TITLE: The challenge of treating the severest forms of chronic non-infectious posterior and panuveitis
SESSION TITLE: Clinical Uveitis and Scleritis: Therapies and Outcomes
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: C. Spartalis, N. Stübiger, M. Spitzer, U. Bartsch, Y. Atiskova, Department of Ophthalmology, Universitatsklinikum Hamburg-Eppendorf, Hamburg, Hamburg, GERMANY|
Commercial Relationships Disclosure: Christoph Spartalis: Commercial Relationship: Code N (No Commercial Relationship) | Nicole Stübiger: Commercial Relationship(s);Code R (Recipient):Allergan;Code R (Recipient):Abbvie;Code R (Recipient):Novartis;Code R (Recipient):Visupharma | Martin Spitzer: Commercial Relationship: Code N (No Commercial Relationship) | Udo Bartsch: Commercial Relationship: Code N (No Commercial Relationship) | Yevgeniya Atiskova: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The aim of the study was to evaluate a cohort of patients, suffering from the severest forms of NIUP or panuveitis, with a special focus on therapy efficacy, therapy-associated adverse side effects and the need of medication switch.

Methods: In the present study a cohort of 18 patients (35 eyes) presenting with the severest forms of chronic non-infectious posterior or panuveitis (ocular Behçet's syndrome, Birdshot Chorioretinopathy, Vogt-Koyanagi-Harada syndrome and Serpiginous Choroiditis) were included. All patients were evaluated regarding the clinical course of the disease with a particular focus on best-corrected visual acuity, treatment duration, remission rates, reported negative side effects and the necessity of switching the medication.

The study was performed in accordance with the Declaration of Helsinki and approved by the medical ethics committee of the General Medical Council Hamburg, Germany (2020-10344-BO-ff)

Results: The cohort's mean age was 45.4 years, twelve patients were male, six were female. The mean follow-up period was 27.8 months. The best-corrected visual acuity improved significantly from baseline to end of follow-up ($p=0.048$). However, complete or partial remission was observed in only 66.7%. 72.2% of the patients underwent a switch of the medical treatment due to either adverse events or inefficacy of medication.

Conclusions: Despite new immunosuppressive therapies, effective treatment of severe non-infectious posterior and panuveitis remains a major challenge. As several therapy changes were necessary in the presented cohort for achieving partial or complete remission. The data shows the urgent need for additional and novel treatment strategies, to prevent systemic adverse effects, and to effectively improve visual outcome and prevent blindness.

SUBMITTER (NAME ONLY): Gulgun Tezel

TITLE: Immunomodulatory Outcomes of Astroglial p65 Deletion in Experimental Mouse Glaucoma

SESSION TITLE: Neurodegeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Tezel, X. Yang, Q. Zeng, Ophthalmology, Columbia University Irving Medical Center, New York, New York, UNITED STATES|

Commercial Relationships Disclosure: Gulgun Tezel: Commercial Relationship: Code N (No Commercial Relationship) | Xiangjun Yang: Commercial Relationship: Code N (No Commercial Relationship) | Qun Zeng: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Recent studies of IκKβ deletion in astroglia showed an essential role of NF-κB for the regulation of neurodegenerative inflammation in glaucoma that besides astroglia responses, astroglial NF-κB can shape microglia responses by regulating the astroglia-microglia crosstalk. This study sought a temporal analysis of the overall impacts of astroglial p65 deletion on neuroinflammation in experimental mouse glaucoma.

Methods: Bead occlusion-induced ocular hypertension was modeled in mice with conditional p65 deletion in astroglia (crossbreds of $p65^{f/f}$ and GFAP-cre/ERT2) and $p65^{f/f}$ controls. Through an ocular hypertensive period of 12-weeks, cytokines/chemokines were profiled in the retina, optic nerve, and vitreous samples using multiplex immunoassays. Transgenic effects on glial morphological responses were determined in retinal whole mounts and optic nerve sections by immunolabeling-based quantitative parameters (such as the coverage/intensity of GFAP or Iba1 immunolabeling). Transgenic effects on neurodegeneration were analyzed by counting RGCs and axons.

Results: Pro-inflammatory molecules exhibited a noticeable reduction in samples from ocular hypertensive GFAP/p65 mice, accompanied by protected RGC and axon survival ($P < 0.001$) compared to ocular hypertensive $p65^{f/f}$ controls. The pro-inflammatory cytokines presenting decreased titers with astroglial p65 deletion included transcriptional targets for NF-κB, such as ILs, TNF-α, IFN-γ ($P < 0.01$). The coverage and intensity of GFAP immunolabeling were significantly decreased with astroglial p65 deletion in ocular hypertensive eyes ($P < 0.001$). Similar to recent observations, microglia also exhibited a lessened morphological response to ocular hypertension with p65 deletion in astroglia. A characteristic shift of microglia from ramified morphology to reactive morphology with ocular hypertension was less prominent, and the Iba1 coverage and intensity were over 30% less ($P = 0.002$, $P = 0.01$, respectively) in ocular hypertensive GFAP/p65 mice than ocular hypertensive $p65^{f/f}$ controls.

Conclusions: These findings further support the importance of astroglial NF-κB as a transgenic treatment target to reduce neurodegenerative inflammation in glaucoma. The ability to detect immunomodulatory responses by vitreous cytokine profiling may also be promising to guide future translational studies for predictive, prognostic, and therapeutic testing for personalized patient care.

TITLE: Predicting Visual Outcome in Patients with Idiopathic Epiretinal Membrane Using A Novel Convolutional Neural Network

SESSION TITLE: Machine Learning: Segmentation and Classification

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Yeh, Y. Ko, Y. Chou, S. Chen, Ophthalmology, Taipei Veterans General Hospital, Taipei, TAIWAN|A. Luo, Y. Deng, Industrial technology research institute, TAIWAN|

Commercial Relationships Disclosure: Tsai-Chu Yeh: Commercial Relationship: Code N (No Commercial Relationship) | Yu-Chieh Ko: Commercial Relationship: Code N (No Commercial Relationship) | Yu-Bai Chou: Commercial Relationship: Code N (No Commercial Relationship) | Shih-Jen Chen: Commercial Relationship: Code N (No Commercial Relationship) | An-Chun Luo: Commercial Relationship: Code N (No Commercial Relationship) | Yu-Shan Deng: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Vitrectomy with epiretinal membrane (ERM) peeling is considered the current standard treatment for ERM; however, some patients may experience unfavorable prognosis with limited visual improvement. It remains as a challenge to determine a more rational surgical indication and timing but the guidance or predictive model is lacking currently. Thus, we aim to develop a deep convolutional neural network (CNN) that enables prediction of postoperative visual outcomes based on preoperative optical coherence tomography (OCT) images and clinical prognostic factors to refine surgical decision-making.

Methods: A total of 529 patients with idiopathic ERM who received standard vitrectomy with ERM peeling surgery between January 1, 2014 and June 1, 2020 were enrolled. The newly developed CNN model was introduced to predict postoperative visual acuity (VA) outcome (improvement ≥ 2 lines in Snellen chart or not) 12th months after surgery based on preoperative cross section OCT images and clinical factors, including age, gender and preoperative VA.

Results: The model demonstrated an overall accuracy for visual outcome prediction of 90.2% (95% CI, 79.0%-95.7%) with an AUC of 97.8% (95% CI, 86.8%-98.0%), sensitivity of 87.0% (95% CI, 67.9%-95.5%), specificity of 92.9% (95% CI, 77.4%-98.0%), precision of 0.909, recall of 0.870 and F1 score of 0.889. The heatmaps identified the critical area for prediction as the fovea subjected to tangential traction of the proliferative membrane and the adjacent ellipsoid zone of photoreceptors.

Conclusions: The novel CNN model demonstrated high accuracy in automated prediction of visual outcome based on preoperative macular OCT images. Our study suggests that deep learning has the potential to weigh and leverage the complete data of the patient, and simultaneously process a broad range of clinical information including OCT images. The model has the potential to predict visual outcome of ERM surgery through weighing and leveraging clinical information including OCT images. This approach may be helpful in setting personalized therapeutic strategy for ERM management.

TITLE:

Comparison of Surgical Outcomes: Scleral Buckling versus Pars Plana Vitrectomy versus combined Scleral Buckling/Pars Plana Vitrectomy for primary repair of uncomplicated rhegmatogenous retinal detachment

SESSION TITLE: Vitreoretinal surgery/VR Interface/PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Heydinger, A. Wang, Ophthalmology, The University of Texas Southwestern Medical Center, Dallas, Texas, UNITED STATES|

Commercial Relationships Disclosure: Stanton Heydinger: Commercial Relationship: Code N (No Commercial Relationship) | Angeline Wang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The mainstay of treatment for uncomplicated rhegmatogenous retinal detachment (RRD) has been surgical intervention using various techniques often decided at the level of individual surgeons. While previous research suggests certain approaches may yield better outcomes based upon pre-operative characteristics such as lens status, a superior method has not been elucidated. We performed a retrospective, observational study comparing the outcomes of primary RRD repair using pars plana vitrectomy (PPV), scleral buckling (SB), or combined SB with PPV (SB/PPV).

Methods: 179 patients between 2015-2020 with RRD managed at a large university hospital system were included. Outcome measures included: primary anatomical success rate, improvement in best-corrected visual acuity (BCVA), and functional success rate. Primary success was classified as maintained anatomical integrity of the retina following one intervention measured 6 months postoperatively. Functional success was defined as measuring a postoperative BCVA of 20/200 or better. BCVA was converted to logMAR for comparison between groups. Statistical analysis was performed using the chi-square test and ANOVA. We excluded patients with: less than 6 months of follow-up, previous retinal surgery, giant retinal tears, aphakia, secondary forms of RRD, or extensive proliferative vitreoretinopathy.

Results: SB/PPV yielded the best results in each outcome measure. Primary anatomical success was achieved in 147 of the 179 eyes (82.1%), with SB/PPV showing the greatest success rate (90.3%; p=0.15) amongst the interventions. Functional success was achieved in 125 of the 179 eyes (69.8%), with SB/PPV showing significantly greater functional success (83.9%; p=0.02) than SB (60.0%). SB/PPV showed significantly greater improved mean BCVA (0.87; p=0.04) when compared to SB (0.40); this result held in sub-group analysis of phakic eyes.

Conclusions: SB/PPV yielded the best results for primary anatomical success, functional success, and BCVA improvement out of the three interventions studied. SB/PPV showed significantly better functional success rates (p=0.02) and mean BCVA improvement (p=0.04) when compared to SB. In phakic patients, SB/PPV showed significantly greater BCVA improvement (p=0.03) when compared to SB.

SUBMITTER (NAME ONLY): William Wong

TITLE: Lycium barbarum polysaccharide promotes corneal re-epithelization upon alkaline injury

SESSION TITLE: Corneal epithelial biology and repair mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W. Wong, Y. Bu, Y. Chan, K.C. Shih, Ophthalmology, The University of Hong Kong Li Ka Shing Faculty of Medicine, Hong Kong, HONG KONG|

Commercial Relationships Disclosure: William Wong: Commercial Relationship: Code N (No Commercial Relationship) | Yashan Bu: Commercial Relationship: Code N (No Commercial Relationship) | Yau Kei Chan: Commercial Relationship: Code N (No Commercial Relationship) | Kendrick Shih: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: 1) To evaluate the effectiveness of Lycium barbarum polysaccharide (LBP) in promoting corneal repair after alkaline injury.

2) To evaluate the role of LBP in suppressing the secretion of pro-inflammatory cytokines in the corneal epithelium.

Methods: The corneas of C57BL/6J mice were pre-treated with topical phosphate-buffered saline or LBP (0.2/ 2/ 20 mg/mL) for 7 days 4 times per day, followed by 0.1M sodium hydroxide injury for 30 seconds and washing with distilled water for another 30 seconds. Area of epithelial defect and thickness of the cornea were evaluated using sodium fluorescein staining and hematoxylin and eosin stain. The proportion of apoptotic cells was assessed by TUNEL assay. Inflammatory cytokines, including interleukin-1 beta (IL-1β), matrix metalloproteinase 12 (MMP12), and platelet-derived growth factor-B (PDGF-BB) levels were assessed using immunohistochemistry and Western blot.

Results: 0.2, 2, 20 mg/mL LBP topical solution induced no significant apoptosis to the corneal cells. No significant difference in the total corneal, epithelium and stromal thickness was found between control and LBP pre-treated groups. Compared to the injury group, mice with 2 mg/mL LBP pre-treatment revealed a significant decrease in the fluorescein-stained area upon injury ($p=0.025$), with increased epithelial layer thickness ($p=0.004$). The corneal opacity was significantly reduced in the group with 2 mg/mL LBP pre-treatment followed by injury ($p=0.02$). The expression of matrix metalloproteinase 12 ($p=0.033$) and platelet derived growth factor-BB ($p=0.03$) resulted in a decrease in expression level in group with 2 mg/mL LBP pre-treatment compared to the injury group.

Conclusions: The study presented the efficacy of topical 2 mg/mL LBP pre-treatment, with a safety profile, in promoting corneal epithelial wound healing. We have also demonstrated the promising therapeutic effect of LBP in promoting the restoration of corneal transparency after injury, which is attributable to its anti-inflammatory effect. Our findings suggest that LBP may be considered as a potential preventative method against the formation of chemical-induced cornea defects, particularly those related to alkali burn injury.

ABSTRACT BODY:

Purpose: Since the onset of the coronavirus disease 19 (COVID-19) pandemic, people's lives have adapted, with the use of face masks becoming a part of our daily routine. Despite being a useful device to prevent disease contagion, a marked increase in dry eye and stye symptoms has been detected. We aimed to perform an observational correlation analysis between face-mask use and to report both objective and subjective ocular surface measurements performed on a multi-purpose advanced corneal topographer and a high-definition camera.

Methods: This study included 25 healthy subjects without any ocular diseases, ages ranging from 19 to 68 years. We measured tear meniscus height, Non-Invasive Tear Breakup Time (NIBUT), overall redness score, and tear film lipid layer characterization using Keratograph 5M (Oculus, Wetzlar, Germany), as well as Ocular Surface Disease Index (OSDI) scores for dry eye symptomatic assessments. Patients were asked the number of hours of mask-use at the moment of enrollment, the average hours of mask use daily, and the type of face mask used. We assessed for differences between OSDI scores and gender and type of mask used, as well as correlation coefficients for all subjective and objective measurements.

Results: The mean age of the subjects was 42.44±14.49 years. OSDI scores had no significant differences according to gender ($p = 0.1664$) or type of mask used ($p = 0.0791$). Correlation between hours of mask use at the time of testing and ocular surface modifications were minimal. Hours of mask-use at the time of the test and OSDI scores were moderately correlated ($r= 0.5047$, $p=0.01$). No correlation was found between the average hours of mask use and any ocular surface measurements or OSDI scores.

Conclusions: The use of face masks increased subjectively dry eye symptoms. Nevertheless, ocular surface objective measurements remain unchanged by mask-wearing.

ABSTRACT BODY:

Purpose: The human anterior segment perfusion culture model is important for trabecular meshwork (TM) and aqueous humor outflow research. The traditional model relies on whole eye globes with high cost and limited availability. Here, we developed a glue-based method which enabled us to use human corneal rims for perfusion culture experiments.

Methods: Human corneal rim perfusion culture plates were designed with CAD and 3D printed. Human corneal rims containing intact TM were attached and sealed to the plate using low viscosity and high viscosity glues, respectively. The human corneal rims were perfused using the constant flow mode, and the pressure changes were recorded using a computerized system. Outflow facility, TM stiffness, and TM morphology were evaluated.

Results: When perfused at rates from 1.2 to 3.6 µl/ml, the outflow facility was 0.359 ± 0.216 µl/min/mmHg among 10 human corneal rims. The stiffness of the TM in naïve human corneal rim was similar to that of perfusion cultured human corneal rim. Also, the stiffness of TM of corneal rims perfused with dexamethasone was significantly higher than the control. Human corneal rims with glue contamination in the TM could be differentiated by high baseline intraocular pressure as well as high TM stiffness. Histology studies showed that the TM tissues perfused with plain medium appeared normal.

Conclusions: We believed that our glued-based method is a useful, low-cost alternative to the traditional anterior segment perfusion culture model using whole eye globes.

ABSTRACT BODY:

Purpose: Uveal melanoma (UM) arises from melanocytes in the eye and is distinct from skin melanoma. Half of these patients succumb to metastatic disease in the liver. There is currently no approved therapy for metastatic UM (mUM). Experimental therapies have not shown promising outcomes, with poor response to the targeted and immune therapies. There is an urgent need for new therapeutic strategies for mUM patients. We have previously shown upregulated Oxidative Phosphorylation (OXPHOS) effectors in mUM. In this study we aimed to target them in the mitochondria using Imipridones, inducers of the mitochondrial protease ClpP. ClpP controls the degradation of the mitochondrial OXPHOS proteins and regulates their level in the cell.

Methods: We tested the effect of imipridones (ONC201, 206,212) on UM cell survival in in vitro cell survival assays and also on the levels of SDHA, SDHB and other OXPHOS effectors using western blots. We determined the effect of imipridone treatment on proliferation, apoptotic and integrated stress response (ISR) pathway markers from UM cells. We studied the global proteomic and metabolomic profile of UM cells with imipridone-treatment using RPPA analyses and mass spectrometry-based metabolomics profiling respectively.

Results: The imipridones blocked UM cell survival in all UM cell lines tested. SDHA and SDHB protein levels were significantly reduced in imipridone-treated UM cells. The phosphorylation of AMPK increased post treatment, signaling a metabolic stress in the treated cells. Apoptosis was induced, as shown by increased processing of PARP as well as Caspases 9 and 3. ISR markers were also induced post treatment with imipridones. A global metabolic profile of cells post treatment showed reduction in protein biosynthesis pathways and alteration of lipid metabolism.

Conclusions: Treatment with imirpidones reduced UM cell survival, induced apoptosis, ISR and metabolic stress on UM cells. Finally, protein biosynthesis and lipid metabolism were affected with treatment. Taken together, our data show imipridones can target metabolic vulnerabilities of metastatic UM due to elevated mitochondrial OXPHOS and control cell growth. Appropriate validation of these data in a suitable in vivo model can lead to a clinical study in mUM patients to develop new therapeutic avenues.

TITLE: Protective effect of Fas inhibition in mouse models of inherited retinal degeneration

SESSION TITLE: Photoreceptor Biology, Protection and Degeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Yao, T. Wang, L. Jia, D.N. Zacks, Ophthalmology & Visual Sciences, University of Michigan Michigan Medicine, Ann Arbor, Michigan, UNITED STATES|T. Wang, Ophthalmology, Central South University Xiangya School of Medicine, Changsha, Hunan, CHINA|

Commercial Relationships Disclosure: Jingyu Yao: Commercial Relationship: Code N (No Commercial Relationship) | Tiantian Wang: Commercial Relationship: Code N (No Commercial Relationship) | Lin Jia: Commercial Relationship: Code N (No Commercial Relationship) | David Zacks: Commercial Relationship(s);Code P (Patent):ONL Therapeutics;Code C (Consultant/Contractor):ONL Therapeutics;Code I (Personal Financial Interest):ONL Therapeutics

ABSTRACT BODY:

Purpose: Inherited retinal degeneration (IRD), a common cause of blinding disease in the United States, is a class of retinal diseases resulted from mutations in nearly 300 different genes. This extreme genetic heterogeneity has limited the development of mutation-specific therapies, and there is an urgent need for approaches targeting broadly shared pathophysiologic pathways in IRD patients. The CD95 death receptor, also known as Fas, has been reported as a contributor to retinal cell death and inflammation in a wide variety of ocular diseases. The purpose of the study is to examine the effects of genetic inhibition of Fas on retinal degeneration in 2 distinct IRD mouse models, P23H and rd10, as a proof-of-concept study of targeting Fas pathway as a novel mutation-independent approach to IRD.

Methods: The basal levels of Fas activation and inflammation in the P23H, rd10 and C57 (wild-type) controls were evaluated by TUNEL cell counts, caspase 8 activity assay, rt-PCR, and IHC. Genetic inhibition of Fas was achieved by crossing Fas-lpr, a functionally Fas-deficient mouse line, with P23H or rd10 to generate P23H/Fas-lpr and rd10/Fas-lpr mice. Retinal structure and function were evaluated by IHC, OCT and ERG analysis. The activation of microglia and the production of inflammatory cytokines were also assessed.

Results: Retinas from both P23H and rd10 mice showed elevated transcript and protein levels of Fas receptor, increased caspase 8 activity and TUNEL (+) photoreceptor cells as compared to wild-type C57 mice. Microglial activation and migration to photoreceptor layer was detected in the retinas of both P23H and rd10 mice, consistent with increased levels of inflammatory cytokines in these two models. Genetic Fas deficiency resulted in preservation of photoreceptor viability and retinal functions in both P23H and rd10 mice. Microglial activation and cytokine production was also reduced in both P23H/Fas-lpr and rd10/Fas-lpr mice compared with age-matched controls.

Conclusions: Our observation of protective effect of genetic Fas inhibition in two different mouse models of retinal degeneration suggests that while the individual IRD mutation may be specific, the retina’s response to the different stress appears to be shared and driven by cell death-inducing receptor Fas. Deletion of Fas might represent a potential mutation-independent therapeutic approach to preserve retinal structure and function in patients with IRD.

ABSTRACT BODY:

Purpose: Congenital cataracts (CCat) are a major cause of vision impairment in children worldwide, and are caused by mutations in more than 50 genes. The purpose of this study was to identify the genetic causes of CCat in three Pakistani families.

Methods: Three unrelated consanguineous pedigrees (F1, F2 and F3), were recruited from the Punjab region of Pakistan and were genetically studied at the Institute of Molecular and Clinical Ophthalmology Basel by whole-exome sequencing and Sanger sequencing. Clinical examination of probands was performed by standard procedures.

Results: Patients from F1 and F2 families had non-syndromic bilateral cataracts whereas patients from F3 family had CCat with microcytic hypochromic anaemia, B-cell immunodeficiency, physical developmental delay, muscular dystrophy, and speaking difficulties without intellectual disabilities. Fundus examination of all patients showed normal retina. Genetic analysis of patients from F1 revealed a novel homozygous stop-gain mutation (NM_001318327.1:c.988C>T, p.[Arg330*]) in DNMBP, whereas patients from F2 carried a new missense mutation (NM_000786.4:c.268T>A, p.[Phe90Ile]) homozygously, in the CYP51A1 gene. Finally, patients from F3 were found to have compound heterozygous variants in the TRNT1 gene: the previously unreported nonsense variant (NM_182916.2:c.433C>T, p.[Gln145*]) and the known mutation (NM_182916.2:c.1246A>G, p.[Lys396Glu]). All variants co-segregated with disease in the respective families.

Conclusions: Our findings expand the mutational spectrum of congenital cataracts and provide new information for further functional studies on the molecular mechanisms leading to these conditions.

ABSTRACT BODY:

Purpose: The COVID-19 lockdown resulted in appointment cancellations that affected the medical management and visual health of glaucoma patients. This study aimed to examine COVID-related factors leading to decreased patient perception of visual health. We surveyed glaucoma patients to examine the impact of COVID-related office changes on perceived visual health and level of concern with care.

Methods: 65 patients presenting to an Albany outpatient glaucoma practice in June 2021 were orally surveyed prior to appointment. Survey consisted of Y/N questions and Likert Scale responses examining patients' perception of care and concern over condition management during the March 2020 lockdown period. Likert responses from 1 to 5 regarding difficulty scheduling appointments, knowledge of COVID-19, level of concern regarding condition management, and patient reported vision-related quality of life (VRQOL) were used to gauge perceived visual health and level of concern with care. Patients were grouped into one of two cohorts based on whether they reported an institutional appointment cancellation during lockdown, and Mann-Whitney U and Spearman Correlation analysis were used for statistical analysis of cohorts.

Results: Patients with appointment cancellations during lockdown reported significantly greater concern regarding condition management and impacted VRQOL ($p<0.05$). On a Likert scale up to 5, the level of concern regarding VRQOL in the noncancellation group was lower (1.2 ± 0.4) compared to the cancellation group (1.8 ± 1.0). Concern regarding condition management was also lower in the noncancellation group (1.7 ± 0.6) versus the cancellation group (3.0 ± 1.1). There was no significant difference in how informed the two groups felt about COVID-19. Correlation analysis confirmed these trends and showed that increased perceived ease of obtaining appointments was positively correlated with increased patient perception of visual health, represented by impact on VRQOL.

Conclusions: This study demonstrates that COVID-related appointment cancellations caused patient concerns over care to grow and perception of visual health to decrease. Patient-reported visual health and VRQOL may be directly related to the ease of obtaining appointments and maintaining communication with their ophthalmologist, in addition to the medical management of their condition.

ABSTRACT BODY:

Purpose: To better understand the visual experience and ocular symptoms that influence eye preference in individuals that received wavefront-guided (WFG) LASIK and wavefront-optimized (WFO) LASIK treatments in a fellow eye controlled randomized study.

Methods: A prospective randomized controlled clinical trial (NCT02565537) was conducted where 102 myopic individuals were randomly assigned to receive WFO-LASIK in one eye and WFG-LASIK in the contralateral eye. At the pre-operative visit and subsequent post-operative visits, individuals were asked to identify eye preference. The survey responses of individuals who preferred WFG-LASIK were compared with those who did not preferred WFG-LASIK. The same was done for responses to WFO-LASIK treatments.

Results: At POM#12, 45% of subjects did not have an eye preference, 33% preferred WFO-LASIK treated eye, and 22% preferred WFG-LASIK treated eye ($p=0.2$). For individuals who did not prefer the WFG-LASIK eye, they noted significantly worse “hazy vision” and “blurry vision” compared with those who preferred the WFG-LASIK treatment ($p<0.05$). No differences in visual experience or ocular symptoms were reported by individuals who did prefer or did not prefer WFO-LASIK treatment.

Conclusions: At 12 months post WFG-LASIK treatment in one eye and WFO-LASIK treatment in the contralateral eye, most individuals did not have eye preference. Individuals who did not prefer WFG-LASIK noted hazy and blurry vision compared with individuals who preferred the WFG-LASIK treatment.

TITLE: Comparison of Concomitant Administration of Dexamethasone in One Eye versus Fluocinolone Acetonide in the Fellow Eye in Patients with Similar Degrees of Diabetic Macular Edema

SESSION TITLE: Diabetic macular Edema

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y.C. Akduman, Saint Louis University School of Medicine, Saint Louis, Missouri, UNITED STATES|J.D. Grodsky, E.B. Rodrigues, Ophthalmology, Saint Louis University School of Medicine, Saint Louis, Missouri, UNITED STATES|

Commercial Relationships Disclosure: Yigit Akduman: Commercial Relationship: Code N (No Commercial Relationship) | Jacob Grodsky: Commercial Relationship: Code N (No Commercial Relationship) | Eduardo Rodrigues: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In this case series, we outline and analyze the structural and tomographic changes in three cases of individuals that received a dexamethasone intravitreal implant (Ozurdex®) injection in one eye and a fluocinolone acetonide intravitreal implant (Iluvien®) injection in the fellow eye at the same time.

Methods: The three cases were studied retrospectively to evaluate the relative efficacy between the two drugs. Best corrected visual acuity (BCVA), intraocular pressure (IOP), and maximum macular thickness (MMT) with optical coherence tomography (OCT) were taken as measurements along the timeline of follow up for comparison between the treatments.

Results: Ozurdex® appeared to have a more pronounced and prompter effect when compared to Iluvien®. In two cases, Ozurdex® showed a quick onset with decreased MMT and improved BCVA within two months while Iluvien® took 4-6 months to provide a similar effect. The response to Ozurdex® demonstrated by these variables began to decrease by the fourth month of follow up, requiring repeat injection of medication. In the third case, where macular edema was less pronounced prior to treatment, Iluvien® provided a quick response that was sustained throughout a 22-month follow-up period. In this case, Ozurdex® also showed significant response in the fellow eye but required two additional doses to maintain this effect throughout the same 22-month period. In addition, the eyes injected with Ozurdex® appeared to maintain the structural integrity of the external limiting membrane (ELM) and photoreceptor outer segments (OS) throughout the follow-up period, while OCT of the eyes injected with Iluvien® began to demonstrate structural disintegration of these critical layers as soon as four months after injection.

Conclusions: In patients with significant macular edema, intravitreal injection of Ozurdex® appears to provide quicker and more significant improvement in macular thickness, as well as better preservation of the outer retinal layers, when compared to intravitreal injection of Iluvien®. Further controlled studies comparing these two drugs are necessary.

ABSTRACT BODY:

Purpose: To examine if geographic access to surgical treatment for glaucoma and cataracts varies among Medicare beneficiaries living in rural or urban California

Methods:

This was a cross-sectional study of the 2017 California (CA) Medicare population. We included beneficiaries with glaucoma or cataracts using ICD-10 diagnosis codes. Beneficiaries were included if they resided in CA in 2017, were 65 years or older, had at least one Part B claim, and a valid CA ZIP code.

Urban or rural residence was determined by ZIP codes using the Health Resources and Services Administration definitions. Distance travelled to eye care providers was measured between patients' and providers' ZIP codes with ArcGIS. Multivariable linear regression models were performed to compare mean distance travelled to surgery by urban versus rural residence, controlling for age, sex, race/ethnicity and Charlson Comorbidity Index score. Multivariable logistic regression models were used to assess the effect of travel distance on the odds of receiving glaucoma or cataract surgery, controlling for the covariates above.

Results: The study sample included 336,117 glaucoma patients, of whom 82,583 (24.6%) were rural residents and 445,164 cataract patients of whom 127,314 (28.6%) were rural residents. A total of 24,324 (7.2%) patients received glaucoma surgery and 93,460 (21.0%) patients received cataract surgery. In adjusted analyses, beneficiaries in rural regions travelled 14.7 miles more (95% confidence interval [CI]: 13.8 to 15.7) for glaucoma surgery and 9.7 miles more (95% CI: 9.3 to 10.2) for cataract surgery than their urban counterparts. For every additional 100 miles travelled, the odds of cataract surgery decreased by 14% (OR: 0.86, 95% CI: 0.84 to 0.87). However, the odds of glaucoma surgery increased by 13% (OR: 1.13, 95% CI: 1.09 to 1.16) for every additional 100 miles travelled.

Conclusions: In 2017, Medicare beneficiaries who resided in rural California travelled farther to undergo their cataract and glaucoma surgery than beneficiaries in non-rural areas. Longer travel distance was associated with lower odds of cataract surgery, and, paradoxically, was also associated with greater odds of glaucoma surgery. This perhaps points toward the lack of glaucoma subspecialists in rural areas which necessitates further travel; however, additional studies are needed to understand such complex relationships.

SUBMITTER (NAME ONLY): Taiichi Hikichi

TITLE: Sub-Tenon’s capsule triamcinolone acetonide injection to prevent brolucizumab-associated intraocular inflammation

SESSION TITLE: Anti-VEGF in AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Hikichi, Hikichi Eye Clinic, Sapporo, JAPAN|

Commercial Relationships Disclosure: Taiichi Hikichi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Since the approval of brolucizumab, a number of post-marketing cases of severe visual acuity loss resulting from severe intraocular inflammation (IOI) and retinal vasculitis and/or retinal artery occlusion have been reported after intravitreal injection (IVI) ofbrolucizumab. To investigate the efficacy of sub-Tenon’s capsule triamcinolone acetonide (STTA) injections for preventing development of IOI related to brolucizumab IVI for neovascular age-related macular degeneration (nAMD).

Methods: Consecutive patients with nAMD treated with brolucizumab IVIs were studied retrospectively. All eyes treated with brolucizumab in the clinic were switched from another anti-vascular endothelial growth factor agent. After the fourth case of IOI related to brolucizumab IVI, all eyes treated with brolucizumab received a STTA injection. The patients were divided into two groups: brolucizumab alone and brolucizumab combined with a STTA injection.

Results: Thirty-three eyes (33 patients) treated with at least one brolucizumab IVI were studied: 14 eyes received brolucizumab IVI alone and 19 eyes received the combination therapy. IOI related to brolucizumab IVIs developed in four (28.6%) of 14 eyes in the brolucizumab group; IOI was severe in one eye, moderate in two eyes, and mild in one eye according to the HAWK and HARRIER trial definition; IOI did not develop in the 19 eyes that received combination therapy, the difference of which reached significance (p=0.025). Regarding combination therapy, intraocular pressure in one (5.3%) eye increased to 22 to about 24 mmHg after the STTA injection and returned to normal range within 2 months without medication; no cataracts developed during this short mean follow-up period follow-up period of 7.8 ± 0.7 months.

Conclusions: The results indicated the possible preventative effect of a STTA injection on development of brolucizumab-associated IOI. The combination therapy of a brolucizumab IVI with a STTA injection may be recommended for patients with apoor or no response to other anti-VEGF agentsor for those who require frequent IVIs of anti-VEGF agents, especially in the dominant eye.

TITLE: Intraocular pressure sensitivity and specificity in ocular hypertension and open-angle glaucoma with Goldmann and modified Goldmann tonometry

SESSION TITLE: IOP and laser therapy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.J. McCafferty, Reichert Technologies, Depew, New York, UNITED STATES|S.J. McCafferty, Intuor Technologies, Tucson, Arizona, UNITED STATES|

Commercial Relationships Disclosure: Sean McCafferty: Commercial Relationship(s);Code I (Personal Financial Interest):Intuor Technologies;Code C (Consultant/Contractor):Reichert

ABSTRACT BODY:

Purpose: Evaluate the sensitivity and specificity of IOP in detecting a need for treatment or progression of glaucomatous optic neuropathy by loss of retinal nerve fiber layer (RNFL) in ocular hypertension (OHT) and open-angle glaucoma (OAG) using Goldmann applanation tonometry (IOPg) and modified applanation surface Goldmann tonometry (IOPc)

Methods: A retrospective cross-sectional study was performed in a multi-specialty ophthalmology practice on 1741 eyes in 952 patients: 164 N, 502 GS, 490 OHT,491 POAG, and 89 normal tension glaucoma (NTG) eyes. Primary outcome measures included glaucomatous optic neuropathy (GON) demonstrated by RNFL loss measured by serial OCT over a period of 2.8 years (average of 3.9 visits) to produce receiver operating characteristic (ROC) curves of sensitivity and specificity with paired IOPc and IOPg measurements. Secondary outcome measures were corneal hysteresis (CH), and central corneal thickness (CCT).

Results: Maximum sensitivity and specificity in diagnosing new onset POAG or NTG using IOPc (77%/91%@23mmHg) and using IOPg (70%/86%@22mmHg)($p<0.001$). OHT, being defined by IOP, was included in a separate analysis of those patients with POAG/NTG/OHT requiring treatment (OHT≥26mmHg): IOPc (91%/96%@24mmHg) and IOPg (82%/88%@23mmHg)($p<0.001$). An increase of IOPc ≥ 2mmHg over IOPg indicated a 79% probability of progressive GON by RNFL loss in treated POAG/NTG ($p<0.001$). Likewise, a CH of < 9.0mmHg also indicated 79% probability of progressive GON ($p<0.001$).

Conclusions: IOP is a primary indicator in the diagnosis of OAG but not significantly reliable alone to make a decision to treat or alter treatment. A modified Goldmann prism demonstrated significantly higher sensitivity and specificity diagnosing POAG and NTG as well as directing treatment. IOP remains a valuable leading indicator of GON with significantly high sensitivity and specificity depending upon where in the spectrum of open-angle glaucoma it is measured. The IOP information may be improved by newer methods of measurement.

ABSTRACT BODY:

Purpose: In this case series, we aim to describe electroretinographic responses and assess their correlation with clinical and angiographic findings in retinal vasculitis.

Methods: Medical records of patients who were diagnosed with retinal vasculitis at a tertiary eye center from December 2017 to May 2021 were reviewed. Cases in which both fluorescein angiography (FA) and electroretinography (ERG) were done within one month were included. Cases with other retinal diagnoses or significant media opacities were excluded. FAs were graded according to the Angiography Scoring for Uveitis Working Group scoring system from 0 to 40, where 0 is normal. Individual ERG waves were graded for both timing and amplitude, based on their corresponding Z (standard deviation) scores from 0 to 5, where 5 is normal and 0 is absent response. General ERG score was determined by mean of individual scores plus 1 point if the oscillatory potential was present. Relevant clinical data were obtained. General and individual ERG scores were correlated with FA scores and clinical findings.

Results: 34 eyes of 20 patients were included. Mean age was 43.9 ± 19.8 years; 70% were female. Underlying ocular diagnoses were isolated vasculitis (70%), intermediate uveitis (20%) and panuveitis (10%). Median (range) best corrected visual acuity (BCVA) was 0.8 (0.08-1). Optical coherence tomography was normal in 59% of eyes. Mean FA severity score was 12.6 ± 6.5. Median general ERG score was 5 (0 to 6). 68% and 91% of eyes had responses with general scores ≥ 5 & 4, respectively. Among ERG parameters, flicker timing was the most commonly and severely affected.

FA scores weakly correlated with delayed photopic cone b wave and flicker timing ($P = 0.03$ and 0.016, respectively). FA scores did not correlate with general ERG or any other individual wave scores. Vitreous haze gradings moderately correlated with delayed cone b wave timing ($P < 0.001$), delayed flicker timing ($P = 0.002$) and weakly correlated with lower flicker amplitude ($P = 0.03$). Lower BCVA weakly correlated with delayed cone b wave timing ($P=0.046$).

Conclusions: Retinal vasculitis is not frequently associated with severe retinal dysfunction. Lower BCVA, higher FA scores, and vitreous haze gradings are weakly correlated with cone related ERG abnormalities. ERG may provide functional assessments not otherwise predicted by clinical or angiographic finding in retinal vasculitis.

TITLE: A new USH2A mutation in a Chinese family with retinitis pigmentosa
SESSION TITLE: Retinal metabolism and physiology
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: L. xuejiao, Ophthalmology, Sanmenxia Central Hospital, CHINA|
Commercial Relationships Disclosure: li xuejiao: Commercial Relationship: Code N (No Commercial Relationship)
ABSTRACT BODY:
Purpose: To detect USH2A mutations in a Chinese family with retinitis pigmentosa (RP).
Methods: A Chinese RP family with four members was enrolled in this study. Genomic DNA was extracted from peripheral blood and Next Generation Sequencing was performed to detect exonic mutations. Sequencing data were aligned and identified for genetic variants using XYGeneRanger2.0. RCR and Sanger sequencing was used to validate the gene mutations. The segregation test and Silico predictive tool were used to predict the pathogenicity of these mutations.
Results: We identified two heterozygous USH2A variations in this family which were c.8559-2 A> G and c.151 A> T (p.ile51phe). The variant c.8559-2 A> G, which was previously reported as a pathogenic mutation, was detected in the three members in this family (the proband, her father, and her daughter), while the proband's father and daughter were without any RP symptom. Another mutation c.151 A> T was detected in the proband and her mother. Both were diagnosed with RP. It was a novel variant located in chr1-216595528, the second exon of the USH2A gene. This mutation changed nucleotide at position 151 from A to T, resulting in the change of amino acid at position 51 from isoleucine to phenylalanine. c.151 A> T (p.ile51phe) was predicted to be benign by Silico predictive tools, however, co-segregation test indicated c.151 A> T (p.ile51phe) might be pathogenic.
Conclusions: We first identified c.151A> T (p.Ile51Phe) as a new mutation for RP, which was probably a pathogenic mutation. This study expands the spectrum of USH2A variants in RP patients.

TITLE: Clinical Characteristics and Response to Eye Muscle Surgery in 15 Children Patients With Dyschromatopsia and Infantile Nystagmus Syndrome (INS)

SESSION TITLE: Nystagmus and Strabismus: Genetics, animal models and imaging

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: R.W. Hertle, I. Boydstun, A. Juric De Paula, Akron Children's Hospital, Akron, Ohio, UNITED STATES|R.W. Hertle, Northeastern Ohio Medical University, Rootstown, Ohio, UNITED STATES|

Commercial Relationships Disclosure: Richard Hertle: Commercial Relationship: Code N (No Commercial Relationship) | Ian Boydstun: Commercial Relationship: Code N (No Commercial Relationship) | Ana Juric De Paula: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To report the clinical characteristics and their response to eye muscle surgery in children with dyschromatopsia

Methods: This is a prospective cohort analysis of 15 dyschromatopsic patients who had eye muscle surgery. Data collected included: 1) demography, 2) clinical and electrophysiological findings, 3) associated non-ophthalmic characteristics, 5) special testing findings and 7) treatments and their results.

Results: The data were collected prospectively as an IRB approved registry. Age range 3mos-12yrs (~7.2yrs) (FU 1-10yrs), 53% male, 23% were other than Caucasian, 17% premature, 94% had delayed visual maturation, 100% had INS, 86% (13/15) with a dual jerk waveform, 100% no vergence damping, latent component or periodicity, 53% had strabismus, 40% had amblyopia, 93% had an anomalous head posture (predominant chin-down), 100% had a significant refractive error, 47% with anisometropia. Ellipsoid and/or outer retina dysmorphology was present in 100%. ERG testing showed cone dysfunction in 100% with varied rod dysfunction in 6, (40%). Positive CNGA3, CNGB3 or CAPB4 homozygosity was found in 4 patients. Systemic findings were present in 29%. Optical and amblyopia treatments were completed prior to eye muscle surgery in all patients. Best binocular acuity after eye muscle surgery ranged from Log MAR 0.55-1.2 (~.72) with a group mean improvement of .24 Log MAR ($p<0.01$). In addition, all patients had improvement in contrast sensitivity and their nystagmus characteristics, including; foveation and breadth, depth and position of their eccentric null zones.

Conclusions: A less common waveforms seen in patients with INS is dual jerk (DJ) or dual pendular which are etiologically connected to disruption in the nucleus of the optic tract. DJ INS is a low-amplitude, high-frequency nystagmus whereas typical INS is a high-amplitude, low-frequency nystagmus, the combination of the two is recognized using eye-movement recordings and seems to be characteristic in dyschromatopsia. In addition to confirming some of the typical clinical characteristics of dyschromatopsia-achromatopsia this series analysis has demonstrated a unique, consistent, pattern of novel ocular motor findings and significant improvements nystagmus and visual function after eye muscle surgery.

ABSTRACT BODY:

Purpose: Uveal melanoma (UM) is the most common intraocular cancer; 50% of patients develop metastases, usually to the liver, that prove fatal within 2-years due to lack of successful therapies. BAP1 mutations are frequently associated with metastatic UM (mUM), and also with malignant pleural mesothelioma (MPM). Through multi-omics analysis to identify common BAP1-dependencies in UM and a gene-edited model of MPM, we tested the hypothesis that adaptation to BAP1 alteration creates therapeutic vulnerabilities in UM.

Methods: A novel function-driven multi-omics analysis, which included pathway-based and gene-based approaches, was used to integrate mRNA, protein and miRNA datasets from isogenic BAP1-mutant mesothelial MeT5A cells with in-house and publicly available UM patient sample transcriptome datasets (Fig 1A). Genes were then filtered (Fig 1B) and candidates validated by qRT-PCR in MeT5A cells and FFPE primary UM (pUM) samples (n=19). Statistical analyses used one-sample or Wilcoxon t-test for MeT5A and two-tailed t-test or Mann Whitney test for UM, depending on whether data were normally distributed.

Results: Multi-omics integration and filtering identified 24 BAP1-dependent candidates: 14 from pathway-based and 17 from gene-based approaches, with 7 in common (Fig 1B). 16 candidates were validated by qRT-PCR ($p<0.05$) in MeT5A cells, whilst qRT-PCR in pUM samples highlighted 3 lead candidates: BIRC3 significantly increased 9.3-fold in BAP1 altered ($4.38\pm5.66\times10^{-2}$ relative to actin) compared to BAP1 normal pUM ($4.69\pm7.57\times10^{-3}$;$p=0.02$), HSP90AB1 decreased 2.3-fold in BAP1 altered ($3.81\pm0.87\times10^{-1}$) compared to BAP1 normal pUM ($8.75\pm2.85\times10^{-1}$;$p=0.0001$), and KCND3 increased 13.2-fold in BAP1 altered ($1.73\pm1.73\times10^{-1}$) compared to BAP1 normal pUM ($1.32\pm1.56\times10^{-2}$;$p=0.0015$).

Conclusions: This function-driven approach identified novel BAP1-dependent adaptations in UM that may provide therapeutic targets for mUM: increase in BIRC3, an anti-apoptotic gene, decrease in HSP90AB1, a pro-apoptotic gene, and increase in KCND3 which has been shown to promote migration. Assessment of protein expression in UM cell lines and UM patient samples is underway. UM cell line viability will be tested in response to drugs targeting these candidates: LCL-161 (BIRC3), polaprezinc (HSP90AB1 agonist) and dronedarone (KCND3).

TITLE: Deep Augmentation Lamellar Keratoplasty (DALK 2.0) for Severe Keratoconus.

SESSION TITLE: Corneal Cell and Molecular Biology | Corneal Development

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.Z. Soliman, Ophthalmology, Southwest Eye Institute, El Paso, Texas, UNITED STATES|

Commercial Relationships Disclosure: Ahmed Soliman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To report the initial clinical outcomes of Deep Augmentation Lamellar Keratoplasty (DALK 2.0) in eyes with severe keratoconus (KC).

Methods: Six eyes (6 patients) with progressive KC underwent DALK 2.0. Patients were divided into two groups based on the maximum keratometry (Kmax): Group A: patients with Kmax >65 diopters and group B: patients with Kmax <65 diopters. Best-corrected visual acuity, Kmax, central corneal thickness, thinnest point thickness were recorded before and at the last follow up visit after the procedure (minimum follow up of 6 months with the longest follow up period being 24 months). Any surgical complications or progression of KC were documented.

Results: Best contact lens corrected visual acuity improved in both groups postoperatively with no patients losing any vision. An average Kmax reduction of 7.6 D and 4.8 D was noted in groups A and B respectively at the last follow up visit ($P < 0.001$). Contact lens tolerance improved in 4 patients (two in each group) ($P = 0.3$). One eye underwent topography guided photorefractive keratectomy (PRK) 6 months after the surgery (this eye underwent standard epithelial off corneal crosslinking prior to the transplant). No postoperative KC progression was noted in any of the operated eyes thus far. No postoperative complications were observed.

Conclusions: Deep Augmentation Lamellar Keratoplasty improved best contact lens corrected visual acuity, stabilized KC, improved contact lens tolerance and allowed for subsequent topography guided PRK in select cases. More corneal flattening was achieved in patients with more advanced disease. Allogenic stromal corneal augmentation is a promising technique that will hopefully be utilized more frequently in cases of severe keratoconus.

SUBMITTER (NAME ONLY): Tongalp Tezel

TITLE: SPATIAL FEATURES OF CYSTOID MACULAR EDEMA ACT AS A BIOMARKER FOR THE ANATOMIC AND FUNCTIONAL STATUS OF THE RETINA IN RETINITIS PIGMENTOSA

SESSION TITLE: Retinal Degenerations, Gene Therapy, Transplantation, and Prostheses

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T.H. Tezel, Ophthalmology, Edward S Harkness Eye Institute, New York, New York, UNITED STATES|

Commercial Relationships Disclosure: Tongalp Tezel: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine the anatomical and functional correlates of intraretinal cysts in retinitis pigmentosa.

Methods: One hundred three patients (196 eyes) with untreated cystoid macular edema (CME) were identified from a pool of 578 genotyped patients with retinitis pigmentosa. Three central horizontal OCT scans were used to calculate the size of the retinal nerve fiber layer, outer retinal, inner retinal area, cysts, and total retinal areas. Ellipsoid zone and outer limiting membrane lengths were also measured. Best-fit curves were used to analyze the factors that play a role in the size of the retinal cysts and the patient's visual acuity. Correlations between the visual acuity, morphometric and clinical data were sought.

Results: Twenty-five percent of the screened patients (103/578) had CME. Patients with autosomal dominant retinitis pigmentosa had the highest incidence of CME (43.6%, $p<0.001$) but also had the best visual acuity (20/34±20/30, $p=0.02$). The total cyst area was 0.14±0.18 mm2. Outer retinal area ($B=0.214$; $p=0.008$), age ($B=-0.003$; $p<0.001$) and retinal nerve fiber area ($B=0.411$; $p=0.005$) were main determinants of the ($r=0.44$; $p<0.001$) cyst size. Cysts resolved with progressing retinal degeneration. Length of the intact ellipsoid zone ($B=-5.16E-5$; $p<0.001$), the inheritance pattern ($B=0.04$; $p=0.028$) and retinal nerve fiber area ($B=0.751$; $p<0.001$) were the main determinants of visual acuity.

Conclusions: Retinal nerve fiber layer emerges as a significant morphologic parameter correlating with the intraretinal cyst size and decreasing visual acuity. This finding suggests axonal compression and subsequent visual loss as a possible complication of intraretinal cysts in retinitis pigmentosa.

ABSTRACT BODY:

Purpose: To describe the clinical characteristics and clinical transitions between acute idiopathic blind spot enlargement (AIBSE), acute zonal occult outer retinopathy (AZOOR), and multiple evanescent white dot syndrome (MEWDS) with longitudinal follow up.

Methods: Patients were identified by searching electronic medical records using diagnostic codes. Testing reviewed included visual fields, ophthalmic imaging and electroretinography. Demographic and clinical characteristics were compared. Charts were reviewed by both a neuro-ophthalmologist and a uveitis/retina specialist. Transition between diseases was defined by new appropriate funduscopic findings or testing that best fit with a different phenotype. Statistical analysis was performed using STATA 17 software.

Results: A total of 43 patients were identified with a distribution of cases as follows: 14 AIBSE, 26 AZOOR, 1 AIBSE to AZOOR transition, 1 AZOOR to MEWDS transition, and 1 co-occurring AZOOR and MEWDS. AIBSE patients (mean age, 33 years) were younger than AZOOR patients (mean age, 41 years) at diagnosis. Women accounted for 93% of AIBSE patients and 77% of AZOOR patients. All transition patients were women. Time from initial diagnosis to clinical transition was 4 years in AIBSE to AZOOR and 0.75 years in AZOOR to MEWDS. AZOOR patients had longer mean follow up time (AIBSE 28 months, AZOOR 44 months) compared to AIBSE patients. Common misdiagnoses at the time of referral were migraines (42% of AIBSE patients, 32% of AZOOR patients) and optic neuritis (29% of AIBSE patients, 23% of AZOOR patients). AZOOR patients were more likely to present bilaterally at initial visit (Fisher's exact test $p < 0.05$). Unilateral to bilateral occurrence (21% AIBSE eyes, 35% AZOOR eyes) and recurrences (14% AIBSE eyes, 38% AZOOR eyes) were more frequently observed in AZOOR patients. By the final visit, 30% of AZOOR eyes experienced worsening scotoma area by 20%, and 5% of AZOOR eyes experienced worsening visual acuity by 2 or more Snellen lines compared to no AIBSE eyes. Treatment was initiated in 8 AZOOR patients (31%), all transition patients and no AIBSE patients.

Conclusions: A greater percentage of AZOOR patients exhibited worsening visual acuity and scotoma area and received immunosuppressive therapy when compared to AIBSE patients. Patients transitioning between these diseases are uncommon. Specifically, only a single case was observed for AIBSE converted to AZOOR.

ABSTRACT BODY:

Purpose: Medications can result in side effects which may lead to medication non-adherence and, eventually, to poor outcomes. This study aimed to quantify to what extent the side effects of dry eye disease (DED) medications (burning/stinging sensation and blurring) are important to patients as opposed to medication benefits or costs.

Methods: Patients who were diagnosed with DED were recruited at a referral eye centre in Singapore (n=139). This study utilized a Discrete Choice Experiment where patients were presented with 10 choice tasks where they were asked to choose between their current medication (or no medication), and two hypothetical medications that varied based on five attributes: duration of burning/stinging, duration of blurring, time to medication effectiveness, medication frequency, and out-of-pocket cost. The main outcomes were relative attribute importance and predicted uptake.

Results: Latent class logistic regressions found two groups with distinct preferences. Classes 1 and 2 constituted 62.5% and 37.5% of the sample. For both classes, duration of burning/stinging (Class1=12%, Class2=20%) and cost (Class1=12%, Class2=19%) were the most important attributes while duration of blurring (Class1=8%, Class2=6%) was the least important. The predicted uptake of a medication increased 18 percentage-points when burning/stinging duration decreased from 2 hours to a few minutes. The increase was 41 percentage-points for Class 2 who were more likely to report neutral/poor control of their dry eye symptoms.

Conclusions: This study showed that side effects should be considered, in parallel with therapeutic efficacy, when choosing anti-inflammatory medications in DED. Incorporating patient preferences in treatment decisions could potentially improve patient acceptance of a treatment regimen.

TITLE: Influence of tobacco smoking on developing age-related ectropion and entropion

SESSION TITLE: Public Health I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Z.Z. Yu, P. Rizzuto, Division of Ophthalmology, Brown University Warren Alpert Medical School, Providence, Rhode Island, UNITED STATES|

Commercial Relationships Disclosure: Zane Yu: Commercial Relationship: Code N (No Commercial Relationship) | Philip Rizzuto: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Studies have shown that tobacco smoking significantly impacts general health and well-being. Tobacco smoking also has a multitude of negative consequences on ocular health, increasing the risk of age-related macular degeneration, cataracts, and glaucoma. The purpose of this study was to assess the impact of tobacco smoking on age-related ectropion and entropion.

Methods: Data on ectropion and entropion cases from a clinical practice from the years 2017 to 2019 were analyzed. Ages of non-smoking ectropion and entropion patients were compared with ages of ectropion and entropion smokers using normal distributions.

Results: The null hypothesis was that the average age of a smoker presenting with ectropion or entropion would not be significantly different from that of a non-smoking patient. The alternative hypothesis was the average age of a smoker presenting with ectropion or entropion would be younger. There were 101 non-smokers and 50 smokers in the dataset. The average age of a non-smoking patient presenting with ectropion or entropion was 77.78 with a standard deviation of 10.31. From a sample size of 50, the average age of a smoker presenting with ectropion or entropion was 74.44 with a standard deviation of 11.84. Z-test analysis reveals a Z-statistic of 1.70, giving a p-value of 0.045 for a one-tailed hypothesis. Using a standard confidence interval of 95%, this allows us to reject the null hypothesis.

Conclusions: Given the significantly lower average age of presentation with age-related ectropion or entropion in smokers compared to non-smokers, tobacco smoking is evidently associated with earlier age of onset in cases of age-related ectropion or entropion. The data only includes patients from around the Rhode Island area – potentially including Massachusetts and Connecticut – and cannot be reliably extrapolated to broader populations; additionally, this study did not address potential increases in risk of age-related ectropion or entropion in smokers. More research will need to be done to elucidate the association between tobacco smoking and age-related ectropion and entropion.

ABSTRACT BODY:

Purpose: To find out the factors that determine the risk of radiation retinopathy development after Plaque radiation treatment.

Methods: Retrospective analysis of all patients who underwent plaque brachytherapy with Iodine-125 for choroidal melanoma between 2004-2020 was done. Forty-eight patients who had minimum follow-up of 12 months post treatment were included in the analysis.

Results: Thirty of the 48 patients developed radiation retinopathy (62.5%) of which 23 patients had non-proliferative retinopathy and 7 patients had proliferative retinopathy. Twenty-five (83.33%) of the 30 patients also developed radiation maculopathy. Kaplan Meir survival analysis showed that proportion of patients free from radiation retinopathy is 50% at 5 years and 20% at 10 years. On univariate analysis, risk factors predictive of radiation retinopathy included increased width of the tumour (Hazard ratio (HR)= 1.14191, p=0.038), surface area of the tumour (HR= 1.0082, p=0.0371), total radiation dose to the apex of the tumour (HR= 1.01413, p=0.0371) and radiation to the optic nerve head (HR=1.0056, p=0.0374). On multivariate analysis, total radiation to the optic nerve head was the best predictor of radiation retinopathy (HR=1.0056, p=0.0380). Risk factors predictive of radiation maculopathy included total radiation dose to the apex of tumour (HR= 1.0468, p=0.0357) and radiation to the optic nerve head (HR= 1.0069, p=0.0182) on univariate analysis and radiation dose to the apex of tumour (HR= 1.0486, p=0.0334) and radiation to the optic nerve head (HR= 1.0067, p=0.0159) on multivariate analysis also.

Eighteen of the 23 patients with radiation maculopathy were treated with Intravitreal-Anti VEGF injections and 1 patient received an intravitreal dexamethasone implant. A mean of 2.4 (Range 1-6) injections were given.

Conclusions: Radiation retinopathy is a common complication of plaque brachytherapy for choroidal melanoma occurring in 50% of the patients at 5 years. The main predictive risk factors for development of radiation retinopathy in our study was total radiation dose to the apex, radiation to the optic nerve head as well as increased width and surface area of the tumour. All patients undergoing plaque brachytherapy for choroidal melanoma should be followed up closely for signs of radiation retinopathy.

ABSTRACT BODY:
Purpose: To examine the economic impact of vision impairment (VI) and dementia on older adults and caregivers
Methods: We used data from the 2011 National Health and Aging Trends Study (NHATS), a nationally representative survey of Medicare beneficiaries, linked to their family/unpaid helpers from the National Study of Caregiving (NSOC). VI was defined as self-reported blindness or difficulty with distance/near vision. Dementia was based on survey-report, interviews, and cognitive tests. Outcomes included (1) having debt, and receiving (2) financial help from relatives, and government-based (3) Supplemental Nutrition Assistance Program (SNAP) (4) other food assistance, and (5) utility assistance, for NHATS older adults, and (6) financial difficulty for NSOC caregivers.
Results: Of 7,608 NHATS older adults, 84% did not have VI or dementia, 6% had VI only, 7% had dementia only, and 3% had VI and dementia. In fully adjusted, logistic regression analyses, older adults with VI and dementia had greater odds of having debt (OR=3.9 [95%CI=2.1, 7.4]), and receiving financial help (OR=2.5 [1.6, 3.7]), SNAP (OR=2.6 [1.7, 4.1]), and other food assistance (OR=3.5 [2.1, 5.9]), but not utility assistance (OR=1.0 [0.6, 1.9], than older adults without either impairment, (Table 1). Of 2,007 NSOC caregivers, 54% cared for older adults without VI or dementia, 13% for VI only, 25% for dementia only, and 12% for VI and dementia. In logistic regression, caregivers to older adults with VI and dementia had greater odds of reporting caregiving-related financial difficulty (OR=2.8 [1.8, 4.3]) than caregivers of those without either impairment.
Conclusions: Older adults with VI and their caregivers experience similar financial outcomes as compared to older adults with dementia and their caregivers, respectively. However, these results are magnified for older adults with co-occurring VI and dementia, and their caregivers.

ABSTRACT BODY:

Purpose: To explore the effects of NCX 470, a nitric oxide (NO)-donating prostaglandin analog, on aqueous humor dynamics in ocular normotensive non-human primates.

Methods: Ocular hypotensive activity after topical dosing with NCX 470 ophthalmic solution 0.1% or its vehicle was tested in ocular normotensive non-human primates (n=6-12) using a randomized, investigator-masked, parallel-group design. Baseline intraocular pressure (IOP) was measured (pneumatonometer, Reichert), after which animals were treated twice daily (10:00AM & 4:00PM) for 3 consecutive days and once (AM dose) on day 4 (experimental day). On day 4 IOP measurements were taken at 90, 180 and 300min after the AM dose. Additionally, on day 4, animals were dosed topically with 10% fluorescein and fluorophotometric scans (Fluorotron Master, OcuMetrics) of the cornea and anterior chamber were taken at 45min intervals throughout the experimental period to address changes in aqueous inflow, outflow facility and uveoscleral outflow.

Results: Baseline IOP was similar between groups (23.7±0.9 and 23.3±1.1mmHg in NCX 470 0.1% and vehicle, respectively). On day 4, the IOP reductions with NCX 470 were greater than those with vehicle and were sustained throughout the entire experimental period [Change From Baseline (CFB), $NCX\ 470_{CFB}$ =7.8±0.7, 5.5±0.9 and 6.5±1.0mmHg and VEH_{CFB}=4.8±0.9, 2.9±0.9 and 3.5±1.4mmHg at 90, 180 and 300min post-dosing, respectively]. In addition, NCX 470 increased outflow facility (0.64±0.17 and 0.37±0.09µl/min/mmHg for NCX 470 and vehicle, respectively) and uveoscleral outflow (2.58±0.61 and 1.24±0.26µl/min for NCX 470 and vehicle, respectively) leaving unaltered aqueous inflow (1.93±0.31 and 2.03±0.22µl/min for NCX 470 and vehicle, respectively).

Conclusions: NCX 470 increased uveoscleral outflow and outflow facility in ocular normotensive non-human primates suggesting that changes in both pathways contribute to the IOP-lowering effect of this compound.

ABSTRACT BODY:

Purpose: To perform a comprehensive review of literature and meta-analysis of risk factors that accelerate progression of intermediate age-related macular degeneration (AMD) to late AMD.

Methods: The full protocol was registered on PROSPERO (CRD42021266710).

The search strategies were developed by an information specialist (C.A.-H.). The electronic databases Embase via Elsevier and Medline via Ovid were searched using text word synonyms and database-specific subject headings for AMD and disease progression (last search November 10, 2020). Records published before 1991 were excluded. No language restrictions were applied. The titles and abstracts of references were screened against eligibility criteria including: only studies with a defined grading system; a clear end point of advanced AMD; yearly follow up; in English and fellow eye AMD status known. Selected references were retrieved in full-text and independently assessed for eligibility by two reviewers. Any disagreements over eligibility were solved by discussion with other team members.

A data extraction sheet was constructed based on the modified checklist for critical appraisal and data extraction for systematic reviews of prediction modelling studies (CHARMS-PF). The risk of bias in each of the included studies was assessed using the quality in prognostic factor studies (QUIPS) tool. Data extraction and risk of bias assessment for each article was performed by two reviewers independently.

Results: Our electronic searches identified 3229 unique records. After initial title/abstract screening, 3130 records were deemed ineligible, and 99 papers were selected for the full-text screening. Eight articles met the inclusion criteria and will proceed to the data extraction and risk of bias assessment stages.

Conclusions: Despite extensive studies assessing progression of early or intermediate AMD to late AMD only 0.3 % met our requirements for inclusion in a systematic review. This reflects the heterogeneity of the assessed studies and suggests further consensus is needed on AMD classification systems and acceptable follow up times for cohort studies to ensure they can be included in future meta-analyses.

ABSTRACT BODY:

Purpose: It is often impractical to follow patients over decades to study the long-term natural course of a chronic disease. Here, we developed a statistical method for investigating the long-term natural history of diseases using data from patients followed over short durations.

Methods: We manually delineated geographic atrophy (GA) lesions on 1607 fundus photographs of 318 eyes in the age-related eye disease study (AREDS). We developed Bayesian entry time realignment (BETR), a hierarchical Bayesian change points method (Fig. 1), which estimated a patient's disease progression rate and disease duration at enrollment based on a hypothesized progression model. The best model was selected based on the lowest deviance information criterion (DIC). We tested BETR in 100 rounds of simulated trial data generated from GA data in the AREDS. We then applied BETR in the actual GA data from the AREDS.

Results: BETR identified the correct model in 100 out of 100 simulations when the true disease progression model was the first order, second order, or exponential model. The intraclass correlation coefficient (ICC) between the estimated and true disease duration and progression rate ranged from 0.73 to 0.93. Applying BETR in patients with GA in the AREDS showed that the second order model (DIC = -358) was better than the first order model (DIC = -6) and exponential model (DIC = 365). The results remained the same among 100 rounds of random subsamplings of 159 eyes. BETR reconstructed an approximately 30-year natural history of GA progression among individual eyes (Fig. 2).

Conclusions: BETR could identify the correct long-term disease progression model and estimate patient-level disease progression parameters with high accuracy, demonstrating BETR as a promising method to study long-term natural history of diseases. The square root of GA area enlarged linearly and at different rates among different eyes over approximately 30 years.

ABSTRACT BODY:

Purpose: Recent work highlights that lower salt diffusivity (D_s) of a soft contact lens (SCL) can prevent post-lens tear-film (PoLTF) hyperosmolarity and that the PoLTF osmolarity is significantly different from that of the tear meniscus and the pre-lens tear film (PrLTF) [Kim et al. 2021]. That effort focused on the spatially averaged PoLTF osmolarity and did not address localized tear break-up areas, which cause localized PrLTF osmolarity spikes that can be greater than 1000 miliosmolar (mOsM) [Peng et al. 2014]. Here, we assess the effect of localized PrLTF hyperosmotic spikes on PoLTF osmolarity and whether SCL wear can protect the cornea from hyperosmotic spikes.

Methods: SCL and PoLTF were designed with Comsol Multiphysics 5.5 platform and incorporated into a 2D continuum diffusion model to determine the PoLTF osmolarity transiently. Lens-salt partition coefficient (k_s), D_s, and lens thickness (h_{lens}) were varied to assess their effect on PoLTF osmolarity. Localized hyperosmolarity spike follows the time-dependent results of Peng et al. [2014] and were used as the anterior lens-surface boundary-layer condition (Figure 1a). A no-flux boundary was incorporated at the PoLTF/cornea interface. Initial conditions for SCL and tear compartments were obtained from steady-state solutions of Kim et al. [2021] for normal and dry eyes with various D_s, k_s, and h_{lens}.

Results: Figure 1b provides PoLTF osmolarity for normal eye with a given D_s, k_s, and h_{lens} (specified in Figure 1b) during various time points within an interblink while experiencing the PrLTF osmolarity spike of Figure 1a. Localized PoLTF osmotic spike did not occur until ~10 s into the interblink and the spike osmolarity was significantly lower than that of the PrLTF spike. For dry eye, osmolarities in break-up and non-break-up areas were elevated for a given D_s, k_s, and h_{lens}. Change in D_s significantly alters the peak magnitude.

Conclusions: SCL wear can protect the cornea against localized hyperosmolarity caused by tear break-up spots on the PrLTF. The magnitude of protection increases as the value of D_s lowers. Infrequent blinking results in higher hyperosmolarity spikes for the cornea; however, high osmolarity spikes can be prevented by lowering the D_s.

TITLE: Intriguing linear semi-logarithmic relationships of oxygen permeability with water, silicon, and fluorine contents of silicone-hydrogel contact lens materials

SESSION TITLE: Contact lens

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T.E. Dupre, W.J. Benjamin, Vision Science Research Center, University of Alabama at Birmingham, Birmingham, Alabama, UNITED STATES|T.E. Dupre, Nova Southeastern University, Fort Lauderdale, Florida, UNITED STATES|W.J. Benjamin, Material Performance Assessments, LLC, Hoover, Alabama, UNITED STATES|

Commercial Relationships Disclosure: Terin Dupre: Commercial Relationship: Code N (No Commercial Relationship) | William Benjamin: Commercial Relationship(s);Code C (Consultant/Contractor):LenTechs Inc, Mojo Vision Inc;Code O (Owner):Material Performance Assessments LLC;Code F (Financial Support):Professor Emeritus Dr. Benjamin performs research under contract by a great number of companies in the contact lens field as part of his post retirement business Material Performance Assessments LLC.

ABSTRACT BODY:

Purpose: Previously, the quadratic relationships between oxygen permeability (Dk), water (W) content, and combination of silicon and fluorine (Si+F) contents of available silicone-hydrogel (SiHy) contact lens materials were inspected (Dupre & Benjamin: Optom Vis Sci, 2020). Surprisingly, here, the relationships could also be described as linearly semi-logarithmic using the logarithm of Dk.

Methods: Sixteen contact lens brands were obtained on the market in a range of refractive powers from −3 to +6 D in single lots. Sixteen lenses per brand were tested after equilibration at 35°C in a standard saline according to ANSI Z80.20-2016 and ISO 18367-3:2017. W, Si, and F contents were obtained in % (Dupre & Benjamin: Eye & Contact Lens, 2019). Dk and the 3 contents were determined for the same lots of lenses of each lens brand.

Results: The relationships between log (Dk), W content, and (Si+F) content were described linearly: log (Dk) - 0.0098(W) + 2.3643, R2 = -0.7905 and log (Dk) = +0.0277(Si+F) + 1.6932, R2 = 0.6860. A point of equality for water and (Si+F) contents was found at W Content = (Si+F) Content = 17.9%, Dk = 154.5 Dk units and a point of equality for water contents of SiHy and conventional hydrogels (Young & Benjamin: Eye & Contact Lens, 2003) was found at W Content = 72.3%, Dk = 45.2 Dk units. The points of equality were similar to those found using the quadratic analyses.

Conclusions: There was a negative semi-logarithmic relationship between log Dk and W content and a positive linear semi-logarithmic relationship between log (Dk) and (Si+F) content. The coefficients of determination were slightly greater for the semi-log analyses as for the quadratic analyses. Thus, quadratic or linear semi-logarithmic equations can be used to describe the relationships within the ranges of values found in this investigation.

Note: Color digital copies of the publications cited in this abstract are available from Dr. Terin E. Dupre at td936@mynsu.nova.edu.

ABSTRACT BODY:

Purpose: PACG is a major cause of irreversible blindness worldwide. It is characterised by the mechanical apposition of the iris to the trabecular meshwork, resulting in anterior chamber angle narrowing and obstruction of the aqueous outflow, IOP elevation and subsequent optic neuropathy. EPDR1 was previously identified by GWAS to be a susceptibility locus in PACG, but its role in disease pathogenesis remains unknown. Our lab had previously shown EPDR1 expression in human and mouse lens epithelium, and the aim of our current study is to determine the ocular phenotype of Epdr1^{tm1b} knockout (KO) mice and elucidate the function of EPDR1 in human lens epithelial cells (HLECs).

Methods: The ocular phenotype of wildtype (WT) and Epdr1-KO mice was determined by serial IOP measurements and anterior segment OCT imaging. The HLEC line B-3 was transfected with an EPDR1 overexpression vector and the protein localisation was determined by confocal microscopy. Oxidative stress was induced in the cells by treatment with H_2O_2 and the expression of various unfolded protein response markers was analysed by qRT-PCR and western blot.

Results: For mice up to 24 weeks of age, there was a significant correlation between lens vault and age for Epdr1-KO mice but not for WT mice, suggesting that the loss of EPDR1 may cause an increase in lens thickness. No difference in IOP and anterior chamber depth was detected between KO and WT mice. EPDR1 is predominantly localised in the endoplasmic reticulum (ER) of B-3 cells and its overexpression in B-3 cells resulted in an increase in the baseline levels of the ER chaperone protein BiP and the ER stress-regulated transcription factor ATF6, suggesting a role of EPDR1 in ER stress response. Furthermore, B-3 cells treated with H_2O_2 expressed higher levels of BiP in the presence of EPDR1 overexpression, although EPDR1 overexpression did not protect cells from oxidative stress-induced apoptosis.

Conclusions: Our findings suggest that the in vivo loss of EPDR1 expression may affect lens vault and thickness as a potential mechanism in angle closure pathogenesis. BiP may work in tandem with EPDR1 during acute oxidative stress to promote the survival of lens epithelial cells. However, EPDR1 overexpression may not be able to protect against apoptosis during prolonged oxidative stress.

ABSTRACT BODY:

Purpose: Ocular mucous membrane pemphigoid (OcMMP) is a rare and potentially blinding condition for which consensus treatment guidelines do not exist. The purpose of this study was to assess the effectiveness and safety of various immunomodulatory agents in the treatment of OcMMP in a private practice setting.

Methods: We conducted a 10-year retrospective chart review of patients managed with OcMMP between 2011 and 2021 (n=22) at Northwest Eyelid & Orbital Specialists (Spokane, WA). Median age at diagnosis was 73 (Range: 35-91) and 59% (13/22) of patients were female. Visual acuity, Foster stage, and adverse effects (AE) were documented. A treatment episode (TE) was defined as initiation of a single immunomodulatory agent or a therapeutic combination of agents. For each TE, treatment outcomes were qualified at 3 months as a complete response (CR), response (R), or failure (F). After 3 months, CR was then further qualified as either sustained CR (CR_s), reactivation after initial CR (CR_r), or AE after initial CR (CR_a). Fisher's exact test p-values were calculated for each TE's outcome and discontinuation rate due to AE in comparison with mycophenolate.

Results: Twenty patients were treated with an immunomodulatory agent for a total of 55 TEs. Treatment outcomes are displayed in Figure 1. In comparison to dapsone, mycophenolate was more likely to achieve CR_s (50% vs. 0%, p=.022) and R (100% vs. 50%, p=.007), and less likely to fail (0% vs. 50%, p=.007). Figure 2 displays a Kaplan-Meier persistence curve for each immunomodulatory agent. Dapsone was also more likely to be discontinued due to AE than mycophenolate (40% vs. 6%, p=.041). Foster stage progression occurred in 14% (6/44) of eyes, and visual acuity worsened in 20% (9/44).

Conclusions: Mycophenolate is a superior first-line agent to dapsone in the treatment of OcMMP. Although not statistically significant, mycophenolate trends toward superiority over methotrexate as well. Mycophenolate is very effective when used in combination with rituximab. Azathioprine remains a reasonable second-line agent.

Commercial Relationships Disclosure: ByungJin Kim: Commercial Relationship: Code N (No Commercial Relationship) | Gee Hyun Kim: Commercial Relationship: Code N (No Commercial Relationship) | Mee Yon Lee: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the efficacy and clinical outcomes of one-way air-fluid exchange(AFE) procedure for treatment of post vitrectomy diabetic vitreous hemorrhage (PDVH) in patients with proliferative diabetic retinopathy (PDR).

Methods: We performed a retrospective study including 233 patients with PDR who underwent vitrectomy. One-way AFE procedure was performed for 24 eyes of 24 (10.30%) patients with persistent vitreous cavity rebleeding after the operation. Pre-procedural and post-procedural best corrected visual acuity (BCVA) were achieved. Occurrences of intra-procedural and post-procedural complications were analyzed.

Results: Significant visual improvement was observed at one month after the one-way AFE procedure (2.62 ± 0.60 LogMAR at baseline vs. 0.85 ± 0.94 LogMAR at post-procedure, $p < 0.0001$). Nineteen (79.17%) cases needed the procedure only once. Five (20.83%) cases underwent the procedure more than twice. In three (12.50%) cases, reoperation was eventually required due to persistent rebleeding despite several AFEs. No complication was observed during follow-ups.

Conclusions: One-way AFE procedure can be an excellent alternative to re-vitrectomy for patients suffering from PDVH on PDR by removing the bloody content in the vitreous cavity efficiently and permitting rapid visual recovery without causing obvious complications.

TITLE: Perioperative prednisolone administration attenuates systemic immune activation following intravitreal injection of AAV2, but fails to enable repeated gene transfer to the inner retina

SESSION TITLE: Gene Therapy and Gene Editing for Ocular Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Whitehead, P. Yu-Wai-Man, Institute of Ophthalmology, University College London, London, London, UNITED KINGDOM|

Commercial Relationships Disclosure: Michael Whitehead: Commercial Relationship: Code N (No Commercial Relationship) | Patrick Yu-Wai-Man: Commercial Relationship(s);Code C (Consultant/Contractor):GenSight

ABSTRACT BODY:

Purpose: Injection of adeno-associated virus serotype 2 (AAV2) vectors into the vitreous is associated with the induction of innate and adaptive immune responses that may limit therapeutic efficacy and inhibit vector readministration. Prednisolone is a glucocorticosteroid immunosuppressant that is commonly administered alongside intravitreal (IVT) injection of AAV2 in patients to limit the onset, duration and severity of intraocular inflammation. Whether this strategy can be utilised to enable vector readministration via attenuation of humoral immune activation, however, is unclear.

Methods: Adult male C57BL6/J mice were treated with 0.75 mg/kg/day prednisolone or PBS via intraperitoneal injections throughout the study. At 3wk, bilateral IVT injections of 1E10 viral genomes (vg)/eye AAV2.CAG.GFP were performed. At 6wk, mice received a second set of bilateral IVT injections of 1E10 vg/eye AAV2.CMV.mCherry. Mice were sacrificed at 9wk and eyes were processed into cryosections for immunohistochemical analysis. Spleens were extracted and lymphocyte populations were assessed with flow cytometry. Serum samples were collected throughout the study to assess levels of neutralising antibodies (NAbs) and total antigen-binding antibodies (TAbs).

Results: Prednisolone treatment was associated with significant reductions in NAb and TAb synthesis, and attenuated CD4 & CD8 T-cell and activated B-cell infiltration into the retina. Mechanistically, this was correlated with the inhibition of splenic germinal centre reactions and B-cell class-switching, however, regulatory T-cell levels were not changed in immunosuppressed mice. Despite the significant reduction in humoral immune activation exhibited in prednisolone-treated mice, the immunosuppressant alone proved insufficient in enabling vector readministration to the inner retina.

Conclusions: The present study highlights a cellular and molecular basis for perioperative steroid immunosuppression in attenuating anti-AAV2 immune activation when delivered via IVT injection. However, further improvements to circumvent humoral immune responses are likely to be required to enable vector readministration.

TITLE: Practitioners' perspectives on Demodex blepharitis: a comparison between eye care practitioners in India and Australasia

SESSION TITLE: Ocular surface health and conjunctiva

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Sharma, E. Martin, I. Pearce, S. Hagan, Vision Sciences, Glasgow Caledonian University, Glasgow, Glasgow, UNITED KINGDOM|J.P. Craig, The University of Auckland, Auckland, Auckland, NEW ZEALAND|

Commercial Relationships Disclosure: Nikhil Sharma: Commercial Relationship: Code N (No Commercial Relationship) | Eilidh Martin: Commercial Relationship: Code N (No Commercial Relationship) | Ian Pearce: Commercial Relationship: Code N (No Commercial Relationship) | Suzanne Hagan: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Craig: Commercial Relationship(s);Code C (Consultant/Contractor): Théa Laboratoires, Azura Ophthalmics, E-Swin, Alcon, Manuka Health NZ

ABSTRACT BODY:

Purpose: Demodex blepharitis remains an under-diagnosed condition, lacking universally-accepted diagnostic and management protocols. The primary aim of this study was to compare how eye care professionals in different regions of the world diagnose and manage Demodex blepharitis.

Methods: Ophthalmologists and optometrists in India and Australia/New Zealand were invited to complete an online survey on Demodex blepharitis. Practitioner demographics and views on eyelid health in general, as well as details of diagnostic and management practices from those reporting that they treat Demodex blepharitis in clinical practice, were collected. Mann-Whitney U, and Fisher's exact tests were used for statistical analysis.

Results: A total of 261 eyecare professionals completed the survey, 207 from India (84% optometrists); 54 from Australia and New Zealand (91% optometrists). Almost 70% of practitioners across the 3 countries considered Demodex blepharitis to be a cause of ocular discomfort, yet only 45% reported attempting to identify Demodex in their patients. There were significant differences in practice patterns between practitioners in Australasia and India. Practitioners' views differed in terms of perceived prevalence of Demodex blepharitis (60% in Australasia vs 27% in India; $p<0.001$), choice of slit lamp magnification used to detect the mites (25x in Australasia vs 16x in India; $p = 0.002$), preferred treatment option to manage Demodex blepharitis (tea tree oil in Australasia vs Standard lid hygiene in India; $p = 0.001$), treatment duration (3-4 weeks to more than 12 weeks in Australasia vs 3-4 weeks in India; $p = 0.002$) and frequency of treatment (once a day in Australasia vs twice a day in India; $p = 0.001$).

Conclusions: This study highlights differences in clinical evaluation and treatment practices between practitioners in India and Australasia. Overall, practitioners in Australia and New Zealand were more rigorous in their investigation and management. However, in both regions interprofessional differences in perceived optimal treatment duration and frequency were reported, highlighting a need for standardised treatment protocols to be developed for Demodex blepharitis.

TITLE: Metformin-mediated suppression of EMT in lens epithelial cells

SESSION TITLE: Lens epithelial cell stress and function

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J. Petrash, B. Shieh, M. Pedler, Ophthalmology, University of Colorado - Anschutz Medical Campus, Aurora, Colorado, UNITED STATES|

Commercial Relationships Disclosure: J. Mark Petrash: Commercial Relationship: Code N (No Commercial Relationship) | Biehuoy Shieh: Commercial Relationship: Code N (No Commercial Relationship) | Michelle Pedler: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In a study of patient outcomes from cataract surgery at our institution, we previously observed that patients with a history of metformin exposure had a lower risk for YAG capsulotomy (PMID: 34415985). This observation indicated that metformin may have a protective effect against development of posterior capsule opacification (PCO). The purpose of the current study is to use a mouse model to test whether metformin protects against early steps of PCO development.

Methods: We carried out extracapsular lens extraction (ECLE) in mice as a model for cataract surgery. Metformin was given in drinking water (10-50 mg/kg/day), starting 2 days prior to ECLE, and continued until animals were euthanized at day 5 after surgery and eyes processed for immunohistochemistry or extraction of RNA and protein. Molecular markers associated with epithelial-to-mesenchymal transition (EMT) were quantified by Western blotting or qRT-PCR. Mouse lens epithelial cells (LEC) cultures produced from lenses of wild type and aldose reductase-transgenic mice (AR-Tg) were also used to probe the effect of metformin on TGF-β-induced changes in markers associated with EMT.

Results: Treatment of primary LEC cultures with TGF-β led to upregulation of αSMA ($p<0.05$) and stimulation of ERK phosphorylation ($p<0.05$), well established markers of early steps in development of PCO. Treatment with 1 mM metformin suppressed activation of Smad2/3 and upregulated the inhibitory Smad7, resulting in downregulation of αSMA ($p<0.01$). Similarly, immunohistochemical staining showed that expression levels of αSMA in lens capsular bags 5 days following ECLE were substantially reduced by metformin in drinking water as compared to surgical eyes from animals provided regular drinking water. In mouse LEC cultures, metformin treatment led to a dose-dependent increase in AMPK activation as evidenced by levels of AMPKα-subunit phosphorylation ($p<0.01$). Levels of αSMA transcripts in capsular bags of ECLE mice remained suppressed for up 9 days following termination of metformin therapy ($p=0.003$), suggesting a durable effect of metformin against EMT during this timeframe.

Conclusions: Metformin, a well established AMPK activator, is an effective inhibitor of signaling pathways known to be activated in the pathogenesis of EMT. Further studies are warranted to determine the utility of this safe and effective drug against the onset and progression of changes leading to PCO following cataract surgery.

ABSTRACT BODY:

Purpose: Ocular pathology from soccer ball-induced trauma to the eye has been documented in detail, but the underlying mechanics are not as well-studied. This study utilized a computer simulation to evaluate the biomechanical events following the collision of a soccer ball with the eye to better understand the pathophysiology of ocular and retinal injuries that commonly arise. These injuries and their mechanisms were also compared to those observed in abusive head trauma (AHT).

Methods: A finite element computer model of the eye containing 140,770 analyzable nodes was simulated and subjected to a collision by a soccer ball simulated with regulation parameters. Resulting changes in intraocular pressure and stress within the ocular tissue and retina were measured.

Results: Impact of the soccer ball with the eye generated a pressure wave in the vitreous. The pressure wave created pockets of high and negative pressure within the vitreous as it traveled posteriorly. Pressure in the vitreous near the posterior pole flucuated between 39.6 kPa and -30.9 kPa before stabilizing. Stress in ocular tissue was greatest near the point of contact and peaked at 66.6 kPa. Stress in the retina was largely concentrated at the vasculature, especially at distal branches where stress rose to 15.4 kPa. On average, the retinal layer that experienced the most stress was the subretinal layer, but when only considering vascular tissue, the preretinal layer experienced the most.

Conclusions: High intraocular pressure and stress in ocular tissue near the point of soccer ball impact suggest that anterior segment injuries can be attributed to direct transmission of force from the ball. The pressure wave that follows likely accounts for injuries to the posterior segment as the positive and negative pressures in the vitreous exert compressive and tractional forces on the retina. The linear movement of the pressure wave may cause the localization of retinal lesions to the posterior pole. This differs from the diffuse distrubution of retinal hemorrhage in AHT, likely due to the presense of repetitive angular force in AHT, which is absent in soccer ball truama. These quantitive findings provide a foundation for future comparisons of the efficacy of protective eyewear models for soccer ball trauma.

TITLE: Computational evaluation of a novel intraocular lens design for controlling negative peripheral pseudophakic dysphotopsia

SESSION TITLE: Crystalline lens and IOLs

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: A. Ho, Brien Holden Vision Institute, Sydney, New South Wales, AUSTRALIA|A. Ho, School of Optometry & Vision Science, University of New South Wales, Sydney, New South Wales, AUSTRALIA|

Commercial Relationships Disclosure: Arthur Ho: Commercial Relationship(s);Code P (Patent):WO 2021/181300 A1

ABSTRACT BODY:

Purpose: Pseudophakic individuals experiencing negative peripheral dysphotopsia (DYS) report a persistent 'shadow' in their far peripheral visual field. The optical basis of DYS has been identified previously.[1] While some designs have been evaluated[2], no IOL designed specifically for controlling DYS are currently clinically available. In this study, the efficacy of a novel IOL design for controlling DYS is evaluated through computational modelling.

Methods: A 3D model of a pseudophakic eye based on the Escudero-Navarro Eye Model[2] was constructed (Figure 1). For control evaluation, an equiconvex intraocular lens (+22 D power, refractive index 1.55, 6 mm optic diameter) was placed in the model. Non-sequential optical ray-tracing using OpticStudio (Zemax, Kirkland WA) was conducted with incident light angle ranging from 55° to 100° in 0.5° steps. At each incident angle, 10,000 randomly distributed parallel rays were traced through the model. Using an analysis method based on Simpson (2019)[3], the relative retina intensity distribution (RID) was computed from the range of incident angles. The analysis was repeated for all combinations of pupil diameters (PD) from 2.0 mm to 5.0 mm in 0.5 mm steps, and lens axial positions (LAP) from 0.0 mm to 1.0 mm in 0.1 mm steps. The evaluation process was repeated for an IOL comprising the same central optical zone parameters but enhanced with novel peripheral surface contours described using cubic Bezier curves for preventing DYS.

Results: For the control lens, discrete combinations of PD and LAP resulted in illumination gaps in the RID (e.g. Figure 2a), indicating potential presence of DYS. An interplay between PD and LAP was evident leading to DYS at various PD over different LAP (and vice versa). For the novel lens design, RID results show no illumination gaps at any combinations of PD and LAP (e.g. Figure 2b).

Conclusions: The novel IOL design appears to be effective in controlling DYS over a range of PD and LAP. The seemingly quasi-random clinical presentation of DYS may be partially explained by the interplay of PD and LAP on the formation of retina illumination gaps.

ABSTRACT BODY:

Purpose: Flavoprotein fluorescence (FPF) imaging provides a readout of retinal oxidative stress by quantifying natural autofluorescence of oxidized retinal mitochondrial flavoproteins (535 nm) after blue light excitation (467 nm). Natural fluorophores in a patient's lens get brighter with oxidative stress and so may confound the desired retinal FPF signal, resulting in a combined lens and retinal fluorescence signal that elevates the FPF score. At the same time, natural lens aging can attenuate the signal. The purpose of this study was to generate and evaluate a lens correction algorithm (LCA) for use with FPF imaging.

Methods: Lens fluorescence and transmission were accounted for in a two-step process. First, interpolation was used to generate an estimate of lens fluorescence and isolate the retinal component. Second, after an adjustment for instrument calibration, natural lens attenuation was compensated using a third-order model. The efficacy of the LCA was assessed in 544 images of healthy control patients with no ocular pathology from different databases obtained automatically generated by Ocumet ® Image Analysis software at the time of patient presentation. A case study is also presented of a patient with images before and after cataract surgery, highlighting clinical relevance of this application.

Results: After the LCA was applied the raw FPF scores of 554 images, the slope of best fit was attenuated (m= 1.4556 vs m= 0.0584) suggesting the correction algorithm was successful in accounting for native lens autofluorescence. Signals clustered tightly around line of best fit before and after compensation. A positive age-dependent relationship was maintained, although largely adjusted for (R^2= 0.7012 vs 0.0185). After adjustment, FPF intensity scores displayed similar strength positive relationships with age when compared to patients with intraocular lens implants (IOL), which display minimal fluorescence (R^2= 0.0165 vs 0.0193).

Conclusions: The LCA reduced the effects of the aging lens and addressed an important confounder in measuring retinal FPF. Future work may test this algorithm on a large cohort of cataract patients after phacoemulsification and IOL implantation to confirm the FPF signal changes from aging lens fluorescence contribution

ABSTRACT BODY:

Purpose: Glaucoma is the leading cause of irreversible blindness. Despite treatments to lower intraocular pressure many patients will continue to go blind. Neuroprotective therapies that target the retina and optic nerve in glaucoma are of great therapeutic need. Repleting NAD robustly protect from glaucoma-related insults in a variety of animal models and improves visual function in existing glaucoma patients.

Methods: The aim of this study is to assess the role of NMNAT2 in glaucomatous neurodegeneration and neuroprotection. NAD production in retinal ganglion cells is controlled through two terminal enzymes; NMNAT1 (localized to the nucleus) and NMNAT2 (localized in the cytoplasm). NMNAT2 is expressed exclusively in neurons and shows high expression in retinal ganglion cells. We used rodent and cellular systems to assess the role of high and low NMNAT2 in retinal ganglion cell susceptibility to neurodegeneration (genetic, viral gene therapy, and pharmacology).

Results: We demonstrate that there is down-regulation of NMNAT2 in models of glaucoma and retinal ganglion cell axon degeneration and confirm this in post-mortem human glaucoma tissue. Gene therapy restoring NMNAT2 levels to retinal ganglion cells robustly protects from glaucoma and axon injury (in vivo and ex vivo models). Supporting this, mice with genetically depleted NMNAT2 show increased susceptibility to glaucoma related injury. To further target NMNAT2 function, we have identified novel NMNAT2 activators that work in an NAD/NMN- and NMNAT2- dependent mechanism (this specificity was confirmed by using pharmacological and genetic inhibition of enzymes in the NAD-salvage pathway in vitro and in vivo). We are now developing novel pharmacology based on this.

Conclusions: NMNAT2 is an important generator of NAD in retinal ganglion cells and low NMNAT2 critically drives retinal ganglion cell susceptibility to glaucoma-related stresses. Targeting NMNAT2 via viral gene therapy or novel small molecule pharmacology generates NAD and protects from neurodegeneration.

ABSTRACT BODY:

Purpose: Glucose metabolism in the retina is carefully orchestrated, with glucose being delivered to photoreceptors from the choroidal circulation through the RPE. In photoreceptors, glucose is processed principally by aerobic glycolysis, from which the lactate byproduct is provided to the RPE and Müller glia for their energetic needs. In this study, we utilize a modified arrestin1 protein to enhance the glycolytic output of lactate from rod photoreceptors through disinhibition of enolase1 activity with the goal being to use this increased lactate production as a gene-agnostic approach for slowing retinal degeneration.

Methods: Mouse arrestin1 with E362G/D363G amino acid substitutions (referred to “ArrGG”) was packaged into AAV2-quadY-F+T-V serotype and tested for safety and for efficacy in increasing retinal lactate production. The modified arrestin1 was then delivered intravitreally to the P23H rhodopsin knock-in mouse model of retinitis pigmentosa ($Rho^{P23H/+}$) to determine if enhancing glycolysis in photoreceptors can slow retinal degeneration. Retinal health was measured by electroretinograpy, optical coherence tomography, and histology.

Results: Overexpression of ArrGG in C57BL/6J mice did not result in any detectable changes in either ERG function or photoreceptor survival as measured by outer nuclear layer thickness. However, mouse retinas expressing ArrGG showed a ~25% increase in the rate of lactate secretion. In P23H rhodopsin mice, expression of ArrGG slowed the decline of both scotopic and photopic ERG function. Correspondingly, there was significant preservation of ONL thickness in mice treated with ArrGG compared to controls. Furthermore, ArrGG-treated retinas showed a significantly higher rate of lactate secretion compared to controls.

Conclusions: Our studies show that expressing ArrGG in C57BL/6J mouse retina resulted in an increase in lactate production, consistent with an upregulation of glycolysis. In the P23H rhodopsin model of retinitis pigmentosa, the expression of ArrGG led to significant preservation of photoreceptor function and slowing of retinal degeneration. These findings suggest that enhancing glycolysis by targeting increased enolase1 activity with a modified arrestin1 in photoreceptors may offer a gene-independent therapeutic approach to slowing retinal degeneration.

ABSTRACT BODY:

Purpose: Mitochondrial DNA (mtDNA), a 16.7kb circular DNA, is damaged in diabetic retinopathy and its transcription is impaired, and the electron transport chain is compromised, fueling into the vicious cycle of free radicals. Diabetes also alters expressions of many long non-coding RNAs (LncRNAs), the RNAs with more than 200 nucleotides and no open reading frame for translation. Although most of the LncRNAs are encoded by nuclear genome, mitochondrial genome also encodes three LncRNAs, and the expression of mtDNA-encoded LncRNA Cytochrome B (LnCytB) is decreased in diabetes. The aim of this study was to investigate the role of LncCytB in mtDNA stability in diabetic retinopathy.

Methods: Human retinal endothelial cells, incubated in normal (5mM) or high (20mM) D-glucose for four days, were analyzed for LncCytB expression by qRT-PCR and strand-specific PCR, and its mitochondrial localization by RNA fluorescence in situ hybridization (RNA-FISH)-immunofluorescence technique. Packaging of the mtDNA was determined by Flow Cytometry and by its sensitivity to Micrococcal nuclease digestion. The role of LncCytB in mtDNA stability was confirmed in HRECs transfected with LncCytB by quantifying mtDNA damage (by extended length PCR) and its protective nucleoids (by SYBR green staining).

Results: Compared to normal glucose, high glucose decreased LnCytB levels in the mitochondria. While the sensitivity of mtDNA to Micrococcal nuclease was increased, packaging of mtDNA and its protective nucleoids were decreased. Overexpression of LnCytB ameliorated glucose-induced increase in mtDNA damage and decrease in mtDNA-encoded nucleoids.

Conclusions: Downregulation of LncCytB in the mitochondria in hyperglycemic milieu reduces the protective nucleoids, which makes mtDNA more susceptible to the damage. The damaged mtDNA compromises the electron transport chain and the vicious cycle of free radicals continues to self-propagate. Thus, regulation of LnCytB has potential to prevent mtDNA damage, and the progression of diabetic retinopathy.

ABSTRACT BODY:

Purpose: We investigate the relationship between macular retinal thickness and glucose tolerance in a large population-based study.

Methods: All participants with available measurements (C-peptide, fasting plasma glucose, HbA1c, and OCT scans) from the LIFE-Adult study, a population-based, sex- and age-stratified study, were included. Macular volume scans (97 B-scans by 512 A-scans) from Spectralis OCT were automatically segmented into ten layers after excluding low-quality (< 20 dB) B-scans. The Early Treatment Diabetic Retinopathy Study (ETDRS) grid was used to calculate average sectorial thickness, adjusted by scan length and location of the fovea center. Figure 1 shows the abbreviations of layers and sectors. ANOVA, t-test (significance level: $p<0.05$), and linear regression (Akaike Information Criterion [AIC] difference >6 defining a strong effect) were used to identify and compare impacts on retinal thickness.

Results: Figure 1A shows the average of ETDRS sectorial thickness in ten layers of the selected 13138 eyes (7234 participants), grouped as diabetic, prediabetic, and normal glucose tolerant. As we did not find significant lateral differences, only right-eye results are presented (6597 eyes/participants). Figure 1B-C reveals extensive retinal thinning in the diabetic group compared with the subjects with normal glucose tolerance, especially in inner layers, with stronger effects for males compared to females. Increasing age was significantly associated with retinal thinning in nearly all layers except RNFL, OPL, and IZ, where age had no or opposite effects (Figure 2A). Apart from age, diabetes-related parameters (e.g., C-peptide) exhibited additional effects on retinal thinning (Figure 2B-C). In males, strong effects of C-peptide were observed in the inner sectors of RNFL, GCL, IPL, outer sectors of ONL, and MZ,

while in females, effects were more pronounced in the outer sectors of ONL, MZ, and some sectors in EZ+OS.
Conclusions: In this large population-based sample, participants with diabetes showed extensive retinal thinning compared to normal glucose tolerant subjects. Age had strong effects on retinal thinning. In addition, diabetes-related parameters were linked to thickness of specific layers, with different patterns in males and females.

ABSTRACT BODY:

Purpose: Failure of retinal ganglion cell (RGC) axon regeneration prevents recovery of vision in optic neuropathy conditions like glaucoma. Due to the poor regenerative capacity of the adult mammalian central nervous system, finding ways to stimulate successful axonal regeneration in humans remains challenging. Unlike patients and mammalian model organisms, adult teleost fish can fully regenerate RGC axons enabling functional recovery from optic nerve injury. We are using the zebrafish model to probe the mechanisms of successful axon regeneration with the hopes of translating these findings to improve regeneration in mammals and eventually patients.

Methods: Laser Capture Microdissection RNA-seq (LCM-seq) was used to determine differentially expressed genes in the retinal ganglion cell layer of adult zebrafish 3 days post optic nerve crush versus uninjured control. Bioinformatic analysis was used to identify pathways and gene sets that are enriched in differentially expressed genes. To test the importance of srebf2 specifically, fatostatin drug treatment and morpholino antisense were used to antagonize its function. Axon regeneration into optic nerve at 3 days and optic tectum at 7 days post injury was analyzed by measuring GFP intensity using gap43:GFP transgenic zebrafish. The dorsal light response test was used to measure visual recovery at multiple times post injury. To assay RGC survival, whole mount retina with Hoechst stain was used to counting cell densities after each treatment.

Results: Retinal ganglion cell layer LCM-seq identified genes in the mevalonate/cholesterol synthesis pathway that are upregulated during axon regeneration. The master transcriptional regulator of this pathway, srebf2, was also highly upregulated. In comparison to untreated or vehicle treated control groups, srebf2 inhibited by either fatostatin or morpholino decreased axon regeneration into the optic tectum at both 3 days and 7 days post injury and delayed recovery of the dorsal light response over the course of normal optic nerve regeneration without causing any significant loss of RGCs.

Conclusions: These data indicate that srebf2 plays an important role in regulating efficient axon regeneration in the zebrafish visual system and suggests that the mevalonate/cholesterol synthesis pathway and its downstream products may have a role in this effect.

ABSTRACT BODY:

Purpose: Our conceptual framework for how visual function changes from normal aging to early and intermediate AMD specifies that the first visual dysfunction in AMD is delayed rod-mediated dark adaptation (RMDA), impacting photoreceptor sustenance (eg retinoid re-supply), including changes in choriocapillaris and RPE, and appearance of lipoprotein containing deposits. While evaluating this framework requires a longitudinal analysis, this cross-sectional analysis compares RMDA and other visual functions (acuity, contrast sensitivity, light sensitivity) between aged normal, early and intermediate AMD eyes, providing insight as to the validity of our framework.

Methods: ALSTAR2 is a prospective cohort study to examine functionally validated structural endpoints in normal aging and early and intermediate AMD. At baseline participants were recruited based on ICD10 codes in EHR. AMD disease presence and severity was determined via color fundus photos evaluated by a masked grader using the AREDS 9-step system. Visual functions evaluated were RMDA (5° eccentricity, 83% equivalent bleach), acuity and contrast sensitivity (photopic, mesopic), and light sensitivity for a 21-target grid in the macula (scotopic, mesopic, photopic) using S-MAIA and HFA.

Results: N=482 eyes from 482 persons (M age 72, 60-90 years) were evaluated (60% women, 91% white). Delayed RMDA was the most common visual dysfunction present in 36% of eyes in normal aging, increasing in prevalence to 51% and 94% in early and intermediate AMD respectively (Table 1). The difference in the prevalence of other visual dysfunctions was considerably less than for RMDA. Using z-scores to standardize measures, the largest difference in function by AMD status and severity was for RMDA between aged normal and intermediate AMD. While other functions were reduced among intermediates compared to normal, all differences were less than half that of RMDA (e.g., scotopic light sensitivity=0.75 SD). Of all functions, RMDA also had the greatest difference between aged normal and early AMD (0.30 SD).

Conclusions: Among the visual functions considered, the greatest difference between AMD and normal eyes is for RMDA. This finding provides indirect support for the hypothesis that RMDA is the first visual function impacted during the natural history of AMD, which will be examined longitudinally at the ALSTAR2 three-year follow-up visit.

Commercial Relationships Disclosure: Mark Bullimore: Commercial Relationship(s);Code C (Consultant/Contractor):Alcon Research;Code C (Consultant/Contractor):Coopervision;Code C (Consultant/Contractor):Essilor;Code C (Consultant/Contractor):Eyenovia;Code C (Consultant/Contractor):Genentech;Code C (Consultant/Contractor):Johnson & Johnson Vision;Code C (Consultant/Contractor):Novartis;Code C (Consultant/Contractor):Vyluma | Noel Brennan: Commercial Relationship(s);Code E (Employment):Johnson & Johnson Vision
ABSTRACT BODY:
Purpose: Myopia severity has a profound impact on visual impairment in later life. A patient's final level of myopia may be lowered by myopia control, but also by delaying onset. Here we evaluate the influence of age of onset on the final recorded level of myopia.
Methods: Data were extracted from the following reports:
- two prospective cohort studies of myopia progression in East Asia where final recorded level of myopia is presented as a function of age of onset (Chua et al., 2016; Hu et al., 2020)
- two retrospective studies of myopia progression in India and the Netherlands (Verkicharla et al., 2004; Polling et al., 2021)
- two cross-sectional studies in Argentina and the UK (Iribarren et al., 2004; Williams et al., 2013).

For the above, age of onset was based on self-report of age at first spectacle prescription and the midpoint was used for all age ranges.
A seventh set of data comprised Finnish subjects originally recruited for a clinical trial and followed into adulthood (Parssinen et al., 2019). Subjects were divided into five groups according to age at recruitment which was used as a surrogate for age of onset.
Results: Figure 1 shows the final recorded level of myopia as a function of age of onset for the seven studies. Figure 1A shows data for the two East Asian studies. The myopia level is different because the reference ages are 11 and 17 years. The slopes are 0.97 and 0.68 D/year, meaning that each year later age of onset is associated with 0.97 or 0.68 D less myopia at the final refraction. Figure 1B shows data for the five non-East Asian studies. For four studies the slopes are substantially flatter, with slopes between 0.23 and 0.35 D/year. In contrast, the slope for the Finnish study was 0.87 D. Among subjects of European descent, increasing age of final refraction tended to be associated with higher levels of myopia.
Conclusions: Among East Asians, delaying onset of myopia by just one year has potential to lower the final level myopia by 0.75 D or more—equivalent to multiple years of myopia control with existing modalities. The benefit is lower, but meaningful, among non-East Asians. The trend linking age of final refraction with final myopia level suggests ongoing adult progression.

ABSTRACT BODY:

Purpose: To describe trends in the number of men and women reporting a subspecialty practice focus among American Board of Ophthalmology (ABO) Diplomates.

Methods: The de-identified records of all ABO-certified ophthalmologists between 1992-2020 were obtained. Certification year, gender, and self-reported primary practice area for each ophthalmologist were extracted. Subspecialty was defined as the self-reported primary practice area. The data was then organized (Table 1) and longitudinal trends were graphed using Microsoft Excel. Chi-square analysis was conducted using R (R Foundation, Vienna, Austria).

Results: A total of 12,844 board-certified ophthalmologists were included: 8,459 men (66%) and 4,385 women (34%). Of those, 3,940 (46%) men and 2,102 (48%) women reported a subspecialty. A significantly greater proportion of women than men reported primary practice in pediatrics (9.9% vs. 3.7%, $p < 0.001$) and glaucoma (10.4% vs. 7.4%, $p < 0.0001$). A significantly greater proportion of men than women reported primary practice in vitreoretinal surgery (22.0% vs. 10.6%, $p < 0.0001$). There was no difference between the proportion of men and women reporting cornea ($p=0.15$) or oculoplastics ($p=0.31$). The gender composition of different subspecialties has changed from 1992-2020 (Figure 1). For new ophthalmologists certifying with the ABO, Oculoplastics has shifted from 27% of women certifying in 1992 to 49% in 2020. Specialization of women has increased from 21% certifying in glaucoma and 25% certifying in cornea to almost 56% in 2020 for both specialties. Representation of women certifying per year has increased in surgical retina from 12% to 25%, however, men still outnumber women 3:1, even among ABO diplomates from 2020. Women became the majority in pediatric ophthalmology around the year 2000, and in 2020 they made up 76% of new subspecialists.

Conclusions: The number of men entering ophthalmology outnumbers that of women 2:1 over the time period of this study, hence they remain the majority in ophthalmology and consequently, in most subspecialties. The gender makeup of ophthalmology subspecialties has changed between 1992 and 2020. The changes are not uniform across subspecialties, with some subspecialties closing the gender gap.

TITLE: Evaluating different thresholding methods for vessel density calculations in optical coherence tomography angiography scans of diabetic macular edema eyes

SESSION TITLE: OCT Angiography Clinical Applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B.B. Huang, J.X. Ong, A.A. Fawzi, Ophthalmology, Northwestern University Feinberg School of Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Bonnie Huang: Commercial Relationship: Code N (No Commercial Relationship) | Janice Ong: Commercial Relationship: Code N (No Commercial Relationship) | Amani Fawzi: Commercial Relationship(s);Code C (Consultant/Contractor):Boehringer Ingelheim, Regeneron, Roche/Genentech

ABSTRACT BODY:

Purpose: Different thresholding methods to remove background noise in optical coherence tomography angiography (OCTA) scans have not been studied in diabetic macular edema (DME) eyes. We tested whether vessel density (VD) values from a built-in AngioVue Analytics software (Method 1) or a deep capillary plexus (DCP) vessel length density (VLD)-based thresholding method (Method 2) would be more accurate for DME eyes.

Methods: We examined 9 DME eyes, each with 5 repeated OCTA scans. For each eye, we performed image segmentation, registration, and averaging to generate an averaged scan for the full retina as well as the SCP, MCP, and DCP slabs. We calculated the parafoveal VD of each averaged scan using an automated method available in ImageJ and used this VD as the ground truth VD. Then, for the best quality scan of each layer, we calculated the VD using both Methods 1 and 2. For statistical analysis, we calculated the mean absolute error (MAE) of each of the two methods (using the averaged scan VD as the ground truth value) and performed the two-sided paired t-test.

Results: For the DCP layer, the MAE of Method 2 was smaller than that of Method 1 ($p=0.042$). For the SCP layer, the opposite was true ($p=0.037$). For the full retina and MCP layer, Method 1 had a smaller MAE than Method 2, but the difference between the two methods was not statistically significant ($p = 0.46, 0.42$ respectively for these two slabs).

Conclusions: For DME eyes, the DCP VLD-based thresholding method (Method 2) is significantly more accurate for the DCP slab, while the AngioVue VD (Method 1) more closely matches the ground truth VD for the SCP layer. The two methods perform similarly for the full retina and MCP slab. This study highlights the importance of validating different thresholding methods for different retinal slabs in order to accurately calculate parameters such as VD for downstream analysis in eyes with different pathologies, including DME.

TITLE: Modelling the expected effect of correcting chromatic aberration on visual performance

SESSION TITLE: Functional imaging and wavefront correction

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Nankivil, Research & Development, Johnson & Johnson Vision, Jacksonville, Florida, UNITED STATES|A. Roorda, N. Ivzan, M. Banks, Herbert Wertheim School of Optometry & Vision Science, University of California at Berkeley, Berkeley, California, UNITED STATES|

Commercial Relationships Disclosure: Derek Nankivil: Commercial Relationship(s);Code E (Employment):Johnson & Johnson Vision;Code I (Personal Financial Interest):Johnson & Johnson Vision;Code P (Patent):Johnson & Johnson Vision;Code R (Recipient):Johnson & Johnson Vision | Austin Roorda: Commercial Relationship: Code N (No Commercial Relationship) | Nadav Ivzan: Commercial Relationship: Code N (No Commercial Relationship) | Martin Banks: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Longitudinal Chromatic Aberration (LCA) and Transverse Chromatic Aberration (TCA) adversely affect retinal image quality. Thus, one expects improved visual performance when chromatic aberrations are minimized or eliminated. Systematic evaluation of the impact of LCA and/or TCA correction under broadband illumination is needed. The purpose of this study is to characterize the expected impact of LCA and/or TCA correction under ecologically valid broadband illumination.

Methods: Simulations utilized an ocular wavefront with +3D of spherical error and +0.06D/mm^2 of spherical aberration and a wavefront correction with a spherical aberration of -0.06D/mm^2 and a paraxial power of -2.87D. Entrance pupil diameter was 4.3mm. LCA was modeled using Thibos et al.'s (1992) chromatic eye and TCA was modeled using Thibos's (1987) modified Gullstrand reduced-eye model. Considering the human population, a range of LCA, TCA or both LCA and TCA were modeled, such that low LCA = 1.29D, high LCA = 3.57D, low TCA = 0.4, 0.2 arcmin, and high TCA = 6.3, 3.1 arcmin in the sagittal and transverse meridians from λ = 400 to 700nm. The spectral weighting function was derived considering three OLED stimuli (white, purple, and green). With the purple stimulus, luminance was equal for all three primaries. The normalized cumulative photopic efficacy weighted foveal Point Spread Function (PSF) and Modulation Transfer Function (MTF) were calculated. To provide an estimate of the perceptual impact of chromatic aberrations, the areas of the MTF from 3 to 12cpd with and without LCA and/or TCA correction were compared.

Results: The area of the photopic efficacy weighted MTF is reduced by approximately 4 to 30%, 13 to 57%, and 1 to 16% due to low and high amounts of LCA and 0 to 12%, 0 to 32%, and 0 to 2% due to low and high amounts of TCA for white, purple, and green stimuli, respectively. Collectively, typical ocular LCA and TCA reduces the area of the photopic efficacy weighted MTF by approximately 4 to 33% for white stimuli, 13 to 59% for purple stimuli, and 1 to 18% for green stimuli.

Conclusions: Chromatic aberration varies widely in the population. Many subjects have negligible foveal TCA, while all subjects have a substantial amount of LCA. Thus, LCA correction improves visual performance more than TCA correction. Correction of LCA should result in salient improvements in visual performance with either white or purple stimuli.

ABSTRACT BODY:

Purpose: The angioarchitecture of choroidal tissue exhibits an array of manifestations in healthy eyes. This study analyzed the age-related changes in the macular choroid in healthy eyes using swept-source optical coherence tomography angiography (SS-OCTA) in Indian subjects.

Methods: This was a cross-sectional, prospective, observational study enrolling 222 eyes of 116 healthy participants. SS-OCTA images were captured using the PLEX Elite 9000 (Carl Zeiss Meditec Inc., Dublin, CA, USA) with a 6x6mm pattern centered on the foveal center. Subfoveal choroidal thickness (CT) and choroidal volume (CV) were generated automatically through manufacturer tools available in the ARI hub network. Choroidal vascularity index (CVI) and choriocapillaris flow deficits (CCFD) were computed using ImageJ.

Results: CV was found to be significantly higher in females as compared to males (table). Overall, there was a significant positive correlation of CVI and CCFD, and a significant negative correlation of CT and CV with age. The relationship, however, was more complex, as decade-wise analysis showed that CT and CV increased until the 2^{nd} decade, followed by a decrease until the 6^{th}, and then an increase again in the 7^{th} and 8^{th} decades. CVI was highest in the 7^{th} decade. In contrast, CCFD increased consistently with age and in all the ETDRS rings (figure). CCFD was negatively correlated with CVI from the 3^{rd} to 6^{th} decades of life.

Conclusions: Choroidal parameters can show significant variations with age. While choriocapillaris shows a consistent worsening with age with increasing flow deficits, the relationship between age and the other choroidal parameters is more complex. These differences are not uniform or consistent with age, highlighting the importance of a normative reference database to assess the significance of choroidal alterations associated with disease.

TITLE: Dual optical coherence tomography and microscopy for topographical and cellular evaluation of the cornea

SESSION TITLE: Corneal Imaging and Corneal Nerves

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Canavesi, A. Cogliati, LighTopTech Corp., New York, UNITED STATES|H.B. Hindman, The Eye Care Center, New York, UNITED STATES|

Commercial Relationships Disclosure: Cristina Canavesi: Commercial Relationship(s);Code I (Personal Financial Interest):LighTopTech Corp.;Code P (Patent):LighTopTech Corp. | Andrea Cogliati: Commercial Relationship(s);Code I (Personal Financial Interest):LighTopTech Corp.;Code P (Patent):LighTopTech Corp. | Holly Hindman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We investigate the feasibility of dual imaging of corneal tissue with optical coherence tomography (OCT) and Gabor-Domain Optical Coherence Microscopy (GDOCM) to simultaneously visualize corneal morphology in three dimensions and resolve cellular features.

Methods: Imaging of donor corneal tissues was conducted with the novel dual-mode imaging system. The corneas, which are stored in a PMMA viewing chamber after recovery from donors, were imaged through the container to avoid contamination. The OCT imaging modality was used to quantify corneal thickness and overall topography over a field of view of 10 mm x 10 mm. The GDOCM imaging modality was used to visualize cellular structures including endothelial cells over a maximum field of view of 3.7 x 3.7 mm^2 with isotropic resolution of <3 µm in 3D. A numerical flattening method was applied to the 3D GDOCM images to compensate for the natural curvature of the cornea and produce a view of the endothelial cells in a single en face view, which can be compared to the conventional output of specular microscopes commonly used at eye banks to assess cell count density. Automated cell counting with machine learning methods was applied to the GDOCM images to assess endothelial cell density in an unbiased manner.

Results: The thicknesses of the corneal layers were assessed with the OCT imaging modality; the GDOCM imaging modality demonstrated cellular resolution in all corneal layers. The cell counts automatically obtained with machine learning from the numerically flattened GDOCM images of the endothelium were compared with the gold standard of specular microscopy.

Conclusions: Corneal imaging was conducted for the first time with two modalities (GDOCM and OCT) in the same instrument. Non-contact imaging provides a volumetric field that enables quantification of key cellular features of corneal tissue. This label-free approach to imaging may help us to better understand changes occurring in disease states or with age over time.

ABSTRACT BODY:

Purpose: To evaluate the intra-visit variability of quantitative measurements of SS-OCTA metrics.
Methods: One eye each from subjects with glaucoma and healthy controls were prospectively recruited from four sites. If two eyes were eligible, one eye per subject was designated randomly as the study eye. Each eye was imaged using the Angio 6x6 mm scan centered on the macula and centered on the optic disc on PLEX® Elite 9000 (ZEISS, Dublin, CA). Scans were repeated at each location on each device 3 times per visit, and the subjects were expected to complete 3 visits within one month.

Data were processed on the Advanced Imaging Network Hub using the algorithms: a) “Peripapillary Nerve Fiber Layer Microvasculature Density v0.9”, which quantifies microcirculation (with large vessels removed) in the radial peripapillary capillary layer, summarizing data over an annulus centered at the optic disc and b) “Superficial and GCIPL analysis v0.5”, which quantifies microcirculation in the superficial slab, summarizing data over the ETDRS grid centered on the macula.

Perfusion density (PD) is defined as the total area of perfused microvasculature per unit area. Flux index (FI) is defined as the total weighted area of perfused microvasculature per unit area in a region of measurement. The weight is the normalized flow intensity corresponding to each pixel. Vessel density (VD) is defined as the length of perfused microvasculature per unit area.

Intra-visit variability was determined by averaging the within-subject variance across visits for all eyes. The square root of this variance is the repeatability standard deviation.
Results: 33 healthy eyes (mean age 56.8, SD 11.5 years) and 31 eyes with glaucoma (mean age 61.1, SD 11.5) were imaged.

Table 1 shows the mean and coefficient of variance (CV) for legacy segmentation for disc-centered PD and FI measurements, which ranged from 1.7% to 3.2%. Table 2 shows the mean and CV for macula-centered VD and PD measurements, which ranged from 8.8% to 16.0%.

Conclusions: Coefficients of intra-visit variation are acceptable for both macula-centered and optic disc-centered SS-OCTA metrics, with optic disc-centered metrics showing excellent intra-visit variation. These parameters may have clinical utility for monitoring glaucomatous damage.

ABSTRACT BODY:

Purpose: To assess the diagnostic accuracy of an automated macular fluid volume (MFV) quantification for treatment required diabetic macular edema (DME).

Methods: The evaluation included macular structural optical coherence tomography (OCT) raster scans (Spectralis, Heidelberg), and 3x3-mm macular OCT angiography volumetric scans (Avanti, Optovue). Central subfield thickness (CST) was measured on Spectralis OCT scans using the embedded software. A custom deep-learning algorithm automatically quantified MFV within 3x3-mm on the OCTA scans. Physicians treated patients per standard of care based on clinical and Spectralis OCT findings without access to MFV. We calculated the area under the receiver operating characteristic curve (AROC) and sensitivity and specificity of CST, MFV, and visual acuity for treatment decision.

Results: Of 139 eyes, 39 (28%) eyes underwent treatment for DME. The algorithm detected fluid in all eyes with a mean (SD) MFV of 0.062 (0.14) mm^3, but only 54 (39%) eyes met the DRCR.net criteria (CST>=320mm in male or CST>=305mm in female) for center-involved macular edema. The AROC of MFV for a treatment indication (0.81; 95% CI, 0.73 to 0.90) was larger than the AROC of CST (0.67; 95% CI, 0.56 to 0.78; P = 0.0048) (Fig 1). With the specificity fixed at 80%, the sensitivity of MFV for treatment indication was 74.4% (95%CI, 61.5% to 87.2%), higher than that of CST of 41.0% (95%CI, 25.6% to 56.4%, P = 0.0007). The eyes that met the threshold for treatment based on MFV (>0.031 mm^3) but the physicians chose not to treat had better visual acuity (mean [SD], 77.9 [7.3] letters) compared to the eyes that were treated (70.3 [10.8] letters; P = 0.0053). A multivariate logistic regression model showed that MFV (Estimate = 13.6, [95% CI, 6.7 to 22.7], P = 0.0008) and visual acuity (Estimate = -0.082 [95% CI, -0.14 to -0.026], P = 0.0056) were significantly associated with treatment.

Conclusions: MFV may better predict the need for treatment for DME compared to CST. This may make treatment and screening referral decisions more objective in DME.

ABSTRACT BODY:

Purpose: It has been shown that a period of dark exposure (DE) restored ocular dominance (OD) plasticity in animals. If the DE has any prompting effect on vision in human subjects, it could be an additional method for refractory amblyopia treatment. However, it is unknown whether DE has any effect on vision improvement in patients with amblyopia. We will report effects of 10-day-darkness on vision improvement in patients with amblyopia.

Methods: Eighteen patients (age: 6-28 years old) with 23 amblyopic eyes were recruited. Patients whose best corrected visual acuity (BCVA) is lower than their age-based norms are included. Patients with retinal disorders and mental health conditions were excluded. All subjects stayed in the dark room for 10 days. They were followed for 1-3 weeks after DE while visual training was performed.

Results: A rapid vision improvement was observed after DE. The mean of BCVA from all patients was 0.55 logMAR before DE and became 0.24 logMAR measured after DE & visual training. The difference was significant (P=0.0056). The BCVA is also improved in adult patients. No vision loss was observed in all patients.

Conclusions: DE is a safe and effective approach for vision improvement in amblyopia. Thus, it could be a new way for refractory amblyopia treatment and for further amblyopia research on human patients.

TITLE: Investigating the Utility of Near Infrared Reflectance (NIR) Imaging for Diabetic Retinopathy Screening

SESSION TITLE: Diabetic retinopathy epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.A. Patil, S. Pandit, N. Mehta, Y. Modi, Ophthalmology, New York University, New York, New York, UNITED STATES|A. Nair, Ophthalmology, Vanderbilt University Medical Center, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure: Sachi Patil: Commercial Relationship: Code N (No Commercial Relationship) | Archana Nair: Commercial Relationship: Code N (No Commercial Relationship) | Saagar Pandit: Commercial Relationship: Code N (No Commercial Relationship) | Nitish Mehta: Commercial Relationship: Code N (No Commercial Relationship) | Yasha Modi: Commercial Relationship(s);Code C (Consultant/Contractor):Allergen,Alimera, Genentech, Thea, Zeiss

ABSTRACT BODY:

Purpose: An investigation of the reliability of near infrared reflectance (NIR) imaging as a method of assessing severity and stage of diabetic retinopathy (DR) by quantitative assessment of hyporeflective foci.

Methods: Retrospective cohort study of spectral domain optical coherence tomography (SD-OCT) images from patients with type I and type II diabetes seen at a tertiary academic center. 195 near infrared images were reviewed by 2 independent graders to document the number of hypo reflective foci and presumptive DR staging based on the image. The benchmarked DR staging was made by the retinal specialist in clinic and recorded in the electronic medical record. Interrater reliability was confirmed via one-way random effects model of intraclass correlation coefficients. A third rater was consulted if there were discrepancies in number of hyporeflective spots between the two original raters. Demographic data was collected. Analysis of variance was conducted to estimate differences between sub-groups based on severity. Receiver operating curves were created to validate the reliability of the model.

Results: A statistically significant difference in mean number of hypo-reflective foci was found between none and moderate NPDR ($p<0.0001$*), none and severe NPDR ($p<0.0001$*), none and PDR ($p<0.0001$*), mild and moderate NPDR ($p=0.008$*), mild and severe NPDR ($p<0.001$*), mild NPDR and PDR ($p<0.001$*). A statistically significant difference did not exist between moderate and severe, moderate and proliferative disease, or between severe and proliferative disease. Upon creation of the receiver operating characteristic curve, the area under this curve was 0.849 (CI: 0.792, 0.905). Based on this curve, the ideal threshold for detection of moderate nonproliferative diabetic retinopathy or worse was 4.75 hypo reflective foci, with a sensitivity of 79.0% and a false positive rate of 20.0%.

Conclusions: Near infrared imaging may be a useful adjunct tool in screening for diabetic retinopathy as discrete hyporeflective foci can provide understanding of DR staging. These findings should be established on newly diagnosed DR patients with reading center evaluations of DR staging and hyporeflective foci counts to further establish the validity of NIR imaging as a screening tool.

ABSTRACT BODY:

Purpose: Vision Threatening Diseases (VTDs) (age-related macular degeneration, cataracts, diabetic retinopathy, glaucoma) affect 36 million individuals in the United States. 50% are unaware they have a VTD, disproportionally affecting minorities and low-income groups with less access to eye care. While screening programs in underserved communities result in early detection, less than half of subjects with findings follow up with a specialist. This number is four times lower during COVID-19.

Methods: Robotic Telepresence (RT) was implemented in this pilot study during COVID-19 to increase real-time access to specialist care. 58 subjects (age 56, 45% male) underwent a non-mydriatic screening protocol over five screenings. They were divided into three groups for consult: In Person (IP) followed by RT (N = 21), RT followed by IP (N = 19), and IP only (N = 18). IP consult was done by an on-site certified reader. RT consult was done by an off-site glaucoma or retina specialist with access to blood pressure, visual acuity, intraocular pressure, 45° retinal images, and ocular coherence tomography B-scans via cloud-based software. Video connection for RT was established via HIPAA-compliant mobile hotspot. Subject demographics and preferences were collected afterwards via survey.

Results: Of 40 RT consults, 26 were second opinion for VTD suspect and 14 were wellness encounters. 24 reported their last eye care visit >3 years ago or never. Following RT consult, 18 subjects received one or multiple VTD diagnosis and 3 with glaucoma were referred for pressure-lowering eye drops. In the group with IP consult first, preferences were 5% RT, 52% IP, and 43% none. In the group with RT consult first, preferences were 5% RT, 58% IP, and 37% none. There was no significant difference in number of questions asked, wait time, or encounter length between IP and RT consults.

Conclusions: RT consults proved valuable in community-based VTD screenings, particularly during COVID-19 when access to eye care is further limited. Most subjects preferred IP. However subjects with VTD that face socioeconomic barriers benefit from immediate RT consult and management directives from remote subspecialists. Further studies should incorporate consults from additional specialties (endocrinologists, general practitioners, social workers) and include telehealth CPT code for reimbursement.

ABSTRACT BODY:

Purpose: Maternal uteroplacental insufficiency (UPI) has been reported to be associated with lower or greater risk of infant retinopathy of prematurity (ROP). UPI induces erythropoietin (EPO) expression, and EPO, as a ligand, can be vasoprotective against high oxygen in experimental models but was not found to be neuroprotective for premature infants in a recent clinical trial. To dissect the role of ligand and receptor signaling, we tested the hypothesis that signaling through the EPO receptor (EPOR) in the setting of maternal UPI reduced high oxygen-induced retinal vascular loss. We used humanized EPOR knock-in mice (hWT) with hypoactive signaling through the EPOR and littermate control wild-type mice (mWT) in a combined UPI/oxygen-induced retinopathy (OIR) mouse model.

Methods: Heterozygous hWT mice were bred for homozygous hWT and littermate homozygous mWT pups. On embryonic day 12.5, pregnant hWT dams were implanted with microosmotic pumps that released a thromboxane A2 analogue dissolved in 0.5% ethanol to create UPI or 0.5% ethanol (control). After birth, pups were transferred to a foster heterozygous hWT dam. Postnatal day 7 (p7) pups with foster dams were placed into the mouse OIR model (75% O_2) for 5 days. At p12, pups were euthanized, and blood, serum, and retinae were collected. Retinal flat mounts were stained with isolectin, and imaged with a fluorescent microscope. The images were analyzed for avascular to total retinal area (AVA) with ImageJ. Serum EPO was measured by ELISA. Hematocrits were read with a capillary microhematocrit reader. Data were analyzed with 1) a multilevel linear regression model with eyes nested within animals and animals nested within litters for AVA, and 2) a two tailed t-test for serum EPO and hematocrit.

Results: Compared to mWT, hWT mice born to dams with UPI or control dams had reduced hematocrit ($p<0.0001$) despite increased serum EPO ($p<0.0001$). In p12 mWT pups born to dams with UPI (mWt;UPI), there was reduced AVA ($p<0.05$) compared to mWT;control. However, in p12 hWT;UPI, there was no difference in AVA ($p=0.766$) compared to hWT;control.

Conclusions: Maternal UPI-induced endogenous EPOR signaling may provide some retinal vascular protection from hyperoxia-mediated vascular loss. Further studies are needed to determine the mechanisms involved in EPO/EPOR or other receptor mediated vascular protection.

ABSTRACT BODY:

Purpose: Macrophage chemoattractant protein-1 (MCP-1), a potent chemokine for myeloid cells, has been associated with disease progression in patients with normal-tension glaucoma and animal models of age-related macular degeneration and retinitis pigmentosa. Blocking Müller cell MCP-1 expression reduced macrophage/microglia infiltration and activation in a rat model of retinal degeneration. We previously showed that decreasing macrophage/microglia activation reduced astrogliosis and rescued retinal ganglion cells (RGCs) in a mouse model of glaucoma (PMID 33147455). Using the microbead occlusion model of hypertensive glaucoma, we examined the effect genetic knockout of MCP-1 has on RGC survival and function, retinal myeloid cell density, and pro-inflammatory cytokine expression.

Methods: Five-month-old C57BL/6J (WT) or MCP-1 knockout (KO) mice received bilateral injections of either magnetic microbeads to elevate IOP or sterile BSS in the anterior chamber of both eyes. IOP was measured immediately before injection, 3 days post-injection, and then weekly thereafter. After 8 weeks, immunolabeling of retina flat mounts for RBPMS and Iba1 quantified density of RGCs and myeloid cells, respectively. Quantitative PCR was used to assess expression of pro-inflammatory cytokines C1q, IL-1α, and TNF-α in cellular populations enriched for macrophage/microglia (CD11b+). A multiple electrode array (MEA) recording system was used to characterize RGC function.

Results: IOP remained elevated for 7 weeks in bead- but not BSS-injected eyes ($p<0.05$). In WT mice, RGC density was 16% lower in bead vs. BSS eyes while myeloid cell density was 50% higher ($p<0.05$ for both). In contrast, RGC and myeloid cell density did not differ between bead and BSS eyes in KO mice. Expression levels of pro-inflammatory cytokines did not differ between groups in either WT or KO mice at the end of 8 weeks. MEA recordings suggest that RGCs are viable and more sensitive to light in KO mice compared to WT mice after IOP elevation.

Conclusions: Genetic ablation of MCP-1 rescued RGCs and decreased macrophage/microglia density in the retina without altering pro-inflammatory cytokine expression by macrophage/microglia. Results suggest that reduced retinal infiltration by myeloid cells, as opposed to decreased cytokine activation in these cells, improved RGC survival following loss of MCP-1 in the setting of ocular hypertension.

ABSTRACT BODY:

Purpose: That visual experience is important for proper visual system development is known, but its molecular basis is poorly understood. This study examines the role of visual experience in wiring of the visual cortex during the visual critical period at the molecular level.

Methods: We performed single-nucleus RNA sequencing on mouse primary visual cortex during visual cortical development (P8 – P38) under a variety of visual experience perturbations: normal visual experience, dark rearing during the critical period (P21-28, 21-38), and dark rearing followed by light exposure (P21-28, followed by 8 hours of light). A total of 144,725 cells were clustered and parsed using machine learning to uncover novel cell types and map cell type specific transcriptomes across time. Single-cell fluorescent in-situ hybridization was used to examine in vivo localization of cell types. The function of one candidate cell surface protein selectively regulated by light during the critical period was studied in vivo in knockout mice through 2 photon imaging of the cortex in awake animals and by immunohistochemistry.

Results: We discovered three glutamatergic cell types form three sublayers in L2/3 of the visual cortex. Vision is required for the formation and maintenance of these cell types. By contrast, cell types in deeper layers are specified independent of vision. Cell types exhibit a transcriptomic continuum, defined by graded expression of genes that could be split into eight modules which vary dynamically with time. Cell surface proteins were encoded by many of these genes, and one (Igsf9b) stood out as having a layered distribution that increased during the critical period and was activity regulated. Mice lacking Igsf9b had reduced numbers of binocular cells, changes in their responses to visual stimuli and a reduction in inhibitory synapse proteins.

Conclusions: Vision is necessary for the specification of cell types in L2/3 of the visual cortex. Igsf9b, a homophilic cell adhesion molecule, is necessary for cortical wiring, formation of binocular cells, and the responses of excitatory neurons to visual stimuli. Our transcriptomic atlas of visual cortical development from synaptogenesis to the end of the critical period is an important resource for future studies on cortical development.

ABSTRACT BODY:

Purpose: Genetic predisposition can contribute to treatment response, and predictive variants may explain response direction and/or magnitude. In the VIEW 1 and 2 Phase 3 randomized controlled trials (RCTs), intravitreal aflibercept (IVT-AFL) provided rapid and robust gains in visual acuity (VA) in patients (n=2419) with neovascular age-related macular degeneration (nAMD). This analysis aimed to identify any associations between gene variants and clinical endpoints in VIEW 1 and 2.

Methods: A genome-wide association study (GWAS), utilizing the Illumina HumanOmniExpress Exome v1.3 platform, was conducted on a subgroup of patients from VIEW 1 and 2 (NCT00509795/NCT00637377) consenting to the optional pharmacogenetic analysis.

Results: Data were pooled from 780 patients (VIEW 1, n=362; VIEW 2, n=418), who were representative of the overall VIEW 1 and 2 population. After Bonferroni correction for multiplicity and statistical adjustment for baseline risk factors, there were no significant associations between known gene variants and treatment response according to the pre-specified VIEW 1 and 2 endpoints. Genome wide there were no significant genetic associations in participants experiencing gains ≥15 ETDRS letters after 1 or 2 years of treatment. Investigating participants with VA loss ≥5 letters, a cluster of variants in the ANO2 gene on Chromosome 12 reached $p<5x10^{-8}$. Exploring VA scores at Year 1 and 2, the ANO2 rs2110166 single-nucleotide polymorphism (SNP) also reached $p<5x10^{-8}$. Carriers of the rs2110166 TC genotype showed a smaller improvement in VA score in response to IVT-AFL or ranibizumab (effect size 2.19) compared to those without. The minor allele frequency was 3% in VIEW; these participants lost, on average, ≥5 letters at 1 year.

Conclusions: Based on data from two large, robust RCTs, preliminary analyses suggest an association of ANO2 with retinal function, with a potential impact on VA of ~1 line over 1–2 years. Typical associations between known and potential target candidate AMD variants and clinical endpoints were not found. ANO2 encodes anoctamin 2, a calcium-activated chloride channel expressed on photoreceptor cells and is a gene meriting further investigation of its function in retinal pathophysiology. Further studies may elucidate whether the variants identified are predictive or prognostic in nAMD.

ABSTRACT BODY:

Purpose: To evaluate the efficacy and safety of retinal gene therapy in a pre-clinical model of CDHR1-associated retinal degeneration – an as yet untreatable, blinding disorder characterised by progressive cone and rod photoreceptor degeneration.

Methods: $Cdhr1^{-/-}$ (n=28) and C57BL/6J control mice (n=23) underwent paired sub-retinal injections of AAV8.GRK1.CDHR1 ($1.5x10^{8}$) and PBS vehicle control in the fellow eye at 4 weeks of age. Dark- and light-adapted electroretinography (ERG) was undertaken to 8 months post-injection. Photoreceptor layer thickness and outer retinal morphology were compared using optical coherence tomography (OCT) imaging to 6 months post-injection.

Results: In $Cdhr1^{-/-}$ mice, sub-retinal AAV8.GRK1.CDHR1 rescued A-wave amplitudes ($p<0.0001$ at all time points) and B-wave amplitudes ($p<0.0001$ from 6 months) on dark-adapted ERG versus PBS-injected control eyes (Fig.1). Light-adapted flicker ERG amplitudes were greater in AAV-treated eyes at 8-months post-injection ($p<0.0001$).

AAV8.GRK1.CDHR1 preserved photoreceptor layer thickness in the superior retina versus PBS-injected eyes at 6-months post-injection (mean: 76.6µm versus 49.7µm; $p<0.0001$; Fig.2). OCT changes consistent with the regeneration of photoreceptor outer segments and restoration of ellipsoid zone reflectivity were only identified in AAV-treated eyes ($p<0.0001$; Fig.2).

In C57BL/6J mice, there was no difference in ERG assessments (A-wave, $p=0.65$; B-wave, $p=0.47$; Cone responses, $p=0.09$; Fig.1) or photoreceptor thickness measurements at 6 months between AAV and PBS-injected eyes ($p=0.19$; Fig.2).

Conclusions: These data provide proof-of-principle of the efficacy and safety of CDHR1 gene therapy in a pre-clinical model of CDHR1-associated retinal degeneration. Rod and cone rescue occur through prevention of photoreceptor cell death and photoreceptor outer segments may regenerate. A follow-on clinical trial in patients with CDHR1-associated retinal degeneration is warranted.

ABSTRACT BODY:

Purpose: Recent studies on humans showed an impact of the light spectrum on ocular growth parameters. However, it deserves further research whether the eye processes chromaticity or rather the defocus being induced by the longitudinal chromatic aberration (LCA) as a growth signal. The current study therefore investigated the influence of defocus-free monochromatic light on choroidal thickness as a rapid biomarker for ocular growth.

Methods: In total, n=19 left eyes were illuminated for 20min with isoluminant short-wavelength light (“S” 450nm), mid-wavelength light (“M” 550nm), long-wavelength light (“L” 650nm) and polychromatic light (“P” 450nm to 680nm). The right eye was occluded while serving as control eye. A custom-built laser-interference setup generated monochromatic and defocus-free grid patterns with changing spatial frequency content between 3cpd and 18cpd. The patterns covered the central 10° of the retina. Choroidal thickness was measured before and after each exposure period in the illuminated and non-illuminated area using swept-source optical coherence tomography (ZEISS PlexElite 9000, Carl Zeiss Meditec Inc., USA). Paired t-tests and two-factor analysis of variance were performed to compare choroidal reactions from baseline, between eyes, illumination conditions and choroidal regions. Numerical results are reported as mean and standard error and were rounded to full microns.

Results: As seen in Figure 1, there were no significant pre-vs-post-illumination changes for any light condition in the central, illuminated choroidal regions (S: 0±2µm, M: 0±1µm, L: +2±2µm, P: +1±1µm, all $p>0.05$). Statistically significant choroidal thinning occurred only in the non-illuminated area after polychromatic light with a mean change of -2±1 µm ($p=0.04$). No significant effect for "color" ($p=0.80$), "region" ($p=0.29$) and the interaction between both factors ($p=0.21$) was revealed. Furthermore, no differing responses between test eye and control eye could be found (all $p>0.05$).

Conclusions: Monochromatic and defocus-free light did not lead to a significant choroidal response after short-term exposure. Therefore, it can be suggested that the LCA-induced defocus, rather than the chromaticity of the light spectrum, presents the primary signal for guiding ocular growth.

ABSTRACT BODY:

Purpose: While studies have suggested relationships between neurotoxic heavy metals (HM) and diabetes (DB), they did not correlate such findings with complications like diabetic retinopathy (DR). We performed a retrospective, observational cohort study to assess the relationship between HM and DR.

Methods: We extracted all patient data from CDC's NHANES with DB and ophthalmic parameters, corresponding to NHANES 2005/6 and 2007/8 cycles. We recorded socio-demographic factors, DB-related factors, HM measures and DR severity. To correct for cycle variations in testing, HM levels were transformed into cycle-specific quartiles. We performed statistical tests (Mann-Whitney U, Pearson Chi^2, Spearman's Rho Coefficient (p), Welch's T-test, multivariable logistic regression), in SPSS, v26. Outcome measures included: serum and urine levels of HMs compared to the degree of DR, past medical history and social history.

Results: 884 eligible patients were classified into 4 groups based on their DR severity: no DR (n=565, 46.5% men), mild DR (n=203, 56.7% men), moderate DR (n=85, 56.3% men), and proliferative DR (n=31, 35.5% men). The average age in each group was respectively 63.1±10.6, 65.1±11.0, 61.4±10.2 and 63.4±7.4 years. Mean serum HM levels for lead, cadmium, total mercury and inorganic mercury did not differ significantly in the presence or absence of DR ($p>0.05$, Welch's t-tests). All mean urinary metal levels were not significantly different in the presence or absence of DR, except for thallium (UThal) which had significant lower levels in DR ($p<0.013$). Adjustments for cycle variations confirm the independent association of DR and UThal, and the absence of correlation with other blood and urinary HM levels (Figure 1). UThal was the most significant correlation with a Spearman p of -0.214 (p=0.0003). We then analyzed the population to see which other parameter was associated with UThal levels. UThal was significantly associated with eGFR (p=0.002), hemoglobin (p=0.040), and insulin therapy (p=0.010). Multivariate logistic regression with 3 models are presented in Table 1. UThal was still independently associated with DR in all models (p=0.011-0.042).

Conclusions: UThal is significantly associated to DR severity in the NHANES database. Additional validation for geographic factors are warranted. If validated, these findings suggest a possible role for thallium, a neurotoxic HM, in DR.

Commercial Relationships Disclosure: Jaime Dickerson: Commercial Relationship(s);Code E (Employment):Sight Sciences Inc | Kavita Dhamdhere: Commercial Relationship(s);Code E (Employment):Sight Sciences Inc

ABSTRACT BODY:

Purpose: Assess effectiveness of medication regimen in intraocular pressure (IOP) lowering pre/post-surgically in open-angle glaucoma (OAG) patients scheduled for canaloplasty and trabeculotomy combined with cataract surgery; evaluate relationship between medication number (meds) and IOP reduction.

Methods: Prospective, multicenter, clinical study. Subjects were adults with cataract and mild/moderate OAG. Medicated IOP <33 mmHg on 1-4 meds at screening and post-washout mean diurnal IOP (DIOP) ≥21 and ≤36 mmHg. Subjects underwent medication washout (28 days for prostaglandin analogues, beta blockers, and rho kinase inhibitors, two weeks for alpha agonists, and five days for carbonic anhydrase inhibitors) prior to baseline and Month 12 IOP measurements. All IOP measurements were Goldmann (operator/reader protocol). DIOP was the mean of three timepoints (9AM, 12PM, 4PM). Descriptive statistics (Mean, SD) were calculated for screening medicated IOP, baseline DIOP, Month 12 medicated IOP, and washed out DIOP for all subjects and for subgroups on 1, 2, 3, 4 meds. Paired t-tests compared IOP post-washout pre-surgically and at Month 12 for all patients and for the medication subgroups. Simple linear regression evaluated the relationship between medication number and increase in IOP post-washout.

Results: IOP increased 6.5 (2.8) mmHg (n=141) post-washout pre-surgically (p=0), and 6.0 (2.5) mmHg (1 med, n = 71), 5.9 (2.0) mmHg (2 meds, n = 36), 8.1 (3.4) mmHg (3 meds, n = 30), and 8.9 (3.9) mmHg (4 meds, n = 4). Meds were reintroduced for 22 subjects; 1 (n = 16), 2 (n = 5), or 3 (n = 1) meds. Average increases were 4.1 (all; p=.0024), 3.0 (1 med), and 5.8 mmHg (2 meds). A single patient on three meds went from 17.0 to 30.0 mmHg following washout, an increase of 13 mmHg.

Conclusions: Medication washout results in increases in IOP correlated with number of meds in OAG patients. The results agree with independent results from the COMPASS and HORIZON trials (Johnson and Jampel, 2020) but extend the anaysis to medication washout IOP increase post-surgically. There is a diminished increase in IOP following washout post-surgically and an overall lower unmedicated IOP relative to pre-surgical IOP indicating 1) the surgical treatment provided an IOP-lowering benefit independent of the adjunctive medications and 2) that response to medication post-surgically may be diminished compared to surgically naive patients.

ABSTRACT BODY:

Purpose: The Permeability Reference Material Repository is depleted of the original 7 reference materials denoted R1 to R7. Dk values for these materials were reported in Invest. Ophthalmol. Vis. Sci. 2006; 47(13):97. Materials denoted R8 to R12 in single lots were recently supplied by 3 manufacturers of rigid contact lens materials.

Methods: Seven sites having the apparatus, calibrating specimens, and versed in the measurement and calibration of Dk according to the International Organization of Standardization (ISO) 18369-4:2017 and American National Standards Institute (ANSI) Z80.20-2016 determined the Dk of materials R8-R12. A set of R8-R12 reference samples was sent to each of the sites. They were monocentric, uniform-thickness lenses in nominal thicknesses of 0.11, 0.14, 0.18, 0.23, 0.29, and 0.40 mm such that the linearity between oxygen resistance (t/Dk) and thickness (t) could be inspected. Buttons were manufactured into samples by Valley Contax, Inc. (Springfield, Oregon, USA). The diameter was 10.0mm and back curve radius 7.80 or 8.60mm depending on the electrode in use at each site. To reduce fracture during handling, the thinner samples (0.11, 0.14mm) had thicker peripheries produced by a minus carrier and front junction of 8.0mm diameter.

Results: Reference Dk values were taken as the mean calibrated Dk values (n = 7) of the R8 to R12 materials. For R8: mean 68.7, Standard Error of the Mean (SEM) 2.4, 95% Confident Limits (CL) 64.0-73.5 Fatt Dk units; for R9: mean 120.8, SEM 5.9, CL 109.2-132.5 Fatt Dk units; for R10: mean 161.2, SEM 5.4, CL 150.5-171.9 Fatt Dk units; for R11: mean 145.2, SEM 6.5, CL 132.6-157.9 Fatt Dk units; and for R12: mean 171.7, SEM 4.9, CL 162.1-181.3 Fatt Dk units. Linear regressions between the Dk values from each site and the reference Dk values resulted in coefficients of determination (R^2) ranging from 0.9448 to 0.9922. Three of 7 were above 0.9900. The carrier of the 0.11 and 0.14mm samples did not appear to influence the linearity of t/Dk vs. t.

Conclusions: Dk values from different operators and sites assessing different sets of samples were highly correlated linearly with the reference values. The order of Dk progression for the materials from low to high was the same at each site. The spread of Dk values for each material supported the Dk measurement error (±10%) and tolerance (±20%) in the ISO and ANSI standards.

ABSTRACT BODY:

Purpose: Late infantile neuronal ceroid lipofuscinosis type 2 (CLN2) is a neurodegenerative, blinding lysosomal storage disorder. The purpose of the current study was to characterize the progression of CLN2-associated retinal degeneration in patients under intraventricular enzyme replacement therapy (ERT) with cerliponase alfa.

Methods: We analyzed visual function, retinal morphology and neuropediatric data using preferential looking test (PLT), Weill Cornell Batten Scale (WCBS), OCT imaging and the Hamburg motor-language scores (M-L score).

Results: Fifty-six eyes of 28 patients had baseline PLT, WCBS and OCT. 15 patients underwent serial examinations, resulting in a total of 132 OCT scans and WBCS results, 67 Hamburg M-L scores and 49 PLT results during a mean follow up time of 18.2 months (range 5-40). A negative correlation ($r=-.69$, $p<0.001$) was found between CRT and age at exam with a maximum annual decrease (23 µm) within the time intervals 56-80 months. A significant correlation was observed between the PLT and the age at examination ($r= .46$, $p=0.001$), the WBCS ($r= .62$; $p<0.001$) and CRT ($r=-.64$; $p<0.001$). The M-L score correlated with the ocular measurements (CRT: $r= .58$, $p<0.001$; WCBS $r= -.64$, $p<0.001$; PLT score: $r= -.57$, $p<0.001$).

Conclusions: Despite intraventricular ERT, retinal degeneration associated with CLN2 disease manifests as a progressive decline, which appears to accelerate during a critical period at 56 to 80 months of age. Retina-specific therapy should occur ideally before or as early as possible within this period. PLT, WCBS are valuable outcome measures to monitor disease progression.

ABSTRACT BODY:

Purpose: Glycans function as useful markers of stem cells but also regulate the ability of these cells to differentiate. Approximately 1–2% of the human genome encodes for genes involved in the biosynthesis of glycans. In the present study, we evaluated the expression of a small subset of glycogenes in human limbal epithelial cells with distinct clonogenic potential.

Methods: Human postmortem corneoscleral tissues were generously donated by the Lions VisionGift. Epithelial cells were cultured and expanded in vitro using growth-arrested mouse 3T3 fibroblasts. Individual clones were isolated with cloning cylinders and used in parallel for both colony formation and transcriptional assays. The analysis of 84 genes involved in the biosynthesis of glycans was carried out using a human RT2 Profiler PCR Array. Quantification of gene expression in primary cultures of human limbal epithelial cells was achieved by qPCR.

Results: Individual clones were classified as abortive or clonogenic based on the fraction of abortive colonies produced. Clones leading to >99% abortive colonies were referred as abortive while those with 50% or less as clonogenic. Analysis of glycogene expression in clonogenic colonies revealed a high content of transcripts regulating galactose and mannose metabolic pathways. Abortive colonies were characterized by increased levels of GCNT4 and FUCA2, two genes responsible for the branching of mucin-type O-glycans and the hydrolysis of fucose residues on N-glycans, respectively. Expansion of primary cultures of human limbal epithelial cells for 10 days resulted in stratification and a concomitant increase in MUC16, GCNT4 and FUCA2 expression.

Conclusions: These data indicate that the clonogenic potential of human limbal epithelial cells is associated with specific glycosylation pathways. Mucin-type O-glycan branching and increased fucose metabolism are linked to limbal epithelial cell differentiation.

TITLE: Pou4f1-mediated regulatory network in the development of retinal ganglion cells

SESSION TITLE: Retina Development and Regeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Kiyama, Ophthalmology and Visual Science, The University of Texas Health Science Center at Houston, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure: Takae Kiyama: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: POU family transcription factors play pivotal roles in the development of retinal ganglion cells (RGCs). Pou4f1 is a member of the family and is expressed in the newly differentiated RGCs. Although its roles in RGC differentiation and dendritic morphogenesis have been described, it is unclear how Pou4f1 regulates downstream effector genes to promote newly differentiated RGCs into functional RGC subtypes.

Methods: To identify genes regulated directly by Pou4f1, we conducted CUT&TAG sequencing using an anti-Pou4f1 antibody and developing mouse retinas. We performed immunostaining and in situ hybridization on control and Pou4f1-deleted retinas to validate potential targets.

Results: CUT&TAG sequencing revealed ~8000 Pou4f1 binding regions in developing mouse retinas. Many of these Pou4f1-bound regions are located in genes that encode transcription factors, and some of these TFs are known to play a role in retinal development and RGC subtype formation. Additionally, many genes involved in axon guidance and nervous system development are also direct targets of Pou4f1. We have validated some of these candidate targets in control and Pou4f1-deleted retinas. We are currently exploring whether some of these Pou4f1-bound regions can serve as RGC subtype-specific enhancers.

Conclusions: We have revealed a Pou4f1-mediated regulatory network in RGC development through direct and indirect modes. Pou4f1 directly regulates genes involving in axon guidance and neuronal development. Indirectly, Pou4f1 may control transcription factors functioning in RGC subtype specification and differentiation. We have also uncovered the self-regulation of Pou4f1, confirming a previous study. Furthermore, we discovered that Pou4f1 binds to the promoters of several upstream regulators, including Atoh7, Pou4f2 and Isl1, implicating potential feedback regulatory loops between Pou4f1 and these key RGC regulators in RGC formation.

ABSTRACT BODY:

Purpose: Among patients with dry eye disease (DED), those with systemic autoimmune disease (AID) experience signs and symptoms often more serious with worse treatment effect and prognoses. This analysis evaluated the outcome of DED subjects with documented AID treated with OC-01 (varenicline solution) nasal spray (OC-01 VNS), a cholinergic agonist, compared to vehicle control (VC). OC-01 VNS has been shown to activate the trigeminal parasympathetic pathway to produce basal tear film by stimulating the lacrimal functional unit.

Methods: In ONSET-1, 182 patients were randomized 1:1:1:1 to receive 0.006 mg, 0.03 mg, or 0.06 mg OC-01 VNS or VC. In ONSET-2, 758 patients were randomized 1:1:1 to receive 0.03 mg or 0.06 mg OC-01 VNS or VC. Subjects administered OC-01 VNS or VC once to each nostril twice daily for 4 weeks. For this sub-population of interest, a total of 31 AID subjects were analyzed based on OC-01 VNS treated (0.03 mg or 0.06 mg, n=20) and VC (n=11) groups. Respectively, OC-01 VNS treated and VC mean baseline (BL) values were Schirmer's Test Score (STS, mm): 5.6 and 4.2; Eye Dryness Score (EDS, 0-100): 59.2 and 52.7. Outcome measures from BL to Week 4 included STS and mean change in EDS. Differences in OC-01 VNS treated and VC subjects were compared using t-test and chi square tests.

Results: OC-01 VNS treated subjects showed directional benefit in STS and EDS outcomes compared to VC. For OC-01 VNS treated and VC groups from BL to Week 4, respectively, percentage of eyes demonstrating improvement in STS ≥10 mm: 61.1% and 0.0% (95% CI, 46.0-76.2%); mean change in STS: 13.6mm and 1.8mm (6.5-17.1); and mean change in EDS: -19.6 and -10.3 (-26.8-8.2). OC-01 VNS was well tolerated in the trials. Most common adverse reaction in OC-01 VNS treated groups was sneeze (82-84%); the majority (98%) reported it as mild. Other adverse reactions >5% included cough, throat, and instillation site (nose) irritation.

Conclusions: In a sub-population with potential to have worse DED, OC-01 VNS treated AID subjects demonstrated directional signaled benefits in DED signs and symptoms at Week 4 compared to VC despite a limited sample size. OC-01 VNS was shown to have a favorable safety and tolerability profile in the trials. Future prospective studies with larger AID subject sample sizes are recommended.

ABSTRACT BODY:

Purpose: Survivors of Ebola virus disease (EVD) experience decreased intraocular pressure (IOP) relative to unaffected close contacts during the first year of convalescence. Whether this effect persists over time, and its relationship to intraocular pathology, is unclear. We sought to determine if IOP remained lower in survivors of EVD over four years of follow-up, and to identify associated risk factors.

Methods: PREVAIL III is a 5-year, longitudinal cohort study of survivors of EVD and their close contacts and is a collaboration between the Liberian Ministry of Health and the United States National Institutes of Health. Participants who enrolled in PREVAIL III at John F. Kennedy Medical Center in Liberia, West Africa from June 2015 to March 2016 underwent comprehensive ophthalmic evaluation annually for 5 consecutive visits. IOP was measured at each visit by a handheld rebound tonometer using sterile tips. Comparisons are made between antibody-positive survivors and antibody-negative close contacts. Among survivors, we tested for associations between IOP and findings on physical examination, optical coherence tomography, or diagnosis of uveitis at baseline.

Results: Of 565 antibody-positive survivors and 644 antibody-negative close contacts enrolled in the study at baseline, the majority of participants returned annually, with 383 (67.8%) and 407 (63.2%) participants, respectively, presenting for the final study visit at a median of 60 months after symptom onset. A sustained, relative decrease in IOP was observed in survivors relative to close contacts, with mean difference of -0.87 mmHg (95% confidence interval -1.24 to -0.51) across all follow-up study visits. This difference remained constant over time ($p=0.23$ for interaction over time). Among survivors, physical examination findings of vitreous cell, optical coherence tomography findings of vitreous opacities, and eyes with diagnosis of uveitis all demonstrated a significant association with decreased IOP at baseline ($p<0.05$ for all).

Conclusions: In this study, survivors of EVD experienced a sustained decrease in IOP relative to close contacts over a five-year period following EVD infection. Clinical implications are unknown, but further research is required to elucidate the physiological origin of such changes. The results highlight the importance of considering long-term sequelae of emerging infectious diseases within a population.

ABSTRACT BODY:

Purpose: Diclofenac instillation is useful for preventing intraoperative miosis and suppressing postoperative inflammation and macular edema in cataract surgery; however, optimum efficacy is not attained when the instilled diclofenac strongly binds to albumin in patients' aqueous humor. Therefore, a method that inhibits diclofenac binding and increases the concentration of its free fraction is required. We conducted a study regarding the effects of inhibitors on the binding of diclofenac to albumin and endogenous substances in the aqueous humor.

Methods: At the time of cataract surgery, aqueous humor samples from 15 patients with cataract who had received diclofenac instillations were collected and mixed to prepare pooled aqueous humor, from which diclofenac was extracted. The free-fraction and concentrations of diclofenac were measured using ultra-high performance liquid chromatography in various experiments with pooled and mimic aqueous humor samples. The endogenous substances in the aqueous humor were quantified using a BiOLiS 24i premium, gas chromatography-mass spectrometry, and liquid chromatography-mass spectrometry.

Results: The binding of diclofenac, a site-II drug, to albumin in pooled aqueous humor was significantly inhibited by phenylbutazone (PB), a site-I inhibitor; however, no significant inhibition by ibuprofen, a site-II inhibitor, was observed. To unravel this unexpected result, endogenous substances associated with albumin binding in pooled aqueous humor were investigated. The inhibition of diclofenac binding by PB in mimic aqueous humor containing these endogenous substances revealed significant binding inhibition in the presence of palmitic acid (PA) and L- tryptophan (L-Trp) (PA > L-Trp).

Conclusions: The presence of PA and L-Trp in the aqueous humor inhibited diclofenac from binding to site II, the high-affinity binding site on albumin, and induced a conformational change in albumin. This change caused site I, the low-affinity binding site, to become high-affinity; thus, diclofenac was strongly bound to site I. Therefore, PB, a site-I inhibitor, significantly inhibited the albumin binding of diclofenac. Instilling site-I inhibitors prior to diclofenac may increase the free fraction of diclofenac and enhance its effect.

ABSTRACT BODY:

Purpose: Fluorescein angiography (FA) remains the gold standard used to evaluate the morphology and leakage of retinal vasculature, but it requires an intravenous injection of fluorescein dye and a skilled photographer. OCT angiography (OCTA) is a newer noninvasive (contrast agent free) imaging technique developed to evaluate morphology of the retinal vasculature. This study evaluated whether retinal vascular density noted in murine eyes with diabetic retinopathy using FA is comparable to those observed using OCTA.

Methods: Simultaneous FA and OCTA images were obtained, using custom build mouse retinal OCT/SLO system, from STZ (Streptozotocin)-induced diabetic mice 6 months after induction of diabetes. The acquired images (FA fundus and OCTA enface projections) were processed to obtain a better profile of the vascular parameters. At first, the Contrast-Limited Adaptive Histogram Equalization (CLAHE) was used to improve the background-vessel contrast. Then, a two-dimensional matched filter was applied by using a Gaussian kernel with two different standard deviation values to enhance both thick and thin vessels. Images of total areas of retina were obtained and analyzed using ImageJ software with the Vessel Analysis plugin to quantify the retinal vascular density of the entire imaged retina ~50deg FOV (total) on FA and OCTA.

Results: Retinal vascular density of the total area on standard FA and OCTA images did not correlate significantly (N=14; correlation r=0.081, p value=0.783, using ANOVA regression). However, when analysis was performed on enhanced images using CLAHE and two-dimensional matched filter, vascular density on FA and OCTA images significantly correlated (N=14; correlation r=0.742, p value=0.002, using ANOVA regression).

Conclusions: Retinal vascular density obtained using FA correlates well with retinal vascular density obtained using OCTA in murine eyes with diabetic retinopathy after application of Contrast-Limited Adaptive Histogram Equalization (CLAHE) and two-dimensional matched filter with Gaussian kernel. Vascular density on FA and OCTA was found to correlate better after image enhancement improved contrast of the fine retinal capillaries.

ABSTRACT BODY:

Purpose: To calculate and compare the average interval between injections of Aflibercept (AFL), Bevacizumab (BEVA), and Ranibizumab (RAN) for patients with retinal vascular occlusions (RVO).

Methods:

A retrospective cohort study was performed at a private retinal practice in Ohio. The Institutional Review Board (Sterling) determined this study consisted of non-human subjects. All data was collected through the practice management of Retina Associates of Cleveland, Inc. Data was collected from patients who received injections of AFL, BEVA, and RAN from July 2020 through June 2021 and includes: patient number, injection service dates, anti-vegf drug injected, procedure codes, and primary diagnoses. The patients were limited to those injected unilaterally and diagnosed with RVO, and the number of days between injection service dates was calculated for each injection. The data set was then organized by primary diagnosis and injection type, and the average number of days between injection service dates was determined for RVO and each corresponding drug. Statistical analysis included calculating the average interval in days between injections for each medication, standard deviation, and two tailed t-test for comparison between medications.

Results: From July 2020 through June 2021, 14,911 injections were placed unilaterally for any diagnosis. There were 2,812 injections for RVO with an average interval between injections of 54 days for all medications. Of the RVO injections, the average interval was BEVA 55 days with standard deviation (SD) +/- 30 days, AFL 55 days SD +/- 32 days , and RAN 46 days SD +/- 19 days. In comparing the interval of BEVA versus AFL, the two-tailed t test yields a p value = 0.85; BEVA vs. RAN p = 0.00003; AFL vs. RAN p= 0.000001.

Conclusions: The results of the study suggest that AFL and BEVA seem to have a longer interval of injection than RAN in patients diagnosed with RVO. There does not appear to be a difference in average injection intervals for BEVA vs. AFL.

