Conclusions: Of the eight mutants lines, four showed a change in refractive status. Our study provides functional evidence that these candidate genes selected from GWAS studies induce changes in eye growth and presents new zebrafish eye models for the study of refractive error.

SUBMITTER (NAME ONLY): Phattharaphong Tantichariyangkul

TITLE: Visual Performance of 2 Trifocal Intraocular Lens Models in Different Illuminance

SESSION TITLE: IOLs and Presbyopia

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Tantichariyangkul, B. Khambhiphant, Ophthalmology, King Chulalongkorn Memorial Hospital, Bangkok, THAILAND|

Commercial Relationships Disclosure: Phattharaphong Tantichariyangkul: Commercial Relationship: Code N (No Commercial Relationship) | Bharkbhum Khambhiphant: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To compare the monocular and binocular corrected defocus curves between 2 non-toric trifocal IOL models in 3 different illuminance conditions.

Methods: Patients who underwent phacoemulsification by a single surgeon with bilateral implantation of TFNT00 or ATLISA TRI839 IOLs were enrolled in this study. The main outcome was the comparison of the binocular and the monocular corrected defocus curves plotted from the distance-corrected visual acuity (DCVA) between 2 IOLs within 3 different ambient illuminations of 360, 130, and 30 lux. The uncorrected distance visual acuity (UDVA), distance-corrected intermediate (DCIVA), and near visual acuity (DCNVA) were also measured. Mixed-model analysis of variance (ANOVA) and multilevel mixed-effects linear regression were used to determine the difference of DCVA at each defocus step.

Results: Seventeen patients aged 50 to 77 years with 34 eyes, 9 of whom had bilateral TFNT00 implantation and 8 had bilateral ATLISA TRI839, were enrolled in the study. The average UDVA of TFNT00 and ATLISA TRI839 implanted eyes were 0.003 and 0.029 LogMAR respectively. The monocular corrected defocus curve showed significantly higher visual acuity for TFNT00 at intermediate range (-1.5 D) at 130 and 30 lux, and also (-2.0 D) at 360, 130, and 30 lux (all $p < 0.05$). At near range (-3.0 D), the monocular corrected defocus curve showed significantly higher visual acuity for ATLISA TRI839 at 130 and 30 lux (all $p < 0.05$). There was no significant difference of monocular corrected defocus curve at distant range (+1.0 D to -1.0 D) and at near-intermediate range (-2.5 D) between 2 IOLs. Binocular corrected defocus curves showed no significant difference between 2 IOLs in all illuminance conditions.

Conclusions: Monocular implantation of TFNT00 yielded better intermediate visual acuity scores at all illuminance whereas ATLISA TRI839 performed better at near range in dimmer conditions. There was no significant difference of binocular DCVA between these 2 IOL models.

ABSTRACT BODY:

Purpose: To review outcomes of patients with proliferative diabetic retinopathy (PDR) who received pars plana vitrectomy (PPV) with endolaser panretinal photocoagulation (PRP).

Methods: Retrospective chart review study that included patients who underwent PPV with endolaser PRP between June 1, 2010 to May 31, 2020.

Results: PPV with PRP was performed in 287 eyes of 250 patients. Two hundred forty-six (85.7%) eyes had preoperative vitreous hemorrhage (VH) and 114 (39.7%) eyes had preoperative retinal detachment (RD). Mean preoperative best-corrected visual acuity (BCVA) was 20/781. Mean postoperative BCVAs were 20/150, 20/142, 20/150, 20/136, and 20/142 at 3 months, 6 months, 12 months, 2 years, and 3 years, respectively ($P < 0.001$). Postoperative complications included VH (18.1%), RD (12.5%), cataract (31.6%), macular hole (2.1%), and endophthalmitis (1.0%). There were negative correlations between age and BCVA at 12 months ($r = -0.27$, $P = 0.002$), 2 years ($r = -0.28$, $P = 0.007$), and 3 years ($r = -0.28$, $P = 0.009$) postoperatively. Individuals with hypertension had worse visual acuity than individuals without hypertension at 3 months ($P = 0.02$), 6 months ($P < 0.001$), and 12 months postoperatively ($P < 0.001$). Individuals with hypertension were also more likely to undergo an additional PPV than individuals without hypertension ($P = 0.002$). Eyes with traction on ultrasound had a greater frequency of postoperative VH ($P < 0.001$), cataract ($P < 0.001$), and need for additional PPV ($P = 0.001$) and PRP ($P < 0.001$) compared to eyes without traction. Patients with type 2 diabetes had superior postoperative BCVA at 2 years ($P = 0.004$) and 3 years ($P = 0.02$) compared to patients with type 1 diabetes. Preoperative PRP, anti-vascular endothelial growth factor, aspirin, warfarin, and clopidogrel therapy were not associated with superior postoperative visual acuity or reduced rates of postoperative complications including VH ($P > 0.05$). There were no relationships between postoperative BCVA and hemoglobin A1c, duration of diabetes, duration of PDR, smoking history, hemodialysis status, or insulin dependence ($P > 0.05$).

Conclusions: PPV with PRP yields significant improvements in visual acuity. Certain factors including diabetes type, hypertension, age, and preoperative exam findings may affect postoperative outcomes.

ABSTRACT BODY:

Purpose: Inherited retinal diseases (IRDs) are a major cause of early-onset vision loss. While mutations in coding regions explain 60% of IRDs, non-coding variants can be a source of missing heritability. A major knowledge-gap lies in the role of long non-coding RNAs (lncRNAs), highly tissue-specific molecules that regulate gene expression at the right time and place. However, little is known about their function in the retina. Here we identified a novel retina-specific lncRNA located upstream ABCA4, the gene implicated in Stargardt (STGD1) disease.

Methods: Expression specificity was determined by re-analysis of published short-read RNAseq data (GTEx, adult human retina, retinal organoids) as well as single-cell data (adult human retina). Long-read sequencing on adult human retina was performed using nanopore sequencing (PCR-cDNA kit, PromethION, ONT). Single-molecule RNA in situ hybridization (RNAScope/BaseScope) was conducted to elucidate cell-type expression. Chromatin interaction profiles (UMI-4C) were generated to evaluate interaction with the ABCA4 promoter. Genomic variation was evaluated in smMIPS data of the ABCA4 locus in 1,054 STGD1 cases.

