-1.22, p=0.212).

Conclusions: The MedDiet may be protective against the development of AMD, and this protection may depend on the genetic risk. However, it is crucial to carry out further studies on different populations, to clarify the interplay of AMD risk factors, particularly on the MedDiet, in the establishment of the pathophysiology of the disease.

Commercial Relationships Disclosure: Ismael Romero-Castillo: Commercial Relationship: Code N (No Commercial Relationship) | Laura Garcia-Posadas: Commercial Relationship: Code N (No Commercial Relationship) | Kieran Brennan: Commercial Relationship: Code N (No Commercial Relationship) | Alfonso Blanco: Commercial Relationship: Code N (No Commercial Relationship) | Yolanda Diebold: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The scarcity of in vitro models is an important drawback to study conjunctiva pathophysiology. The Immortalized Human Conjunctival Epithelial Cell line IM-HConEpiC is commercially available, but has not been widely used in research, yet. The aim of this study is to characterize this cell line and to use it as a source of conjunctival extracellular vesicles (EVs).

Methods: IM-HConEpiC cells were cultured with DMEM/F12 supplemented medium. Total protein was isolated in RIPA buffer and used for Western blot (WB). RNA was isolated in RLT lysis buffer and used for reverse transcription-PCR. Cells grown in slides were fixed and used for immunofluorescence (IF) microscopy. The expression of cytokeratin (CK) 7, CK8+18, CK19, E-cadherin, ZO-1, mucin (MUC) 4, and MUC5AC was analyzed by WB, IF, and/or PCR. IM-HConEpiC cells (passages 7-20) were also used to obtain EVs. Cells were grown to 70% confluence and treated with EVs free-FBS supplemented medium for 48 h. Medium was collected and EVs obtained by differential ultracentrifugation (UC) using two different methods (M): M1, at 4°C, with SW28 rotor, and M2, at 20°C and combination of SW28/SW60Ti rotors. All EVs were resuspended in PBS/trehalose and stored at -80°C for further analysis. The ExoStep Kit (ImmunoStep) was used for the detection and determination of the concentration of EVs by flow cytometry using a Beckman Coulter Navios cytometer. A Beckman Coulter CytoFLEX LX flow cytometer was used to individually characterize the EV content. EVs were morphologically analyzed by atomic force microscopy.

Results: IM-HConEpiC cells expressed CK7, CK8+18, CK19, E-cadherin, ZO-1, MUC4, and MUC5AC, as demonstrated by WB, IF and/or PCR. EVs were isolated from IM-HConEpiC with the two methods. The CytoFLEX results showed that IM-HConEpiC-EVs expressed the EV markers: CD9, CD63, CD81 and CD147 and that the majority of the EV subpopulation was made up of small EVs, with 66.06±2.23% (M1) and 62.63±0.4% (M2) having a similar violet SSC to 80nm Apogee beads.

Conclusions: Cultured IM-HConEpiC cells express typical conjunctival epithelial markers, suggesting that this cell line is a valuable tool for in vitro research. Although the EVs were properly isolated from the conditioned supernatants by UC, an exhaustive analysis is necessary to elucidate the abundance and composition of the different populations.

ABSTRACT BODY:

Purpose: GA, the advanced form of dry age-related macular degeneration (AMD), is a leading cause of blindness in the elderly; however, there is limited research on patient experiences. We conducted a qualitative study of the clinical, financial, and humanistic burden of GA to characterize patient perspectives on living with the disease. The results of this qualitative study guided the design of a global GA patient survey launched in 2021 and are being presented here for the first time.

Methods: Semi-structured interviews were conducted with 28 purposively sampled patients in the US (n=22), UK (n=4), and Australia (n=2). Inclusion criteria were age ≥60 years, a diagnosis of GA in at least 1 eye that did not also have neovascular AMD, and English fluency. Patients were excluded if they had neovascular AMD in both eyes, Stargardt disease, major cognitive impairment, or if they were in an AMD clinical trial or on any investigational agent to treat GA. Consensus-based coding and thematic analysis, using a primarily inductive approach, was conducted using ATLAS.ti. Thematic saturation was assessed in 5 waves and achieved in wave 4.

Results: Mean participant age was 80, and 48% of the sample was female. Major clinical burden concerns among patients included the lack of GA treatment and disease information, poor patient-provider communication, unpredictability of progression, and confusion about the difference between GA and wet AMD or other eye conditions. Major humanistic burden concerns included: impacts on mental health; impacts of visual changes on daily activities (reading, driving, shopping, cooking, cleaning, hygiene, personal care, and hobbies); impacts on social and family life. Patients reported the current or threatened loss of independence was their overriding concern. Key markers of independence included: driving, walking in unfamiliar places, and doing daily activities with little assistance. Patients reported personal injuries and driving accidents due to GA and worried about safety. Financial worries included affording products and services for the vision-impaired, job loss, and needing to hire care.

Conclusions: There is a clear significant unmet need for patients beyond therapy, including GA treatment, disease information, and social and mental health support. Further research is needed to understand the clinical, financial, and humanistic burden of GA on patients.

ABSTRACT BODY:

Purpose: Epidemiological studies demonstrated an association between elevated plasma high-density lipoprotein-cholesterol (HDL-c) levels and AMD. This is in contrast to the negative association of plasma HDL-c levels with the risk of cardiovascular disease. Apart from the statistical association, little is known with respect to the functional change of HDL in AMD patients. The capacity to mediate cellular cholesterol efflux is one of the major functions of HDL, followed by the transportation of cholesterol by HDL to the liver via a process called reverse cholesterol transport. Genetic studies identified genes associated with AMD, including ABCA1, CETP, LIPC and APOE that are also related to HDL-mediated cholesterol efflux. In accordance, we hypothesized that the cholesterol efflux capacity (CEC) of HDL is impaired in AMD patients, consequently leading to cholesterol accumulation underneath retinal pigment epithelium (RPE) cells, facilitating drusen formation.

Methods: To approach this, HDL was isolated from 30 AMD patients and 30 age-matched controls, and the capacity of HDL to mediate cellular cholesterol efflux from [^{3}H]-cholesterol-loaded ARPE-19 cells was assessed by measuring the percentage of [^{3}H]-cholesterol secreted into the culture medium. Unpaired T test and Mann-Whitney U test were used to assess the difference between patients and controls.