ABSTRACT BODY:

Purpose: We have reported that peptides belonging to the calcitonin superfamily, such as adrenomedullin (AM) and CGRP, have various biological activities, including vasodilation, angiogenesis, and anti-inflammatory effects that play critical roles in interocular vascular diseases. Intermedin, a newly added peptide to the calcitonin superfamily, is also called adrenomedullin 2 (AM2) because of its structural similarity to AM. In our previous study using a laser-induced choroidal neovascularization (LI-CNV) model, we found that pathological angiogenesis, inflammation, and fibrosis were exacerbated in AM2 knockout mice (AM2-/-). In contrast, exogenous administration of AM2 ameliorated these pathological conditions (ARVO 2020, 2021). In the present study, we performed transcriptome analysis to elucidate the mechanism of the ameliorating effects of AM2 on LI-CNV.

Methods: Wild-type mice (WT) were subjected to LI-CNV and systemic administration of PBS, AM, or AM2 using an osmotic pump. One week later, total RNA was extracted from retinal pigment epithelium-choroid-sclera complex specimens, and transcriptome analysis was performed using the Clariom™S Array. We then compared gene expression levels between WT and AM2-/- by quantitative real-time PCR analysis of angiogenesis-, inflammation-, and fibrosis-related genes found in the transcriptome analysis.

Results: There were 113 genes in the AM-treated group and 82 genes in the AM2-treated group whose expression was significantly changed by more than twofold or less than one-half. Of these, 15 genes, including Meox2, were commonly altered in the AM and AM2-treated groups, and 63 genes were differently altered in the two groups. In quantitative real-time PCR analysis, in samples from the early phase of LI-CNV, the expression of CD68, IL-6, VCAM-1, PAI-1, and fibronectin was significantly up-regulated in AM2-/- compared to WT, and the expression of Meox2 and Angpt-1 was significantly down-regulated.

Conclusions: Meox2, a homeobox transcription factor known to repress epithelial-mesenchymal transition (EMT), was up-regulated by AM2 treatment and conversely down-regulated in AM2-/-. Therefore, Meox2 could be a potential factor in the ameliorating effects of AM2 on LI-CNV. Further transcriptome analysis is expected to reveal functional similarities and differentiation between AM and AM2.

TITLE: Vitreoretinal Amyloidosis:
Clinical Features, OCTA Appearances, Gene Mutations, and Treatment Outcomes of Vitrectomy Surgery

SESSION TITLE: Retinal Degeneration

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: N. Zhou, W. wei, Beijing Tongren Hospital, Beijing, Beijing, CHINA|

Commercial Relationships Disclosure: Nan Zhou: Commercial Relationship: Code N (No Commercial Relationship) | wenbin wei: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To report the clinical characteristics and surgical outcomes of vitrectomy encountered in eyes with vitreous amyloidosis. The novel term named vitreoretinal amyloidosis, systemic evaluation and visual outcome after vitrectomy are discussed. Transthyretin gene (TTR) mutations in Asian patients with familial amyloidosis are described.

Methods: Nineteen eyes of 10 Asian patients with a diagnosis of vitreoretinal amyloidosis from January, 2008, to September, 2021. Detailed history, genetic analysis, systemic and ocular examination of 19 eyes of 10 patients were carried out. Vitreous biopsy, followed by 23- to 25-gauge vitrectomy was performed in all patients. Patients were followed up on days 1, 7, and 30 and then every 3 months. The main outcome measures were best-corrected visual acuity (BCVA), intraocular pressure, SD/SS-OCT/OCTA insights, pathology, TTR mutations, treatment and disease course on follow-up outcomes were investigated.

Results: Mean age at presentation was 51 years, with a 1:1 male-to-female distribution. Family history was positive in 4 patients. Eighteen eyes had pseudopodia lentis, whereas all 19 eyes had glass wool-like vitreous. Waxy or cotton-wool vitreous with firm vitreous adhesions beyond major arcades and along retinal vessels was noted during surgery in all eyes. Congo red staining and polarized microscopy demonstrated vitreous amyloidosis. Most of preoperative BCVA was < 20/200, whereas the postoperative BCVA improved to 20/100 to 20/25.

We identified the OCTA features of vertical hyperreflective lesions that appeared as punctate with moderate or high reflectivity affecting all layers of the neuroretina in 18 eyes of 9 patients (18 eyes of 19 eyes [94.7%]), and the subtle needle-shaped patterns in 17 of 19 eyes (89.5%). Gene sequencing revealed the heterozygous Val30 Met TTR mutation in 2 patients of 1 pedigree, a heterozygous mutation G, p.R54G TTR (late-onset) in another 2 patients of 1 pedigree, confirming the diagnosis of familial amyloidosis. No patients subsequently were found to have systemic amyloidosis during the follow-up.

Conclusions: We firstly described and named the novel terms of "vitreoretinal amyloidosis" mainly based on OCT/OCTA features corresponding to the tissue structures. In addition, the heterozygous mutations of TTR in four patients of familial amyloidosis with vitreoretinal amyloidosis from Chinese are reported.

ABSTRACT BODY:

Purpose: Non-accidental trauma (NAT) examinations in children are not entirely benign and preclude neurological examination. The majority of ophthalmic exams routinely ordered for patients suspected of NAT are negative. Our study elucidates clinical and imaging factors that correlate to retinal findings to increase the yield of positive exams and decrease the burden of potentially unnecessary exams, validating previous studies and introducing new screening variables.

Methods: Our study is a retrospective chart review from May 2014 - August 2021 at a level-1 trauma center. 274 patients met the inclusion criteria of: 1) children </= 36-months-old, 2) concern for NAT, and 3) an ophthalmology consultation was placed. Through univariate and multivariate logistic regression, our study produces a screening algorithm for ophthalmic workup in NAT.

Results: Due to a strong association of “abnormal neuroimaging” and retinal hemorrhage (RH) (OR of 170 (95% CI (10.245, >999.999)), multivariate logistic regression controlling for “abnormal neuroimaging” was performed to analyze all variables associated with RH. 1 or more abnormal neuroimaging finding had a statistically significant association with retinal hemorrhages and produced the strongest association with a univariate OR of 170. The multivariate model (p-value<0.0001 with a c-statistic of 0.980) proposes using the following variables for predicting retinal hemorrhage on exam: Abnormal neuroimaging, Glasgow coma score (GSC) < 15, altered mental status on examination, seizure activity, vomiting, burising, scalp hematoma/swelling, and skull fractures.

Conclusions: If neuroimaging is obtained in the evaluation of suspected NAT, the yield of positive ophthalmologic findings would increase if certain non-ocular findings are present. If absent, ophthalmologic exams may not be necessary.

ABSTRACT BODY:

Purpose: Attempts to characterize the connection between AMD and atherosclerotic disease (ASD) and its risk factors have yielded conflicting and inconclusive results, but there has been a growing appreciation of the distinction between subretinal drusenoid deposits (SDD) and soft drusen (SD) subtypes in AMD. Here, we investigate whether the SDD and SD subtypes of AMD show differences in prevalence of ASD or levels of vascular serum risk factors.

Methods: Volume spectral-domain optical coherence tomography (SD-OCT) scans, self-reported health history questionnaire, and blood samples were obtained for 200 subjects with AMD. The presence of SDD or SD or mixed subtype was judged by two retina specialists. The presence of ASD was determined by reported history of angina, stroke, transient ischemic attack, amaurosis fugax, stenting or bypass surgery, documented carotid artery stenosis >50%, or abnormal stress test results. Categorical variables were compared across groups using chi-square testing, while continuous variables were compared using Kruskal-Wallis non-parametric testing with posthoc Mann-Whitney U testing for subgroup analysis.

Results: SD-OCT analysis showed that 103 subjects had pure SD, 26 had pure SDD, and 71 subjects had a mixed subtype. The prevalence of ASD was 15.5% for pure SD, 26.8% for mixed subtype, and 38.5% for pure SDD ($p=0.028$ for pure SD vs pure SDD). Subfoveal choroidal thickness in the right eye was 196 (153-240), 148.5 (118.75-189), and 145 (108.5-173.5) for the SD, mixed, and pure SDD groups respectively ($p<0.001$). There was no significant difference in serum lipid levels among the groups; however, there was a significant difference among the groups in high sensitivity C-reactive protein (hsCRP) level ($p=0.042$): hsCRP was 1.17 (0.6-2.4), 1.72 (0.96-3.72) and 2.09 (0.775-4.115) for the pure SD, mixed SD/SDD, and pure SDD groups respectively.

Conclusions: These findings contribute to a growing body of evidence that SDD and SD phenotypes associate with different risk factors, and that the SDD subtype may have a more robust relationship with ASD, potentially through inflammatory processes related to higher levels of hsCRP found in this subtype. Further studies based on AMD subtype may further elucidate separate risk factors and disease mechanisms underlying these different types of AMD.

ABSTRACT BODY:

Purpose: While severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) is well known for its respiratory complications, ocular manifestations are emerging. This case report describes a patient with bilateral optic neuritis associated with coronavirus disease 2019 (COVID-19).

Methods: A 46-year-old male presented with two weeks of pain with eye movement immediately after testing positive for COVID-19 and four days of bilateral blurry vision. Data including history, ocular examination, Humphrey visual field testing (HVF), magnetic resonance imaging (MRI), and serological testing was collected.

Results: Visual acuity (VA) was 20/100 in the right eye (OD) and 20/70 in the left eye (OS) with pinhole VA of 20/40 in each eye. Pupil exam, intraocular pressures, and confrontational visual fields were normal. Ocular motility was full, however the patient endorsed pain with eye movement in all directions. The right optic nerve had blurred disc margins while the left optic nerve was unremarkable on exam. Color vision was decreased to 13/15 by Ishihara testing in each eye. MRI of the brain and orbits revealed bilateral thickening and T2 hyperintensity and hyperenhancement of the intercanalicular and intraorbital optic nerves with sparing of the nerve sheath and no demyelinating lesions (Figure 1). Bilateral central scotomas were seen on HVF (Figure 2). At this point, the patient’s clinical picture was concerning for optic neuritis associated with COVID-19. A complete blood count, comprehensive metabolic panel, myelin-oligodendrocyte glycoprotein antibody, and aquaporin 4 antibody were unremarkable. Testing for tuberculosis, sarcoidosis, syphilis, thyroid disease, and rheumatologic and autoimmune disorders was normal. The patient was treated with corticosteroids. Within three to six weeks, the patient's symptoms and abnormal exam findings resolved.

Conclusions: Infectious pathogens and their subsequent inflammation can cause optic neuritis. It is postulated that T cells release inflammatory mediators and cytokines that cross the blood brain barrier and lead to destruction of myelin, neuronal cell death, axonal degeneration, and vision loss. SARS-CoV-2 could cause a similar inflammatory response leading to optic neuritis and is important to consider in cases without a clear etiology.

ABSTRACT BODY:

Purpose: Proliferative diabetic retinopathy (PDR) is a potentially blindness-inducing complication of diabetes that affects 17 million persons worldwide. Since the 1980s, pan-retinal photocoagulation (PRP) has been the reference treatment, but its side effects involve loss of the peripheral field of vision. The main objective of this study was to evaluate neovascularisation regression by means of anti-VEGF intravitreal injections (IVI) of aflibercept (EYLEA®) in uncomplicated proliferative diabetic retinopathy at 12 months.

Methods: Phase II, interventional, prospective, open-label, multicenter pilot study. Randomized into 2 arms (PRP or IVI group) and monitored for 18 months. Participants had type 1 or type 2 diabetes with uncomplicated proliferative diabetic retinopathy, excluding macular oedema greater than 350 µm. As regards the examination, visual acuity assessment was carried out using an ETDRS Log-MAR scale at 4 meters, optical coherence tomography (OCT) for retinal thickness, OCT angiography for the foveal avascular zone (FAZ) and fluoresceine angiography (Spectralis HEIDELBERG) for surface area measurement.

Results: A total of 40 patients were randomized to the 2 groups between May 2014 and August 2018. As regards the primary endpoint, there was a significant difference, with neovessel regression exceeding 50% in 88.9% of the IVI group at 12 months, compared with 26.3% in the PRP group ($p = 0.0002$). As regards variation in macular retinal thickness, the 12-month test was likewise significant, with a mean reduction of 20.8 µm in the IVI group versus a mean increase of 16.9 µm in the PRP group ($p = 0.0004$). There was no significant difference concerning best corrected visual acuity, area of the foveal avascular zone or non-perfusion index.

Conclusions: The study showed greater regression of neovascularisation at 12 months with intravitreal aflibercept compared to PRP in treatment of proliferative diabetic retinopathy. No significant difference in visual acuity gain appeared. Our study is in line with the S Protocol by Gross (2015, JAMA) and the CLARITY study by Sivaprasad (2017, LANCET). However, instead of focusing on visual acuity, the primary endpoint here is neovessel regression on angiography, showing superior efficacy of IVTs that become a valid alternative to RRP and its adverse effects.

ABSTRACT BODY:

Purpose: Oxidative stress and apoptosis have been implicated as drivers of various vision impairing retinal diseases. These stressors increase the pool of oxidized retinal mitochondrial flavoproteins relative to reduced ones. Oxidized flavoproteins display autofluorescence when excited by 467 nm light, emitting 535nm light in response. The emission signal, termed flavoprotein fluorescence (FPF), can be measured and used as a quantifiable marker for oxidative damage-induced mitochondrial dysfunction. In retinal dystrophies there is a high level of oxidative strain in the retina, which has not been characterized by retinal FPF signal measurements and patterns in a large cohort. Furthermore, these measurements may provide physiologically relevant metrics of disease progression that can complement currently utilized fundus autofluorescence (FAF) imaging.

Methods: This prospective cohort study examined 70 eyes from 35 patients with isolated genetically confirmed Cone-rod dystrophies (Retinitis Pigmentosa, Usher Syndrome), Stargardt disease, and Bardet-Biedl syndrome between 2020-2021. Patients with other ocular pathology were excluded. 70 control eyes from 40 patients were healthy age-matched individuals. In instances of bilateral involvement, each eye was considered separately. FPF score intensity and heterogeneity were recorded using the OcuMet Beacon (OcuSciences, Ann Arbor, MI). Statistical analysis was done to compare scores.

Results: The final analysis included 140 images of 75 patients. Mean FPF intensity was significantly increased between age matched controls and patients with confirmed rod-cone dystrophy, Stargardt disease, and Bardet-Biedl syndrome ($P=0.0014$, $P<0.0001$, and $P<0.0001$). Mean FPF heterogeneity was significantly increased between age matched controls and patients with confirmed cone-rod dystrophy, Stargardt disease, and Bardet-Biedl syndrome ($P<0.0001$, $P<0.0001$, and $P<0.0001$). FPF lesions were noted to visually correlate with patterns of FAF signals in cases with macular involvement.

Conclusions: FPF intensity and heterogeneity are significantly increased in patients with retinal dystrophies compared to matched controls. Correlation of the pattern of FPF lesions with FAF lesions suggests FPF has capacity to be explored as a measurable indicator of disease progression in these patient populations.

ABSTRACT BODY:

Purpose: There is a lack of consensus guidelines regarding intravitreal anti-vascular endothelial growth factor (VEGF) therapy for retinopathy of prematurity (ROP). This multicenter, retrospective, consecutive series compares national and international practice patterns and outcomes data of intravitreal injections for ROP.

Methods: Subgroup analysis from the ROP Injection Consortium (ROPIC) data from 23 sites (16 national from the USA and 7 international from Canada, Chile, Dominican Republic, Japan, Mexico, Taiwan and Turkey) from 2007 to 2021. Primary outcomes included rates and types of retreatment as well as complications. Secondary outcomes included specifics of the injection protocol.

Results: 1677 eyes (873 national and 804 international) of 918 patients were included. Mean birth weight and gestational age were lower in the national (665.6 g and 24.5 weeks respectively) compared with the international group (912.7 g and 26.9 weeks respectively) ($p<0.0001$). The percentage of APROP and plus disease were higher in the national (26.2% and 88.7%, respectively) compared with the international group (8.7% and 81.9% respectively) ($p=0.0001$). Ranibizumab was used more frequently in the national group (30.9% versus 17.4%; $p<0.0001$) versus Aflibercept in the international group (5.3% versus 0.8%; $p<0.0001$). Ranibizumab dosage was lower in the national (0.15 mg in 75.2%) compared to the international group (0.25 mg in 65.7%). Intravitreal injection was administered with a 32-gauge short needle in 48.2% of national cases versus 5.5% of international cases ($p<0.0001$) where a 30-gauge needle was primarily used (68.2%). Rates of retreatment with anti-VEGF reinjection or laser post-injection were higher in the national compared to the international group (8.5% vs 4.7% [$p=0.0016$] and 55% vs 7.2% [$p<0.001$] respectively). Average time to retreatment with laser was longer nationally (134.2 days vs. 36.4 days, $p<0.0001$). However, retreatment time with injection was similar between both groups (62.2 vs. 48.7; $p=0.082$). There was no difference in the incidence of complications including endophthalmitis between the two geographical subgroups.

Conclusions: ROP treatment paradigms vary depending on geography. Infants with ROP receiving anti-VEGF injection nationally tended to be younger, smaller, treated earlier, and have more anti-VEGF retreatments compared to international neonates with ROP.

ABSTRACT BODY:

Purpose: Drug delivery to the retina remain a challenge, limiting the therapeutic possibilities for a myriad of blinding diseases. Ocular barriers and fast clearing of intravitreally injected drugs are recognized as the main obstacles for efficient retinal drug delivery. Encapsulation of drugs into nano-sized vehicles hold the promise of prolonging retention times and enhancing delivery to the retina, however, poor understanding of clearing mechanisms limits the clinical realization of nano-sized drug delivery systems (DDS) for intravitreal injection. Here we investigate the involvement of active transport in clearing intravitreally injected liposomes.

Methods: Liposomes were formulated with 10% cationic lipid (DSTAP) and 5% lipid anchored poly-ethylene-glycol (DSPE-PEG). The metal tracer drug Oxaliplatin (OxPt) was loaded in the core of the liposomes. Liposomes were intravitreally injected in 6-10-week-old female C57BL/6JrJ mice. A subset of 4 mice were pre-injected with chloroquine to inhibit active transport. 24h post injection eyes were harvested and dissected into tissue fractions. The amount of Pt in the tissues were quantified by induced coupled plasma mass spectrometry.

Results: The resulting liposomes were unilamellar, had a diameter of 120.2±2nm and slight positive zeta-potential of 7.6±2mV (Figure 1 A and B). The liposomes showed a clear tendency of retaining OxPt in the vitreous, compared to free OxPt (Figure 1C). Interestingly, free OxPt resulted in the highest retinal concentration of OxPt, while liposomal OxPt by-pass the retina and is transported to the RPE/Sclera. Pre-treatment with chloroquine, an inhibitor of active endosomal transport, significantly reduced the clearing of the cationic liposomes to the RPE/Sclera.

Conclusions: The liposomes enhanced the retention of OxPt after intravitreal injection, however, led to significant lower retinal concentrations compared to free drug, due to active transport from the vitreous to the RPE/Sclera. Active transport mechanisms significantly impact the biodistribution of intravitreally injected liposomes and needs consideration when designing DDS targeting the posterior eye.

ABSTRACT BODY:

Purpose: When creating a lipid eye drop, there is a desire to have a small oil droplet size. This allows a more uniform and stable product and a higher surface area leading to higher bioavailability. In vitro testing was conducted to analyze the oil droplet size and emulsion stability profile of the Blink Triple Care lipid eye drop and 4 marketed lipid eye drops. Additionally, a clinical study was done to evaluate the improvement in overall ocular comfort and overall quality of vision after 30 days of use of Blink® Triple Care lipid eye drop.

Methods: The droplet size of the lipid phase was measured using a Dynamic light scattering instrument (Malvern Zetasizer Nano). The clinical study was a double masked, bilateral, multi-site, 30 day dispensing trial. Subjects 18-69 years of age were dispensed eye drops for 30 days of use. Endpoints included change from baseline in overall ocular comfort, end of day comfort, overall vision, and end of day vision, all on a 0-100 visual analog scale (VAS).

Results: Blink Triple Care shows a bimodal distribution of the lipid phase, with 83.8% (V) at 25nm & 16.2% at 195nm. Systane Complete shows a peak at 105nm, Systane Balance at 226nm, Refresh Optive Advanced at 309nm. Soothe XP has a size of ~ 8880 nm using a leaser diffraction technique. The surface areas of the lipid estimated from droplet size and lipid concentration were: Blink Triple Care 6.45, Systane Complete 5.71, Systane Balance 2.65, Refresh Optive Advanced 0.49 and Soothe XP 0.34 cm^2 per ml of eye drop. Emulsion instability, expressed as changes in transparency after a sample was centrifuged for 24 hours at 40^oC, was 1.4% for the Blink Triple Care, 4.3% for Systane Complete, 121.8% for Systane Balance, 282% for Refresh Optive Advanced, and 4096% for Soothe XP. Sixty-three subjects successfully completed the clinical study. The mean (std) change from baseline after 30 days us of Blink Triple Care was 21.4 (24.5) for overall comfort, 34.6 (26.8) end of the day comfort, 14.2 (22.5) overall vision, and 24.4 (26.0) end of the day vision.

Conclusions: Blink® Triple Care has the smallest oil droplet size among the lipid eye drops tested, yielding the highest lipid surface area as well as the highest emulsion stability. There was a large improvement in comfort and quality of vision scores, particularly at the end of day after a month of using the Blink® Triple Care lipid drop in a clinical study.

ABSTRACT BODY:

Purpose: Transplantation of the cornea is a standard procedure for the treatment of corneal blindness, but there is a severe scarcity of donor corneas. The development of an artificial cornea could help to quell the demand. Collagen-based artificial corneas, in which the collagen has been chemically crosslinked, have shown promise in human trials. However, most crosslinking agents are cytotoxic. In the absence of crosslinking, collagen implants are mechanically weak and susceptible to enzymatic degradation. In this work, we successfully fabricated transparent hydrogels as corneal substitutes from collagen, without using any crosslinkers or modifying the native collagen structure.

Methods: We developed a pyrene conjugated dipeptide amphiphile PyKC consisting of lysine and cysteine for supramolecular gelation where collagen molecules are intertwined inside the PyKC network without any alteration of the collagen. Hydrogels of 10% and 15% collagen (as controls), 10% collagen-1% PyKC, 10% collagen-2% PyKC, 15% collagen-1% PyKC, and 15% collagen-2% PyKC, are referred to as $Coll_{10}$, $Coll_{15}$, $Coll_{10}$-$PyKC_1$, $Coll_{10}$-$PyKC_2$, $Coll_{15}$-$PyKC_1$ and $Coll_{15}$-$PyKC_2$, respectively. We measured physicochemical properties, biocompatibility, immunogenicity and antiviral property of the hydrogels. One-way ANOVA with Tukey post hoc test was performed to compare between groups.

Results: Light transmission studies showed the hydrogels are transparent in visible light and block UV light. The hydrogels were mechanically comparable with controls ($Coll_{10}$ and $Coll_{15}$-$PyKC_2$, $p=0.0555$), enzymatically stable, and the tolerance for sutures was increased compared to controls ($Coll_{10}$ and $Coll_{15}$-$PyKC_2$, $p=0.0128$). The hydrogels also supported the growth and function of corneal epithelial, stromal, and endothelial cells. In vitro immune response studies showed that the hydrogels suppressed the inflammatory differentiation of human monocyte-derived dendritic cells. The hydrogels also restricted adenovirus propagation ($Coll_{15}$ and $Coll_{15}$-$PyKC_1$, $p=0.0007$).

Conclusions: Our newly developed crosslinker-free fabrication strategy may dramatically impact the development of corneal implants. The hydrogels can also be modified to encapsulate cells, drugs, growth factors, and/or antibodies for therapeutic use.

ABSTRACT BODY:

Purpose: The BLINK Study was a 3-year clinical trial that evaluated center-distance multifocal contact lenses (MFCLs) for myopia control and found reduced myopia progression and eye growth with +2.50 add MFCLs compared to single vision contact lenses (SVCLs). This analysis explores whether pupil size influenced the magnitude of the treatment effect.

Methods: Myopic children (n = 294; 7-11 years old; 60% female) were enrolled (mean ± SD age = 10.3 ± 1.2 years) and randomly assigned to one of 3 groups: SVCL, +1.50 MFCL, or +2.50 MFCL. Children had -0.75 D to -5.00 D of myopia (most hyperopic meridian) and <1.00 D astigmatism at enrollment (mean ± SD spherical equivalent = -2.39 ± 1.00 D). Pupil size (right eye) was measured at baseline and each annual visit under photopic (~500 lux) and mesopic (~2 lux) lighting with a NeurOptics VIP-200 pupillometer. Models of the 3-year change (right eye) in cycloplegic spherical equivalent refractive error (RE; measured by autorefraction) and axial length (AL; measured by optical biometry) were fit with mean photopic or mesopic pupil size, either baseline RE or AL, treatment group, sex, study site, and age. Interactions between pupil size and treatment group were evaluated as the main outcome of interest.

Results: Mean (± SD) photopic and mesopic pupil size were 5.0 ± 0.6 mm (range: 3.3 to 6.9 mm) and 6.4 ± 0.7 mm (range: 4.5 to 8.4 mm), respectively, with no difference between treatment groups (photopic p = 0.60; mesopic p = 0.62). When modelling the 3-year change in spherical equivalent RE, neither photopic (p = 0.67; 95% CI: -0.40 to +0.25 D/mm pupil size) nor mesopic pupil size (p = 0.47; 95% CI: -0.41 to +0.19 D/mm pupil size) modified the slowing of myopia progression found in the +2.50 MFCL group (i.e., no treatment by pupil size interaction). With respect to change in AL, neither photopic (p = 0.92; 95% CI: -0.13 to 0.15 mm AL change/mm pupil size) nor mesopic pupil size (p = 0.37; 95% CI: -0.07 to 0.19 mm AL change/mm pupil size) modified the slowing of AL found in the +2.50 MFCL group.

Conclusions: Larger pupils have been hypothesized to have a greater treatment effect with center-distance MFCLs by exposing the retina to additional plus power. Pupil size did not modify the size of the treatment effect when children wore MFCLs in the BLINK Study. These results do not support using pupil size as a criterion when evaluating which myopic children to fit with this MFCL.

ABSTRACT BODY:

Purpose: Enhanced S-Cone Syndrome (ESCS) is a rare retinal degenerative disease mostly caused by pathogenic variants in the NR2E3 gene. Rod photoreceptor differentiation is disrupted during ESCS retinal development, resulting in a retina where short (S) wavelength cones predominate, long (L) and middle (M) wavelength cones are present in reduced numbers, and rods are absent. This study explores the topographic macular cone distribution in ESCS subjects and examines the impact of abnormally high extrafoveal cone density on spatial vision.

Methods: We used an adaptive optics scanning laser ophthalmoscope (AOSLO) to measure cone spacing in 5 ESCS subjects. A custom display channel was added in the AOSLO to measure L/M- and S-cone mediated visual acuity along with retinal imaging. Acuity measurement used a 4-alternative forced choice, tumbling-E paradigm. S- and L/M-cone acuities were measured along the temporal meridian between the fovea and 4° eccentricity. S-cone isolation was achieved using a two-color chromatic adaptation method that was validated on 3 control subjects. L/M acuity was tested by presenting long-pass-filtered (Wratten 16) optotypes on a black background. Quest staircases with 50 trials were used for each experimental condition.

Results: Normal eyes had ~0.5 arcmin cone spacing at the fovea that increased to ~1.5 arcmin at 3° and ~1.9 arcmin at 8°. The 5 ESCS patients had relatively constant cone spacing throughout the macula with arcmin values of 0.9-1.5 for the 4 youngest ESCS subjects, and 1.8-2.2 for subject 10055. The 4 youngest ESCS patients had increased foveal cone spacing (lower cone density) compared to normal, but beyond 2-3°, cone spacing was lower, and cones were more densely packed than normal. In 7 normal subjects, L/M-cone acuity behaved similarly to normal achromatic acuity. Foveal S-cone acuity was about 20/220, and declined with eccentricity. L/M-cone acuity in the ESCS subjects had high intersubject variability, but showed near normal performance at the fovea and got worse with eccentricity. Two of the ESCS subjects had better than normal S-cone acuity across all eccentricities. The third ESCS subject had worse S-cone acuity near the fovea but better than normal S-cone acuity beyond 2° eccentricity.

Conclusions: Higher-than-normal parafoveal cone densities (presumably dominated by S-cones) in ESCS subjects confer better-than-normal S-cone mediated acuity.

ABSTRACT BODY:

Purpose: ELOngation of Very Long-chain fatty acids-4 (ELOVL4) is an enzyme that catalyzes the biosynthesis of very long chain saturated (VLC-SFA) and polyunsaturated (VLC-PUFA) fatty acids, collectively known as very long chain fatty acids (VLC-FA). ELOVL4 is only expressed in the retina, brain, skin, testis, and Meibomian glands. Different mutations in ELOVL4 affect these tissues in different ways. Some known mutations in humans only affect the retina causing a juvenile form of macular degeneration known as Autosomal Dominant Stargardt-like Macular Dystrophy (STGD3), while other mutations affect the brain and/or skin leading to Spinocerebellar Ataxia-34 (SCA34) and skin lesions. How the different ELOVL4 mutations cause such different tissue-specific pathologies are not well understood. We hypothesize that the various mutant ELOVL4 enzymes synthesize less and varying amounts of VLC-FA in a tissue-specific manner to cause the different tissue-specific pathologies.

Methods: We transduced ELOVL4 variants (L168S, L168F, W246G, and STGD3) in human embryonic kidney cells (HEK 293T) or human retinal epithelial cells (ARPE-19) and treated the cells with VLC-FA precursors lignoceric acid (24:0) and eicosapentaenoic acid (EPA; 20:5n3). The cells were harvested for fatty acid analyses to determine the level of VLC-FA biosynthesis. The effect of the different ELOVL4 variants on cell health was also examined using cell-based assays.

Results: The truncated ELOVL4 mutations that cause STGD3 did not synthesize VLC-FA. However, the SCA34 proteins, although enzymatically active, synthesized lesser quantities of VLC-FA than that of wild-type ELOVL4. Further, the accumulation of mutant ELOVL4 protein triggers endoplasmic reticulum (ER) stress through the eIF2α–ATF4 pathway and leads to cell death. We were able to alleviate the ER stress and cell death by supplementation with unsaturated fatty acids (EPA) while saturated fatty acids (24:0) exacerbated cell death.

Conclusions: The SCA34 ELOVL4 proteins make less VLC-FA product and promote cell death via ER stress, which can be alleviated with EPA supplementation. Future experiments will delve deeper into understanding the mechanisms of retinal degeneration in ELOVL4-related diseases.

ABSTRACT BODY:

Purpose: Evaporative-salinity increases in the pre-corneal tear film can lead to hyperosmotic stress-induced discomfort [Liu et al. 2013]. By shielding the cornea, soft contact lenses (SCLs) can, in principle, protect the cornea against such hyperosmotic stresses. Because SCLs are hydrogels, salt can permeate through the lens [Guan et al. 2011] and post-lens tear film (PoLTF) to reach the cornea [Kim et al. 2021]. Permeation through the lens requires time for the salt to diffuse across the lens. If the time required for salt to transport across the lens is of order hours, lens wearers could remove and reinsert the lens during the midday to forestall PoLTF hyperosmolarity. Here, to ascertain whether midday reinsertion is suitable method to mitigate PoLTF hyperosmolarity, we determine the time it takes for the PoLTF osmolarity to reach a periodic steady state.

Methods: The SCL osmolarity model of Kim et al. [2021] was modified to determine the time it takes to reach steady state for various lens salt partition coefficients (k_s), lens salt diffusivities (D_s), and lens thicknesses (h_{lens}). The mathematical model is scripted and computed with Matlab R2019b. Modified script counts the number of iterations required to reach periodic steady state and converts iteration number into the time to reach steady state. Analyses are conducted for both normal and dry-eye scenarios.

Results: Figure 1 provides calculated PoLTF osmolarity for normal eye for various D_s and fixed interblink period (t_{ib}), k_s, and h_{lens} (specified in Figure 1). The D_s range in Figure 1 accounts for most commercially available silicone-hydrogel and hydrogel contact lenses today. PoLTF osmolarity reaches steady state within the first 30 min of lens wear. This is also the case for the dry-eye scenario (i.e., increased tear-evaporation and decreased tear-production rates). Time to attain steady state was still less than 30 min even after varying h_{lens} and t_{ib} over physically realistic values.

Conclusions: Time to steady state for the PoLTF osmolarity occurs within the first hour of lens insertion for all adjustable parameters. Therefore, midday lens removal is not a viable way to regulate PoLTF osmolarity. Lowering D_s is the most effective way to mitigate PoLTF hyperosmolarity.

TITLE: Effect of Minocycline Ointment on Meibomian Gland Dysfunction Rat Model

SESSION TITLE: Dry eye regulators: lacrimal gland, Meibomian gland, basic mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Cho, S. Shin, H. Lee, M. Lee, Ophthalmology, Dankook University Hospital, Cheonan, Chungcheongnam-do, KOREA (THE REPUBLIC OF)|H. Kim, H. Kim, J. Kim, Dankook University - Cheonan Campus, Cheonan, Chungnam, KOREA (THE REPUBLIC OF)|

Commercial Relationships Disclosure: Kyong Jin Cho: Commercial Relationship: Code N (No Commercial Relationship) | Hoon Kim: Commercial Relationship: Code N (No Commercial Relationship) | Hong-Bee Kim: Commercial Relationship: Code N (No Commercial Relationship) | Seon-Pil Shin: Commercial Relationship: Code N (No Commercial Relationship) | Hyo-Sun Lee: Commercial Relationship: Code N (No Commercial Relationship) | Moon-Hyung Lee: Commercial Relationship: Code N (No Commercial Relationship) | Jeong-Yun Kim: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Meibomian gland dysfunction (MGD) is known to be a major cause of dry eye disease, with various ocular surface disorders. Currently, appropriate eye drops are prescribed to deal with MGD, as well with thermal and mechanical means such as warm compresses or lid scrubs. Minocycline is one of the tetracycline antibiotics, routinely being prescribed to MGD patients for oral administration. It is proven to be effective in dealing with MGD symptoms but has potential risks such as photosensitivity, gastrointestinal disturbances (emesis, diarrhea, and dyspepsia), and genitourinary symptoms, etc. If possible, the use of minocycline ointment may reduce some of the known risks with the same effect. Since there is no study yet regarding the use of minocycline ointment on MGD, the authors aimed to investigate the effect of minocycline ointment in the MGD rat model.

Methods: Cell viability test was conducted using human corneal epithelial cells and the appropriate concentration of minocycline without toxicity was confirmed. Then the proven concentration was compared with the currently available minocycline ointment for in vivo experiment. MGD rat model was established using CFA injection on the nasal and lateral eyelid margin of six-week-old male SD rats. After MGD induction for a week, the rats were treated with minocycline ointment twice a day for three weeks. A total of six experimental groups were used, including control, control with minocycline ointment, MGD, MGD with hyaluronic acid, MGD with oxytetracycline, MGD with cyclosporine, and MGD with minocycline ointment. Symptom scores (tear break-up time, corneal fluorescent staining score, telangiectasia score, and eyelid swelling score) were assessed every week for three weeks, then the rats were sacrificed for immunohistochemistry.

Results: The use of minocycline ointment in MGD rat model alleviated the symptoms showing decreased corneal fluorescent, lid swelling, and telangiectasia scores, as well with increased tear break-up time. Also, the level of inflammatory cytokines, IL-1b, IL-6, and TNF-a, were lowered after minocycline ointment treatment in corneal, conjunctiva, and meibomian gland tissues.

Conclusions: In conclusion, this study confirmed the positive effect of minocycline ointment in the MGD rat model, having lower symptom scores, higher tear break-up time, and showing the reduced level of inflammation in cornea, conjunctiva, and meibomian gland tissues.

ABSTRACT BODY:

Purpose: First-line anti-VEGF therapies for diabetic macular edema (DME) are efficacious in around half of DME patients and repeated administrations are associated with complications.

Anti-VEGF therapies fail to address inflammation and retinal cell loss associated with this disease and furthermore, hemolysis has been observed in primates treated with aflibercept through IgG-Fc gamma receptors. Therefore, we have designed a gene therapy to address the complex pathophysiology of DME that requires a single ocular injection.

Methods: Multi-cistronic plasmids and rAAV2/2 vectors expressing a novel anti-VEGF component and Tie2 receptor agonist together with a retinoprotective PEDF polypeptide were evaluated in HEK293T, ARPE-19 cells and co-cultures of human fibroblast/HUVECs. HUVEC monolayers were grown on transwells to assess permeability (TEER). The lead vectors were evaluated using rodent models.

Results: In a co-culture model of angiogenesis, lead constructs demonstrated significantly reduced capillary length and branch number versus controls equivalent to aflibercept (capillary length (mm); control = 13.7 ± 0.5, IKC113 = 3.8 ± 0.4***, aflibercept = 3.9 ± 0.3***; mean ± SEM of 12 replicates; ***P<0.001 by ANOVA with Bonferroni modified t-tests). A lead construct reduced angiopoietin-2 concentrations (ng/mL) in the co-culture medium (control = 1.29 ± 0.20, IKC113 = 0.09 ± 0.00***, aflibercept = 0.06 ± 0.00***; mean ± SEM of 3 replicates; ***P<0.001). Furthermore, a lead construct, acting through the Tie2 agonist component, attenuated TNF-alpha (TNFα)-induced reduction in TEER (Ohms/cm^2) over 24h in HUVEC monolayers (control minus TNFα = 23.5 ± 0.3, control Null plasmid plus TNFα = 15.1 ± 0.6, IKC113 plasmid plus TNFα = 20.1 ± 0.4; mean ± SEM of 3-6 replicates; **P<0.001 versus Null plasmid with TNFα) demonstrating reduced cytokine-induced vascular permeability. In the laser CNV study a lead tri-cistonic rAAV demonstrated a 60% reduction in CNV leakage compared to the vehicle control.

Conclusions: In addition to robust anti-VEGF activity, we have demonstrated that the multi-cistronic rAAV2/2 gene therapy has the ability to reduce vascular leakage and inflammation through Tie2 receptor activation. These novel gene therapies are set to become a valuable new treatment option for patients with DME.

ABSTRACT BODY:

Purpose: To compare the diagnostic accuracy of OCTA parameters and circumpapillary retinal nerve fibre layer thickness (cRNFLT) for perimetric glaucoma.

Methods: Northern Ireland Cohort for the Longitudinal Study of Ageing participants with vertical cup to disc ratio ≥0.7 and/or intraocular pressure ≥25mmHg were invited to clinical examination by a glaucoma expert and full-threshold 24-2 perimetry. Eyes were diagnosed as “glaucoma”, “glaucoma suspect” or “control”. Participants underwent OCTA and SD-OCT scans with Heidelberg Spectralis OCT2 at the same visit. OCTA en face images were segmented using ImageJ and quantitatively analysed using AngioTool. Areas under the receiver operating characteristic (AUROC) curves were calculated for diagnostic parameters using funcs_clusteredROC.R. Comparisons of AUROC curves were made between the mean global OCTA parameters and mean global cRNFLT.

Results: 63 eyes from 46 participants (mean age [SD] 65.33 [7.39]; 43.48% female) were included. Circumpapillary vasuclar flow density (cVFD) was statistically significantly lower in glaucoma eyes (n=20; 23.77%) compared to control eyes (n=16; 26.14%; $p<0.05$) and glaucoma suspect eyes (n=27; 25.65%; $p<0.05$). OCTA total number of vessel junctions was statistically significantly lower in glaucoma eyes (165.10) compared to control eyes (210.18; $p<0.05$) and glaucoma suspect eyes (207.07; $p<0.05$). OCTA mean lacunarity was statistically significantly higher in glaucoma eyes (0.705) compared to control eyes (0.666; $p<0.05$) and glaucoma suspect eyes (0.670; $p<0.05$). Mean global cRNFLT was statistically significantly lower in glaucoma eyes (70.05 µm) compared to control eyes (92.19 µm; $p<0.05$) and glaucoma suspect eyes (88.63 µm; $p<0.05$). AUROC (SE) was 0.83 (0.07) for OCTA cVFD, compared to 0.82 (0.06) for OCTA total number of vessel junctions ($p=0.80$), and 0.81 (0.07) for OCTA mean lacunarity ($p=0.76$). AUROC was 0.85 (0.06) for cRNFLT compared to 0.83 (0.07) for cVFD ($p=0.74$).

Conclusions: In participants referred from a population-based cohort study, OCTA mean global cVFD was the best performing OCTA parameter. Mean global cRNFLT was the overall best performing diagnostic parameter, however, it was not statistically significantly different from OCTA mean global cVFD. Longitudinal studies are required to assess the role of OCTA in detecting glaucoma progression.

ABSTRACT BODY:

Purpose: To investigate the relationship between Bruch's Membrane Opening Minimum Rim Width (BMO) and ocular biomechanics in glaucomatous and non-glaucomatous eyes.

Methods: A cross-sectional study of prospectively acquired data was used to evaluate 323 eyes of 181 healthy controls (NRL) and 66 eyes of 42 subjects diagnosed with primary open angle glaucoma (GLA). Biomechanical response was characterized using the Corvis ST by comparing the stiffness parameters at first applanation (SP-A1) to indicate corneal stiffness and the stiffness parameter at highest concavity (SP-HC) to quantify scleral stiffness in the seated position. Spectralis OCT imaging was used to measure BMO. Pneumatonometry was used to measure intraocular pressure (IOP) and ocular pulse amplitude (OPA). BMO was compared to IOP by group with univariate regression analysis. BMO was also compared between GLA and NRL using ANCOVA with IOP as a co-variate. Finally, two multiple regression analyses were performed with BMO as the dependent variable, and IOP, age and either SP-A1 or SP-HC as the independent variables, using SAS statistical analysis software with $p<0.05$ as the significance threshold.

Results: Global BMO was significantly smaller in GLA compared to NRL eyes (211 ± 59 µm vs 358 ± 60 µm; $p<0.001$), and significantly negatively related to IOP only in NRL ($p<0.001$). Both corneal and scleral stiffness were significantly greater in GLA (SP-A1 $p<0.001$; SP-HC $p<0.027$). The two multiple regression analyses showed a significant, negative relationship of BMO with SP-A1 ($p<0.001$, $R^2=0.088$) and SP-HC ($p<0.001$, $R^2=0.078$) in NRL but not in GLA.

Conclusions: BMO decreases as IOP increases in NRL, but IOP has no effect on the significantly smaller BMO in GLA. As corneal and/or scleral stiffness increases, the BMO decreases in NRL but has no effect in the significantly stiffer GLA. These in vivo findings indicate that increasing stiffness may be an additional risk factor to increasing IOP for decreased BMO, and to the development of glaucomatous damage. Our results provide insight into the role of ocular biomechanics in glaucoma and identify parameters that may increase the risk of glaucoma development.

ABSTRACT BODY:

Purpose: The aim of this study is to identify small molecule compounds that can reprogram retinal Müller cells (MCs) into photoreceptor cells and to evaluate the recovery of retinal function in animal models of retinal degeneration.

Methods: In vitro, MCs were stimulated with all combinations of candidate compounds, and rhodopsin (Rho) expression was confirmed on day 7 by Polymerase Chain Reaction and immunostaining. In vivo, we used 6-week-old N-methyl-N-nitrosourea [MNU]-treated and 4-week-old rd10 mice, representative models of retinal degeneration. The optimal combination of compounds determined by in vitro screening was injected into the vitreous and the changes in Rho expression were evaluated on day 7. The origin of Rho-positive cells was also validated in td-Tomato reporter mice. PAAV.GFAP.Cre.WPRE.hGH, which is an adeno-associated virus (AAV) containing human GFAP promoter, was injected into the vitreous of 2-week-old B6.Cg-Gt(ROSA)26Sortm14(CAG-tdTomato)Hze/J mice so that MCs could be visualized. On day 7 after MNU administration, co-expression with td-Tomato and Rho in the outer retina was confirmed by immunohistochemistry. Finally, the recovery of retinal function was assessed by electroretinography.

Results: In vitro, mRNA expression of Rho in MCs increased 30-fold, and 25% of MCs expressed Rho protein 7 days after stimulation with the combination of 4 compounds: tumor growth factor-β inhibitor, bone morphogenetic protein inhibitor, glycogen synthase kinase 3 inhibitor, and γ-secretase inhibitor. In vivo, Rho mRNA expression and the number of Rho-positive cells in the outer retina were significantly increased on day 7 after the intravitreal injection of these 4 compounds in both MNU-treated and rd10 mice. Lineage tracing in td-Tomato mice treated with MNU showed that the regenerated Rho-positive cells were originated from endogenous MCs, accompanied with recovery of Rho-derived scotopic function, which suggested Rho-positive cells may have the properties of photoreceptor cells.

Conclusions: These results suggest that photoreceptor cells can be regenerated from endogenous retinal MCs via direct reprogramming by small molecule compounds.

ABSTRACT BODY:

Purpose: Purpose: A new, one-day disposable soft contact lens (SCL), the Verofilcon A (Precision 1®), constructed of silicone hydrogel material, has recently become available in Japan. This SCL has a very smooth surface produced by using the Smart Surface® technology. The purpose of this study was to compare the comfort of wearing eyeglasses and SCL for first time SCL wearers.

Methods: Methods: A total of 10 new SCL wearer were participated in this study. We compared the scores for comfort when wearing spectacles and Verofilcon-A.

Results: Results: The Subjective comfort scores (1-10) for glasses and SCL were (8.2 ± 1.5 vs 8.7 ± 1.3, $p = 0.13$) at insertion, (8.0 ± 1.3 vs 8.7 ± 1.1, $p = 0.07$) at daytime, and (6.0 ± 2.3 vs 8.7 ± 1.2, $p < 0.01$) at the end of the day, and (7.0 ± 1.6 vs 8.8 ± 1.2, $p = 0.02$) throughout the day, which were relatively higher for SCL than for glasses.

Conclusions: Conclusions: These findings indicate that the Verofilcon-A 1DSCL is more comfortable than eyeglasses and may be effective as an introductory lens for SCL initial wear.

TITLE: Novel Gene Therapy for the Regeneration of Schlemm's Canal for Patients with Ocular Hypertension

SESSION TITLE: Gene Therapy and Gene Editing for Ocular Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Binley, E.F. Warner, K. Boyd, P.S. Widdowson, A. Osborne, Ikarovec Limited, Norwich, UNITED KINGDOM|

Commercial Relationships Disclosure: Katie Binley: Commercial Relationship(s);Code E (Employment):Ikarovec Limited;Code P (Patent):Ikarovec Limited | Emily Warner: Commercial Relationship(s);Code E (Employment):Ikarovec Limited | Kara Boyd: Commercial Relationship(s);Code E (Employment):Ikarovec Limited | Peter Widdowson: Commercial Relationship(s);Code E (Employment):Ikarovec Limited;Code P (Patent):Ikarovec Limited;Code O (Owner):Ikarovec Limited;Code S (non-remunerative):Ikarovec Limited | Andrew Osborne: Commercial Relationship(s);Code E (Employment):Ikarovec Limited

ABSTRACT BODY:

Purpose: Ocular hypertension (OHT) is a primary risk factor for developing glaucoma. Narrower Schlemm's canal (SC) and reduced SC epithelial cell pores have been observed post-mortem in glaucoma eyes indicating higher aqueous outflow resistance. Lower Tie2 receptor activity resulting from reduced angiopoietin-1 (Ang1) agonist levels may underlie this pathology. We have developed a regenerative gene therapy capable of restoring SC epithelium through release of a novel Tie2 agonist within the anterior chamber. This novel approach for OHT would eradicate the need for regular eye drops that have been hampered by poor adherence.

Methods: Novel plasmids and self-complementary rAAV2/2 vectors were examined for phospho-Tie2 levels using HEK293Ts transiently expressing Tie2 receptors. Intraocular pressure (IOP) was periodically measured by tonometry in normotensive mice and rats following intracameral injection of vector and compared to animals injected with a Null control vector. Expression levels were examined by immunohistochemistry.

Results: A series of proteins were designed based on the fusion of the fibrinogen-like domain of Ang1 and short coiled-coil regions of human proteins that could be accommodated within the capacity-limited scAAV2/2. The lead agonist construct (IKC074) was able to significantly activate Tie2 receptors (ratio of p-Tie2/total Tie2; IKC074 = 2.09 ± 0.35 $P<0.01$, mean ± SEM for n = 4 replicates). Intracameral injection of the IKC074 vector in mice and rats produced a sustained significant reduction in IOP (mmHg) versus animals administered with Null control vector and correlated with transgene expression levels (mouse IOP 14 days after injection controls = 16.3 ± 0.4 versus IKC074 = 13.1 ± 0.7 and at 42 days controls = 16.5 ± 0.5 versus IKC074 = 14.1 ± 0.6; $P<0.001$; Student's t-test, n = 10).

Conclusions: This gene therapy expresses a novel Tie2 agonist that has significant IOP reduction in both normotensive mice and rats through improved SC function and aqueous drainage. This experimental treatment requires only a single intracameral injection with anticipated efficacy to last several years. It would provide a valuable addition to the armamentarium for glaucoma treatment and prevention for patients with poor adherence or tolerance to eye drop medication.

TITLE: Systematic Review and Meta-Analysis of Long-Term Metastasis-free Survival in Untreated Uveal Melanoma

SESSION TITLE: Intraocular tumors - Uveal melanoma and retinoblastoma

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Stålhammar, St. Erik Eye Hospital, Stockholm, SWEDEN|G. Stålhammar, V.T. Gill, Clinical Neuroscience, Karolinska Institutet, Stockholm, Stockholm, SWEDEN|V.T. Gill, Department of Pathology, Västmanland Hospital Västerås, Västerås, SWEDEN|

Commercial Relationships Disclosure: Gustav Stålhammar: Commercial Relationship: Code N (No Commercial Relationship) | Viktor Gill: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The impact of primary tumor treatment on the survival of patients with uveal melanoma is uncertain and it is debated if a beneficial survival effect exists at all.

Methods: PubMed, Web of Science and Embase were searched for articles published in any language and in any year. Publications were included if they reported patients with primary melanoma of the choroid or ciliary body with ≥ 5-year follow-up for patients without metastases. Studies were excluded if patients had received any kind of treatment for their primary tumor within 5 years from diagnosis. The long-term cumulative metastasis-free and overall survival of the included patients was estimated and contrasted to cohorts of treated tumors.

Results: Seven studies with a total of 19 patients were included. Seven of the patients that initially refused treatment were eventually enucleated at a mean of 13 years after diagnosis (SD 10). Tumor size at diagnosis and last follow-up was available for eight patients. All of these were either small or medium-sized. Five tumors with specified diameter and/or thickness grew to a mean of 2.4 times its original size until last follow-up. The cumulative metastasis-free survival for 17 patients with choroidal or ciliary body melanoma was 71 % at five years (95 % CI 49-93 %), 29 % at 10 years (7-51 %), 18 % at 15 years (0-36 %) and 11 % at 30 years (0-27 %). This was significantly worse than the survival in comparison cohorts of both medium-sized (Log-rank $p<0.001$) and large treated tumors (Log-rank $p<0.01$).

Conclusions: Patients that do not undergo treatment for their primary uveal melanoma are exceedingly rare in the literature. Of the published cases, eight or nine out of ten have eventually developed metastases. This indicates that primary tumor treatment may prevent metastases.

ABSTRACT BODY:

Purpose: Given the surge in global antimicrobial resistance infections, insight into the bacteria etiology is essential in the choice of antibiotic therapy among ophthalmic clinicians in their routine management of eye infections. Considering the paucity of data from Ghana, this study investigated the bacteria etiology of external ocular and periocular infections, and antimicrobial treatment patterns among ophthalmic patients in Ghana.

Methods: The multicenter cross-sectional study enrolled patients from three hospital facilities in Ghana. One hundred and fourteen eligible subjects were enrolled and underwent comprehensive ophthalmic assessments. Clinical profile and demographic characteristics were collated with a pretested structured questionnaire. Ocular specimens including conjunctival swabs and corneal scrapes were obtained from patients' eyes and subjected to microbial analyses. Bacterial pathogens were isolated and characterized by differential media, colony morphology, gram reactions under light microscopy, and biochemical testing. All procedures were performed under aseptic conditions.

Results: About 95% of ocular samples were positive for bacteria culture. The proportion of Gram-negative bacteria was 58.2%, and the predominantly isolated bacteria species were Pseudomonas aeruginosa 38.8% and Staphylococcus aureus 27.6%. Pseudomonas aeruginosa was mostly implicated in cases of conjunctivitis and keratitis and with a proportionate distribution of 40.0% versus 75.0%, respectively. The routinely used antimicrobial therapy in the clinical management of eye infections was polymyxin B 41.2%, neomycin 35.1%, and ciprofloxacin 31.6%. Participants' demographic and clinical characteristics were not associated ($p > 0.05$, for all) with the presence of positive bacteria culture.

Conclusions: Our results demonstrate a markedly high burden of bacteria ocular infections with variations in etiology. Bacterial infection-control and antimicrobial agent management programs should be urgently instituted to prevent the emergence of potential resistant infections.

ABSTRACT BODY:

Purpose: Over 150,000 people in the United States are afflicted with keratoconus (KCN)—a corneal ectatic disease characterized by progressive corneal thinning. Until the recent advent of corneal crosslinking (CXL), one of the only treatment options for advanced KCN was corneal transplantation. Early diagnosis of KCN and subsequent CXL treatment has been shown to improve outcomes in patients suffering from KCN. At Wake Forest Baptist Health (WFBH), we have noticed a trend in referral patterns in which black patients often present to our department with more advanced KCN than non-black patients, which may lead to a delay in treatment and poorer outcomes.

Methods: We performed a retrospective review of patients presenting to WFBH between 2018-2020 for KCN evaluation. For each patient, demographic and referral information was collected. Exclusion criterion included prior corneal surgery or CXL. Outcome measures were best corrected visual acuity (BCVA), presence of corneal scarring, keratometry values, ABCD score, and recommended treatment plan. Follow-through with the recommended treatment plan was evaluated between groups within 6-months of initial consultation. Chi squared tests were used to perform statistical analyses.

Results: 128 patients were included the study. According to demographic information collected, black patients presented with a higher BMI and a more evenly distributed (1:1) male-to-female ratio. Tomographic outcomes showed that black patients presented with worse BCVA ($p < 0.0001$), worse tomographic keratoconus staging ($p < 0.0001$), and were more likely to have corneal thinning ($p < 0.0001$) or scarring ($p < 0.0001$) precluding corneal cross-linking when compared to non-black patients. There was no significant difference in the likelihood that black patients would follow through with a proposed treatment plan. However, there were poor follow-up rates among both groups—thus limiting the strength of this conclusion.

Conclusions: When compared to their non-black counterparts, black patients presented to our institution with more advanced KCN which often precluded CXL as a viable treatment option. Black patients were also just as likely to follow through with a proposed treatment plan.

ABSTRACT BODY:

Purpose: According to the extended protocol for the photopic negative response (PhNR) of the full-field electroretinogram from the International Society for Clinical Electrophysiology of Vision (ISCEV), the preferred method of eliciting PhNR is a red flash on a rod saturating blue background (ROB). However, PhNR can also be elicited by a white flash on a white background, under stimulus conditions like the one used to elicit an ISCEV standard Photopic 3.0 ERG (Ph3) response. The purpose of the current study is to compare the baseline noise between the two conditions in patients with various retinal pathologies.

Methods: A retrospective chart review and data analysis of patients aged 18 and over undergoing routine ERG testing at the University of South Florida Eye Institute (Tampa, FL) between July 2018 and October 2021 were conducted. Throughout the study period, Ph3 was recorded in the same way while ROB response was generated in three different ways, resulting in three comparison groups. Group 1 (Gr1) ROB protocol used a ~5 cd•s/m^2 red flash (627 nm) on a 30 cd/m^2 blue background (470 nm), Group 2 (Gr2) protocol used a ~2.5 cd•s/m^2 red flash on a 10 cd/m^2 blue background, while Group 3 (Gr3) protocol used a ~5 cd•s/m^2 red flash on a 10 cd/m^2 blue background. The level of background bioelectrical activity (30 ms before the flash) was compared between the Ph3 and ROB conditions by calculating the root mean square (RMS) of the signal under all three protocols.

Results: The records of 69 patients/138 eyes (19M, 50F, mean age 50.7 +/- 14.5 years) were evaluated (Gr1=14; Gr2=27; Gr3=28). The baseline level of activity was higher in all three ROB conditions compared to Ph3 for both right (OD) and left (OS) eyes. Specifically, in Gr1, OD RMS = 0.95 µV (Ph3) vs. 1.66 µV (ROB) ($p=0.003$, Wilcoxon matched-pairs signed-rank test) and OS RMS = 1.1 vs. 1.7 µV ($p=0.006$); in Gr2, OD RMS = 0.80 vs. 1.98 µV ($p=0.0003$) and OS RMS = 0.90 vs. 1.79 ($p<0.0001$); in Gr3, OD RMS = 0.87 vs. 1.27 µV ($p<0.0001$) and OS RMS = 0.96 vs. 1.14 µV ($p=0.02$).

Conclusions: Baseline activity was higher under ROB stimulation in all conditions compared to Ph3, indicating more eyelid muscle activity and a higher level of visual discomfort consistent with anecdotal patient reports. The results of our study suggest that a white flash on a white background may reduce patient discomfort while generating a comparable PhNR.

ABSTRACT BODY:

Purpose: To determine the effects of whole body animal exposure to airborne particulate with a diameter of <10µm (PM_{10}) in vivo in the mouse cornea and in vitro in immortalized and primary human corneal epithelial cell cultures.

Methods: C57BL/6 mice were exposed to ambient air or an acute, high dose of PM_{10} (500µg/m^3) for 2 weeks for 3h/day/5days/week and rested on the weekends. At 2 weeks, tear levels and corneal sensitivity were measured using phenol treated threads and a Cochet and Bonnet Esthesiometer, respectively. Hematoxylin and eosin staining of paraffin embedded tissue was used to evaluate corneal morphology. Corneal levels of reduced glutathione (GSH) and malondialdehyde (MDA) were evaluated by assay kit or ELISA. RT-PCR and ELISA evaluated levels of Nrf2 pathway molecules and pro-inflammatory markers. SKQ1 (Visomitin), a novel mitochondrial targeted antioxidant, was used to treat the 2 week PM_{10} exposed mice. Ambient air and PM_{10} exposed mice were pretreated with 7.5µM SKQ1 or PBS (control) topically 3 times one day before and then once/day/each day of exposure and tested for oxidative stress and Nrf2 pathway molecules. In vitro, cells were treated with 100µg/ml PM_{10} ± 50nM SKQ1. MDA levels were analyzed by ELISA, Nrf2 protein levels by western blot, mitochondrial ROS by a mitoSOX assay and ATP levels by an assay kit.

Results: No significant changes in tear secretion and sensitivity were observed in PM_{10} vs ambient air exposed mice at 2 weeks. PM_{10} significantly decreased GSH and increased MDA levels in cornea at 2 weeks over controls. Focusing on 2 weeks exposure, PM_{10} exposure caused thinning of the corneal epithelium and stroma. PM_{10} exposed corneas showed significantly higher mRNA levels for Nrf2 pathway and pro-inflammatory molecules over controls. Nrf2 protein was significantly reduced vs controls. SKQ1 treatment restored GSH and Nrf2 protein to control levels and lowered lipid peroxidation. In vitro, in immortalized human corneal epithelial cells, PM_{10} application reduced Nrf2 levels, increased MDA and mitochondrial ROS, but reduced ATP levels; while SKQ1 treatment reversed these effects.

Conclusions: Whole body PM_{10} exposure triggers corneal oxidative stress and disrupts the Nrf2 pathway which regulates antioxidant defenses. SKQ1 treatment reverses these deleterious effects. In vitro corneal epithelial cell data parallel the in vivo effects, suggesting human applicability.

ABSTRACT BODY:

Purpose: Heterozygous RPGR mutations may cause progressive photoreceptor degeneration in female carriers. In this single-center, retrospective, observational study, we assessed retinal structure and function in female carriers of RPGR mutations.

Methods: Adaptive optics (AO) imaging and microperimetry (MAIA) were performed in female carriers of RPGR mutations. Cone density (CD) at 1.4° (4 loci/eye) and 3.2° (8 loci/eye) from the foveal center, and point-wise sensitivity (PWS) at 68 loci spanning central 20° (the 10-2 test grid) were analysed (Figure 1). Normality of measured values was defined against 10 (AO cohort) and 25 (MAIA cohort) age-matched healthy controls: normal < 1 SD, moderate defect 1–2 SD and severe defect > 2 SD from the normal average.

Results: AO and MAIA data were available in 8 and 12 patients, respectively. CD at 1.4° and 3.2° eccentricities showed severe defect in at least 2 locations in 4/8 and 5/8 patients, respectively (overall 38 locations at both eccentricities across the cohort). Severe PWS defect at 1.4° and 3.2° eccentricities was observed in at least 2 locations in 3/12 and 4/12 patients, respectively. Overall, PWS was normal in 25/38 (66%) loci with severe CD defect within the central 3.2° across the cohort (Figure 2). In addition, PWS showed at least moderate defect in ≥ 10/68 loci in 9/12 patients.

Conclusions: AO imaging and microperimetry detected localised defects in cone mosaic and retinal sensitivity in RPGR mutation carriers. Severe cone loss in locations with normal PWS in the parafoveal region suggests that structural damage preceded functional loss in this cohort.

TITLE: Axial length changes induced by positive defocus correlate with changes in choroidal blood flow

SESSION TITLE: Myopia: Structure-Function Relationship

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: B. Swiatczak, G. Calzetti, F. Schaeffel, Institute for Molecular and Clinical Ophthalmology IOB, Basel, SWITZERLAND|F. Schaeffel, Eberhard Karls Universitat Tubingen, Tubingen, Baden-Württemberg, GERMANY|

Commercial Relationships Disclosure: Barbara Swiatczak: Commercial Relationship: Code N (No Commercial Relationship) | Giacomo Calzetti: Commercial Relationship: Code N (No Commercial Relationship) | Frank Schaeffel: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: It has previously been shown that imposed positive defocus induces significant changes in axial length and choroidal thickness after only 30 minutes. We investigated in young adult subjects whether these changes result from changes in ocular blood flow.

Methods: Sixteen young adult subjects (average age: 28±3 years, average refraction: -0.75±1.65D withing the range: +1.7 to -6D) watched a movie from a large screen (LG OLED65C9, 65 inch, 2019) at 2 m distance. Fifteen minutes wash-out period (watching a movie in a dark room with habitual refractive error correction) was followed by 30 minutes of watching a movie with a monocular positive defocus (+2.5D) in the right eye and a habitual correction in the left eye. Changes in axial length and blood flow were measured in both eyes before and after the defocus. Eye biometry was measured by using low-coherent interferometer (LS 900 with autopositioning system; Haag-Streit, Switzerland). Blood flow was measured by using a laser speckle flowgraphy (LSFG) RetFlow unit (Nidek Co., LTD, Japan). Two regions were analyzed: (1) the macular area, where choroidal blood flow can be measured, and (2) the optic nerve head.

Results: All subjects responded to imposed positive defocus as previously found: hyperopes and emmetropes displayed eye shortening while myopes showed axial elongation (Pearson's correlation coefficient between axial length change and refractive state: $R2 = 0.50$, $p<0.01$, Figure 1A). Control eyes did not show any significant changes in axial length after 30 minutes of watching a movie. Changes in axial length were significantly correlated with changes in choroidal blood flow in the macular region ($R2 = 0.43$, $p<0.01$, Figure 1B) and in the optic nerve head ($R2 = 0.27$, $p<0.05$, Figure 1C).

Conclusions: Transient changes in axial length induced by positive defocus appear to be linked to changes in choroidal blood flow which may affect the thickness of the choroid. Blood flow in the macular region showed better correlation to the axial length changes than blood flow in the optic nerve probably because the macular LSFG measurement is less affected by the retinal circulation.

Commercial Relationships Disclosure: Sara Safari: Commercial Relationship: Code N (No Commercial Relationship) | Katherine Tsay: Commercial Relationship: Code N (No Commercial Relationship) | Radouil Tzekov: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The photopic negative response (PhNR) is a component of the full-field electroretinogram (ERG) reflecting the function of the retinal ganglion cells. The current recommendation to optimally elicit the PhNR response is with a red flash stimulus on a blue background (ROB) as defined by the International Society for Clinical Electrophysiology of Vision (ISCEV). The purpose of this study was to compare PhNR and b-wave amplitudes in patients between two conditions: ROB and standard Photopic 3.0 ERG (Ph3) under two different protocols.

Methods: A retrospective chart review and data analysis of patients aged 18 and over undergoing routine ERG testing at USF Eye Institute (Tampa, FL) between July 2018 and October 2021 was conducted. Throughout the study period, while Ph3 was recorded in the same way, ROB response was generated in two different ways. Group 1's ROB protocol used a ~2.5 cd.s/m2 red flash (627 nm) on a 10 cd/m2 blue background (470 nm), Group 2 protocol used a 5 cd.s/m2 red flash on a 10 cd/m2 blue background. PhNR was measured before and after the i-wave, as PhNR1 and PhNR2, respectively. Eyes where the average signal did not come from at least 5 individual quality runs or those whose b-wave amplitude responses were less than 10 µV were excluded.

Results: The records of 55 patients / 110 eyes (13 M, 42 F; mean age 50.1 +/- 14.3 years) were selected: 27 patients (Group 1) and 28 patients (Group 2). There was no significant difference between the linear regression slopes of PhNR amplitudes under Ph3 vs. ROB between left and right eyes for either group ($p>0.05$), although the slopes in Group 1 were steeper compared to Group 2 (1.0 vs. 0.44). Furthermore, no significant difference was observed between the slopes of PhNR1 vs. PhNR2 in either group ($p>0.05$), although PhNR2 peaks were less reliably determined compared to PhNR1 (41.7% in Group 1 and 74.5% in Group 2). Similarly, the slopes of the b-wave amplitudes were not significantly different between right and left eyes ($p>0.05$) and appeared to be no different between Group 1 and Group 2 ($p>0.05$).

Conclusions: Consistent and predictable correlations were found between the PhNR responses obtained under Ph3 and ROB recording conditions at two different strengths of ROB stimulation.

TITLE: Small non-coding RNA (sncRNA1) within latency associated transcript (LAT) modulates HSV-1 virulence and host immune response during acute but not latent infection

SESSION TITLE: Infection and Immunity

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Tormanen, H. Matundan, U. Jaggi, S. Wang, H. Ghiasi, Surgery, Cedars-Sinai Medical Center, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Kati Tormanen: Commercial Relationship: Code N (No Commercial Relationship) | Harry Matundan: Commercial Relationship: Code N (No Commercial Relationship) | Ujjaldeep Jaggi: Commercial Relationship: Code N (No Commercial Relationship) | Shaohui Wang: Commercial Relationship: Code N (No Commercial Relationship) | Homayon Ghiasi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: HSV-1 latency associated transcript (LAT) plays a major role in establishing latency and reactivation; however, the mechanism by which LAT controls these processes is largely unknown. The LAT locus contains two sncRNA sequences (sncRNA1 and sncRNA2) that are not miRNAs. We recently reported that sncRNA1 is more important for in vitro activation of the herpes virus entry mediator (HVEM) than sncRNA2, but its in vivo function is not known. In this study, we sought to establish the role of sncRNA1 during HSV-1 ocular infection by constructing a recombinant HSV-1 lacking sncRNA1.

Methods: The 62 bp sncRNA1 sequence in HSV-1 strain McKrae was deleted by homologous recombination using HSV-1 strain McKrae and a plasmid containing the region of LAT from -161 to +1667 relative to the LAT transcription start site and lacking sncRNA1 region, generating recombinant virus ΔsncRNA1. Deletion of the sncRNA1 in ΔsncRNA1 virus was confirmed by complete sequencing of ΔsncRNA1 virus and its parental virus (i.e., McKrae). Mice were ocularly infected with $2x10^5$ PFU HSV-1 McKrae, dLAT2903 (LAT-minus) or ΔsncRNA1 virus. Virus titers in tear films were determined by standard plaque assay. Mouse survival, level of latency and reactivation and extent of eye disease were monitored, and expression of viral and host transcripts were measured by qRT-PCR and Nanostring assays.

Results: Replication of ΔsncRNA1 in tissue culture or in the eyes of infected mice was similar to McKrae and dLAT2903 viruses. Absence of sncRNA1 reduced LAT expression in trigeminal ganglia (TG), but not in corneas of infected mice by day 5 post infection (PI). Levels of eye disease in mice infected with ΔsncRNA1 and McKrae viruses were similar, and absence of sncRNA1 did not affect latency or ex-vivo reactivation. However, mice infected with ΔsncRNA1 virus were more susceptible to ocular infection than their WT counterparts. Expression of host immune response genes in corneas and TG of infected mice during primary infection showed reduced IFNβ and IFNγ expression and altered activation of key innate immune pathways, such as the JAK-STAT pathway in ΔsncRNA1 virus compared with parental WT virus.

Conclusions: Our results reveal novel functions for sncRNA1 in up-regulating host immune response and suggest sncRNA1 has a protective role during primary ocular HSV-1 infection.

ABSTRACT BODY:

Purpose: Prior cross-sectional studies have revealed decreased macular perfusion density (PFD) and increased peripapillary capillary PFD in Parkinson's disease (PD). We assess longitudinal rate of change of retinal microvascular and structural parameters in PD vs controls with normal cognition.

Methods: Subjects were imaged using Zeiss Cirrus HD-5000 AngioPlex. Those with confounding medical or ocular comorbidities were excluded and image quality was manually reviewed. Superficial capillary plexus PFD, vessel density (VD), and foveal avascular zone (FAZ) were assessed using ETDRS 6x6 zones (circle, inner ring, outer ring), and 3x3 zones (circle, inner ring). PFD, VD, FAZ, peripapillary retinal nerve fiber layer (RNFL) thickness, ganglion cell-inner plexiform layer (GC-IPL) thickness, and central subfield thickness (CST) were measured at 2 time points roughly 1 year apart. Rate of change was calculated per year and compared between groups using generalized estimating equations.

Results: 74 eyes of 40 patients with PD (60% male, mean age 67.4±7.9 years) & 149 eyes of 78 controls (28% male, mean age 70.3±5.8 years) were included. No demographic differences were observed between groups except a higher proportion of females in controls (p=.001). PD had a greater decline in PFD in the 6x6 circle (mean change per year in PD= –0.021, control=0.00; p=.001), 6x6 inner ring (PD= –0.018, control=0.001; p=.007), 6x6 outer ring (PD= –0.022, control=0.00; p=.001), 3x3 circle (PD= –0.016, control=0.002; p<.001), 3x3 inner ring (PD= –0.016, control=0.002; p<.001). PD had greater decline in VD in the 6x6 circle (mean change per year in PD= –.072/mm, control= –0.054/mm; p=.006), 6x6 inner ring (PD= –0.636/mm, control= –0.048/mm; p=.03), 6x6 outer ring (PD= –0.746/mm, control= –0.054/mm; p=.005), 3x3 circle (PD= –0.939/mm, control=0.006/mm; p<.001), 3x3 inner ring (PD= –0.942/mm, control=0.013/mm; p<.001). PD had greater decrease in GC-IPL thickness (mean change per year in PD= –0.403µm, control=0.128µm; p=.01). There were no significant differences in rate of change in FAZ, CST, RNFL thickness, and no significant differences in rate of change when stratified by PD severity.

Conclusions: PD may be associated with more rapid loss of retinal microvascular perfusion and vessel density, and more rapid thinning of the GC-IPL compared to normal aging in healthy controls with normal cognition.

ABSTRACT BODY:

Purpose: To determine mechanisms underlying neuroprotective effects of the core peptide of a-B crystallin, peptain-1 (P1) conjugated to a cell-permeable peptide CPP (P1-CPP) in retinal ganglion cells (RGCs) in a rodent model of glaucoma and human retinal explants.

Methods: Ex vivo human retinal explants (n=3 donors) were obtained within 12h postmortem and were incubated with 12.5 µg/ml P1-CPP or vehicle for 7 days. Explants were stained with RGC marker, RBPMS, and surviving RGCs were counted using ImageJ. In a separate set of experiments, intraocular pressure (IOP) was elevated in Brown Norway (BN) rats and intravitreally injected with 2 µl of either P1-CPP or vehicle, once a week for a period of 2 weeks. Rats were euthanized, primary adult RGCs were isolated by the immunopanning method. Total RNA was isolated using the Trizol/column method. RNA-sequencing was performed using an Illumina platform. The resulting FASTQ files were uploaded into Galaxy for analysis with FASTQC, RNASTAR, featureCounts, and finally DESeq2. The results from DESeq2 were then assessed with Qiagen's Ingenuity Pathway Analysis (IPA) to identify significantly upregulated pathways.

Results: P1-CPP treatment, at 7 days significantly ($p<0.005$) prevented RGC loss by 35% compared to the vehicle. RNA-seq analysis from rat RGCs isolated following 2 weeks of IOP-elevation revealed that P1-CPP treated groups had several differentially expressed (DEGs), compared to vehicle-treated groups, including 6343 significantly upregulated and 5960 significantly downregulated. Some significantly upregulated pathways following P1-CPP treatment include phagosome formation, synaptic long-term depression, and CREB signaling in neurons. The IOP and vehicle-treated groups, when compared to the naïve group, demonstrated a decreased expression of members of the CREB signaling pathway (Creb-1, c-RAF, MEK1/2, ERK1/2, and p90RSK). This decline was prevented by P1-CPP treatment. Quantitative PCR further confirmed the RNA-seq findings of the increased expression of Creb-1 in P1-CPP treated rats compared to that of vehicle-treated group.

Conclusions: P1-CPP was neuroprotective against neurotrophic factor deprivation-mediated RGC loss in human retinal explants. Mechanism of action of P1-CPP in a rodent model of glaucoma includes the activation of the pro-survival CREB signaling pathway, phagosome formation, and long-term synaptic depression to prevent cell death and vision loss.

ABSTRACT BODY:

Purpose: Usher Syndrome (USH) is an inherited disorder characterized by hearing loss, vestibular dysfunction, and visual impairments. Most of the identified gene loci do not account for all known USH cases. The role of Myosins have been implicated in the pathophysiology of USH. Interestingly, mutations in the motor protein, Myosin 1C (MYO1C) are associated with deafness. We developed a Myo1c-knockout mouse line to investigate a functional role for MYO1C in retinal cell physiology and to confirm its role in hearing.

Methods: Whole-body Myosin 1C knockout (Myo1c-KO) mice were generated and visual function tests using electroretinogram (ERG) and Auditory Brain Response (ABR) tests for hearing were performed on wild-type (WT) and Myo1c-KO animals, at 2-6 months of age. Immunofluorescence and trafficking analysis of key photoreceptor outer segment (OS) proteins were performed on retinal sections from both genotypes. Histology and electron microscopy (TEM) analysis were performed to determine photoreceptor cell structure and to quantify retinal cell layer thickness. Co-immunoprecipitation and reciprocal IP assays were performed to access direct binding of MYO1C to retinal proteins.

Results: Systemic loss of MYO1C in mice specifically affected rhodopsin trafficking, where rhodopsin mislocalized to the rod photoreceptor inner segments and cell bodies, while trafficking of other OS proteins (CNGA1, Arrestin, and Transducin) were largely un-affected. ERG analysis of Myo1c-KO mice showed a progressive loss of visual function. OCT analysis showed thinner photoreceptor cell layer and a reduction of outer nuclear layer thickness, while histological and TEM analysis confirmed shorter photoreceptor OS lengths in Myo1c-KO animals, at the 6-months' time point. ABR thresholds were significantly decreased in Myo1c-KO vs. WT animals, at 6-months of age, indicating that these mice also suffer from deafness.

Conclusions: We have identified a physiological role for the motor protein, Myosin 1C (MYO1C), in the pathophysiology of Usher Syndrome. Our novel Myo1c knockout mouse model mimicked BOTH the visual dysfunction and hearing loss phenotypes observed in Usher Syndrome patients. The study specifically identified rhodopsin as a cargo of MYO1C. The ongoing goals are to identify the precise molecular mechanisms of visual dysfunction and hearing loss in Myo1c-KO animals and to screen for MYO1C variants in patients with syndromic RP and Usher Syndrome.

ABSTRACT BODY:

Purpose: It is well known that best-corrected visual acuity (BCVA) practically does not change during accommodation. Thus, it should be possible to measure BCVA by situating an appropriately scaled test within the subject's interval of clear vision. This can be achieved by means of a mobile device placed at a handheld distance. In an effort to address the need for an accurate tool for the measurement of BCVA, the purpose of the present study was to clinically validate BCVA measures obtained with VisionApp by comparing them to the gold standard.

Methods: BCVA was measured in n=48 eyes using VisionApp installed in four electronic devices. The app displayed a Landolt C optotype and utilized a 4-force choice procedure loosely based on the FrACT (Freiburg Visual Acuity & Contrast Test). The angular size of the optotype was automatically scaled as a function of the face-to-screen distance, which was continuously measured by means of the front camera. Results were compared to clinical BCVA measurements taken using a standard ETDRS chart placed at 10 feet (3 m). To assess the similarity of measurement methods, a statistical analysis was performed based on a two-tailed, paired t-test.

Results: The t-test revealed no significant difference in measured VA ($p = 0.415$), with a mean difference between clinical and app measurements of less than one letter (0.005 logMAR). The Bland-Altman analysis showed that the mean difference between measurement methods was 0.05 LogMAR (95% CI), with a standard deviation of 0.153.

Conclusions: The high agreement in measurements of BCVA between the app and the gold standard facilitates home monitoring for adult patients providing ophthalmologists with a reliable and accessible method to communicate BCVA results remotely between providers and patients. Further studies are needed to validate the results in children.

ABSTRACT BODY:

Purpose: Choroidal abnormalities (CAs) have recently been introduced as new clinical criteria for the diagnosis of neurofibromatosis type 1 (NF1).The purpose of this study was to assess the long term natural history of CAs in a large pediatric NF1 population, quantifying their progression in number and dimensions.

Methods: Pediatric patients (<16 years old) affected by NF1 with a minimum follow-up of 3 years with at least one CA in one eye were consecutively recruited. Near-infrared (NIR) imaging was performed to identify CAs, which were quantified in number and size using the open-source ImageJ software (National Institutes of Health, Bethesda, Maryland, USA)(Fig 1). CAs area and perimeter were normalized for the optic disc dimensions, to avoid possible bias related to the growing process of the eye.

Results: This study enrolled 99 eyes of 53 patients (31 males and 22 females), with a mean age of 7.1 ± 3.8 years old. All 99 eyes were examined at baseline and at least at 3-years follow-up (T3); 1-year follow-up (T1) was available for 80 eyes, 5-years follow-up (T5) for 59 eyes and 7-years follow-up (T7) for 36 eyes. Mean number of CAs increased from baseline (3.6 ± 3.2) to different follow-up visits (4.6 ± 3.5 at T1, 6.4 ± 4.1 at T3, 8.1 ± 4.8 at T5 and 9.6 ± 5.3 at T7), with a statistically significant trend ($p<0.0001$), and an estimated growth rate of 0.82 CAs per year, adjusted for age and for CAs number at baseline ($p<0.0001$). CAs area and perimeter also significantly increased during follow-up ($p<0.0001$ for each parameter). Patient age at baseline was inversely correlated with CAs number along time (coefficient=-0.1313, $p=0.0068$), while no correlation was found between patient age and CAs progression in size.

Conclusions: In NF1 pediatric patients CAs increased both in number and dimensions, independently from the physiological growth of the eye. While the increase of CAs number occurs particularly at an earlier age, the increase in CAs dimensions is a slow process that remains constant during childhood.

ABSTRACT BODY:

Purpose: SCLT1 gene has been reported in the pathogenesis of oral-facial-digital syndrome, Senior-Loken syndrome and Bardet-Biedl syndrome. SCLT1 encodes a linker protein associated with the sodium voltage-gated channel alpha subunit 10 and clathrin, and was identified as one of the component proteins involved in ciliogenesis. Only few patients with SCLT1-related rod-cone dystrophy have been reported. Here, we present two siblings with cone dystrophy and some features resembling ciliopathy.

Methods: Comprehensive eye exam was performed together with fundus images, fundus autofluorescence (FAF), optical coherence tomography (OCT), color vision test, visual fields, full-field electroretinography (ffERG) and multifocal ERG. The patients were assessed for ciliopathy features including echocardiography, ultrasonography of abdomen, and blood tests for liver and kidney function, and glucose levels. Genetic testing (NGS retinal dystrophy panel, 285 genes) was performed for probands and parental testing of SCLT1 variants.

Results: Two male children, age 10 and 8 years, were affected with ADHD and well-controlled obesity. Abnormalities of the heart, liver or kidneys, and postaxial polydactyly were not present. Children had mild light sensitivity and esotropia. Cycloplegic refraction revealed moderate hyperopia and significant astigmatism. BCVA was reduced (0.4 right eye/0.5 left eye logMAR in older patient; 0.3 logMAR both eyes in younger one) and moderate red-green color vision defects were noticed. Fundus exam was largely normal. FAF revealed decreased foveal FAF surrounded by increased FAF signal. OCT macula showed retinal thinning. Central visual field defects were observed. Further ffERG confirmed cone dystrophy. Ciliopathy was suggested as a possible diagnosis. Retinal dystrophy panel showed homozygous likely pathogenic, splice-site variant in SCLT1 gene NM_144643.3: c.1439+1del. This variant was not reported in ClinVar or gnomAD, and was heterozygous in the healthy parents.

Conclusions: In this report, we highlight the importance of extensive diagnostics in patients with unexplained reduced vision, strabismus, refractive errors and autism/ADHD spectrum disorders. Ciliopathies may present with milder systemic and ocular phenotype and thereby can be underdiagnosed. SCLT1-related retinal degeneration is rare and cone dystrophy was not observed until now.

TITLE: Anti-ceramide immunotherapy for diabetic retinopathy

SESSION TITLE: Lipid signaling and homeostasis in retinal health and disease

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: T.F. Dorweiler, P. Nolan, J.V. Busik, Physiology, Michigan State University, East Lansing, Michigan, UNITED STATES|R.N. Kolesnick, Department of Molecular Pharmacology, Memorial Sloan Kettering Cancer Center, New York, New York, UNITED STATES|

Commercial Relationships Disclosure: Tim Dorweiler: Commercial Relationship: Code N (No Commercial Relationship) | Peter Nolan: Commercial Relationship: Code N (No Commercial Relationship) | Richard Kolesnick: Commercial Relationship(s);Code O (Owner):Ceramedix | Julia Busik: Commercial Relationship(s);Code C (Consultant/Contractor):Ceramedix

ABSTRACT BODY:

Purpose: Previous work highlights the detrimental effects of increased ceramide generation in diabetic retinopathy (DR) progression. We have shown that ASM mediated ceramide generation leads to chronic low-grade inflammation in various cell types such as endothelial cells. We hypothesize that underlying mechanism is based on the formation of pro-inflammatory ceramide rich platforms (CRP). The focus of this project is to address the novel concept of functional and highly-specific ceramide inhibition using cutting edge anti-ceramide immunotherapy to prevent early onset diabetes induced pro-inflammatory and pro-apoptotic changes in the retinal vasculature.

Methods: Ischemia reperfusion (I/R) studies were utilized to mimic acute vascular degeneration in mice as observed in DR. Streptozotocin was utilized to induce hyperglycemia-induced vascular degeneration as a type-1 diabetes model. Anti-ceramide single chain variable fragment (scFv) treatment was administered via a 2 ug single dose into the vitreous. Pro-inflammatory markers (IL-1β, VEGF and ICAM-1) as well as ASM expression levels were analyzed via qRT-PCR. Ceramide species were analyzed via lipidomics (nESI-MS/MS). Vascular degeneration was captured using FITC-albumin technique and confocal microcopy and quantified using MetaMorph software.

Results: In vivo I/R studies in $asm^{+/+}$ and $asm^{-/-}$ mice identified significant upregulation of ASM, C16 and C18 ceramide production, as well as IL-1β, VEGF and ICAM-1 gene expression in $asm^{+/+}$ but not in $asm^{-/-}$ mice (n=6 per group; $p<0.05$). To determine feasibility of anti-ceramide immunotherapy, intravitreal injection of anti-ceramide scFv was first performed in the mouse I/R model. We found significant upregulation of IL-1β, VEGF and ICAM-1 gene expression in WT untreated retinas injured by I/R. These pro-inflammatory changes were inhibited by a single injection of anti-ceramide scFv 12 hours prior to I/R injury (n=6-8 per group; $p<0.05$). Impact of intravitreal injection of scFv was next tested in STZ-induced Wistar rat diabetes model. A single injection of scFv at the onset of hyperglycemia prevented diabetes-induced increase in retinal vascular permeability (n=3-10 per group; $p=0.08$).

Conclusions: These results suggest that anti-ceramide scFv immunotherapy may represent a novel approach to targeting deleterious ceramide-rich platform mediated pro-inflammatory and pro-apoptotic changes prevalent in the early stages of vasculopathy in the diabetic retina.

TITLE: Dynamic OFF stimulation reduces perceived saturation of red color, similarly in myopes and emmetropes

SESSION TITLE: Myopia: Structure-Function Relationship

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: F. Schaeffel, B. Swiatczak, Myopia Research Group, Institute of Molecular and Clinical Ophthalmology Basel, Basel, SWITZERLAND|F. Schaeffel, Section Neurobiology of the Eye, Ophthalmic Research Institute University of Tuebingen, Tuebingen, GERMANY|

Commercial Relationships Disclosure: Frank Schaeffel: Commercial Relationship: Code N (No Commercial Relationship) | Barbara Swiatczak: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: It has previously been shown that predominant activation of OFF pathways in the retina induces choroidal thinning and transient axial eye elongation, while stimulation of ON pathways can thicken the choroid. Because the balance between ON and OFF input strength has been linked to refractive error development, we developed a novel psychophysical procedure to quantify ON vs. OFF input strength in emmetropes and myopes.

Methods: Sixteen young healthy subjects (7 males, average age: 28±3 years, average refraction: -1.0±1.9D, range: +1.6 to -5.5D) were asked to match the saturation of a red bar presented on the computer screen with the perceived saturation of red squares (RGB(255,0,0) that randomly appeared inside a dynamic ON or OFF stimulus field (Figure 1A). The field consisted of 1400 grey squares with saw–tooth shaped temporal luminance profiles that could be reversed by the user. Cycle repetition frequency was 7.5 Hz. Temporal profiles in each field were randomly phase shifted with respect to each other. Each stimulus (ON or OFF) was repeated four times in each subject in random order. Subjects were blinded regarding the type of stimulation.

Results: Dynamic OFF stimulation severely reduced perceived saturation of the red squares in 13 out of 16 subjects. They appeared darker and pale. In contrast, red squares appeared fully saturated with dynamic ON stimulation (ON: matched red pixel values 202±20; OFF: 154±11, $p<0.001$). Three subjects (2 emmetropes and 1 myope) did not perceive changes in red saturation between ON and OFF (gray bars, Figure 1B, left). However, no trend was observed that OFF stimulation was more effective in myopes than in emmetropes (Figure 1B, right).

Conclusions: Perceived saturation of small red squares in a field with dynamic OFF stimuli was considerably reduced, suggesting an interaction of chromatic pathways and OFF pathways. The effect was not dependent on refractive error, suggesting that ON and OFF pathways are not affected in myopic subjects. This is in line with previous findings showing that the choroid in emmetropic and myopic eyes responds similarly to reading of text with normal and inverted contrast.

ABSTRACT BODY:
Purpose: Corneal biomechanical properties are inherently tied to its shape and function but noncontact measurements of corneal biomechanical properties can be difficult due to physiological motion. In this work, we developed and tested an ultra-fast line-field optical coherence elastography (LFOCE) system capable of single-shot measurements of wave propagation in the cornea.
Methods: We developed a parallel line-field spectral domain optical coherence tomography system based on a supercontinuum laser (EXR-9 OCT, NKT Photonics) and a line-field Michelson interferometer. The spectral interference was imaged onto a high speed 2D camera (Phantom v2512, Vision Research). An air-pulse induced elastic waves, which were imaged by the LFOCE system. Figure 1 is a schematic of the system. The equivalent A-scan rate was 11.5 MHz based on 460 spatial pixels with a framerate of 25 kHz.
Validation measurements with LFOCE and uniaxial mechanical testing were made in tissue-mimicking gelatin phantoms (8%, 10%, and 12% w/w, N=3 of each type). Measurements were made in in situ and in vivo rabbit corneas. In vivo measurements were made in an anesthetized rabbit, and all procedures were approved by the University of Houston Institutional Animal Care and Use Committee.
Results: The LFOCE-measured elasticity of the 8%, 10%, and 12% phantoms was 13.8 ± 1.5 kPa, 21.4 ± 2.8 kPa, and 32.5 ± 3.1 kPa, respectively. Mechanical testing measured the stiffness of the 8%, 10%, and 12% phantoms as 15.6 ± 1.8 kPa, 23.7± 2.1 kPa, and 36.1 ± 1.6 kPa, respectively. Figure 2 shows the elastic wave propagation in the in situ rabbit cornea at 10 mmHg IOP at the noted times after excitation. The average wave speed of 3 repeated measurements in the in situ cornea at 10, 15, and 20 mmHg IOP was 3.03 ± 0.05 m/s, 4.66 ± 0.03 m/s, and 8.85 ± 0.08 m/s, respectively. In the in vivo rabbit cornea, the wave speed was 11.10 ± 0.32 m/s.
Conclusions: The LFOCE system was capable of imaging the wave propagation in the cornea successfully in a single shot. Future work will focus on improving the system sensitivity, incorporating a scanner for 3D imaging, and reducing the spectral band imaged by the camera to adhere to safety limits.

SUBMITTER (NAME ONLY): Conor Delaney

TITLE: Transcriptional landscapes of the retina and RPE/choroid in the Cldn5-inducible model of retinal degeneration

SESSION TITLE: Pathobiology of AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Delaney, N. Hudson, A. Reddy, K. Byrne, M. Campbell, The University of Dublin Trinity College, Dublin, IRELAND|

Commercial Relationships Disclosure: Conor Delaney: Commercial Relationship: Code N (No Commercial Relationship) | Natalie Hudson: Commercial Relationship: Code N (No Commercial Relationship) | Avril Reddy: Commercial Relationship: Code N (No Commercial Relationship) | Kieva Byrne: Commercial Relationship: Code N (No Commercial Relationship) | Matthew Campbell: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: This study aimed to examine transcriptional changes with progression of age-related macular degeneration (AMD)-like phenotypes in a novel mouse model of retinal degeneration, examining the retinal and retinal pigment epithelium(RPE)/choroid transcriptomes.

Methods: Inducible Cldn5 downregulation mice were fed a specialized high cholesterol diet (HCD) and retinas imaged using optical coherence tomography and fundus fluorescein angiography to monitor pathology progression. Control groups consisted of animals on normal diet and Cre-negative mice on HCD. Two bulk RNA-seq datasets were generated using mRNA isolated from retina and RPE/choroid, and sequenced using the Illumina NextSeq550 platform.

Results: RNA-seq analyses revealed distinct pathological processes occurring in the retina and RPE/choroid. Within the retina, 398 genes were identified to have significant expression changes unique to the pathology cohort. Pathway analyses revealed significant decreases in lens structural and extracellular matrix (ECM) gene expression networks, accompanied by upregulation of wound healing and cell motility pathways. The apical cell junction and cell leading edge were identified as GO cellular compartments enriched for increased gene expression.

A total of 661 genes displayed significantly altered expression in the RPE/choroid. In contrast to the structural and extracellular changes of the retina, decreased immune activation, angiogenesis and signalling receptor activity were observed. Gene networks governing neurotransmission increased, particularly those regulating ion channels. The synaptic membrane and external plasma membrane were identified as GO cellular compartments enriched and depleted respectively within the cohort.

Conclusions: The etiology of retinal degeneration in AMD has yet to be fully elucidated, and we have previously proposed inner-retinal vasculature dysfunction as an initiator of early AMD progression. Here we demonstrate unique responses of the retina and RPE/choroid to endothelial Cldn5 downregulation and HCD. Loss of ECM integrity and changes in cell localization may represent actions of infiltrating leukocytes driving wound healing pathways within the retina. This immune response is absent from RPE/choroid. Understanding molecular changes unique to each compartment of the eye will be essential for targeting therapeutic intervention for retinal degeneration and AMD.

ABSTRACT BODY:

Purpose: The 13-lined ground squirrel (13-LGS), a cone-dominant hibernator, has emerged as an accessible animal model for vision research. Induction of cone degeneration through exposure to cytotoxic chemicals has revealed variable effectiveness in the 13-LGS. Here, we sought to examine how the time of year (relative to hibernation emergence) influenced the degree of cone damage in 13-LGS following intravitreal injection of adenosine triphosphate (ATP).

Methods: Eighteen (9M,9F) 13-LGS were placed into three active season experimental groups, early-season (N=6), mid-season (N=6), and late-season (N=6), to determine the time of intravitreal ATP injection. Each animal underwent baseline imaging OU using near-infrared reflectance and short wavelength autofluorescence scanning light ophthalmoscopy (SLO) as well as optical coherence tomography (OCT). Animals then received a 10µL intravitreal injection of 0.723M ATP in one eye, followed by OCT and SLO imaging at 1, 3, 10, and 21 days post-injection. Among mid-season and late-season animals where no retinal damage was observed in follow-up imaging, adaptive optics SLO (AOSLO) was performed. Retinal thickness and cone density measures from the late-season cohort were compared to values from a control group of wild-type animals (N=12 eyes, OCT; N=6 eyes, AOSLO).

Results: Five animals showed retinal damage following ATP injection, including 4/6 early-season, 0/6 mid-season, & 1/6 late-season (Fisher’s exact test, p= 0.065). A two-way ANOVA showed significant differences in axial length between early-season & mid/late season cohorts (p = 0.029; p = 0.035). All animals with retinal damage displayed lesions on SLO and disrupted retinal lamination on OCT. Follow-up imaging with AOSLO on mid-season and late-season animals without observed retinal damage showed no evidence of photoreceptor disruption at any of the 97 ROIs analyzed. In late-season animals, 518 of 528 eccentricity matched locations imaged by OCT were within the normative range (mean +/- 2SD) from the control group, consistent with no ATP-induced damage.

Conclusions: The 13-LGS retina may be more susceptible to retinal damage by intravitreal ATP injection during the early season. However, differences in both axial length and vitreous volume between groups may impact the effective dose. Future studies adjusting dose based on ocular biometry may help elucidate the impact of time of year on chemical response.

ABSTRACT BODY:

Purpose: Achromatopsia (ACHM) is an autosomal recessive disease that results in reduced or absent cone function. There is controversy regarding the extent to which cone structure shows progressive degeneration in ACHM. Here we performed a retrospective review of optical coherence tomography (OCT) images to evaluate cone structure over time in patients with genetically confirmed ACHM.

Methods: Sixty-three patients with ACHM (due to CNGA3, CNGB3, or ATF6 mutations) with Bioptigen or Cirrus OCT images from multiple time points stored in the Advanced Ocular Imaging Program Bank were included. Integrity of the ellipsoid zone (EZ) was assessed twice by a single grader (GG) in a masked fashion using the grading scale from Sundaram et al (2014).[1] Images with disparate grades between the two assessments were finalized by a second grader (JC).

Results: A total of 457 OCT images were processed and graded, 236 OD and 221 OS. The baseline distribution of EZ grades was highly symmetrical between eyes (OD: I=8, II=33, III=2, IV=17, V=3; OS: I=8, II=32, III=2, IV=17, V=2). The average patient age was 23.01 years at the first visit and 25.99 at the last visit, with an average time between visits of 2.88 years for OD images and 2.56 years for OS images (range from 5 months to 10 years). A total of five eyes showed change in EZ grade (OD: n=3, OS: n=2) across follow-up from a grade II (EZ disruption) to grade IV (hyporeflective zone). These eyes belonged to three individuals (aged 24, 29, & 35 years), representing 4.76% of the total study group. The remaining 60 subjects, 95.24% of the total study group, retained the same EZ grade throughout the follow-up period.

Conclusions: ACHM appears to be a generally stable condition, at least over the follow-up period assessed here. Even with stable EZ appearance there may be other factors that impact the therapeutic potential of a given ACHM retina, which may change/progress over time.

ABSTRACT BODY:

Purpose: To examine the effect of hypomorphic alleles in the tyrosinase gene (TYR) on best corrected visual acuity (BCVA) in patients with albinism.

Methods: We retrospectively analyzed BCVA and genetic data from 75 individuals with suspected albinism. We did not include individuals with a history of premature birth or retinal pathology, or those who had mutations in multiple albinism genes. Patients were organized by albinism subtype and number of mutations. For individuals with OCA1, 16 had a single pathogenic TYR mutation, while 25 had two or more pathogenic TYR mutations. For individuals with OCA2, 10 had a single pathogenic mutation and 17 had two pathogenic mutations. Seven individuals had OA1 caused by hemizygous mutations in GPR143. For each albinism subtype, we further grouped individuals based on the number of TYR hypomorphic alleles that were identified. One-way ANOVA and Tukey's multiple comparisons tests were performed to assess the difference in BCVA within groups.

Results: For patients with OCA1 who had two or more pathogenic mutations, we observed a significant difference in BCVA between the TYR hypomorphic allele groups (p=0.0013). Post hoc testing revealed significant differences between patients with zero versus two hypomorphic alleles (p=0.04) and one versus two hypomorphic alleles (p=0.001). For subjects with OCA1 who had one pathogenic mutation, there was no significant difference in BCVA between the TYR hypomorphic allele groups (p=0.56). For subjects with OCA2 who had either one or two pathogenic mutations, there was no significant difference in BCVA between the TYR hypomorphic allele groups (p=0.96 and p=0.22, respectively). For subjects with OA1, there was no significant difference in BCVA between the TYR hypomorphic allele groups (p=0.67).

Conclusions: In patients with OCA1 with two or more pathogenic mutations, the presence of hypomorphic alleles in TYR is associated with worse visual acuity, which could be due to further reduced tyrosinase function. While TYR hypomorphic alleles have been shown to alter foveal structure in individuals with normal vision,[1] it remains to be seen if the hypomorphic allele-related changes in visual acuity described here are also associated with changes in foveal structure in albinism.

ABSTRACT BODY:

Purpose: To assess the survival of transplanted human induced pluripotent stem cell (hiPSC)-derived photoreceptors in the cone dominant 13-lined ground squirrel (13-LGS; Ictidomys tridecemlineatus).

Methods: Cone-rich 3D-retinal organoids were differentiated from hiPSC with GFP knocked in at the AAVS1 safe harbor locus. 13-LGS retinas were degenerated via experimental retinal detachment (RD, n=18) or by intravitreal chemical injection of either adenosine triphosphate (ATP, n=16) or tunicamycin (Tm, n=6). 13-LGS were immunosuppressed using cyclosporine A for 14 days. Organoids were dissociated with papain and cell viability was assessed by flow cytometry. Cells were transplanted into the subretinal space of all eyes ($0.7\text{-}1.4\text{x}10^6$ cells/eye) at least two weeks post-damage. To track survival of transplanted cells, eyes were imaged in vivo immediately post-transplantation and at 1 week, and 1-,2-,3-, and 4-months later, using SLO, OCT, and AOSLO. AOSLO images were acquired at 3-mo to capture high resolution images of the cell patches. After the 4-mo imaging time point, retinas were analyzed by immunohistochemistry (IHC) with marker antibodies to GFP (reporter), Otx2 (photoreceptor), and HuNu and LMNB2 (human-specific).

Results: Cell viability using flow cytometry was 61.2%-93.5%. Locations of transplanted cells were observed with OCT, and initial transplantation was deemed successful when cells were deposited and retained subretinally. 15 of 40 transplants failed for technical reasons: reflux of cells into the vitreous space (ATP, RD; n=3); degeneration of GFP signal over time (ATP, RD; n=7); and hemorrhage that obstructed imaging (Tm; n=5). GFP signal was detected with SLO at all time points post-transplantation in 25 of 40 eyes (ATP, n=11; Tm, n=1; RD, n=13), demonstrating survival of transplanted cells. AOSLO showed clumps of transplanted cells settled above the surviving cones of the host retina. IHC confirmed the expression of GFP, Otx2, HuNu, and LMNB2 in the transplanted cells. Integration of cells in RD retinas was restricted to the outer retina/subretinal space, whereas chemically degenerated retinas exhibited additional signal integration into the inner retina.

Conclusions: hiPSC-derived photoreceptors survived in the outer retina of 13-LGS eyes for up to 4-mo post-transplantation. Further studies are needed to examine the functional properties of these cells.

ABSTRACT BODY:

Purpose: To characterize retinal phenotypes in elderly thirteen-lined ground squirrel (13-LGS) eyes.

Methods: Eleven (2M, 9F) elderly 13-LGS (> 5 years old) were included. OCT imaging was used to assess anterior segment structure (22 eyes) and retinal morphology (20 eyes). NIR reflectance and SW-AF imaging were used to assess retinal and RPE health (22 eyes). Adaptive optics scanning light ophthalmoscopy (AOSLO) images were used to examine the cone mosaic (8 eyes). Retinal thickness and cone density measurements of elderly animals were compared to a control group of 1 year old animals (n=12 eyes, OCT; n=6 eyes, AOSLO).

Results: NIR images showed abnormal expansion of the hyperreflective optic nerve head (ONH) signal, with a concomitant hypofluorescent signal on SW-AF images in 14 eyes. Hypofluorescent puncta were observed on SW-AF images in 10 eyes. Anterior segment OCT revealed lens opacifications in 19/22 eyes, obviating AOSLO imaging of 2 animals and precluding AOSLO analysis for 1 other animal. Posterior chamber OCT showed numerous abnormal phenotypes including hyperreflective vitreous laminations (20/20 eyes), hyperreflective inner retinal puncta (6/20 eyes), and a hyporeflective outer retinal cavity (1 eye). Disrupted outer retinal lamination adjacent to the optic nerve head (ONH) was observed in 17/20 eyes. Retinal and choroidal thickness values were within normative ranges for 5/20 eyes - the remaining 15 eyes had at least one retinal location with altered thickness of at least one layer, with 54% of the outliers being associated with disrupted retinal lamination within 5° of the ONH (Fig. 1). AOSLO images from 2 eyes showed a loss of discernable structure within 2.5° inferior of the ONH. The cone mosaic was otherwise normal, appearing contiguous with 91% of locations having density values within the normative range (Fig 2).

Conclusions: Elderly 13-LGS have abnormal lamination surrounding the optic nerve head and variable differences in retinal thickness when compared to young adult 13-LGS controls. In addition, the anterior segment findings can impose challenges with high quality imaging in all animals. It will be important to control for age in cross-sectional studies of 13-LGS retinal structure.

ABSTRACT BODY:

Purpose: Galectin-3 has been associated with many proinflammatory functions by triggering the migration of monocytes; nevertheless, the mechanism underlying this process has not been fully established. Monocyte recruitment is initiated by multiple adhesive interactions between vascular selectins and the sialyl Lewis^X (sLe^X) glycan on circulating monocytes. Here, we investigated whether galectin-3 regulates the expression of sLe^X in activated monocytes and, therefore, their recruitment following injury.

Methods: Human monocytes were purified from the blood of healthy donors. Mouse monocytes were purified from the bone marrow of galectin-3 knockout (Gal3$^{-/-}$) and wild-type (WT) mice. Galectin-3 expression and binding in human monocytes were inhibited using galectin-3 siRNA (siGal3) and the thiodigalactoside analog TD139, respectively. Competitive migration assays were carried out in immunocompromised WT chimera by intravenous injection with fluorescently labeled WT and Gal3$^{-/-}$ monocytes. The glycogene expression profile of mouse monocytes was evaluated using real-time PCR array. Parallel plate flow chamber assays were performed on vascular endothelial cells using galectin-3 deficient monocytes glycoengineered to express human FUT7.

Results: Inhibition of galectin-3 expression or binding in activated human and murine monocytes led to impaired biosynthesis of sLe^X. Conversely, the addition of human recombinant galectin-3 led to increased levels of sLe^X. Injured corneas of Gal3$^{-/-}$ mice displayed lower numbers of CD45$^+$ CD11b$^+$ sLe^X cells compared to WT mice. Deficiency in sLe^X expression was concomitant with impaired recruitment of Gal3$^{-/-}$ monocytes into wounded corneas of WT chimeric mice. Using a PCR array, we found that galectin-3 regulates the biosynthesis of sLe^X on activated monocytes by inducing the expression of FUT7. Enforced fucosylation of human galectin-3 deficient monocytes resulted in augmented rolling capability on activated endothelial cells under flow conditions in vitro.

Conclusions: Overall, these data demonstrate a novel mechanism by which galectin-3 positively regulates the recruitment of monocytes into inflamed tissues by inducing the expression of FUT7.

ABSTRACT BODY:

Purpose: Dry-eye disease (DED) is a chronic progressive ocular surface disorder that has been extensively investigated in the adult population, but in the pediatric population, DED prevalence and its characteristics remains largely unstudied. It is a significant healthcare problem which impairs visual functioning and can severely affect patients' quality of life at any age. The American Academy of Ophthalmology IRIS® Registry (Intelligent Research in Sight) was used to investigate differences in demographics and prevalence of DED between pediatric and adult patients.

Methods: A total of 4,795,979 patients with at least one diagnosis of DED between 2013-2019 was identified by ICD code in the IRIS Registry. Of these, 203,171 were pediatric patients, defined as patients under the age of 18 (PDED) at the time of initial diagnosis, while 4,592,808 were adults, defined as patients aged 18 or older (ADED). The earliest-recorded diagnosis of DED for each patient was included, and demographics that were investigated included biological sex, race, ethnicity, and U.S. geographical region. Descriptive statistics, Pearson's chi-squared tests, and two-sample proportions tests were conducted to compare key demographic distributions between the ADED and PDED cohorts.

Results: Demographic characteristics were compared between the ADED and PDED groups. The average age at onset for ADED patients was 61.06 (±14.75) years, while the average age at onset for PDED patients was 12.51 (±3.86) years. Characteristics with the largest discrepancies between ADED and PDED patients included female sex (68.12% vs. 58.08%), male sex (31.55% vs. 41.58%), White race (67.06% vs. 50.24%), Hispanic/Latino ethnicity (9.03% vs. 17.04%), and Northeast region residency (21.04% vs. 32.20%), respectively. Comparisons of each category within each demographic between ADED and PDED patients were statistically significant (all $p<0.01$), with the exception of unreported sex ($p=0.48$).

Conclusions: Our results characterize significant differences within major demographic factors between pediatric DED patients and adult DED patients in the IRIS Registry. There was a significantly higher proportion of females and Whites in adults with DED as compared to pediatric patients with DED, and a significantly lower proportion of Hispanic/Latino individuals and Northeast region-dwelling individuals in adults with DED as compared to pediatric patients with DED.

TITLE: Effects of glycemic control on anti-VEGF regimens in the management of diabetic retinopathy

SESSION TITLE: Diabetic Retinopathy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Chang, R.A. Adelman, Yale University School of Medicine, New Haven, Connecticut, UNITED STATES|

Commercial Relationships Disclosure: Thomas Chang: Commercial Relationship: Code N (No Commercial Relationship) | Ron Adelman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To study whether patients with diabetic retinopathy (DR) who have lower mean hemoglobin A1c levels had either a decrease of total anti-VEGF intravitreal injections, or an increase in interval between injections.

Methods: Retrospective chart review of DR patients at the Yale Eye Center including Hb A1c values, the number of anti-VEGF injections, and the intervals between anti-VEGF injections. Inclusion criteria were adults with DR who received anti-VEGF injections and regular A1c tests. Exclusion criteria were other retinal pathologies, inconsistent follow-up, or deferment of anti-VEGF treatment. Patients were divided up into two groups, those with anti-VEGF treatment and those with both anti-VEGF and panretinal photocoagulation (PRP) therapy. These two groups were further divided with mean A1c either > or < 7%, and into A1c tertiles. Welch's t-test was performed.

Results: In patients who received only anti-VEGF treatment (n=60), there was a significant difference in the number of injections (p=0.006) between the middle (7.7 inj.) and top (3 inj.) tertiles of average A1c. There was also a difference (p=0.024) in interval between the bottom (1.3 months) and middle (1.8 months) tertiles of A1c. There was no statistically significant differences in either mean number of injections or mean interval between injections when comparing groups with mean A1c<7 and >7. In the group who received anti-VEGF and PRP (n=79), there were no significant differences in mean number of injections or mean interval between injections in groups with A1c<7 and >7 or when comparing tertiles.

Conclusions: Individuals with average A1c below 7 did not have a decrease in number of anti-VEGF injections when compared with those with A1c>7. Surprisingly, in some cases the higher tertiles of A1c were found to have a lower mean of injections, as well as increased time between injections. One possible explanation is that those with poor glycemic control may refuse treatment and are less likely to follow up with care regularly.

ABSTRACT BODY:

Purpose: The appearance of cone photoreceptors in confocal adaptive optics scanning light ophthalmoscope (AOSLO) images is highly variable, which can present challenges for cone detection algorithms. We sought to develop a method to induce intra-video variability in cone reflectance whereby processed images would have less intercell variability in cone reflectance.

Methods: Six individuals with no known eye disease were recruited. One eye from each individual was imaged nine times in a single session with a confocal AOSLO (772±13nm source). Six videos had a 3-second 30Hz stimulus presented halfway through acquisition (three using 450nm light and three using 550nm light), and three videos were acquired with no stimulus. Videos were collected in a randomized order. Videos were then trimmed into two separate videos: frames from the first half of the video and frames from the second half of the video (i.e., before and after the stimulus presentation). These trimmed videos were processed, averaged, and co-aligned for analysis. Cone coordinates identified using a semi-automated program and cone reflectance values were extracted. The change in cone reflectance between before and after stimulus presentation was calculated for each stimulus condition.

Results: With no stimulus, cones changed reflectivity by an average of 20.4% (range:12.8-30.1%). Greater changes in reflectivity were observed for the 450nm stimulus (average=25.9, range:14.4-45.4%) and for the 550nm stimulus (average=28.4%, range:17.7-45.8%). Of the 36 total stimulus videos, 27 (75%) had a greater average change in reflectivity than the no stimulus condition. Standard deviation (SD) of the percent difference for individual cones was also greater for the stimulus conditions: 450nm average SD = 18.3% (range:12.0-24.1%), 550nm average SD = 20.1% (range:15.6-25.1%), no stimulus average SD = 15.9% (range:10.9-19.4%). Of the 36 total stimulus videos, 28 (78%) had a greater SD across cone reflectivity changes than observed for the no stimulus condition.

Conclusions: The presentation of a stimulus during AOSLO imaging increases the amount of change in reflectance of individual cones over the course of a single video. Leveraging this variable cone reflectance across an AOSLO stimulus video may result in processed images with more uniform cone appearance and thus easier detection of cones by either automated algorithms or manual graders.

TITLE: Prevalence of Refractive Error in Inherited Retinal Dystrophies

SESSION TITLE: Inherited Retinal Disease Genetics II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Yassin, E. Walker, S. Borooah, Ophthalmology, University of California at San Diego Department of Ophthalmology at the Shiley Eye Institute, La Jolla, California, UNITED STATES|

Commercial Relationships Disclosure: Shaden Yassin: Commercial Relationship: Code N (No Commercial Relationship) | Evan Walker: Commercial Relationship: Code N (No Commercial Relationship) | Shyamanga Borooah: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Ametropia has been associated with Inherited Retinal Dystrophies (IRDs). However, the prevalence of ametropia in IRDs and its genetic associations is poorly studied. We aim to address this knowledge gap by studying refractive error in a cohort of IRD patients at an academic ophthalmology referral center.

Methods: We performed a single center cross-sectional retrospective study of cases identified from the IRD database of the Shiley Eye Institute, University of California San Diego, containing all patients seen in the dystrophy clinic. Patients were included with clinical and molecular confirmed IRD. Demographic and clinical data retrieved from medical records included age, gender, disease phenotype, best corrected visual acuity, objective and subjective refraction. Distributions and mean spherical equivalent (SE) were calculated for causal genes. Analysis of SE was conducted on a per subject eye level through Linear Mixed Effects modeling. Statistical analyses were performed using R statistical software (R Version 3.6.3).

Results: The database contained 571 patients with IRD. We represent 162 patients with clinical and molecular confirmed IRD, 82 (51%) were males, mean age was 37.6 years (SD +/-2.4). Of these, 112 patients had refractive data, 61 (54%) were ametropic (Fig. 1). Investigating genes associated with myopia, RPGR (n=10, 6%) had the highest odds ratio of myopia 403.43 (P<0.02; SE 1.90 D [SD 34.20]); followed by NYX (n=3, 2%)(78.02, P<0.04; SE 2.59 D [SD 46.62]); and ABCA4 (n= 15, 9%)(54.60, P<0.03; SE 2.92 D [SD 52.56]). For genes associated with hyperopia, NMNAT-1 (n= 3, 2%) had the highest odds ratio of hyperopia 971.57 (P<0.001; SE 2.81 D [SD 50.58]); followed by AIPL1 (n= 2, 1%)(405.45, P<0.001; SE 2.92 D [SD 52.56]); and CNGB3 (n= 3, 2%)(40.04, P<0.001; SE 3.17 D [SD 57.06]). n=number of subjects, 2 eyes per subject was used for SE analysis.

Conclusions: Ametropia was commonly seen in IRD patients and appears similarly prevalent as in the unaffected US population which contrasts previous reports. The pattern of error of refraction varied widely by causal gene. Our findings confirm previous reports in some genes such as myopia associated with NYX. However, in our cohort, AIPL1 variants were associated with hyperopia contrasting with previous reports of myopia. Genes identified require further validation in larger cohorts but are candidates for more in-depth investigation in functional studies of refractive error.

ABSTRACT BODY:

Purpose: Adaptive optics scanning light ophthalmoscopes (AOSLO) are a valuable tool for assessing retinal health. AOSLO image quality can degrade from factors such as poor media quality and eye motion, resulting in lost subject and analysis time. Here we assess the performance of a novel image quality metric against human graders.

Methods: We retrospectively obtained confocal and split-detection images of normative and pathological retinas (>8 diseases) from two AOSLOs with similar designs (Denoted as AOSLO 1 and 2). The dataset was comprised of 125 images from each modality and AOSLO (500 images total) at 1, 2, 4, and 8° from the fovea with field of views between 1 and 3°. For each image, we first determined its quality using a custom algorithm: First, the radial average of the log power spectrum of each image was obtained and differentiated. Next, the differentiated radial average was divided into “signal” and “noise” ranges by selecting a cutoff based on the plausible frequency range of photoreceptors. Finally, a signal to noise ratio (SNR) was determined as the ratio of the summed “signal” and “noise” ranges in decibels. For comparison to a gold standard, three individuals graded the same images (randomized, masked) for cell identifiability on a scale from 0-5, where 0 was considered unanalyzable and 5 easily identifiable. We examined the correlation between log-transformed SNR and grader scores and assessed grader agreement using intra-class correlation (ICC; R package: irr).

Results: On average (±std dev), confocal images had SNR values of 56.2±3.1 and 38.2±6.9 and split-detection images had SNR values of 72.2±1.3 and 30.2±6.4 for AOSLO 1 and 2, respectively. On average, grader scores for confocal images were 3.5±1.3 and 2.4±1.3, and grader scores for split-detection images were 2.5±1.3 and 1.5±1.2 for AOSLO 1 and 2, respectively. These data are summarized in Table 1. All SNR and grader scores exhibited weak (r^2 <0.35), but significant correlations ($p<0.01$). Grader ICC was 0.71, implying moderate agreement amongst the graders.

Conclusions: The algorithm presented here successfully quantifies image quality in both confocal and split-detection AOSLO images. On average, graders showed agreement with our algorithm, and moderate agreement with each other.

ABSTRACT BODY:

Purpose: Rhegmatogenous retinal detachment (RRD) often requires urgent surgery to restore vision.Studies have found variation in RRD presentation and outcomes by age,gender,race,and income.However,the impact of patients' residential location on RRD severity remains unclear.

Methods: Retrospective chart review of adult patients who underwent an RRD repair at Cole Eye Institute from 2012 to 2020.Patients were excluded for previous penetrating trauma, posterior intraocular segment surgery to the presenting eye, or outliers in travel distance above 95th percentile.Demographic differences were characterized. Google Maps was used to calculate the travel distance in miles from the residential zip code to the presenting and surgery location addresses.Multivariable logistic and univariable linear regressions were used to compare macula-off status and Best Visual Acuity (BVA) in ETDRS letters at presentation and 6-month follow-up with patient travel distance by tertile or continuously.

Results: 1063 patients were identified for the study. Demographics and baseline ocular characteristics are shown in Table 1.Average distance to the presenting location was 25.22 mi and to the surgery location was 31.38 mi.Average (SD) BVA at 6-month follow-up for patients with data available was 60.96 (23.36),n=705.The reattachment rate was 95.8% for closest tertile, 96.3% for second tertile, and 94.9% for furthest tertile (p=0.66).In multivariable analysis including age,race,gender,ethnicity,median household income,insurance,and smoking status,distance tertile to presenting location was not predictive of macula-off status (OR 0.9978,95% CI 0.992,1.003,p=.25,n= 1061) or BVA at follow-up (first tertile 0.19 letters more than third tertile,95% CI -2.68,3.06,p=.896,n= 690).A subset analysis of patients with median household income less than$25,000 revealed that further distance to surgical location was associated with longer time to surgery (0.69 days longer per mile of distance, 95% CI 0.41,0.97,p<.0001,n=28),but was not associated with BVA at follow-up (-0.13 letters,95% CI -0.51,0.24,p=.25,n=21).

Conclusions: Further distance is significantly associated with a delay in time from diagnosis to surgery for low-income patients, but distance does not impact macula-off status or BVA at follow-up. This suggests that patients who are further from the hospital may be able to achieve equivalent outcomes from RRD repair, despite delays in surgery.

ABSTRACT BODY:

Purpose: While genetic alterations in uveal melanoma (UM) have been extensively studied, epigenetic factors of UM are still not well understood. It is also evident that UM differs significantly from skin melanoma regarding clinical behaviour, genetic profile as well as responsiveness to various therapies. However, differences between skin and uveal melanocytes are not obvious. We therefore studied histone posttranslational modifications (hPTMs) which are epigenetic mechanisms regulating gene expression. HPTMs were analyzed in different UM cell lines and healthy melanocytes (from skin and uvea) to provide a deeper insight into the pathogenesis of UM.

Methods: Human skin (n=6) and uveal melanocytes (n=2) as well as human UM cell lines (n=7) were analyzed by quantitative mass spectrometry for 52 histone modifications involved in the dynamics of active and repressive chromatin.

Results: Hierarchical clustering showed clear differences between melanocytes and UM cell lines. Uveal melanocytes showed a different hPTM pattern than skin melanocytes. With regard to the UM cell lines, those with a monosomy 3 signature (MP65 and UPMM1) were distinguishable from cell lines with a disomy 3 signature (Mel 202, 92.1, UPMD1, UPMD2). The BAP1-associated mark H3K27me3 was unaltered in melanocytes and non-specifically altered in UM cell lines.

Conclusions: Our study demonstrated different hPTM patterns between skin and uveal melanocytes which both originate initally from the same precursor of melanocytes. Since the potential neoplasms arising from these melanocytes (skin and uveal melanoma, respectively) differ in their clinical behaviour and their genetic profile, hPTM may be a step towards understanding the differences between these two melanocyte subtypes. In addition, healthy uveal melanocytes were distinct from UM cell lines which could be further subgrouped with regard to chromosome 3 status. Thus, hPTM signature may be an additional prognostic marker and further studies on human tissues are warranted.

TITLE: The anisotropy of retinal blur in the human periphery
SESSION TITLE: Refractive Error: Myopia, Hyperopia, vision and models
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: L. Zheleznyak, Clerio Vision, Inc., New York, UNITED STATES|
Commercial Relationships Disclosure: Len Zheleznyak: Commercial Relationship(s);Code E (Employment):Clerio Vision, Inc.
ABSTRACT BODY:
Purpose: Retinal image blur in the periphery varies remarkably between individuals and their refractive state. Furthermore, the sign and shape of peripheral blur may provide a cue for the sign of defocus, and hence may play a role in accommodation and emmetropization. This study sought to investigate the peripheral image quality through-focus and how it depends on the eye's refractive error.
Methods: Previously published [1] Zernike coefficients across retinal eccentricity (0, 10, 20 and 30 deg horizontal visual field) were used to compute the monochromatic modulation transfer function (MTF) at 555 nm for a 4 mm pupil. Two-dimensional MTF was computed through-focus, from -3 to +3 D in 0.1 D steps at each eccentricity and used to define two metrics of image quality: (1) overall image quality defined as the volume under the MTF (vMTF) and (2) blur anisotropy defined as the ratio of the horizontal to vertical meridians of the MTF (HVRatio).

[1] Romashchenko, D, R. Rosén, and L. Lundström. "Peripheral refraction and higher order aberrations." Clinical and Experimental Optometry 103.1 (2020): 86-94.
Results: Across the horizontal visual field (at 10, 20, 30 deg), through-focus vMTF revealed best focus (max vMTF) close to the retina in emmetropes (-0.3, -0.3, 0.0 D, respectively), as opposed to myopes whose best focus was behind the retina (-0.1, 0.4, 1.5 D, respectively) and hyperopes in front of the retina (-0.5, -0.6, -0.6 D). At 0.0 D (on the retina), emmetropes and hyperopes both exhibited radially elongated blur, whereas myopes had circumferentially elongated blur (HVRatio = 0.3, 0.7 and 2.8, respectively, at 30 deg eccentricity). In all groups, peak vMTF (best focus) coincided with radially elongated blur.
Conclusions: Blur in the peripheral retina is dominated by so-called "odd-error" blur signals, primarily due to oblique astigmatism. Thus orientation of peripheral blur (radial vs circumferential) provides the eye with an optical cue for the sign of defocus and may play a role in mechanisms of accommodation and emmetropization. All subject groups had anisotropic blur in the periphery: myopes exhibited a circumferentially elongated peripheral blur, whereas emmetropes and hyperopes exhibited radial blur. These differences may be due to the interaction between peripheral wavefront aberrations and field dependent axial length (i.e. globe shape).

ABSTRACT BODY:

Purpose: Social Determinants of Health (SDoH) have been shown to play a substantial role in the development and treatment of eye conditions. Electronic health records (EHRs) offer a potential source for obtaining information regarding social determinants, but missing data are a known limitation of EHRs. In this study, we aimed to quantify the availability of SDoH data in our institutional EHR system for patients with common eye conditions.

Methods: Based on diagnosis codes, we identified adult patients (18 years and older) in the University of California San Diego (UCSD) EHR with the following conditions: cataracts, glaucoma, age-related macular degeneration (AMD), and diabetic retinopathy (DR). For each cohort, we extracted SDoH data from the EHR. SDoH variables included demographics (age, race, ethnicity, gender), social history (alcohol, tobacco, drug use), and other relevant variables (income, education, housing security, food insecurity, stress levels, physical activity). We calculated data coverage per variable (i.e. the proportion of patients with available data for that variable) and analyzed the distribution of data coverage across variables within each cohort. We evaluated whether SDoH data coverage differed significantly among cohorts using chi-squared analyses, defining statistical significance as $p<0.05$. All analyses were performed using R.

Results: We identified 40,429 patients with cataracts, 26,794 patients with glaucoma, 6,713 patients with AMD, and 6,616 patients with DR. Demographic data across all cohorts had the highest rate of coverage at 98%. Tobacco-related variables had 80-90% coverage across all cohorts, while alcohol-related variables had 40-90% coverage. All remaining SDoH variables such as education, food insecurity, and income had an average of approximately 2-5% coverage (Figure 1). SDoH variables had low rates of data coverage across all cohorts.

Conclusions: There is increasing interest in understanding how social determinants influence the risk of eye disease and outcome. However, our study demonstrates that coverage of SDoH in our institutional EHR was highly variable, with large amounts of missing data. This highlights the need to develop standard practices for collecting SDoH data as well as to understand how to overcome potential barriers to data collection.

ABSTRACT BODY:

Purpose: The Treat-and-Extend (T&E) regimen with anti-VEGF agents is often used by retina specialists in clinical settings in the treatment of neovascular age-related macular degeneration (nAMD). This study evaluated the real-world long-term eight-year visual acuity outcomes of regular intravitreal anti-VEGF agents in patients with nAMD in the United States.

Methods: This is a retrospective, interventional, consecutive case series. 165 eyes from 137 treatment-naïve patients diagnosed with nAMD after August 2010 were treated at a single site by one physician with ranibizumab, aflibercept, bevacizumab, or brolucizumab for ≥1 year using a T&E regimen. Patients needed to receive ≥6 injections in the first year and ≥3 injections in the following years to be included in this study. Snellen best-corrected visual acuity (BCVA) was converted to ETDRS letters using a standardized formula. The main outcome measures were: BCVA change from baseline to end of patient follow-up; mean number of injections per year, and percentage of eyes losing ≥15 letters, gaining ≥15 letters or maintaining vision within 15 letters.

Results: The average (standard deviation [SD]) baseline patient age was 78 years (8.5); 60% of patients were female. The mean follow-up period was 5.4 years, with 165, 158, 143, 126, 102, 78, 48, and 26 eyes completing 1, 2, 3, 4, 5, 6, 7, and 8 years of follow up, respectively. The average BCVA at baseline was 53 letters. Mean (SD) changes from baseline in BCVA were 8.3 (21.8) letters, 7.1 (25.0) letters, 4.7 (26.5) letters, 4.5 (27.1) letters, 4.5 (28.3) letters, 5.1 (26.5) letters, and -0.5 (34.8) letters and -4.3 (38.9) letters for years 1-8 respectively. Mean number of injections during years 1-8 were 7.9, 6.1, 5.8, 6.0, 6.2, 5.9, 6.2, and 6.0, respectively. At the final follow-up, 24.2% of eyes had lost ≥15 letters, 26.1% of eyes had gained ≥15 letters and 49.7% of eyes had maintained vision within 15 letters.

Conclusions: 75.8% of patients on the T&E regimen either maintained or improved their vision at the final follow up. The T&E regimen has been effective in maintaining visual acuity in nAMD patients treated with ranibizumab, aflibercept, bevacizumab, or brolucizumab for up to six years of treatment. Patients lost vision in the 7th and 8th year

of treatment and further analysis is needed to evaluate the cause of vision loss.

ABSTRACT BODY:

Purpose: Charles Bonnet Syndrome (CBS) is a condition involving visual hallucinations as a result of vision loss, but it is not well characterized nor routinely assessed for. Some patients with Leber's Hereditary Optic Neuropathy (LHON) experience CBS, but there is limited published data. This is the first study screening for and characterizing CBS in a large cohort of the LHON patient population.

Methods: A recently validated French-Canadian CBS screening questionnaire was adapted to an online bilingual (English-French) format, tailored to LHON patients (Cantin et al. CJO, 2019;54:323–7). The 59-item questionnaire was distributed to numerous mailing lists, online communities and social media platforms consisting of LHON patients. Quantitative and qualitative response data was used for cross-sectional analysis.

Results: A total of 155 affected LHON patients, 59% male and 41% female with over 85% of participants between the ages of 18 to 65, completed the questionnaire – with 54% screening positive for CBS. Of the participants who screened positive for CBS, 55% were affected by the 11778G>A mutation, 13.3% by 14484T>C, 14.5% by 3460G>A, 8.4% by other mutations and 8.4% by an unknown mutation. In addition, 41% of these participants have been diagnosed with LHON for more than 10 years while 38.5% have been diagnosed for less than 5 years.

Among CBS-positive patients, 90% of patients reported experiencing the hallucinations within the past year. Furthermore, 39% of patients reported that the images disturb their sleep, while 53% reported that the images negatively affect their mood. Additionally, only 55% had heard of CBS before and only 12% (10 participants) had been diagnosed with CBS by a health-care professional.

Conclusions: Our results yielded a high proportion of LHON patients screening positive for CBS (54%), indicating the condition may be a lot more common than previously suspected, and only a minority of LHON patients are being adequately assessed and managed for the condition. There is also an indication that their CBS tends to be long-lasting and can be associated with various negative health outcomes. Overall, this study provides a better understanding of the prevalence of CBS in LHON and the need for proactive discussions by health care providers.

TITLE: A Novel ATF6-Achromatopsia Allele Regulated by Nonsense-Mediated mRNA Decay

SESSION TITLE: Genetic variants in human ocular disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Al Moujahed, L. Safarta, D. Vollrath, J. Lin, Stanford University School of Medicine, Stanford, California, UNITED STATES|

Commercial Relationships Disclosure: Ahmad Al Moujahed: Commercial Relationship: Code N (No Commercial Relationship) | Lance Safarta: Commercial Relationship: Code N (No Commercial Relationship) | Douglas Vollrath: Commercial Relationship: Code N (No Commercial Relationship) | Jonathan Lin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Achromatopsia is an autosomal recessive form of cone dysfunction that is characterized by reduction of visual acuity, photophobia, nystagmus, and poor color vision. To date, six genes have been found to cause achromatopsia. ATF6 is the most recent of these genes to be identified with multiple types of mutations affecting it, including single-nucleotide changes, small deletions and duplications of the gene, and large multi-exon deletions. The purpose of this study is to describe a novel ATF6 mutation in 2 patients diagnosed with achromatopsia.

Methods: Patients were clinically evaluated and retinal images were obtained using standard methods with findings that were consistent with achromatopsia. Genetic testing of the two patients was performed using an inherited retinal degeneration disease gene panel. All ATF6 exons were further amplified by polymerase chain reaction (PCR) and analyzed by direct sequencing. The resulting sequence data were compared to the human ATF6 gene reference sequence NM_007348.3.

Results: Two siblings from a consanguineous family of Arab descent were diagnosed with ACHM. We identified a homozygous mutation in the exon 10 of the ATF6 gene c.1243dup, which leads to introduction of a premature stop codon p.(Arg415Lysfs*10) in the new coding frame. This premature stop codon is located 534 nucleotides from the last exon-exon (exon 15-exon 16?) or (exon 17-exon 18?) junction and satisfies the >60-65 nucleotide criteria for transcripts that are subject to nonsense-mediated decay (NMD).

Conclusions: This is the first report of a new homozygous single-nucleotide duplication mutation in the ATF6 gene c.1243dup in 2 patients with achromatopsia that leads to a premature stop codon. We also show the predicted regulation of this ATF6-achromatopsia allele by NMD of the variant transcript mRNA.

ABSTRACT BODY:

Purpose: To identify a time-dependent role of mTORC1 in retinal development using hiPSC-derived retinal organoids, especially retinal ganglion cell (RGC) differentiation, and retinal lamination process during early stages of retinal organoids (ROs).

Methods: We utilized American Type Culture Collection (ATCC)-DYR0100 hiPSCs for retinal organoid differentiation. Rapamycin and MHY1485 were prepared at final concentrations of 100 nM and 10 μM, respectively. From 35 days of differentiation, organoids were transferred to the wells of a 96 well plate and treated with rapamycin and MHY1485 until 40 days of differentiation. The development of RGCs was assessed by the expression of various specific markers (HuC/D, AtoH7, Islet-1, and Brn3b) We examined the relative expression of total mTOR, Raptor, and Rictor, S6K1 to investigate the dynamics of mTOR activity in ROs. RGC markers HuC/D, AtoH7 and mTORC1 marker S2448, ps6 were detected in ROs by immunofluorescence staining.

Results: mTORC1 activity in ROs was the highest at 40 days of differentiation. Hyperactivation of mTORC1 during this period using MHY1485 resulted in the significantly increased overall size of ROs compared to untreated controls and rapamycin-treated ROs, while showing markedly increased proliferative activity both in inner and outer layers of ROs. Also, MHY1485-treated ROs showed a significantly increased number of ectopic RGCs in outer layers, indicating disruption of retinal laminar structure, with robust expression of HuC/D in inner layers

Conclusions: mTORC1 plays a critical role in the development of hiPSC-derived ROs, especially during the early stages of differentiation. Moreover, our results also outline the feasibility of using hiPSC-derived ROs as a tool for translational research on retinal development.

ABSTRACT BODY:

Purpose: The development of many therapies involving retinal delivery of biologics or cells by intravitreal injection is greatly hampered by obstruction of the therapeutics at the inner limiting membrane (ILM). Therefore, we explore photodisruption of the ILM to generate therapeutic entryways that can greatly enhance retinal delivery. To this end, the photothermal dye indocyanine green (ICG) is applied to the ILM and irradiated with pulsed laser light in order to create vapor nanobubbles (VNBs) which upon their collapse can disrupt the ILM (Fig 1).

Methods: To perforate the ILM, we applied varying concentrations of ICG (0,1 mg – 1mg/ml) on top of bovine retinal explants followed by scanning of the laser beam at lower and higher laser energies (0,24 or 0,4 J/cm^2). For the latter, an Nd:YLF laser was applied to generate 800 nm single laser pulses of a 2 picosecond pulse width and frequency of 1 kHz. Propidium iodide staining was applied to assess retinal cell death right after treatment and after 24 hours in retinal cryosections (n=3). To assess the impact on delivery, 120nm-sized Lipid Nanoparticles (LNPs) loaded with luciferase-mRNA were dripped on top of explants (according with a dose of 1 µg of mRNA) prior to their culture for 24 hours after which retinal luciferase expression was measured in intact explants using an IVIS sytem (n=4). During these experiments, untreated, ICG-only and laser-only controls were added. Finally, dark-field microscopy was applied to image VNB formation upon laser pulse irradiation in patient-derived isolated human ILM (n=2).

Results: The strongest conditions (1 mg/ml ICG; 0,43 J/cm2) elicited significant cell death, especially in the GCL and INL layer, yet, milder conditions (0,1 mg/ml ICG; 0,43 J/cm2) did not affect retinal viability, even after 24 hours. Strikingly, the latter conditions elicited a nearly 5-fold increase (4.7 ± 0.4 SD, $p<0001$) in retinal luciferase expression when compared to explants treated with LNPs only. Dark-field microscopy on the human ILM confirmed that this effect is based on pore formation owing to VNB generation.

Conclusions: This ex vivo study reveals that ICG-mediated photodisruption of the ILM can greatly enhance delivery of nanoparticles into the retina in a safe manner. Driven by this positive outcome, future plans include assessment of the safety and efficacy of our technology in vivo.

ABSTRACT BODY:

Purpose: X-linked juvenile retinoschisis (XLRS) is an early onset inherited condition characterized by abnormal retinoschisin (RS1) expression, early visual deficiencies and cystic retinal lesions. We characterize a series of novel dysfunctions at the cellular level of the developing retina of mice lacking RS1.

Methods: We studied spontaneous intracellular calcium dynamics in male mice expressing GCaMP6f in neuronal, glial, and vascular cells and compared results from Rs1 knockouts ($Rs1^{-/Y}$) and controls ($Rs1^{+/Y}$). Optophysiological assessment was carried out in live wholemount retinal explants of cohorts aged P10-11, P14-15, P20-22, and P60-65. Additionally, we performed in vivo OCT imaging of retinal cysts and immunohistochemical characterization of retinoschisin expression in the retina.

Results: The development of retinal cysts imaged in vivo by OCT is paralleled by the appearance of aberrant spontaneous neuro-glial signals after postnatal day 13. These presented as glutamate-driven wavelets of neuronal and Müller glia activity spanning all retinal layers that disrupt light-induced signaling.

Conclusions: This study highlights the critical role that RS1 plays in early retinal development. Additionally, it confers a functional role to RS1 beyond the scope of an adhesion molecule and identifies a tight bracket for the onset of dysfunction, a potential temporal target for therapeutic intervention.

TITLE: Predicting Deep Perimetric Defects from Retinal Nerve Fiber Layer (RNFL) Reflectance at the Optic Disc

SESSION TITLE: Structure-Function Relationship

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: W.H. Swanson, B. King, School of Optometry, Indiana University, Bloomington, Indiana, UNITED STATES|M.S. Alluwimi, Optometry, Qassim University, Buraidah, Al Qassim, SAUDI ARABIA|R. Malik, Ophthalmology, University of Alberta Faculty of Medicine & Dentistry, Edmonton, Alberta, CANADA|

Commercial Relationships Disclosure: William Swanson: Commercial Relationship: Code N (No Commercial Relationship) | Muhammed Alluwimi: Commercial Relationship: Code N (No Commercial Relationship) | Rizwan Malik: Commercial Relationship: Code N (No Commercial Relationship) | Brett King: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To use RNFL reflectance at the optic disc to distinguish hemifields with deep perimetric defects from hemifields with no perimetric defect.

Methods: Volume scans for a 30° x 15° scan covering the optic disc were gathered on one eye per person with Spectralis optical coherence tomography (OCT), and used to compute en face maps of log attenuation coefficient (AC) at 24 μm below the inner limiting membrane (ILM). The analysis method was developed by analyzing results for 15 patients with glaucoma and 15 age-similar controls recruited and tested at Indiana University School of Optometry (IUSO) in the United States. Then this method was applied to an independent data set for 23 patients with glaucoma and 10 age-similar controls recruited and tested at King Khaled Eye Specialist Hospital (KKESH) in Saudi Arabia. For each eye, both superior and inferior visual hemifields were scored as having a deep defect when the location with deepest total deviation had a value of -24 dB or worse. A grid of 338 square cells was overlaid on an en face image, pixels containing vasculature and/or optic disc were excluded and mean AC was computed for each cell. For each eye, the 85th percentile for AC was computed as a reference value and cells for which mean AC fell 0.3 log unit or more below the reference value were scored as abnormal. A hemifield was considered abnormal if there was a cluster of defects corresponding to inferior temporal or superior temporal RNFL sectors.

Results: For the hemifields in the IUSO dataset, all 11 hemifields with deep perimetric defects were identified and none of the 38 hemifields with no perimetric defect. For the KKESH dataset, 17 of the 23 hemifields with deep perimetric defects were identified and none of the 22 hemifields with no perimetric defect. The 95% confidence limit for specificity for perimetrically normal hemifields was 91%-100% for the IUSO dataset and 85%-100% for the KKESH dataset. The 95% confidence limit for sensitivity for hemifields with deep perimetric defects was 74%-100% for the IUSO dataset and 54%-87% for the KKESH dataset.

Conclusions: A method with good specificity and sensitivity was developed, and then tested on an independent dataset. Specificity remained high, but sensitivity was at the lower end of the 95% confidence interval for the first data set. Further work is needed to improve sensitivity of en face reflectance analysis at high specificity.

ABSTRACT BODY:

Purpose: To determine if online medical education for ophthalmologists (Opht) could improve their knowledge and confidence to assess patients with ocular surface pain, in particular those with a neuropathic component and recall new mechanisms of action for emerging treatments

Methods: Opht participated in an online 30 min video, 3 expert roundtable discussion with accompanying slides. A repeated pairs pre-/post-assessment study design was used, assessing 3 multiple choice knowledge and one confidence question. Statistical significance tests: McNemar's test for individual questions (5% significance level, $P < .05$), paired sample t-test for overall average correct responses and confidence rating; data collected Apr 16, 2021 to Jul 15, 2021. Test completers: 441

Results: At baseline, 38% of Opht (n=441) answered all 3 questions correctly, increasing to 71% ($P < 0.01$) on post-assessment. 49% of Opht reported improved confidence in their ability to assess patients with ocular surface pain. The activity significantly increased knowledge on neuropathic causes as contributing factor to ocular surface pain (pre: 81%, post: 89%, $p<.001$), on selecting assessment methods to differentiate between neuropathic corneal pain of central and peripheral origin (pre: 68%, post: 88% $p<0.001$) as well as recalling the mechanism of action for an emerging therapy inhibiting transient receptor potential cation channel subfamily V member 1 (TRPV1) which plays a key role in ocular surface pain. (pre: 60%, post: 82%, $p<.001$). 93% of test completers polled stated a need for new therapies to treat chronic ocular surface pain.

Conclusions: Online medical education in the form of expert roundtable discussions with accompanying slides can significantly improve ophthalmologists' knowledge and confidence on assessing patients with ocular surface pain to raise awareness and improve diagnosis of peripheral and central neuropathic pain and increase knowledge on emerging treatments, such as topical TRPV-1 inhibitors. Polling confirmed a high unmet need for new treatments to better control chronic ocular surface pain. Additional education is warranted to shorten time to diagnosis for neuropathic ocular pain, disseminate latest clinical data for emerging treatments and evidence based patient selection guidance for clinical practice.

ABSTRACT BODY:

Purpose: New therapies are urgently needed to slow or stop myopia progression in children, and therefore reduce the risk of long-term, sight-threatening complications from myopia. The discovery that polymorphisms at the myopia genetic locus, MYP1, are associated with splicing-defective cone opsin genes (OPN1LW and OPN1MW) led to the hypothesis that contrast signaling in the retina plays an important role in myopia development and progression. This hypothesis predicted that reducing the contrast of images on the retina could slow myopia progression. Novel spectacle lenses (DOT lenses) were developed to evaluate this hypothesis, and a multi-center, double-masked, randomized, controlled clinical trial was initiated.

Methods: CYPRESS (NCT03623074) evaluated two investigational spectacle lenses (Test 1, Test 2) designed to slightly reduce contrast compared to control spectacle lenses for the ability to reduce myopia progression in children 6-10 years of age over a period of 3 years. Two hundred and fifty-six (256) eligible myopic subjects were randomized and dispensed spectacles at 14 clinical sites in North America. Subjects were asked to wear the study spectacles constantly, except for activities in which standard spectacle wear would be inappropriate, such as contact sports and swimming. “Full time wearers” were defined as those subjects whose parents reported that they did not remove the study spectacles for near vision activities. Axial length (AL) and cycloplegic autorefraction (SER) were measured at baseline and annual follow-up visits, now through 24-months.

Results: Approximately two-thirds of study subjects (61, 45, and 66 in Test 1, Test 2, and Control, respectively) met criteria for “full-time wearers”. After 24-months, the mean (± SD) change from baseline in AL was 0.33 ± 0.23, 0.34 ± 0.39, and 0.53 ± 0.33 mm for Test 1, Test 2, and Control respectively. The mean change from baseline in SER after 24-months of usage was -0.36 ± 0.54, -0.48 ± 0.85, and -0.88 ± 0.77 D for Test 1, Test 2, and Control, respectively. The difference in means (Test 1 minus Control) for change from baseline of AL (-0.21 mm) and SER (0.52 D) were statistically significant ($p<0.0001$).

Conclusions: DOT spectacle lenses were designed to reduce retinal contrast to slow the progression of myopia. After 24-months of usage, subjects who wore DOT lenses full-time had less myopia progression than control subjects.

SUBMITTER (NAME ONLY): Joseph Demer

TITLE: Masquerading Superior Oblique Palsy Mimics All Features of Congenital and Acquired Superior Oblique (SO) Muscle Weakness

SESSION TITLE: Nystagmus and Strabismus: Genetics, animal models and imaging

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J.L. Demer, Ophthalmology, University of California Los Angeles, Los Angeles, California, UNITED STATES|J.L. Demer, Neurology, University of California Los Angeles, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Joseph Demer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Unilateral SO palsy is typically diagnosed by the 3-step test criteria requiring ipsilateral hypertropia, that increases in contralateral gaze, and with ipsilateral head tilt. I asked if this pattern, in congenital & acquired cases, is specific for SO atrophy that occurs reliably after SO denervation.

Methods: In a prospective study of head-position dependent hypertropia, quasi-coronal, surface coil MRI was performed in central gaze, and in some cases supraduction, and infraduction. The hypertropic SO of 57 subjects had max. cross section <80% of contralateral, indicating unilateral SOP: 22 subjects had congenital (mean age 29±19 yrs, standard deviation, SD) & 35 had acquired strabismus onset (age 46±19 yrs, symptoms for 6±7 yrs). There were 26 similarly hypertropic subjects with normal SO muscles that were considered masquerading cases: 8 subjects had congenital (mean age 36±16 yrs) & 18 had acquired onset (age 34±18 yrs, symptoms for 6±9 yrs). Alignment was measured using prisms in diagnostic positions with & without head tilt, & with double Maddox rods.

Results: Maximum SO cross section averaged 7.7±3.8mm^2 in congenital & 10.7±3.5mm^2 in acquired SOP (P=0.003), significantly less than contralesionally at 17.9±3.7 mm^2 & 18.9±3.9mm^2, respectively (P<10^{-9}). Maximum hypertropic SO cross section in congenital (18.4±3.0 mm^2) & acquired (20.7±3.1mm^2) masquerading cases was statistically identical to contralateral in all groups (P>0.4). The contractile increase in SO cross section from up to down gaze was statistically similar in hypertropic & fellow eyes of masquerades (P>0.6). The 3-step test was fulfilled in all congenital but only 72% of acquired SO atrophy, tending even less than 81% in masquerades (P=0.27). Alignment & torsion measures were statistically indistinguishable in all diagnostic positions between cases of SO atrophy & masquerades, except that hypertropia in infraversion was slightly larger at 14.5±11.5Δ in SO palsy than 9.2±9.1Δ in masquerades (P=0.04). There were supranormal vertical fusional amplitudes of up to 27Δ in 56% of masquerading cases.

Conclusions: Masquerading SO palsy occurs in the presence of normal SO morphology and contractile function, quantitatively mimicking all alignment features of actual SO unilateral weakness manifested by SO atrophy, including supranormal vertical fusional amplitudes with both congenital & acquired onset.

TITLE: Neuropathic Ocular Surface Changes, Corneal Nerve Imaging and neuromediator Profiles in Small Incision Lenticule Extraction (SMILE) and Femtosecond Laser-Assisted in-situ Keratomileusis (LASIK)

SESSION TITLE: Refractive and non-refractive corneal surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Liu, M. Lin, I. Lee, Singapore Eye Research Institute, Singapore, SINGAPORE|J.S. Mehta, Singapore National Eye Centre, Singapore, Singapore, SINGAPORE|

Commercial Relationships Disclosure: Yu-Chi Liu: Commercial Relationship: Code N (No Commercial Relationship) | Molly Tzu-Yu Lin: Commercial Relationship: Code N (No Commercial Relationship) | Isabelle Xin Yu Lee: Commercial Relationship: Code N (No Commercial Relationship) | Jodhbir Mehta: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate and compare the neuropathic ocular surface changes, corneal nerve imaging and neuromediator profiles in small incision lenticule extraction (SMILE) and femtosecond laser-assisted in-situ keratomileusis (LASIK)

Methods: In this prospective study, 25 SMILE patients (n=50 eyes) and 25 LASIK (n=50 eyes) were followed up for 1 year. Five clinical neuropathic ocular surface assessments, 7 corneal nerve parameters evaluated by ACCMetrics software, OSDI questionnaire, and the levels of 4 tear neuromediators, were evaluated preoperatively, and 1 week, 1, 3, 6, and 12 months postoperatively.

Results: SMILE, compared to LASIK, had significantly better corneal sensitivity at 1 week, 1, 3 and 6 months, better tear break-up time (TBUT) at 3 months, lower corneal NEI scores at 1 week, 6 and 12 months, and lower ocular surface Oxford scores 1 week. SMILE had significantly better corneal nerve fiber length (CNFL), density (CNFD), total branch density, fiber area, fiber width (CNFW) and fiber fractal dimension (CFracDim) than LASIK throughout 1year. At 1 year, the nerve metrics were significantly impaired in LASIK, while fiber area and width had been restored in SMILE. There were significant increase in nerve growth factor at 1 month, and decrease in substance P (SP) at 1 month in LASIK, while the changes were insignificant in SMILE. CNFL, CNFD, CNFW, CFracDim and tear SP level were significantly associated with TBUT. Tear SP, neuropeptide Y (NPY) and calcitonin gene-related peptide (CGRP) concentrations were significantly correlated all the nerve parameters, except CNFW.

Conclusions: This is the first study comprehensively evaluate and correlate the molecular profiles, morphological changes and clinical functional changes in patients with refractive surgery. The postoperative corneal denervation was long-lasting, with faster restoration in SMILE. SMILE was also associated with less negative impact on ocular surface clinically, as well as less fluctuations in neuroinflammatory reaction. Even though clinical symptoms and signs have subsided, significant alterations in corneal neurobiological status, nerve morphology and quantity were still observed. Our study provides new insights into the biological responses on the ocular surface after refractive surgery.

ABSTRACT BODY:

Purpose: To evaluate the in vivo ocular biocompatibility of a novel intravitreal bispecific protein, RO-634, designed to target Vascular Endothelial Growth Factor-A (VEGF-A) and Angiopoietin-2 (Ang-2) using electroretinogram (ERG).

Methods: All experiments were performed in accordance with the ARVO statement for Use of Animals in Ophthalmic and Vision Research. Five Brown Norway rats received intravitreal injections of RO-634 in the right eye and balanced saline solution (BSS) in the left eye to evaluate for possible retinal toxicity. One month after intravitreal injection, ERGs were performed to assess potential damage to the retina. Animals were dark-adapted overnight prior to the ERG. ERGs were performed on the Celeris device (Diagnosys LLC, Lowell, MA). The test consisted of flash stimuli at 0.01, 0.1, 1.0, and 3.0 cd-s/m^2. Student Paired T-test was used for statistical comparison of the amplitude and peak times between the control and experimental eye at each level of stimuli.

Results: RO-634 was well tolerated in brown Norway rats, demonstrating biocompatibility. ERG analysis of scotopic and photopic light response showed cone and rod functional activity with no statistically significant difference in the A and B wave amplitudes and peak times between the control and the experimental eye. Figure 1 is an illustration of similar ERG response in the experiment and control arm at flash stimuli of 3.0 cd-s/m^2.

Conclusions: In this preclinical animal study, the novel bispecific, RO-634, showed physiologic ocular compatibility as measured by ERG. Future studies are needed to evaluate the clinical potential of this novel and promising agent for treatment of back of the eye disease.

ABSTRACT BODY:

Purpose: The cornea is transparent and innervated by a dense collection of sensory nerves originating from the ocular branch of the trigeminal nerve. This study was designed to comprehensively analyze alterations of corneal sub-basal nerve plexus in a mouse model of tauopathy (P301L transgenic mice) to test the possibility of using corneal nerves as a biomarker for tauopathy and to investigate its potential underlying mechanisms.

Methods: Corneal sensitivity, thickness and epithelial wound healing were measured non-invasively by aeshesiometer, optical coherence tomography and fluorescein staining, respectively. Tau, corneal nerves and immune cells were examined by immunohistochemistry or Western blot. Transcriptome changes in the trigeminal ganglion (TG) were determined by RNAseq.

Results: At the early stage of tauopathy, although corneal sensitivity, thickness and nerve fiber density were not greatly altered, corneal nerve abnormalities were observed in the peripheral region of young P301L mice. With aging, the density of abnormal nerves increased, while corneal sensitivity, epithelial thickness, nerve fiber density and length decreased in middle-aged P301L mice compared with WT mice. After corneal epithelial injury in young mice, no difference in reepithelialization was observed between two groups of mice, however, the regeneration of corneal nerves in P301L mice lagged behind WT mice, which was reflected by delayed recovery of corneal sensitivity, decreased corneal nerve density and length and density of $CD45^{+}$ dendriform cells in P301L mice. RNAseq analysis revealed that gene sets related with ribosome, proteasome and protein export were significantly downregulated in TGs from 3-month old P301L mice compared with those from age-matched WT mice.

Conclusions: Our data provide compelling evidence that corneal nerves were changed in a mouse model of tauopathy in an age-dependent manner. Moreover, tau overexpression impairs corneal nerve regeneration, which may involve tauopathy-induced decreases in de novo protein synthesis and transportation. These results suggest that cornea may serve as a promising ocular site for the early diagnosis of tauopathy.

TITLE: Pointwise Comparison of the 24-2C and 10-2 for Central Field Defects
SESSION TITLE: Visual Fields and Psychophysics
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: L. Harrison, A. Chen, P.P. Chen, P. Luong, University of Washington, Seattle, Washington, UNITED STATES|
Commercial Relationships Disclosure: Luke Harrison: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Chen: Commercial Relationship: Code N (No Commercial Relationship) | Philip Chen: Commercial Relationship: Code N (No Commercial Relationship) | Preston Luong: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The 24-2C SITA Faster on the Humphrey Field Analyzer is a relatively newly introduced visual field-testing algorithm. Preliminary studies demonstrate agreement of global metrics between the 10-2 and 24-2C. We conducted a retrospective, observational study to perform pointwise comparisons of the 24-2C and 10-2 visual field at their 14 points of overlap.

Methods: Chart review was performed for glaucoma patients who had visual testing between 2019 and 2020. Inclusion criteria included diagnosis of POAG, pigmentary glaucoma, or NTG, and refraction between -8.00 and + 8.00. The exclusion criteria included BCVA < 20/60, ocular surgery other than uncomplicated cataract, SLT, YAG or ALT, age < 18 yrs, neurological disease, angle closure glaucoma. The following statistical tests were used: paired T test for pointwise threshold decibel data, McNemar's test for defect probabilities and Wilcoxon's signed rank test for pointwise comparison of defect probabilities.

Results: Figure 1 depicts the overlay of the 10-2 and 24-2C. There were 39 eyes included with testing separated by 219 ± 281 days. Average MD and PSD were -6.66 ± 7.01, 6.41 ± 4.13 and -6.55 ± 6.98, 6.74 ± 5.03 for the 24-2C and 10-2 respectively. For threshold sensitivity, the mean difference (24-2C dB – 10-2 dB) and paired T-test p-value for each point are listed. Statistically significant points: 43 (2.56 dB, p=0.03), 47 (-1.69 dB, p=0.0038), 50 (-2.95 dB, p=0.005), 60 (2.05 dB, p=0.02), and 61 (2.59 dB, p=0.027). The remaining points are: 3 (1.31 dB, p=0.26), 9 (0.85 dB, p=0.54), 12 (3.38 dB, p=0.13), 19 (0.02 dB, p=0.98), 22 (-0.56 dB, p=0.70), 32 (2.05 dB, p=0.17), 57 (1.59 dB, p=0.17), and 67 (1.56 dB, p=0.089). Probability comparison is displayed in figure 2, points 32 (p=0.016) and 43 (p=0.026) were statistically significant. The 24-2C and 10-2 were significantly different across all points with (p=0.044).

Conclusions: The threshold sensitivities of the 24-2C and 10-2 visual field tests are statistically different at 5 points of overlap. In contrast, the probability plots of the 24-2C and 10-2 are different at only 2 points. When comparing the 14 points of overlap in aggregate, for defect probability, we found that the 24-2C and 10-2 were different. These results suggest that the 24-2C can "miss" defects that would otherwise be appreciated on the 10-2. However, the 24-2C could still be a valuable screening tool for central defects.

ABSTRACT BODY:

Purpose: To establish baseline performance data for a process/quality improvement (PI/QI) program for detection and follow-up of Military Health System (MHS)-eligible infants at risk for retinopathy of prematurity (ROP).

Methods: All births in the MHS from 2016-2019 were identified in the M2 database. Demographic information and gestational age were extracted, and ROP diagnosis, laterality, and stage were determined by ICD-10 codes. Infants at risk for sequelae of ROP were defined as those born <31 weeks GA and/or were diagnosed with ROP during the birth admission. Outpatient claims from military and civilian providers were linked to each at-risk infant, and the timing and diagnoses of each claim determined. Secondary visual diagnoses were determined by ICD-10 code. Chi-squared tests determined differences in percentages, and non-parametric tests determined differences in medians.

Results: 1,457 (91.6% of all at-risk infants) could be matched to outpatient claims and formed the population for analysis. 404 infants (27.7%) were diagnosed with ROP. 114 (28.2%) were initially diagnosed with Stage 0, 127 (31.4%) with stage 1, 77 (19.1%) with stage 2, 31 (7.7%) with stage 3, 13 (3.2%) with stage 4 and 5 (1.2%) with stage 5. 37 (9.2%) had unknown stage. The 50^{th} percentile time from birth to first ophthalmic examination was 34 days (IQR 29-48 days). The median first follow-up after discharge for patients with ROP occurred at 18.5 days.

Compared to at-risk patients not diagnosed with ROP, ROP patients had a higher prevalence of strabismus (16% vs 9.6%; p<0.001), refractive error (41% vs 28%, p<0.001), and visual disturbance (12% vs 9.0%; p=0.04). There was no significant difference in the prevalence of blindness and low vision (0.3% vs 0.5%; p=0.73) and nystagmus (1.5% vs 1.2%; p=0.35). Only one patient in the ROP group developed a retinal detachment and none in the non-ROP group (p=0.05).

Conclusions: Retinopathy of prematurity is a high risk, low volume ophthalmic condition for which many MHS-eligible beneficiaries are at risk. The incidence of ROP in infants born in the MHS is similar to infants in other large single payer systems although the incidence of severe ROP stage 4 and 5 may be higher. These patients are at increased risk for strabismus and refractive error and require frequent long-term outpatient follow-up.

ABSTRACT BODY:

Purpose: Achieving independence from spectacles and overall satisfaction are challenging goals after cataract surgery. The purpose of this investigator-initiated study is to assess patient satisfaction over one year after implantation of the Tecnis Symfony intraocular lens during cataract surgery. These results assist future patients and surgeons in choosing the intraocular lens that will provide the most benefit long term.

Methods: This was a prospective study of patients who had cataract extraction with Symfony intraocular lens placement between 2015 and 2019 at Loma Linda University Eye Institute by one experienced surgeon. These patients were called by the investigator over one year after their surgery. The patients proceeded with a subjective questionnaire via telephone to assess spectacle independence, photic phenomenon, and satisfaction with vision. The data were recorded using a Google Sheets spreadsheet and analyzed using SPSS software.

Results: 92 patients who had cataract surgery with the Symfony intraocular lens over one year prior were called. Of these subjects, 40 patients agreed to participate in the telephone questionnaire. 82.1% of patients did not require spectacles for distance vision, 70% of patients did not require spectacles for intermediate vision, and 20% did not require spectacles for near vision. 60% of patients never experienced glare, and 25% experienced mild glare. 47.5% of patients never experienced halos, and 45% experienced mild halos. 77.5% of patients never experienced starbursts of light, and 20% experienced mild starbursts. In terms of overall satisfaction, 47.5% of patients were extremely satisfied and 40% were satisfied. 87.2% would choose the same intraocular lens again.

Conclusions: This study demonstrates that after at least one year, patients continue to have high levels of spectacle independence, minimal photic phenomenon, and good overall satisfaction with the Symfony intraocular lens. This information should assist patients in choosing this lens in the future.

ABSTRACT BODY:

Purpose: During the COVID-19 pandemic, mask-associated dry eye (MADE) has increased worldwide possibly because the breath leaks from the top of the masks changes the ocular surface conditions. We tested the hypothesis that surgical taping of the top edge of the mask to the skin reduces the risk of ocular surface damage.

Methods: We enrolled 60 volunteers (30 females, 30 males; mean age, 27.1±5.2 years) who wear face masks over 5 hours a day. We measured the fluorescein tear break-up time (FBUT), ocular surface temperature, and conjunctival blood flow before wearing masks, after wearing masks taped on the top edge, and after wearing masks without tape. We used the Ocular Surface Disease Index (OSDI) to record participants' symptoms of MADE and measured their corneal tactile and pain sensitivity using a Cochet-Bonnet esthesiometer.