Results: Short-read RNAseq analysis of ~7,400 transcriptomes of 54 tissues (GTEx) and 152 transcriptomes of adult human retinas revealed a potential novel lncRNA upstream of ABCA4, with expression restricted to the human retina. Long-read sequencing of donor retina identified at least two novel multi-exonic isoforms, for which expression was demonstrated in the outer nuclear layer of adult human retina. The lncRNA is transcribed from an active retinal enhancer interacting with the ABCA4 promoter, suggesting a cis-acting effect on ABCA4. In smMIPS data from 1,054 STGD1 cases we identified 5 heterozygous novel copy number variants overlapping the lncRNA, representing likely pathogenic or modifying alleles. Perturbation knockdown studies in human retinal explants are ongoing to further elucidate its function.

Conclusions: We identified and characterized a novel retina-specific lncRNA, potentially implicated in ABCA4-associated IRD. This study provides novel insight into the role of this lncRNA - an unexplored class of molecule in the

retina field - in gene regulation and IRD pathogenesis, which may ultimately entail therapeutic perspectives.

TITLE: Analysis of Retinogeniculate Synapses in the DBA/2J Mouse Model of Glaucoma

SESSION TITLE: Neurodegeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. King, Virginia Tech Carilion School of Medicine, Roanoke, Virginia, UNITED STATES|A. Monavarfeshani, M. Fox, Fralin Biomedical Research Institute at VTC, Roanoke, Virginia, UNITED STATES|

Commercial Relationships Disclosure: Rebecca King: Commercial Relationship: Code N (No Commercial Relationship) | Aboozar Monavarfeshani: Commercial Relationship: Code N (No Commercial Relationship) | Michael Fox: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Glaucoma is a degenerative disease of retinal ganglion cells (RGC). More than 30 distinct types of RGCs exist in the mammalian retina, and studies of experimental glaucoma suggest that some types may be more vulnerable to injury from elevated intraocular pressure (IOP). In addition to different morphologies, functional responses, and susceptibility to neurodegeration, RGCs form different types of synapses in retinorecipient nuclei. For example, in the mouse dorsal lateral geniculate nucleus (dLGN), RGC axons generate both simple (single retinal input) and complex (multiple retinal inputs converging on shared regions of relay cell dendrite) retinogeniculate (RG) synapses. At present, it is unclear whether simple and complex RG synapses are generated by distinct RGC types. Here, our goal was to enhance our understanding of RGC vulnerability to injury from elevated IOP by exploring changes to simple and complex RG synapses in the DBA/2J (D2) mouse model of glaucoma.

Methods: To assess RG synapse morphology, we employed serial block-face scanning electron microscopy (SBFSEM), which was performed on dLGN from D2 mice at 6 and 9 months of age. Image analysis and quantification was performed using TrakEM2 in Fiji. Retinal terminals, their axons, and the post-synaptic relay cell dendrites were traced throughout the volume of imaged tissue. At least 50 distinct axons were traced in each data set. Retinal bouton size, complexity, and active zone numbers were quantified and compared to controls.

Results: SBFSEM shows axons with dark axoplasm, a sign of axon degeneration, in the 9-month D2 data set and abnormal membranous organelles in relay cell dendrites in both data sets. In a preliminary analysis of data collected to date, 57% of RG synapses in D2 mice were classified as complex compared to 90% in controls. Additionally, only 11% of complex synapses in D2 mice contained 4 or more retinal terminals while the vast majority (86%) of complex synapses in control mice contained 4 – 14 retinal terminals.

Conclusions: Evidence of axon degeneration suggests the SBFSEM data sets being analyzed are from glaucomatous D2 mice. Currently, our results indicate that glaucomatous D2 mice exhibit changes in relay cell dendrites before axon withdrawal and have significantly fewer complex RG synapses with fewer retinal terminals per complex synapse than controls.

ABSTRACT BODY:

Purpose: Characterizing the photoreceptor mosaic morphology is essential to understand the basis of vision in normal subjects and to detect disease. A novel technique to visualize these cells in vivo is through an Adaptive Optics Scanning Laser Ophthalmoscope (AOSLO). After visualization of these cells, the next challenges is the development of robust, accurate, and automated cell detection strategies. This is followed by the challenge of defining the normal parameters of cone density, thereby allowing more precise and accurate detection of pathological anomalies. This project seeks to identify the correct combination of cell detection strategies to build and annotate a normative database.

Methods: A bespoke BMC Apaeros built AOSLO was used. Images were acquired using 1.5×1.5° FOV at 49 locations in 35 healthy subjects. Images were stabilized and averaged using BMC's proprietary AOImageProcessing software. Two cell detection strategies were used, depending on the eccentricity. For foveal and parafoveal regions (0° to 3°), an original intensity-based image analysis method was developed, which we called Automatic Adaptive Thresholding and Maxima Search (ATMS). To more peripherical regions (4° to 10°), a recently published Deep Learning method was applied (without retraining) (MDRNN, by Davidson et al., 2018).

Results: A normative database of cone density was built in all four cardinal meridians from 0° to 10° eccentricities, currently comprising 35 subjects divided into 3 groups defined as [age range; Male/Female; mean axial length +/- stdev]. Group 1 - 20 to 35; 4/7; 25.09 +/- 1.24; group 2 - 36 to 50; 4/9; 23.91 +/- 1.15; group 3 - 51 to 65; 2/9; 23.67 +/- 0.87. Cone density estimates were consistent with measurements reported in other normative databases (e.g. Chang et al., 2013, Woog et al., 2018).

Conclusions: This normative database of cone density was created using a pipeline based on a combination of cell detection strategies optimized to be effective at different eccentricities, which included an original algorithm for automatic cone count in the fovea. This normative database offers support for the stratified analysis of the relationship between (several) eye phenotypes and cone photoreceptor density. Leveraging our automatic method, the database will incrementally grow through consenting patients at our hospital and through cooperations with other research groups.

ABSTRACT BODY:

Purpose: We previously proposed that TENM4 and CSMD1 are susceptible causative gene for high myopia (PNAS 2017). This study aims to investigate the prevalence of TENM4 and CSMD1 variants in pathologic myopia (PM) in a Chinese cohort.

Methods: One hundred unrelated non-syndromic PM patients were recruited in this study. Patients with fundus changes including posterior staphyloma and myopic maculopathy equal to or more serious than diffuse choroidal atrophy were defined as PM. DNA were subjected to whole-exome sequencing. Variants of TENM4 and CSMD1 were selected and analyzed by multistep bioinformatics analyses.