Results: We found no significant differences in CEC between AMD patients and controls when comparing HDL isolated from 1 ml of plasma from each individual. However, HDL from AMD patients with high, but not low plasma HDL-c levels, showed a decreased CEC (11.62%, p=0.027) per HDL particle as compared to healthy controls.

Conclusions: Together, our data suggest that impaired cholesterol efflux capacity of HDL is not causal for AMD pathogenesis but may be a result of other metabolic dysfunctions in AMD patients. Elevated plasma HDL-c levels in AMD patients might compensate for the decreased CEC per HDL particle.

ABSTRACT BODY:

Purpose: The most widely used classifications of age-related macular degeneration (AMD) are still based on color fundus photographs (CFP). Yet, OCT is the foundation of real-world clinical assessments of patients with AMD and may better subclassify the wide variety of its phenotypes. While it has been proven that AMD patients have a distinct plasma metabolomic profile compared to controls, all studies to date have used the traditional CFP classification systems. This study examined whether plasma metabolomic profiles are associated with OCT features commonly seen in AMD, a potential step forward towards a more comprehensive classification system for AMD.

Methods: Prospective, cross-sectional study, including subjects with AMD and a control group (> 50 years) from Boston, United States and Coimbra, Portugal. All participants were imaged with CFP, used for AMD staging (AREDS classification), and with spectral-domain OCT (Spectralis, Heidelberg). OCT images were graded by two independent graders for the presence of characteristic AMD features (i.e. presence of classic drusen, subretinal drusenoid

deposits, atrophy, among others), according to a predefined protocol. Fasting blood samples were collected for metabolomic profiling (using non-targeted high resolution mass spectrometry by Metabolon, Inc.). Multilevel mixed regression models were used for analysis, adjusting for sex and age. Analyses were first conducted for each cohort (US and Portugal), with subsequent meta-analysis using a fixed-effect inverse variance method.
Results: We included data on 477 subjects (n= 953 eyes), 381 with AMD and 96 controls, and on 718 named endogenous metabolites. Nine metabolite-OCT associations were identified ($p< 0.001$). Most associations were seen with amino acids (n=5). In particular, levels of histidine were associated with the presence of hyperreflective foci, ellipsoid zone disruption and extent of classic drusen. The presence of hyperreflective foci was the OCT feature associated with more metabolites (n= 4).
Conclusions: To our knowledge, we show for the first time that plasma metabolites have associations with specific OCT features seen in AMD. Metabolomics may offer a useful biomarker for an improved classification system for this complex disease with many clinical phenotypes.

ABSTRACT BODY:

Purpose: Fungal endophthalmitis is a relatively uncommon but serious complication of intraocular surgery or trauma and is often associated with poor prognosis. Its incidence has increased in recent years, particularly in tropical countries, with the main aetiology being filamentous fungi, particularly Aspergillus sp. The purpose of this study was to understand the protein cargo of Extracellular Vesicles (EVs) in a murine model of Aspergillus flavus endophthalmitis.

Methods: EVs were isolated by differential ultracentrifugation from C57BL/6 mice eyes challenged with A. flavus at 24-72 hours post-infection (p.i). Isolated EVs were characterized by Dynamic Light Scattering (DLS), ExoCet assay, western blot, and cytokine analysis. Mass spectrometry (LC-MS/MS) quantitative analysis was also performed for comparing the protein profile of these EVs with uninfected mice.

Results: EVs derived from eyes infected with A. flavus ranged from 200-250nm in diameter and the concentration was higher at 24 h p.i. $1.55x10^{10}$ ±554665251, in comparison to EVs from control -$1.24x10^{9}$ ($p = 0.001$). Western blot analysis confirmed the presence of markers: CD9, CD63, and CD81. In addition, IL-6 was significantly elevated at 72 h p.i in EVs from infected eyes ($p=0.02$). Proteomic analysis identified 81 differentially expressed proteins, of which 22 were upregulated and 59 were downregulated. Gene Ontology (GO) functional enrichment analysis of differentially upregulated proteins were enriched for transferase activity, protein complex, and tubulin binding such as CDS-diacylglycerol synthase-1(CDS1), fibrillin 1 (FBN1), microtubule-associated protein-4 (MAP4) and calmodulin-dependent protein kinase-2 (CAMK2G). Among the downregulated proteins, S100 calcium-binding protein (S100A9), annexin A1 (ANXA1), lactotransferrin (LTF), and transferrin (TRF) were associated with transport, negative regulation of apoptotic process, and phagocytosis. Additionally, KEGG pathway analysis revealed that differentially upregulated proteins participate in the glucagon signaling while downregulated proteins participate in metabolic and carbon signaling pathways.

Conclusions: Our findings reveal that EVs cargo in A. flavus endophthalmitis plays a key role in immune regulation and disease progression. Further validation of these proteins can serve as important prognostic markers in patients with fungal endophthalmitis.

ABSTRACT BODY:

Purpose: Tissue plasminogen activator (tPA) has been used as an adjunct to control intraocular inflammation after cataract surgery, with limited data on its use at the time of cataract surgery. We report the operative outcomes of intracameral tPA administered at the time of cataract surgery in eyes with uveitis, which are most at risk for post-operative inflammation.

Methods: A retrospective chart review identified patients with uveitis who received intracameral tPA at the time of cataract surgery between 2015 and 2021. Patients were excluded if they did not have a history of uveitis or if the surgery was not a primary cataract extraction. Surgeries were performed by four surgeons at one institution.

Results: Thirty-six eyes from 31 patients were identified. Mean ± standard deviation age was 36.3 ± 19.9 years. Anterior (66.7%) and idiopathic (41.7%) uveitis were most common. Eyes were absent of active intraocular inflammation for 5.8 ± 4.7 months prior to surgery. >90% had at least one coexisting ocular disease, including cystoid macular edema (50.0%), glaucoma (19.4%), steroid response (13.9%), epiretinal membrane (19.4%), and retinal detachment (5.6%). Anterior or posterior synechiae was present in 97.2% and intraoperative synechiolysis was performed in 94.4%. 52.8% were combined with planned pars plana vitrectomy. Acrylic (100%) single-piece (88.9%) lens placed in the capsular bag (94.4%) was most common. tPA dose of 12.5 µg (50.0%) or 25 µg (50.0%) was injected intracamerally at the surgeon's discretion. Thirty-four cases (94.4%) were uncomplicated. There was one anterior (2.8%) and one posterior capsular (2.8%) tear. LogMAR best corrected visual acuity (BCVA) improved from 1.0 ± 0.7 pre-operatively to 0.7 ± 0.7 post-operatively. 46.2% achieved BCVA ≤0.3 logMAR at 12 months, and only five (19.2%) remained at BCVA ≥1.3 logMAR. Improvement in BCVA was significant across all post-operative time points (p=0.0002). By month 1, 80.0% achieved anterior chamber cell grade of ≤0.5. Two eyes required repeat intracameral tPA injection at week 1 for fibrin formation. Posterior synechiae improved from 8.2 ± 3.8 clock hours pre-operatively to 0.1 ± 0.6 clock hours by month 12. Six eyes (16.7%) experienced hyphema; five (83.3%) resolved spontaneously.