Results: The FBUT with masks without tape (4.4±2.4 seconds) was significantly shorter than that without masks (6.4±3.1 seconds) and with taped masks (5.8±3.2 seconds) ($P<0.01$ and $P=0.05$, respectively, Tukey HSD test). There was no significant difference in the FBUT between use of no masks and taped masks ($P>0.05$). The differences in the corneal and conjunctival temperatures after wearing masks without tape (0.19±0.28 and 0.13±0.28°C, respectively) were significantly higher than after wearing taped masks (0.05±0.27 and 0.06±0.24°C, respectively, $P<0.01$, paired t-test). The conjunctival blood flow with masks without tape was significantly higher than that of taped masks ($P<0.01$). Of the 60 subjects, 13 (21.7%) subjects reported MADE symptoms. In the MADE group, the OSDI ($P=0.001$, analysis of covariance) was significantly higher and the FBUT of masks without tape ($P=0.006$) was significantly shorter than in the non-MADE group. Pain sensitivity in the MADE group was significantly higher than in the non-MADE group ($P<0.01$), indicating that subjects in the MADE group were significantly hypersensitive to corneal pain.

Conclusions: Wearing masks decreased FBUT and increased ocular surface temperature and blood flow. Taping the top edge of the mask prevented those changes. Fitting masks tightly to the nose or applying tape over the mask may reduce the MADE risk, which can be associated with ocular surface hypersensitivity.

ABSTRACT BODY:

Purpose: To evaluate the dynamics of Bruch's membrane opening-based morphometrics of the optic nerve head (ONH) using spectral domain optical coherence tomography (SD-OCT) during the first week after glaucoma surgery by trabeculectomy with mitomycin C.

Methods: Prospective, longitudinal analysis of 25 eyes of 25 patients treated by trabeculectomy. Twenty-four eyes had evaluable postoperative SD-OCT examinations. Bruch's membrane opening minimum rim width (BMO-MRW) and peripapillary retinal nerve fiber layer (RNFL) thickness were analyzed at baseline before surgery, one day, two to three days and one week after surgery. Changes compared to baseline were correlated to intraocular pressure (IOP).

Results: One day after surgery, BMO-MRW changed on average by +24.0%, p=0.002 (IOP reduction by 5.4±13.9 mmHg). This increase persisted on day 2-3 with a mean increase of BMO-MRW of +19.8%, p<0.001 (IOP reduction by 9.2±14.7 mmHg) and by week 1 with a mean BMO-MRW increase of+25.3%, p=0.002 (IOP reduction by 9.9±16.1mmHg). The increase in BMO-MRW correlated significantly with the reduction of IOP on day 1 (Spearman's rho ρ=0.656, p=0.003) and d2-3 (Spearman's rho ρ=0.479, p=0.038). There was no statistically significant correlation found between the IOP and the increase in BMO-MRW in week 1. RNFL thickness showed no significant changes at all three follow up intervals (p≥0.096 respectively).

Conclusions: Structural reversal of disc cupping in BMO-MRW occurs as early as one day after trabeculectomy and correlates to the extent of the IOP reduction. During the whole first week after surgery a strong increase in BMO-MRW can be noted. The changes in BMO-based parameters need to be considered when evaluating patients' longitudinal follow-up.

TITLE: Tear film breakup and dynamics analyzed and displayed with pseudo-color images

SESSION TITLE: Dry eye regulators: lacrimal gland, Meibomian gland, basic mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P.E. King-Smith, Optometry, Ohio State University, Columbus, Ohio, UNITED STATES|R.J. Braun, Mathematical Sciences, University of Delaware, Newark, Delaware, UNITED STATES|C.G. Begley, Optometry, Indiana University, Bloomington, Indiana, UNITED STATES|

Commercial Relationships Disclosure: Peter King-Smith: Commercial Relationship: Code N (No Commercial Relationship) | Carolyn Begley: Commercial Relationship: Code N (No Commercial Relationship) | Richard Braun: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In this study, we describe a method to demonstrate tear film dynamics using pseudo-color images to provide information about underlying mechanisms of tear breakup. Pseudo-color images, superimposing two or three grayscale images in different colors have had many applications in analyzing and displaying scientific findings. Here we show the use of pseudo-color images in studying a particularly complex pattern of tear breakup and dynamics.
.

Methods: Fig. 1 shows the how a pseudo-color image can be generated by superimposition of two grayscale fluorescein images captured at different times after a blink. Fig. 1A was captured 0.2 s after a blink and colored green, while Fig. 1B was captured 6.5 s after the same blink and colored magenta. Fig. 1C shows the superimposition of these two images after alignment of the images using punctate stains indicated by arrows. Grey indicates no intensity change of an area over the time interval, black indicates probable breakup, green indicates dimming, whereas magenta indicates brightening, e.g., convergent flow of the tear film or a dark object has moved out of the area.

Results: Just after a blink, Fig. 1A, the pattern is dominated by round dark ‘globs’, g, thought to be generated by the expansion of thick globs of lipid; they are often surrounded by a lighter grey halo. Later, Fig. 1B, many vertical ‘squiggles’, s, have formed, together with a horizontal ‘rising tide’, rt.

Fig. 2 shows pseudo-color images for the indicated intervals; color contrast has been increased to emphasize changes in fluorescent intensity. Insets are enlargements of two globs. Magenta borders beneath globs, g, are seen initially, Fig. 2A, indicated thickening of the surrounding haloes, but these borders become narrower, Fig. 2B and eventually disappear, Fig. 2C. While the dark centers of the four upper globs retain their original position and shape, the two lower globs move upwards, Fig. 2A, and give rise to squiggles, Fig. 2C. The squiggles in Fig. 2C, s, are black inferiorly indicating breakup, but are green superiorly indicating thinning, presumably triggered by the inferior breakup. The rising tide, rt, becomes prominent later, Fig. 2D, and is at the level of the top of the squiggles.

Conclusions: Pseudo-color images demonstrate changes that are not evident from viewing a video recording and so provide additional evidence about tear film dynamics and breakup.

TITLE: Safety of aflibercept for the eye under HTLV-1 infection status in vitro

SESSION TITLE: Antimicrobial Resistance, Epidemiology and New Antimicrobials

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. ZONG, K. Kamoi, H. Kurozumi-Karube, K. Ohno-Matsui, Ophthalmology & Visual Science, Tokyo Medical and Dental University, JAPAN|

Commercial Relationships Disclosure: YUAN ZONG: Commercial Relationship: Code N (No Commercial Relationship) | Koju Kamoi: Commercial Relationship: Code N (No Commercial Relationship) | Hisako Kurozumi-Karube: Commercial Relationship: Code N (No Commercial Relationship) | Kyoko Ohno-Matsui: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To clarify the safety of aflibercept for the eye under HTLV-1 infectious conditions in vitro.

Methods: Human retinal pigment epithelial cell line (HRPE) cell line was used as ocular resident cells, and MT2 and TL-Om1 were used as HTLV-1-infected cells. HRPE and MT2/TL-Om1 were co-cultured, and then aflibercept was administered. Production of cytokines and chemokines, HTLV-1 proviral load, cell growth rate and apoptosis of HRPE cells were measured to assess the effects of Aflibercept.

Results: When HRPE and MT2 or TL-Om1 were co-cultured, the secretion of inflammatory cytokine IL-6, IL-8, IFN-γ and chemokines MCP-1, IP-10, RANTES, MIG was increased significantly. The addition of aflibercept did not affect the level of IL-8, IFN-γ, MCP-1, IP-10, RANTES, MIG. IL-6 secretion in HRPE and TL-om1 co-culture was significantly increased. HTLV-1 proviral load of MT2 and TL-Om1was not significantly changed with treatment. No change in cell growth rate or apoptotic rate of HRPE was seen with the addition of Aflibercept.

Conclusions: Aflibercept could be used safely for the eye under HTLV-1 infectious conditions from the perspective of in vitro assessment.

ABSTRACT BODY:

Purpose: In cataract surgery, intraocular temperature changes when irrigating fluid and ophthalmic viscosurgical devices (OVD) are injected, and this temperature variation affects the unfolding of the intraocular lens (IOL). Extracted porcine eyes are used for experimental observation, which are unsuitable for observing the IOL in the capsule due to the low temperature of the eyes. In this study, we developed an eye holder that maintained ocular temperature close to body temperature and allowed the observation of temperature changes during cataract surgery.

Methods: An aluminum holder was designed to fit porcine eyes and to control ocular temperature. The temperature of the eye was set at approximately 36 degrees Celsius. Changes of intraocular temperature were monitored by a sensor placed inside the vitreous cavity. Cataract surgery consisting of anterior capsulotomy, hydrodissection, phacoemulsification and aspiration (PEA), and IOL insertion was performed.

Results: During cataract surgery, intraocular temperature varied. The most significant change was observed at the time of OVD injection into the capsular bag after PEA. The temperature dropped 5 degrees Celsius and remained stable during the unfolding of the IOL. The temperature changes were small during anterior capsulotomy, hydrodissection, and PEA.

Conclusions: The porcine eye holder enabled the observation of temperature changes during cataract surgery under similar conditions as clinical cases. The temperature reduction at the time of IOL implantation may decelerate the IOL unfolding process and cause an axis misalignment in the use of toric IOL.

TITLE: Exposure to subthreshold dose of UVR-B does not induce apoptosis in the rat lens in vivo during the first 24 hours.

SESSION TITLE: Lens proteins and cataracts

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Galichanin, Z. Yu, Uppsala Universitet, Uppsala, SWEDEN|

Commercial Relationships Disclosure: Konstantin Galichanin: Commercial Relationship: Code N (No Commercial Relationship) | Zhaohua Yu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The aim of this study is to investigate the time evolution of active caspase 3 in the rat lens after in vivo exposure to subthreshold dose of UVR-B.

Methods: Twenty six-week-old female albino Sprague-Dawley rats were exposed to subthreshold dose (1 kJ/m^2) of UVR-B unilaterally and sacrificed at 1, 8, 16 and 24 hours after exposure. Lenses were enucleated and active caspase 3 protein was detected by Western Blot. The time evolution was then plotted as a function of relative mean difference in active caspase 3 between exposed and nonexposed lenses.

Results: There is an expression of active caspase 3 in both exposed and nonexposed lenses but there is no difference in relative mean difference in active caspase 3 between exposed and nonexposed lenses in all four postexposure groups.

Conclusions: Exposure to subthreshold dose of UVR-B does not induce apoptosis in the rat lens in vivo within first 24 hours. Apoptosis occurs in the rat lens independently from the exposure to subthreshold dose of UVR-B.

ABSTRACT BODY:

Purpose: To develop a prognostic test based on serum samples obtained at diagnosis of uveal melanoma.

Methods: Eighty-three patients diagnosed with primary melanoma in the choroid or ciliary body at St. Erik Eye Hospital, Stockholm, Sweden between 1996 and 2000. Serum samples from peripheral blood were obtained at diagnosis and kept at -80 °C until this analysis.

Proteome profiling of 84 different cancer-related proteins was used to screen for potential biomarkers. ELISA was then performed to evaluated serum levels of the best candidates. Receiver operating characteristics were used to define thresholds for metastatic risk. A prognostic test was developed (serUM) in a training cohort and tested in a validation cohort.

Results: Of the 83 included patients, 43 (52 %) were female. Their mean age at diagnosis was 65 years (12.6 SD) their mean tumor diameter and thickness was 9.8 mm (3.7 SD) and 4.9 mm (2.3 SD). In proteome profiling, five proteins (Leptin, Osteopontin, Progranulin, Tenascin C and DLL-1) were included for further analysis. Receiver operating characteristics were used to define thresholds for metastatic risk. serUM, based on Leptin and Osteopontin concentrations, was developed in a training cohort (n=17) and then tested in a validation cohort (n=62) after exclusion of three patients with unreliable total protein fractions. Patients had gradually shorter cumulative metastasis-free survival with each increasing metastatic risk category (Log rank p for trend = 0.01). In multivariate Cox regression, serUM was an independent predictor of metastasis when entering all of tumor diameter, tumor thickness and patient age at diagnosis as covariates (hazard ratio 2.4, 95 % CI 1.0 to 5.3).

Conclusions: serUM, a prognostic test based on serum obtained from a peripheral blood sample at diagnosis of uveal melanoma, is a strong predictor of metastasis. Future prospective studies should aim to validate these findings.

ABSTRACT BODY:

Purpose: Automatic diagnosis of ocular anomalies using fundus photographs has shown great promises to scale-up screening. However, the generalization of the automated algorithms to new data which are very different from the training data, i.e issued from a different population, is a challenging problem. The objective of this study is to assess the generalizability of an AI algorithm on four datasets. Each dataset was collected from a specific population and annotated for a pre-defined set of ocular anomalies.

Methods: Four datasets were considered: OPHDIAT (France, diabetic population, 77,827 images), OphtaMaine (France, general population, 17,120 images), RIADD (India, general population, 3,200 images) and ODIR (China, general population, 7,000 images). In order to unify the ground-truth annotations, the annotation of each dataset was analyzed and converted into the ODIR annotation class system: Normal, Diabetes, Glaucoma, Cataract, AMD, Hypertension, Myopia and Other anomalies. Each dataset was then split into a training, a validation and a testing subset. Different scenarios were studied: the AI algorithm was trained using one of the four training subset and then tested on all the four testing subsets. In addition, AI was trained on the whole four training subsets (joint model). The AI algorithm was evaluated using the mean Area under the receiver operating characteristic curve (mAUC): the AUC was calculated independently for each pathology and then the average was computed.

Results: On OphtaMaine, the mAUC was 0.8799 for the AI trained on OphtaMaine, the best mAUC obtained without training on OphtaMaine was 0.8341 and the mAUC was 0.9338 for the joint model. On RIADD, the AI trained on RIADD reached a mAUC of 0.9164, the best mAUC obtained without training on RIADD was 0.8680, and the mAUC was 0.9169 for the joint model. On ODIR, the mAUC was 0.8803 for the AI trained on ODIR, the best mAUC obtained without training on ODIR was 0.8284, and the mAUC was 0.8865 for the joint model.

Conclusions:

The performances of the AI algorithm trained on a specific dataset were good when tested on data coming from the same population. However, when tested on different datasets, the performances of the AI algorithm degraded. This highlights the variability of experts interpretations among the four datasets. An AI trained on the four datasets performed better on the small datasets.

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) is a common neurovascular complication of diabetes. Retinal accumulation of the acrolein-derived advanced lipoxidation end-product, FDP-lysine (N^{ε}-(3-formyl-3,4-dehydropiperidino-lysine), has been implicated in the pathogenesis of this condition. We have identified a new drug called 2-HDP that is effective in scavenging acrolein and preventing retinal FDP-lysine accumulation during diabetes. The aim of this study was to determine whether 2-HDP can protect against neurovascular dysfunction during diabetes.

Methods: Male Sprague-Dawley rats were divided into three groups: (1) non-diabetic; (2) streptozotocin-induced diabetic; and (3) diabetic treated with 2-HDP administrated in their drinking water. In vivo analysis of blood pressure, body weights, water intake, HbA1c and electroretinography (ERG) were measured at 1-,3- and 6-months after diabetes induction. Immunolabelling, western blotting, cytokine arrays and the Evan’s blue dye assay were carried out to study the vascular, neuronal, and glial components of the retina. Molecular Dynamics (MD) simulations were performed to investigate 2-HDP drug permeation across cellular membranes.

Results: ERG a- and b-wave amplitudes were significantly reduced in diabetic controls after 3- and 6-months of diabetes and these changes were completely prevented by treatment with 2-HDP ($P<0.01$). This drug also prevented retinal FDP-lysine accumulation, the activation of Müller cells and microglia, and neuro and vasodegenerative changes in the diabetic retina ($P<0.05$). MD simulations have revealed that most 2-HDP molecules are protonated and do not readily cross cell membranes.

Conclusions: Our studies provide strong evidence for a key role of acrolein and FDP-lysine in the development of the neurovascular lesions associated with DR.

TITLE: The effect of past cataract surgery within the medium to long-term period on patients with Dry Eye Disease

SESSION TITLE: Dry Eye, Clinical

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Siew, L. Tong, Singapore Eye Research Institute, Singapore, SINGAPORE|L. Siew, National University of Singapore, Singapore, SINGAPORE|L. Tong, Singapore National Eye Centre, Singapore, Singapore, SINGAPORE|

Commercial Relationships Disclosure: Lei Siew: Commercial Relationship: Code N (No Commercial Relationship) | Louis Tong: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: With the prevalence of cataract surgery and increased patient expectations of improved vision, side effects increasing morbidity such as tear disorders should not be neglected. Several studies investigating the short-term effect of cataract surgery on Dry Eye Disease (DED) lack evaluation in the medium and longer term (beyond 3 months) and it was uncertain if dry eye parameters had returned to baseline. Hence, this study aims to evaluate the effects of cataract surgery on severity of clinical tear film parameters of patients with DED in the medium to long term period (6 months to 5 years) post-surgery.

Methods: A cross-sectional study was conducted on 448 eyes on first visit to a tertiary clinic (224 eyes with cataract surgery within timeframe, i.e. pseudophakic dry eye group, 224 comparison eyes without such history, i.e. comparison dry eye group). Parameters evaluated include Ocular Surface Disease Index (OSDI), Schirmer's I test score, Tear Break-up Time (TBUT), number of liquid expressing glands in lower lid, cornea fluorescein staining, corneal sensation, meibum character and follicular papillary reaction grade in the upper and lower fornices.

Results: A significantly greater proportion of pseudophakic dry eye group (49%) experienced frequent blurred vision (≥1 episode per week) compared to dry eye control group (37%) (OR=1.57, 95%CI 1.07, 2.31). Those with ocular discomfort before surgery were more likely to experience blurring at least once a day. In addition, a significantly greater proportion of pseudophakic dry eye group (34%) had Schirmer's I >8mm compared to the comparison group (24%) (OR=0.605, 95% CI 0.398, 0.921), though the difference was not clinically significant (7.51mm versus 6.51mm respectively, p>0.05). Other signs such as TBUT, number of liquid expressing glands in lower lid, cornea fluorescein staining, corneal sensation, meibum character and follicle grade did not differ between the two groups.

Conclusions: While uncomplicated cataract surgery does not worsen signs of DED, up to half of participants experienced greater frequency of blurred vision 6 months to 5 years post-cataract surgery, especially in those with ocular discomfort suggestive of dry eyes prior to surgery. Counselling for increased risk of transient blurred vision post-cataract surgery and dry eye prevention measures should be undertaken, especially those with suggestive symptoms pre-operatively.

ABSTRACT BODY:

Purpose: To quantify depolarization properties of the retinal pigment epithelium (RPE) to gain more insight into its structure and composition.

Methods: A custom-built spectral domain PS-OCT system operating at 860 nm with an A-scan rate of 70 kHz and an integrated retinal tracker was used to image 45 healthy volunteers (43 ± 16 years) and 19 glaucoma patients (62 ± 10 years) three times each at seven distinct regions around the macula (resulting in 21 measurements each consisting of 250 B-scans × 1024 A-scans and covering an area of 8 × 6 mm^2). After standard OCT data processing, the degree of polarization uniformity (DOPU) was calculated and DOPU at the RPE was projected onto an en-face map. The seven maps from the different regions imaged in each subject were averaged over the three measurements per measurement location and stitched together to create a map with a large field of view. On the large maps, a circular grid centered at the fovea, consisting of seven rings with diameters of 0.5, 1, 2, 3, 6, 9, and 12 mm and divided into 8 equal sectors, was placed. The mean DOPU value in each field of the grid was calculated for each participant.

Results: The averaged depolarization map of the 45 healthy volunteers (centered at the fovea) in Fig. 1(a) shows DOPU values at the RPE, where low values indicate stronger depolarization. Fig. 1(c) shows that the depolarization is strongest (lowest DOPU) in the rings next to the center (B, C) and that the depolarization is weaker at the center (A) and decreases towards the periphery (D to G). The results don't seem to differ between men and women, but DOPU values decrease with age.

The averaged depolarization map of the 19 glaucoma patients is shown in Fig. 1(b). It can be observed in Fig. 1(d) that the DOPU distribution in glaucomatous eyes appears to be very similar to healthy eyes, but the DOPU values are in general smaller. Since the glaucoma patients are in average older than the healthy volunteers, this could also be an age effect.

Conclusions: The polarization scrambling properties of the RPE of 45 healthy volunteers and 19 glaucoma patients were displayed in a large field of view map and quantified by calculating DOPU. A varied distribution of depolarization in the fundus could be shown, indicating a heterogeneous distribution of RPE pigmentation and geometry. Glaucomatous eyes showed lower DOPU values but a qualitative distribution similar to healthy eyes.

ABSTRACT BODY:

Purpose: Variable methods of analysing optical coherence tomography angiography (OCTA) images makes comparing different OCTA studies challenging. We performed a prospective observational study investigating agreement between retinal blood flow metrics calculated using different techniques and within different analysis packages. We hypothesised that measures assessing an underlying physiological parameter would show high agreement, whilst measures that did not relate to the patients' underlying physiology would not.

Methods: We recruited patients undergoing major upper gastrointestinal surgery with planned post-operative care in the intensive therapy unit (ITU) and individuals already admitted to the ITU with sepsis. OCTA scans from 31 right eyes (24 males, 7 females) and 29 left eyes (24 males, 5 females) were included in the final analysis. Custom metrics from MatLab (vessel density [VD], fractal dimension [FD], and their skeletonised analysis [SVD and SFD respectively]) and Heidelberg Engineering ([HE]; Mean vessel length density and Skeletonised analysis) were compared for agreement using intraclass correlation coefficient (ICC).

Results: There was strong agreement between HE Mean and Matlab VD measures, reaching an ICC of 0.84, and moderate agreement between HE Skeleton and Matlab VD with ICCs between 0.48-0.65 depending on eye and vascular layer. There was no agreement between any HE measures and FD with ICCs between 0.24-0.49, or between any of the metrics and Matlab skeletonised values with ICCs as low as 0.04. There was variable agreement between eyes, ranging from 0.28 for SFD to 0.90 for VD.

Conclusions: Our results showed moderate to good agreement between the metrics of the different analysis packages, except for FD, and that skeletonising OCTA scans for retinal blood flow analysis reduced agreement between analysis packages and techniques. The low agreement between HE and FD suggests that these measures assess different and unrelated blood flow parameters. The poor agreement from the skeletonised values suggest that non-skeletonised metrics may be preferred and reported in OCTA studies.

ABSTRACT BODY:

Purpose: Existing clinical assessment methods for ocular chemical exposures are primarily qualitative examinations limited to the surface of the eye and can be subjective. Anterior segment optical coherence tomography (AS-OCT) offers a solution to this issue, allowing for non-invasive and high-resolution imaging of anterior segment structures. AS-OCT thereby provides the ability to quantify pathological changes over time, even in the presence of corneal opacity or fibrosis, which are both considerable hinderances to current methods.

Methods: Following an IACUC-approved protocol, acute injury model of chemical exposure was performed in a mouse model through topical application of a 2 mm diameter circle of filter paper soaked in 2.5 mg/mL acrolein or 1.0M NaOH to the right eye for 30 seconds. AS-OCT was performed on the cornea and iris simultaneously, before the chemical burn and up to 21 days following the burn. OCT angiography (OCTA) was performed using a custom algorithm that is designed to reconstruct the morphological and vascular features of the cornea. Corneal thickness of each eye was measured in ImageJ. Eyes were enucleated on day 21 for histology.

Results: For both chemical agents, AS-OCT/OCTA revealed corneal neovascularization and ulceration by day 21; however, the progression of injury differs significantly. Acrolein exposure initially presents with minor injury (e.g., slight corneal swelling) that apparently recovers until a rebound occurs between 14-21 days, including neovascularization and corneal thickness changes. In contrast, alkali exposure led to an immediate inflammatory response accompanied by severe corneal opacification and swelling (146%) that progressively worsened, peaking at 296% on day 14. Neovascularization was first detectable at day 7 by OCTA and encroached into the central cornea.

Conclusions: AS-OCT was able to clearly visualize the progression of chemical injury and identified qualitative and quantitative image-based biomarkers that assess injury severity and progression, validated through histology. The clinical availability of AS-OCT has the potential to enhance our understanding of ocular injury and different patterns of progression in chemical exposures to improve clinical assessment for better management and treatment development.

TITLE: Association of proton pump inhibitors use with severity of dry eye symptoms and signs in the DRy Eye Assessment and Management (DREAM©) Study

SESSION TITLE: Dry Eye, Clinical

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Yu, P.A. Asbell, G. Ying, Ophthalmology, University of Pennsylvania Perelman School of Medicine, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Yinxi Yu: Commercial Relationship: Code N (No Commercial Relationship) | Penny Asbell: Commercial Relationship(s);Code C (Consultant/Contractor):Glia, Senju, Blephex;Code F (Financial Support):Regeneron, Mitotech, Sylentis, Tear Science, MC2, NIH/NEI, RPB | Gui-Shuang Ying: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A recent large population-based hypothesis-free study found that proton pump inhibitors (PPIs) use is highly associated with presence of dry eye disease (DED) symptoms[1]. In this study, we examined the association between PPIs use and severity of DED symptoms and signs among participants in the DREAM© study, a multi-center randomized clinical trial to evaluate the effect of omega-3 fatty acid supplements for the treatment of dry eye.

Methods: At baseline, self-reported PPIs use and the specific drug name were collected using medication log. At baseline, 6 and 12 months, DED symptoms were evaluated using the Ocular Surface Disease Index (OSDI), DED signs in each eye were evaluated for tear break up time (TBUT), Schirmer's test, corneal fluorescein staining, conjunctival lissamine green staining, and Meibomian gland dysfunction (MGD). Generalized linear models were used to compare the scores of DED symptoms and signs between PPIs users and non-users, with adjustment for age, gender, race, visit, history of acid reflux, comorbidities that were previously found to be associated with severity of DED symptoms and signs in the DREAM study. The correlation among repeated measures of DED symptoms and signs at baseline, 6 and 12 months and the inter-eye correlation of DED signs were accounted for by using generalized estimating equations.

Results: Among 535 participants with moderate-to-severe DED, 114 (21.3%) were PPIs users at baseline, with 71 (13.3%) using Omeprazole, and 22 (4.1%) using Pantoprazole. Compared to PPI non-users, PPIs users were significantly older (mean [SD] age 62.7 [10.7] vs. 56.7 [13.5], $p<0.001$), more likely to self-report ongoing acid reflux (82.5% vs. 19.5%, $p<0.001$). When data from baseline, 6 and 12 months were combined, PPIs use at baseline was not associated with severity of dry eye symptoms or signs (Table 1, all adjusted $p\geq0.24$). Specifically, uses of either Omeprazole or Pantoprazole were not associated with severity of DED symptoms or signs compared to non-users (Table 2, all adjusted $p\geq0.08$).

Conclusions: Among DREAM participants with moderate-to-severe DED, PPIs use was not associated with severity of dry eye symptoms and signs.

ABSTRACT BODY:

Purpose: Retinal ischemia is implicated in many vision-threatening eye diseases, yet no effective treatment is available. Creatine serves a critical role in protecting tissue during ischemia. We hypothesize that prophylactic treatment with Creatine and Metformin will prevent impairments of retinal oxygen metrics and retinal layer thinning after bilateral common carotid artery occlusion (BCCAO).

Methods: Twenty rats were divided into 3 groups: sham, treatment (Tx), and vehicle. Rats in Tx and vehicle groups received intraperitoneal injections of Creatine + Metformin and saline, respectively. Daily administrations were initiated 7 days prior to and continued 7 days after BCCAO. Multimodal imaging was performed 7 days after BCCAO to measure retinal arterial and venous oxygen contents (O_{2A}, O_{2V}), total retinal blood flow (TRBF), and total retinal thickness (TRT). Arteriovenous oxygen content difference (O_{2AV}), oxygen delivery (DO_2), metabolism (MO_2), and extraction fraction (OEF) were calculated. Retinal sections were stained to measure retinal layer thickness. Linear mixed model analysis and ANOVA were used to compare metrics among groups.

Results: Compared to the sham group, TRBF, DO_2, and MO_2 were reduced, while O_{2AV} was increased in the vehicle group ($P<0.02$). In the Tx group, no differences were detected in O_{2AV}, DO_2, and TRBF compared to the sham group ($P>0.2$), whereas MO_2 was reduced ($P= 0.002$). Compared to the vehicle group, O_{2AV} was decreased in the Tx group ($P=0.04$), whereas no differences were detected in TRBF, DO_2, MO_2, OEF, O_{2A}, and O_{2V} ($P>0.1$). No differences were observed in O_{2A}, O_{2V}, and OEF among groups ($P>0.08$). Compared to the sham group, TRT and thickness of inner retina (IRL) and photoreceptor (PRL) layers were reduced in the vehicle group ($P<0.02$). In the Tx group, TRT and thickness of inner nuclear layer (INL) were not different compared to the sham group ($P>0.4$), whereas thickness of IRL and PRL were reduced ($P<0.03$). Compared to the vehicle group, thickness of retinal ganglion cell + nerve layers (RGC/NFL) was increased in the Tx group ($P=0.04$), whereas no differences were detected in IRL, inner plexiform layer (INL), and PRL ($P>0.1$). No differences were detected in outer plexiform and outer nuclear layers among groups ($P>0.3$).

Conclusions: Prophylactic treatment with Creatine and Metformin prevented elevations in O_{2AV} and increased RGC/NFL thickness after incomplete retinal ischemia.

ABSTRACT BODY:

Purpose: To characterize the impact of SLC4A11 mutations associated with congenital hereditary endothelial dystrophy (CHED) and Fuchs endothelial corneal dystrophy type 4 (FECD4) on corneal endothelial cell (CEnC) function and SLC4A11 protein localization.

Methods: Human $SLC4A11^{-/-}$ CEnC lines were generated by CRISPR-Cas9 mediated gene editing. SLC4A11 wildtype ($SLC4A11^{WT}$) and SLC4A11 mutant ($SLC4A11^{MU}$) human CEnC lines were generated by stable transduction with lentiviruses containing either $SLC4A11^{WT}$ or $SLC4A11^{MU}$ expression vectors harboring CHED-/FECD4-associated SLC4A11 mutations (CHED: c.374G>A, c.1813C>T, c.2263C>T; FECD4: c.2224G>A). Functional assays were performed to assess cell migration, proliferation, viability after induced oxidative stress and NH_4Cl-induced membrane conductance in the generated $SLC4A11^{WT}$, $SLC4A11^{MU}$ and $SLC4A11^{-/-}$ CEnC lines. Cell barrier function in $SLC4A11^{WT}$ and $SLC4A11^{-/-}$ CEnC were assessed by electric cell-substrate impedance sensing (ECIS). Immunostaining was performed to determine the subcellular localization of SLC4A11 protein in the generated $SLC4A11^{WT}$ and $SLC4A11^{MU}$ CEnC lines and human primary CEnC.

Results: $SLC4A11^{-/-}$ CEnC and the majority of the $SLC4A11^{MU}$ CEnC lines exhibited significantly increased migration rates, altered proliferation, and decreased cell viability under oxidative stress compared to $SLC4A11^{WT}$ CEnC. Induction with 10mM NH_4Cl led $SLC4A11^{WT}$ CEnC to depolarize; conversely, $SLC4A11^{-/-}$ CEnC hyperpolarized and the majority of $SLC4A11^{MU}$ CEnC either hyperpolarized or had minimal membrane potential changes following NH_4Cl induction. Based on ECIS modeling, $SLC4A11^{WT}$ CEnC demonstrated increased cell-substrate adhesion and membrane capacitances compared to $SLC4A11^{-/-}$ CEnC. Immunostaining of primary CEnC and $SLC4A11^{WT}$ CEnC lines for SLC4A11 demonstrated predominately cell surface staining with partial colocalization with mitochondrial marker COX4 within punctate subcellular structures. $SLC4A11^{MU}$ CEnC lines also displayed mainly cell surface staining of SLC4A11, except for $SLC4A11^{MU}$ c.2263C>T CEnC, which exhibited mostly perinuclear staining.

Conclusions: CHED- and FECD4-associated SLC4A11 mutations likely lead to CEnC dysfunction, and ultimately CHED and FECD4, by interfering with cell migration, proliferation, viability, membrane conductance, barrier function, and/or cell surface localization of the SLC4A11 protein in CEnC.

TITLE: Altered Mitochondrial Dynamics and Diabetic Keratopathy

SESSION TITLE: Corneal Cell and Molecular Biology | Corneal Development

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Mohammad, R.A. Kowluru, Department of Ophthalmology, Visual and Anatomical Sciences, Wayne State University, Detroit, Michigan, UNITED STATES|

Commercial Relationships Disclosure: Ghulam Mohammad: Commercial Relationship: Code N (No Commercial Relationship) | Renu Kowluru: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Keratopathy is one of the most frequent clinical problems faced by diabetic patients, and this potentially sight-threatening condition is caused mainly by corneal epithelial disturbances. Diabetes impairs corneal epithelial cells functionally, morphologically and biochemically, and overproduction of mitochondrial superoxide radicals is considered as a causal link between elevated glucose and the major biochemical pathways implicated in the development of keratopathy. Mitochondria are dynamic structures, and depending on the energy demand, they continuously fuse and divide. An imbalance in the fusion-fission can alter their membrane potential, respiration and bioenergetics. Mitochondria dynamics is regulated by GTPases; fission is mainly controlled by dynamin-related protein1 (Drp1) and fusion by mitofusin-2 (Mfn2) and optic atrophy1. During mitochondrial fission, fission protein 1 (Fis1) and mitochondrial fission factor (Mff) direct Drp1 to the fission site. The aim of this study was to investigate the role of mitochondrial dynamics in the development of diabetic keratopathy.

Methods: Cornea from streptozotocin-induced diabetic rats (3 months duration) were used to quantify mitochondrial reactive oxygen species (ROS) by DCFDA, and expression of Drp1, Fis1, Mff, Mfn2 and OPA1 by quantitative real time PCR (β-actin as a housekeeping gene). Effect of diabetes on the expressions of Drp1 and Mfn2 was confirmed in the corneal cryosections by immunohistochemical technique.

Results: Compared to normal rats, ROS were elevated, and while Drp1, Fis1 and Mff expressions were increased, Mfn2 and OPA1 were decreased in the cornea from diabetic rats. While immunofluorescence of Drp1 was increased in the corneal epithelial cell layer from diabetic rats, that of Mfn2 was significantly decreased.

Conclusions: Our data demonstrate an impaired corneal mitochondria fusion-fission machinery in diabetes, suggesting an important role of mitochondrial dynamics in the development of diabetic keratopathy.

ABSTRACT BODY:

Purpose: Endothelial signal transducer and activator of transcription 3 (STAT3)-induced intravitreal neovascularization (IVNV) in oxygen-induced retinopathy (OIR) represents retinopathy of prematurity (ROP). To understand pathways involved in endothelial STAT3-induced IVNV, we performed bulk RNA-sequencing of transcripts isolated from human retinal microvascular endothelial cells (HRMECs) transfected with STAT3 siRNA or control siRNA, and treated with vascular endothelial growth factor (VEGF) or vehicle control. We found STAT3 was necessary to differentially regulate genes involved in VEGF-induced mitosis and vascular development signaling pathways. In this study, we used a data-driven approach to cluster the differentially expressed genes based on expression patterns and tested the hypothesis that VEGF-induced STAT3 mediates angiogenic signaling pathways involved in ROP.

Methods: Hierarchical clustering with Ward's linkage method and Euclidean distance metric was performed using scaled regularized log counts of the differentially expressed genes (n=353). Pathway enrichment analysis of the differentially expressed genes within the clusters was assessed by Ingenuity Pathway Analysis (IPA) software. An adjusted p-value < 0.05 was considered statistically significant following Benjamini and Hochberg multiple testing correction.

Results: Hierarchical clustering resulted in the visual identification of 4 clusters of genes. Regardless of VEGF or PBS treatment, knockdown of STAT3 downregulated cluster 1 (n=113) and upregulated cluster 3 (n=116) compared to control. Compared to control, knockdown of STAT3 reduced upregulation of cluster 2 (n=44) by VEGF and reduced downregulation of cluster 4 (n=80) by VEGF. IPA identified significant pathway enrichment in G2/M cell cycle checkpoint regulation, IGF-1 signaling, or JAK/STAT signaling in cluster 1, and glioblastoma multiforme signaling or signaling by Rho family GTPases in cluster 3. No significant pathway enrichment was observed in cluster 2 or 4.

Conclusions: Our results corroborate our previous analysis that STAT3 regulates angiogenesis in HRMECs by mediating transcripts involved in mitosis and identified additional pathways implicated in angiogenesis. Further testing of the identified signaling pathways in cultured HRMECs and the OIR model might lead to a better understanding of the mechanisms involved in IVNV in ROP.

ABSTRACT BODY:

Purpose: To report the estimated incidence, cumulative rate, risk factors, and outcomes of submacular hemorrhage (SMH) with loss of vision in neovascular age-related macular degeneration (nAMD) receiving intravitreal injections (IVT) of vascular endothelial growth factor (VEGF) inhibitor in routine clinical practice.

Methods: Retrospective analysis of treatment-naïve eyes receiving IVT of VEGF inhibitors (ranibizumab, aflibercept, or bevacizumab) for nAMD from 1 January 2010 to 31 December 2020 that were tracked in the Fight Retinal Blindness! registry. Estimated incidence, cumulative rate, and hazard ratios (HR) of SMH with loss of vision were measured using Poisson regression, Kaplan-Meier survival curves, and Cox-proportional hazards models. Locally weighted scatterplot smoothing curves were used to plot visual acuity (VA) between SMH cases and matched controls.

The main outcome measures were the estimated incidence of SMH with loss of vision and change in VA 12 months after SMH.

Results: This study included 7642 eyes (6425 patients) with a total of 135095 IVTs over a 10-year period. One hundred five eyes developed SMH with loss of vision with a rate of 1 per 1283 injections (0.08% 95% confidence interval [95%CI] [0.06; 0.09]). The estimated incidence [95%CI] was 4.6 [3.8; 5.7] SMH with loss of vision per year per 1000 treated patients during the study. The cumulative [95%CI] rate of SMH per patient did not increase significantly with each successive injection ($p = 0.947$). Men (hazard ratio [HR] [95%CI] = 1.71 [1.26; 2.16] vs. women, $p = 0.019$) and patients with disciform scar CNV type (HR = 12.35 [10.76, 13.94] vs. Type 1 CNV; $P = 0.002$) at baseline were significantly more likely to develop SMH with loss of vision in our study. There was little evidence that SMH was related to under-treatment. SMH cases had a mean VA drop of around 6 lines at diagnosis, which then improved moderately to a 4-line loss at one year.

Conclusions: SMH with loss of vision is an uncommon complication that can occur at any time in eyes treated for nAMD in routine clinical practice, with only limited recovery of vision one year later.

ABSTRACT BODY:

Purpose: Anti-VEGF therapies for neovascular age-related macular degeneration (nAMD) have significantly revolutionised outcomes for millions of people. However, anti-VEGF drug efficacy and vision deteriorates in a significant proportion of individuals due to subretinal fibrosis. We designed a gene therapy capable of preventing, or reversing, subretinal fibrosis and neutralising pathological VEGF concentrations responsible for neovascularisation.

Methods: Bi-cistronic plasmids and rAAV2/2 vector constructs expressing both anti-VEGF and anti-fibrotic components were examined in HEK293T, ARPE-19 cells and on co-cultures of human fibroblast/HUVECs. The lead constructs were evaluated in rodent models.

Results: The lead constructs express a novel anti-VEGF capture protein that has a reduced affinity for human IgG-Fc gamma receptors than aflibercept. The constructs reduce endogenous VEGF concentrations (ng/mL) in HEK293Ts (control Null plasmid = 663 ± 15, IKC116P = 275 ± 7***, aflibercept = 296 ± 4***; $P<0.001$ by ANOVA followed by Bonferroni modified t-tests, mean ± SEM of 3 replicates) and attenuates capillary formation in co-cultures with equivalent efficacy to aflibercept. The anti-fibrotic component attenuates transforming growth factor (TGF)-beta-induced epithelial-mesenchymal transition, a precursor to subretinal fibrotic scar formation, as shown by the reduction in ARPE-19 fibronectin (control Null plasmid = 2.64 ± 0.32, IKC116P = 1.96 ± 0.26; $P<0.05$, n=4) and release of matrix metalloprotease-2 (control Null plasmid = 1.46 ± 0.09, IKC116P = 0.28 ± 0.04; $P<0.0001$, n=4) by western blot. Intravitreal injection of the lead vectors completely prevented vascular leakage after laser-induced CNV in mice compared to the vehicle controls.

Conclusions: The novel anti-VEGF component is equipotent to aflibercept in VEGF neutralisation. Moreover, the incorporation of an anti-fibrotic transgene reduced TGF-beta induced early scar formation in ARPE-19 cells. This bi-cistronic gene therapy has the potential to address subretinal fibrosis in patients with deteriorating vision currently treated with anti-VEGF therapies.

TITLE: Semi-Automated Blood Velocity Determination Using Adaptive Optics Scanning Laser Ophthalmoscopy XT Images

SESSION TITLE: Multidisciplinary Ophthalmic Imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Huang, N. Konopek, J. Moonjely, A.A. Fawzi, Department of Ophthalmology, Northwestern University Feinberg School of Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Jonathan Huang: Commercial Relationship: Code N (No Commercial Relationship) | Nicholas Konopek: Commercial Relationship: Code N (No Commercial Relationship) | Jessica Moonjely: Commercial Relationship: Code N (No Commercial Relationship) | Amani Fawzi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal blood velocity can be determined by measurement of erythrocyte streak angles relative to vessel angles on Adaptive Optics Scanning Laser Ophthalmoscopy (AOSLO) space-time or XT images, in which successive one-dimensional scans of retinal vessels are stacked. Variability in manual erythrocyte angle determination may contribute error to blood velocity assessment. We evaluated inter-rater concordance between manual and semi-automated measurements of erythrocyte streak angles on AOSLO XT images.

Methods: We implemented a novel semi-automated method in which regions of interest are manually drawn around erythrocyte streaks. An algorithm automatically performs Yen thresholding and weighted least squares regression to determine streak angles measured against the horizontal. The three shallowest angles are averaged to enable maximal blood velocity calculations. For comparison, two reviewers manually measured and averaged the three shallowest angles of each XT image using ImageJ software. Bland-Altman plots and concordance correlation coefficients were evaluated to compare measurement methods.

Results: Our analysis included 16 XT image frames from 4 eyes of 4 patients. The mean difference in average angle measurement was -3.07 and -1.75 degrees for the semi-automated method compared to the first and second reviewers, respectively, indicating that the semi-automated method identified shallower erythrocyte angles than manual reviewers. The mean difference was -0.58 degrees when comparing the semi-automated method with the minimum of the two angles measured between the two manual reviewers. The concordance correlation coefficient was 0.92 for the two manual reviewers, 0.93 and 0.97 for the semi-automated method and the respective manual reviewers, and 0.99 for the semi-automated method and the smaller of the two manual measurements.

Conclusions: By evaluating a range of streaks in an individual AOSLO XT image, the semi-automated method more consistently identified the shallowest erythrocyte streak angles than manual evaluators. Implementation of this semi-automated workflow may improve measurement consistency, increase throughput, and reveal more insights about retinal blood flow metrics.

ABSTRACT BODY:

Purpose: The opioid epidemic remains a public health concern in the United States. This study investigated current opioid dosage rates in ophthalmology based on patient demographics and diagnosis and quantified the effect of an opioid alert system on prescription practices in this retrospective, pre and post implementation study.

Methods: A retrospective chart review was conducted of opioid prescriptions written by ophthalmologists between January 3, 2015, and November 3, 2021. An opioid alert system was implemented in December 2017. The study population was divided into three cohorts based on when an individual's prescription was written: prior to system implementation (cohort 1), while the system was active, but not recorded in the EHR (cohort 2), or while the system was both active and recorded in the EHR (cohort 3). Dosage was measured in morphine equivalent daily dose (MEDD). Mean MEDD per prescription and mean number of prescriptions per patient were compared based on patient demographics, diagnosis, and cohort. For statistical analysis, independent t-tests and linear mixed effects models were completed.

Results: 8014 individuals were included in this study with 4388, 2276, and 1350 individuals in cohorts 1, 2, and 3 respectively. The majority of individuals were female (59.26%) and white (82.31%). There was no significant difference in mean MEDD based on patient demographics when comparing cohorts. However, when considering all cohorts together, black individuals received the highest mean MEDD (33.93 MEDD, $p = 0.03$ compared to white individuals) and male individuals received a higher mean MEDD when compared to females (33.53 MEDD; $p < 0.001$). While not statistically significant, glaucoma was the diagnosis category with the highest mean MEDD per prescription (34.94 MEDD). Mean MEDD per prescription decreased by 15.44 between cohorts 1 and 3 ($p < 0.001$) after implementation of the electronic alert system.

Conclusions: This study demonstrates significant differences in opioid prescription dosage based on patient demographics. The observed decrease in opioid prescription dosage following the alert system may indicate system realization. Patient demographics provide foci for opioid prescription reform in ophthalmology however significant differences between patient diagnosis were not demonstrated.

ABSTRACT BODY:

Purpose: Lens surface properties can contribute to improved contact lens comfort. Herein, in-vitro lens surface characteristics of a novel silicone hydrogel contact lens (SHCL) of verofilcon A and a traditional SHCL of narafilcon A were assessed by both sessile drop contact angle (SDCA) and coefficient of friction (CoF).

Methods: 10 lenses each of verofilcon A and narafilcon A were assessed using both SDCA and a micro-tribometer. Prior to measurement, study lenses were prepared to remove package solution components by using 20 mL of saline solution. This step was repeated until the surface tension demonstrated they were free of surfactants. Each study lens was placed into the cycling machine for 1, 2, 3, 4, 6, 8, 10, 12, 14 and 16 hours (repetitive cycles of 1 sec in saline solution and 10 sec in air). The lens holder was positioned directly beneath the dosing needle of the micro syringe on the sample holder stage of the SDCA equipment. A 3 µL drop of phosphate buffer solution (PBS) was formed on the tip of the dosing needle. Micro-tribometer assessment was performed at both 0.1mm/s and 8cm/s sliding speed with artificial tear solution including lysozyme and PBS. For frictional aging, 50 tribometer cycles were assessed after the saline/air cycling. Statistical analyses were performed using two sample t-test.

Results: For SDCA at 16 hours, verofilcon A was 42.5° and narafilcon A was 91.4°, verofilcon A was superior to narafilcon A including remaining assessment hour ($p<0.0001$). CoF at 8cm/s sliding speed after 50 tribometer cycles and 16 hours showed verofilcon A was 0.8667 and narafilcon A was 1.5251 ($p<0.001$). Assessment after 1 hour to 14 hours also showed verofilcon A was superior to narafilcon A ($p<0.001$). CoF without the 50 cycle frictional aging at both 8cm/s and 0.1mm/s sliding speed showed statistical differences of verofilcon A compared to narafilcon A at 16 hours (each $p<0.0001$).

Conclusions: This is the first in-vitro study for both SDCA and CoF on lens surface assessment with multiple hour blink emulation between verofilcon A and narafilcon A. SMARTSURFACE® Technology in verofilcon A maintained excellent lens surface properties in an assessment of both SDCA and CoF.

TITLE: Diabetic Retinopathy: Regulation of Ceramide Production and Rac1 Activation

SESSION TITLE: Cell biology of retinal diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Alka, R.A. Kowluru, Department of Ophthalmology, Visual and Anatomical Sciences, Wayne State University, Detroit, Michigan, UNITED STATES|

Commercial Relationships Disclosure: Kumari Alka: Commercial Relationship: Code N (No Commercial Relationship) | Renu Kowluru: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In the development of diabetic retinopathy, cytosolic reactive oxygen species (ROS) are elevated before mitochondrial damage can be observed, and NADPH-oxidase 2 (Nox2) and its regulatory cytosolic component, small molecular weight G protein (Rac1), are considered to play a major role. Hyperglycemia is shown to accelerate and exacerbate transcriptional and functional activation of retinal Rac1, and its promoter undergoes active DNA methylation-hydroxymethylation, leading to increased levels of 5hydroxymethyl cytosine (5hmC). Lipid excess also leads to increased ceramide, and serine palmitoyl-transferase (SPT) is the first and the rate-determining enzyme in its biosynthesis. Our aim was to investigate the mechanism by which ceramide promotes Rac1 activation in diabetic retinopathy in type 2 diabetic (T2D) model.

Methods: C57BL/6 mice were fed high fat diet (45% kcal) for 8 weeks, after which a group of mice were administered a low dose of streptozotocin (30 mg/kg body weight; T2D). Soon after establishment of diabetes, a group of mice received intravitreal administration of 2µg/2µl SPT-siRNA, and these mice were maintained on the same high fat diet for 5 weeks. Age-matched normal mice on a regular mice chow were used as controls. Retinal microvessels (prepared by osmotic shock method) were used to measure Rac1 activity (G-LISA), Nox2 activity (lucigenin) and ROS (DCFDA method). Transcriptional regulation of Rac1 was determined by quantifying 5hmC levels (immuno-capture technique) at its promoter.

Results: Compared with normal mice, the activity of Rac1, Nox2 and ROS were significantly increased in T2D group, and Rac1 transcripts and 5hmC levels at its promoter were also significantly elevated. Administration of SPT-siRNA prevented increase in Rac1, Nox2, ROS, and also ameliorated 5hmC at Rac1 promoter.

Conclusions:

Thus, accumulation of ceramide in diabetes increases ROS production through transcriptional and functional activation of Rac1. This suggests that regulation of ceramide in diabetic patients with hyperlipidemia may be equally important as regulating their blood sugar to prevent the development of retinopathy.

ABSTRACT BODY:

Purpose: (1) To develop a deep learning algorithm to automatically and simultaneously identify major tissue structures of the optic nerve head (ONH) in 3D optical coherence tomography (OCT) scans; (2) to exploit such information to robustly differentiate among healthy, optic disc drusen (ODD), and papilledema ONHs.

Methods: This was a cross-sectional comparative study including ethnically diverse patients from 3 sites (in Singapore, Australia, Denmark) with confirmed ODDs (105 eyes), papilledema due to high intracranial pressure (51 eyes), and healthy controls (100 eyes). Volume raster scans of the ONHs were acquired using Spectralis OCT, then processed with adaptive compensation to improve deep-tissue visibility. In a first step, a deep learning algorithm was developed using 984 B-scans (from 130 eyes) in order identify: major neural and connective tissues, and ODD regions whenever present. The performance of our segmentation algorithm was assessed (against manual segmentations) using the dice coefficient. In a second step, a classification algorithm (random forest) was designed using 150 OCT volumes to perform 3-class classifications (class 1: ODD, class 2: papilledema, class 3: healthy) strictly from their drusen and prelamina swelling scores that were directly calculated from the segmentations. To assess performance, we reported the area under the receiver operating characteristic curves (AUCs) for each class (one-vs-all).

Results: Our segmentation algorithm was able to simultaneously isolate neural & connective tissues, and ODD regions whenever present (Figure). This was confirmed by an averaged Dice coefficient of 0.93±0.03 on the test set, corresponding to very good segmentation performance. Classification was achieved with very high AUCs, i.e. 0.99±0.01 for the detection of ODD, 0.99±0.01 for the detection of papilledema, and 0.98±0.02 for the detection of healthy ONHs.

Conclusions: A relatively simple AI approach allows to accurately discriminate ODD from papilledema, strictly using a single OCT scan of the ONH. Our classification performance was excellent, with the caveat that validation in a much larger population is warranted for clinical acceptance. Our approach may have the potential to establish OCT as the mainstay of diagnostic imaging for optic nerve disorders in neuro-ophthalmology.

TITLE: Accommodation-induced changes in ciliary body length and thickness, peripheral choroidal thickness and peripheral axial length

SESSION TITLE: Myopia: Clinical Interventions and Diagnostics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D.A. Atchison, D. Kaphle, M. Suheimat, K.L. Schmid, Optometry and Vision Science, Queensland University of Technology Faculty of Health, Kelvin Grove, Queensland, AUSTRALIA|

Commercial Relationships Disclosure: David Atchison: Commercial Relationship(s);Code F (Financial Support):Carl Zeiss Vision | Dinesh Kaphle: Commercial Relationship: Code N (No Commercial Relationship) | Marwan Suheimat: Commercial Relationship(s);Code F (Financial Support):Carl Zeiss Vision | Katrina Schmid: Commercial Relationship(s);Code F (Financial Support):Carl Zeiss Vision

ABSTRACT BODY:

Purpose: To determine relationships between accommodation-induced changes in ciliary muscle parameters, peripheral choroidal thickness, peripheral axial length. We hypothesized that changes in ciliary muscle parameters and in choroidal thickness are correlated.

Methods: There were 29 young adults aged 18 and 27 years. All had good ocular and general health. Measurements of right eyes were made for 0 D and 6 D stimuli to accommodation at both nasal and temporal locations.

Axial length AL was measured with a Lenstar LS 900 biometer (Haag-Streit, Switzerland), with an auxiliary system to allow eye rotation in 10° steps to ±30°. Participants turned eyes without head movement to fixate targets and to make the target “as clear as possible” during measurements. Choroidal thickness CTh was measured with the Nidek RS-3000 Advance spectral-domain (SD)-Optical Coherence Tomography (OCT) in 10° steps to ±30°. For peripheral images, the internal cross target on the capture screen was moved from the centre to 17.25° nasal/temporal positions. Ciliary muscle length CML and maximum thickness were determined by imaging ciliary bodies of right eyes with a Carl Zeiss Meditec Visante OCT and an external fixation target placed at 40° to the instrument axis.

Changes in AL, CTh, CML and CMT with accommodation were denoted as ΔAL, ΔCTh, ΔCML and ΔCMT. For each participant, the three ΔCTh on each retinal side were averaged for comparison with corresponding muscle parameters.

Results: Nasal ΔCMT and ΔCML mean±SEs were 88±19 and −89±34μm, respectively. Corresponding temporal changes were 82±20 and −111±57μm.

Fig. 1 shows correlations between ΔCTh and ΔCMT on the nasal (r 0.30, p 0.13) and temporal (r 0.31, p 0.19) sides, neither of which were significant. Neither ΔCTh v. ΔCML correlation was close to significance (p 0.87, 0.89).

Fig. 2 shows ΔAL and ΔCTh as a function of visual field position; error bars are standard errors. ΔAL was greater than −ΔCTh at all positions. Maximum changes occurred on-axis Correlations were non-significant at all positions.

Conclusions: Individual parameters changed in expected directions with accommodation: AL, CMT increased; CTh, CML decreased. However, correlations between changes in parameters were not significant. This may be because of considerable variation between individuals and because individual accommodation responses were not the same for all instruments.

ABSTRACT BODY:

Purpose: To evaluate corneal endothelial cell number and the expression of neurokinin-1 receptor (NK1R) in the endothelium in normal vs. ocular GVHD (oGVHD) corneas and to correlate the density of endothelial cells with clinical and histological inflammatory parameters.

Methods: Pre-conditioning was performed in BALB/c using myeloablative total body irradiation. Subsequently, allogeneic bone marrow transplantation was infused without (BM, n=8) or with mature T cells (BM + T, n=8). BM and normal wild type mice (n=7) were used as controls. Corneal transparency and blepharitis were assessed at the end of the experiment (day 29). After sacrifice, endothelial cell number, corneal thickness, and CD3+ cells were quantified, and the expression of NK1R was investigated in the corneal endothelium through immunofluorescence and quantified by immunohistochemistry.

Results: oGVHD mice showed a significant reduction in the endothelial cell number compared to controls ($p<0.0001$). In addition, NK1R expression was found in the endothelium, and it was significantly increased in oGVHD vs. control mice ($p<0.05$). Corneal transparency and thickness remained unchanged in all groups. An inverse correlation was found between endothelial cell number and the CD3+ cell infiltrate (Pearson $r= -0.8712$, $p<0.05$) and with blepharitis severity (Pearson $r= -0.5959$, $p<0.01$).

Conclusions: Our findings suggest that oGVHD is associated with reduced corneal endothelial cell density and increased expression of endothelial NK1R. Corneal endothelial cell loss correlates with increased expression of clinical and histological markers of inflammation.

TITLE: Evaluating the performance of naive trainees on a virtual reality cataract surgery simulator

SESSION TITLE: Cataract surgery 1

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Z. Yu, A. Popa, Uppsala Universitet, Uppsala, SWEDEN|

Commercial Relationships Disclosure: Zhaohua Yu: Commercial Relationship: Code N (No Commercial Relationship) | Alexandru Popa: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the phacoemulsification performance of non-experienced trainees using a virtual reality cataract surgery simulator.

Methods: Ten medical students familiar with the anatomy and physiology of the eye, but naive to cataract surgery, were admitted to the study. Each subject was introduced to the simulator and then registered 40 simulations spanning 10 consecutive days with 4 simulations each day. Each simulation contains two phases, the capsulorhexis plus sculpting phase and the evacuation phase. The simulator automatically measured 38 variables during the simulation. All the variables were converted to performance index previously formulated by Söderberg et al. to assess the performance in both phases.

Results: In the capsulorhexis plus sculpting phase the asymptote of the trainee overall performance index was, estimated as 95% CI, 0.9±0.7 and a number of simulations needed to reach 90% of the asymptote was 37±24, indicating that the performance asymptote of a naive trainee achieves approximately after 40 simulations. An average incidence of capsular damage was 30% for the first 10 simulations whereas 9% for the last 10 simulations. In the evacuation phase the trainee overall performance index of 1 which is equivalent to the reference performance index was reached within the first 5 simulations and quickly plateaued, and less performance variation and better performance correlated with more training on the simulator.

Conclusions: A high-level performance asymptote occurs in the capsulorhexis plus sculpting phase after 40 simulations. In the evacuation phase performance asymptote can be reached at very early stage. Evacuation is less difficult than capsulorhexis plus sculpting.

ABSTRACT BODY:

Purpose: Multiple Sclerosis (MS) causes progressive neurodegeneration characterised by demyelination of neurons and axonal loss. MS also affects the visual system with evidence of inner retinal degeneration; however, this does not fully explain vision loss experienced by patients. The Belfast Eye and Multiple Sclerosis (BEAMS) study aims to investigate if outer retina photoreceptor cells display changes in MS.

Methods: Sixteen patients with MS and 24 controls were enrolled. All patients underwent OCT (Heidelberg Spectralis) and AO (Imagine-Eyes RTX1). OCT analysis used in-built HEYEX automatic segmentation software (aberrations manually corrected) for peripapillary retinal nerve fibre layer (pRNFL), macular ganglion cell layer-inner plexiform layer (GCIPL), and photoreceptor layer (PRL) thicknesses (photoreceptor inner and outer segments). AO images were analysed semi-automatically by the cone segmentation algorithm (AODetect) and manually corrected. Images were captured at 2, 4 and 6-degree eccentricity. Control (ctrl) participants were compared to patients with MS with optic neuritis (MSON) or without optic neuritis (MSnON). Data were analysed using SPSS and GraphPad Prism.

Results: Results identified significant thinning of the pRNFL (Ctrl 106.63±1.60; MSON 89.08±3.94 $p<0.0001$; MSnON 106.54±2.81) and macular GCIPL (Ctrl 73.19±1.24; MSON 61.48±1.91; $p<0.0001$; MSnON 71.21±1.30). No significant differences were observed in MSnON compared to ctrl. In contrast, there was significant thickening of the PRL in patients with MS (Ctrl: 66.24±0.29; MSON 68.76±0.58 $p<0.0001$; MSnON 67.67±0.46 $p=0.011$). After analysing the AO images, we found a significant decrease of cone outer-segment densities in patients with both MSON and MSnON compared to ctrl at 2, 2.5 and 3 degrees (MSON $p<0.0001$; MSnON $p=0.0002$). At >3 degrees the cone densities remained significantly lower in MSON ($p=0.0002$) but not in MSnON ($p=0.0614$).

Conclusions: OCT analysis in the BEAMS study replicates the previously reported thinning of the inner retinal layers. However, we report here for the first time, significant thickening of the photoreceptor layer on OCT, a loss of cone outer segments in patients on images from AO in patients with MS. These results highlight a potential involvement of the outer retina in the pathophysiology of MS changes that could become a marker for monitoring the progression of MS.

ABSTRACT BODY:

Purpose: It seems that, among others, immune processes, elevated intraocular pressure (IOP), or a combination of these factors are responsible for glaucomatous damage. Here, we combined two glaucoma models to examine if multifactorial risk factors (IOP and immune response) lead to a more severe damage of retinal ganglion cells (RGCs) and additional microglia activation.

Methods: Six-week-old wildtype (ONA) and βB1-CTGF mice (combination), a genetic OHT model, were immunized with 1 mg ONA (optic nerve antigen). A wildtype (control) and a βB1-CTGF control group (CTGF) received NaCl instead. 6 weeks after immunization, retinae were evaluated for RGCs (RBPMS), microglia/macrophages (Iba1), and microglia (Iba1 and Tmem119) via immunohistology. Further, mRNA levels of corresponding genes were analyzed via RT-qPCR.

Results: A significant RGC loss was noted in ONA ($p=0.02$), but not in CTGF mice ($p=0.60$) compared to controls. In the combination group, significantly fewer RGCs were noted compared to WT ($p<0.001$) and CTGF mice ($p=0.03$). The Pou4f1 mRNA levels (RGCs) were significantly downregulated in CTGF and combination retinae (both: $p=0.04$) compared to controls, while only a trend towards a downregulation was noted in ONA animals ($p=0.055$). The number of $Iba1^+$ cells in the ganglion cell layer (GCL) was significantly increased in CTGF ($p<0.05$) and combination mice ($p<0.001$) compared to control and ONA animals. Significantly more $Iba1^+$ and $Tmem119^+$ microglia were only found in the GCL of combination retinae (1.93±1.30 cells/mm) compared to control (0.29±0.44 cells/mm) and ONA mice (0.38±0.43 cells/mm; both $p<0.001$). The number of $Iba1^+$ and $Tmem119^+$ cells was also increased in the combination group compared to CTGF retinae (0.48±0.64 cells/mm; $p=0.001$). Similar results for $Iba1^+$ and $Iba1^+$ and $Tmem119^+$ cells were observed when counting from GCL to outer plexiform layer. The mRNA expression levels of Iba1 showed no difference within the groups, while a significant upregulation of Tmem119 mRNA could be observed only in CTGF retinae ($p=0.02$).

Conclusions: We revealed an enhanced RGC degeneration accompanied by an increased microglia activation. These results underline the important role of immunological processes, not only in autoimmune glaucoma, but also in IOP-dependent pathologies. Hence, this new model could help to study the pathomechanisms of this multifactorial disease more precisely.

TITLE: Machine learning approaches to automated prediction of fibrosis development in neovascular age-related macular degeneration using optical coherence tomography images

SESSION TITLE: Machine Learning: Segmentation and Classification

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Maunz, I.L. Jones, B.G. Armendariz, S. Yu, F. Hoffmann-La Roche Ltd., Basel, SWITZERLAND|J. Hernandez-Sanchez, Roche Products Ltd, Welwyn Garden City, Hertfordshire, UNITED KINGDOM|L. Barras, Genentech Inc, South San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure: Andreas Maunz: Commercial Relationship(s);Code E (Employment):Roche, Inc. | Ian Jones: Commercial Relationship(s);Code E (Employment):Roche, Inc. | Jules Hernandez-Sanchez: Commercial Relationship(s);Code E (Employment):Roche, Inc. | Beatriz Armendariz: Commercial Relationship(s);Code E (Employment):Roche, Inc. | Laura Barras: Commercial Relationship(s);Code E (Employment):Genentech, Inc. | Siqing Yu: Commercial Relationship(s);Code E (Employment):Roche, Inc.

ABSTRACT BODY:

Purpose: To build and validate machine learning (ML) models using optical coherence tomography (OCT) volume scans for predicting the onset of fibrosis in patients with neovascular age-related macular degeneration (nAMD).

Methods: 935 OCT volume scans from 1097 treatment-naïve eyes with nAMD treated with ranibizumab 0.5 or 2.0 mg on a monthly or as-needed basis over 12 months were selected post hoc from the phase 3, randomized, multicenter HARBOR trial (NCT00891735). Retinal layers and pathological features were automatically detected in the OCT volume scans using a pretrained segmentation model. ML models were trained and evaluated using OCT and/or clinical variables (choroidal neovascularization [CNV] type assessed using fluorescein angiography [FA], baseline visual acuity, and age) in 2 approaches. For feature-based learning, 90 quantitative OCT features were automatically extracted from the segmentations. For end-to-end deep learning (DL), 2 models were trained with raw (DL-raw) and segmented (DL-seg) OCT B-scans.

Results: Binary classification of fibrosis development was assessed as area under the receiver operating characteristic curve (AUC), sensitivity, and specificity, using cross-validation. The DL-seg model predicted fibrosis development with average AUC values of 0.802, similar to the DL-raw model and feature-based learning (AUC = 0.786 for both), and was generally on par with the predictive performance of clinical variables only (AUC = 0.794). Notably, CNV type alone achieved an AUC of 0.747. Adding clinical variables did not considerably improve performance for DL-seg (from 0.802 to 0.809), but improved performance for DL-raw (from 0.786 to 0.808) and feature-based learning (from 0.786 to 0.821).

Conclusions: Fully automated models using OCT segmentation data can predict fibrosis development well. The DL-seg model, DL-raw model, and feature-based learning all achieved comparable performance in predicting fibrosis and were also comparable to the clinical variables only model, which requires invasive procedures and expert training for image interpretation (FA). These findings show that ML using OCT segmentations is a promising noninvasive approach to predicting fibrosis development in nAMD.

ABSTRACT BODY:

Purpose: As a pleiotopic pathway with great angiomodulatory potential, the STAT3 pathway represents an attractive therapeutic target for the treatment of vasoproliferative retinal diseases. IL11, a member of the IL6 cytokine family, is a potent activator of the STAT3 pathway. However, the role of IL11 in the retina is still poorly understood. The aim of this study is to characterize the modulatory effect of IL11 on retinal angiogenesis.

Methods: The concentrations of IL11 and IL11 receptor (IL11R) in human vitreous samples from 16 proliferative diabetic retinopathy (PDR) and 16 control patients were determined by ELISA.

The angiomodulatory effects of VEGF, IL11, soluble IL11R and combinations thereof on human vascular endothelial cells (HUVECs) were determined by spheroid sprouting and migration assays. Transcriptomic shifts were assessed by RNA sequencing.

In the model for oxygen induced retinopathy the retinal vasculature of Bl6/J mice were examined after injection with either IL11, IL11+sIL11R or PBS.

Intracellular signaling pathways in HUVECs and murine Müller cells were studied by Western blot.

Results: While IL11R is significantly upregulated in vitreous samples from PDR patients (ñ=118 pg/mL) compared to the control patients (ñ=1 pg/mL), the concentration of IL-11 showed no significant difference (ñ≈3 pg/mL).

In-vitro, IL11 primarily activated the STAT3 signaling pathway (cis-signaling) and caused a significant reduction of VEGF-induced sprouting in HUVECs (Δ= -15%; $p<0.05$). Interestingly, the combination of IL11 and sIL11R (trans-signaling) enhanced cell sprouting and migration (Δ= +21.6%; $p<0.05$). Western blot analyses revealed that IL11 trans-signaling simultaneously activated STAT3 and STAT1 as well as AKT in HUVECs resulting in a significant transcriptomic shift favoring angiogenesis.

In-vivo, IL11 and IL11+sIL11R both led to a significant reduction in retinal neovascularization (N=15; $p<0.05$). Cryosections of murine eyes after injection suggested that Müller cells respond to IL11 treatment with no differences in intracellular signaling in response to IL11 cis- or trans-signaling.

Conclusions: The different angiogenic properties of IL11 and IL11+sIL11R can be explained by individual signaling responses and associated transcriptomic shifts. The elevated IL11R levels in vitreous samples from PDR patients suggest that IL11 signaling play an important role in PDR pathogenesis, providing an entirely new perspective on its role in angiogenesis.

ABSTRACT BODY:

Purpose: The risk of retinal, RPE damage and vitreous reflux increases with increased injection pressure during subretinal injections. Using a model chamber in which injection and chamber pressure can be modulated, this study aims to identify the optimal injection characteristics for subretinal drug delivery.

Methods: A 38 G outer diameter subretinal injection cannula proximally attached to a MicroDose™ Injection device filled with colored water was inserted through a 23 G valved trocar into a 38 cm^3 closed chamber with a defined inner pressure generated by an external compressor. The foot pedal-controlled viscous fluid injection (VFI) modes of two different vitrectomy systems (R-Evolution™ CR from BVI-Optikon and Stellaris Elite™ from Bausch and Lomb) were used to inject the solution with an injection pressure ranging from 1 to 50 psi with predefined chamber pressures of 10 , 20 and 30 mm Hg. Each injection was recorded using a video recording system. The following parameters were analyzed : pressure recording in the model, injection pressure, velocity of the injected solution, presence of an unintentional flow after release of the foot pedal.

Results: The predefined pressure recorded inside the model was constant and unaffected by the different injections pressure levels chosen on the VFI. A minimal pressure of 6 psi was needed to generate a flow inside our model. From 6 to 9 psi, the velocity of the flow was categorized as slow. Higher than 10 psi, we observed a flow with high exit velocity (figure). In all cases, a persistent flow was observed after releasing the foot pedal in VFI mode. The quantity of fluid increased when increasing the level pressure of injection.

Conclusions: Increased Injection pressure are associated with less controlled, high exit velocity flow characteristics. The model appears appropriate to study flow control and its possible role in RPE loss in the context of gene therapy.

TITLE: An Evolution of Telerehabilitation for Low Vision Follow-ups

SESSION TITLE: Mental Health Outcomes and Vision Rehabilitation Services

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: A.K. Bittner, Ophthalmology; Stein Eye Institute, University of California Los Angeles, Los Angeles, California, UNITED STATES|N. Ross, New England College of Optometry, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Ava Bittner: Commercial Relationship(s);Code C (Consultant/Contractor):jCyte, Inc. | Nicole Ross: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: For studies of telerehabilitation to provide follow-up assessment and training to low vision (LV) patients with newly prescribed magnification devices, we examined whether different approaches to reduce the burden of the technology over the past 5 years had impact on ratings of the telerehabilitation encounter.

Methods: Our previous telerehabilitation studies for follow-ups with LV subjects at home connected loaner Android/iPad tablets to zoom videoconferencing via either remote phone-based support by investigators (phase 1 in 2016-17; n=10) or local Lions Club volunteers who went to participants' homes (phase 2 in 2018-19; n=11), followed by a randomized controlled trial (phase 3 in 2020-21) in which remote control access software connected loaner smartphones to zoom (n=20) or training was provided in-office (control group; n=12). Subjects in all phases completed the same post-telerehabilitation phone survey.

Results: A significantly greater proportion of phase 3 subjects indicated they strongly or mostly agreed that the technology did not interfere with the session (95%) than in phase 1 (60%; OR:3.6; 95%CI:1.1-11.7; p=0.036) or phase 2 (55%; OR:15.8; 95%CI:1.5-164; p=0.02), whereas there was no significant difference in this aspect between phases 1 and 2 (p=0.80). The majority (76%) agreed that telerehabilitation was as accurate as in-person, and 84% strongly or mostly agreed they were interested in another future session, with no significant differences between phases (all p>0.10). Despite only 39% who had previously used any videoconferencing, nearly all (93%) strongly or mostly agreed they were comfortable with evaluation and training via telerehabilitation; there were no significant differences in comfort, prior videoconferencing, or frequency of Internet use between phases (all p>0.10). In phase 3 when comparing ratings for telerehabilitation to in-office training, there were no significant differences for subjects' comfort level (p=0.29), overall satisfaction (p=0.67), whether self-rated magnifier use improved after the session (p=0.22) or interest to have another session (p=0.30).

Conclusions: Study participants across all phases reported high levels of acceptance for telerehabilitation, with less interference of technology when remote control access was used during the pandemic. There were no significant differences in ratings when comparing subjects randomized to telerehabilitation or in-office care during the pandemic.

ABSTRACT BODY:

Purpose: To investigate immobilisation of a novel antifouling cyclic peptide APi1775 (gr14Z-BBC2) onto contact lenses which can produce antifouling activity against ocular pathogenic bacteria P. aeruginosa.

Methods: Increasing concentration (0.1 µM, 1.0 µM and 10 µM) of APi1775 (gr14Z-BBC2) peptide (amino acid sequence Cyclo[Lys-Ser-Val-His-Ser-Phe-Asp-Tyr-Asp-Trp-Tyr-Asn-val-BetaAla]) was immobilized on to Acuvue2® (Etafilcon A) contact lenses using EDC covalent binding as described earlier. Peptide immobilization was characterised by amino acid analysis. Antifouling and antimicrobial activity of the coated contact lenses were tested against Pseudomonas aeruginosa strain 6294 and strain 142 in the presence of saline and tear like fluid over 18 hours by viable plate count. The peptide coated contact lenses were tested for in vitro toxicity towards mammalian cells following ISO standard 10993-5 guidelines.

Results: Amino acid analysis revealed that contact lenses processed with 0.1 µM, 1.0 µM and 10 µM peptide were able to bind 3.71µg, 19.94µg and 23.16µg peptide respectively. The peptide immobilised contact lenses showed a dose-response with respect to antifouling activity against P. aeruginosa adhesion. Inhibition by the peptide coated lenses ranged between 77% (0.8 log) to 96% (1.5log) against P. aeruginosa adhesion when they were processed with 1.0 µM, and 10.0 µM peptide respectively. The cytotoxicity tests confirmed that the peptide coated contact lenses are not toxic to mammalian cells in vitro.

Conclusions: The current study showed that APi1775 peptide coating on commercial contact lenses can demonstrate significant antifouling activity leading to inhibition of bacterial adhesion to contact lenses. The APi1775 peptide coating may have the capacity to reduce microbial eye infections during human contact lens wear.

ABSTRACT BODY:

Purpose: Indonesia is a rapidly growing county with over 262 million inhabitants, but among highly populated countries it has one of the lowest concentrations of eye care providers. This study evaluates the cost-effectiveness of a program implemented in South Sulawesi, Indonesia that trained schoolteachers to conduct vision screenings, organized in-school evaluations by opticians, and provided free eyeglasses to schoolchildren with refractive error (RE).

Methods: Schoolteachers across 6 districts in South Sulawesi were trained to screen children with possible RE for subsequent evaluation by opticians. All costs associated with designing and implementing the program (administration, training personnel, labor, service delivery, etc.) were assessed. Expenditures and outcomes data were utilized to calculate the cost per disability-adjusted-life-year (DALY) for this intervention using 2010 and 2016 Global Burden of Disease (GBD) weights.

Results: 521 teachers screened 41,212 students across 172 schools in South Sulawesi. 4,506 (10.9%) students failed screening, 2,652 were seen by optometrists, and 2,038 received glasses. 1,854 (41.1%) students that failed screenings did not follow-up. The total program cost was $97,380, which included glasses (39.6%) and labor (23.3%). In districts with school-based refraction services, the costs per student screened, refracted, and receiving glasses were $2.57, $31.33, and $41.40, respectively; costs were $2.04, $59.80, and $73.22 when district services were instead provided centrally. Assuming an 18.4% prevalence of uncorrected refractive error in South Sulawesi, the estimated cost per DALY averted was $89.04 by GBD 2010 weights.

Conclusions: Treating children with correctable RE in limited resource settings can be done cost-effectively through school-based models.

TITLE: Selective elimination and analysis of nestin (+) optic nerve laminar region-neural progenitor cells (ONLR-NPCs)

SESSION TITLE: Neuro-ophthalmology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.L. Bernstein, Y. Guo, Z. Mehrabyan, Ophthalmology and Visual Sciences, University of Maryland School of Medicine, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Steven Bernstein: Commercial Relationship(s);Code C (Consultant/Contractor):Constant Pharmaceuticals;Code P (Patent):PCT/US19/16303 | Yan Guo: Commercial Relationship: Code N (No Commercial Relationship) | Zara Mehrabyan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Dissociating the roles of Nestin(+)/Sox2(+) NPCs present in the optic nerve laminar region (ONLR) from those in the retina are difficult to achieve because: 1) Most current approaches to eliminate Sox2(+) cells result in depletion of these cells in both the retina and ONLR. 2) Most Nestin(+) transgenic animals do not express the nestin-associated transgene in the ONLR. 3) It is difficult to determine whether effective treatments are reaching the target cells. We wanted to identify an appropriate model and approach to selectively deplete ONLR-NPCs, using transgenic mice expressing nestin-promotor drivers.

Methods: The C57BL/6-Tg(Nes-cre/ERT2)KEisc/J strain was crossed with ROSA 26-LoxP (DTA), and following Tamoxifen induction, ONLR's were assayed for elimination of nestin expression. The C57BL/6-Tg(Nes-TK*,-EGFP)145Sker/J) strain constitutively expresses GFP and viral thymidine kinase (Kernie, 2012). GFP(+) cells in the ONLR and retina were evaluated using immunohistochemistry. Nestin(+) cells were eliminated in the latter transgenic strain using either IP injection X 3 weeks of Ganciclovir (50mg/kg/d) or 3 week CNS adminstation of ganciclovir (GCV: Cytovene, 47.5mg/ml) using 2 or 4 week Alzet pumps attached to a intraventricular pump (Alzet pump 3). We evaluated ganciclovir distribution by doping the GCV fill with 0.5-2% fluorescein, and analyzing retinal and optic nerve fluorescence using a Heidelberg SD-OCT instrument with the blue peak fluorescent setting.

Results: No elimination of ONLR-nestin(+) cells occurred in the the Eisch strain. The Kernie strain exhibited scattered GFP(+) cells in the retina and ONLR. Systemic GCV administration resulted in the loss of GFP immunopositivity in both tissues. Administration of GCV by intraventricular pump using both the 2- and 4 week (1/2 the rate of dosing) eliminated GFP(+) NPCs in the ONLR, but not the retina.Positive continuous GCV dosing in the intraventricular cannalized mice was demonstrable best with 1% fluorescein, but also easily detectable with 0.5% fluorescein.

Conclusions: Selective elimination of ONLR-NPCs is possible via intraventricular dosing of GCV, and this can be reproducibly demonstrated at 2-, 3- and 4 weeks administration.The single 4 week Alzet pump used eliminated >90% of GFP(+) cells in the ONLR, while sparing retinal GFP(+) cells. Analysis of isolated ONLR-NPC functions in vivo are possible using this approach.

ABSTRACT BODY:

Purpose: Ascertain the one-year outcome of patients who sustained open eye injuries from the Beirut Port Ammonium Nitrate (AN) Explosion.

Methods: Retrospective chart review of the operated eyes in 2 major eye hospitals. The recorded data included age, gender, laterality, initial visual acuity, anterior and posterior segment examinations, the type of injury, and the Zone of Injury (Zone 1: wound limited to the cornea, Zone 2: wound of the sclera and no more posterior than 5 mm from the limbus, and Zone 3: wound posterior to anterior 5 mm of sclera).

Results: Out of 42 patients with open globe injury that was originally sutured, 29 patients (34 eyes) were followed at the one-year mark. The initial vision in logMAR (mean±SD) was 2.93±0.87 (hand motion equivalent) and the final vision was 1.80±1.47 (counting finger 2m equivalent). No light perception (NLP) vision was noted in 12 eyes on presentation and 10 eyes remained so, while 2 eyes reached light perception (LP) vision. Eight eyes had an intraoperative expulsive choroidal hemorrhage (7 NLP and 1 LP both pre- and postoperatively), and 6 of the 8 developed phthisis. All eyes that developed phthisis had NLP preoperatively and postoperatively. Ocular Trauma Score (OTS) correlated inversely with both initial and final vision ($p<0.001$). Zone of injury inversely correlated with initial vision ($p=0.02$) and positively with final vision ($p<0.001$). Final vision was significantly worse in Zone 3 vs. Zones 1 and 2 (3.2±0.5) vs. 0.9±1.1) ($p<0.001$) injuries, as was the initial vision (3.3±0.5 vs. 2.7±0.8; $p=0.002$).

Conclusions: The OTS, which provides prognostic information for serious ocular trauma, also yields valuable prognostic information for AN-associated ocular injuries. Expulsive choroidal hemorrhage and NLP vision at presentation remain very poor prognostic signs.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is a degenerative disease of the retina which can be classified into early, intermediate, and advanced phenotypes. It is recognized that the complement system plays a key role in the pathogenesis of AMD. While advances have been made in the treatment of wet AMD, the only approved therapy for dry AMD to date is AREDS supplementation. There is a paucity of research on the mechanisms behind the effectiveness of AREDS supplementation in reducing the risk of AMD progression. Given the important prognostic and therapeutic value of the intermediate phenotype of AMD (iAMD), the goal of this study was to determine if there was a difference in complement factors among patients with iAMD taking AREDS supplementation compared to those with iAMD not taking AREDS supplementation

Methods: Patients with iAMD were drawn from a biorepository registry of patients with AMD. The diagnosis of iAMD was confirmed with multimodal imaging. Plasma complement factor levels were measured by ELISA and multiplex Luminex immunoassays. Non-parametric Wilcoxon tests were used to compare levels for each analyte by AREDS supplementation

Results: We identified 211 patients with iAMD, of which 92 were on AREDS supplementation at time of study enrollment and 119 were not. The results for all the complement factors measured are shown in Table 1. We found lower levels of C3 ($p=0.05$) and C5a ($p<0.01$) in patients taking AREDS supplementation compared to those not on AREDS supplementation. There were no differences between the groups for the other complement factors measured

Conclusions: We demonstrate significant differences in two important components of the complement system including complement factor C3 and the activation fragment C5a in patients with iAMD taking AREDS supplementation compared to patients not taking AREDS. Our results suggest that further studies are needed in a larger cohort of patient with iAMD to establish the relationship of complement system activity and AREDS supplementation. These results can shed light on the mechanism of action of AREDS supplementation and the reason for reducing risk of progression to advanced AMD forms

ABSTRACT BODY:

Purpose: Glaucoma is a leading cause of blindness affecting millions of people worldwide. Glaucoma is characterized by neurodegeneration of retinal ganglion cells (RGCs), the projection neurons of the retina. The mammalian retina lacks an endogenous regenerative capacity so loss of RGCs results in permanent blindness. Therefore, an impetus exists to develop strategies to replace lost neurons to offer therapeutic hope to patients. In this study, we provide evidence that Muller glia (MG) cells in the adult mouse retina can be stimulated to regenerate RGC-like cells.

Methods: To induce retinal regeneration we previously developed a transgenic mouse model that allowed for MG-specific inducible expression of the proneural transcription factor Ascl1 (Glast-CreER/LNL-tTA/TetO-Ascl1-GFP). We developed a regeneration paradigm in which Ascl1 induction followed by NMDA-induced neural toxicity and histone de-acetylase inhibition stimulated MG-mediated regeneration of bipolar neurons in the adult mouse retina. In this project, we sought to regenerate retinal ganglion cells by overexpressing RGC-fate determining factors in combination with Ascl1. We generated a mouse to overexpress the RGC-factors Pou4f2 (Brn3b) and Islet1 in MG in vivo (Glast-CreER/LNL-tTA/TetO-Ascl1-GFP/TetO-Pou4f2-Islet1). We then used our previously established in vivo regeneration paradigm to test whether overexpression of Pou4f2 and Islet1 in Ascl1-expressing MG could alter the fate of regenerated neurons towards the RGC-lineage. We used immunohistochemistry, scRNA-seq, and scATAC-seq to characterize the regenerated neurons.

Results: Following our in vivo regeneration paradigm, immunohistochemistry analysis of MG-lineage traced cells revealed that the combination of Pou4f2/Islet/Ascl1 stimulated around 25% of MG to regenerate neurons expressing RGC markers (Pou4f2, Satb1, HuC/D). This neural phenotype was not observed with Ascl1-alone. Follow up characterization using scRNA-seq, reveal these regenerated neurons express many genes associated with developing RGCs and axon outgrowth. scATAC analysis confirms that Pou4f2/Islet1 shifts the chromatin accessibility of Ascl1-induced neurons to a state more akin to endogenous RGCs

Conclusions: This work demonstrates a strategy to induce endogenous regeneration of RGC-like cells from MG.

ABSTRACT BODY:

Purpose: Red–green color vision deficiency (CVD) is the most common single locus genetic disorder in humans; however, only 25% of CVD individuals are dichromats who rely on two cone types for color vision. 75% are anomalous trichromats whose CVD is milder, being based on three cone types, but who are nevertheless referred to as “colorblind.” Here, we present an algorithm that computes the relative loss of color discrimination in red-green CVD individuals with varying degrees of deficiency and simulates these conditions by transforming the colors in a digital image.

Methods: Our algorithm uses the association between discrimination data from the Nagel anomaloscope and measured spectral separations from anomalous trichromats to simulate color discrimination in anomalous trichromats more generally. Using the measured primaries of an anomaloscope and cone fundamentals derived from a physiologically based photopigment template, we can predict the Rayleigh match and matching range for any pair of middle-to-long wavelength cone photopigments. This information is used to simulate the relative loss in color discrimination of an anomalous trichromat by comparing the predicted matching range against the average color normal range and applying that % loss to a digital image through LMS Daltonization.

Results: The resulting model generates accurate simulations of CVD at any severity, as defined by the spectral separation between the two middle-to-long wavelength cones, with Rayleigh match and matching range values that agree with results from anomalous trichromats who have had their cone photopigments characterized by molecular genetics. We used the model to transform a wide range of test images, all of which illustrate the significant gap in color discrimination between dichromats and even the most severe anomalous trichromats. Even a spectral separation of 2.5 nm, with a corresponding 87.9% loss in color discrimination, leaves sufficient color information to pass the Farnsworth D-15 and identify the primary colors in most real-world scenes.

Conclusions: An accurate simulation of CVD at every level of severity could play an important role in establishing more inclusive employment standards for color critical work by educating the public on the difference between color “deficient” and color “blind.” As our model illustrates, most CVD individuals are very capable of discerning the colors in their environment.

ABSTRACT BODY:

Purpose: We have previously reported optic nerve head (ONH) lamina cribrosa deformation, thickening and insertion migration in NHP early EG. Here we test the hypothesis that retrolaminar (RL) myelin alterations accompanied by alterations of astrocyte and microglial markers are also present in NHP early EG.

Methods: Four unilateral early EG NHPs were sacrificed by 4% paraformaldehyde perfusion fixation. For each NHP, EG and Control (C) eye ONH tissues were trephined (10 mm circular blade), and cut vertically, embedded in paraffin and serially sectioned 5µm sections (Fig 1). For-each immunohistochemical (IHC) marker, n=4 near-adjacent ONH sections were deparaffinized, stained with the primary antibody [myelin basic protein (MBP), 2',3'-Cyclic-nucleotide 3'-phosphodiesterase, (CNPase), glial fibrillary acidic protein, (GFAP), or ionized calcium binding adaptor molecule 1, (Iba1)] incubated with fluorescent secondary antibodies and cover slipped using a NucBlue mountant. Whole section images were acquired and ONH anatomic landmarks were manually segmented, allowing signal intensity per unit area or cell density to be assessed in consistent RL anatomic regions. Animal specific (AS) and experiment wide (EW) EG versus C eye signal differences were analyzed using a series of linear mixed effects models.

Results: CNPase and MBP decreased significantly in EG versus C eyes (EW, ($p<0.001$)) in both RL regions and in at least 1 RL region of 3 of 4 NHPs individually (AS, $p<0.02$) (Table 1). GFAP decreased and NucBlue and Iba1(+) cell counts increased in both retrolaminar regions (EW, $p<0.01$), and in 3 or 4 NHPs individually for (GFAP and NucBlue only). CNPase, GFAP and MBP expression decreased (EW, $P<0.05$) in the peripheral versus central (Fig 1) RL sub-regions in C eyes. EG vs control eye increases in Iba1(+) expression were greater peripherally than centrally ($p=0.023$).

Conclusions: Decreased myelin–related protein expression within the immediate retrolaminar ONH tissues in NHP early EG is accompanied by decreased GFAP expression and increased NucBlue and Iba1(+) cell counts. Retrolaminar myelin homeostasis may be a neuroprotective target for enhancing axonal survival in glaucoma whether its disruption primarily contributes to axonal injury or is secondary to its occurrence.

TITLE: A Descriptive Study of Diabetic Retinopathy Disparities among Millions of Patients

SESSION TITLE: Diabetic retinopathy epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.K. Shaia, Population and Quantitative Health Sciences, Case Western Reserve University, Cleveland, Ohio, UNITED STATES|D. Kaelber, The MetroHealth System, Cleveland, Ohio, UNITED STATES|

Commercial Relationships Disclosure: Jacqueline Shaia: Commercial Relationship: Code N (No Commercial Relationship) | David Kaelber: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) is a leading cause of blindness that affects one third of the diabetic population worldwide. The prevalence of this condition is only expected to grow with estimates of 16 million American's being affected by DR by 2050. The purpose of this study was to complete a descriptive study of patients with DR in the United States among tens of millions of patients.

Methods: 53,287 and 345,420 patients with Type 1 (T1) and Type 2 (T2) DR were identified in the TriNetX database (a combined electronic health records database of over 50 systems) utilizing encounter ICD codes. Data was gathered ondemographics, average body mass index (BMI), and average glycated hemoglobin (A1C) values. Proportions, percentages, and chi-square tests were calculated to evaluate T1 and T2 DR.

Results: Of the 74 million patients, 0.77% and 6.1% of patients had T1 or T2 diabetes. Of those patients, 9.3% of T1 and 7.1% of T2 had DR. When comparing ethnicity among those with T2 DR, the odds of DR among those who were Black was 1.41 times the odds of DR among those who were white (CI 1.40, 1.42). This opposite disparity was found among those with T1 DR who were Black as it was 0.96 times the odds of DR among those who were white (CI 0.94, 0.97). Additionally, when calculating the odds of Black women having T2 DR, they were 1.04 times more likely to have DR then Black men (CI 1.03, 1.05). This was similar in T1 DR patients where Black women were also more likely than Black men to have DR with an odds ratio of 1.08 (CI 1.04, 1.12). When comparing men and women who were white who had T2 DR, the odds ratio was 1 indicating no difference between genders (CI 0.99, 1.01) whereas in T1 DR, the odds of being a white woman was 1.04 (CI 1.04, 1.06). Lastly, the odds of having T1 or T2 diabetes without DR among white women was 0.79 and 0.80 times the odds compared to white men (CI 0.78, 0.79; 0.8, 0.8). A comparison of A1C levels and BMI did not find any significant differences between gender or ethnicity ($p>0.001$).

Conclusions: This large population descriptive study highlights increased odds of DR in Black individuals with T2 diabetes compared to white individuals and an increase in all types of DR in Black women compared to black men. Further research is needed to understand why these differences exist.

ABSTRACT BODY:

Purpose: To characterize central corneal thickness (CCT), tear osmolarity and blink rate longitudinally in a non-human primate (NHP) model, the common marmoset (Callithrix Jacchus), in untreated compared to animals treated with contact lenses (CL).

Methods: Longitudinal changes in CCT (N=20; 10CL), osmolarity (N=10; 6CL) and blink rate (N=18; 10CL) were assessed using high frequency A-scan ultrasound (25 MHz, Panametrics, NDT), I-PEN Vet Tear Osmolarity System (I-MED Pharma Inc), and a video recording system (745 frames/minute) from 70 days to 150 days (5 months) at approx. 9am, and again after 9hrs of CL wear (methafilcon A, 55% water content; Capricornia, Australia). Data was assessed for normality. Repeated measures ANOVA and student T-test were used to compare treated to control eyes over time.

Results: At baseline, untreated marmosets had a mean±SD CCT of 0.305±0.008 mm, osmolarity 311.67±11.48 mOsms/L and blink rate 1.83±1.79 blinks per minute (bpm), which remained stable over 5 months, except blink rate that increased to 5.32±1.58 bpm ($p<0.01$) after 5 months. In CL-treated marmosets, CCT increased during the second month of CL wear (baseline: 0.299±0.007 mm; 2 months: 0.307±0.008 mm, $p<0.05$) and stabilized afterwards. Osmolarity progressively decreased after 2, 3 and 4 months of CL wear (baseline: 316.11±13.63; 2 months: 302.63±11.27, $p<0.05$; 3 months: 302.92±14.58, $p<0.05$; 4 months: 301.50±12.90, $p<0.05$). This longitudinal decrease in osmolarity occurred in parallel to an increase in blink rate (baseline: 0.98±1.18 bpm; 1 month: 2.58±2.50 bpm, $p<0.05$; 2 months: 3.46±3.04 bpm, $p<0.05$; 3 months: 3.73±1.50 bpm, $p<0.001$), which later decreased after 4 months (2.11±1.49 bpm, $p<0.05$).

Conclusions: Juvenile untreated marmosets exhibit CCT, osmolarity and blink rates that remain stable from 2 to 7 months of age, except blink rate that increased at 7 months of age. Marmosets treated with CL for 5 months, however, experienced an increase in blink rate and CCT, along with a decrease in osmolarity within the first 3 months of CL treatment. We hypothesize that CL wear might be inducing mild corneal edema and an increased blink rate, in turn delaying the development of hyperosmolarity. These findings support the marmoset as a new animal model for ocular surface research, and its potential to assess CLIDEM.

ABSTRACT BODY:

Purpose: Biofeedback training (BT) improves oculomotor control and was never used before in patients with hemianopia post-brain injury. This study analyzes the impact of BT on visual functions and quality of life (QoL) on this population.

Methods: This is a prospective controlled randomized study. The control group did baseline and 1week control measures using a MAIA microperimeter (Centervue, Padova, Italy). Control group patients crossed over to the treated group. Retinal sensitivity, 20" fixation stability (BCEA 63%), reading speed, QoL Massof questionnaire, contrast sensitivity, ETDRS visual acuity (BCVA) and stereopsis were the outcomes. For the treated group, 5 BT weekly sessions of 20' were delivered. BT displaced the visual fields in 1^{0}. Outcome measures were repeated 1 week after BT.

Results: 6 subjects were studied. The average age was 67.5 (± 18.46). 3 patients were in the control group, 2 crossed over, and 5 patients were in the treated group. The control and treatment groups were not significantly different in demographics. 50% were female. Brain injury was from stroke in 4 patients, brain tumor 1, and encephalitis in 1. Time post injury was 9.6 ± 7.7 months. In the treated group, post-BT showed for the BCEA 63% an improvement from 0.72 (± 0.4) to 0.34 s^{02} (± 0.3), p=0.037. QoL showed a significant improvement in visual ability from 0.79 (± 2) to 1.8(± 1.6) p=0.009, reading from 2 (± 2.3) to 3.9 (± 1.5) p=0.02, mobility from -0.2 (± 2.7) to 0.36 (± 2.6) p=0.02, and visual information from 1.2 (± 1.7) to 2.2 (± 1.2) p=0.04. BCVA in the treated eye increased from 0.2 (± 0.2) to 0.1(± 0.08), contrast sensitivity from 1.76 (± 0.25) to 1.87 logMar (± 0.10), reading speed from 106.9 (± 61.6) to 138.8 wpm (± 60.3), and stereopsis from 918 (± 1204) to 708” (± 1291). Retinal sensitivity improved from 16.4 (± 3.4) to 17.2 (± 4). In the control group, outcomes did not change from baseline to control measures.

Conclusions: A significant improvement was noticed in their QoL on visual ability, reading skills, mobility, and visual information post-BT. Oculomotor functions improvement may be involved in this mechanism, as the fixation stability improved significantly. All the variables showed a trend for improvement post-BT.

ABSTRACT BODY:

Purpose: Retinotopic maps acquired by fMRI provide a valuable adjunct in the assessment of macular dysfunction at the level of the visual cortex. The present study quantitatively assesses the performance of different visual stimulation approaches for mapping visual field coverage.

Methods: Twelve patients with geographic atrophy (GA) secondary to age-related macular degeneration were examined using high-resolution 7 Tesla fMRI (Siemens Magnetom 7T[CW1]) and microperimetry (MP, Nidek MP-3). We compared pRF-based coverage maps obtained with two stimulus variants (moving bars; rotating wedges and expanding rings) with the results of MP. Correspondence between MP and pRF mapping was quantified by calculating the simple matching coefficient (SMC).

Results: We find that stimulus choice biases the spatial distribution of pRF centres. In addition, eccentricity values and pRF sizes obtained from wedge/ring or bar stimulation runs show systematic differences. Wedge/ring stimulation results show lower eccentricity values and strongly reduced pRF sizes compared to bar stimulation runs. Statistical comparison shows significantly higher pRF centre numbers in the foveal 2.5° region of the visual field for wedge/ring compared to bar stimuli. However, these differences do not have an effect on SMC values when compared to MP (bar below 2.5° : 0,88 plusminus 0,13 bar above 2.5°: 0,88 plusminus 0,11; wedge/ring below 2.5°: 0,89 plusminus 0,12 wedge/ring above 2.5° 0,86 plusminus 0,10) for the peripheral visual field.

Conclusions: Both visual stimulation designs examined in this study can be applied successfully in GA patients. Although the two designs show systematic differences in the distribution of pRF centre locations, this variability has no impact on the SMC when compared to MP outcome.

ABSTRACT BODY:

Purpose: Investigate the natural history of CRB1-associated retinal dystrophies (RDs) over the course of 4 years to define optimal clinical endpoints for upcoming gene therapy trials.

Methods: Fifteen patients with genetically confirmed CRB1-associated RDs were included in this prospective study with a mean age of 26.5 years (SD ± 10.2, range 10.5 – 45.5 years) and mean follow-up time of 4.1 years (SD ± 0.2, range 4.0 – 4.7 years). Patients underwent extensive characterization including slit-lamp examination, color fundus photography, spectral-domain OCT, fundus autofluorescence, best-corrected visual acuity (BCVA) using the ETDRS letter chart, Goldmann kinetic perimetry, microperimetry, and full-field stimulus threshold (FST) testing.

Results: Patients were diagnosed with retinitis pigmentosa (13 patients, 86.7%), cone-rod dystrophy (1 patient, 6.7%), or isolated macular dystrophy (1 patient, 6.7%). Analysis revealed a non-significant decrease in BCVA from 0.82 logMAR (Snellen visual acuity 20/132) at baseline to 0.94 logMAR (Snellen visual acuity 20/174) after four years ($p = 0.105$). Furthermore, overall retinal sensitivity using FST was not significantly altered over four years (-0.9 dB; $p = 0.685$). Macular sensitivity, measured using microperimetry, demonstrated a significant reduction in average threshold from 9.7 dB to 7.1 dB (-2.6 dB, $p = 0.001$).

Conclusions: The current analysis of the four-year natural history study in patients with CRB1-associated RD revealed that BCVA and general retinal sensitivity on FST did not change significantly. However, macular sensitivity did show progressive significant decline, and may therefore be a useful and more time-sensitive clinical endpoint for upcoming gene therapy trials for CRB1-associated RDs.

ABSTRACT BODY:

Purpose: Mutations in RDH12 are primarily associated with severe early onset Leber congenital amaurosis, and in rare cases autosomal dominant mutations are linked to late onset retinitis pigmentosa. Aim: to generate a rdh12 zebrafish mutant model and characterise the retinal phenotype to study disease mechanisms.

Methods: CRISPR/Cas9 gene editing was used to generate rdh12 mutant zebrafish. Fish were characterised by retinal histology, TUNEL staining for apoptotic nuclei and immunostaining for rhodopsin and cone opsins. Levels of all-trans retinal were quantified by HPLC. Transmission electron microscopy was used to examine retinal ultrastructure. Expression of oxidative stress and autophagy markers were analysed by RT-qPCR.

Results: The rdh12^{u533} mutant line was generated and carried a 7 base pair (bp) deletion in exon 1 (c.17_23del; p.(Val6AlafsTer5)), which resulted in significantly reduced expression of rdh12 mRNA transcript at 5 days post-fertilisation (5 dpf). Characterisation of rdh12^{u533} fish at 5 dpf did not reveal a retinal phenotype. At 12 mpf, no gross abnormalities were detected in retinal histology and TUNEL staining, however rhodopsin was mislocalised to the inner segments and TEM revealed significantly larger phagosomes in the RPE of mutant fish. Expression of autophagy marker atg12 and oxidative stress marker sod2 were also significantly reduced at 12 mpf.

Conclusions: Mutant rdh12 fish displayed a late onset rod-predominant degeneration, with early indications of disrupted pathways in adult fish. However, stress in the retina is effectively controlled so as not to cause severe disruption. This phenotype corresponds more with the autosomal dominant RP phenotype. Fish are currently being followed up at 24 mpf to assess further degeneration.

ABSTRACT BODY:

Purpose: Non-infectious retinal vasculitis (RV) is a rare, heterogeneous clinical condition which may result in sight-threatening consequences. Biologic agents are promising particularly in refractory cases. The index study aimed to evaluate the efficacy of infliximab (IFX) and tocilizumab (TCZ) infusions in non-infectious RV using the Angiographic Scoring for the Uveitis Working Group (ASUWOG) fluorescein angiography (FA) scoring system.

Methods: Records of 15 patients (27 eyes) who received IFX (5-10mg/kg) (Group 1) and 7 patients (10 eyes) who received TCZ (4-8mg/kg) (Group 2) were retrospectively evaluated to assess visual acuity (VA), anterior chamber cell and flare, vitreous haze, central subfield thickness (CST), and FA scoring at baseline and at 12 months of follow-up. The measurements were employed to assess the change in 12 months in each group.

Results: In Group 1 and 2, there was no underlying disease in 9 (60%) and 3 (42.9%) patients, respectively. Three (42.9%) patients in Group 2 had juvenile idiopathic arthritis (JIA) as the most common identified cause. Mean improvement in VA (log MAR) and CST were 0.08±0.25 and 42.2±80.8 μm in Group 1 ($p=0.053$ and <0.001); 0.02±0.24 and 58.9±85.9 μm in Group 2 ($p=0.344$ and 0.492), respectively. Mean FA scores were reduced from 13.3±5.3 and 11.6±4.6 at baseline to 5.3±5.8 and 4.2±2.5 at 12-months in Group 1 and 2 ($p<0.001$ and $p=0.004$), respectively. 15 eyes of 9 patients and 4 eyes of 3 patients had FA score <4 at 12 months in Group 1 and 2, respectively. In Group 2, 8 eyes of 5 patients (71.4%) had been treated with IFX prior to TCZ initiation. There were no significant safety concerns requiring treatment discontinuation during the follow-up in either Group 1 or 2.

Conclusions: IFX and TCZ infusions showed statistically significant improvement of non-infectious RV as shown by ASUWOG FA Scoring System. Both TCZ and IFX are appropriate therapeutic options for non-infectious RV. TCZ seems to be an effective treatment for patients with JIA-associated RV or those who failed IFX therapy.

ABSTRACT BODY:

Purpose: Inherited retinal diseases are a group of clinically and genetically heterogeneous disorders with ~270 genes involved. IMPG2 is associated with adult onset vitelliform macular dystrophy (VMD). Here, we investigated two unrelated VMD patients in order to identify the underlying genetic cause.

Methods: Whole-exome sequencing identified a rare putative causal complex allele consisting of c.3023-15T>A and c.3023G>A (p.(Gly1008Asp)) in IMPG2 in both individuals. To assess its effect, in vitro splice assays using midigenes were conducted in HEK293T and further characterization of patient-derived iPSC differentiated towards to photoreceptor precursor cells (PPCs) was performed through qPCR and RT-PCR studies.

Results: Clinical assessment showed a typical VMD-features in both patients. The results of the midigene splice assays showed that the complex allele mainly affects splicing by the generation of an in-frame deletion of 48 nt and also the skipping of multiple exons. In contrast, patient-derived PPCs showed a significant increase of out-of-frame transcripts lacking one or multiple exons compared to control. Overall, control PPCs consistently showed low levels of aberrantly spliced IMPG2 transcripts that were highly elevated in patient-derived PPCs. These differences were even more obvious upon inhibition of nonsense-mediated decay with cycloheximide.

Conclusions: We report a heterozygous complex allele in IMPG2 causative for adult-onset VMD in two unrelated individuals with mild visual loss and bilateral vitelliform lesions. The predicted causal missense mutation c.3023G>A, located in the consensus splice acceptor site, enhances the splicing effect of the upstream variant c.3023-15T>A, leading to the generation of aberrant transcripts that decrease the full-length IMPG2 levels. These results suggest an haploinsufficiency mechanism of action and highlights the importance of using different models to functionally assesses splicing defects.

ABSTRACT BODY:

Purpose: To investigate WF SS-OCTA metrics, including nonperfusion area (NPA) and neovascularization (NV), in proliferative diabetic retinopathy (PDR) patients with and without neovascular glaucoma (NVG).

Methods: This prospective, observational, single-center study was conducted from November 2018 to February 2020. A total of 85 eyes of 60 PDR patients without NVG and 9 eyes of 8 PDR patients with NVG were imaged using WF SS-OCTA. Retinal ischemic parameters (NPA; ischemia index [NPA/total retinal area]) and neovascularization features (NV number; NV area; NV vessel density) were evaluated. Foveal avascular zone (FAZ), macular thickness/volume and choroidal thickness/volume were obtained using the Zeiss ARI Network. WF SS-OCTA retinal and choroidal metrics, systemic, and ocular parameters were screened using Least Absolute Shrinkage and Selection Operator (LASSO) logistic regression for variable selection. Firth's Bias-Reduced logistic regression model (outcome: presence of NVG) was subsequently used to identify parameters associated with NVG.

Results: Ischemia index (cutoff 0.406; odds ratio [OR]=77.1, 95% confidence interval [CI]:9.1-1402.4, P<0.001) and BCVA (cutoff 0.185; OR=25.2, 95%CI:1.7-4138.2, P=0.015) were associated with the presence of NVG, and ischemia index remained significantly associated with NVG after exclusion of fellow eyes of NVG and adjustment for sex, age, and diabetes duration. NV metrics, FAZ, and choroidal parameters were not related to NVG.

Conclusions: Retinal ischemia but not neovascularization was associated with the presence of NVG in patients with PDR using WF SS-OCTA. Larger, longitudinal studies are needed to validate imaging biomarkers associated with diabetic NVG.

ABSTRACT BODY:

Purpose: ROP, a retinal neurovasculopathy, is a leading cause of childhood blindness. We reported recently that activation of the molecular chaperone, Sig1R, provides a novel rescue of neuronal deficits in the oxygen-induced retinopathy (OIR), model of ROP (Wang et al, ARVO 2020). Here, we focus on Sig1R and its novel therapeutic potential in vascular injury characteristic of ROP.

Methods: C57BL/6J pups (P7 with nursing dam) were subjected to OIR or room air (CT). (+)-Pentazocine ((+)-PTZ), a high affinity Sig1R ligand, was administered starting P7 (0.5 mg/kg, IP, every other day). Retinal vasculature was imaged by fluorescein angiography & vascular tortuosity analyzed by MATLAB at P17& P48. At P17, retinal vascular distribution (neovascularization (NV) and avascular area) & vascular barrier function (Evans blue (EB) leakage assay) were evaluated. Oxidative stress (DHE, 3-NT, 4-HNE), reactive gliosis (anti-GFAP), expression of proteins/cytokines (Sig1R, ZO-1, Occludin, p-STAT3 and VEGF, IL-6, TNFα) were assessed by immunohistochemistry (IMH), Dot/Western blotting (WB) & ELISA.

Results: Vascular tortuosity: Retinal arteries in OIR mice were more tortuous (~1.3) v. CT (1.0), whereas (+)-PTZ significantly reduced arterial tortuosity (~1.1) in OIR mice at P17 & P48. Vascular distribution: Retinal avascular region (OIR-non: ~30% v. OIR+PTZ: ~12%) and NV (OIR-non: ~7.8% v. OIR+PTZ: ~2.5%) were significantly decreased in OIR+PTZ mice. Retinal vascular barrier: EB extravasation was elevated in OIR mice, but decreased significantly in OIR+PTZ mice. ZO-1 & Occludin levels decreased significantly in OIR mice, whereas (+)-PTZ preserved their levels. Oxidative stress and reactive gliosis: Detection of oxidative stress by DHE staining, 4-HNE and 3-NT immunostaining showed that (+)-PTZ attenuated superoxide and lipid peroxide levels in OIR mice. (+)-PTZ treatment diminished reactive gliosis in OIR mice. Exploration of Sig1R-STAT3-Inflammation axis. In OIR mice, we observed a significant decrease of Sig1R, along with increase of p-STAT3, VEGF, IL-6 and TNFα, whereas (+)-PTZ treatment normalized these effects.

Conclusions: (+)-PTZ treatment attenuated OIR-induced vasculopathy, retinal barrier dysfunction, reactive gliosis, oxidative stress and STAT3-mediated inflammation, suggesting that Sig1R is a promising therapeutic target for vascular injury in ROP.

ABSTRACT BODY:

Purpose: Our study proposes a method for margin reflex distances-1 (MRD1) measurement through facial photographs.

Methods: A deep learning U-net based model was trained with 100 external ocular photography to automate segmentation of the iris image. Images were acquired from pre-operative photos of patients prior to ptosis surgery. For each patient's photo, the segmentation result was used to extract the iris edge. A circle of best fit was generated based on the visible iris edges. The margin reflex distance 1 (MRD1) was calculated as the distance between the center of this circle to the margin of the upper eyelid. A fixed size reference marker on the patient's forehead was used to convert pixel measurements to millimeters. The proposed deep-learning-based MRD measurement algorithm was then evaluated with 500 single eye photos by comparing the measurement results from the model with measurements taken by a physician using the same photos. The physician was provided with custom software to enable measurement (available at https://gosienna.github.io/MRD_measurement/)

Results: A total of 500 photos, with MRD's ranging from -3mm to 6.15mm were used to evaluate the performance of the model. Using the physician measurements as the ground truth, we found that 95[1] % of the model measurements were within 1mm[2] of the ground truth. The Pearson's correlation[3] between model measurements and the ground truth was 0.95. The P-value for non-correlation testing was less than 0.001.

The Bland-Altman plot shows good agreement between automatic and manual MRD measurements (95% limits of agreement). Prediction errors occur in images without distinct upper eyelid margins. For example, long eyelashes, severe ptosis or large pterygium can result in difficulty for the model to recognize the iris edge.

Conclusions: Using a deep learning segmentation model, the MRD can be measured from clinical photos with a high degree of accuracy.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD), diabetic retinopathy (DR), and glaucoma are vision-threatening diseases (VTDs) affecting 36 million people in the USA. With 5.7 ophthalmologists per 100,000 Americans, over 50% of VTDs go undetected. We assessed deep learning Artificial Intelligence (DLAI) in VTD detection in community and clinical settings.

Methods: 223 subjects (mean age 54.6, 58% male) from community screenings (A) and clinic (B) underwent 45-degree retinal imaging. In A (non-dilated), an onsite telemedicine reader (R1) and remote ophthalmologist (R2) graded image quality (gamma and alignment, 1-5 scale) and referable VTD using the international grading scales for AMD and DR, and cup-to-disc ratio and nerve fiber layer for glaucoma. In B (dilated), gradings were collected from R1 and the clinical diagnosis (d). A senior ophthalmologist (R3) adjudicated disputed findings. In A, DLAI VTD referral was compared to R1/R2/R3 consensus (S); in B, overall referral was compared to R1/d/R3 consensus (C). Images were uploaded to a cloud-based DLAI (SELENA+, EyRIS Pte Ltd) (Fig 1). Cohen's kappa assessed intergrader agreement.

Results: R1 and R2 found 4.7% eyes ungradable. DLAI marked 55.6% ungradable; 74.6% of them were for AMD. Of the DLAI ungradable eyes, image quality was ≤ 3, and 56.2% had ≥ 1+ cataract (R1). Compared to in A, in B DLAI had higher sensitivity (97.1% vs. 63.2%) and positive predictive value (69.4% vs. 32%). In A, DLAI had higher specificity (94.5% vs.16.7%) and negative predictive value (98.4% vs. 75.0%) (Table 1). In A, Cohen's kappa was 0.946 between R1 and R2, with a 13% disagreement rate. In 56% of the disagreements, R3 agreed with R1. In B, Cohen's kappa was 0.874 for R1 and d; R1 referred more than d. In A and B, DLAI referred more than R1, R2, and H/C. DLAI referred all eyes with > 1 VTD (1%) for further examination. Grading times for DLAI, R1, and R2 were 30, 129, and 68 seconds.

Conclusions: DLAI performed best in DR and glaucoma detection; a potential solution for the high ungradable rate can be for DLAI to re-center uploaded images. DLAI can increase efficiency and accessibility of screenings for multiple VTDs, in both underserved populations and clinic. The ability to minimize direct contact confers an advantage during COVID-19. Further studies will investigate DLAI use in VTD progression.

ABSTRACT BODY:

Purpose: Topical corticosteroids are commonly used to treat ocular surface and post-operative inflammation. Topical corticosteroid use is limited by its potential for ocular adverse events, such as elevated intraocular pressure. We have previously described a new class of compounds comprised of a corticosteroid covalently linked to a Rho-kinase inhibitor (ROCKi), termed "ROCK'Sters" that are designed to mitigate steroid-induced intraocular pressure (IOP) elevation. Herein, is described the synthesis, biochemical, and cellular activity of ROCK'Sters as well as a demonstration of their anti-inflammatory efficacy in a rabbit model of post-operative inflammation.

Methods: ROCK'Sters were evaluated for inhibition of ROCK enzyme isoforms in kinase biochemical assays. Steroidal activity of several ROCK'Sters was characterized by inhibition of the pro-inflammatory IL-23 pathway in mouse splenocytes. In vivo, anti-inflammatory efficacy of ROCK'sters was evaluated in a rabbit model of post-operative inflammation after cataract surgery. Post-surgery, ocular examinations evaluated surface morphology and anterior/posterior inflammation using a modified Hackett and McDonald ocular grading system. ROCK'Ster activity in the post-op model was compared to marketed steroids, Pred-Forte® and Durezol®.

Results: Several of the ROCK'Sters demonstrated potent inhibition of Rho kinase activity in enzymatic assays with IC_{50} < 10 nM. In a cellular context, these compounds strongly inhibited the pro-inflammatory IL-23 pathway in mouse splenocytes with IC_{50} values ranging from approximately 1 nM to 30 nM. In a rabbit post-operative inflammation model, ROCK'Sters displayed significant efficacy for resolution of inflammation that was noninferior to both Pred-Forte® and Durezol®.

Conclusions: ROCK'Sters represent a proprietary compound class with in vitro Rho kinase inhibitory activity, cellular steroidal activity, and anti-inflammatory efficacy in an animal model of post-operative inflammation. This class of compounds provides potent efficacy for the treatment of ocular surface and post-operative inflammation coupled with the potential for extended therapeutic use by providing a reduced risk of steroid-induced IOP elevation.

ABSTRACT BODY:

Purpose: Artificial intelligence (AI) has the potential to improve risk stratification in glaucoma, but interface design and usability of AI-based clinical decision support tools have been understudied. GLANCE is a visualization tool depicting predicted mean deviation of visual fields (VFs) based on a deep learning model trained on optical coherence tomography (OCT) images, with the potential to reduce VF testing frequency (van den Brandt A, et al., Eurographics Workshop on Visual Computing for Biology and Medicine, 2020). Here, we conducted a pilot study of clinicians using an updated prototype of GLANCE to assess usability, trust in the tool, and utility for clinical management.

Methods: Our updated prototype of GLANCE included dynamic visualization of the AI model output (predicted VF mean deviation) alongside prior VFs and model predictions, intraocular pressure measurements, and clinical history (Fig.1). An online survey consisting of six patient cases with the GLANCE tool was disseminated to clinicians at the University of California San Diego. Participants were asked to comment on whether GLANCE provided additional useful information and whether it impacted their clinical management using 5-point Likert scale items (Fig. 2). They also completed a System Usability Scale (SUS) questionnaire, a standardized instrument for assessing usability.

Results: Seven clinicians (two attendings, two fellows, two residents, and one optometrist) participated in the pilot. The mean SUS score of GLANCE was 62.5/100, which is normalized into the 35th percentile. The mean SUS score among respondents ages 35-44 (75) was greater than ages 65-74 (45). The mean score among female respondents (67.5) was greater than male respondents (57.5). Respondents generally agreed that they trusted GLANCE and that it provided useful information, but disagreed that they would decrease VF testing frequency (Fig.2).

Conclusions: Clinicians agreed that GLANCE provided useful information but were generally not yet willing to allow AI tools to significantly alter their clinical management. Further research is needed to understand how to increase trust in AI models, improve the usability of visualization tools and interfaces, and optimize the integration of AI-based tools into ophthalmic workflows among a diverse group of clinicians.

ABSTRACT BODY:

Purpose: To develop machine learning (ML) algorithms to predict visual and anatomic outcomes and treatment frequency in patients with macular edema secondary to central retinal vein occlusion (MEfCRVO) at 52 weeks after undergoing treatment with aflibercept.

Methods: A dataset of 198 patients with MEfCRVO treated with monthly IAI 2 mg for 24 weeks in the COPERNICUS (n=107) and GALILEO (n=91) trials was used to develop ML algorithms. In both trials, patients were switched after 6 monthly intravitreal aflibercept injection (IAI) at week 24 to pro-re-nata (PRN) dosing through Week 52. The ML algorithm was used to predict the absolute and mean change best-corrected visual acuity (BCVA) from baseline to Week 52, the proportion of patients with ≥15-letter gain at Week 52, the absolute and mean change from baseline in central subfield thickness (CST) at Week 52, and IAI frequency during Weeks 24−52. Random Forest was used to develop the ML algorithms. Algorithm performance was assessed using correlation coefficient (r) and area under the curve (AUC) for continuous and categorical variables, respectively. Predictive factors identified with ML algorithms were confirmed using univariate analyses.

Results: The ML algorithm predicted the actual observed values at Week 52 with strong correlation (r) for absolute BCVA (r=0.87), change in BCVA from baseline (r=0.76), gain of ≥15 letters (AUC=0.81), and change in CST from baseline (r=0.76). BCVA at weeks 16, 20, and 24 were predictors of absolute BCVA; BCVA at baseline, week 20 and week 24 were predictors of change in BCVA; BCVA at baseline and at Week 20 were predictors of ≥15-letter gain; and CST and BCVA at baseline were predictors of change in CST. There was no correlation (r=0.07) between predicted and observed absolute CST at Week 52. ML algorithm predicted PRN injection frequency from Week 24 through Week 52 with high accuracy (AUC=0.83). Key factors predicting injection frequency were CST at baseline and at Week 4. Univariate analyses confirmed all predictive factors described herein.

Conclusions: ML algorithms successfully predicted visual and anatomic outcomes as well as dosing frequency with high accuracy, except for absolute CST. ML may help inform patient`s and clinician`s expectations during management of MEfCRVO.

TITLE: Toward a Comprehensive Account of Orientation Selectivity in the Retina

SESSION TITLE: Retinal and central processing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.L. Zipperer, Anatomical Sciences and Neurobiology, University of Louisville, Louisville, Kentucky, UNITED STATES|

Commercial Relationships Disclosure: Megan Zipperer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: While Orientation Selectivity (OS) is a fundamental computation in the visual system, a comprehensive characterization of OS ganglion cell types (OSGCs) in the retina is lacking, the cellular and circuit mechanisms that generate the OS response are incompletely understood, and contributions of OSGCs to subsequent stages of visual processing remain unknown. The purpose of this study was to identify OSGC types in mouse, to investigate the mechanisms that generate their orientation selective selective response, and to identify the contribution of OSGCs to visual processing in downstream thalamic nuclei.

Methods: This study used two-photon fluorescence calcium imaging to survey ganglion cell populations with a genetically encoded calcium indicator in Thy1-GCaMP6f mice, followed by cluster analysis to identify functional types. Innovative intra-experimental analysis of visually-evoked responses allowed targeting of OSGCs for detailed study using electrophysiology and morphological reconstruction. To identify OSGC targets to downstream visual centers, we used state-of-the-art retrograde rabies tracing from thalamus and superior colliculus followed by calcium imaging in the retina.

Results: Our calcium imaging surveys identified six apparent OS types with selectivity for both horizontal and vertically oriented drifting gratings. We identified types that have not been previously described as OS, including a horizontal-preferring RGC matching the 4on type from the Seung Eyewire museum. Amongst these types we identified cells with tuned excitation and tuned inhibition — some with a combination of the two — demonstrating sources for the OS tuning. Preliminary data from retrograde tracing studies implicated one of the vertical-preferring types as synapsing with Wide Field Vertical Cells in superior colliculus (SC), potentially driving OS tuning in SC.

Conclusions: This study identified multiple OSGC types in mouse and provides new insight into the circuit-level tuning mechanisms of these cells. We have begun to resolve correspondences between reported OS RGCs from our dataset and incompletely categorized cell types from previous studies, contributing to a more complete understanding of RGC types and their functional role in the mouse retina. Our novel identification of central targets of OSGCs is an important step toward understanding the role of retinal OS in visual processing of downstream visual centers.

ABSTRACT BODY:

Purpose: Intraoperative OCT (iOCT) provides real-time imaging data that can be used to aid clinical decision-making and verify completion of surgical goals. However, video-rate 4D iOCT imaging of surgical dynamics is limited by the need to manually align the OCT field-of-view (FOV) to the region-of-interest, thus significantly impacting surgical workflow. Here, we demonstrate automated instrument-tracking at over 120 Hz for 4D imaging and tracking of 25G internal limiting membrane (ILM) forceps at 16 volumes/second.

Methods: A custom spectrally encoded coherence tomography and reflectometry (SECTR) system was used to simultaneously acquire en face spectrally encoded reflectometry (SER) and cross-sectional OCT images. A GPU-accelerated convolutional neural network (CNN) was trained to detect 25G ILM forceps from SER images and corresponding instrument position outputs were used to dynamically modify scan waveforms via a DAQ for tracking. An adaptive-sampling scan protocol was used to densely sample the center of each frame to enhance visualization of tissue interactions (Fig. 1).

Results: Automated instrument-tracking was performed in a retinal phantom with simulated ocular features. SER and OCT images were acquired simultaneously with 1664 x 500 x 50 pix. (spectral x lines x frames) at 16 volumes/second. Images were acquired over a 25 mm x 7 mm lateral FOV and tracking was performed across a 25 mm x 25 mm maximum FOV. Despite out-of-plane motion, the 25G ILM forceps remain centered and localized in the OCT FOV (Fig. 2).

Conclusions: We demonstrate an automated instrument-tracking method that enables video-rate 4D visualization of ophthalmic surgical maneuvers. We believe the proposed methods overcome critical barriers to the adoption of iOCT technology by improving surgical workflow and are broadly applicable for tracking arbitrary surgical instruments during iOCT-guided procedures.

ABSTRACT BODY:

Purpose: Oxidative stress has been implicated as a driver of various vision-impairing retinal diseases, including age-related macular degeneration (AMD). Oxidized retinal mitochondrial flavoproteins emit green light (535 nm) when excited by blue light (467 nm). This flavoprotein fluorescence (FPF) can be measured and used as a quantifiable marker for oxidative damage-induced mitochondrial dysfunction. This study aims to measure FPF average intensity and heterogeneity in patients with early, intermediate, and advanced non-exudative AMD as well as neovascular AMD.

Methods: This prospective cohort study enrolled patients with isolated AMD of any Beckman stage between 2017 and 2021 excluding patients with comorbidities such as glaucoma, ocular hypertension, concomitant retinopathy or uveitis, history of non-cataract ocular surgery, or fluorescein angiogram prior to imaging. Controls were healthy age-matched individuals. In instances of bilateral involvement, each eye was treated separately. FPF average intensity and heterogeneity were recorded using the OcuMet Beacon (OcuSciences, Ann Arbor, MI).

Results: The final analysis included images of 654 eyes (327 AMD eyes, 327 control eyes). The multivariable regression included stage of AMD, age, gender, ethnicity, and smoking status. Intermediate and advanced non-exudative AMD as well as neovascular AMD were correlated with significantly increased FPF average intensity (4.86, CI 2.37-7.34, $p < 0.001$; 11.9, CI 7.70-16.11, $p < 0.001$; 7.24, CI 4.61-9.88, $p < 0.001$, respectively), but early non-exudative AMD was not. Early, intermediate, and advanced non-exudative AMD as well as neovascular AMD were correlated with significantly increased FPF heterogeneity (0.19, CI 0.08–0.30, $p = 0.001$; 0.43, CI 0.36–0.51, $p < 0.001$; 0.59, CI 0.46–0.71, $p < 0.001$; 0.58, CI 0.51–0.66, $p < 0.001$, respectively).

Conclusions: All stages of AMD were associated with increased FPF average intensity and heterogeneity, except early non-exudative AMD, which was only associated with increased heterogeneity. Because FPF imaging provides insight into the health of the retina on a cellular level, this finding of an isolated increase in FPF heterogeneity in early non-exudative AMD could assist with early detection of disease before structural changes are seen on optical coherence tomography.

TITLE: Absence of signal peptide peptidase in peripheral sensory neurons affects latency-reactivation in HSV-1 ocularly infected mice

SESSION TITLE: Immunobiology: Ocular Surface, Glaucoma and Retinal Degeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Wang, U. Jaggi, K. Tormanen, S. Hirose, H. Ghiasi, Surgery, Cedars-Sinai Medical Center, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Shaohui Wang: Commercial Relationship: Code N (No Commercial Relationship) | Ujjaldeep Jaggi: Commercial Relationship: Code N (No Commercial Relationship) | Kati Tormanen: Commercial Relationship: Code N (No Commercial Relationship) | Satoshi Hirose: Commercial Relationship: Code N (No Commercial Relationship) | Homayon Ghiasi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We previously reported that HSV-1 glycoprotein K (gK) is involve in exacerbation of eye disease in ocularly infected mice and its binding to signal peptide peptidase (SPP) is required for increased eye disease. In the present study, we investigated the impact of absence of SPP expression in peripheral sensory neurons on HSV-1 infectivity using Avil-SPP$^{-/-}$ mice

Methods: We generated mice lacking SPP specifically in peripheral sensory neurons by crossing Advillin-Cre mice with SPP$^{fl/fl}$ mice. Avil-SPP$^{-/-}$ mice and control mice were infected ocularly with 2 X 10^5 PFU/eye of HSV-1 strain McKrae. Virus replication in the eye and trigeminal ganglia (TG), survival, eye disease, and latency-reactivation were determined in infected mice.

Results: Expression of SPP mRNA and protein were significantly lower in neurons of Avil-SPP$^{-/-}$ mice than in control mice despite similar levels of HSV-1 replication in the eyes of Avil-SPP$^{-/-}$ mice and control mice. Viral transcript levels in isolated neurons of infected mice on day 5 post infection were lower than in control mice. Significantly less LAT, gB, and PD-1 expression was seen during latency in isolated neurons and total trigeminal ganglia (TG) of Avil-SPP$^{-/-}$ mice than in control mice. Finally, reduced latency and reduced T cell exhaustion in infected Avil-SPP$^{-/-}$ mice correlated with slower or no reactivation.

Conclusions: Overall, our results suggest that blocking SPP expression in peripheral sensory neurons does not affect primary virus replication or eye disease but does reduce latency-reactivation. Thus, blocking of gK binding to SPP may be a useful tool to reduce latency-reactivation.

TITLE: Narrow-band, long-wavelength lighting caused hyperopia in normal eyes and retarded minus lens-induced myopia and form deprivation myopia for juvenile tree shrews

SESSION TITLE: Mechanisms of Refractive Error and Eye Development

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Z. She, T.T. Norton, T. Gawne, The University of Alabama at Birmingham School of Optometry, Birmingham, Alabama, UNITED STATES|

Commercial Relationships Disclosure: Zhihui She: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Norton: Commercial Relationship(s);Code P (Patent):University of Alabama at Birmingham | Timothy Gawne: Commercial Relationship(s);Code P (Patent):University of Alabama at Birmingham

ABSTRACT BODY:

Purpose: To examine the effects of narrow-band, long-wavelength (red) ambient light on the maintenance of emmetropization, lens-induced myopia and form-deprivation myopia in juvenile tree shrews.

Methods: Seventeen tree shrews (Tupaia belangeri) were reared in red light (14-hr red, 10-hr dark; peak wavelength = 634 nm, half bandwidth = 9μm; ~600 lux on cage floor) from 24 to 35 days of visual experience either without visual treatment (Binocular Red Controls, n = 7), with concurrent monocular -5D lens (Red -5D, n = 5), or monocular diffuser treatment (Red FD, n = 5). Non-cycloplegic refractions and ocular dimensions were measured in awake animals using an autorefractor and an optical biometer, respectively. Data were compared with those obtained from animals previously reared in colony “white” light without visual treatment (Colony Controls, n = 7), with concurrent monocular -5D lens (Colony -5D, n = 5) or monocular diffuser (Colony FD, n = 10).

Results: Red light produced relative hyperopia in the Binocular Red Controls (closed red circles in both panels. Averaged refraction, Red-Controls vs. Colony-Controls: +3.0 ± 0.7D vs. +1.0 ± 0.4D) and in the untreated eyes of the lens-rearing subjects (panel A: Red -5D vs. Colony -5D, +2.5 ± 0.5D vs. +1.3 ± 0.3D; panel B: Red FD vs. Colony FD, +2.4 ± 0.3D vs. +1.0 ± 0.2D). The hyperopia in the untreated eyes of the Red -5 D and Red FD groups occurred with a two-day delay compared with the Binocular Red Controls and remained about 1 D less hyperopic. Red light slowed the myopic changes in the treated eyes of the Red -5D and Red FD subjects and reduced the final degree of myopia (Red -5D vs. Colony -5D, -1.1 ± 0.9D vs.-3.8 ± 0.3D, $p < 0.05$; Red FD vs. Colony FD, -0.3 ± 0.6D vs. -5.4 ± 0.7D, $p < 0.05$). The degree of lens-induced myopia (treated – untreated eyes, -3.6 ± 0.4D vs. +5.1 ± 0.2D of Colony -5D) and form-deprivation myopia (Red FD vs. Colony FD, -2.7 ± 0.4D vs. -6.4 ± 0.6D) were also reduced ($p < 0.05$). The refractive changes were inversely correlated with the changes in vitreous chamber depth ($r = -0.91$, $p < 0.05$).

Conclusions: For tree shrews, red light slowed ocular growth and caused hyperopic shifts not only in eyes that had previously attained a near-emmetropic refractive state (Gawne et al., 2017), but also in minus-lens-treated eyes and diffuser-treated eyes.

TITLE: Evaluation of tensile strength and burst pressure of slipknots and surgeon’s knots

SESSION TITLE: Refractive and non-refractive corneal surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Wang, School of Medicine, Queen's University, Kingston, Ontario, CANADA|D. Johnson, Ophthalmology, Queen's University, Kingston, Ontario, CANADA|

Commercial Relationships Disclosure: Patrick Wang: Commercial Relationship: Code N (No Commercial Relationship) | Davin Johnson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Despite the frequency and importance of corneal suturing by ophthalmologists, there is a paucity of data comparing the tensile strength of these knots. This study aims to compare the tensile strength of the slipknot versus surgeon’s (3-1-1) knot using 10-0 nylon sutures.

Methods: Initial testing of cadaveric phakic eyes was performed by closing a 5mm linear full-thickness corneal wound with either a slipknot or surgeon’s knot using 10-0 nylon suture material. Burst pressure was measured using a cardiac transducer inserted into the vitreous cavity and defined as the intraocular pressure (IOP) at suture failure after constant infusion of saline solution via a 25-gauge needle into the anterior chamber (Fig 1). Follow-up testing of tensile suture strength was performed using a digital force tensiometer. A loop of suture was tied around a tuberculin syringe and the loop was gently removed and mounted on a stand with the tensiometer. Tensile testing was performed at a rate of 0.25mm/s on each type of knot and ultimate tensile strength was measured as the maximum load just prior to knot failure (Fig 2). Light microscopy was used to analyze the site of suture failure. All suture knots were tied by an experienced corneal surgeon and outcome assessors were blinded to each knot type.

Results: 6 cadaveric eyes (3 slipknot, 3 surgeon’s knot) were obtained to assess burst pressure. Minor aqueous leakage through the wound was observed in all cadaveric eyes however both suture knots did not fail despite measured IOP over 300mmHg. A total number of 50 knots (25 surgeon’s knot, 25 slipknot) were tied for tensile testing. The ultimate tensile force upon breakage was higher in the surgeon’s knots compared with that in slipknots (0.75 vs. 0.59 N, $p = 0.02$). After tensile testing, light microscopy revealed that within the collected slipknot sutures (n=8), 3 unraveled and 5 experienced breakage. Of collected surgeon’s knot sutures (n=11), 2 had unraveled and 9 experienced breakage.

Conclusions: Surgeon’s knots provide higher tensile strength compared to slipknots in an experimental model. However, when properly tied, both types of knots provide excellent strength, but it is unclear if this difference is clinically relevant with in vivo conditions.

TITLE: Evaluation of Venturi flow in new phacoemulsification packs with small-bore, dual-durometer aspiration tubing

SESSION TITLE: Cataract surgery 1

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Zhou, Research and Development, Johnson and Johnson Surgical Vision, Inc., Santa Ana, California, UNITED STATES|

Commercial Relationships Disclosure: Jianbo Zhou: Commercial Relationship(s);Code E (Employment):Johnson & Johnson Surgical Vision, Inc.

ABSTRACT BODY:

Purpose: A relatively large size aspiration tubing in fluidics pack could result in increased flow during cataract surgery when using Venturi mode in a gravity-based phacoemulsification system, causing chamber instability and compromising the balance of holdability and followability. New fluidics packs using small-bore, dual-durometer aspiration tubing were constructed. This study will evaluate aspiration flow of the newly constructed fluidics packs with a new phacoemulsification machine in Venturi mode in a laboratory setup.

Methods: The inner layer of the aspiration tubing of the new fluidics packs uses a stiffer material with a smaller inner diameter than existing products, while the outer layer is soft and maintains flexibility. These packs were tested with a Phaco handpiece and three different Phaco tips (19, 20, and 21 Gauges) in a newly available phacoemulsification machine set to Venturi mode, along with existing packs as the control arm. A glass beaker filled with deionized (DI) water was placed on a weight scale with water level started for each test run at the same height as the vacuum sensor in the Phaco machine. The Phaco tip was submerged in the DI water and the Venturi vacuum was applied for 15 seconds. The loss of the water in the beaker was measured for calculation of the aspiration flow rate with Venturi vacuum ranging from 100 to 600 mmHg in 100 mmHg step. Additionally, the effect of viscous fluid (a water/glycerin mixture) on the aspiration flow rate was also investigated with the 20 Gauge Phaco tip.

Results: The relationship between the aspiration flow and vacuum was nonlinear. The new fluidics packs produced smaller aspiration flow rates than the existing packs, with a 20% reduction for the 20 Gauge Phaco tip configuration. The differences were statistically significant ($p < 0.01$). At least 30% higher vacuum can be used with the new fluidics packs to achieve the same flow rate compared to the existing packs. Using viscous fluid also lowered the flow rate further.

Conclusions: In laboratory test, new fluidics packs with small-bore, dual-durometer aspiration tubing produced markedly smaller aspiration flow rates compared to the existing packs at the same vacuum settings in Venturi mode. The use of the new fluidics packs provides a better flow and vacuum control for improved chamber stability and a more balanced followability and holdability during phacoemulsification.

TITLE: Long-term visual acuity outcomes of fovea-involving rhegmatogenous retinal detachments following pars plana vitrectomy (PPV) or combined PPV/scleral buckle surgery

SESSION TITLE: Vitreoretinal surgery/VR Interface/PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Awh, J. Abraham, R.P. Singh, Cleveland Clinic Cole Eye Institute, Cleveland, Ohio, UNITED STATES|K.E. Pedersen, Northeastern Ohio Medical University, Rootstown, Ohio, UNITED STATES|

Commercial Relationships Disclosure: Caroline Awh: Commercial Relationship: Code N (No Commercial Relationship) | Karina Pedersen: Commercial Relationship: Code N (No Commercial Relationship) | Joseph Abraham: Commercial Relationship: Code N (No Commercial Relationship) | Rishi Singh: Commercial Relationship(s);Code C (Consultant/Contractor):Genentech/Roche;Code C (Consultant/Contractor):Alcon/Novartis;Code C (Consultant/Contractor):Apellis;Code C (Consultant/Contractor):Graybug;Code C (Consultant/Contractor):Zeiss;Code C (Consultant/Contractor):Bausch + Lomb;Code C (Consultant/Contractor):Regeneron Pharmeceuticals, Inc

ABSTRACT BODY:

Purpose: Macular involvement is often reported as a poor prognostic factor of rhegmatogenous retinal detachments (RRD). Although patients who undergo RRD repair are reported to reach stable vision 3-6 months after surgery, few studies report visual outcomes longer than 2 years after repair of macula-off RRD with pars plana vitrectomy (PPV), the current preferred method of repair. The purpose of this study is to evaluate visual outcomes of fovea-involving RRD repair with PPV or combined PPV/scleral buckle (SB) in eyes with at least 5 years of post-operative data.

Methods: This retrospective case series evaluated eyes that underwent fovea-involving RRD repair with PPV or PPV/SB at the Cole Eye Institute. Eyes with single operation anatomic success and 5 years or more of follow-up were included. Eyes with other ophthalmic pathology affecting central vision were excluded. Best visual acuity (BVA) was measured in Snellen visual acuity and converted into Early Treatment Diabetic Retinopathy Study (ETDRS) score. Paired t-test analysis compared changes in BVA between two time-points. Multiple linear regression analyses evaluated the impact of age, lens status at baseline, and pre-operative BVA on final BVA and total gain in BVA.

Results: 51 eyes were included. Mean time to final follow-up was 6.55±1.38 years. Mean pre-operatively BVA was 21.47±23.20 (~20/400) and improved to 72.72±16.52 (~20/32) and 78.14±10.16 (~20/25) at the 1-year and final follow-up, respectively ($p<0.001$). Thirteen of 45 eyes (28.89%) had an improvement in BVA of at least 10 letters from the 1-year to the final follow-up. Mean 1-year BVA was significantly different from final BVA ($p=0.002$). Average BVA was 20/40 or better in 35/45 eyes (75.56%) at 1-year and 45/51 eyes (88.24%) at final follow-up. Average BVA was 20/200 or worse in 1/51 (1.97%) eyes at final follow-up. In regression analysis, a greater total gain in BVA was associated with a lower pre-operative BVA ($p<0.001$) but not with age or lens status. In linear regression, no parameter correlated with final BVA.

Conclusions: Patients with fovea-involving RRD successfully repaired with PPV or PPV/SB have favorable long-term visual acuity outcomes. BVA may continue to significantly improve even beyond 1 year after surgery, and the majority of patients have a BVA of 20/40 or better 5 years after surgery.

ABSTRACT BODY:

Purpose: To characterize experiences with diabetic retinopathy screening among Spanish-speaking adults living with diabetes.

Methods: Two trained authors conducted in-depth, semi-structured video interviews with 5 Spanish-speaking adults living with diabetes in New Haven, CT between March and June of 2021. Non-Spanish-speaking Hispanic participants were non-eligible for the study. Two independent readers coded each interview transcript and identified thematic categories based on grounded theory and constant comparative methodology. Emerging themes were organized around the socio-ecological framework using unique codes (Figure 1). Themes and quotes were translated to English to facilitate consensus analysis. We achieved thematic saturation for five themes.

Results: Five recurrent cultural and linguistic-sensitive themes emerged in our interviews: personal accountability, reliable support systems, continuity of care, clear communication, and seasonal barriers. 1) At the individual level, participants viewed loss of vision as an act of self-negligence and held themselves accountable for managing their disease. 2). At the interpersonal level, participants relied on a trusting support system that extended outside of their family including their social networks (e.g., friends). 3) At the community level, participants valued long-term familial-like interactions with providers. 4) At the organizational level, participants valued thorough communication with all members of the care team and equated clear communication with provider excellence. 5). At the structural level, inclement weather and transportation were identified as barriers to appointment attendance.

Conclusions: Understanding the specific needs and preferences of Hispanic adults living with diabetes is important to delivering high-quality ophthalmologic care. This is particularly important among patients with limited English proficiency who face further barriers to care, such as language and cultural differences. Understanding the beliefs and attitudes of Hispanic patients can help providers develop behaviors and interventions that specifically motivate this high-risk population to participate in diabetic retinopathy screening.

ABSTRACT BODY:

Purpose: The antimicrobial peptide (AMP) expression pattern of the equine ocular surface and amniotic membrane are currently undefined. We hypothesized that putative orthologs of both cathelicidins and defensins, two AMP subfamilies, expressed by the ocular surface of humans would be expressed by the equine cornea, conjunctiva and amniotic membrane. This study characterized AMP expression from healthy equine eyes and amniotic membrane to serve as a reference for future investigations of equine microbial keratitis and for the potential use of amniotic membrane for therapeutic corneal grafts.

Methods: RNA was extracted from equine corneal epithelium (n=5), conjunctiva (n=4), amniotic membrane (n=6), testis (n=4) and epididymis (n=4). Testis and epididymis were used as positive controls as they have been shown to highly express AMPs in other species. A targeted qPCR approach was used to investigate the equine orthologs of the three most functionally relevant beta-defensins (DEFB1, DEFB4B, and DEFB103A) of the ocular surface and amniotic membrane of humans. RNA from one sample of corneal epithelium, conjunctiva and amniotic membrane were submitted for 3'Tag-sequencing to further investigate their AMP expression.

Results: Expression of equine orthologs of DEFB1, DEFB4B and DEFB103A were identified in equine corneal epithelium, conjunctiva and amniotic membrane. DEFB103A was expressed at the highest amounts in corneal epithelium, while DEFB4B was most highly expressed in conjunctiva and amniotic membrane. 3'Tag-sequencing confirmed these findings and identified expression of five additional beta-defensins, 11 alpha-defensins and two cathelicidins. The alpha-defensins showed higher normalized read counts than the beta-defensins in these tissues.

Conclusions: This study characterized the AMP expression profile of the equine cornea, conjunctiva and amniotic membrane. We identified high expression of DEFB103A in the cornea suggesting that it plays a key role in the innate immunity of the equine eye. We also determined that equine amniotic membrane expresses a moderate amount of AMPs suggesting it could provide an antimicrobial effect as a surgical corneal graft in structurally compromised eyes. Finally, we identified high expression of alpha-defensins in ocular tissues and amniotic membrane. Future studies will focus on defining the antimicrobial activity of these AMPs and determining their role in microbial keratitis.

ABSTRACT BODY:

Purpose: Recently impaired glycolysis was reported in patients with age-related macular degeneration (AMD) with a high lactate/pyruvate ratio suggesting that increased lactate levels may be implicated in AMD pathogenesis. Elevated serum homocysteine (Hcy) (known as Hyperhomocysteinemia, HHcy) was reported in many AMD clinical studies, suggesting an association between HHcy and the risk of AMD. We reported a direct impact of HHcy on retinal pigment epithelium (RPE) structure, barrier function, and choroidal neovasularization(CNV). We hypothesis that HHcy contributes to AMD via inducing metabolic switch in the mitochondria, in which cells predominantly produce energy by the high rate of glycolysis simulating cancer cells “Warburg” effect, rather than by comparatively low rate of glycolysis followed by oxidation of pyruvate in mitochondria as in normal cells. Increased glycolysis results in an increase in the rate of glucose uptake and preferential production of lactate, increasing cellular acidity with subsequent activation of angiogenesis, RPE barrier dysfunction, and CNV induction.

Methods: Evaluation of cellular energy production under HHcy was evaluated (both in vivo, using mice with HHcy ($cbs^{+/-}$ & $cbs^{-/-}$) and in vitro, using RPE cells) by Seahorse Analyzer, multitracker-based cytofluorimetry, immunofluorescence, and the western blot (WB) experiments. The Seahorse extracellular flux (XF) analyzer evaluates mitochondrial respiration by measuring oxygen concentration and proton flux in the cell supernatant over time. These measurements are expressed as mitochondrial oxygen consumption rate (OCR) and extracellular acidification rate (ECAR) as indicative of oxidative phosphorylation and glycolysis.

Results: HHcy showed a significant increase of both OCR and ECAR both in CBS mice ($cbs^{+/-}$ &$cbs^{-/-}$) and in vitro (Hcy-treated Human ARPE-19) compared to wild-Type mice retina and untreated ARPE-19 cells. Furthermore, HHcy upregulated glycolytic enzyme in RPE cells and inhibition of Glut1(the main glucose transporter in the RPE) was able to reduce glycolysis in Hcy-treated RPE and improve albumin leakage& CNV induction in Hcy-injected mouse eyes.

Conclusions: The current study suggests that Homocysteine causes a metabolic switch from mitochondrial respiration to glycolysis in RPE during AMD. Resulting in the activation of angiogenesis via activation of VEGF. Therefore, targeting Homocysteine clearance could be a novel therapeutic strategy for AMD.

ABSTRACT BODY:

Purpose: Clinical indicators for diabetic eyecare were previously developed from clinical guidelines published before 2013 and were tested in a nationwide patient record card audit (iCareTrack study), to assess the appropriateness of optometric diabetic eyecare delivery in Australia. To reflect emerging evidence, updated guidelines, and contemporary optometry practice, this study aimed to update the diabetic eyecare clinical indicators.

Methods: Candidate indicators included existing iCareTrack and new indicators derived from nine high-quality evidence-based guidelines identified through a systematic review. A two-round modified Delphi process with an expert panel (eight optometrists and one ophthalmologist) was used for consensus on the candidate indicators. In round-1, the experts rated the impact, acceptability, and feasibility of the indicators on a 9-point scale and voted for inclusion or exclusion. Consensus on inclusion was defined when the median scores for impact, acceptability, and feasibility were ≥7 and >75% of experts voted for inclusion. Any indicator that failed to reach consensus was presented for re-evaluation in round-2, with updated evidence summaries, de-identified group feedback and any modification suggestions from round-1.

Results: Of the 45 candidate indicators presented in the Delphi process, 33 were retained in the final list. The final indicators were grouped in the domains of history taking (13), examination (8), recall (5), referral (6), and patient education (1). All 13 iCareTrack indicators were retained either in the original format or with minor modifications. New history taking indicators included documenting the type of diabetes, serum lipid level, pregnancy status, systemic medications, renal disease, Indigenous status, non-English speaking background, and details of patient's general practitioner. Examination of pupil, intraocular pressure, optical coherence tomography, and diabetic retinopathy grading were added. Recall period for high-risk group without retinopathy, communication with general practitioner, referral of high-risk proliferative retinopathy, and patient education on regular follow up were also added.

Conclusions: The study described a systematic process of updating clinical indicators. These updated indicators will be the basis for a self-audit tool and allow assessment of diabetic eyecare appropriateness in Australia.

ABSTRACT BODY:

Purpose: Surgery cancellations affect patient satisfaction and ocular health, and negatively impact the efficiency of healthcare systems. By understanding causes of ophthalmic surgery cancellations and related predictive factors, they can be minimized. This study is a retrospective, non-randomized study that aims to determine risk factors for ophthalmic surgery cancellations.

Methods:

The study included a consecutive sample of patients above the age of 18 who had an ophthalmic surgery scheduled at Cole Eye Institute, Cleveland Clinic, OH between January 2012 and December 2019. An automated search pull identified 75,908 scheduled surgeries (63,987 completed and 11,921 cancelled surgeries; Figure 1). Statistical analysis was performed using R (version 3.5.1) to examine factors that impact risk for surgery cancellation.

Results: Analysis was performed on 69,963 scheduled surgeries (57.37% Female, 42.63% Male; Mean age of 62.72 years; 59,959 completed and 10,004 cancelled surgeries). Cataract surgery was the most common surgery scheduled, accounting for 56.32% of scheduled surgeries. Of the 2,384 cancelled surgeries with reasons provided, the most common causes of cancellation were patient refusal (38.42%), patient health condition (18.79%), and reschedule (15.27%). Female sex, black race, patient age less than 50 years, cataract surgeries, regional mean household income greater than $82,900, Medicare insurance, and geographical distance of less than 10 miles from home to the surgery site all significantly increased the risk of surgery cancellation ($p<0.01$; Table 1).

Conclusions: This study successfully identified several factors predicting ophthalmic surgery cancellation. The clinical insights gained from these lines of inquiry may be used to construct models that not only identify patients at greater risk for cancellation but also highlight which interventions would have greatest efficacy in preventing ophthalmic surgery cancellations.

ABSTRACT BODY:

Purpose: Near-infrared reflectance (IR) and fundus autofluorescence (FAF) have been shown to be more sensitiive than traditional flash color fundus photographs (CFP) for detection of reticular pseudodrusen (RPD). IR and FAF images, however, are not always available, particularly in historical datasets which may only contain CFP iamges. In this study, we evaluate whether an embossing image processing technique can improve the detection of RPD on CFP.

Methods: Seventy one eyes of 41 subjects (mean age 61.2 ± 5.5 years; range: 53 - 74 years) with RPD were used in this study. Ground truth determination of the presence of RPD in these eyes was established based on the identification of RPD on both IR and FAF images by two independent, masked retinal specialists. A single CFP from the same visit for each case was processed using an embossing technique in which each pixel was replaced by a highlight or a shadow depending on light and dark boundaries present in the original CFP image to yield and embossed photograph (EP). The CFP and EP images were grader separately by two additional masked graders for the presence of RPD. RPD were also classified into two types: dot and ribbon. The dot and ribbon type RPD detection rate on CFP and EP images were assessed indivisually by two other graders. Sensitivity of EP and CFP for detection of RPD was compared to the IR/FAF ground-truth assessment.

Results: Dot type RPD were noted in all 71 eyes in the IR and FAF images, but were detected in only 39 eyes on the CFP images (54.9%), whereas they were detected in 65 eyes from based on the EP images (91.5%). Ribbon type RPD were noted in all 71 eyes in the IR and FAF images, but in only 27 eyes on the CFP images (38.0%) and 14 eyes on the EP images (19.7%). Post-hoc review of the images, confirmed that EP images could visualize dot type RPD lesions not evident on the original CFP image (Figure, arrow). Whereas all 39 eyes in which RPD were noted on CFP also showed RPD on the EP images, EP images demonstrated RPD in 26 of the 32 eyes (81.3%) in which RPD were not visible on the CFP image.

Conclusions: Embossing CFPs can improve the detection of RPD, particurly dot type RPD. As eyes with ribbon type RPD generally also feature dot type RPD, the embossing technique may be a useful tool for better assessing the true frequency of RPD in datasets where only CFP images are available.

TITLE: Retinal vasomotion is increased by increased systemic blood pressure and is reduced by flickering light in normal persons

SESSION TITLE: Retinal metabolism and physiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Petersen, T. Bek, Department of Ophthalmology, Aarhus Universitetshospital, Aarhus, DENMARK|

Commercial Relationships Disclosure: Line Petersen: Commercial Relationship: Code N (No Commercial Relationship) | Toke Bek: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal vasomotion is spontaneous oscillations in the diameter of retinal arterioles with consequent changes in retinal blood flow. The phenomenon has been shown to be important for oxygenation and fluid homeostasis, and it has been hypothesized that disturbances in retinal vasomotion may be involved in the pathogenesis of diabetic retinopathy. However, it is unknown how retinal vasomotion is affected by physiological changes in the blood pressure and retinal metabolism.

Methods: 55 normal persons aged 20-30 years were studied. Video recordings (25 frames/sec) were performed over 120 seconds at an upper or lower temporal arteriole at rest, during an increase in the arterial blood pressure induced by lifting a hand weight of 2 kg and during exposure to flickering light at 25 Hz. The arteriolar diameter was determined based on the contrast to the surrounding retina in each of the 3000 consecutive image frames. The diameter changes were subjected to Fourier analysis and the power was calculated for the very low (VLF: <0.04 Hz), low (LF: 0.04-0.15 Hz), high (HF: 0.15-0.4 Hz), very high (VHF: 0.4-2.0 Hz) and the ultra-high (HF: 2-12.5 Hz) frequency bands.

Results: During rest the powers were (mean±SD): VLF: (1.48 ± 0.97), LF: (2.69 ± 1.69), HF: (2.48 ± 1.90), VHF: (5.33 ± 1.94), and UHF: (8.42 ± 2.76). Isometric exercise significantly increased the power of the VLF and the VHF bands ($p<0.0001$ for both comparisons), whereas exposure to flickering light reduced the power to at least the half at all frequency bands ($p<0.0001$ for all comparisons).

Conclusions: The amplitude of spontaneous oscillations in the diameter of retinal vessels are increased by increased blood pressure and reduced by stimulation of retinal metabolism by flickering light. These responses may play a role in the regulation of retinal blood flow under normal conditions. Disturbances in these responses might be involved in the pathogenesis of retinal vascular disease.

Yam: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Myopia is the most common ocular disorder worldwide and axial elongation in myopic eyes is accompanied by scleral remodeling of around the optic nerve head (ONH).This study aims to assess the characteristics and the prevalence of the peripapillary gamma zone among the myopic, emmetropic, and hyperopic eyes of Chinese children.

Methods: This is a population-based study. 1274 children aged 6–8 years were recruited from the Hong Kong Children Eye Study (HKCES). All participants completed ocular examinations, including cycloplegic auto-refraction and axial length (AL) measurements. The optic disc was imaged using a Spectralis OCT unit (Heidelberg Engineering, Heidelberg, Germany), adopting a protocol with 24 equally spaced radial B-scans. The peripapillary gamma zone was defined as the region between the Bruch's membrane opening (BMO) and the border of the optic disc, which was defined by the peripapillary border tissue.

Results: The prevalence of the peripapillary gamma zone was much higher in myopic eyes (36.3%) than in emmetropic (16.1%) and hyperopic eyes (11.5%; P<0.001). In the subgroup analysis, the axial length (AL) of eyes with a peripapillary gamma zone was significantly longer than for eyes without a peripapillary gamma zone among the myopia group (24.28mm vs. 23.79mm; P<0.001), but not in the emmetropia (23.21mm vs. 23.15mm; P=0.117) or hyperopia groups (22.79mm vs. 22.67mm; P=0.119). Longer AL was associated with a higher chance of peripapillary gamma zone occurrence in the myopic eyes (OR=1.874, P<0.001), but not in the emmetropic (OR=1.033, P=0.913) or hyperopic eyes (OR=1.044, P=0.883) after adjusting for demographic, systematic, and ocular variables. The locations of the peripapillary gamma zone were different between myopic and non-myopic eyes (P<0.001).

Conclusions: The peripapillary gamma zone was observed in both myopic and non-myopic children, whereas it was associated with an AL elongation only in myopic eyes, suggesting that the mechanisms peripapillary gamma zone were different in myopic and non-myopic eyes.

ABSTRACT BODY:

Purpose: Recently, the remote control of machines using virtual reality technology has been attracting wide attention because it avoids the risk of infection and secondary disasters. However, a concern has been identified that conventional three-dimensional (3D) images worsen the accuracy of work due to deterioration in-depth perception. Therefore, since head-mounted displays (HMDs) based on the light field (LF) technology have the advantage of reproducing light flux for each pixel and creating an environment close to natural vision, we compared the depth of LFHMD, 3DHMD, and real space-based visions in this study.

Methods: A total of 25 young healthy volunteers (mean age: 20.6 ± 0.7 years) participated in the study. First, TransRay^{TM} (Toppan Inc.), which can construct a virtual space for both LFHMD and 3DHMD at 0.2–1.2 m in front of the eyes; AS-7JS7 (Kowa Co., Ltd.), was used for depth of vision in real space. Then, the LFHMD depth of vision was measured at a reference distance of 0.5 m. Next, the depth of vision in real space was measured at a reference distance of 2.5 m. Subsequently, bilateral stationary targets were used as cones, the central moving target as a sphere, and three reciprocal measurements were made six times at a speed of 5 cm/s.

Results: As observed, although the deviation from the reference distance was insignificantly different between LFHMD (9.0 ± 22.9 mm) and real space (−6.5 ± 9.3 mm; $P = 0.092$), the deviation from the reference distance was significantly greater in 3DHMD (11.8 ± 32.9 mm) than in real space ($P = 0.038$).

Conclusions: Thus, our findings propose that LFHMD provides better depth perception closer to real space than 3DHMD.

ABSTRACT BODY:

Purpose: Cone-rod homeobox (CRX) is an essential protein for the development and maintenance of rod and cone photoreceptors. Mutations in the gene can lead to several forms of inherited retinal degeneration. In this multicenter study, we describe the phenotypic, genotypic and histopathological characteristics of CRX-associated retinal dystrophies.

Methods: In order to characterize the phenotypic and genotypic features, medical records were reviewed. Clinical data and imaging was collected from multiple European centers to describe the phenotypic and genotypic spectrum. Furthermore, immunohistochemistry was performed on the retina of a patient with CRX-associated retinal dystrophy, to visualize photoreceptor degeneration. Tissue fragments were excised from the macular and peripheral areas of the patient's retina and an age- and gender-matched control. Cryosections were obtained and immunostained for rod, cone and bipolar cell specific proteins and imaged with a confocal microscope.

Results: In 39 patients from 31 families, 21 different autosomal dominant CRX variants were identified, including missense and frameshift mutations. Phenotypes were highly heterogeneous, ranging from mild, late-onset macular dystrophy to Leber congenital amaurosis leading to congenital blindness. Age at onset ranged from at birth to the 8th decade. Mean visual acuity was 0.16±0.21 Snellen at a mean age of 52.3±19.9 years.
Immunohistochemical analysis of the eye of a 17-year-old patient with a deletion of exons three and four in one allele of CRX revealed extensive photoreceptor degeneration and loss of laminar integrity in the neuroretina. The degeneration was concentrated in the central retina, where the thickness of the outer nuclear layer was markedly reduced. Near the macula, complete loss of rods and short-wavelength cones was observed. Mislocalized photoreceptor nuclei and outer segment proteins were observed throughout the retina.

Conclusions: This study found a large phenotypic variation in patients with mutations in CRX. Histopathological analysis demonstrated widespread photoreceptor cell loss, especially in the central retina. These findings mimic features commonly found in animal models for CRX-associated retinal disease and align with clinical observations.

ABSTRACT BODY:

Purpose: Adaptation to high- or low-contrast is a known process of the visual system. Moreover, adaptation, guided by retinal mechanisms, also influences refractive development. So far, central contrast adaptation has been measured centrally or peripherally after peripheral adaptation, however not centrally after peripheral adaptation. Therefore, this study aimed to investigate the short-term influence of different levels of peripheral optical scattering on central visual performance, by assessing chromatic and achromatic contrast sensitivity (CS).

Methods: In total, 19 participants were included in the study. Each participant performed three blocks of scattering conditions: control, 0.4 and 0.8 Bangerter foil, each with a clear central aperture of 8.0 mm. For each block, CS was tested monocularly at three different adaptation times (at 0 min, 30 min and 90 min) using a 2IFC-modified version of the Tuebingen CS test for 3 cpd and 12 cpd, while the fellow eye was covered. Chromatic stimuli were designed to match the cone type sensitivities of S-, M- and L-cones using the method of silent substitution. During CS testing, pupil size was controlled to ensure a smaller pupil size than the clear central zone of the Bangerter foils. CS changes were analyzed using linear mixed models.

Results: The sensitivity of cone-types differed significantly from each other (all $p<0.05$), except the achromatic and L-cone type ($p=0.87$), where the S-cone type showed the minimum sensitivity across all testing conditions and M-cone CS exhibited the maximum, see Figure 1. Overall, CS was also influenced by the level of peripheral contrast reduction, while the 0.4 Bangerter foil showed a significant reduction compared to the control condition ($p=0.04$) and the 0.8 Bangerter foil condition ($p=0.0008$). Moreover, no central contrast adaptation to peripheral scattering was found, but reversely, a reduction of 0.11 log(CS) after 90 min and of 0.08 log(CS) between 30 min and 90 min (both $p<0.0001$).