Results: Pathologic mutations of TENM4 and CSMD1 were detected in 15 (15%) and 8 (8%) unrelated patients respectively. These mutations were rare or absent in the 1000 Genomes Project and Exome Aggregation Consortium. Age and axial length distribution are presented in figures below.

Conclusions: TENM4 and CSMD1 might be responsible for high myopia. This finding provides supportive information for further study of causative gene of high myopia.

ABSTRACT BODY:

Purpose: Lockdowns from the COVID-19 caused a significant increase in the use of digital devices. This increase could result in ocular sequelae such as eyestrain. We used a cross-sectional survey to assess the magnitude severity and determinants of eye strain among Saudi population during the COVID-19 pandemic, lockdown and abuse of digital devices.

Methods: Saudi population of both genders, aged > 15 years old were invited. The questionnaire included demography, eye strain related symptoms, severity, and use of optical aid during covid-19 lockdown. The frequency and severity of eye strain were calculated. Based on the sum of 15 eye strain related sign and symptom, Computer Vision Syndrome (CVS) score was graded as none/ mild moderate and severe CVS. CVS was associated/correlated to determinants. The total score was calculated using a formula score of A X B for each sign and symptom,. The sum of 15 eye strain related sign and symptom score was further graded as <30 = no or mild CVS, 30 to 59 = moderate CVS and more than 60 = severe CVS.

Results: There were 2,009 surveyed participants. Their median age was 20 years. The purpose of using digital devices was work and social purposes for 68.4%, and 61% used the digital devices for more than 6 hours daily. The prevalence of knowledge about CVS and '20-20 rule for using digital devices' was 9.4% and 6.9 respectively. Two hundred and eighty-two (14%) of the study participants were diagnosed with COVID-19, and 223 (11.1%) were quarantined. Three fourth of participants did not use contact lens (CL) or spectacles, 393 (19.6%) were using spectacles, 59 (2.9%) were using CL and 55 (2.7%) were using both Spectacles and CL. The most experienced symptoms of eye strain due to digital devices use were headache, burning, itching, tearing, and redness of eyes. The median of eye strain symptom score was 20 (IQR 10: 32). Based on the symptom score, 'no/ mild' grade of eye strain was perceived by 1,486 (74%), moderate eye strain by 468 (23.3%) and severe eye strain by 55 (2.7%) participants. The daily six hours usage of digital devices was found to have a significant and positive association to the eye strain severity grade during COVID-19 lockdown.

Conclusions: Saudi-population suffered from eye strain during COVID-19 lockdown due to excessive digital devices use. Health care provider should educate general population about healthy measures during daily use of digital devices.

ABSTRACT BODY:

Purpose: SARM1 (sterile alpha and armadillo motif-containing protein) is a highly conserved Toll/IL-1 Receptor (TIR) adaptor with important roles in mediating immune responses. Studies in the CNS have shown that SARM1 plays a role in induction of neuronal axon degeneration in response to a variety of injuries. Activated SARM1 consumes essential metabolite NAD^+ leading to cellular metabolic catastrophe and axon degeneration. Retinal degenerative diseases (RDDs), such as retinitis pigmentosa (RP) and age-related macular degeneration (AMD), are leading causes of incurable blindness and share a common endpoint, the degeneration of specialized neurons; photoreceptor cells. We sought to investigate whether SARM1 serves a pro-degenerative function during photoreceptor cell degeneration in models of RDD.

Methods: Using models of photoreceptor ($Rho^{-/-}$ mice) and RPE (intravenous administration of sodium iodate) degeneration we investigated the role of SARM1 during retinal degeneration, by generation of $Rho^{-/-}Sarm1^{-/-}$ mice and use of $Sarm1^{-/-}$ mice respectively. We performed ocular coherence tomography (OCT), electroretinography (ERG) and histological analysis of retinal tissue sections to characterize the extent of retinal degeneration in these models in the absence of SARM1. We performed fluorescence lifetime imaging microscopy (FLIM) on retinal explant tissue to measure the levels of NADH in the $Rho^{-/-}$model in the presence of absence of SARM1.

Results: In both models Sarm1 deficiency delayed retinal degeneration, preserving photoreceptor cells as assessed by both OCT and hematoxylin & eosin staining of tissue sections. In $Rho^{-/-}$ mice there is reduced NADH levels at 4 weeks of age, this is in contrast to $Rho^{-/-}Sarm1^{-/-}$ mice where NADH pools are maintained. As NADH exists in a relationship with NAD^+ we can infer that SARM1 is cleaving NAD^+ during retinal degeneration in this model. ERG analysis demonstrates preserved function of photoreceptor cones in the RDD models in the $Sarm1^{-/-}$ mice, indicating that the preserved photoreceptor cells are viable and retain light sensitivity for a visual response.

Conclusions: Our present data identifies a previously unappreciated role for SARM1 in photoreceptor cell death but not RPE cell death. SARM1 serves a distinct function in the course of photoreceptor degeneration to its previously described role in other neuronal cell types mediating cell death in addition to axon degeneration.

ABSTRACT BODY:

Purpose: When the methods and data of vision screening programmes are known in detail, and software is available to calculate their cost-effectiveness, it should be possible to compare their cost-effectiveness. We assessed the current state of data collection and its availability in all countries in Europe.

Methods: In the EUSCREEN Survey (2017-2019) representatives of 42 European countries provided data on demography, existing screening programmes, coverage and attendance, screening tests, follow-up, diagnosis, treatment, benefit and adverse effect of screening. As part of the EUSCREEN Study, software was developed to calculate the cost-effectiveness of screening programmes (miscan.euscreen.org). By sensitivity analysis 6 items essential for cost-effectiveness analysis were identified: prevalence, sensitivity, specificity, coverage, attendance, loss to follow-up. Five others: age at screening, screening test, test threshold, screening professional and costs are determined in the screening protocol or can be calculated with relative ease. In the autumn of 2021, Survey items on data collection, monitoring and evaluation, and the six items essential for cost-effectiveness analysis were updated with an additional questionnaire.