Conclusions: Intracameral tPA administered at the time of cataract surgery in patients with uveitis appears to be effective in controlling acute post-operative inflammation.

ABSTRACT BODY:

Purpose:

Under physiological conditions, calcium and phosphate concentrations are tightly regulated, ensuring that calcification is restricted to bones and teeth. However, ectopic calcification in the extracellular space of soft tissues has been associated with ageing disorders including age-related macular degeneration (AMD), pseudoxanthoma elasticum (PXE), and generalized calcification in infancy (GACI). Ectopic calcification is associated with mutations on ectonucleotide pyrophosphatase/phosphodiesterase 1 (ENPP1). Here, we characterised the effects of exon 9 deletion in ENPP1 on ocular calcification and retinal structure and function.

Methods: ENPP1 transgenic mice were generated by breeding mice with loxP sites flanking ENPP1 exon 9 with mice expressing Cre recombinase behind a CAG synthetic germline promoter.. Wild type, heterozygous and knockout animals were maintained for up to 6 months. Animals were regularly assessed by colour fundus photography (CFP), optical coherence tomography (OCT) and electroretinography (ERG). In addition, cadaveric eyes were assessed for calcification using OsteoSense680EX and confocal fluorescent microscopy. $ENPP1^{-/-}$ animals were compared to $ENPP1^{+/-}$ and $ENPP1^{+/+}$ controls.

Results: On CFP we identified visible lesions in the $ENPP1^{-/-}$ animals. No measurable difference could be found in OCT segmentation. Analysis of the ERG traces showed no appreciable changes to scotopic A-wave. However, scotopic B-wave amplitudes were significantly increased with increased implicit time in $ENPP1^{-/-}$ animals(2.5 cd.s/m2: 567.7 µV vs. 442.8 µV, P value: 0.0193; 8.0 cd.s/m2: 685.2 µV vs. 511.2 µV, P value: 0.0037; 25.0 cd.s/m2: 779.8 µV vs. 561.2 µV, P value: 0.0015) . Staining of cadaveric eye tissues with Osteosense showed ectopic calcification in the Bruch's membrane but not in the retina. BrM calcification was more extensive in $ENPP1^{-/-}$ animals compared to $ENPP1^{+/-}$ and $ENPP1^{+/+}$ animals.

Conclusions:

Our preliminary studies indicate that deletion of exon 9 in the ENPP1 results in changes to retinal structure and function. The functional changes in the retina and the associated Bruch's membrane calcification could become a model for studying the effects of calcification and for the development of intervention strategies for diseases like AMD, PXE and GACI.

ABSTRACT BODY:

Purpose: To prospectively evaluate handheld retinal images assessed by AI at the time of imaging as compared to standard retinal image graders at a centralized reading center (RC).

Methods: Prospective comparative study of AI assessment of referable DR [(refDR) moderate nonproliferative DR (NPDR) or worse, or any level of diabetic macular edema (DME)] and vision threatening DR [(vtDR) severe NPDR or worse, or any level of center involving DME (ciDME)]. AI assessment of disc and macular images performed at the time of imaging was compared with RC evaluation of validated 5-field handheld retinal images [(5F) disc, macula, temporal, superior and inferior]. RC evaluation of the 5F images followed the international DR/DME classification. Sensitivity and specificity (SN/SP) for ungradable images, refDR and vtDR were calculated.

Results: 1,733 eyes from 869 diabetic (DM) patients were enrolled in the study. Cohort demographic: age 59.5±10.0, 64.7% female, 98.4% type 2, DM duration 6.6±7.2 years. RC distribution of DR severity: no DR 70.5%, mild NPDR 9.3%, moderate NPDR 7.6%, severe NPDR 3.7%, PDR 2.9%, ungradable 6.0%. DME severity: no DME 82.2%, DME 6.2%, ciDME 4.2%, ungradable 7.3%. RefDR was present in 13.8% and vtDR in 7.8% of eyes. Images were ungradable for DR or DME in 7.7% by RC and 20.7% by AI. Table 1 summarizes the SN/SP and operating characteristics of POC AI grading. SN/SP of AI grading compared to RC evaluation was 0.83/0.95 for refDR and 0.96/0.91 for vtDR. 4 eyes with vtDR (3 severe NPDR and 1 proliferative DR) were missed by AI. Comparisons of performance of the POC AI with existing FDA approved algorithms are presented in table 2.

Conclusions: This study demonstrates that POC AI following a defined retinal imaging protocol at the time of imaging has SN/SP for refDR that meets the current acceptable thresholds of 0.80 and 0.95. Integrating AI at the POC could substantially reduce centralized reading center burden and speeds information delivery to the patient, allowing more prompt eye care referral.

ABSTRACT BODY:

Purpose: One possible barrier to AI deployment in healthcare is over-reliance from users. This, known as automation bias (AB), has not been assessed in ophthalmology but may impact clinical decisions. We tested whether AB was present when optometrists used AI diagnostic support for retinal disease using an online experiment.

Methods: Thirty hospital optometrists (15 more experienced and 15 less experienced) assessed 30 cases. Ten consisted of an OCT scan, basic clinical information, and a fundus image (manual). Ten also displayed AI diagnoses suggestions (AI). Ten additionally displayed an AI-produced OCT segmentation map (segmentation). Participants chose the most probable diagnosis per case and gave their diagnostic confidence. Level of trust in the AI outputs was also reported. Cases were chosen to be matched across conditions and to give 70% accuracy on the AI diagnoses.