Conclusions: Central visual performance depends on the level of peripherally imposed scattering, which affects all cone types equally and non-selective. Adaptation to scattering was not found, but a decrease in CS over the time. Further research is required to determine whether peripheral contrast reduction leads to long-term retinal driven refractive changes.

ABSTRACT BODY:

Purpose: Pseudoxanthoma elasticum (PXE) is a rare genetic disorder leading to ectopic calcification of Bruch's membrane (BrM). This can result in a reduced metabolic exchange between the retina and choroid, atrophy of retinal pigment epithelium, and formation of angioid streaks with choroidal neovascularization, all of which can lead to vision loss. Here, we present a histopathological study to investigate the molecular composition and distribution of calcified BrM in eyes with PXE, followed by correlation with clinical images.

Methods: Six cadaveric eyes that were clinically diagnosed with PXE were obtained from the Netherlands Institute for Neuroscience, Amsterdam or the Dutch National Expertise Center for PXE, Utrecht. Eyes were either flat-mounted on to glass slides or embedded in paraffin wax and sectioned to 7 µm. To visualize the distribution of calcified BrM, flat-mounted and cross-sectioned tissues were stained with OsteoSense 680EX, a fluorescent dye specific for the calcium phosphate, hydroxyapatite. The elemental composition of BrM was analysed using energy dispersive x-ray spectroscopy (EDX) whilst time of flight-secondary ion mass spectrometry (TOF-SIMS) was used for mineral composition analysis.

Results: In PXE eyes, the distribution of BrM calcification changes across the central-peripheral axis. On flat-mounted eyes, extensive OsteoSense labelling was observed in the central region with a marked reduction and a patchy distribution towards the periphery. On cross-sections, OsteoSense labelling confirmed the presence of a confluent layer of calcification in the central region with intermittent staining in peripheral regions. EDX analysis confirmed the enrichment of calcium and phosphorus in the BrM of PXE eyes and showed a distribution similar to OsteoSense staining. TOF-SIMS confirmed that some calcifications, at least, were formed of hydroxyapatite.

Conclusions: Extensive calcification is present in the BrM of eyes from PXE patients. Correlation of histopathology and molecular analyses with clinical images suggests that the phenotype observed on fundus imaging modalities is likely associated with the distribution of calcification in the BrM. For example, confluent calcification is associated with angioid streaks whilst the patchy calcification observed in the periphery is likely associated with regions of p'eau d'orange.

ABSTRACT BODY:

Purpose: Elevated intraocular pressure (IOP) is the main risk for glaucoma factor, though it is known today that autoimmune factors also contribute to disease development. Likely, a combination of multiple factors is responsible for the damage. Hence, we combined two glaucoma risk factors (IOP and autoimmune response) to examine if the combination leads to greater optic nerve damage.

Methods: For the multifactorial model, six-week-old wildtype mice (ONA) and βB1-CTGF mice (combination) were immunized with 1 mg/ml ONA (=optic nerve antigen). These were compared to wildtype (control) and βB1-CTGF control mice (CTGF). Hence, four groups in total (n=8-10/group). Longitudinal sections were investigated (immuno-)histologically for inflammation (H&E), myelin (LFB), apoptosis (cleaved caspase 3), and the complement system (factor C3). HE and LFB were analyzed using a score to evaluate cell infiltration and demyelination, while cleaved caspase 3^+ and $C3^+$ cells were counted using ImageJ. Further, RT-qPCR analysis of Olig2 mRNA levels were performed.

Results: In comparison to the control group, more inflammatory cells were visible in the other groups ($p<0.001$). Regarding the optic nerve myelin structure, a significantly higher LFB damage score was noted in the combination group compared to controls ($p<0.001$), ONA ($p=0.003$), and CTGF mice ($p=0.01$). Also, more apoptosis was seen in the ONA ($p=0.02$), the CTGF ($p=0.03$), and the combination group ($p=0.04$) compared to controls. The complement system factor C3 was upregulated in the combination group in comparison to the control group (control: 1.43±0.14 cells/mm; combination: 2.18±0.40 cells/mm; $p=0.03$). The mRNA levels of Olig2 were significantly downregulated in ONA, CTGF, and combination optic nerves compared to controls ($p<0.05$). Further, a significant downregulation was noted in the combination group compared ONA optic nerves ($p=0.04$).

Conclusions: Through combining two glaucoma risk a heightened pathological damage could be seen. An increase in demyelination in the combination group and an elevated apoptosis rate was visible. Additionally, the complement factor C3 was upregulated in the combination optic nerves. These results suggest a potential additive role of high IOP and immune factors in glaucoma development, which could be helpful for further investigations of this multifactorial disease.

Dick: Commercial Relationship: Code N (No Commercial Relationship) | Sven Schnichels: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The pathological events of age-related macular degeneration (AMD) are characterized by degenerative processes involving the photoreceptor cells, retinal pigment epithelium (RPE), the Bruch's membrane and choroidal alterations. To examine the interactions between photoreceptor cells and RPE cells ex vivo complex models are required. The aim of this study was to investigate the beneficial effects of a primary RPE cell co-culture or conditioned medium from these cells on neural retina explants.

Methods: Porcine neural retina explants were co-cultured with primary RPE cells (ppRPE) or with medium derived from RPE cells (medium). Individually cultivated neural retina explants served as controls (control). After eight days, RT-qPCR (n=6-7/group) and immunohistology (n=7-10/group) were performed to analyze the amount, condition, and expression of photoreceptors, synapses, macroglia, microglia, complement factors, and pro-inflammatory cytokines (e.g., Il-1β, Il-6, Tnf-α).

Results: The presence of ppRPE cells preserved the expression of photoreceptor specific markers (opsin: $p=0.016$, rhodopsin: $p=0.027$), whereas the medium group only showed a preservation of opsin+ cells in immunohistology ($p<0.001$), but not with RT-qPCR. Only minor differences between the three groups were noted in regard to microglia, $Iba1^+$ cell counts were lower in the ppRPE group ($p=0.042$). Increased Il-6 levels were noted in ppRPE and medium samples, while Tnf-α was only upregulated in the ppRPE group and Il-1β was elevated in medium samples. In regard to synaptic activity, $PSD95^+$ area was increased in ppRPE ($p=0.024$) and medium samples ($p=0.043$).

Conclusions: In conclusion, a co-culture of ppRPE cells and neural retina seems to have a beneficial effect, preserving photoreceptors and synaptic activity in vitro. These organ culture models could be used to mimic the complex interactions between the retina and RPE cells and gain further insights into neurodegenerative pathomechanisms occurring in retinal disease like AMD.

ABSTRACT BODY:

Purpose: To determine the prevalence of fast progressors based on both global and central visual field loss in a clinical cohort of glaucoma patients.

Methods: A retrospective review of patients under routine care at an ophthalmology clinic in Melbourne was undertaken to identify those with glaucoma without any other confounding conditions that had undergone ≥5 visual field tests over a 1–5 year period. The rates of change in the global mean deviation from the entire 24-2 visual field test (MD_{24}) and mean total deviation of the 12 locations in the central 10° (MTD_{10}) were calculated using ordinary least squares regression.

Results: Amongst the 295 eyes from 190 patients with glaucoma included in this study, 6.1% and 9.2% of eyes had a rate of change of <-1.0 dB/year on for MD_{24} and MTD_{10}, and 18.7% and 23.0% had a rate of change <-0.5 dB/year respectively. Furthermore, 17.7% and 21.7% of eyes exhibited a rate of change in the top 5% of the estimated normal distribution (based on the positive slopes) for MD_{24} and MTD_{10} respectively.

Conclusions: Although most patients with glaucoma under routine care in this cohort showed relatively slow rates of global visual field loss, nearly one-quarter of eyes exhibited central visual field loss <-0.5 dB/year, a rate that is relatively fast considering the significance of central vision on functional disability. These findings underscore the need for new management strategies and/or interventions to better prevent functional impairment in patients with glaucoma.

ABSTRACT BODY:

Purpose: To evaluate the prevalence of diabetic retinopathy (DR) and 5-year rates of incident DR, 2-step-or-more progression of DR, as well as progression to proliferative DR along with associated markers in a Danish national cohort.

Methods: We included all persons in the Danish Registry of Diabetic Retinopathy, who had attended at least one episode of DR-screening in 2013-2018. DR was classified by the International Clinical Diabetic Retinopathy Severity Scale with levels 0-4 indicating increasing severity. Data were linked with various national databases to indicate type and duration of diabetes, marital status, comorbidity, systemic medication and screening facility. Baseline DR-level at the worse eye was used for analysis.

Results: Among 170,237 persons with diabetes, mean (with interquartile range) age and duration of diabetes were 65.7 (55.5-73.1) and 5.9 (2.2-11.0) years, respectively, 56.6% were male, and 90.0% had type 2 diabetes. DR-prevalence and 5-year incidences of DR, 2-step-or-more progression of DR and progression to proliferative DR were 12.4%, 4.6%, 0.9% and 0.4%, respectively. The highest rates were found in those below 30 years (21.6%, 13.2%, 2.8%, and 1.2%), with type 1 diabetes (44.2%, 16.0%, 3.4%, and 2.3%), duration of diabetes above 20 years (57.3%, 16.2%, 3.5%, and 2.8%), using insulin (31.8%, 11.0%, 2.4%, and 1.3%), and attending screening at a hospital facility (33.6%, 10.3%, 2.6%, and 1.3%). In multivariable models, use of insulin was identified as a leading marker of all four outcomes (odds ratio 2.24, 95% confidence interval [CI] 2.14-2.34, hazard ratio [HR] 1.90, 95% CI 1.78-2.03, HR 2.23, 95% CI 1.94-2.56, and HR 2.68, 95% CI 2.09-3.43). On the other hand, gender, marital status, Charlson Comorbidity Index score, non-insulin glucose lowering therapy, antihypertensive or cholesterol lowering treatment did not consistenly affect the risk of DR. For patients who entered the registry in the years of 2013, 2014 and 2015, risks of progression to proliferative DR decreased continuously (2.13 vs. 0.97 vs. 0.45, and 2.72 vs. 1.12 vs. 0.70 events per 1,000 person-years for 1- and 3-year progression, respectively).

Conclusions: In a 5-year longitudinal study of a national cohort of persons attending DR-screening, we identified low age, type 1 diabetes, long duration of diabetes, and in particular use of insulin as the most important markers of presence and development of DR.

ABSTRACT BODY:

Purpose: To analyze the use of teleophthalmology during the COVID-19 pandemic, with regard to patient demographics, diagnostic precision, therapeutic effectiveness, and patient satisfaction.

Methods: The records of 520 consecutive patients who had telemedicine visits at Stony Brook Ophthalmology between March 30 and June 2, 2020, were reviewed to create a retrospective, cross-sectional analysis. Telemedicine visits were offered to all new patients requesting care and established patients who were scheduled or due for follow-up or postoperative visits. The visits were reviewed and the chief complaint, past medical history, past ocular history, diagnoses, treatment/management, and sub-specialty of the provider were analyzed. Precision was determined by comparing the examination findings and diagnoses of the telemedicine visit with the subsequent in-person, follow-up examination. Progression or resolution of the patients' symptoms was determined by the attending physician's assessment at follow-up visits. A post telemedicine visit satisfaction survey was sent to all patients and the results were analyzed.

Results: Telemedicine visits were offered to 783 patients, 520 (66.4%) of whom accepted (mean age= 34.9 years; range 1-95). Of these 520 patients, 409 (78.7%) were established and 105 (20.2%) had in-person follow-up visits., Overall, the diagnostic precision of the follow-up visits was 89.5%. Of the patients who had in-person follow-up visits, 56.8% remained stable, 32.4% improved, and 10.8% worsened. Established patients presented with more extensive ocular histories/procedures, and experienced a higher percentage of worsening symptoms/disease stage compared to new patients. In total, 78 (15.0%) patients completed the survey. Overall satisfaction was reported by 91.9% of patients, although only 23.0% preferred telemedicine to an in-office visit.

Conclusions: Teleophthalmology provides high levels of precision and patient satisfaction for a wide range of ophthalmologic visits, although most patients still preferred in-office examinations. Employing teleophthalmology for follow-up and emergency care may provide patients with an effective alternative during pandemic situations and beyond.

Dick: Commercial Relationship: Code N (No Commercial Relationship) | Stephanie Joachim: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Damage to the retinal pigment epithelium (RPE), a hallmark of AMD, leads to production of oxidative stress and hypoxia which in turn ends in retinal damage. Therefore, the influence of oxidative stress and hypoxia on a human RPE cell line (ARPE-19) was investigated in this study.

Methods: 300 µM $NaIO_3$ or $CoCl_2$ was applied to ARPE-19 cells (3h) to induce oxidative stress or hypoxia. Untreated ARPE-19 cells served as controls. After 4 days of cultivation, RT-qPCRs were performed (n=5/group). Cell samples were analyzed for specific genes relevant to autophagy (MTOR, SQSTM1, BNIP3) or apoptosis (FASLG, CASP3, CASP9). In addition, different concentrations of $NaIO_3$ (0.5 mM, 1 mM, 5 mM and 10 mM) were compared and analyzed by RT-qPCRs (n=10/group). Immunohistochemical stainings were made to visualize apoptotic effects (e.g. cleaved caspase 3) and a cell damage assay was performed (BrdU).

Results: 300 µM $NaIO_3$ or $CoCl_2$ led to increased CASP3 mRNA expression (rel. exp.: 1.44; p=0.018). In addition, a significantly increased FASLG expression was identified in the $NaIO_3$ group (rel. exp.: 4.17; p=0.026). No significant differences were found in regard to autophagy markers. The concentration series with $NaIO_3$ showed apoptotic as well as autophagic effects. An increased FASLG (rel. exp.: 3.77; p=0.008), MTOR (rel. exp.: 3.20; p=0.007), CASP9 (p=0.048), HIF1α (p=0.046), and NFkB expression (p=0.016) was noted with 0.5 mM $NaIO_3$. Additionally, 5 mM $NaIO_3$ led to significantly more FASLG (rel. exp.: 3.12; p=0.037) and NFkB (rel. exp.: 1.70; p=0.031). A higher expression of SQSTM1 (rel. exp.: 2.12; p=0.021) was observed for 10 mM $NaIO_3$. The cleaved caspase 3 staining visualized the apoptotic effect mediated by $NaIO_3$.

Conclusions: The RT-qPCR analyses and stainings suggest that both forms of damage have primarily an apoptotic effect on ARPE-19 cells, but higher concentrations of the stressors also induce autophagic effects. Further investigation at protein level should provide more insight into the effects of the stressors which is important for establishing novel therapeutic approaches.

ABSTRACT BODY:

Purpose: Intravitreal injections of anti- vascular endothelial growth factor (anti-VEGF) agents are considered the gold standard for treatment for diabetic macular edema (DME). While monthly and as needed (PRN) injections schemes have been shown to be effective, they constitute a burden for patients and providers in real world clinical settings. Alternatively, treat and extend (T&E) dosing can be used titrate the anti-VEGF dosing based on an individual's clinical response while minimizing treatment burden. This study aims to pool available data on change in visual acuity (VA), number of injections, and change in central subfield thickness (CST) as reported by T&E regimens for DME compared to monthly and PRN regimens.

Methods: PubMed, Science Direct, and EMBASE databases were queried for studies that met the following criteria: retrospective or prospective design, T&E regimen reported in comparison to a monthly or PRN regimen for the treatment of DME, and a 12 month follow up period. After data were extracted, analysis was performed using a random effect model. Publication bias was examined using a funnel plot and Egger's linear regression test. An I^2 test was utilized to determine heterogeneity.

Results: Six total randomized clinical trials were identified. Three studies compared monthly regimens to T&E. The remainder compared PRN regimens to T&E. Comparing monthly and T&E regimens, no significant difference was found between average VA improvement (p=0.30), CST improvement (p=0.28), or number of injections (p=0.20). Comparing PRN and T&E regimens, no significant difference was found between average VA improvement (p=0.64), CST improvement (p=0.11), or number of injections (p=0.89).

Conclusions: In terms of VA and CST, T&E regiments were non-inferior to monthly or PRN regiments. No significant difference in number of injections was detected. These conclusions are limited by study design and outcome: only six studies, which included conservative T&E regimens were included. Furthermore, the criteria did not filter for treatment naïve patients. Future studies need to characterize the long-term reduction of treatment burden in T&E protocols.

ABSTRACT BODY:

Purpose: HIV-1 infection can cause visual impairment in 73% of patients. The HIV viral load is often detected in ocular fluids and the retina. Therefore, understanding the effect of HIV on retinal inflammation and homeostasis is of great importance.

Methods: We used a localized HIV eye model developed by injecting 2.5ng/uL of HIV-Tat protein into the eyes of female Sprague Dawley rats (21 days). After five days, rats were euthanized, and their retinas enucleated. Immunohistochemical analysis and confocal microscopy was used to semi-quantitatively evaluate physiological changes in the BRB components using glial fibrillary acidic protein (GFAP), Aquaporin 4 (AQP4) and potassium channel Kir 4.1 for glial cell markers; intercellular adhesion molecule 1 (ICAM-1) for BRB markers; and Interleukin 1 Beta (IL-1B) and Tumor Necrosis Factor Alpha (TNFa) for inflammation markers. In addition, Western Blot was performed to quantitatively assess differences in Kir 4.1, AQP4 and GFAP expression between sham and HIV-Tat treated eyes.

Results: Immunofluorescence results showed an increased expression of Kir4.1 and AQP4 in Müller glial cells in the retinas treated with HIV-Tat. Additionally, there was also an upregulation of ICAM-1 observed in the outer-BRB/RPE cells. Western Blot analysis showed that Kir 4.1 and AQP4 protein level expression was increased in retinas treated with HIV-Tat compared to sham.

Conclusions: In conclusion, we suggest that such upregulation of Kir 4.1 and AQP4 are rather compensating effects of glial cells to maintain normal potassium and water buffering than commonly expected degradative process. Additionally, results suggests that ICAM-1 could be a promoter of HIV adhesion to the RPE cells by facilitating viral load invasion into the ocular tissues during HIV. Still, further investigation is needed.

ABSTRACT BODY:

Purpose: Best corrected visual acuity (BCVA) and FST are quantitative measures affected by inherited retinal degenerations (IRDs). There are few available estimates for rates of change in IRDs. Here we provide estimates of change over 2 years from the Rate of Progression in USH2A-related Retinal Degeneration (RUSH2A) study using mixed effects models.

Methods: Participants with BCVA ≥ 20/80, stable fixation, and kinetic visual field of ≥ 10° at baseline in the study eye had BCVA (ETDRS letter score) and FST measured at baseline, 1, and 2 years. FST was measured with white, blue and red stimuli in triplicate and was performed only in centers having the required equipment. Mixed effects models were used to estimate the annual rates of change and percentage rates of change using log transformed data with 95% confidence intervals (95% CI). Sensitivity analyses were performed by down-weighting results from eyes with outlier rates of change. Spearman correlation coefficients (r) were calculated among BCVA and FST measures.

Results: The average decline of BCVA score [N=102] was 0.87 (0.48, 1.26) letters/year or 1.1 (0.6,1.6) %/year (Table 1). For FST measures [N=73], the average increase of thresholds was 1.28 (0.85, 1.71) dB/year for white stimulus, 1.25 (0.82, 1.67) dB/year for blue stimulus and 0.76 (0.42, 1.10) dB/year for red stimulus. Models that down-weighted outliers yielded lower rates of decline for BCVA and lower rates of increase for FST measures compared to models that weighted equally all data points. There was no significant correlation between 2-year changes in BCVA letter score and the three FST measures (r between -0.08 and -0.12; Table 2). 2-year changes in the three FST measures were highly correlated with each other (r between 0.61 and 0.77; $p<0.001$). Among eyes [N=65] that had FST testing at baseline and year 2, the response was cone mediated (FST white > -30 dB) in 31 (48%) at both times, rod mediated (FST white ≤ -30 dB) in 29 (45%) at both times and switched from rod- to cone-mediated in 5 (8%).

Conclusions: Based on 2 years of follow-up in RUSH2A, average decline in BCVA was small. Average white and blue FST values deteriorated a similar degree. Sensitivity changed from rod- to cone-mediated in 8% of patients.

SUBMITTER (NAME ONLY): Nancy Barrett

TITLE: Artificial Intelligence (AI) Enabled Pre-Screening for Diabetic Retinopathy (DR) Clinical Trials

SESSION TITLE: Machine Learning: Segmentation and Classification

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Barrett, R. Slater, R. Channa, A. Domalpally, B.A. Blodi, Department of Ophthalmology and Visual Sciences, University of Wisconsin-Madison, Madison, Wisconsin, UNITED STATES|

Commercial Relationships Disclosure: Nancy Barrett: Commercial Relationship: Code N (No Commercial Relationship) | Robert Slater: Commercial Relationship: Code N (No Commercial Relationship) | Roomasa Channa: Commercial Relationship: Code N (No Commercial Relationship) | Amitha Domalpally: Commercial Relationship: Code N (No Commercial Relationship) | Barbara Blodi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Preventive therapies to reduce progression of non-proliferative DR (NPDR) to proliferative DR are underway. Clinical trial enrollment criteria typically include a baseline DR severity scale (DRSS) of moderately severe (level 47) or severe NPDR (level 53) determined from stereoscopic 7-field retinal color photographs by certified graders at the Wisconsin Reading Center (WRC). The estimated screen failure rate after WRC confirmation is 50% with the most common reason being level < 47. We developed an AI algorithm to enable real-time prescreening of color photographs for DRSS to reduce the screen failure rate.

Methods: Grader training images at WRC were utilized for training the EffcientNetB4 model starting from Imagenet weights and fine tuned to a binary classifier with an input resolution of 768x768 utilizing an 80:20 split for training and internal validation. The dataset included 572 training images stratified across the NPDR scale (levels 35, 43, 47 and 53). 132 images were set aside for internal validation with the same stratification. The algorithm was trained to identify ineligible eyes (levels 35 – 43) and eligible eyes (levels 47-53) using macula centered field 2 images only. WRC graders used the DRSS scale to assess NPDR severity in all 572 eyes.

Results: Of the 37 eyes considered eligible by the AI, the grader agreed on 62.9%. Of 97 eyes considered ineligible by AI, the grader agreed on 90.7%. The best model had an area under the curve (AUC) of 0.91. The overall accuracy (weighted by class) was 83%. The sensitivity of the eligible class was 0.59, specificity of 0.71 giving an F1 score of 0.65. A review of the false positive and negative images showed image quality and an imbalance in DR features between F2 and peripheral fields to be the two largest contributing factors to false results.

Conclusions: The AI algorithm is effective at identifying levels <47 and can exclude them from clinical trial submissions. A tiered approach with AI prescreening for eligible participants followed by WRC grader confirmation reduces the screen failure rate, creating cost efficiency and reduced burden for participants and clinical site staff. Real time automated assessment of potential eligibility could improve enrollment in DR clinical trials.

Commercial Relationships Disclosure: Raymond Warner: Commercial Relationship: Code N (No Commercial Relationship) | David Brainard: Commercial Relationship(s);Code P (Patent):US Patent App. 16/389,942 | Jessica Morgan: Commercial Relationship(s);Code P (Patent):US Patent 8226236 ;Code P (Patent):US Patent App. 16/389,942;Code F (Financial Support):F: AGTC

ABSTRACT BODY:

Purpose: Optoretinography assesses photoreceptor function. To develop optoretinography as a biomarker for disease affecting cones, we characterize the reliability of the cone optoretinogram in healthy subjects, as well as its dependence on stimulus duration.

Methods: Healthy subjects (N=5, 28-41 years) were imaged with an adaptive optics scanning laser ophthalmoscope (AOSLO). In each session, 270 AOSLO videos were acquired (785 nm, 1° x 1° imaging field, 1.5° temporal retina). A visible light stimulus (545Δ10 nm) was presented 1 s after the start of each video. The confocal reflecances of identified cones were extracted for each video frame, and the optoretinogram reflectance response for that frame was taken as the pooled standard deviation of the reflectances across cones (Cooper et al., 2017). We analyzed the peak response after stimulus initiation, taken from the fit of a smooth curve to the frame-by-frame response. We studied four intensity/exposure duration conditions, each with stimulus energy of 153 nJ/deg^2: 1) 153nW/1s, 2) 306nW/0.5s, 3) 917nW/0.167s, 4) 2.75μW/0.056s. To measure intra-session variation, condition 4 was measured twice per session. For each subject, the full set of measurements was repeated in two sessions separated by at least a week.

Results: Stimulus condition effects were not significant [$F(3,39) = 7.69$, $p = 0.355$]. Peak response varied significantly with subject [three-way ANOVA; subject, session, stimulus condition; $F(4,39) = 9.42$, $p = .025$]. Individual subject mean responses ranged from 2.4 to 4.5 on our response scale (arbiturary units). There was no main effect of session, but there was a significant subject by session interaction [$F(4,39) = 15.75$, $p < .001$]. This size of the session effect was small (mean absolute value 0.63) relative to intersubject differences. Within session variation for condition 4 was not significant in session 1 [one-way ANOVA; $F(1,49) = 0$, $p = 0.975$] nor session 2 [$F(1,49) = 0.06$, $p = 0.810$].

Conclusions: The population cone optoretinogram is reliable for individual subjects, with a single session and a short duration stimulus sufficient for characterizing a subject's response. Though the magnitude of the response varied across subjects, reciprocity between stimulus irradiance and duration held. Future work to establish optoretinography norms in larger numbers of healthy subjects is needed to apply optoretinography in studies of disease.

TITLE: Simulated myopic defocus counteracts a myopiagenic environment in juvenile tree shrews producing hyperopia

SESSION TITLE: Mechanisms of Refractive Error and Eye Development

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Gawne, Z. She, T.T. Norton, Optometry and Vision Science, University of Alabama at Birmingham, Birmingham, Alabama, UNITED STATES|

Commercial Relationships Disclosure: Timothy Gawne: Commercial Relationship(s);Code P (Patent):Provisional patent for related technology | Zhihui She: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Norton: Commercial Relationship(s);Code P (Patent):Provisional patent for related technology

ABSTRACT BODY:

Purpose: To examine the effects of a video display of simulated myopic blur on refractive development (emmetropization) in juvenile tree shrews.

Methods: Seven tree shrews (Tupaia belangeri, diurnal mammals closely related to primates) were removed from standard colony housing at 24 days of visual experience (DVE; days after eye opening) and placed in closed solid-wall cubical cages, 28 cm on a side internal dimension, with black and white patterns on the walls, until 35 DVE. Five animals were placed in the same size cage, but one wall consisted of a video display of simulated myopic blur (see Figure 1) of brightness 147 cd/m2, that was achieved by blurring the blue channel. Non-cycloplegic refractions and ocular dimensions were measured in awake animals using an autorefractor and an optical biometer, respectively. Data were compared with those obtained from seven animals previously reared in standard colony conditions with open-view wire mesh cages.

Results: At the end of the treatment period, the animals in the closed cages without the simulated myopic blur become slightly myopic: -1.0±0.4 (stderr) Diopters (see Figure 2). Animals in the open-view colony caging were slightly hyperopic at this age: 1.0±0.2 Diopters, significantly different from the animals in the closed view cage by t-test ($P<0.001$, $t=4.805$, $df=12$). In contrast, animals exposed to simulated myopic blur were hyperopic: +4.1±0.6 Diopters. The closed cage vs. myopic defocus group difference was 5.1 diopters, significant by t-test ($P<0.001$, $t=7.3638$, $df=10$). Changes in vitreous chamber depth were consistent with the refractive effects.

Conclusions: Cages with restricted viewing distance cause significant myopia in juvenile tree shrews. However, under these conditions simulated myopic blur more than overcomes the effect of restricted viewing distance and causes robust hyperopia. This emphasizes the importance of chromatic cues in emmetropization. This effect could potentially be developed into a powerful anti-myopia visual therapy for children.

TITLE: At-Home Refraction Measurement
SESSION TITLE: Vision Impairment, Visual Function, and Quality of Life
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: N. Sapiens, A. Ramic, J. Serri, EyeQue Corp., California, UNITED STATES|
Commercial Relationships Disclosure: Noam Sapiens: Commercial Relationship(s);Code E (Employment):EyeQue | Amra Ramic: Commercial Relationship(s);Code E (Employment):EyeQue Corp. | John Serri: Commercial Relationship(s);Code E (Employment):EyeQue Corp.;Code O (Owner):EyeQue Corp.

ABSTRACT BODY:

Purpose: Performing accurate refraction measurement at home will elevate eyecare and increase accessibility for many. The purpose of this study is to determine if the refraction results obtained from measurements in an at-home setting yields Best Corrected Visual Acuity (BCVA) results within 1 line of 20/20 (LogMAR 0.0). the study utilizes the EyeQue VisionCheck which is a smartphone based (figure 1), handheld, ophthalmic refractometer.

Methods: An open-label distributed study to assess the BCVA using glasses with correct PD created from the VisionCheck measurement results included 35 subjects (Female = 13, Male = 22). The age range was between 30-80, with mean 50.4 and SD = 24. Subjects were measured with VisionCheck and had OD Spherical Equivalent (SE) range of -6.0D and +2.25D and OS SE between -6.25D and +1.75D. Each subject performed 3 Visual Acuity tests without correction and 3 tests with glasses made from the VisionCheck results. BCVA measurements were done with the EyeQue Insight, an ETDRS visual acuity screener with logMAR range of 0.0 to 1.0.

Results: Statistical analysis was conducted using a student t-test for each eye separately as well as for both eyes measurement. The analysis included the mean and confidence intervals for both the BCVA measurement without any correction and for that with the VisionCheck based correction. The analysis showed significance for the confidence interval ($p < 0.001$). Table 1 shows a summary of the analysis.

Conclusions: Both the mean acuity and the confidence intervals are significantly lower for the VisionCheck based correction compared to uncorrected vision. The EyeQue VisionCheck refraction measurements on average provides BCVA within 1 letter of 20/20. This study indicates that at home self-refraction is practical and a promising alternative to in office testing.

ABSTRACT BODY:

Purpose: Redlining, a discriminatory practice in the 1930s to 1960s to categorize geographic areas based on investment risk, has negatively impacted communities and individuals. This practice has largely impacted residents of racial and ethnic minority groups and was a form of residential segregation. We hypothesize that neighborhoods with worse redlining scores are associated with visual impairment and blindness (VIB), defined as higher rates of self-reporting blindness or having serious difficulty seeing even when wearing glasses.

Methods: Census tract-level data were obtained from the American Community Survey, including the percent of respondents by tract who had VIB, sex, race, median age, state, and population size. Average redlining scores per census tract (CT) were obtained from OpenICPSR, with scores ranging from 1 to 4 (worst). CTs with missing data or margins of error >15% were excluded. Logistic regression was used to model the effect of redlining on the probability of a CT having a rate of VIB greater than the national average (>2.51%). Results are presented with odds ratios (OR) and 95% confidence intervals (CI). Linear regression was used to estimate the effect of redlining on the logarithm of average VIB. Results are presented with estimates (exponentiated for interpretation on a percentage scale) and 95% CIs.

Results: A total of 12,888 CTs in the US had redlining scores. Of these, 12,227 had complete data meeting inclusion criteria. The average percentage of residents with VIB across our CTs was 2.51% (standard deviation, SD=1.82), and 41% of these CTs had rates of VIB above the national average. The mean redlining score for these tracts was 2.94 (SD=0.78). Logistic regression found worse redlining scores were associated with significantly increased odds of VIB above the national average (OR:1.09; 95% CI:1.08-1.10; p<0.001), after controlling for aggregate measures of age, sex, race, state, and CT population. Similarly, linear regression found that a 1 unit increase in average redlining score was associated with an increase of 10.77% in the percentage of VIB (95% CI: 9.70% -11.85%; p<0.001).

Conclusions: Historical residential segregation through redlining was found to be associated with higher proportions of people living with VIB in these neighborhoods today. This study can aid in the understanding of how geographic area could impact VIB outcomes to inform public health planning and the delivery of eye care.

TITLE: Development of an Artificial Intelligence Classifier for Follicular Trachoma

SESSION TITLE: Machine Learning and Image Processing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C.J. Brady, Surgery/Ophthalmology, University of Vermont College of Medicine, Burlington, Vermont, UNITED STATES|R.C. Cockrell, D. Socia, Surgery/Research, University of Vermont College of Medicine, Burlington, Vermont, UNITED STATES|S.K. West, Wilmer Eye Institute, Johns Hopkins Medicine, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Christopher Brady: Commercial Relationship: Code N (No Commercial Relationship) | R. Cockrell: Commercial Relationship: Code N (No Commercial Relationship) | Damien Socia: Commercial Relationship: Code N (No Commercial Relationship) | Sheila West: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Despite intensive efforts, trachoma remains the most important infectious cause of vision loss and one of the overall leading causes of global blindness. Current methods for detection may be inadequate for elimination programs, so we sought to develop an artificial intelligence classifier (AI) for follicular trachoma (TF) using conjunctival images to allow for rapid, low-cost remote detection.

Methods: A smartphone camera collected 2614 upper eyelid images during a 2019 district survey in Chamwino, Tanzania. The subset of 2285 gradable images with concordant field and photo grades were re-sized to 224 x 224 pixels and randomly divided into equal training and test sets. To enrich the training set, oversampling of TF cases with data augmentation methods (horizontal flipping, rotation, perspective shift, and color jitter) were applied. Additionally, color space exploration and follicle enhancement methods were employed. Two commonly used pre-trained convolutional neural networks (VGG16 and Resnet101) were further trained on “training set.” Class weighting and batch accumulation were used to improve model performance.

Results: With a goal of maximizing recall, a ResNet101 model generated the best results, with a recall of 89%. This translated to a 75% reduction in skilled grader burden as only positive images require confirmation. Additionally, the misclassification of images in this work is typically due to poor image quality (e.g., failure to capture entire tarsal plate, image focus, etc.).

Conclusions: AI methods show promise in identifying TF, though the training data was limited by low case numbers of TF and non-standardized images. Future studies will retrain the model with larger datasets with more TF and will develop standardized photographic techniques (improved image quality, centration and lighting). While trachoma efforts are decentralized and organized at the country level, we believe photographic standardization using smartphone camera technology is reasonable given the widespread utilization of a single mHealth app (Tropical Data) to support TF prevalence surveys. To allow for practical value in areas of low network connectivity, edge computing strategies such as in-handset classification may be needed.

ABSTRACT BODY:

Purpose: Human aqueous humor (AH) plays an important role in maintaining intraocular pressure and metabolic balance in the anterior chamber of the eye. Increasing evidence indicates the incidence of ocular disorders vary by race and sex. Several ocular diseases are more prevalent in females than males. Also, the risk of developing glaucoma is higher among African Americans than Caucasians. In this study, we examined the race and sex-specific differences in human AH proteins.

Methods: Human AH samples from 177 subjects undergoing cataract surgery (without any other ocular disorders) were analyzed using liquid chromatography-tandem mass spectrometry (LC-MS/MS). A total of 233 AH proteins were detected in more than half of the samples. A regression model was used to test the effect of race and sex on the protein levels.

Results: The levels of 21 AH proteins were significantly different between males and females (5 higher and 16 lower in females). The proteins with higher levels in females include retinoschisin X-linked juvenile retinoschisis protein (RS1), extracellular superoxide dismutase (SOD3), and enolase 1 (ENO1). The proteins with lower levels in females include complements C6 and C9, inter-alpha-trypsin inhibitor heavy chain H2, and H4 (ITIH2, ITIH4), and apolipoprotein A-IV (APOA4). The levels of 56 proteins were significantly different between African American and Caucasian subjects (9 higher and 47 with lower levels in African Americans). The proteins with higher levels in African Americans include coagulation factor V (F5), low-density lipoprotein receptor-related protein 2 (LRP2), and several keratins including KRT1, KRT2, KRT10. The proteins with lower levels in African Americans include tetraspanin-14 (TSPAN14), six immunoglobulins (IGHG2, IGHG3, IGHV6-1, IGHLV1-40, IGHLV1-47, IGHLV3-9), and heparan sulfate proteoglycan core protein (HSPG2). Expression of three apolipoproteins (APOA1, APOA2, and APOA4) were significantly lower while SOD3 was higher in both African American and female subjects.

Conclusions: A total of 233 proteins were detected in more than 50% of healthy human AH samples. 69 of these proteins demonstrated race and sex-specific variations. The intra-population variation in AH protein levels highlights the importance of these two factors in future study designs. Additionally, these specific alterations may be associated with higher risks of glaucoma in females and African Americans.

ABSTRACT BODY:

Purpose: Gender inequality in medicine has been well established in literature. Female physicians tend to have lower salary, less representation in academia and research funding. Previous studies have shown that women in ophthalmology are underrepresented in terms of private industry payments and dollar amounts paid. Gender-based disparities in private industry payments to optometrists have not yet been studied. The present study investigates such disparities.

Methods: This study was deemed exempt by the Mayo Clinic IRB because it utilized only publicly available data from Centers for Medicare and Medicaid services (CMS) open payments database. U.S. optometrists listed in the database who had received at least one payment during 2019 were identified. Payments were compared in the following four categories: 1, compensation for non-consulting services (e.g., serving as faculty or speaker at a venue other than a continuing education program), 2, serving as faculty or a speaker for continuing education program, 3, consulting fees, and 4, honoraria were included. The total number of optometrists practicing in 2019 was obtained from a public website using a combination Census Bureau, Bureau of Labor Statistics, and Bureau of Economic Analysis databases. Statistical analysis was completed using RStudio 2021.09.1+372. Independent sample t-test was used to compare means, Wilcox rank-sum test was used to compare medians.

Results: A total of 50,700 practicing optometrists were identified in 2019; 22,100 (43.6%) were female. 630 (2.9%) female and 1033 (3.6%) male optometrists received payments. For all payment categories, mean payment for females was $3354.55 and for males was $7150.60 ($p<0.001$). Median payment for females was $450 and for males was $1238.18 ($p<0.001$).

Conclusions: These results confirm the trend previously reported within ophthalmology is also evident within optometry. Female optometrists are underrepresented in private industry payments. Dollar amounts paid to female optometrists were significantly less in all categories compared amounts paid to male optometrists.

ABSTRACT BODY:

Purpose: Social determinants of health can limit access to regular eye care, but their role in ophthalmology is underexamined. The purpose of this cross-sectional study is to assess the relationship between patient characteristics and self-reported barriers to eye care among patients attending a free vision screening event.

Methods: We conducted a 12-question survey of adult patients attending a community vision screening event. Our survey queried patients' current general and ocular health status, barriers to obtaining eye care, and demographic information. Associations between patient characteristics and self-reported barriers to eye care were assessed using binary logistic regression and reported as odds ratios (OR).

Results: The survey was completed by 183 of the 269 event attendees (68% response rate), with an average age of 53±15 years. The majority of respondents were women (105, 59%), and most self-identified as black (74, 46%) or white race (67, 41%). The plurality was employed or self-employed (67, 41%), and most others were retired (29, 18%), looking for employment (25, 15%) or unable to work (18, 11%). While about a third of patients reported having no health insurance (60, 34%), most had either public (84, 48%) or private coverage (34, 19%). Only a quarter reported having vision insurance (50, 28%). Three-quarters of respondents indicated at least one barrier to receiving regular eye care (136, 76%), most commonly cost (89, 50%) and insurance issues (73, 41%). Getting time off work (21, 12%) and transportation (13, 7%) were other commonly cited barriers to care. Not having health insurance or vision insurance was strongly associated with reporting at least one barrier to care (OR 5.00, $p=0.002$, and OR 7.463, $p<0.001$). Those with self-reported eye disease had challenges with transportation (OR 4.454, $p=0.013$) and getting time off work was a barrier for younger and employed persons ($p\leq0.01$ for both).

Conclusions: Three quarters of patients at a vision screening event reported at least one barrier to regular eye care. Although most had insurance coverage, medical costs and insurance issues were the leading barriers to receiving an eye exam. Other barriers were associated with specific patient characteristics. Targeted interventions are warranted to address barriers to vision care among underserved communities.

TITLE: Self-DNA induces inflammation in myoepithelial cells of the lacrimal gland by AIM2 inflammasome activation

SESSION TITLE: Dry eye regulators: lacrimal gland, Meibomian gland, basic mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Yang, D.A. Dartt, Ophthalmology, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Menglu Yang: Commercial Relationship: Code N (No Commercial Relationship) | Darlene Dartt: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Primary Sjögren's Syndrome (pSS) is an autoimmune disease that mainly affects the lacrimal glands and salivary glands. Antibodies against nuclear materials have been found in patients but the mechanism is unclear. When foreign DNA enters the cells, several mechanisms will be activated to defend against viral infection or local tissue damage. In this study, we focus on one of the mechanisms, namely Absent in Melanoma (AIM)2 inflammasome, in myoepithelial cells of the lacrimal gland. AIM2 non-selectively binds the double-stranded DNA in the cytoplasm, causing the formation of the AIM2 inflammasome to activate caspase-1, which cleaves immature pro-IL-1ß to mature IL-1ß that contribute to inflammation. We hypothesize that in pSS patients, self-DNA from the bloodstream of SS patients triggers the activation of AIM2 inflammasome which in turn causes inflammation to damage the healthy lacrimal gland.

Methods: Primary MECs culture was acquired from female wildtype C57Bl/6 mice aged 4-6 weeks. Genomic DNA (gDNA) extracted from the same culture was used to resemble the self-DNA. A random double-stranded DNA poly A:T was used as a positive control for AIM2 activation. Immunofluorescent (IF) was used to detect the assembly of inflammasomes; RT-PCR was used to detect the expression of AIM2. The activation of caspase-1 was measured using FAM-FLICA assay.

Results: The MECs were treated with gDNA for 6 hours, with random double-stranded DNA poly A:T as a positive control. Immunofluorescent (IF) staining result shows the accumulation of AIM2 signals and a speck of Apoptosis-associated speck-like protein containing a CARD (ASC), indicating the assembly of AIM2 inflammasome in both gDNA and poly AT treated groups. RT-PCR showed a significantly increased expression of Aim2 in both gDNA and poly AT treated groups compared to the non-treated group. FAM-FLICA assay showed that the activation of caspase-1 is significantly increased in both poly AT and gDNA treated groups compared to the non-treated group. We next applied the inhibitor of AIM2, A151, to the MECs together with gDNA or poly AT, and the ratio of AIM2 or ASC speck positive cells was measured from each group. We found that A151 significantly terminated the presence of AIM2 and ASC speck compared to the gDNA or poly AT group.

Conclusions: Self-DNA induces caspase-1 activation in MECs through AIM2 inflammasome, which may be a key mechanism in pSS.

ABSTRACT BODY:

Purpose: We propose to identify mechanisms that underlie the initiation and early progression of diabetic retinopathy (DR) via dissecting the genes and pathways controlling diabetes-induced responses in Müller glial cells (MG), which are one of the first responders of diabetes in the retina. In our studies, we discovered zinc finger protein 36 (ZFP36) are significantly altered by diabetes and contribute to the development of DR.

Methods: Streptozotocin (STZ)-induced diabetic rats were used as models to study DR. RNA-seq, histological immunostaining and fluorescence mRNA in situ hybridization (FISH) were utilized to capture diabetes-induced transcriptomic changes in the retinal MG at early stages. Endogenous ZFP36 gene expression was detected and quantified by quantitative single molecule FISH (smFISH) on rat MG. We also developed novel adeno-associated virus (AAVs) that can specifically and efficiently label and manipulate MG in vivo in rat retinas. These AAVs were used to knock down or overexpress ZFP36 in rat MG in vivo under normal and diabetic conditions. The DR-related retinal phenotypes were characterized as described in the literature, including MG gliosis, RGC survival rate, and vascular permeability and neovascularization.

Results: We detected increased ZFP36 expression in MG starting from 1 month after STZ injection in rats compared to WT controls. The upregulation of ZFP36 diminished at around 3 months after STZ injection. Knocking down ZFP36 in rat MG in vivo using AAVs resulted in accelerated development of DR in diabetic rats, while over-expression can delay the development of the disease.

Conclusions: Diabetes-induced upregulation of ZFP36 in MG plays a beneficial role, and failure to maintain ZFP36 levels contributes to the initiation and early progression of DR.

ABSTRACT BODY:

Purpose: While it is known that patients with generalized retinal dystrophy are less likely to develop diabetic retinopathy (DR)[JO1] , no prior study in West Virginia has investigated prevalence and severity[JO2] of DR in patients with confirmed molecular diagnosis of inherited retinal diseases (IRD). We performed a retrospective chart review of diabetic IRD patients to determine the prevalence of diabetic retinopathy.

Methods: We identified 415 patients with IRD seen at the West Virginia University Eye Institute between January 2010 and November 2021. 27 of these patients had diabetes (12 males and 15 females of ages 34-85). All 27 had confirmed molecular diagnosis of IRD in themselves or an affected family member.. Their molecular diagnosis, clinical findings, laboratory values, retinal images, and electrodiagnostic tests were reviewed.

Results: Three of the 27 IRD patients with diabetes (11%) were identified to have DR.

A 70-year-old male with type 2 DM and IMPG2 mutation with vitelliform maculopathy presented with moderate NPDR in both eyes. Visual acuity (VA) was 20/40 in both eyes.

A 60-year-old male with type 2 DM and PRDM13 mutation with North Carolina macular dystrophy presented with bilateral tractional retinal detachment with final VA of HM and LP.

A 47-year-old female with type 1 DM and XLRP [RP2] developed tractional retinal detachment bilaterally. Final VA was 20/400 and 20/25.

Conclusions: DR is less frequently observed in diabetic IRD patients with prevalence of 11%, compared to 28.5% in general population. Despite the lower prevalence, it is important to monitor diabetic IRD patients for DR, particularly female XLRP patients or North Carolina macular dystrophy patients.

ABSTRACT BODY:

Purpose: Ethnic differences in the prevalence of diabetic retinopathy (DR) have been reported but differences in the DR phenotype have not been well described. In this retrospective study, we evaluate the distribution of DR lesions among various ethnicities.

Methods: We enrolled a cohort of 228 eyes with DR consisting of 49 East Asian eyes (Second Hospital of Tianjin Medical University), 103 South Asian eyes (Narayana Nethralaya Eye Institute), 30 Caucasian eyes (UCLA), and 46 Latino eyes (UCLA) with ultrawidefield images. Both treatment naïve and treated cases were included. Images were manually annotated for DR lesions including microaneurysms, hemorrhages, intraretinal microvascular abnormalities, cotton wool spots, neovascularization, and venous beading. The DR severity was assessed according to the International Clinical Diabetic Retinopathy scale. In accordance with previous publications, eyes were classified as having predominantly peripheral or central lesions (PPL or PCL) based on comparing the frequency of lesions in peripheral fields 3 to 7 versus their respective adjacent ETDRS field 3 to 7 (i.e. >50% of lesions in one or more peripheral fields= PPL). The percent of eyes rated to be PPL were compared among the groups.

Results: The proportion of eyes which featured a PPL distribution was highest in East Asians (85.7%) and lowest in South Asians (35.9%) regardless of prior treatment or DR severity. Among treatment naïve eyes, a total of 39 (84.8%) East Asian eyes, 20 (35.7%) South Asian eyes, 12 (57.1%) Caucasian eyes, and 18 (46.2%) Latino eyes were classified as having PPL. For moderate NPDR, treatment naïve eyes, a PPL distribution was observed in 84.8% of East Asian eyes, 34.9% of South Asian eyes, 38.5% of Caucasian eyes, and 44.4% of Latino eyes. This greater PPL distribution among East Asian eyes was significantly different from South Asian eyes ($P<0.0001$), Caucasian eyes ($P=0.0017$), and Latino eyes ($P=0.001$). East Asian eyes were also more likely to have multiple PPL fields.

Conclusions: The distribution of DR lesions appears to vary among different ethnicities. DR lesions tend to be distributed more peripherally in East Asian eyes compared to other ethnicities, particularly South Asian eyes, which tend to have more central lesions. The prognostic implications of these ethnic differences in DR lesion distribution warrant further study.

ABSTRACT BODY:

Purpose: In the pathogenesis of subretinal fibrosis associated with age-related macular degeneration, epithelial to mesenchymal transition (EMT) of retinal pigment epithelium (RPE) plays a vital role, and we have reported Ripasudil (Ripa) could inhibit EMT of RPE in the subretinal fibrosis related to choroidal neovascularization (CNV). The purpose was to investigate the therapeutic effect of liposome-encapsulated-ripasudil (Lipo-Ripa) on laser-induced CNV model.

Methods: C57BL/6J mice underwent laser photocoagulation to induce CNV-related fibrosis. Single intravitreous injections of BSS, Ripa and Lipo-Ripa in each group were performed at 14^{th} day after laser injury at 28^{th} day. Volume of the CNV and subretinal fibrous tissue (SRF) were measured in choroidal flat mounts. To evaluate the drug distribution in the eyes, localization of FITC-labeled Lipo-Ripa was examined.

Results: In BSS，Ripa and Lipo-Ripa groups，the average volume of CNV were respectively 3.7, 3.2 and 2.9($\times 10^4$ μm^3) while SRF were 11.2, 9.0 and 6.8($\times 10^4$ μm^3). The volume of SRF in Lipo-Ripa group was smaller with statistical significance ($P<0.05$) compared to Ripa group. The accumulation of FITC-signal could be found in the CNV lesions after 48 hours post injection.

Conclusions: Lipsome encapsulation has the therapeutic potential to enhance the suppressive effect of Ripasudil on subretinal fibrosis.

SUBMITTER (NAME ONLY): Andrew Anderson

TITLE: Investigating the relationship between critical flicker fusion frequency and symptoms of eye strain

SESSION TITLE: Fundamental and Applied Psychophysics and Color Vision

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.J. Anderson, S. Singh, L.E. Downie, Optometry & Vision Sciences, The University of Melbourne, Melbourne, Victoria, AUSTRALIA|

Commercial Relationships Disclosure: Andrew Anderson: Commercial Relationship: Code N (No Commercial Relationship) | Sumeer Singh: Commercial Relationship: Code N (No Commercial Relationship) | Laura Downie: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Critical flicker fusion frequency (CFF) has been used in clinical studies to measure visual fatigue. Here, we examine the correlation between CFF and subjective reports of eye strain in a group of participants with computer-induced eye strain, to consider whether CFF may be used as a surrogate for subjective measures of strain.

Methods: We analyzed data from a previous randomized controlled trial that examined the effect of blue-blocking lenses on eye strain (Singh et al (2021). Am J Opthalmol, 226: 243). One hundred and twenty adults, aged ≤40 years and diagnosed with computer vision syndrome, had CFF and eye strain symptoms quantified pre- and post- a visually demanding two-hour computer task. Symptoms were assessed using a questionnaire with nine subcomponents that summed to a total score out of 900. CFF (2° diameter green light emitting diode) was measured using a two-interval forced choice method, with flicker rate altered by a computer-controlled staircase procedure. For our primary analysis, we determined Spearman correlation coefficients between post-task symptom scores and CFF, and between change-from-baseline symptom scores and CFF. We also used a bootstrap procedure to consider if symptom score subcomponents were significantly (Bonferroni corrected alpha = 0.0056) different from overall scores with regards to their correlations with CFF.

Results: Although eye strain symptom scores altered significantly post-task (median difference 51 units, $p<0.001$ (Wilcoxon); 96.5% CI: 36 to 99), CFF did not (mean change −0.7 Hz, $p=0.17$ (paired t-test); 95% CI: −1.6 to 0.3). There was no significant correlation between symptoms and CFF either post-task ($r= −0.13$; 95% CI: −0.31 to 0.06) or for the change-from-baseline ($r = −0.17$; 95% CI: −0.34 to 0.02) analysis. Subcomponents of the symptom questionnaire did not show a significantly different correlation with CFF than did the overall symptom score, either for post-task or change-from-baseline values.

Conclusions: CFF is unlikely to be a useful surrogate for symptoms of eye strain, given its low — and insignificant — correlation with scores on an eye strain symptom questionnaire.

TITLE: Subretinal fibrosis in patients with choroidal neovascularization based on spectral-domain optical coherence tomography classification: findings from the HARBOR trial

SESSION TITLE: Subretinal fibrosis – clinical challenges, mechanism, and diagnostic tools

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S. Adrean, Retina Consultants of Orange County, Fullerton, California, UNITED STATES|L. Hill, M.J. Amador-Patarroyo, Genentech Inc, South San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure: Sean Adrean: Commercial Relationship(s);Code R (Recipient):Alimera, RegenXBio;Code F (Financial Support):Genentech, Inc., Regeneron;Code C (Consultant/Contractor):Allergan, Amgen, Apellis, Genentech, Inc., IvericBio, NGM Biopharmaceuticals, Regeneron, RegenXBio | Lauren Hill: Commercial Relationship(s);Code C (Consultant/Contractor):Aerpio, Alimera, Genentech Inc., PolyPhotonix, Recens Medical | Manuel Amador-Patarroyo: Commercial Relationship(s);Code E (Employment):Genentech, Inc.

ABSTRACT BODY:

Purpose: Clinicians increasingly use spectral-domain optical coherence tomography (SD-OCT) to diagnose and follow neovascular age-related macular degeneration (nAMD). The purpose of this analysis of pooled data from HARBOR was to evaluate rates of fibrosis from choroidal neovascularization (CNV) based on SD-OCT classification.

Methods: SD-OCT scans from the phase 3 HARBOR trial (NCT00891735) of ranibizumab in patients with nAMD were reread by Doheny Image Reading and Research Laboratory, and CNV was classified as type 1, 2, and/or 3. Month 24 fibrosis status/location by baseline CNV type were evaluated using pooled observed data.

Results: At month 24, fibrosis was present in 31% (67/216) of eyes with type 1 lesions, 53% (176/332) with type 2 lesions, 45% (120/264) with mixed type 1/2 lesions, and 33% (17/51) with any type 3 lesions (overall $P < 0.0001$; Figure 1). Of those eyes with subretinal fibrosis, the majority had subfoveal involvement at month 24 (% patients for each lesion type: type 1, 75%; type 2, 78%; mixed type 1/2, 73%; type 3, 65%). Results were generally similar when stratified by treatment regimen (monthly vs pro re nata [as-needed]; Figure 2).

Conclusions: These findings demonstrate that eyes with type 2 CNV lesions had higher rates of fibrosis at month 24 than those with other lesion types.

Commercial Relationships Disclosure: Man-Ru Wu: Commercial Relationship: Code N (No Commercial Relationship) | Cheng-Hui Lin: Commercial Relationship: Code N (No Commercial Relationship) | Sui Wang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The dysregulation of glutamate homeostasis in retina is associated with many retinal diseases, such as glaucoma, diabetic retinopathy and age-related macular degeneration. The study aims to uncover the molecular mechanisms that control retinal glutamate homeostasis via dissecting the regulation of the Glul gene, which is one of the key genes that regulate glutamate homeostasis.

Methods: Retinal Müller glial cells (MG) play key roles in regulating glutamate homeostasis in the retina by converting glutamate into glutamine via glutamine synthetase (GS), which is encoded by the Glul gene. We first examined whether the expression levels of Glul /GS changes in response to different levels of extracellular glutamate in the retina. We then determined how the Glul expression is regulated by identifying novel cis-regulatory modules (enhancer) and revealing the upstream transcription factors.

Results: We found that Glul mRNA levels and GS protein levels were significantly upregulated when we increased the extracellular levels of glutamate in the retina via intravitreally injection of Glutamate or NMDA. Based on ENCODE database, we identified a novel enhancer of Glul gene located in the second intron (referred as M11). We found that Glul expression is regulated via the M11 enhancer, and discovered that Sox9 binds to M11 and positively regulates the expression Glul gene. Notably, over-expression of Sox9 can protect the retina from the damage induced by excessive extracellular glutamate.

Conclusions: Sox9 regulates Glul expression and is essential for glutamate homeostasis in the retina. Elevation of Sox9 levels in MG can protect the retina in acute injury models with excessive extracellular glutamate.

ABSTRACT BODY:

Purpose: Changes in choroidal thickness observed after short-term optical defocus support the theory that eye growth is optically guided. Most previous studies used a monocular optical appliance to manipulate the potential myogenic factors, which may introduce confounders by disrupting the natural functionality of the visual system. We explored if optical defocus generated by an ecological environment can predict choroidal thickness changes while habitual binocular vision is maintained.

Methods: A custom 3D eye tracker (Pupil Labs Core, Pupil Labs GmbH, Germany) monitored compliance to fixating the hand-held device (at ~3D, 30min) to estimate dioptric demand over a wide field of view (with magnitudes of ~0.5D up to 4.5D) using a miniature time-of-flight camera (Pico Flexx, PMD Technologies AG, Germany). The spatially diverse peripheral environment around the hand-held device generated an optical defocus at the retinal periphery. Temporal accumulation of dioptric demand was mapped onto a wide field of choroidal locations using gaze direction estimates from the 3D Eye-Tracker. Intra- (3 repeats per participants, pre and post intervention) and inter- participant topographical choroidal maps were landmark matched and subtended a congruent visual field. Local and regional choroidal thickness exposed to different dioptric defocus were evaluated for change with a global, sensitivity enhanced model.

Results: The average intra-participant random error of choroidal thickness estimation (1×s.d. at each pixel within the topographical map, n ~100k) could be reduced by ~20% to 5.2 ± 2.1 μm by truncation of outliers. No significant difference in thickness change was found for choroidal regions exposed to different optical defocus (GLM n=21, eye $p=0.62$, area $p=0.21$, eye*area $p=0.46$). Some apparently randomly positioned loci showed significant difference (Fig. 1).

Conclusions: A change in topographical choroidal thickness consistent with local relative dioptric defocus was not found. The proposed topographical choroidal thickness model showed a sensitivity comparable to theoretical longitudinal resolution of swept-source OCT (wavelength 1060 nm). The presented methods and device can contribute to a better understanding of the ecologically valid dioptric landscape, and with further development, may provide further insight into short-term myopia models.

ABSTRACT BODY:

Purpose: Although convolutional neural networks (CNN) can accurately predict GA growth rate using fundus autofluorescence images (FAF), what drives the prediction accuracy remains unknown. Here, we ablate different regions of FAF to study their contribution to GA progression prediction.

Methods: The dataset included baseline (BL) FAF of patients with bilateral GA enrolled in NCT02479386, NCT02247479, and NCT02247531. GA progression, measured by annualized lesion growth rate (mm^2/y), was derived as the slope of a linear fit on available measurements of GA lesion area. Data were split into training (n=1041) and holdout (n=255) sets stratified by BL factors. The training set was further split into 5 stratified folds.

GA lesion masks were generated using a segmentation algorithm for each image. Three regions were delineated using the mask: inside the lesion (Lesion), a 500-µm rim around the lesion (Rim), and the remaining region. All possible combinations of these regions were ablated with black pixels to create new datasets. The VGG16 architecture was trained using a random hyperparameter search on each dataset to predict GA progression. The square of the Pearson correlation coefficient (r^2) between predicted and observed GA growth rate was averaged across the 5 folds and used for model selection. The same metric was then used to test performance on the holdout set.

Results: Each 5-fold cross-validation experiment yielded 5 independent models. Fig 1 depicts the holdout r^2 of each of these models for each dataset.

Compared with the full FAF (r^2=0.44), nearly half of the variability in prediction was explained by capturing only shape and size in the Mask Only dataset (r^2=0.24). The No Rim dataset (r^2=0.39) showed a greater decrease in performance compared with the Lesion and Rim (r^2=0.43) or No Lesion (r^2=0.42) datasets. Further, the Rim Only dataset (r^2=0.37) performed better compared with the Lesion Only (r^2=0.33) and No Lesion or Rim (r^2=0.27) datasets.

Conclusions: The intensity and texture within the rim of the FAF contains more predictive features for GA growth rate. We interpret that intensity/texture and morphology have additive contributions to the predictive performance of the CNN. Our findings can be further confirmed by quantifying these features using oculomics and observing predictive performance.

Hoffmann-La Roche Ltd. | Jian Dai: Commercial Relationship(s);Code E (Employment):Genentech, Inc. | Carlos Quezada Ruiz: Commercial Relationship(s);Code E (Employment):Genentech, Inc.

ABSTRACT BODY:

Purpose: This pilot study aimed to develop machine learning models to predict the optimal dosing regimen for patients with nAMD using baseline (BL) characteristics for patients treated with faricimab, the first bispecific antibody for intraocular use, in the phase 2 AVENUE (NCT02484690) and STAIRWAY (NCT03038880) trials.

Methods: Predicting optimal regimen, defined as the least frequent dosing regimen that achieves the maximum best-corrected visual acuity (BCVA) potential, is converted to a regression problem on the BCVA ETDRS letter score using treatment regimen as input. Because treatment arm is randomly assigned in clinical trials, we can alternate the treatment regimen feature to predict BCVA letter score for different regimens. To predict an optimal regimen for a new patient, BL characteristics are entered into the trained model together with each possible treatment regimen (Figure 1).

For the regression problem, BCVA at month 9 was set as the target. Linear model, random forest, extreme gradient boosting (XGBoost), and support vector machine are trained and evaluated. Age, sex, BCVA, and central subfield thickness at BL are selected as benchmark features. In addition, image-derived features, such as fluids and layer thickness, obtained by an automated segmentation algorithm on SD-OCT scans, are considered for full models. To evaluate the model's discriminative power between treatment regimens, we define a metric called mean difference, which is the mean difference between the maximum and minimum prediction over all possible treatment regimen assignments.

The methods are applied to a data set consisting of all patients in AVENUE and STAIRWAY, including patients treated with ranibizumab (N = 324).

Results: For the regression problem, XGBoost achieved the highest performance (R^2 = 0.38) with benchmark features and image features (Table 1). The mean difference value varies between models, with no obvious relationship between model performance and discriminative capability of treatment regimens.

Conclusions: The results of this study highlight the potential of a method to predict an optimal treatment regimen for patients with nAMD using a regression model. To fully understand advantages and limitations of this method, validation at a larger scale is warranted.

TITLE: Later bedtime associated with greater myopic refractive error and variations in axial length rhythms

SESSION TITLE: Myopia: Clinical Interventions and Diagnostics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: X.N. Liu, T.J. Naduvilath, P. Sankaridurg, Brien Holden Vision Institute, Sydney, New South Wales, AUSTRALIA|X.N. Liu, T.J. Naduvilath, P. Sankaridurg, School of Optometry and Vision Science, University of New South Wales, Sydney, New South Wales, AUSTRALIA|

Commercial Relationships Disclosure: Xiao Liu: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Naduvilath: Commercial Relationship: Code N (No Commercial Relationship) | Padmaja Sankaridurg: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Late bedtime was identified as a risk factor for childhood myopia and disturbance to the sleep/wake cycle was found to induce myopia in chicks accompanied with altered axial length (AL) diurnal rhythms. This study explored the relation between participants' habitual bedtime, diurnal changes in AL and refractive status.

Methods: A total of 25 young, healthy adults (mean age ± SD: 25±4.75 years; 13 myopes, 52%; spherical equivalent mean ± SD: -1.45 ± 1.90D) attended seven consecutive visits over 24 hours. All participants had a best-corrected visual acuity of 20/20 or better, and no history of travelling across different time zones within one month before participating in the study. At each visit, noncycloplegic open-field auto-refraction (NVision-K 5001; Shin-Nippon, Japan) and ocular biometry (LenStar; Haag-Streit, Switzerland) of the right eye was conducted. Myopia was defined as spherical equivalent ≤-0.75D. Sleep habits including usual bedtime were assessed using questionnaires (Pittsburgh Sleep Quality Index, PSQI) at the first visit; those with a usual sleep time of 12am or later were categorised as late sleepers (n=16). Diurnal changes in AL were analysed using repeated measures ANOVA, where repeated visits were modelled as the within-patient factor and usual bedtime categories and refractive status (myopic/non-myopic) were used as between-subjects factors.

Results: Significant time-related differences in AL were observed over the 24-hour period ($p < 0.001$). The diurnal patterns of AL were different between early versus late sleepers ($p = 0.01$). Specifically, while the patterns amongst early sleepers presented a bi-phase rhythm, such characteristic was less apparent for late sleepers. The maximum and minimum values of AL were detected at different times for the two groups, with late sleepers lagging four hours behind (Fig. 1). Additionally, late sleepers were more myopic compared to the early ones (-1.83±2.01D vs -0.78±1.55D, $p = 0.04$) after adjusting for age and gender.

Conclusions: In this adult population, diurnal rhythm in AL varied between early versus late sleepers and late sleepers exhibited greater myopic refractive error. The effect of the variation in sleep and diurnal rhythm in AL needs investigation in children to determine if it has a role to play in the onset of myopia.

ABSTRACT BODY:

Purpose: The goal of this research is to evaluate the reading performance at different distances when wearing progressive power lenses (PPL) with different power distributions. The reading performance has been assessed by means of eye tracking technology.

Methods: 16 presbyopic subjects participated in a double-masked trial. A wearable eye-tracker system (Tobii-Pro Glasses 3) was used to record gaze position when reading at near and distance vision while using 2 types of PPLs (PPL-D and PPL-N). According to Sheedy's criteria, the distance-vision areas of the PPL-D and PPL-N are 48.2mm^2 and 21.6mm^2 respectively. The near-vision areas are 36.8mm^2 and 54.1mm^2 for PPL-D and PPL-N respectively. Subjects were asked to read a text showed on a digital screen placed at 5.25m and 0.37m when looking through the center and peripheral regions of the lens. Different reading texts with similar difficulty level and same letter size (Visual acuity=0.4logMAR) were used. Reading time and fixations characteristics (count, total duration, and average duration), were analyzed for each reading condition and PPL. Statistical analysis was performed using Statgraphics Centurion XVI.II software.

Results: The analysis of the eye movements at distance-reading showed a statistically significant lower reading time and lower total duration of fixations for PPL-D (Table 1). At near-reading the lens PPL-N provided statistically significant lower reading time, lower total duration of fixations and less fixation count (Table 2).

Conclusions: Reading performance at different distances is affected by the PPL power distribution; a design with wider distance area provides better distance-reading performance while a PPL with wider near area is better for near-reading. This experiment demonstrates that the power distribution of PPLs clearly influences the user performance at vision-based tasks. Henceforth, PPL selection must consider user needs to provide the best visual experience

ABSTRACT BODY:

Purpose: To develop and evaluate a method for predicting 5-year risk of progression to a vision-threatening complication (VTC) in patients with diabetes and absent or mild diabetic retinopathy (DR).

Methods: Systemic and retinal imaging–based measurements (optical coherence tomography [OCT] and color fundus photographs) were collected from a cohort study (NCT03010397) of 172 patients with diabetes (32% female; mean age at baseline, 63 years). Per inclusion criteria, maximum level of DR at baseline was 35, as classified by the Diabetic Retinopathy Severity Scale. Patients were followed up annually for up to 5 years or until they developed a VTC (OCT-defined centrally involved macular edema, clinically significant macular edema, or proliferative DR). Of 172 patients, 27 (15.7%) progressed to ≥ 1 VTC. Linear regression models were trained and evaluated using 5-fold cross-validation for predicting VTC progression events. Features were either specified via an unsupervised hierarchical clustering method that reduced dimensionality of the feature space or selected manually guided by expert domain knowledge. The selected features of the manual approach consisted of 3 systemic and 5 imaging-based features, summarized in Table 1. Area under the receiver operating characteristic curve (AUC) was used as the performance metric.

Results: The trained models predicted progression to VTC with a mean (SD) AUC of 0.76 (0.04) when using the unsupervised dimensionality reduction approach and 0.78 (0.09) when using the 8 manually selected features. The models performed with a mean (SD) AUC of 0.72 (0.11) when using only the 5 selected imaging–based features versus 0.64 (0.05) when using only the 3 selected systemic features.

Conclusions: In this cohort of patients with absent or mild DR, the models predicted progression events with a mean AUC of 0.78 despite the low progression rate to a VTC and with comparable performance for both the manual and unsupervised approaches. Our results also indicate that imaging features alone are more powerful than systemic features alone in predicting progression to a VTC. With validation from larger and more diverse patient sets, predictive models of VTC in patients with DR could be valuable for informing personalized monitoring and follow-up in both clinical development and clinical practice.

ABSTRACT BODY:

Purpose: FIREFLEYE was the first randomized, controlled, multicenter, international Phase 3 trial of patients with treatment requiring retinopathy of prematurity (ROP) that compared the treatment effects of intravitreal aflibercept (IVT-AFL) to laser. It was also the first ROP study to include Zone II Stage 2+ eyes, permitting unilateral treatment, and using a low injection volume of only 0.01 mL IVT-AFL per eye (20% of the approved adult dose and injection volume). Previously reported primary results demonstrated treatment success (absence of active ROP and unfavorable structural outcomes at Week [W] 24 based on investigator assessment) with IVT-AFL to be numerically higher compared with laser (85.5% versus 82.1%). This was considered clinically relevant, while non-inferiority could not be formally shown. Here, we report a post hoc analysis of the primary endpoint for subgroups stratified by gestational age and weight at treatment.

Methods: FIREFLEYE (NCT04004208) enrolled infants born at gestational age ≤32 weeks or birth weight ≤1500 g, weighing ≥800g at time of first treatment, who had ROP Zone I Stage 1+, 2+, 3+/-; Zone II Stage 2+, 3+; or aggressive posterior ROP in at least one eye. Infants were randomized 2:1 to receive IVT-AFL 0.4 mg or laser photocoagulation. Re-treatment and/or rescue treatment (IVT-AFL rescue for the laser group, laser rescue for the IVT-AFL group) was administered if any of the prespecified criteria were met.

Results: Treatment success in the subgroup of infants with low weight <1500 g at first treatment (n=24) was 87.3% in the IVT-AFL group (n=14) compared to 66.0% in the laser group (n=10). In infants with gestational age <27 weeks (n=77), treatment success was 85.7% for IVT-AFL (n=49) versus 80.0% for laser (n=28). Results for additional subgroups, e.g., infants with Zone II Stage 2+ ROP and infants treated unilaterally, will also be presented.

Conclusions: Overall, FIREFLEYE data consistently show that treatment of ROP patients with IVT-AFL 0.4 mg is clinically efficacious and safe. Subgroup analyses suggest that IVT-AFL may be a sensible alternative to laser treatment particularly for infants born at less than 27 weeks of gestational age and/or weighing less than 1.5 kg at time of first treatment.

ABSTRACT BODY:

Purpose: As an important retinal neurotransmitter, GABA has been proposed to modulate eye growth and refractive development. This study aimed to explore the specific role of GABA B receptors (GABABR) during experimentally induced hyperopia and myopia development.

Methods: Exp. 1: Chicks were intravitreally injected with 25 µg baclofen (GABABR agonist) in one eye and saline into the fellow eye. Choroidal thickness (ChT) was measured by OCT before and 2, 4, 6, 8, 24 hours after injection. Exp. 2: Chicks were monocularly treated with a +7D lens or translucent occluder, respectively, and randomly assigned to baclofen (25 µg) or saline treatment. Drugs were intravitreally injected daily into experimental eyes, for 4 days. Refraction (RE), axial length (AL) and ChT were measured before and after treatment. Dopamine (DA) and its metabolites were analyzed via HPLC.

Results: Experiment 1: ChT decreased strongly at 6 and 8 hours after baclofen injection (-53.5 µm, p = 0.0006; -48 µm, p = 0.002) and returned back to baseline level after 24 hours. Experiment 2: Baclofen inhibited plus lens compensation: eyes got only slightly hyperopic (ΔRE: 1.15 ± 0.67 D), grew significantly more than +L treated saline-injected eyes (ΔAL: 0.32 ± 0.07 mm vs. 0.09 ± 0.07 mm, P = 0.02) and ChT decreased in +7D treated eyes (ΔChT: -78.2 ± 14.1 µm), an effect opposite to the increase in +L saline-treated chicks. Plus lens treatment reduced vitreal DOPAC and DA content in saline (ΔDOPAC: -1.68 ± 0.17 ng/100 mg weight) and baclofen treated eyes compared to fellow eyes (ΔDOPAC: -2.22 ± 0.07 ng/100 mg weight), but significantly more in the baclofen treated eyes. Baclofen also significantly reduced the myopic shift in deprived eyes (ΔRE: -2.83 ± 0.22 D vs -4.30 ± 0.79 D, p = 0.004). However, it did not change ChT compared to deprived saline-injected eyes (ΔChT: -69.7 ± 10.8 µm vs. -65.6 ± 11.6 µm, n.s.). Vitreal DOPAC and DA were reduced in all deprived eyes compared to untreated fellow eyes, with content in the baclofen group decreasing more.

Conclusions: Activation of GABABR downregulated retinal DA release and reduced ChT in chicken eyes. It attenuated the response to modulated visual stimuli, with more eye growth in lens-induced hyperopia and less eye growth in form-deprivation myopia. Since GABA is a ubiquitous transmitter, interference with its signaling may not only interfere with myopia development but also with visual function.

ABSTRACT BODY:

Purpose: The decision to perform simultaneous versus sequential cataract extraction (CE) surgery and pars plana vitrectomy (PPV) has several implications for both the patient and the surgeon. We performed a retrospective, clinical study to compare outcomes of simultaneous versus sequential CE and PPV surgery in terms of postoperative visual acuity and refractive outcomes.

Methods: We assessed three possible combinations of PPV and CE surgery: simultaneous PPV and cataract surgery (PPV+CE); PPV followed by cataract surgery (PPV/CE), and cataract surgery followed by PPV (CE/PPV). A two-year retrospective chart review of 427 eyes with history of PPV and CE was performed. Assessments of UCVA and BCVA, spherical equivalent (SEQ), and target refraction were done. Outcomes studied were UCVA, BCVA, SEQ and refractive prediction error (RPE) at the 1 month, 3 months, 6 months, 1 year, and 2 years postoperative visits. Only patients with epiretinal membrane (ERM) or vitreous opacity (VO) indications in the PPV+CE and PPV/CE were included in the SEQ and RPE calculations.

Results: In total, 427 eyes of 404 patients were included, of which 113 eyes underwent PPV/CE, 261 eyes underwent PPV+CE, and 53 eyes underwent CE/PPV. Improvement in UCVA and BCVA of the whole patient cohort was seen at every follow-up visit compared to preoperative measures. There was a statistically significant difference in BCVA measures of the PPV/CE, PPV+CE, CE/PPV groups (LogMAR 0.34 ± 0.40, 0.65 ± 0.61, and 0.55 ± 0.60, respectively; $P < 0.001$) at POM1, and at POM12 (LogMAR 0.25 ± 0.34, 0.53 ± 0.68, and 0.44 ± 0.48, respectively; $P = 0.04$). At the POM1+3 visits, RPE was within ± 1.0 D in 11 eyes (65%) in the PPV/CE group, and 44 eyes (86%) in the PPV+CE group, while it was within ± 2D in 16 eyes (94%) in the PPV/CE and 51 eyes (100%) in the PPV+CE group.

Conclusions: Simultaneous PPV and cataract surgery demonstrated a significant improvement in visual and refractive outcomes that were comparable to sequential surgery results. A simultaneous approach may be a suitable option in elective situations as it avoids the gradual deterioration in vision that arises with the progression of cataracts following PPV.

ABSTRACT BODY:

Purpose: We previously developed and evaluated a DL model to identify eyes with moderately severe and severe NPDR from 7F-CFP leveraging a large cohort of patients with diabetes from the United States.[1] In this study, we evaluate and report performances of the DL model on an independent cohort of patients with DR from Portugal.

Methods: The DL model presented previously[1] was developed using 7F-CFP collected from the eyes of 37,358 patients with diabetes between 1999 and 2016 (Source: Inoveon Corporation, Oklahoma City, OK). DR severity and presence of clinically significant macular edema were assessed from 7F-CFP (Zeiss FF 450+) by expert graders at a centralized reading center using the Early Treatment Diabetic Retinopathy Study Diabetic Retinopathy Severity Scale (DRSS). Prevalence of moderately severe or severe NPDR (DRSS 47–53) in this cohort was 2.2%. The dataset was used to develop a DL Inception v3 model with transfer learning to detect eyes with DRSS 47–53.

The independent evaluation dataset was collected from a natural history study of DR progression (NCT03010397). Enrolled patients had less than mild NPDR at baseline (32% female; mean age at baseline, 63 years) and were followed up annually over 5 years. From 172 patients who completed the study, 635 unique eyes/visits were imaged by 7F-CFP (Topcon TRC-50DX) and had a valid DRSS, of which 14 eyes were identified with DRSS 47–53. Model performance was assessed using the area under the receiver operating characteristic (AUROC) curve, specificity, and sensitivity, using a cutoff computed on the development dataset.

Results: The model performed on the evaluation dataset with an AUROC of 0.900 (95% CI, 0.864, 0.944), sensitivity of 1.0 (95% CI, 1.0, 1.0), and specificity of 0.699 (95% CI, 0.667, 0.734) using a cutoff computed on the development set that maximizes the Youden index.

Conclusions: Despite differences between the development and evaluation datasets in terms of geographic location of patients and CFP imaging instruments used, the DL model rendered good performance and generalizability for identification of eyes with DRSS 47–53. Provided additional validation of this model on more diverse datasets, the model could be used to inform screening of patients at high risk of progression to vision-threatening DR.

ABSTRACT BODY:

Purpose: To describe a method of temporary tarsorrhaphy augmentation using an add-on bolster element.

Methods: The add-on bolster was made from 3 plastic tubings of approximately equal length, cut from a pediatric butterfly cannula or other IV tubing. One of the plastic tubings was cut lengthwise on one side. A double-armed non-absorbable suture, such as a 4-0 nylon, silk, or prolene, was passed in a horizontal mattress fashion through one wall of the cut tubing, and through the first uncut tubing. The same procedure is performed on the second uncut tubing, resulting in 3 cylinders connected by the 2 arms of the suture in a parallel fashion. Finally, the 2 needles were passed through the opposite wall of the original tubing, the one with the lengthwise cut, and tied in a horizontal mattress fashion.

Results: The optimal size of the add-on bolster was calculated using a formula which includes the length of the tarsorrhaphy and the size of the palpebral fissure. A 17-year-old corneal graft recipient female with cicatricial lagophthalmos, the add-on bolster was slipped between the original tarsorrhaphy suture and bolster, augmenting its effect and resulting in re-approximation of the eyelid margins and protection of the ocular surface for an additional 2 months. The only complication observed was loss of the add-on bolster that was replaced.

Conclusions: The use of the add-on bolster to augment a temporary tarsorrhaphy is a simple technique to salvage the suture tarsorrhaphy and prolong its usefulness.

ABSTRACT BODY:

Purpose: The COVID-19 pandemic exposed the need for increased mobilization of tele-ophthalmology resources. Artificial intelligence (AI) may serve as a tool to assist physicians in triaging highest need patients if the AI's assessment of disease is comparable to the physician's assessment. This study assesses the ability of AI software to diagnose diabetic retinopathy (DR) as compared to Tele-ophthalmology and in-person examination by a retina specialist.

Methods: Records of forty patients (average age 55.1±10.9 years) presenting to an urban retina clinic were reviewed retrospectively for factors including demographics, retinal photos taken by Canon CR-2 Plus AF Retinal Imaging camera (Tokyo, Japan), and diagnosis of DR based on the International Clinical Diabetic Retinopathy (ICDR) classification scale during an in-person clinic visit in which a fundus exam was performed. Retinal photos were graded by AI software, EyeArt (EyeNuk, CA), as Normal, Mild DR, or More than Mild DR. Retinal images were also graded remotely by a retina specialist using the ICDR classification scale via TeamViewer software (Tele). Agreement between Tele, AI, and in-person DR diagnosis was assessed using Cohen's Kappa (κ) coefficient using IBM® SPSS® Statistics software.

Results: Among 80 eyes, 33 were diagnosed in-person with no DR, 5 with mild non-proliferative DR (NPDR), 9 with moderate NPDR, 3 with severe NPDR, 7 with proliferative diabetic retinopathy (PDR), and 23 with regressed PDR. Eleven and 26 eyes could not be graded by Tele or AI, respectively. κ±SE for in-Person diagnosis vs Tele was 0.859±0.058 ($p<.001$), in-person vs AI was 0.751±0.082 ($p<.001$), and Tele vs AI was 0.883±0.063 ($p<.001$).

Conclusions: AI is a reliable tool for screening patients for DR and referring them for physician evaluation since AI had a substantial rate of agreement with the in-person diagnosis and near perfect agreement with Tele. Tele grading was in near perfect agreement with the in-person diagnosis, showing that Tele is a reliable option for a physician to remotely screen patients that may be ungradable by AI. However, improvements are needed due to the high number of images that are ungradable via Tele and AI. Further studies should assess ways to reduce the number of ungradable images via Tele and AI and create a trend analysis for multiple visits for a given patient.

ABSTRACT BODY:

Purpose: Year 1 data from the phase 3 YOSEMITE/RHINE trials support the hypothesis that dual angiopoietin-2/vascular endothelial growth factor (VEGF)-A pathway inhibition with faricimab, the first bispecific antibody designed for intraocular use, may promote vascular stability and durable efficacy beyond current anti-VEGF therapies for diabetic macular edema (DME). Year 2 of YOSEMITE/RHINE will inform the longer-term efficacy, durability, and safety of faricimab in patients with DME.

Methods: YOSEMITE (NCT03622580) and RHINE (NCT03622593) were randomized, double-masked, active comparator–controlled, 100-week trials of faricimab in treatment-naïve and previously anti-VEGF–treated patients with center-involving DME (YOSEMITE, N = 940; RHINE, N = 951). Patients were randomized 1:1:1 to faricimab 6.0 mg every 8 weeks (Q8W) after 6 initial Q4W doses, faricimab 6.0 mg per personalized treatment interval (PTI) after 4 initial Q4W doses, or aflibercept 2.0 mg Q8W after 5 initial Q4W doses. The PTI algorithm was a protocol-driven treat-and-extend regimen, with dosing intervals extended, maintained, or reduced (from Q4W up to Q16W) based on central subfield thickness (CST) and best-corrected visual acuity (BCVA) change at active dosing visits. The primary efficacy endpoint was mean BCVA change from baseline at 1 year, averaged over weeks 48, 52, and 56. Key 2-year outcomes included mean BCVA change from baseline averaged over weeks 92, 96, and 100; the proportion of patients in the faricimab PTI arm who achieved Q4W, Q8W, Q12W, or Q16W dosing at week 96; mean CST change from baseline over 2 years; the proportion of patients with ≥ 2-step Diabetic Retinopathy Severity Scale improvement

from baseline at week 96; and the incidence and severity of adverse events through study end.

Results: At 1 year, faricimab Q8W or per PTI resulted in durable vision gains that were noninferior to aflibercept Q8W and achieved with Q16W dosing in > 50% of patients in the PTI arms. Faricimab Q8W or per PTI demonstrated anatomic improvements compared with aflibercept Q8W and was well tolerated, with low rates of intraocular inflammation. Year 2 results from YOSEMITE/RHINE will be presented at the meeting.

Conclusions: Year 2 data from YOSEMITE/RHINE will examine whether year 1 vision gains, anatomic improvements, and extended (up to Q16W) dosing with faricimab are maintained over 2 years.

TITLE: Geometrical-optics approach to the Stiles-Crawford effect of the first and second kind

SESSION TITLE: Fundamental and Applied Psychophysics and Color Vision

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Vohnsen, Q. Kennedy, N. Sharmin, Physics, University College Dublin, Dublin, IRELAND|

Commercial Relationships Disclosure: Brian Vohnsen: Commercial Relationship: Code N (No Commercial Relationship) | Qi Qi Kennedy: Commercial Relationship: Code N (No Commercial Relationship) | Najnin Sharmin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The photopic Stiles-Crawford effect of the first kind (SCE-I) is typically described by waveguiding whereas the Stiles-Crawford of the second kind (SCE-II) is attributed to self-screening by visual pigments. Here, both effects are analyzed experimentally and compared to a geometrical-optics absorption model. This will show whether both effects are caused by light leakage rather than waveguiding.

Methods: Light absorption and optical path length in foveal outer segments is simulated for a hexagonal packing foveal cones across a retinal patch of up to 37 cones: 2 S-cones (5%), 11 M-cones (30%) and 24 L-cones (65%), respectively using Comsol^{TM}. Excess light is absorbed by the retinal pigment epithelium layer RPE. Absorption data are fitted to a Gaussian SCE-I and an Airy function representative of the collective light-capture efficiency for stacked visual pigments (Vohnsen, BOE 2014). The SCE-I directionality is evaluated and compared to psychophysical results obtained for two emmetropic subjects using a uniaxial digital micromirror device (DMD) flicker system (Carmichael Martins and Vohnsen, OPO 2018) and a liquid crystal bandpass filter for spectral tuning. Power-weighted absorption in adjacent outer segments is used to calculate an effective SCE-II hue shift as a function of wavelength for oblique light.

Results: Outer segment data in combination with ray optics and absorption can explain the typical Gaussian SCE-I visibility function with directionality parameters in the range of 0.03/mm^2 – 0.10/mm^2. In turn, if all outer segments contain the same class of visual pigment, such as rhodopsin in rods, the directionality becomes negligible confirming the absence of the SCE-I in scotopic conditions. The SCE-II hue shift matches psychophysical observations with no on-axis hue shift but a parabolic hue shift at for oblique incidence. The SCE-II distribution is fully contained within the spectral data of the SCE-I.

Conclusions: The study shows that leakage of light in outer segments can fully explain the SCE-I and crosstalk the related SCE-II without enforcing waveguiding. This shows the visual importance of the retina and photoreceptor optics on par with the optics of the anterior eye and the need for their careful consideration both in Maxwellian and normal Newtonian view. Ultimately, such knowledge may be applied in the development of new ophthalmic optics.

ABSTRACT BODY:

Purpose: We have developed a consistent and scalable cell source of induced MSCs (iMSCs) generated by differentiating the induced pluripotent stem cells (iPSC) derived from urinary epithelial cells through a non-insertional reprogramming approach. We tested the hypothesis that intravitreal delivery of iMSC exosomes will ameliorate retinal vascular and neuronal damage induced in diabetes.

Methods: Conditioned medium from iMSC that were exposed to TNFα/IFNγ in serum-free media was used to purify exosomes by ultracentrifugation method. Differential expression of proteins was analyzed by proteomic analysis. About 8-month-old $Ins2^{Akita/+}$ mice were intravitreally injected with exosomes (5mg protein/2μL) or saline. Littermate $Ins2^{+/+}$ receiving saline served as control. After 3 weeks post IVT, mice were tested for vascular permeability by FITC-BSA leakage method, visual function by ERG and OKN, and assessed for changes in dendritic complexity and postsynaptic targets by immunohistology.

Results: About 463 proteins were identified in the exosomes. Differential expression analysis revealed ~33 proteins enriched (>1.5 fold) in primed exosomes compared to unprimed exosomes. While $Ins2^{+/+}$ mice had minimal vascular leakage (30.7±6.0 RFU), $Ins2^{+/Akita}$ mice that received saline showed 70.7±10.7 RFU with a significant reduction in $Ins2^{+/Akita}$ mice that received exosomes (38.2±10.8 RFU, $p<0.03$). Similarly, a significant reduction in visual acuity (0.25±0.2 vs. 0.3±0.01 c/d, $p<0.04$), increased in contrast sensitivity threshold (57±8.6 vs. 39.1±6.5 %, $p<0.05$) and decreased b-wave amplitudes (220.2±7.8 vs. 306.2±16.3 mV, $p<0.02$) in $Ins2^{+/Akita}$ mice were improved with exosomes. Finally, immunohistology and confocal microscopy revealed loss of dendrites in cone bipolar (Secretagogin), rod bipolar (PKCα), and horizontal cells (Calbindin D28k) in $Ins2^{+/Akita}$ mice regenerated in mice that received exosomes.

Conclusions: Our data showed that a single intravitreal injection of iMSC-exosomes in $Ins2^{Akita/+}$ mice, reversed the ongoing vascular leakiness, regeneration of dendrite retraction, and re-establishment of synaptic disruption to rescue visual function. Future studies aiming at in-depth analysis of differentially expressed proteins within the exosomes will help establish the molecular processes leading to changes in the diabetic retina post iMSC-exosome transplantation.

TITLE: Treatment of Pediatric Lyme Meningitis with Neuro-Ophthalmic Complications: A Case Series

SESSION TITLE: Neuro-ophthalmology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: V. Rana, P.B. Greenberg, T. Bakaeva, W. Chen, Ophthalmology, Brown University, Providence, Rhode Island, UNITED STATES|E. Kim, Brown University, Providence, Rhode Island, UNITED STATES|

Commercial Relationships Disclosure: Viren Rana: Commercial Relationship: Code N (No Commercial Relationship) | Eric Kim: Commercial Relationship: Code N (No Commercial Relationship) | Paul Greenberg: Commercial Relationship: Code N (No Commercial Relationship) | Tatiana Bakaeva: Commercial Relationship: Code N (No Commercial Relationship) | Wendy Chen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A recent change in the Red Book: 2018-2021 Report of the Committee on Infectious Diseases now recommends either oral doxycycline (DCN) or intravenous ceftriaxone (IV CTX) for treatment of pediatric Lyme meningitis irrespective of neuro-ophthalmologic involvement. We describe three cases which highlight the challenges of managing pediatric Lyme meningitis with neuro-ophthalmic complications.

Methods: Retrospective case series

Results: Three pediatric patients - < 18 years of age with symptoms suggestive of meningitis, positive 2-tier Lyme serology (ELISA and western blot), +/- cerebrospinal fluid Lyme antibodies, and neuro-ophthalmologic complications (optic nerve edema +/- cranial nerve palsy) - were treated with either DCN or IV CTX initially. Case 1 (Figure 1, A) had optic nerve edema which worsened after 10 days of DCN treatment, necessitating advancement of treatment to IV CTX. Case 2 (Figure 1, B) had persistent grade 4 papilledema and cranial nerve six 6 palsy (CN6P), requiring a prolonged course of treatment with IV CTX. Case 3 (Figure 1, C) developed a new CN6P along with grade 4 papilledema OU after being treated initially with DCN. All three patients ultimately completed treatment with IV CTX to remove the confounding factors associated with use of DCN, and all had resolution of optic nerve edema and CN6P.

Conclusions: Cases of pediatric Lyme meningitis with neuro-ophthalmic complications are difficult to treat. The recent change in treatment recommendations allowing use of DCN as first line therapy further complicates initial treatment and subsequent management of systemic and eye disease associated with Lyme infection.

ABSTRACT BODY:

Purpose: A possible gateway to effective disease-modifying intervention for Alzheimer's disease (AD) is starting treatment pre-symptomatically, facilitated by early-detection. Retinal amyloid beta (Aβ) deposition – reported to predate symptoms by over a decade – has been the subject of experiments investigating the Aβ binding compound curcumin, with controversial findings, partly attributable to the variable absorption from oral administration. Using a novel DMSO-based nasally-applied route of curcumin delivery, we hypothesised that a higher in vivo fluorescent retinal spot-count (using confocal laser scanning ophthalmoscopy) could be used to differentiate transgenic AD model mice from healthy controls, in addition to demonstrating ex vivo Aβ antibody colocalisation with curcumin.

Methods: A total of 10 triple transgenic (3xTg) AD model mice (Jackson labs) and 10 C57 control animals (Jackson labs), aged 2-6 months, were investigated. 10 μL of DMSO-based curcumin formulation was administered intranasally to awake animals. Animals' eyes were imaged using a confocal laser scanning ophthalmoscope at baseline (before curcumin administration) and 2 hours after curcumin, under gas anaesthesia. Whole retinal mounts were immunolabelled for Aβ with the 6E10 antibody, which was fluorescently labelled with a secondary antibody. Colocalisation of nasally delivered curcumin and 6E10 antibody was studied using fluorescent microscopy.

Results: 3xTg animals appeared to have more curcumin staining than controls in vivo. Using a one-way between-subjects ANOVA, a significant ($p<0.05$) effect of transgenic status on spot count was found, revealing that 3xTg animals showed significantly more spots than, and could be differentiated from, healthy animals. Furthermore, histology revealed that curcumin colocalises with 6E10 antibody in the retina.

Conclusions: Intranasally administered curcumin appears to label retinal Aβ, and the resulting fluorescent spots can be used to identify disease state in young transgenic and healthy mice. These results suggest that such an approach may warrant further development and investigation for the early detection of AD.

ABSTRACT BODY:

Purpose: Deep learning–based segmentation models for spectral-domain optical coherence tomography (SD-OCT) images have been used for automatic identification of retinal fluids to support clinicians in patient management. Images from different acquisition devices or retinal diseases, hereafter referred to as domains, typically require distinct models. We propose an effective unified solution applicable to multiple domains.

Methods: SD-OCT images were acquired with Cirrus HD-OCT (Carl Zeiss Meditec), denoted as C, and Spectralis OCT (Heidelberg Engineering), denoted as S, on patients with neovascular age-related macular degeneration (nAMD) and diabetic macular edema (DME). The dataset was grouped into 3 domains: S/nAMD (AVENUE, NCT02484690), S/DME (BOULEVARD, NCT02699450), and C/nAMD (HARBOR, NCT00891735), which respectively included 1769, 1686, and 959 B-scans (corresponding to 303, 303, and 160 eyes) with manual pixel-wise annotations. The annotations denote IRF and SRF for patients with DME, as well as PED and SHRM for patients with nAMD (Figure 1). Annotated B-scans from 10% of eyes in each domain were randomly split into a test set for evaluation.
Different domain-specific models with a UNet architecture were trained on each of the 3 domains as a baseline (Figure 1, left). Our cross-domain model was trained collectively on B-scans from all 3 domains (Figure 1, right). Experiments were repeated 5 times to minimize the effect of randomness in network initialization. Performance was measured using the Dice coefficient.

Results: Domain-specific models were confirmed to be superior (5.68 higher Dice overall) when training and evaluation domains were the same (Figure 2). Segmentation results from our cross-domain model were comparable (3/10 cases) or superior (7/10 cases) to any domain-specific alternative for all domains and fluid labels (2.43 higher Dice overall). Training of the cross-domain model was also found to be > 2.5× faster.

Conclusions: Overall, our proposed cross-domain segmentation model is more accurate and faster to train compared with domain-specific models and eliminates the need for customizing models domain-specifically. The benefits of our approach may facilitate automated SD-OCT segmentation in the clinics.

TITLE: Posttransplant VEGFR1R2 Trap eye drops improve corneal high-risk allograft survival

SESSION TITLE: Corneal Immunology and Neovascularization

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W. Zhang, A.P. Schönberg, F. Bock, C. Cursiefen, Department of Ophthalmology, Universitat zu Koln, Cologen, Nordrhein-Westfalen, GERMANY|

Commercial Relationships Disclosure: Wei Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Alfrun Schönberg: Commercial Relationship: Code N (No Commercial Relationship) | Felix Bock: Commercial Relationship: Code N (No Commercial Relationship) | Claus Cursiefen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Pathological neovascularization of the corneal recipient is one of the main risk factors for graft rejection after corneal transplantation. This study aims to assess whether topical application of VEGFR1R2 Trap eye drops after corneal transplantation can impair the outgrowth of blood vessels (BVs) and lymphatic vessels (LVs) and promote murine high-risk corneal allograft survival.

Methods: Topical VEGFR1R2 Trap or human IgG Fc eye drops (as control) were delivered 3 times per day for 2 weeks after murine high-risk corneal transplantation. VEGFR1R2 Trap in corneal tissue after application was detected by immunohistochemistry. Corneas and draining lymph nodes (dLNs) were excised at week 2 and 8 post-transplantation. Corneal BVs and LVs were quantified by immunohistochemistry and morphological assessment. Dendritic cells (DCs) and regulatory T cells (Tregs) in dLNs were analyzed by flow cytometry. Allograft survival was determined by an 8-week evaluation of corneal opacity scores.

Results: Topically applied VEGFR1R2 Trap penetrated into the corneal bed and graft stroma after high-risk keratoplasty. Additional, postsurgical hemangiogenesis ($P<0.0001$) and lymphangiogenesis ($P<0.01$), and infiltration of CD45+ ($P<0.001$) as well as macrophages ($P<0.01$) in corneas were significantly reduced in the VEGFR1R2 Trap group compared to controls after transplantation. VEGFR1R2 Trap eye drops significantly decreased the frequency of CD11c+ DCs ($P<0.01$), MHC II+CD11c+ DCs ($P<0.01$) and CD40+CD11c+ DCs ($P<0.05$), and enhanced the frequency of CD200R+ regulatory DCs ($P<0.05$) and Tregs in dLNs ($P<0.01$). Moreover, long-term allograft survival was improved ($P<0.05$).

Conclusions: Temporary, posttransplant, topical application of VEGFR1R2 Trap eye drops can achieve sufficient anti-VEGF activity, inhibit additional posttransplant hem- and lymphangiogenesis and significantly improve high-risk corneal allograft survival. VEGFR1R2 Trap eye drops post transplantation may become a new therapeutic option for patients undergoing high-risk corneal transplantation.

ABSTRACT BODY:

Purpose: To evaluate the toxicology, safety, and tolerability of D-4517.2 in rats, dogs and humans at doses anticipated to be efficacious in the treatment of wet AMD and DME.

Methods: D-4517.2 is comprised of a hydroxyl dendrimer covalently linked to a potent inhibitor of vascular endothelial growth factor receptor (VEGFR) tyrosine kinases. A single subcutaneous (SC) or oral dose of D-4517.2 inhibited choroidal neovascularization (CNV) comparable or better than a single intravitreal injection of aflibercept in laser-induced CNV mice[1]. Single-dose GLP toxicology, safety pharmacology studies (rat neurobehavioral and pulmonary studies, dog cardiovascular study, in vitro hERG ionic conductance study) and genotoxicology studies were conducted. A healthy volunteer Phase 1 study has been initiated with regulatory approval to enroll single ascending SC cohorts (n=4/cohort) from 0.25 to 2 mg/kg D-4517.2.

Results: A single SC dose of D-4517.2 was generally well tolerated in rats at levels up to 1000 mg/kg and at levels up to 200 mg/kg in dogs with a no-observed-adverse-effect level of 200 mg/kg. In vitro and rat genotoxicity tests conducted up to limit doses were negative. No findings of toxicologic importance were obtained in safety pharmacology evaluations in rats or dogs treated with D-4517.2 up to doses of 1000 mg/kg and 200 mg/kg, respectively. Analysis of the pharmacokinetics in mice, rats and dogs enabled allometric scaling to determine that the potential efficacious human doses are 0.25 to 2 mg/kg. A Phase 1 study is ongoing and the safety, tolerability, and pharmacokinetics of a single SC dose of D-4517.2 in healthy volunteers will be presented.

Conclusions: The GLP toxicology and safety pharmacology studies conducted in rats and dogs indicated a 100-fold safety margin above the maximum proposed human single SC dose (2.0 mg/kg D-4517.2). Allometric scaling of the D-4517.2 efficacious SC doses in the laser-induced CNV mouse model indicated that a SC dose of D-4517.2 of 0.25 to 2 mg/kg may be effective in treating patients with wet AMD or DME. Although D-4517.2 is renally cleared within 24 hours in animals, CNV lesion formation was suppressed for 2 weeks after a single SC in the CNV mouse model[1]. D-4517.2 may provide a safe SC administered chronic anti-angiogenesis treatment.

ABSTRACT BODY:

Purpose: Magnitude of cholesterol rich myelin debris clearance after demyelination in Multiple Sclerosis (MS) limits recovery. The purpose of our study is to determine if augmentation of cholesterol efflux transporter 1 (Abca1) by gentisic acid (GA) influences synaptogenesis, myelination, and rescue of the ocular phenotype in an experimental autoimmune encephalomyelitis (EAE) optic neuritis model.

Methods: Brain organoids and Brn3a-GFP expressing retinal organoids were grown with or without 400μM GA. Organoids were analyzed for Abca1, PSD95, NG2, and Olig2 expression. EAE-related optic neuritis was induced in 52 female C57BL6 mice by immunization with MOG33-55, complete Freund's Adjuvant and pertussis toxin. 22 EAE mice received intraperitoneal GA weekly (EAE+GA), another 25 naïve mice served as controls. Clinical progression was monitored using a 5-point EAE scoring scheme. At day 60, visual acuity, pattern electroretinography (PERG) and retinal ganglion cell (RGC) complex thickness were measured. Grades of demyelination and cell infiltration in optic nerves were determined. Differences were evaluated using Tukey's post-hoc test.

Results: Retinal organoids+GA show accelerated maturation, evident by increased number of Brn3a+RGC and increased expression of PSD95. Brain organoids+GA demonstrated a 10-fold increase in NG2 and Olig2 expression as well as a 4-fold increase in PLP. EAE+GA animals show significantly lower motor-sensory impairment (EAE:122±4 vs. EAE+GA: 78±5; p=0.0001). Treatment also preserved visual acuity (EAE:0.23±0.08c/d vs. EAE+GA: 0.34±0.09c/d; p=0.0001), improved the PERG amplitude (EAE:16±4 vs. EAE+GA:20±4 μV; p=0.03) and slightly diminished RGC complex thinning (EAE:59±4μm vs. EAE+GA:62±3μm; p=0.2) when compared to untreated EAE mice. Grades of demyelination in the optic nerve was less severe in EAE+GA mice (EAE:2.1±0.8 vs. EAE+GA: 1.1±0.6; p=0.0001) and fewer infiltrating cells were observed (EAE:2.2±1 vs. EAE+GA: 1±0.5; p=0.0001).

Conclusions: GA supplementation in organ specific organoids accelerates retinal development and myelination. In EAE mice, GA administration significantly lessens motor-sensory deficits and promotes visual system recovery that is related to increased clearing of myelin debris and preservation of synaptic plasticity. In summary, this study suggests that interventions to improve cholesterol homeostasis might be a viable approach to promote rehabilitation in MS.

TITLE: Point of Care Diagnosis of Dry Eye Disease with Sensitive Dual Biomarker Detection

SESSION TITLE: Dry eye regulators: lacrimal gland, Meibomian gland, basic mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.D. Zhang, D. Wang, Westview Optometry and Eye Institute, San Diego, California, UNITED STATES|

Commercial Relationships Disclosure: Sydney Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Dorothy Wang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Current diagnosis of dry eye disease (DED) has significant challenges with limited accuracy and poor correlation of clinical symptoms. The goal of this study is to develop a sensitive lateral flow immunoassay (LFIA) for point of care (POC) diagnosis of DED. The authors tested the hypothesis of targeting dual biomarkers Interleukin-6 (IL-6) and lactoferrin in tears for multiplexing detection, as to increase the accuracy of POC diagnosis for DED. A standardized tear collection protocol was also developed with the use of disposed contact lenses. The initial trial of 20 tear samples provided positive LFIA results for future clinical studies.

Methods: 1. Production of LFIA paper strips printed with gold nanoparticle conjugates, antibodies against human IL-6 or lactoferrin & antimouse antibody.

2. Determination of lowest detection limits of LFIA with serial diluted concentrations of rIL-6 or lactoferrin solutions

3. Confirmation of LFIA results with the conventional ELISA method

4. De-identified and discarded contact lens were collected with the consent of the patients

5. Application of 50 µL tear samples onto a LFIA paper strip for detection of tear IL-6 or lactoferrin

6. Image capture of LFIA paper strips 10 minutes after LFIA test

7. Quantitative data analysis of LFIA paper strips with ImageJ software

8. Student t test was used for statistical analysis

Results: A paper-based LFIA was successfully developed in a double-antibody sandwich fashion with gold nanoparticles acting as probes. The minimal detection concentrations were 0.1 ng/ml and 10 ng/ml for IL-6 and lactoferrin, respectively. Separated ELISA tests were also performed with data confirming results from LFIA tests. A trial study was conducted with 20 tear samples. Compared to the controls, all 10 DED tears exhibited statistically significantly higher levels of IL-6 and decreased levels of lactoferrin. A quantitative analysis of LFIA images was carried out using ImageJ software for an accurate data interpretation. A smartphone-based platform is being developed for LFIA imaging, data reporting and storage.

Conclusions: In summary, a POC enabled DED diagnostic kit has been successfully developed by targeting two important biomarkers. Tear testing of IL-6 and lectoferrin demonstrated a positive correlation of LFIA results with DED symptoms. Further investigations are warranted to improve its accuracy for clincal diagnosis of DED

TITLE: Peptide Lv promotes angiogenesis through intermediate conductance calcium-dependent potassium (K_{Ca} 3.1) channels in endothelial cells

SESSION TITLE: Biochemistry and Molecular Mechanisms of Diabetic Retinopathy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Pham, A. Niemi, G.Y. Ko, Veterinary Integrative Biosciences, Texas A&M University, College Station, Texas, UNITED STATES|

Commercial Relationships Disclosure: Dylan Pham: Commercial Relationship: Code N (No Commercial Relationship) | Autumn Niemi: Commercial Relationship: Code N (No Commercial Relationship) | Gladys Ko: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Peptide Lv is an endogenous pro-angiogenic peptide that is upregulated in the retina of diabetic animals and patients with early diabetic retinopathy. Although peptide Lv promotes pathological angiogenesis, the mechanisms of its angiogenic action remains unclear. Activation of endothelial potassium channels, including intermediate conductance calcium-dependent potassium (K_{Ca}3.1) channels, promotes angiogenesis. We hypothesize that peptide Lv augments endothelial K_{Ca}3.1 to promote endothelial proliferation and pathological angiogenesis.

Methods: Membrane potentials and K_{Ca}3.1 currents were recorded from human umbilical vein endothelial cells (HUVEC) treated with peptide Lv (500 ng/ml). TRAM 34 was perfused at the end of each recording to isolate the K_{Ca} 3.1 current from other outward currents. Western blots for K_{Ca}3.1, small conductance calcium-dependent potassium (K_{Ca}2.3), and ATP-sensitive potassium (Kir6.1) were performed after HUVECs and human retinal endothelial cells (HRECs) were treated with peptide Lv (500 ng/ml) or PBS (vehicle control) for 4 hours. For testing the endothelial proliferation, HUVECs were seeded onto 24-well plates and allowed to adhere overnight. Peptide Lv (500 ng/ml), VEGF (5 ng/ml), DMH4 (5 μM), TRAM 34 (10 μM) and PBS/0.1% DMSO (vehicle controls) were added to cultures for another 48 hrs. Then the MTT (3-[4,5-dimethylthiazol-2-yl]-2,5 diphenyl tetrazolium bromide) colorimetric assays were performed on these cultures. The absorbance at 560 nm was measured using the Chromate microplate reader.

Results: Endothelial cells treated with peptide Lv had significant increase in the mRNA and protein expression of K_{Ca} 3.1 but not other types of K channels. Peptide Lv hyperpolarized the endothelial cells and increased the K_{Ca}3.1 current densities. Blocking K_{Ca}3.1 with TRAM 34 attenuated peptide Lv-elicited endothelial cell proliferation.

Conclusions: The angiogenic property of peptide Lv is in part through the augmentation of endothelial K_{Ca}3.1.

ABSTRACT BODY:

Purpose: Development of novel anti-angiogenic therapies distinct from VEGF is critical for the identification of new treatments for blindness-inducing age-related macular degeneration. Leukemia inhibitory factor (LIF), a member of the IL-6 cytokine family, has recently been identified as a potent endothelial cell (EC) mitogen in vitro and in vivo. Surprisingly, although the same results were seen in vitro for oncostatin M (OSM), another member of the IL-6 family, intravitreal (iv) injection of this cytokine decreased vascular density and inhibited laser-induced CNV in vivo. We hypothesize that LIF and OSM act through distinct mechanisms to exert their mitogenic potential on ECs.

Methods: Bovine choroidal, aortic, and retinal ECs were treated with various concentrations of LIF and OSM and key signaling mechanisms were tested by western blot and RT-qPCR. siRNA was used to knock-down the main receptors for LIF and OSM. Retinas from mice subjected to LIF and OSM iv injections were flat mounted, and neovascularization and inflammatory cell infiltration were assessed by confocal microscopy.

Results: OSM promoted proliferation of choroidal and retinal ECs through the JAK-STAT3 pathway. Conversely, OSM inhibited bovine aortic EC growth also via activation of JAK-STAT3 pathway. Interestingly, OSM, but not LIF, was able to upregulate IL-6 mRNA in choroidal and retinal ECs, as opposed to aortic ECs. Moreover, the mitogenic potential of OSM was mediated by different receptors in choroidal and aortic ECs. In vivo, as opposed to LIF, OSM inhibited neovascularization at low concentrations and was associated with an increase macrophage infiltration into the retina. However, high concentrations of OSM were able to stimulate retinal angiogenesis and were associated with reduced macrophage infiltration.

Conclusions: OSM exerts opposing responses in various EC subtypes via activation of the same signaling pathway. Additionally, OSM signals through different receptors, suggesting that different EC types have unique gene expression patterns, which determines their differential responses to the same stimulus. Moreover, our in vivo data points towards a role for OSM in the recruitment of inflammatory cells such as macrophages to the retina in a concentration-dependent manner. Overall, these data demonstrate that LIF and OSM act through distinct mechanisms in ECs.

TITLE: Sequential OCTA scans have greater signal variability around venules.

SESSION TITLE: OCT Angiography Clinical Applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N.B. Patel, University of Houston, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure: Nimesh Patel: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Optical coherence tomography angiography (OCTA) slab projections represent vasculature in which blood flow meets or exceeds threshold. Sequential OCTA scans have regional variability, and averaging slabs improves visualization of capillaries. We hypothesize that some of the regional variability reflects on blood flow physiology. The purpose of this study was to quantify regional OCTA signal variability from sequential scans for vessels in the superficial vascular complex.

Methods: Data were collected from seven non-human primates with no ocular pathology. Prior to imaging, animals were sedated with ketamine and xylazine, and pupils dilated with 1% tropicamide. Six sequential, high speed 384x384 (15°x15°) OCTA raster scans (Spectralis OCT2), centered on the macula, were acquired from one eye of each animal. Scan volumes were imported into Matlab, registered in 3D, and the thresholded signal between the inner limiting membrane and inner plexiform layer isolated. Variability was quantified as the standard deviation of the theresholded signal using a 20x20 A-scan sliding window for identical regions of the six scans. Major vasculature was manually traced on the averaged 2D slab projection, and a 16 pixel dilated region used to compute the average variability surrounding each vessel. Arterioles were identified based on the capillary free zone.

Results: All animals had healthy eyes at the time of imaging, and the mean ganglion cell complex thickness was 103±5.3μm. The average superficial vascular complex slab density was 40.6±3.5%, and volumetric vascular density was 6.9±0.7%. A total of 47 arterioles and 46 venules were identified and traced. The mean standard deviation of OCTA signal was greater around venules (1.11x10-3) compared to arterioles (9.25x10-4, $p<0.01$).

Conclusions: Averaging OCTA scans improves visualization of capillaries. The variability in OCTA signal is greatest around venules, which is likely a reflection of regional differences in blood flow. In addition to vessel density, OCTA signal variability from sequential scans may provide important physiological information when assessing ocular health.

ABSTRACT BODY:

Purpose: To compare biomechanical metrics between eyes of subjects with asymmetric glaucoma (ASYMM) and those with symmetric glaucoma (SYMM).

Methods: A total of 46 subjects were prospectively recruited. ASYMM was defined as C/D difference > 0.1 between eyes (C/D difference range 0.12 to 0.65) and SYMM was defined as a C/D difference <= 0.1 between eyes (C/D difference range 0 to 0.1). There were 32 eyes of 16 subjects in the ASYMM group and 60 eyes of 30 subjects in the SYMM group. Within the ASYMM group, best eye and worst eye were determined and all parameters were subtracted as worst eye minus best eye. Biomechanical metrics included corneal hysteresis (CH) from the Ocular Response Analyzer, and stiffness parameters at first applanation (SP-A1) and highest concavity (HC), as well as Integrated Inverse Radius and Deformation Amplitude Ratio, all from the Corvis ST. In addition, pulsatile ocular blood volume (POBV) was calculated based on intraocular pressure (IOP) and ocular pulse amplitude (OPA) from pneumatonometry and axial length. Paired T-test comparisons were performed between eyes of both ASYMM and SYMM groups for each variable. Statistical analyses was performed with SAS with the significance threshold set to $p < 0.05$.

Results: Within ASYMM group, CH was significantly different by -0.76 (SD 1.22, $p = 0.025$) with the worst eye having lower CH. POBV was significantly different by -0.38 (SD 0.305, $p = 0.016$) with the worst eye having lower POBV. For SYMM there were no significantly different variables.

Conclusions: Low CH is associated with greater glaucomatous damage between eyes in asymmetric glaucoma, which is consistent with literature reporting CH as a risk factor. In addition, this study showed that the eye with greater glaucomatous damage in asymmetric glaucoma was also associated with lower pulsatile ocular blood volume which may have contributed to the more severe disease.

ABSTRACT BODY:

Purpose: Controversy exists regarding the inclusion of nonexudative age-related macular degeneration (AMD) patients in clinical studies based on structural vs. functional criteria. In a prior analysis, cone contrast testing (CCT) red distinguished intermediate AMD (iAMD) vs. controls at 12 and 24 months. Our goal was to further analyze the longitudinal changes in CCT in normal, early and iAMD participants.

Methods: As part of the single-site, prospective, observational Duke FEATURE study, 69 participants (16 healthy control, 22 early AMD, 31 iAMD) were evaluated. Study participants were assessed at baseline, 12 and 24 months using CCT red and green, dilated exam, and optical coherence tomography. CCT blue was not included in this analysis due to the potential effect of mild cataract on test performance and lack of longitudinal change over 24 months in a prior analysis.

Results: At 12 and 24 months, there was a significant difference across the three groups in the proportion of individuals with no functional deficits based on a normative database (CCT score ≥ 80), moderate deficits (score 50-80), or severe deficits (score ≤ 50) for both CCT red (baseline $p=0.01$; 12 and 24 months $p< 0.01$ Fisher's exact test) and green (12 and 24 months $p< 0.02$). This significant difference between groups was only found at the baseline visit for CCT red ($p=0.01$) but not for CCT green ($p=0.07$).

Compared to normal and early AMD participants, those with iAMD were more likely to show a decrease in total CCT score (red + green) of ≥40 points from any prior visit ($p< 0.05$) throughout the study. Notably, of the control population, 0% had severe CCT red or green, 56% had moderate CCT red and 37% CCT green deficits at baseline. Proportions of control participants with moderate-severe CCT deficits increased over time: 6% progressed to severe and 56% to moderate deficits on CCT red at 24 months, and 6% to severe and 44% to moderate deficits on CCT green at 24 months.

Conclusions: CCT tests for red and green colors represent early functional measures of disease progression in eyes with early-iAMD. We noted a longitudinal decline in CCT function over 24 months. A subgroup of healthy control participants demonstrated functional deficits on CCT red and green, suggesting that both visual function and structural inclusion criteria should be employed in future clinical trials of nonexudative AMD.

Marin: Commercial Relationship: Code N (No Commercial Relationship) | Jesse Smith: Commercial Relationship: Code N (No Commercial Relationship) | Niranjan Manoharan: Commercial Relationship: Code N (No Commercial Relationship)
ABSTRACT BODY:
Purpose: The clinical course and outcomes of patients with advanced chronic retinal detachments (RDs)—detachments greater than one month—have not been well-studied. The goal of this case series was to investigate the outcomes associated with surgical intervention of advanced chronic macula-off RDs.
Methods: Thirty-eight patients that presented to Denver Health Medical Center, a safety-net hospital system, from 2016 to 2021, with a retinal detachment that was not repaired for greater than one month were identified. These patients were analyzed for proliferative vitreoretinopathy (PVR) on presentation, type of surgical intervention, pre-operative and final best-corrected visual acuity (BCVA), initial surgical re-attachment rate, final surgical attachment rate, and occurrence of phthisis. Additionally, post-operative complications were identified and recorded including ocular hypertension and cataract formation.
Results: Mean duration of RD was 153 days. Twenty-eight out of 38 (74%) patients had PVR on initial presentation. Initial surgical intervention included pars plana vitrectomy (PPV) without scleral buckle (SB) (5%), pars plana vitrectomy with scleral buckle (79%), and scleral buckle with cryotherapy (16%). Initial attachment rate was 55.26% and the final attachment rate was 94.74%. Mean number of RD surgeries was 1.50 (SD 0.77). All six patients who underwent SB with cryotherapy failed initial surgery and required PPV. Other post-operative complications included ocular hypertension (76%), cataract formation (66%), and phthisis bulbi (5%). Of patients that developed ocular hypertension, 7/29 (24%) required surgery. Mean final BCVA was 1.60 (0.71) and final globe salvage rate was 38/38 (100%).
Conclusions: We demonstrate the clinical characteristics of advanced chronic RDs with various surgical approaches. We found that initial retinal reattachment in advanced chronic RD was much lower than reported rates of uncomplicated acute RDs. Additionally, a majority of patients developed ocular hypertension and almost a quarter of whom required surgical management. Finally, primary scleral buckle might be less successful in advanced chronic RDs. Poor patient compliance with post-operative positioning and follow-up also appeared to affect patient outcomes. However, most patients had successful final re-attachment, globe salvage, and ambulatory vision. Further studies are needed to optimize surgical outcomes in these patients.

ABSTRACT BODY:

Purpose: Sex-related differences in dry eye disease (DED) are acknowledged but are not well-characterized. This study evaluates how DED signs and symptoms differ between men and women, as well as between pre- and post-menopausal women, in the Dry Eye Assessment and Management (DREAM) study.

Methods: This secondary analysis of the data from the DREAM study included 101 male and 434 female participants (59 pre-menopause and 375 post-menopause). Participants self-reported prior medical history and underwent a DED assessment using the Ocular Surface Disease Index (OSDI), Brief Pain Inventory (BODI), Tear Break-Up Time (TBUT)(sec), Schirmer's test (mm/5 min), conjunctival staining, corneal staining, meibomian gland dysfunction evaluation, and tear osmolarity (mOsms/L) at baseline, 6 months, and 12 months. Multivariable linear regression models were used to compare the scores in symptoms and signs between groups while adjusting by age, race, smoking status and existing comorbidities associated with DED signs or symptoms.

Results: In a multivariable analysis of combined data at baseline, 6 months, and 12 months, women had significantly worse DED signs than men with lower Schirmer's test score (9.27 vs 12.16; $p<0.001$), higher corneal staining score (3.59 vs. 2.70; $p=0.006$), and worse composite DED scores (0.52 vs. 0.40; $p<0.001$) [Table 1]. Post-menopausal women experienced significantly worse DED signs than pre-menopausal women with lower TBUT (3.37 vs. 3.93, $p=0.047$), higher corneal staining scores (3.74 vs. 2.58, $p<0.001$), higher conjunctival staining scores (2.80 vs. 2.22, $p<0.001$), worse meibomian gland dysfunction (3.05 vs. 2.62, $p=0.04$), higher tear osmolarity (304 vs. 299, $p=0.004$), and worse composite DED scores (0.54 vs. 0.42, $p<0.001$) [Table 2]. There were no significant differences in DED symptoms between sex and between pre- and post-menopausal women (all $p\geq0.13$) [Tables 1 and 2].

Conclusions: In the DREAM study, women experienced more severe DED signs compared to men, independent of age, race, smoking status and comorbidities. Further, post-menopausal women presented with more severe DED signs compared to pre-menopausal women. These findings may improve DED diagnosis and provide future direction in understanding sex-associated differences in DED.

ABSTRACT BODY:

Purpose: Electroretinography (ERG), which measures the electrical activity of retinal photoreceptors, has been employed in the management of retinal diseases. Recently, a simplified flicker ERG system has been developed. This cross-sectional study explores whether the Diopsys® flicker ERG system can be used in the monitoring of posterior uveitis patients.

Methods: Patients with posterior uveitis from a single institution were included. Patients with concomitant retinal disease such as diabetic retinopathy or age-related macular degeneration were excluded. Demographic and clinical data, including flicker ERG (Diopsys® NOVA), were collected. Statistical analyses were performed with STATA 16.0 software, and the Student’s t-test was used to compare means of different groups.

Results: A total of 85 patients (134 eyes) were studied. Diagnoses included juvenile idiopathic arthritis associated uveitis, Birdshot, and Behçet’s disease among others. Mean age was 36.89 ± 18.06 years. Fifty-two eyes had retinal vasculitis and 62 eyes had optic disc inflammation. There was a statistically significant difference in magnitude between eyes with (n=52) and without (n=82) retinal vasculitis (p=0.02). In addition, eyes with diffuse (posterior and peripheral) vasculitis (n=13) had reduced magnitude compared to eyes with only peripheral vasculitis (n=39) (p<0.01). However, no significant difference was found between eyes with and without optic disc inflammation (p=0.08).

Conclusions: Based on the index study, the Diopsys® flicker ERG system may aid in the monitoring of eyes with posterior uveitis.

ABSTRACT BODY:

Purpose: A new femtosecond laser aiming for tissue-bridge-free corneal refractive surgery has been developed. The new laser is designed with the shortest pulse duration, the smallest focal spot, and continuous dissection surface to perform corneal incision at the lowest energy per pulse. Two critical-to-quality characteristics (CTQ) of the new surgical laser are the plasma forming threshold and the accuracy of the cutting-depth baseline. We developed an innovative method to measure these two CTQs simultaneously, which is much more precise, robust, and simpler than the previous gel-cutting method.

Methods: The new femtosecond laser is designed with an Auto-Z detector to measure the reflected light at the laser focal point. By scanning the focus through the patient interface's glass surface, the Auto-Z signal will show a sharp peak if the pulse energy is above the glass plasma threshold, and no peak if the energy is below the plasma threshold. We can measure the threshold energy at sub-nJ precision and measure the glass surface position at sub-μm precision. Using this method, we characterized the system's glass burn threshold and the Auto-Z signal as a function of pulse energy; measured the glass burning position stability for the femtosecond laser for a month; and characterized the impact of pulse energy on the Auto-Z signal's peak position.

Results: First, the new femtosecond laser system can achieve ≤ 50 nJ glass burn threshold. This means that the corneal incision can be achieved at ≤ 70 nJ per pulse. Second, within a month, the system's preset zero depth position can vary by about 15 μm due to laser, optical, and thermal variations. This small drift will be corrected to sub-μm accuracy in each procedure by the Auto-Z device. Third, we found that the glass burn position is a function of pulse energy, indicating that the focal volume of the laser beam that has the light intensity above the glass burn threshold is growing with the increasing pulse energy.

Conclusions: We have developed a precise, robust, and simple-to-operate method to measure the CTQs of the new femtosecond laser. With this method, we can ensure that the new femtosecond laser system can perform tissue incision at the lowest energy per pulse and can ensure that depth variation due to either internal system variation or due to patient interface variation can be corrected to sub-micron accuracy for each procedure.

ABSTRACT BODY:

Purpose: Intraocular anti-vascular endothelial growth factor (anti-VEGF) therapies are the front-line treatment for diabetic macular edema (DME), however, treatment response varies widely. This study aims to identify genetic determinants associated with anti-VEGF treatment response in DME patients.

Methods: We performed a genome-wide association study on 220 DME patients treated with anti-VEGF therapy, genotyped on Illumina Global Screening Array. Changes in central macular thickness (CMT) and best-corrected visual acuity (BCVA) after 12 months were our primary outcome measures. Association between single nucleotide polymorhphism (SNP) genotypes and DME outcomes were evaluated by linear regression (additive model) using PLINK2.0, adjusting for the first three principal components, age, baseline CMT/BCVA, duration of diabetic retinopathy, and HbA1c.

Results: In the GWAS for CMT change, a single SNP on chromosome 6 (rs78466540, P=1.16E-09) and a locus on chromosome 12 (top SNP rs11614480, P=2.69E-08) reached genome-wide significance (Figure 1A). The chromosome 12 locus was supported by four nearby SNPs rs11615848, rs11614887, rs11615870, rs11615833 in linkage disequilibrium which also showed genome-wide significance (P≤5E-08). For BCVA change we found five SNPs reaching genome-wide significance(Figure 1B), three on chromosome 11, (rs148980760, P=5.30E-09; rs117744949, P= P=6.57E-09 and rs57801753, P= P=1.71E-08), and a SNP each on chromosome 5 (rs187876551, P=1.52E-08) and chromosome 6 (rs118074968, P=4.94E-08). In silico investigations of each locus identify multiple eQTLs and potentially relevant candidate genes warranting further analysis.

Conclusions: Multiple genetic loci predicting treatment outcomes for anti-VEGF therapies in DME have been identified. This work will potentially lead to personalized medicine approaches for managing DME.

ABSTRACT BODY:

Purpose: Previous estimates of the prevalence of global uncorrectable visual impairment (VI) have not accounted for the increasing prevalence of myopia, particularly in older individuals. We estimate the global prevalence of uncorrectable VI in 2020 accounting for the distribution of both age and myopia.

Methods: Age distribution of the global population in 2020 were taken from www.populationpyramid.net. Overall prevalence of myopia (<–0.50 D) of 33.9% was used, based on Holden et al. (2016). Distribution of myopia, by severity, was calculated using the model of Brennan et al. (2020) Uncorrectable VI as a function of age and refractive error was modelled by multiple linear regression (Bullimore et al., 2021) from a large data set of an advanced European population (Tideman et al., 2016). This data set is agnostic with respect to the disease condition associated with VI. By convolving the distributions of myopia and age with the cumulative risk of VI, the number of individuals with uncorrectable VI in 2020 was calculated.

Results: The 2020 global population is 7.79 billion, of whom 2.64 billion are myopic and 0.46 million have high myopia (<–5D). The cumulative odds of uncorrectable VI (20/40 or worse) is $10^{(0.057Age - 0.122Rx - 4.03)}$ and the estimated global population with uncorrectable VI is 113
million (1.5%). Of these, 60 million are myopes compared with 53 million non-myopes. An estimated 32 million cases of VI (29%) can be directly attributed to increased risk of eye disease associated with myopia; > 40% of cases below 60 years. At 65 years, myopes comprise 60% of individuals with VI, while representing 33.9% of the population. At 81 years, myopes still account for half of the visually impaired.

Conclusions: Assuming that the data from Tideman et al. are applicable to the global population, we estimate that some 29% of global uncorrectable VI is attributable to myopia. Failure to account for the increasing prevalence of myopia among the aging population leads to a substantial underestimate of the prevalence of VI. In our 2020 model each 1% increase in myopia prevalence results in an additional 1.2 million VI. Projecting for 2050, each 1% increase in myopia is associated with 2.7 million increased VI. Approaches that treat diseases associated with myopia are needed to reduce VI, along with programs that reduce myopia prevalence and severity.

TITLE: PHARMACOLOGICAL AND SAFETY PROFILE OF TWO NEW BETAMETHASONE/CHLORAMPHENICOL GEL OPHTHALMIC FORMULATIONS

SESSION TITLE: Anti inflammatory agents, antibiotics and antivirals

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Bucolo, F. Lazzara, G.L. Romano, F. Conti, F. Drago, Biomedical and Biotechnological Sciences, University of Catania, Catania, ITALY|C. Bucolo, G.L. Romano, F. Drago, Center for Research in Ocular Pharmacology (CERFO), University of Catania, Catania, ITALY|C. Piazza, Unifarm, Catania, ITALY|

Commercial Relationships Disclosure: Claudio Bucolo: Commercial Relationship: Code N (No Commercial Relationship) | Francesca Lazzara: Commercial Relationship: Code N (No Commercial Relationship) | Giovanni Romano: Commercial Relationship: Code N (No Commercial Relationship) | Federica Conti: Commercial Relationship: Code N (No Commercial Relationship) | Cateno Piazza: Commercial Relationship: Code N (No Commercial Relationship) | Filippo Drago: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the pharmacological and safety profile of two new betamethasone/chloramphenicol gel formulations with or w/o preservative, versus other steroid/antibiotic combinations.

Methods: Corneal epithelial cells were used. After cell exposure to ocular formulations, cell viability, along with occludin levels, were assessed by ATPlite and WB, respectively. Wound healing was carried out by scratch assay. Cells were exposed to: Ziclor$_P$ gel [0.1% betamethasone (BET)/0.25% chloramphenicol (CHL) with parabens; Alfa Intes], Betabioptal gel (0.1% BET/0.25% CHL with thiomersal; Thea), Netildex eye-drops [0.1% dexamethasone (DEX)/0.3% netilmicin with benzalkonium chloride (BAK); SIFI] and Ducressa eye-drops (0.1% DEX/0.5% levofloxacin; with BAK; Santen). Albino rabbits were used for ocular pharmacokinetic (PK) study (ARVO Statement for Use of Animals in Ophthalmic Vision Research). Two groups of rabbits were treated with a single topical administration (30µl) of 0.1% BET gel formulation w/o parabens (Ziclor$_{PF}$) and 0.1% DEX eye-drops (Ducressa), respectively. Aqueous was collected at 30, 60, 120, 180, and 240 mins after treatment, and levels of steroid detected by LC-MS/MS.

Results: ATP levels were significantly ($p<0.05$) reduced by the three formulations exposure compared to the new gel Ziclor$_{P.}$ A significant ($p<0.05$) wound closure area was observed after the exposure with Ziclor$_P$ compared with the other products. Occludin expression was maintained at physiological levels in the cells exposed to Ziclor$_P$; on the contrary the other formulations elicited a significant ($p<0.05$) protein's reduction. PK study showed no significant difference in terms of AUC and C_{max} between Ziclor$_{PF}$ and Ducressa (AUC_{0-240} 1943 and 1827 ng/ml*min, C_{max} 11.75 and 11.42 ng/ml for gel and eye drops formulations, respectively). However, after 180- and 240-min BET levels were significantly ($p<0.05$) higher compared to DEX.

Conclusions: The new ophthalmic gel formulations have a good pharmacological and safety profile. PK study showed higher levels of steroid in anterior chamber with Ziclor$_{PF}$, suggesting a longer pre-corneal residence time compared to Ducressa eye drops. Cells treated with Ziclor$_P$ showed a better viability and wound healing compared to the other formulations, preserving cell barrier connections, and suggesting that Ziclor$_P$ has a minimum impact on cell repair process.

TITLE: A systematic review of laser peripheral iridotomy placement for reducing the incidence of dysphotopsia symptoms in primary-angle closure

SESSION TITLE: IOP and laser therapy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Xuan, K. Ong, University of Sydney, New South Wales, AUSTRALIA|R. Xuan, K. Ong, Royal North Shore Hospital, St Leonards, New South Wales, AUSTRALIA|

Commercial Relationships Disclosure: Rachel Xuan: Commercial Relationship: Code N (No Commercial Relationship) | Keith Ong: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess the incidence of dysphotopsia symptoms in patients with priarmy angle-closure glaucoma and/or primary angle-closure suspect with various positions of laser peripheral iridotomies (LPI).

Methods: The authors searched five electronic databases including CENTRAL, MEDLINE, EMBASE and trial registries for randomised controlled trials (RCTs). The search was last conducted on October 4, 2021. Language was not limited to English. Articles were excluded if LPI was compared to other interventions or if the measured outcome did not include dysphotopsia symptoms. Risk ratio was used for binary outcomes.

Results: Five RCTs involving 2364 eyes of 1182 patients were included in the review. Four studies compared superior with nasal/temporal LPIs; one study compared superior with inferior LPIs. The main weakness was potential selection bias for two studies and the lack of blinding for investigative personnel. Risk of bias was assessed at the individual study and outcome level with GRADE approach vigorously applied. Moderate-certainty evidence shows no difference between superior and nasal/temporal LPIs. Low-certainty evidence demonstrated conflicting results.

Conclusions: Various LPI positions used to reduce incidence of dysphotopsia symptoms have been studied. More high-certainty RCTs are needed as clinical decisions currently need to be made based on the available evidence.

TITLE: Impact of indeterminant ranges around the cut-off for antibody positivity on the use of serology for trachoma monitoring

SESSION TITLE: Public Health

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: X. Chen, B. Munoz, S.K. West, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|C. Gaydos, L. Dize, T. Quinn, Infectious Diseases, Johns Hopkins University School of Medicine, Baltimore, Maryland, UNITED STATES|H. Mkocha, Kongwa Trachoma Project, TANZANIA, UNITED REPUBLIC OF|T. Quinn, Division of Intramural Research, National Institutes of Allergy and Infectious Diseases, Bethesda, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Xinyi Chen: Commercial Relationship: Code N (No Commercial Relationship) | Beatriz Munoz: Commercial Relationship: Code N (No Commercial Relationship) | Harran Mkocha: Commercial Relationship: Code N (No Commercial Relationship) | Charlotte Gaydos: Commercial Relationship: Code N (No Commercial Relationship) | Laura Dize: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Quinn: Commercial Relationship: Code N (No Commercial Relationship) | Sheila West: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Serologic testing for chlamydial antibodies is a potential tool for trachoma surveillance. However, the impact of indeterminate ranges around the cut-off for seropositivity remains unclear. To understand this, we followed a longitudinal cohort of children in a formerly trachoma endemic district.

Methods: A total of 1719 children aged 1-9 years in Kongwa, Tanzania were followed for three years. We assessed their Median Fluorescence Intensity value (MFI-BG) of the antibodies to Chlamydia trachomatis antigen pgp3 at the baseline and three follow-up surveys. The cutoff for seropositivity was determined by receiver operative characteristic (ROC) curve analyses, using sera from children who were positive for both infection and clinical trachoma and a sample of US children who had never been exposed to trachoma. The indeterminate range was defined as the interval between the highest MFI-BG from the negative panel and the lowest MFI-BG from the positive panel.

Results: The overall seropositivity rate was 31.5% at baseline and 36.4% at the last follow-up. The different trajectories of change in serostatus are shown in Table 1. Of the seropositive children at baseline, 12.1% seroreverted; 25.4% of these seroreversions occurred with an MFI-BG in the indeterminate range. Of the seronegatives, 13.0% seroconverted, with 1.9 % of those seroconversions having an MFI-BG in the indeterminant range. Thirty-one children (2% of 1719) experienced a transient seroconversion or seroreversion (Group 3 or 6). Only one child (3% of the 31) had MFI-BG in the indeterminate range for the survey that placed them as a transient change. Eight out of the 1719 children (0.5%) had unstable serostatus. If the serostatus instances where the values fall in the indeterminate range are instead counted as the alternate, then these children would fall into a more regular pattern, and only 3 children were truly alternating between seropositivity and seronegativity at each survey.

Conclusions: The majority of seroconversion and seroreversion was not influenced by indeterminate ranges for antibody levels. Transient changes in serostatus are real and not due to indeterminate values. The indeterminate ranges had the greatest impact on apparent unstable serostatus changes.

TITLE: Elongation of Axial Length in Older Patients with Degenerative Myopia

SESSION TITLE: Macular diseases/Macular edema/Functional testing/evaluation/Laser

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Sonne, Y.C. Akduman, Saint Louis University, Saint Louis, Missouri, UNITED STATES|C. Meyer, Augenklinik, SWITZERLAND|S. Saxena, retina service, INDIA|

Commercial Relationships Disclosure: Scott Sonne: Commercial Relationship: Code N (No Commercial Relationship) | Yigit Akduman: Commercial Relationship: Code N (No Commercial Relationship) | Carsten Meyer: Commercial Relationship: Code N (No Commercial Relationship) | Sandeep Saxena: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate the axial length changes in older patients presenting with myopic maculopathy secondary to degenerative myopia.

Methods: Five eyes of three consecutive patients (ages 61-88) with myopic maculopathy secondary to degenerative myopia were studied. All eyes were aphakic or pseudophakic following cataract surgery performed 9-18 years prior. The current axial lengths were compared with the axial lengths measured at the time of cataract surgery.

Results: The follow-up time was between 9-18 (13+/-3.94) years. The initial axial length was between 27.94-30.84 (29.15+/-1.08) mm. The final axial length was between 29.35-32.00 (30.47+/-1.11) mm. The axial length increased by 0.10-2.04 (1.32+/-0.75) mm, which corresponds to an average 3.96 diopter myopic shift, during the average follow-up of 13 years. Initial maculopathy findings were pigment stippling of posterior macular staphyloma, diffuse hypopigmentation, and patchy atrophic scars not involving the fovea. None of these affected the best corrected visual acuity. Additional maculopathy in the final visit included the formation of choroidal neovascular membrane (CNVM), epiretinal membrane (ERM) formation, vitreomacular traction (VMT), and maculoschisis.

Conclusions: Axial length may increase in older patients with degenerative myopia presenting with myopic maculopathy. Determining cause and effect relationship requires further study. The patients' initial axial measurements were made at the time of cataract surgery. They then experienced an undesirable myopic shift averaging 3.96 diopters over a mean of 13 years. Patients with myopic degeneration undergoing cataract surgery should be informed of the potential for increase in their ocular axial length over the following decade and longer; moreover, they may need further attention due to potential development of myopic shift and progression of myopic maculopathy. Some of those maculopathies (such as CNVM formation) may require immediate intervention. The elongation trend seen in degenerative myopia may have been occurring even prior to cataract surgery, but lack of long-term monitoring measurements before surgery makes it difficult to determine.

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) is the leading cause of vision loss in working-age adults. Understanding the retinal metabolic response to circulating high glucose levels in diabetic patients is critical for development of new therapeutic strategies to treat DR. Measuring retinal metabolic function using the Seahorse analyzer is a promising technique to investigate the effect of hyperglycemia on retinal glycolysis and mitochondrial respiration. Here, we analyzed the retinal metabolic function in young and old diabetic and control mice. We also compared the expression of key glycolytic enzymes between the two groups.

Methods: The Seahorse XF analyzer was used to measure the metabolic function of retina explants from young (7 months) and old (14 months) type 1 diabetic Akita ($Ins2^{Akita/+}$) mice and their control littermates. Rate-limiting glycolytic enzymes were analyzed in retina lysates from the two age groups. Furthermore, retina metabolic function and glycolysis enzyme expression were measured in an acute retinal ischemia-reperfusion (IR) injury model that is routinely used to model the ischemic phase of DR.

Results: Retinas from young adult Akita mice showed a decreased glycolytic response as compared to controls. However, this was not observed in the older mice. Western blotting analysis showed decreased expression of the glycolytic enzyme PFKFB3 (6-Phosphofructo-2-kinase/fructose-2, 6-bisphosphatase, isoform 3) in the young Akita mice retinas. Measurement of the oxygen consumption rate showed no difference in retinal mitochondrial respiration between Akita and WT littermates under normal glucose conditions despite evident mitochondrial fragmentation as examined by electron microscopy. However, Akita mice retinas at both 7 and 14 months showed decreased mitochondrial respiration under glucose-free conditions. Retinal metabolic function and glycolysis enzymes expression did not change in the IR injury model.

Conclusions: This is the first study to our knowledge to examine glycolytic enzyme expression and retinal metabolic function under diabetic conditions. Diabetic retinas display a decreased glycolytic response during the early course of diabetes which is accompanied by a reduction in PFKFB3. Diabetic retinas exhibit decreased mitochondrial respiration under glucose deprivation. Further investigation of the retinal metabolic function in response to hyperglycemia will help elucidate the pathophysiology underlying DR.

TITLE: Risk of Diabetic Retinopathy (DR) Progression in Patients during 1 year of Semaglutide use

SESSION TITLE: Diabetic Retinopathy

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: B. Cooper, K. Howe, A. Cooper, Retina Associates, LLC, Lenexa, Kansas, UNITED STATES|M. de la Paz, Washington University in St Louis, St Louis, Missouri, UNITED STATES|

Commercial Relationships Disclosure: Blake Cooper: Commercial Relationship(s);Code C (Consultant/Contractor):Genentech, Regeneron | Kellie Howe: Commercial Relationship: Code N (No Commercial Relationship) | Amelia Cooper: Commercial Relationship: Code N (No Commercial Relationship) | Matthew de la Paz: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Semaglutide is a medication used for the treatment of type 2 diabetes. Rapid glycemic control and hemoglobin A1c and have been associated with worsening of DR in a preapproval cardiovascular outcomes study with Semaglutide. Paradoxical worsening of DR after a sudden drop in blood glucose is a well-documented phenomenon with other medications; however, for Semaglutide, the long-term effects of acute worsening of DR remain unclear. We hypothesize if worsening of DR occurs with Semaglutide in patients with type 2 diabetes (T2D) it is temporary and not associated with continued DR progression.

Methods: Retrospective data analysis identified 4086 patients with T2D and DR by ICD-10 codes (E11.3XXX) in a Retina only practice from January to June 2020. The use of Semaglutide was found in 116 patients. Inclusion criteria included at least 1 year of Semaglutide and documentation of the level of non-proliferative (NPDR) and proliferative (PDR) retinopathy, visual acuity (VA), and Central Subfield Thickness (CST). 87 patients were included for descriptive analysis.

Results: 87 patients met the inclusion criteria; 36 (41.4%) Female; average age 62.4 years with a range (38-84); baseline level of DR range (10-85); 11.5% mild NPDR (level 10); 38.5% moderate NPDR (level 35-43); 14.4% severe NPDR (level 47-53); 35.6 % PDR (level 61-85). The level of retinopathy progressed over one year in 5.7% of eyes, improved in 8% of eyes, and remained stable in 86.2% of eyes. Over the course of one-year visual acuity remained unchanged in 72.4% of patients while 12.6% of patients lost > 2 lines of vision in at least one eye and 14.9% gained > 2 lines of vision in at least one eye. CST remained unchanged in 44.2%, increased by at least 10% in one eye of 25.6%, and decreased by at least 10% in one eye of 30.2% of patients. Intravitreal injections were required in at least one eye of 63.2% of patients with an average number of injections of 6.1 per patient.

Conclusions: Semaglutide use was not associated with an increased risk of progression of DR, visual loss, or an increased number of intravitreal injections over a 12-month period of time. If confirmed by prospective clinical trials, these findings would offer reassurance the long-term use of Semaglutide does not lead to progression of DR and sight-threatening disease.

Hoffman-La Roche Ltd. (Basel, Switzerland), Apellis, Novartis, Boehringer Ingelheim, LumiThera, Gemini Therapeutics

ABSTRACT BODY:

Purpose: Development of new therapeutics to prevent disease progression in early and intermediate dry AMD requires novel endpoints that can be employed in clinical studies. The purpose of this prospective longitudinal observational study was to investigate if the change in Low Luminance Questionnaire (LLQ) scores over time can detect progression of early and intermediate stages of AMD (eAMD and iAMD, respectively).
Methods: As part of the single-center, prospective, longitudinal, observational Duke FEATURE study (Duke study of Functional Endpoints for Age-related Macular Degeneration), 101 subjects (33 eAMD, 47 iAMD, and 21 controls) were administered the LLQ during the baseline visit. 70 (22 eAMD, 31 iAMD, and 17 controls) completed the longitudinal study and received the LLQ instrument at 24 months.
Results: The composite mean LLQ score at baseline was significantly lower in iAMD (75.5, SD 16.7) compared to eAMD (86.8, SD 12.4) or normal control (90.1, SD 8.0). Similar between group differences were found at the 24 months visit (iAMD 72.8, SD 16.7; eAMD 85.3, SD 13.7; control 89.5, SD 7.0). However, the change in mean composite LLQ score from baseline to 24 months for each comparison was not significant.

By defining early or intermediate AMD subjects with an LLQ composite score less than the control baseline mean - 2SD=74.2 as “affected outliers," we identified among subjects with eAMD 5 of 22 (22.7%) as outliers at baseline and at 24 months, while among subjects with iAMD at baseline and at 24 months, 14 of 31 (45.2%) were identified as “affected outliers.”

When pooling the non-outlier participants in eAMD and iAMD groups (n=34), the composite and all subscale scores apart from the emotional distress subscore were significantly lower at 24 months than baseline ($P<0.05$). In contrast, in the "affected outlier" subset (n=19), there was no significant difference in LLQ composite or subscale scores at 24 months and baseline except for the extreme lighting subscore ($p=0.008$).
Conclusions: Our results suggest that the sensitivity of the LLQ to monitor change in function in eAMD and iAMD over time may be limited by a floor effect. LLQ is a useful PRO to detect disease progression in eAMD and iAMD subjects that are not significantly impaired at baseline (composite LLQ score ≥75).

ABSTRACT BODY:

Purpose: Eyelid lacerations are a common cause of eye injuries presenting to the Emergency Department (ED), comprising around 10% of all visits. However, the epidemiology of eyelid laceration injuries has not been well documented in the literature. The objective of this study was to investigate the etiologies, demographic factors, and management strategies of patients presenting with eyelid lacerations to a U.S. tertiary academic center ED.

Methods: A retrospective chart review of all patients with eyelid lacerations presenting to the ED of a tertiary academic center from April 2018 to December 2020 was performed. An eyelid laceration was defined as any laceration involving the eyelids, its margins, and/or the canaliculus. Data on demographics, clinical characteristics, and management were analyzed. Variables associated with mechanism of injury in eyelid lacerations were assessed using multivariate logistic regression.

Results: Out of 303 eyelid laceration cases identified, 56% were non-marginal and non-canalicular lacerations, followed by 24% with canalicular involvement and 20% crossing the eyelid margin. Animal bite or scratch was the most common etiology of canalicular involving lacerations (29%), with the majority (66%) of these injuries occurring in children. Mechanical fall was the most common etiology in patients over age 60 (62%). Patients that were assaulted were more likely to present with concomitant ophthalmic injuries (OR 2.25 [95% CI 1.20-4.29]; P = 0.012), with the most common being orbital fracture (25%), corneal abrasion (21%), traumatic iritis (19%) and commotio retinae (17%). Black patients and those with Medicaid insurance were more likely to have an eyelid laceration injury due to assault when compared to Caucasian patients and ones with private insurance (OR 3.57 [95% CI 1.78-7.41]; P = <0.001 and OR 2.66 [95% CI 1.14-6.57]; P = 0.027, respectively). Of all the eyelid lacerations, 78% underwent surgical repair,15% were observed and 3% were repaired by tissue glue.

Conclusions: Animal-related injury was the most frequent cause of canalicular involving eyelid lacerations, occurring mostly in children. The most common etiologies for eyelid lacerations in the elderly and Black patients were fall and assault, respectively. Identifying the most common etiologies for eyelid lacerations can help raise awareness to emphasize preventive measures in specific patient populations.

SUBMITTER (NAME ONLY): Jason Fan

TITLE: Management Outcomes in Patients with Suprachoroidal Hemorrhage after Anterior Segment Surgery

SESSION TITLE: Vitreoretinal surgery/VR Interface/PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Fan, J.L. Hudson, P. Pakravan, K.C. Fan, H.W. Flynn, Ophthalmology, University of Miami Health System Bascom Palmer Eye Institute, Miami, Florida, UNITED STATES|

Commercial Relationships Disclosure: Jason Fan: Commercial Relationship: Code N (No Commercial Relationship) | Julia Hudson: Commercial Relationship: Code N (No Commercial Relationship) | Parastou Pakravan: Commercial Relationship: Code N (No Commercial Relationship) | Kenneth Fan: Commercial Relationship: Code N (No Commercial Relationship) | Harry Flynn: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Suprachoroidal hemorrhage (SCH) remains one of the most devastating complications associated with intraocular surgery. Although advances in surgical technique have been made, the outcomes of SCH management have generally remained poor. The current study reports management outcomes of SCH after anterior segment surgery at a single institution, and identifies clinical features associated with visual prognosis.

Methods: Retrospective chart review of patients with suprachoroidal hemorrhage occurring after anterior segment surgery.

Results: The study includes 112 eyes of 112 patients treated between 2014 and 2020. Factors associated with better visual acuity outcomes included SCH occurring after glaucoma surgery, hypotony at time of presentation, and management by observation. Factors associated with worse visual acuity outcomes included presence of APD (p=0.02), concurrent retinal detachment (p=0.02), appositional SCH (p=0.002), management by delayed drainage (p=0.013), and duration of apposition greater than 7 days (p=0.002). Visual acuity outcomes after management generally remained poor at last follow-up: 58% of patients had a visual acuity (VA) of ≤ 20/200, 17% had light perception (LP), and 10% had no light perception (NLP). Appositional SCH was not found to be associated with worse visual outcome in patients managed with delayed drainage or PPV (n = 66). Both appositional SCH (p=0.01) and duration of apposition (p=0.04) were correlated with worse outcome only in patients that were observed. Regarding management, 53% of patients were observed, 31% underwent delayed drainage, and 31% underwent pars plana vitrectomy (PPV) with or without scleral buckling. Of those with appositional SCH, 12 patients were observed (mean final VA 1.78, SD 1.16), 15 underwent delayed drainage (mean final VA 1.951, SD 0.73), and 13 underwent PPV (mean final VA 1.891, SD 0.73).

Conclusions: Overall visual outcomes in patients with SCH after anterior segment surgery remain poor. The majority of patients with SCH were of advanced age and pseudophakic. Roughly half of all cases occurred after glaucoma surgery (n=59). Appositional SCH is associated with worse VA outcomes when observed (mean difference = 0.859, p= 0.01), but not when delayed drainage or PPV were undertaken. Observation remains a reasonable management strategy for non-appositional SCH.

ABSTRACT BODY:

Purpose: Long-term use of contact lens (CL) alters the structure of Meibomian glands (MG), which may lead to discomfort. This study aimed to develop and validate a morphometric automated algorithm to analyse features of MGs and predict symptoms of discomfort among CL wearers

Methods: This retrospective study consisted of 179 (96 upper eyelids & 83 lower eyelids) anonymised meibography images from 69 participants aged ≥18 years to develop and train a morphometric automated algorithm. Images were obtained using the Oculus Keratograph 5M (Oculus GmbH, Wetzlar, Germany) from the database of the School of Optometry & Vision Science, UNSW, Sydney. A custom macro was developed and used to batch-process all images, quantifying gland width and intergland distance at the lid margin, centre, and distal end. A second set of images from participants with contact lens discomfort (CLD) (n=45 CL users with CLDEQ-8 score > 12 and evidence of MG obstruction) were analysed to evaluate associations between these morphological parameters, contact lens dry eye questionnaire score (CLDEQ-8), and ocular surface signs including lid wiper epitheliopathy, non-invasive tear break up time, lipid layer thickness, and telangiectasia. Univariate and multivariate analyses were conducted to develop a multiple regression equation to predict the CLDEQ-8 score. This predictive model was validated on a third independent set of images (n=68 CL users with CLD) using a Bland Altman method comparison between the actual and the predicted CLDEQ-8 score.

Results: In univariate analysis, CLDEQ-8 scores were significantly associated with gland width at the lid margin ($r=0.31$, $p=0.04$), the distal end ($r=0.43$, $p=0.01$), and intergland distance at the upper eyelid margin ($r=-0.48$, $p=0.02$). There were no significant associations between the CLDEQ-8 score and ocular surface signs. Using these variables in multivariate regression, produced a model which accounted for 68% ($R^2=0.68$, $p<0.05$) of the variance in symptoms of discomfort. Bland Altman plot between the predictive and actual CLDEQ-8 score demonstrated ±2.7 limits of agreement around the mean difference of -0.1.

Conclusions: This morphometric algorithm is capable of analysing morphological features of MGs that can predict symptoms of discomfort among contact lens users with reasonable accuracy. This approach may be suitable as a screening tool in the early detection of CLD.

TITLE: Involvement of calpains and caspases in RGC damage in human iPSCs-derived OV cultured under hypoxia

SESSION TITLE: Retinal ganglion cells

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Orihara, C. Fukiage, M. Azuma, Senju Pharmaceutical Co., Ltd., JAPAN|T. Yokoi, N. Azuma, National Center for Child Health and Development, JAPAN|

Commercial Relationships Disclosure: Kana Orihara: Commercial Relationship(s);Code E (Employment):Senju Pharmaceutical Co., Ltd. | Chiho Fukiage: Commercial Relationship(s);Code E (Employment):Senju Pharmaceutical Co., Ltd. | Mitsuyoshi Azuma: Commercial Relationship(s);Code E (Employment):Senju Pharmaceutical Co., Ltd. | Tadashi Yokoi: Commercial Relationship(s);Code E (Employment):National Center for Child Health and Development | Noriyuki Azuma: Commercial Relationship(s);Code E (Employment):National Center for Child Health and Development

ABSTRACT BODY:

Purpose: We previously demonstrated calpain activation and retinal ganglion cell (RGC) damage in human retinal explants cultured under hypoxia. Recently, functional RGCs were produced from human pluripotent stem cells (iPSCs)-derived optic vesicles (OV).The purpose of the current experiment was to investigate if human iPSCs-derived OV are suitable experimental models of human retina. For this purpose, activation of calpains and caspases by hypoxia was studied in human iPSCs-derived OV.

Methods: RGCs were induced from human iPSCs as previously described. Dissociated iPSCs were cultured in V-bottomed, 96-well plates. On Day 27, aggregated embryoid bodies were cultured on adhesive substrates. Damage of elongated neurites in OV was evaluated after culture under hypoxia/reoxygenation. When tested, caspase-8 (IETD) and caspase-9 (LEHD) inhibitors, and calpain inhibitor (SNJ1945) were added along with hypoxia. Activation of caspase-3 was assayed by cytochemical staining after dissociation of mechanically isolated OV. Cell lysates were immunoblotted for caspase-3 and α-spectrin.

Results: Hypoxia/reoxygenation induced damage in human iPSC-derived RGCs in a time dependent manner. Activated caspase-3-positive cells were observed after 12 h hypoxia/3 h reoxygenation. Immunoblotting confirmed activation of caspase-3. RGC degeneration and activation of caspase-3 were ameliorated by caspase-8 and caspase-9 inhibitors. Calpain inhibitor inhibited RGC damage, but not caspase-3 activation. Inhibition of caspase-3 was confirmed by observing proteolyzed α-spectrin. Calpain inhibitor ameliorated production of calpain-specific α-spectrin breakdown product (SBDP145), but not caspase-3-specific 120 kDa SBDP. Caspase-9 inhibitor prevented production of caspase specific SBDP, but not calpain-specific SBDP145.

Conclusions: Calpains and caspases are involved in hypoxia/reoxygenation-induced damage to iPSCs-derived RGCs. Human iPSCs derived RGCs are useful for research where access to human eye tissues is limited.

TITLE: The Use of a Convolutional Neural Network Predicted 60-4 Visual Field to Predict the Effect of Facial Contour on Visual Field Defects in Glaucoma Patients

SESSION TITLE: Data science, machine learning, and AI

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Kaplan, S. Jamali, M. Mousavi, C. Khanna, Ophthalmology, Mayo Foundation for Medical Education and Research, Rochester, Minnesota, UNITED STATES|

Commercial Relationships Disclosure: Tyler Kaplan: Commercial Relationship: Code N (No Commercial Relationship) | Sepideh Jamali: Commercial Relationship: Code N (No Commercial Relationship) | Mostafa Mousavi: Commercial Relationship: Code N (No Commercial Relationship) | Cheryl Khanna: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The purpose of this paper is to determine if a convolutional neural network (CNN) can be used to predict the contribution of facial contour induced visual field defects in glaucoma patients. This can be utilized to differentiate visual field loss from glaucomatous damage from visual field defects due to facial contour.

Methods: Glaucoma patients were consecutively enrolled and underwent a 60-4 visual field test. A single photograph was taken of each subject. A CNN was used to create a three-dimensional reconstruction based on the two-dimensional image. A map of the intersection between the visual axis and the face on the 3D reconstruction was used to predict the location and extent of visual field defects which corresponded to an individual's facial contour. A python script was then utilized to create a visual field which demonstrated the visual field defects due to facial contour. The predicted 60-4 and the actual 60-4 visual field were superimposed to determine the amount of visual field attributed to glaucoma.

Results: 14 glaucoma patients were included in this study. 28 eyes were included in this study. Each eye completed a 60-4 visual field. The predicted 60-4 visual field related to a patient's facial contour was superimposed on the patient's actual 60-4 visual field. The duration of the 60-4 visual field tests ranged from 8 minutes 17 seconds to 11 minutes 55 seconds. In 27/28 eyes, the predicted visual field loss coincided with areas of visual field loss on their actual 60-4 visual field. The total thresholds, which were generated as a summation of each individual threshold point, ranged from 854-1534 in the right eye and 949-1604 in the left eye. The range of visual field affected by facial contour was 0-7% with an average of 3.14%.

Conclusions: This study demonstrates the utility of a CNN assisted 60-4 visual field in monitoring glaucomatous progression. This tool can help differentiate visual field loss from glaucomatous damage from facial contour. In this study, facial contour commonly corresponded to nasal visual field defects. This methodology may be helpful in determining if a visual field defect is due to glaucoma or facial contour, assist in accurate identification of glaucoma progression, and reduce variability of visual fields by accounting for the role of facial contour in the peripheral field.

TITLE: Common antidiabetic drug metformin reduces the development of age-related macular degeneration

SESSION TITLE: Tissue, drug and genome engineering

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G.S. Khurshid, Ophthalmology, University of Florida, Gainesville, Florida, UNITED STATES|

Commercial Relationships Disclosure: Gibran Khurshid: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: AMD is a debilitating disease affecting the elderly. Currently, there are no definitive treatments that clinicians can offer to prevent AMD onset or progression. Metformin is a relatively well-tolerated and widely used medication, proven successful in diabetes treatment. This study examined whether metformin use is associated with decreased risk of AMD development

Methods: This was a retrospective case-control study that included patients over age 55 who were seen at the University of Florida ophthalmology clinics between June 1, 2011, to June 1, 2017. Cases (n=1947) included patients with ICD-9 diagnostic code for macular degeneration who were followed for at least four visits before their diagnosis. Controls (n=5841) were patients who had at least four visits in that time period without the diagnosis of AMD. Cases and controls were propensity score-matched with a 1:3 ratio for variables such as age, CCI, hypertension, and anemia. Univariate regression analysis was used to determine metformin's relationship to the development of AMD. Conditional multivariable logistic regression was used to explore this relationship with consideration of the other covariates of the patients.

Results: Patients on metformin had a statistically significant decreased odds ratio of developing AMD when using univariate analysis (OR, 0.39; 95% CI, 0.31-0.49) as well as conditional multivariable logistic regression (OR, 0.58; 95% CI, 0.43-0.79). Because diabetes can act as a prominent confounder, subgroup analysis was performed studying only patients with diabetes. Through conditional multivariable logistic regression, it was illustrated that metformin use was still associated with decreased odds of developing AMD when diabetes was removed as a confounder (OR, 0.70; 95% CI 0.49-0.98). Other medications assessed such as DPP4 inhibitors, SSRIs, tetracyclic antidepressants, and statins were not found to have a statistically significant relationship with AMD incidence.

Conclusions: In this study we found that metformin decreased the likelihood of developing AMD by 42%, suggesting that this ubiquitous antidiabetic drug may contribute to delaying AMD progression or stopping it altogether. We hope that the relationship between metformin and AMD development will be further established with prospective studies in the future.

ABSTRACT BODY:

Purpose: The activation of the renin-angiotensin system (RAS) contributes to the destruction of blood-retinal barrier (BRB) and neovascularization in diabetic retinopathy (DR). Although blocking RAS in clinical studies reduced the incidence of DR, it did not reduce the progression of DR. The goal of this study was to decipher the role of epoxyeicosatrienoic acids (EETs), cytochrome P450 (CYP)-derived eicosanoids, and EETs degrading enzyme soluble epoxide hydrolase (sEH) in angiotensin II (Ang II)- and diabetes-induced retinal microvascular damage. We also determine the interactions between EETs/sEH and angiotensin receptor-1 (AT1) in the retina.