Results: Data was obtained from all countries in Europe and Israel and Turkey, not from Norway and Portugal. For 3 countries, vision screening was reported for a large region instead of a country. The practice of data collection in vision screening was reported in 36% (N=42) of countries; collected data were published in 10%. Procedures for quality assurance in vision screening were reported in 19%, research of screening effectiveness in 43%, whereas cost-effectiveness analysis was performed in 12%. Data on prevalence of amblyopia were reported in 40% of countries, on sensitivity of screening tests in 17%, on their specificity in 19%, on coverage of screening in 45%, on attendance in 21% and on loss to follow-up in 12%.

Conclusions: Data collection in vision screening programmes is deplorable: data essential for cost-effectiveness comparison could not be reported from most countries. It mostly takes place at a local or regional level, for quality assurance or for accountability to commissioners, and the data is often not accessible. The resulting inability to compare cost-effectiveness of vision screening programmes perpetuates their diversity and inefficiency.

ABSTRACT BODY:

Purpose: The possibility to make a “Disease-in-a-Dish” using patient-derived induced pluripotent stem cells (iPSCs) represent an unexpected opportunity to elaborate useful research tools for drug development. Part of the challenge in cell-based drug discovery is the production of large number of identical cells of interest. In this way, we present here innovative cell-based approaches for large production and banking of specific epithelial, glial or neuronal retinal cells to model retinal dystrophies as retinitis pigmentosa (RP), diabetic retinopathy (DR) or age-related macular degeneration (AMD).

Methods: Defined culture of adherent human iPSC (hiPSCs), floating hiPSC-derived retinal organoids (ROs) and RO-isolated retinal progenitor cells (hiRPCs) were used to produce all retinal cells types. HiPSC-derived retinal pigmented epithelial cells (hiRPE) were produced directly from adherent hiPSC cultures. HiPSCs-derived Muller glial cells (hiMGCs) were selected and expanded from mature ROs. Expandable and multipotent hiRPCs were selected from early ROs using innovative culture conditions and RPC-dedicated medium.

Results: Both hiRPE, hiMGCs and multipotent hiRPCs can be cryopreserved while retaining their proliferation capacity for large-scale productions. The development of a hiRPE-based model of retinitis pigmentosa coupled to high throughput screening (HTS) identified potential repositionable drugs from the FDA-approved compound library. HiMGCs recapitulated inflammatory and angiogenic features of DR in pathological-like culture condition compatible with HTS. Different neuroretinal cells such as photoceptor precursors, ganglion, amacrine and horizontal cells can be easily differentiated from previously expanded hiRPCs. Moreover, specific culture conditions to direct photoreceptor differentiation of hiRPCs allowed the production of large and high enriched cultures of photoceptor precursors (>90%) in 2 weeks without purification step.

Conclusions: Large-scale productions of relevant human retinal cells such as hiRPEs, hiMGCs, hiRPCs and photoreceptor precursors are now available. This retinal cell library offers new biological tools to better understand the different retinal dystrophies and to develop new treatments adapted to each type of the disease.

ABSTRACT BODY:

Purpose: The CRISPR-Cas9 knockin mouse (NOD.129(Cg)-Gt(ROSA)26Sor$^{tm1.1(CAG-cas9*,-EGFP)Fezh}$/J) was originally reported by Platt et al (2014) and is now commercially available from Jax Laboratories, Bar Harbor, Maine. The mouse, which has a CAG-3xFLAG-SpCas9-P2A-EGFP cassette inserted at the Rosa26 locus, theoretically displays ubiquitous Cas9 and EGFP expression in nucleated cells. Previous studies showed Cas9 expression and successful gene knockdown across bone marrow, brain, and lung tissues using AAV and lentiviral-delivered sgRNA (Platt et al., 2014). Our aim was to characterise retinal expression of SpCas9 to determine the suitability of this mouse as a model for optimising retinal gene knockdown.

Methods:

Cas9EGFP homozygotes were killed by cervical dislocation. For Western blot, retinae were dissected and underwent dissociation and magnetic-activated cell sorting (MACS) into CD73+ve (rod photoreceptors) and CD73-ve (remaining retinal cells) populations. Western blot was carried out for FLAG, SpCas9 and α -tubulin. For immunohistochemistry (IHC), eyes were fixed in 4% PFA for 30 minutes, embedded in OCT and frozen. Cryostat sections were stained for SpCas9, FLAG, PKC-a, and calbindin, with secondary Alexa-Fluor goat antibodies, and imaged on a Zeiss LSM710 confocal microscope. In vivo imaging took place using the Heidelberg SLO and OCT.

Results: Western blot showed clear whole retina SpCas9 expression, but weak expression in the CD73+ve extracted cell population (rods). IHC showed Cas9 and EGFP expression in the retinal ganglion cell and inner nuclear layer, but not in the outer nuclear layer or photoreceptor outer segments. Cas9 and EGFP expression did not co-localise with PKC-α or with calbindin, indicating limited horizontal and bipolar cell expression, but showed an expression pattern characteristic of Müller glia.

Conclusions: The NOD.129(Cg)-Gt(ROSA)26Sor$^{tm1.1(CAG-cas9*,-EGFP)Fezh}$/J mouse would be a suitable model for optimising Cas9 knockdown in retinal ganglion cells or Müller cells, but may be a poor model for photoreceptor targets. The apparent lack of both Cas9 and EGFP in this model may reflect variable expressivity from the ROSA26 locus in retinal cell populations.

ABSTRACT BODY:

Purpose: Iron-induced oxidative stress has been implicated in retinal degenerative diseases. Mouse models with systemic, or neural retina-specific knockout (KO) of homologous ferroxidases ceruloplasmin (Cp) and hephaestin (Heph) have retinal iron overload. We previously reported age-dependent iron overload in the retina of Cp/Heph DKO mice by 6mo, and retinal degeneration with features of age-related macular degeneration by 9mo. Because Cp and Heph can facilitate cellular iron export by ferroportin (Fpn), we hypothesized that the impairment of ferroxidase-facilitated, Fpn-mediated iron export from retinal neurons and glia might account for these results.

Methods: To investigate the role of Fpn in retinal iron regulation, we developed mice with neural retina-specific Fpn KO (mRx-Cre+, $Fpn^{flox/flox}$). Mice were aged to 7-10 months of age, and retinal iron levels were analyzed using qPCR and immunolabeling for ferritin light chain (Ft-L). To further test the hypothesis that a combination of elevated ferrous iron plus deletion of Fpn might cause retinal iron accumulation, we developed mice with neural retina-specific Fpn KO and systemic Cp KO. To increase the serum iron level, mice were given an intraperitoneal injection of iron at 3 months of age. Retina iron levels were analyzed using qPCR and immunolabeling for Ft-L.