Results: Compared to the gold standard clinical diagnoses, 670/900 (74%) responses were correct. There were significantly fewer correct responses for segmentation (204/300, $p<0.001$) and AI (224/300, $p=0.049$) than manual (242/300) and for segmentation compared to AI ($p=0.010$). Agreement with correct AI diagnosis decreased when segmentations were displayed (174/210 vs 199/210, $p<0.001$)(Table 1), with examples suggesting that this may be due to participants paying more attention to segmentation maps over AI diagnoses. There was no significant effect of experience on the number of correct responses across the three conditions ($p=0.24$). More experienced participants were more confident in their diagnoses ($p=0.012$) and trusted the AI less ($p=0.038$). Participants trusted the AI more when segmentation was displayed ($p=0.029$) but AI did not affect diagnostic confidence ($p=0.461$).

Conclusions: Using an imperfect AI system has a significant negative effect on correct diagnoses irrespective of experience. Displaying segmentation maps may increase the likelihood of acceptance if used in practice due to an increased level of trust. If used together in practice, the synchronization of algorithms for segmentation maps and diagnostic suggestions must be improved.

ABSTRACT BODY:

Purpose: To determine the distribution of ocular pathology found in abnormal retina and optic nerve photos from an inner city vision screening program.

Methods: The goal of this study was to conduct vision screenings using in person and telemedicine modalities to improve vision care for residents of 10 New York City Housing Authority buildings in Upper Manhattan. Screening involved obtaining visual acuity, intraocular pressure, offering refraction services, and obtaining fundus and disc photos using a non-mydriatic hand-held fundus camera. Images were read by two ophthalmologists in the specialties of glaucoma and retina. Participants with abnormal image findings as well as those who had failed their screening and saw the on-site optometrist were referred to an ophthalmologist.

Results: A total of 382 participants were screened to date during the first phase of the study from March 2021-December 2021, with 6 months of screening remaining. Of these 382 participants, 110 were found to have failed screening (VA 20/40 or worse, IOP > 23-29 mmHg) and had an abnormal image (as determined by an ophthalmologist).

Participant ages ranged from 42 to 93 years, with mean 69 and median 70. 35 (32%) identified as male, and 75 (68%) as female. 57 (52%) participants identified as Black/African American, 46 (42%) as Latino/Hispanic, and 7 (6%) as American Indian, Asian, White, or Multiracial. 60 participants (55%) were referred as glaucoma suspects, and 73 (67%) were referred for retina findings. Several had overlapping findings. 26 participants (24.3 %) demonstrated non-proliferative diabetic retinopathy (dot blot hemorrhages, macroaneurysms, cotton wool spots), with 7 of these referred for treatment of edema. 1 (.9%) was found to have retinal neovascularization requiring treatment. 3 (2.7%) demonstrated findings consistent with retinal venous occlusion, with 2 of 3 requiring treatment for edema. 3 (2.7%) were found to have hypertensive retinopathy. 15 (13.6%) had findings of age-related macular degeneration. Regarding optic disc photos, 53 (48.2%) were found to have abnormal cup-to- disc ratio, and 13 (11.8%) were found to have peripapillary atrophy.

Conclusions: This study demonstrates that community-based vision screening using non-mydriatic fundus and disc photography detected significant pathology including diabetic retinopathy, age-related macular degeneration, and glaucoma, among the most common causes for blindness.

ABSTRACT BODY:

Purpose: For the image quality control of intraocular lenses (IOLs), ISO 11979-2 standard recommends the usage of small (2 to 3 mm) apertures for monofocal designs and both small and large (4 to 5 mm) apertures for multifocal ones. Historically, monofocal and multifocal IOL designs from different manufacturers were characterized by various amounts of pupil dependent optical behavior. JJSV developed IOL designs whose image quality is characterized by progressively higher pupil independence. In this context, for selected monofocal and multifocal designs, the current study evaluates the predictive reliability of 5 mm Modulation Transfer Function (MTF) metric for small apertures.

Methods: A large sample of TECNIS monofocal (ZCB00) and TECNIS Synergy (ZFR00V) IOLs was used for the evaluation of image quality in quality control conditions. Optical bench measurements were performed in an ISO11979-2 model eye 2 (c(4,0) = 0.27 micrometers). MTF at FAR was recorded for both 3 and 5 mm pupils and 546 nm wavelength. For each lens model and figure of merit, statistical evaluations were conducted to assess the measurements capability as well as their reliability to detect failed IOLs. Additionally, a correlation analysis by means of 2D histograms was conducted.

Results: For both lens models and MTF FAR metrics the standard deviations were ≤ 0.02 MTF units. Furthermore, the distance from the average to the specification limit for MTF at FAR with 5 mm was higher than 6.0 deviation units. For both lens models, for the 5 mm FAR metric the critical value corresponds to > 99.9% reliability for detecting failed IOLs with 95% confidence. For both lens models, the correlation analysis between the two MTF metrics evidenced a statistically significant ($p < 0.05$) and positive correlation.

Conclusions: For lens model TECNIS monofocal and TECNIS Synergy, the MTF at FAR with a 5 mm pupil is predictive for and more sensitive to variations than MTF at FAR with 3 mm pupil. Therefore, for specific lens designs, since the 5 mm measurement is a worst-case test condition, the addition of small pupil measurement is not relevant for IOL image quality control. Hence, for specific monofocal and multifocal IOL designs the ISO 11979-2 requirements for image quality control might be considered generic.

TITLE: Investigating the impact of degenerating photoreceptors on the behaviour of the retinal vasculature

SESSION TITLE: Photoreceptors and disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Byrne, N. Hudson, M. Campbell, Smurfit Institute of Genetics, The University of Dublin Trinity College, Dublin, IRELAND|

Commercial Relationships Disclosure: Kieva Byrne: Commercial Relationship: Code N (No Commercial Relationship) | Natalie Hudson: Commercial Relationship: Code N (No Commercial Relationship) | Matthew Campbell: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The influence of neuronal activity on the behaviour of the vasculature within the CNS is becoming increasingly recognized. Within the retina, this concept is not yet widely explored and the impacts of neuronal cell types such as photoreceptors on the retinal vasculature remain elusive. In this study we make use of the Rhodopsin knockout (Rho KO) mouse model to analyse the effect of decreasing photoreceptor activity on retinal vascular behaviour. In this model the key rod photoreceptor protein, Rhodopsin is knocked out, resulting in a progressive loss of photoreceptors over the course of 16 weeks, thus effectively allowing us to determine the relationship between the activity of these cells and the vasculature of the retina.

Methods: Transcript analyses were performed by quantitative PCR (qPCR) on Rho KO mice at 3-, 6-, 9- and 16-weeks of age, at AM and PM timepoints, and compared to age-matched wildtype controls at the same timepoints. Samples were screened for key Tight Junction proteins.