Methods: We induced experimental diabetes in wild-type and sEH knockout mice by intraperitoneal injection of streptozotocin (STZ). Some mice received chronic treatment with Ang II via SC minipump (3 mg/kg/day), with or without AT1 blocker telmisartan (2.5 mg/kg/day). Some mice received intravitreal injection of Ang II with or without 11,12 EET. Integrity of blood retinal barrier (BRB) was assessed by analysis of albumin leakage in the retina. Analysis of the plasma levels of bioactive lipids in normal and diabetic mice was done using LC/MS/MS.

Results: Ang II increases retinal expression of sEH by 2.8-fold (2.84 ± 1.1 vs. 1 ± 0.08, $P < 0.05$, n = 4), which is blunted by AT1 blockade. Moreover, sEH blockade and knockout (KO), which accumulate EETs, enhance Ang II-induced BRB injury as shown by 1.58 folds increase in retinal albumin leakage (1.58 ± 0.4 vs. 1 ± 0.13, $P < 0.05$, n = 4) and 2.8-folds (2.8 ± 1.7 vs. 1 ± 0.09, $P < 0.05$, n = 4), respectively. These results were confirmed by fluorescein angiogram (FA) analysis. Administration of synthetic 11,12-EET enhances intravitreal Ang II-induced retinal albumin leakage by 2.2-fold (2.2 ± 0.5 vs. 1 ± 0.18, $P < 0.05$, n = 4). In addition, 11,12-EET induces retinal hyperpermeability by FA and retinal albumin leakage. Moreover, sEH KO potentiates diabetes-induced retinal damage. This was associated with upregulation of retinal vascular endothelial growth factor (VEGF) and glucose transporter-1 (GLUT-1).

Conclusions: Our data indicate that in DR, the activation of retinal AT1 triggers a compensation mechanism by increasing retinal sEH, thereby reducing the production of EETs. Therefore, the combined use of EETs blockers and AT1 blockers is expected to become a new treatment strategy to prevent or reduce DR.

SUBMITTER (NAME ONLY): Enzo Maria Vingolo

TITLE: Reaction Time (RT) a new Microperimetry (MP) diagnostic tool, basic evaluation

SESSION TITLE: Imaging of posterior segment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Vingolo, E. Rigoni, Ophthalmology, Universita degli Studi di Roma La Sapienza, Rome, Lazio, ITALY|P. Iimoli, Low Vision, Centro studi ipovisione, Milano, Milano, ITALY|

Commercial Relationships Disclosure: Enzo Maria Vingolo: Commercial Relationship: Code N (No Commercial Relationship) | Paolo G Iimoli: Commercial Relationship: Code N (No Commercial Relationship) | Erika Rigoni: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: MP has been used as strong disgnostic tool in several eye diseases. nevertheless its complexity there are functional parameters that are very helpful in evaluating clinical conditions as fixation, scotometry and retinal sensitivity. Reaction time is idefinited as the interval recorded by the device from stimulus presentation and patient's answer. Our goal is tho understand if there are relationships between RT and retinal localization of the stimulus and if this may be as early marker of the disease.

Methods: Using MP3 (Nidek Co. Jpn) mean RT was evaluated in msec. in different retinal areas, 12 points in central 5° area, and 40 point in perpheral retina between 15-20°, tests were performed starting from 0 dB every 10dB, with 31.4 asb background luminance and Goldmann III stimulus (reference value for Humfries), with presentation seen/not seen screening strategy. Were tested 7 healthy subjects and 5 patients with soft drusen (sized >63microns). No statistical differences were found between two groups for age, sex composition and visual acuity.

Results: Average RT value for central area was 549ms. (SD±136ms) for group A while average RT for Group B was 837ms (SD±255ms) differences were statistically significant (p=0.007). RT value for peripheral area was 1003ms. (SD±74ms) for group A while peripheric average RT for Group B was 981ms (SD± 95ms) differences were not significant (p=0.081). Our data underlines that patients in group B patients presented a better performance at higher luminance.

Conclusions: Our interesting data, show very clear difference in central area between healthy people and those presented small soft drusen, this outcome may be due to an irregular intraretinal signaling or neurotransmission as speculated by Curcio, there is a topographic correlation between drusen, cones and rods, that realized exchange pathways among outer retinal cells and across Bruch's membrane and the subretinal space, in service of highly evolved, eye-specific physiology that can slower in these zones retino-cerebral reaction time. In peripheral area soft drusen are ususally more rare due to a slower methabolic speed. Obviously this is a preliminary report of new approach to microperimetry and our intent is to add a new approach to early disease diagnostics with the aim to intercept individuals in which retinal damage may go wider in a short time so that would be possible to start a more efficient treatment.

ABSTRACT BODY:

Purpose: Retinal pigment epithelium (RPE) modulates the exchange of metabolite products to and from the retina, maintains the photoreceptor function by phagocytosis and processing of photoreceptor outer segments allowing their renewal. The human RPE cell-line ARPE-19 is commercially available and widely used as an alternative to primary RPE. However, these cells undergo epithelial-mesenchymal transition losing many features of primary RPE such as polarity, pigmentation, and expression of RPE signature markers. We aimed to determine whether a combination of laminin coating and media supplementation with nicotinamide could improve ARPE-19 expression of genes and proteins, along with morphological phenotype resembling mature RPE.

Methods: ARPE-19 cells were cultured for up to 3 months with or without 10mM nicotinamide supplementation and/or coated with human recombinant laminin 521. Gross cell morphology was evaluated by phase microscopy. Assessment of maturation was performed by immunocytochemistry and gene expression by qPCR.

Results: Laminin 521, in combination with nicotinamide supplementation, promoted cytoskeletal reorganization and expression of differentiation markers such as VMD2, RPE65 and PDGFRB compared to non-supplemented culture condition. Moreover, the combination of nicotinamide media supplementation and laminin 521 coating reduced the expression of the of EMT markers, TNFα and TGF-β1; and NCAM1, an immature phenotype RPE marker.

Conclusions: This study demonstrates that the combination of nicotinamide and laminin 521 coating accelerated the kinetics of expression of mature RPE signature genes, reduced expression of EMT genes, accompanied with improved epithelial cell morphology and cytoskeletal organization, bringing the dedifferentiated ARPE-19 closer to their in vivo phenotype.

ABSTRACT BODY:

Purpose: Retinoblastoma (RB) is the most common ocular tumor of the child, in most instances initiated by mutations in the RB1 gene. Molecular biomarkers determining its aggressiveness and progression have so far only been partially elucidated, due to a significant risk of tumor cells' dissemination following classical biopsies. Recently, the so-called "liquid biopsies" from the aqueous humor (AH) have demonstrated to be a valid alternative to direct tissue sampling for retinoblastoma. By sequencing tumor cell-free DNA (cfDNA) from the AH, we aim to gain insights into the genetic makeup of retinoblastoma and relate specific genotypes to clinical outcomes, such as tumor aggressiveness and therapeutic response.

Methods: Following the collection of approximately 100ul of AH, cfDNA was isolated, and genetic analysis was performed by whole-genome sequencing (WGS) and whole-exome sequencing (WES). Raw data were analyzed with an internal pipeline for the identification of mutations, including single-base variants and genomic copy number variations.

Results: We completed a proof-of-concept analysis on a small set of 5 AHs, and we are now performing the analysis on the bulk of our collection, consisting in approximately 370 samples. Our preliminary results show a considerable genetic heterogeneity of somatic variations in different tumors, despite the relatively small fraction of samples that were sequenced. Nevertheless, we also found some recurrent genomic alterations, such as 1q gain, 16q loss, and 6p gain.

Conclusions: Overall, our data indicate that retinoblastoma is more diverse at the genetic level than previously thought, and that such heterogeneity may shape in the end its clinical characteristics.

ABSTRACT BODY:

Purpose: To study transmission of thermal energy in posterior scleritis and choroiditis in an experimental model and in practice.

Methods: Model cadaveric eyes for posterior scleritis and choroiditis were created by eviscerating intraocular contents leaving behind scleral strip attached to sclero-corneal button (SCB) and by peeling sclera leaving behind choroidal tissue attached to SCB respectively. (Figure 1) Scleral and choroidal tissue was immersed in hot water and temperature changes on the SCB were noted using a non-contact thermal camera (FLIR Cat S 60 mobile phone). Using same device thermography was done for at least 4 visits between the active and resolved disease for posterior scleritis, VKH disease and control. Difference between the Central Corneal Temperature (CCT) and the ipsilateral temporal eye brow temperature was studied during the follow up and the maximum (Δt Max) and the minimum difference (Δt Min) was calculated. The difference between Δt Max and Δt Min called amplitude of fluctuation (Δt amp). (Figure 2) Comparison of means for all groups was done using the ANOVA test and a p value of <0.05 was considered significant.

Results: In model choroiditis and scleritis eye temperature changed by 3.23°C and 3.52°C respectively at 5 min. Nine eyes of 9 patients of posterior scleritis and VKH disease and 10 eye of 10 controls were studied. Mean highest CCT in scleritis, VKH and the control was 33.2°C (range: 31.5°C – 34.4°C), 33.8°C (range: 32.2°C -35.1°C), and 33.8°C (range: 32.7°C - 35.3°C) respectively. (p: 0.416) Mean Δt Max in scleritis, VKH and control was 2.3 (range: 1.7-3.7), 1.9 (range: 0.4-2.8) and 2.2 (range: 0.8-3.8) respectively. (p: 0.669) Mean Δt Min in scleritis, VKH and control was 0.4 (range: -1.1- 1.1), 0.6 (range: 0-1.4), and 0.1 (range: -0.2 – 2.8) respectively. (p= 0.249) Mean Δt amp in scleritis, VKH and control was 1.8 (range: 0.8-3.2), 1.3 (range: 0.3-1.9) and 1.2 (range: 0.5-1.8) respectively. (p= 0.082).

Conclusions: In model eyes scleral tissue conducted more thermal energy. No significant difference was noted in Δt amp of scleritis, VKH and control eyes. The significance level increased for the parameter ”Δt amp” compared to “Δt Max” or “Δt Min.”

ABSTRACT BODY:

Purpose: To compare intraoperative material utilization during phacoemulsification surgeries performed by trainees versus experienced surgeons.

Methods: This study included phacoemulsification surgeries performed by three experienced surgeons (EX) and seven resident trainees (RS) over one academic year. Exclusion criteria included prior ocular surgeries or intravitreal injections, combined surgery, preoperative best-corrected visual acuity worse than 20/200, and history of trauma or pseudoexfoliation syndrome. Resources additional to that of routine cataract surgery were enumerated for each case, including viscoelastic, trypan blue, balanced salt solution (BSS), iris expanders, miotic agents, sutures, and capsular support devices. The surgery duration and presence of complications were also noted. Data analysis using rank sum, chi square, Fischer, or student t-tests were used when appropriate.

Results: The 584 EX and 149 RS cases had no significant differences in patient demographics. EX used 23 additional units of resources per 100 cases, while RS used 58 ($p<0.001$). Overall, 111 (19%) EX cases required extra materials compared to 52 (35%) RS cases ($p<0.001$). The majority of these cases required only one additional resource (16% of EX and 23% RS), compared to those that needed two (2.7% EX and 6.7% RS) or more than three additional resources (0.68% EX and 5.4% RS). Additional viscoelastic, trypan blue, BSS, and sutures were used more frequently in the RS cases, whereas there was no statistical difference in the utilization of intracameral miotic agents, iris expander, or capsular support devices between the two groups. Junior residents (PGY-3) consumed more resources than their senior counterparts (PGY-4), 58% versus 22% respectively, ($p<0.001$). More complications occurred in the RS group (2.0%) than in the EX group (0.0%, $p=0.008$). The median surgery duration was 21 minutes [interquartile range: 18-27] for RS compared to 10 minutes [8-12] for EX ($p < 0.001$).

Conclusions: Overall, residents used more intraoperative materials than experienced surgeons did during cataract surgeries. The additional utilization of resources, increased surgery duration, and higher complication rate of resident-performed cataract surgeries are likely associated with increased costs for institutions where trainees perform surgery.

ABSTRACT BODY:

Purpose: FN3K is a natural intracellular repair enzyme for condensation products of glucose with protein primary amine groups. The enzymes action on AGEs, high molecular weight compounds enhancing oxidative stress and covalent crosslinking, is yet unknown. We produced active recombinant FN3K enzyme (rFN3K) and inactive mutant FN3K (mFN3K) in yeast (Pichia pastoris) and investigated the activity of rFN3K against AGEs in human lenses.

Methods: A DNA construct encoding human FN3K flanked by a N-terminal His-tag with a caspase-cleavable D–E–V–D site was codon-optimized for Pichia pastoris and cloned into the pKai61 vector for intracellular expression. For mFN3K, human FN3K carrying a K41L substitution (FN3K–K41L) in the putative F–V–K catalytic triad was made. After gel filtration, kinase activity (or lack thereof for mFN3K) was tested in vitro. The protein was further characterized on SDS-PAGE and Western blot. Human lens material obtained after phacoemulsification (n=20), was incubated for 3 h with rFN3K or mFN3K. AGEs were measured by Maillard-type autofluorescence (AF) (excitation 365 nm, emission 390–700 nm). Fructose containing AGEs were investigated in the urea-soluble fraction of rFN3K treated human lens material by gel filtration. Individual fractions were photometrically tested (488 nm) by Seliwanoff reaction.

Results: Remarkable decreases of AF were observed for rFN3K compared to mFN3K. Pronounced decrease of AF was found after 1 h incubation (43.6–49.7% decrease compared to baseline). Additional decrease of AF was found after 2 h incubation (56.7–70.8% decrease compared to baseline), and remained stable thereafter. At lower concentration range of rFN3K (12.5 µg/mL, 6.25 µg/mL and 1.25 µg/mL) a more notable time- and dose dependent effect was seen. Gel filtration showed breakdown of fructose-containing AGEs in human lens fragments by rFN3K. Before treatment, presence of AGEs was observed by two peaks with molecular mass of 2500 Da and 1660 Da. After rFN3K treatment, breakdown products with molecular mass ranging between 1500 and 2500 Da were detected.

Conclusions: rFN3K and mFN3K enzyme were successfully produced in Pichia pastoris. AF kinetics on human lens material revealed a dose and time dependent effect of treatment with rFN3K. A breakdown of high molecular mass fructose related AGEs by rFN3K was observed. Further research is needed to identify the exact substrates of rFN3K in human lenses.

TITLE: Outcomes of vitreoretinal complications requiring surgery after abusive head trauma

SESSION TITLE: Endophthalmitis & Trauma

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: Y. Islam, Ophthalmology, University of Miami Health System Bascom Palmer Eye Institute, Florida, UNITED STATES|Y. Islam, S. Khurshid, Ophthalmology, University of Florida, Gainesville, Florida, UNITED STATES|

Commercial Relationships Disclosure: Yasmin Islam: Commercial Relationship: Code N (No Commercial Relationship) | Syed Gibran Khurshid: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Abusive head trauma (AHT) can result in non-clearing vitreous hemorrhages (VHs), retinal detachments (RDs), and retinal tears that require vitreoretinal surgery. There is ample guidance from professional societies emphasizing the importance of urgent ophthalmologic evaluation after AHT, but there is no available literature evaluating the outcomes of vitreoretinal surgery in aggregate and providing guidance on the timing of vitreoretinal intervention in these patients. This case series combined with literature review aims to fill this knowledge gap.

Methods: A case series of three patients from a large academic medical center were combined with cases obtained during a literature search for studies reporting outcomes of vitreoretinal surgery in children with AHT from 2011-2021. Nine studies were included. The visual acuity (VA) and anatomical outcomes were compared between patients who received vitreoretinal surgery within four weeks of diagnosis and those who had delayed surgery.

Results: A total of 78 eyes from 57 patients received interventions ranging from panretinal photocoagulation to pars plana vitrectomy (PPV) and scleral buckling. Most required a PPV (74 eyes/95%). 72 eyes (92%) had a non-clearing VH, while 7 eyes (9%) had an RD. 75 eyes (96%) had anatomical success after surgery, defined as an attached retina without vitreous hemorrhage. Surgery performed within four weeks of injury showed a trend towards improved anatomical and VA outcomes as compared to delayed surgery.

Conclusions: Vitreoretinal surgery after AHT has excellent anatomical success rates, but there is a trend towards improved VA outcomes when surgery is performed within four weeks of diagnosis. This highlights the importance of urgent ophthalmologic evaluation and referral to a pediatric retina specialist for non-clearing VH, RDs, and retinal tears after AHT.

ABSTRACT BODY:

Purpose: Since circadian clock proteins have been identified in the rat lens, this study aimed to determine whether glutathione homeostasis is controlled in a circadian manner.

Methods: Lenses and aqueous humor were collected every 4 hours over a 24-hour period from 6-week male Wistar rat lenses (n=8 for each time point) and glutathione levels (reduced and oxidised GSH) measured using HPLC. Western blotting and immunohistochemistry were used to confirm and localize the rhythmic expression of circadian clock core proteins (BMAL1 & CLOCK) and confirm if this expression pattern was linked to the rhythmic expression of the glutathione synthesis enzyme, gamma- glutamylcysteine ligase (GCL), the glutathione regeneration enzyme, glutathione reductase (GR) and NRF2, a transcription factor involved in regulating the expression of genes related to GSH homeostasis.

Results: GSH levels in the lens and aqueous humor oscillated throughout the 24-hour period. Western blotting confirmed protein expression of BMAL1, CLOCK and NRF2 in the lens. Immunohistochemistry revealed differences in the localisation and sub-cellular distribution of BMAL1, CLOCK and NRF2. During the day, BMAL1 and CLOCK were present in the germinative zone of the lens with strong labelling present in the nuclei of epithelial and fiber cells. On the other hand, NRF2 labelling was present in the germinative zone but was not co-localised with the nuclei and instead appeared cytoplasmic. These differences in localisation patterns may correlate with fluctuations in GSH synthesis and GSH levels in the lens at different times of the day to protect against oxidative stress.

Conclusions: Collectively, these findings provide preliminary evidence that glutathione levels may be under the control of a circadian clock. In the future, work will be performed on older rats to determine if decreased circadian rhythmicity alters glutathione levels and predisposes lenses to cataract formation.

ABSTRACT BODY:

Purpose: Fluctuations in macular thickness over time have been shown to be more predictive of visual outcomes than absolute macular thickness in patients with diabetic macular edema (DME) treated with anti- vascular endothelial growth factor (VEGF). However, it is unclear whether this association exists in DME patients treated with intravitreal steroids. We performed a retrospective, non-comparative, observational cohort study to investigate the effect of steroid treatment on macular thickness fluctuations (MTF) and visual outcomes in patients with DME.

Methods: Central subfield thickness (CST) and best visual acuity (BVA) were collected in 4-month intervals over two years for DME patients over the age of 18 without concomitant maculopathies who had at least one intravitreal steroid injection. Paired t-test was used to compare MTF (quantified by CST standard deviation (CST-SD)) before and after initiation of steroid treatment. A mixed-effects linear regression model was used to determine the association between CST-SD and BVA, adjusting for baseline characteristics and treatment patterns.

Results: Of the 108 patients included, 105 (97.2%) received anti-VEGF treatment prior to steroid initiation. Mean 12-month CST-SD after steroid initiation was significantly lower than mean 12-month CST-SD prior (53.469 ± 49.9 vs. 61.139 ± 56.77; $p = 0.04$). Mean BVA after 12 months was not significantly different from baseline (62.717 ± 15.2 vs. 62.997 ± 13.7; $p = 0.4$). There was no significant association between post-steroid CST-SD and 12-month BVA nor any significant differences in post-steroid CST-SD among the different treatment pattern groups.

Conclusions: MTF decreased after initiation of steroid treatment with maintenance of stable visual acuity. There was no significant correlation between decreases in MTF and visual outcomes which is expected in this prior treated DME patient population receiving intravitreally steroid treatment. This reflects the routine clinical practice of using steroids as second-line treatment after anti-VEGF injections. This study demonstrates the efficacy of intravitreal steroids in reducing MTF and maintaining stable visual acuity, confirming its role in the treatment of DME.

ABSTRACT BODY:

Purpose: The Merit-based Incentive Payment System (MIPS) is intended to promote high value healthcare through quality-related Medicare payment adjustments. We sought to assess the economic impact of MIPS scoring and reporting category on ophthalmology providers.

Methods: A retrospective, cross-sectional economic evaluation of MIPS performance and related payment adjustments was performed for ophthalmology providers registered for Medicare Part B with participation in the Quality Payment Program (QPP) in performance year (PY) 2019 using Centers for Medicare & Medicaid Service (CMS) public data files. Reported CMS methodology and PY 2019 payment percentages were used to estimate payment adjustments in USD for the following categories of MIPS scores: positive MIPS adjustment plus potential additional adjustment for exceptional performance (75.00-100.00 points), positive MIPS adjustment (30.01-74.99 points), neutral payment adjustment (30.00), negative MIPS payment adjustment (7.51-29.99 points), maximum negative MIPS payment adjustment (0-7.50 points).

Results: For PY 2019, roughly 99% of providers received non-negative reimbursement adjustments and 92.6% received positive adjustments. Participants submitted data through MIPS eligibility categories of Advanced Alternative Payment Models (APM) (2102, 15.43%), Group (8369, 61.44%), Individual (3144, 23.08%), and Virtual Group (6, 0.04%). The total average MIPS score differed statistically significantly by filing category for APM, Group, and Individual providers with average scores of 95.39 (3.17), 86.04 (15.12), and 68.72 (28.74), respectively ($p < .001$). Individuals were significantly less likely to achieve exceptional performance (75.00-100.00) than APM and Group participants with OR 0.0003 (95% CI 0.00002- 0.00481) and OR 0.21013 (95% CI 0.19020-0.23215), respectively. The estimated total national payment adjustment ranges for ophthalmology providers for PY 2019 were $2,146,835 to $42,698,167, $0 to $19,960, -$41 to -$28,347, and -$83,544 to -$83,544 for those with exceptional performance, positive performance, negative, and maximum negative performance, respectively.

Conclusions: There are differences in MIPS scores across filing entities, and the specific scoring methodology may be responsible for meaningful economic incentives as performance thresholds become increasingly rigorous in subsequent years.

ABSTRACT BODY:

Purpose: The purpose of the current study is to demonstrate the prevalence of ocular complications in patients suffering with MIRM, an eruption clinically distinct from Stevens-Johnson syndrome/toxic epidermal necrolysis (SJS/TEN).

Methods: In this retrospective observational study, we identified all patients in our hospital database who were diagnosed with MIRM. Diagnosis was confirmed by clinical information and a positive Mycoplasma pneumoniae serology. Only patients with available records with formal ophthalmology consults were included. Clinical and laboratory data were collected from our electronic medical record system.

Results: A total of 11 patients were included in our study. The average age was 22 ± 15.2 years, and the majority were male (63.6%). In all 22 eyes, the acute ocular findings were limited to conjunctival hyperemia (n=18, 81.8%), meibomitis (n=2, 9.1%), and conjunctival epithelial defects (n=1, 4.5%). None of the patients were treated with amniotic membrane transplantation in the acute phase. Three patients received follow-up eye examinations; none showed ocular complications.

Conclusions: Ocular complications from MIRM appear to be milder in comparison to ocular complications found in other bullous and inflammatory conditions such as SJS/TEN. Understanding the ocular sequelae of MIRM is important to better inform acute and chronic management.

ABSTRACT BODY:

Purpose: Pentosan polysulfate sodium (PPS) is an oral-based medication used for interstitial cystitis that has recently been linked to retinal toxicity. Recent guidelines indicate that PPS patients should undergo baseline retinal examination upon treatment initiation with periodic monitoring while continuing treatment. This study aims to understand current PPS practice patterns and examine the utility of an EMR alert system for patients on PPS to help non-ophthalmic prescribing providers make appropriate referrals.

Methods: Phase one of this study characterized the population receiving PPS at a single institution with an IRB-approved retrospective study and included patients older than 18 taking PPS from 2005-2020. Variables studied included PPS exposure time and cumulative dosing, demographic information, the presence of ophthalmology monitoring, and the types of physicians prescribing the medication. An automated electronic medical record (EMR) best practice alert (BPA) was developed and implemented to fire upon PPS prescription or renewal. Rates of alert firing, ophthalmic referrals, and imaging were periodically collected.

Results: Our single institution initially identified 1407 patients who have taken PPS for characterization with a majority being female (1220, 86.7%). Starting age was 48.0 ± 15.7 and mean cumulative drug exposure was 669.7 ± 569.2 grams. 151 (10.7%) of PPS users had an eye exam within our institution. Before BPA intervention, 31 (2.2%) had optical coherence tomography (OCT) imaging to document baseline retinal status. 3-month post-BPA intervention results show the alert fired for 12 patients on 14 encounters. Of these 14 visits, ophthalmology was consulted 7 times (50%, $p<0.001$) and OCT macula were ordered 3 times (21.4%, $p<0.001$).

Conclusions: These results indicate that a limited number of patients taking PPS may be receiving appropriate ophthalmic monitoring per recent guidelines. Notwithstanding, many patients fit the criteria for screening for maculopathy onset (e.g., after 500 grams cumulative exposure). An EMR-based alert is a useful tool to improve ophthalmic screening and referral rates for PPS maculopathy. More work needs to be done to explore cross- specialty understanding of PPS drug-induced maculopathy and their role in detecting and minimizing deleterious effects of this condition.

ABSTRACT BODY:

Purpose: the development of a deep learning algorithm to detect OCT-determined geographic atrophy (GA) and to predict the progression from intermediate age-related macular degeneration (AMD) to GA in the short-term on spectral domain optical coherence tomography (SD-OCT) scans.

Methods: We analyzed SD-OCT imaging data from 316 patients with iAMD enrolled in the longitudinal, observational Age-Related Eye Disease Study 2 (AREDS2) Ancillary Spectral-Domain Optical Coherence Tomography (A2A) Study with adequate imaging for repeated measures. We designed an end-to-end, position-aware volumetric image classification model motivated by the observation that scan locations within a SD-OCT have different levels of predictive power for GA progression prediction. The model was developed with a proactive pseudo-intervention learning strategy to jointly allow for robust learning with small sample size and interpretation of predictions via saliency (attention) maps. To improve model performance given the small sample-size of the available dataset, we employed a second publicly available dataset consisting of 108,312 individual OCT B-scans from 4,686 individuals with various retinal diagnoses. The main outcome measure was the predictive performance for GA detection and progression to GA in 1 year, examined based on the area under the curve (AUC) of the receiver operating characteristic.

Results: The proposed deep learning model (multi-scan position-aware model) outperforms simpler image-based models and a model based on qualitative and quantitative features of SD-OCT provided by human experts. The AUC for GA prediction was 0.945 for current year, and 0.937 for the following year. The addition of expert annotated features only improved the AUC for GA prediction by an AUC of 0.008. The method automatically identified and highlighted specific structural features on OCT most predictive of GA, essentially opening the “black box” of this AI algorithm.

Conclusions: Our deep-learning method had excellent performance characteristics for detecting GA and for predicting progression from intermediate AMD to GA in the short-term (one year). Further validation in additional, independent datasets will be needed to determine the utility of this algorithm for prediction of vision-threatening nonexudative AMD and potential modifications for outcome prediction in other retinal diseases.

ABSTRACT BODY:

Purpose: The sunset glow fundus (SGF) appearance is an important finding of Vogt–Koyanagi–Harada (VKH) disease, originated from the choroidal depigmentation. We used polarization-sensitive OCT (PS-OCT) for volumetric evaluation of choroidal depigmentation.

Methods: We evaluated 40 eyes (20 patients) with chronic VKH disease and 59 healthy eyes (59 age-matched controls) with 1-μm swept-source PS-OCT. Eyes with VKH disease were divided into three groups according to color fundus images: sunset (17 eyes), potential sunset (13 eyes), non-sunset (10 eyes). The mean thickness of melanin containing tissue in choroid (thickness of MeCh: thickness of low degree of polarization uniformity (<0.8) area within the choroidal interstitial stroma) and the mean choroidal melanin occupancy ratio (occupancy of the low degree of polarization uniformity area within the choroidal interstitial stroma) within a 5-mm circular region from the foveal center were calculated. To evaluate regional variations, the 5-mm circular region was divided into a center area and an outer ring area.

Results: The mean thickness of MeCh was significantly lower in sunset eyes than non-sunset or control eyes ($P = 0.003$). The mean choroidal melanin occupancy ratio of sunset or potential sunset eyes were significantly lower than non-sunset or control eyes ($P = 0.04$). The area under the receiver operating characteristic curves for the combined sunset group (sunset and potential sunset) and the non-sunset group were 0.983 and 0.997 for the thickness of MeCh and the choroidal melanin occupancy ratio, respectively. Regional evaluation of thickness of MeCh and the choroidal melanin occupancy ratio showed that choroidal depigmentation predominantly occurred in the macula's outer ring area ($P = 0.002$). Time course evaluation of 12 eyes for 18 months from disease onset showed that both thickness of MeCh and choroidal melanin occupancy ratio significantly decreased over time.

Conclusions: PS-OCT is useful for objective evaluation of choroidal depigmentation of the SGF in VKH disease.

ABSTRACT BODY:

Purpose: The purpose of this study is to better evaluate the contribution of deep intronic splicing mutant alleles to inherited retinal diseases (IRD).

Methods: Whole-genome sequencing was performed for 741 patients who lack a confident molecular diagnosis from a cohort of approximately 7000 IRD patients. We filtered and annotated genomic alterations with a custom pipeline and predicted the effects of intronic variants on splicing using SpliceAI. The candidate splicing variants were restricted to those found in IRD genes and with a SpliceAI score ≧0.02. The candidates were further filtered based on allele population frequency, the distance from the exon-intron junctions, mode of genetic inheritance, and clinical phenotype. To further validate the in silico predictions, we utilized an in vitro minigene system to test a set of 130 candidate deep intronic splicing mutations with a score range of 0.02 to 1. DNA oligos with which sequences include the candidate mutation, SpliceAI-predicted cryptic exon, and flanking regions were synthesized, PCR-amplified, and cloned into a minigene vector. Each construct was separately transfected into HEK293 cells, from which RNA was extracted and RT-PCR was performed to assess the splicing products.

Results: Within the 741 unresolved patients, 18182 candidate deep-intronic splicing mutations were identified with a SpliceAI cutoff score of 0.02, but only 279 candidates have a score above 0.2, which is the cutoff commonly used by clinical labs. Among the selected 130 candidate IRD deep-intronic splicing mutations that were tested in vitro, all high-scored candidates (≧0.5) resulted in the generation of aberrant transcripts. However, for the mid-scored candidates (0.1≦ SpliceAI score <0.5), only half of the candidates affected splicing in vitro, while the majority of candidates with a score less than 0.1 failed to be validated to affect splicing.

Conclusions: Our study is the largest-scale study on deep-intronic splicing variants in IRD diseases. Our findings demonstrated that although there is a good correlation between SpliceAI score and splicing effects, given that many low-scored deep-intronic candidates also generated aberrant transcripts, the contribution of intronic variants, especially those deep within introns, to genetic diseases might be underestimated and further optimization of the prediction tool is needed.

ABSTRACT BODY:

Purpose: New digitally-enabled options for high-definition, heads-up stereoscopic visualization during surgery recently became available for an immersive 3D visualization of both the surgical field and the intraoperative OCT (iOCT) datastream. The purpose of this study was to compare conventional microscope-integrated iOCT and digitally-enabled microscope-integrated iOCT surgical platform.

Methods: This was a post-hoc case-control analysis from the DISCOVER study, a prospective, IRB-approved multi-surgeon case series, comparing the use of a conventional microscope-integrated iOCT (Rescan 700; Zeiss, Germany) with a digitally-enabled iOCT (Artevo 800; Zeiss). The two groups were optimally matched for surgeon and preoperative diagnosis. Standardized surgeon questionnaires were collected immediately following surgery. The primary objective was comparative assessment of surgical visualization efficiency [i.e., proportion of surgical field-based visualization (i.e., ocular heads-up display in the conventional group, 3D screen-based visualization in the digitally-enabled group) and non-surgical field-based (e.g., external 2-D monitor)]. Additional variables of comparison included iOCT utility and impact of iOCT on surgical decisions.

Results: 200 eyes from 200 subjects were included with 100 subjects in each arm. The most common indications for surgery were epiretinal membrane (conventional iOCT = 35%; digital iOCT = 33%) followed by retinal detachment and macular holes (conventional iOCT = 21%, 19%; digital iOCT = 21%, 20%, respectively). Surgical field-based visualization of iOCT datastream was significantly higher in the digitally-enabled group compared with conventional iOCT group (88% vs 7%, $p < 0.0001$). Surgeon-perceived utility of iOCT was similar between groups (conventional iOCT = 53%; digital iOCT = 60%, $p = 0.32$). The direct impact of iOCT on surgical decision-making was also similar between both groups (16% vs 21%, $p=0.36$).

Conclusions: Digitally-enabled microscope-integrated iOCT resulted in greater surgical visualization efficiency with a significantly higher proportion of cases with surgical-field based visualization of the iOCT datastream compared to the conventional system. Surgeon-perceived utility of iOCT was high in both groups.

ABSTRACT BODY:

Purpose: Benzalkonium chloride (BAK) is a widely used preservative in ophthalmic medications, as well as hygiene and cosmetic products. Experimental studies showed BAK's presence in ocular tissues, however the extent to which it accumulates during chronic topical glaucoma therapy is uncertain. A prospective case-control study was performed to test for the presence of BAK in tear and in anterior chamber fluid (ACF) samples in patients undergoing long-term topical therapy for open angle glaucoma (OAG).

Methods: Study group consisted of 22 cataract patients with OAG who received topical treatment for >2 years and 34 controls free from eye disease (other than cataract) with demographics in Figure 1.

Figure 1. Demographics of study groups.

A full ophthalmic examination and Schirmer's test to collect tear fluid samples were performed in all study patients scheduled for routine cataract surgery, during which 0.1 ml ACF samples of were collected. Analytical sample preparation was carried out by ultrasonic-assisted extraction. Schirmer's test paper strips were placed into the vials containing 1 ml of a mixture of methanol and acetonitrile (50/50) and sonicated for 30 min at 40°C. Extracts were evaporated using nitrogen gas and dry residue dissolved in 100 µl of acetonitrile. Test samples were assayed by LC-MS/MS in positive ionization mode using Acquity UPLC H-Class module and TQD MS detector (Waters, Milford USA). Methanol containing 0.1% of formic acid was used as mobile phase. Empty Schirmer's strips without tear samples were found to have BAK and were used as negative control. A positive result in tear samples was assumed when a higher BAK peak area was detected compared to empty strips. Statistical analysis was performed with SPSS v23.0 program package.

Results: Mean (SD) of glaucoma medication drops/day containing BAK in OAG group was 2.9 (0.7) while the control group did not receive any treatment.

Figure 2. BAK presence in tear fluid samples did not differ significantly between groups (X^2 =3,221, df = 1, p = 0,092). None of the ACF specimens were found to have detectible BAK in either OAG or control groups.

Conclusions: Our data suggests that there is not a significant presence of BAK in tears of OAG patients undergoing long term topical therapy. In addition, no detectible level of BAK was found ACF samples in the for either OAG or control groups.

ABSTRACT BODY:

Purpose: This project studied the reaction of tissue plasminogen activator (tPA) on corticosteroid-induced ocular hypertension (CIH) and glaucoma using a guinea pig animal model. The molecular mechanism underlying was also explored.

Methods: Ocular hypertension in guinea pigs was induced by sub-conjunctival injection of 5% dexamethasone (DEX) into both eyes. After 6 weeks, tPA was then injected into the treated eyes while PBS was used to inject into contralateral eyes. Trabecular meshwork (TM) tissue in both eyes of the guinea pigs were then collected for proteomic analysis after intraocular pressure (IOP) measurement. Differentially expressed proteins were quantified by liquid chromatography tandem mass spectrometry (LC-MS/MS) using SWATH^{TM} technologies.

Results: The average IOP at baseline was 18.5 ± 2.8 mmHg (mean ± SD) and 18.7 ± 2.8 mmHg (mean ± SD) in both eyes respectively. After 6 weeks of DEX treatment, IOPs increased to 22.9 ± 2.2 mmHg (mean ± SD) and 23.1 ± 2.8 mmHg (mean ± SD) in both eyes respectively. The average inter-ocular difference (IOD, treated minus control IOP) of IOP between 2 eyes was, at day 0 of injection, - 0.2 ± 0.8 mmHg (mean ± SD) while it reached - 6.7 ± 1.6 mmHg (mean ± SD) after 2 days of tPA treatment. IOPs of the tPA-treated eyes were lower than the contralateral eyes. Eight differentially expressed proteins (p-value ≤ 0.05 and fold-change ≥1.3 or ≤ 0.77) were identified by SWATH-MS. Among them, phospholipid scramblase (PLSCR3) was found to be regulated by tPA in CIH TM tissue of guinea pigs. It was found that phospholipid scramblase activity was regulated in a genome-wide association study of glaucoma subjects.

Conclusions: An albino guinea pig CIH model was successfully developed and IOP could be induced after 6 weeks of DEX injection via subconjunctiva. tPA was found to significantly reduce the IOP in CIH guinea pig's eyes. Our results revealed that tPA can also regulate multiple differentially expressed proteins. Furthermore, our result will inform new clinical study to assess the development of a novel therapeutic drug in patients with glaucoma.

ABSTRACT BODY:

Purpose: Retinal degenerative diseases cause progressive and irreversible visual impairment while effective therapies are still not available. Hypoxia-inducible factors (HIFs) are transcriptional factors that regulate angiogenesis, erythropoiesis, intracellular metabolism, and programmed cell death mainly depending on oxygen availability. In this study, we investigated the therapeutic effects of halofuginone (HF) focussing on HIFs and its target gene BNIP3 in a murine model of light-induced retinopathy (LIR).

Methods: The HIF inhibitory effect of HF on CoCl2-induced HIF activity was confirmed by Luciferase assay and qPCR using a 661W cell line. Eight-week-old male BALB/c mice were exposed to white LED light (3000 Lux) for 1 hour to create an LIR model. Neural retinas were harvested from LIR-treated mice, and qPCR and WB were performed to confirm the expression of HIF-1α and BNIP3. Mice were divided into HF group (0.4 mg/kg/day) and PBS group, and HF or PBS was administered 5 times in total before light exposure. Electroretinography (ERG) and Optical Coherence Tomography (OCT) were performed 7 days after light exposure. TUNEL staining was performed on the retinas of LIR model mice treated with HF or PBS.

Results: Luciferase assay and qPCR using 661W cell line showed that HF significantly suppressed the expression of HIF in a concentration-dependent manner. Light exposure significantly increased the expression of HIF-1α (qPCR: 1.9-fold, $p < 0.001$; WB: 2.9-fold, $p < 0.01$) and BNIP3 (qPCR: 1.3-fold, $p < 0.05$; WB: 1.3-fold, $p < 0.05$) in the retina. OCT results showed a significant inhibitory effect of HF on the retinal damage. TUNEL staining showed an inhibitory effect of HF on apoptosis of photoreceptors.

Conclusions: This study suggests the possibility of therapeutic effects of HF on retinal degeneration via the HIF/BNIP3 axis.

ABSTRACT BODY:

Purpose: A key factor in the pathophysiology of dry eye disease (DED) is the interaction between intercellular adhesion molecule 1 (ICAM1) on antigen-presenting cells (APCs), such as dendritic cells (DCs), and lymphocyte function-associated antigen 1 (LFA-1) on T cells, resulting in immunological synapse (IS) formation and T cell activation. Previous in vitro studies have shown that lifitegrast may inhibit LFA-1 to ICAM1 interaction, thus preventing IS formation or disrupting established IS's between T cells (CD3+ or CD4+) and human DCs, thereby inhibiting T cell activation. The exact mechanism of action of lifitegrast in DED is unclear. The present analysis aimed to visually demonstrate the kinetics of lifitegrast's effects on APCs to T cell binding using a live cell imaging assay.

Methods: Two cell lines (Raji [as APC] and Jurkat [as T cells]) were used. Raji cells were infected with a lentivirus encoding human ICAM1 fused to enhanced green fluorescent protein, and Jurkat cells were labeled with Hoechst 33258 (blue).To detect prevention of IS formation, live cells were pretreated with either lifitegrast (10μM) or vehicle control followed by staphylococcal enterotoxin B (SEB). Data were captured as time-lapse movies to show kinetic changes and indicate IS formation and the effect of lifitegrast in real-time. Presence of IS's in cells was evaluated using fluorescence microscopy. To detect disruption of established IS, live cells were stimulated with SEB and subsequently treated with lifitegrast and IS was assessed in real-time.

Results: In activated cells, lifitegrast prevented IS formation and disrupted the established IS's (Fig. 1A-C). In control cells, IS formation was evidenced by the green signal unevenly distributed between cells (white arrow; Fig. 1A). Pretreatment with lifitegrast prevented IS formation as shown by the green signal distributed uniformly around cells (Fig. 1B). Post-treatment with lifitegrast disrupted the established IS as evidenced by the green signal (arrow) that became more uniform with the increasing time of lifitegrast action (Fig. 1C).

Conclusions: Our findings show kinetic changes, indicating that lifitegrast can prevent IS formation and disrupt established IS between APCs and T cells. A study with primary cells or LFA-1-labeled T cells is ongoing. These findings may further validate the mechanism of action of lifitegrast in DED.

ABSTRACT BODY:

Purpose: To explore whether single cell analysis allows a more detailed characterization of the IGH clonality, gene usage and the correlation with MYD88 mutational status.

Methods: Vitreous fluid or CSF (n = 12) from 9 cases with PVRL and 3 cases with chronic inflammation based on cytological examination and 12 months' follow-up were recruited in accordance with the Singapore Personal Data Protection Act. Single B (CD19/20+, CD3-) cells were isolated using DEPArray™Nxt technology, followed by the single cell IGH sequencing and MYD88 mutation analysis.

Results: Compared with bulk cell sequencing, single cellular characterization displayed more heterogeneous IGH profiles of targeted vitreous/CSF B cells. Higher frequency of the dominant IGH clone in PVRL patients was observed compared with chronic inflammation patients (p=0.0089, Figure 1A). Majority cases (66%) who were diagnosed as PVRL showed the IGHV3 and IGHV4 as dominant clone (Figure 1B). We screened each single B cells (n=61) isolated from PVRL cases for both IGH sequencing and MYD88 mutation. The presence of MYD88 ^{L265P} mutation was more frequently detected in the single B cells with IGHV5 (100%), IGHV4 (71%) and IGHV3-7 (68%) gene sequencing (Figure 1C).

Conclusions: Single cells analysis of vitreous fluid or CSF displayed the complexity of tumor B cell population in PVRL, as well as the bias in the IGH gene sequencing and MYD88 mutational status in cellular level, which adds unique ontogenetic information for disease prognosis and development.

ABSTRACT BODY:

Purpose: Netilmicin is an aminoglycoside antibiotic indicated for the treatment of bacterial ocular infections of the anterior segment of the eye and ocular adnexa. Combined with dexamethasone, it's indicated in inflammatory ocular conditions including post-operative cases. Marketed formulations with netilmicin and dexamethasone have a dosing schedule of 4 administrations per day. To predict clinical efficacy of netilmicin when administered 2 (b.i.d.) or 4 (q.i.d.) times a day, killing kinetic experiments were performed against S. aureus (S.a.) and S. epidermidis (S.e.) using a standard and a pulsed protocol to mimic the posology scheme used in human.

Methods: S.a. 6538 and S.e. 12228 ATCCs grown to reach 10^8 cfu/ml on supplemented Mueller-Hinton (MH) broth were then diluted to 10^6 cfu/ml in the same broth containing 32 µg/ml netilmicin. An antibiotic-free control was similarly inoculated.

Standard protocol: at 0, 1, 2, 6, 12 and 24h, 0.1ml was diluted in phosphate-buffered saline, inoculated onto MH agar plates and incubated at 37°C for 24h, to determine viable cfu/ml.

Pulsed protocol: in the b.i.d. regimen, bacteria were exposed to netilmicin at 0 and 12h while in the q.i.d. regimen, 4 exposures were carried out every 4h along the 12h. In both protocols, contact time of bacteria with netilmicin was 2h. At the end of this period, 0.1ml of each sample were processed as above. Data represent mean±SEM of $\log_{10}$ cfu/ml. Statistical analysis were sought by unpaired t-test.

Results: In the standard protocol, netilmicin showed a bactericidal effect against S.a. at 6h (5 $\log_{10}$ decrease) and this activity is stronger at 12 and 24h (6 $\log_{10}$ decrease). Moreover, netilmicin confirmed bactericidal effect against S.e., and importantly this activity starts 1h after exposure (3 $\log_{10}$ decrease). Data obtained in the pulsed protocol, showed that netilmicin retains its bactericidal effect against S.a. (Fig.1A) and S.e. (Fig.1B) when administered b.i.d. or q.i.d. within 12h (6 $\log_{10}$ decrease) and also at 24h, i.e. after 12h washout.

Conclusions: Interestingly, pulsed protocol demonstrated that bactericidal effect of netilmicin against Staphylococci is maintained unchanged when administered 2 or 4 times a day. Therefore, in order to reduce the antibiotic resistance and improve the patient's compliance, the hypothesis to reduce the posology of marketed products containing netilmicin could be taken into account.

TITLE: Development and validation of prognostic models to increase power of clinical trials for geographic atrophy (GA)

SESSION TITLE: AMD and Geographic Atrophy

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: V. Steffen, N. Anegondi, Q. Yang, M. Friesenhahn, D. Ferrara, S.S. Gao, C. Rabe, Genentech Inc, South San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure: Verena Steffen: Commercial Relationship(s);Code E (Employment):Genentech Inc., San Francisco, California, United States | Neha Anegondi: Commercial Relationship(s);Code E (Employment):Genentech Inc., San Francisco, California, United States | Qi Yang: Commercial Relationship(s);Code E (Employment):Genentech Inc., San Francisco, California, United States | Michel Friesenhahn: Commercial Relationship(s);Code E (Employment):Genentech Inc., San Francisco, California, United States | Daniela Ferrara: Commercial Relationship(s);Code E (Employment):Genentech Inc., San Francisco, California, United States | Simon Gao: Commercial Relationship(s);Code E (Employment):Genentech Inc., San Francisco, California, United States | Christina Rabe: Commercial Relationship(s);Code E (Employment):Genentech Inc., San Francisco, California, United States

ABSTRACT BODY:

Purpose: Covariate-adjusted clinical trial analysis can improve power and decision making. Here, we report the development, validation, and comparison of different models to predict GA progression and quantify their impact on power.

Methods: This study was performed using data from patients in the lampalizumab program. The outcome was defined as growth rate (mm^2/year) of GA lesion area (measured on fundus autofluorescence [FAF]). The data from the Proxima A (NCT02479386), Chroma (NCT02247479), and Spectri (NCT02247531) trials were split into development (n = 1279) and holdout (n = 443) sets. Three different classes of models were developed: (1) benchmark model: a baseline simple feature-based model using GA area, location, contiguity, and low-luminance deficit; (2) run-in model: uses a 6-month initial lesion growth rate with or without clinical features; and (3) imaging model: a baseline deep learning model using FAF images. These models were validated on 2 additional datasets that were not used for model development: MAHALO (NCT01229215; n = 122) and Proxima B (NCT02479386; n = 175). Performance was evaluated by calculating the squared Pearson correlation coefficient (r^2). Additionally, the effective sample size increase (ESSI) that would result from using the respective model for adjustment in the clinical trial analysis was calculated. ESSI was calculated relative to no adjustment or adjustment with the benchmark model.

Results: The FAF-based imaging model outperformed the feature-based benchmark and run-in models in all datasets, with an r^2 of 0.48 on the holdout set, 0.63 on the MAHALO dataset, and 0.48 on the Proxima B dataset. This translates into ESSIs of 92%, 174%, and 91%, respectively, compared with an unadjusted analysis. Compared with the benchmark model, the imaging model provides an additional effective increase in sample size of 61%, 82%, and 43%, respectively.

Conclusions: These findings suggest that the FAF-based imaging model, using a single image at baseline, is robust and shows a higher prognostic performance than models with simple features derived at baseline and during a run-in phase. These results suggest that the imaging models can significantly improve trial power and decision making.

TITLE: Effects of the spectral energy distribution of ambient lighting on L-, M- and S-cone abundancies and emmetropization in the chicken

SESSION TITLE: Myopia: Mechanism of Emmetropization and Eye Growth

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S. Gisbert Martinez, F. Schaeffel, Universitatsklinikum Tubingen Forschungsinstitut fur Augenheilkunde, Tubingen, Baden-Württemberg, GERMANY|S. Wahl, Carl Zeiss Vision GmbH, Aalen, Baden-Württemberg, GERMANY|F. Schaeffel, Institute of Molecular and Clinical Ophthalmology Basel, Basel, Basel-Stadt, SWITZERLAND|

Commercial Relationships Disclosure: Sandra Gisbert Martinez: Commercial Relationship: Code N (No Commercial Relationship) | Siegfried Wahl: Commercial Relationship: Code N (No Commercial Relationship) | Frank Schaeffel: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: It was previously found that M to L cone ratios were correlated with refraction and ocular length and that chicks develop longer eyes when they have more L-cones. It was also found that less deprivation myopia was induced when chicks were raised in narrow-band blue or UV light, compared to narrow-band red light. Because the spectral composition of ambient lighting can be easily controlled, it may represent a non-invasive and easily applicable intervention of myopia. Therefore, the aim of this study was to find out how light with different spectral compositions interferes with emmetropization and cone ratios.

Methods: Three lighting conditions were used with different energy contributions in the short wavelength range: (1) laboratory light, (2) blue-enriched white light, and (3) white LEDs, all adjusted to approximately 285 (human) lx. Chickens were monocularly treated with diffusers to induce deprivation myopia and exposed to these conditions for a period of one week. Refraction and ocular biometry were determined at the beginning and the end of the experiment and L, M, and S cone photoreceptors were counted in fresh retinal tissue based on the color of their oil droplets.

Results: No differences were found in deprivation myopia among the three lighting conditions. Chickens raised under laboratory light displayed significant correlations of M to L ($p<0.01$) and L to S ($p<0.05$) cone ratios in both eyes. The key finding of this study was that not only M to L but also L to S ($p<0.05$) cone ratios were significantly correlated with refractions in eyes with normal vision. Lower L to S cone ratios were linked to more hyperopic refractions. Unexpectedly, these ratios were inverted when deprivation myopia was induced.

Conclusions: (1) Broadband white light with added energy in the short wavelength range had no effect on deprivation myopia, different from narrow-band short-wavelength light as previously described. (2) Also L to S cone ratios are linked to refractions in eyes with normal vision, in line with the hypothesis that cone photoreceptor densities are linked to refractive development. (3) Inverted correlations of M to L and L to S cone ratios in eyes with deprivation myopia suggest that contrast reduction by the diffusers may affect the mechanism underlying emmetropization. Interesting future questions are why and how.

ABSTRACT BODY:

Purpose: The combination of corticosteroid and antibiotic is the most commonly post-operative therapy use to prevent ocular infections. When the epithelial integrity is compromised the composition of the formulation, in terms of active ingredients and excipients, is important for the biocompatibility. The purpose of this study was to evaluate the potential cytotoxic effect of two different marketed preservative-free eye drops solutions containing corticosteroid and antibiotic.

Methods: Human corneal epithelial cells (HCE) were repeatedly exposed (6 times) for 5 min (short time repeated exposure, S.T.R.E.) at 1.5h intervals to Netildex (0.3% netilmicin + 0.1% dexamethasone) or Betabioptal (0.5% chloramphenicol + 0.2% betamethasone) at two different concentrations: undiluted and 1:20 of the marketed concentration. Benzalkonium 0.01% was used as CTRL+. This protocol was designed to simulate the posology and the residence time of eyedrops considering blinking and tearing. Cell viability was assessed in wash and no wash condition by MTT assay. Statistics were by One-way ANOVA.

Results: None of the products tested diluted (1:20) had any significant cytotoxic effect following S.T.R.E. protocol in both wash (Netildex 102.2%±4.3, Betabioptal 103.6%±3.2, respectively, as cell viability) and no wash conditions (Netildex 99.0% ±1.6, Betabioptal 101.2%±4.4, respectively, as cell viability). Interestingly, when tested undiluted, Betabioptal produced significant cytotoxic effects in both wash (24.2%±0.6 of cell viability) and no wash conditions (25.1%±0.3 of cell viability), with respect to Netildex which did not show any cytotoxic effect in both conditions (99.9%±3.5 and 107.8%±2.5, respectively), see figure A-B.

Conclusions: Netildex and Betabioptal, both preservative-free solutions, when used diluted according to Takahashi et. al, 2011, showed no cytotoxic concerns on corneal epithelium. On the contrary, when tested undiluted Betabioptal was found cytotoxic, while Netildex was found to be endowed with an advantageous cytocompatibility profile even at the concentration used in clinical ophthalmological practice.

ABSTRACT BODY:

Purpose: Pathological increases in vascular permeability lead to oedema and swelling, causing a host of retinal and neurological disorders. Few barrier-enhancing factors have been discovered to specifically increase barrier integrity and make vessels resistant to fluid leakage. In this study, we explore the effects of IL-36 on angiogenic processes and vascular permeability in vivo and in vitro.

Methods: The ability of IL-36 cytokines to modulate angiogenic properties in vitro was examined in human retinal microvascular endothelial cells using wound healing, proliferation and tube formation assays. Flux assays were performed to analyse the monolayer integrity of the cells following IL-36 stimulation. RNA sequencing, qPCR and western blot were used to ascertain potential mechanisms underlying these functional readouts. In vivo, laser induced choroidal neovascularisation were performed in C57BL/6J mice injected intravitreally with vehicle or IL-36β. Fluorescein angiography was used to assess the permeability of these CNV and the surrounding retinal microvasculature before tissue was harvested and analysed to ascertain if IL-36 altered the volume of CNV.

Results: IL-36β enhanced endothelial cell barrier function, reducing vascular permeability. IL-36 cytokines also induced primary endothelial cell proliferation, migration, and tube formation in vitro. Importantly, we demonstrate that the IL-36 signalling axis has potential to be useful clinically for reducing microvascular leakage, as the pro-angiogenic features of IL-36 in vitro are uncoupled from the potent ability of IL-36 to enhance vascular integrity in adult mice in vivo in an acute setting. Mechanistically IL-36 regulates endothelial cell tight/adherens junctions, in addition to inducing vessel remodelling and maturation providing a stabilised vascular network. Network analysis of RNA sequencing data support these functional assays.

Conclusions: Our data present IL-36 cytokines as novel promoters of vascular integrity, with barrier enhancing properties that prevent pathological vascular permeability.

ABSTRACT BODY:

Purpose: The prevalent cause of retinal detachment is a full-thickness retinal break, which allows fluid to enter the subretinal space from the vitreous cavity. To prevent progression of the detachment, laser photocoagulation (LPC) lesions are placed around the break in clinical practice to seal the tissue. The treatment is usually performed under indirect ophthalmoscopy. Therefore, the subretinal damage can be difficult to delineate and an experienced operator is required for a successful outcome. In this work, optical coherence tomography (OCT) is used for optimal treatment planning, and LPC is subsequently applied in a navigated and user-friendly procedure.

Methods: The novel method was integrated in a modified OCT diagnostic system (SPECTRALIS OCT, Heidelberg Engineering, Heidelberg, Germany) with integrated treatment laser (Merilas 532 shortpulse, Meridian, Thun, Switzerland). To reliably seal the break, LPC lesions must be applied in regions of still attached retina. Therefore, OCT B-scans were used to manually mark the boundary of the surrounding detachment, which allowed to compute an optimally placed elliptical treatment area. To evaluate the method, artificially provoked retinal breaks were treated accordingly in 10 ex-vivo porcine eyes and the outcome was assessed by fundus photography and OCT imaging.

Results: Ex-vivo experiments showed that OCT-based laser treatment is feasible and the visibility of the subretinal space allows precise treatment planning. A total of 99 to 227 automatically applied lesions per eye at 200 ms and 200 mW were evident as coagulation in color fundus photography. Furthermore, OCT cross-sectional scans showed the required ruptures of the retina at the LPC application sites (Figure 1).

Conclusions: The results indicate the potential of OCT navigated laser retinopexy to achieve high treatment accuracy, efficiency, and safety. Future studies should address treatment of peripheral breaks and the integration of the existing tracking and follow-up functionalities to further enhance and facilitate the treatment.

ABSTRACT BODY:

Purpose: Diagnosing cataractous retinal images is error-prone due to the severe haze-effect produced by the scattering of cataract layers that decreases the image contrast. To support clinical diagnosing, we propose an image processing algorithm termed multilevel-stimulated denoising (MUTED) that can significantly increase the visual quality and suppresses the haze effect of cataractous retinal images.

Methods: We introduce the double pass fundus reflection model and a multilevel stimulated denoising algorithm. The transmission matrix of the cataract layer is expressed as the superposition of denoised raw images of different levels weighted by stimulated functions. An intensity-based cost function was designed, and the gradient descent with adaptive momentum estimation is used to update the parameters resulting in the final refined transmission matrix of the cataract layer. We tested our methods on a total of 194 images from both public and proprietary databases and compared the performance of our method with other state-of-art enhancement methods. We used fog-ware density estimation (FADE) to evaluate the dehazing quality, and use multiscale contrast to evaluate the contrast of the image. In addition, we collected retinal images before and after cataract surgery to see whether our proposed method leads to unexpected artificial structures and test its reliability.

Results: Figure 1 shows experimental results for visual assessment. MUTED effectively improved the clarity of retinal images as structures like blood vessels that were hidden behind the cataract in the raw image could be observed after enhancement. In addition, by comparing retinal structures presented in pre- and post-cataract surgery images, we found that MUTED did not lead to unexpected artificial structures and maintained the correct information from the images. Table 1, comparing of contrast and FADE scores of the raw and of two methods to enhance images. The MUTED has the highest contrast and the lowest FADE values denoting good dehazing results.

Conclusions: The MUTED is able to reveal the information of cataractous retinal images and significantly increases the visual quality of cataractous retinal images. Both visual and objective assessment using fog-ware density estimation show the superiority of our method.

ABSTRACT BODY:

Purpose: While there is evidence that congenital blindness leads to structural and functional brain reorganisation, the impact of blindness on the vasculature in brain regions involved in vision is not well defined. This project aimed to fully characterise the vasculature along the visual pathway in both sighted and genetically blind mice. Immunohistochemistry-based techniques were used to quantify vascular density and integrity; glial and mural cell coverage; and expression of blood-brain barrier (BBB) components across several visuorecipient brain regions in wild-type (WT) mice and the rhodopsin knockout (Rho$^{-/-}$) model of rod photoreceptor degeneration.

Methods: Brain sections were obtained from 12-week old WT and Rho$^{-/-}$ mice, with regions of interest being located by staining with DAPI and comparing anatomical landmarks to the Allen Mouse Brain Reference Atlas. Sections were immunostained for the vascular marker isolectin-IB4; tight junction proteins claudin-5, occludin, and ZO-1; transporter proteins GLUT-1, P-gp, and LRP-1; the pericyte marker PDGFR-ß; the astrocyte marker GFAP; and the microglial marker IBA-1. Vascular density was quantified as the percentage area covered by isolectin-IB4 staining in images of brain regions of interest. Protein expression was quantified by normalising signal intensity for each marker to that of isolectin-IB4. The extravasation of a biotinylated agent (600 Da) and fibrinogen (340 kDa) was quantified as a proxy for BBB integrity.

Results: A distinct profile of BBB protein expression; mural and glial cell coverage; and vascular integrity was observed between WT and Rho$^{-/-}$ mice and between brain regions along the visual pathway in each group. Notably, claudin-5, a key tight junction component, was detected at significantly higher levels in the visual cortex than in thalamic visuorecipient regions, such as the dLGN and the LP in WT mice, with similar trends being observed in Rho$^{-/-}$ group.

Conclusions: Distinct BBB profiles along the visual pathway and between sighted and blind mice highlight the impact that the structural and functional brain reorganisation caused by blindness can have on the neurovascular unit. Given reports that visually impaired individuals are at increased risk of cognitive decline, these results highlight the vasculature as a possible contributing factor to this association, with altered vascular profiles leading to downstream neuronal dysfunction.

TITLE: Semi-automatic segmentation for gonioscopic images
SESSION TITLE: Machine Learning and Image Processing
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: G. Spagnuolo, A. De Giusti, NIDEK Technologies Srl, Albignasego, Padova, ITALY|
Commercial Relationships Disclosure: Giusi Spagnuolo: Commercial Relationship(s);Code E (Employment):NIDEK Technologies Srl | Andrea De Giusti: Commercial Relationship(s);Code E (Employment):NIDEK Technologies Srl
ABSTRACT BODY:
Purpose: NIDEK GS-1 (NIDEK CO., LTD. Japan) collects color images of the Irido-Corneal Angle (ICA) angle split into 16 sectors, each acquired in 17 foci. The manual segmentation of these images could be time consuming and error-prone because the anatomical structures of the ICA have complex boundaries, adjacent tissues are not clearly separated, and some regions may not be in focus. This work proposes a semi-automatic segmentation algorithm based on image processing and prior knowledge of the ICA geometry with the aim of making the user interaction minimal, fast, and effective.
Methods: A boundary is a sequence of curved lines between seed points (i.e., points on the border between two structures) so that the path connecting them has a minimum cost. The cost function is based on 3 components: the gradients of the RGB input image (1280x960) and the optimizer of a geometrical approximation of ICA's anatomical structures. The gradients locate the edges and the geometrical component reinforces the weakest contours. The algorithm's sensitivity to each cost component is automatically evaluated during the segmentation process. A measure of the edges' strength in the neighborhood of the drawn boundary permits to balance the gradient and the geometrical components. The resulting contour is smoothed with a moving average filter.
Results: A qualitative evaluation of the results was assessed on a dataset of 40 GS-1 images. For comparison, images were firstly segmented with a manual tool approximating the regions with polylines based on the user-defined seed points. The same images were then segmented with the proposed algorithm using the same seed points (Fig 1). The outcomes demonstrated that our algorithm permits to trace the tissue boundaries more precisely. Moreover, on average, 19% of seed points, frequently located on strong and complex edges, were redundant (Fig. 2). Finally, the effort for the clinician and both the intra- and inter-user variability were reduced.
Conclusions: The proposed algorithm provides satisfactory segmentations of gonioscopic images and can be also used to collect training data for automatic segmentation and classification algorithms. In fact, it minimizes imperfections due to computer-human interaction, meaning that differences in delineations from multiple experts will only reflect differences in their clinical opinions. Further evaluation should be performed to define a quantitative measure of the algorithm's performance.

ABSTRACT BODY:

Purpose: There are no approved treatments for dry age-related macular degeneration (AMD) and advanced geographic atrophy (GA). Experimental anti-complement treatments achieve less than 30% annual reduction in GA progression and some patients develop neovascularisation. We designed a series of novel gene therapy constructs to improve retinal pigment epithelial (RPE) survival via reduced complement activation and prevention of neovascular pathology. Tissue analysis from AMD patients without defined genetic complement factor mutations has revealed early loss of complement regulatory factors and reduced pigment epithelium-derived factor (PEDF). In particular, early loss of complement membrane cofactor CD46, may play a pivotal role in GA progression and PEDF consistently demonstrates anti-neovascular activity in preclinical AMD models. Therefore, enhancing these proteins is an attractive therapeutic approach to treating AMD.

Methods: Bi-cistronic plasmids and rAAV2/2 vectors coding for PEDF and a variety of complement regulatory components were examined in HEK293T and ARPE-19 cells using C3b cleavage assays.

Results: Constructs expressing PEDF in ARPE-19 cells lead to a significant reduction in endogenous VEGF (ng/mL) levels (control = 457 ± 19, IKC030P = 374 ± 12; P=0.01, mean ± SEM n=4, Student's t-test). In a C3b cleavage assay which models the GA retina (e.g., moderate complement factor I (CFI; 11nM) and low cofactors (CFH; 0.5nM), a bi-cistronic plasmid expressing a soluble form of CD46 significantly increased C3b breakdown versus Null control plasmid. In contrast, a plasmid expressing CFI (to further increase CFI concentration) failed to further increase C3b breakdown (% C3b breakdown products/iC3b; Null plasmid = 65 ± 3; sCD46 plasmid = 89 ± 1***; CFI plasmid = 67 ± 1; mean ± SEM, ***P<0.0001 ANOVA/Bonferroni modified t-test). Recombinant C3b degradation by CFI did not occur in the absence of any cofactor.

Conclusions: Lead constructs demonstrate increased endogenous PEDF levels and an ability to reduce VEGF secretion whilst simultaneously attenuating complement activation by enhancing co-factor availability. This multimodal gene therapy approach has the potential to provide greater efficacy against GA progression compared to monotherapies that only target the complement system whilst minimising the risk of developing VEGF-induced neovascular pathology.

TITLE: Disturbances of the retinal endothelial cells' barrier induced by long-term treatment with $VEGFA_{165}$ are independent of the growth factor's action

SESSION TITLE: Biochemistry and Molecular Mechanisms of Diabetic Retinopathy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H.L. Deissler, A. Wolf, Department of Ophthalmology, Universitat Ulm, Ulm, Baden-Württemberg, GERMANY|M. Rehak, Department of Ophthalmology, Justus Liebig Universitat Giessen Fachbereich Medizin, Giessen, Hessen, GERMANY|

Commercial Relationships Disclosure: Heidrun Deissler: Commercial Relationship: Code N (No Commercial Relationship) | Matus Rehak: Commercial Relationship: Code N (No Commercial Relationship) | Armin Wolf: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: $VEGFA_{165}$ induces a persistent dysfunction of the barrier formed by immortalized endothelial cells of the bovine retina (iBREC), completely prevented but only transiently reverted by inhibiting VEGF signaling. Here we investigated how duration of exposure to the growth factor affects the cells' response.

Methods: Confluent iBREC were exposed to 1.2nM $VEGFA_{165}$ for 1 to 9 days. As a measure of barrier function, we continuously determined the cell index (CI) of iBREC cultivated on gold electrodes. Levels of proteins regulating paracellular or transcellular flow, i.e. claudin-1, claudin-5, vascular endothelial cadherin, caveolin-1, plasma lemma vesicle associated protein (PLVAP), of adhesion proteins CD9/TSPAN29, integrins α5 and β1, and of nuclear β-catenin were assessed by Western-blotting; intra- and extracellular VEGFA levels by ELISA.

Results: VEGFA treatment sginificantly reduced CI values still low after 9 days of exposure. Inhibition of VEGFR2 alone or in combination with PDGFRα/β or FGFR1/2/3 by tivozanib or nintedanib led to complete recovery of the low CI values when the inhibitor was added to iBREC pre-treated with VEGFA for 1 day; the effect was stable for 2 days. Reversion of the low CI was not successful when inhibitors were added to cells exposed to the growth factor for more than 3 days. VEGFA concentrations in the cells' supernatant declined from 0.6nM to 0.1nM measured 2 or 9 days after addition, respectively, but its intracellular levels remained stable. Levels of tight junction (TJ)-protein claudin-1 remained low in VEGFA-exposed iBREC from days 1 to 9; those of TJ-protein claudin-5 were elevated, but only on day 6. VEGFA induced expression of PLVAP which was very high on days 2 and 6 after addition, but extremely low on day 9. Levels of integrin α5 - higher on day 2 - declined over time and were lower on day 9 compared to those of control cells; levels of integrin β1 remained slightly elevated at all time points. Only on day 2, VEGFA induced a significant increase of nuclear β-catenin. Levels of the other proteins investigated remained stable.

Conclusions: Only barrier disturbances, i.e.deregulated para- and transcellular flow, observed early during VEGFA exposure depend on the growth factor's action. Changes observed later include impaired TJs and adhesion, and are independent of the presence of the growth factor.

TITLE: GA area measured by SD-OCT shows good correspondence with FAF-based measurements in patients enrolled in the FILLY trial

SESSION TITLE: Imaging of posterior segment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Mai, D. Lachinov, S. Riedl, G.S. Reiter, W. Vogl, H. Bogunovic, U. Schmidt-Erfurth, Medizinische Universitat Wien, Wien, Wien, AUSTRIA|

Commercial Relationships Disclosure: Julia Mai: Commercial Relationship: Code N (No Commercial Relationship) | Dmitrii Lachinov: Commercial Relationship: Code N (No Commercial Relationship) | Sophie Riedl: Commercial Relationship: Code N (No Commercial Relationship) | Gregor Reiter: Commercial Relationship: Code N (No Commercial Relationship) | Wolf-Dieter Vogl: Commercial Relationship: Code N (No Commercial Relationship) | Hrvoje Bogunovic: Commercial Relationship(s);Code F (Financial Support):Apellis Pharmaceuticals | Ursula Schmidt-Erfurth: Commercial Relationship(s);Code F (Financial Support):Apellis Pharmaceuticals

ABSTRACT BODY:

Purpose: To compare spectral-domain optical coherence tomography (SD-OCT) and fundus autofluorescence (FAF) measurements of geographic atrophy (GA) secondary to age-related macular degeneration (AMD) in patients enrolled in the FILLY trial.

Methods: In this post-hoc explorative study, SD-OCT images from the phase 2 FILLY clinical trial were analyzed. The phase 2 FILLY trial was a sham controlled clinical study of intravitreal pegcetacoplan, targeting complement C3, for patients with GA secondary to AMD. A-scan based manual annotation of complete loss of retinal pigment epithelium (RPE) was performed on whole baseline and year one OCT volumes. The RPE-loss measured on OCT was compared to the hypofluorescent GA areas measured on FAF by the centralized reading center of the FILLY trial. The correlation between the GA areas in mm^2 from baseline and year 1 was reported using Pearson's correlation coefficient (r) and coefficient of determination (R^2). In addition the limits of agreement were evaluated with Bland-Altman plots.

Results: 144 OCT volumes of 144 patients at baseline and 111 OCT volumes of 111 patients at year 1 from the FILLY trial were included, resulting in a total of 12 495 manually annotated B-scans. The comparison of GA areas measured on FAF and the RPE-loss measured on OCT revealed a correlation coefficient of r = 0.97 with an R^2 = 0.86 at baseline and r = 0.97 with an R^2 = 0.81 at year 1 (Figure 1). The Bland-Altman plots comparing the GA areas assessed on both imaging modalities show a bias towards higher GA area measurements assessed by FAF as compared to OCT, especially in larger lesions at year 1. Mean difference in measured GA areas between the two imaging modalities was 0.91 ± 0.95 mm^2 at baseline and 1.28 ± 1.23 mm^2 at year 1 (Figure 2).

Conclusions: Our results show a very good correlation of GA measurement between FAF and OCT. Given the fact that OCT has become more established than FAF, this is an essential finding for the design and endpoints in future clinical trials as well as disease monitoring in clinical practice, especially once a treatment will be available.

ABSTRACT BODY:

Purpose: NCX 470 is a nitric oxide (NO)-donating prostaglandin analog in development for the reduction of intraocular pressure (IOP) in patients with open-angle glaucoma or ocular hypertension. This work evaluated the ocular hemodynamic effects and neuroprotective activity of NCX 470 in rabbits.

Methods: Endothelin-1 (ET-1)-induced ischemia/reperfusion rabbit model was used. ET-1 was injected next to the optic nerve twice/week for 6 weeks. Animals received NCX 470 (0.1% twice daily, 6 days/week) or vehicle from week 3 until the end of ET-1 treatment. Functional endpoints were IOP, ophthalmic artery resistive index (OA-RI) and photoreceptor function (electroretinogram, ERG). Biochemical endpoints included: oxidative stress markers [manganese superoxide dismutase (MnSOD) and gluthatione GSH)], as well as markers of apoptosis [8-hydroxydeoxyguanosine (8OH-dG)] in retina and iris/ciliary body.

Results: ET-1 increased OA-RI over time [0.30±0.02, 0.39±0.02* and 0.42±0.03* at baseline, week 2 and 6, respectively (*$p<0.05$ vs baseline)]. Treatment with NCX 470 restored baseline OA-RI (0.33±0.02, $p<0.05$ vs vehicle at the same time point) by week 6. Photoreceptor response (dark-adapted 3.0) decreased after treatment with ET-1 (109.8±12.9, 98.6±6.6 and 87.6±10.1μV at baseline, week 2 and 6, respectively) and NCX 470 reversed this effect of ET-1 (122.8±11.4μV, $p<0.05$ vs vehicle). NCX 470 also neutralized ET-1-induced changes in MnSOD ($NAIVE_{MnSOD}$ = 30.1±1.1, VEH_{MnSOD}=18.9±2.3 and NCX 470_{MnSOD}=30.1±3.1mU/mg of protein, $p<0.05$ vs vehicle) and GSH ($NAIVE_{GSH}$= 1301.4±33.6, VEH_{GSH}=371.5±43.7 and NCX 470_{GSH}=1314.6±253.0pmoles/mg protein, $p<0.05$ vs vehicle) in the retina at week 6. Similarly, markers of apoptotic cell death were decreased in the retina from animals receiving NCX 470 compared to vehicle ($NAIVE_{8OHdG}$=18.9±0.7, VEH_{8OHdG}=57.5±6.3 and NCX 470_{8OHdG} =34.1±5.0pg/mg DNA, $p<0.05$ vs vehicle). Similar effects were observed in iris ciliary body.

Conclusions: NCX 470 reduces oxidative stress and apoptosis in the retina after ET-1-induced ischemia/reperfusion and ameliorates ocular perfusion as well as photoreceptor function. Additional studies are needed to establish whether these effects are interdependent.

ABSTRACT BODY:

Purpose: To characterize the human iridocorneal angle (ICA) in vivo with gonioscopic Optical Coherence Tomography (OCT) imaging using a customized goniolens and a clinically available OCT device (Heidelberg Spectralis). The trabecular meshwork (TM) and Schlemm's canal (SC) located within the ICA are the target for many glaucoma treatments. However, in vivo study of the TM and SC lying at the apex of the ICA is difficult, and most of our knowledge comes from human post-mortem or animal model studies.

Methods: A clinical single-mirrored gonioscopy lens was modified with a 12mm button lens placed on its anterior surface to provide an image plane at the approximate distance of the ICA structures. The subjects' eye was anesthetized with 1 drop of Proparacaine Hydrochloride USP 0.5% . The goniolens was placed on the eye coupled with gonio-gel and aided by a 3D adjustable mount fixed to the head mount of the OCT device to provide additional stability. The waist of the OCT beam was set to fall on the goniolens mirror and steering was available by tilting the OCT device. Radial and tangential dense OCT scans with minimum spacing were performed on 6 young healthy subjects and 1 with pigment dispersion syndrome, focused on the inferior ICA apex.

Results: The TM was seen in all 7 subjects showing more detailed structure of the uveoscleral meshwork, with an average signal penetration depth of 636±116 μm (signal dropped to 2x the noise level). Schlemm's canal was seen in 4 subjects. The penetration depth was 560 μm through the TM and SC for one subject. Schlemm's canal size varied rapidly over space, with the cross-sectional area varying 35% between individual b-scans tangentially and 19% radially.

Conclusions: OCT gonioscopy imaging of the human ICA in vivo has been proved successful, providing both sufficient resolution to depict the structure of the uveoscleral meshwork, and penetration depth past Schlemm's canal.

ABSTRACT BODY:

Purpose: To compare the performance of a Convolutional Neural Network (CNN) model with experienced glaucoma specialists’ grading in detecting glaucomatous optic neuropathy using color images collected with the Compass fundus perimeter (CMP, Centervue, Italy).

Methods: The data used for this project were collected during an international multicentric clinical study. The dataset consisted of 1930 color images of the Optic Nerve Head (ONH, 400x400 pixels) automatically captured by the Compass. Each image was labelled as healthy (NRM) or glaucoma (GLC) based on a glaucoma experts’ evaluation (clinical judgment of the nerve including ophthalmoscopy, fundus image and OCT) performed during the main study, for a total of 1010 NRM and 920 GLC.The original image was resized to 200x200 pixels for the CNN. The CNN model consisted of sequential convolutional and max pooling layers for a total of 1,278,113 trainable parameters. The model was trained using 90% of the dataset (80% train, 10% validation) and tested using the remaining 10% of the data randomly sampled across all study sites. The output of the final sigmoid activation function (AF) was used to build a Receiver Operating Characteristic (ROC) curve. Additionally, two experienced glaucoma specialists (clinician 1 and 2), involved in the main study, were asked to independently grade the test set images with no extra information and no knowledge of group assignment. Their performance was compared to that of the CNN at the same specificity on the ROC curve.

Results: The performance obtained by the CNN, clinician 1 and clinician 2 on the test set (101 NRM, 92 GLC) is shown in Figure 1 and reported in Table 1. The sensitivity of Clinician 2 was just below the 2.5%-Confidence bound of the CNN. The table also reports the performance of the CNN for a threshold of 0.5 on the AF.

Conclusions: The CNN had a performance that ranged from similar to significantly better than the expert graders. The methodology could have applications for automated case finding in glaucoma care.

ABSTRACT BODY:

Purpose: Anti-vascular endothelial growth factor (anti-VEGF) intravitreal injections are efficacious treatments for neovascular age-related macular degeneration (nAMD) and diabetic macular edema (DME), but optimal real-world outcomes require frequent treatment and monitoring that can be burdensome to patients and hinder their ability or willingness to follow their management plan. This study aimed to understand patient treatment experience with anti-VEGF standard of care.

Methods: This observational study employed a cross-sectional quantitative survey comprising de novo questions, patient-reported outcome (PRO) measures and medical chart extraction. Adult patients in the USA, UK and Canada with nAMD or DME, and treated with anti-VEGF injections for ≥12 months, were recruited via 21 (9 USA, 6 UK, 6 Canada) clinical sites.

Results: Between January and August 2021, 148 (67 USA, 33 UK, 48 Canada) DME and 219 (98 USA, 54 UK, 67 Canada) nAMD patients completed their surveys. While 159 (43%) patients had a study eye visual acuity at most recent reading >70 approxETDRS letters, PRO scores indicated that patients across the two conditions had relatively high vision-related functioning (NEI-VFQ-25) and were generally satisfied with their current treatment (MacTSQ and RetTSQ). Eighteen DME patients (12%; 12% in the US, 27% in the UK, 2% in Canadian samples) and 9 nAMD patients (4%; 3% USA, 3% UK, 4% Canada) missed at least 1 injection visit in the past 12 months. Reported barriers were mainly related to treatment, clinic and appointment factors, and the COVID-19 pandemic. Half of the patients reported some level of impairment in their daily activities due to the treatment. Following treatment, the majority recovered within 1 day; however, a sizable portion (24%; 21% USA, 31% UK, 22% Canada) needed >1 day to recover. Among the working patients (N = 55), 34 (62%; 58% USA, 67% UK, 65% Canada) reported some level of productivity impairment in the form of absenteeism.

Conclusions: Despite high adherence and treatment satisfaction levels, patients reported impairment of daily activities, burden, and barriers related to treatment. In general, more DME patients missed at least 1 visit than nAMD patients. More durable treatments with longer intervals could further reduce treatment burden and address the current barriers faced by patients.

ABSTRACT BODY:

Purpose: Macular fibrosis, observed at the end stage of neovascular AMD, is the leading cause of irreversible blindness in AMD and has been identified as a cause of poor anti-VEGF therapeutic outcomes. Although the pathogenesis of macular fibrosis is still unclear, excessive extracellular matrix deposition by myofibroblasts appears to be a key event. Here, using Collagen-1 (Col1)-YFP reporter mice, we compare the dynamics of collagen production in vivo over time in mice receiving the traditional laser-induced choroidal neovascularization (LiCNV) model to mice receiving the recently described two-stage LiCNV model of subretinal fibrosis, and ex vivo, we examine the CNV tissue for fibrovascular markers in both models.

Methods: LiCNV was carried out using the Micron IV platform (532 nm, 300mW, 100 ms, 50 um spot size, 3 spots per eye) in 8-12 week old Col1-YFP reporter mice. After 7 days, a cohort of the mice received a second laser burn directly over the initial lesion. Mice were fundus imaged every 2-3 days using the YFP filter on the Micron IV to monitor the dynamics of collagen-producing cells infiltrating the CNV lesions. Retinal pigment epithelium flatmounts were harvested 2- and 3-weeks post LiCNV and stained for fibrotic markers, while retinas were harvested for ELISA, RT-PCR and flow cytometry analysis.

Results: Mice that received the two-stage LiCNV showed significantly larger Col1-YFP lesions from 7 days on and YFP was maintained for the 3 weeks post LiCNV induction. In contrast, much smaller Col1-YFP lesions were observed in mice receiving the one-stage LiCNV and YFP was diminished by 3 weeks post induction. Isolectin IB4 staining revealed a more complex networked vasculature in the two-stage lesions, accompanied with enhanced alpha smooth muscle actin and collagen-hybridizing peptide staining, indicative of increased EMT and collagen remodelling, respectively. Interestingly, flow cytometry showed negligible YFP positive cells in the retina in both LiCNV models, indicating that cells involved in collagen production were not in the retina, which was supported by RT-PCR data showing limited changes in EMT and fibrosis markers.

Conclusions: Overall, our in vivo and ex vivo data support the two-stage LiCNV model as a more suitable model for studying subretinal fibrosis over the traditional one-stage LiCNV model, which is better representative of a wound healing model.

ABSTRACT BODY:

Purpose: It is not known what determines the location of the preferred retinal locus (PRL) in patients with macular degeneration. In this study, we tested the hypothesis that binocularity requirements for correspondence play a role in establishing the PRL.

Methods: PRL locations of 101 patients (79±10 years old) with macular degeneration were recorded for both eyes (N=202 eyes) with the MP1 microperimeter, during short fixation tests. The better eye (BE) and the worse eye (WE) were identified from clinical charts. For each eye, the outcome measures were PRL distance from former fovea, polar angle, scotoma size, and fixation stability. Corresponding PRLs were those with the same polar angle and distance from former fovea in the BE and the WE.

Results: Two groups were identified based on the status of the BE: 1) functioning central retina (N=55) and 2) central scotoma (N=46). For group 1, the PRL in the BE was in the foveal proximity (within 1.1±1deg) and that in the WE was: A) on functioning, corresponding location (N=13), B) on functioning, non-corresponding location (N=16), and C) on corresponding, non-functioning location (N=26). No PRL was located further away in eccentricity in the BE to allow for a PRL on functioning and corresponding retinal location in the WE. The BE's outcome measures were equal to those of the WE in subgroup A, different in subgroup B, and different except for polar angle in subgroup C ($p < .05$). For group 2, the PRL in the BE was located eccentrically (6.9±3.4 deg from former fovea) and that in the WE was: A) on functioning, corresponding location in patients with equal scotomas in both eyes (N=15), and B) closer to a location corresponding to the PRL of the BE rather than to the former fovea in patients with unequal scotomas (N=19); C) in those with extensive scotomas in both eyes (size >20deg), the PRLs were generally not in correspondence and at extreme eccentricity suggesting limited functionality (N=12). The BE's outcome measures were equal to those of the WE in subgroup A, different except for polar angle in subgroup B, and different except for the fixation stability in subgroup C ($p < .05$).

Conclusions: In patients with functioning central retina in the BE, the PRL develops in the foveal proximity in this eye and likely drives binocular control. In those with central scotoma in the BE, the PRLs develop to maximize the binocular peripheral inputs from both eyes rather than to be at the closest location from the former fovea.

ABSTRACT BODY:

Purpose: To determine the long-term, all-cause mortality rate in patients with neovascular glaucoma (NVG) treated with tube shunt surgery (TS) in a tertiary referral center.

Methods: Retrospective cohort study of 320 eyes of 320 NVG patients who had TS from 1996-2019. Clinical and demographic data were recorded. Death dates were determined using publicly-available Internet data. Kaplan-Meier survival curves were created; subgroups were analyzed with a Bonferroni-corrected $p<.007$ for pre-operative visual acuity (VA), intraocular pressure (IOP), diabetes and complications (i.e. renal, cardiac, stroke, amputation), insulin dependency, and disease control and laterality. Multivariable regression was used to evaluate odds ratios adjusted for these factors.

Results: Median survival after TS was 9.24 years (range 0.00-23.81 years) with 50.7% (151/298 patients) 10-year mortality. Mean±SD patient age at first TS was 59.5±18.5 years; 42% were white, 29% were black. 188 (59%) patients had diabetes. Patients requiring additional ipsilateral treatment had lower mortality (HR=0.45, 95% CI 0.27-0.72; p=.001) and 27.7% (12/45 patients) 10-year mortality. In multivariable analysis, older age (OR= 0.90, 95% CI 0.85-0.94; p<.0001), insulin use (OR=0.25, 95% CI 0.06-0.81; p=.028), and white race (vs. black, OR=0.30, 95% CI 0.10-0.84; p=.028) were associated with increased mortality. Other variables were not associated with mortality in either analysis.

Conclusions: NVG has been suggested to negatively impact mortality. The 10-year, all-cause mortality rate for NVG patients who had TS is greater than 50% with median survival <10 years. This rate is worse than a historical control group of diabetic patients with minimal diabetic retinopathy, better versus ocular ischemic syndrome, and worsens with age and insulin dependency. These results may be useful for pre-operative counseling and decision-making. In conclusion, this retrospective analysis revealed that NVG patients requiring TS have poor long-term survival; older and insulin-dependent individuals exhibit worse mortality rates.

ABSTRACT BODY:

Purpose: To evaluate repeatability, reproducibility, and accordance between NITBUT, tear meniscus and meibography measurements within three different ocular surface imaging devices.

Methods: We performed an observational study on 66 healthy eyes. Tear meniscus, NITBUT (non-invasive tear break-up time) and meibography were measured using 3 types of corneal imaging devices: Keratograph 5M (Oculus, Wetzlar, Germany), Antares (Lumenis, Sidney, Australia) and LacryDiag (Quantel Medical, Cournon d'Auvergne, France). One-way ANOVAs and Welch ANOVAs were used to calculate correlation. Reliability and accordance between the tear meniscus and NITBUT were defined using Tukey Honest Significant Differences, Bonferroni corrections and plotted in Tukey mean difference plots. Accordance from meibography classification was analyzed by calculating Fleiss' Kappa Index and presented visually in Venn diagrams.

Results: We observed discordance between measurements of tear meniscus height between the three devices, $F_{2, 195} = 15.24$, $p<0.01$. Measurements performed with Antares were higher; 0.365±0.0851, than those with both the Keratograph5M and LacryDiag; 0.293±0.0790 and 0.306±0.0731. NITBUT measurements also showed discordance between devices, $F_{2,111} = 13.152$, $p < 0.01$. Measurements performed with LacryDiag were lower (10.4±1.82) compared to those obtained with Keratograph5M (12.6±4.01) and Antares (12.6±4.21). Fleiss' Kappa coefficient showed a value of -0.00487 for the upper lid and 0.128 for the inferior lid Meibography classification, suggesting discrete to poor agreement between measurements.

Conclusions: Depending on the device used and the parameter analyzed, measurements varied between each other, showing difference in image processing.

ABSTRACT BODY:

Purpose: Literature shows that the tolerance to residual refractive errors (TRE) varies for different intraocular lens (IOL) designs. While patients with multifocal IOLs generally do not tolerate residual astigmatism well, and astigmatism as low as 0.5 D to 0.75 D can affect their visual acuity, extended depth of focus (EDOF) IOLs are less sensitive with an acceptable threshold of residual astigmatism of approximately 1D. The purpose of this study is to preclinically evaluate the TRE of different IOL models.

Methods: Visual performance of an aspheric monofocal (M1), an aspheric monofocal designed to slightly extend depth of focus (M2), a diffractive bifocal (B) (+3.25D add power) and diffractive EDOF IOL designs were evaluated with corrected cylinder and in the presence of up to 1D of residual astigmatism. A set of 46 physiological model eyes that included higher order aberrations were used to predict the clinical defocus curves for the four IOL models. The percentage of eyes with 20/20 or better visual acuity (pVA) in the presence of residual defocus or astigmatism were considered as the metric to evaluate TRE.

Results: When all refractive errors are corrected, the pVA was similar for all lens models. In the presence of 0.5D of residual defocus, both monofocals and the EDOF design showed a greater tolerance, with up to 80%, 100% and 60% of patients having 20/20 VA or better, for M1, M2 and the EDOF IOL, respectively. With the same level of residual defocus, the pVA was reduced to 15% for the multifocal IOL, indicating a lower tolerance to residual defocus. When 0.75D of astigmatism was induced, the pVA was similar (96% for M1, 98% for M2 and 91% for the EDOF), while it was drastically reduced to 35% for the multifocal design, indicating a lower tolerance to astigmatism as well.

Conclusions: This study preclinically assessed the TRE of different IOL models. Computer simulations showed that the monofocal aspheric, the monofocal design to slightly extend depth of focus and diffractive EDOF IOLs preserve high levels of visual acuity in the presence of residual defocus and astigmatism, while multifocal IOLs are more sensitive to them, demonstrating the robustness of the diffractive EDOF IOL and the limited tolerance of multifocal IOLs, as reported in the literature. Therefore, this study validates the use of computer simulations to evaluate the TRE of IOLs.

TITLE: Dissection of the SDC1-GPR87 Coreceptor-Receptor Complex that Captures Tear Lacritin for Promotion and Restoration of Ocular Surface Homeostasis

SESSION TITLE: Corneal Cell and Molecular Biology | Corneal Development

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Dias Teixeira, G.W. Laurie, Cell Biology, University of Virginia, Charlottesville, Virginia, UNITED STATES|M. Adli, Northwestern University, Chicago, Illinois, UNITED STATES|J. Doench, Broad Institute, Cambridge, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Karina Luiza Dias Teixeira: Commercial Relationship: Code N (No Commercial Relationship) | Mazhar Adli: Commercial Relationship: Code N (No Commercial Relationship) | John Doench: Commercial Relationship: Code N (No Commercial Relationship) | Gordon Laurie: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Dry Eye Disease affecting 7- 10% of the world’s population is characterized by loss of ocular surface homeostasis yielding chronic inflammation. Lacritin is a prosecretory and regenerative tear (and apparently plasma and CSF) glycoprotein necessary for homeostasis and yet lacking in dry eye. Efficacy was recently validated in a 204-patient phase 2 clinical trial in Primary Sjögren's Syndrome dry eye. We also identified cornea-expressed 'G protein-coupled receptor 87' (GPR87) as the lacritin signaling receptor out of a genome-wide CRISPR/Cas9 death screen using C-terminal lacritin synthetic peptide N-94 as agonist and determined that GPR87 forms an agonist- independent complex with the cell surface heparan sulfate proteoglycan syndecan-1 (SDC1) - an interaction requiring glycosaminoglycan and mutual cytoplasmic domains. Here we further dissect the complex using mutation and peptide inhibition approaches.

Methods: Eleven different synthetic peptides corresponding to or together spanning each of GPR87's extracellular or intracellular strands or loops were introduced as soluble inhibitors at 20, 100 and 400 μM. Binding studies were performed out of GPR87 and SDC1 expressing cells treated with 25-, 50- or 100-mM chlorate to suppress sulfation, or with glycosaminoglycan assembly inhibitor 4-methylumbelliferyl-b-D-xylopyranoside (xyloside) at 0.01, 0.1 or 1 mM. SDC1 lacking 20 ('del 1-21'), 30 ('1-31') or 200 ('del 51-251') N-terminal amino acids was introduced to GPR87.

Results: Outer loop peptides - particularly outer loop 3, but no others, inhibited lacritin-GPR87 targeting. Chlorate and xyloside treatment each inhibited SDC1 - GPR87 coupling, in keeping with lack of binding when heparan sulfate could not be substituted at S15, nor chondroitin sulfate at S184 and S185, and new data pointing to the importance of elements within SDC1 amino acids 1 - 21, 1 - 31 and 51 - 252.

Conclusions: Lacritin targets the outer loop domains of GPR87 (particularly loop 3) as part of a preformed SDC1-GPR87 complex - the latter linked by glycosaminoglycans and by cytoplasmic SDC1 (PDZ binding) and GPR87 ('DRY') domains to regulate ocular surface health.

ABSTRACT BODY:

Purpose: Hyperopic defocus can accelerate eye growth in young eyes. Conversely, introduction of myopic defocus can slow eye growth and may counteract the grow signal from simultaneously present hyperopic defocus. Dual focus (DF) lenses for myopia control in children are designed to introduce myopic defocus. This study examined the optical impact of a DF contact lens during near viewing in a sample of children being treated with a DF lens.

Methods: Seventeen myopic children (14 to 18 years, mean ± SD: 16.61 ± 1.63 years) who had completed 3 or 6 years of treatment with a DF lens (MiSight 1 day, CooperVision, Inc., Pleasanton, CA) were fit bilaterally with a DF and a single vision (SV) contact lens (Proclear 1 day, CooperVision, Inc., Pleasanton, CA). Wavefront measurements along the visual axis of the right eye were acquired using a pyramidal aberrometer (Osiris, CSO, Italy) while subjects accommodated binocularly to high contrast letter stimuli (20/40 equivalent) at 6 target vergences (-0.25D, -1D to -5D in 1D steps). Wavefront error data were used to develop pupil maps of refractive error with each lens type.

Results: During near viewing, children fit with SV accommodated to achieve approximate focus in the pupil center but experienced up to 2D of hyperopic defocus in the pupil margins due to increasing levels of negative spherical aberration (C_4^0 changed from -0.27μm at distance to -0.76μm at near) and accommodative lag. With DF, children accommodated similarly achieving approximate focus in the pupil center. The +2D myopic defocus of the DF lens was sufficient to shift the mean defocus in the treatment zone from hyperopia (+0.75D) to myopia (-1.00D) at near (50 cm to 25 cm). The DF lens reduced the % of hyperopic defocus (≥ +0.75D) in the foveal image from 50% to 28% over these target distances leading to an increase in myopic defocus (≤ -0.50D) from 18% to 40%. Lowering the criteria for defocus to > ±0.25D, increased the % of defocused light (65% to 45% for hyperopia and 24% to 47% for myopia), but the shift towards myopic defocus created by the DF lens remained.

Conclusions: The DF contact lens did not alter the accommodative behavior of children. The +2D myopic defocus in the treatment zones successfully removed hyperopic defocus and introduced myopic defocus in the foveal image. These results are consistent with the hypothesis that myopia control with this DF design is achieved by the added myopic defocus.

ABSTRACT BODY:

Purpose: Prior studies report impressive diabetic retinopathy (DR) detection performance using deep learning systems (DLS). However, the utility of DLS for predicting DR and maculopathy progression is unknown. Predicting DR progression could enable individualised, risk-based follow-up or interventions via the early identification of high and low-risk individuals. We aimed to develop multimodal DLS to predict progression to referable DR and maculopathy over 1, 2 and 3 years using curated, two-field retinal images and screening data.

Methods: From 202 928 eyes of 102 446 patients attending the Southeast London Diabetic Eye Screening Programme (Sept 2013 to Dec 2019), 124 418, 89 360 and 71 125 eyes with 1, 2 or 3-year follow-up data were eligible. DLS outcomes were incident (1) referable DR, (2) referable maculopathy or (3) either during follow-up. Detection of any DR at baseline was an auxiliary training task. Inputs were macula/nasal images and screening data (age, gender, ethnicity, diabetes type, diabetes duration, visual acuity and deprivation rank). Data from 68 980 eyes without eligible follow-up were used for DLS pretraining. Image and screening data DLS were developed independently and ensembled for test predictions.

Results: Screening data DLS area-under-the receiver operating characteristic curve (AUROC) for referable DR, maculopathy or either at 2 years were 0.760 (0.684-0.836), 0.733 (0.705-0.761) and 0.733 (0.705-0.760). Image DLS AUROC for referable DR, maculopathy or either at 2 years were 0.898 (0.846-0.951), 0.820 (0.793-0.847) and 0.824 (0.798-0.849). Multimodal DLS AUROC for referable DR, maculopathy or either at 2 years were 0.916 (0.873-0.959), 0.842 (0.819-0.866) and 0.845 (0.823-0.867). Generally, DLS had lower AUROC for all outcomes if initialised without pretraining. Compared to 2-year outcomes, DLS AUROC was higher for 1-year but lower for 3-year intervals.

Conclusions: DLS accurately predicts progression to referable DR and maculopathy using retinal images with modest improvements with additional screening data. Developed DLS for predicting DR or maculopathy progression could enable individualised, risk-based follow-up or interventions with significant time/cost savings for DR screening services/low-risk patients and more timely referrals for high-risk patients.

ABSTRACT BODY:

Purpose: The RPE serves as the blood/retina barrier and facilitates removal of metabolic byproducts from the subretinal space to the choroid. Slc16a8 (Mct3) is an RPE-specific proton coupled monocarboxylate transporter responsible for lactate export identified by human genetic analyses to be associated with age-related macular degeneration (AMD). We investigated the loss of Slc16a8 under constant light exposure (CLE) conditions as a potential stress model, similar to that seen in aging patients, to gain new functional insights into AMD pathobiology.

Methods: Mice with CRISPR mediated deletion of Slc16a8 were used to generate 10-week old $Slc16a8^{-/-}$ (n=6), $Slc16a8^{+/-}$ (n=13), and $Slc16a8^{+/+}$ (n=8) mice. Full-field ERGs (150 $cd*s/m^2$) were measured at baseline and after CLE to determine photoreceptor, bipolar, and RPE cell function using a-, b-, and c-wave amplitudes. OCT was measured at baseline and after CLE to evaluate retinal thickness. Mice were subjected to a CLE of 100k lux for 7 days to induce retinal degeneration.

Results: At baseline (Fig. 1A), eyes from $Slc16a8^{-/-}$ mice had decreased a-, b-, and c-wave amplitudes compared to $Slc16a8^{+/-}$ and $Slc16a8^{+/+}$ eyes (all $p<0.0001$). Eyes from $Slc16a8^{+/-}$ mice had decreased a- ($p=0.0002$) and c-waves ($p=0.01$) compared to $Slc16a8^{+/+}$ eyes. No differences in retinal thickness between genotypes at baseline were found. After CLE, all eyes had decreased a- and b-waves ($p<0.0001$). Retinas from $Slc16a8^{+/-}$ and $Slc16a8^{+/+}$ thinned after CLE ($p<0.0001$), but eyes from $Slc16a8^{-/-}$ slightly thickened ($p=0.011$). Eyes from $Slc16a8^{+/-}$, but not $Slc16a8^{-/-}$, mice showed more loss of a- and c-waves and more retinal thinning compared to eyes from $Slc16a8^{+/+}$ mice (Fig. 1B, $p=0.0002$, 0.002, and <0.0001).

Conclusions: Slc16a8 (Mct3) is necessary for retinal function, but does not affect retinal morphology prior to CLE. After CLE, eyes with complete loss of Slc16a8 do not have increased RPE cell dysfunction, but appear to have retinal edema, perhaps due to proton coupled lactate buildup. Mice with partial loss of Slc16a8 are prone to more photoreceptor and RPE cell dysfunction and more retinal thinning after CLE. These results show that Slc16a8 is key for proper retinal function, both before and after the CLE model of stress-induced retinal degeneration.

ABSTRACT BODY:

Purpose: Vascular endothelial growth factor-A (VEGF-A) orchestrates endothelial cell (EC) phenotypic heterogeneity to drive vessel formation; however, we are only beginning to understand how VEGF-A signaling coordinates pericyte (PC) investment. Here, we identify how VEGF-A signaling regulated by VEGF-A decoy receptor Flt-1 (VEGFR-1) affects PC coverage in an in vivo model of angiogenesis, thereby guiding the pursuit of therapeutic targets for sight-threatening diseases. We hypothesize that a VEGF-A signaling gain-of-function, through loss of Flt-1, reduces PC coverage along forming retinal vessels.

Methods: We dissected, stained, imaged, and analyzed postnatal day 7 mouse retinas (N=3) that underwent EC-specific conditional deletion of Flt-1. Presence of a conditional reporter signal, TdTomato, was presumed to correlate with Flt-1 loss. Neural/glial antigen-2 (NG2) antibodies labeled PCs, and platelet-endothelial cell adhesion molecule-1 (PECAM-1) antibodies marked ECs. PC coverage of retinal vessels and TdTomato signals were visualized by confocal. ImageJ facilitated mosaic analysis of (i) TdTomato normalized to PECAM-1 and (ii) NG2 relative to PECAM-1 in regions containing high/low TdTomato. Initial statistical analysis included paired two sample t-tests.

Results: There was a significant difference in the overall TdTomato between areas of high and low TdTomato signal (p-value=0.0025); these differences likely reflect a change in localized Flt-1 deletion within selected regions. PC coverage was significantly higher in regions with high TdTomato and presumed increased Flt-1 deletion compared to areas assumed to lack substantial Flt-1 deletion (i.e., low TdTomato) (p-value=0.035).

Conclusions: In contrast to our initial hypothesis, mosaic analysis of retina areas presumed to contain widespread Flt-1 deletion showed increased PC coverage. VEGF-A signaling, likely elevated by Flt-1 loss, may increase PC investment in remodeling retinal vessels. This observation demonstrates that mis-regulated VEGF-A signaling may aberrantly shift PC coverage, thus, dysregulating vascular growth. Diseases such as diabetic retinopathy are characterized by abnormal VEGF-A signaling and vascular growth, fueling blindness. By investigating context-dependent changes in vascular components, new therapeutic targets may be identified for sight-threatening diseases.

ABSTRACT BODY:

Purpose: Retinoblastoma (Rb) is a malignant tumour of developing retina with a typical presentation occurring during the first five years of life. Caused in more than 97% of cases by biallelic inactivation of the RB1 tumour suppressor gene, the frequency of Rb is estimated at about 1 in 15,000 live births. Despite the progress in treatments, and high survival rate in developed countries Rb survivors are left with impaired vision having a negative effect on correct motion processing, depth perception and judging distances. Patients can suffer hearing loss, cataracts, cosmetic deformities as well as a neurocognitive deficit. The urgent need to introduce novel treatments warranted our study to develop and characterise a 3D in vitro model of Rb for drug discovery, repurposing and testing.

Methods: We generated a patient-specific iPSC model (c.2082delC) encompassing the heterozygous ($RB1^{+/-}$), homozygous ($RB1^{-/-}$) and fully corrected isogenic control. We compared the retinal organoids established from the patient-specific iPSC model to those derived from the RB1 knock-out hESC line applying single cell RNA-Seq analysis combined with IHC, TEM, western-blot and colony-forming assay.

Results: Both pRB-depleted models presented significant enrichment in proliferating cone precursors ($RXR\gamma^{+}Ki67^{+}$), defined as Rb clusters by single cell RNA-Seq analysis and displayed tumorigenic features, including mitochondrial cristae aberrations and rosette-like structures. Cells isolated from pRB-deficient organoids were able to undergo growth in an anchorage-independent manner, indicative of cell transformation in vitro. Importantly, the pRB-depleted models, showed an accumulation of retinal progenitor cells at the expense of amacrine, horizontal and retinal ganglion cells, indicating an important role for retinoblastoma protein in the differentiation of these cell lineages. Remarkedly, Rb cells expressed retinal ganglion and horizontal cell markers in addition to cone markers, a novel finding which could help to better characterise these tumours with possible therapeutic implications.

Conclusions: Our data provide robust evidence that pRB-depleted organoids mimic the development and malignant transformation that occurs in vivo, providing a powerful tool for novel drug screening and further retinoblastoma analysis.

ABSTRACT BODY:

Purpose: Older adults, especially those with visual impairments are at risk of falls. Executive functions decline with age and dual-task studies have demonstrated an increase in the postural instability of older adults when performing a cognitive task. However, less is known about the role of cognitive load on the postural stability in visually impaired older adults. The current study examines the separate and combined role of cognitive load and visual impairment on postural stability in older adults.

Methods: A total of 57 normally sighted participants (NSP; M_{age} = 69.7), and 31 visually impaired participants (VIP; M_{age} = 82.5) were included. Measures of postural control (total displacement and mediolateral [ML] movement) were obtained during a static balance task using a Wii Balance Board under normal vision conditions, and by 17 VIP (M_{age} = 80.7), and all 57 NSP while performing a cognitive task (serial-3 subtraction). In addition, the NSP performed all tasks under simulated visual impairment with a visual acuity simulated to either 20/80 (n = 27) or 20/200 (n = 30).

Results: The VIP had greater ML movement compared to NSP under normal vision conditions ($t(39.1) = 3.78$, $p = <.001$, $d = 0.91$) and this difference remained even under simulated impairment conditions (20/80: $p = .001$; 20/200: $p = .002$). With the cognitive task introduced, VIP increased in total displacement ($t(16)$, $p = 0.01$, $d = -0.63$) and NSP increased in both total displacement ($W = 47$, $p = <.001$, $r = -0.94$) and ML movement ($W = 140$, $p = .001$, $r = -0.46$). With the introduction of the cognitive task, the difference in ML movement between VIP and NSP was no longer found regardless of the visual condition NSP were in.

Conclusions: Visually impaired participants had greater ML movement compared to NSP. Movement in the ML direction indicates the use of a hip strategy, which has been associated with increased fall risk. This may point to additional factors contributing to differences in postural control in VIP besides decreased visual function. Given that the NSP experienced a similar increase in ML movement once a cognitive task was introduced, these factors in question may be related to changes in task prioritization and sensory reweighting that the VIP have adopted over time. This can have implications in the type and timing of mobility interventions used for the visually impaired.

ABSTRACT BODY:

Purpose: To evaluate the impact of scleral lens size and scleral lens wear duration on the intraocular pressure (IOP) of the central cornea and sclera.

Methods: Subjects presenting with no active ocular diseases were recruited for this randomized and crossover study. Each subject wore bilaterally scleral lenses of fluorosilicone acrylate material with two lens diameters (15.6mm and 18.0mm) for 5 hours on two separate days. IOP was measured with the pneumotonometer (Model 30^{TM}, Reichert Technologies, Inc., Buffalo, New York) at the central cornea before and after scleral lens wear, and at the superotemporal sclera 4mm from the limbus before, after, and during 5 hours of scleral lens wear. The primary outcome measure was the change from baseline (i.e., pre-lens insertion) scleral IOP at four predetermined time intervals: 1) immediately after lens insertion, 2) 2.5-hr post-lens insertion, 3) 5-hr post-lens insertion, and 4) immediately after lens removal. Diurnal variations of each subject's corneal and scleral IOP were also determined at a separate day without lens wear.

Results: Seventeen subjects with mean (SD) age of 26.1 (8.5) years completed the study. There was no significant diurnal variability of both IOPs during the 5-hour visit without lens wear ($p>0.05$). The mean [95% CI] changes of corneal IOP after 5 hours of wear for 15.6 mm and 18.0mm lenses were -0.3 [-0.7, 0.1] mmHg and 0.0 [-0.6, 0.6] mmHg, respectively. Both lens diameters did not affect the corneal IOP after 5-hr lens wear ($p>0.05$). The mean [95% CI] changes of scleral IOP were 0.9 [0.2, 1.6] mmHg immediately after lens insertion, 1.6 [0.8, 2.3] mmHg after 2.5-hr lens wear, 1.1 [0.4, 1.9] mmHg after 5-hr lens wear, and 0.2 [-0.4, 0.8] mmHg immediately after lens removal with small-diameter lenses, compared with -0.1 [-1.0, 0.8] mmHg, 1.4 [0.5, 2.3] mmHg, 0.8 [0.0, 1.6] mmHg, and -0.2 [-1.0, 0.6] mmHg with large-diameter lenses. Both lens diameters did not affect the scleral IOP after 5 hours of wear ($p>0.05$). However, 73.5% of the scleral IOP measurements increased at 2.5 hours after lens insertion with 15.6mm lenses ($p=0.021$) and with 18.0mm lenses ($p=0.074$).

Conclusions: The intraocular pressures of healthy eyes restored to the baseline values after 5 hours of scleral lens wear. The smaller scleral lens size induced a statistically but not clinically signficiant increase in scleral IOP at 2.5 hours after lens insertion.

ABSTRACT BODY:

Purpose: Retinal gene therapy using messenger RNA (mRNA) therapeutics is a promising strategy to induce transient (days-months) protein expression in the retina. However, only few mRNA-lipid nanoparticles reach the retina after intravitreal delivery due to the presence of the vitreous and the inner limiting membrane. We explore the use of self-amplifying mRNA (saRNA) that, as a result of its self-replicative nature can be effective at lower doses, making it an interesting candidate to achieve protein expression in difficult to reach tissues, like the retina.

Methods: The ability of mRNA and saRNA to induce protein expression was compared using the carrier MessengerMAX® in a dose titration experiment. Furthermore, two strategies were tested to limit immune activation and enhance protein expression: i) cellulose-based purification to remove double-stranded RNA byproducts, ii) type I IFN decoy receptor B18R. All transfections were performed in ARPE-19 and Müller (MIO-M1) cells (eGFP expression, flow cytometry), and ex vivo on bovine explants (luciferase expression, bioluminescent imaging) (n=3). Immune responses were measured with a LEGENDplex assay.

Results: In the dose titration experiment, we found that a low dose, saRNA outperformed mRNA in terms of eGFP expression, while at a high dose, saRNA seemed to lose its self-replicative advantage as a comparable dose of non-replicative mRNA induced more expression. This was attributed to the immunogenicity of saRNA as a gradual increase in the secretion of innate immune-related cytokines (IL-1β, IL-6, TNF-α, IFN-β, IFN-λ1, IFN-λ2/3) was observed with an increasing dose of saRNA. The immunogenicity of saRNA could be reduced by cellulose purification and addition of B18R. Moreover, cellulose purification of saRNA led to 274x and 66x more eGFP expression in ARPE-19 and MIO-M1 cells respectively, compared to its standardly purified counterpart (silica-membrane columns). B18R increased expression 2.4-times in ARPE-19 cells. Similarly, cellulose purification of saRNA led to a 6-fold increase in retinal luciferase expression in bovine explants.

Conclusions: Overall, saRNA has potential to induce protein expression in the retina provided that measures to temper its innate immune-stimulating activity, like cellulose-based purification and combination with an immune inhibitor (e.g. B18R), are taken into account.

ABSTRACT BODY:

Purpose: MD or a simulation of it induces an adaptive eye behaviour to compensate central visual loss: eccentric viewing. Extended reality (XR) tools are currently presented binocularly to assist eccentric viewing. Recent studies showed effective assistance of eccentric viewing behaviour with monocular peripheral assistance. How monocular and binocular peripheral augmentations affect eccentric viewing is unknown.

Methods: Participants played a 2D Pong game in virtual reality (VR) requiring tracking a 3° moving ball. A circular scotoma was gaze-contingently simulated, and it covered 12° of the central visual field. Five different augmentations were concentrically applied at 7.5° away from the simulated scotoma's edges. A 2° broad black ring, an area of 7.5° diameter, either blurred in or out were applied monocularly to the dominant eye. Zoom and fisheye distortions strategies were applied binocularly. Six participants were tested for each augmentation type in three different conditions: control, assisted scotoma, and scotoma simulation. For every condition, the median gaze-target distance was calculated. Kruskal–Wallis and post-hoc Dunn-Šidák tests were used to investigate the effect of condition type over median gaze-target distance. Polar histograms were used to analyse gaze directionality.

Results: All peripheral augmentations tested induced a significant change in gaze-target distance between conditions (ring: χ^2 (2) = 11.47, p = 0.003; blur-out: χ^2 (2) = 8.43, p = 0.01; blur-in: χ^2 (2) = 8.22, p = 0.02; zoom: χ^2 (2) = 11.94, p = 0.003; fisheye: χ^2 (2) = 8.29, p = 0.02). The post-hoc Dunn revealed that the scotoma condition was significantly different from the normal condition when presented after the ring (p=0.006), blur-out (p=0.01), blur-in (0.01), zoom, (p=0.003), and the fisheye (p=0.01) augmentation. Only after the monocular augmentations, the target was always kept visible throughout all blocks during the scotoma condition. Polar histograms indicated an upwards gaze-directionality for the ring and the zoom. Both monocular blurring augmentations had a back-and-forth strategy between the upper left and right hemisphere (Table 1).

Conclusions: Monocular or binocular peripheral assistance differently influenced the eccentric gaze-behaviour of simulated MD participants. Blurring and ring augmentations seem to better improve eccentric viewing over magnification ones, even when applied monocularly.

Bispo, Harvard Medical School Department of Ophthalmology, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Camille Andre: Commercial Relationship: Code N (No Commercial Relationship) | Michael Gilmore: Commercial Relationship: Code N (No Commercial Relationship) | Paulo Bispo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Antimicrobial resistance (AMR) in microbial keratitis is a concerning issue that can result in treatment failure and poor visual outcome. The aim of this study was to characterize phenotypically and genomically the AMR patterns of gram-positive bacteria (GPB) isolated from keratitis at Massachusetts Eye and Ear from 2014 to 2017.

Methods: Whole Genome Sequencing was performed on 161 GPB keratitis isolates using Illumina HiSeq. Molecular typing was performed by MLST. CARD algorithm was used to identify genes and mutations that confer AMR. Minimum inhibitory concentrations were determined by broth microdilution.

Results: Staphylococcus aureus was the most common pathogen (53.4%) and its population structure was dominated by lineages grouped within the clonal complex 5 (32.6%), which includes epidemic MRSA strains commonly associated with multidrug-resistant (MDR) infections. Compared with methicillin-susceptible S. aureus, resistance to other antibiotics was more prevalent among MRSA isolates, with rates of resistance higher than 70% for fluoroquinolones (FQ) and azithromycin. The newest FQ (besifloxacin and moxifloxacin) had lower MIC_{90} overall compared with the earlier ones. More than 30% of coagulase-negative Staphylococcus were resistant to FQ and half of them were resistant to azithromycin (52.9%). We found between 2 and 4 mutations in the quinolone resistance-determining regions (QRDR) of gyrA and parC genes for staphylococci isolates (21.7% of S. epidermidis and 25.0% of S. aureus). 52.1% of S. epidermidis and 22.1% of S. aureus were MDR. CARD analysis revealed that 26.7% of S. aureus co-harbored ant(9)-Ia and ermA genes that confers resistance to aminoglycosides, and to macrolides, lincosamides and streptogramin B, localized in a Tn554 transposon, whereas macrolide resistance in S. epidermidis was frequently associated with mphC/msrA genotype. S. epidermidis were also positive for the dfrC (82.6%) and tetK genes (21.7%) which confers resistance to diaminopyrimidine and tetracycline respectively. Among S. pneumoniae isolates, resistance rates were less than 10% to all antibiotics tested except for ofloxacin (14.4%), azithromycin (30.8%) and penicillin (30.8%).

Conclusions: We provided an overview of current rates of resistance to antibiotics commonly used to treat keratitis caused by GPB and a characterization of the diversity of the associated molecular mechanisms that confer antimicrobial resistance.

TITLE: Canonical and non-canonical EphA2 signaling in the lens

SESSION TITLE: Lens development and differentiation

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: C. Cheng, School of Optometry and Vision Science Program, Indiana University, Bloomington, Indiana, UNITED STATES|

Commercial Relationships Disclosure: Catherine Cheng: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Eph-ephrin bidirectional signaling is essential for lens transparency, and mutations in the EphA2 receptor and ligand ephrin-A5 cause a variety of cataracts in humans and mice. Eph receptor canonical signaling is induced by ephrin ligand binding leading to autophosphorylation on tyrosine residues (Y588 on EphA2) and increased kinase activity. EphA2 can also signal in a non-canonical ligand-independent manner that depends on phosphorylation of S897, leading to increased cell invasion and EMT. We determined whether there is canonical and/or non-canonical activation of EphA2 in the lens and whether non-canonical EphA2 signaling is increased in ephrin-A5 knockout (KO) lenses.

Methods: Specific antibodies to detect phosphorylated isoforms of EphA2 were used for capillary electrophoresis Westerns and immunostaining and confocal microscopy to examine control, ephrin-A5 KO and EphA2 KO mouse lenses. Lack of signal in EphA2 KO samples were used to verify antibody specificity.

Results: Capillary electrophoresis Westerns revealed EphA2 is present in the epithelial and cortical fiber lysates from control and ephrin-A5 KO lenses. Canonical ligand-mediated activation of EphA2 due to phosphorylation at Y588 is only detected in the epithelial cell fraction. Surprisingly, non-canonical ligand-independent activation of EphA2 at S897 is detected weakly in the epithelial cell fraction and strongly in the cortical fiber cell fraction. In ephrin-A5 KO samples, we detected increased non-canonical phosphorylation of EphA2 in the epithelial and cortical fiber cell lysates. Using immunofluorescence staining, in control and ephrin-A5 KO lens sections, we found pEphA2-Y558 staining is restricted to epithelial cells while pEphA2-S897 staining is mainly observed in mature lens fibers in the lens cortex.

Conclusions: In summary, both canonical and non-canonical EphA2 signaling are active in the lens. This is the first demonstration of physiological, rather than pathological, non-canonical activation of EphA2 in a normal tissue. Increased non-canonical EphA2 activation due to loss of ephrin-A5 indicates EphA2 and ephrin-A5 may interact in a subpopulation of lens cells, consistent with our recent findings showing EphA2 KO and ephrin-A5 KO lenses have a similar suture patterning defect and lens resilience alteration. Diverse activity EphA2 in different lens cell populations may explain the variability of human lens phenotypes associated with EphA2 mutations.

ABSTRACT BODY:

Purpose: Previous studies have shown differences in peripheral refractive errors between phakic and pseudophakic eyes and tested the impact on peripheral contrast sensitivity using an adaptive optics (AO) visual simulator. In this study, peripheral contrast sensitivity and peripheral refractive errors were measured in age-matched phakic and pseudophakic human eyes in a clinical setting.

Methods: Peripheral contrast sensitivity at 20 degrees of the nasal field of view was measured monocularly in photopic lighting conditions in two age-matched groups of phakic (29 eyes) and pseudophakic (31 eyes) subjects wearing their best on-axis distance correction. The mean age of the subjects was 64 years (range: 57 to 75 years) and all pseudophakic eyes had the same monofocal IOL model implanted. Central and peripheral refractive errors were measured for the same eyes at 30, 20, 10 and 0 degrees of the nasal and temporal field of view using the Grand Seiko and the Complete Analysis System Aberrometer (COAS).

Results: The difference in peripheral contrast sensitivity between the phakic and the pseudophakic group, 0.21 log units, was statistically significant (p=0.007). The M and J0 values at that eccentricity were -0.5±0.7D and -0.7±0.4D for the phakic group, and -1.1±1.3D and -1.1±0.4D for the pseudophakic group measured with the Grand Seiko. Differences in peripheral aberrations were statistically significant in this study but lower than previously reported in the literature. Peripheral contrast sensitivity was also statistically significantly correlated with the amount of peripheral blur quantified by M+J0 (R2=0.32 and p=0.023). Additionally, good correlation was found between the peripheral refractive errors measured with the Grand-Seiko and the COAS devices (R2 = 0.83 and 0.93 for M and J0 respectively).

Conclusions: This study found a significant correlation between peripheral contrast sensitivity and peripheral refractive errors measured in age-matched phakic and pseudophakic eyes. The results of this study showed a good agreement between the peripheral contrast sensitivity differences measured between phakic and pseudophakic eyes and the value predicted using an AO system to simulate similar optical conditions [Venkataraman et al, BOE 2021].

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) is the most common cause of blindness in the middle age group. Therapies targeting early stages of DR are urgently needed. One of the earliest changes in DR is endothelial basement membrane thickening, via extracellular matrix (ECM) deposition. The current study tests the hypothesis that bone morphogenetic protein 2 (BMP2) participates in ECM deposition in early DR, representing a possible therapeutic target.

Methods: We evaluated levels of fibronectin in human retinal endothelial cells (HRECs) treated with BMP2 or High glucose (HG) in presence or absence of BMP2 or VEGF inhibitors (LDN1, 100 nM and SU5416, 10μM respectively). We injected wild type mice intravitreally with BMP2 (50ng/ml) or its vehicle (n=4/group). One week later, Western Blot (WB) analysis of retinal fibronectin was performed. Injected mice were also used to prepare flat-mounted retinas co-stained with Isolectin B4 and fibronectin. Conditional endothelial knockout (cKo) mouse model was generated, with deleted BMP receptors (ALK2/3) in endothelial cells. ALK2/3 cKo mice and their littermate controls with/without diabetes of 8 weeks duration (n=3-4 /group) were evaluated with fluorescein angiogram (FA) followed by retinal RT-PCR for inflammatory, apoptotic and fibrotic markers. The results are expressed as means ± SEM. One-way ANOVA or two-tailed t test were used for statistical analysis. Results were considered significant for $p < 0.05$.

Results: BMP2 significantly upregulated fibronectin in HRECs ($p=0.012$). Inhibition of BMP signaling but not VEGF significantly attenuated HG-induced fibronectin production ($p=0.0013$). BMP2 injected mice showed a dense membrane of fibronectin obscuring retinal vessels in flat mounted retinas and also a significant increase of fibronectin levels ($p= 0.0013$) compared to the vehicle injected eyes evaluated by WB. Apoptotic markers; caspase-3 and Fas Ligand mRNA levels were significantly increased with diabetes ($p< 0.05$); however, Fas ligand levels were restored to normal in retinas of diabetic ALK2/3 cKo mice. FA didn't detect any significant vascular changes in diabetic ALK2/3 cKo mice.

Conclusions: BMP2 induces ECM deposition and promote apoptosis which may contribute to microvascular dysfunction and permeability during DR. BMP2 could be a possible therapeutic target for early stage DR.

ABSTRACT BODY:

Purpose: Leber congenital amaurosis type 9 (LCA9) is a blinding retinal degenerative disease characterized by early childhood onset associated with a mutation in the gene coding for nicotinamide mononucleotide adenylyltransferase 1 (NMNAT1). We demonstrated in mice that a germline NMNAT1 null mutation caused photoreceptor degeneration that was prevented by concurrently knocking out the inducible NAD^+ cleavage enzyme, sterile alpha and TIR motif containing 1 (SARM1). We aim to assess the viability of knocking down SARM1 in other retinal degeneration and NMNAT1 mutation models to explore the relevance of SARM1 as a therapeutic candidate to prevent retinal degeneration.

Methods: SARM1 knockout mice were crossed with NMNAT1 floxed CAG-CreERT2, NMNAT1 E247K, rd10, and RhoP23H mice respectively to create SARM1 double knockout mice with different retinal degeneration models. A SARM1 dominant negative expressing AAV7m8 (SARM1DN) was injected intravitreally as a tractable modality of SARM1 knockdown in the aforementioned models. Mice were characterized for retinal phenotypes using funduscopy/optical coherence tomography (OCT), in vivo electroretinography (ERG), and histology.

Results: ERG (n=7) showed no appreciable scotopic a and b, and photopic b waveforms 33 days post-tamoxifen injection in NMNAT1 KO while NMNAT1/SARM1 KO showed no significant changes compared to wild-types. Hematoxylin and eosin (H&E) staining of retina sections and OCT imaging of NMNAT1 KO mice showed outer nuclear cell loss unseen in imaging of NMNAT1/SARM1 double knockout retinas. NMNAT1 KO mice injected with SARM1DN showed transient preservation of ERG waveforms 1 week after injection that is undetectable 18 days after injection. RhoP23H mice 10 weeks after SARM1DN injection showed no ERG (n=3) significant differences in scotopic waves, but showed significant differences in 15, 20, and 25 dB intensities of photopic measurments by Bonferroni multiple comparisons test. ERG (n=3) of rd10/SARM1 KO showed no appreciable waveforms.

Conclusions: SARM1 inhibition directly plays a role in NMNAT1 null related retinal degeneration. SARM1DN can be a promising tool to test for relevance of SARM1 in models of retinal degeneration. SARM1 may play a role in cone preservation in RhoP23H degeneration. Further investigation is warranted to test the relevance of SARM1 in other models of degeneration.

TITLE: Social Media Evaluation of Seasonal and Geographic Trends of Corneal Ulcers in the United States

SESSION TITLE: Corneal epithelial biology and repair mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.H. Choi, E. Ong, W. Munir, Department of Ophthalmology and Visual Sciences, University of Maryland School of Medicine, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Jamie Choi: Commercial Relationship: Code N (No Commercial Relationship) | Erin Ong: Commercial Relationship: Code N (No Commercial Relationship) | Wuqaas Munir: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Prior studies have examined social media and internet-based search data to study epidemiological factors of infectious eye diseases. None have looked at infectious keratitis. The purpose of this study is to if social media and Google search data could identify seasonal and geographic trends in the incidence of corneal ulcers in the United States.

Methods: This is a case series of all corneal ulcer-related data collected from two major social media websites and Google trends from 2017 to 2021. Instagram and Twitter were searched for posts and hashtags related to “corneal ulcer.” Web and image search volume of “corneal ulcer” were collected from Google trends (https://trends.google.com). Data was compared between seasons, defined by 3-month intervals, and chi-square tests used to determine statistical significance.

Results: 165 individuals (79% female) and 164 individuals (79% female) posted personal new corneal ulcer diagnoses on Twitter and Instagram, respectively. Summer resulted in the highest number of both Twitter (34%, p=0.07) and Instagram (33%, p=0.68) posts. Similarly, summer was the most popular season for Google web and image searches of “corneal ulcer” (search volume average of 58.4 and 41.2, p=0.74 and p=0.01, respectively, with 100 being peak popularity). Of the 66 Twitter posts with available geographic data, 14% comprised New York residents. Of the 71% Instagram posts with available geographic data, 18% were from California residents. Both Google Web and Image searches were evenly distributed between most states, averaging about 2-4%. Across all platforms, the South was the most represented (32% Twitter, 38% Instagram, 32% Google Web, 33% Google Images).

Conclusions: Our results indicate that social media and Google trends may reflect seasonal and geographic patterns of corneal ulcer incidence in the US. However, further study with increased power is needed.

ABSTRACT BODY:

Purpose: To study the efficacy and long-term effects of infliximab and adalimumab in patients with active refractory non-infectious intermediate, posterior or panuveitis (NIPPU).

Methods: Retrospective, longitudinal study.

Results: Included were 61 patients (104 eyes) of whom 34 were males (55.74%). Mean age at diagnosis of uveitis was 26.5±16.14 years. All patients had active uveitis at baseline (time of biologic therapy initiatoin). Median interval between start of conventional immunomodulatory therapy (IMT) to introduction of biologic therapy was 13.0 (IQR 26.0) months. Ocular inflammation was effectively controlled in 92 eyes (88.46%).The most commonly used TNF-α inhibitor was adalimumab in 47 patients (77%). In the year preceding the institution of TNF-α inhibitors, average number of flares was 1.5 ±1.1 /year and it decreased to 0.08 ±0.29/year in the first year after baseline ($p<0.0005$). Forty-four eyes (42.30%) experienced flare over the entire period. Mean time to first flare was 14.5±9.26 months. At baseline, mean dose of prednisone was 25.5-±20.8 mg/day. Marked decrease to mean prednisone dose of 7.85±9.7 mg/day was observed at 6 months ($p=0.03$). In patients treated with adalimumab, mean time to prednisone dose of 7.5 mg/day was 4.02±4.89 months compared to 15.64±21.34 months in patients treated with infliximab ($p =0.03$). Eyes treated with adalimumab experienced first flare at a mean time of 14.11±6.29 months whereas eyes treated with infliximab experienced first flare at 18.29±14.24 months after baseline ($p<0.0005$). The risk for moderate and severe visual loss was lower with shorter duration of uveitis before initiating anti-TNF-α treatment (odds ratio, 0.003; 95% CI, 0.000-0.005; $p=0.023$), better presenting logMAR VA (odds ratio, 0.266; 95% CI, 0.172-0.361; $p <0.0005$) and when adalimumab was used (odds ratio, 0.354; 95% CI, 0.190-0.519, $p <0.0005$).

Conclusions: Anti-TNF-α therapy was successful in controlling refractory NIPPU. It significantly reduced flare rate, exerted steroid-sparing effects and preserved visual potential. Both adalimumab and infliximab exhibited similar effectivity in controlling active inflammation and flare-ups with adalimumab exerting faster and bigger steroid-sparing effects. Adalimumab use, better initial visual acuity and earlier introduction of anti-TNF- α therapy were associated with a lower risk of visual loss.

ABSTRACT BODY:

Purpose: Glaucoma is one of the leading causes of blindness. Elevated intraocular pressure (IOP) is the major risk factor of glaucoma. The TGFβ2-induced ocular hypertension mouse model has been widely used to study the pathological changes in the glaucomatous trabecular meshwork (TM). Since most of the published studied used old and female mice with $2.5X10^7$ PFU Ad5-CMV-TGFβ2 virus, in this study, we determined if age and sex affect IOP in this well-established ocular hypertensive mouse model.

Methods: We used young (3 month, n=14) and old (5 month, n=10) male C57BL/6J mice. One eye was injected intravitreally with Adenovirus expressing human TGFβ2 (Ad5-CMV-TGFβ2) at $2.5X10^7$ PFU or $5.0X10^7$ PFU and the fellow eye with the same amount of Ad5-CMV-GFP adenovirus as a control. IOP was measured up to 11 weeks. At the end of the study, the mice were euthanized and the eyes were used for ELISA, qPCR and immunofluorescent staining.

Results: We observed a significant IOP elevation in both 3 and 5 month old male mouse eyes injected with $5.0X10^7$ PFU Ad5-CMV-TGFβ2. However, 5 month old male mice respond early with higher IOP compared to 3 month old male mice. In contrast, no IOP elevation was observed in either groups of mouse eyes treated with $2.5X10^7$ PFU Ad5-CMV-TGFβ2. ELISA and qPCR showed a robust expression of human TGFβ2 expression in the aqueous humor in Ad5-CMV-TGFβ2 injected eyes. Similarly, immunofluorescent staining showed elevated levels of human TGFβ2 and fibronectin in the TM region in Ad5-CMV-TGFβ2 injected eyes.

Conclusions: Male C57BL/6J mice requires high dose of adenoviruses to develop IOP elevation compared to female mice. Also, older male mice are more sensitive to the Ad5-CMV-TGFβ2 virus.

ABSTRACT BODY:

Purpose: A period of monocular patching (MD) briefly increases the contribution of the previously patched eye to binocular vision. The magnitude of this effect, known as ocular dominance plasticity, provides an index of short-term visual cortex neuroplasticity.

We used ocular dominance plasticity to assess whether physical exercise and/or visual cortex transcranial random noise stimulation (tRNS), a form of non-invasive brain stimulation, enhance short-term visual cortex neuroplasticity in adults with normal vision.

Methods: Participants (n = 10, mean age = 25 ± 2) completed four daily sessions involving two hours of dominant eye patching while watching a movie. Exercise (cycling) and visual cortex tRNS were applied during patching according to the following conditions: 1) cycling and tRNS, 2) cycling and sham (placebo) tRNS, 3) tRNS sitting still, 4) sham tRNS sitting still. Cycling was completed in six 10-minute blocks interleaved with 10-minute rest periods. High-frequency tRNS (100-640 Hz, 1mA) was delivered during the final 20 minutes of patching. Eye dominance was measured using a computerized dichoptic letter luminance judgement test (Bossi et al., 2018) before and after patching.

Results: As expected, MD increased patched eye dominance in most participants. Two-way repeated measures ANOVA revealed that the magnitude of ocular dominance plasticity was not affected by exercise, visual cortex tRNS or their combination.

Conclusions: Physical exercise and tRNS, individually or in combination, do not enhance short-term ocular dominance plasticity in adults with normal vision.

ABSTRACT BODY:

Purpose: There is little information with inconsistent results in vitrectomized eyes with DME treated with anti-VEGF. The aim of the study is to evaluate the efficacy of intravitreal aflibercept injection (IAI) for vitrectomized eyes with diabetic macular edema (DME) at two years.

Methods: This is a prospective, non-comparative, multicenter observational study including patients with diabetic macular edema, who have undergone vitrectomy since at least 3 months before the first aflibercept injection. All patients received 5 monthly aflibercept injections during the loading phase followed by a ProReNata until month 12. Participants were then managed at clinician discretion using Treat and Extend or Observe and plan regimen during the second year. Visual acuity, OCT findings and number of IAI were assessed at month 6, one year and two years. Change in visual acuity and central retinal thickness was assessed using Student paired t-test. Chi-squared test was used to compare the frequency of qualitative OCT parameters among eyes between baseline and at 2 years.

Results: 46 previously vitrectomized eyes were enrolled in this study. Median duration of macular edema was 3 years. Median interval between vitrectomy and first visit was 9 months. Data was available for 36 eyes at 6 months, for 34 eyes at 1 year and for 28 eyes at 2 years. Visual gain was significant: +4.6 letters at 6 months, +6 letters at 1 year and +5.4 letters at 2 years. Central macular thickness decreased significantly by 15% (- 65µm) at month 6, by 25% (-108µm) at 1 year, and by 14% (-62µm) at 2 years. Resolution of macular edema allowing discontinuation of aflibercept was observed in 7 eyes (15%). The frequency of eyes with intraretinal cyst decreased significantly from baseline to 2 years (from 89% to 64%, p = 0.046). Proportions of eyes with ellipsoid zone disruption, external limiting membrane disruption did not change significantly thorough the study. Mean number of injections was 9.3 ± 1.8 for the first year and 5.2 ± 3.1 for the second year. Mean interval injections was 1.6 ± 0.3 month for overall 2-year period.

Conclusions: These results suggest that intravitreal Aflibercept Injection is beneficial in vitrectomized eyes leading to improvement of visual and anatomical outcome from baseline to 2 years.

ABSTRACT BODY:

Purpose: Optic neuropathies are the leading cause of irreversible blindness, characterized by degeneration of retinal ganglion cells (RGCs) and their axons comprising the optic projection. Not all RGC types appear equally susceptible to disease or injury. Cells with sustained firing to light decrement (OFF-S) appear to be more susceptible than those firing to light increment (ON-S), which may be due to intrinsic physiologic properties. Here, we evaluate if action potential (AP) shape reflects differences in firing dynamics and susceptibility to stress.

Methods: C57Bl6/J mice were sacrificed, and retinas dissected in the dark. Retinas were perfused with glucose-supplemented Ames' medium. Recording pipettes were filled with K-gluconate based solution and Alexa-fluor dye. Whole-cell current clamp signals were amplified and digitized. RGCs were classified by light response and dendritic stratification. 41 ON-S and 34 OFF-S RGCs were recorded during stepwise depolarizing current injections from 0-300pA. An additional 7 ON-S and 6 OFF-S were recorded before and after adding 5mM KCl to the extracellular medium.

Results: OFF-S RGCs had more depolarized resting potentials ($p < 0.001$), higher spontaneous spike rates ($p < 0.001$), and faster spiking to current injections ($p < 0.001$). A plateau of the current-spike rate relationship for OFF-S began at 200pA of current injection, indicating depolarization block, but did not occur at baseline for ON-S. APs widened with increased depolarization for both cells, but more appreciably in OFF-S. However, plots of spike rate vs. measures of AP shape (area, depolarization and repolarization rates) had similar slopes for both RGC types (p range 0.17-0.38). Adding 5mM KCl to the extracellular medium induced depolarization block in ON-S RGCs at 200pA. AP shape analysis showed that K+ significantly altered the repolarization rate of ON-S ($p < 0.001$), and that depolarization block in ON-S + K occurred at similar repolarization rate values as baseline OFF-S RGCs.

Conclusions: Increasing firing rate causes a widening of RGC APs. OFF-S RGCs undergo depolarization block at lower current injections at baseline, but it can be experimentally induced in ON-S. Analyses of AP shape vs. spike rate demonstrate that differences correlate with rate and occur at similar thresholds for both cell types, suggesting that mechanisms underlying depolarization block are cell type-agnostic.

TITLE: Discovery and preclinical development of VVN539，a novel ROCK and NO dual MOA agent for the treatment of glaucoma in normotensive rabbits model with minimal hyperemia.

SESSION TITLE: IOP and laser therapy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Li, L. Yao, K. Dang, Q. Han, C. Lu, E. Xia, W. Shen, VivaVision Biotech, Inc., CHINA|

Commercial Relationships Disclosure: Yong Li: Commercial Relationship: Code N (No Commercial Relationship) | Lili Yao: Commercial Relationship: Code N (No Commercial Relationship) | Kuifeng Dang: Commercial Relationship: Code N (No Commercial Relationship) | Qiao Han: Commercial Relationship: Code N (No Commercial Relationship) | Caroline Lu: Commercial Relationship: Code N (No Commercial Relationship) | Erning Xia: Commercial Relationship: Code N (No Commercial Relationship) | Wang Shen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The inhibitory activities of VVN539 on ROCK were assessed in multiple in vitro studies, demonstrating that both molecules inhibit both ROCK 1 and ROCK2. Additionally, the potency of VVN539 as a NO donator were verified in vitro studies. The objectives of this study were to evaluate the ocular hypotensive activity and tolerability of 0.02% VVN539 ophthalmic solution compared to Netarsudil (coded as VIP-5001) in the same vehicle in normotensive Dutch Belted (DB) rabbits.

Methods: VVN539 was tested in vivo and vitro for its ability to release functionally active NO through analyzing the levels of intracellular cGMP by which many biological actions of NO are mediated. 0.02% VVN539 and 0.02% VIP-5001 formulations were administered topically to one eye of each animal once daily (AM) for 10 consecutive days and the other eye was untreated as control. Intraocular pressure (IOP) was measured daily for both eyes in the conscious animals at pre-dose, 4, 8, 12 and 24 hours after dosing from Day 1 to Day 10. Hyperemia was scored on a scale of 0 to 3 (none to severe) with 0.5 increment by a masked ophthalmologist under slit lamp at 2 hours post dosing on Day 1 to Day 3 and on Day 10.

Results: VVN539 increased intracellular cGMP formation. Peak IOP-lowering effect of 0.02% VVN539 and VIP-5001 formulations in the normotensive rabbits was -5.28±0.40 mmHg and -3.36±0.42 mmHg, respectively. VVN539 produced a about 50% greater peak IOP lowering activity than VIP-5001 at the same concentration on the last dosing day (Day 10). The maximum reduction in IOP was achieved at 4 hours after each dose once per day. The ROCK kinase inhibition combined with another validated IOP lowering mechanism of NO releasing resulted better efficacy vs. the Rho kinase inhibitor, VIP-5001 in ocular normotensive Dutch Belted rabbits.

Conclusions: Topical ocular VVN539 was well tolerated and lowered IOP in normotensive rabbits, demonstrating increased efficacy with only minimal conjunctival hyperemia when compared with topical ocular VIP-5001. Our study indicates that the VVN539, a highly selective Rho-Kinase Inhibitor with dual MOA are superior to VIP-5001 (Netarsudil) in lowering IOP in normotensive rabbit model.

ABSTRACT BODY:

Purpose: Caveolae are specialized invaginations of the plasma membrane. Caveolin-1 (Cav1) is required for caveolae biosynthesis. Polymorphisms at the Cav1/2 gene loci impart increased risk for primary open angle glaucoma. Caveolae are abundant in the trabecular meshwork (TM), serving as mechanosensors that detect and respond to changes in intraocular pressure (IOP). The mechanism by which Cav1 contributes to IOP homeostasis is unknown. Protein kinase C (PKC) interacts with the Cav1 scaffolding domain (CSD), and plays a key role in TM contractility; an important mediator of conventional outflow resistance, and subsequently IOP. Thus, we used the CSD peptide, cavtratin, to test the hypothesis that the CSD regulates TM contractile tone via sequestration and inhibition of PKC.

Methods: Experiments were conducted using 8 different human TM cell strains. Adenoviruses encoding shRNA targeted to Cav1 were used to silence Cav1 expression in TM cells. Western blotting was used to determine relative protein levels, phosphorylation status, and PKC activity. Cells were treated with the CSD mimetic, cavtratin (1μM), a CSD peptide fused to the cell-permeable Antennapedia internalization sequence (AP), and compared to those treated with AP (1μM) alone as a vehicle control. Data are expressed as mean ± SEM.

Results: We used subcellular fractionation to separate the cytosol and membrane portions of lysates from Cav1-competent and Cav1-deficient TM cells. We found a 42% reduction of PKC expression in Cav1-deficient membrane fractions (0.58±0.08, n=4, p=0.013). Additionally, immunohistochemical analysis showed that PKC and Cav1 co-localized at the plasma membrane (3 different TM cell strains). Using phosphorylated myosin light chain (pMLC) as a surrogate indicator for contractile tone, we found that 24 h treatment with PKC inhibitor, Gö6983, reduced pMLC levels in TM cells compared to control (0.74±0.06, n=7, p<0.004). TM cells treated with cavtratin exhibited a 30% reduction in pMLC compared to control (0.7±0.05, n=7, p=0.001). Treatment with cavtratin also resulted in a 9% reduction of PKC activity as compared to control (0.91±0.02, n=7, p=0.008).

Conclusions: Taken together, these data suggest that caveolae act as scaffolds that sequester PKC at the TM cell membrane, inhibiting signal transduction to downstream effectors controlling contractile tone.

ABSTRACT BODY:

Purpose: The regulation of retinal ganglion cell (RGC) death and survival in disease is a complex process controlled in part by changes in gene expression, including that regulated by histone deacetylases (HDACs). However, roles of individual HDACs in RGCs remain poorly understood. In this study, we first screened the potential relevance of individual HDACs to RGC death and survival after optic nerve crush injury. Next, we explored the role of class IIa HDAC4 in injured RGCs and further defined underlying molecular mechanisms.

Methods: To study the effect of individual HDACs in RGC after injury, small hairpin RNAs for individual HDAC isoenzymes were expressed using adeno-associated virus (AAV). Optic nerve crush (ONC) injury was used to induce severe axon damage and RGC loss 2 weeks after AAV intravitreal injection in mice. Two weeks after ONC, retina flat mounts were stained with the RGC marker RBPMS to quantify RGC survival. A nuclear localized phosphoablative HDAC4 mutant (3SA) and a truncated HDAC4 mutant (NT) containing only the N-terminal fragment of HDAC4 were also studied. Flag-tagged wildtype and mutant HDAC4 expressed using AAV2 were detected in retina by immunohistochemistry (IHC). Signal intensity in nuclear and cytosol were measured using ImageJ to determine HDAC4 intracellular localization. To test whether nuclear HDAC4 preferentially enhances RGC survival, RGC loss was assessed 2 weeks post ONC by flat mount IHC. Cholera toxin b was intravitreally injected 2 days before endpoint to label regenerated axons.

Results: Inhibited expression of no individual HDAC significantly improved RGC survival after crush injury. Instead, the inhibited expression of only HDAC4 significantly decreased RGC survival. Flag-HDAC4 3SA was localized preferentially to the nucleus, whereas wildtype Flag-HDAC4 was mainly cytosolic. Notably, HDAC4 3SA significantly increased RGC survival and promoted axon regeneration 2 weeks after ONC when compared to GFP control. Overexpression of wild type HDAC4 also tended to increase RGC survival after injury, although not reaching statistical difference. In addition, there was greater RGC survival and axon regeneration following HDAC4 NT expression.

Conclusions: Nuclear localized HDAC4 promotes RGC survival after injury. Enhanced HDAC4 nuclear activity might comprise a new therapy for the prevention of vision loss in diseases like optic nerve injury and glaucoma.

ABSTRACT BODY:

Purpose: Digital devices are used in nearly every aspect of modern life. While digital devices have improved our lives, some consumers develop bothersome ocular symptoms. The purpose of this investigation was to determine if topical ocular application of a hyaluronic acid- and hydroxypropyl guar-containing artificial tear (Systane Hydration PF) was able to alleviate dryness symptoms and improve the quality of life of patients who have ocular symptoms associated with digital device use.

Methods: This was a 2 week, 3 visit study that recruited participants who used digital devices ≥8 hours per day. Each participant was required to have symptomatic Impact of Dry Eye on Everyday Life (IDEEL) Quality of Life (QoL) Work domain scores (≤80) and Ocular Surface Disease Index (OSDI) scores (13 and 32). All participants were treated with Systane Hydration PF ≥4 times per day. Everyone was randomized to Systane Hydration PF unit-dose or multi-dose system for 1 week. Participants switched to the alterative dosing system at 1 week. The full IDEEL-QoL module and OSDI questionnaire were completed at each visit. A visual analog scale (VAS) home diary was completed to probe ocular comfort. A Likert questionnaire that evaluated dispensing system preferences was completed at the 1- and 2-week visits.

Results: The mean ± SD age of the participants was 28.6 ± 12.0 years (n = 30; 70% female). The mean digital device use at 1 day, 1 week, and 2 weeks was 12.4 ± 3.9, 12.9 ± 5.0, and 10.7 ± 4.2 hours per day, respectively. IDEEL-QoL Daily Activities (83.8 ± 5.4, 88.8 ± 6.1, 91.7 ± 5.6), Feelings (82.9 ± 11.1, 88.1 ± 11.5, 90.0 ± 11.9), and Work (59.0 ± 12.8, 74.0 ± 15.0, 81.4 ± 12.7) scores and OSDI (24.8 ± 6.0, 16.3 ± 7.4, 14.3 ± 8.6) scores all significantly improved across the 3 visits (all $p < 0.0001$). VAS end of day eye comfort significantly improved at 2 weeks compared to 1-day (56.9 ± 21.5 vs. 74.9 ± 19.3; $p < 0.0001$). Participants had a similar preference for the two dosing systems in most respects, though more participants indicated that the multi-dose system was more environmentally friendly than the unit-dose system.

Conclusions: Consistently treating symptomatic heavy digital devices users with Systane Hydration PF for 2 weeks significantly improved dryness symptoms and patient quality of life. Participants were overall equivocal with regards to drop dosing systems suggesting that practitioners should discuss both options with patients.

ABSTRACT BODY:

Purpose: To determine the frequency of various optical coherence tomography (OCT) biomarkers of intermediate age-related macular degeneration (int-AMD) and their relationship with the development of complete retinal pigment epithelium and outer retinal atrophy(cRORA) after 3 or more years.

Methods: This retrospective study enrolled 1118 eyes of 765 consecutive patients with int-AMD and at least 12 months of follow-up (including OCT) who were evaluated between October 2016 and October 2020 in Retina Consultant of Houston eye clinics. 250 of these eyes had 36-48 months of follow-up and were included in this analysis. Spectralis OCT 49 slice volume scans at baseline were evaluated for biomarkers including a high central drusen volume (define as ≥ $0.03mm^3$), intraretinal hyperreflective foci (IHRF), subretinal drusenoid deposits (SDD), hyporeflective drusen cores (hDC), incomplete RORA (iRORA), and a thin or thick double layer sign (DLS). Demographic and systemic factors at baseline were also collected. The presence of cRORA was assessed at the final visit between 36 and 48 months. Odds ratios for the baseline features for development of cRORA were assessed using logistic regression and generalized estimating equations.

Results: The frequency of the various OCT biomarkers in this int-AMD cohort is shown in Table 1. Several baseline features were associated with a significantly higher risk for development of cRORA at 3 years including iRORA, IHRF, SDD, hDC, and a thin DLS. (Table 2). Interestingly, hypertension was associated with a significantly lower risk.

Conclusions: Several OCT biomarkers are associated with an increased risk for development of cRORA over three years. These biomarkers may be useful for prognostication and for selecting patients for enrollment into future early intervention clinical trials for AMD.

ABSTRACT BODY:

Purpose: To investigate the association of α-crystallin with membranes prepared from total lipids isolated from a single bovine eye lens, measure the physical properties of membranes, and illustrate the feasibility that such experiments can be conducted for membranes prepared from total lipids isolated from a single human eye lens.

Methods: Small unilamellar vesicles were prepared with and without decreasing the cholesterol (Chol) content from total lipids isolated from a single lens cortex of two-year-old bovine using the rapid solvent exchange method and probe-tip sonication. Chol content in the cortical membranes was decreased by adding lipid (phospholipids and sphingolipid) mixtures resembling bovine lens lipid composition. The electron paramagnetic resonance spin-labeling method was used to measure the percentage of membrane surface occupied (MSO) by α-crystallin, the association constant (K_a), and the physical properties (hydrophobicity, mobility parameter, and maximum splitting) of membranes.

Results: No association of α-crystallin with bovine lens lipid membranes derived from the single-lens cortex was observed. However, α-crystallin association with cortical membranes with reduced Chol content was observed. The smaller the Chol content in cortical membranes, the larger the MSO and K_a, and vice-versa. These results imply that the membrane Chol is a key component in preventing α-crystallin association with the bovine lens lipid membrane. Hydrophobicity near the surface of cortical membranes increased with the increased α-crystallin association, supporting the hypothesis that α-crystallin association with lens membranes forms a barrier to polar molecules. The profiles of mobility parameters decreased and maximum splitting showed no significant change with the increased α-crystallin concentration, indicating that cortical membranes became less mobile with no significant change in order near the surface with the α-crystallin association.

Conclusions: Results show that the membrane Chol plays a crucial role in inhibiting α-crystallin association with the bovine lens lipid membrane, and such association alters the physical properties of membranes playing a vital role in modulating the integrity of membranes. Moreover, this study demonstrates that it is feasible to investigate the association of α-crystallin with membranes derived from a single human lens.

ABSTRACT BODY:

Purpose: To investigate the population-based incidence of ocular tumors in a single U.S. Midwestern county population.

Methods: A retrospective review was conducted of all residents of Olmsted County, Minnesota diagnosed with any ocular tumor from January 1, 2006 to December 31, 2015. International Classification of Diseases, 9th and 10th Edition codes associated with ocular tumors were searched using the Rochester Epidemiology Project, a record-linkage system that captures virtually all medical care provided in this single Midwestern U.S. county population. Medical records were reviewed to confirm diagnoses. Age- and sex-adjusted incidence rates were calculated and adjusted to the 2010 U.S. White population.

Results: There were 1,852 incident cases of ocular tumors during the 10-year study period, of which 948 (51.2%) were intraocular, 717 (38.7%) were extraocular/orbital, and 187 (10.1%) were ocular surface. Females accounted for 1,017 (54.9%) cases and 1,685 (91.0%) subjects were White. The overall age- and sex-adjusted incidence rate of all ocular tumors was 142.67 per 100,000 per year (95% confidence interval [CI]: 136.12 to 149.22). Benign tumors accounted for 1,584 (85.5%) cases, while 268 (14.5%) were malignant. Among benign neoplasms, the most frequent intraocular, extraocular/orbital, and ocular surface tumors were choroidal nevus in 837 (52.8%) cases, epidermal inclusion cyst in 264 (16.7%), and conjunctival nevus in 75 (4.7%), respectively. The most common malignant neoplasm was basal cell carcinoma in 182 (67.9%) subjects. The incidence rate of benign tumors was 120.80 per 100,000 per year (95% CI: 114.80 to 126.80), compared to 21.87 per 100,000 per year (95% CI: 19.25 to 24.50) for malignant tumors. Incidence rate for all ocular tumors overall increased with age ($p<0.001$). No difference in ocular tumor incidence rate existed between sexes ($p=0.13$). The incidence rate in adults (≥18 years old) was 137.28 per 100,000 per year (95% CI: 130.83 to 143.73), compared to incidence in pediatric patients of 5.39 per 100,000 per year (95% CI: 4.25 to 6.53).

Conclusions: This population-based investigation may provide a more accurate assessment of ocular oncology epidemiology, demographics, and risk factors compared to referral center or claims data-based studies and may assist clinicians in formulating their differential diagnosis when encountering ocular neoplasms.

ABSTRACT BODY:

Purpose: To apply high-sensitivity proteomic analysis to human tears and identify differentially abundant proteins in contact lens wearers.

Methods: Tears were collected from both eyes of 48 volunteers using a 5-min Schirmer’s strip collection then stored individually at -80^{O}C until protein extraction. Volunteers also completed questionnaires about dry eye and ocular pain symptoms. Samples from individuals with features of interest (contact lens use; aqueous production as Schirmer's strip wetting length; ocular symptoms; topical anesthetic) were selected for quantitative proteomic analysis. Proteins were extracted from Schirmer's strips using S-Trap protocol, digested into peptides, and 16-plex Tandem Mass Tag (TMT) analyses were conducted using an Orbitrap Fusion mass spectrometer. Identified peptides were verified with open source databases and results were sorted with quality filters to identify candidates for differential abundance between groups.

Results: For contact lens use analysis, we examined samples from 14 eyes of 14 subjects (5 males; 9 females; age 23-29 years) with no history of ocular surgeries, no current eye infections, and no topical ophthalmic medication use. 5 subjects were contact lens wearers and 9 were not; half were anesthetized with topical 0.5% proparacaine HCl. Over 3000 unique proteins were identified in the volunteers’ tear fluid based on peptide sequence matching from curated databases. Application of the Benjamini-Hochberg multiple-testing correction to limit the false discovery rate and rigorous data quality filtering revealed 4 proteins with differential abundance between contact lens wearers and non-wearers, with cystatin D (CST5) demonstrating the greatest (8-fold higher) differential abundance in contact lens wearers. In addition, we found differential abundance of selected proteins previously reported in the literature, including lipocalin-1, lacritin, S100-A2, cystatins M and C, prolactin-inducible protein and zinc-alpha-2-glycoprotein. Subject age, sex, Schirmer's strip wetting length, dry eye and ocular pain scores, and topical anesthetic use were not different between the groups.

Conclusions: Unbiased TMT proteomics analyses demonstrated highly sensitive and reproducible analysis of human tear protein composition, thus showing promise as a technique in biomarker discovery. Contact lens wear significantly altered the tear proteome, while topical anesthetic use, subject sex and age did not.

TITLE: Average Scleral Lens Lifespan at a Tertiary Care Hospital

SESSION TITLE: Contact lens

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Pritikin, G. Chiu, Ophthalmology, Keck Hospital of USC, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Ethan Pritikin: Commercial Relationship: Code N (No Commercial Relationship) | Gloria Chiu: Commercial Relationship(s);Code C (Consultant/Contractor):Glaukos, Acculens, BostonSight

ABSTRACT BODY:

Purpose: Scleral lenses (SLs) have become an effective treatment option for patients (pts) with irregular corneas (IC) and ocular surface disease (OSD). While their popularity has increased over the last decade, the average (avg) lifespan of a SL remains unknown.

Methods: A retrospective study was conducted at the USC Department of Ophthalmology to determine the avg lifespan of a SL. SL wearing pts were identified through evaluation of clinical visits from 01/01/2019 to 12/12/2019 via electronic medical records (EMR). Inclusion criteria included established SL pts fit at USC who had reordered a SL at least once in at least one eye. SL order histories were evaluated to determine the number of SLs ordered and avg days between orders during the pt's duration of care between 12/2009 and 09/2021. Data for OD and OS lenses were combined, and a multivariable mixed methods linear regression model was used to evaluate the effect of independent variables of interest while controlling for other variables. All tests were two-sided and a p-value of <0.05 was considered statistically significant. All analyses were done in R version 4.1.2.

Results: 251 pts (120 males, 131 females; avg age = 57.1±17.4 yrs) and a total of 445 eyes (IC 199, 44.7% and OSD 246, 55.3%) were included in the analysis. The avg lifespan for a SL in this pt cohort was 728.4 ± 434.3 days (1.99 ± 1.19 years; min 5 days, max 7.2 yrs). The avg number of lenses ordered per patient was 2.16 ± 1.47 and the avg duration of care was 2152.0 ± 1033.5 days (5.90 ± 2.83 yrs). There was no statistically significant correlation between avg SL lifespan and gender ($p = 0.67$), primary diagnosis ($p = 0.46$), or brand of SL ($p = 0.14$). Pts with greater SL experience had a statistically significant increase in their avg SL lifespan; for every one year of additional experience wearing SLs, the avg lifespan of SLs increased by 1 month (32.1 days) ($p = 0.001$). The exact reason for lens reordering could not be determined, but included need for updated fit or prescription and lens breakage/loss.

Conclusions: Many factors may affect SL lifespan, including medical indication and individual pt handling and care. The avg SL lifespan in this cohort of IC and OSD pts at a tertiary care hospital was 728.4 ± 434.3 days. There was no significant relationship between SL lifespan and gender, primary diagnosis, or SL brand.

ABSTRACT BODY:

Purpose: Although the phenotype of pterygium has known as high levels of proliferation, inflammation, angiogenesis, and extensive amount of extracellular matrix accumulation, the specific molecular mechanism of pterygium pathogenesis is still unclear. Here, we aim to understand the underlying molecular mechanism of pterygium pathogenesis.

Methods: Transcriptome analyses using human pterygium epithelial cells and fibroblasts isolated from primary pterygium tissue. Quantitative polymerase chain reaction (PCR) and wound scratch test were performed to compare characteristics between pterygial and normal conjunctival cells. Traction force microscope (TFM) analysis and migration ability in different matrix stiffness conditions (matrix stiffnesses to mimic normal (~2.5 kPa) and pterygial (~60 kPa) tissue) were compared between pterygial and normal conjunctival cells.

Results: Cell adhesion and migration-associated signaling pathways were significantly upregulated in the pterygium epithelial cells and fibroblasts compared to cells isolated from normal conjunctival tissue, which were validated by quantitative PCR (matrix metalloproteinase, integrin alpha) and wound scratch assays. TFM analyses revealed that pterygium cells showed significantly higher levels of mechano-sensitiveness to their microenvironment and underwent mechanotransduction. Cells cultured on a stiff matrix exhibited increased growth, elongation, and numbers of vinculin, and furthermore, the same cell behaviors were significantly increased in both pterygium-derived cells, compared to cells on soft matrix.

Conclusions: These findings may offer insight into the important roles of cell-matrix interactions in pterygium pathophysiology, which could provide a valid tool to develop potential therapeutic candidates.

ABSTRACT BODY:

Purpose: To investigate the axial elongation (AE) in children wearing orthokeratology (ortho-k) lenses with different back optic zone diameters (BOZD).

Methods: Seventy Chinese children aged 6 to <11 years, with myopia between -4.00 to -0.75 D and astigmatism ≥ -2.50 D, were randomly assigned to use ortho-k lenses with 6mm (6-MM group) and 5mm (5-MM group) BOZD for two years. Corneal topography, sub-foveal choroidal thickness (ChT), and axial length were measured at baseline and 6-monthly visits. Treatment zone (TZ) was defined as the central area of corneal flattening bordered by the circumferential ring, where no dioptric change on the tangential subtractive map (difference between the pre- and the post- treatment) was observed. The horizontal and vertical TZ sizes were determined with the aid of a customized computer software. Linear mixed models were used to investigate factors (TZ sizes and changes of ChT) that may affect AE, considering baseline parameters (sex, age, pupil size, refraction, axial length and visual acuity).

Results: Data of the right eye of 45 subjects (23 in 6-MM and 22 in 5-MM group) who completed the study were analysed. At the 24-month visit, AE and TZ size were significantly reduced in the 5-MM group (AE: 0.15 ± 0.21 mm; horizontal/vertical TZ size: 2.69 ± 0.28/2.65 ± 0.22 mm) compared to the 6-MM group (AE: 0.35 ± 0.23 mm; horizontal/vertical TZ size: 3.84 ± 0.39/3.42 ± 0.34 mm) ($p = 0.005$; $p < 0.001$, respectively). ChT was not significantly changed after 24 months of lens wear in both groups ($p > 0.05$). Linear mixed models showed that the horizontal and vertical TZ sizes ($\beta = 0.130$, $p = 0.001$; $\beta = 0.136$, $p = 0.003$, respectively) and changes in ChT ($\beta = -0.002$, $p < 0.001$) were significantly associated with AE, controlling for the baseline parameters.

Conclusions: The 5-MM group exhibited a smaller TZ size which was associated with smaller AE. The findings also suggested that changes in ChT, although weak, may play a role in regulating myopia progression.