Results: There was no indication of retinal iron overload in neural retina-specific Fpn KO mice at 7-10 months of age: the mRNA levels of transferrin receptor (Tfrc) measured by qPCR were not altered in retina-specific Fpn KO mice and immunolabeling for Ft-L showed similar intensity in retina-specific Fpn KO mice and controls. Iron injected mice with systemic Cp KO and retina-specific Fpn KO had a significant but small decrease in retinal Tfrc mRNA. There was no effect on Dmt1 mRNA no change in Ft-L immunolabeling, which we have typically observed are less sensitive measures of retinal iron overload than levels of Tfrc mRNA.

Conclusions: These results indicate that impaired Fpn mediated cellular iron export is not sufficient to explain the retinal iron overload observed in Cp/Heph DKO mice. Elevated levels of ferrous iron are likely to contribute in the absence of ferroxidases. Supporting this, injection of ferrous sulfate into the vitreous increased retinal iron levels indicated by significantly decreased Tfrc mRNA followed by rapid retinal degeneration.

TITLE: Adeno-associated virus Type 2-mediated Expression of HSPB1 Protects Retinal Ganglion Cells against Ocular hypertension in Mice

SESSION TITLE: Neuroprotection and Neuroregeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Nam, A. Dhillon, R.B. Nahomi, M.B. Pantcheva, R.H. Nagaraj, Ophthalmology, University of Colorado Denver School of Medicine, Aurora, Colorado, UNITED STATES|

Commercial Relationships Disclosure: Mihyun Nam: Commercial Relationship: Code N (No Commercial Relationship) | Armaan Dhillon: Commercial Relationship: Code N (No Commercial Relationship) | Rooban Nahomi: Commercial Relationship: Code N (No Commercial Relationship) | Mina Pantcheva: Commercial Relationship: Code N (No Commercial Relationship) | Ram Nagaraj: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate the protective effect of adeno-associated virus type 2 (AAV2)-mediated expression of HSPB1 in retinal ganglion cells (RGCs) against ocular hypertension-induced RGC death in mice.

Methods: We constructed an AAV2 vector encoding human HSPB1 with a mini RGC-specific neurofilament light chain promoter PLE345 for specific expression in RGCs. Microbeads were injected into the anterior chamber of mice two weeks before or two weeks after the AAV2-HSPB1 injection. IOP was measured using a tonometer. Retinal flatmounts were fixed and immunostained for RGCs and activated microglia with specific antibodies. Anterograde axonal transportation was assessed by intravitreal injection with Alexa fluor-555 conjugated cholera toxin-B subunit (CTB).

Results: Intravitreal injection of AAV2-HSPB1 resulted in robust expression of HSPB1 in both the soma and axons of RGCs. The IOP was significantly elevated one week after microbeads injection. The microbead-injected mice showed a gradual decrease in RGCs, with a 36% decrease at six weeks post-injection. AAV2-HSPB1 administration one week after microbead injection resulted in significant prevention of RGC loss, with only a 12% decrease at six weeks. The microbead-injected mice showed defective anterograde transportation of CTB along the length of the optic nerve. The AAV2-HSPB1 administration inhibited these axonal defects. In addition, the administration of AAV2-HSPB1 prevented the activation of microglia in microbead-injected mice.

Conclusions: Intravitreal administration of AAV2-HSPB1 resulted in RGC-specific expression of HSPB1. HSPB1 expression protected RGC somas and axons in mice with ocular hypertension. Our results suggest that AAV2-HSPB1 could be advanced as a therapy for neuroprotection in glaucoma.

TITLE: Comparison of erythrocyte flowrates in retinal and nailfold capillaries in human subjects

SESSION TITLE: Biomechanics and ocular blood flow

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Park, S. Chen, V. Chen, O. Saeedi, Department of Ophthalmology and Visual Sciences, University of Maryland School of Medicine, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Ashley Park: Commercial Relationship: Code N (No Commercial Relationship) | Shih-En Chen: Commercial Relationship: Code N (No Commercial Relationship) | Victoria Chen: Commercial Relationship: Code N (No Commercial Relationship) | Osamah Saeedi: Commercial Relationship(s);Code F (Financial Support):Aerie Pharmaceuticals, Heidelberg Engineering, and Vasoptic Medical Inc.

ABSTRACT BODY:

Purpose: Impaired ocular blood flow is associated with major ocular disease, and impaired retinal and peripheral capillary circulation has been observed in glaucoma patients. Nailfold capillaroscopy allows visualization and quantification of peripheral blood flow, while erythrocyte mediated angiography (EMA) permits in vivo determination of retinal capillary blood flow. The purpose of this study is to compare erythrocyte velocities in the retina and the nailfold.

Methods: We conducted a cross-sectional study of five control subjects to determine nailfold and retinal capillary velocities. Nailfold erythrocyte velocities were measured by tracking blood gap displacement in the capillaries across the image frames, and retinal erythrocyte velocities were determined using a MATLAB script as previously described (Tracey et al., Scientific Reports, 2019). Three second and ten second videos of the nailfold were obtained. ARIA in MATLAB was used to obtain diameter measurements.

Results: We analyzed five nailfold capillaries in five control patients. The average nailfold capillary velocity was 0.29 ± 0.08 mm/s and the coefficient of variation for velocity and diameter were 0.012 and 0.03 respectively. The average retinal capillary velocity was 0.94±0.03 mm/s, which was significantly different from nailfold capillaries ($p<0.01$). There was no correlation between retinal and nailfold capillary flowrates (R^2 of 0.286, $p=0.465$).

Conclusions: We found that retinal capillary velocities are significantly higher than nailfold capillary velocities, consistent with high metabolic rates of the retina. Our nailfold capillary velocities were within range of what is reported in literature. We also present high reproducibility rates of our nailfold velocity and diameter measurements.

ABSTRACT BODY:

Purpose: To provide human grading results which describe features of suspicious glaucomatous disc damage on CF images in UKBB and preliminary results from the DL assisted image interpretation applied to these images.