For immunohistochemical analyses a combination of retinal cryosections as well as retinal flatmounts were utilized at the same ages mentioned and stained with vascular markers such as IB4 and Claudin 5.

Results: Analyses reveal a changing behaviour within retinal vasculature with progressive photoreceptor loss. In particular, Cldn5 expression levels and patterns are altered in the model, with an apparent loss of normal circadian cycling of the gene as well as an overall decreased level of expression in Rho-/-mice. Additional immunohistochemical analyses reveal further changes to vascular patterning including tortuous vasculature in Rho-/- mice. Isolectin staining also reveals potential regression of blood vessels at late stages in this model.

Conclusions: Insights gained from this investigation indicate that loss of photoreceptor activity is impacting the expression profile of key vascular genes and proteins, most especially the key barrier forming component Claudin-5. This is indicative of a cross-communication between these cells and the retinal vasculature and provides some interesting insights into the factors involved in the complex regulation of the retinal vasculature.

ABSTRACT BODY:

Purpose: Retrospective case-control evaluation of neuroimaging findings acquired over 8 years in 6 distinct pediatric groups (142 subjects) was performed to objectively analyse whether periventricular white matter changes on magnetic resonance imaging (MRI) in esotropic (ET) subjects denoted perinatal insults, as anecdotally reported.

Methods: The study cohort comprised developmentally and neurologically normal ET (Group A, n=26, 5.2±3.3 years, 14 males) exotropic (XT, Group B, n=29, 9.1±4.2 years, 14 males) and orthotropic (Group C, n=19, 7.8±4.5 years, 10 males) subjects, as also, children with established perinatal insult and global developmental delay (GDD) presenting with ET (Group D, n=24, 3.3±3.2 years, 17 males), XT (Group E, n=11, 5.8±6.2 years, 7 males) and orthotropia (Group F, n=33, 4.3±3.9 years, 20 males). Sequential brain MRI analysis (1.5T, Siemens Symphony) evaluated gross changes like ventricular dilatation, encephalomalacia and gyral atrophy as well as subtle periventricular and other non-specific white matter changes.

Results: Structural brain parenchymal changes were ubiquitously seen in all three groups with established GDD though they were significantly less in the orthotropic versus the ET group (p=0.007) and completely absent in the group without GDD irrespective of the presence or type of strabismus. Periventricular white matter changes, while observed in all groups was significantly more in all three GDD groups (Group A versus Group D, ET, p=0.004; Group B versus Group E, XT, p=0.0002; Group C versus Group F, orthotropic, p=0.008). Subjects with orthotropia with no GDD had significantly lesser periventricular changes than those with ET and XT (Group D versus Group F, p=0.006; Group E versus Group F, p=0.02).

Conclusions: ET subjects with GDD demonstrated significantly more encephalomalacia than orthotropic subjects with GDD. Significantly greater extent of periventricular white matter changes was observed in developmentally and neurologically normal ET and XT subjects versus orthotropic subjects (Figure 1a-f). This novel clinico-radiological spectrum generates thoughts on its role in the genesis of concomitant strabismus in neurologically normal children.

TITLE: Applications of Ripasudil Beyond Descemet Stripping Only: A Case Series

SESSION TITLE: Refractive and non-refractive corneal surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Tseng, R. Feder, Ophthalmology, Northwestern University Feinberg School of Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Michael Tseng: Commercial Relationship: Code N (No Commercial Relationship) | Robert Feder: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Ripasudil is a rho-kinase inhibitor that is approved in Japan as a twice daily treatment for glaucoma. Ripasudil has gained popularity recently, particularly when used in conjunction with Descemet stripping only (DSO) to hasten visual recovery. Ripasudil has been shown to increase corneal endothelial cell proliferation, intercellular adhesion, and decrease endothelial cell apoptosis. We present 4 cases in which persistent corneal edema following various anterior segment surgeries was successfully treated with ripasudil.

Methods: Retrospective chart review revealed 4 patients who were started on ripasudil due to persistent corneal edema that failed to improve with conventional, non-surgical treatments.

Results: All patients were women. The median age was 73 (mean age was 73, range 66-80. Each patient had symptomatic, persistent corneal edema following anterior segment surgery. All cases achieved improved vision and resolution of edema with the use of ripasudil after 4-6 weeks. One patient had a DSEK that required re-bubbling twice, but had persistent nasal detachment and edema involving the visual axis. Topical Ripasudil 4 times daily was initiated. After 1 month the graft was adherent to the host with resolution of edema. One patient had corneal edema involving the temporal 50% of a penetrating keratoplasty graft following routine cataract surgery which did not improve after intensive topical and oral steroids. The edema cleared after one month on ripasudil. Two patients had persistent edema after cataract surgery. Both patients failed to improve over time with topical steroids or hypertonic sodium chloride ointment. Ripasudil improved the patients' edema and vision after 4-6 weeks of use.

Conclusions: In patients with corneal edema resulting from surgical trauma to the endothelium, who failed to clear over time despite conservative measures, ripasudil was shown to be an effective treatment option that helped prevent the need for endothelial transplantation.

TITLE: The Role of Oxidative Phosphorylation in Müller Glia Survival

SESSION TITLE: Novel animal models and neuroprotection in the retina

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Nsiah, D.M. Inman, Pharmaceutical Science, University of North Texas Health Science Center, Fort Worth, Texas, UNITED STATES|N. Nsiah, D.M. Inman, North Texas Eye Research Institute, Fort Worth, Texas, UNITED STATES|

Commercial Relationships Disclosure: Nana Yaa Nsiah: Commercial Relationship: Code N (No Commercial Relationship) | Denise Inman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The importance of mitochondria to the energy production of Müller glia (MG), the main glial cells of the retina, is controversial. Previous studies showed MG are mainly glycolytic. Others challenge this view because MG are deficient in key glycolytic enzymes. Our goal is to potentially settle this debate by destabilizing the electron transport chain in MG mitochondria and assessing how retinal metabolism may be impacted.