TITLE: The transporter of the omega-3 fatty acid DHA (MFSD2a) is expressed in the human neural retina.

SESSION TITLE: Novel animal models and neuroprotection in the retina

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Ruiz-Pastor, X. Sánchez-Sáez, A. Noailles, N. Martínez-Gil, P. Lax, N. Cuenca, Physiology, Genetics, and Microbiology, Universitat d'Alacant, Alicante, SPAIN|V. Maneu, Optics, Pharmacology and Anatomy, Universitat d'Alacant, Alicante, SPAIN|

Commercial Relationships Disclosure: María José Ruiz-Pastor: Commercial Relationship: Code N (No Commercial Relationship) | Xavier Sánchez-Sáez: Commercial Relationship: Code N (No Commercial Relationship) | Agustina Noailles: Commercial Relationship: Code N (No Commercial Relationship) | Natalia Martínez-Gil: Commercial Relationship: Code N (No Commercial Relationship) | Victoria Maneu: Commercial Relationship: Code N (No Commercial Relationship) | Pedro Lax: Commercial Relationship: Code N (No Commercial Relationship) | Nicolas Cuenca: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The omega-3 fatty acid docosahexaenoic acid (DHA) is an essential component of neural membranes and has an anti-inflammatory and neuroprotective effect on the retina. DHA is being widely administered to patients with neurodegenerative diseases, as diminished levels of this fatty acid were found in the central nervous system of these patients and of animal models with neural diseases. Nevertheless, the transport mechanism of DHA remains unclear in the retina. MFSD2a was described as the putative transporter of DHA in the blood-retina barrier, but it is unknown if this protein is expressed in the neurons. We assessed to describe if this transporter is expressed in the neural retina using immunofluorescence.

Methods: We performed immunohistochemistry with anti-MFSD2a and specific markers of retinal populations in cryostat sections of the human retina. We used the transcriptional factors Chx10 for the identification of pan-bipolar cells, Pax6 for amacrine cells, and Brn3a for ganglion cells. For the identification of horizontal cells, we used parvalbumin. We identified the Müller cells and the retinal pigmented epithelium (RPE) with anti-CRALBP, and the cones with anti-cone arrestin. Additionally, we used LaminB2 to detect the nuclear membrane and KDEL and SERCA2 for the immunodetection of the endoplasmic reticulum.

Results: MFSD2a was extensively expressed in the neural retina. We have found that MFSD2a is expressed in the inner segments of photoreceptor cells, as well as in the outer nuclear layer, where somas of photoreceptor cells are localized. We also detected immunostaining in the inner nuclear layer, as well as in the ganglion cell layer. In the double immunostaining with the transcriptional factors Chx10, Pax6, and Brn3a we have found that all bipolar, amacrine, and ganglion cells expressed the DHA transporter. Horizontal cells also expressed MFSD2a in their nucleus. Müller cells showed anti-MFSD2a immunoreaction in the external limiting membrane. However, the RPE did not show immunolabeling with anti-MFSD2a. We have found MFSD2a immunolabelling in the endothelial cells of the blood vessels of the human retina.

Conclusions: MFSD2a is expressed by endothelial cells of the human retina, but also by the neural cells. Photoreceptor cells, Müller cells, and all populations of bipolar, amacrine, horizontal, and ganglion cells expressed MFSD2a in their cytosol and in their nuclear membrane.

ABSTRACT BODY:

Purpose: To report the longterm safety and stability of two suprachoroidal retinal prosthesis trials (NCT01603576, NCT03406416), comprising of seven patients, with followup ranging from two to nine years.

Methods: Three patients with retinitis pigmentosa were implanted with our prototype 24 channel suprachoroidal retinal prosthesis in May - August 2012. One patient had the entire device removed following the trial in 2014 for a medical reason unrelated to the device. The other two patients had the intraocular array left in situ and the percutaneous connector removed, as planned. Ocular followup has continued since that time, albeit interrupted due to the Covid 19 pandemic.

Four patients with retinitis pigmentosa were implanted with our second generation 44 channel fully implantable device in February to August 2018. They continue to use the device in the home enviroment.

Ocular assessments including clinical examination, colour fundus photographs and optical coherence tomography (OCT) have been used to assess stability of the devices and retinal health longitudinally in patients (P) 1-7.

Results: Electrode to retina distance OCT measurements over two to nine years, calculated by comparing group means, showed an increase over time. (Wilcoxon, p=0.03) In the prototype trial, the increase appeared linked to fibrosis and stimulation, with no progression once devices were inactivated, in the second generation trial, it seemed primarily due to passive fibrosis.

Retinal thickness OCT measurements showed a slow reduction in central retinal thickness, as expected, due to progression of dystrophic disease. (Wilcoxon, p=0.11)

Device position compared to the optic nerve head (ONH) was calculated and three patients demonstrated some temporal movement. P1 position returned to baseline over seven years, P2 stabilised over three months and P6 had a temporary choroidal effusion event which settled spontaneously.

Function of the four Generation two fully implantable devices remains stable.

Conclusions: Using fundus photography and OCT measurements we demonstrate that retinal prostheses implanted in the suprachoroidal space for up to nine years are overall stable in position and cause mild progressive fibrosis in the suprachoroidal space. Longterm assessment of the changes in the retina are all consistent with the underlying

retinal dystrophy.
This provides further evidence of the safety of the suprachoroidal surgical approach for retinal prostheses.

ABSTRACT BODY:

Purpose: Targeting RGD-binding integrins can affect multiple disease hallmarks such as vascular leakage, inflammation, angiogenesis and fibrosis. Therefore, an RGD-integrin inhibitor may have therapeutic benefit for various retinal disorders. In this study, we investigated the therapeutic potential of THR-687, a potent pan-RGD integrin antagonist, in the streptozotocin (STZ)-induced diabetes rat model.

Methods: Following STZ-induced diabetes, different doses of THR-687 (6.7, 16.7 or 75 µg/eye) or its vehicle were administered via 3 consecutive intravitreal injections in both eyes (with 1-week interval, n=7 rats/group). Untreated, non-diabetic rats served as controls (n=5 rats). At 4 weeks after diabetes-induction, the effect of THR-687 was investigated by histological analysis for retinal vascular leakage (using the tracer FITC-BSA), for inflammatory cell activation (Iba1 immunoreactivity) and Müller cell gliosis (vimentin immunoreactivity). Statistical analysis was performed with a one-way analysis of variance using a Bonferroni multiple comparison test.

Results: THR-687 reduced diabetes-induced increases in retinal permeability versus vehicle in a dose-dependent manner. The highest dose (75 µg/eye) completely prevented vascular leakage ($p<0.001$) while the mid dose (16.7 µg/eye) significantly decreased this pathology by 34 ± 21% ($p<0.05$) and the low dose (6.7 µg/eye) had no effect. All doses of THR-687 also significantly reduced the number of inflammatory cells, as compared to vehicle. Indeed, a reduction of 57 ± 12% was seen after administration of the highest dose ($p<0.01$), a decrease of 43 ± 19% for the mid dose ($p<0.05$) and the low dose induced a reduction of 51 ± 13% ($p<0.05$). The highest dose of THR-687 also reduced the diabetes-induced increase in vimentin expression within the Müller cells back to baseline ($p<0.05$ versus vehicle), whereas no significant differences following injections of the mid or low dose were observed.

Conclusions: RGD-integrin antagonism using THR-687 potently inhibits vascular permeability, inflammation and gliosis induced by STZ in the diabetic rat retina. Given its broad mode of action, THR-687 is a promising drug candidate for the treatment of vision-threatening retinal pathologies and is currently in a phase 2 clinical trial in diabetic macular edema patients (INTEGRAL - NCT05063734).

ABSTRACT BODY:

Purpose: Human eye's perception of near-infrared (NIR) light results from the two-photon absorption by retinal photoreceptors. In such a setting, pulsed NIR laser produces color sensation that corresponds (closely but not precisely) to the so-called visible spectrum with half of the wavelength used. The mechanism of NIR vision has recently been elucidated, and its clinical application sought. In this case-control study, we determined retinal sensitivity to NIR in patients with age-related macular degeneration (AMD) and compared it to visible-light microperimetry.

Methods: We recruited 24 AMD patients and 20 healthy controls and measured their visual function in one (better) eye. The NIR threshold was assessed using a two-photon excitation setup, which employs a femtosecond laser to project 1045-nm stimuli with ultrashort pulses. An array of neutral-density filters attenuates the laser power to meet the safety requirements of ANSI Z136.1-2014. Retinal sensitivity to visible light was measured using an MP-1 microperimeter (Nidek Technologies Srl). A customized 12-degree grid consisting of 44 retinal loci was applied. Best-corrected visual acuity (VA) and the logarithm of straylight were secondary outcome measures.

Results: The median (interquartile range) age of AMD and control subjects was 77.2 (71.8 to 79.9) years and 71.3 (67.8 to 78.3) years, respectively. AMD resulted in decreased logMAR VA, i.e., 0.09 (0.04 to 0.22), which in normal eyes was -0.04 (-0.06 to 0.02). A comparable level of straylight was found in the two populations with 1.18 (1.07 to 1.45) log(s) in the study and 1.16 (1.01 to 1.30) log(s) in the healthy group. The NIR threshold of AMD and control groups differed significantly (Mann-Whitney, P=.0001): 7.9 (7.1 to 9.5) dB vs. 10.5 (9.5 to 10.7) dB. In visible-light microperimetry, retinal sensitivity was also significantly decreased (Mann-Whitney, P=.0001) in AMD (14.4; 11.1 to 15.3 dB) compared to the controls (17.5; 16.5 to 18.3 dB).

Conclusions: We demonstrated that NIR retinal sensitivity in AMD patients is significantly impaired compared to healthy subjects, similarly to standard microperimetry. Although further research is needed, this proof-of-concept study suggests that this (new) functional parameter can be used in AMD patients' retinal-function assessment beyond standard VA measurements.

ABSTRACT BODY:

Purpose: DRAKO (NCT02850263) is an observational, multicenter study, and is the first study to prospectively evaluate the effectiveness of intravitreal aflibercept (IVT-AFL) for the treatment of patients with diabetic macular edema (DME) within routine clinical practice in the UK. Results are reported for the anti-vascular endothelial growth factor treatment-naïve cohort upon completion of the 2-year follow-up period.

Methods: Adult patients diagnosed with center-involving DME were enrolled and treated according to local practice. Primary endpoints were mean change from baseline in best-corrected visual acuity (BCVA) and central subfield thickness (CST) at 12 months (12M). Secondary endpoints included mean change from baseline in BCVA and CST at 24 months (24M), proportion of patients with ≥5, 10 or 15 letter gain or loss and the number of injections administered.

Results: At 12M (n=388), mean (SD) changes from baseline in BCVA of 2.5 (12.2) letters and CST of -119.1 (116.4) µm were reported. At 24M (n=326), mean (SD) BCVA remained above baseline (0.7 (12.7) letters) and CST was further reduced to -123.3 (104.3) µm from baseline. (24M Baseline; BCVA=71.5 letters; CST=447.6µm). At 24M, 38.0%, 16.6%, and 8.3% of patients gained ≥5, 10, and 15 letters, respectively; 26.1%, 15.3%, and 7.4% of patients lost ≥5, 10, and 15 letters, respectively. Patients received mean (SD) of 6.4 (2.0) injections in year 1 and 3.7 (2.3) injections in year 2. No correlation between the letter gain or loss and number of injections administered was observed. A total of 6.7% patients discontinued IVT-AFL treatment. In the safety population (n=507), 297 serious treatment emergent adverse events (TEAE) were reported, of which 22 were eye disorders. Serious TEAEs with a reasonable causal relationship with the injection procedure (n=4) or IVT-AFL treatment (n=4) were reported in 6 (1.2%) patients. Endophthalmitis was reported in 2 (0.4%) patients.

Conclusions: The DRAKO results indicate that IVT-AFL is an effective and well tolerated treatment for patients with DME in routine clinical practice, preserving or improving functional and anatomical outcomes over the 2-year treatment period. Functional outcomes were not correlated with number of injections administered. The safety profile of IVT-AFL was consistent with previous studies.

ABSTRACT BODY:

Purpose: Current rehabilitation for visual field loss frequently involves computer and screen-based visual search tasks. This experiment was conducted to determine if the new generation of low-cost remote video eye trackers are suitable to measure eye movements whilst patients complete visual search tasks and could therefore be considered for use in rehabilitation training.

Methods: Twenty-six visually normal participants aged (mean ± S.D.) 21.36 ± 2.48 years performed a visual search task on a 17” VDU at 60cm without head restraint. The search was conducted under normal viewing (NV) conditions and with a simulated visual field defect (SVFD) of right sided homonymous hemianopia locked to the participant’s binocular eye position. In each condition there were 96 trials with targets which comprised 16 everyday objects presented in 6 different arrangements on a crowded background. During each trial, the eyes binocular position was recorded with a Tobii EyeX video eye tracker at 60 Hz. All trials were conducted under one condition then the other with the order randomised. Search time, maximum saccadic speed and the length of the scanpath were assessed offline.

Results: There was a significant ($p<0.05$) correlation between search time and the length of the scanpath. Search times (SVFD: 1.56 ± 0.03s, NV: 1.00±0.03s) and scanpath lengths (SVFD:72.5±3.2mm NV:51.0±2.9) were significantly longer in the SVFD trials compared to the normal condition ($p<0.01$). This was due to an increase in the length of the scanpath in the hemianopic field while search times between the SVFD and NV condition were similar when the target was in presented the visible part of the field ($p = 0.26$). Maximum velocities of eye movements also varied between the two conditions (SVFD mean±SD: 33.59±0.52°/s, NV: 41.63±1.06) and were significantly lower in the SVFD condition ($p<0.01$). The search time, scanpath and eye movement speed did not improve with practice.

Conclusions: Results of increased search time and scanpath with SVFD match previous research. The low-cost, remote video eye tracker was able to reliably quantify differences in visual search behaviour with a simulated visual field defect. Remote video eye trackers have the potential to improve the visual rehabilitation of patients with VF loss due to their ability to monitor eye movements, provide feedback and quantify progress during the rehabilitation process.

ABSTRACT BODY:
Purpose: R-shiny apps can be useful in maintaining and analyzing data collected in clinical trials of rare diseases, where a suite of measures is used to characterize retinal and visual function, functional vision, and safety courses over time following the treatment.

In a phase 3 trial, participants with biallelic RPE65 mutation-associated inherited retinal dystrophy (IRD), an ultra-rare genetic disorder, received bilateral, subretinal injections of gene augmentation therapy, voretigene neparvovec and followed-up annually.

We explored the development of a novel data visualization tool, VNEAN (R-shiny application), to help in maintenance and analyses of complex trial data into a visual storytelling form that is easier to understand for healthcare audience.
Methods: We developed an interactive and dynamic application using Shiny package for R programming language. This app improves the ability to explore the longitudinal trajectory of main efficacy outcomes (mobility testing and full-field light sensitivity) in concert with other data, including visual function and safety that can be visualized overall and in subsets.
Results: This app has 11 modules of data analyses (Figure 1), including longitudinal visualization, analyses of correlation between changes, and timeline of adverse events. It presents the durability in improvement of functional vision, retinal and visual function, and the safety data at the group, subset and participant levels. The dynamic interface allows the user to define a subset based on the measures at baseline and/or their changes and select measures and/or timepoints.
Conclusions: COVID-19 demonstrated digital engagement at its peak. The R shiny app has the potential to provide alternative data visualization and interpretations of analyses that offer a comprehensive representation of the data generated in rare diseases, not easily achievable via traditional didactic lectures and static data methods. This patient-centric and enduring visualization approach enables health care professionals to learn and retain information for the management and engagement of IRD patients in their clinical practice.

Additionally, this application can progress the knowledge and understanding of treatment effects of rare diseases and help inform the design of future small- or large-scale trials.

ABSTRACT BODY:

Purpose: To examine the effectiveness of a culturally/linguistically appropriate training program, using video clips (so people who could not read or write could understand) and individual patient-centred reporting, to improve knowledge, awareness, lifestyle and diabetic retinopathy (DR) screening uptake in newly diagnosed diabetic patients in Nepal.

Methods: The training program was developed using video clips by a multidisciplinary team of experts. The training included advice on diabetes, diet, physical activity, the importance of retinal screening etc. A total of 110 participants with newly diagnosed diabetes (mean age=46±11 years) were recruited and divided randomly into two groups: intervention (n=55) and control (n=55). Baseline data on knowledge/awareness, diet, physical activity, glycated haemoglobin (HbA1c), blood pressure (BP), cholesterol, etc. were collected from both groups. All participants received doctor's recommended treatment for diabetes and were followed up after three (n=110) and six (n=41) months. Changes in HbA1c, cholesterol, BP, uptake of DR screening, knowledge/awareness about diabetes, diet, physical activities, etc. were recorded.

Results: Mean age, gender and HbA1c, BP, cholesterol, knowledge/awareness about diabetes, diet and physical activity did not differ significantly between the groups at baseline ($p \geq 0.12$). After three months, a significantly greater number of participants in the intervention group showed: (i) improved knowledge/awareness about diabetes control, physical activity levels and healthy eating ($p \leq 0.05$); (ii) significantly reduced HbA1c, low-density lipoprotein, and systolic BP levels ($p \leq 0.06$). All (100%) participants in the intervention group had retinal screening done as confirmed by their clinical reports (13% had already developed early signs of DR), compared to 0% in the control group. Improvement in knowledge/awareness about diabetes and clinical outcomes in the intervention group were found to be sustained after six months.

Conclusions: A culturally/linguistically appropriate training program using video clips is effective in improving knowledge/awareness about diabetes control, lifestyle, and promoting DR screening uptake in Nepal. This may be vital in reducing the risk of diabetic complications including diabetes-related blindness.

ABSTRACT BODY:

Purpose:

X-linked juvenile retinoschisis (XLRS) is a degenerative retinopathy characterized by retinal splitting. Although it is well known that the disease is caused by defects in the gene RS1, clinical and genetic heterogeneity hampers early detection and diagnosis. Despite all the efforts, there is no treatment available to prevent vision loss or to delay XLRS progression. Self-organizing 3D in vitro models known as retinal organoids, have emerged as a powerful platform to use in preclinical research for eye diseases. Retinal organoids give us the chance to perform disease modeling, which is also crucial in XLRS since more than 200 mutations have been identified along the RS1 gene and no clear genotype–phenotype correlation has been found. To improve RS1 organoid modeling, we compared three mainstream protocols for retinal organoid development.

Methods:

We use three protocols: Matrigel-embedding protocol established by our group (Wagstaff et al., 2021), Free-floating 96-well plate protocol (Huang et al., 2019) and AMASS protocol (Cowan et al., 2021). Retinal organoids were differentiated up to 180 days. Samples were collected in early stages, as well as multiple time points at later stages to analyse RS1 expression using IHC, PCR and western blot. Functional characterization will be done using multielectrode arrays.

Results:

Free-floating 96-well plate protocol and Matrigel-embedding protocol have both generated long-term XLRS retinal organoids. Both protocols revealed differences in RS1 expression between control and patient, demonstrating the success in mimicking XLRS phenotype. Furthermore, at day 180 the retinal organoids displayed a splitting phenotype characteristic of the disease. We are currently applying the AMASS protocol as well to assess its similarities, strength and limitations.

Conclusions: It is possible to generate long-term retinal organoids with Free-floating 96-well plate and Matrigel-embedding protocols that mimic XLRS pathology. Based on RT-PCR and immunohistochemistry. Differences in RS1 protein expression can be observed comparing patient retinal organoids and controls. This demonstrates that retinal organoids are a suitable model to study XLRS. This will not only allow us to study the molecular mechanisms underlying XLRS, but also will provide us with an excellent in vitro platform to progress for experimental new gene therapy strategies.

ABSTRACT BODY:

Purpose: To evaluate pulmonary function in school-age children who have received intravitreal bevacizumab (IVB) for retinopathy of prematurity (ROP).

Methods: In this retrospective, cross-sectional case-control study of 118 school-aged children were separated into three groups: full-term control children (group 1), preterm children who had not received IVB treatment (group 2) and preterm children with ROP who had received IVB treatment (group 3). Pulmonary function, measured by spirometry and impulse oscillometry, was assessed at approximately 7 years of age and compared among the three groups.

Results: One hundred and eighteen children (65 boys and 53 girls; mean age, 6.67±0.52 years) were included in this study. Pulmonary function was significantly better in group 1 than in groups 2 and 3 (all $p < 0.05$ in forced vital capacity (FVC), forced expiratory volume in 1 second (FEV_1), forced expiratory flow between 25% and 75% of FVC (FEF_{25-75}), resistance of the respiratory system at 5 Hz (R5) and difference between R5 and R20 (R5-R20)). There were no statistically significant differences between group 2 and group 3 in FVC, FEV_1, ratio of FEV_1 to FVC (FEV_1 /FVC), FEF_{25-75}, resistance of the respiratory system at 20 Hz (R20), reactance of the respiratory system at 5 Hz (X5) or R5-R20 after adjusting for important perinatal factors.

Conclusions: By school age, preterm infants with a history of receiving IVB for ROP had comparable pulmonary function to their preterm peers who had not received IVB treatment.

ABSTRACT BODY:

Purpose: Albinism is a genetic disorder characterized by absent/reduced melanin pigment in eyes, skin and hair. In addition, the retina exhibits foveal hypoplasia and misrouting of the axonal tracts to the brain, resulting in blurred vision. In (ocular) albinism, the RPE has a melanosomal pigment deficiency. The molecular mechanisms that link pigmentation to neural retinal development and disease are yet unclear. To model the disease in vitro, we compared stem cell derived iRPE of OCA1 patients and controls.

Methods: Human oculocutaneous albinism 1 (OCA1) patient derived iPSCs and controls were embedded in Matrigel for 5 days and cultured in N2B27 medium. The formed embryoid bodies were subsequently plated as single cells on growth factor reduced Matrigel coated trans-well inserts and medium changed to 20% KOSR medium. Produced iRPE was analyzed using RT-PCR and immunohistochemistry (IHC).

Results: As expected, OCA1 patient stem cell-derived RPE showed no pigmentation at all, while control WT iRPE cell lines started to pigment gradually from day 24 onward. To confirm the RPE identity of the differentiated cells, two general mature RPE markers were analyzed: BEST1 and RPE65. BEST1 is a regulator of fluid flux across the RPE and peaks earlier in patient derived iRPE but is lower than controls in later stages. RPE65 is an enzyme involved in the visual cycle and its expression is lower in later stage patient-derived iRPE. At day 60, expression of a number key disease genes involved in human albinism was different between the OCA1 iRPE control derived iRPE. These results were confirmed using IHC.

Conclusions: We created and characterized a new stem cell-derived in vitro model for OCA1. This model has been validated and can be used to study molecular mechanisms and signaling pathways of human albinism in vitro.

ABSTRACT BODY:

Purpose: Gyrate atrophy of the choroid and retina (GACR) is an rare autosomal recessive metabolic eye disorder. GACR patients suffer from progressive vision loss, starting with near sightedness and night blindness in the first decade of life which progresses to complete blindness around the age of 50. Mutations in the gene encoding for ornithine amino transferase (OAT) impair the function of the encoded enzyme and thereby the ability of the cell to convert ornithine to 1-Pyrroline-5-carboxylic acid (P5C). It is currently unknown by which mechanism OAT deficiency results in deterioration in vision. In this study we developed GACR in vitro models which can be used to gain a better understanding of the disease mechanism responsible for inducing retinal pigment epithelial (RPE) cell death.

Methods: Skin biopts and blood was collected from 2 clinically well characterized GACR patients, 1 of which has a start codon mutation. From these materials, we generated 2 induced pluripotent stem cell lines (iPSCs). We performed RNA analysis, western blot and immunostainings to determine the presence of OAT in all cell lines. Both patient and healthy control iPSCs were exposed to a range of ornithine and arginine concentrations and subsequently assayed for cell viability.

Results: DNA mutation analysis showed that the patient iPSCs carry the c.1 A>G and c.1058 G>A OAT mutations. Using RT-PCR, western blot and immunostainings we have been able to determine the presence of OAT in our healthy control cell lines. Interestingly, 1 of the patient cell lines showed almost no loss of OAT activity. In contrast, the patient cell line with a start codon mutation showed only residual expression of OAT protein. The cell viability assay demonstrated an increased sensitivity towards ornithine in our patient iPSCs compared to the healthy controls. Similar increased sensitivity was also observed in the patient iPSCs when exposing them to arginine.

Conclusions: We have demonstrated that our patient derived iPSC model displays the key characteristic of GACR, which is toxicity as a result of hyperornithinemia. Our first functional results are promising and encourages further use of the iPSC model to further identify the disease mechanism responsible for ornithine induced toxicity. We are currently differentiating our iPSCs to iRPE cells yielding more specifically relevant information about the effect of OAT deficiency in the eye.

TITLE: Comparing the effect of AMD on face discrimination and face recognition

SESSION TITLE: Visual Function: perception, adaptation, spatial, visual acuity and binocular vision

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.J. Logan, G.E. Gordon, G. Loffler, Department of Vision Sciences, Glasgow Caledonian University, Glasgow, UNITED KINGDOM|

Commercial Relationships Disclosure: Andrew Logan: Commercial Relationship: Code N (No Commercial Relationship) | Gael Gordon: Commercial Relationship: Code N (No Commercial Relationship) | Gunter Loffler: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) impairs several aspects of face perception, including face discrimination (identify differences between faces) and face recognition (recognize a previously-viewed face). Both involve processing of face identity, but it is unclear if AMD impairs one more than the other. We aimed to quantitatively compare the effect of AMD on two face perception tasks: one with a memory requirement (recognition) and one without (discrimination).

Methods: 16 patients with non-exudative AMD (VA = 0.12 to 0.6 LogMAR) and 16 age-matched controls (-0.18 to 0.06) completed two computerised face tests. The discrimination task presented four simultaneously-visible faces and required participants to identify the odd-one-out. The recognition task asked participants to identify a previously-viewed face from four alternatives. Both tests measured the face threshold- the minimum difference required between identities for either reliable discrimination or recognition. Thresholds were measured separately for full-faces, internal features (eyes, mouth and nose) and external features (head and hair).

Results: Relative to controls, discrimination (1.71X) and recognition (1.66X) thresholds for full-faces were significantly higher (i.e. poorer sensitivity) in patients with AMD (both $p<0.001$). Thresholds measured with the discrimination and recognition tests were equivalent ($p<0.001$). Compared to the full-face condition, the difference in thresholds between controls and patients with AMD was significantly greater when only the internal features were visible ($p<0.001$). Relative to controls, thresholds for the internal features were 2.24X poorer in patients with AMD. External feature performance was impaired to a lesser extent (1.62X).

Conclusions: AMD impairs both face discrimination and recognition. Face recognition performance (significant memory demand) was equivalent to that on a memory-free discrimination task. Our data indicate that the severity of the face perception impairment in AMD is dependent on the face information available, rather than task memory demands. Specifically, patients with AMD demonstrated the most severe impairment when only the internal features were visible. Overall, these results suggest that impaired encoding of visual information- particularly that from the internal features- underlies the difficulties that patients with AMD experience with both face discrimination and recognition.

ABSTRACT BODY:

Purpose: To describe the continuum of spatial patterns in various levels of papilledema, a deep-learning variational autoencoder (VAE) was proposed to create a 2D latent space map for better visualization (Fig. 1a). We also evaluated the extent that the VAE latent variables can be used to quantify and monitor the pattern of optic nerve swelling over time.

Methods: A paired VAE encoder and decoder were trained using TRT maps from 1509 optic-nerve-head (ONH) optical coherence volume (OCT) volumes from the multiple visits of the 125 subjects in the Idiopathic Intracranial Hypertension Treatment Trial (IIHTT) OCT-substudy. For each input TRT map, the trained encoder computes two latent variables (d1, d2) as a succinct representation of the swelling pattern; the trained decoder reconstructs the input TRT map based on d1 and d2. Longitudinal changes in spatial patterns were quantified and rendered based on d1 and d2 to map the trajectories of improvement over time.

Results: Papilledema swelling pattern trajectories over time were plotted for each of the selected 42 subjects treated with acetazolamide and 37 subjects treated with weight reduction only (Fig. 1b). The distribution of d1 is illustrated in Fig 2a; a significant difference occurred after only three months in the treatment group but took six months in the placebo group (Tukey's analysis). Fig. 2b shows an extremely high correlation between the original and the VAE reconstructed TR volumes, demonstrating the utility of coding the swelling patterns into only two variables.

Conclusions: The VAE latent space (Fig. 1a) can be seen as a visual map to depict the trajectory of improvement of the swelling spatial pattern over time for individual eyes. Latent variable d1 appears to primarily encode a volumetric measure, while latent variable d2 appears to encode the spatial pattern of swelling reflecting which axon bundles are thickened at various levels of severity of papilledema. VAE may provide a robust approach to differentiate causes of optic disc swelling in future studies.

ABSTRACT BODY:

Purpose: We recently developed a rigorous and reproducible model of glaucoma in the common marmoset (Callithrix jacchus) (Kumar et al., 2022, TVST). The microbead/occlusion model provides for a consistent elevation of IOP across a 10-week experimental period. Here we tested the hypothesis that the gap junction (GJ)-mediated bystander effect is mechanistically linked to progressive cellular damage in retina and optic nerve associated with glaucoma.

Methods: Experimental glaucoma in marmosets was initiated by IOP elevation induced by an intracameral injection of 10 µm-diameter polystyrene microbeads. The GJ blocker meclofenamic acid (MFA, 50 mM) was delivered by intravitreal injection weekly for 10 weeks. Functional changes were monitored by ERG recordings and structural changes were assayed by immunohistochemistry and SD-OCT imaging.

Results: We found that pretreatment of microbead-injected eyes with MFA largely prevented the loss of RGCs normally seen at 10 weeks after IOP elevation. MFA also prevented the loss of RGC axons and disruption of the mosaic structure of the optic nerve observed in microbead-injected eyes. In electrophysiological experiments, we observed a reduction in the photopic negative response (PhNR) beginning at 8 weeks after microbead injection, but no significant change in the a- and b-waves of the ERG. At 10 weeks, the PhNR amplitude continued to decrease, but there was also a significant reduction in amplitude of the a- and b-waves, suggesting a pattern of late damage to photoreceptors and bipolar cells, respectively. However, following MFA application, all ERG components were maintained at control levels in microbead-injected eyes. Finally, we found that MFA prevented the enlarged optic nerve cupping seen in microbead-injected eyes.

Conclusions: Our results indicate that blockade of GJs offers significant protection of retina and optic nerve in a marmoset model of glaucoma. Taken together with our pervious results from the mouse (Akopian et al., 2017 JCI), the present findings provide further support for our hypothesis that GJs play a critical role in progressive cell death and thereby form novel targets for neuroprotection therapy in glaucoma.

ABSTRACT BODY:

Purpose: Our limited understanding of the signals that regulate retinal ganglion cell (RGC) death and axon regeneration after axon injury has prevented the development of curative therapies. Inhibiting DLK (MAP3K12) and LZK (MAP3K13) signaling after axonal injury is highly neuroprotective but blocks axonal regenerative capacity even in the presence of a strongly pro-regenerative treatment. The objective of our studies is to investigate the role of transcription factors downstream of DLK and LZK to identify gene regulatory networks (GRNs) that may independently regulate RGC cell death and axon regeneration.

Methods: Conditional deletion of DLK/LZK in RGCs was achieved using intraocular delivery of AAV2-CRE in $DLK^{fl/fl}$;$LZK^{fl/fl}$ mice. Selective knockout of the transcription factors (TFs) known to lie downstream of DLK/LZK was achieved by intraocular delivery of AAV2-gRNAs into mice with RGC-specific Cas9 expression (Vglut2-CRE;ROSA26-LSL-Cas9). Gene manipulation was conducted 2-3 weeks prior to mouse optic nerve injury (ONI). DLK/LZK signaling was assessed via immunofluorescent staining at 1 and 5 days post-injury (dpi), the onset and peak of signaling, respectively. RGC survival and axon regeneration was assessed at 14 dpi.

Results: We found that deletion of both DLK and LZK in RGCs dramatically increased RGC survival at 14 dpi (63.4±6.5% survival in DKO vs 21.5±2.4% in wildtype), but blocked axon regeneration (89±18% reduction) and induction of regeneration associated genes (RAGs), including Gap43, even in the presence of strongly pro-regenerative treatments (incl. Zymosan + CPT-cAMP). We next investigated the roles of the downstream TFs. Independent knockout of Jun, Sox11, Mef2a, and Atf2 in RGCs resulted in significantly increased RGC survival at 14 days after ONI with no improvement of endogenous axon regeneration. However, when axon regeneration was stimulated using pro-regenerative treatments, we identified particular TFs that either enabled or suppressed axon regeneration.

Conclusions: These results show that there are discrete GRNs that independently regulate cell death versus axon regeneration, pointing to novel gene therapies that can function in combination with other well-known treatments to both improve RGC survival while also improving axon regeneration after optic nerve injury.

ABSTRACT BODY:

Purpose: Reliability of OCTA measurements can be affected by various factors including ocular media opacity, imaging artifacts, and patient cooperation during image acquisition. The potential for variation in OCTA measurements may limit its widespread clinical adoption. Studies validating (or refuting) the repeatability of OCTA measurements are essential. In this cross-sectional study, we report the intrasession repeatability and interocular symmetry of macular OCTA parameters in patients with Alzheimer disease (AD), mild cognitive impairment (MCI), and Parkinson disease (PD).

Methods: OCTA images (3x3mm and 6x6mm) centered on the macula were acquired using the Zeiss Cirrus HD-5000 AngioPlex. Perfusion density (PFD), vessel density (VD), and foveal avascular zone (FAZ) area repeatability were assessed using intraclass correlation (ICC) analysis. Interocular symmetry of PFD, VD, and FAZ area were also assessed.

Results: Sixty-one eyes of 36 AD patients, 81 eyes of 52 MCI participants, 55 eyes of 32 PD participants, and 57 eyes of 31 normal cognition participants who underwent 3x3mm OCTA imaging were analyzed. 59 eyes of 35 AD patients, 86 eyes of 53 MCI participants, 63 eyes of 36 PD participants, and 55 eyes of 31 participants with normal cognition who underwent 6x6mm OCTA imaging were analyzed. For 3x3mm OCTA images, ICC values for PFD circle were as follows: AD (0.68; 0.50-0.78 CI), MCI (0.68; 0.53-0.77 CI), PD (0.63; 0.41-0.75 CI), and normal cognition (0.38; 0.22-0.64 CI). For 6x6mm OCTA images, ICC values for PFD circle were as follows: AD (0.64; 0.44-0.76 CI), MCI (0.74; 0.64-0.83 CI), PD (0.57; 0.35-0.70 CI), and normal cognition (0.60; 0.37-0.73 CI). Similar ICC values were observed for VD and FAZ area, although values trended slightly higher for FAZ area. Apart from inner ring PFD on 6x6mm OCTA images in normal cognition participants (0.40; 0.15-0.60 CI) and MCI (0.74; 0.62-0.82 CI), there were no significant differences in repeatability among or between groups. Interocular differences in OCTA parameters were only observed in AD patients who underwent 6x6mm OCTA imaging.

Conclusions: Overall, similar macular OCTA repeatability was observed between normal cognition participants and those with neurodegenerative disease. Regardless of diagnostic group, macular OCTA metrics demonstrated moderate repeatability. On average, FAZ area was more repeatable than VD or PFD.

ABSTRACT BODY:

Purpose: To evaluate the real-world efficacy of netarsudil 0.02% ophthalmic solution dosed once daily before bed (q.h.s.) in reducing intraocular pressure (IOP) in eyes on multiple glaucoma medications.

Methods: In this retrospective cohort study subject eyes recruited were patients at the New York Eye and Ear Infirmary of Mount Sinai (NYEEI) resident glaucoma clinic prescribed with netarsudil between November 2020 and February 2021. These eyes were diagnosed with glaucoma and had IOP above target despite being on ≥ 2 ocular hypotensive agents. Subject eyes were excluded if they were unable to tolerate or adhere to netarsudil for a period of 4-8 weeks after initiation of therapy. The main subject measure was the IOP-reducing effect of netarsudil after 4-8 weeks of therapy, with comparisons made between types of glaucoma and between eyes that did and did not have prior glaucoma surgery. Data was further assessed via t-test and interpreted as a percentage change in IOP.

Results: Netarsudil was prescribed for 222 eyes. 50 eyes were excluded from analysis due to lack of adequate follow up or inability to adhere to therapy, leaving 172 eyes for analysis. 114 eyes had open angle glaucoma (OAG) and 17 had mixed mechanism glaucoma (MMG). The mean baseline IOP for eyes with OAG and those with MMG were 21.1 ± 5.8 mm Hg and 19.4 ± 5 mm Hg, respectively. After 4-8 weeks of treatment the mean IOP for eyes with OAG and those with MMG were 16.3 ± 4.8 mm Hg ($p < 0.001$) and 16.2 ± 4.6 mm Hg ($p < 0.001$), respectively. 110 eyes had prior glaucoma surgery and 62 had not. Mean baseline IOPs for eyes that did and did not have glaucoma surgery were 20.7 ± 5.9 mm Hg and 21.6 ± 5.7 mm Hg, respectively. After 4-8 weeks of treatment with netarsudil, the mean IOPs were 16.4 ± 5 mm Hg ($p < 0.001$) and 15.4 ± 4.5 mm Hg ($p < 0.001$), respectively.

Conclusions: This study demonstrates that netarsudil is efficacious in eyes already on multiple glaucoma medications, regardless of the type of glaucoma or whether prior glaucoma surgery was performed and can help delay the need for incisional glaucoma surgery. This efficacy coexists with barriers to accessing and using the medication including cost and the burden of taking multiple ocular hypotensive drops. Patients indoubtedly benefit from the availability of netarsudil and particular attention should be paid to facilitating their ability to access it.

ABSTRACT BODY:

Purpose: Microglia become activated in parallel with neurodegeneration in the retinas of humans with diabetic retinopathy (DR) and in rodent models but their role in mediating functional vision loss remains unclear. This study tested the hypothesis that chronic ablation of activated retinal microglia can prevent visual function deficits during early-stage DR in the mouse.

Methods: Male Cx3cr1$^{YFP\text{-}CreER/+}$; Rosa26$^{DTA/+}$ (TG) mice were given single intraperitoneal (IP) injections of Streptozotocin (STZ; 150mg/kg) delivered in a sodium citrate buffer (pH~4.5) or buffer solution as a control. STZ diabetic (>250mg/dL blood glucose) and non-diabetic mice were transfered to cages containing tamoxifen-infused chow (500mg/kg) or regular chow for 8 weeks to compare control (CTRL), diabetic (STZ), microglia-ablated control (TAM), and microglia-ablated diabetic (TAM+STZ) groups (N=4-5). 9-step scotopic (rod-specific) intensity and 7-step photopic (cone-specific) intensity electroretinography (ERG) assessments were performed on anesthetized mice at 4- and 8-weeks. Retinas were processed post-hoc for immunostaining to assess microglial ablation efficacy. One-way and two-way ANOVA tests were used for statistical analysis.

Results: Tamoxifen-treated TG mice showed reduced microglial density within one week of treatment (Mean±SEM), corresponding to a >93% decrease (14.4±5.4/mm^2 retina; p<.0001) compared to untreated control mice (206.2±6.6) that sustained through 8 weeks of treatment. Comparing STZ to TAM+STZ, the following scotopic measurements showed statistical difference at 4 weeks: (a-wave) 193.9±16.6μV vs. 249.3±14.6 (-4db; p<.0054), 231.0±16.8μV vs. 305.0±15.5 (0db; p<.0001), 307.1±23.3μV vs. 391.0±19.4 (5db; p<.0001); (b-wave) 455.0±48.0μV vs. 589.6±35.8 (0db; p=.0126), 553.6±46.7μV vs. 668.4±32.3 (5db; p=.0499). No significant differences in scotopic measurements were found between TAM+STZ, CTRL, and TAM groups. No significant differences in photopic measurements were found between all groups.

Conclusions: Our results support our hypothesis that ablation of activated retinal microglia can prevent DR-associated functional vision loss during early-stage DR. Further examination of microglial activation in DR will be needed to understand their unique contribution to neuro-retinal dysfunction.

ABSTRACT BODY:

Purpose: Dry eye disease (DED) is a symptomatic ocular surface condition that imposes a substantial health burden and can affect a patient's daily activities and quality of life (QoL). AR-15512 is a TRPM8 cold thermoreceptor agonist that stimulates both tear production and a cooling sensation across the ocular surface. A phase 2b study was conducted to evaluate DED symptoms and QoL following administration of AR-15512.

Methods: Prospective, double-masked study evaluating two formulations of AR-15512 (0.0014% and 0.003%) versus vehicle dosed twice daily for 84 days in 369 DED subjects. Following vehicle run-in, eligible subjects were randomized 1:1:1 and evaluated where applicable at Days 1, 14, 28 and 84. Outcomes included tear production (unanesthetized Schirmer test, performed at D1 and D14 only), symptoms (Symptom Assessment iN Dry Eye [SANDE] and visual analog scales [VAS] for ocular discomfort [ODS] and eye dryness [EDS]) and QoL (7 VAS questions evaluating activities of daily living: driving, workplace productivity, reading books, reading fine print, using electronic devices, watching TV, and feeling depressed).

Results: Overall, 369 subjects enrolled (mean age 63.7; 72% female) and of these, 345 (93.5%) completed the study. Statistically significant improvements were achieved in the ITT population with 0.003% AR-15512 vs vehicle for both signs and multiple symptoms. Increased tear production was observed after initial dose and repeat dosing (D1: 20.2 vs 8.1mm and D14: 19.5 vs 5.9mm, $p<0.0001$). Symptom improvements were observed as follows: SANDE on D14 (-7.4 vs -2.9, $p=0.0254$), D28 (-12.9 vs -5.0, $p=0.0005$) and D84 (-17.2 vs -8.3, $p=0.0015$), ODS (-20.6 vs -13.6, $p=0.0281$) and EDS (-17.1 vs -10.8, $p=0.0302$) at D84. Lastly, statistically significant improvements ($p<0.05$) from baseline were also seen with 0.003% AR-15512 relative to vehicle on all 7 QoL measures as early as D14, with the magnitude of difference relative to vehicle continuing to widen throughout the 84-day study on most of the measures. AR-15512 was well tolerated, with few discontinuations (n=7; 1.9%) due to adverse events.

Conclusions: In addition to improving signs and symptoms, 0.003% AR-15512 demonstrated improvements in functional vision which were observed within 2 weeks and continued to improve over time. AR-15512 represents a novel treatment for DED with the potential to improve patient quality of life.

ABSTRACT BODY:

Purpose: Morpholino (MO) and 2′ O-methoxyethyl (MOE) are two chemical modifications frequently applied to antisense oligonucleotides (ASOs) that are being used to manipulate gene expression for therapeutic applications. The fate of the ASO-targeted RNA depends on the ASO mechanism of action, which can be influenced by its chemical modifications. MO and MOEs are chemical modifications to the ribose sugar, which, when combined with modifications to the phosphate backbone, significantly improve ASO pharmacokinetic properties, innate immune response, and stability, making them ideal drugs for the treatment of diseases with defined genetic targets. Retinitis pigmentosa (RP) affects 1 in 4000 individuals worldwide, yet there are no effective treatments. In this study, we tested ASOs with MO or MOE modifications for the treatment of visual dysfunction in a mouse model of Usher syndrome (USH). USH is a form of RP that includes hearing impairment. Transgenic mice with a splicing mutation (216A) in the Ush1c gene, which causes USH in humans, have retinal dysfunction characteristic of RP, as well as profound hearing and vestibular deficits. Previously, we showed short-term rescue of hearing, balance, and vision in USH mice treated with a 216A-targeted-MOE-ASO. Here, we demonstrate that a combination of MO- and MOE-ASOs (Combo-ASO) significantly extends the duration of improved visual function in USH mice.

Methods: Juvenile USH mice were treated with MOE-, MO-, or Combo-ASOs by intravitreal injection. Visual function was then measured at 3-12 months of age using electroretinogram (ERG) analysis. Retinal Ush1c and protein expression was measured by Next generation sequencing (NGS) and immunohistochemistry (IHC), respectively.

Results: At 3 months of age, ERGs were significantly increased in all USH mice treated with ASOs compared with untreated USH control mice. The increased ERGs persisted for up to 12 months of age in USH mice treated one time with Combo-ASOs, compared with 3-6 months of age after treatment with MOE- or MO-ASOs alone. Further, NGS and IHC showed significantly improved Ush1c splicing and protein expression in the retinas of ASO-treated USH mice.

Conclusions: These data demonstrate that a single dose of Combo-ASO significantly extends the duration of improved vision in USH mice and the potential for annual administration of ASO therapy for a long-term benefit to vision.

ABSTRACT BODY:

Purpose: To utilize federated learning (FL), a method of collaboratively training deep learning (DL) models without sharing patient data, to differentiate inter-institutional diagnostic patterns and disease epidemiology in retinopathy of prematurity (ROP).

Methods: 5,245 retinal images were obtained from exams of patients in the neonatal intensive care units of 7 institutions. Images were labeled according to both the bedside clinical grading (CL) of plus disease (plus, pre-plus, no plus), and a reference standard diagnosis (RSD) determined by a consensus of three masked graders and the clinical diagnosis. Birthweight (BW), gestational age (GA), and clinical grades for all eye exams were recorded. DL models were trained on clinical labels for plus disease classification using either a centralized multi-institutional dataset, or an FL approach. Area under the receiver operating characteristic curve (ROC) was used as a measure of model performance. A DL-derived vascular severity score (VSS) was calculated for each eye exam. An “institutional VSS” was calculated by averaging the VSS of the most severe eye exam for each baby at each site. Demographics, clinical diagnosis of plus disease, and VSS between institutions were compared with simple linear regression, McNemar-Bowker test and one-way ANOVA.

Results: The performance of FL and central models trained on clinical labels was found to be equivalent (ROC = 0.93±0.06 vs 0.95±0.03, p=0.0175). The proportion of patients diagnosed as no plus and pre-plus by CL and RSD methods varied significantly (p<0.00l). Vascular severity and VSS corresponding to “no plus” diagnoses varied significantly across institutions (p<0.001). We found an inverse relationship between institutional VSS and mean GA (Figure 1, p=0.049, adjusted R^2=0.49).

Conclusions: FL enabled the development of an accurate, DL-derived ROP VSS by drawing from multiple institutions’ labels without inter-institutional sharing of data. We identified differences in the clinical diagnosis of plus disease, and levels of objective ROP severity between institutions. FL has promise for objectively assessing differences in clinician diagnostic paradigms and disease severity across institutions.

ABSTRACT BODY:

Purpose: The Joslin Medalist Study found increased concentrations of Retinol Binding Protein 3 (RBP3) in people with type 1 diabetes for 50 years or longer with no to mild non-proliferative diabetic retinopathy (DR) versus those with proliferative DR (PDR). RBP3 potentially protects the retina by inhibiting glucose uptake and inflammation. This study correlated inflammatory cytokines and vascular endothelial growth factor (VEGF) in the vitreous and plasma with vitreous RBP3, DR severity, and DR progression in a diverse population of individuals with type 1 and type 2 diabetes.

Methods: Plasma and vitreous samples (N=205) were collected from individuals undergoing retinal surgery at the Joslin Beetham Eye Institute or as part of the Medalist Study, which collected vitreous postmortem. RBP3 and VEGF concentrations were measured by ELISA, and inflammatory cytokines by multiplex assay. Individual neural retinal layer thicknesses in the foveal area were obtained from optical coherence tomography (OCT) images using automated layer segmentation software (Heidelberg v6.0c) for the Medalist subjects.

Results: Elevated vitreous RBP3 concentrations were associated with less severe DR in all eyes ($p<0.0001$), and in both postmortem Medalist specimens ($P<0.0001$), and surgical samples from type 1 diabetes of shorter duration and type 2 diabetic patients ($P=0.03$). No difference in RBP3 concentration was identified between people with type 1 and type 2 diabetes ($P=0.19$). Higher RBP3 concentration was associated with reduced risk of PDR onset ($N=30$, $P<0.0001$), and with increased photoreceptor layer thickness ($P=0.04$). Higher concentrations of RBP3 were associated with lower levels of TNF-a, TNF-b and VEGF in the vitreous ($P<0.05$). PDR was associated with lower levels of vitreous IFN-γ ($P=0.001$) and IL-10 ($P=0.007$), and higher levels of vitreous IL-6 ($P=0.02$), IL-15 ($P=0.01$), and VEGF ($P<0.0001$), but was not associated with plasma concentrations of these cytokines. Vitreous VEGF levels did not correlate with its plasma levels.

Conclusions: These data suggest that RBP3's association with less severe DR and slower progression to PDR may be mediated by decreasing diabetes-induced inflammatory cytokines and VEGF in the retina. These findings support RBP3's potential as both a diagnostic and therapeutic approach to preventing or delaying progression of DR.

ABSTRACT BODY:

Purpose: Charles Bonnet syndrome (CBS) is characterised by visual hallucinations secondary to sight loss. Aside from sight loss, other risk factors associated with CBS include social isolation, loneliness, and post-traumatic stress. The health and lifestyle circumstances of visually impaired military veterans place this profile at an increased risk of developing CBS. The purpose of this study was to estimate the prevalence of CBS through an analysis of health records for members of a UK sight loss charity (Blind Veterans UK) and report experiences of CBS during the COVID-19 pandemic.

Methods: A retrospective analysis and screening/filtering of military veterans' electronic membership records at Blind Veterans UK. Text analysis was used to identify CBS cases. A cross sectional survey of individuals with active CBS was used to measures patient-reported features of hallucinatory experiences during the COVID-19 pandemic and perceived episode triggers.

Results: Analysis was conducted on 4109 members of Blind Veterans UK. Following screening and exclusion of members with non-sight loss related hallucination risk factors (e.g., Alzheimer's disease), 532 members were identified as CBS cases, representing 12.9% (95% CI: 11.1%-14.7%) of the cohort. Forty-five individuals with CBS completed the survey. Loneliness during the pandemic was associated with changes in the nature of visual hallucinations ($p=0.04$). Individuals experiencing greater loneliness were, on average, older than those with no changes to their feelings of loneliness ($p=0.03$). Despite experiencing greater feelings of loneliness (67%), most individuals had not accessed support services.

Conclusions: The relative high prevalence of CBS among visually impaired military veterans indicates that this cohort may be at greater risk of the condition. Approximately half of survey respondents experienced exacerbation of visual hallucinations during the COVID-19 pandemic, which may partly be explained by loneliness and/or environmental triggers.

TITLE: Evaluation of 8 mg Intravitreal Aflibercept Injection for Neovascular Age-Related Macular Degeneration: Results from the Phase 2 CANDELA Study

SESSION TITLE: Anti-VEGF in AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D.M. Brown, Retina Consultants of Texas, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure: David Brown: Commercial Relationship(s);Code C (Consultant/Contractor):Regeneron, Bayer, Genentech/Roche ;Code F (Financial Support):Regeneron, Bayer, Genentech/Roche

ABSTRACT BODY:

Purpose: Preclinical data suggest that an 8 mg intravitreal aflibercept injection (IAI) may intensify and prolong the therapeutic effect of IAI 2 mg. CANDELA, a phase 2, randomized, single-masked, open-label, 44-week clinical trial (NCT04126317) assessed the safety and efficacy of IAI 8 mg versus IAI 2 mg in patients with neovascular age-related macular degeneration (nAMD).

Methods: Treatment-naïve patients (≥50 years old) with active subfoveal choroidal neovascularization secondary to nAMD and a best corrected visual acuity (BCVA) of 78 to 24 letters (approximately 20/32 to 20/320) in the study eye were enrolled. A total of 106 patients were randomized 1:1 to receive 3 monthly doses of either IAI 2 mg (n=53) or IAI 8 mg (n=53) followed by doses at Week 20 and 32. The primary end points were safety and the proportion of eyes without retinal fluid in the center subfield at Week 16.

Results: Overall, majority of the patients were female (62.3%); the mean (SD) age was 77.4 (8.0) years and mean (SD) baseline BCVA was 58.0 (12.1) letters. The incidence of ocular-related adverse events (AEs) through Week 16 was 17.0% (9/53) for the IAI 8 mg group and 22.6% (12/53) for the IAI 2 mg group. No new safety signals were identified; no AEs of intraocular inflammation, occlusive vasculitis, or anti-platelet trialists' collaboration (APTC)-defined arterial thromboembolic events were reported through Week 16. The proportion of eyes with no retinal fluid in the center subfield at Week 16 was 50.9% (27/53) for the IAI 8 mg group and 34.0% (18/53) for IAI 2 mg group (treatment difference, 17.0% [95% CI, −1.6%, 35.5%]; P=0.0770). Compared to the IAI 2 mg group, eyes in the IAI 8 mg group showed a numerically greater reduction from baseline in median central subfield thickness (−161 µm vs −96 µm), and a numerically higher increase from baseline in mean BCVA (8.4 vs 6.5 letters) at Week 16.

Conclusions: The overall safety of IAI 8 mg was similar to that of IAI 2 mg at Week 16. The observed anatomic and functional improvements with IAI 8 mg suggest potential additional therapeutic benefit over IAI 2 mg in patients with nAMD. The data support further development of IAI 8 mg.

TITLE: Optical Coherence Tomography Findings in Choroidal Melanoma-Associated Subretinal Fluid

SESSION TITLE: Intraocular tumors - Uveal melanoma and retinoblastoma

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Kabaalioglu Guner, T.W. Olsen, L.A. Dalvin, Ophthalmology, Mayo Clinic Minnesota, Rochester, Minnesota, UNITED STATES|

Commercial Relationships Disclosure: Melis Kabaalioglu Guner: Commercial Relationship: Code N (No Commercial Relationship) | Timothy Olsen: Commercial Relationship: Code N (No Commercial Relationship) | Lauren Dalvin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To report the optical coherence tomography (OCT) findings of choroidal melanoma with subretinal fluid.

Methods: This is a single center, retrospective review of spectral domain OCT images of treatment naïve choroidal melanoma cases with associated subretinal fluid, presenting between July 2009 and August 2021. Demographic characteristics and tumor features were reviewed. Tumors were grouped according to Collaborative Ocular Melanoma Study (COMS) categories. OCT features were categorized as elongated photoreceptors, photoreceptor/ellipsoid zone (EZ) loss, retinal pigment epithelium (RPE) loss, RPE hyperplasia, intraretinal fluid, retinoschisis (inner layer, outer layer, or both), pigment epithelial detachment (PED), retinal thinning, outer plexiform layer (OPL) splitting, bacillary layer detachment (BALAD) (horizontal, circular or both), and subretinal hyperreflective material (SRHM) (homogenous, heterogenous or both). Statistical analysis was performed using SPSS Statistics Software Version 28 (IBM, Armonk, New York).

Results: OCT features of 236 patients, from the most to least common included: photoreceptor and/or EZ loss or disruption in 174 (73.7%), RPE hyperplasia in 153 (64.8%), photoreceptor elongation in 118 (50.0%), macular subretinal fluid in 92 (39.0%), intraretinal fluid in 84 (35.6%), heterogenous SRHM in 72 (30.5%), BALAD in 67 (28.4%), RPE loss or disruption in 67 (28.4%), retracted photoreceptors in 56 (23.7), retinal thinning in 50 (21.2%), OPL splitting in 50 (21.2%), homogenous SRHM in 48 (20.3%), PED in 38 (16.1%), and retinoschisis in 5 (2.1%) patients. Photoreceptor/EZ loss increased progressively with small vs. medium vs. large tumors (52.0% vs. 86.9% vs. 94.9%, $p<0.001$), and this difference remained significant when further analyzed with subretinal fluid extent as a confounder ($p<0.001$). BALAD was more common in medium compared to small melanomas and was associated with greater extent of subretinal fluid. This difference remained significant when subretinal fluid was considered as a confounding variable ($p=0.006$).

Conclusions: Choroidal melanoma-associated subretinal fluid has many unique OCT features including BALAD and SRHM. Future longitudinal studies are needed to evaluate the diagnostic and prognostic importance of these findings in patients with choroidal melanoma.

ABSTRACT BODY:

Purpose: The real-time stimulation of electrodes implanted in the visual pathway using a head-mounted camera creates visual perception through the activation of neurons at a close distance of the electrodes. Transferring camera frames to electrical pulses that create a meaningful and uniform percept requires understanding the relationship between the stimulation parameters and different percept properties such as brightness, location, shape, and size. Variable brightness across electrodes would cause images to look "mottled;" variable size could affect blurriness. Here, we studied the relative brightness and size of the percepts created by different Argus II epiretinal electrodes.

Methods: Three people with Argus II implant participated in this study. We tested 10 and 5 electrodes for S1 and S2, respectively, and three groups of 4, 5, and 10 electrodes for S3. The relative brightness and size of the percepts were studied in a 2-AFC task with all pair combinations in the group repeated three times in random order. In each trial, a pair of electrodes was stimulated, one by one, at an amplitude level corresponding to a 0.75 detection rate specific to the given electrode (previously estimated using a Bayesian adaptive threshold test). The participant was asked to choose which electrode in the pair was brighter regardless of the size and which was bigger regardless of brightness. Electrodes were ranked from 0 to 1 based on the percentage of trials in which they were judged brighter or bigger, and ranks were plotted against threshold; the average rank is expected to be 0.5, and the standard deviation (SD) represents uncertainty.

Results: Brightness ranks of all electrodes had a mean of 0.50 and a SD of 0.20 (range: 0.13 - 0.88). The average size rank was 0.50 with a SD of 0.17 (range: 0.07 - 0.81). Across electrodes, brightness ranks show a linear correlation with threshold ($r = 0.45$; $p = 0.007$), but the correlation between the size ranks and thresholds was not significant ($r = 0.27$; $p = 0.1$).

Conclusions: We showed phosphenes size is not affected by threshold differences. However, electrodes with higher thresholds do create brighter percepts. Therefore, uneven brightness may be corrected by scaling stimulus amplitudes according to the threshold, but it is unlikely that the image blur can be reduced. This should be considered when normalizing brightness and size of the percept elicited by implanted electrodes.

ABSTRACT BODY:

Purpose: Antibodies against Vascular Endothelial Growth Factor-A (VEGF-A) and Angiopoietin-2 (Ang-2) are validated targets in the treatment of retinal disease. With the introduction of a novel bispecific protein, RO-634, dual targeting of VEGF-A and Ang-2 is possible. This study investigates the ocular biocompatibility of the bispecific, RO-634, using histological analysis.

Methods: All experiments were performed in accordance with the ARVO statement for Use of Animals in Ophthalmic and Vision Research. Five Brown Norway rats received intravitreal injections of RO-634 in the right eye, and BSS in the left eye to evaluate for potential retinal toxicity. One month post intravitreal injection, the rats were sacrificed, and retinal tissue was collected for histological analysis. The tissues were sectioned, stained, and analyzed via Imagepro software to quantify the number of cells present in ganglion, inner nuclear, and outer nuclear cell layers. Each layer was identified by the software in three distinct areas to increase accuracy in quantification. Following automated check, a manual count was conducted to ensure all cells were counted. Those samples that did not have adequate

sectioning and fixation were discarded.

Results: RO-634 was well tolerated in the Brown Norway rats. Histological analysis between RO-634 and BSS did not demonstrate a statistically significant difference in cell count between ganglion cell layer (L=17.90 ± 1.31, R = 16.33 ± 1.11, T test = 0.40), outer nuclear cell layer (L= 156.04 ± 2.49, R = 153.09 ± 3.19, T test = 0.42) or inner nuclear cell layers (L=56.33 ± 2.11, R = 56.38 ± 1.42, T test = 0.98) within the retina (Figure 1), suggesting biocompatibility of RO-634.

Conclusions: The novel VEGF-A and Ang-2 bispecific protein (RO-634) demonstrates biocompatibility in this animal model. Further studies are needed to understand the therapeutic potential of this bispecific protein in retinal disease.

ABSTRACT BODY:

Purpose: Optic neuritis (ON) is a common manifestation of auto-immune demyelinating disorders such as myelin oligodendrocyte glycoprotein associated disease (MOGAD) and neuromyelitis optica spectrum disorder (NMOSD). The purpose of our study was to establish an animal model that replicates the clinical and histopathologic features of each disorder via injection of disease-specific autoantibodies under the optic nerve sheath of rats.

Methods: Long Evans rats (n=12/group) received a unilateral injection of NMO patient derived recombinant Aquaporin4 (rAQP4) autoantibodies or MOGAD serum IgG (MOGIgG) into the subarachnoidal space of the optic nerve. Changes in pattern electroretinography (PERG) and visual evoked potential (VEP) recordings, retinal ganglion cell (RGC) complex thickness, and optic nerve histopathology were determined. Results were compared to naïve rats using ANOVA and Tukey's test.

Results: Impaired RGC function was evident by significant declines in the P1 and P1 to N2 PERG amplitude in both MOGIgG (P1:7.6±2.9 µV, p=0.007; P1 to N2:-7.4±2 µV, p=0.001) and rAQP4-injected optic nerves (P1:6.0±1.3 µV, p=0.001; P1 to N2:-6.7±1.4 µV, p=0.001) when compared to naïve rats (P1:11.2±2.3 µV; P1 to N2:-11.3±1.5 µV). Rats having received antibodies displayed a similarly decreased P1 to N2 amplitude in the pattern VEP (naïve:8.3±1.7 µV; MOGIgG:5.1±1.1 µV, p=0.001; rAQP4:3.0±0.7 µV, p=0.001). While PERG indicates notable delays in conduction speed, flash VEP demonstrates significantly prolonged P2 latency in rAQP4-injected optic nerves (102±126 ms, p=0.003), but not after MOGIgG injection (73±19 ms, p=0.84), compared to naïve controls (69±7 ms). Optical coherence tomography reveals RGC complex thinning in both cohorts 21 days after antibody administration which was more severe in eyes from animals with rAQP4 injected optic nerve (naïve:99±8 µm; MOGIgG:92±6 µm, p=0.13; rAQP4:87±6 µm, p=0.005). Optic nerve histopathology revealed distinct patterns of demyelination and presence of anti-human IgG and complement deposition.

Conclusions: Structural and functional analysis of the visual system after MOGIgG or rAQP4 optic nerve injection shows disease-specific patterns of degeneration, with a more progressive nature in NMO-like ON, which parallels the human condition. This novel model of autoantibody-induced ON will provide an invaluable resource for future translational and therapeutic studies.

ABSTRACT BODY:

Purpose: Glaucoma disease modeling and ex-vivo stem cell approach to RGC degeneration require that human pluripotent stem cell derived RGCs are capable of responding to intra- and extra-retinal guidance cues to reach, recognize and connect with their targets. Here, we demonstrate that human RGCs generated from embryonic stem (ES) cells respond to the evolutionarily conserved intra-retinal cues for the guidance of axons towards the optic disc.

Methods: Human RGCs were generated from RGC reporter hES cells (Sluch et al., 2017, Stem Cells 6:1972) using a modified chemical induction protocol, which recapitulates RGC development. hRGCs were co-cultured with the central/peripheral retinal cells, isolated from embryonic day 16 (E16) rat embryos in the presence of IgG/anti- DCC, IgG/anti-Robo2, or after treatment of cells with chondroitinase. RGC morphology was examined by immunofluorescence coupled Sholl analysis, RGC function by electrophysiology, and transcriptional response by RNA seq analysis.

Results: The ES cell derived RGCs expressed transcripts corresponding to guidance receptors (eg. DCC, Robo2, EPHs and NRP1). When cultured on central retinal cells hRGCs elaborated long and complex neurites. The length and complexity of neurites were compromised when hRGCs were pre-incubated with DCC-antibody. There were more collapsed growth cones (GC) and decrease in Na currents amplitude in DCC antibody treated groups versus controls. In contrast, those co-cultured with peripheral retinal cells displayed short and simple neurites. The length and complexity of neurites improved significantly when peripheral retinal cells were treated with chondroitinase or hRGCs were pre-incubated with Robo2 antibody versus controls. There were more active GCs (increased number of filopodia) and significantly improved amplitude of Na currents in chondroitinase/Robo2 antibody treated groups compared to controls. The transcriptional response to intra-retinal guidance cues will be presented.

Conclusions: The human ES cell derived RGCs recognize the intra-retinal central versus peripheral guidance cues that restrain and guide RGCs axons towards the optic disc. These cues are evolutionarily conserved and may underlie the possible spatial physiological and transcriptional characteristics of RGCs.

ABSTRACT BODY:

Purpose: Retinal imaging is the gold standard in tele-ophthalmology. Limitations in two-dimensional imaging can lead to poor triage or unnecessary clinical referrals, especially during COVID-19. Combined retinal imaging with Optical Coherence Tomography-B scan (OCT-B) in detecting vision threatening diseases (VTDs) such as glaucoma in community-based screenings adds a third dimension to subject data.

Methods: A non-mydriatic Topcon 3D Maestro1 imaging system was deployed in this pilot study to screen 120 subjects (43.3% male, mean age 55.1) in community-based screenings. Measurements of vertical cup-to-disc ratio (VCDR), nerve fiber layer (NFL) thickness and macular and ganglion cell layer (GCL) thickness were collected along with color retinal images by the Maestro1. Visual acuity and intraocular pressures (IOP) were obtained as part of the screening protocol. Four types of OCTs were acquired: 78.33% 3D Wide, 13.33% 3D Macula, 5.83% 3D Disc, and 2.51% 5-Line Cross. An on-site certified reader (CR) interpreted results and provided consultation follow-up to a remote ophthalmic subspecialist.

Results: Of 222 eyes, OCT-B confirmed follow-up in 86.94%. 88.3% of subjects had referable eye pathology: 23.33% to general or specialty eye clinic and 65% to telemedicine. CR glaucoma referral based on OCT-B scan, VCDR and NFL defects was compared to OCT-B referral based on VCDR ≥0.65. Cohen's kappa was 0.546 with 30% disagreement. Compared to CR, OCT-B generated VCDR had a 91.1% specificity and 42.3% sensitivity in detecting glaucoma. VCDR, IOP, NFL, and GCL measurements were significantly correlated with CR glaucoma referral ($p<0.05$). Only VCDR, NFL, and GCL were significantly correlated with Maestro 1 glaucoma referral ($p<0.05$).

Conclusions: OCT-B images provide valuable added diagnostic information about referrals in glaucoma. Its ability to capture greater depth of information about the eye, such as NFL and GCL measurements, compared to traditional two-dimensional retinal photography, warrants consideration for OCT-B as a replacement for non-mydriatic retinal photography as the gold standard in ophthalmic diagnostics. Further studies can investigate the utility trend analysis of OCT-B in predicting VTD's progression over time.

ABSTRACT BODY:

Purpose:

Timely strabismus diagnosis may improve amblyopia outcomes or prevent need for surgery. We assessed factors associated with delayed diagnoses and worse outcomes in pediatric strabismus.

Methods: We analyzed electronic health record data from the American Academy of Ophthalmology IRIS® Registry (Intelligent Research in Sight), including children ≤10 years with exotropia or esotropia diagnosis codes. Primary outcome was age at strabismus diagnosis. Associations between strabismus surgery or residual amblyopia and race/ethnicity, insurance, population density, and access to pediatric ophthalmology were analyzed using multivariable linear, logistic regression, and survival analysis.

Results:

Of 161,600 children with new diagnosis of esotropia (107,005) or exotropia (54,595), 43.5% were diagnosed before age of 4. Esotropic Hispanic, Black, and Asian children were diagnosed an average of 5.2 (95% CI: 2.8, 7.5),14.1 (11.2, 17.1) and 8.2 (3.2,13.3) weeks earlier compared to White children, and those with Medicaid were diagnosed 9.5 (7.9,11.2) weeks earlier compared to those with commercial insurance. Exotropic Hispanic and Asian children were diagnosed 10.6 (7.4, 13.8) and 40.9 weeks (35.3, 46.6) later than White children, and Medicaid patients (vs. commercial insurance) 12 weeks earlier (9.5, 14.4). The hazard ratio of strabismus surgery for Medicaid vs. commercial insurance was 1.28 (1.23, 1.32) for esotropia and 1.22 (1.17, 1.27) for exotropia.(Figure) Odds of developing residual amblyopia were significantly higher in children with Medicaid vs. commercial insurance both for esotropia [OR 1.75; 95%CI 1.68, 1.8] and exotropia (1.57; 1.46, 1.69).(Table) Controlling for age of strabismus diagnosis had minimal impact on our results.

Conclusions:

Strabismic children with Medicaid did not appear to have a delayed diagnosis yet were more likely to require surgery and develop residual amblyopia.

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) is a neurovascular complication of diabetes with limited therapeutic options due to lack of neuroprotection. We have established the role of 12/15Lipoxygenase (12/15-LO) in inducing microvascular dysfunction in DR. The purpose of this work was to characterize the role of 12/15-LO- metabolite 12-hydroxyeicosatetraenoic acids (12-HETE) in retinal neuronal dysfunction in DR.

Methods: We generated diabetic mouse model that lacks 12/15-LO ($Ins2^{Akita}$/12/15-$LO^{-/-}$). The functional alterations of retinal ganglion cells (RGCs) in diabetic ($Ins2^{Akita}$) mice were assessed using Electroretinogram (ERG) compared to control and ($Ins2^{Akita}$/12/15-$LO^{-/-}$). We also evaluated retinal thickness in hematoxylin and eosin stained retinal sections from various mouse groups using image-J. To understand the pathological role of 12-HETE in diabetes-induced visual impairment, we characterized retinal expression of the 12-HETE receptor G-protein coupled receptor 31 (GPR31) in retinal sections using specific antibody. Colocalization of GPR31 with RBPMS marker of RGCs was also performed. Moreover, we evaluated specific RGC protein Brn3 in retinas of various groups by Western blots. N=3-8.

Results: The total thickness of retina (from the inner limiting membrane or ILM to retinal pigment epithelium or RPE) was significantly reduced in central and peripheral retina of diabetic mice compared to the age-matched control retina (207± 7 vs 254±29 μm in central retina and 172±12 vs 216±31 μm in peripheral retina). While the thickness of inner retina (from ILM to outer plexiform layer or OPL) was also significantly reduced in diabetic mice compared to control (97 +5 vs 133+4 mm), the thickness of outer retina (from OPL to RPE) was not altered. Deletion of 12/15-LO preserved total and inner retina thickness in $Ins2^{Akita}$/12/15-$LO^{-/-}$ mice (258+14 and 125+10 mm respectively in central retina). ERG studies showed significant decrease of the peak amplitudes of pSTRs elicited by moderately high stimuli in diabetic mice. Deletion of 12/15-LO KO partially reversed the reduced amplitudes of pSTRs across a range of light intensities. Immunostaining manifest GPR31 is primarily localized in RGCs and Muller cells. Western blot showed 12/15-LO deletion restored retinal expression of Brn3 in diabetic mice.

Conclusions: 12/15-LO contributes to neuronal dysfunction and could be a therapeutic target to prevent visual impairment in DR.

TITLE: Survey of Alternative Treatments for Glaucoma
Patton, A.; Pandher, M.; Khouri, AS
SESSION TITLE: Pharmacology/cellular mechanisms
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: A. Patton, M. Pandher, A. Khouri, Rutgers New Jersey Medical School, Newark, New Jersey, UNITED STATES|
Commercial Relationships Disclosure: Alisa Patton: Commercial Relationship: Code N (No Commercial Relationship) | Meher Pandher: Commercial Relationship: Code N (No Commercial Relationship) | Albert Khouri: Commercial Relationship: Code N (No Commercial Relationship)
ABSTRACT BODY:
Purpose: Glaucoma is a common cause of irreversible blindness worldwide and new treatments are still being developed. Interest in and use of “alternative” treatments for many diseases by adults in the US has grown. The purpose of this study is to evaluate the prevalence of patient use of alternative treatments for glaucoma.
Methods: A survey was adapted from two prior surveys on alternative treatments, one validated and one published in an AAO study. Surveys were administered from November-December 2021 to patients of the Rutgers Department of Ophthalmology and Visual Science glaucoma clinic. Surveys were administered in an interview format with medical students reading survey questions to patients in a private room.
Results: A total of 100 survey results were collected and analyzed. Average age of respondents was in their 60s, with the majority having glaucoma for 10 years or less (Table 1). Of respondents, 95% use at least 1 prescription eyedrop for glaucoma and 68% had prior surgery to treat their glaucoma. Data showed that 32% reported using nonconventional therapies to treat their glaucoma. Of those who use nonconventional therapies, the most common were use of vitamins (84.4%), changes to diet (28.1%), exercise (12.5%) and use of cannabis (18.8%) (Table 2). Common vitamin supplements used included Vitamins A, B, C, D, Vitamin B12, multivitamins, Turmeric, Omega 3, CoQ10, AREDS 2 (Age-Related Eye Disease Vitamins), and an eye specific formulation with bilberry, lutein and antioxidants. When asked if patients believed their use of nonconventional therapies lowered eye pressure, halted worsening of glaucoma, improved vision, or worked in general, most patients were unsure (43%, 59%, 53.1%, and 53.1% respectively). Very few patients discussed use of nonconventional therapies with their doctor (6.3%). Patients answered they were only “somewhat confident” that their dietary supplements would do as they claim (53%) or that their supplements are safe to consume (46.9%).
Conclusions: The most common alternative treatment for glaucoma is vitamins followed by diet changes and cannabis. One in three glaucoma patients use alternative treatments, yet less than a tenth discussed it with their doctor, and most were unsure whether it had a definitive effect on their glaucoma. This indicates a need for increased research in the space as well as patient education on this evolving area of treatment.

TITLE: Comparison of diurnal variations in ocular biometrics and intraocular pressure between hyperopes and non-hyperopes

SESSION TITLE: Refractive Error: Myopia, Hyperopia, vision and models

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Moukaddem, N. Strang, L. Gray, Department of Vision Sciences, Glasgow Caledonian University, Glasgow, UNITED KINGDOM|P. McGraw, C. Scholes, School of Psychology, University of Nottingham, Nottingham, UNITED KINGDOM|

Commercial Relationships Disclosure: Diana Moukaddem: Commercial Relationship: Code N (No Commercial Relationship) | Niall Strang: Commercial Relationship: Code N (No Commercial Relationship) | Lyle Gray: Commercial Relationship: Code N (No Commercial Relationship) | Paul McGraw: Commercial Relationship: Code N (No Commercial Relationship) | Chris Scholes: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Circadian variation in ocular biometry and intraocular pressure (IOP) is well documented and is thought to play an important role in refractive error development. While previous studies have compared emmetropic and myopic subjects, little is known about circadian variation in hyperopia. In this study, we examine the diurnal variation of ocular biometry and intraocular pressure in subjects with and without hyperopia.

Methods: Pre-presbyopic adults (mean (±SD) age 24.00 ±3.89 years) participated; 18 subjects were hyperopic (MSE ≥ +1.25 DS; mean group MSE = +4.33 ± 2.24 DS) and 17 were non-hyperopes (MSE < +1.25 DS; group mean MSE = -1.44 ± 2.27 DS). Nine of the non-hyperopes were myopes. Subjects had the following ocular parameters measured at 6 equally spaced time points between 8am and 9pm: Choroidal thickness (ChT) in the nine regions defined by the EDTRS protocol across the central 30° of fundus, axial length (AL) and IOP.

Results: Group mean AL increased through the morning until 1:12pm ± 13min, and decreased throughout the rest of the day, in both groups. Group mean IOP decreased throughout the day in both groups as well. Group mean sub-foveal ChT reached a minimum value at 3:41pm ±14 min in both groups. However, peripheral ChT was different between the groups: in the hyperopic group, mean peripheral ChT reached a minimum at 6:15pm±13min, while in the non-hyperopic group it reached a minimum at 1:12pm±13min. Diurnal variation amplitudes was not statistically different between hyperopes and non- hyperopes for AL (33.89 ± 16.85μm vs 35.29 ± 29.18μm), sub-foveal ChT (19.72 ± 9.29 μm vs 22.77 ± 11.44μm), peripheral ChT (15.12 ± 9.43μm vs 13.26 ± 5.8μm), or IOP (4.17 ± 1.82mmHg vs 4.82 ± 2.1mmHg).

Conclusions: Diurnal variation of peripheral ChT in hyperopic subjects shows a phase-delay when compared to the non-hyperopic group. This phase-delay aligns the peripheral diurnal variation in ChT more closely to the diurnal variation in AL. This is consistent with ocular growth studies in young chicks (Nickla, 2006) and pre-presbyopic humans (Chakraborty et al., 2012) where ChT and AL cycles phase-align in order to slow their growth response to ocular defocus.

ABSTRACT BODY:

Purpose: Recessive Stargardt disease (STGD1) is an inherited maculopathy caused predominantly by mutations in the ABCA4 gene. The buildup of auto-fluorescent lipofuscin within the retinal pigment epithelium (RPE) is a pathological hallmark of STGD1. Daily phagocytosis of outer-segments membranes requires a functional endolysosomal system to prevent additional stress on the RPE. Cathepsin D (CatD) is a primary lysosomal protease responsible for protein degradation in the RPE. Both CatD activity and protein maturation are dependent on acidic pH in the endolysosomal compartments. We previously reported impaired maturation and reduced activity of CatD in the STGD1 mouse model ($Abca4^{-/-}$). Here, we sought to investigate CatD activity using induced pluripotent stem cell (iPSC)-derived RPE cells from three STGD1 patients.

Methods: Immature CatD protein was evaluated by immunostaining in iPSC-RPE cells from STGD1 patients with confirmed ABCA4 mutations, and unaffected control (no ABCA4 mutations) at 1-and 2-mo in-culture. Distribution of immature CatD with endolysosomal markers was assessed in iPSC-RPE cells by immunocytochemistry using super-resolution and confocal microscopy. Lysosomal pH was measured using LysoSensor Yellow/Blue DND-160 ratiometric probe (n=3), and CatD functional activity by fluorometric assay (n=4-7) in iPSC-RPE cells. Statistical significance was determined by ANOVA testing with Tukey-Kramer post-hoc analysis.

Results: At 1- and 2-mo, STGD1 iPSC-RPE cells exhibit aggregation of immature CatD. Interestingly, immature CatD in STGD1 iPSC-RPE cells co-localizes with both Rab5 and Lamp1 endo-lysosomal markers respectively. In contrast, immature CatD only co-localizes with the early endosome marker Rab5 in control iPSC-RPE cells. Lysosomal pH was elevated in all three STGD1 patients' iPSC-RPE cells vs control ($p<0.05$). Notably, CatD functional activity was significantly reduced ($p<0.05$) in two of the donor STGD1 iPSC-RPE cell lines compared to control.

Conclusions: Consistent with studies in the STGD1 mouse model, we provide further evidence for endo-lysosomal dysfunction in STGD1 patient-derived iPSC-RPE cells, mediated by CatD deficiency. Improper localization of immature CatD coupled with reduced functional activity indicates an amplified degrative burden in STGD1 RPE cells. These findings support the contribution of CatD in developing a STGD1 phenotype and suggest its potential as a therapeutic target.

TITLE: Demographic Factors Associated with Treatment Modalities in California Medicare Beneficiaries with Diabetic Retinopathy

SESSION TITLE: Diabetic retinopathy epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.Y. Ko, C. Felix, A.L. Coleman, University of California Los Angeles David Geffen School of Medicine, Los Angeles, California, UNITED STATES|F. Yu, H. Hosseini, A.L. Coleman, Jules Stein Eye Institute, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Michelle Ko: Commercial Relationship: Code N (No Commercial Relationship) | Christian Felix: Commercial Relationship: Code N (No Commercial Relationship) | Fei Yu: Commercial Relationship: Code N (No Commercial Relationship) | Hamid Hosseini: Commercial Relationship: Code N (No Commercial Relationship) | Anne Coleman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To examine the association of demographic factors with the use of diabetic retinopathy (DR) treatments in the 2017 California Medicare beneficiaries diagnosed with DR.

Methods: The study population included all Medicare beneficiaries diagnosed with DR with at least one part B claim in California in 2017, using data obtained from the Centers for Medicare & Medicaid Services (CMS). The diagnosis of DR was based on the International Classification of Diseases 10th Revision, Clinical Modification (ICD-10-CM) diagnosis codes. The demographic factors included sex (male, female) and race (White, Black, Asian, Hispanic, Other). The outcomes of interest were major DR treatment modalities, including anti-VEGF intravitreal injections (IVI), laser photocoagulation, panretinal photocoagulation (PRP), and vitrectomy, which were identified based on the Healthcare Common Procedure Coding System (HCPCS) codes or the Current Procedural Terminology (CPT) codes. Multivariable logistic regression modeling was performed to examine the association between demographic predictors and use of DR treatments, adjusting for age, sex, race, and presence of hypertension.

Results: There were 83,085 Californian Medicare DR patients, of which the majority had type 2 DR (78,233, 94.2%). Compared with White DR patients, all other racial groups were less likely to receive the IVI treatment in the adjusted analysis: Asian (odds ratio[OR]=0.65, $p<0.001$), Black (OR=0.83, $p<0.001$), and Other (OR=0.83, $p=0.005$); but were more likely to receive laser photocoagulation: Hispanic (OR=1.84, $p<0.001$), Other (OR=1.34 $p=0.0035$), Black (OR=1.23, $p=0.0245$), and Asian (OR=1.19, $p=0.0033$), and to receive PRP: Hispanic (OR=2.27, $p<0.001$), Black (OR=1.68, $p<0.001$), Other (OR=1.44, $p=0.0004$), and Asian (OR=1.40, $p<0.001$). Compared with male DR patients, females were less likely to receive all types of DR treatment: OR=0.89 ($p<0.001$) for IVI, OR=0.85 ($p<0.001$) for PRP, and OR=0.58 ($p=0.0002$) for vitrectomy, except for laser photocoagulation (OR=1.0, $p=0.95$).

Conclusions: Among all California Medicare DR patients in 2017, Black, Asian, Hispanic, or Other -identifying patients were generally less likely to receive IVI but more likely to receive laser photocoagulation, and PRP compared to their White counterparts. Female patients were less likely to receive IVI, PRP, and vitrectomy compared to their male counterparts.

TITLE: High concentration of adrenaline blocks key cell cycle genes and exhibits potent antifibrotic and vasoconstrictor effects in glaucoma surgery

SESSION TITLE: Surgery and Wound Healing

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: C. Yu-Wai-Man, K. Thong, P. Andriesei, J. Ng, P.G. Hysi, King's College London, London, London, UNITED KINGDOM|

Commercial Relationships Disclosure: Cynthia Yu-Wai-Man: Commercial Relationship: Code N (No Commercial Relationship) | Kai Xin Thong: Commercial Relationship: Code N (No Commercial Relationship) | Petru Andriesei: Commercial Relationship: Code N (No Commercial Relationship) | Jia Ng: Commercial Relationship: Code N (No Commercial Relationship) | Pirro Hysi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Adrenaline is a sympathomimetic that is used in the irrigating solution to maintain pupil dilation during cataract surgery, and as a vasoconstrictor to decrease the risk of bleeding (Xylocaine- Adrenaline 0.0005%). It is less cytotoxic than Mitomycin-C and 5-Fluorouracil, which are currently used to prevent scarring in glaucoma surgery. We hypothesise that adrenaline could also have antifibrotic effects in glaucoma surgery.

Methods: Adrenaline (0% to 0.05%) was tested in fibroblast-populated collagen contraction and cell viability assays. Human Tenon's fibroblasts were treated with Adrenaline 0%, 0.0005%, 0.01% for 24 hours and mRNA was sequenced on the Illumina NextSeq 2000. FASTQ files were aligned to the human genome UCSC hg38 using RNA-STAR 2.5.2b. Differential expression was carried out using DESeq2. Adrenaline 0.05% (0.1 ml) was also injected subconjunctivally in 3 patients during trabeculectomy, Baerveldt tube and Microshunt surgeries, and the patients were monitored for ocular and systemic adverse effects. Two-tailed Student's t-test was used for statistical analyses.

Results: There was a dose-response decrease in fibroblast contractility: matrices decreased to 47.4% ($p=0.0002$) and 86.6% ($p<0.0001$) with Adrenaline 0.0005% and 0.01%, respectively, compared to control (0%) where matrices decreased to 25.2%. There was no significant decrease in cell viability even at high drug concentrations ($p>0.05$). High quality RNA was extracted (RIN≥ 9.4) and principal component analysis revealed tight clustering for each drug concentration. Adrenaline 0.01% significantly upregulated 25 G1/S genes and 11 S-phase genes, and downregulated 23 G2-phase and 17 M-phase genes ($p<0.05$) (Fig 1A). Adrenaline 0.05% also caused a significant decrease in conjunctival vascularity and there was no significant change in pupil size, pulse, blood pressure, and respiratory rate during glaucoma surgery ($p>0.05$) (Fig 1B).

Conclusions: Adrenaline is a safe and cheap antifibrotic drug (£1 per vial) that significantly blocks key cell cycle genes when used at high concentrations. Adrenaline inhibits the proliferation of fibroblasts, which enter a period of growth arrest but do not die. Unless contraindicated, we recommend subconjunctival injections of Adrenaline 0.05% to 0.1% in all glaucoma surgeries. Future aim is to include adrenaline in clinical trials of new antifibrotic drugs.

TITLE: Scotoma Replacement: simulation of vision with photoreceptor scotoma

SESSION TITLE: Mobility, Reading and Driving with Vision Impairment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Peli, R. Goldstein, J. Jung, Ophthalmology, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Eli Peli: Commercial Relationship: Code N (No Commercial Relationship) | Robert Goldstein: Commercial Relationship: Code N (No Commercial Relationship) | Jae-Hyun Jung: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Most simulations of vision with scotomas are wrongly represented as black patches over the image. While paracentral scotomas are not explicitly observable by patients, central scotomas due to photoreceptor damage are reported as “blurred” vision. Pyramidal models representing the multiscale contrast processing of the visual system have been used to simulate vision with field loss. However, these simulations blended the low frequency image content, without completely removing it. Here, we present a physiologically plausible computation scheme for scene appearance with photoreceptor scotomas.

Methods: After the pixel values in scotomatous areas in an image are replaced with “not a number” (NaN), we apply a pyramidal model (Peli, JOSA 1991, 2001) in the spatial domain. The interaction of the NaN with the pyramidal structure results in a simulated image that replaces the scotoma.

Results: Content from outside the scotomatous area is drawn into the scotoma by the response of cells higher in the visual pathway centered within the scotoma but with wide receptive fields extending outside the scotoma. The resulting simulation with no black patch is consistent with patients’ descriptions (Figs 1 & 2). Due to the high spatial correlation typical of natural images, the replacement image is highly consistent with the elided part of the scene. The areas outside the scotomatous area are seen by the residual functioning normal peripheral low-resolution retina. The result is a filling-in like effect without any cortical processing or adaptation.

Conclusions: The simulations provide insight into the lack of visibility of scotomas and further point to possible distinctions between field loss due to photoreceptor loss and higher cells loss (Peli, ARVO 2020).

ABSTRACT BODY:

Purpose: Genetic testing for diseases with complex inheritance such as glaucoma will become increasingly accessible with the development of polygenic risk scores (PRS) testing. Integrating polygenic risk scores (PRS) into healthcare has the potential to stratify an individual's risk of glaucoma across a broad population. Glaucoma is the most common cause of irreversible blindness worldwide, therefore effective screening for glaucoma endorsed by the population is highly important. Public acceptability is crucial before PRS testing can be integrated into clinical practice.

Methods: This study assessed the attitude of unaffected individuals towards PRS testing for glaucoma, and sought to identify factors associated with interest in testing. We performed a cross-sectional, questionnaire based survey of 418 unaffected individuals including those with a first-degree relative with glaucoma (n=193), those who had a recent eye examination (n=117), and general members of the community (n=108).

Results: Overall, 71.3% indicated an interest in taking a polygenic risk test for glaucoma. Interest was more likely in those who believed glaucoma to be a severe medical condition (OR 14.58, 95%CI (1.15-185.50), p=0.039), those concerned about developing glaucoma (OR 4.37, 95%CI (2.32-8.25), p<0.001), those with an intention to take appropriate measures regarding eye health (OR 2.39, 95%CI (1.16-4.95), p=0.019), and those preferring to know if considered to be at-risk or not (OR 4.52, 95%CI (2.32-8.83), p<0.001). These findings represent a valuable assessment of general public interest in glaucoma polygenic risk testing, which will be integral to the implementation and uptake of novel PRS based tests into clinical practice.

Conclusions: PRS has the potential to stratify individual risk across a broad population for many common conditions, including glaucoma. We found positive interest toward glaucoma PRS testing among three different groups of unaffected individuals from the community and have identified possible target populations for initial clinical implementation. These findings support the clinical implementation of polygenic risk scores for glaucoma to reduce irreversible vision loss.

ABSTRACT BODY:

Purpose: The use of minimally invasive glaucoma surgery (MIGS) during cataract surgery for patients with glaucoma has increased, accelerated by shorter surgical times and potentially less complications compared to glaucoma drainage device (GDD) implantation or trabeculectomy. Additionally, MIGS may help decrease eye drop burden, which is limited by patient adherence and can cause ocular surface toxicity. While several studies have evaluated clinical parameters following MIGS, information about longer term visual field (VF) outcomes is not widely available. The goal of this study is to evaluate long term clinical and VF outcomes following MIGS combined with cataract surgery.

Methods: This is a retrospective single-center case series of patients with glaucoma who had MIGS during cataract surgery between 11/2015 and 10/2019. Inclusion criteria were at least a 1-year of post-operative follow up, no history of prior incisional surgery, a reliable pre-operative VF, and a reliable post-operative VF at least 1 year after surgery. Clinical and VF metrics were assessed pre-operatively and at 1, 2, and 3 years post-operatively. Data collected included visual acuity (VA), intraocular pressure (IOP), number of glaucoma medications, VF mean deviation (MD), pattern standard deviation (PSD), and visual field index (VFI).

Results: 73 eyes of 60 patients were included, 50% male. The most common glaucoma diagnosis was primary open angle glaucoma (81%). MIGS devices included iStent, Trabectome, and Cypass Micro-Stent. Mean±SD IOP before surgery was 16.8±3.6 mmHg on 2.4±1.3 medications. At 3-year follow up (n=34 eyes), mean IOP was 16.4±2.9 mmHg (P=0.07) on 1.5± 1.4 glaucoma medications (P<0.001). Baseline VF metrics included MD of -6.2±5.9 dB, PSD of 5.3±4.0 dB, and VFI of 84±19%. There were no significant changes in MD, PSD, or VFI over time compared to baseline. VA improved from LogMAR 0.19±0.14 pre-operatively to 0.08±0.15 post-operatively (P<0.001).

Conclusions: Over the 3 year post-operative period of our cohort, MIGS combined with cataract surgery was associated with stable VF metrics as well as stable IOP with significant reduction in the number of glaucoma medications.

TITLE: Metabolic ecosystems exist between retina and RPE in vivo

SESSION TITLE: Retinal metabolism

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: D. Hass, C. Bisbach, J.B. Hurley, Biochemistry, University of Washington, Seattle, Washington, UNITED STATES|E. Giering, VA Puget Sound Health Care System Seattle Division, Seattle, Washington, UNITED STATES|

Commercial Relationships Disclosure: Daniel Hass: Commercial Relationship: Code N (No Commercial Relationship) | Elizabeth Giering: Commercial Relationship: Code N (No Commercial Relationship) | Celia Bisbach: Commercial Relationship: Code N (No Commercial Relationship) | James Hurley: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Our lab has proposed a working model for a metabolic ecosystem between the retina and retinal pigment epithelium (RPE). In this model, lactate derived from photoreceptor glycolysis fuels energy metabolism and minimizes glycolysis in RPE. We based this model on findings from ex vivo retina tissue and cultured RPE cells. The tissue microenvironment is different in vivo and ex vivo. These differences could influence metabolism and affect the physiological relevance of our model. In this study we directly evaluate the metabolic ecosystem hypothesis in vivo using ^{13}C-labeled glucose infused into the circulation of wild-type mice and mice lacking photoreceptors.

Methods: We infused a 100 mg/kg bolus of $^{13}C_6$-glucose though external jugular catheters in freely moving 3 month-old C57BL/6J or C57BL/6J; AIPL1$^{-/-}$ mice. Photoreceptors degenerate by 1 month of age in AIPL1$^{-/-}$ retinas. We euthanized mice 1-, 2-, 3-, or 5-minutes post-infusion and collected retina and eyecup (RPE, choroid, and sclera) tissue. We extracted and derivatized metabolites from both tissues then assessed metabolite abundance and ^{13}C labeling with gas chromatography-mass spectrometry.

Results: Following the infusion, ^{13}C labeling is saturated at the earliest time points on glycolytic intermediates in retina and eyecup tissue. In contrast, labeling of TCA cycle intermediates accumulates linearly over 5 minutes, suggesting this time period is optimal for assessing differences in ^{13}C flux. We compared ^{13}C labeling on C57BL6/J and AIPL1$^{-/-}$ eyecup tissue 3 minutes following a $^{13}C_6$-glucose infusion. If photoreceptor-derived lactate is a metabolic intermediate in the eyecup, ^{13}C labeling of downstream intermediates should decrease in AIPL1$^{-/-}$ eyecups. In AIPL1$^{-/-}$ eyecups, ^{13}C enrichment is significantly higher in middle glycolytic intermediates and significantly lower on late glycolytic intermediates (lactate, pyruvate) and TCA cycle intermediates.

Conclusions: Our data illustrates that without photoreceptors, flux of glucose through glycolysis to phosphoenolpyruvate increases in eyecup tissue. In contrast, flux of ^{13}C from glucose to lactate, pyruvate, and TCA cycle intermediates decreases. This disconnect in eyecup glucose metabolism in vivo can be explained by shuttling of photoreceptor-derived lactate to feed RPE metabolism. This is the first experimental evidence that a glucose/lactate metabolic ecosystem occurs in a mammalian eye in vivo.

ABSTRACT BODY:

Purpose: The lipid composition of meibum and tears is believed to play a role in meibomian gland dysfunction (MGD) and dry eye (DE). Sphingomyelinases (SMase) are enzymes that participate in the metabolism of sphingolipids (SPL), which have structural and bioactive functions on the ocular surface. We prospectively analyzed the tears of individuals with good versus poor meibum quality and quantified the activity of SMases with acidic (aSMase) and neutral (nSMase) pH optimums. We predicted that SMase expression would differ in individuals with good versus poor meibum quality.

Methods:

Participants were grouped by meibum quality (n=25 controls; n=25 with poor quality, MGD group). Meibum was forcefully expressed and collected on a cotton swab and tears were collected on Schirmer strips. Activity of tear SMases were determined by Amplex™ Red Sphingomyelinase Assay Kit (Thermo Fisher). DE symptoms and signs were assessed in a comprehensive manner. First, SMase expression between the MGD and control groups was compared. Next, correlations were conducted to examine relationships between SMases and SPL composition determined previously from meibum and tears. Finally, linear regression analyses examined how DE symptoms/signs relate to SMase expression.

Results: The mean population age was 57 ± 9 years; 84% identified as male, and 38% as white. Demographics were similar between the groups. aSMases (23,748 RFU, IQR=26,392 vs. 4,205 RFU, IQR=13,341, $p<0.001$) and nSMases (30,893 RFU, IQR=51,181 vs. 0 RFU, IQR=6263, $p<0.001$) expression in tears was greater in the control versus MGD group. SMase expression correlated with compositional changes in meibum and tear SPL. In meibum, SMases positively correlated with Sph (aSMase, $\rho=0.45$, $p<0.001$; nSMase, $\rho=0.45$, $p<0.001$). In tears, SMase negatively correlated with SM (aSMase, $\rho=-0.30$, $p<0.05$; nSMase, $\rho=-0.29$, $p<0.05$) and positively with S1P (aSMase, $\rho=0.51$, $p<0.001$; nSmase, $\rho=0.49$, $p<0.001$). Higher nSMase expression correlated with more severe DE symptoms (Dry Eye Questoinnaire-5; $\rho=0.29$, $p<0.05$) but less severe meibomian dropout (nSmase, $\rho=-0.35$, $p<0.05$).

Conclusions: SMase expression was reduced in the tears of individuals with MGD and expression levels were associated with altered concentrations of SPLs in meibum and tears. Enzymes of SPL lipid metabolism, such as SMase, may represent a target of therapeutic intervention in the treatment of MGD.

ABSTRACT BODY:

Purpose: Up to 50% of patients with uveal melanoma will develop metastatic disease, and novel treatments are needed to improve survival. We performed cell culture studies to determine the impact of early growth response-1 (EGR1) expression on uveal melanoma (UM) viability and treatment resistance against MEK inhibitors.

Methods: MP46 primary UM cells were maintained in RPMI media. EGR1 knockdown was accomplished using a lentiviral vector with shRNA against EGR1, and trametinib was used for MEK inhibition. Viability was assessed using an ATP assay, with quantitative real-time PCR and capillary western for gene and protein expression analysis, respectively.

Results: Treatment with trametinib or direct EGR1 knockdown alone reduced UM viability to 75% and 73%, respectively, compared to DMSO control. Combining trametinib and EGR1 knockdown further reduced viability to 50% (Figure 1) with in an approximate 2.5-fold reduction in EGR1 gene expression (n=3, p=0.01) and undetectable EGR1 protein expression compared to scramble plus DMSO control. Associated gene expression changes included upregulation of the metastasis suppressor NDGR1 and upregulation of COL11A1 and COX6A2, two of the top twenty genes downregulated in metastasis-developing uveal melanoma according to a subanalysis of The Cancer Genome Atlas (TCGA) consortium data.

Conclusions: Knockdown of EGR1 reduces viability and overcomes resistance to MEK inhibition in UM cell culture, implicating EGR1 as a key effector molecule in UM survival.

ABSTRACT BODY:

Purpose: Neurotrophic keratopathy (NK) is a degenerative disorder of the cornea characterized by decreased sensory innervation, epitheliopathy, and impaired epithelial healing. In this study, we performed an objective assessment of ocular pain and quality-of-life-related parameters in ocular graft-versus-host disease (oGVHD) patients with or without NK.

Methods: We included 184 oGVHD patients in this retrospective study, including 29 patients with NK defined as decreased corneal sensation as assessed by Cochet-Bonnet esthesiometer. We assessed their records for ocular pain assessment survey (OPAS) scores and clinical parameters, including corneal sensation, corneal fluorescein staining (CFS) score, Schirmer's test, tear break-up time (TBUT), and ocular surface disease index (OSDI) score.

Results: oGVHD patients with NK had lower corneal sensation (3.4±1.4 vs. 5.9±0.3, p≤0.0001), higher CFS scores (6.4±4.2 vs. 4.7±4.0, p=0.040), and lower TBUT scores (1.2±2.1 vs. 2.2±3.1, p=0.049) compared to oGVHD patients without NK and additionally had significantly higher ocular pain intensity scores (OPAS 24 hour average eye pain intensity: 2.0±2.8 vs. 1.1±1.9, p=0.03). Patients with NK more commonly reported burning (0.2±0.3 vs. 0.3±0.4, p=0.021) and sensitivity to light (0.2±0.3 vs. 0.3±0.4, p=0.049) as compared to patients without NK.

Conclusions: Clinical signs of ocular surface disease are worse in oGVHD patients with NK than in oGVHD patients without NK. These patients experience higher intensity ocular pain and lower quality of life-related parameters.

ABSTRACT BODY:

Purpose: It is unknown how eyecare professionals take care of their own eye health. This study aims to evaluate the presence of eye diseases and the frequency of eye examinations among eyecare professionals.

Methods: In this cross-sectional study, an anonymous questionnaire survey was distributed among eyecare professionals. The following parameters were evaluated in the survey: demographics, family history, medical and surgical history, refractive error, known eye diseases, previous ocular procedures, and previous eye examinations.

Results: 98 eyecare professionals responded which included 50 ophthalmic technicians, 27 ophthalmologists, 7 ophthalmology residents, 6 optometrists, and 8 ophthalmology clinic administrative staff. These included 36 men and 59 women; 3 preferred not to disclose their sex. The mean age was 41.9 ± 12.2 years (range, 21-75 years). Among these, 7.1% had diabetes. Family history was positive for glaucoma in 22.4%, age-related macular degeneration in 14.3%, and retinal detachment in 4.1%. 25 respondents (25.5%) had previous ocular surgery, including refractive surgery (22.4%), retinal laser surgery (2.0%), and cataract surgery (1.0%). Refractive error in the participants included myopia in 61.2%, hyperopia in 13.3%, and astigmatism in 33.7%. These eyecare professionals were known to have dry eye disease (36.7%), cataract (5.1%), amblyopia (3.1%), strabismus (2.0%), diabetic retinopathy (1.0%), and Fuchs' corneal dystrophy (1.0%). Participants' most recent eye exam was within the past 6 months in 16.3%, 6 to 11 months in 25.5%, 1 year in 14.3%, 2 years in 15.3%, or 3 to 5 years in 14.3%. The last eye exam was over five years ago in 11.2%; 4.1% never had any eye exam before. The average number of eye examinations obtained in the past year was 0.7±0.72. In the past five years, the participants had an average of 2.4±2.0 eye examinations and 6.7±9.4 non-ophthalmic medical examinations.

Conclusions: A significant percentage of eyecare professionals studied had personal or family history of eye diseases, especially dry eye disease and glaucoma, respectively. However, almost half of the participants did not have an eye exam in the past year. Eyecare professionals need to be reminded of the maintenance of their own eye health.

TITLE: Dorsal and ventral stream associations with autistic traits in children

SESSION TITLE: Vision assessment and Clinical applications

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J.E. Harding, C.J. McKinlay, D.W. Dai, S. Nivins, R.K. Shah, Liggins Institute, The University of Auckland, Auckland, NEW ZEALAND|A.E. Silva, B. Thompson, School of Optometry and Vision Science, University of Waterloo, Waterloo, Ontario, CANADA|C.J. McKinlay, Kidz First Neonatal Care, Auckland, NEW ZEALAND|B. Thompson, Centre for Eye and Vision Research Limited, HONG KONG|

ABSTRACT BODY:

Purpose: The dorsal stream vulnerability hypothesis posits that dorsal stream function is uniquely susceptible to damage during development. Consistent with this idea, an association between autistic spectrum disorder (ASD) and impaired global motion perception has been reported. We explored associations among dorsal stream functions (global motion perception, fine motor function), ventral stream functions (global form perception), and autism spectrum quotient (AQ), a measure of ASD traits, in 9-year-old children born with neurodevelopmental risk factors. We hypothesized that AQ would be associated with dorsal but not ventral stream functions.

Methods: The Children with Hypoglycaemia and their Later Development (CHYLD) study is a prospective cohort study of children born at risk of neonatal hypoglycaemia. At age 9-10 years, 397 children from the cohort completed measures of AQ, global motion (random dot kinematogram) and global form (Glass pattern) perception, fine motor function (Movement ABC, v2), and visual-motor integration (Beery VMI, v6). We used linear regression to quantify the associations among these measures. All models contained an intercept, and interactions with sex, socio-economic status, academic performance at age 9-10, preterm birth, and hypoglycaemia were assessed.

Results: Motion coherence thresholds ($\beta = 0.10$, $R^2 = 0.01$, $p = 0.045$), Movement ABC score ($\beta = -.30$, $R^2 = 0.09$, $p < 0.001$), and the Beery motor subtest score ($\beta = -.23$, $R^2 = 0.09$, $p < 0.001$), were significantly associated with AQ, but the Beery VMI subtest score was not. Additionally, form coherence thresholds interacted with sex ($\beta = 0.43$, $R^2 = 0.07$, $p = 0.001$), such that boys with higher thresholds (worse performance) exhibited higher AQ scores (more ASD traits; $\beta = 0.28$, $R^2 = 0.08$, $p < 0.001$), but no association was observed for girls.

Conclusions: Most measures of dorsal stream function were significantly associated with AQ, such that worse performance predicted higher AQ scores. Additionally, in boys, worse form perception was associated with higher AQ scores. Therefore, while the results support the presence of abnormal dorsal stream processing in children with high AQ, they also suggest that abnormal visual processing associated with high AQ extends beyond the dorsal stream. Further, the results implicate a sex difference in the association between AQ and visual function.

ABSTRACT BODY:

Purpose: Nutritional status is linked to onset and progression of advanced forms of age-related macular degeneration (AMD). Among various nutrients, higher dietary and plasma status of B vitamins has been associated with reduced AMD risk in several studies, but prospective studies are scarce. We report the associations of dietary intake and plasma status of B vitamins with the incidence of advanced AMD in French elderly subjects.

Methods: The Alienor study is an ongoing population-based cohort of 963 elderly residents of Bordeaux followed every 2-year since 2006. AMD was classified on the basis of color fundus photographs and spectral domain optical coherence tomography examinations (2006-17), and with self-reported AMD (2001-06). Dietary intakes of vitamins B1, B2, B3, B5, B6, B9 and B12 and total energy intake (TEI) were estimated from a 24-hour dietary recall performed at home by trained dieticians (2001). Plasma status of vitamins B6, B9 and B12 were measured from fasting blood sample (1999). Cox models were used to assess associations between B vitamins and AMD. Models were adjusted for age, sex, smoking status, HDL-cholesterol, genetic risk score, oral supplementation for AMD, BMI and physical activity, with additional adjustment for TEI for dietary B vitamins.

Results: Among 861 participants at risk for advanced AMD with available data for B vitamins, 93 (10.8%) developed advanced AMD. At any time after inclusion, the hazard of advanced AMD onset was significantly 28% lower when the intake of vitamin B5 was 1-SD (1.84mg) higher at inclusion (HR=0.72; 95%CI: 0.53-0.99). The hazard of advanced AMD onset was significantly 10% lower when intake of vitamin B6 was 1-SD (0.60mg) higher at inclusion (HR=0.90; 95%CI: 0.81-0.99). No statistically significant associations were found with intakes of other B vitamins.

At any time after inclusion, participants with a normal status for vitamin B9 (≥10 nmol/L) at inclusion had a 2-fold lower hazard of advanced AMD onset compared with participants with a deficient status for vitamin B9 (HR=0.49, 95%CI: 0.25-0.95). Plasma vitamins B6 and B12 were not significantly associated with AMD.

Conclusions: Higher dietary intake of vitamin B5, B6 and plasma vitamin B9 were associated with a lower risk of AMD. Sufficient intakes of B vitamins, mainly B5 (animal products, whole grains) and B6 (whole grains, liver), as well as a normal status of plasma vitamin B9, may help to prevent development of advanced AMD.

TITLE: Detecting patients with ocular comorbidities when screening for diabetic retinopathy (DR): an out-of-distribution (OOD) perspective

SESSION TITLE: AI in the Retina

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Novosel, F. Benmansour, F. Hoffmann-La Roche Ltd., Basel, SWITZERLAND|J. Dai, D. Ferrara, Genentech Inc, South San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure: Jelena Novosel: Commercial Relationship(s);Code E (Employment):F. Hoffmann-La Roche Ltd. | Jian Dai: Commercial Relationship(s);Code E (Employment):Genentech, Inc. | Daniela Ferrara: Commercial Relationship(s);Code E (Employment):Genentech, Inc. | Fethallah Benmansour: Commercial Relationship(s);Code E (Employment):F. Hoffmann-La Roche Ltd.

ABSTRACT BODY:

Purpose: When screening for DR in a patient population with diabetes, occurrence of ocular comorbidities, such as glaucoma, neuropathy, or age-related macular degeneration, remains possible. We frame the detection of patients with such ocular comorbidities as an OOD detection problem. Here we evaluated 3 state-of-the-art OOD methods for DR screening by using deep learning (DL) models trained from 7-field color fundus photos (7F-CFP).

Methods: Data, including images, from eyes of 37,358 patients with diabetes were analyzed (Inoveon Corporation). Early Treatment Diabetic Retinopathy Study Diabetic Retinopathy Severity Scale and the presence of referable ocular comorbidities (OOD samples) were assessed from 7F-CFP by professional graders. The prevalence of OOD patients was 1%. The data were split into train:tune:test sets (80:10:10).

A DL ResNet-50 model with transfer learning was trained at the image level using all 7F-CFP for either being more than mild DR (mtmDR) or not. Then, we assessed the ability of ResNet-50 to detect OOD samples by 2 methods: (1) uncertainty estimation (UE) using Monte Carlo Dropout (Gal et al, NIPS 2016), and (2) confidence score (CS) using class-conditional Gaussian distributed feature maps and Mahalanobis distance (Lee et al, NIPS 2018). We also trained an OOD binary classification (BC) model to classify patients as having referable ocular comorbidities or not. Performance was assessed with area under the receiver operating characteristic (AUROC) curve, specificity, sensitivity, and precision.

Results: The OOD BC evaluation results are listed in Table 1 and the method shows high sensitivity and specificity. The UE and CS results are illustrated in Figure 1 and both scores show overlapping values for patients with and without referable ocular comorbidities, making the 2 groups inseparable.

Conclusions: UE and CS render limited ability to identify patients with referable ocular comorbidities when the primary DL model is trained for detecting patients with mtmDR. In contrast, the OOD BC model performed better in detecting OOD samples. This indicates that real-world deployment of DL models for mtmDR detection might require an additional model, such as our OOD BC model, that detects patients with referable ocular comorbidities.

TITLE: Characterising DARC (Detecting Apoptosing Retinal Cells) spots in glaucoma and healthy eyes

SESSION TITLE: Data science, machine learning, and AI

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Maddison, S. Choi, M. Cordeiro, Novai Ltd, UNITED KINGDOM|S. Choi, M. Cordeiro, Glaucoma & Retinal Neurodegnrtn Res Grp, Imperial College, UCL IOO, Western Eye Hsp London, UNITED KINGDOM|

Commercial Relationships Disclosure: John Maddison: Commercial Relationship(s);Code E (Employment):Novai Ltd;Code P (Patent):Novai Ltd | Soyoung Choi: Commercial Relationship(s);Code E (Employment):Novai Ltd | M Francesca Cordeiro: Commercial Relationship(s);Code E (Employment):Novai Ltd;Code C (Consultant/Contractor):Visufarma;Code C (Consultant/Contractor):Allergan;Code C (Consultant/Contractor):Aerie Pharmaceuticals;Code R (Recipient):Novartis;Code F (Financial Support):Santen;Code F (Financial Support):Thea;Code F (Financial Support):Heidelberg Engineering

ABSTRACT BODY:

Purpose: Apoptosis is recognised as one of the earliest pathological processes in glaucoma. DARC technology is a retinal imaging technique the utilises an intravenous fluorescently labelled annexin 5 (ANX776) to identify cells in stress and apoptosis. We have previously shown, using a convolutional neural network (CNN)-aided algorithm, that the quantification of DARC spots (CNN DARC count) can predict progression of glaucoma up to 18 months ahead of OCT RNFL global changes. Here, we assess the qualitative characteristics of CNN-identified DARC spots by comparing their common descriptive measures (DM) in glaucoma and healthy eyes.

Methods: Anonymised retinal images were used from over-40year old glaucoma (n = 28 eyes) and healthy subjects (n = 68 eyes) from the Phase 2 DARC clinical trial (ISRCTN10751859). These subjects were recruited following informed consent, being obtained according to the Declaration of Helsinki and study approval by the Brent Research Ethics Committee. A previously described CNN-aided automated algorithm was used to identify DARC spots. Assessment of DM characteristics included analysis of mean, std (standard deviation), skew, kurtosis, cv (coefficient of variation), bvdist (Euclidean distance from the nearest blood vessel) and the 7 Hu moments from CNN-algorithm identified DARC spots averaged per eye. These DMs were analysed using single logistic regression (SLR) and bootstrapping (n = 1000) to classify glaucoma and healthy eyes.

Results: SLR identified cv as the best independent DM variable (AUC=0.75), with a log-likelihood ratio (LLR) p-value <0.0001. Then applying bootstrapping (n = 1000) to SLR to obtain confidence intervals gave an AUC of 0.75±0.07.

Conclusions: Our findings suggest that standard DMs of CNN-algorithm identified DARC spots (averaged per eye), may be used to classify glaucoma and healthy subjects. The cv DM appeared most promising using SLR, and can be easily applied to continuing DARC studies. In the future it may be possible to use an increased number of features to improve results. Future analysis of planned larger studies using DMs could further help improve disease classification, but these results support use of DM with CNN DARC for glaucoma diagnosis.

ABSTRACT BODY:

Purpose: ON is a common feature of Multiple Sclerosis (MS). Around 25% of MS patients present with ON as their initial symptom and approximately 50% of MS patients experience ON. DARC consists of an intravenously administered fluorescent-tagged annexin V (ANX776) which binds to phosphatidylserine, identifying cell stress and apoptosis, with retinal imaging. Here, we sought to differentiate DARC spots in ON subjects from healthy subjects by observing common descriptive measures (DM) of DARC spots identified by a previously described convolutional neural network (CNN)-aided algorithm.

Methods: DARC images were obtained and anonymised from ON (mean age = 46) and healthy (mean age = 48) participants from the Phase 2 DARC clinical trial (ISRCTN10751859). Recruitment of participants was achieved with informed consent, following the Declaration of Helsinki. The study was approved by the Brent Research Ethics Committee. DARC spots were identified from DARC retinal images obtained at 120 minutes after ANX776 administration in ON (n = 12) and healthy (n = 68) subjects using the CNN-aided algorithm. DM characteristics including the mean, std (standard deviation), skew, kurtosis, cv (coefficient of variation), bvdist (Euclidean distance from the nearest blood vessel) and the 7 Hu moments, were analysed on DARC spots from ON (n = 357) and healthy (n = 2457) eyes using two-tailed student t-tests. The distributions of individual spot metrics were then analysed using the two-sample Kolmogorov-Smirnov (KS) test.

Results: The mean, cv and kurtosis ($p \leq 0.0001$) and hu1 and std ($p \leq 0.001$) were found to be significantly different (using the two-sided t-test) between DARC spots in ON and healthy controls. The distributions of the individual metrics analysed using the two-sample KS test, showed a significant difference ($p \leq 0.0001$) between ON and healthy spots for the same variables (mean, cv, kurtosis, hu1 and std).

Conclusions: Our findings indicate that mean, cv, kurtosis, hu1 and std DM analysis of automatically identified DARC spots, can be used to distinguish DARC spots in ON and healthy subjects. Further planned trials with larger ON groups will involve DMs in the analysis between ON and healthy controls; these early results support use of DARC for ON diagnosis.

ABSTRACT BODY:

Purpose: Treat-and-extend (T&E) has become a dominant treatment regimen in anti-VEGF therapy in neovascular age-related macular degeneration (nAMD). However, retinal morphology and dynamics predictive of patient outcomes are still unclear. We developed and evaluated a predictive model of one-year visual outcomes based on machine learning to determine predictive optical coherence tomography (OCT)-based quantitative biomarkers.

Methods: Patient visual acuity trajectories were modeled with latent class mixed models (LCMM) parametrized with six classes and being a quadratic function of time. Macular OCT volume scans of treatment-naïve eyes, at baseline and four weeks after the first anti-VEGF injection, were analyzed with artificial intelligence (AI). Intraretinal fluid (IRF), subretinal fluid (SRF), pigment epithelial detachment (PED), and subretinal hyperreflective material (SHRM) were quantified using deep learning. Retinal morphology was represented with Early Treatment Diabetic Retinopathy Study (ETDRS) grid-based quantitative measurements to characterize spatial distribution and its change after the first injection. Using the computed set of biomarkers, a model to predict the responders/non-responders was built using a machine learning classifier, and was evaluated with a ten-fold cross-validation

Results: Pooled clinical trial data of 550 evaluable eyes from as many patients, receiving ranibizumab T&E therapy for one year were used. Based on LCMM analysis of visual acuity trajectories, 23% of eyes were considered as clinical non-responders (Figure 1). The developed machine learning model was able to predict the non-responders with an area under the receiver-operating curve (AUROC) of 0.74 (95% CI: 0.71-0.78), corresponding to a conservative operating point with 0.9 specificity and 0.4 sensitivity. The amount of IRF remaining after the first injection at Month 1 was found to be the most important predictive biomarker.

Conclusions: We proposed and evaluated an AI methodology to predict T&E visual outcomes. Predictive retinal OCT biomarkers help explain the different functional results after treatment between patients having similar baseline visual acuity initially. The result of this study is a promising step toward AI-based prediction of patient outcomes and may help to further personalize and optimize anti-VEGF therapy in clinical practice.

ABSTRACT BODY:
Purpose: To evaluate the use of the flow density map in Optical Coherence Tomography Angiography (OCT-A) in noninfectious uveitic macular edema.
Methods: Prospective observational study of 11 consecutive uveitis patients, in 16 eyes with 19 disease episodes, measured with density flow OCT-A in the Topcon DRI OCT Triton plus at edema and at remission. Patient mean age and standard deviation (SD) was 39.1 (20.6) years, where 6/11 (55%) were females. Layers were measured with the built-in automatic software layer segmentation as superficial, deep, outer and choriocapillaris, regardless of edema configuration. Density values in the nasal, central, temporal, superior and inferior macular area were recorded. Main outcome measures were visual acuity (VA) at edema and remission, OCT central retinal thickness (CRT) decrease and difference in layer density OCT-A flow at edema and remission. Mean (SD), median and interquartile range (IQR) as well as Wilcoxon rank sum and rank sum exact test was computed.
Results: The mean (SD) duration of uveitis disease at edema was 7.9 (6.8) years. The uveitis was anterior in 4/11 (36%) and intermediate in 7/11 (64%), where onset was sudden in 5/11 (45%) and insidious in 6/11 (55%). Median (IQR) VA was 0.50 (0.40, 0.75) at edema and 0.90 (0.70, 1.00) at remission, where mean (SD) OCT CRT decreased 154 µm, from mean (SD) 429 (114) µm to 275 (45) µm ($p < 0.001$).

The mean (SD) density flow in the choriocapillaris was significantly lowered $p = 0.001$ in the central macular area in edema 44.31 (5.63), compared to remission 50.59 (5.04), see Table 1.

Table 1: Choriocapillaris density flow in edema and remission per macular area

Macular area	Edema(1)	Remission(1)	p-value(2)
Nasal	51.05 (3.29)	53.58 (2.72)	0.015
Central	44.31 (5.63)	50.59 (5.04)	0.001
Temporal	53.30 (3.91)	53.99 (1.33)	0.48
Superior	52.18 (3.97)	52.97 (2.16)	0.54
Inferior	53.21 (3.36)	53.00 (2.12)	0.75

1 Mean (SD)
2 Wilcoxon rank sum exact test; Wilcoxon rank sum test
Conclusions: In eyes with noninfectious uveitis with macular edema the choriocapillaris density flow in the central macular area is decreased in both anterior and intermediate uveitis. The decreased flow might be a part of the patophysiology of the macula in uveitis. If this reflects the severity or duration of the macular edema, then furhter work can show if it can be used as marker for treatment dosage.

ABSTRACT BODY:

Purpose: Retinitis pigmentosa (RP) is a retinal degenerative disease characterized by the progressive loss of photoreceptors. It affects more than 1 million people worldwide. Despite the genetic heterogeneity, one common phenomenon is shared in RP that the death of rods always precedes the death of cones. The mystery was solved by the discovery of rod-derived cone viability factor (RdCVF) encoded by NXNL1 gene acting as a tropic factor secreted by rods to promote the utilization of glucose by cones, thus sustaining the survival of cones. Interestingly, NXNL1 encodes two proteins due to alternative splicing, the short form RdCVF, and the long-form RdCVFL with a typical thioredoxin (TXN)-like structure. It has been shown by our group that adeno-associated virus (AAV)-mediated expression of RdCVF and RdCVFL could be a potential gene therapy of RP. The short protein, RdCVF, has been well-studied, however, the mechanism of action of RdCVFL remains unclear.

Methods: The RdCVFL was recombinantly purified. Then the biochemical property of RdCVFL as a TXN-like protein was examined by coupling the two major antioxidant systems, the TXN system and the glutathione (GSH) system. The chaperone activity of RdCVFL was also examed.

Results: RdCVFL can be reduced by TXN and GSH systems, and the reduced RdCVFL exhibited an S-denitrosylase activity. However, it is not a highly selective substrate of both systems, showing little activity to reduce cystine, oxidized-GSH, and S-glutathionylated proteins. Interestingly, RdCVFL exhibited a prominent chaperone activity in thermal aggregation assays.

Conclusions: RdCVFL, as a TXN-like protein, may participate in antioxidant defense and redox signaling regulation in the retina. In addition, its chaperone activity may contribute to protein quality control during outer segment renewal or in the prevention of aggregation of the microtubule protein τ (TAU).

Commercial Relationships Disclosure: Magdalena Schneider: Commercial Relationship: Code N (No Commercial Relationship) | Andrea Dillinger: Commercial Relationship: Code N (No Commercial Relationship) | Ernst Tamm: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Axonal optic nerve (ON) damage in glaucoma is characteristically associated with increased amounts of active Transforming Growth Factor-β2 (TGF-β). Data from Quigley et al., (2015) indicate that TGF-β-signaling promotes IOP-induced ON damage, an effect that involves remodeling of the sclera. In the present study we investigated the functional role of scleral TGF-β-signaling in glaucoma. To this end we induced ocular hypertension (OHT) in mice with an inducible deficiency of TGF-β receptor type II (Tgfbr2) in scleral fibroblasts.

Methods: $Tgfbr2^{fl/fl}$ ($T2^{fl/f}$) mice with a floxed allele of Tgfbr2 were crossed with Col1a2-CreER (Col1) mice. The mouse Col1a2 promoter is specifically active in fibroblasts, including those of the sclera. 14 days after Tamoxifen (TX) treatment OHT was induced in one eye, using the magnetic-microbead-model. IOP was measured by rebound tonometry. After six weeks of OHT, ON axons were PPD-stained and quantified. Somata of retinal ganglion cells (RGC) were quantified on whole mounts by RBPMS-staining. TGFBR2 and its mRNA were analyzed by western blotting and real time RT-PCR. IOP data was analyzed using one-way ANOVA, mRNA expression, protein synthesis, axon loss (Δaxons) and RGC loss (ΔRGC) were compared using two-tailed students t-tests.

Results: Following TX-treatment, scleral TGF-β RII mRNA and protein were significantly decreased ($p \leq 0.05$). IOP was significantly elevated up to six weeks after injection. No difference in IOP of injected and un-injected eyes could be found between $T2^{fl/fl}$ and $Col1xT2^{fl/fl}$ animals at any timepoint. After six weeks of OHT, reduced numbers of ON axons (11±2%, n=17, $p \leq 0.001$) were seen in OHT eyes in comparison to contralateral eyes. Moreover, OHT also led to a decrease of retinal ganglion cell somata (22,87±9,87%; n = 10; $p \leq 0.001$). Axon loss was significantly higher in mice with a fibroblast specific deficiency of TGF-β RII in comparison to control animals (Δaxons $T2^{fl/fl}$ = 9.29±5.76%; n=9; Δaxons $Col1xT2^{fl/fl}$ = 14.89±4.85%; n=8; $p \leq 0.01$). $\Delta RGC/mm^2$ was not changed in $Col1xT2^{fl/fl}$ mice ($\Delta RGC/mm^2$ $T2^{fl/fl}$ = 22.21±6.49%; n=5; $\Delta RGC/mm^2$ $Col1xT2^{fl/fl}$ = 22.37±15.09%; n=5; p=0.88).

Conclusions: We conclude that the ablation of scleral TGF-β signaling increases the susceptibility to IOP-induced optic nerve damage. Scleral TGF-β signaling in mutant mice appears to be beneficial for ON axon survival in experimentally induced OHT.

ABSTRACT BODY:

Purpose: To investigate the rates of structural and functional progression in an African ancestry cohort and to determine the risk factors for progression.

Methods: Glaucoma cases in the Primary Open-Angle African American Glaucoma Genetics cohort, with ≥2 retinal nerve fiber layer (RNFL) thickness values and ≥2 mean deviation (MD) measurements over ≥6 months follow-up, were examined. The rates of structural progression (change in RNFL thickness/year) and functional progression (change in MD/year) for each eye were calculated from linear mixed effects models, accounting for inter-eye correlation from the same subject and longitudinal correlation for the same eye over time. Eyes were categorized as slow, moderate, and fast progressors (Table 1). Demographic and clinical risk factors for progression rates were assessed using univariate and multivariate regression models.

Results: A total of 1424 eyes were classified as slow, moderate, or fast progressors (Table 1). The median (inter-quartile) rates of progression were -1.60 (-2.05, -1.15) μm/year for RNFL thickness and -0.40 (-0.44, 0.34) dB/year for MD. In multivariate analysis, faster RNFL progression was independently associated with thicker baseline RNFL ($p<0.0001$), lower (worse) baseline MD ($p=0.005$), and beta peripapillary atrophy ($p=0.04$; Table 2). Faster MD progression was independently associated with higher baseline MD ($p<0.0001$), higher cup-to-disc ratio ($p=0.02$), and lower body mass index ($p=0.0004$; Table 2).

Conclusions: This African ancestry cohort had faster median rates of structural and functional progression than other ethnic groups. Higher baseline RNFL thickness and MD values were associated with faster rates of structural and functional progression, respectively, likely due to a “floor effect,” where progression in early disease exhibits a steeper slope before plateauing in advanced stages. Results highlight the importance of monitoring structural and functional glaucoma progression to provide timely treatment in early disease stages.

ABSTRACT BODY:

Purpose: Differences in sociodemographic factors contribute to health disparities in various ophthalmic conditions. We hypothesized that racial minorities, compared to white patients, have worse visual acuity outcomes following rhegmatogeneous retinal detachment repair. We conducted a retrospective chart review of patients at a tertiary medical center to compare the presentation and outcomes of retinal detachment repair based on race.

Methods: This study included 186 eyes of 181 patients who underwent primary retinal detachment repair at from 2013 to 2021. Eyes with rhegmatogeneous retinal detachment which underwent repair with at least three months of follow-up were included. Eyes with other visually significant pathology were excluded. Baseline characteristics, surgical repair techniques, and final visual acuity outcomes were recorded. Statistical analyses were performed to identify significant differences between the minority and non-minority patient groups.

Results: 144 patients identified their race as white and 42 patients identified with a minority race. Gender and baseline visual acuity were similar between the two groups. Age (p=.0005) and insurance status (p=.011) were statistically significant differences between the two groups. 91% of white patients had health insurance, while 23.8% of non-white patients had health insurance. Time from evaluation to surgery was significantly longer in non-white patients (p=.027). Minority patients were less likely to be pseudophakic at presentation (p=.003) and at final follow-up (p=.005). Visual outcomes were not significantly different between the two groups.

Conclusions: Although the average final visual acuity did not differ between white and non-white patients undergoing retinal detachment surgical repair, minority patients who underwent operative management were of younger age, more likely to be uninsured, less likely to have cataract surgery before and after repair, and experience longer waiting times for surgical treatment following clinical evaluation. These findings may help increase physician awareness of barriers to ophthalmic surgical care associated with race.

ABSTRACT BODY:

Purpose: Pathologic insults like chemical burn, transplant rejection or trauma lead to blindness and to a so called “high risk situation” with increased rejection rates after subsequent corneal transplantation.
All these insults cause different immunological tissue responses. Aim of this study was to evaluate the impact of different types of corneal injuries on immune cell recruitment in the cornea.

Methods: We used 5 kinds of corneal injury models and naïve cornea as the control (n=5). The suture model is the corneal intrastromal placement of three nylon sutures. Alkali burn was induced by 1 M NaOH placed on the central corneal. Incision injury was induced in the central cornea with a linear perforating incision with 1 mm length. Corneal grafts were placed either into an avascular recipient bed as the normal-risk keratoplasty (NR-KPL) or a prevascularized recipient as the high-risk keratoplasty (HR-KPL). 1 week after incision and 2 weeks after other different injuries, corneas were excised and stained with F4/80, CD11c, Ly6G, MHC class II, CD3, CD4 and CD8. Furthermore, the draining lymph nodes (dLN) were analyzed by flow cytometry.

Results: HR-KPL and NR-KPL initiated significantly higher recruitment of F4/80+ macrophages (Mφ), CD11c+ dendritic cells (DCs), Ly6G+ neutrophils as well as MHC II expression compared to all other groups. Suture placement and alkali burn induced only a significant increased recruitment of macrophages compared to incision and naïve eyes. The incision model did not induce a significant increase of any immune cells. Regarding T cell recruitment , only HR-KPL and NR- KPL provoked a significant higher invasion of CD3+CD4+ and CD3+CD8+ T cells, whereas in HR-KPL compared to NR-KPL significantly more CD3+CD4+ T cells were recruited. Interestingly, in the dLNs significantly less DC and Mφ could be detected in all groups compared to control. In contrast, MHC II expression was increased in HR-KPL and NR-KPL on DCs and Mφ. Only in NR-KPL CD8+ T cells were significantly increased compared to all groups.

Conclusions: In this study we established for the first time a comparative corneal immune cell profile of different clinically relevant types of corneal injuries. This immune cell profiles will allow the establishment of a more personalized treatment regimen of high risk patients according to their individual preexisting pathologies.

ABSTRACT BODY:

Purpose: Alström syndrome is a rare autosomal recessive disorder affecting multiple systems including the eyes. Despite knowing the causative gene, ALMS1, the spectrum of its clinical manifestations has not been fully characterized, which has been a challenge due to the great variability of presentation, reduced life expectancy, and the less-than-one-per-million prevalence of this disease. This study aims to summarize the clinical ophthalmic findings in children with Alström syndrome using data from the largest known existing cohort, and to familiarize ophthalmologists with these findings.

Methods: Thirty patients of all ages with a known diagnosis of Alström syndrome participated at biannual multidisciplinary Alström syndrome clinics (2015 – 2020) at a centralized academic center. These patients received comprehensive eye examination by a pediatric ophthalmologist. Clinical data were then extracted and summarized from the charts.

Results: Twenty-five pediatric patients had a median age of 7, ranging from 15 months to 16 years. Among these children, nystagmus (22/25) and photophobia (22/25) are not only the most commonly documented ophthalmic findings, but also the most common first presenting symptoms. Retinal vascular attenuation (19/25) and retinal internal limiting membrane changes (15/25) are the most commonly documented retinal findings. In contrast, only 2 children had documented retinal pigment clumps. Previous misdiagnoses included achromatopsia, cone-dystrophy, cone-rod dystrophy, retinitis pigmentosa, and spasmus nutans.

Conclusions: We believe that knowledge of these clinical findings would benefit ophthalmologists to better recognize this potentially vision-threatening and life-threatening condition.

ABSTRACT BODY:

Purpose: Proliferative vitreoretinopathy (PVR) is the most common cause of failure of surgically repaired rhegmatogenous retinal detachment (RRD). Chemically-induced and cell-injection PVR models have been developed, but there is an unmet need for translational models in which to evaluate potential therapies specific to RRD-PVR. The objective of this study was to characterize the histologic and immunohistochemical features of a rabbit model of RRD-PVR at acute and chronic time points.

Methods: Posterior segments of enucleated globes from male and female Dutch Belted rabbits were harvested and frozen or formalin-fixed at 6 hours and 2, 14, and 35 days following unilateral induction of RRD-PVR by vitrectomy and retinotomy followed by retinal cryotherapy and intravitreal platelet-rich plasma injection (n = 8 rabbits/time point); contralateral globes served as controls. Routine H&E and Masson’s trichrome staining and immunolabeling for glial fibrillary acidic protein (GFAP), vascular endothelial growth factor receptor 2 (VEGFR2), CD68, retinal pigment epithelium 65 kDa protein (RPE65), and laminin were performed on all sections, and labeling intensity was scored (0: absent, 1: weak, 2: moderate, 3: strong).

Results: Acute histopathologic changes included intravitreal and intraretinal hemorrhage, heterophilic vitritis, chorioretinitis, and retinal necrosis, while chronic lesions included retinal atrophy, gliosis, subretinal fibrotic membranes, and epiretinal fibrovascular proliferation in the region of the medullary streak. Trichrome-positive fibrillar collagen was present in the subretinal fibrocellular and epiretinal fibrovascular membranes at days 14 and 35 along with increased expression of laminin. Moderate to strong GFAP and VEGFR2 labeling was detected in chronic RRD-PVR lesions. RPE65 expression was absent in dedifferentiated subretinal RPE cells in chronic RRD-PVR lesions.

Conclusions: Histologic features of this rabbit model may effectively simulate important late features of human RRD-PVR including epiretinal and subretinal membrane formation. These findings suggest that developing high-fidelity in vivo models for RRD-PVR is essential to enable further research on targeted treatment interventions.

TITLE: Adenosine receptor 2A-mediated HIF signaling enhances endothelial-to-mesenchymal transition (EndMT) and promotes subretinal fibrosis

SESSION TITLE: AMD Translational Research

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: Q. Yang, Q. Ma, X. Mao, R.B. Caldwell, Y. Huo, Vascular Biology Center, Augusta University, Augusta, Georgia, UNITED STATES|A. Sodhi, Retina Division, Wilmer Eye Institute, Johns Hopkins Medicine, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Qiuhua Yang: Commercial Relationship: Code N (No Commercial Relationship) | Qian Ma: Commercial Relationship: Code N (No Commercial Relationship) | Xiaoxiao Mao: Commercial Relationship: Code N (No Commercial Relationship) | Akrit Sodhi: Commercial Relationship: Code N (No Commercial Relationship) | Ruth Caldwell: Commercial Relationship: Code N (No Commercial Relationship) | Yuqing Huo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A number of patients with neovascular AMD (nAMD) do not respond well to standard anti-vascular endothelial growth factor (VEGF) therapy. One of underlying mechanisms is development of fibrosis in nAMD lesion. Thus, therapeutic strategies for the inhibition of subretinal fibrosis are imperative. Our past work shows that knockout/blockade of adenosine receptor 2A (ADORA2A for human/Adora2a for rodents) exhibits anti-inflammatory and anti-angiogenic effects. In this study, we examined whether and how knockout/blockade of ADORA2A/Adora2a suppresses the development of subretinal fibrosis.

Methods: Laser injury-induced mouse choroidal neovascularization (CNV) displays subretinal fibrosis lesions. We performed this model in mice deficient in Adora2a globally or in choroidal endothelial cells (CECs) selectively. We collected RPE/choroid complex of mice at day 7, 21- and 35-days post laser injury, and characterized subretinal fibrosis by immunostaining RPE/choroid complex with antibodies against isolectin B4, collagen I and Acta2. In vitro, we initiated EndMT by treating cultured human CECs with TGFβ-2. With loss- and gain-of function approaches, we examined underlying mechanism with quantitative PCR and Western blotting. Two-tailed Student's t-test or One-way ANOVA was used for statistical analysis.

Results: Adora2a/ADORA2A expression was significantly increased in mouse subretinal fibrotic lesions and TGFβ-2-treated CECs. Compared with littermate control mice, mice with deficiency of global and EC-specific Adora2a exhibited 50-60% reduction in the size of CNV and subretinal fibrosis at day 7, 21 and 35 post laser injury. Mechanistically, ADORA2A knockdown in CECs suppressed TGFβ-2-induced EndMT and HIF signaling, and ADORA2A overexpression in CECs increased the levels of HIF and SNAIL1. ADORA2A antagonist KW6002 inhibited TGFB2-induced induction of EndMT, and inhibited subretinal fibrosis in mice of the laser injury-induced CNV model.

Conclusions: Our results demonstrate that ADORA2A-mediated activation of HIF signaling in CECs promotes their transition to mesenchymal cells and then myofibroblasts, and increases production of profibrotic and proinflammatory factors, resulting in formation of subretinal fibrotic lesions. These findings provide the basis for using ADORA2A inhibition as a novel approach in the prevention and treatment of blinding retinal disease.

ABSTRACT BODY:

Purpose: Loss of vision is caused by irreversible death of retinal neurons. Müller glia (MG) are the primary support cell of the retina and are capable of reprogramming into progenitor cells with potential to regenerate neurons following retinal damage. The capacity for MG mediated retinal neuron regeneration varies widely across species. In lower vertebrate species, MG undergo a neurogenic reprogramming event that results in regeneration of functional neurons to restore loss of vision. However, in mammalian systems, MG undergo a “gliotic” response associated with activation of inflammatory gene networks, and fail to regenerate neurons. NFkB signaling is a master regulator of a pro-inflammatory response, and our previous work established that NFkB regulates MG reprogramming in the chick retina. The goal of this study was to investigate the role that NFkB signaling plays in regulating the neurogenic vs. gliotic response in MG after damage in the mammalian retina.

Methods: We investigated patterns of NFkB activation in the mammalian retina after NMDA damage using an NFkB-eGFP reporter mouse line, as well as probing for NFkB signaling components in single cell RNA-seq (scRNAseq) libraries from damaged mouse retinas. Additionally, we utilized an Ascl1 overexpressing mouse line (GlastER-cre/LNL-tTA/tetO-Ascl1-GFP) to investigate neuron regeneration after NMDA damage. We performed intraocular injections of NMDA and a pharmacological inhibitor of NFkB signaling (PGJ2) followed by immunohistochemistry or scRNAseq library preparation to identify retinal neuron regeneration and transcriptomic networks underlying the response, respectively.

Results: We found that NFkB signaling is rapidly activated in Müller glia cells after NMDA damage, and that this activation is dependent on the presence of microglia in the retina. Additionally, inhibition of NFkB signaling decreases macrophage populations within the retina (n=5, p=.03) and promotes Ascl1-mediated retinal neuron regeneration by 30% (n=8, p=.002). Further, scRNA-seq analysis showed that inhibition of NFkB signaling decreases pro-inflammatory and anti-neural gene regulatory networks via coordination with Tgfb signaling and Id factors.

Conclusions: We conclude that NFkB is a key signaling hub that is activated in MG after damage, mediates the accumulation of immune cells, and suppresses the neurogenic potential of MG.

ABSTRACT BODY:

Purpose: To investigate the benefits of spatial filters in the detection of visual field (VF) progression.

Methods: VF sequences with controlled progression rates were simulated based on the longitudinal VF data of 500 glaucoma patients. One VF per patient was selected as the simulation baseline for stable and progressing sequences (15 fields/sequence, 6 months apart). The number of simulated progressing clusters was determined by the probability distribution of progressing points in the patients' data. Spatial correlations filters based on anatomical and spatial distances of VF test points were applied to the simulated data (Figure 1). Mean deviations (MD), means of total deviation (TD) clusters, and pointwise TD values were analyzed with linear regression (LR) models to monitor global, regional, and local trends, respectively. VF progression was defined as the detection of one negative LR slope (three for local trends) with probability<T. The values of T were adjusted to achieve 95% specificity when testing in stable fields. The time to detect 80% progressing fields and the detection agreements (Fleiss' kappa) between global, regional, and local trends using filtered and unfiltered data were compared.

Results: The mean MD progression rates (±SD) of the simulated stable and progressing VF sequences were -0.03 (±0.05) and -0.21 (±0.10) dB/year. The average time (±SD) to detect 80% progression with filtered data were 7.0 (±0.4), 5.0 (±0.3) and 4.8 (±0.2) years for global, regional, and local trends methods, respectively. The time required for regional and local trends methods to detect progression with unfiltered data (5.5±0.3 and 6.2±0.3 years) was significantly longer ($p<0.001$). With spatial filters, the mean detection agreements (±SD) between the three methods after 2, 3, and 5 years (5, 7, and 11 fields) were 0.47 (±0.03), 0.64 (±0.01) and 0.73 (±0.01), respectively. These were significantly better ($p<0.0001$) than using unfiltered data, which had lower agreements of 0.31 (±0.03), 0.46 (±0.04), 0.59 (±0.03) after 2, 3, and 5 years.

Conclusions: Spatial correlation filters based on anatomical and spatial distances of VF test points can improve the time to detect VF progression with regional and local trends methods, but not with the global trend method. The detection agreements between global, regional, and local trends improve when using such filters.

TITLE: Loss of retinal ganglion cell synaptic outputs to the visual thalamus in the DBA/2J mouse model of glaucoma

SESSION TITLE: Electroretinography and disease

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: M.J. Van Hook, J. Thompson, J.C. Smith, Truhlsen Eye Institute, Ophthalmology & Visual Sciences, University of Nebraska Medical Center, Omaha, Nebraska, UNITED STATES|J. Thompson, Pharmacology & Experimental Neuroscience, University of Nebraska Medical Center, Omaha, Nebraska, UNITED STATES|M.J. Van Hook, Cellular & Integrative Physiology, University of Nebraska Medical Center, Omaha, Nebraska, UNITED STATES|

Commercial Relationships Disclosure: Matthew Van Hook: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Thompson: Commercial Relationship: Code N (No Commercial Relationship) | Jennie Smith: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Thalamocortical (TC) relay neurons in the dorsal lateral geniculate nucleus (dLGN) of the thalamus receive convergent retinogeniculate (RG) synaptic input from retinal ganglion cells (RGCs) and convey signals to the primary visual cortex. The goal of this study was to determine how RGC synapses to TC neurons are altered in the DBA/2J (D2) mouse model of glaucoma.

Methods: Experiments were performed with male and female D2 mice at 4-month (m), 6m, 9m, and 12m of age. Controls were the strain-match DBA/2J-gpnmb+ mice. We measured RG synaptic function using optic tract stimulation in parasagittal brain slices while performing whole-cell voltage clamp recordings from post-synaptic TC neurons. Anterograde RGC axon transport was measured as the fraction of dLGN area labeled by a unilateral intravitreal injection of cholera toxin-B-594 (CTB) tracer while microglia activation and RGC synaptic terminal loss was quantified using immunofluorescence staining for Iba1 and vGlut2, respectively. Data were analyzed with a one-way ANOVA and Dunnett's post-hoc multiple comparison tests. Nested statistical tests were used to avoid pitfalls from pseudoreplication. Data are mean±SEM.

Results: CTB transport was reduced in 9m D2 mice (29±10% dLGN labeled, n=7 mice) compared to controls (81±1%, n =14, $p<0.0001$). Microglia showed signs of activation at 9m and 12m including increased cell number and decreased total process length and process endpoints per cell. vGlut2 puncta were reduced at 9m and 12m ($p=0.02$ and $p<0.0001$, respectively). vGlut2 density weakly correlated with microglia activation ($R^2=0.3$; $p=0.0004$ for microglia branch length). There was a statistically significant reduction in the maximum synaptic current amplitude (EPSCmax) detected in slices from 12m D2 mice (822±189 pA; n=31 cells, 9 mice) compared to controls (2269±226 pA; n=35 cells, 12 mice; $p=0.0009$). Reducing stimulus strength to isolate inputs from single RGC axons showed that single-fiber EPSC (EPSCsf) was similar between groups ($p>0.05$). EPSCsf/EPSCmax ratio was higher in slices from 12m D2 mice (0.42±0.07) compared to controls (0.15±0.03; $p=0.004$), indicative of reduced numbers of RGC inputs to each TC neuron.

Conclusions: RGC synaptic loss is functionally detectable in older DBA/2J mice while microglial activation might contribute to pathological synaptic pruning.

ABSTRACT BODY:

Purpose: Abnormal responses during binocular rivalry have been reported in patients with mild glaucoma when using traditional stimuli. In this study, we tested binocular rivalry using complex images (i.e., face, house) to probe the integrity of higher order visual processing. These stimuli are broadband in spatial frequency and orientation and are processed in stimulus-specific areas: fusiform face area (FFA) for face and parahippocampal place area (PPA) for house.

Methods: Seven patients (4F/3M, 61±7 years old) with mild glaucoma and 9 healthy controls (5F/4M, 51±11 years old) participated. The 2 groups were equivalent in visual acuity and stereo-acuity. Rivalry stimuli were gray-scale images of a house and a face, presented in 4.5 x 6deg rectangular areas, viewed dichoptically. There were 3 stimulus location presentation conditions: centrally, and eccentrically at 3deg in the right (RH) and in the left hemifield (LH), respectively. A 0.5deg fixation cross was presented centrally in all conditions. Participants kept their gaze stable on the cross and used a button-response box to indicate if they perceived the house, the face, or both. The outcome measures were rivalry rate (i.e., switches/min) and time of exclusive dominance of the face or house percept.

Results: A 3 (location: central, LH, RH) x 2 (group: glaucoma, control) mixed factorial ANOVA revealed that rivalry rate was significantly higher for the control group than for the glaucoma group in the LH, $F(2,28) = 3.72$, $p = 0.03$. Compared to central and RH locations, rivalry rate in the LH was highest for the control group (17±6 switches/min) and lowest for the glaucoma group (12±6 switches/min). For the control group, the face dominated 24% longer than the house in the LH location, but the 2 stimuli dominated equally in the central and RH locations. For the glaucoma group, the time dominance for the face percept was 22%, 30%, and 34% longer than the house in the central, LH, and RH conditions, respectively.

Conclusions: Binocular rivalry with complex stimuli produces different pattern of responses compared with traditional stimuli. The control group showed a lateralization of responses that mirrors the FFA's laterality (i.e., FFA is larger in the right hemisphere). Overall, patients with mild glaucoma have stronger responses to faces than to houses, indicating that the function of stimulus-specific areas of FFA and PPA may be unequally affected.

ABSTRACT BODY:

Purpose: To introduce and validate a new system and methodology to evaluate photic phenomena (halos, glare and starbursts) induced by different intraocular lens (IOL) technologies using a “see-through” IOL analyzer system in phakic subjects.

Methods: The IOL Telescope Type 1 (IT1) system allows subjects to look through the optics of an IOL. It consists of an eye model into which an IOL is loaded and then attached to a system of relay optics that allows a subject to “look through” the IOL and view a scene including any photic phenomena induced by the IOL.

Twenty subjects looked through the IT1 system under different conditions. Five different IOL designs with different clinical levels of photic phenomena were evaluated by the subjects.

Subjects performed the following tests: First, a subjective rating of the level of bother perceived in a natural scene with a central glare source. After, a ring test was conducted where the size of a ring was adjusted to match the size of the veiling luminance perceived by the subject around the glare source. Two brightness levels were used for the rings, one brighter (Inner) and one dimmer ring (Outer).

The results of this study were compared to the clinical outcomes of the subjective perception of halo, glare and starbursts of implanted cataract patients.

Results: The outer ring test provided results that were well correlated with the clinical questionnaire levels of halo ($R^2 = 0.97$), glare ($R^2 = 0.99$) and starbursts ($R^2 = 0.81$) bother. The inner ring test showed much lower correlation with the clinical levels ($R^2 < 0.48$). Correlations between subjective grading and clinical responses were strongly dependent on the luminance level of the glare source and the photic phenomena evaluated, being $R^2 = 0.72$ in the best of cases.

Conclusions: The results of this study show that the IT1 system can be used to simulate photic phenomena induced by different IOL technologies in phakic eyes. Certain quantitative methods showed a high correlation with the subjective perception of photic phenomena found in cataract patients implanted with the same IOL models. However, exact conditions under which the tests are performed (glare source brightness, scene selection/brightness, subject expectations/variability) can have large effects on test results. The exact visual experience of an implanted subject may not directly map onto the subjective impression in this and similar “see-through” systems.

ABSTRACT BODY:

Purpose: Health systems' responses to the coronavirus disease 2019 (COVID-19) pandemic created a surgical backlog of unknown size, limiting the ability to develop strategies to effectively address the backlog. We assessed the volume of deferred ophthalmic surgeries associated with the COVID-19 pandemic from March-December 2020 and suggested strategies and duration to clear the backlog in Ontario, Canada.

Methods: Ontario Health Insurance Plan physician billing data from 2017-2020 were analyzed. The ophthalmic surgical backlog associated with the pandemic was estimated using time series forecasting models on training set (115 weeks), validation set (52 weeks) and forecasting set (42 weeks). Clearance time was calculated based on the queuing theory using various scenarios.

Results: In 2020, there were 5.13 million ophthalmologist services, a reduction of 22% compared to the 6.60 million services in 2019. This included a 27% decrease in ophthalmic surgeries that require the use of operating rooms (OR) and a 6% decrease in anti-VEGF (vascular endothelial growth factor) injections (a common procedure for macular degeneration) that can be done in clinics.

From March 16 to December 31, 2020 (a pandemic period), the estimated backlog in ophthalmic surgeries requiring an OR was 92,150 surgeries (95% prediction interval [PI] 71,288-112,841), increasing on average by 2,194 surgeries per week. Roughly 90% of the delayed surgeries were cataract surgeries and 4% were retinal detachment surgeries. Nearly half of the provincial backlog (48%, 44,542/92,150) involved patients from the West health region. Estimated provincial clearance time was 248 weeks (95% confidence interval [CI] 235–260) and 128 weeks (95% CI 121–134) if 10% and 20% of OR surgical capacity per week were added, respectively, based on the weekly ophthalmic surgical volume in 2019. Furthermore, an estimated 23,755 (95% PI 14,656-32,497) anti-VEGF injections were missed.

Conclusions: The magnitude of ophthalmic surgical backlog in Ontario in 2020 alone raises serious concerns for meeting the ophthalmic surgical needs of patients. As the pandemic continues the accrued backlog size is likely increasing. Planning and actions are needed urgently to manage the collateral impact of the pandemic on the ophthalmic surgical backlog in Ontario.

ABSTRACT BODY:

Purpose: γ-Crystallins play a major role in maintaining age-related lens transparency. Their destabilization by mutations and physical chemical insults is strongly associated with cataract. Therefore, drugs that increase their stability should have anti-cataract properties. To this end we have screened 2560 drugs and natural compounds for their ability to suppress H_2O_2 and/or heat mediated aggregation of bovine γ-crystallins and various recombinant human and mouse γ-crystallins.

Methods: Protein unfolding, aggregation and binding affinity were determined using absorption, fluorescence and CD spectroscopy, dynamic light scattering, transmission electron microscopy and fluorescence quenching. Protein binding sites were determined using AutodockVIna.

Results: The top two drugs, Closantel (C), an antihelmintic drug, and Gambogic Acid (G), a xanthonoid compound prevented or attenuated to variable degree thermal-induced protein unfolding when tested against Human or Mouse recombinant crystallins such as deamidated HγS mutants, wild-type HγD & MγS and their respective mutants W43R, R14C and R58H, and F9S/OPJ. Binding studies using fluorescence quenching and ANS method revealed static binding of drugs C & G to hydrophobic sites of medium to low affinity ranging from -5.9 to -7.9 kcal/mol (HγD) and -4.1 to -8.2 kcal/mol (MγS) with Kb values ranging from $1.34x10^5$ to 6.1×10^5 M^{-1}(HγD) and $0.073 x10^5$ to $1.38 x10^5$ M^{-1} (MγS). Molecular docking to HγD and other γ-crystallin revealed two binding sites, one in the “NC-pocket” including residues in the 50-150 sequence of HgD, and one in the “NC-tail” spanning residues 56-61 from the N-terminal to the residues 168-174 in C-terminal domain. Several of these binding sites overlapped with those of the protective α-crystallin mini-chaperone peptide “MAC”.

Conclusions: These results support the existence of a new class of α-crystallin mimetic drugs with chaperone effect and anti-cataract potential whereby Closantel and Gambogic acid emerge as the most promising candidate compounds. However, their binding activity to gamma crystallins is relatively low and it remains to be tested whether inhibtion of gamma crystallin aggregation can prevent cataract formation in appropriate congenital or environmentally induced animal models of cataract.

TITLE: Treatment of drusen in dry age-related macular degeneration with photobiomodulation : single-center study

SESSION TITLE: AMD: Clinical and translational research/AMD therapies (excluding anti-VEGF)

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Benlahbib, C. Mehanna, H. Le, E. Souied, ophtalmologie, Centre Hospitalier Intercommunal de Creteil, Creteil, Île-de-France, FRANCE|

Commercial Relationships Disclosure: Manal Benlahbib: Commercial Relationship: Code N (No Commercial Relationship) | Carl Joe Mehanna: Commercial Relationship: Code N (No Commercial Relationship) | Hoang Mai Le: Commercial Relationship: Code N (No Commercial Relationship) | Eric Souied: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess the efficacy and safety of photobiomodulation (PBM) treatment for patients with drusen in dry age-related macular degeneration (AMD).

Methods: Thirteen eyes with dry AMD (age related eye disease study (AREDS) categories 3-4) were included in the study and treated with the Valeda Light Delivery System. All subjects underwent two treatments per week for 5 weeks. Outcome mesures included ; best corrected visual acuity (BCVA), microperimetry- scotopic testing, drusen volume (DV), central drusen thickness (CDT), central retinal thickness (CRT) and retinal volume.

Results: BCVA improved in eyes treated with photobiomodulation with a mean score gain of 4 letters at month 6 (M6). Retinal sensitivity increased by 0.70 dB on average. Mean fixation losses decreased by 7.83 % at M6. Drusen volume and retinal volume decreased by 0.28 mm^3 and 0.21 mm^3 on average respectively. Central drusen thickness and central retinal thichness was reduced by a mean of 36.5 µm and 40.16 µm respectively at M6.

Conclusions: This study confirm efficacy and safety of using photobiomudulation for treatment of drusen in dry AMD. The functional and anatomical improvements in our patients support previous reports. PBM may provide a therapeutic option for patients with dry AMD mainly in the earliest stages and may potencially slow the progression of the disease. Further studies are needed to confirm if a repeated PBM treatments are necessary to maintain the benefits.

TITLE: Epidemiology and burden of astigmatism: a systematic literature review
SESSION TITLE: Anterior Segment and Trauma Epidemiology
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: J. Zhang, M. Dhariwal, Y. wu, Alcon Laboratories Inc, Fort Worth, Texas, UNITED STATES|M.A. Bullimore, University of Houston, College of Optometry, Texas, UNITED STATES|
Commercial Relationships Disclosure: Jun Zhang: Commercial Relationship(s);Code E (Employment):Alcon | Mukesh Dhariwal: Commercial Relationship(s);Code E (Employment):Alcon | yifei wu: Commercial Relationship(s);Code E (Employment):Alcon | Mark Bullimore: Commercial Relationship(s);Code C (Consultant/Contractor):Alcon
ABSTRACT BODY:
Purpose: To identify published literature on epidemiology, patient and economic burden of astigmatism through a systematic literature review. The unmet needs of astigmatic patients with co-existing ocular conditions (such as cataract, glaucoma, dry eye, presbyopia, or macular degeneration) and the risks associated with untreated astigmatism were also reviewed.
Methods: Using Cochrane methodology, a systematic literature review was conducted in MEDLINE, EMBASE, and Cochrane library (January 1996-May 2021). Studies published in the English language reporting on epidemiology and burden of astigmatism were included. Proceedings (2018-2021) from eye congresses were searched for evidence. A grey literature search was conducted using Google Scholar to identify relevant studies that were not captured by the database searches.
Results: The literature search yielded 6,804 citations, of which 125 met the inclusion criteria (epidemiology: 68; patient burden: 60; economic burden: 6) and were summarized in this SLR. The prevalence of astigmatism in the general population varied from 7.6% to 61.7%, with higher rates in older individuals (≥70 years). The prevalence of with-the-rule astigmatism was higher in the younger population (≤40 years), while rates of against-the-rule and oblique astigmatism increased with age. The prevalence of astigmatism was higher for low levels (<1.5 D: 32.7%-100%) than higher levels (≥1.5 D: 0%-39.1%). Astigmatic patients experienced decreased quality of vision, increased rates of glare (52.9%-77.0%), halos (28.1%-80.0%), night-time driving difficulties (66.0%), risk of falls (particularly with oblique astigmatism), and spectacle dependence (44.8%-85.0%) leading to decreased vision-related quality of life. Astigmatic patients performed vision-related tasks slower (-1 D: 8.9% slower, -2 D: 28.7% slower) and made more errors (-1 D: 38.1% more errors, -2 D: 370% more errors) compared to fully corrected astigmatic patients. In astigmatic patients undergoing cataract surgery, post-operative spectacle cost (mean: $51-$916), outpatient visit cost (mean: $35-$348), travel cost (mean: $14-$21), and informal care cost (mean: $39-$71) contributed to the overall economic burden.
Conclusions: Uncorrected astigmatism decreases patients' vision-related quality of life; increases productivity losses among working-age adults; and poses an economic burden on patients and their families.

TITLE: Ultra-widefield Imaging versus Ophthalmoscopic Examination in a Routine Patient Population

SESSION TITLE: Imaging of posterior segment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T.R. Ahmad, W. Au-Yeung, N. Chan, J.D. Keenan, J.M. Stewart, Ophthalmology, University of California San Francisco, San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure: Tessnim Ahmad: Commercial Relationship: Code N (No Commercial Relationship) | Winnie Au-Yeung: Commercial Relationship: Code N (No Commercial Relationship) | Nicholas Chan: Commercial Relationship: Code N (No Commercial Relationship) | Jeremy Keenan: Commercial Relationship: Code N (No Commercial Relationship) | Jay Stewart: Commercial Relationship(s);Code C (Consultant/Contractor):Genentech;Code C (Consultant/Contractor):Merck

ABSTRACT BODY:

Purpose: Prior studies have established ultra-widefield imaging in the assessment of diabetic retinopathy. The primary aim of this study was to determine its use, compared to slit lamp biomicroscopy, for the detection of fundus pathology in a routine patient population.

Methods: In this prospective randomized study, patients underwent biomicroscopy by certified optometrists and ultra-widefield imaging. Ultra-widefield photos were independently graded by two optometrists. Clinical findings from examiners and photo-graders were coded into themes using inductive thematic analysis, and then clinically significant findings were extracted. Discrepancies between photo-graders were adjudicated by a retinal ophthalmologist to create a consensus interpretation. Cohen’s kappa was used to estimate agreement between the two photo-graders and between the examinations and photo-grades.

Results: Nine-hundred eyes of 450 patients were examined and imaged. Of the clinically significant examination findings, inter-photo-grader agreement was moderate to substantial for most, including optic disc hemorrhage (k = 0.8), macular exudates (k = 0.7), and macular pigmentary changes (k = 0.7). Agreement between examination and photo-grades was moderate to substantial for optic disc hemorrhage (k = 1), indistinct optic disc margins (k = 0.5), macular drusen (k = 0.4), and peripheral retinal pigmentary changes (k = 0.4), drusen (k = 0.4), and hemorrhage (k = 0.8). A total of 187 findings were detected by imaging but not examination, compared with 42 that were detected on examination but not imaging.

Conclusions: Ultra-widefield imaging agreed substantially with standard-of-care examinations in a routine patient population and detected more fundus findings than clinical examination.

ABSTRACT BODY:

Purpose: The purpose of this study was to develop deep learning models to recognize ophthalmic examination components from free text clinical progress notes in electronic health records (EHR), while using a weak supervision approach to amass a large training corpus.

Methods: A corpus of 39,099 ophthalmology progress notes labeled for 24 anterior and posterior segment anatomical components (named entities) of the ophthalmic examination was assembled from the EHR of a single academic center using a weakly supervised approach that automatically matches labeled EHR fields with corresponding words in the notes. The corpus was split into training, validation, and test sets. Four massively pre-trained transformer-based language models (DistilBert, BioBert, BlueBert, and ClinicalBert) were fine-tuned to this named entity recognition task. Results were compared to a baseline model based on regular expressions. Precision, recall, F1-score were reported for each entity and micro-averaged across the test set. The same metrics were also reported on a sample of human-annotated ground truth notes from the test set, and a sample of human-annotated notes from an independent set of notes.