Methods: Topcon 3D OCT–1000 Mark II system was used to acquire a single CF image of the optic disc and macula on un-dilated eyes. CF images were graded by NetwORCUK (a network comprising Belfast, Liverpool and Moorfields Ophthalmic Reading Centres) to answer pre-determined questions on features of the optic disc. Quality assurance was carried out at a rate of 1 in 20 gradings. CF images in the first batch graded, totaling 33222 participants, were cropped using the 'You Only Look Once' DL model to produce a sub-image of 299x299 pixels centred at the predicted centre of the optic disc before a novel end-to-end DL regression algorithm using an InceptionV3 based network was applied in order to predict CDR.

Results: 68517 participant image sets were analysed by graders for signs of glaucoma; 67985 right eye and 67613 left eye CF images were available. Of these 61,020 right eye and 60,242 left eye CF images were gradable.

CF images, regardless of quality, were included in the AI assisted image interpretation. High level of suspicion for glaucoma, defined as CDR >=0.7 was identified in 481 (0.70%) right eyes and 421 (0.61%) left eyes. There were an additional 299 (0.44%) of right eyes and 237 (0.35%) of left eyes with CDR < 0.7, with suspicious features such as haemorrhage on the disc or notching. In addition, there were 1210 participants with a difference of >=0.2 in CDR between eyes.

Preliminary AI results on the first batch graded using 62398 eyes (31788 right; 30610 left) allowed successful cropping in 54377 eyes (87%), of which 80% were used for training, 10% for validation and 10% for testing. The results on 5444 independent testing images showed the error between the predicted and true measurement of CDR to be <0.05 in 56% (95% CI: 54%, 57%), < 0.1 in 74% (95% CI: 76%, 78%) and <0.2 in 97.6% (95% CI: 97%, 98%) of images.

Conclusions: These data provide human grading for future projects on topics that require optic disc grading in both health and disease. AI assisted image interpretation has shown high accuracy when compared to human grading of the CDR on a large-scale.

SUBMITTER (NAME ONLY): Carmelina Gordon

TITLE: Poor response to anti-VEGF treatment in macular edema secondary to central retinal vein occlusion and its baseline predictors: a post hoc analysis of COPERNICUS and GALILEO

SESSION TITLE: Retinal vascular diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Gordon, Specialty Eye Institute, Jackson, Michigan, UNITED STATES|

Commercial Relationships Disclosure: Carmelina Gordon: Commercial Relationship(s);Code F (Financial Support):Alcon, Alimera, Allergan, Genentech, NIH, Novartis, Regeneron Pharmaceuticals, Inc., Santen Pharmaceutical Co., Ltd., and Topco

ABSTRACT BODY:

Purpose: To characterize poor responders to intravitreal aflibercept injection (IAI) following 24-week treatment, evaluate their longer-term visual and anatomic outcomes through week 52, and identify baseline factors associated with poor response in patients with macular edema secondary to central retinal vein occlusion (MEfCRVO).

Methods: Patients with MEfCRVO who received IAI 2 mg every 4 weeks for 24 weeks followed by pro-re-nata (PRN) dosing from Week 24 through Week 52 in COPERNICUS and GALILEO were analyzed post hoc. Poor response at Week 24 was defined by a combination of visual acuity (<58 letters [Snellen <20/80] or ≤5 letters gain from baseline) and anatomic criteria (central subfield thickness [CST] ≥300 µm or presence of intraretinal or subretinal fluid). All other patients were considered responders. Univariate analysis examined baseline factors (sex, ethnicity, race, age, BMI, perfusion status, time since diagnosis, BCVA and CST) associated with poor response at Week 24.

Results: Of 217 eligible IAI-treated patients,18 (8.3%) were poor responders, 184 (84.8%) were responders, and 15 (6.9%) were indeterminate at Week 24. Baseline characteristics were comparable between the two groups with the exception of lower mean BCVA for poor responders vs responders (42.1 vs 52.7; P=0.0145). Poor responders vs responders received more PRN injections through Week 52 (4.2 vs 2.5; P<0.05). Mean difference (95% CI) in absolute BCVA between poor responders vs responders was −23.3 (−30.2, −16.4) letters at Week 24 and −22.3 (−29.8, −14.8) letters at Week 52. A lower proportion of poor responders vs responders had gain of ≥5 letters (61.1% vs 88.6%), ≥10 letters (50.0% vs 81.1%) and ≥15 letters (16.7% vs 66.9%) at Week 52. Mean difference (95% CI) in absolute CST between poor responders vs responders was 77.7 (24.3, 131.1) µm at Week 24 and 40.7 (−12.8, 94.2) µm at Week 52. The odds of having a poor response at Week 24 decreased by 21% for every 5-letter increase in baseline BCVA (P=0.0062).

Conclusions: A small proportion of patients with MEfCRVO had poor response to IAI at Week 24 in COPERNICUS and GALILEO. These patients had smaller BCVA gains at Week 52 despite similar reduction in CST and receiving more PRN injections. Baseline vision was a key predictor of poor response at Week 24.

TITLE: Pre-operative Parameters and Post-operative Outcomes for Transscleral Fixated Intraocular Lenses in a Bronx-based population: A Retrospective Review

SESSION TITLE: Cataract surgery 1

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Kumar, Z. Zhou, BronxCare Health System, Bronx, New York, UNITED STATES|

Commercial Relationships Disclosure: Shaina Kumar: Commercial Relationship: Code N (No Commercial Relationship) | Zimei Zhou: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Although placement of an intraocular lens (IOL) in the capsular bag is ideal during cataract surgery, complications require ophthalmologists to know alternative methods of IOL implantation. We performed a retrospective chart review to learn about the pre-operative parameters/indications and post-operative outcomes in patients that underwent transscleral-fixated IOL (TSFIOL) implantation at our institution. Our hope is to better understand which patients may be more suitable for TSFIOL's based on these considerations.

Methods: We conducted a retrospective chart review of 30 patients (22 males and 8 females; mean age of 68.6) at our institution that underwent TSFIOL implantation by a posterior segment surgeon. Data was collected from EyeMD (the ophthalmology clinic electronic medical record (EMR)) and Allscripts (hospital EMR), and then separated into 2 main categories: pre-operative parameters/indications for surgery and post-operative outcomes/complications.

Results: Review of pre-operative parameters revealed that 14 patients were aphakic, 7 had a ruptured capsule, 8 had a dislocated IOL, 9 had a traumatic event, 11 had iris damage, 6 had a shallow anterior chamber, and 9 had corneal pathology. Initial preoperative visual acuity (VA) was compared with final VA (3 months post-operatively). The majority displayed an improvement in VA (n = 23), while a minority had a decline (n=2; the remaining were lost to follow up or had no change in VA). We further divided our population into emergent (7 cases) or planned surgeries (22 cases) and compared improvement in VA between the 2 groups. No significant difference was found between the 2 groups in terms of improvement in VA (p=0.748). The overall complication rate was 48.28%, which includes choroidal detachment, hypotony, corneal edema, Irvine Gass syndrome, and elevated intraocular pressure.