Methods: MG that lack oxidative phosphorylation in vivo through destabilization of Complex IV were generated using $GLAST^{CreERT2}::Cox10^{fl/fl}$ transgenic mice. Mice received daily tamoxifen injections for 5 consecutive days beginning at P30. Confirmation of recombination of the floxed Cox10 locus and enzyme activity was performed using PCR analysis of genomic DNA isolated from the retina and sequential cytochrome c oxidase (COX)/succinate dehydrogenase (SDH) histochemistry, respectively. Cell lysates from primary Müller cells were used for western blotting and total protein analysis. Full-field electroretinography (ERG) was performed to assess MG function from transgenic and wild-type mice in vivo. Scotopic ERGs were recorded (OcuScience® HMsERG, Xenotec Inc., Henderson, NV) in response to six light flash intensities ranging from −3 to 1 log cd x s/m^2 on a dark background. Each stimulus was presented in a series of three. Data were analyzed with GraphPad Prism and ERG b-wave amplitudes were compared using a paired two-tailed Student's t-test. The b-wave amplitude was measured from the trough of the a-wave to the peak of the b-wave.

Results: A 465bp DNA fragment amplified from genomic DNA of mutant mice, with no corresponding fragment from control, confirmed Cox10 locus recombination. Total protein analysis, with normalization to the mitochondrial protein VDAC1, showed lower levels of cytochrome c oxidase protein from mutant mice compared to controls. Scotopic ERG b-wave was not significantly different between mutant and wild-type age-controlled mice at all light intensities. No overt retinal abnormalities were observed in $GLAST^{CreERT2}::Cox10^{fl/fl}$ transgenic mice.

Conclusions: Our results show that cre recombinase induction in $GLAST^{CreERT2}::Cox10^{fl/fl}$ successfully inhibits cytochrome c oxidase activity in MG from adult mice. Our in vivo experiments suggest that oxidative phosphorylation is not necessary for Müller glia energy metabolism under physiological conditions.

ABSTRACT BODY:

Purpose: Visual Acuity (VA) is usually measured at a distance of 3-6m (10-20 feet) because it is affected not only by neural (i.e. amblyopia) but mostly by optical (i.e. myopia) factors. VA can be measured using a smartphone, however the size of the device's screen can limit the maximum measurement distance to less than 2 m for low VA's due to the target not fitting on the screen. We study a new method to measure VA interactively with smartphones, at a distance comfortable for the patient, avoiding the optical limitations due to its proximity to the patient.

Methods: Standard clinical measurements of not corrected VA were performed in both eyes of 24 subjects of different ages (35 ± 16 years), using an ETDRS optotype placed 6 m away. These measurements were compared with those obtained with a mobile application (app) used on four different devices. The test used for the measurements with the electronic device consisted of a Landolt C optotype following a four-choice algorithm. Target's size is rescaled automatically by a continuous measurement of the distance device-user by means of the front camera of the device. A blue letter on a black background was used as target so that the measurement made at a distance of 1 or 1.5 m was equivalent to that of a black and white test located at a distance of 3 m or infinity, respectively, due to the longitudinal chromatic aberration of the human eye.

Results: The mean difference between clinical and experimental values of VA for both eyes were 0.013 ± 0.155 and 0.009 ± 0.174 logMAR for the test located at 1m and 1.5 m, respectively. The statistical analysis showed no significant differences between the clinical values and those obtained by the device (p-value 0.443 and 0.461 for measurements at 1 and 1.5 m, respectively). Statistical analysis performed for each eye separately yielded similar results.

Conclusions: The results show that it is possible to measure VA with this novel method, and obtain results on par with the clinical standard (mean difference less than one letter on a line). The method can be used to screen for anomalies limiting patients' VA so that they can be referred to an eye care professional, as well as for a remote follow-up of the evolution of a treatment such as amblyopia.

TITLE: Qualitative investigation of information behaviour in individuals with visual impairment to inform virtual digital-assistant design

SESSION TITLE: Quality of Life Outcomes, Rehabilitation and Training Programs

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Taylor, A. Freitas, D. Mendes Ferreira, C. Dickinson, The University of Manchester, Manchester, Manchester, UNITED KINGDOM|A. Subramanian, City University of London, London, London, UNITED KINGDOM|

Commercial Relationships Disclosure: John Taylor: Commercial Relationship: Code N (No Commercial Relationship) | Ahalya Subramanian: Commercial Relationship: Code N (No Commercial Relationship) | Andre Freitas: Commercial Relationship: Code N (No Commercial Relationship) | Deborah Mendes Ferreira: Commercial Relationship: Code N (No Commercial Relationship) | Chris Dickinson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: People living with visual impairment (VI) can find it difficult to access the right information to help support them with their rehabilitation needs. We used a questionnaire and interviews to investigate the information seeking behaviour of individuals with VI and how they would view the use of a virtual digital assistant to obtain information.

Methods: Qualitative data were collected from UK resident adults who were either visually impaired, a carer or family member of someone with VI, or a professional involved in the support of those with VI. A survey was developed and completed online by 120 participants. In addition, 10 in-depth 1:1 semi-structured interviews were conducted to investigate opinions in more detail. Thematic analysis was used to analyse the findings.

Results: Analysis of information needs identified 7 major themes as important: (1) ocular condition (2) equipment, technology and adaptations (3) daily activities (4) registration (5) finance/employment (6) emotional support (7) support for the carer. Participants used a wide variety of methods to access information across a broad range of sources, and highlighted experience of numerous barriers while accessing information. Participants appeared to be accepting of the potential merits of a dialogue system (virtual digital assistant) aiding in a goal-directed search for a specific piece of information, but often expressed reservations about its abilities in other areas such as dealing with more complex issues and providing emotional support. They described potential advantages including: ease of use (accessible format), control over the timing, quantity and type of information provided, help with navigating and integrating the large array of information sources available, and providing a foundation of basic information to help support those who don’t know what to ask about. Participants also reported that information provided needs to be relevant, targeted, understandable, accurate and trusted.

Conclusions: Participants highlighted potential benefits, limitations and requirements in using a digital virtual assistant. These findings will inform the design of a virtual assistant aimed at improving access to information and support for populations with VI.

TITLE: The effect of uncorrected astigmatism on the reading performance of contact lens neophytes

SESSION TITLE: Optics: Accommodation, Lens and Ocular Biometry

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Gil Fernández, J. Tabernero, Electromagnetismo y Electrónica, Universidad de Murcia, Murcia, Murcia, SPAIN|P. Gil Fernández, A. Farcas, C. Hernandez, A. Benito, J. Tabernero, Laboratorio de Óptica, Universidad de Murcia, Murcia, Murcia, SPAIN|

Commercial Relationships Disclosure: Pedro Gil Fernández: Commercial Relationship: Code N (No Commercial Relationship) | Alexandra Farcas: Commercial Relationship: Code N (No Commercial Relationship) | Celia Hernandez: Commercial Relationship: Code N (No Commercial Relationship) | Antonio Benito: Commercial Relationship: Code N (No Commercial Relationship) | Juan Tabernero: Commercial Relationship(s);Code F (Financial Support):Alcon

ABSTRACT BODY:

Purpose: To compare the effect of toric contact lenses versus spherical soft contact lenses on the reading performance of novel contact lens users with low astigmatism.