Results: On the weakly labeled test set, all transformer-based models had micro-averaged recall over 0.92, with precision varying from 0.44-0.85. The baseline model had lower recall (0.77) and comparable precision (0.68). On human-annotated notes from the test set, the baseline model had high recall (0.96) with precision variable depending on the entity (0.11-1.0, micro-averaged 0.57). Bert models had better performance, with recall ranging from 0.77-0.84, and micro-averaged precision >=0.95 for all models. On the independent notes, precision was 0.93 and recall 0.39 for the Bert model, whereas the baseline model had better recall (0.72) but poor precision (0.44).

Conclusions: We have developed the first deep learning system to recognize eye examination components from clinical progress notes, leveraging a novel opportunity for weak supervision to produce a large training corpus from EHR. Transformer-based models had very high precision when evaluated against human-annotated ground truth labels, whereas the baseline model had poor precision but higher recall. This system hold potential to improve ophthalmology cohort design and feature identification using free-text clinical progress notes.

Commercial Relationships Disclosure: Nuria Guardia Ruiz: Commercial Relationship: Code N (No Commercial Relationship) | Yolanda Diebold: Commercial Relationship: Code N (No Commercial Relationship) | José Ramón Juberías: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To identify whether there is a decrease in intraocular pressure (IOP) values and the number of hypotensive active principles (AP) required in patients diagnosed with suspected angle closure (SAC), angle closure (AC), and angle closure glaucoma (ACG) who underwent phacoemulsification surgery with intraocular lens (IOL) implantation and goniosynechialysis.

Methods: Retrospective observational study of patients diagnosed of SAC, AC or ACG who received phacoemulsification with IOL implantation and goniosynechialysis by the same glaucoma surgeon in the last 10 years at the Glaucoma Units of the Valladolid Clinic Hospital and the Institute of Applied OphthalmoBiology (University of Valladolid, Valladolid, Spain). We evaluated the difference between baseline and pre-surgical IOP compared to IOP at different times of postoperative follow-up (1, 3 and 12 months), and the difference between numbers of hypotensive AP administered before and after surgery at the same follow-up months.

Results: We analyzed 64 eyes, 31 with AC, 26 with ACG, and 7 with SAC. A statistically significant decrease between baseline and pre-surgical IOP and IOP assessed 1, 3 and 12 months after surgery in AC and ACG patients was observed ($p<0.001$). AC patients showed a 43.6% decrease between baseline and pre-surgical IOP, a 51.3 to 56.6% decrease between baseline and post-surgical IOP, and a 13.3 to 22.9% decrease between pre-surgical and post-surgical IOP. ACG patients showed a 41.5% decrease in pre-surgical IOP compared to baseline IOP, a 53.2 to 56.5% decrease in post-surgical IOP compared to baseline IOP, and a 19.7 to 25.7% decrease in post-surgical IOP compared to pre-surgical IOP. SAC patients showed a 9.47 to 11.74% decrease in postsurgical IOP compared to pre-surgical IOP ($p<0.05$). Regarding numbers of administered AP, we observed a statistically significant decrease in AP at 1, 3, and 12 months after surgery compared to prior to surgery in both AC (53.4 to 61.5%) ($p<0.001$) and ACG (41.9 to 54.5%) ($p<0.05$) patients. In SAC patients, no differences were observed.

Conclusions: Phacoemulsification surgery with IOL implantation, together with goniosinechialysis, significantly lowers the IOP and the AP number required for long-term IOP control in AC and ACG patients. In SAC patients, surgery contributes to a small decrease in IOP, but it does not affect the number of AP required.

TITLE: Analysis of Variability of the Spiral of Tillaux and Corneal Diameters: a Cadaveric Study

SESSION TITLE: Mechanisms of Refractive Error and Eye Development

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Kim, V. Rana, A. Barton, J. Tanzer, J. Schaefer, Brown University Warren Alpert Medical School, Providence, Rhode Island, UNITED STATES|

Commercial Relationships Disclosure: Eric Kim: Commercial Relationship: Code N (No Commercial Relationship) | Viren Rana: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Barton: Commercial Relationship: Code N (No Commercial Relationship) | Joshua Tanzer: Commercial Relationship: Code N (No Commercial Relationship) | Jamie Schaefer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The distances of the extraocular rectus muscle insertions from the limbus and corneal diameters are clinically relevant in surgical ophthalmology. It is widely accepted that the corneal diameters are about 11.7 x 10.6 mm and that the medial, inferior, lateral, and superior recti muscles on average insert 5.5, 6.5, 6.9, and 7.7mm, respectively, from the limbus. This descriptive cadaveric study investigates the measurements of the Spiral of Tillaux and corneal diameters.

Methods: Thirty cadavers were included for a total of 60 eyes. For each eye, a lateral canthotomy and cantholysis followed by a peritomy were performed. Muscle hooks were used to isolate the rectus muscles. Corneal diameters and distances from the midpoint of recti muscle insertions to the limbus were measured using calipers (Fig. 1). Using mixed effects modeling, the mean distance from the limbus to each rectus muscle was found.

Results: Of the 30 cadavers, 50% were female, with a mean age of 81.9 years. Table 1 reports the measurements from the limbus to the rectus muscle insertion (medial rectus = 5.28 mm, inferior rectus = 5.72 mm, lateral rectus = 6.40 mm, superior rectus = 6.78 mm). When compared to the historical benchmarks, nearly all of these measurements in this study were shorter ($p < 0.01$). No meaningful heterogeneity was identified across ages or by right and left eye ($p > 0.05$). Women tended towards approximately half a millimeter shorter measurements on average (limbus to rectus: $t(45.35) = -1.91$, $p = 0.0624$). Mean corneal diameters were found to be 11.7 mm horizontally and 10.7 mm vertically, and were not found to be significantly different from the expected values ($p > 0.05$).

Conclusions: Nearly all measurements from the limbus to rectus muscle insertions demonstrated variations from the accepted Spiral of Tillaux measurements, particularly with females having shorter distances. However, we found that the recti muscles followed the same pattern to the historical Spiral of Tillaux measurements, with the medial rectus inserting most closely to the limbus and the inferior, lateral, and superior rectus inserting successively farther from the limbus. We found no significant differences in the expected corneal diameter measurements.

TITLE: Wavefront superposition for predicting retinal image quality with zonal, dual-focus and multifocal contact lenses

SESSION TITLE: Refractive Error: Myopia, Hyperopia, vision and models

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Jaskulski, P.S. Kollbaum, School of Optometry, Indiana University Bloomington, Bloomington, Indiana, UNITED STATES|P. Lazon de la Jara, Research Programs, Coopervision Inc, Pleasanton, California, UNITED STATES|A. Bradley, Research Programs, Coopervision Inc, Pleasanton, California, UNITED STATES|

Commercial Relationships Disclosure: Mateusz Jaskulski: Commercial Relationship: Code N (No Commercial Relationship) | Percy Lazon de la Jara: Commercial Relationship(s);Code E (Employment):CooperVision | Arthur Bradley: Commercial Relationship(s);Code E (Employment):CooperVision | Pete Kollbaum: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Novel zonal, dual-focus contact lenses (CL) for myopia control and multifocal (MF) CLs designed for presbyopia employ spatially separated zones containing different optical properties. While wavefront aberrometry can be used to evaluate CL performance on eye, a novel methodology was evaluated of using pupil-plane superposition of ocular wavefronts with measured and modeled ex-vivo wavefronts to predict retinal image quality of eyes wearing these optics.

Methods: Ocular wavefronts were measured in-vivo using a pyramidal wavefront sensor (Osiris, CSO, Italy) for “eye only” and “eye wearing lens” scenarios. CL wavefronts were measured with a single-pass Shack-Hartmann aberrometer (ClearWave, Lumetrics, Rochester, NY), and modeled using geometrical ray tracing. Numerical superpositions of “eye + measured lens” and “eye + modeled lens” wavefronts were compared to “eye wearing lens” wavefronts for center-distance multifocal (CDMF), center-near multifocal (CNMF), and center-distance dual-focus (CDDF) designs. Point-spread functions (PSF) and corresponding retinal image simulations were computed from the wavefronts.

Results: Peak image quality (VSX) scores for CDMF, CNMF, and CDDF (6.0 mm pupils) were, respectively, 0.15, 0.15; and 0.10 for “eye wearing lens”, 0.12, 0.10; 0.15, for “eye + measured lens”, and 0.13, 0.08; 0.14, for “eye + modeled lens”. Corresponding peak AreaMTF scores were 0.20; 0.16, and 0.15; 0.16; 0.17, 0.15; and 0.14; 0.28, 0.14. The morphology (size, shape, orientation) of the PSFs matched well (Fig. 1).

Conclusions: The three approaches to assess image quality in eyes fit with the different MF and DF lenses reveal a common pattern with the Strehl ratio-based VSX metric with values generally between 10% and 15% of the diffraction limit, and slightly higher values for the AreaMTF metric. The three approaches generally produced similar results, being slightly higher for "eye wearing lens" with the two MF designs, and slightly lower with the DF design. The slight variations in PSF shape can be attributed to differences in lens centration between “eye wearing lens” and “eye + lens” scenarios and data collection interval between “eye alone” and “eye wearing lens” conditions.

TITLE: Effect of scheduled breaks on Digital Eye Strain

SESSION TITLE: Vision Impairment, Visual Function, and Quality of Life

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Rosenfield, S. Johnson, SUNY College of Optometry, New York, New York, UNITED STATES|

Commercial Relationships Disclosure: Mark Rosenfield: Commercial Relationship: Code N (No Commercial Relationship) | Sophia Johnson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The use of digital devices has increased substantially over the past two decades across all age groups for both vocational and avocational purposes. Today, the use of digital screens is almost universal. Digital eye strain (DES) involves a range of visual and ocular symptoms that can be categorized into oculomotor/refractive abnormalities or dry eye symptoms. There are a wide range of proposed therapeutic and management options for this condition, including optical, medical and ergonomic interventions. Regular breaks are frequently recommended by clinicians. Indeed, the so-called 20-20-20 rule, whereby individuals are advised to fixate on an object at least 20 feet (6m) away for at least 20 seconds every 20 minutes is widely cited. Unfortunately, there is little or no peer-reviewed evidence to support this so-called rule. The aim of the present investigation was to determine whether scheduled breaks are indeed effective in reducing the adverse effects of digital device usage, and if so, to identify the specific schedule that has the greatest success in controlling symptoms.

Methods: The study was performed on 30 young, visually-normal subjects who were required to perform a 40-minute, cognitively demanding reading task from a tablet computer. The task required them to read random words and to identify which began with a specific letter chosen at random by the experimenter. The task was undertaken on four separate occasions, with 20-second breaks being allowed every 5, 10, 20 or 40 (i.e., no break) minutes, respectively. Both before and immediately after each trial, subjects completed a questionnaire regarding ocular and visual symptoms experienced during the session. Additionally, both reading speed and task accuracy was quantified during each trial.

Results: A significant increase in post-task symptoms (with respective to the pre-task value) was observed for all four trials ($p<0.001$). However, there was no significant effect of scheduled breaks on reported symptoms ($p=0.70$), reading speed ($p=0.93$) or task accuracy ($p=0.55$).

Conclusions: While widely cited as a treatment option, these results do not support the proposal of using scheduled breaks as a therapeutic intervention for DES.

ABSTRACT BODY:

Purpose: Mice are widely used to study intraocular pressure (IOP) regulation due to the similarities of their conventional outflow pathway to humans. Elevated IOP is the primary risk factor for glaucoma—a leading cause of irreversible blindness worldwide, but measuring IOP in mice is challenging. The aim of this study is to optimize conditions for reliably measuring IOP using a newly designed system for mice.

Methods: Modeled after a system designed by Dr. Simon John, our system includes an AmScope stereo microscope, custom-designed mouse platform that rotates in two planes, TonoLab rebound tonometer with a mounting clamp, foot pedal trigger, isoflurane anesthesia system, and monitors for heart rate (HR) and oxygen saturation percentage (O2S). For experiments, the same group of C57/B6 mice were used to evaluate two methods of anesthesia: Isoflurane (iso, 2% induction, 1% nosecone) vs. ketamine/xylazine (ket/xy, ~70mg/7mg/kg). Experiments were performed on different days, repeated 9 times for iso and 5 for ket/xy. IOP was measured with and without a microscope for tonometer positioning. IOP, HR, and O2S were recorded at 0 and 5 min after induction of sleep.

Results: For ket/xy vs. iso, IOP was not significantly different (16.19±1.9 vs. 15.32±3.7 mmHg, $p=0.46$), but HR and O2S were significantly lower (HR: 328.57±37.2 vs. 560.35±62.6 per min, $p<0.001$; O2S: 81.68±8.6 vs. 75±7.4, $p=0.01$). After 5 min, IOP dropped 2.5 mmHg with ket/xy (16.19±1.9 vs 13.68±1.9 mmHg, $p<0.001$) but only 0.5 mmHg with iso (15.32±3.7 vs. 14.80±2.3 mmHg, $p=0.68$). HR decreased for both iso and ket/xy but was not significantly different at 5 min. IOP readings with vs. without a microscope did not show a significant difference for iso at 0 and 5 min (0 min: 15.32±3.7 vs. 14.73±1.9 mmHg, $p=0.61$; 5 min: 14.80±2.3 vs. 14.72±2.3 mmHg, $p=0.93$) or ket/xy (0 min: 16.19±1.9 vs. 16.33±1.3 mmHg, $p=0.81$; 5 min: 13.68±1.9 vs. 13.65±2.6 mmHg, $p=0.97$). There was a significant difference between IOPs in iso vs. ket/xy datasets at 0 min without a microscope (14.73± 1.9 vs. 16.33±1.3 mmHg, $p=0.004$).

Conclusions: With our newly designed IOP system, similar IOP readings were obtained using iso or ket/xy, and IOP drops more rapidly with ket/xy than iso. HR is not a determining factor for IOP readings. The use of a microscope for tonometer positioning and consistent time between induction of sleep and IOP collection are the most important parameters for reliable IOP measurements.

TITLE: Local Macular Retinal Oximetry Increases with Disease Duration in Type 2 Diabetes without Retinopathy

SESSION TITLE: Diabetic Retinopathy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Smith, K. Bisignano, W.W. Harrison, Optometry, University of Houston, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure: Jennyffer Smith: Commercial Relationship: Code N (No Commercial Relationship) | Kelly Bisignano: Commercial Relationship: Code N (No Commercial Relationship) | Wendy Harrison: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Diabetes can have profound effects on vision through changes to the neurons and vasculature in the retina. To prevent these vision threatening changes, such as diabetic retinopathy and edema, early detection of retinal changes is key. One potential biomarker for early change in the retina is alteration in retinal oximetry. The purpose of this study is to characterize differences in retinal tissue oximetry and superficial vascular density in controls and subjects with type 2 diabetes without retinopathy (DM).

Methods: 36 subjects (51.5 ± 9 years) participated in this study; 19 controls and 17 DM with no retinopathy. Duration of DM was noted for all DM subjects. Testing included HbA1c testing (Siemens) and retinal oximetry (Zilia) measurements of the right eye, within the macula at 3.1 degrees from the fovea; with one measurement sup/temp, inf/temp, sup/nasal, inf/nasal, which were averaged together. Also, OCTA imaging (Zeiss Cirrus) was completed, once available, with OCTA completed on 26 of the 36 subjects. Superficial vascular plexus (SVP) slabs were analyzed with ImageJ for density and compared between groups and correlated with oximetry metrics. Foveal avascular zone was measured and considered in SVP analysis.

Results: In DM subjects, increased duration of disease was associated with increased oximetry ($p = 0.038$), but duration was not associated with vessel density changes ($p = 0.351$). Decreased vessel density was associated with increased retinal oximetry overall ($p = 0.036$). There was no correlation with HbA1c and oximetry in controls and DM ($p = 0.244$, $p = 0.832$, respectively) or HbA1c and SVP density in either group ($p = 0.957$, $p = 0.786$). FAZ was controlled for in density measures and not statistically different between groups ($p = 0.58$).

Conclusions: These data suggest that retinal tissue oximetry appears to be correlated to duration of disease in subjects with DM without retinopathy. This may be related to changes in vessel density. This pairs well with literature that has shown duration is also associated with retinopathy development. These data suggest oximetry measurements may be a useful subclinical biomarker in predicting impending retinopathy, but more follow up in longitudinal work is needed.

ABSTRACT BODY:

Purpose:

Geographic atrophy (GA) is the defining atrophic lesion of advanced non-neovascular age-related macular degeneration (AMD). Detection and segmentation of GA from optical coherence tomography (OCT) imaging is necessary for diagnosis, monitoring, prognosis, and to inform therapy research for this orphan disease. The current standard of segmentation requires specialist manual effort, which is labour intensive and prone to inter-grader variability.

There is a need for validated and fully automated deep-learning approaches to qOCT detection and segmentation of GA that are applicable in clinical care of non-neovascular AMD patients with GA and potential to facilitate therapy research.

Methods:

Deep-learning GA segmentation models were developed for complete GA and its constituent features on 5049 manually segmented optical coherence tomography (OCT) B-scans from 399 eyes (200 patients) with GA secondary to AMD included in the FILLY2 trial (NCT02503332). Predictive performance was validated on an external clinical dataset comprising 884 OCT B-scans from 192 eyes (110 patients) examined at Moorfields Eye Hospital NHS Foundation Trust. The primary outcome was agreement (DSC [dice similarity coefficient] and ICC [intraclass correlation coefficient]) between model GA prediction and consensus of independent graders during external validation.

Results:

Our models accurately segmented GA (median DSC [Dice similarity coefficient] ± SD [standard deviation] 0.96 ± 0.15) and all its constituent features: retinal pigment epithelium (RPE)-loss (0.95 ± 0.21), photoreceptor degeneration (0.96 ± 0.21), hypertransmission (0.97 ± 0.15). Model performance was greater than agreement between specialist human graders (RPE-loss 0.93 ± 0.31, photoreceptor degeneration 0.89 ± 0.20; hypertransmission 0.81 ± 0.30;GA 0.80 ± 0.30). GA segmentation performance remained high in the presence of additional retinal pathologies, including nAMD, PED, and ERM.

Conclusions:

We report development and validation of a scalable deep-learning tool to automatically process OCT scans for

detection and quantification of GA, with a predictive performance equivalent to human specialist graders that is robustly retained beyond the sample used for model development.

TITLE: Transformers-based retinal nerve fiber layer (RNFL) segmentation in optical coherence tomography (OCT)

SESSION TITLE: Machine Learning: Segmentation and Classification

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Nair, R. Guimares, H. Bagherinia, N. Manivannan, Carl Zeiss Meditec, Inc., Dublin, California, UNITED STATES|

Commercial Relationships Disclosure: Aditya Nair: Commercial Relationship(s);Code E (Employment):Carl Zeiss Meditec, Inc. | Rogerio Guimares: Commercial Relationship(s);Code C (Consultant/Contractor):Carl Zeiss Meditec, Inc. | Homayoun Bagherinia: Commercial Relationship(s);Code E (Employment):Carl Zeiss Meditec, Inc. | Niranchana Manivannan: Commercial Relationship(s);Code E (Employment):Carl Zeiss Meditec, Inc.

ABSTRACT BODY:

Purpose: OCT retinal layer analysis is an important diagnostic tool for ocular diseases. In this work we develop an algorithm to predict RNFL layer boundaries using a novel Transformer based deep-learning architecture to improve the performance (accuracy, runtime and memory) of RNFL segmentation. The purpose of this algorithm is to develop a generalized and adaptable algorithm for various scan field of views (FOV).

Methods: Training data consists of 645 volumes of 2mm x 6mm x 6mm CIRRUS^{TM} 4000 HD-OCT (ZEISS, Dublin, CA) data. We used a knowledge-based algorithm to generate the ground truth segmentation for this problem. The ground truth consisted of 2-layer position values each corresponding to every A-scan position as well as 2 confidence of segmentation values. We trained a transformer encoder that takes in an OCT B-scan image patch of 6 mm and outputs the ILM and RNFL segmentations and their confidence values. The input image is passed through a linear projection layer to compress the image in the A-scan direction, then sinusoidal positional encoding is added to retain positional information. Transformer outputs are passed through fully-connected and sigmoid activation layer to output layer position and confidence values. The network setup is shown in figure 1. We also made use of knowledge-based algorithm's confidence value to weigh the loss function (hence learning from noisy training data in a semi-supervised manner). We measured the performance of algorithm on manual segmentation for inferior, superior and central B-scans for held out 35 subjects.

Results: The Transformer-based OCT segmentation provided a better agreement with the ground truth than the knowledge-based algorithm as shown in figure 2. The runtime of this algorithm was 2.12 secs vs the 2.90 secs for the knowledge-based algorithm on Intel(R) Core^{TM} i7-9850H CPU@2.60GHz with a NVIDIA GeForce MX150 GPU. The Transformer method also used significantly lower GPU memory than standard methods (<2 Gigabytes).

Conclusions: We developed a Transformer-based deep learning method to segment the RNFL layer in OCT B-scan. We showed that our method using Transformer performs better than the knowledge-based approach on speed, efficiency, and accuracy while being adaptable to different scan FOV.

ABSTRACT BODY:

Purpose: Otx2 is a transcription factor necessary for the development of photoreceptor and bipolar cells in the retina. How Otx2 expression is regulated to produce these cell types is unknown. We identified three enhancers (DHS2, 4, and 15) that potentially explain the spatial and temporal regulation of Otx2 expression and perturbed them to determine how they control retinal development.

Methods: To determine enhancer activity, we constructed plasmids containing enhancer sequences driving a GFP or Cre recombinase reporter. These plasmids were electroporated into retinal explants cultured in vitro or into live newborn mouse retinas. To remove enhancer function, we electroporated CRISPR/Cas9 plasmid systems to delete the targeted sequences. To prevent enhancer activity, we epigenetically silenced the sequences by electroporating a dead Cas9 CRISPRi system. Immunohistochemistry was conducted to determine enhancer activity, OTX2 expression, and changes in cell fate in the electroporated retinas.

Results: Reporter assays and lineage tracing showed that the DHS2 and DHS15 enhancers were expressed in the developing retina, gave rise to photoreceptor and bipolar cells, and remained active in adult photoreceptors. In contrast, DHS4 had an earlier expression pattern that was limited to development. CRISPR-mediated knock-out of DHS4 caused a strong reduction in OTX2 expression embryonically, whereas targeting DHS2 and DHS15 resulted in a pronounced reduction of OTX2 expression postnatally. Targeting DHS4 with CRISPRi caused a strong reduction in OTX2 both embryonically and postnatally and resulted in an increase in amacrine cells.

Conclusions: DHS4 acts early in Otx2 regulation, while DHS2 and DHS15 enhancers act later. Perturbing these enhancers showed that each is important for Otx2 expression. The incomplete phenotypes seen upon deletion suggest that these enhancers act in a partially redundant or compensatory fashion during development, either with each other or with unidentified enhancers. This is supported by the stronger CRISPRi phenotype, which suggests that the Otx2 enhancers are looped in a complex where they can act interchangeably. Ongoing experiments are testing how these enhancers work together to control Otx2 expression and cell fate choice in the developing retina.

ABSTRACT BODY:

Purpose: Current commercially available training eye models are expensive while low-cost models have difficulty replicating the feel of real human tissues. In this study, we aim to develop an affordable and accurate model eye that can be used to improve microsurgical skills assessments. We created model eyes using six different polymer materials to determine which materials were the most appropriate in simulating real human sclera and extraocular muscle (EOM).

Methods: Five 3-D printed polymers (FlexFill, PolyFlex, PCTPE, Soft PLA, NinjaFlex) and one silicone material were systematically tested by seventeen board certified ophthalmologists and five PGY-4 ophthalmology residents. Participants performed scleral passes through each material's "sclera" and "EOM" components of their respective eye models. They then completed a questionnaire asking to rank each polymer material from 1-6 (1 = best in the group, 6 = worst in the group) to identify which would be most suitable for simulation training. The Wilcoxon Signed-Rank Test was conducted to determine if there was a statistically significant difference in the distribution of ranks between the polymer materials.

Results: The distribution of ranks for Silicone material's "sclera" and "EOM" components were statistically significantly higher than the distribution of ranks for all other tested polymer materials (all $p < 0.05$). Participants agreed that it effectively simulated real human sclera and EOM.

Conclusions: Silicone model eyes have substantial educational value for incorporation into a microsurgical training curriculum. It provides a low-cost teaching tool that allows for independent practice of microsurgical techniques.

ABSTRACT BODY:

Purpose: Given increasing US healthcare costs, decision analysis can help assess various medical and surgical interventions. We aim to build, validate and test a model for open angle glaucoma incorporating current practices.

Methods: Using Markov cycles, progression through 4 glaucoma severity stages (mild (0 to -6 decibels (dB)), moderate (-6.01 to -12 dB), advanced (-12.01 to -20 dB), and severe/unilateral blindness (<-20 dB)) and death was simulated in TreeAge Pro. In the default case, patients entered at age 65 in mild glaucoma and received care per American Academy of Ophthalmology Preferred Practice Patterns. Those with persistently good/moderate adherence progressed following visual field mean deviation decline rates for treated individuals in the Early Manifest Glaucoma Trial (EMGT) while those with poor adherence followed patterns of the untreated. IOP reductions from interventions were converted to glaucoma state transition probabilities using EMGT data. Retinal nerve fiber layer thinning faster than -1.0 µm/year on optical coherence tomography (OCT) imaging related to IOP control was a decision point for further interventions. Whole costs in glaucoma stages were estimated at US Medicare rates and utility values were obtained from previous work. We externally validated the model by comparing the 20-year cumulative incidence of blindness to that reported in a study from Olmsted, Minnesota, which was 13.5% (95% Confidence Interval: 8.8-17.9%.) We further tested the validity and reliability by excluding OCT-based decisions for intervention and instead, substituted progression on visual fields. We conducted test cases of various minimally invasive procedures and varied initial glaucoma severity.

Results: In the default case, 15.5% of the cohort progressed to blindness over 20 years, within the range in Olmsted. Over 35 years, using 10,000 iterations of random draws from parameter distributions, the cohort accrued 10.47 QALY (Standard Deviation (SD): 1.45) at a cost of $51,387.66 (SD: $7,415.93). By excluding OCT-based decisions, 17.0% of the cohort progressed to blindness after 20 years and accrued $46,080.04 (SD: $8,994.55) in cost and 10.45 QALY (SD: 1.44) after 35 years. In the test cases, the 20-year incidences of blindness ranged from 7.9% to 16.6%. Over 35 years, QALYs ranged from 12.09 to 12.27 at costs of $48,025.13 to $64,018.42.

Conclusions: Our model is validated and tested for use in open angle glaucoma cost studies.

TITLE: Impact of the dorzolamide/timolol shortage on patients with moderate to severe open-angle glaucoma

SESSION TITLE: Clinical studies and trials

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C.Q. Zhu, M. Desai, Ophthalmology, Boston Medical Center, Boston, Massachusetts, UNITED STATES|J.A. Tran, Ophthalmology, Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Catherine Zhu: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Tran: Commercial Relationship: Code N (No Commercial Relationship) | Manishi Desai: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Topical antihypertensives remain the mainstay of treatment for glaucoma, as reduction of intraocular pressure (IOP) is the only proven method to prevent disease progression. We conducted a retrospective, observational study to examine the clinical implications of the limited dorzolamide/timolol supply on patients with moderate to severe primary open angle glaucoma (POAG) at an urban academic safety-net hospital. We predicted that the shortage would increase the mean IOP in our patients as well as the number of medication-related phone encounters.

Methods: Our study included 1,093 patients with a diagnosis of moderate or severe POAG on dorzolamide/timolol. IOP measurements were divided into two groups: those recorded before the FDA-reported shortage date of January 14, 2018 and those recorded following this date. The mean IOPs were calculated from both eyes for each patient. The mean difference between post- and pre-shortage IOPs was calculated using paired t-tests. We also examined data on the number of documented phone encounters; the difference before and after the shortage was calculated using a z-test.

Results: Compared to the mean pre-shortage IOPs, there was no statistically significant change in IOP following the reported shortage onset (pre-shortage IOP 15.9±4.0 mmHg, post-shortage 16.0±3.9 mmHg, $p=0.45$). Notably, only 159 patients had a documented discontinuation of dorzolamide/timolol during the post-shortage period; within this cohort, there was no difference in mean IOPs between the two timeframes (pre-shortage IOP 16.0±4.6 mmHg, post-shortage 16.0±4.6 mmHg, $p=0.87$). There was a significant increase in the proportion of medication-related phone encounters following the reported shortage date (pre-shortage 68/995, post-shortage 97/525, $z = -6.74$, $p<0.001$).

Conclusions: There was no appreciable difference in the outcome measure of IOPs of patients with moderate to severe POAG. This suggests that the detrimental effects of the dorzolamide/timolol shortage may be mitigated with patient education and alternative treatments and medications. Interestingly, there was an increase in the number of medication-related phone encounters following the reported shortage date, implying that there may be negative downstream administrative implications of medication shortages. However, the increase in phone calls may have also helped mitigate detrimental IOP increases through patient education.

ABSTRACT BODY:

Purpose: Motion artifacts in OCT imaging have been an important topic in OCT data analysis. Periodic motion artifacts during OCT image acquisition of a patient can be caused by various sources such as muscular, peristaltic, cardiovascular, respiratory, as well as mechanical vibration in the instrument. Here we present a new periodic motion correction method for OCT data. We demonstrate the performance of the method by evaluating RPE (retinal pigment epithelium) elevation with and without motion correction.

Methods: Our method uses ILM (internal limiting membrane) and RPE segmentation in low-cost OCT volume scans. The Fourier transformation of ILM layer is used to estimate the periodic motion. The frequency bands associated with periodic pattern were removed prior to the inverse Fourier transformation. The estimated motion is then used to remove periodic motion artifact from the RPE layer. A polynomial surface is fitted to the RPE layer (RPE-fit) to mimic Bruch's membrane. The RPE elevation map is created by measuring the difference between the RPE-fit and RPE surfaces. We evaluated this method using scans from 17 subjects, either left or right eye, with retinal pathology. Each eye was scanned twice using a prototype low-cost OCT device that had a macula scan with 128x512 A-scans over 7x5.8 mm. The RPE elevation map from the 2nd scan was registered to that of the 1st scan. The RPE elevation volumes (in cubic micrometers) were averaged over central 3-mm and 5-mm zones. Regression and Bland-Altman plots were derived to evaluate the agreement of RPE elevation map.

Results: Figure 1 shows the algorithm pipeline and examples of RPE elevation maps with and without periodic motion correction. Figure 2 illustrates the Bland-Altman plots comparing the RPE elevation volume (in cubic micrometers) of the two scans from the same eye in the central 3-mm and 5-mm zones. Our results show that there is a good correlation agreement between the two methods. The method with motion correction shows smaller mean difference and tighter 95% confidence interval, which indicate a more repeatable method.

Conclusions: We presented a method to compensate for periodic motion in low-cost OCT data prior to the RPE elevation map creation. We demonstrated that the motion compensation is essential for visualization of the RPE elevation map as well as better agreement between repeat scans.

ABSTRACT BODY:

Purpose: Optical coherence tomography angiography (OCTA) imaging is known to be prone to artifacts. Floaters, large motion, wavefront error from dry eyes or media opacities when present during the acquisition can reduce the visibility of small capillaries resulting in an inaccurate interpretation and quantification of the images. A flow quality algorithm (AI quantification of OCTA en face image quality – Charles Wu, Luis de Sisternes, IOVS, Aug. 2019, Vol.60, PB099) was recently developed to address the need for a reliable assessment of the quality of OCTA scans. In this study, we analyze how the flow image quality index impacts the repeatability of OCTA measurement to derive a quality index threshold.

Methods: 19 diabetic retinopathy (DR) eyes and 20 heathy eyes (HE) were imaged on PLEX® Elite 9000 swept-source OCT (ZEISS, Dublin, CA) by acquiring 4 consecutive 6×6 mm angiography scans at 100 kHz A-scan rate. For the DR eye cohort, the image quality index, vessel density (VD) and perfusion density (PD) were computed over the 9 ETDRS sectors of the retinal slab. For each eye, the 4 scan values for each ETDRS sector were averaged and the standard deviation from that mean calculated. The mean VD and PD were computer as well on the heathy eye cohort to establish the measurement baseline.

Results: Figure 1 displays the distribution in the image quality index on a 1-5, scale, 5 being the highest quality. Figures 2a and 2b show the VD and PD standard deviation scattered plots as a function of the flow quality index. These plots show a trend for improved measurement repeatability with index quality score. To better visualize this trend, the standard variation computed over a half-unit quality window is shown on Figures 2c and 2d. At a quality index of 3, the standard deviation in VD and PD of 1.3 and 0.027 respectively corresponds to less than 7% deviation from nominal values (VD = 23.2 mm^{-1} and PD = 0.4) obtained from healthy eyes.

Conclusions: The measurement repeatability in vessel and perfusion densities is related to the index quality metric of the flow images. An image quality threshold of 3 is recommended to provide sufficient confidence in the reported flow quality metrics.

ABSTRACT BODY:

Purpose: To evaluate the association between lamina cribrosa depth (LCD) and severity of glaucomatous damage in bilateral Normal-Tension Glaucoma (NTG) patients who have more damage in one eye.

Methods: Optic nerve heads (ONH) were scanned using enhanced-depth spectral-domain optical coherence tomography. LCD was measured at the three locations spaced equidistantly across the vertical optic disc diameter using ONH horizontal B-scan images. LCDs were compared between more damaged and contralateral eyes. The association between LCD and the severity of glaucomatous damage was analyzed by using logistic regression analysis. Additionally, the conditional logistic regression analysis was performed to identify the ocular risk factors associated with more damage between both eyes in the individuals.

Results: A total of 72 eyes of 36 bilateral NTG patients were included. The mean age of patients was 66.8 ± 13.0 years, and 21 patients (58.3%) were male. More damaged eyes had thinner global retinal nerve fiber layer thickness ($P < 0.001$), worse visual field mean deviation ($P = 0.032$), and pattern standard deviation than contralateral eyes ($P < 0.001$). In contrast, there were no significant inter-eye differences in intraocular pressure, spherical equivalent, and axial length. Average LCD was significantly larger in more damaged eyes (514.2 ± 129.3 vs. 481.9 ± 114.2 μm, $P = 0.006$). While the severity of the glaucomatous damage was not correlated with the degree of LCD in more and less damaged eyes, the eye with deeper LCD had a higher risk for having severe damage between both eyes with similar systemic condition (odds ratio, 1.017; 95% confidence interval, 1.003-1.301; $P = 0.021$).

Conclusions: Average LCD was significantly larger in eyes with more damage, suggesting that LC deformation would be associated with glaucomatous ONH damage in the NTG eye.

ABSTRACT BODY:

Purpose: Achromatopsia (ACHM) is an autosomal recessive retinal disorder associated with photosensitivity, absent color discrimination, and decreased visual acuity. We describe the effects of the subretinal gene therapies AGTC-401 and AGTC-402 on photosensitivity at Month(M) 12 and M24 post-treatment.

Methods: Participants with ACHM due to biallelic mutations in either CNGA3 (n=15; 2<18y) or CNGB3 (n=25; 4<18y) were sequentially assigned to one of 5 (CNGA3) or 6 (CNGB3) dose levels before receiving a single subretinal injection of AGTC-402 (rAAV2tYF-PR1.7-hCNGA3) or AGTC-401 (rAAV2tYF-PR1.7-hCNGB3) involving the macula of the study eye (SE). Safety and efficacy assessments included best-corrected visual acuity (BCVA; ETDRS letter score) and photosensitivity, which was measured as the light discomfort threshold (LDT). Two tests assessed LDT: LDT-1 using a full-field light stimulus generated by the Diagnosys ColorDome and LDT-2 using the Ocular Photosensitivity Analyzer. A meaningful post-treatment response in LDT was defined as an increase from baseline >1 loglux.

Results: In these participants with at least 12 months of follow-up, AGTC-401 and AGTC-402 were generally well-tolerated; serious adverse events were related to the surgical procedure (n=1) and steroid-associated elevated intraocular pressure (n=2). Mean BCVA changed by < 3 letters in both trials. Mean LDT at M12 was higher on LDT-1 in the CNGB3 trial (p=0.002) but unchanged on LDT-1 in the CNGA3 trial and on LDT-2 in both trials. The CNGB3 trial had 4 LDT-1 and 9 LDT-2 responders with the greatest number (LDT-1, n=3; LDT-2, n=6) in the pediatric and highest dose groups ($1.1e^{12}$ and $3.2e^{12}$ vg/ml). All LDT-1 responders were also LDT-2 responders. Improved LDT was sustained in 3 of 4 LDT-2 responders with M24 data. Untreated fellow eyes showed >1 loglux change in 75% of LDT-1

and 67% of LDT-2 responders. The CNGA3 trial had 2 LDT-1 and 2 LDT-2 responders among 3 participants with sustained improvement at M24 for the 2 responders for whom data was available.

Conclusions: Subretinal gene therapy with AGTC-401 resulted in clinically-meaningful and sustained improvement in light discomfort in some participants with CNGB3 ACHM. Fewer individuals showed a response after treatment with AGTC-402 in the CNGA3 trial. Further study is needed to understand the bilateral nature of the LDT improvement.

ABSTRACT BODY:

Purpose: Time restricted feeding has multiple benefits without the detrimental side effects of calorie restriction. However, the mechanism of action in which time the restricted eating paradigm exerts positive outcomes remains inadequately studied. Previously, we showed that a high caloric state in diabetes leads to downregulation of SIRT1/LXRα activity resulting in retinal cholesterol accumulation. Herein, we investigated the retinal specific effects of long term IF using in vitro and in vivo models.

Methods: To model IF, we used human retinal endothelial cells (HREC) and serum depleted the cultures for 24hrs followed by exposure to cholesterol crystals for 24hrs. A type 2 diabetes (T2D) model, the db/db mouse was used and db/m mice was used as controls. Food restriction for 24hrs was followed by a 24hrs feeding period during this time mice had access to water ad libitum. After 6 months of diabetes, animals were sacrificed, and retinas analyzed for cholesterol crystal formation, inflammatory cytokine expression, and levels of SIRT1/LXRα and cholesterol. CC were quantified using ImageJ software analysis. Quantitative Real Time PCR was used to assay inflammatory marker production. Trypan blue exclusion assay was used to measure cell death.

Results: In vitro CC administration resulted in elevated levels of inflammatory markers (IL6, IL8, VCAM1, ICAM1, IL-1ß, n=3; $p<0.001$), complement pathway activation (C5aR, n=3; $p<0.001$) and apoptosis (n=3; $p<0.01$) in HREC which were improved by serum starvation. Long term diabetes resulted in decreased SIRT1 expression (n=5; $p<0.05$), elevated retinal cholesterol levels, CC formation (n=5; $p<0.05$) and inflammation marker expression (n=5; $p<0.05$). While CC were not found in retinas of non-diabetic aged, matched controls, they were observed in db/db mice. Long term IF increased retinal SIRT1/LXRα signaling, cholesterol efflux, prevented retinal cholesterol accumulation, CC formation and inflammation.

Conclusions: IF-mimicking conditions improved HREC response to CC exposure and lowering retinal cholesterol levels via IF prevented formation of CC and DR progression. Thus, this study suggests that IF is an effective and safe therapeutic strategy in combating the deleterious retinal effects associated with long term diabetes by reducing retinal levels of cholesterol, CC formation and deceasing retinal inflammation.

ABSTRACT BODY:

Purpose: Written materials are the dominant medium to convey educational and instructional information to patients. Given the significant proportion of patients with visual impairment in ophthalmology clinics, we hypothesize that these patients would prefer information presented through alternative media formats.

Methods: Patients were recruited from the University of Michigan Kellogg Eye Center Retina clinics (n=60) who had low vision, were scheduled for retina surgery or their first intravitreal injection, or were from the cornea clinic (n=50) at their pre-operative cataract surgery appointment. Best corrected visual acuity (BCVA), age, gender, electronic device usage, and previous usage of educational materials were collected. Each patient completed a Likert scale questionnaire to evaluate preference for written, infographic, audio, and video mediums of education. Data were analyzed through two-tailed Student’s t-test. An institutional review board reviewed this study protocol.

Results: Patients with BCVA of 20/50 or worse comprised 50% of the retina clinic and 30% of the cornea clinic participants. Their most preferred medium was audio while least preferred was written. Lower visual acuity positively correlated with preference for audio ($p<0.001$) and video ($p<0.001$) mediums while negatively correlating with written ($p=0.0004$) and infographic ($p=0.0024$) mediums. Patients with lower visual acuity were also less likely to use written handouts from any physician at prior encounters ($p<0.001$).

For all patients, video was most preferred and audio least preferred. In patients with BCVA 20/40 or better, written was the most preferred medium.

Conclusions: Patients with visual impairment tend to not use written materials from physicians and prefer alternate mediums of receiving information. Low visual acuity was associated with preference for audio and video over written and infographic mediums, with audio being most preferred. The patient population as a whole preferred video. Further investigation will be needed to see if these mediums are effective for educating visually impaired patients. Physicians may consider investing in alternative educational methods to increase accessibility of information to their patients.

ABSTRACT BODY:

Purpose: Early changes in age-related macular degeneration (AMD) are suggested to extend beyond the outer retina, although locations of these changes are unclear. This study examines anatomical topographical differences across all retinal layers in early/intermediate AMD using high-density OCT analysis.

Methods: OCT macular cube scans of 96 early/intermediate AMD and 96 normal eyes from individual participants propensity-score matched on age, sex, and refraction were retrospectively recruited. High-density (60×60 0.01mm^2) grid thicknesses were custom-extracted and compared between AMD and normal eyes corrected for confounding. 'Normal-differences' were formed and underwent cluster analysis to reveal topography for the retinal nerve fibre (RNFL), ganglion cell (GCL), inner plexiform (IPL), inner nuclear (INL), outer plexiform (OPL), outer nuclear+Henle's fibre (ONL_{+HFL}) layers, inner- and outer-segments (IS/OS), and retinal pigment epithelium-to-Bruch's membrane (RPE-BM).

Results: AMD macular clusters across the inner retina (Fig 1) displayed extensively thinned RNFL, GCL, IPL, and paracentral INL (mean±SD, up to −8.44±1.51μm, P=0.63 to <0.0001) and thickened INL elsewhere. The outer retina (Fig 2) exhibited thinned OPL/ONL_{+HFL} paracentrally, IS/OS centrally, RPE-BM peripherally (up to −2.14±0.48μm, P=0.18 to <0.001), and thickened RPE-BM centrally (up to +5±1.14μm, P<0.01). Effect sizes (−2.74−+18.37SD), cluster sizes (2.2−60.1% area), and eccentricity effects varied.

Conclusions: Anatomical topographical differences are evident across all retinal layers in early/intermediate AMD. These results help define where changes may lie in the early stages of AMD.

ABSTRACT BODY:

Purpose: To investigate for evidence of effect measure modification (EMM) by race/ethnicity on the association between myopia and primary open angle glaucoma (POAG); in other words, to determine whether race/ethnicity modifies the association between myopia and POAG.

Methods: A cross-sectional study was conducted in the 100% sample of 2019 California (CA) Medicare beneficiaries from the Centers for Medicare & Medicaid Services. Inclusion criteria were: age 65 or older, CA residence, and active coverage with Medicare Part B. The outcome of interest was POAG and the primary exposure was myopia, both defined by having International Classification of Diseases, Tenth Revision diagnosis codes for their respective conditions. To test for statistically significant EMM, a multivariable logistic regression model was created with myopia, POAG, and the following covariates: age, sex, race/ethnicity, systemic disease burden defined by Carlson Comorbidity Index (CCI) score, and an interaction term between myopia and race/ethnicity. To compare the effect of myopia on POAG modified by race/ethnicity, separate multivariable models were fitted for the effect of myopia on POAG, stratified by race/ethnicity, and adjusted for age, sex and CCI.

Results: The study population included 2,717,346 CA Medicare beneficiaries. About 1.9% (n = 52,517) of beneficiaries had a diagnosis of myopia and 37.2% (n = 1,010,539) identified as non-White. Subjects with myopia had 2.15 times the adjusted odds of POAG (95% confidence interval [CI], 2.09-2.21) compared to subjects without myopia, and there was evidence of statistical interaction between myopia and race/ethnicity ($p<0.0001$). In our multivariable models stratified by race/ethnicity, myopia was associated with greater adjusted odds of POAG than those without myopia within Black (odds ratio [OR]: 2.49, 95% CI, 2.19-2.82), Hispanic (OR: 3.13, 95% CI, 2.93-3.34), and Asian subjects (OR: 2.22, 95% CI, 2.05-2.41), as compared to White counterparts (OR: 1.92, 95% CI, 1.86-1.99).

Conclusions: In the CA Medicare population, myopia is associated with greater odds of POAG among minorities as compared to White subjects, after adjusting for covariates. There is significant EMM between race/ethnicity and myopia on the likelihood of having POAG. We cannot discern whether this is completely due to health disparities or other factors, such as gene-environment interactions.

TITLE: Studying corneal endothelial cell migration from outer graft rims

SESSION TITLE: Corneal Endothelium

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Miron, S. Oellerich, G. Melles, V. Kocaba, R&D, Netherlands Institute for Innovative Ocular Surgery, Rotterdam, NETHERLANDS|A. Miron, Ophthalmology, Leiden University Medical Center (LUMC), Leiden, NETHERLANDS|S. Ní Dhubhghaill, Ophthalmology, Universitair Ziekenhuis Antwerpen, Antwerp, BELGIUM|

Commercial Relationships Disclosure: Alina Miron: Commercial Relationship: Code N (No Commercial Relationship) | Silke Oellerich: Commercial Relationship: Code N (No Commercial Relationship) | Sorcha Ní Dhubhghaill: Commercial Relationship: Code N (No Commercial Relationship) | Gerrit Melles: Commercial Relationship(s);Code C (Consultant/Contractor):DORC | Viridiana Kocaba: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Predicting in vivo endothelial cell migration after surgical removal of central diseased endothelium is challenging since the capacity of endothelial cells (EC) to migrate can vary. In this study, outer corneal graft rims were cultured in a temperature-reversible hydrogel matrix to simulate in vitro the EC migration after Descemet stripping only (DSO) with and without ROCK-inhibitor.

Methods: Twenty-one outer rims with the trabecular meshwork still attached were prepared from Descemet membrane-endothelial cell (DM-EC) sheets (from 12 research-grade donors (mean age 76±5 years)) by a 6.5-mm trepanation. For the initial proof-of-concept, 7 outer rims were cultured in a thermo-reversible hydrogel matrix for up to 45 days. To assess the effect of ROCK-inhibitor on the in vitro cell migration, 7 paired outer rims were cultured either with or without ROCK-inhibitor. At the end of culture, tissue was retrieved from the polymer matrix to examine cell viability and expression markers (ZO-1, Na^+/K^+-ATPase, NCAM, glypican and vimentin).

Results: All cultured outer rims remained viable and displayed single regions (n=5/21) or collective (n=16/21) cell migration, regardless of the presence or absence of ROCK-inhibitor. Collective migration started on average after 4±2 days and continued for at least 29 days. Migrated cells showed a more regular cell morphology when cultured in the presence of ROCK-inhibitor than not. Furthermore, 7 outer rims additionally demonstrated a phenotypically distinct late-onset, but fast growing cell population emerging from the far periphery of the endothelium. This occurred after 3 weeks of culture and displayed characteristics for undifferentiated cells. Immunostaining showed that migrated EC maintained the expression patterns of endothelial cell markers.

Conclusions: Using a 3D-culture system, we observed the migration of two morphologically distinct cell populations. The first type was triggered by a broken physical barrier, consistent with disruption of contact inhibition. The second, late-onset type showed a higher proliferative capacity, which appears to be mediated by other stimuli next to cell exposure to free space and ROCK-inhibitor. Further exploration of the differences between these cell types may assist in learning how to selectively stimulate cell migration from DM-EC areas that harbor the latter cell type and may ultimately help to improve DSO outcomes.

ABSTRACT BODY:

Purpose: Frequent use of OCT to monitor retinal fluid is essential in the treatment of nAMD and DME. The ALBATROS data collection was set up to measure how the number of sequential OCTs as recommended by 3 German Ophthalmology Societies affects patient quality of life (QoL).

Methods: Parameters collected were BCVA, central retinal thickness (CRT), QoL (NEI-VFQ-25) at baseline and month 12, number of anti-VEGF treatments and number of OCT scans. VFQ-25 was calculated in overall, composite and Rasch-transformed scales.

Results: Data was collected from 102 sites (n=1444 nAMD, n=445 DME). nAMD patients had a mean improvement in vision of 3.4±19.3 (ETDRS letters±SD) from baseline to last visit, DME patients a mean improvement in vision of 4.1±13.3 letters, respectively. For nAMD patients a mean of 7.2 OCTs and 5.2 anti-VEGF injections were performed. For DME patients 7.1 OCTs and 5.0 injections were recorded (median observation time for both groups: 365 days). No relevant change was seen in Rasch-transformed QoL scales for either group. In the nAMD group the VFQ-25 subscale score showed patient relevant improvement (56.4±17.93 to 62.1±17.30) for distance vision, but not for near vision. In DME patients clinically relevant improvement was seen in VFQ-25 subscales for both distance and near vision. In DME higher VFQ-25 scores were seen when more OCT examinations were conducted. Specifically, the general health scale declined by 2.4 when >3 to ≤6 OCTs were done (3.5 injections in this group), but increased by 2.6 with >6 to ≤9 OCTs (5.3 injections) and increased by 6.5 when >9 OCTs (8.3 injections) were completed. In nAMD an increasing injection rate in the 3 OCT subgroups (3.8 vs. 5.5 vs 7.7) was not reflected by a change in VFQ-25 score despite the increase in BCVA in the higher OCT-subgroups (1.4. vs. 4.4 vs 4.1).

Conclusions: Improvement in QoL was seen in both nAMD and DME groups with increasing number of injections and OCT examinations for distance vision and in the DME group for near vision. In DME patients there was a trend for higher scores in the VFQ-25 QoL with increasing number of OCT scans performed although this was not seen in nAMD. Management of these conditions according to the recommendations of the German Ophthalmology Societies results in a reasonable number of OCT examinations and improved patient QoL.

ABSTRACT BODY:

Purpose: To compare individual retinal layer thickness in peripapillary (ppOCT) and macula (mOCT) OCT scans in high myopia (HM) and low/non-myopia (NM) eyes without visual field (VF) defects.

Methods: HM was defined as spherical equivalent (SE) of ≤-6D or axial length (AL) of ≥26mm, NM was defined as SE of 0 to -3D and AL of <24 mm. Subjects with diabetes, neurological disease, neuroretinal rim thinning, intraocular pressure of >21mmHg or other ocular disease apart from myopia were excluded. Eyes with indeterminate neuroretinal rim thickness underwent VF testing, and were included if ≥2 reliable VF showed glaucoma hemifield test within normal limits, and VF index ≥97%. Two different 200 x 200 scans were acquired in the same eye using Cirrus spectral-domain OCT: mOCT centered on the macula and ppOCT centered on the optic disc. Poor quality scans were excluded. PpOCT scans were divided into superior (S), nasal (N), inferior (I) and temporal (T) sectors; mOCT scans were divided into S, S-N, S-T, I, I-N and I-T sectors and analyzed using Iowa Reference Algorithms 3.8.0 and MATLAB to delineate individual layer thickness and sectoral boundaries. Ocular magnification was corrected using Littmann's formula, based on axial length. Thickness measurements were compared between HM and NM eyes using linear mixed effect models to account for fellow-eye correlation, after adjusting for age and gender.

Results: 159 eyes from 111 HM subjects and 153 eyes from 98 NM subjects were included. Sector-wise differences were noted in all 10 layers of the retina i.e. RNFL, GCL, IPL, INL, OPL, ONL, IS/OS, OSL, OPR, RPE when considered individually, in both ppOCT and mOCT scans ($p<0.05$). Combining the outer retinal layers into INL to RPE (INL-RPE) however, showed no significant difference between HM and NM eyes at any mOCT sector. Combining the inner retina layers into GCL to IPL (GC-IPL) also showed no significant difference in mOCT, apart from superiorly (mean HM GC-IPL 85.0±1.6μm, NM 82.7±1.4μm, $p=0.03$). HM and NM eyes differed in all ppOCT sectors ($p<0.05$).

Conclusions: HM eyes without VF defects have similar INL-RPE thickness in all macula sectors, and similar GC-IPL thickness apart from superiorly, compared to NM eyes after correcting for magnification error, age and gender. Mapping VF defects in HM to localized INL-RPE or GC-IPL SD-OCT measurements may increase diagnostic accuracy of glaucoma in HM eyes.

ABSTRACT BODY:

Purpose: To evaluate clinical outcomes and graft survival in a large cohort of patients up to 10-years after Descemet Membrane Endothelial Keratoplasty (DMEK) based on surgical indication and Fuchs endothelial corneal dystrophy (FECD) severity.

Methods: In this retrospective cohort, we included 750 eyes (572 patients) which underwent DMEK for FECD (86%), bullous keratopathy (BK, 9%), and other indications (5%). Based on the modified Krachmer grading, 186 eyes (29%) had moderate FECD (Krachmer grade 3 and 4) and 440 eyes (68%) advanced FECD (Krachmer grade 5 and 6). Best-corrected visual acuity (BCVA), central corneal thickness (CCT), endothelial cell density (ECD), endothelial cell loss (ECL), postoperative complications, and graft survival were assessed up to 10-years after DMEK.

Results: BCVA outcomes and CCT remained stable between 1- to 5-years and 5- and 10-years postoperatively (all $P>0.05$). Mean 10-year BCVA was 0.08±0.28 logMAR (n=96) and mean 10-year CCT was 545±39 µm (n=98). Mean ECD was 1136±460 cells/mm^2 (n=460) at 5-years and 890±381 cells/mm^2 (n=96) at 10-years with an ECL of 56% and 66%, respectively ($P<0.05$). Allograft rejection was diagnosed in 3% (n=24) of the eyes. Graft survival rate for the total cohort was 0.85 (95% CI, 0.82-0.89) at 10-years after DMEK. BCVA and ECD differed at 1-5 years between eyes with different surgical indications (all $P<0.05$). Eyes with FECD surgical indication had a higher graft survival rate compared to BK eyes (0.90 vs 0.60, $P=0.001$). Eyes with moderate FECD had better BCVA and ECD outcomes than advanced FECD eyes ($P<0.05$), except for the difference in 10-year ECD where it did not reach statistical significance ($P=0.392$). Furthermore, eyes with moderate FECD stage had a higher graft survival rate compared to advanced FECD eyes (0.94 vs 0.88, $P=0.018$).

Conclusions: Long-term clinical outcomes and graft survival after DMEK are related to surgical indication (FECD versus BK) and to disease severity for FECD eyes. Eyes operated for moderate FECD showed the highest graft survival probability and excellent long-term clinical outcomes.

ABSTRACT BODY:

Purpose: The aim of the study is to establish what preoperative factors influence the trabeculectomy outcome.

Methods: In this prospective study, we followed 80 glaucomatous eyes for 5 years after trabeculectomy. At baseline, prior to surgery, tear fluid samples and clinical data were collected from the patients. All postoperative complications, i.e., needling, restart of a glaucoma medication and reoperation, were recorded. The patients' postoperative statuses (success (S) vs qualified success (QS) and failure (F)) were then compared against the baseline tear proteomics and clinical variables with Wilcoxon rank sum test. Proteomic pathway analyses were performed using Ingenuity Pathway Analysis (IPA) software.

Results: One year after surgery, 15 (19%) QS+F patients were recorded. Respective numbers 3 and 5 years after surgery were 20 (26%) and 23 (38%). According to pathway analysis results, patients with QS+F status after first year had a decreased generation of reactive oxygen species (ROS) (P=0.02) and an increased development of vasculature and cell movement of immune cells (all P=0.02) at baseline. Patients with QS+F status 1 and 3 years after trabeculectomy had also inhibited estrogen receptor 2 (ESR2) at baseline according to the upstream analysis (P=0.02 and P=0.04, respectively). The patients with QS+F status 1, 3 or 5 years after surgery had statistically higher baseline IOP in comparison to patients with a successful outcome (median IOP value differences were 7 (P=0.003), 3.5 (P=0.008) and 4.5 (P=0.01) mmHg, respectively).

Conclusions: Tear proteomics results revealed that the states of biological functions in the ocular surface are associated with the trabeculectomy outcome. In addition to inflammation, the instability of ROS merits further studies to establish whether they could be used as trabeculectomy outcome indicators or as druggable targets to improve the surgical outcome.

ABSTRACT BODY:

Purpose: USH2A variant c.2276G>T (p.(Cys759Phe)) has been described as a frequent cause of autosomal recessive retinitis pigmentosa (arRP). However, its pathogenicity has been a matter of debate since the description of two a-symptomatic individuals homozygous for this variant. In this study, we therefore aimed to assess pathogenicity of the USH2A c.2276G>T variant using extensive genetic and functional analyses.

Methods: Whole genome sequencing and optical genome mapping were performed for three arRP cases homozygous for USH2A c.2276G>T to exclude alternative genetic causes, including variants in potential regulatory regions of USH2A. A minigene splice assay was designed to investigate the effect of c.2276G>T, in the presence or absence of the nearby c.2256T>C variant, on pre-mRNA splicing. A molecular model of the fifth laminin–epidermal growth factor like domain was generated to observe a putative structural effect. Moreover, an ush2a$^{p.(Cys771Phe)}$ zebrafish knock-in model mimicking human p.(Cys759Phe) was generated and phenotypically evaluated using functional and immunohistochemical analyses.

Results: Besides the homozygous c.2276G>T USH2A variant, no other potentially causative DNA variants could be identified with our genetic approaches. Furthermore, p.(Cys759Phe) is predicted to be detrimental for usherin folding and function, based on molecular modeling. Evaluation of the ush2a$^{p.(Cys771Phe)}$ zebrafish model revealed significantly reduced levels of usherin expression at the photoreceptor periciliary membrane, increased levels of rhodopsin localization to the photoreceptor cell body and decreased ERG b-wave amplitudes as compared to wildtype controls.

Conclusions: We confirmed pathogenicity of USH2A c.2276G>T (p.(Cys759Phe)). Consequently, persons homozygous for c.2276G>T can now receive a definite genetic diagnosis and can be considered eligible for QR-421a-mediated exon 13 skipping therapy in the future.

ABSTRACT BODY:

Purpose: Multimodal imaging was used to identify and characterize the cause of hyperpigmentation seen on color fundus images (CFIs) in eyes with intermediate age-related macular degeneration (iAMD).

Methods: At the Bascom Palmer Eye Institute, a retrospective review of a prospective observational case series of eyes with iAMD was performed. CFIs with macular hyperpigmentation were compared with same day images obtained using fundus autofluorescence (FAF), near infrared reflectance (NIR) and swept-source optical coherence tomography (SS-OCT) imaging. Two SS-OCT en face slabs were generated for analysis: a retinal slab to identify hyper-reflective foci within the retina and a slab from beneath the retinal pigment epithelium (sub-RPE slab) that was used to detect regions that cause decreased light transmission into the choroid, also known as hypo-transmission defects (hypoTDs). All images were registered to allow for qualitative comparisons by two independent graders.

Results: Six representative cases from this study are shown. Compared with CFIs, FAF imaging appeared to be the least sensitive method for the detection of hyperpigmentation while NIR and SS-OCT imaging reliably detected these foci of hyperpigmentation. While NIR imaging detected most of the hyperpigmentation seen in CFIs, SS-OCT imaging detected all the areas of hyperpigmentation, and these areas were anatomically localized by using both en face and B-scan images. En face OCT slabs of the retina and sub-RPE region were registered to the CFIs and areas of hyperpigmentation were shown to correspond to hyper-reflective foci in the retina and regions of thickened RPE seen on OCT B-scans. While both hyperpigmentation and early atrophic lesions appeared bright on NIR imaging, en face SS-OCT imaging was able to distinguish these lesions since hyper-pigmentation appeared dark and early atrophic lesions appeared bright on the sub-RPE slab.

Conclusions: En face OCT imaging in conjunction with OCT B-scans were able to reliably identify and localize the hyperpigmentation seen on CFIs, and unlike previous reports that associated hyperpigmentation with intra-retinal hyper-reflective foci, we found that this hyperpigmentation could also be associated with a thickened RPE.

ABSTRACT BODY:

Purpose: The fovea is specialized for high spatial resolution and color vision, but there is a paucity of recordings that elucidate how retinal ganglion cells (RGCs) at the very center of the fovea facilitate this specialization. Here, we optically record responses to spatial and chromatic stimuli using a calcium indicator in the living eye to characterize the receptive field (RF) properties of RGCs serving the foveal center.

Methods: The calcium indicator GCaMP6s was expressed in the ganglion cell layer of a female macaque. Adaptive optics scanning light ophthalmoscopy (AOSLO) was used to image fluorescence (488nm ex., 520/35nm em.) from RGCs whose RF centers were driven by cones in the central 6 arcmin of the fovea. By recording responses to cone isolating and luminance flicker (1.3deg, 0.15Hz, LED 420nm, 530nm, 660nm), we derived cone weights in 34 RGCs. By recording responses to drifting gratings (1.9deg, 6Hz, 4-50c/deg, 561nm), we derived the spatial frequency responses of 15 L/M chromatic opponent RGCs. Employing computational modeling (ISETbio toolbox, isetbio.org) that accounted for residual blur in the instrument, the eye's optics, cone aperture, and the spacing of individual cones, we inferred the number of cones feeding into RF centers and surrounds.

Results: Of the 34 RGCs, 44% exhibited L/M chromatic opponency, 15% were L+M ON, 6% were -L-M OFF, while the remaining 35% showed only L or only M responses. The spatial frequency response functions of 12/15 L/M opponent cells peaked at high spatial frequencies (25-40c/deg) and had a strong bandpass characteristic. Our model indicates that the responses of at least 9/15 L/M opponent cells are consistent with single cone input to their RF centers [Fig 1].

Conclusions: Using AOSLO to image calcium-mediated responses allows the study of the cone inputs to and spatial frequency responses of the very centermost foveal RGCs in the living primate eye. Our model establishes a framework for estimating sources of optical and neural information loss. The high spatial frequency tuning and single cone inputs we observed in L/M opponent cells emphasize the foveal specialization for spatial and chromatic vision by preserving information at the resolution of the photoreceptor mosaic.

ABSTRACT BODY:

Purpose: An increasing number of gene-specific therapies are being developed for IRDs. Identification of well characterised patients is an emerging need. We conducted the second multinational survey among the EVICR.net and ERN-EYE members to understand the management of IRDs in Europe, and compared it to the 2019 survey[1, 2].

Methods: An electronic survey questionnaire was developed and sent to the 126 EVICR.net and ERN-EYE clinical centers (25 countries). Statistical analysis was performed with Excel and R.

Results: The overall response rate was 44% but varied among countries. Only 9% of responding centers do not see IRD patients (1st survey 14%); 42% follow at least 200 patients per year, 18% follow 500-999 and 2% more than 1000. Databases exist in 86% of the centers (local 86%; national web-based 12%). IRD patients are referred to EVICR.net and ERN-EYE centers mainly by general ophthalmologists, patient self-referral, or medical retina specialists. Most IRD patients are first seen as adults. Signs and symptoms depend on age of onset (infancy: nystagmus, older ager night blindness and reduced visual acuity [VA]). Mean time from asking for 1st appointment and clinical diagnosis varies among countries: 36% of centers < 4 weeks, up to 12 months in others (1st survey ≤35 months). Comprehensive ophthalmic examination always includes VA, in 98% visual fields, and imaging (FAF and/or NIRAF, OCT and/or OCTA), in 96% fundus photography and electrophysiology, in 94% color vision testing and in 92% refraction. Identification of genotypes is possible in 72% of centers in 40-80% (1st survey 69%) of cases. The time for confirmation of the genetic diagnosis varies from 2-4 weeks to 24 months (1st survey > 4 weeks and ≤ 10 years). Genetic testing is covered by public health service in 83%, private health insurance in 29%, research funds in 24%; 5% do not have access to genetic testing (1st survey 15%).

Conclusions: This 2nd multinational survey on management of IRDs in Europe highlights important differences in the number of IRD patients managed per center, comparable diagnostic work-up, and increasing genotyping. The data are particularly useful in the era of rapidly increasing gene therapy trials for IRDs.

ABSTRACT BODY:

Purpose: To present the 100-week results from the KESTREL and KITE studies that evaluated efficacy and safety of brolucizumab (BRO) versus aflibercept (AFL) in patients with DME.

Methods: KESTREL (NCT03481634) and KITE (NCT03481660) were two 100-week (W), double-masked, active-controlled, Phase 3 studies. In KESTREL, patient randomization was 1:1:1 to BRO 3mg, BRO 6mg or AFL 2mg; in KITE, randomization was 1:1 to BRO 6mg or AFL 2mg. The BRO arms received 5 loading doses every 6 weeks (q6w) followed by q12w dosing, with an option to adjust to q8w at predefined disease activity assessment visits. At W72 in KITE, based on the disease stability assessment by the masked investigator, there was an option to extend the treatment interval for BRO patients by 4 weeks i.e. from q12w to q16w or q8w to q12w. The AFL arms received 5 monthly loading doses followed by fixed q8w dosing until end of study.

Results: In both studies, BRO 6mg was non-inferior to AFL for the change in BCVA at W52 (primary endpoint) and the VA gains were maintained to W100 (change in BCVA (letters) from baseline: BRO 6mg +8.8 vs AFL+10.6, difference −1.7 [95% CI, −3.8, 0.4] in KESTREL; BRO 6mg +10.9 vs AFL +8.4, difference +2.6 [95% CI, 0.2, 4.9] in

KITE). The change in central subfield thickness (CSFT) from baseline over the period W88 through W100 in BRO 6mg and AFL arms were −171.9µm vs −168.5µm in KESTREL; −196.6µm vs −173.4µm in KITE. Fewer BRO 6mg patients had IRF and/or SRF vs AFL at W100 (KESTREL, 41.8% vs 54.0%; KITE, 40.8% vs 56.9%). Of the BRO 6mg patients who successfully completed the first q12w cycle immediately after the loading phase, 70.2% remained on q12w interval in KESTREL and 69.6% on q12w/q16w interval in KITE up to W100. In KESTREL, intraocular inflammation (IOI) rates were 5.3%, 4.2% and 1.1% in BRO 3mg, BRO 6mg and AFL, respectively; incidence of retinal vascular occlusion (RO) and retinal vasculitis (RV) were 1.6% and 1.6% in BRO 3mg, 1.6% and 0.5% in BRO 6mg and, 0.5% and 0% in AFL arms, respectively. No new RV reported in Year 2 in KESTREL. In KITE, IOI rates were 2.2% in BRO 6mg vs 1.7% AFL; incidence of RO was 0.6% in both BRO 6mg and AFL arms; there were no cases of RV through W100.

Conclusions: The 100-week results from KESTREL and KITE reaffirm the efficacy of brolucizumab for the treatment of DME seen in the Year 1 data. The overall safety profile of BRO 6mg remained unchanged through Year 2.

TITLE: PAX6-positive microglia evolve locally in hiPSC-derived ocular organoids

SESSION TITLE: Microglia in AMD and other immune factors in Retinal Degenerative Diseases

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: N. Shiraki, K. Maruyama, R. Hayashi, S. Sakimoto, K. Nishida, Ophthalmology, Osaka Daigaku, Suita, Osaka, JAPAN|

Commercial Relationships Disclosure: Nobuhiko Shiraki: Commercial Relationship: Code N (No Commercial Relationship) | Kazuichi Maruyama: Commercial Relationship: Code N (No Commercial Relationship) | Ryuhei Hayashi: Commercial Relationship: Code N (No Commercial Relationship) | Susumu Sakimoto: Commercial Relationship: Code N (No Commercial Relationship) | Kohji Nishida: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Microglia are the resident immune cells of the central nervous system (CNS). Since the immune cells from the general circulation cannot reach the CNS due to the blood-brain barrier, the brain and spinal cord microglial cells provide immune protection for CNS. Also, the microglia provide immune protection to the posterior eye, including the neural retina, and are involved in some sight-threatening conditions, such as age-related macular degeneration, uveitis, glaucoma, and retinal degeneration. However, it is not known how the microglia develop in the eye.

Methods: We studied human-induced pluripotent stem cells (hiPSCs) that had been expanded into a self-formed ectodermal autonomous multi-zone (SEAM) (Hayashi et al. Nature 2016;531:376-380) of cells that partially mimicked the human eye development. We searched and investigated the microglia-like cells, sorted them, and examined them by quantitative polymerase chain reaction (qPCR), cytokine analysis, RNA sequencing (seq), and single-cell RNA seq.

Results: We discovered that they contained immune cells that were significantly similar to the microglia cells in SEAM. Moreover, the RNA-seq data and qPCR showed that the cells were more similar to primary microglia cells than to immortalized human microglia. The results of the functional stimulation assays revealed that the sorted cells are likely govern immune tolerance in the ocular tissue. Furthermore, single-cell RNA seq revealed that the cells resembled yolk sac-derived myeloid progenitors and not macrophages.

Conclusions: Our results showed that microglia-like cells showing characteristics of yolk sac-like linage cells naturally develop in SEAM organoids, which lack vascular components. These cells are unique because they are paired box protein 6 (PAX6)-positive, yet possess some characteristics of the mesoderm. Our data support the possibility of the existence of an isolated and locally developing immune system in the eye, which is independent of the body’s vasculature and general immune system.

ABSTRACT BODY:

Purpose: The aim of the study is to investigate the quantity and distribution of fluid in neovascular age-related macular degeneration (nAMD) and the difference between the initial, treatment-naïve, presentation, at the beginning and the end of a treatment break.

Methods: Using data from one site of the Fight Retinal Blindness (FRB) Registry (University of Zurich, Switzerland), the distribution of retinal fluid in treatment-naïve nAMD patients compared to retinal fluid recurrence has been studied in a longitudinal manner. Study eye eligibility required treatment-naïve nAMD, receiving at least three anti-VEGF injections within the first six months of treatment, followed by a treatment pause of at least six months and fluid recurrence afterwards. To quantify fluid, a verified deep learning algorithm was used (Vienna Fluid Monitor, RetInSight, Vienna, Austria). Fluid volumes and proportions were compared between different time points using Friedman test and Wilcoxon signed rank test, respectively.

Results: Fifty-five eyes of 55 patients with the mean age of 76.86 ± 6.04years at baseline matched the inclusion criteria. A median of 12.66 (IQR 11) injections and 18.96 (IQR 22) months of treatment were needed to enable a treatment pause of at least six months. Visual acuity was 0.57 logMar at baseline, 0.47 logMar at start of the break and 0.48 logMar at the end of the break. At baseline, SRF showed a median of 55.29nl (IQR 243.79nl), IRF a median of 1.55nl (IQR 133.37nl) and PED a median of 0nl (IQR 520.73nl) in the central 6 millimeters. At disease recurrence, SRF showed a median of 8.07nl (IQR 86.29nl), IRF a median of 4.88nl (IQR 24.85nl) and PED a median of 0nl (IQR 551.61nl) in the central 6 millimeters (Figure 1). From baseline to start of the break, SRF and IRF decreased significantly ($p<0.01$) and PED did not change significantly ($p=0.215$). At baseline, the proportions of IRF, SRF and PED were 21%, 53% and 26%, respectively, with no significant shift except SRF at end of break to 27%,41% and 32% ($p=0.123$, $p=0.029$ and $p=0.374$), respectively.

Conclusions: Retinal fluid proportions were distributed predominantly in the subretinal compartment in treatment-naïve patients, whereas it was spread more equally between all fluid compartments after a treatment break. These morphological differences may contribute to our understanding of disease activity.

TITLE: Does Intravitreal Anti-VEGF Therapy with Ranibizumab, Bevacizumab, and Aflibercept Cause Rebound Supranormal Systemic VEGF Levels?

SESSION TITLE: Anti-VEGF in AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Frenkel, Eye Research Foundation, Stuart, Florida, UNITED STATES|R. Frenkel, East Florida Eye Institute, Stuart, Florida, UNITED STATES|

Commercial Relationships Disclosure: Ronald Frenkel: Commercial Relationship(s);Code C (Consultant/Contractor):Regeneron;Code C (Consultant/Contractor):Opthea;Code C (Consultant/Contractor):Apellis;Code C (Consultant/Contractor):Novartis;Code C (Consultant/Contractor):Santen;Code C (Consultant/Contractor):Gemini;Code C (Consultant/Contractor):Sandoz;Code C (Consultant/Contractor):Iveric

ABSTRACT BODY:

Purpose: To determine PK and plasma VEGF evels at baseline, 4 weeks, 6 weeks, or 8 weeks from intravitreal administration of bevacizumab, ranibizumab, or aflibercept and compare them to untreated controls.

Methods: 77 patients, including 8 untreated controls, who were treated with bevacizumab, ranibizumab, or aflibercept at a precedent time interval of 4, 6, or 8 weeks continued to receive the same drug at the same interval and had serum PK and plasma VEGF levels measured at baseline, 4 weeks, and 6 or 8 weeks.

Results: Untreated controls had little variability in plasma VEGF levels which were almost uniformly <20 pg/ml. (Fig1). Following intravitreal administration of bevacizumab, ranibizumab, or aflibercept as the dosing interval increased there were in general more pronounced decreases of the mean plasma VEGF levels as drug concentration increased, especially in the bevacizumab and aflibercept 6 week and 8 week treatment groups. Mean plasma VEGF levels were less affected by ranibizumab than bevacizumab and aflibercept; the drug concentration effect was most marked in the bevacizumab and aflibercept 6 and 8-week treatment groups. Bevacizumab in the 4-week group induced the lowest mean plasma VEGF levels. Surprisingly many treated patients, as exemplfied in the 4 week groups, at times had much higher plasma VEGF levels (up to 47 pg/ml) than individuals in the control group (Fig. 2). This was also true in the 6 and 8 week groups.

Conclusions: Aflibercept and bevacizumab, 6 and 8 week groups showed the most pronounced decrement in mean plasma VEGF as drug concentration increased. Paradoxically, plasma VEGF levels were sometimes much higher in treated individuals than in the control group suggesting an attempted homeostatic influence; this is of unknown significance. Perhaps there is up-regulation of systemic VEGF production in response to the anti-VEGF drug challenge. Ranibizumab disturbed mean plasma VEGF levels the least, as did monthly dosing with all agents, and minimizing systemic VEGF disturbances may be beneficial in terms of systemic homeostasis. A more “regular” anti-VEGF drug effect might be more easily compensated than large loads of anti-VEGF that occur irregularly, and theoretically this may have homeostatic benefits both in the eye and systemically.

TITLE: A Comparison of the XEN Gel Stent and Ahmed Valve Devices in Preventing Postoperative Hypotony in Patients with Primary Open Angle Glaucoma

SESSION TITLE: Surgery & Wound Healing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P.B. Wu, F.J. Gross, Ophthalmology, Eastern Virginia Medical School, Norfolk, Virginia, UNITED STATES|N. Chaganty, Mathematics and Statistics, Old Dominion University, Norfolk, Virginia, UNITED STATES|

Commercial Relationships Disclosure: Patrick Wu: Commercial Relationship: Code N (No Commercial Relationship) | Fredric Gross: Commercial Relationship: Code N (No Commercial Relationship) | N Rao Chaganty: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The XEN gel stent and Ahmed valve are both designed to prevent postoperative hypotony. We performed a retrospective study to compare the efficacy of these devices.

Methods: Patients who had either XEN gel stent or Ahmed valve surgery were screened and those with primary open angle glaucoma (POAG) were identified for further analysis. Patients with low-tension glaucoma, a complicated ocular history, and/or prior glaucoma surgery were excluded. The final study population had 41 eyes from 37 patients with 21 XEN gel stents and 20 Ahmed valves. Pre- and postoperative intraocular pressures (IOP) at day 1 (POD1), week 2 (POW2), and month 1 (POM1) were recorded. We defined hypotony as an IOP < 6.5 mmHg within the first postoperative month. The primary outcome was the rate of hypotony. Secondary outcomes were the mean IOP at each postoperative visit and the rate of short-term failures (defined as an IOP > 21 mmHg at the POM1 visit).

Results: Baseline characteristics were comparable between the XEN gel stent and Ahmed valve groups. At the POD1 visit, hypotony rates were 19.0% and 5.0% for the XEN and Ahmed valve groups, respectively. At the POW2 visit, hypotony rates were 4.8% and 10.5% for the XEN and Ahmed valve groups, respectively. By the POM1 visit, postoperative hypotony had resolved in all eyes in both groups. The differences between the rates of postoperative hypotony of each group were not statistically significant at the specified postoperative visits [p=0.154 (POD1), p=0.494 (POW2), p=N/A (POM1) as there were no cases of hypotony by POM1]. The differences between the mean IOP at each postoperative visit were not statistically significant between the two groups [p=0.887 (POD1), p=0.266 (POW2), p=0.211 (POM1)]. Short-term failures occurred in 23.8% of eyes in the XEN group and there were no short-term failures in the Ahmed valve group.

Conclusions: Both the XEN gel stent and Ahmed valve devices effectively decrease IOP and reduce the risk of early postoperative hypotony in patients with uncontrolled POAG. Any cases of postoperative hypotony were transient and resolved by POM1. Interestingly, all short-term failures occurred in the XEN group and in African American patients only. Additional studies can be performed to determine potential contributing factors.

TITLE: Perimetric simulations of 24-2C SITA Standard visual fields
SESSION TITLE: Visual Fields and Psychophysics
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: G.C. Lee, B. Cunningham, T. Callan, Carl Zeiss Meditec, Inc., Dublin, California, UNITED STATES|L. Chong, School of Medicine (Optometry), Deakin University, Geelong, Victoria, AUSTRALIA|J.G. Flanagan, School of Optometry and Vision, University of California, Berkeley, Berkeley, California, UNITED STATES|T. Severin, East Bay Eye Center, San Ramon, California, UNITED STATES|I.A. Falkenstein, Glaucoma Specialists of San Francisco, Oakland, California, UNITED STATES|

ABSTRACT BODY:
Purpose: Perimetric simulators have traditionally been used to develop and optimize visual field (VF) tests. In this preliminary study, we developed and evaluated a new simulator for simulating the relative performance of 24-2C SITA Standard (SS) VFs compared to 24-2C SITA Faster (SFR).
Methods: Retrospective 24-2C SS and 24-2C SFR VFs acquired in a study at each of two visits on one eye each for healthy and glaucomatous subjects on an HFA3 Model 860 perimeter (ZEISS, Dublin, CA) were analyzed. Two SITA 10-2 VFs also acquired at each visit were not used for these analyses.

HFA3 software was modified for use with a simulator [Lee et al. IOVS 2020; 61(7): PB0037] to provide subject responses to SITA VFs. Slopes of frequency of seeing (FOS) responses were modeled as previously described [Henson et al. IOVS 2000; 41(2)]. False answer rates were set to 5%.

Visit 1 data were used as substitutes for true (REF) fields. Mean absolute differences (MAD) between the REF fields and: a) Visit 2 VFs (TEST) and b) simulated VFs (SIM) were calculated for both 24-2C SS and SFR as a measure of “relative accuracy". Analyses were also repeated for the 24-2 test locations and the 10 new central 24-2C test locations.
Results: For 28 healthy eyes, mean age was 57.3 (standard deviation, SD: 7.6; range: 44.3 to 74.7) years and mean 24-2 SS MD was 0.38 (SD: 1.17; range: -1.89 to 2.62) dB. For 28 glaucoma eyes, mean age was 71.3 (SD: 9.0; range 54.0 to 97.9) years and mean MD was -7.92 (SD: 7.72; range: -23.42 to 1.63) dB.

$MAD_{SIM,REF}$ was comparable but slightly lower than $MAD_{TEST,REF}$ overall (see Table 1). $MAD_{SIM,REF}$ and $MAD_{TEST,REF}$ for both SS and SFR were similar in all and healthy eyes. SFR had slightly higher MAD than SS (~0.2 to 0.5 dB) in glaucoma eyes with more and deeper defects. $MAD_{SIM,REF}$ and $MAD_{TEST,REF}$ were more comparable for both SS and SFR in the ten new 24-2C test locations than in all or 24-2 only locations.
Conclusions: Given expected small differences in SS and SFR strategies [Heijl et al. AJO 2019; 198(2)], the study results may support that SS and SFR have similar performance in healthy eyes and SS is marginally better in regions of VF defects. Limitations of this study include the lack of true fields, use of a single representative FOS model, and no fatigue effects. Comprehensive simulations may continue to be a powerful tool in the development of future SITA strategies.

TITLE: Behavior of the accommodation response during the subjective refraction

SESSION TITLE: Optics: Accommodation, Lens and Ocular Biometry

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Turull Mallofre, C. García-Guerra, M. Aldaba, M. Vilaseca, J. Pujol, Centre for Sensors, Instruments and Systems Development, Universitat Politecnica de Catalunya, Barcelona, Catalunya, SPAIN|

Commercial Relationships Disclosure: Aina Turull Mallofre: Commercial Relationship: Code N (No Commercial Relationship) | Carlos E. García-Guerra: Commercial Relationship: Code N (No Commercial Relationship) | Mikel Aldaba: Commercial Relationship: Code N (No Commercial Relationship) | Meritxell Vilaseca: Commercial Relationship: Code N (No Commercial Relationship) | Jaume Pujol: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Subjective refraction is considered the gold standard when assessing refraction. In this method the control of accommodation plays a key role. The purpose of this work was to study the relationship between the subjective refraction and the accommodative response. In particular, we analyzed the residual relative accommodation for the subjective refraction and the relationship between the transition between relaxed and activated accommodation and the subjective refraction.

Methods: The accommodative response of the right eye of 27 young healthy subjects between 18 and 30 years old was obtained with the subjective refraction. The setup used was a system based on a Hartmann-Shack aberrometer coupled to a phoropter that provides an estimation of the accommodative state every 100ms. First, the subjective refraction of each participant was obtained. Then a sweep of spherical lenses (ΔS) from +1.5D to -1.5D, in 0.25D steps, was presented in front of the corrected eye with the subjective refraction while monitoring the accommodation. The residual relative accommodation for the subjective refraction was obtained as the value for ΔS=0 D minus the minimum measured value of accommodation.

The transition between relaxed and activated accommodation within the measured response was obtained as follows: first, two linear fitting were obtained for each spherical power ΔS, one considering the curve between -1.5D and ΔS, and another between ΔS and +1.5D; then, the spherical lens ΔS producing the linear fittings with the best cumulative coefficient of determination was selected as the transition point between relaxed and activated accommodation.

Results: Results showed that the mean relative accommodation ± SD with the subjective refraction was 0.19±0.12D. Bland-Altman analysis was done to determine the agreement between the value of the traditional subjective and the value obtained by finding the transition point of accommodation. The mean ± SD of the differences between methods and 95% limits of agreement were 0.019 ±0.42D (1.01D, -0.64D).

Conclusions: Considering the values of relative accommodation with the subjective refraction a tendency to have a residual activated accommodation can be observed. Moreover, the transition between relaxed and activated accommodation may be a significant information and could be a useful tool to detect accommodative anomalies during subjective refraction.

Commercial Relationships Disclosure: Javier Moreno-Montanes: Commercial Relationship(s);Code C (Consultant/Contractor):Sylentis, S.A.;Code C (Consultant/Contractor):Horus;Code F (Financial Support):Zeiss;Code F (Financial Support):Alcon;Code F (Financial Support):Bausch & Lomb;Code F (Financial Support):Thea;Code F (Financial Support):Santen | Leire Extramiana: Commercial Relationship: Code N (No Commercial Relationship) | Maria Bikuña: Commercial Relationship: Code N (No Commercial Relationship) | Jacobo Paredes: Commercial Relationship: Code N (No Commercial Relationship) | Elena Carnero: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The aim of this study is to create a bio-engineered 3D model of the trabecular meshwork (TM) and to evaluate its response to several external stresses. The morphology and composition of the TM and the mechanical properties were analyzed to evaluate similarities with the physiological features of the human TM and moreover, the effect of the stresses on its growth and functionality.

Methods: The development of the 3D TM polycaprolactone (PCL) material is based on electrospinning techniques combined with fused deposition modeling or Melt electrospinning writing. Different fiber sizes, orientation and deposition density were applied to replicate the micro-anatomy of the human TM. Changes in fiber diameter facilitated the modification of the meshwork cell density and hence, scaffolds with different degrees of stiffness could be obtained. Human TM cells (HTMC) were received from human donors and cultured according to standard protocols. We evaluated the growth, distribution and functionality of HTMC in the 3D model. We used RNA sequencing to assess the HTMC response to increasing stiffness conditions as compared to HTMC cultivated in the classical 2D model.

Results: HTMC demonstrated a fibroblasts-like morphology with slight differences depending on the donor. These cells were expanded according to the confluence observed in the traditional 2D models. HTMC remained functional and responded to dexamethasone stress in the 3D model. RNA sequencing analysis comparing HTMC growth in the 3D model with the 2D model showed changes in genes associated with gene ontology (GO) pathways. These changes included collagen binding, fibronectin binding, microtubule binding, extracellular matrix (ECM) structural constituent conferring compression resistance, among others.

Conclusions: A bioengineered 3D HTM model using electrospinning techniques can reproduce human TM features. We achieved an emulation of the TM in varying degrees of stiffness. HTMCs were able to adhere and grow in the 3D structure. The induction of specific TM markers using dexamethasone demonstrated the functionality of the HTMC in our model. The HTMC responded to the changes in the stiffness by altering the expression of genes implicated in the ECM remodelling. These results facilitate the identification of new target genes associated with ECM remodelling, and other pathways.

TITLE: Investigating the role of mutational load and cis modifiers of disease severity in RHO P23H autosomal dominant Retinitis Pigmentosa

SESSION TITLE: Molecular Mechanisms Underlying Inherited Ocular Disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Sangermano, E. Galdikaite-Braziene, E. Zampaglione, E.A. Pierce, A.V. Segrè, J. Comander, K.M. Bujakowska, Massachusetts Eye and Ear Department of Ophthalmology, Boston, Massachusetts, UNITED STATES|

ABSTRACT BODY:

Purpose: The RHO-P23H mutation is a well-known cause of autosomal dominant Retinitis Pigmentosa. Although affected patients share the same primary sequence defect, their phenotype displays a spectrum of disease severity. We hypothesized that the phenotypic variability could be due to an increased mutational load in the known inherited retinal disease (IRD) genes or to a differentially expressed wild-type RHO allele, that alters the ratio of the wild-type and mutant rhodopsin protein. Therefore, we tested for correlation of: 1) sequence variability in known IRD genes; and 2) wild-type RHO allele haplotypes with RHO-P23H phenotype severity.

Methods: We investigated a cohort of 130 RHO-P23H patients. Variable retinal severity was documented by retrospective analysis of ophthalmological data. We selected electroretinographic (ERG) measurements, in particular the 30Hz flicker ERG amplitude as the most comprehensive single parameter demonstrating phenotypic variability, adjusted for age. Targeted sequencing of all known IRD genes and genotyping of the RHO locus were performed using an in-house sequencing panel and a genotyping array (Illumina GSA), respectively. Deleteriousness of rare IRD variants was assessed using CADD, where for each patient we summed CADD scores for rare (MAF=<0.05) high-impact (loss-of-function) and missense variants. Genotyped variants surrounding the RHO locus (850kb) were phased using Eagle-v2 and samples of European ancestry from the Haplotype Reference Consortium panel.

Results: No significant correlation (r^2<0.01) was observed between retinal disease severity in RHO-P23H patients and the mutational load of rare loss-of-function or missense variants in other known IRD genes. Analysis of the RHO locus confirmed that the RHO-P23H allele is a founder allele in the US population, with only one family showing a different haplotype for the RHO-P23H allele. No particular wild-type allele segregated with mild or severe cases in any of the families.

Conclusions: Our results do not support two of our original hypotheses: 1) that mutational load in IRD genes can lead to the modulation of RHO-P23H disease severity, and 2) that the wild-type RHO allele can have an effect on disease severity. Differences in disease severity in the RHO-P23H patients may be the result of genetic modifiers elsewhere in the genome.

TITLE: Robust macula thickness analysis using low-cost OCT
SESSION TITLE: OCT Clinical Applications
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: A. Fard, H. Bagherinia, C. Leahy, S.A. Bello, Carl Zeiss Meditec, Inc., California, UNITED STATES|
Commercial Relationships Disclosure: Ali Fard: Commercial Relationship(s);Code E (Employment):Carl Zeiss Meditec, Inc | Homayoun Bagherinia: Commercial Relationship(s);Code E (Employment):Carl Zeiss Meditec, Inc | Conor Leahy: Commercial Relationship(s);Code E (Employment):Carl Zeiss Meditec, Inc | Simon Bello: Commercial Relationship(s);Code E (Employment):Carl Zeiss Meditec, Inc

ABSTRACT BODY:

Purpose: Remote OCT applications require cost-effective acquisition devices. This challenging constraint often leads to technology choices that provide inferior image quality compared to state-of-the-art clinical devices, and thereby result in unreliable image analysis. The purpose of this work is to demonstrate a strategy for robust macula thickness analysis using low-cost OCT that can navigate data quality limitations and improve correlation of thickness values compared with benchmark clinical systems.

Methods: Our method relies on acquiring multiple OCT scans of the same region and intelligently combining the macula thickness maps generated by individual scans. In this method, inner limiting membrane and retina pigment epithelium are delineated, and the corresponding thickness map and segmentation confidence map (SCM) are generated for each OCT volume. Subsequently, all thickness maps are registered to the thickness map (reference) with highest confidence derived from the SCM. The registration transformation parameters are then used to register and combine the thickness maps into a single map based on the local quality of individual SCMs.

To evaluate this method, we acquired OCT scans over an area of 5.78mm x 5.78mm from each eye, repeated 3 times on a low-cost OCT. 38 patients with retina pathology were enrolled in an IRB-approved study. The OCT macula thickness map was compared to one acquired using CIRRUS^{TM} 5000 HD-OCT (ZEISS, Dublin, CA). Thickness values were compared over an ETDRS grid.

Results: Figure 1 shows examples of thickness maps acquired using the low-cost OCT (before and after combining) and using CIRRUS 5000 HD-OCT. Bland-Altman analysis was performed to compare the results of single acquisition and triple acquisition of the low-cost system with a single acquisition of CIRRUS 5000 HD-OCT. The results are summarized in Table 1. The combined acquisition provides slightly higher mean difference while improving the correlation with the clinical system in the outer ring.

Conclusions: Our analysis suggests that combining macula thickness maps from multiple acquisitions provides an overall improved correlation between the low-cost system and clinical system, and thereby improves the diagnostic utility of the low-cost OCT instrument.

ABSTRACT BODY:

Purpose: Recent studies support the use of metformin to prevent the development of age-related macular degeneration (AMD). However, the mechanism by which metformin is protective is unclear. We performed a retrospective, cross-sectional clinical study to assess the association between metformin use and AMD when controlling for glycemic control in patients with diabetes mellitus type II.

Methods: We identified 461 unique patients over the age of 55 years with a diagnosis of diabetes mellitus type II seen in our academic retina clinic in Stony Brook, New York between 12/31/2019 and 12/31/2020. Manual chart review was performed to extract the most recent A1c within 3 months and the presence of an active metformin prescription. The population was split based on presence of AMD diagnosis. A series of multivariate regression analyses was then performed comparing metformin use between groups while controlling for A1c. Secondary endpoints included demographic differences, smoking status, and prevalence of diabetic retinopathy (DR) between groups.

Results: Among the 461 patients, 118 (25.6%) had a diagnosis of AMD. Compared to patients without AMD, patients with AMD were older (69 compared to 66; $p=0.005$) and less likely to have DR (37.3% compared to 59.2%; $p<0.001$). There was no difference in use of metformin and average A1c between groups. After multivariate regression, variables found to be associated with AMD include age (OR 1.05; $p=0.001$) and DR (OR 0.35; $p<0.001$). Metformin use was not found to be associated with AMD and controlling for A1c did not change the association. Stratifying glycemic control using various A1c cutoffs also showed no changes in the relationship between AMD and metformin use.

Conclusions: This is the first reported study assessing the relationship between AMD and metformin use while controlling for glycemic control using A1c. Given our results, the previously described relationship between metformin use and the development of AMD is not likely driven by the antihyperglycemic effects of metformin, but rather by other properties inherent to the drug. Lastly, the use of DR as a surrogate for poor diabetic control in the context of AMD is not ideal, as we found DR to be significantly associated with AMD even after holding A1c constant.

TITLE: Use of Mobile Apps for Vision Assistance - Handheld vs. Head-mounted Modes

SESSION TITLE: Assistive Devices, Visual Function Assessment, and Vision Restoration Therapies

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Luo, S. Pundlik, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Gang Luo: Commercial Relationship: Code N (No Commercial Relationship) | Shrinivas Pundlik: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Handheld video magnifiers, such as magnifier apps, are used by visually impaired to assist with daily visual tasks. The same magnification functionality can be implemented in head-mounted devices, to provide hands-free vision assistance. We compared the usage patterns of a handheld mobile app with the head-mounted version, to understand how the two modes may address different visual needs of visually impaired.

Methods: Handheld Supervision Magnifier and head-mounted Supervision Goggles are freely available vision assistance mobile apps intended for people with low vision. Aggregated app use data over 8 months, from Aug. 2020 to Mar. 2021, was collected from the active users, without individually identifiable data. Additionally, the targets in a scene image snapshot viewed during each app launch were tagged in 11 different common object categories via a cloud-based object recognition service. Average launches per user and the distributions of viewing targets over the object categories were compared between the two apps.

Results: There were 40,866(mean)±3372(SD) monthly users of the handheld app and 134±11 for the head-mounted app. The average monthly launches per user were significantly lower ($p<0.001$) for the head-mounted app (4.6±0.91) compared to the handheld app (6.9±0.38). The top 3 target categories with the handheld app were ‘text’ (41%), ‘indoor’ (30%) and ‘art’ (7%), whereas for the head-mounted app the top categories were ‘indoor’ (49%), ‘human’ (14%), and ‘text’ (11%). The chi-square test of independence between the histograms for handheld and head-mounted viewing targets failed to reject the hypothesis that the two distributions were independent ($df=10$, $\chi^2=0.99$, $p = 0.99$), which suggesting they were different.

Conclusions: The relatively low app launch frequency and different viewing targets with the Supervision Goggles app indicate that head-mounted visual aids are probably used for a set of niche visual tasks different for that with handheld visual aids. Head mounted vision assistance may need to be considered as one of options in low vision rehabilitation.

ABSTRACT BODY:

Purpose: Genetic variants located at the non-coding part of the genome, such as enhancers and promoters, can have a significant impact on the cellular state and phenotype of an individual. However, identifying and characterizing functional variants in gene regulatory elements remains challenging. We sought to overcome this challenge by integrating genomic sequencing with recent developed single-cell omics technologies.

Methods: To identify causal genetic variants that affect gene expression in the retina, multi-omics profiling, including whole genome sequencing (WGS), single nuclei RNA-sequencing (snRNA-seq), and single nuclei ATAC-seq (snATAC-seq), were performed on the donor retina. Open chromatin regions in each retinal cell type and potential regulatory elements were identified. Candidate genetic variants that affect gene expression and/or chromatin accessibility in each cell type were identified through integrative analysis of single-cell expression QTLs (sc-eQTLs), single-cell chromatin accessibility QTLs (sc-caQTLs), single-cell allelic specific expression (sc-ASE), and single-cell allelic specific chromatin accessibility (sc-ASCA).

Results: A total of 191,818 and 245,456 nuclei from 20 human donor retinae were profiled with snRNA-seq and snATAC-seq respectively. These data were organized into 11 major cell types in the retina with a total of about 500K open chromatin regions identified. Through co-accessibility and co-expression analysis, 75,477 open chromatin regions were linked to 14,053 genes as candidate regulatory elements. A significant proportion of these elements is cell type specific. Integrative analysis of WGS with the single nuclei multi-omics data leads to the identification of sc-eQTL, sc-caQTL, sc-ASE, sc-ASCA. Strikingly, the majority of these quantitative trait loci are cell type specific. Finally, integration of the single-cell genetic association analyses with GWAS studies leads to the identification of candidate causal variants and genes in cell type context.

Conclusions: Our results indicate that the impact of vast majority of genetic variants on gene regulation is cell context specific. Furthermore, we demonstrated that integrative analysis of genomics and single cell omics data is an effective strategy for genetic fine mapping and casual variant identification underlying human quantitative traits and complex diseases.

TITLE: Characterizing early residual fluid in neovascular age-related macular degeneration using a machine learning algorithm in routine clinical practice

SESSION TITLE: AMD: Clinical and translational research/AMD therapies (excluding anti-VEGF)

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.K. Wu, R.P. Singh, Center for Ophthalmic Bioinformatics, Cleveland Clinic Cole Eye Institute, Cleveland, Ohio, UNITED STATES|A.K. Wu, Case Western Reserve University School of Medicine, Cleveland, Ohio, UNITED STATES|S.W. Perkins, Cleveland Clinic Lerner College of Medicine of Case Western Reserve University, Cleveland, Ohio, UNITED STATES|

Commercial Relationships Disclosure: Anna Wu: Commercial Relationship: Code N (No Commercial Relationship) | Scott Perkins: Commercial Relationship: Code N (No Commercial Relationship) | Rishi Singh: Commercial Relationship(s);Code I (Personal Financial Interest):Novartis, Genentech, Regeneron, Alcon, Bausch and Lomb, 41 Gyroscope;Code F (Financial Support):Apellis, Aerie, Graybug

ABSTRACT BODY:

Purpose: Treating neovascular age-related macular degeneration (nAMD) often starts with intensive therapy with anti-vascular endothelial growth factor (VEGF) injections. In prior post-hoc studies, early residual fluid (ERF), defined as intraretinal fluid (IRF) and/ or subretinal fluid (SRF) after the loading dose, was associated with poorer long-term visual acuity. This retrospective study examined the impact of ERF on visual acuity using a machine learning (ML) algorithm to quantify fluid on optical coherence tomography (OCT) in routine clinical practice.

Methods: 286 treatment naïve patients with nAMD were identified from a retrospective analysis. Only one eye was included per patient. Best visual acuity (BVA) (ETDRS letters) and OCT data were collected every 3 months from baseline to 12 months. OCTs were analyzed by the Notal OCT analyzer ML algorithm, quantifying IRF, SRF, and total retinal fluid (TRF). The ERF group was defined as those with fluid at week (W) 12. Fluid type at W12 was stratified and volumes were divided into quartiles to see their predictive value for W52 BVA. Paired t-tests and ANOVA compared BVA and fluid changes within and between fluid subgroups.

Results: At W12, 58.4% of patients had ERF. The breakdown of subgroups at W12 were no fluid (41.6%), IRF-only (21.6%), SRF-only (45.5%), and IRF & SRF (32.9%). When comparing long term BVA outcomes according to W12 fluid status, ERF and ERF-free groups had similar mean BVA gains from baseline to W52 (+5.70±15.44 vs. +4.89±17.95; p= 0.69). There was also no significant difference in mean BVA gains from baseline to W52 when comparing the W12 fluid subgroups of no fluid (+4.89±17.95), IRF-only (+4.56±16.36), SRF-only (+5.55±12.49), and IRF & SRF (+6.61±18.45), p=0.93. Quartile analysis of W12 IRF, SRF, and TRF quantities revealed no predictive pattern for W52 BVA.

Conclusions: These results from routine clinical practice diverge from prior post-hoc studies, since there was no significant difference in long-term BVA gains between W12 ERF and ERF-free cohorts, as well as between the various fluid subgroups. In addition, fluid quantifications of ERF did not appear clinically relevant when predicting long term BVA. Thus, the clinical utility of a ML algorithm for predicting visual outcomes of ERF cohorts in nAMD warrants further exploration.

ABSTRACT BODY:

Purpose: It has been well-documented that lysosomal clearance in the retinal pigment epithelial (RPE) cells is tightly regulated by the circadian clock. However, the details of this regulation are still unclear. We hypothesize that βA3/A1-crystallin, a protein known to be important for maintaining lysosomal homeostasis in the RPE, may also provide an important link between lysosomal clearance and the circadian rhythm in the RPE.

Methods: Wild-type (C56Bl/6J) mice (6-8 weeks old) were maintained at LD (light-dark) 12:12 cycle and sacrificed at ZT0, ZT2, ZT8, ZT14, ZT20 (Zeitgeber time; hours after lights on). A second set of mice was kept in complete darkness for 3 days prior to euthanasia. Western blotting and qPCR were performed on WT RPE to detect oscillations in the expression of Cryba1 (gene encoding βA3/A1-crystallin) and known circadian genes. For the in vitro studies, human fetal RPE (fRPE) cells were cultured and entrained with serum shock. Samples were collected every 4 hours after entrainment. qPCR was performed to analyze the expression of Cryba1 and the known circadian genes. Bioinformatic analysis of the Cryba1 gene sequence was performed with MoLoTool and miRDB.

Results: Cryba1 expression oscillates at both mRNA and protein levels during the day in the RPE from WT mice, with the peak of protein expression coinciding with the peak of RPE lysosomal activity. Entrainment of fRPE cells with serum shock resulted in successful entrainment of Cryba1 expression, consistent with the circadian regulation of Cryba1 transcription in the RPE. Bioinformatic analysis revealed potential regulation of Cryba1expression by the circadian machinery (through NR1D1 transcription factor and miR-206).

Conclusions: We have shown that Cryba1 expression is regulated by circadian rhythm. This work contributes to a more complete understanding of the circadian rhythm entrainment in the RPE cells and introduces a novel, RPE-specific member into the circadian network.

TITLE: Effect of Supine Position on Episcleral Venous Pressure in Normal Human Eyes using a Portable Electronic Episcleral Venomanometer

SESSION TITLE: Aqueous humor dynamics and IOP

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: A. Kazemi, A.J. Sit, Ophthalmology, Mayo Clinic Minnesota, Rochester, Minnesota, UNITED STATES|

Commercial Relationships Disclosure: Arash Kazemi: Commercial Relationship: Code N (No Commercial Relationship) | Arthur Sit: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: It has been shown that intraocular pressure (IOP) changes with body position, but the mechanism is not well understood. In this study, we evaluated changes in episcleral venous pressure (EVP) between seated and supine positions and compared with changes in IOP and blood pressure in normal subjects.

Methods: Twenty eyes from 10 normal subjects (all females; 30 ± 7 years, mean ± SD) were included in the study. Blood pressure, pulse rate, IOP, and EVP of both eyes were first measured in the seated position. Thirty minutes later and after being in the supine position for 5 minutes, the same measurements were repeated. Systolic and diastolic blood pressures (SBP and DBP), and pulse rate (PR) were determined by a digital monitor. IOP was measured by pneumatonometry. EVP was assessed in a selected episcleral vein by using a computer-controlled portable electronic episcleral venomanometer with video recording and image processing to determine the pressure required to initiate collapse of the vein. Changes in IOP, EVP, systolic and diastolic blood pressures, and pulse rate between 2 body positions and correlations between changes in those variables were analyzed by using generalized estimating equation models and regression analysis, respectively.

Results: Mean IOP increased from 15.5 ± 2.0 mmHg in the seated position to 19.5 ± 2.2 mmHg in the supine position ($P < 0.001$, Table 1) but the change in EVP was smaller in magnitude (from 6.0 ± 1.0 mmHg to 6.9 ± 0.9 mmHg, $P < 0.001$, Table 1). DBP and PR but not SBP were lower in the supine position (Table 1). The change in EVP was not correlated with the change in IOP but showed moderate correlations with blood pressure changes (Table 2). Also, there were no significant correlations between IOP change and BP and PR changes (Table 2).

Conclusions: Both IOP and EVP are higher in the supine position compared to the seated position, but the magnitude of changes is not the same. EVP change is more strongly correlated with blood pressure change than IOP change. Future studies are required to identify the other contributing factors of postural IOP change.

TITLE: Machine learning prediction of limited early response to anti-VEGF therapy in neovascular age-related macular degeneration in routine clinical practice.

SESSION TITLE: AMD: Clinical and translational research/AMD therapies (excluding anti-VEGF)

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.W. Perkins, Cleveland Clinic Lerner College of Medicine of Case Western Reserve University, Cleveland, Ohio, UNITED STATES|A.K. Wu, R.P. Singh, Center for Ophthalmic Bioinformatics, Cleveland Clinic Cole Eye Institute, Cleveland, Ohio, UNITED STATES|A.K. Wu, Case Western Reserve University School of Medicine, Cleveland, Ohio, UNITED STATES|

Commercial Relationships Disclosure: Scott Perkins: Commercial Relationship: Code N (No Commercial Relationship) | Anna Wu: Commercial Relationship: Code N (No Commercial Relationship) | Rishi Singh: Commercial Relationship(s);Code F (Financial Support):Apellis, Aerie, Graybug;Code I (Personal Financial Interest):Novartis, Genentech, Regeneron, Alcon, Bausch and Lomb, 41 Gyroscope

ABSTRACT BODY:

Purpose: Patients with neovascular age-related macular degeneration (nAMD) have varying responses to anti-vascular endothelial growth factor (anti-VEGF) treatment. Those with residual intraretinal fluid (IRF) and/or subretinal fluid (SRF) after intensive anti-VEGF injections in the first 3 months of therapy have been defined as having limited early response (LER) to treatment. Prior post-hoc studies have associated LER status with reduced long-term visual acuity. Predicting LER from baseline data may be useful in identifying treatment-resistant patients who would benefit from more intensive treatment or targeted selection of anti-VEGF therapy.

Methods: Data was obtained from a retrospective chart review of 286 treatment naïve patients diagnosed with nAMD. Age, best visual acuity (BVA), central subfield thickness (CST), and optical coherence tomography (OCT) data were obtained at baseline, three, six, and twelve months. IRF and SRF were quantified from OCT data using the Notal OCT Analyzer machine learning algorithm (Tel Aviv, Israel). Data were pre-processed by one-hot encoding and min-max scaling. Predictive models were trained and evaluated using a 10-fold cross-validated approach.

Results: LER was predicted from baseline age, BVA, IRF, SRF, and CST by ridge logistic regression, k nearest neighbors classification, and radial basis function kernel support vector classification with 10-fold cross-validated accuracy of 0.66, 0.63, and 0.64, respectively. Area under the cross-validated receiver operating characteristic curve was 0.63, 0.59, and 0.62, respectively. T-distributed stochastic neighbor embedding did not show clusters separated by LER status.

Conclusions: These results demonstrate the potential of machine learning techniques for predicting nAMD outcomes in routine clinical practice. While age, BVA, IRF, SRF, and CST confer predictive accuracy, incorporation of additional variables may further improve predictive models. This would be beneficial for supporting physician decisions regarding anti-VEGF treatment in nAMD. Further studies could incorporate treatment data to determine which anti-VEGF therapies may be most suitable for patients at risk of LER.

ABSTRACT BODY:

Purpose: To report the anatomic and functional outcomes of retinectomy without lensectomy in eyes with rhegmatogenous retinal detachment (RRD) and proliferative vitreoretinopathy (PVR).

Methods: A retrospective review of patients treated with vitrectomy and retinectomy without lensectomy from January 1st 2015 to January 1st 2020 was performed. The primary outcome was the final attachment rate and single surgery anatomic success (SSAS) 3 months after retinectomy. Secondary outcomes included predictors of final visual acuity, the mean number of subsequent operations required for complete retinal reattachment, incidence of cataract surgery, and number of eyes that ultimately had successful silicone oil removal (SOR).

Results: Complete final retinal reattachment was achieved in 111/112 eyes (99.1%), with a mean (SD) follow-up of 29 (14) (range, 8-62) months after retinectomy. The 3-month SSAS was achieved in 84/112 eyes (75%). The final visual acuity improved or stabilized in 76/112 (67.9%) eyes. Silicone oil removal was performed in 72 of 112 patients (64.3%) during the study period, and cataract surgery was performed on 101 (90.2%) eyes before the last follow-up visit.

Conclusions: Retinectomy without lensectomy to repair RRDs complicated by PVR demonstrated anatomic and functional results that were comparable to historical reports of retinectomy with lensectomy. This study suggests that removing the lens when there is no significant cataract may not be necessary in these cases to obtain reasonable outcomes.

ABSTRACT BODY:

Purpose: To analyze the changes in self-reported QoL metrics in a 24-month interval in non-acute VKHD patients and to correlate these changes with visual function, inflammation and treatment

Methods: 22 patients, participants of a prospective ongoing study with a minimum 12-month follow-up since acute disease onset, were evaluated at two 24-month apart time points. They had systematic clinical, multimodal imaging and electroretinogram (ERG) exams with predefined treatment protocols. After acute phase, anterior uveitis and/or macular edema defined clinical inflammation; optic disc or perivascular leakage, dark dots and/or increase in subfoveal choroidal thickness were defined as subclinical inflammation. Visual function was measured by best corrected visual acuity, visual field, contrast sensitivity (CS) and ERG. Self-reported health-related and vision-related QoL were assessed by SF36 and VFQ25 questionnaires, respectively. Visual function and QoL data were collected at 2 moments 24mo apart: Jul-Dec 2017 (M1) and Jul-Dec 2019 (M2). Questionnaire scores were classified as an improvement, unchanged or worsening considering a difference >5 points between M1 and M2 results. Changes in visual function, inflammation and treatment data and significant changes between QoL scores at the 2 time points were compared with likelihood ratio test. This study was approved by Institutional Ethics Committee and followed the Helsinki declaration.

Results: Table represents QoL scores at M1 and M2. Figure shows clinical associations with change on QoL scores. In general health domain on SF-36 questionnaire, patients who remained without systemic treatment or absence of optic disk hyperfluorescence had unchanged or better score at M2. In VFQ25 questionnaire, improvement in binocular CS resulted in better ocular pain score at M2; absence of anterior uveitis relapse, stable fundus findings and absence of intravitreal injections resulted in unchanged or better dependency score, while use of cyclosporin resulted in worse results at M2; absence of intravitreal injection resulted in unchanged or better mental health score.

Conclusions: After 24mo, improvement in QoL scores was associated with less inflammation, better visual function and less need of treatment, reinforcing our previous results (2019, Ocular Immunol Inflamm).

ABSTRACT BODY:

Purpose: Optical coherence tomography angiography (OCTA) expands the ability to detect and monitor retinal vascular changes. Both vessel density (VD) and perfusion density (PD) are parameters that can be quantified from OCTA en face images. This study looks at these parameters and compares the results generated by both a spectral domain (SD) and a swept-source (SS) OCT system.

Methods: Subjects were scanned multiple times with the PLEX® Elite 9000 (ZEISS, Dublin, CA) SS-OCT and the CIRRUS™ HD-OCT 5000 (ZEISS, Dublin, CA). Three groups of eyes (41 total) were evaluated: 30 diseased eyes of 15 patients with varying diabetic retinopathy severity were imaged on PLEX Elite with the Angio 6x6 mm at 100 kHz scan and on CIRRUS using the 3x3 mm Angiography scan. One cohort of 6 healthy eyes and another cohort of 5 diseased eyes were imaged 3 times on both PLEX Elite and 3 times on CIRRUS. These results were pooled. VD is the total length of perfused vasculature per unit area in a region. PD is defined as the total area of perfused vasculature per unit area in a region. The inner ETDRS subfields (1-5) these scans have in common were used. The intra-instrument coefficient of variation (COV), defined as the ratio of the standard deviation to the mean, was calculated for each device. In addition, the relative mean difference in measurement between the 2 devices were determined.

Results: Data analysis of these repeated scans showed a similar intra-device coefficient of variation between PLEX Elite and CIRRUS. The COV for vessel density was 3.4% for Plex and 4.7% for CIRRUS. The COV for perfusion density was 3.8% for PLEX Elite and 5.4% for CIRRUS. The relative mean difference in vessel density between CIRRUS and PLEX Elite was 0.02%. The relative mean difference in perfusion density between CIRRUS and PLEX Elite was 1.3%. Both values are smaller than the combined intra-device COVs for the two quantities.

Conclusions: The relative differences in measurement between PLEX Elite and CIRRUS for vessel density and perfusion density are much smaller that the intra-device variability. This indicates the measurement between the two instruments can be considered substantially similar when considering these OCT vascular parameters.

ABSTRACT BODY:

Purpose: The human retina, as part of the central nerve system and the key light sensing tissue in the eye, has high cell heterogeneity, with an estimate of over 60 distinct cell types distinguished by morphology and physiology. To better understand the gene expression and regulation in each cell type, our study generates the multi-omics atlas at the single-cell level for adult human retina.

Methods: Single-nuclei RNA-seq and single-nuclei ATAC-seq were performed for retinae from human donors using the 10x Genomics technologies. For each donor retina, both the fovea and peripheral regions are profiled. Rare cell types, including the amacrine and retinal ganglion cell, are enriched based on the NeuN gradient. Integrative analysis of transcriptomic and epigenomic data is performed to identify gene regulator networks (GRNs), transcriptional factor binding motif enrichment, and putative gene cis-regulatory elements.

Results: A large single nuclei multi-omics dataset containing over 250K cells with single-nuclei RNA-seq and over 150K cells with single-nuclei ATAC-seq from human adult retina was generated. The atlas contains over 60 distinct cell types with an estimated sensitivity of 0.01%. Cross-species comparison among human, monkey, and mouse retina reveals that cell subtypes are overall conserved with RGCs are most divergent. In contrast, significant difference is observed at the transcriptomic level in corresponding cell types. With a large-scale single-nuclei ATAC-seq, we uncovered 10 times more open chromatin regions than the bulk study. Many of these regions are specific for rare cell types and were not observed in bulk ATAC-seq data. By combining snRNA/ATAC-seq data, 18% of these open chromatin regions (~47K) can be linked to their target genes as putative regulatory elements. Strikingly, a significant portion of these cis regulatory elements are novel and show cell-type-specific activity. Finally, the single nuclei multi-omics data allows fine mapping and functional annotation of genomic variants through integration of eQTL and GWAS results.

Conclusions: Our study represents the most comprehensive transcriptome and epigenome atlas of the human retina to date. This atlas enables in-depth integrative analysis at individual cell type resolution, making it a highly valuable resource for the research community.

ABSTRACT BODY:

Purpose: Quantify eye growth as a function of age, upon cessation of a dual-focus soft contact lens myopia control treatment. Are the accrued treatment effects retained independent of age?

Methods: Arumugam et al. (ARVO,2021) established models of estimated annualized axial length elongation for children fit with either MiSight 1 day (omafilcon A, dual focus, CooperVision, Inc.; M1d) or Proclear 1 day (omafilcon A, single vision, Coopervision, INC.; P1d) soft contact lenses. Following completion of a 6-year study to assess efficacy of M1d myopia control lenses, 83 subjects were refitted for one year with P1d. Axial elongation rates (mm/yr) observed after cessation of treatment were compared to previously defined age-matched model predictions for both treated and untreated myopic eyes. Annualized post-treatment measures of axial length (age range 14-18 years) were collected from children who were aged 8-12 at study inception.

Results: Average post-treatment growth for eyes following either 6 or 3 years of treatment were below the upper 95% confidence interval of the untreated average control model growth. Post-treatment annual average elongation rates ranged between 0.15 mm/yr, 95% CI [0.11, 0.19] and 0.05 mm/yr, 95% CI [0.03,0.07] for the ages 14 to 18 years. In general, a younger age at cessation of treatment was associated with greater axial elongation rate in the following year when wearing P1d, in concordance with the untreated eye growth model. There was no evidence of a rebound effect in the 14-18 year-old age range upon cessation of M1d wear.

Conclusions: Post treatment return of eye growth to age normal levels reveals that accrued reductions in eye growth from myopia control with M1d were retained following treatment cessation. Data and models reveal that starting myopia control treatment with MiSight 1 day at a younger age and continuing throughout the teenage years will reduce the number of years during which untreated eye growth will occur, maximizing myopia control benefit.

ABSTRACT BODY:

Purpose: Full thickness injuries, in particular full thickness lacerations, render the eye susceptible to infection and vision loss. They are particularly difficult to manage in low resource/emergency settings and repair typically requires extensive surgical skill with high frequency post-operative eyedrop regimens. To address these issues, we have developed a hydrogel sealant with the potential to be used as a rapid repair system to stabilize the globe for laceration type injuries while concurrently permitting sustained drug delivery of an antibiotic, Moxifloxacin (MFX), using a nanoparticle (NP) hydrogel system.

Methods: MXF NPs were synthesized and characterized using dynamic light scattering (DLS) to determine particle diameter (PD) and polydispersity index (PDI), and the encapsulation efficiency (EE) was determined. The sealant, composed of gelatin methacryloyl (GelMA) and glycidyl methacrylate-hyaluronic acid (HAGM), was characterized for degree of methacrylation (DM) and biocompatibility. Lastly, free MFX and MFX NPs were loaded into the hydrogel, and drug release profiles were determined via dialysis. Antimicrobial efficacy was assessed by zone of inhibition studies (ZOI) against a gram + (Staphylococcus Aureus; SA) and gram - (Pseudomonas Aeruginosa; PA) bacteria. The MFX NP hydrogel was further assessed in vitro for sealant capabilities via burst pressure testing.

Results: MFX NPs demonstrated a PD of 221 ± 11 nm, PDI of 0.21 ± 0.02, and EE of 93.8 ± 8.2%. Polymers exhibited a 61% and 11% DM for GelMA and HAGM, respectively, and no signs of cytotoxicity. The drug release profiles showed a 74.7 ± 2.38% and 29.65 ± 2.65% burst release within 2 h, with remaining MFX released within 24 h and 5 days respectively for hydrogels loaded with free MFX and MFX NPs. The MFX NP hydrogel demonstrated high antimicrobial efficacy with a ZOI > 30 mm against PA and > 28 mm for SA over 5 days. Lastly, the MFX NP hydrogel showed a high burst pressure of 40.8 ± 4.2 kPa.

Conclusions: The hydrogel sealant is capable of successfully loading NPs containing antibiotic which allows for efficacious levels of drug release for up to 5 days. Furthermore, it was highly adhesive and able to withstand high levels of pressure. Our drug eluting sealant has the potential to address critical factors in emergency ocular injury care by rapidly restoring the globe and concurrently allowing for efficacious levels of antibiotic to prevent infection.

TITLE: Utility of Fluorescein Angiogram to Identify Neovascularization in Sickle Cell Retinopathy
SESSION TITLE: Retinal vascular diseases
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: L. Young, A. Rai, U. Mian, Albert Einstein College of Medicine, Bronx, New York, UNITED STATES|A. Rai, T. Toribio, U. Mian, Montefiore Medical Center, Bronx, New York, UNITED STATES|
Commercial Relationships Disclosure: Lily Young: Commercial Relationship: Code N (No Commercial Relationship) | Anvit Rai: Commercial Relationship: Code N (No Commercial Relationship) | Tiana Toribio: Commercial Relationship: Code N (No Commercial Relationship) | Umar Mian: Commercial Relationship: Code N (No Commercial Relationship)
ABSTRACT BODY:
Purpose: Currently, screening guidelines for sickle cell retinopathy require a dilated fundus exam (DFE). As neovascularization (NVE) is found in the peripheral retina, it may be missed on DFE. Our study compares the identification of NVE by DFE and fluorescein angiogram (FA) in the same patient.
Methods: This is a retrospective chart review of sickle cell patients (N=146) at Montefiore Medical Center (Bronx, New York) between 2016 and 2021. Inclusion criteria: Adult sickle cell patients who have had at least one fluorescein angiogram (FA) and a DFE within six months. Electronic Medical Records were used to identify NVE on DFE and FA reports. Sensitivity and specificity of DFE were calculated to compare to FA. McNemar's test was applied to compare sensitivities of DFE and FA. A kappa coefficient was calculated to compare the agreement of the two tests. Fisher's exact test was used to compare the proportion of patients with NVE across genotypes.
Results: 146 patients met the inclusion criteria. The patient population was predominantly Non-Hispanic Black or African American (75.3%) and a majority female (64.4%). 52.1% of the population had the SS genotype, 37.0% had the SC genotype, and 10.9% were classified as Other (Sß+/Sß0). The average age was 43, with a range from 18 to 74.

Nearly half of the patients had NVE on FA, which was significantly higher than on DFE (49.3% vs.15.8% respectively, $p < .001$). This correlates to a sensitivity of 31.9% and a specificity of 96.0% for DFE. The p-value for McNemar's test was <0.001, indicating that FA is significantly more sensitive than DFE. The agreement between DFE and FA was poor, with a kappa coefficient (95% CI) of 0.2813 (0.1605,0.4622).

SC patients were found to have significantly more NVE on FA than SS patients (71.2% vs. 36%, $p < .001$). The detection rate of NVE on DFE was higher in SC patients than in SS patients (37.8% vs. 25.9%).
Conclusions: Our small, single-center study suggests that FA is a better approach to identifying NVE than DFE in sickle cell patients. This would be clinically important as subsequent treatment with laser therapy, anti-VEGF treatment, or observation with closer follow up typically depends on identification of NVE. Our findings highlight an important improvement in identifying NVE, but more research is required to establish routine FA as part of standard guidelines.

TITLE: Versican GAG-α domain deficiency causes rosette formation and detachment of the sensory retina in the mouse eye

SESSION TITLE: Modeling inherited retinal degeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.E. Dillinger, N. Bauer, M. Schneider, R. Seitz, R. Fuchshofer, E.R. Tamm, Institute of Human Anatomy und Embryology, Universitat Regensburg, Regensburg, Bayern, GERMANY|

Commercial Relationships Disclosure: Andrea Dillinger: Commercial Relationship(s);Code C (Consultant/Contractor):Boehringer Ingelheim | Nadine Bauer: Commercial Relationship: Code N (No Commercial Relationship) | Magdalena Schneider: Commercial Relationship: Code N (No Commercial Relationship) | Roswitha Seitz: Commercial Relationship: Code N (No Commercial Relationship) | Rudolf Fuchshofer: Commercial Relationship: Code N (No Commercial Relationship) | Ernst Tamm: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Versican is a large chrondroitin sulphate proteoglycan and major component of the extracellular matrix. It consists of four isoforms (V0, V1, V2, V3) that show molecular differences in their respective glycosaminoglycan (GAG) attachment domain. To learn more about the specific function of versican and its isoforms in the retina, we analyzed mutant mice with deficiency in V0 and V2.

Methods: $VCAN^{(tm1Zim)}$ mice were investigated with a splice-variant specific gene inactivation of V0 and V2 resulting in GAG-α domain deficiency. Four- and eight-week-old versican$V0/V2^{-/-}$ and versican$V0/V2^{+/-}$ mice were analyzed and compared with wildtype littermates. Semithin sections were investigated by light microscopy. Retinal thickness and the number of optic nerve (ON) axons was quantified. The distribution and expression of GFAP and of the major versican binding partners fibronectin and hyaluronan was investigated by immunohistochemistry.

Results: The loss of V0 and V2 isoforms resulted in the formation of retinal rosettes, affecting the outer nuclear layer, and photoreceptor inner and outer segments. The defects were first seen in 4-week-old homozygous mice. Essentially similar defects were seen in heterozygous mice, though with later onset (8 wks of age). Rosette formation was frequently associated with detachment of the sensory retina. Analysis of the anterior chamber showed a wide-open angle with no obvious structural changes in the trabecular meshwork outflow pathways. GFAP immunoreactivity in Müller cells of mutant mice was identical to that seen in wildtype littermates, even in mutant eyes with rosette formation and retinal detachment. Immunoreactivity for fibronectin was dramatically reduced in the retina of mutant mice but unchanged in the chamber angle. Reactivity for hyaluronan was markedly decreased in the inner plexiform layer but increased in the ganglion cell layer and the vitreous of versican $V0/V2^{-/-}$ mice. Retinal thickness and number of ON axons showed no difference in versican $V0/V2^{-/-}$ mice compared to wildtype littermates.

Conclusions: Deficiency of the versican isoforms V0 and V2 causes retinal changes that indicate its critical role for attachment of the sensory retina to the retinal pigment epithelium.

ABSTRACT BODY:

Purpose: CFAP418 is a causative gene for several inherited retinal degenerative diseases. Cfap418 knockout in mice leads to photoreceptor cell death by disrupting the membrane disk alignment and reducing the membrane proteins in the outer segment (OS). In this report, we investigated the moculuar mechanism that underlies the retinal phenotypes in Cfap418 knockout mice.

Methods: We systematically examined the protein expression and phosphorylation profiles as well as membrane lipid composition in Cfap418$^{-/-}$ retinas using various quantitative mass spectrometry at the onset and during the robust progress of the phenotypes. Semi-quantitative immunoblotting analysis and standard immunofluorescence were conducted to verify the omics findings. Affinity purifications coupled with mass spectrometry and proten lipid overlay assays were performed to identify CFAP418-binding partners.

Results: We observed differentially expressed proteins that are involved in membrane remodeling and mitochondrial function. In Cfap418$^{-/-}$ photoreceptors, the expression and localization of endosomal sorting complex proteins, mitochondrial morphology, and OS targeting were affected. The phosphorylation of lipid-binding and -activated protein kinase Ca was significantly increased. In addition, a broad range of membrane lipids were altered in abundance. Affinity purifications failed to identify stable CFAP418-interacting proteins, but revealed an indirect associated protein RAB28, which is encoded by another retinal degeneration gene. However, CFAP418 protein binds to lipid metabolism precursor phosphatidic acid and mitochondrial-specific cardiolipin.

Conclusions: Our findings indicate that CFAP418 is a lipid-binding protein and functions in membrane lipid homeostasis, membrane remodeling, and mitochondrial function during photoreceptor OS development.

ABSTRACT BODY:

Purpose: The purpose of this retrospective study was to characterize dry eye disease (DED) in patients taking finasteride, a potent targeted anti-androgenic medication.

Methods: An extended case series with retrospective chart review of all cases of patients on finasteride seen in the Scheie Eye Institute Dry Eye Clinic at the University of Pennsylvania from January 1, 2005 to the December 1, 2021. Patient demographics, diagnosis, prior treatment, questionnaire data, and DED clinical exam outcomes were extracted. Statistical analysis was performed to assess clinical characteristics and Ocular Surface Disease Index (OSDI) quality of life measures among patients on varying doses of finasteride.

Results: 116 patients with a history of DED on finasteride were included with an average age of 67.9 years (SD 13.9). The population was predominantly male (95%), and Caucasian (86%). 23 patients were on a finasteride dosage of 1 mg or 2.5 mg, and 93 patients were on a finasteride dosage of 5 mg. Mean follow up was 55.3 months (SD 35.1, range 2.5 to 119.2). When comparing exam findings during initial and followup visit, a significantly greater percent of patients was noted to have meibomian gland disease (MGD) (62.9% [initial] vs 85.3% [followup], $p = 0.0001$), conjunctival abnormalities (21.1% [initial] vs 41.9% [followup], $p = 0.0002$), and corneal abnormalities (26.3% [initial] vs 40.5% [followup], $p = 0.0047$) at final exam. Mean OSDI score was 24.4 (SD 19.6) and was slightly higher in patients taking 5mg, though this was not statistically significant. Lower dose finasteride use was significantly associated with a greater frequency of cyclosporine use at first exam (26.1% vs 6.5%, $p = 0.01$) and last exam (25.0% vs. 3.4%, $p = 0.0168$). Otherwise, treatment modalities were no different between the lower and high dose groups.

Conclusions: To our knowledge, this represents the largest demographic study over 15 years of DED patients on finasteride, demonstrating an association with finasteride usage and MGD, conjunctival, and corneal abnormalities. The androgen sensitive meibomian glands may be altered in those taking anti-androgen medications, and especially finasteride given its unique potency and targeted effects compared to other anti-androgenics. This study reinforces the importance of considering the long-term effects of finasteride use on DED as part of the systemic sequelae of androgen depletion and provides anticipatory guidance for patients and ophthalmologists.

ABSTRACT BODY:

Purpose: Posterior pole asymmetry analysis (PPAA) is a spectral domain optical coherence tomography (SD-OCT) software that compares posterior pole retinal thickness measurements between the superior and inferior hemispheres of each eye. We sought to determine whether these structural abnormalities were correlated with functional retinal ganglion cell (RGC) loss, as quantified by steady state pattern electroretinogram (ssPERG) parameters, in glaucoma suspects (GS).

Methods: Twenty GS (34 eyes) were enrolled in a prospective single-center study at the Manhattan Eye, Ear, and Throat Hospital in New York City. All subjects underwent comprehensive ophthalmological examination, including Humphrey visual field, Spectralis (Glaucoma Module Premium Edition) SD-OCT PPAA, and ssPERG testing. The ability of ssPERG parameters (Magnitude [Mag, μv], MagnitudeD [MagD, μv], and MagD/Mag ratio) to predict PPAA thickness measurements (total, superior, and inferior thickness, in μm) was tested via multivariate linear regression analysis.

Results: When total, superior, and inferior PPAA parameters were independently entered as dependent variables, and after controlling for age, spherical equivalent (SE), and central corneal thickness (CCT), Mag explained 8% of variance in total PPAA change ($F(1,29)=6.33$, $B=6.86$, 95% CI: 1.29-12.44, $p=0.018$), 8% in superior PPAA change ($F(1,29)=5.57$, $B=6.92$, 95% CI: 0.92-12.92, $p=0.025$), and 7.1% in inferior PPAA change ($F(1,29)=5.83$, $B=6.80$, 95% CI: 1.04-12.56, $p=0.022$). In the same analysis, MagD explained 9.7% of variance in total PPAA change ($F(1,29)=8.09$, $B=6.47$, 95% CI: 1.82-11.13, $p=0.008$), 10% in superior PPAA change ($F(1,29)=7.33$, $B=6.63$, 95% CI: 1.62-11.63, $p=0.011$), and 8.5% in inferior PPAA change ($F(1,29)=7.25$, $B=6.36$, 95% CI: 1.53-11.18, $p=0.012$). No significant associations between MagD/Mag ratio and PPAA measures were found.

Conclusions: To the best of our knowledge, this is the first report describing the positive relationship between RGC dysfunction and structural retinal changes in the posterior pole. These findings demonstrate possible morphological changes in RGCs prior to cell death, including shrinkage, reductions in the dendritic tree, and thinning of the retinal nerve fiber layer. The detection of asymmetrical structural RGC loss, combined with RGC function assessment using PERG, may be a more informative tool for glaucoma diagnosis in GS.

TITLE: Certainty of evidence in Cochrane Eyes and Vision systematic reviews
SESSION TITLE: Public Health I
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: R. Qureshi, T. Rittiphairoj, S. Ng, T. Li, Ophthalmology, University of Colorado Denver School of Medicine, Aurora, Colorado, UNITED STATES|G. Han, Health, Behavior, and Society, Johns Hopkins University Bloomberg School of Public Health, Baltimore, Maryland, UNITED STATES|J. E, R. Wilson, Epidemiology, Johns Hopkins University Bloomberg School of Public Health, Baltimore, Maryland, UNITED STATES|
Commercial Relationships Disclosure: Riaz Qureshi: Commercial Relationship: Code N (No Commercial Relationship) | Jianyu E: Commercial Relationship: Code N (No Commercial Relationship) | Genie Han: Commercial Relationship: Code N (No Commercial Relationship) | Renee Wilson: Commercial Relationship: Code N (No Commercial Relationship) | Thanitsara Rittiphairoj: Commercial Relationship: Code N (No Commercial Relationship) | Sueko Ng: Commercial Relationship: Code N (No Commercial Relationship) | Tianjing Li: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Systematic reviews (SRs) are often considered the highest level of evidence, yet the certainty of the evidence which they present can be low and unusable in practice because the estimates are not precise, the primary study populations are not directly relevant to the target population, the risk of bias of primary studies is high, there may be too much heterogeneity in the estimates, or there may be a potential for publication bias. Grading of Recommendations, Assessment, Development and Evaluation (GRADE), is one approach to assessing the certainty of evidence collected in systematic reviews. Our objective is to assess the distribution of certainty of evidence from SRs published by Cochrane Eyes and Vision (CEV) and to identify reasons for which evidence is commonly downgraded or upgraded.

Methods: So far, we have assessed all CEV systematic reviews that included at least one GRADE Summary of Findings (SoF) table published between January 1, 2008 and February 25, 2020 (N = 275). GRADE was developed, published, and adopted by Cochrane in 2008. We abstracted data from all SRs into a Qualtrics form (single abstraction) and conducted all analyses using Stata 15.

Results: Of the 275 reviews assessed thus far, 149 (54%) presented GRADE SoF tables, which together included 1854 outcomes. Most outcomes were assessed with a median [IQR] of 190 [66 – 551] participants and 2 [1 – 4] studies (Table). Randomized controlled trials were the most common study type used as evidence for outcomes, but 27% (507) of outcomes did not specify the study type (Table). Only 6% (116) of outcomes were judged at a “high” certainty of evidence whereas 47% (869) were either “low” or “very low” certainty, with “risk of bias” and “imprecision” being the most common reasons for downgrading the evidence (Table). Five hundred and fifty-nine (30%) of the outcomes in SoF tables did not have a GRADE rating due to a lack of studies with evidence.

Conclusions: Overall, the certainty of evidence within CEV reviews, according to GRADE, is generally low and SoF tables often failed to report the specific study types contributing to the outcome. Our findings highlight the necessity to improve the quality of primary research: specifically, studies should be properly powered and focus on minimizing their risk of bias. Additionally, future reviewers should ensure their SoF tables are informative and consistent in all aspects to support transparent decisions.

TITLE: Quantitative optical coherence tomography for longitudinal monitoring of postnatal retinal development

SESSION TITLE: Retina Development and Regeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Ma, J. Ding, X. Yao, Biomedical engineering, University of Illinois at Chicago, Chicago, Illinois, UNITED STATES|X. Yao, Department of Ophthalmology and Visual Sciences, University of Illinois at Chicago, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Guangying Ma: Commercial Relationship: Code N (No Commercial Relationship) | Jie Ding: Commercial Relationship: Code N (No Commercial Relationship) | Xincheng Yao: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: This study is to validate in vivo optical coherence tomography (OCT) for longitudinal monitoring of postnatal retinal development in developing mouse eyes.

Methods: A custom-designed optical OCT was employed for in vivo retinal imaging of C57BL/6J mice. Three-dimensional (3D) retinal OCT volumetric images were recorded at postnatal 14, 17, 21, 28, and 56 days. The retinal images were manually segmented, and the layer thickness was measured by MATLAB.

Results: Figure 1 and Table 1 shows the longitudinal OCT monitoring of developing retina. After eye-opening, the retinal layer thickness kept changing until 28 days. Figure 1A shows the enface image of the superior quadrant, which indicates the location of the B-scans in Figure 1B. Figure 1B shows the representative B-scans used for layer thickness measurement. The red arrows indicate an hyporeflective layer (HRL) which was unambiguously observed between postnatal day 14 (p14) to p17, and gradually disappeared after p28. Figure 1C shows the reflectance profiles of the B-scans in Figure 1B. Figure 1D1 shows a comparative analysis of inner retinal layer thicknesses with ages from p14 to p56. The nerve fiber (NFL) thickness decreased from p14 to p21 and then remain the same. The HRL thickness kept decreasing after eye-opening and disappeared at about p28. The inner plexiform layer (IPL) thickness did not change significantly between p14 to p56. The INL thickness kept decreasing after eye-opening until p28. Figure 1D2 shows layer thickness change in the outer retina. The outer nuclear layer (ONL) thickness kept decreasing until p28. On the contrary, the external limiting membrane to retinal pigment epithelium (ELM-RPE) thickness kept increasing until p28. Figure 1D3 shows the thickness change of the inner retina, outer retina, and the whole retina. The thickness of the inner retina and the whole retina kept decreasing until p28. On the contrary, the thickness of the outer retina slightly increased after the eye-opening.

Conclusions: In vivo OCT provides a feasible solution for longitudinal monitoring of postnatal retinal development. Quantitative OCT analysis revealed distinct outer and inner retinal layer changes, corresponding to eye development. An HRL between the NFL and IPL was observed in developing eyes and gradually disappeared with aging.

TITLE: Automated scan quality assessment in low-cost OCT
SESSION TITLE: OCT Clinical Applications
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: A. Kho, H. Bagherinia, C. Leahy, S.A. Bello, Carl Zeiss Meditec, Inc., Dublin, California, UNITED STATES|
Commercial Relationships Disclosure: Aaron Kho: Commercial Relationship(s);Code E (Employment):Carl Zeiss Meditec, Inc. | Homayoun Bagherinia: Commercial Relationship(s);Code E (Employment):Carl Zeiss Meditec, Inc. | Conor Leahy: Commercial Relationship(s);Code E (Employment):Carl Zeiss Meditec, Inc. | Simon Bello: Commercial Relationship(s);Code E (Employment):Carl Zeiss Meditec, Inc.

ABSTRACT BODY:

Purpose: Optical coherence tomography (OCT) in the remote care setting can be challenging due to self-scanning limitations. Patient-operated OCT systems need to detect the state of patient alignment and determine the OCT image quality for fully automated imaging. Here, we demonstrate an algorithm that automatically assesses the OCT image quality using machine learning.

Methods: A total of 141 volumes were acquired with a prototype low-cost OCT system from 18 subjects using either one or both eyes. The size of each volume was 7.00 mm x 5.78 mm x 2.77 mm and all volumes were centered on the fovea. For each volume, multiple feature maps were created based on signal strength, signal to background ratio, and individual A-scan contrast. These feature maps were then combined into a joint probability map previously presented (Elezaby et al., IOVS, 2020). By placing a threshold on the joint probability map, we generated groups of likelihood functions as inference models for each of the feature maps. The OCT quality map was formed using the likelihood functions and a posterior probability from the inference model. The OCT scan quality was assessed using the ETDRS grid consisting of three concentric circles (radii of 0.5 mm, 1.5 mm, and 2.9 mm) divided into nine subfields. An OCT volume was considered poor quality based on two criteria. The first involved three or more central and inner ETDRS subfields having low confidence. The second involved two or more ETDRS subfields that include at least one outer subfield having low confidence. OCT volumes were assessed manually by an experienced grader to obtain the ground truth.

Results: Out of the 141 volumes, there were 90 true positives (good quality), 44 true negatives (poor quality), 4 false positives, and 3 false negatives. Fig. 1 shows an example for each scenario. The algorithm yielded a sensitivity of 0.97 with 95% confidence interval (CI) [0.91, 0.99], specificity of 0.92 with 95% CI [0.80, 0.98], and success rate of 0.95 with 95% CI [0.90, 0.97].

Conclusions: We demonstrated a new machine learning method that automatically grades OCT volumes with high sensitivity and specificity using the ETDRS grid. This algorithm could help acquire good quality data in the remote care setting.

TITLE: Optimizing Photorefractive Keratectomy Oucomes in Myopia with Topical Mitomycin C

SESSION TITLE: Refractive and non-refractive corneal surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E.M. Bolton, N. Zhang, P. Bryar, R. Feder, Ophthalmology, Northwestern University Feinberg School of Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Elizabeth Bolton: Commercial Relationship: Code N (No Commercial Relationship) | Nigel Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Paul Bryar: Commercial Relationship: Code N (No Commercial Relationship) | Robert Feder: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To examine the impact of various preoperative characteristics, mitomycin C 0.2 mg/ml (MMC) exposure time, and reduction in refractive correction (backoff) when using topical MMC on the outcome of photorefractive keratectomy (PRK) for myopia.

Methods: In this retrospective analysis, data collected included demographics, pre and postop manifest refraction (MR), preop pachymetry, percent reduction in treatment (sphere reduced by 0 to >10% of SE), MMC exposure time, presence of post PRK haze, and postop uncorrected visual acuities. Outcome measures included uncorrected postop acuity, residual refractive error, and incidence of haze. Inclusion criteria were preoperative myopia defined as > -4.00 D with regular preoperative astigmatism < 5.00 D, with mean of -6.75, [-12.75, -0.50] in patients who underwent PRK with MMC. Patients presenting for enhancement surgery, patients with preexisting corneal disease or tear deficiency were excluded. Linear mixed model and generalized linear mixed model were used to assess the associations between MMC exposure time with 3-month log mar visual acuity and incidence of haze respectively.

Results: A total of 91 eyes from 57 patients were included. The mean (standard deviation, SD) of 3-month log mar visual acuity was 0.06 (0.16). The incidence of haze was 28.6% (30). There was no significant difference in the development of corneal haze with increased MMC exposure time (odds ratio 1.22). There were 71 eyes with 20/25 vision or better defined as group 1, and 20 eyes with 20/30 or worse acuity (up to 20/70) in group 2.The mean (SD) back off in group 1 was 6.6% (4.5) of SE, mean preoperative MR -6.9 (2.3 [-11.75, -1], and mean postop MR -0.4 D (0.67 [-2.25,-0.25]). In group 2, the mean backoff was 9.7% (4.5), the mean preoperative MR -8.9 (2.4 [-12.75, -3.75]), and mean postoperative MR 1.2 D (0.69 [-3.25, 1.75]).

Conclusions: Incidence of haze was higher than expected, but not visually significant. There was no significant difference in refractive outcome even when MMC exposure time was <20 seconds. Extending exposure time beyond 20 seconds was not necessary to prevent visually significant haze. A larger percent backoff of 10% or greater may contribute to undercorrection after PRK.

ABSTRACT BODY:

Purpose: To investigate utilization and payment of Laser Trabeculoplasty (LTP) performed by ophthalmologists and optometrists in three key US states based on CMS Public Use File.

Methods: We analyzed the Medicare Provider Utilization and Payment Data furnished by the CMS to identify LTP (CPT code 65855) claims in three key US states with optometric-expanded surgical authority in 2015 and 2018. We utilized regression, chi-square, and two-way t-tests to compare PUF metrics.

Results: The total sum of Medicare allowed payments to ophthalmologists and optometrists performing LTP amongst Fee-for-Service (FFS) Medicare beneficiaries in the US in 2018 was about 33% lower compared to 2015 while the total sum of Medicare Allowed payments in Kentucky (KY), Louisiana (LA), and Oklahoma (OK) in 2018 was about 26% lower compared to 2015. However, the optometric proportion of total Medicare allowed payments furnished by optometrists in three states increased from 11.3% to 17.9% between 2015 and 2018 (Fig. 1). Additionally, we observed significant increases in optometric-to-ophthalmologic average Medicare allowed payments between 2015 and 2018 in KY, LA, OK, and the tri-state cohort (all $p<0.001$) (Table 1). Significant optometric-to-ophthalmologic ratio increases in summed provider counts ($p=0.007$), summed unique Medicare beneficiary counts ($p<0.001$), and ultimately, summed service counts ($p<0.001$) were observed. Uniquely, we noticed that only one state amongst our tri-state cohort, LA, displayed non-significant differences in all three categories ($p=0.91$, $p=0.35$, $p=0.29$, respectively), despite significantly disproportionate changes in summed Medicare allowed LTP payments ($p<0.001$). Within the ophthalmologic cohort, female-to-male provider ratio significantly increased ($p=0.008$); however, the optometric cohort demonstrated no significant increases ($p=0.99$).

Conclusions: Optometric surgical authority is a continually expanding landscape throughout the United States. We investigated the latest edition of the CMS Medicare database to characterize LTP-associated metrics between ophthalmologists and optometrists in KY, LA, and OK states. Between 2015 and 2018, optometrists significantly increased their share of LTP-associated Medicare-allowed payments, unique beneficiary counts, service provider counts, and provider service counts.

ABSTRACT BODY:

Purpose: The purpose of this study was to evaluate the functional and anatomical effects of switching to brolucizumab in exudative age-related macular degeneration.

Methods: This retrospective study assessed 41 eyes of 41 patients of exudative age-related macular degeneration cases treated with aflibercept and switched to brolucizumab for one year. We evaluated functional and anatomical parameters including best-corrected visual acuity (BCVA), central retinal thickness(CRT), central choroidal thickness(CCT) and pigment epithelial detachment (PED) height at 1,3,6 and 12 months after the first brolucizumab injection. Change in the interval of anti-VEGF injections between before and after switching to brolucizumab was also evaluated.

Results: The patients did not show a significant change in BCVA at all time points from baseline.CRT was significantly decreased at all time points ($p<0.05$). CCT and PED height decreased significantly at 6 months after the first brolucizumab injection (each $p<0.05$), but not at 12 months. The injection interval was significantly extended from 6.3±3.2 weeks to 13.7±9.2 weeks ($p<0.01$). The mean change of the injection interval was 7.4±8.1. The mean number of brolucizumab injections during the observation period was 5.4±1.9.

Conclusions: Switching from aflibercept to brolucizumab was effective for anatomical improvement and extending injection intervals. Switching to brolucizumab is expected to reduce the burden of frequent injections in patients with exudative age-related macular degeneration.

ABSTRACT BODY:

Purpose: The most common cause of blurry vision in the United States is refractive error. Despite being a correctable condition, over 8.2 million people are estimated to have their refractive error go undiagnosed or untreated. Minorities and low-income groups in particular have significantly increased odds of inadequate correction and double the rates of near-vision impairment. We aimed to address this gap in care through the provision of refractive glasses during community-based tele-ophthalmology screenings.

Methods: Eight free eye screening events were held in Newark and West New York, NJ. Demographic information, intraocular pressure, visual acuity, auto-refraction, retinal imaging, and optical coherence tomography were obtained from each subject as part of a comprehensive tele-ophthalmology protocol. Reading glasses were provided as needed based on the recommendation of a certified telemedicine reader. Eligible recipients completed surveys on site regarding access to eye care. They were surveyed again by phone after one month to assess degree of satisfaction and vision improvement.

Results: 38 subjects (mean age 53, 47% male) qualified for presbyopia correction and received reading glasses. 97% were Hispanic and 3% were African American. Of the 33 that returned surveys, 88% reported not seeing an eye doctor annually. The most common reason was lack of insurance or inability to pay (71%). Others included having no need to see an eye doctor (10%), disliking eye doctors (7%), not knowing the importance of regular eye exams (3%), and COVID-19 (3%). Of the 25 subjects that were reached for follow-up, 92% reported using the glasses daily. Those that did not reported the power was too strong or they did not feel they needed them. Subjects noted an average improvement in vision of 4.4 out of 5 and an average satisfaction of 4.7 out of 5 (Figure 1).

Conclusions: Glasses distribution is an effective way to address refractive error in underserved communities. Given the gaps in knowledge and utilization of eye care identified in our study, there is an obvious need for continued outreach to these areas. Further studies will include larger populations and evaluate mobile refraction devices to increase ease and reach of glasses provision.

TITLE: Work-related Musculoskeletal Problems among Eyecare Professionals
SESSION TITLE: Eyecare delivery and economics
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: L.S. Azeez, E. Sherry, D. Mojica, A. Kheirkhah, Ophthalmology, The University of Texas Health Science Center at San Antonio, San Antonio, Texas, UNITED STATES|
Commercial Relationships Disclosure: Leen Azeez: Commercial Relationship: Code N (No Commercial Relationship) | Emily Sherry: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Mojica: Commercial Relationship: Code N (No Commercial Relationship) | Ahmad Kheirkhah: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:
Purpose: Ergonomics are an integral component of eyecare professionals' health. This study reports on the work-related musculoskeletal problems among eyecare professionals.
Methods: In this cross-sectional study, an anonymous questionnaire survey was distributed among eyecare professionals including ophthalmologists, optometrists, ophthalmology residents, ophthalmic technicians, and ophthalmology clinic administrative staff. The following parameters were evaluated in the survey: demographics, musculoskeletal symptoms due to their occupation, and the effects of these symptoms on their work.
Results: 98 eyecare professionals responded which included 50 ophthalmic technicians, 27 ophthalmologists, 7 ophthalmology residents, 6 optometrists, and 8 ophthalmology administrative clinic staff. These included 36 men and 59 women; 3 preferred not to disclose their sex. The mean age was 41.9 ± 12.2 years (range, 21-75 years). Overall, 63 (65.3%) participants had musculoskeletal problems within the past month. These involved the lower back in 38 (38.8%), neck in 36 (36.7%), hand/wrist in 29 (30.0%), shoulder in 24 (24.5%), upper back in 20 (20.4%), and elbow in 8 (8.2%). To manage musculoskeletal problems, the participants had used the following: exercise in 30 (30.6%), analgesics in 21 (21.4%), change of equipment/tools in 12 (12.2%), physical therapy in 10 (10.2%), additional breaks during workdays in 8 (8.2%), taking time off from work in 6 (6.1%), injection of medications in 4 (4.1%), reducing work hours in 2 (2.0%), and 2 (2.0%) with reducing the scheduled cases.
Conclusions: Eyecare professionals have a high prevalence of occupation-related musculoskeletal symptoms, which significantly affect their work. Considering the long-term effects of such musculoskeletal problems on these individuals' health, proper education and work adjustment are necessary to minimize morbidity associated with such problems.

TITLE: The Impact of Open Angle Glaucoma on ON-OFF Perimetry
SESSION TITLE: Visual Fields and Psychophysics
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: J. Tan, M.W. Dul, V. Moore-Stoll, S. Dellostritto, H.R. Nasrabadi, J.Z. Jin, J. Alonso, SUNY College of Optometry, New York, New York, UNITED STATES|
Commercial Relationships Disclosure: Jia Tan: Commercial Relationship: Code N (No Commercial Relationship) | Mitchell Dul: Commercial Relationship: Code N (No Commercial Relationship) | Veronica Moore-Stoll: Commercial Relationship: Code N (No Commercial Relationship) | Stephen Dellostritto: Commercial Relationship: Code N (No Commercial Relationship) | Hamed Nasrabadi: Commercial Relationship: Code N (No Commercial Relationship) | Jian Jin: Commercial Relationship: Code N (No Commercial Relationship) | Jose-Manuel Alonso: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Traditional white-on-white perimetry is limited to the functional assessment of the ON pathway. We investigated visual deficits in both ON and OFF pathways in patients with glaucoma and similarly-aged controls and compared these findings with standard automated perimetry (SAP).

Methods: Fourteen eyes from 14 subjects, 7 with glaucoma (48-76 years old; mean, 64 ± 10.28; severity from MD -0.48 to -18.25) and 7 controls (48-78 years; mean 65.14 ± 9.63) were tested at 8 Michelson contrast levels (5-20%) within the central 30 degrees of the visual field.

A single test included 579 trials (27 catch trials), at 92 locations, repeated 3 times for both light and dark stimuli. Each participant completed 8 tests (4,632 trials) using a head mounted display with eye tracker (HTC Vive Pro Eye, 90 Hz, maximum luminance: 110 cd/m^2). Stimuli were light or dark squares generated with Unity software, presented on a spherical binary noise background, and with their size increasing with eccentricity.

Eye movements were measured at 120 Hz and restricted within 2.5 degrees for controls and 3.5 for glaucoma patients. Correct responses were measured across the entire visual field and within each quadrant. Differences between control and glaucoma subjects were plotted as a function of glaucoma severity.

Results: There was a positive correlation between the control - glaucoma subject difference in percent correct responses measured with ON-OFF perimetry and the visual sensitivity of glaucoma subjects measured with SAP for both the full visual field (r=0.74, p=0.0027) and the quadrant most affected by glaucoma (r=0.58, p=0.0297). Between each pair of subjects, the error rate was greater for glaucoma than control subjects for the full visual field and nasal quadrants, even if the quadrants were not flagged as significantly deviating from the SAP reference data base (see representative example in figure 1).

Conclusions: Glaucoma increases error responses within the central 30 degrees when compared to similarly-aged controls in ON-OFF perimetry, across the entire visual field and within field quadrants most associated with glaucomatous visual loss. Ongoing work is aimed toward the utility of this technology in a clinical setting.

ABSTRACT BODY:

Purpose: Closed globe ocular trauma may result in potentially serious injury to vital eye structures. We sought to identify baseline clinical factors associated with ophthalmic complications, including a need for future surgery.

Methods: We analyzed longitudinal data from the American Academy of Ophthalmology IRIS® Registry. We identified patients with a trauma between 2014 and 2019 and performed time-split Cox regression. Demographic factors and the following baseline features were entered as predictors: corneal edema or opacity, traumatic hyphema (TH), iris/angle injury, lens injury (LI), lens displacement, vitreous hemorrhage (VH), retinal break, retinal detachment (RD), commotio retinae, macular scar, macular hole, choroidal injury, and optic nerve injury. Our outcomes of interest included: RD, glaucoma surgery (GS), and cataract surgery (CS). We performed a univariate regression for each feature and selected features with $p <= 0.1$ to be included in the multivariate regressions. For anterior segment complications, we used splits at 60 and 180 days following the date of trauma. For RD, we used a split at 60 days.

Results: A total of 214,163 patients had a trauma diagnosis. The strongest risk factors for CS during the first 60 days were LI (hazard ratio 12.2 95%CI 10.1-14.6), and TH (2.64, 2.32-2.99) (Fig. 1A). The strongest risk factor for GS was TH (8.00, 5.00-12.8), during the first 60 days (Fig. 1B). Baseline TH (4.18, 3.42-5.12), and VH (12.7, 10.3-15.6) were significant risk factors for a subsequent RD and remained significant even after the first 60 days (Fig. 2).

Conclusions: Baseline characteristics at the time of trauma diagnosis are strongly associated with both anterior and posterior segment complications. Regular, long-term follow up is warranted following ocular trauma.

ABSTRACT BODY:

Purpose: Voretigene neparvovec (VN) is the first approved ocular gene therapy for patients with RPE65-mediated inherited retinal dystrophy and sufficient viable retinal cells. PERCEIVE is a post-authorization safety study assessing long-term safety and effectiveness of VN in a real-world setting.

Methods: PERCEIVE is an ongoing (2019–2029), prospective, longitudinal, multicenter (ex-US), registry-based observational study. All VN-treated patients, including those treated prior to enrollment, were considered eligible. Patients are treated according to local prescribing information and followed-up as per the routine clinical practice for 5 years. The primary objective is to collect adverse events (AEs), including AEs of special interest (AESIs). Secondary objectives include assessment of pregnancy outcomes and visual function over time.

Results: Up to August 2021, 106 patients were enrolled, of whom 103 received VN (mean age [SD]: 19.5 [10.85] years; females: 52 [50.5%]). Mean (SD) duration of follow-up was 0.8 (0.64) years (maximum: 2.3 years). A total of 35 patients (34.0%) reported ≥1 ocular AEs including those with ocular AESIs (number of patients [n] = 17 [16.5%]). Events of chorioretinal atrophic changes (at injection site and/or elsewhere, n = 13) were the most common ocular AEs. Ocular AESIs included foveal degeneration (n = 4), vitritis (n = 4), eye inflammation (n = 3), retinal tear (n = 2) and increased intraocular pressure (IOP; n = 5). Two patients had ocular serious AEs (SAEs: eye inflammation, n = 1; increased IOP, n = 1). Non-ocular AEs occurred in 8 patients; most frequent AE was headache (n = 4). One patient, with no previous history, reported 3 events of psychiatric disorder (non-ocular SAEs). Visual function improved in terms of full-field light sensitivity threshold, and best-corrected visual acuity (LogMAR) at Year 2 with a mean (SD) change from baseline of −13.67 (22.62) decibels and −0.03 (0.55), respectively (Table).

Conclusions: Overall, the safety and effectiveness of VN observed in the PERCEIVE study, with up to 2-years data, are consistent with the findings of VN clinical trials. Chorioretinal atrophy has been identified as a new adverse drug reaction, which so far has not been associated with loss of visual function. These events and overall longer-term safety will be further characterized in the ongoing study.

ABSTRACT BODY:

Purpose: Abnormal angiogenesis is a characteristic feature of many blinding eye diseases, including proliferative diabetic retinopathy (PDR) and neovascular age-related macular degeneration (nAMD). Inhibiting excessive blood vessel growth and leakage is effective in preserving vision. Current anti-angiogenic drugs are dominated by vascular endothelial growth factor (VEGF) inhibitors. However, a substantial number of patients do not respond well to anti-VEGF drugs. Targeting VEGF independent pathways may offer an alternative strategy to treat ocular angiogenic diseases.

Methods: Proteomic analysis was performed in vitreous samples collected from PDR and control patients. Human secreted frizzled-related protein (SFRP) and its C-terminal domain were fused to Fc to generate chimera protein SFRP-Fc and SFPRC-Fc. Their impacts on endothelial cell proliferation and tube formation were studied using in vitro cell-based assays. Ex vivo angiogenesis assays including choroid, aortic ring, and metatarsal assays were used to study the anti-angiogenic effect of SFRP-Fc and SFRPC-Fc in a multi-cellular environment. The efficacies of SFRP-Fc and SFRPC-Fc were further evaluated in a mouse model laser-induced choroidal neovascularization (CNV) and a rabbit model of persistent retinal neovascularization (PRNV). Phosphoproteomics, quantitative RT-PCR, and Western bot analysis were used to investigate the mechanism of action of SFRP.

Results: Our study showed that SFRP is expressed at a significantly lower level in the vitreous of PDR patients as compared to that in control patients. SFRP-Fc and SFRPC-Fc strongly inhibit human retinal microvascular endothelial cell (HREC) proliferation, viability, and tube formation as well as vessel outgrowth from the choroid, aortic ring, and metatarsal bones. SFRPC-Fc is able to prevent and reverse laser-induced CNV in mice and demonstrates an additive effect with Aflibercept. In the rabbit model of PRNV, a single intravitreal injection of 2mg SFPRC-Fc could lead to persistent suppression of retinal angiogenesis and leakage for at least six weeks. Mechanistically, SFRP inhibits angiogenesis in a VEGF-independent fashion via Caveolin-1.

Conclusions: This study leads to the discovery of a novel inhibitor of angiogenesis SFRP and confirmed that its functional domain is located at the C-terminal domain of the protein. We further showed that SFRP exerts its anti-angiogenic effect through Caveolin-1.

ABSTRACT BODY:

Purpose: Bruch's membrane opening minimum rim width (BMO-MRW) has been popularly used to evaluate and monitor glaucoma. Neuroretinal rim (NRR) thickness also shared good diagnostic ability. This study investigated repeatability and agreement among multiple NRR thickness acquisitions. We also evaluated its ISNT/IST patterns and effect from axial length (AL).

Methods: 100 eyes (100 healthy subjects) had NRR thickness measured 5 times consecutively. Signal strength was at least 7 with no obvious artifacts. NRR thickness and retinal nerve fiber layer (RNFL) thickness were obtained. An average from all 5 acquisitions was considered as reference standard. The first, average from the first 2, first 3, and first 4 acquisitions were compared with the reference standard. AL was measured using partial coherence interferometry. Correlations between AL and NRR thickness, and RNFL thickness were studied. Number of eyes following the ISNT and IST patterns were counted.

Results: 87 eyes fulfilled the inclusion criteria. Table 1 shows repeatability and coefficient of variation among 5 acquisitions. They demonstrated comparable results. Table 2 shows agreement between different averaging methods with the reference standard. Agreement improved with averaging from more acquisitions. There were significant correlations between superior/inferior RNFL thickness and AL ($r=0.28$, $p=0.008$ and $r=0.40$, $p<0.001$, respectively). No significant correlations were found between superior/inferior NRR thickness and AL. There was 5% of the eyes following the ISNT pattern using RNFL thickness, and 36% when referring to IST pattern. There was 20% of the eyes following the ISNT pattern using NRR thickness, and 64% when referring to IST pattern.

Conclusions: One NRR acquisition could provide valid information for clinical use. NRR thickness is less affected by AL for evaluating ganglion cell axons.

ABSTRACT BODY:

Purpose: To evaluate vessel density changes using optical coherence tomography angiography (OCTA) and wide-field fluorescence angiography (WF-FA) in a rat model of vasoconstriction induced by intravitreal injection of endothelin-1 (ET-1).