Conclusions: Long-term data on functional outcomes after TSFIOL implantation is limited. Overall, 79.31% of patients had unchanged/improved VA. Therefore, the majority had improved VA after TSFIOL implantation. Improvement in VA's among planned and emergency cases was not significantly different. The most common complication in our cohort was ocular hypertension. We hope to include additional patients in our retrospective review to better understand which patients may be more suitable candidates for a TSFIOL.

ABSTRACT BODY:

Purpose: Rubeosis Iridis (RI) is characterized by an increase in neovascularization and inflammation factors in the iris. During angiogenesis, the urokinase plasminogen activator (uPA) and its receptor (uPAR) play a pivotal role in extracellular matrix remodeling, where uPAR regulates endothelial cell migration and proliferation through assembly with transmembrane receptors. Here, in a context of hypoxia-induced angiogenesis, the antagonist effects of UPARANT onto the uPA/uPAR system were investigated using a novel ex vivo human iris organotypic angiogenesis assay. Additionally, to further elucidate whether UPARANT acts on epithelial or endothelial cells, in vitro assays were performed on human iris epithelial cells (hIEC) versus human retinal endothelial cells (hREC).

Methods: hIEC, hREC and human iris organotypic cultures were kept in normoxia (20% O_2) or exposed to hypoxia-stimulated angiogenesis (1% O_2), and treated with UPARANT and control-vehicle. UPARANT anti-angiogenic effects were analyzed by in vitro wound healing and spheroid sprouting assays, ex vivo human iris sprouting assay, immunofluorescence, quantitative PCR and protein assays (western and dot blots, and co-immunoprecipitation). The effects of UPARANT in human ex vivo iris angiogenesis were focal to endothelial cells.

Results: UPARANT does not affect iris epithelial wound recovery yet reduces sprouting angiogenesis in hREC spheroids and ex vivo human iris organotypic cultures. Western blot analysis demonstrates that UPARANT leads to a decrease of hypoxia-inducible factor (HIF)-1α protein levels, concomitantly with a decrease in phosphorylation levels of protein kinase B (AKT) and cyclic AMP response element-binding protein (CREB) when compared to vehicle treated.

Phospho-protein array illustrated an unidentified antagonism of UPARANT in the interaction of uPAR with the low-density lipoprotein receptor-related protein-1, resulting in inhibition of b-catenin–mediated angiogenesis in this model.

Conclusions: These findings corroborate the role of UPARANT as a multifactor inhibitor of ocular vascular endothelial cells, which could benefit the treatment of RI in patients afflicted with multiple other ocular neovascular diseases.

ABSTRACT BODY:

Purpose: To functionally investigate candidate splice altering variants in inherited retinal dystrophy (IRD) genes including non-coding variants in genes with restricted expression using RT-PCR and nanopore single-molecule sequencing for transcripts from patient blood derived total RNA samples.

Methods: Patients were recruited from the inherited retinal disease clinics at Moorfields Eye Hospital (London, UK) as part of the UK 100,000 genomes project with an additional individual identified at Radboud University Medical Center (Nijmegen, the Netherlands). Ten probands who were identified to carry a candidate pathogenic non-coding or synonymous variant were selected for investigation. RT-PCR was performed on total RNA derived from affected individuals and control blood to amplify fragments flanking the affected intron or whole transcripts where possible. Nanopore sequencing was performed using the Oxford Nanopore Technologies Genomic DNA by Ligation (SQK-LSK109) protocol and sequencing on a flongle flow-cell.

Results: Ten affected individuals diagnosed with IRD were identified to carry candidate variants that were otherwise only classed as variants of uncertain significance. Variants were identified in CDH23, COQ5, NMNAT1, PDSS1, PROM1, PRPF31 and TULP1 following interrogation of whole genome sequencing data and multidisciplinary team investigation. This study demonstrated mis-splicing for nine intronic variants in genes CDH23, COQ5, PDSS1 (N=2), PROM1, PRPF31 (N=3) and TULP1 and a reduced transcript level for an upstream variant in NMNAT1. It was possible to detect transcript alteration for genes that are not expressed in blood (CDH23, PROM1, TULP1) and where standard techniques failed to demonstrate mis-splicing.

Conclusions: This study shows that nanopore sequencing is effective for detecting transcript alterations from blood derived RNA for retinal disease genes, allowing functional characterisation of non-canonical splice and upstream variants, where no mis-splicing was apparent by agarose gel electrophoresis precluding Sanger sequencing analysis. Thus, simple blood samples can be collected for investigation without the need for complicated cloning or induced pluripotent stem cell derived retinal progenitor or organoid experiments. The functional evidence provides the crucial support for interpretation of pathogenicity of these candidate variants.

ABSTRACT BODY:

Purpose: The purpose of this study is to characterize a novel CRISPR-Cas9-generated rat model of Pde6b-associated retinal degeneration and test the ability of clinical-grade AAV vectors (serotypes 1 and 5) to deliver PDE6B to rat photoreceptor cells and mitigate disease progression.

Methods: Pde6b-null rats were generated on a Sprague-Dawley background via CRISPR-Cas9 genome editing (Cyogen Biosciences). Small guide RNA pairs and in vitro transcribed Cas9 mRNA were co-injected into fertilized eggs for generation of animals. The genotypes of founder animals and subsequent matings were verified via PCR and sequencing analysis. Animals were evaluated at post-natal days 14 (P14), 30, 60 and 90 via optical coherence tomography (OCT), electroretinography (ERG), and immunohistochemistry with histological quantification of outer nuclear layer (ONL) cell density and thickness at each time point. For gene augmentation experiments, Pde6b-null animals received a single subretinal injection (3ml) of either AAV2/1-PDE6B or AAV2/5-PDE6B (total dose of $2x10^9$ vg) into one eye. The fellow eye was used as a vehicle-injected control. A cohort of wild-type animals were also treated with each vector to confirm delivery and lack of overexpression toxicity. ONL measurements were compared in a masked fashion to determine efficacy of gene augmentation.