Methods: The reading test consisted of two paragraphs of 92 and 97 words divided into six lines (Arial 10 font) shown on a 23.6” screen at a reading distance of 60 cm. Reading performance parameters (reading time, number of fixations, number of regressions and magnitude of saccades) were recorded using an eye-tracking device (GP3 HD, Gazepoint, Vancouver, Canada) at a frequency of 150 Hz. Additionally, contrast sensitivity (CS) was measured with a Visual Adaptative Optics simulator (VAO; Voptica SL, Murcia, Spain) at frequencies of 9 and 15 cpd, respectively. Nineteen first-year university students were recruited. They were all contact lens neophytes, divided into two groups, matched by age and refractive error (no statistically significant differences). Subjects in group one (N=10; age 19 ± 2 years; sphere -2.3 ± 0.7 D; cylinder -0.9 ± 0.3 D) were monocularly fitted with a spherical contact lens (Precision1, Alcon Laboratories, Inc, Fort Worth, TX) while subjects in group two (N=9; age 21 ± 3 years; sphere -2.3 ± 1.3 D; cylinder -1.0 ± 0.4 D) were fitted with a toric lens (Precision1 for Astigmatism).

Results: Saccadic regressions during reading were larger ($p<0.05$) in the group of spherical lenses (mean 22 ± 15) than in the group of toric lenses (mean 14 ± 6). On average, all parameters that characterize reading performance showed a similar tendency, being slightly worse and showing more variability in the spherical group than in the toric group of subjects. For instance, the number of fixations, saccade magnitude and reading time reduced by 10%, 9% and 7%, respectively in the toric group compared to the spherical group. We also observed a significant reduction ($p<0.05$) of the contrast sensitivity threshold at 9 cpd from 9 ± 7% in the spherical group to 4 ± 1% in the toric group and also at 15 cpd, with a 52% reduction of the threshold in the toric group.

Conclusions: A full correction of astigmatism with a toric CL (Precision1 for Astigmatism) improved visual performance in a broad sense, with better CS but also better reading performance. These results may suggest instantaneous visual benefits of fitting toric lenses versus spherical lenses in contact lens neophytes with low astigmatism.

ABSTRACT BODY:

Purpose: To obtain on-eye clinical performance data and assess contact lens alignment and fit characteristics of a novel toric silicone hydrogel contact lens (verofilcon A) for astigmatism

Methods: In this prospective, open-label, single-arm, bilateral, multicenter clinical study, eyes of healthy participants were fitted with verofilcon A contact lenses. The study evaluated lens alignment and fit characteristics. Lens alignment was determined in terms of the percentage of lenses with axis orientation within ±5°, ±10°, and ±20° from the intended 90° axis; and lens oscillation with blink on a 4-point scale (none, <3°, 3° to 5°, and >5°). The lens fit characteristics were recorded in terms of lens position and movement. Safety endpoints assessed include adverse events (AEs), device deficiencies, and biomicroscopy findings

Results: A total of 39 subjects (78 eyes; mean (SD) age, 34.1 (10.8) years; female, 66.7%) were exposed to study lenses. The mean (SD) lens settling time was 40.1 (56.8) seconds. At 10 minutes, the proportions of lenses orienting within ±20°, ±10°, and ±5° from the intended axis were 100%, 98.7%, and 89.7%, respectively. The mean (SD) absolute axis orientation at 2 minutes was 2.7 (3.6) degrees. The majority of lenses (98.7%) had less than 5° of oscillation or no oscillation with blink. All lenses studied achieved optimal or acceptable fit (optimal, 88.5%; acceptably tight, 6.4%; and acceptably loose, 5.1%) and optimal or acceptable centration (optimal, 97.4%; and acceptable decentration, 2.6%). There were no AEs, device deficiencies, or clinically relevant changes to biomicroscopic findings

Conclusions: The novel toric verofilcon A contact lens showed optimal alignment and fit without any safety concerns. Owing to the unique material features, advanced surface technology, optimal lens alignment, and fitting characteristics of this lens, it could offer astigmats a better contact lens wearing experience

ABSTRACT BODY:

Purpose: The programmable double-strand break (DSB) inducing endonuclease CRISPR/Cas9 has emerged rapidly over the past years. Non-homologous end joining (NHEJ), microhomology mediated end joining (MMEJ) and homology directed repair (HDR) compete in the repair of the DSB, leading to unwanted insertions/deletions. Inactivation of one of the two catalytic active cleavage domains of the Cas9 molecule generates a nicking Cas9 (nCas9), which cleaves only one DNA strand, recruiting single strand repair molecules instead of DSB repair proteins. The Prime Edit (PE2) system uses a transcriptase fused to an nCas9 in combination with an extended prime edit guide RNA (pegRNA) containing a transcriptase template harboring the desired edit. The PE3 system uses an additional nicking guide RNA (ngRNA) targeting the opposite DNA strand. Employing the PE system, we aim to quantify the correction efficiency of the porcine Abca4 V1965X mutation (insertion of an adenine), using a cellular bioluminescence resonance energy transfer (BRET) based reporter system.

Methods: Porcine Abca4 sequence containing the target mutation was cloned into the BRET reporter plasmid. Overall, 15 different pegRNAs were designed and cloned into a plasmid containing a U6 RNA promotor. HEK293-T cells were transfected with the Prime Edit Cas9, pegRNA (with/without additional nicking guide RNAs) and the BRET reporter. Correction of the target was analyzed by fluorescence microscopy, western blot and a BRET assay.

Results: Prime editing using the PE2 system did not result in a significant correction as shown by western blot, fluorescence microscopy and the BRET assay. Additional nicking of the opposite DNA strand with the PE3 system generated a massive enhancement in correction activity of up to 91 ± 5 % measured with the BRET assay in dependence of pegRNA composition and ngRNA nicking position. Resulting correction measured with the BRET assay could be verified by fluorescence microscopy and western blot.

Conclusions: We showed that the correction of an adenine insertion using the Prime Edit system can be reliably measured and quantified with the cellular BRET assay. Especially the PE3 can be a potential alternative to MMEJ- and HDR-based genome editing approaches, with comparably high correction rates, notably in post-mitotic cells.