Methods: Vehicle or ET-1 (20 pmol/eye) was injected into the vitreous body in Brown Norway rats. Retinal vessels were observed using OCTA (RS3000A; Nidek) and WF-FA (Mirante; Nidek). OCTA images (20° × 20° field) were taken using a custom-made rat-specific adapter. Retinal layers—the internal limiting membrane and the photoreceptor inner–outer segment junction—were segmented using custom-made software, and en face OCTA images of these volumes were acquired. WF-FA images (Φ110° field) were taken with a wide-field adapter. Retinal vasculature was imaged before, and every 5–10 min until 50 min after, intravitreal injection (n = 4 rats/group). OCTA and WF-FA images were enhanced and vascular binary images were generated by using the Fiji package in the ImageJ software. Vessel density was presented as vessel area/total area*100% and normalized by baseline values (100%).

Results: The binarized WF-FA images showed mainly large vessels. ET-1 caused a significant decrease in vessel density 5 min after injection, peaking at 30 min (vehicle, 97% ± 4%; ET-1, 49% ± 14%, $P < 0.01$) and lasting up to 50 min. The binarized OCTA image detected both capillaries and large vessels. ET-1 significantly decreased vessel density 5 min after injection; most capillaries were invisible by 10 min. Dramatically decreased vessel density was observed by 15 min (Vehicle, 88% ± 10%; ET-1, 16% ± 11%, $P < 0.01$), lasting up to 50 min.

Conclusions: Under the conditions in this study, WF-FA was suitable for evaluating a wide range of large vessels, and OCTA for evaluating large vessels and capillaries. OCTA and WF-FA are useful for different purposes in detailed research evaluation of retinal vasculature.

TITLE: Asymmetries in the vertical optokinetic reflex result from disproportionate excitation to complementary ON direction-selective retinal ganglion cell types

SESSION TITLE: Retinal ganglion cells and central processing

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S.C. Harris, F.A. Dunn, Department of Ophthalmology, University of California San Francisco, San Francisco, California, UNITED STATES|S.C. Harris, Neuroscience Graduate Program, University of California San Francisco, San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure: Scott Harris: Commercial Relationship: Code N (No Commercial Relationship) | Felice Dunn: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: An asymmetry exists between the fidelity of the optokinetic reflex (OKR) in the dorsal-to-ventral (“Inferior”) and ventral-to-dorsal (“Superior”) directions. The neural underpinnings of this asymmetry are unknown. We made electrophysiological recordings from mouse ON direction-selective retinal ganglion cells (oDSGCs) to test the hypothesis that behavioral asymmetries in vertical OKR are associated with physiological asymmetries between oDSGCs that prefer Inferior and Superior motion.

Methods: A retrograde tracer was injected into the projection nucleus of Inferior and Superior oDSGCs in adult, wild-type mice of both sexes (N=33). Following dark-adaptation, retinas were harvested for electrophysiology. We compared the direction tuning of Inferior and Superior oDSGCs by making patch-clamp recordings from labeled cells in response to a drifting bar. Direction selectivity indices (DSIs) and tuning curve widths were compared across cell types and recording conditions (mean±SEM, rank sum). A computational model was built to examine the relationship between input currents and spike tuning curves. Vertical OKR was measured in a separate cohort of head-fixed mice.

Results: Our data indicate that Inferior oDSGCs spike less (spikes per stimulus: Inf. 27.40±1.57, Sup. 38.71±2.04, $p<0.0001$), are more direction-selective (DSI: Inf. 0.37±0.01, Sup. 0.28±0.01, $p<0.001$), and have narrower tuning curves (width at half maximum (degrees): Inf. 213.89±6.36, Sup. 258.49±6.12, $p<0.0001$) than Superior oDSGCs (n = 155 Inf., 115 Sup.). Voltage-clamp recordings demonstrated that this asymmetry is not explained by the canonical model of retinal direction selectivity, as there was no difference in inhibitory inputs across cell types ($p>0.05$ for peak IPSC of each stimulus direction). Instead, we found a difference in the magnitude of directionally untuned excitation across oDSGC types ($p<0.02$ for peak EPSC of each stimulus direction). Current-clamp experiments and modeling revealed a mechanism by which such excitation influences tuning curve shape. Finally, we found an analogous asymmetry in the vertical OKR of behaving mice.

Conclusions: Our results demonstrate that Inferior and Superior oDSGCs encode motion asymmetrically due to disproportionate excitatory input, and link this phenomenon to corresponding behavioral asymmetries in vertical OKR.

ABSTRACT BODY:

Purpose: Vernal keratoconjunctivitis (VKC) is a recurrent bilateral ocular allergic inflammatory disease characterized by severe type 2 inflammation and tissue remodeling. Using a transcriptomic analysis, we examined the epithelial conjunctival gene expression related to the barrier function and the potential evolution to epithelial mesenchymal transition (EMT) in VKC.

Methods: Cells from conjunctival imprints from active VKC patients (n=15) and normal subjects (CT; n=5) were collected and their RNA isolated with Qiagen RNeasy Mini kit. 10 ng of RNA were processed with GeneChip Pico Reagent kit prior to a 9-cylcle PCR amplification and reverse transcription. Final cDNA was analyzed with Affymetrix Clarion S arrays system. Differential expression (DE) analysis included comparisons between VKC, VKC-subgroups and CT. Enrichment analyses on DE genes (adjusted p <0.05 and absolute log2 fold change >1) and regression analysis genes (p value<0.05) was performed using Gene Ontology Biological Process (GOBP) and Reactome.

Results: The difference between VKC and CT showed 333 probes (325 genes) significantly DE: 92 over-expressed and 241 down-regulated. Considering all VKC samples vs CT, 169 out of 325 identifiers were found in Reactome, where 646 pathways were hit by at least one of them. In tarsal VKC several GOBP were related to tissue remodeling, cytokine production and B cells regulation while in limbal VKC the ribonucleoprotein complex biogenesis was the most represented. We found a significant overexpression of MUC1, MUC3A, MUC4, MUC16, LGALS3BP, KRT23, GJB2, TJP1, PCDH, a significant reduced expression of CLDN8, CLDN34, CLDND1, CTNNAL1, SPINK2, EDIL3, and LUM. Many other genes of the cadherin, cingulin, occludin, MARVEL domain, lectin and actin families were either significantly up- or downregulated. We found up-regulation of epithelial marker E-cadherin, a non-increased expression of genes encoding for N-cadherin, vimentin and squamous cell carcinoma antigen (SCCA/SERPINB3) as EMT markers and a significant downregulation of the transcription factors required for EMT, SNAI-1, SNAI-2 and TWIST.

Conclusions: Several biological processes are associated to the pathogenesis of VKC in addition to an epithelial barrier remodeling. EMT is inhibited in VKC, explaining the finding that the majority of VKC patients, after the resolution of the disease, have mild cicatricial consequences.

ABSTRACT BODY:

Purpose: The purpose of this study is to characterize and simulate patient-specific corneal biomechanics to improve the planning of refractive procedures such as LASIK, CLEAR and PRK. The major drawback in surgical planning of these procedures is the lack of patient-specific biomechanical information. In this study, we propose to address this problem by building a simulation platform that combines in vivo Brillouin measurements with mechanical characterization of the imaged corneal tissue. A material model developed based on patient-specific data will then allow the simulation platform to be used to predict the outcomes of these different interventions.

Methods: Experimental: Corneal lenticules extracted from CLEAR surgeries (KEK approval 2021-00145) were tested by uniaxial extension in the nasal-temporal direction or at an angle 45° to it. The tissue was pre-stretched with a force of 10mN and preconditioned with 4 cycles of 15 % strain. The last cycle of force displacement data was recorded for analysis.

Computational: The lenticules were numerically modeled using an in-house algorithm that can accurately build a finite element mesh from the elevation maps obtained from the pre-operative Pentacam data. These lenticules were modelled with orthogonal collagen fibers. A Bayesian optimization procedure was used to identify the material parameters that best fit the experimental data.

Results: The corneal curvature measured from the Pentacam data and the model showed good agreement (figure 1). Parameter identification performed on three patients showed that the model could accurately reproduce the experimental data (figure 2).

Conclusions: Corneal geometry can be accurately replicated, and mechanical characterization of CLEAR lenticules leads to good parameter estimates across patient data. The current limitation of the characterization is that it is only performed ex vivo and on 3 patients. In addition, the lenticules represent only the most anterior part of the cornea. These results need to be complemented by in vivo biomechanical measurements with Brillouin scattering to account for patient-specific corneal biomechanics in surgical planning.

ABSTRACT BODY:

Purpose: Individuals with neuropathic ocular pain are similar to those with chronic neurological disorders in that they often report symptoms of sensory hypersensitivity, such as increased corneal sensitivity and evoked pain to light. The latter, often referred to as "photophobia", is a particular topic of interest in the realm of chronic pain. Specifically within ocular pain, patients with discordant symptoms are more likely to report photophobia, which suggests underlying contribution by centrally-sensitized mechanisms in response to light. In this study, we hypothesized that trigeminal sensory processing contributes to photophobia in patients with neuropathic ocular pain.

Methods: fMRI was used to evaluate brain pathways in individuals with neuropathic ocular pain. Subjects were screened to meet criteria for 1 of 2 groups: dry eye symptoms with chronic ocular pain and photophobia (n=8 cases) and no ocular pain or photophobia (n=8 controls). Subjects were presented with intermittent light stimuli during two scans: 1) a control scan after artificial tear instillation, and 2) after pharmacological blockade of afferents in the ocular surface with instillation of 0.5% proparacaine. Pain ratings elicited by light were acquired, and clinical ophthalmic signs and symptoms were recorded.

Results: Light-induced greater group-level activation in cases vs. controls in the somatosensory cortices (S1), spinal trigeminal nucleus, bilateral insula, anterior mid-cingulate cortex (aMCC). Patients with chronic ocular pain and photophobia reported higher pain intensity and unpleasant ratings to light than controls. Correlations between activity and ratings were greater in cases than controls.

Following proparacaine in cases, decreased light-related activation was observed in S1 and MCC. At the group level, cases demonstrated decreased pain intensity and unpleasantness ratings to light following proparacine, but half of cases did not show a decrease in these ratings.

Conclusions: The trigeminal nociceptive system may contribute to photophobia symptoms among individuals suffering from chronic ocular pain. We demonstrate partial modulation of cortical structures in this pathway by means of topically applied anesthetic to the eyes. Further understanding of the modulatory interactions underlying ocular pain and photophobia is critical for developing effective therapies and guiding treatment plans.

ABSTRACT BODY:

Purpose: Results in corneal transplantation vary depending on the type of transplantation performed and the type of disease. Our purpose was to analyze the results in terms of transparency and Best Corrected Visual Acuity (BCVA) in corneal transplants performed in the ophthalmology unit in the Clinic Hospital of Valladolid (Spain) throughout 2019, comparing them with the literature (in particular the latest European reports on corneal transplantation).

Methods: A cross-sectional, observational, retrospective and single-center descriptive study was conducted based on the review of clinical histories of all corneal transplant patients during 2019, their characteristics before and after surgery, and the characteristics of the graft per year, as well as the results in BCVA per year. A descriptive and inferential statistical analysis was performed.

Results: A total of 100 surgeries were analyzed in 92 eyes from 91 patients. The majority of the surgeries were performed in female sex (60.4%), with an average recipient age of 65.6 ±17 years. The most frequent transplant was DMEK (50.5%), followed by Penetrating Keratoplasty (PK) (22.2%), DSAEK (15.2%) and DALK (10.1%). 3 out of 4 were first transplants, with greater frequency of DMEK. The most frequent type of regrafting was PK. The mean endothelial count of donor corneas was 2601.07 ± 355 cells/mm2. The most frequent indication was Fuchs Endothelial Dystrophy (40.7%), followed by regrafting and Bullous Keratopathy. The highest failure rate was obtained in the DSAEK group (32%), and the lowest one in DALK (11%). Overall, there was an average of 1.9±3.9 lines of VA improvement. Worse results in BCVA were obtained when a higher number of transplants performed in the same eye (Chi2, $p<0.05$). Among those who received cataract surgery, no significant differences in graft transparency were found after one year compared with those who did not.

Conclusions: Results obtained in the series of patients who underwent corneal transplantation are very similar to those in the latest European, American and Australian reports. Results vary depending on the type of diagnosis, the number of regrafting, and the technique used. Given its excellent results, DMEK appears to be the probable standard technique for endothelial dystrophies, although DALK and PK hold their own in specific indications with more complex pathology. Combination with cataract surgery has shown good results.

ABSTRACT BODY:

Purpose: Corneal toxicity secondary to antibody-drug conjugates (ADCs) is a common and clinically significant adverse event that interferes with ADC dosing and could ultimately affect a patient's response to ADC therapy. Effective interventions that either prevent or mitigate this drug-induced keratopathy are lacking. Evidence suggests that ADCs can enter corneal epithelial cells or their precursors indirectly through macropinocytosis, often with no involvement of the targeted receptor. Once internalized, the drug is cleaved from the ADC releasing a cytotoxic small molecule. This present study was based on the rationale that preventing the uptake of an ADC into off-target tissue should mitigate toxicity and the knowledge that charge plays an important role in the interaction of immunoconjugates with cell membranes. The hypothesis that locally delivered poly(L-lysine)-g-poly(ethylene glycol) (PLL-g-PEG) can inhibit ADC uptake into human corneal epithelial cells was tested.

Methods: Rituximab-monomethyl auristatin F (MMAF) was selected as an exemplary ADC that will demonstrate off target corneal epithelial cell toxicity. PLL (not PLL-g-PEG) - coated chamber slides were seeded with human corneal epithelial - transformed (HCE-T) cells (50,000 cells/cm^2). After 48 hours, cells were treated with test article (PLL-g-PEG, or positive control, 5-(N-ethyl-Nisopropyl) amiloride (EIPA)) or vehicle. After 30 minutes, Rituximab-MMAF (75 nM) was added to the wells. The wells were maintained for an additional 3.5 hours before HCE-T cells were fixed and ADC was detected by fluorescent anti-human IgG as viewed under microscopy. Fluorescence intensity was reported utilizing multiple images obtained from multiple replicates. A pilot evaluation was carried out, followed by two validation studies.

Results: The pilot evaluation demonstrated a statistically significant reduction in fluorescence intensity when vehicle was compared to EIPA (150 µmol/L) and PLL-g-PEG 1% solution. Two validation studies demonstrated a dose dependent decrease in fluorescence compared to vehicle for PLL-g-PEG concentrations of 0.05%, 0.1%, 0.5%, and 1% (see images).

Conclusions: PLL-g-PEG exhibited a dose-dependent inhibition of ADC uptake into HCE-T cells. These results suggest PLL-g-PEG may be an effective topical therapy to prevent, mitigate, or otherwise reduce ADC-induced corneal epithelial cell toxicity.

ABSTRACT BODY:
Purpose: Dry Eye Syndrome (DES) has been increased during the pandemic, as a result of wearing masks using electronic devices and working remotely. During COVID-19, we conducted a survey to determine the prevalence of dry eye syndrome.
Methods: This is a cross-sectional study to determine how frequent DES is during COVID-19 in healthy patients in the United States between the ages of 20 and 45. From October 31, 2021, to December 1, 2021, we administered an Ocular Surface Disease Index (OSDI) questionnaire remotely to 40 subjects. The OSDI survey was used to assess DES.
Results: Subjects had a mean age of 29 years old ± SD 14.14 and 23 of them were males (57.5%), and 17 were females (42.5%). Low DES, moderate DES, and severe DES had a prevalence rate of 15%, 77.5 %, and 7.5 %, respectively, according to the OSDI Survey. 50 % are White, 35 % are African Americans, 7.5 % are Asian, and 7.5% are Hispanic. The prevalence of mild DES during COVID is 77.5%, with 64.50 % of males and 35.50% of females.
Conclusions: The prevalence rate of DES during COVID is high which contribute to the fact of wearing the mask, the use of electronic devices and working remotely.

ABSTRACT BODY:

Purpose: Leber hereditary optic neuropathy (LHON) is a mitochondrial DNA disease causing severe visual loss. We performed a phase 1 LHON G11778A gene therapy clinical trial (NCT02161380) to assess the safety and tolerability of AAV2(Y444,500,730F)-P1ND4v2 that utilizes allotopic expression.

Methods: The phase 1 open-label clinical trial was designed as a 3+3 dose escalation of unilateral intravitreal gene therapy injection for each group of G11778A LHON patients with visual loss. Setting: single institution. Participants: 28 adult patients (5 females) with G11778A LHON and chronic bilateral visual loss >12 months (Group 1, n=11), acute bilateral visual loss <12 months (Group 2, n=9), or unilateral visual loss (Group 3, n=8). Intervention: unilateral intravitreal AAV2(Y444,500,730F)-P1ND4v2 injection with low (5.0×10^8 vg), medium (2.5×10^9 vg), high (2.4×10^9 vg), or higher (1.0×10^{10} vg) dose to worse eye (20/200 or worse) for Groups 1 and 2 and better eye (20/40 or better) for Group 3. Outcome Measures: Best-corrected visual acuity (BCVA), visual field, pattern electroretinogram. optical coherence tomography, adverse events, and vector antibody responses. BCVAs were compared to our published prospectively natural history cohort with designated surrogate study and fellow eyes. Longitudinal analysis was performed with generalized estimating equation analysis.

Results: Incident uveitis (8/28,29%), the only vector-related adverse event, resulted in no attributable vision sequelae and was related to vector dose, 5/7(71%) higher-dose eyes versus 3/21(14%) low-, medium-, or high-dose eyes ($p<0.001$). Incident uveitis was not associated with anterior chamber or serum AAV2 neutralizing antibody titers, or serum AAV2 PCR. Improvements of >15 letter BCVA occurred in both treated and fellow eyes of Groups 1 and 2 and surrogate study and fellow eyes of natural history subjects. All study eyes (BCVA ≥20/40) in Group 3 lost >15 letters within the first year despite treatment.

Conclusions: G11778A LHON gene therapy has a favorable safety profile. Our results suggest if there is an efficacy effect, it is likely small and not dose-related. Instances of substantial improvement of >15 ETDRS letters were not uncommon in our natural history patients suggesting demonstration of gene therapy efficacy in LHON likely requires randomization of patients to a group not receiving vector in either eye.

ABSTRACT BODY:

Purpose: Although modern primary macular hole (MH) surgery has excellent closure rates, repair of persistent MHs remains challenging, and numerous surgical approaches have been reported. Given the heterogeneity of techniques, there is a need to investigate how surgeons treat failed MHs, and what the structural and functional outcomes are.

Methods: Anonymized patient records with persistent MHs after primary closure surgery were retrospectively reviewed. All eyes underwent repeat surgery and were grouped in one of three categories based on the surgical approach: 1) manipulation of the internal limiting membrane (ILM) through repeat peeling or ILM translocation, 2) tissue transplantation using amniotic membrane or autologous retina, and 3) other approaches including fibrin glue, induced macular detachment, or autologous blood.

Results: A total of 40 eyes from 40 patients undergoing secondary MH surgeries from 4 continents and 10 centers were included. The average patient age was 63 years, the average number of prior surgeries was 1.6, and 53 % were males. Manipulation of the ILM (N=15) led to MH closure in 53.3% and an improvement of best-correct visual acuity (BCVA) from 20/228 at baseline to 20/156 at month 6 after surgery; tissue transplantation (N= 14) led to MH closure in 85.7 % and an improvement of BCVA from 20/546 to 20/290. Various other approaches (N= 11) led to MH closure in 81.8 % (R^2 = 0.0938) and an improvement of BCVA from 20/235 to 20/84.

Conclusions: Secondary MH closure is possible using various surgical techniques with acceptable anatomical closure rates. We did not observe a meaningful difference in closure rates based on the surgical category but BCVA improved in all groups.

ABSTRACT BODY:

Purpose: The minipig (MP) has become an accepted animal model for the evaluation of ocular toxicity based on structural and function similarity to humans particularly as the availability of nonhuman primates becomes limited. This study evaluated the ocular effects of a small peptide molecule (MW <5kDa) following two intravitreal (IVT) injections.

Methods: Bilateral injections of 0 (vehicle), 200 or 300 µg/eye were given on Day 1 with a second, unilateral injection given on Day 60. Ocular effects were evaluated with IOP, OCT and fundus imaging, direct and indirect ophthalmoscopy and ERG. The MPs (3/timepoint) were sacrificed on Days 6, 14, 28 and 88 for ocular tissue distribution and histopathological examination.

Results: Vitreal haze without the presence of inflammatory cells was observed at 300 µg/eye. Stable, multiple “black streaks” were observed mostly along the superior retinal vessels in the treated eyes at both doses and controls. OCT scans, fundus images and ophthalmological evaluations did not reveal any morphological changes. The black streaks were likely possible focal pigment deposition, typical for MPs. No drug-related IOP or ERG changes were noted throughout the study. Microscopic findings were limited to the presence of drug-related accumulation in the vitreous at all timepoints at 200 and 300 µg/eye with no adverse pathology. Potential vehicle-related microscopic findings were limited to minimal mononuclear cell infiltration in the vitreous at all timepoints. The drug was detected in the choroid, retina and vitreous humor of the left eye at both doses on Days 6, 14, 28 and 88; retinal levels on Day 88 <LLOQ across all dose groups. Vitreal levels were ~10-fold higher on Day 28 or 88 compared to retinal and choroidal levels.

Conclusions: The results reveal the MP is an acceptable species for evaluation of the ocular effects of single and repeated IVT injection. The findings also demonstrate microscopic findings that were typical of a MP.

ABSTRACT BODY:

Purpose: Transient elevation of intraocular pressure (IOP) causes both mechanical and ischemic damage to the optic nerve and retina tissues. The purpose of the study was to test the hypothesis that retinal oxygen metrics are impaired and associated with visual dysfunction, retinal thinning, and retinal ganglion cell (RGC) loss after ischemia/reperfusion injury induced by ocular hypertension.

Methods: Right (study) eyes of 10 rats were subjected to anterior chamber cannulation to elevate the IOP for 90 minutes, followed by 7 days of reperfusion. Fellow eyes served as normal controls. Pattern-evoked electroretinography (PERG) and optical coherence tomography (OCT) were performed to measure RGC function and total retinal thickness (TRT), respectively. Retinal arterial and venous oxygen contents (O_{2A} and O_{2V}) were measured using phosphorescence lifetime imaging. Fluorescence and red-free imaging were performed to quantify total retinal blood flow (TRBF). Retinal oxygen delivery (DO_2), metabolism (MO_2), and extraction fraction (OEF) were calculated. RGCs were counted from immunofluorescence-stained retina whole-mounts. Individual retinal layers thicknesses were measured from retinal histology sections.

Results: During ischemia, IOP measurements were 15.7±0.5mmHg and 88.6±6.6mmHg in control and study eyes, respectively ($p<0.0001$). The PERG amplitudes were 5.2±1.5μV and 1.4±0.35μV in control and study eyes, respectively ($p<0.0001$). TRT was 251±7μm and 166±23μm in control and study eyes, respectively ($p\leq0.0001$). TRBF was 6.6±1.0μL/min and 4.0±0.8μL/min in control and study eyes, respectively ($p<0.0003$). DO2 was 912±183nLO2/min and 574±142nLO2/min in control and study eyes, respectively ($p=0.001$). MO2 was 368±81nLO2/min and 222±65nLO2/min in control and study eyes, respectively ($p=0.003$). OEF did not differ significantly between eyes ($p=0.70$). The number of RGCs was 61±23) and 35±12 in control and study eyes, respectively ($p=0.01$). Decreased DO2 and MO2 were correlated with decreased PERG amplitude ($r\geq0.6$, $p\leq0.005$) and decreased TRT ($r=0.7$, $p\leq0.002$). Decreased RGCs counts were correlated with decreased TRT ($r=0.6$, $p=0.04$).

Conclusions: Impairments in retinal oxygen delivery and metabolism and their correlations with visual dysfunction and cell loss were reported for the first time in an experimental ischemia/reperfusion model of glaucoma.

ABSTRACT BODY:

Purpose: This study evaluated the relationship between statin use and the age of onset of age-related macular degeneration (AMD). Additional covariates such as sex, ethnicity, smoking history, fluoxetine use, obesity, diabetes mellitus (type 1 and type 2), and hypertension were included in the regression model.

Methods: Electronic Health Records (EHR) from 52,840 patients evaluated in the University of California Los Angeles (UCLA) Ophthalmology Clinics between 2014 and 2020 were screened. Subjects with a diagnosis of AMD were included in this study, and their records were reviewed for previously described AMD risk factors: sex, ethnicity, smoking, statins, fluoxetine, obesity, diabetes mellitus, and hypertension. Survival analysis was performed using a Cox proportional hazards regression model and visualized using Kaplan Meier survival curves.

Results: 5,498 of 52,840 patients included in the study (10.4%) were diagnosed with AMD. Statin use appeared to be associated with a later onset of AMD (HR=0.8822, p=0.0006), delaying the age of onset of AMD. However, female sex (HR=1.1382, p=00002), obesity (HR=1.4227, p<0.0001), and usage of fluoxetine (HR=1.3508, p=0.0032) were associated with an earlier onset of AMD. In addition to these factors, when adding ethnicity as a covariate to the model, non-hispanic black ethnicity (HR=0.5687, p<0.0001) and hispanic ethnicity (HR=0.8269, p=0.0028) appeared to be associated with a later onset of AMD. When stratifying for ethnicity, statin use, female sex, obesity, and fluoxetine use were four covariates that appeared to be significant only within the non-hispanic white subjects.

Conclusions: Statin use is associated with a delay in the onset of AMD, particularly in non-hispanic white subjects. Females, obesity, and fluoxetine are associated with an earlier onset of AMD, whereas non-hispanic black and hispanic ethnicities appear to be associated with a later onset of AMD.

ABSTRACT BODY:

Purpose: Over 50% of individuals with vision-threatening disease (VTD) (e.g., diabetic retinopathy, glaucoma, macular degeneration) are unaware of their condition, and once diagnosed, 80% will not follow up for clinical care, especially since the onset of SARS-CoV-2 in 2020. Remote teleophthalmology with real-time robotic teleconsultation was implemented to include automated puff-tonometry (APT) as pre-triage to identify patients who require more detailed clinical assessment and treatment.

Methods: 224 subjects (58% male) of average age 55 years were screened over 8 events. Following COVID-19 protocols screenings took place in New Jersey churches and health fairs featuring a high prevalence of African American and Hispanic subjects. Masked and self-reported vaccinated subjects underwent medical history, blood pressure, visual acuity (with pinhole), automated puff-tonometry (APT) for intraocular pressures (IOP), automated refraction, non-mydriatic retinal imaging, optical coherence tomography (OCT), and wearable visual field device (WVFD) testing. Face masks were fitted with surgical tape on the nose bridge to limit instrument fogging. To minimize equipment contact, all subjects were screened in the standing position, including APT and retinal imaging (Fig.1). Chi-square and t-tests were performed to assess factors associated with glaucoma referral. Subjects without IOP readings were excluded; significance was set at $p<0.05$.

Results: 10.29% of measured eyes had an IOP>18 and underwent additional testing including OCT-B of the optic nerve head, nerve fiber layer, and ganglion cell complex. 31.43% of eyes with IOP>18 underwent teleconsultation with a glaucoma specialist, vs. 8.85% of eyes with IOP≤18 (($p<0.001$), Table 1). The difference in mean age in subjects with glaucoma referral vs. without (57.42 vs. 51.61 years) was significant ($p=0.008$).

Conclusions: APT was useful in supporting on-site OCT-B imaging and WVFD referral (37.67%, 8.52% of total subjects) that yielded 17.94% referral to on-site teleconsultation through a real-time telerobot. Future investigation will include larger and more diverse community-based populations.

TITLE: Nyctalopia Due To Severe Liver Cirrhosis-induced Vitamin A Deficiency: A Case Report

SESSION TITLE: Vision Impairment, Visual Function, and Quality of Life

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Chen, A. Quan, Optometry, VA Medical Center Perry Point, Perry Point, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Shuyi Chen: Commercial Relationship: Code N (No Commercial Relationship) | Amy Quan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Vitamin A is a micro-nutrient critical to retinal functioning. We report a rare case of night blindness secondary to poor vitamin A metabolism due to severe liver cirrhosis. The purpose of presenting this case is to highlight that even though vitamin A deficiency is very uncommon in developed nations, it should be considered as an etiology of nyctalopia in patients with liver diseases.

Methods: A 62-year-old Caucasian female presented with loss of vision in dim and dark lighting that had gotten progressively worse over the past 8 months. She was asymptomatic in daylight, but almost blind in the dark to the extent that she was unable to navigate and thus afraid to go outside at night. There was no personal or family history of night blindness or retinal disorders. Her ocular health was unremarkable with dilation. Her visual fields were full under bright illumination, but after dark adaptation, there were dense peripheral defects encroaching central fixation in both eyes. The patient had a medical history of stage 4 non-alcoholic liver cirrhosis, which led to a malabsorption of vitamin A, as confirmed by the very low vitamin A level in the serum analysis.

Results: Patient’s primary care physician and endocrinologist were notified of the findings, and vitamin A repletion therapy was implemented to prevent further vision loss. Repeated vitamin A level testings, in addition to visual fields after dark adaptation, were performed periodically to monitor for the resolution of the condition. Subjective improvement in symptoms, along with better performance on visual field, were noted after initiating oral vitamin A supplementation for 6 months.

Conclusions: This case report emphasizes the rare possibility of nyctalopia secondary to severe liver cirrhosis-induced vitamin A deficiency. Due to the presence of abundant storage of vitamin A in the liver, symptoms of vitamin A deficiency, such as nyctalopia, likely do not occur till late stage of liver disease. In the literature, cases of vitamin A deficiency have been reported in patients with a history of gastric and intestinal surgery; to our knowledge, this is the first case of nyctalopia reported in a patient with liver cirrhosis that improved after supplementation with exogenous vitamin A. Although vitamin A deficiency is an extremely rare disorder in the United States, it should be suspected in patients with severe liver disease experiencing a loss of night vision.

ABSTRACT BODY:

Purpose: Evaluate the long-term effectiveness of the injectable fluocinolone acetonide (FA) implant in patients for the treatment of non-infectious uveitis.

Methods: This is a retrospective chart review study of patients enrolled from a single site in 2 multi-centered clinical trials of the FA implant (Psividia 1 and Psivida 6). The number of rescues (defined as intravitreal steroid injections or replacement injectable or surgical FA implants) and the number of flares post implant were collected. Eyes were then categorized into successes if no rescues were required for a minimum of two years.

Results: 14 eyes of 12 patients with noninfectious uveitis were included in analysis. The mean age was 54.6 years (range 39-72). There were 10 females (83%). 2 eyes received a sham injection and were thus removed from analysis. Of the 14 analyzed eyes 9 were successes. Amongst the eyes classified as successes, 5 of the 9 have not required rescues to date, with an average time of follow up of 77.1 months. The average time to first rescue amongst successes was 52 months. The average time to first rescue for all patients was 22 months and 8.5 months for the eyes classified as failures. The two sham eyes had an average time to first rescue of 2.25 months.

Conclusions: The injectable FA implant is an effective treatment for noninfectious uveitis. Approximately two thirds of eyes which received the injectable FA successfully reached two years without rescue and 5 out of 9 (55.5%) of the successes did not require rescues five or more years after initial implant injection with regular follow-up. The injectable FA implant can provide several year control for some patients with chronic non-infectious posterior uveitis.

TITLE: Hemodynamic Retinal Changes on Optical Coherence Tomography Angiography After Anti-Vascular Endothelial Growth Factor Injection in Eyes with Diabetic Macular Edema

SESSION TITLE: Diabetic macular Edema

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Song, B.B. Huang, J.X. Ong, N. Konopek, A.A. Fawzi, Northwestern University Feinberg School of Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Jessica Song: Commercial Relationship: Code N (No Commercial Relationship) | Bonnie Huang: Commercial Relationship: Code N (No Commercial Relationship) | Janice Ong: Commercial Relationship: Code N (No Commercial Relationship) | Nicholas Konopek: Commercial Relationship: Code N (No Commercial Relationship) | Amani Fawzi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate retinal hemodynamic responses to anti-vascular endothelial growth factor injection (anti-VEGF) in eyes with diabetic macular edema (DME) using optical coherence tomography angiography (OCTA).

Methods: 26 eyes of 22 subjects (age 60.2 ± 13.7years) who had prospective OCTA scan before and after anti-vascular endothelial growth factor injection (mean interval between OCTA= 31.1 ± 17.3days). Using previously validated thresholding methods based on the FAZ and on the skeletonized deep capillary plexus (DCP), we analyzed Adjusted Flow Index (AFI), Vessel Density (VD), and Skeletonized Vessel Density (SVD) in the parafoveal area (3mm annulus with 1mm inner circle) as shown in Figure 1. In addition to these parameters, we also assessed the Fovea Avascular Zone area (FAZ) and Central Foveal Thickness (CFT). Longitudinal changes were assessed using a generalized linear model correcting for CFT.

Results: We found significantly decreased AFI in the DCP layer ($p=0.026$). Furthermore, FAZ ($p<0.001$) and CFT ($p<0.001$) showed significant decrease from baseline compared to follow-up OCTA scans. Detailed results in Table 1.

Conclusions: AFI decreased significantly in the DCP layer on follow-up OCTA scan suggesting vascular flow disruption and decreased perfusion after anti-vascular endothelial growth factor injection. Consistent with reduced DME, FAZ and CFT decrease significantly with follow up imaging. These results may have important clinical implications for patients receiving long-term anti-VEGF therapy.

ABSTRACT BODY:

Purpose: Cardiovascular diseases and retinal vein occlusion (RVO) share many risk factors in common. We aimed to clarify the association between RVO occurrence and cardiovascular health (CVH) metrics called the Life's Simple 7 advocated by the American Heart Association.

Methods: Design: Retrospective cohort study.

Subjects: Individuals undergoing health checkups from 2005 to 2020 in the JMDC Claims Database (JMDC Inc., Tokyo, Japan).

Methods: We set the two exposures: 1) each component of the CVH metrics: body mass index, blood pressure (BP), fasting blood glucose, total cholesterol, smoking, dietary habits, and physical activity; and 2) the number of non-ideal CVH metrics (non-ideal CVH score, ranging from 0 [healthiest] to 7 [unhealthiest]). The outcome was RVO occurrence, identified by the first date of the diagnosis. We performed Cox regression in which RVO occurrence was regressed on the above exposures, age, and sex.

Main Outcome Measures: Hazard ratios for RVO occurrence of 1) each component of the CVH metrics and 2) the non-ideal CVH score.

Results: A total of 2,093,536 individuals were eligible. During a mean follow-up of 1,070 ± 884 days, 3,265 RVO events occurred. Non-ideal BP was most strongly associated with increased risk of RVO occurrence (hazard ratio [HR], 2.25 [95% confidence interval, 2.06–2.46]), followed by non-ideal BMI (HR, 1.30 [1.20–1.40]). Higher non-ideal CVH scores were associated with increased risk of RVO occurrence: adjusted HRs of the groups with non-ideal CVH scores of 6–7, 5 ,4, 3, 2, and 1 were 3.68 (2.61–5.20), 2.83 (2.03–3.95), 2.54 (1.83–3.53), 2.21 (1.59–3.06), 1.78 (1.28–2.47), and 1.39 (0.98–1.95), respectively, compared to the healthiest group with the score 0. This trend was also observed in the subgroups with and without ideal BP.

Conclusions: The strongest risk factor for RVO was non-ideal BP, followed by non-ideal BMI. Non-ideal CVH score, an indicator of unhealthy lifestyle, was dose-dependently associated with RVO occurrence, which also applied to the individuals with ideal-BP. Public health and individual efforts to manage these modifiable risk factors are essential for preventing RVO.

ABSTRACT BODY:

Purpose: To describe the clinical course and optical coherence tomography (OCT) findings in eyes with spontaneous reattachment of macula-off traction retinal detachments (TRD).

Methods: Retrospective case series of eyes with macula-off TRD that had spontaneous reattachment.

Results: Four eyes of 4 patients with macula-off TRD secondary to proliferative diabetic retinopathy (PDR) (n=3) and proliferative sickle cell retinopathy (n=1) were included. Median (IQR) age was 47.5 (22.8) years. Two of 3 PDR eyes each had 1 anti-VEGF injection at the visit prior to the macula-off TRD, with a median time from injection to TRD of 204 days [range 42-365 days]. Two of 3 PDR eyes had prior panretinal photocoagulation before TRD. OCT confirmed spontaneous resolution of the macular retinal detachment (Figure 1) in all eyes. Median (IQR) logMAR VA at the time of macula-off TRD was 0.544 (0.452) [Snellen 20/70] which improved to a median (IQR) logMAR VA of 0.350 (0.156) [Snellen 20/45, p=0.068] at the first visit with reattachment characterized by OCT. Median (IQR) time from TRD diagnosis to OCT measured reattachment was 6 months, (10.25; range 1-12 months). No complete posterior vitreous separation was seen in any of the eyes. One eye had a recurrent TRD 4 months after initial spontaneous reattachment. The macula remained attached until the last visit in the other eyes at a median of 365 days [range 266-469 days] after the TRD diagnosis. The final median logMAR VA of these three eyes was 0.544 (range 0.301-0.544) [Snellen 20/70, p=0.18].

Conclusions: Non-surgical spontaneous retinal reattachment and significant visual acuity improvement may rarely occur in eyes with TRD. In our cases, no OCT evidence of posterior vitreous separation was found, suggesting that some relaxation of the contractile fibrovascular membranes may have occurred to account for macula reattachment.

ABSTRACT BODY:

Purpose: Diabetic neuropathy is one of the most common microvascular complications in diabetes mellitus (DM). Here, we investigate the effects of peroxisome proliferator-activated receptor (PPAR)-α agonists, fenofibrates, on the prevention of corneal nerve degeneration and the stimulation of corneal nerve regeneration in patients with type II DM.

Methods: A single-arm, open-label, single-center interventional study was conducted in Singapore National Eye Centre. Twenty-six patients (80.8% Chinese; 80.8% males; aged 60.8 ± 9.31 years) were prescribed 100mg/day and 300mg/day oral fenofibrate for 30 days. The patients (52 eyes) underwent comprehensive ocular surface assessment, corneal nerve metrics and wing cells epithelium analysis using in-vivo confocal microscopy scans, before and after treatment. Tear neuromediator analysis included substance P, calcitonin gene-related peptide (CGRP), neuropeptide Y (NPY), and β-nerve growth factor (β-NGF).

Results: Corneal nerve fiber density (CNFD) significantly increased from 9.46 ± 6.20 to 12.6 ± 4.36 number of fibers/mm^2 (P=0.01; figure 1), while corneal nerve fiber width significantly decreased from 0.0225 ± 0.00118 to 0.0218 ± 0.00128 mm/mm^2 (P<0.01). Corneal nerve fractal dimension, which measures spatial loss of nerves, also shows a trend of improvement (pre-treatment: 1.39 ± 0.0641; post-treatment: 1.49 ± 0.0371). After treatment, epithelial cells' circularity significantly improved from 0.726 ± 0.0162 to 0.717 ± 0.0213 (P<0.05; figure 1). Tear breakup time significantly improved, and ocular surface staining evaluated by Oxford scores significantly increased after treatment (both p<0.01). Additionally, tear substance P concentrations significantly increased after treatment (pre-treatment: 1239 ± 712 pg/mL; post-treatment: 1668 ± 948 pg/mL; P=0.02), and the changes of tear substance P concentrations were significantly correlated with the increment of CNFD (r = 0.41; P=0.036).

Conclusions: PPAR-α has protective effect on the ocular surface and corneal nerve degeneration, while stimulating corneal nerve regeneration in diabetic corneal neuropathy. These findings may offer novel treatments for diabetic corneas.

ABSTRACT BODY:

Purpose: To identify predictive factors associated with highly fluctuating macular thickness in neovascular age-related macular degeneration (nAMD), and to explore the effects of fluid fluctuation on visual outcomes.

Methods: This was a real-world retrospective cohort study conducted at five tertiary centers in Thailand (2016-2018). We included one eye per each treatment-naïve nAMD patient who received anti-VEGF injections based on a treat-and-extend regimen for a duration ranged from 1 to 3 years. Other maculopathies including macular atrophy and subretinal fibrosis were excluded from the study. The standard deviation (SD) of 1-mm central subfield thickness (CST) from month 3 to 24 in each patient was organized into ascending order from lowest to highest, and thereafter split equally into three groups: low, moderate, and high CST fluctuation group.

Results: Of 558 eyes, baseline CST was 363±137μm, 384±183μm, and 490±210μm in the low, moderate, and high CST fluctuation group (186 eyes in each group), respectively. Correspondingly, the SD of CST from month 3-24 was 11.8± 6.3, 40.6±10.6, and 114.7±59.3. After controlling for age, baseline CST and a total number of injections, the Generalized Estimating Equations showed that eyes with low fluid fluctuation significantly gained more ETDRS letters than those in the moderate and high fluctuation group (mean differences=6.7 and 10.7 letters, respectively) at 12 months follow-up. These differences between the groups increased further at 24 months (10.1 and 14.0 letters, Figure 1). Baseline CST of ≥405 μm was significantly associated with highly fluctuating CST during the maintenance phase (adjusted odds ratio (AOR)=3.27, sensitivity and specificity of detection=62% and 68%). Such correlations were not observed in baseline BCVA, the presence of polypoidal lesion, and Bevacizumab uses. Among different subtypes of retinal fluid, the presence of intraretinal fluid (IRF) coincided with subretinal fluid (SRF) at the baseline visit was the strongest predictor for high CST fluctuation over the treatment course (AOR=2.48) (Table 1).

Conclusions: The presence of baseline SRF and IRF predicted highly fluctuating retinal fluid over the 2-year course of nAMD treatment. Apart from the retinal fluid per se, unstable macular thickness during anti-VEGF therapy may be an additional factor contributing to poor visual outcomes.

ABSTRACT BODY:

Purpose: Administration of anti-VEGF therapies is the standard of care for the treatment of diseases with the chronic pathology of retinal angiogenesis, such as proliferative diabetic retinopathy, and requires a protracted level of therapeutic intervention to maintain remission. Effective delivery of siRNA would shut down VEGF expression with the potential to extend the therapeutic window of an injection significantly. The purpose of this study was to evaluate an intravitreally injected nanoparticle platform that delivers small interfering RNA (siRNA) targeting vascular endothelial growth factor (VEGF) for its ability to inhibit neovascular leakage.

Methods: We synthesized fusogenic porous silicon nanoparticles (F-pSiNP) containing rabbit VEGF-siRNA and conjugated the surface with iRGD peptide for targeting neovascular and Müller cell surface receptors. The F-pSiNPs were evaluated by intravitreal injection for toxicity and pharmacodynamics in healthy rabbit eyes, and for efficacy in the DL-α-aminoadipic acid (DL-AAA) rabbit model of chronic retinal neovascularization (RNV). Efficacy was measured by a reduction of leakage area and intensity by repeated FA as compared to sham injection controls using ImageJ and by ELISA of VEGF in the vitreous.

Results: The analysis of repeated FA leakage over time (MANOVA) revealed that F-pSiNP treatment significantly inhibited FA leakage from DL-AAA induced RNV compared with the sham control ($p = 0.00137$), which persisted for 12 weeks (Fig. 1A). A corresponding reduction in vitreous VEGF was also observed (Fig. 1B). No toxicity was detected in the healthy F-pSiNP-injected eyes and normal retinal function was observed with ERG. Histological sections revealed penetration of the F-pSiNPs throughout the inner and outer retina and up to the RPE at 72 hr (Fig. 2).

Conclusions: F-pSiNP constructs were observed within Müller cells and throughout the retina, provided a persistent knockdown of VEGF gene expression, and reduced leakage in a rabbit model of RNV. Injection of targeted nanoparticles yielding slow intracellular release of therapeutic anti-VEGF siRNA may be an effective intraocular therapeutic to provide sustained, nontoxic anti-VEGF effects for retinovascular disease.

ABSTRACT BODY:

Purpose: Conjunctival papilloma is often resistant to treatment. Various therapies have been reported with no gold standard. This purpose of this study was to compare treatment outcomes after various therapies.

Methods: A retrospective chart review of 30 conjunctival papilloma patients from 2009 - 2020. Data on demographics, tumor characteristics, primary treatment and outcomes were collected. The primary outcome was the frequency of complete tumor resolution and recurrence rate of each primary therapy. The secondary outcome was treatment related side effects.

Results: The mean age was 57.5 years (3-93 years) with male predominance (n=22, 73.3%). Eleven eyes were treated with interferon α-2b (IFN), seven with 5-fluorouracil (5FU), and 10 with excision biopsy and cryotherapy (6 with adjuvant therapy with IFN). The frequency of tumor resolution was 36.4% (4/11), 28.5% (2/7), and 100% (10/10) in each group, respectively. The mean time to resolution was faster in the surgical group compared to the medical group (1 day vs 159 days, $p<0.001$) There was a trend for a higher tumor recurrence with 11% in the surgical vs 0% in the medical group at 6 months and at 12 months, 22% recurrence in the surgical and 0% in the medical group.

Conclusions: Papilloma resolution is faster with surgical excision as compared to medical therapy. However, recurrences are more frequent after surgical vs medical treatment.

ABSTRACT BODY:

Purpose: Recent studies have demonstrated that very low doses of bevacizumab can be used to treat Type I prethreshold retinopathy of prematurity (ROP). We hypothesized that lower doses of intravitreal bevacizumab may promote the normal outgrowth of retinal vessels following injection. The goal of this pilot study is to compare the rate of vessel outgrowth after conventional dose (0.625 mg) and low-dose (0.125 mg) treatment.

Methods: This was an IRB-approved retrospective chart review of patients treated with intravitreal bevacizumab before and after the institution switched to low-dose bevacizumab in September 2019. All eyes had Retcam color and fluorescein angiography (FA) taken at the time of intravitreal bevacizumab injection and at subsequent laser photocoagulation. Gestational age at birth, birthweight, corrected age at injection, and weeks between injection and laser were tabulated. Six eyes of six infants who met these criteria were identified: 3 eyes treated at low dose and 3 eyes treated with conventional dose. Photos were analyzed using MATLAB R2021a. The average distance from optic disc to ridge were calculated using 15 vectors from the nerve to the temporal ridge encompassing one clock hour.

Results: Baseline parameters including birthweight, gestational age at birth, and zone/stage of ROP were comparable between the two groups. Optic nerve to ridge distance at time of injection and laser were used to calculate vessel outgrowth (pixels) and rate of vessel outgrowth (pixels/week) in 6 eyes of 6 patients. Mean vessel outgrowth was 153 pixels for conventional and 260 pixels for low-dose eyes (one-tailed t-test; $p < 0.015$). When corrected for number of weeks since injection, the rate of vessel outgrowth was 32 pixels/week and 30 pixels/week for conventional and low-dose eyes, respectively ($p > 0.64$). The mean interval between injection and laser was 5 weeks for conventional and 9 weeks for low dose eyes ($p > 0.07$).

Conclusions: Low-dose treated eyes had significantly greater vessel outgrowth, but this could be explained by a longer interval between injection and laser treatment in the low-dose group. This pilot study warrants further quantitative analysis of the potential benefits of low-dose bevacizumab treatment in a larger cohort of patients.

ABSTRACT BODY:

Purpose: Ischemia-induced retinopathy is one of the leading causes of irreversible blindness. Overactivated retinal myeloid cells are a crucial driving force of pathological angiogenesis and inflammation in ischemic retinopathy. The cyclic GMP-AMP (cGAMP) synthase (cGAS) and stimulator of interferon genes (STING) pathway is a key regulator of myeloid cell activation. This study investigated both the functions and regulatory mechanisms of cGAS-STING signaling in oxygen-induced retinopathy (OIR).

Methods: WT C57BL/6J mice and Sting$^{-/-}$ mice were used for OIR. Retinal neovascular and avascular areas were quantified in isolectin-stained retinal flat mounts. Retinal leukocyte adhesion was measured by perfusion labeling with concanavalin A lectin. Retinal myeloid cells were isolated from retinas using CD11b^{+} MACS microbeads. The cGAS, STING, peroxisome proliferator-activated receptor α (PPARα), and autophagy markers were measured using Western blot analysis. Surface and activation markers of retinal myeloid cells were measured by flow cytometry.

Results: The protein levels of cGAS-STING signaling were markedly upregulated in retinal CD11b^{+} cells of OIR mice. Sting knockout (KO) alleviated pathologies of OIR, including retinal neovascular areas, avascular areas, and leukostasis. Sting KO reduced the percentages of active M1 (IL1β^{+}) and M2 (CD163) myeloid cells in OIR retinas. In addition, we found that PPARα was downregulated in retinal CD11b^{+} cells of the OIR model. Pparα$^{-/-}$ mice showed higher cGAS-STING levels in retinal CD11b^{+} cells compared to those in WT mice. PPARα agonists suppressed cGAS-STING signaling in the OIR retinas and mitigated the pathologies of OIR. In primary retinal microglial cells, the cGAS-STING levels were decreased in cells with starvation-induced autophagy and increased when autophagy was blocked by chloroquine. Pparα$^{-/-}$ retinal microglial cells showed defective autophagy and increased protein levels of cGAS-STING. Induction of autophagy decreased cGAS-STING levels in Pparα$^{-/-}$ retinal microglial cells.

Conclusions: Overactivation of cGAS-STING signaling in retinal myeloid cells plays a pathogenic role in ischemic retinopathy. PPARα inhibits the overactivated cGAS-STING signaling via the modulation of autophagy.

ABSTRACT BODY:

Purpose: Limited literature exists on Optic Nerve Head Drusen (ONHD) progression. Thought to be benign, ONHD are globules of mucoproteins and mucopolysaccharides that progressively calcify in the optic disc. Found in 2-3% of the population, ONHD can be categorized as superficial, buried, or surface pearl (the most severe). Pearl type progress superficially and may exert mechanical stress on the surrounding vasculature, resulting in peripheral vision loss over time (1.6% per year on VF) due to thinning of the retinal nerve fiber layer (RNFL) and ganglion cell complex (GCC), similar to glaucoma.

Methods: Non-mydriatic 45-degree color and fundus autofluorescence (FAF) were captured and grayscale reflectance histograms were determined using Photoshop^{TM} V7. Lipofuscin concentrations in overall ONH as well as targeted single ONHD were measured. Visual Field (VF) was assessed via 30-2 central threshold tests. GCC and RNFL thickness were assessed using Ocular Coherence Tomography (OCT-B). Subject 1 is a 24 y/o female with early signs of pearl ONHD who was followed from 2020 to 2021. Subject 2 is a 53 y/o female with 40 years advanced pearl ONHD with documented FAF and progressive VF loss.

Results: After 14 months, subject 1 Rt FAF intensity index value showed an 11% increase in FAF reflectance (37 to 41) (Fig 1A), while Lt value increased by 89% (37 to 70) (Fig 1B) mirroring the progression seen on OCT-B as the drusen rises to the surface (Fig 1C). Subject 1 had minor increased peripheral VF defects Rt but overall stable VF indices in both eyes. Subject 2 had significant peripheral VF loss Rt/Lt over 40 years with an overall ONHD FAF intensity index value of 96 and a single ONHD intensity index value was 170 FAF reflectance on the surface of the ONH. (Fig 2)

Conclusions: Our findings suggest that over time, pearl ONHD rise superficially to the most anterior portion of the optic disc (Fig 1C). This is shown by an increase in FAF fluorescence of subject 1 Lt, measured by a novel approach of grayscale reflectance quantification. Noninvasive FAF may be a more sensitive marker of early ONHD progression than OCT or VF (Fig 1D) and can be used to screen patients for ONHD. As there is no cure, early detection and protective management of intraocular pressures may be warranted. Further studies will include OCT-B with 1080 nm enhanced depth imaging and 3D volumetric imaging.

ABSTRACT BODY:

Purpose: Idiopathic macular telangiectasia type 2 (MacTel) is a retinal disease characterized by bilateral, asymmetric telangiectatic changes. These findings are often missed or misdiagnosed on optical coherence tomography (OCT) alone especially in the early stages, and fluorescein angiography is an invasive imaging technique. The purpose of this case series is to highlight the use of optical coherence tomography angiography (OCTA) as a non-invasive imaging modality to distinguish early or atypical MacTel from other macular conditions with similar presentations and its utility for longitudinal follow-up.

Methods: Retrospective chart review performed at the University of Chicago from 07/2017-07/2021. Participants included in this study were those diagnosed with MacTel based on clinical examination and imaging criteria on OCTA (Optovue RTVue XR Avanti (Optovue Inc, Fremont, California, USA 2018.1.8.60)).

Results: 15 eyes from eight patients were included in this study. The average follow-up time was 13.6 ± 10.2 months. Six patients were referred with previous diagnoses of macular hole, vitreomacular traction, cystoid macular edema, or diabetic macular edema. OCTA revealed telangiectatic vessels in the parafovea of the deep capillary plexus (DCP), cavitary changes, and ellipsoid zone (EZ) disruption in all 15 eyes. Internal limiting membrane draping was observed in 60% of eyes (n=9), while right-angled vessel branching was observed in 33% of eyes (n=5). OCTA highlighted subretinal neovascularization in 46.67% eyes (n=7). 2 of these eyes (28.6%) were treated with an anti-VEGF injection with improvement in VA, while the other 5 eyes (71.4%) were observed over the entirety of the follow-up period. Finally, one patient with a concurrent macular hole was treated with drop regimen with improvement in VA. At follow-up, VA of eyes was stable or improved with appropriate treatment.

Conclusions: OCTA is an imaging modality that is uniquely suited to detect and facilitate the diagnosis and longitudinal follow up of MacTel. Its repeated B-scans capture neurodegenerative changes in MacTel, while its en face angiograms display characteristic vascular patterns or CNV earlier in disease course than OCT, without needing to use invasive FA. Early diagnosis of MacTel with OCTA can be beneficial in guiding appropriate treatment and treating coexisting diseases to prevent future, irreversible vision loss.

TITLE: Stereoscopic 3D videogame play boosts stereoacuity, but not contrast sensitivity

SESSION TITLE: Machine Learning and Augmented Virtual reality

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B.Z. Li, C.V. Ngo, M.M. Antonucci, D.M. Levi, Herbert Wertheim School of Optometry and Vision Science, University of California Berkeley, Berkeley, California, UNITED STATES|R. Li, College of Optometry, Nova Southeastern University, Fort Lauderdale, Florida, UNITED STATES|

Commercial Relationships Disclosure: Betty Li: Commercial Relationship: Code N (No Commercial Relationship) | Charlie Ngo: Commercial Relationship: Code N (No Commercial Relationship) | Michelle Antonucci: Commercial Relationship: Code N (No Commercial Relationship) | Dennis Levi: Commercial Relationship: Code N (No Commercial Relationship) | Roger Li: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Our recent findings suggest that stereoscopic 3-dimensional (3D) videogame play boosts stereoacuity. Here we asked if the immersive 3D video game experience could modify contrast sensitivity.

Methods: Twenty-four healthy young adults with limited previous video game experience were recruited in two groups. In the treatment group (3DVG, n=12), participants were required to play stereoscopic 3D video games for a total of 40 hours (2 hours per session) in 4-5 weeks. First-person shooter action video games were used. In the control group (2DVG, n=12), participants played the same video games but in 2D mode for the same time course. Stereoacuity and contrast sensitivity were measured before and after the video game intervention. (1) Stereoacuity was measured using random dot stereograms. Each random-dot stimulus consisted of a 1-degree central square of random dots embedded in a 3.3-degree square of random dots. The visual task was to determine the stereoscopic depth of the central square (in front of or behind) relative to the outer reference square. (2) Contrast sensitivity was measured binocularly for a range of spatial frequencies (1, 2, 5, 10 & 20 cpd) using a Metropsis system (Cambridge Research Systems, UK). In each trial, a large sinusoidal Gabor patch (Gaussian envelope, SD=1 degree) was displayed randomly at one of four locations on the monitor screen. The visual task was to indicate the target grating location.

Results: After playing 3D video games, the participants in the treatment group showed a significant improvement of 33.5% in stereoacuity (paired t=3.63, p=0.004), but not in contrast sensitivity (two-way repeated measures ANOVA, F=0.18, p=0.95). Note that in the 2DVG control group, we did not observe any significant change in stereoacuity after the intervention (paired t=0.10, p=0.92).

Conclusions: Stereoscopic 3D video game play boosts stereoacuity, but not contrast sensitivity. These findings indicate that the neural alterations for enhanced depth perception might have occurred beyond the early stage of visual processing for contrast perception. Notably, our most recent experiments (Li et al 2018) have shown that these types of video games might have a special benefit for triggering the plasticity of stereo vision in patients with amblyopia.

Commercial Relationships Disclosure: Richard Sather III: Commercial Relationship: Code N (No Commercial Relationship) | Tahsin Khundkar: Commercial Relationship: Code N (No Commercial Relationship) | Jacqueline Ihinger: Commercial Relationship: Code N (No Commercial Relationship) | Erik Van Kuijk: Commercial Relationship: Code N (No Commercial Relationship) | sandra montezuma: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Genetic factors have a major influence on variable expressivity in gene-phenotype relationships. This study aims to identify potential pathogenic gene variants in patients diagnosed with syndromic and non-syndromic retinitis pigmentosa (RP). A genotype-phenotype correlation is important as there are current and future therapies catered to the genetic inheritance and physical expression for this disease.

Methods: This retrospective series identifies patients with RP who had genetic testing using next generation sequencing panel at the UMN. A database was created to record history and examination, genetic report, and diagnostic imaging. Causative pathogenic genes were recorded. Patient disease status was further characterized by ocular coherence tomography (OCT) and fundus autofluorescence (AF).

Results: 200 patients were included consisting of 154 non-syndromic and 46 syndromic RP. Results were only recorded if stated in the patient's chart. 42.8% of patients first noted eye symptoms before the age of 10. 56.6% had a family history of retinal dystrophy. Presenting symptoms included 85.4% with nyctalopia, 60.2% with photosensitivity/hemeralopia, and 54.7% with decreased color vision measured by the Ishihara's test. On average, 38.5% had visual acuity worse than 20/80. 92.4% had evidence of visual field loss. Ellipsoid zone width on the fovea OCT scan of less than 1500 μm was noted in 73.8%. Approximately 99.0% presented with Fundus AF findings of either macula hypo/hyper AF ring and/or peripheral hypo-AF. The genetic report analysis showed the largest contributed RP genetic finding was VUS at 68.7%. The top identifiable pathogenic variants included USH2A (14.3%), RPGR (7.5%), MYO7A (6.8%), EYS (4.1%), and RP1 (3.4%). 11 patients had X-linked RP, all with RPGR mutation. 13 patients had autosomal dominant RP, including 5 with RP1 mutation and a family of 4 patients with PRPH2 mutation.

Conclusions: The results demonstrated that patients within the UMN are often evaluated for their RP in advanced disease independent of the genetic result. VUS comprised most of the genetic findings. This suggests the need to find either a more encompassing genetic analysis to account for the numerous RP genes and the diversity of our patients or promote testing for other affected RP family members to determine if the VUS is pathogenic.

TITLE: The Affects of Distortion

SESSION TITLE: Visual Function: perception, adaptation, spatial, visual acuity and binocular vision

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Cui, P.J. Bex, Psychology, Northeastern University College of Science, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Bliss Cui: Commercial Relationship: Code N (No Commercial Relationship) | Peter Bex: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Affect and face identification are critical activities of daily living that may be impaired by blur or distortions caused by vision loss and in disorders such as autism, prosopagnosia, and prosopometamorphopsia. Distortions alter the spatial relationships among facial features, disrupting configural information. To examine configural information in face processing, we measure how the spatial scale and amplitude of distortions influence the identification of affect and identity.

Methods: Bandpass filtered noise (Fpeak@1-32 cycles/face) was used to generate pixel shifts to distort faces from the IASLab database. The amplitude of distortion was varied using an adaptive staircase. 8 normally-sighted subjects were given unlimited time to identify which of 4 distorted faces (within 6.5°x9.8°ellipses in a 2x2 grid) matched a word representing 1 of 8 universal emotions: sad, excited, happy, fear, calm, anger, or disgust (affect task) or matched the identity of an undistorted face (ID task). Image cues were removed from each face by equalizing the luminance distribution and chrominance to the average face.

Results: Repeated measures ANOVA showed that observers could tolerate significantly more distortion for face rather than affect identification ($F_{1,35}$=13.3;p=.0083). There was a significant effect of distortion spatial scale ($F_{5,35}$ =6.6;p=.0002) and face inversion ($F_{1,35}$=14.0;p=.0073) on affect identification, with no interaction between these factors ($F_{5,35}$=1.4;p=.2504). There was a significant interaction between distortion scale and inversion for face identification ($F_{5,35}$=4.5;p=.003) such that distortions at coarse and fine scales mediated a face inversion effect, but not when distortions were applied at the middle critical scales (4-16 cycles/face).

Conclusions: These results suggest that the face inversion effect for distortion is present in both affect and face identification, while differences in their spatial tuning imply differences in how our brains process the identity of the face compared to its emotion. This may inform future studies with vision-loss patients and neurodivergent individuals to better understand the impact of their disorder on facial identification and emotion recognition and differentiate potential sites of face processing impairment.

ABSTRACT BODY:

Purpose: Epidemiological studies have found that males with diabetes have a higher incidence of diabetic retinopathy (DR) and higher risk for progression of DR than females. However, there have been limited investigations on vascular manifestations of sex-based differences in DR. We performed a retrospective case-control study using optical coherence tomography angiography (OCTA) to investigate microvascular differences between males and females with diabetes without DR or with mild non-proliferative diabetic retinopathy (NPDR).

Methods: We obtained 3x3mm macular OCTA scans of participants with diabetes without DR or with mild NPDR without other ocular comorbidities or prior DR treatments. Images with significant motion or shadow artifact or signal strength index (SSI) of <8 were excluded. One eye per patient was included in the analysis. Superficial capillary plexus (SCP) and deep capillary plexus (DCP) parameters were analyzed to include parafoveal vessel density (VD), vessel length density (VLD)— a skeletonization of the VD to remove disproportionate influence of large vessels on VD—, and flow index (FI). Multivariable linear regression was used to adjust estimates for potential confounders of age, race, SSI, hypertension, duration of disease, and HbgA1c.

Results: 1548 participants with diabetes without DR and 332 participants with mild NPDR were included in the study with 50.7% male participants. In the multivariable analysis, male sex was associated with lower VD ($P < 0.01$, $\beta = -0.004$), lower VLD ($P < 0.01$, $\beta = -0.196$), and higher flow index ($P < 0.001$, $\beta = -0.013$) in the SCP and lower VD ($P < 0.001$, $\beta = -1.348$) and lower VLD ($P < 0.001$, $\beta = -0.413$) in the DCP.

Conclusions: In a large diabetic population with no or mild DR, OCTA demonstrated a significant association between male sex and multiple reduced vascular parameters. These findings suggest that diabetic males may exhibit more advanced microvascular alterations than females, with implications for further sex-based studies to better understand DR.

ABSTRACT BODY:

Purpose: To characterize the pathogenesis of inflammation in rhegmatogenous retinal detachments (RRD) based on duration, and to elucidate inflammatory mediators that may contribute to the development of proliferative vitreoretinopathy (PVR). We report the cytokine profile of patients with RRD ≤2 weeks (acute) and >2 weeks (chronic) and compare them against surgical controls in an observational, case-control study.

Methods: Vitreous humor specimens were collected from 40 patients undergoing pars plana vitrectomy for RRD and noninflammatory vitreoretinal diseases, which served as controls. Quantitative immunoassay was used to measure the levels of 36 cytokine markers on the collected vitreous specimens. We conducted linear regression analyses with duration of detachment symptoms as the predictor and log-transformed cytokine levels as the outcome. The analysis was adjusted for age, sex, and race.

Results: Twenty-seven patients had RRD and 13 were control subjects. We observe significantly elevated levels of monocyte chemoattractant protein-4 (MCP-4) ($p=0.0058$) and basic fibroblast growth factor (bFGF) ($p=0.0007$) between patients with acute RRDs (n=16), chronic RRDs (n=11), and controls. Both cytokines were also significantly elevated (bFGF $p=0.0029$, MCP-4 $p=0.0245$) compared to controls when combining the acute and chronic groups. Additionally, IL-7 was found to be significantly elevated as RRD duration increased from acute to chronic ($p=0.0041$) but was not significant when the acute and chronic groups were combined compared to controls ($p=0.3469$).

Conclusions: MCP-4 and bFGF levels show significant stepwise upregulation as the duration of RRDs increases. While elevated levels of both cytokines have been previously reported, the impact of duration of detachment on its upregulation is unique. The novel increase in IL-7 only from acute to chronic indicates that it may play a role as a late inflammatory marker. Cumulatively, these findings aid in understanding the impact of inflammatory cytokines on RRD and development of complications related to prolonged duration of detachment, such as PVR. This may ultimately serve to identify potential therapeutic targets.

TITLE: Biometric Characteristics of Eyes with a History of Scleral Buckle Surgery
SESSION TITLE: Cataract surgery 1
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: N. Devireddy, E.V. Karakoleva, D. Rosen, N. Cannon, S. Pantanelli, Department of Ophthalmology, Penn State College of Medicine, Hershey, Pennsylvania, UNITED STATES|
Commercial Relationships Disclosure: Nitya Devireddy: Commercial Relationship: Code N (No Commercial Relationship) | Ema Karakoleva: Commercial Relationship: Code N (No Commercial Relationship) | David Rosen: Commercial Relationship: Code N (No Commercial Relationship) | Nathan Cannon: Commercial Relationship: Code N (No Commercial Relationship) | Seth Pantanelli: Commercial Relationship(s);Code F (Financial Support):Alcon, Carl Zeiss Meditec, Ocular Therapeutix, Ziemer;Code R (Recipient):Alcon, Carl Zeiss Meditec;Code C (Consultant/Contractor):Bausch and Lomb, Carl Zeiss Meditec

ABSTRACT BODY:

Purpose: The purpose of this study is to investigate biometric changes after scleral buckle (SB) surgery. This is especially important in the age of artificial intelligence IOL power calculation formulas, which depend upon predictable relationships between axial length (AL), anterior chamber depth (ACD), and post-operative effective lens position.
Methods: This is a retrospective, single-center chart review of eyes that had measurements obtained with a swept-source OCT-based optical biometer (IOLMaster 700, Carl Zeiss Meditec) in anticipation of cataract surgery between February 2020 and May 2021. Chart review was conducted to associate the exported biometric data with clinical variables. Eyes with a history of SB at the time of biometry were included in the study as part of the SB group. These eyes were compared to a control group with no history of SB and to contralateral eyes from the same patient that did not have SB. Eyes with any intraocular media opacity other than cataract, abnormal corneal findings, anterior segment pathologies, history of intraocular or corneal surgery [except SB, pars plana vitrectomy, or retinal detachment surgeries], or poor quality biometry measurements as determined by the device's internal image quality metrics were excluded from the study.
Results: There were 7 eyes included in the SB group and 284 eyes in the surgery naive control group. The mean AL in SB and surgery naive eyes was 27.13 ± 2.66 and 23.88 ± 1.21, respectively (p = 0.0029). The mean ACD in SB and surgery naive eyes was 3.444 ± 0.244 and 3.199 ± 0.420, respectively (p = 0.04). The mean ACD/AL ratio in SB and surgery naive eyes was 0.128 ± 0.013 and 0.134 ± 0.016, respectively (p = 0.34).

Of the 7 SB eyes, biometric data was available for 5 contralateral eyes from the same patient. The mean AL of the SB and contralateral eyes was 26.76 ± 3.16 and 25.28 ± 2.06, respectively (p = 0.23). The mean ACD of the SB and contralateral eyes was 3.322 ± 0.157 and 3.505 ± 0.213, respectively (p = 0.08). The mean ACD/AL ratio in SB and contralateral eyes was 0.125 ± 0.015 and 0.139 ± 0.013, respectively (p = 0.13)
Conclusions: Eyes with SB have a longer AL and deeper ACD than surgery naive eyes. However, there was a trend toward shallower ACD in SB eyes when compared with contralateral surgery naive eyes from the same patient. Additional eyes with a history of SB are needed to further explore the unique biometric properties of this group.

ABSTRACT BODY:

Purpose: Intravitreal injection treatment is the standard of care for numerous retinovascular diseases such as diabetic macular edema (DME) and exudative age-related macular degeneration (AMD). Lack of adherence or undertreatment with respect to evidence from clinical trials remains a significant barrier to optimizing real-world outcomes for patients. Contributing factors and strategies to address this are poorly understood. We wish to identify compliance issues with intravitreal anti-VEGF injections treatment.

Methods: A patient survey analysis from multiple retina centers in Abu Dhabi and Dubai, United Arab Emirates. Included were patients receiving intravitreal anti-VEGF injections for AMD or DME willing to participate in the survey. Exclusion was inability to participate in the survey. The 20-minutes question interview (22 questions) took place in the clinic. Proportions for the whole patient group as well as for AMD and DME groups were calculated.

Results: The study included 78 patients (females 32%, males 68%) with average age of 57 years. There were 52 patients with DME and 26 patients with AMD. More than 40% of patients had >7 doctor visits in the last year (46% for AMD patients and 40% for DME patients). More than 50% went to “1 specialist” ever since diagnosed followed by “2-3 specialists” for 35% of patients. Lack of clarity, inconvenience, change of job location and doctor trust were reasons for seeking >3 specialists. Vision improvement was the highest factor for treatment discontinuation followed by visit frequency and costs. Patients regarded treatment visits as “Extremely important” especially AMD patients (65%). 45% of patients never missed a visit, particularly AMD patients (54%). Inconvenient timing was the most significant factor for missing visits followed by fear of treatment. Patients regard the clinic location as “Extremely convenient” especially AMD patients (46%). Physician reputation accounts for 65% of reasons for patients’ clinic choice followed by insurance plan and clinic location.

Conclusions: Vision improvement was the highest factor for treatment discontinuation followed by frequent visits and costs. Inconvenient timing was the most significant factor for missing treatment visits followed by fear of treatment. Physician reputation was a significant reason for patients’ clinic choice followed by insurance plan and clinic location.

TITLE: Evaluation of alternative approaches to establishing a standardized laser flare photometry value for patients with uveitis

SESSION TITLE: Clinical Uveitis & Orbital Inflammation: Etiology, Epidemiology & Clinical Assessment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Tsui, J.L. Chen, G.N. Holland, Ophthalmology, Jules Stein Eye Institute, Los Angeles, California, UNITED STATES|N.J. Jackson, Medicine, University of California Los Angeles David Geffen School of Medicine, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Edmund Tsui: Commercial Relationship(s);Code C (Consultant/Contractor):Kowa;Code F (Financial Support):Cylite | Nicholas Jackson: Commercial Relationship: Code N (No Commercial Relationship) | Judy Chen: Commercial Relationship: Code N (No Commercial Relationship) | Gary Holland: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Laser flare photometry (LFP) provides prognostic information about patients with uveitis. The current standard approach for establishing final LFP values is to record the mean of 7 LFP measurements after removal of the highest and lowest measurements. We investigated alternative techniques for establishing a final value, in an attempt to identify a simpler approach to achieve the same standard.

Methods: In a prospective study, LFP was performed on 200 eyes (100 patients with uveitis) using both Kowa FM-500 and FM-700 Laser Flare Photometers. A total of 7 measurements were obtained on each eye. We compared results between devices using 8 statistical methods: (1) all raw data; (2) mean of raw data; (3) mean after removal of highest and lowest values; (4) median of raw data; (5) median absolute deviation (MAD) outlier detection with mean (high threshold of 2.24); (6) MAD outlier detection with mean (low threshold of 1.28); (7) boxplot outlier detection (Carling method) with mean; and (8) boxplot outlier detection (Tukey method) with mean. To simulate fewer LFP measurements, analyses were repeated on the first 5 of 7 values. Intraclass correlation coefficient (ICC) was used to compare results. We also compared final values from different techniques on a per-eye basis. ICC of 0.75-0.90 were considered good.

Results: Mean age of participants was 49.5±19.1 years; 72% were female. Using all 7 LFP measurements, ICC for comparison of the two devices did not vary substantially between techniques; ICC were as follows: (1) all raw data, 0.58; (2) mean of raw data, 0.80; (3) mean after removal of highest and lowest values, 0.81; (4) median of raw data, 0.81; (5) MAD outlier detection with mean (high threshold of 2.24), 0.77; (6) MAD outlier detection with mean (low threshold of 1.28), 0.77; (7) boxplot outlier detection (Carling method) with mean, 0.78; and (8) boxplot outlier detection (Tukey method) with mean, 0.78. ICC using first 5 measurements were similar to those using 7 measurements (range 0.58-0.81).

Conclusions: All statistical methods demonstrated similar results between two devices and final values for alternative techniques were similar to those obtained from the current standard approach. Our study suggests that obtaining fewer LFP measurements and using simpler techniques for calculating final LFP values may be suitable for use in patient care and clinical research.

TITLE: Defining the role of swept source anterior segment optical coherence tomography in strabismic eyes
SESSION TITLE: Pediatric ophthalmology and imaging
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: A. Pujari, Ophthalmology, All India Institute of Medical Sciences, New Delhi, Delhi, INDIA|
Commercial Relationships Disclosure: Amar Pujari: Commercial Relationship: Code N (No Commercial Relationship)
ABSTRACT BODY:
Purpose: Purpose: To explore the clinical role of swept source anterior segment optical coherence tomography (SS-ASOCT, CASIA-2, Tomey corp, Nagoya, Japan) in extra ocular muscle imaging under various strabismic conditions.
Methods: Study design: Prospective observational study.

Participants: A total of 1104 extraocular muscles of 150 subjects were imaged. Normal eyes (80 subjects, 640 muscles), eyes undergoing re-operation (30 subjects, 240 muscles), paralytic (4 subjects, 16 muscles) and non-paralytic strabismic eyes (10 subjects, 20 muscles), post-traumatic strabismic eyes (8 subjects, 64 muscles), eyes with thyroid disease (8 subjects, 64 muscles), and other atypical cases (10 subjects, 60 muscles) where extra ocular muscle location was necessary (eyes with rectus muscle hypoplasia or aplasia, eyes with anterior staphyloma, eyes with operated scleral fixated intra ocular lens) were evaluated. In all cases up to four recti muscles were imaged in each eye depending on the need.
Results: Results: Overall, the muscle insertion was comfortably identified in 95% of the subjects, where up to 14 millimetres of the anterior (cross sectional) muscle was studied. The location and prediction on the nature of surgery helped in surgical re-planning in over 90% of the cases. Amongst the four recti, identification of lateral rectus was easy and the medial rectus was technically difficult. Nevertheless, the correlation scanning between vertical and horizontal axis helped in achieving better results than the isolated scanning.
Conclusions: Conclusions: SS-ASOCT with its wider and deeper scanning abilities is able to locate the extra ocular muscles locally. Therefore, this tool can reliably be used for muscle imaging in normal eyes, simple/complex strabismic eyes undergoing routine surgery, surgical planning in re-operations and other technically challenging scenarios where pre-operative muscle localization is necessary.

ABSTRACT BODY:

Purpose: The aim of this study is to establish the reliability of quantitative autofluorescence (qAF) in a multicenter setting in order to validate qAF as an endpoint for interventional clinical trials in Stargardt disease (STGD1).

Methods: A total of 104 STGD1 patients (208 eyes) underwent qAF imaging at two visits (screening and baseline, mean interval 20 ± 13 days), with two qAF recordings per visit, as part of the Stargardt Remofuscin Treatment Trial (EudraCT No. 2018-001496-20) and according to standardized image acquisition protocol including operator training and certification. qAF_8 values were determined by calculating the mean qAF values within the 8 middle segments of the Delori pattern. Eyes were independently graded by the concerned study site and the central reading center. Intra- and inter-visit as well as interobserver (study site versus reading center) reproducibility of qAF_8 levels were obtained using intraclass correlation (ICC) and coefficient of repeatability (CR) based on the method of Bland-Altman.

Results: At the first visit, there were significant differences in qAF_8 values between the six study sites ($p<0.001$). Overall, the mean qAF_8 value at baseline, 463.55±107.81 units, was not significantly different from the value at screening in the same patients, 467.63±108.53 units ($p=0.753$). qAF_8 reproducibility was ± 26.1% for intra-visit, ± 40.3% for inter-visit, and ± 21.6% for the interobserver reproducibility. Intra-visit and interobserver reliability of qAF_8 was good to excellent for all sites (ICC of 0.84-0.99). However, we observed a significant difference of 8.80 ± 56.18 qAF_8 units between both movies acquired on the same day and 17.49 ± 48.60 between observers ($p=0.007$ and $p<0.001$). Variability between visits was higher with ICC of 0.43-0.83, but there was no significant difference in the

qAF_8 units measured at screening and baseline (p=0.210).

Conclusions: Real-life test-retest variability of qAF is higher in the multicenter setting than previously reported in single center studies. Possible explanations include the demanding imaging protocol, operator variability and differences in patient characteristics. qAF is a successful tool to diagnose STGD1. However, when using qAF as clinical trial endpoint, increased variability must be considered, and larger sample sizes may be required to demonstrate treatment effects.

TITLE: Eye position recording after surgery for large-angle exotropia in adults with deep amblyopia
SESSION TITLE: Strabismus
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: J. Tejedor, Ophthalmology, Hospital Universitario Ramon y Cajal, Madrid, Madrid, SPAIN|J. Tejedor, Neuroscience, Universidad Autonoma de Madrid, Madrid, Madrid, SPAIN|F. Gutiérrez-Carmona, Surgery, Universidad Alfonso X el Sabio, Villanueva de la Canada, Comunidad de Madrid, SPAIN|
Commercial Relationships Disclosure: Jaime Tejedor: Commercial Relationship: Code N (No Commercial Relationship) | Francisco J Gutiérrez-Carmona: Commercial Relationship: Code N (No Commercial Relationship)
ABSTRACT BODY:
Purpose: To study change and variability of deviation in operated adult exotropes with deep amblyopia who do not cooperate in cover tests.
Methods: In adult patients (age range: 24-54) who underwent surgery for large angle exotropia (>-40 PD; range: -40 - -60 PD), requiring three-muscle surgery, with deep amblyopia (visual acuity in the amblyopic eye < 0.7 logMAR or 20/100), with or without distance-near disparity, but uncooperative for cover tests, eye movements were recorded 2 months after surgery, using Tobii X120 during near (60 cm) and distance (4 m) fixation. Visual acuity, refraction, ductions, versions, anterior and posterior segment of the eyes, were also examined. Control participants were unoperated age-matched subjects (age range: 26-52).
Results: Ten patients were included in the surgery group and 12 in the control group. Two patients in the surgery group had variable distance angles (range: 0 - -10°) with orthotropia at near, one had variable angle at distance (range: -4° - -12°) and near (range: 0 - -10°), and 7 were orthotropic and stable at distance and near. Peak velocity at 15° eccentricity saccade was slightly lower and latency was larger in the amblyopic compared with the sound eye and eyes of controls in saccades (250°/s vs 305°/s and 296°/s, respectively, p=0.04; 230 ms vs 210 and 205 ms, respectively, p=0.06), whereas pursuit eye movements showed small nonsignificant differences or were difficult to record.
Conclusions: Adult patients with deep amblyopia who undergo surgery for large-angle exotropia have a relatively high likelihood of postoperative variable angle exodeviation, particularly at distance (20-33%).

TITLE: The m6A writer METTL14 is essential for visual function and retinal photoreceptor survival

SESSION TITLE: Photoreceptor Biology, Protection and Degeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Yang, X. Zhu, Medical school, University of Electronic Science and Technology of China, Chengdu, CHINA|

Commercial Relationships Disclosure: Yeming Yang: Commercial Relationship: Code N (No Commercial Relationship) | Xianjun Zhu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: As the most abundant epigenetic modification of eukaryotic mRNA, N6-methyladenosine (m6A) modification has been shown to play a role in mammalian nervous system development and function by regulating mRNA synthesis and degeneration. However, the role of m6A modification in retinal photoreceptors remains unknown.

Methods: We generated the first retina-specific Mettl14-knockout mouse models using the Rho-Cre and HRGP-Cre lines and investigated the functions of Mettl14 in retinal rod and cone photoreceptors. meRIP-seq was employed to explore the underlying pathological mechanism.

Results: Our data showed that loss of Mettl14 in rod cells causes a weakened scotopic photoresponse and rod degeneration. Further study revealed the ectopic accumulation of multiple outer segment (OS) proteins in the inner segment (IS). Deficiency of Mettl14 in cone cells led to the mislocalization of cone opsin proteins and the progressive death of cone cells. Moreover, Mettl14 depletion resulted in drastic decreases in METTL3/WTAP levels and reduced m6A methylation levels. Mechanistically, transcriptomic analyses in combination with MeRIP-seq illustrated that m6A depletion via inactivation of Mettl14 resulted in reduced expression levels of multiple phototransduction- and cilium-associated genes, which subsequently led to compromised ciliogenesis and impaired synthesis and transport of OS-residing proteins in rod cells.

Conclusions: Our data demonstrate that Mettl14 plays an important role in regulating phototransduction and ciliogenesis events and is essential for photoreceptor function and survival.

ABSTRACT BODY:

Purpose: To examine the impact of physician face mask use on the rates and outcomes of postinjection endophthalmitis.

Methods: Design: Retrospective, comparative cohort study. Setting: Multi-center. Study population: Eyes that received intravitreal anti-VEGF injections from January 1, 2005 to January 31, 2020 at Mayo Clinic Rochester (MCR) and at Mayo Clinic Health System (MCHS) sites. Intervention: Cases were divided into the “No Mask” versus “Mask” group depending on whether the ophthalmologist performing the injection wore a mask. Main outcome measures: Rate of endophthalmitis, microbial spectrum, and visual acuity.

Results: 164,824 total injections were performed at MCR and MCHS sites. Of these, 66,098 injections were in the No Mask group and 98,726 injections were in the Mask group. Overall, there were no significant differences in the rates of infectious endophthalmitis in the No Mask vs. Mask cohorts (overall: 0.030% vs. 0.042%; P=0.24; infectious: 0.018% vs. 0.013%; P=0.42). At MCR alone, there was a significant reduction in the infectious endophthalmitis rate between the No Mask vs. Mask groups (0.030% vs. 0.003%; P<0.001). Only 2 cases of infectious endophthalmitis occurred in MCR after the face mask policy was first implemented (1 in 30,000 injections). At presentation and at 6 months, average visual acuity was similar for both groups.

Conclusions: Overall, physician face mask use did not impact the rate or visual outcome of postinjection endophthalmitis. However, there was a significant reduction at MCR after implementation of masks and other quality improvement measures that has led to a low rate of postinjection endophthalmitis.

ABSTRACT BODY:

Purpose: Analysis of preoperative optical coherence tomography (OCT) in patients with macular hole (MH) can provide insight into surgical success and postoperative visual acuity (VA). The aim of this study was to assess the feasibility of deep learning (DL) methods to improve the prediction of VA improvement after MH surgery from a combined model using DL on high-definition (HD) OCT B-scans and clinical features.

Methods: This was a retrospective single-center study (CHU de Québec – Université Laval (Canada)). A DL convolutional neural network (CNN) trained using preoperative HD-OCT B-scans (ZEISS, Dublin, CA) of the macula and combined with a logistic regression model of preoperative clinical features was designed to predict VA increase ≥15 Early Treatment of Diabetic Retinopathy Study letters at 6 months post-vitrectomy in closed MH. A total of 121 MH with 242 HD-OCT B-scans and 484 clinical data points were used to train, validate and test the model. These were randomly split into a training set of 83 eyes (69%), a validation set of 21 eyes (17%), and a held-out test set of 17 eyes (14%). Prediction of VA increase was evaluated using the area under the receiver operating characteristic curve (AUROC) and F1 scores. We also extracted the weight of each input feature in the regression-based hybrid model.

Results: All performances are reported on the held-out test set. Using a regression on clinical features, the AUROC was 80.63, with a F1 score of 79.71. For the CNN, relying solely on the HD-OCT B-scans, the AUROC was 72.83 ± 14.57, with a F1 score of 61.47 ± 23.72. For our hybrid regression model using clinical features and CNN prediction, the AUROC was 81.94 ± 5.22, with a F1 score of 80.35 ± 7.68. In the hybrid model, the baseline VA was the most important feature (59.11 ± 6.94% of the model's weight) while HD-OCT prediction was 9.59 ± 4.17%.

Conclusions: Both the clinical data and HD-OCT models had good discriminative performances. Combining both into a hybrid model did not significantly improve performance.

ABSTRACT BODY:

Purpose: The retinal pigmented epithelium (RPE) is a monolayer of post-mitotic, polarized and highly specialized pigmented cells at the back of the eye. An important and evolutionarily conserved role of the RPE is the absorption of stray light to increase visual acuity and reduce oxidative damage. This activity requires functional melanosomes, which contain enzymes that catalyze the production of melanin. Defective melanosome formation (melanogenesis) causes hypopigmented RPE, leading to RPE cell loss and decline in retinal function. It is known that mTOR plays a key role both in RPE function as well as melanogenesis. We speculated that activation of mTOR specifically in RPE cells by overexpressing mLST8, an important component of both mTOR complexes 1 and 2 (mTORC1 and 2), would have deleterious effects on melanosome formation, resulting in oxidative stress.

Methods: We have generated Best1 (mLST8) constitutive knock-in (KI) mice as a tool for this study. We performed transmission electron microscopy, hematoxylin-eosin (H&E) staining on RPE sections and electroretinography (ERG) on 3- and 9-month-old WT and mLST8 KI mice. Western blot analysis was performed on RPE explants from WT and mLST8 KI mice to evaluate autophagy flux. Expressions of mTORC1 and mTORC2 downstream components, melanosome marker, tyrosinase, and oxidative stress markers, CAT and SOD1 were also determined by western blot.

Results: Our results revealed the presence of abnormal melanosomes, as evident from their marked depigmentation and fragmentation, in the mLST8 KI RPE. H&E staining revealed noticeable hypopigmented patches in the RPE layer along with patchy loss of RPE. ERG analysis also showed a decline in retinal function in mLST8 KI mice, compared to age-matched controls. Western blot analysis indicated reduced autophagy flux, increased expressions (phosphorylation) of mTORC1 and 2 substrates, S6K and Akt2, and oxidative stress markers, SOD1 and CAT, along with decreased expression of tyrosinase in the mLST8 KI RPE, relative to WT. Interestingly, treatment with Torin (mTOR inhibitor) rescued the alterations in phospho- S6K and Akt2, SOD1, CAT and tyrosinase levels in mLST8 KI RPE explants.

Conclusions: Our results suggest that mLST8 overexpression activated both mTORC1 and 2 thereby triggering defects in melanosome formation and leading to oxidative stress in RPE cells.

ABSTRACT BODY:

Purpose: To calculate and compare the average interval between injections of Aflibercept (AFL), Bevacizumab (BEVA), Brolucizumab-Dbll (BROL), and Ranibizumab (RAN) for patients with wet age-related macular degeneration (wAMD).

Methods: All data was collected by the practice management of Retina Associates of Cleveland, Inc. Data was collected from patients who received injections of AFL, BEVA, BROL, and RAN from July 2020 through July 2021 and includes: patient number, injection service dates, injection service ID's, procedure codes, and primary diagnosis. The patients selected were those injected unilaterally and diagnosed with wAMD, and the number of days between injection service dates was calculated for each patient. The data set was then organized by injection type, and the average number of days between injection service dates was determined for each drug. Statistical analysis was performed using a two-tailed t-test to compare the medications.

Results: From July 2020 through July 2021, 10,789 wAMD injections were performed unilaterally with a total average interval between injections of 55 days for all drug types. Within the wAMD patient group, the average injection interval for each medication was as follows: 57 days for BEVA with standard deviation (SD) +/- 33 days, 54 days for BROL SD +/- 23 days, 54 days for AFL SD +/- 29 days, and 56 days for RAN SD +/- 25 days. When comparing the interval of each medication, the two-tailed t-tests calculated a p-value of $p = 0.0003$ for BEVA vs AFL, $p = 0.39$ BEVA vs. RAN, $p = 0.0096$ BEVA vs BROL; $p = 0.003$ AFL vs RAN, $p = 0.99$ AFL vs BROL; $p = 0.05$ BROL vs RAN.

Conclusions: The results of the study suggest that BEVA seems to have a longer interval of time between injections for wAMD patients than BROL and AFL, but not RAN. There does not appear to be a difference between average injection intervals of BROL and AFL.

ABSTRACT BODY:

Purpose: To employ a flow cytometry gating strategy to investigate blood-based monocyte biomarkers of early-intermediate age-related macular degeneration (AMD) and determine the relationship between monocytes and disease stage on flow cytometry and immunohistochemistry (IHC).

Methods: We recruited 30 study participants: 9 with early AMD (eAMD; category 2 AREDS), 11 with intermediate AMD (iAMD; category 3 AREDS), and 10 normal controls. Samples were matched by age (+/-5 years) and gender. Peripheral blood mononuclear cells (PBMCs) were isolated from whole blood samples and then stained with CD45, CD14, CD16, CD163, CD11a, and CD11b antibodies. We used a flow cytometry gating strategy to identify PBMC subsets (classical, intermediate, and non-classical). In parallel, we performed co-localization IHC studies of CD163+ and CD68+ macrophages in the macula of postmortem eyes with iAMD (stage Sarks 4; N=7) and normal control eyes (stage Sarks 1; N=7).

Results: On flow cytometry, the proportion of CD68+ cells was lowest in the PBMCs from iAMD participants (52.3% vs eAMD 77.7% and normal 60.9%), and there was a significant difference between the early and iAMD groups ($p<0.05$). iAMD samples demonstrated the highest percentage of CD163+ cells (8.7% vs eAMD 2.3%, normal 5.3%; $p= 0.54$) and nonclassical monocytes (5.9% vs eAMD 4.5%, normal 4.4%; $p= 0.62$), although the results did not reach significance. Within CD68+ and CD163+ cells, there were no significant differences between groups with respect to PBMC subsets. However, we found a moderate correlation between CD163-high cells and the intermediate PBMC subset ($r^2= 0.35$).

The quantitative IHC analysis showed a decreased expression of CD163 in the macrophages in the choroid and inner retina of iAMD Sarks 4 postmortem eyes and an increased CD163 expression in the outer retina as compared to normal Sarks 1 eyes (all $p<0.05$). No significant differences in CD68 expression were observed between the iAMD Sarks 4 and normal Sarks 1 groups.

Conclusions: Our data suggest that CD163+ monocytes/macrophages are associated with disease stage in early-intermediate AMD, implicating these cells in the pathobiology and progression of AMD. CD163 may represent a useful clinical blood-based biomarker of disease progression on flow cytometry analysis.

ABSTRACT BODY:

Purpose: Vision loss from age-related macular degeneration (AMD) is an expanding, major unmet problem due to the aging population worldwide. Retinal pigmented epithelium (RPE) cells are the first to be affected in the dry form of AMD. Phagocytosis and autophagy, two major functions of the RPE, require functional lysosomes. We have previously shown that in the Cryba1 cKO mouse model (lacks Cryba1 gene, which encodes for βA3/A1-crystallin, only in the RPE), there are alterations in TFEB nuclear activity, lysosomal function and autophagy in the RPE. This is accompanied by increased expression of Akt2, mTORC1 activation and an early/dry AMD-like pathology that develops with age. mTORC1 is a critical regulator of TFEB and lysosomal biogenesis in cells. Since targeting mTOR is known to have damaging side-effects, we speculate that inhibiting Akt2, a mTOR-independent regulator of TFEB, with trehalose (a disaccharide Akt inhibitor) might rejuvenate lysosomal function and alleviate the early RPE changes in this mouse model.

Methods: We have generated Best1-Akt2 constitutive knock-in (KI) and Akt2 conditional knockout (cKO) mice as tools to be used in this study. Autophagy flux was estimated in RPE explants from WT, Cryba1 KO (complete knockout), Akt2 KI and Akt2 cKO mice with or without Trehalose (100 mM). In vivo studies to evaluate coordinated lysosomal expression and regulation (CLEAR) network gene expression along with p62/SQSTM1 expression in the RPE, retinal function (electroretinography) and changes in retinal structure were performed on 5 month old Cryba1 cKO mice with or without Trehalose treatment (1 mg/g/day intraperitoneally injected once a day for 2 days, then 2% in the drinking water for 2 months).

Results: We found increased expression of pAkt2 and diminished autophagy flux in RPE cells from Akt2 KI and Cryba1 KO mice relative to controls, but not in Akt2 cKO cells. Trehalose treatment rescued changes in autophagy flux in Cryba1 KO and Akt2 KI cells. Moreover, in vivo Trehalose treatment rescued lysosomal abnormalities, retinal function, and histological abnormalities in the Cryba1 cKO mice.

Conclusions: It can be concluded from our results that inhibiting Akt2-dependent TFEB activation rejuvenates lysosomal function in the RPE of a mouse model and could be employed as a therapeutic approach in treating dry AMD while avoiding the deleterious effects of mTOR inhibitors.

ABSTRACT BODY:
Purpose: To investigate how the function of ON and OFF visual pathways is affected by myopic refractive error, axial length, and eccentricity.
Methods: Eleven eyes of 11 human subjects (23-30 years old; mean 25.9 +/- 1.9) were tested at 8 Michelson contrast levels (5-20%) out to 30 degrees from fixation.

A single test comprised of 579 trials (27 catch trials), at 92 locations, repeated 3 times for both light and dark stimuli. Each participant completed eight tests (4,632 trials).

Hardware consisted of a head mounted display with an eye tracker (HTC VIVE embedded Tobii) with a refresh rate of 90 Hz, a maximum luminance of 110 cd/m2. Stimuli were light or dark squares on a spherical binary noise background. Stimulus size was increased as a function of eccentricity using a power law relationship.

Unity (version 2017) software was used to generate the stimuli. Eye movements were measured at 120 Hz and restricted within a central 2.5-degree radius circle. Percent of correct responses were measured across the entire visual field and, separately, for each of 6 annual eccentricities 5-10, 11-20, 21-30 degrees from fixation. Percent response errors were plotted as a function of refractive error and axial length for the entire 30 degrees and for each specific eccentricity.
Results: There was no statistically significant correlation between refractive error and percent response errors at any eccentricity or combined over the entire testing area (maximum r value = 0.4015, p = 0.064, between 21-30 degrees). There was a significant positive correlation between axial length and percent response errors across the entire testing area (r= 0.5198, p=0.0132). This was most pronounced at 21-30 eccentricity (r=0.583, p=0.0044). Overall, subjects responded more accurately for dark than light stimuli (14.38 ±8.11 versus 15.98 ± 8.59, p= 0.0127. This was most pronounced at 21-30 eccentricity (p=0.0049).
Conclusions: Decreased accuracy to ON-OFF perimetric stimuli in myopic patients is more closely correlated to axial length than refractive error.

ABSTRACT BODY:

Purpose: Although many studies demonstrate higher prevalence of primary open angle glaucoma (POAG) in those of African descent, no physiologic findings have been identified to explain these phenotypic differences. We tested the hypothesis that there are fundamental differences in mitochondrial function and antioxidant protection between self-reported African American (AA) and White (W) subjects in an in vitro model of trabecular meshwork (TM) from POAG patients and healthy donors (controls).

Methods: TM specimens collected from POAG patients undergoing glaucoma surgery were analyzed by RNA-sequencing (RNA-seq). Control donor and POAG TM tissues, divided by race, were cultured following standard methods and confirmed with specific cell markers. Intracellular reactive oxygen species (ROS) production was measured in live TM cells by CellROX^{TM} Orange after hydrogen peroxide (H_2O_2) challenge. Major antioxidant enzymes superoxide dismutase 2 (SOD2), catalase (CAT), and their transcriptional factor, nuclear factor erythroid 2-related factor 2 (NRF2), were measured at RNA (qPCR) and protein levels (Western blot). Select genes of interest from RNA-seq analysis were also evaluated with qPCR. Student T-Test and Tukey's multiple comparisons test were applied for data analysis.

Results: The most significant expression differences from RNA-seq data were identified in nuclear genes encoding protein components of mitochondrial Complex I, III and IV. POAG TM tissue from AA (n=3) demonstrated higher expression of these genes ($p<0.01$) vs. W (n=4). qPCR assessment of these genes in TM tissues from control donors (6AA, 6W) and POAG patient tissue (4AA, 5W) did not show any racial differential. For the primary cultured TM cells, ROS production in AA TM cells was significantly higher than W ($p=0.004$) following H_2O_2 challenge. qPCR showed NRF2 and SOD2 were significantly lower in AA than W ($p=0.02$, 0.04), with no difference in CAT. Western blot confirmed protein levels of NRF2 and SOD2 were significantly lower in AA TM cells than W ($p=0.003$, 0.04).

Conclusions: Fundamental differences in oxidative stress and antioxidant protection may be important risk factors for racial disparities in POAG risk and severity. The primary TM cell culture model derived from POAG patient tissue and healthy donor controls provides powerful tools to study distinct differences of TM function between AA and W.

TITLE: Clinical Outcomes of Endophthalmitis in Early and Late Presentation after Intravitreal Anti-VEGF Injection

SESSION TITLE: Endophthalmitis/ trauma/Intravitreal/periocular therapies

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: O.E. Uner, Casey Eye Institute, Department of Ophthalmology, Oregon Health & Science University, Portland, Oregon, UNITED STATES|D. Lee, C. Seebruck, Associates In Ophthalmology, Pittsburgh, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Ogul Uner: Commercial Relationship: Code N (No Commercial Relationship) | Diana Lee: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Seebruck: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Intravitreal anti-VEGF injections (IVI) are the most common in-office procedure for retinal diseases. Endophthalmitis is the most feared complication after IVI. Studies suggest that the time elapsed between the causative procedure and diagnosis of endophthalmitis may affect visual potential, but studies investigating timing specifically in the setting IVI are limited. We compared the clinical and microbiological outcomes of endophthalmitis in the setting of early and late presentation after IVI.

Methods: Endophthalmitis cases were identified using ICD-10 codes in 9 clinical practices between January 1, 2017 and October 31, 2021. Patients were defined as presenting early if the elapsed time between IVI and endophthalmitis diagnosis was less than 5 days. Those presenting 5 days or later were placed in the late presenting group. Relationships between elapsed time and visual acuity (VA, logMAR) at baseline, time of diagnosis, and follow-up were analyzed. Culture positivity rates and growth information were also compared between groups.

Results: Among 102,906 IVI, there were 70 (0.07%) cases of endophthalmitis. Forty-one (58.6%) cases presented early and 29 (41.4%) presented late, with median elapsed time (days) of 3 (range 1-4) and 7 (range 5-28). The groups were matched in age, sex, laterality, and baseline VA. The late group had more cases attributable to aflibercept, but this difference was not significant (26.8% in early vs. 48.3% in late, p=0.08). Mean VA at diagnosis was significantly worse for the late group (1.6 in early vs. 2.0 in late, p=0.02). Early and late groups were followed for 2.2 years and 2.1 years, respectively. Mean VA at follow-up was worse for the late group, but the difference was not significant (1.1 for early vs. 1.5 for late, p=0.2). Culture positivity rates were similar between groups (50.0% in early vs. 47.4% in late). Unlike the early group, few cultures in the late group grew gram-negative bacteria (2 cases) and Staphylococcus aureus (2 cases). These patients all had hand motion or worse vision at follow-up.

Conclusions: Compared to early presentation, late presentation for endophthalmitis after IVI is associated with significantly worse vision at time of diagnosis but there seems to be no significant difference in the long term. Though rare, bacteria with higher virulence may be implicated in late presentation and result in poor visual outcomes.

ABSTRACT BODY:

Purpose: The aim of this study is to determine whether the interval at which fellow eyes are monitored impacts the severity of disease at the time of their conversion in patients with unilateral neovascular age-related macular degeneration (nAMD).

Methods: Cross sectional study of patients with unilateral nAMD who subsequently developed nAMD in their fellow eyes between March 2015 to October 2020. Patients were divided into those who were actively receiving treatment in their first eye at the time of second eye conversion and compared with those who had stopped treatment because of reaching end-stages of the disease. Visit intervals, frequency of monitoring fellow eyes, visual acuity (VA), and central macular thickness (CMT) were abstract from the chart.

Results: At the time of fellow eye conversion, 54 patients (71%) were receiving injections in their first eye and 22 patients (29%) had stopped treatment because of having low vision. VA in the first eyes to develop nAMD in the active treatment group was significantly better compared with the VA in eyes that had ceased treatment by the time of their conversion (logMAR 0.587±0.375 vs. logMAR 1.14±0.531, P<0.001). By contrast, VA was similar both at the time of diagnosis of the first eye (logMAR 0.384±0.436 vs. logMAR 0.367±0.328, P=0.867) and conversion of the fellow eye to nAMD (logMAR 0.492±0.412 vs. logMAR 0.465±0.400, P=0.795). The fellow eyes of patients who were actively receiving injections were monitored much more closely compared with those patients who had stopped treatment. At the visit immediately before second eye conversion, patients who were in the active treatment group had completed their last visit an average of 8.1±5.3 weeks compared with 25.5±24.8 weeks for those patients who had stopped treatment (P=0.004). Finally, the average CMT was similar for the fellow eyes that converted to nAMD in both groups (277±51 µm vs. 265±39 µm, P=0.305).

Conclusions: Patients who stopped treatment for nAMD by the time that their fellow eye developed neovascularization were monitored less frequently compared with patients who continued on treatment for nAMD. This is surprising because a majority of these patients were functionally monocular, and therefore had more to lose from the conversion of their remaining eye. Reassuring, however, visual and structural outcomes were not tied to the interval at which the fellow eyes were being monitored.

ABSTRACT BODY:

Purpose: α-Synuclein (α-Syn) is implicated in Parkinson's disease (PD), a neuro-motor disorder with prominent ocular symptoms. Here, we explored whether α-Syn plays a functional role in the anterior segment of the eye, and whether its dysfunction due to aggregation contributes to ocular pathology.

Methods: Primary human trabecular meshwork (TM) cells, cadaveric human and bovine TM tissue and aqueous humor (AH), and human AH collected during cataract surgery were used for this study. Silencing of α-Syn and overexpression of TGFβ2 in TM cells and tissue was achieved by conventional techniques. Expression of fibronectin (FN), α-smooth muscle actin (α-SMA), and ROCK-1 was determined by Western blotting (WB). Binding, uptake, and response of TM cells to extracellular α-Syn was determined by immunostaining and WB.

Results: α-Syn was expressed in the ciliary body and TM, and monomeric and oligomeric α-Syn was present in the AH. Silencing of α-Syn in TM cells downregulated FN, α-SMA, and ROCK-1 expression in the absence and presence of active TGFβ2. Extracellular monomeric and oligomeric α-Syn was internalized by β1-integrin, and upregulated FN, α-SMA, and ROCK-1 in TM cells and TM tissue. Active TGFβ2 was also increased.

Conclusions: Intracellular α-Syn altered the expression of extracellular matrix (ECM) proteins in TM cells through ROCK-1 independently and downstream of TGFβ2, the principal trigger for dysregulation of ECM in primary open angle glaucoma (POAG). Extracellular α-Syn was endocytosed by TM cells through β1-integrin, and likewise, upregulated ECM proteins. These observations have significant implications for POAG, and warrant exploration of the underlying biochemical pathways.

ABSTRACT BODY:

Purpose: Leflunomide (LEF) is a disease-modifying anti-rheumatic drug (DMARD) approved for rheumatoid and psoriatic arthritis in patients over the age of 18. While off-label use has found it to be effective for treatment of childhood conditions such as juvenile idiopathic arthritis (JIA), there has been a lack of literature and good quality evidence on its efficacy in the treatment of noninfectious pediatric uveitis. The aim of this study is to describe the effectiveness of LEF as adjunctive therapy with anti-Tumor Necrosis Factor (anti-TNF) agents in pediatric patients with uveitis who are not able to tolerate methotrexate (MTX).

Methods: A retrospective case series was performed with pediatric patients who were treated with LEF in conjunction with anti-TNF agent therapy after intolerance to a combination of MTX with anti-TNF therapy. Dose and duration of MTX, LEF, and anti-TNF therapy were recorded. Extensive history, laboratory data, demographics, and uveitis flare rate were obtained.

Results: A total of five children were included in the study. Most subjects were initially on MTX and an anti-TNF agent was added subsequently due to inadequate response to monotherapy. After discontinuation of MTX, LEF was initiated with anti-TNF therapy. The replacement of MTX with LEF showed decreased side effects and was associated with lower flare rates and steroid free remission.

Conclusions: LEF was found to be well-tolerated and effective at maintaining uveitis quiescence in conjunction with anti-TNF agents in pediatric patients who do not tolerate MTX.

ABSTRACT BODY:

Purpose: In the pivotal clinical trial that led to FDA approval of the first fully autonomous artificial intelligence (AI) assisted diabetic retinopathy (DR) screening system, 76.4% of patients did not require pharmacological dilation to obtain an AI system disease level output. However, during our real-world, multi-site deployment of this AI system, we found that the non-diagnostic rate was 51% without dilation. We sought to identify patient risk factors associated with non-diagnostic images to strategically identify patients who may require dilation a priori.

Methods: Retrospective chart review of patients who were screened with Digital Diagnostics' IDx-DR® at Johns Hopkins Medicine (8/2020 to 5/2021). No patients underwent dilation. Patients who had a diagnostic result were compared to those with a non-diagnostic result. We used backward stepwise elimination to construct a multivariable logistic regression model for non-diagnostic results. A $p<0.05$ was considered statistically significant.

Results: Of the 241 patients (59% female; median age=59), 123 (51%) were non-diagnostic. Patients with a non-diagnostic result were older (64 years vs. 53, $p<0.001$), had a lower BMI (32.0 kg/m^2 vs. 35.5, $p=0.005$), more likely to be a current smoker (30% vs. 14%, $p=0.002$), and less likely to have type 2 diabetes (T2D) (85% vs. 93%, $p=0.03$) (Table 1). In the multivariable model, every 10-year increase in age was associated with a more than two-fold increased risk for non-diagnosis (adjusted odds ratio/AOR=2.19, 95% CI: 1.67-2.88, $p<0.001$). Type 1 diabetes (T1D) (AOR=4.99, 95% CI: 1.29-19.27, $p=0.02$) and current smoking (AOR=2.74, 95% CI: 1.32-5.69, $p=0.007$) were additional risk factors (Figure 1).

Conclusions: The real-world non-diagnostic imaging rate is much higher than reported in the pivotal clinical trial. Older age, smoking, and T1D were predictive risk factors for non-diagnostic imaging. This information will inform the establishment of a dilation protocol to selectively dilate patients at risk for non-diagnostic testing prior to AI-assisted DR screening, which will decrease the need for dilation after testing has failed and improve screening efficiency and clinic workflow.

TITLE: Evaluation of the double-pass wavefront in model and human eyes

SESSION TITLE: Advances in high resolution imaging

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: V. Akondi, X. Huang, A. Dubra, Byers Eye Institute, Stanford University, Palo Alto, California, UNITED STATES|X. Huang, Institute of Optics, University of Rochester, Rochester, New York, UNITED STATES|

Commercial Relationships Disclosure: Vyas Akondi: Commercial Relationship: Code N (No Commercial Relationship) | Xiaojing Huang: Commercial Relationship: Code N (No Commercial Relationship) | Alfredo Dubra: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Model eyes are used in adaptive optics (AO) ophthalmoscopy to focus imaging channels, calibrate fields of view, distortion correction, and instrument troubleshooting. We evaluate model retinas and AO control strategies to mitigate the double-pass wavefront and allow stable and converging closed-loop operation when using AO scanning ophthalmoscopes.

Methods: We evaluated model eyes with 19 and 100 mm focal length achromatic doublets, and a variety of flat substrates: protected silver mirror, polished glass, polished opal glass, white diffusers ground with different grits, and paper. The double pass was quantified by poking an off-center actuator in the deformable mirror of the AO ophthalmoscope and comparing the relative heights of the wavefront peaks (see Fig. 1). These measurements were performed with a focused beam of 850 nm light that was at first stationary and then scanned across an ~1.1 deg angle using a 13.8 kHz resonant scanner. The same setup was used to estimate the model eyes field curvature by vertically steering the stationary beam.

Results: Wavefronts from model eyes with paper or rough substrates as retinas (similar to a normal human eye), did not show center-symmetry that can be seen with a mirror retina, irrespective of beam scanning (see Fig. 1). The use of finely polished glass substrates as retinas results in a substantial attenuation of first-pass wavefront. The measured field curvature, with the 100 mm lens is ~7.8 smaller relative to the depth of focus (7.75 mm beam diameter) than for the 19 mm case, consistent with ray tracing. The AO control loop can be successfully operated provided that the first-pass wavefront is less than 100% of the second pass. The first pass wavefront induces AO control oscillations that can be mitigated by lowering the closed loop gain.

Conclusions: Decreasing the AO control gain improves convergence even with highly reflective materials, while the use of model eyes with lower field curvature improves the AO control stability. If the field curvature cannot be changed, then, the AO control stability can be improved by changing the wavefront sensor exposure to match the inverse of the scanning ophthalmoscope frame rate, or if the AO and imaging are synchronized, the exposure.

TITLE: End Point Management (EPM) in Clinically Significant Diabetic Macular Edema (CSME)

SESSION TITLE: Macular diseases/Macular edema/Functional testing/evaluation/Laser

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Shekoh, Valley Retina Institute, McAllen, Texas, UNITED STATES|T. Fatima, Jinnah Sindh Medical University, Karachi, Sindh, PAKISTAN|Q. Shekoh, University of Houston, Houston, Texas, UNITED STATES|V.H. Gonzalez, Valley Retina Institute, McAllen, Texas, UNITED STATES|

Commercial Relationships Disclosure: Noor-Ul-Ain Shekoh: Commercial Relationship: Code N (No Commercial Relationship) | Tooba Fatima: Commercial Relationship: Code N (No Commercial Relationship) | Quratulain Shekoh: Commercial Relationship: Code N (No Commercial Relationship) | Victor Gonzalez: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Diabetes causes release of various inflammatory and angiogenic cytokines, glycosylation causes cell damage and structural changes in blood vessels resulting in microaneurysms and abnormal leaky blood vessels that give rise to CSME. According to ETDRS the risk of development of vision impairment is decreased to 50 % after laser photocoagulation. Laser reduces central subfield thickness (CST) and cause some improvement in visual acuity (VA). However, the disadvantage of threshold Laser photocoagulation is scarring/chorioretinal atrophy, scotoma, and visual field defects. With Topcon Pattern Scanning Laser (PASCAL) system streamline yellow it is possible to calculate and apply the sub threshold energy required to stimulate retinal cells without causing damage to photoreceptors and retinal pigment epithelium (RPE). It applies low power density over large spot size and longer pulse to achieve non damaging end point.

Stimulation of retinal pigment epithelial cells causes formation of heat shock proteins that act as chaperones causing refolding of misfolded proteins, prevent apoptosis and down regulate inflammation, improve RPE function, thereby facilitating absorption of macular edema. The absence of retinal scarring and damage can be evidenced on FAF images.

Methods: We included the 21 eyes of pts. having clinically significant diabetic macular edema (CSME) without ischemia in our study.

Baseline VA measurement, OCT, FAF and fluorescein angiography were done in all patients.

The PASCAL streamline yellow laser was used to apply barely visible burn in mid periphery of retina, then the energy was titrated to 30 percent and subthreshold treatment applied over the CSME in a doughnut shape pattern, with spot size 200 µ, max power 200 mW, duration 15 ms. Pt were followed up after 1, 4 and 12 weeks. VA, FAF and OCT acquisition were done on each visit.

Results: Improvement in CST was seen in 71.4% eyes, 14.2% eyes developed recurrent macular edema after initial improvement and needed retreatment and 14.2% eyes showed no improvement, VA improved in 66.6%, stable in 23.8% and worsened in 9.5% .

Conclusions: EPM with subthreshold laser is a safe and effective way of improvement of CST and VA in CSME. It may reduce the treatment sessions with faster resolution of macular edema if used as an adjunct to intravitreal injections or as a rescue treatment.

ABSTRACT BODY:

Purpose: Vitrectomy and corticosteroid-use are known to accelerate cataract development, however, the causative mechanisms are largely unknown. We conducted RNA-sequencing of human lens epithelial cells in steroid-induced and post-vitrectomy cataract to verify and compare gene expression profiles.

Methods: Human anterior lens capsule specimens from post-vitrectomy (n = 8), steroid-induced subcapsular (n = 12) and age-related (n = 2) cataracts were collected from patients following written informed consent from the Alfred Hospital Research and Ethics Committee. Capsulorhexis specimens were collected at the time of cataract surgery for analysis. RNA was isolated using RNeasy Micro Kit and RNA libraries were synthesized using Illumina Stranded Total RNA Prep Ligation with Ribo-Zero Plus followed by sequencing on a NovaSeq S4, 300 cycles at AGRF. Differentially expressed genes (DEGs) were identified and underwent bioinformatics analyses including principal component analysis (PCA).

Results: Approximately 55,000 genes were detected from RNA-seq. We focused on ~15,000 genes with moderate or high average expression of >10 transcripts per million reads sequenced. A dimensionality reduction algorithm known as Principal Component Analysis (PCA) was employed to study gross differences in gene expression profile. PCA clustered steroid induced subcapsular cataract and post-vitrectomy cataract separately (Figure 1), suggesting overall differences in gene expression between the two groups (Figure 2), while age-related cataract samples clustered close to post-vitrectomy samples. Preliminary results indicate a minimum of 28 identified DEGs, 27 were upregulated in post-vitrectomy compared to steroid-induced cataract including IL-33, P2RY6, CAMP, CP, C4B, CFI whilst GPD1 was downregulated.

Conclusions: Our findings suggest that post-vitrectomy cataract and steroid-induced subcapsular cataract have different RNA transcription profiles. Bioinformatics analyses suggest that lens epithelial cells from post-vitrectomy cataract have a similar transcriptome to lens epithelial cells from age-related cataract but the transcriptome from steroid-induced posterior subcapsular cataract lens epithelial cells was quantitatively and qualitatively different.

ABSTRACT BODY:

Purpose: The cornea may lose transparency and cause blindness when Human corneal endothelial cells (HCEnCs) are damaged or diseased. Replacing diseased cells with a healthy donor endothelium is the only currently available treatment. There is increasing interest in the development of cultured graft substitutes and artificial corneas due to the global shortage of donor corneas. The aim of the study is to investigate whether novel Rho-kinase (ROCK) inhibitors can aid in the cultivation and regeneration of HCEnCs.

Methods: Human CEnCs were cultured and treated with Y-27632 (Y0503, Sigma-Aldrich), sovesudil (also known as PHP-201; pH Pharma), or PHP-0961 (pH Pharma) for 24h. We observed cellular responses, including cell viability, cytotoxicity, proliferation and Ki67 expression with ROCK inhibitors. We also assessed wound healing and cell adhesion assays. Porcine corneas were used ex vivo to evaluate wound healing and regeneration effects of Y-27632, sovesudil, and PHP-0961. We performed live/dead cell assays and immunofluorescence staining (for SOX2, b-catenin, and ZO-1) on porcine corneas treated with ROCK inhibitors.

Results: Cell viability, BrdU proliferation assay, and number of Ki67-positive cells was higher in Y-27632, sovesudil and PHP-0961 treated compared with control ($p<0.05$). There was no difference in LDH cytotoxicity test between any groups. Cells treated with Y-27632, sovesudil and PHP-0961 showed faster migration, wound healing, and cell adhesion. In the porcine ex vivo experiments, wound healing, the number of live cells, and SOX-positive cells were higher in Y-27632, sovesudil and PHP-0961 treated corneas ($p<0.05$). Across all experiments, the results of sovesudil and PHP-0961 were equal or superior to the results of the gold standard ROCK inhibitor Y-27632.

Conclusions: Novel ROCK inhibitors have a capacity to regenerate HCEnCs through enhancing the cell proliferation and adhesion between cells.

TITLE: Extended long-term effects of hard contact lens use on the corneal endothelium in healthy eyes: an observational study of 8604 eyes

SESSION TITLE: Corneal Endothelium

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Ono, Y. Mori, R. Nejima, T. Iwasaki, K. Miyata, Ophthalmology, Miyata Eye Hospital, Miyakonojo, Miyazaki, JAPAN|T. Ono, Ophthalmology, University of Tokyo, Bunkyo-ku, Tokyo, JAPAN|

Commercial Relationships Disclosure: Takashi Ono: Commercial Relationship(s);Code R (Recipient):Santen pharmaceutical;Code R (Recipient):Senju pharmaceutical | Yosai Mori: Commercial Relationship: Code N (No Commercial Relationship) | Ryohei Nejima: Commercial Relationship: Code N (No Commercial Relationship) | Takuya Iwasaki: Commercial Relationship: Code N (No Commercial Relationship) | Kazunori Miyata: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Contact lens use affects the morphology and density of the corneal endothelial cells, an important factor affecting normal endothelial function and the maintenance of corneal clarity. However, normal corneal endothelial parameters vary among population subsets worldwide. Research assessing the effects of hard contact lens use across populations has been limited in terms of the numbers and duration of use. This study aimed to analyze the effect of extended long-term use of hard contact lens on corneal endothelial cell density and morphology in healthy Japanese individuals.

Methods: This observational study included individuals using hard contact lenses examined at the Miyata Eye Hospital between 1996 and 2015. Eyes with a previous history of ophthalmologic surgery or diseases—except refractive errors—were excluded. Medical information regarding the individual's age, duration of contact lens use, corneal endothelial cell density (ECD), coefficient of variation (CV), rate of appearance of hexagonal cells (6A), and cell area were reviewed retrospectively. The corneal endothelium data were obtained via non-contact specular microscopy.

Results: We included 8604 eyes of 4302 individuals (mean age, 35.6±10.0 years): including 837 male and 3465 female individuals. The mean duration of hard contact lens use was 14.7±9.1 years. Multivariate analysis revealed that ECD was significantly correlated with age ($P<0.001$), but not to duration of use; however, CV, 6A, and cell area correlated significantly with both factors (all $P<0.001$). Univariate analyses revealed that the CV ($Y=29.9+0.24X$, $R^2=0.31$, $P<0.001$), 6A ($Y=60.7-0.26X$, $R^2=0.23$, $P<0.001$), and cell area ($Y=336.1+1.1X$, $R^2=0.26$, $P<0.001$) correlated significantly with the duration of use.

Conclusions: CV, 6A, and cell area significantly correlated with the duration of hard contact lens use in healthy Japanese individuals. It is important to observe the corneal endothelial morphology in long-term contact lens wearers.

ABSTRACT BODY:

Purpose: Too many people in the world are visually impaired by glaucoma, largely because the disease is detected too late. Aim: to build a labeled dataset for training an AI algorithm for glaucoma screening by fundus photography. To assess the accuracy of the graders and to characterize the features of all eyes with referable glaucoma.

Methods: Color fundus photographs of 113,897 eyes were obtained from EyePACS, California, USA, from a population screening program for diabetic retinopathy. Carefully selected graders (ophthalmologists and optometrists) graded the images. To qualify, they had to pass the EODAT[1] optic disc assessment with at least 85% accuracy and 92% specificity. Of 89 candidates, 30 passed. Each image of the EyePACS set was then scored by varying random pairs of graders as 'Referable glaucoma' (RG), 'No referable glaucoma' or 'Ungradable'. In case of disagreement, a glaucoma specialist made the final grading. RG was scored if visual field damage was expected. In case of RG, graders were instructed to mark up to 10 relevant glaucomatous features. [1]Reus N et al.; Ophthal 2010 117(4):717-23.

Results: During the grading, the performance of each grader was monitored; if the sensitivity and specificity dropped below 80 and/or 95%, respectively (the final grade served as reference), they exited the study and their gradings were redone by other graders. In all, 20 graders qualified; their mean sensitivity and specificity (SD) were 85.6 (5.7) % and 96.1 (2.8) %, respectively. The two graders agreed in 92.45% of the images (Gwet's AC2, expressing the inter-rater reliability, was 0.917). Of all gradings, the sensitivity and specificity (95% CI) were 86.0 (85.2 – 86.7)% and 96.4 (96.3 – 96.5)%, respectively. Of all gradable eyes (n = 111183; 97.62 %) the prevalence of RG was 4.38 %. The most common features of RG were the appearance of the neuroretinal rim inferiorly and superiorly (Figure (top) for all features and their probabilities. Conditional probabilities are also shown (bottom)).

Conclusions: The estimated sensitivity and specificity was above our target of 80% and 95%, respectively, and the annotated dataset should therefore be of sufficient quality to develop AI screening solutions.

ABSTRACT BODY:

Purpose: To assess prevalence and associated factors of depression, anxiety and suicidal ideas in populations from Russia.

Methods: In rural and urban regions in Bashkortostan/Russia, we conducted two population-based studies (Ural Eye and Medical Study (UEMS), Ural Very Old Study (UVOS)) which included participants aged 40+ years and 85+ years, respectively.

Results: In the UEMS with 5893 individuals (age:59.0±10.7 years;range:40-94 years), higher depression score and higher anxiety score were associated with more marked hearing loss (beta:0.07;P<0.001,and beta:0.07;P<0.0012,respectively) and worse visual acuity (beta:0.04;P=0.02; and beta:0.03;P=0.03,resp.), after adjusting for parameters such as female sex, Russian ethnicity, lower educational level, higher prevalence of alcohol consumption, weaker hand grip strength, less physical activity, and higher prevalence of dry eye disease. Attempted suicide was reported by 88 (1.5%;95%CI:1.2,1.8) participants, with 20 individuals indicating financial reasons for their attempt. Having thought of suicide was reported by 63 (1.1%) individuals. Overall, 131 (2.2%;95%CI:1.9,2.6) individuals attempted or thought of suicide. Out of 1491 UVOS participants (age:88.2±2.8 years;range:85-100 years) with a mean depression score of 20.0±10.3 (median:18;range:0-58), 916/1491 (61.4%;95%CI:59.0,63.9) fulfilled the definition of depression (depressions core ≥16). Higher depression score and higher anxiety score correlated with higher hearing loss score (beta:0.07;P=0.02, and beta:0.06;P=0.04,resp.) and worse visual acuity (beta:0.13;P<0.001, and beta:0.11;P<0.001,resp.), after adjusting for variables such as female sex, urban region of habitation, less physical activity, lower number of days with fruit intake, and lower cognitive function. Overall, 15 (1.0%;95%CI:0.50,1.50) individuals had attempted or thought of suicide.

Conclusions: Besides female sex, lower level of education and lower cognitive function, it was sensory impairment, namely vision and hearing impairment, which belonged to the determinants of depression and anxiety in these populations from Russia. Future studies may explore the role of improvement of vision and hearing impairment in the prevention and therapy of depression and anxiety.

TITLE: The effect of sinusoidally modulating backgrounds on flash electroretinograms

SESSION TITLE: Electroretinography: basic mechanisms and disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.J. Aher, C.R. Huchzermeyer, J.J. Kremers, University Hospital Erlangen Department of Ophthalmology, Erlangen, GERMANY|

Commercial Relationships Disclosure: Avinash Aher: Commercial Relationship: Code N (No Commercial Relationship) | Cord Huchzermeyer: Commercial Relationship: Code N (No Commercial Relationship) | Jan Kremers: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To study the effect of sinusoidally modulating background on the photopic flash ERGs.

Methods: Four healthy subjects (age: 28-62 years; one female) participated in the study. We measured the response to flashes (500 cd/m^2, 1ms long) on a steady background (50 cd/m^2) as a control and a sinusoidally modulating (50 cd/m^2 mean luminance) background of 1, 5, 10, and 25Hz temporal frequencies. The flashes were presented at 0° (mean luminance), 90° (100 cd/m^2 instantaneous luminance) and 270° (0 cd/m^2 instantaneous luminance) during the carrier sine wave. The responses to the carriers (sine wave only) were also recorded as control measurements and subtracted from the responses to flash plus sine carriers to obtain the flash ERGs at different phases.

Results: The responses to flashes were strongly altered when presented at different phases on the sine wave and particularly at low frequencies. The response was larger for the flash at 270° phase compared to the control flash ERG (flash on steady background) and the flash at 0° and 90° phases. The response to the flash at 90° was smaller than the other responses. The response to the flash at 0° were comparable to the flash ERG on a steady background. The effects of background modulation on the flash ERG decreased with increasing frequency of the background. The amplitudes of the components could be described by the Weber fraction plus saturation and a delay.

Conclusions: The proposed technique can be useful to enhance the flash ERG responses and to increase signal to noise ratio. Weber fraction of the flashes is an adequate quantification of stimulus strength to describe the amplitudes of the flash ERGs.

ABSTRACT BODY:

Purpose: To evaluate the use of encircling scleral buckling surgical technique for the treatment of retinal detachment (RD) and its complications as well as success rate within the last decade.

Methods: This retrospective observational study included 116 eyes receiving encircling scleral buckling (ESB) or encircling scleral buckling combined with vitrectomy (SBV) between January 2009 and December 2018. The main outcome measures include the development in usage rate of surgical procedures (either ESB or SBV), indications as well as mean age. Furthermore, intra-/postoperative complications, intraocular tamponades as well as the influences on functional outcome (VA) and central retinal thickness (CRT) were evaluated.

Results: During our 10 years of observation, ESB and SBV surgeries decreased in the first six years from initially 28.9% of all RD-operations to 2.9%, before increasing again to 6.7% between 2017-2018 ($p < 0.001$, Chi-Square test). The mean age for receiving ESB or SBV surgery differed significantly over the years from 56.58 ± 17.33 between 2009 – 2010 to 37.89 ± 28.08 between 2017-2018 ($p < 0.001$, ANOVA). Functional outcome after a mean follow-up time of 1501 ± 1266 days increased from 1.318 ± 0.871 logMar at baseline (BSL) to 0.853 ± 0.845 logMar at the latest follow-up visit. Significant influence on VA was expansion of RD (macula on/off) ($p < 0.001$), significant influences on CRT were postoperative macular edema ($p < 0.001$), surgical technique (ESB or SBV) ($p = 0.022$) and expansion of RD ($p = 0.026$).

Conclusions: After an initial decrease, an increase in SB and SBV surgeries was noticed at the end of the observational period, with a significant reduction in mean age. No significant differences in functional outcome as well as intra- and postoperative complications could be observed over the years.

TITLE: Evaluating the impact of customized low vision simulator glasses for parents of children with visual impairment

SESSION TITLE: Visual Function: perception, adaptation, spatial, visual acuity and binocular vision

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Kerr-Niermann, University of Missouri-St Louis, St Louis, Missouri, UNITED STATES|

Commercial Relationships Disclosure: Catherine Kerr-Niermann: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Parents of children with visual impairment often express frustration in their lack of clear explanations of what their child can see. Customized simulator glasses created from low vision rehabilitation evaluation measurements may offer a low cost, personalized, and effective method to satisfy this inquiry. This study utilized a quantitative survey to gauge the impact of customized simulator glasses on parental understanding of children's visual impairment.

Methods: Forty-three families received customized simulator glasses as standard of care in a non-profit clinic between April 2021 and October 2021. The simulators layered various filters on clear safety glasses to represent a personalized range of visual acuity, contrast sensitivity, central and peripheral vision fields following a comprehensive low vision rehabilitation evaluation. An emailed link to an IRB approved survey was sent to one parent or guardian per family. Seventeen surveys were completed (44% responded of 39 email addresses collected).

Results: Survey results indicated that parents use multiple sources of information in attempt to understand their child's vision including consulting with optometrists or ophthalmologists (88%), searching the internet (77%), asking their child directly to explain their vision (71%), interpreting eye reports (59%), and using standard (non-customized) simulator glasses (29%). Of those surveyed, 94% agreed that the customized low vision simulator glasses provided were helpful for understanding their child's vision (76% strongly agreed and 18% somewhat agreed). The vision simulated was largely worse than parents expected (82%).

Conclusions: Customized low vision simulator glasses are an effective tool to help parents understand their child's visual impairment. Parents actively seek multiple sources of information in attempt to understand what their child can see. Most parents who received customized simulator glasses following their child's low vision rehabilitation evaluation found them to be helpful and most parents reported the vision simulated was worse than expected. This study raises important questions regarding the validity of simulators, the feasibility of implementing customized simulators as standard of care, and the implication of children's adaptability as a potential contributing factor in the discrepancy of what a child can see compared to parental perception.

ABSTRACT BODY:

Purpose: Primary open angle glaucoma (POAG) is the most common form of glaucoma worldwide. Increased stiffness and reduced porosity of Schlemm's canal and juxtacanalicular tissues is known to play a key role in POAG pathogenesis. Ultrasound-induced cavitation has been used to increase porosity of tissues, especially when enhanced by the presence of microbubble contrast agents that serve as cavitation nuclei. In this preliminary study, we introduced PFC nanodroplets (NDs) into the anterior chamber (AC) and exposed eyes to focused ultrasound as a potential means for improving outflow in POAG.

Methods: We synthesized NDs with a liquid perfluoropentane core and lipid shell. NDs averaged approximately 100 nm in diameter. Upon exposure to focused ultrasound of sufficient intensity, NDs undergo a transient phase change from liquid to gas. We introduced 0.1 ml of an ND emulsion into the AC of ex vivo pig eyes and 25 µl into 3 in vivo rat eyes. Using a Verasoncs Vantage-128 ultrasound system, eyes were then imaged and NDs activated with linear array ultrasound probes with center frequencies of 18 MHz and 28 MHz at a series of increasing acoustic intensities.

Results: At diagnostic acoustic intensities, scanned focused ultrasound beams provided visualization of anatomy with minimal activation of NDs. At 28 MHz, NDs in the rat AC activated at a peak negative pressure of 5 MPa (mechanical index, MI=1.2), undergoing rapid phase transition from liquid to gas. Acoustic reflection from transient gas microbubbles produced high imaging contrast and microbubble collapse produced cavitation. Ultrasound and OCT Images showed NDs to be distributed widely within the AC, settling into the angle and entering Schlemm's canal. Two days after treatment, rat eyes showed no sign of inflammation, but a few small gas bubbles were present in the AC.

Conclusions: In this application, NDs are advantageous with respect to conventional microbubble ultrasound contrast agents because of their higher density and smaller diameter (< $1/10^{th}$ that of microbubble agents), which facilitate entry into the outflow channels. ND activation occured at an MI of 1.2, which exceeds the diagnostic maximum of 0.23. Future preclinical in vivo studies using glaucoma models will assess safety and the effect of treatment on IOP and outflow facility.

TITLE: Melatonin Prevents Acute Ocular Hypertension-Induced Oxidative Stress, Senescence, and Inflammation by Inducing Sirtuin 1 in Anterior Segment Tissues of Mice

SESSION TITLE: Pharmacology/cellular mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Huang, D. Ye, Y. Xu, Sun Yat-Sen University Zhongshan Ophthalmic Center State Key Laboratory of Ophthalmology, Guangzhou, Guangdong, CHINA|

Commercial Relationships Disclosure: Jingjing Huang: Commercial Relationship: Code N (No Commercial Relationship) | Dan Ye: Commercial Relationship: Code N (No Commercial Relationship) | Yue Xu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The mechanisms underlying the causal link between acute ocular hypertension (AOH) and subsequent pathological changes of anterior segment in acute glaucoma remain unclear, preventing improvements in treatments. Our previous study has demonstrated that oxidative stress, senescence, and inflammation were involved in the anterior segment of acute glaucoma patients. This study aimed to explore the role of melatonin in oxidative stress, senescence, and inflammation induced by AOH in anterior segment and its underlying mechanisms.

Methods: A murine AOH model was used in this study. Melatonin, or sirtuin 1 (SIRT1) inhibitor with melatonin were administered by daily intraperitoneal injection to AOH mice. Pathological changes of the anterior segment were recorded by a slit-lamp microscope. Hematoxylin & eosin staining, and optical coherence tomography (OCT) were used to observe the changes of anterior segment structure. Immunofluorescence, western blot, and real-time PCR were performed to evaluate the protein expression level.

Results: Corneal edema, and dilated pupil were observed immediately after the establishment of AOH model, melatonin treatment significantly ameliorated corneal edema at Day 1, as reflected by reducing the central corneal thickness measured by OCT ($p<0.01$). Iris became thin and stiff in shape at Day 7, and melatonin treatment greatly relieved the morphological changes of iris. SIRT1 expression was decreased in cornea, iris, ciliary body, and anterior lens capsule after AOH injury, and increased after melatonin treatment ($p<0.001$). Meanwhile, SIRT1 inhibitor could counteract the effects of melatonin. In addition, the number of positive cells of oxidative stress markers (8-OHdG, γ-H2AX), senescence markers (p16, p21, p53), and inflammation markers (Iba-1, CD68) and related protein expression levels were dramatically increased in the anterior segment of AOH model, and the number of these positive cells and related protein expression levels were decreased after melatonin treatment ($p<0.05$). While inhibiting SIRT1 pathway could predominantly eliminate the effects of melatonin.

Conclusions: Collectively, melatonin ameliorated morphology of anterior segment and exerts anti-oxidative stress, anti-senescence, anti-inflammation effects via activation of SIRT1 pathway in anterior segment tissues of AOH.

ABSTRACT BODY:

Purpose: Long-COVID is assumed to have an autoimmune component. As a seropositivity of functional active autoantibodies against G-protein coupled receptors (GPCR-AAb) and an impaired retinal microcirculation, measured by OCT-angiography (OCT-A), was observed after COVID-19 infection, it was the aim of the present study to investigate the impact of GPCR-AAbs on retinal microcirculation in patients with Long-COVID.

Methods: Seventy-six patients with Long-COVID (COVID-19 infection was confirmed by real time rt-PCR) were recruited. A seropositivity for GPCR-AAbs (Nociceptin-AAb, ß2-AAb, AT1-AAb, α1-AAb, MAS-AAb, M2-AAb, ETA-AAb) was analyzed by a specific rat cardiomyocyte bioassay in vitro. Macular (superficial vascular plexus (SVP), intermediate capillary plexus (ICP) and deep capillary plexus (DCP)) and peripapillary vessel density (VD) were measured by OCT-A (Spectralis II, Heidelberg, Germany). VD analysis was done by the Erlangen-Angio tool, including an APSifyed and Bruch's membrane opening (BMO) based analysis. Data were analyzed by mixed model (SAS version 9.4). Gender and age were set as covariates. The study was approved by the local ethics committee and was done in accordance with the tenets of the Declaration of Helsinki. Informed consent was achieved.

Results: All patients with Long-COVID showed a seropositivity for GPCR-AAbs (100%). Female patients with Long-COVID showed lower macular and peripapillary VD compared to men. A significant effect of a seropositivity of AT1-AAb on age-corrected least squares means (LS-means) overall VD of DCP ([CI: 0,25; 6.07], p=0.03). A seropositivity of α1-AAb showed a significant effect on age-corrected LS-mean overall VD of SVP ([CI: 0.07; 2.69], p=0.04), of DCP ([CI: 0.36; 3.25], p=0.01), and of PH ([CI: 1.17; 5.59], p=0.01), respectively. A seropositivity of MAS-AAb yielded a significant effect on age-corrected LS-mean overall VD of DH (CI: 1.48; 6.07, p=0.001). A seropositivity of ß2-AAb has a significant effect on age-corrected LS-mean overall VD of MH (CI: 0,02; 1,94, p=0.04). For those effects, the covariate age was significant in the type III tests ($p<0.05$), thus analysis was done considering this age-effect.

Conclusions: As autoimmune mechanisms were reported to be involved in the pathogenesis of Long-COVID, we postulate that functional active GPCR-AAb may have an impact on retinal microcirculation, being a propable correlate to systemic disease.

TITLE: Modeling the frequency-of-seeing curves in patients with glaucoma as a weighted sum of typical psychometric functions

SESSION TITLE: Visual Fields and Psychophysics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Murotani, Kahoku Eye Clinic, JAPAN|

Commercial Relationships Disclosure: Eiji Murotani: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To demonstrate computationally that the frequency-of-seeing (FOS) curves in patients with glaucoma can be modeled as a weighted sum of typical psychometric functions.

Methods: The author prepared a set of psychometric functions that represent each threshold from <0 to 40dB, using zero function (<0dB) and cumulative gaussian function with the same slope (0~40dB) (Fig. 1A). Then, a weighted sum of these functions was calculated based on the following weights assigned to each threshold: λ ($0<\lambda<1$) for <0dB, $(1-\lambda)\varphi(\mu, \sigma)$ for 0~40dB, where $\varphi(\mu, \sigma)$ is the gaussian density function with mean μ and standard deviation σ (Fig. 1B).

Results: The weighted sum resulted in a flat and shallow sigmoid curve, which was similar to the FOS curves at regions with glaucomatous damage (Fig. 1C). The decrease in maximum response probability corresponded to λ, and the steepness of slope was linked to σ. Furthermore, the luminance of inflection point agreed with μ.

Conclusions: This result raises the possibility that a single FOS curve in patients with glaucoma may consist of multiple psychometric functions.

ABSTRACT BODY:

Purpose: Endomucin (EMCN) is a type I integral membrane glycoprotein selectively expressed by venous and capillary endothelium. We have previously shown that EMCN knockdown in vitro significantly inhibits VEGF165-induced VEGFR2 internalization and downstream activities including proliferation, migration and tube formation. The goal of this study is to characterize the role of EMCN in normal retinal vascular development and in pathologic neovascularization using the EMCN knock-out mice.

Methods: Homozygous EMCN knock-out ($EMCN^{-/-}$) mice were obtained by crossing EMCN-floxed mice with the ROSA26-Cre strain. Eyes from adult (8-16 weeks) $EMCN^{-/-}$ mice and $EMCN^{+/+}$ control littermates were collected and retinas and RPE/choroids complex were dissected for RNA extraction, and qPCR to determine gene expression. Eyes from P5 mice and adult mice (12-16 weeks) were collected for retinal flat mounts; retinal vasculature was stained with Isolectin-B4 (IB4). For the oxygen-induced retinopathy (OIR) model, P7 mice were housed in 75% oxygen for five consecutive days and returned to room air at P12, eyes at P12 and P17 were collected and the retinal vasculature was stained with IB4 and the avascular and neovascular areas were quantified using photoshop.

Results: EMCN mRNA in both retinas and RPE/choroids from the $EMCN^{-/-}$ mice was undetectable ($n>4$, $p<0.0001$), compared to $EMCN^{+/+}$ mice by qPCR. The area of retinal vascularization at P5 was significantly lower in the $EMCN^{-/-}$ pups compared to $EMCN^{+/+}$ controls (0.14±0.01 vs 0.2±0.013, $p<0.0001$, $n>10$ for both groups). Adult retinal vascular density remained lower in the $EMCN^{-/-}$ mice compared to $EMCN^{+/+}$ mice (0.135 0.015± vs 0.154±0.017, $p<0.05$, $n= 13$). In the OIR model, the avascular area generated by high oxygen exposure at P12 was similar in the $EMCN^{-/-}$ and $EMCN^{+/+}$ mice (24.57±1.4% vs 23.18±1.0%, $p=0.9$, $n>6$). However, pathological neovascularization at P17 was significantly reduced in the $EMCN^{-/-}$ mice compared to $EMCN^{+/+}$ (8.98 ± 2.9% vs 11.98±1.4%, $p<0.05$, $n>10$) while the avascular area at P17 was comparable between the $EMCN^{-/-}$ and controls (9.9± 1.5% vs 8.85±1.0%, $p>0.5$, $n>10$).

Conclusions: Genetic ablation of the EMCN gene reduces retinal vascularization under normal and pathological conditions. As a critical regulator of retinal angiogenesis, EMCN represents a novel therapeutic target for ocular diseases characterized by pathological blood vessel growth.

TITLE: Assessment of retinal rods and cones function using mesopic full-field stimulus threshold – a preliminary report

SESSION TITLE: Assistive Devices, Visual Function Assessment, and Vision Restoration Therapies

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Nallour Raveendran, R.A. Schuchard, Envision Research Institute, Wichita, Kansas, UNITED STATES|J. Farmer, Diagnosys LLC, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Rajkumar Nallour Raveendran: Commercial Relationship: Code N (No Commercial Relationship) | Jeff Farmer: Commercial Relationship(s);Code E (Employment):Diagnosys LLC | Ronald Schuchard: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The main objective of this preliminary study is to test a protocol of mesopic full-field stimulus threshold (mFST) to assess rod and cone function in controls and individuals with retinitis pigmentosa (RP). Typically, in scotopic background (BG), thresholds for blue and red FST are distinct, and are used to assess the function of rods and cones, respectively. But it requires pupil dilation and dark adaptation for at least 30min. We hypothesized that distinct thresholds for blue and red FSTs can be achieved by performing mFST without either pupil dilation or dark adaptation.

Methods: mFST at 0.1cd/m^2 white BG luminance was measured (ColorDome, Diagnosys LLC) in controls (n=21) and individuals with RP (n=11). In addition, mFST at 1cd/m^2 BG luminance was also measured in 10 controls. After adapting to a room light level for at least 10min, FST in two different wavelengths; blue (448nm) and red (627nm) were measured in a dark room. For each wavelength (λ), FST of one eye, with the other occluded, was measured and the test was repeated three times. The results were analyzed using ANOVA and Tukey HSD.

Results: In controls, there was a significant main effect of BG [$F(1, 10)=257.94$, $p<0.001$], λ [$F(1, 10)=561.88$, $p<0.001$] on mFST measured thresholds. Moreover, threshold difference between blue and red mFST using 0.1cd/m^2 BG (0.95 log cds/m^2) was significantly larger compared to 1cd/m^2 (0.22 log cds/m^2) BG luminance ($p<0.001$). This suggested that mFST at 0.1cd/m^2 has more distinct blue and red mFST thresholds. On comparing individuals with RP and controls, there was a significant main effect of groups [RP vs. controls: $F(1, 19)=18.58$, $p<0.001$]. Individuals with RP had significantly worse thresholds overall compared to controls [blue mFST ($p<0.001$) and red mFST ($p<0.001$)]. In addition, threshold difference between blue and red FST in 0.1cd/m^2 BG luminance in RP (0.47 log cds/m^2) was significantly less than the threshold difference noted in control participants ($p<0.001$).

Conclusions: mFST at 0.1cd/m^2 BG luminance can be used to assess the functions of rods and cones without pupil dilation and dark adaptation. In the future, associations between mFST and other measures such as dark adaptation, low luminance visual acuity and contrast sensitivity should be evaluated for some unique information to consider mFST as an outcome measure in clinical trials and for clinical use.

TITLE: Anti-PANoptosis Is Involved in Neuroprotective Effects of Melatonin in Acute Ocular Hypertension Model

SESSION TITLE: Pharmacology/cellular mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Ye, Y. Xu, J. Huang, Sun Yat-Sen University Zhongshan Ophthalmic Center State Key Laboratory of Ophthalmology, Guangzhou, Guangdong, CHINA|

Commercial Relationships Disclosure: Dan Ye: Commercial Relationship: Code N (No Commercial Relationship) | Yue Xu: Commercial Relationship: Code N (No Commercial Relationship) | Jingjing Huang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Approved effective therapy is still lacking in acute glaucoma. PANoptosis, which is consist of three key modes of programmed cell death—pyroptosis, apoptosis, and necroptosis, may contribute to acute ocular hypertension (AOH)-induced retinal ganglion cell (RGC) death. Previous study has demonstrated that melatonin exerted neuroprotective effects in many retinal degenerative diseases. This study aimed to explore the role of melatonin in PANoptosis after AOH injury, and its underlying mechanisms.

Methods: A murine AOH model was used in this study. Melatonin or the equal volume of saline containing 0.5% ethanol were administered by daily intraperitoneal injection to AOH mice. Hematoxylin & eosin staining, and optical coherence tomography were used to observe the changes of retinal structure. Electroretinogram was used to detect changes in visual function. TUNEL assay and PI assay were used to detect the apoptotic and necrotic cells. Immunofluorescence, western blot and real-time PCR were performed to evaluate the localization and quantitative changes of protein.

Results: Melatonin treatment attenuated the losses of ganglion cell complex thickness, retinal nerve fiber layer thicknesses (both $p<0.05$) and RGCs ($p<0.001$). Meanwhile, melatonin improved the amplitudes of a-wave, b-wave, and oscillatory potentials in the electroretinogram ($p<0.0001$, 0.01, 0.05, respectively). Additionally, melatonin remarkably reduced high IOP-induced RGCs apoptosis by decreasing the number of TUNEL-positive cells and inhibiting the upregulation of cleaved caspase-3, Bax, cleaved caspase-8, p-Bad and downregulation of Bcl-2 induced by AOH injury ($p<0.05$). Moreover, melatonin attenuated high IOP-induced necroptosis in RGCs and microglia, as demonstrated by a diminishing expression of MLKL, RIP1, and RIP3, along with a decline of PI-, RIP3- and p-RIP3-positive cells in RGCs and microglia of melatonin-treated mice ($p<0.05$). Furthermore, melatonin reduced expression of NLRP3, ASC, cleaved caspase-1, GSDMD, and cleaved GSDMD, and decreased the positive cells of Iba-1, and IL-1β in microglia of melatonin-treated mice ($p<0.05$), which means attenuated high IOP-induced pyroptosis and retinal inflammation in microglia.

Conclusions: Collectively, melatonin ameliorated retinal morphology and prevented retinal dysfunction after AOH and exerts neuroprotective effects via inhibition of PANoptosis in AOH retinas.

ABSTRACT BODY:

Purpose: Standard-of care assessment for children with amblyopia includes measuring best-corrected monocular visual acuity (BCVA), with the non-viewing eye occluded. Yet, when visual input from the fellow eye is occluded, the central suppression scotoma that is fundamental to amblyopia may have reduced impact on amblyopic eye (AE) BCVA. As a result, AE BCVA measured with occlusion may not accurately represent AE function during natural binocular viewing. We compared AE BCVA with monocular versus binocular (dichoptic) viewing, and determined whether any differences under the two viewing conditions were associated with performance on tests of fixation instability, reading, and motor skills with natural binocular viewing.

Methods: AE BCVA of 50 children (6-12y) with amblyopia (monocular E-ETDRS AE BCVA: 0.2-0.5 logMAR) was tested under monocular and dichoptic viewing conditions with an Optec Vision Tester. In the monocular condition, 8 Sloan letters were presented to the amblyopic eye on each line. In the dichoptic condition, 4 letters were presented to the fellow eye, 4 letters to both eyes, and 4 letters to the amblyopic eye (8 letters to each eye). In both conditions, AE BCVA was defined as the smallest optotype size at which the child identified >75% of letters presented to the amblyopic eye. Fixation stability was calculated as the 68% bivariate contour ellipse for 20 sec binocular fixation, reading speed was determined with silent binocular reading of age appropriate passages using a Readalyzer, and motor skills were assessed with the Movement Assessment Battery for Children-2.

Results: 72% of children with amblyopia had better AE BCVA when tested in the monocular than dichoptic condition (mean difference+SE=0.12+0.02 logMAR), with 38% of children performing 2-4 lines better in the monocular condition. The difference between conditions was correlated with fixation instability of the amblyopic and fellow eyes (r=0.56 and 0.72, p<0.001), reading speed (r=-0.77, p<.0001), manual dexterity (r=-0.35, p=0.01), and aiming/catching skill (r=-0.41, p=0.01).

Conclusions: AE BCVA measured with occlusion may not accurately represent its function during natural binocular viewing. The difference between dichoptic and monocular AE BCVA is potentially a useful index of suppression, with moderate to strong associations with fixation stability, reading speed, and motor skills.

ABSTRACT BODY:

Purpose: Human stem cell derived retinal organoids (ROs) hold promise for therapy and understanding retinal diseases as well as for studying development of human retina in vitro. In fact, recent gene expression studies show that the developmental timeline in ROs closely matches that of human retina in vivo. During differentiation, ROs can be categorized into three distinct developmental stages. However, not much is known about the functional development of neurons in ROs including photoreceptors. Here, we assess in detail the light sensitivity and electrical properties of cones at distinct time points of RO development. In addition, we determine if lack of a defined retinal pigment epithelium (RPE) limits the availability of chromophore for cone function at different stages of RO development.

Methods: We used electrophysiology to record light responses from >500 cones across 8 distinct developmental time points from ROs (170-340 days in vitro). We treat ROs of different ages with 9 cis-retinal and compare cone light sensitivity with those in untreated ROs.

Results: At d170 (stage 2), we did not observe any light-evoked responses from cones in ROs. This is consistent with previous findings that the photoreceptors are not fully developed at stage 2 and may not have the required phototransduction machinery to elicit light responses. Cones in stage 3 ROs (>d200) exhibit light responses with peak sensitivity between d250-d260. Beyond d300, the fraction of light sensitive cones significantly decreases. Despite the differences in light sensitivity, membrane properties of cones remain comparable across different time points of RO development. Cone light responses also demonstrate adaptation at higher luminance like typical vertebrate cones. Addition of 9-cis retinal significantly improved cone light sensitivity across all time points of RO development probed in this study.

Conclusions: By assaying cone function at various stages of RO development, we identified d250-260 as the timepoint of peak cone sensitivity. The timeline of cone functional maturation suggests that cone phototransduction reaches its maximal sensitivity at later stages of fetal development continuing up to early stages of postnatal development, similar to human retina development in vivo. Our results further show that chromophore availability, most likely from the RPE, plays a significant role in cone light sensitivity in ROs during development.

ABSTRACT BODY:

Purpose: Choroidal lesions can be seen on enhanced depth imaging optical coherence tomography (EDI-OCT) of individuals with birdshot chorioretinitis (BSCR). Some clinicians have assumed that these choroidal lesions are the “birdshot (BS) lesions” seen on clinical exam. Studies have shown that choroidal lesions identified by EDI-OCT are related to certain features of BSCR, including vitreous inflammatory reactions and macular edema, while other studies have shown that the clinical characteristics of BS lesions are not related to the same disease features. We sought to determine whether there is a relationship between BS lesions seen on fundus photographs and choroidal lesions seen on EDI-OCT.

Methods: Using co-localization techniques, we compared BS lesions on color fundus photographs to choroidal lesions identified on EDI-OCT (Heidelberg Spectralis) of four eyes (two individuals) with BSCR. A choroidal lesion was defined as a homogenous hyporeflectivity that was present external to the Bruch membrane and internal to the choroidal-scleral border. Two investigators (GNH, ET) agreed on the borders of three random BS lesions for each eye, and outlined the lesions on the color photographs with ImageJ software. Three B-scans, equidistant from the borders of the BS lesions and from each other, were identified and evaluated by a third investigator (ARS) for underlying choroidal lesions. If choroidal lesions were present, the width of BS lesions and the width of underlying choroidal lesions were compared.

Results: Only 10 (83.3%) of 12 BS lesions had underlying choroidal lesions on one or more of the three scans. For only six (60%) of these 10 BS lesions were choroidal lesions identified on all three scans; choroidal lesions were identified on two of three scans for two lesions, and on one of three scans for two lesions. On all 24 EDI-OCT images with choroidal lesions, the width of the choroidal lesion was greater than the width of the overlying BS lesion on fundus photographs.

Conclusions: Clinically apparent BS lesions are not precise representations of choroidal lesions on EDI-OCT images. EDI-OCT may provide information for evaluation and monitoring of BSCR that cannot be derived from clinical examination alone. Study of additional lesion characteristics may identify how BS lesions are related to choroidal findings on EDI-OCT, if at all.

ABSTRACT BODY:

Purpose: A custom computer system was used to generate a large amount of data to estimate evaporation, osmosis, and different types of flow within regions of TBU in tear films (TF) for normal subjects. A convolutional neural network (CNN) automatically identified TBU and non-TBU in fluorescent (FL) images gathered in vivo. FL intensity data in those regions was extracted for fitting by three ordinary differential equations (ODE) models for TBU. Model parameters were optimized to best fit the FL data in order to identify the mechanisms active within TBU regions.

Methods: The FL intensity data was originally recorded from 25 normal subjects with 20 trials taken over two visits (Awisi-Gyau, Indiana University PhD thesis, 2020). We extract the experimental FL image data from the centers of TBU regions identified by the CNN. The data were fit with the ODE models using parameters representing evaporation rate (v), steady tangential flow (strain) rate (a), or decaying flow (b_1) with decay rate (b_2). A least squares minimization of the difference between experimental and computed intensities determined the parameters. Initial FL concentration and localized film thickness was estimated as in previous work (Wu et al IOVS 2015, 56:4211; Luke et al Bull Math Biol 2020, 82:71). All programs were custom using Python, Julia and/or Matlab.

Results: Extraction resulted in N=467 usable instances of TBU from 15 subjects. Evaporation rates fall near or within experimental ranges. Statistical distributions of thickness and osmolarity were computed for individual subjects and for the population. Findings include: (i) The population of normals exhibited a range of mechanisms active in TBU instances. (ii) Individual subjects exhibited different mechanisms in different instances of TBU, even within a single trial. (iii) Individual subjects could in some cases be distinguished from each other based on the distribution of parameters responsible for their TBUs (Fig 1). (iv) Osmolarity increases with increasing evaporation rate at less than a linear rate (Fig 2).

Conclusions: Intensity decay in TBU areas yielded new data on the mechanisms of TBU in many instances. Quantitative estimates for TBU parameters were variable within and between subjects. The data provides a valuable baseline for the mechanisms and spatial distribution of TBU in normal subjects.

ABSTRACT BODY:

Purpose: Suture breakage and suture degradation are challenges in many anterior segment surgical procedures when corneal sutures are used. We compared the standard of care corneal suture material (10-0 nylon) to a biocompatible novel material (metallic alloy) in an experimental ex-vivo comparison study using porcine eyes.

Methods: Each eye was prepared using an infusion line on a 27 gauge needle placed within the anterior chamber and the bottle height was adjusted to mimic the physiologic intraocular pressure (IOP). A full-thickness wound was created perpendicularly to the central cornea with a 3.2 mm blade to mimic a wound sustained by trauma. The surgeon used the suture material (either 10-0 nylon vs metallic alloy) to achieve closure via a simple interrupted technique on each of the test eyes. The bottle height was then raised to the maximum height, or until failure of the sutures (noted by a positive Seidel test using fluorescein test strip). The IOP at either failure or maximum was recorded.

A total of 7 eyes were tested, 4 of which were included for final statistical analysis. The remaining 3 eyes were excluded due to incomplete closure noted prior to stress testing. The mean IOP at failure was compared (10-0 nylon vs metallic alloy) and compared via Student's t-test.

Results: The mean IOP at baseline prior to stress testing was similar between the 10-0 Nylon vs metallic alloy at 21 mmHg vs 19 mmHg, respectively (with p value=0.2). The mean IOP at failure was also similar between the nylon and metallic alloy groups (86.5 mmHg vs 91 mmHg, respectively) with p value=0.5.

Conclusions: The novel metallic alloy suture device had similar closure efficacy compared to the 10-0 nylon in our study. Future applications for this suture are currently being explored.

ABSTRACT BODY:

Purpose: To develop retinal nerve fiber layer (RNFL) and ganglion cell layer (GCL) probability change maps (pc-map) obtained from optical coherence tomography (OCT) scans.

Methods: The study group consisted of 70 early glaucoma or glaucoma suspect (baseline 24-2 mean deviation >-6 dB) and 29 healthy (HC)] from 99 individuals from a longitudinal, prospective study. All eyes had 24-2 and 10-2 visual fields (VFs) and baseline OCT volume scans and follow-up scans at least 1 year from the baseline date (1.8 ± 0.3 yr; range: 1.3-3.4 yr.). The OCT scans were obtained on both Topcon (12x9 mm scan) and Heidelberg (30°x25° scan) instruments. The OCT pc-map (Fig. 1, bottom rows) of the RNFL and the GCL were generated by comparing the difference in thickness (Fig. 1, top rows) between an individual eye's baseline scan to the last follow-up against a short-term variability group (4 mos between scans), which consisted of 135 eyes (942 scans) for Topcon and 179 eyes (745 scan) for Heidelberg. A reference standard (RS) was employed to assess the diagnostic ability of these pc-maps. For the RS, we required an agreement in the region progressing based upon an evaluation of baseline and follow-up OCT and 24-2 and 10-2 VF tests. Based upon this RS, 10 eyes were classified as progressors (P). The pc-maps of the P and HC eyes were compared to identify patterns that distinguish real progression from artifacts.

Results: For Topcon, 8 of the 10 P eyes had abnormal arcuate regions characteristic of glaucoma on both the GCL and RNFL pc-maps (arrows in[HDC1] Fig. 1). In all 8, there was clear topographic agreement between the progression seen on the RNFL and GCL pc-maps. Of the 29 HCs, 4 (14%) had damage that resembled an arcuate on the RNFL pc-map (red arrows in Fig. 2[HDC2]). However, none of these 4 showed topographic consistent change on the GCL pc-map. Additionally, arcuates in P eyes were more temporal and curved towards fixation, while "arcuates" on HCs appeared straighter. The results for Heidelberg scans were similar. 8 out of the 10 P eyes had damage resembling an arcuate with topographic agreement on the RNFL and GCL pc-maps. Only 1 HC had arcuate-like region, and it was not confirmed on the GCL pc-maps.

Conclusions: RNFL and GCL pc-maps for eyes with early glaucoma show topographically corresponding abnormal regions that reveals the location and extent of the region progressing.

ABSTRACT BODY:

Purpose: We compared the macular choriocapillaris flow deficit density (FDD) using swept-source (SS) and spectral-domain (SD) optical coherence tomography angiography (OCTA) in healthy participants (normal controls; n=104), individuals having ocular hypertension (OHT; n=41), and primary open-angle glaucoma (POAG; n=112).

Methods: In this prospective cross-sectional study, subjects underwent 3x3 mm^2 imaging using both SS-OCTA (Plex Elite 9000) and SD-OCTA (Cirrus AngioPlex). Choriocapillaris OCTA images were extracted from the respective devices' built-in review software and were subsequently loaded into a customized algorithm that evaluted the choriocapillaris FDD.

Results: When using SS-OCTA, older age was independently associated with higher choriocapillaris FDD (all $P \leq 0.026$), after adjusting for confounders. Specifically, the oldest group (70-82 years old) had 1.11% (95% CI = 0.50 to 1.72; $P < 0.001$) more choriocapillaris FDD compared to the youngest group (24-44 years old). In addition, OHT patients had 0.86% (95% CI = 0.10 to 1.62; $P = 0.026$) more choriocapillaris FDD than normal controls, while it did not reach statistical significance for POAG ($\beta = -0.78$, 95% CI = -1.65 to 0.062; $P = 0.08$). In eyes imaged with SD-OCTA, choriocapillaris FDD was not associated with either age or eye disease.

Conclusions: Imaging with SS-OCTA showed higher choriocapillaris FDD in older patients and patients with OHT when compared with normal subjects, and this was not seen when imaged with SD-OCTA.

ABSTRACT BODY:

Purpose: To report prevalence of visual-sensory and oculo-motor impairments at age 5½ among children born preterm.

Methods: Date were extracted from the population based cohort study, EPIPAGE-2 which include preterm born children in France in 2011. At age $5^{1/2}$, 4441 children born at 24-34 Weeks' Gestation (WG) survivied. We included also a sample of 592 term-born children from the cohort ELFE as reference group. All patients were invited to assess complete medical examination in one of the 110 centers specially opened for the assessment.

We reported prevalence of refractive errors, strabismus, amblyopia, nystagmus and binocular visual acuities. Prevalence are reported after multiple imputation for missing data and sub-group analysis on Cerebral Palsy and history of Retinopathy Of Prematurity were performed.