ABSTRACT BODY:

Purpose: DA assessed using optical coherence tomography (OCT) imaging and visual parameters is important for monitoring nAMD. We developed an AI-based DA model to support physicians who treat patients with nAMD with anti-vascular endothelial growth factor (VEGF) agents. We assessed the performance of the DA model in deriving a DA score in an adjudication study.

Methods: Measurements of OCT features and best-corrected visual acuity collected from patients evaluated with Heidelberg spectral domain (SD)-OCT during the phase 3 brolucizumab versus aflibercept HAWK (NCT02307682) & HARRIER (NCT02434328) (H&H) studies were used to develop an AI-based DA model. A retrospective review of selected DA assessments from the H&H dataset was conducted with an independent panel of 10 retina specialists (RS) to further train the model. DA was deemed to be present if the RS indicated treatment was needed and absent if no treatment was indicated. Three categories of DA assessment were defined using model-derived DA score and prediction uncertainty (Table 1).

Results: To train the DA model, 8970 longitudinal DA assessments from a total of 948 patients evaluated with Heidelberg SD-OCT by H&H study investigators were used. This model achieved a cross-validated accuracy of 0.84 (0.87 sensitivity, 0.84 specificity). The RS panel reviewed 486 selected DA assessments from 403 patients. Figure 1 shows the accuracy, sensitivity, and specificity achieved by RS, H&H investigators, and DA model for three categories of DA assessment. The DA model reached 0.94 accuracy and performed as well as RS and H&H investigators for ‘easy’ DA assessments. While the DA model outperformed H&H investigators for both ‘potential label noise’ (accuracy 0.67 vs 0.38) and ‘difficult’ DA assessments (accuracy 0.74 vs 0.58), the DA model underperformed the RS in these categories (mean RS accuracy 0.86 for ‘difficult’ and 0.82 for ‘potential label noise’ assessments).

Conclusions: In this study, we demonstrated encouraging performance of a model in detecting DA in nAMD patients treated with anti-VEGF agents. While further refinements and improvements are planned, these preliminary results suggest the potential of an AI-based DA algorithm in improving the consistency of treatment decisions based on DA assessments.

ABSTRACT BODY:

Purpose: Deep learning enhanced computer aided diagnoses have the potential to help increase the efficiency of image heavy clinical workflows. However, performance of medial deep learning is often limited by (i) lack of large medical training sets due to the high cost of annotations (ii) the heterogeneous, and subtle feature differences in objects of interest. In this work we propose that the inherently structured anatomical topology of a given imaging modality can be leveraged to allow a CNN to learn a more robust embedding by contrasting pairs of normal and abnormal images thereby improving the performance of object detection on pathological features.

Methods: This project leveraged open source Heidelberg Spectralis AMD OCT*, with 600 images expertly annotated for 9 classes of features of interest were. A YOLOv4 network was adapted to contain a novel contrastive induced gated attention module (CIGA) which leverages the anatomical topology to aid detection of pathological objects. The baseline YOLOv4 network was trained on the OCT images and the performance of the CIGA module was assessed by fine-tuning the baseline with the CIGA. The training process was performed with multiple repeats.

*Reza et al, IEEE Transactions on Medical Imaging, 37(4):1024-1034, (2018)

Results: The fine-tuning with the CIGA module produced better overall MAP50 values than the baseline network alone. The CIGA network produced an overall test MAP50 of 0.654(0.023) compared to the baseline performance of 0.635(0.01) and a test mAP50:95 of 0.369(0.007) compared to the baseline performance of 0.355(0.01). Performance was also assessed for the nine classes of pathological feature such as Hyperfluorescent spots where the CIGA achieved an MAP50 of 0.732(0.049) compared to the baseline 0.680(0.021) and PR layer disruption where the CIGA achieved an MAP50 of 0.712(0.095) compared to the baseline performance of 0.635(0.018).

Conclusions: In this work we propose the CIGA network and demonstrate incremental performance gains for the task of object detection in OCT scans. This was achieved by leveraging the structured topological information in the anatomy with the help of gated attention under a contrastive learning framework to enhance the signal of the different pathological objects. This method will improve detection of small biomarkers from imaging, which are traditionally difficult to detect using traditional deep learning methods.

ABSTRACT BODY:

Purpose: In the last decade, association studies have focused on dissecting the genetic factors underlying refractive error (RE). These studies resulted in the identification of almost 500 associated loci and potential candidate genes. To explore the genetic mechanisms driving RE development, we made a prioritization of 11 candidate genes based on biological and statistical evidence (i.e., PRSS56, FBN1, TJP2, PDE11A, SHISA6, LAMA2, LRRC4C, KCNQ5, GNB3, RBFOX1, and GRIA4), and generated mutant zebrafish models. In these models, we screened for abnormalities in axial length (AL) and refractive status.

Methods: Published transcriptome databases were assessed to examine whether candidate genes were expressed in human ocular tissues; expression in zebrafish ocular tissue was confirmed by RT-PCR. CRISPR-cas9 was used to generate 11 mutant zebrafish lines. Ocular biometry assessment was performed in lines without large morphological abnormalities and normal breeding rates (n=8). AL was measured at 2 and 4 months (n=20 eyes per group) using Spectral Domain Optical Coherence Tomography which visualized the entire eye; refractive status was measured using a custom eccentric photorefraction setup.

Results: Our database search and expression study in the zebrafish eyes confirmed that all genes were expressed throughout human and zebrafish eyes. Three of the eight studied mutant lines (lama2$^{-/-}$, lrrc4c$^{-/-}$, kcnq5$^{-/-}$) showed a significant ($p<0.01$) increase in AL and corresponding myopic shift in refractive status ($p<0.01$). Two of the three mutants showed the largest increase in AL at 2 months (lrrc4c$^{-/-}$: 140 µm, kcnq5$^{-/-}$: 151 µm) which stabilized at 4 months (lama2$^{-/-}$: 69 µm, lrrc4c$^{-/-}$: 114 µm, kcnq5$^{-/-}$: 92 µm). In line with previous reports in other animal models, the prss56$^{-/-}$ mutant showed a significant reduction in AL (-157 µm, $p<0.001$) and a nanophthalmos-like phenotype at 2 and 4 months. In the other four studied lines (fbn1$^{-/-}$, tjp2$^{-/-}$, pde11a$^{-/-}$, shisa6$^{-/-}$) no significant changes in AL were observed.