Results: Compared to wild-type and heterozygous animals, Pde6b-null animals displayed early onset by P14 and rapid photoreceptor degeneration that resulted in blindness (i.e., non-recordable ERG) by P30 and near complete loss of photoreceptors by P60. Delivery of AAV2/1-PDE6B or AAV2/5-PDE6B to wild-type rats showed that AAV2/1-PDE6B drives more full-length human PDE6B protein than AAV2/5-PDE6B. No evidence of overexpression toxicity was detected for either vector. In Pde6b-null rats, eyes that received AAV2/1-PDE6B displayed a delay in photoreceptor cell loss compared to buffer-treated controls and eyes treated with AAV2/5-PDE6B.

Conclusions: These preclinical data will be used to guide development of a gene therapy vector for treatment of PDE6B-associated retinitis pigmentosa. In addition to its utility for evaluating the efficacy of gene augmentation vectors, rapid retinal degeneration resulting in near complete photoreceptor loss by 2 months of age makes the Pde6b-null rat ideal for evaluating autologous stem cell-mediated photoreceptor replacement.

ABSTRACT BODY:

Purpose: In recent years, reticular pseudodrusen (RPD) have been identified as risk factors for advanced age-related macular degeneration (AMD). Only two studies explored machine learning (ML) techniques for their automatic detection on OCT, neither allowing for accurate lesion quantification. We developed a deep learning pipeline for the detection and quantification of conventional drusen (CD) and RPD in the UK Biobank (UKBB), a large-scale biomedical database and research resource.

Methods: A ML pipeline consisting of several ML models was developed: a. A classification model and an out of distribution model for ungradable scans. b. A classification model to identify scans with drusen of any type (CD or RPD). d. An image segmentation model to independently segment lesions as RPD or CD, allowing their quantification.

Of 2,622 UKBB participants with a self-reported diagnosis of AMD, 1,284 had OCT scans and were included in the study. Manual delineation of features was performed by five experienced graders for the segmentation model. We used 3D Inception-V1 as the architecture for the classification models and a 2D U-Net architecture for the segmentation model.

To measure overlap in segmented areas between the model and graders we used free-response receiver operating characteristic (FROC) curves. In addition, the intraclass correlation coefficient (ICC) for absolute agreement was used to measure agreement in the area of the different lesions between the model and graders and for interrater reliability analysis.

Results: The first classification model classified ungradable scans with an area under the curve (AUC) of 94%. The deep ensemble models achieved an AUC of 87%. The second classification model achieved an AUC of 99.3% for classifying drusen of any type vs. controls. Considering one false positive lesion per image on average, the segmentation model achieved a sensitivity of 85% for drusen and 62% for RPD. The ICC for CD area was 0.79 and for RPD it was 0.66. This exceeded human interrater agreement (0.72 for CD, 0.37 for RPD).

Conclusions: We present a deep learning pipeline for the elimination of ungradable scans, classification of drusen, and segmentation of CD and RPD. To the best of our knowledge, this is the first pipeline enabling the total workflow, and this is the first DL model to allow accurate quantification of these lesions exceeding human performance.

ABSTRACT BODY:

Purpose: Triamcinolone acetonide injectable suspension, for suprachoroidal use (SCS-TA) provides targeted drug delivery to the choroid and retina while minimizing steroid exposure in nontarget tissues. This integrated analysis evaluated SCS-TA for the treatment of macular edema (ME) secondary to noninfectious uveitis (NIU) across two studies.

Methods: Data from a randomized, double-masked, sham-controlled trial (PEACHTREE) and an open-label trial (AZALEA) were pooled. Only those subjects with ME secondary to NIU defined by a central subfield retinal thickness (CST) ≥300 µm with fluid and a best-corrected visual acuity (BCVA) of ≥5 and ≤70 Early Treatment Diabetic Retinopathy Study (ETDRS) letters in the study eye at baseline were included in the analysis. In both studies, subjects received SCS-TA at baseline and Week 12 and were followed every 4 weeks for 24 weeks. Control subjects received a sham procedure at baseline and Week 12. Outcomes included BCVA, CST, anterior chamber (AC) cells, AC flare, vitreous haze (VH) and adverse events (AEs).

Results: The integrated population included 95 subjects (PEACHTREE 88; AZALEA 7). Increase from baseline in BCVA was greater with SCS-TA vs control with a mean difference of 10.7 letters at Week 24 ($P<0.001$ for all visits). Proportions of subjects achieving a mean ≥15 letters gain were greater with SCS-TA vs control (47.4% vs 16.7% at Week 24; $P<0.001$ for all visits). Reduction in CST was greater and more subjects achieved a CST <300 µm with SCS-TA vs control ($P<0.001$ for all visits). In subjects with baseline inflammation, 72.2%, 71.1% and 72.0% in the SCS-TA group vs 13.6%, 20.0% and 19.0% in the control group achieved resolution of AC cells, flare and VH at Week 24 (all $P<0.01$). Rescue therapy was required by 12.6% and 73.3% of subjects in the SCS-TA and control groups, respectively. AEs were mostly mild and no treatment-related serious AEs were reported. Overall, incidence of elevated intraocular pressure (IOP) was 20% and 15% in the SCS-TA and control groups (7.4% vs 0% at time of procedure; 12.6% vs 15% post-procedure, control IOP events occurred post rescue). Cataract rates were 7.4% and 6.7% for SCS-TA and control respectively.

Conclusions: In this integrated analysis of two Phase 3 clinical trials, SCS-TA was confirmed to be effective and well tolerated in the treatment of ME associated with NIU.

ABSTRACT BODY:

Purpose: Cell specific promoters have long been desired and implemented in gene therapy vectors to enable controlled expression of transgenes. With genome editing strategies likely to dominate future gene therapies, cell specific promoters will be particularly necessary to limit unwanted editing possibilities in multiple cell types. We have validated a short PDE6B promoter (154bp) that drives transgene expression specifically in rod photoreceptor cells. This promoter, combined with an SaCas9 transgene, achieved dose-dependent editing of GFP in the Nrl.GFP mouse model, for which GFP expression is restricted to rod photoreceptor cells.

Methods: The PDE6B promoter was amplified from human DNA and reporter expression assessed in HEK293 cells, Y79 cells, retinal organoids and human retinal explants. Nrl.GFP mice were injected with reporter vectors and eyes harvested at 4 weeks post-injection for immunostaining. PDE6B.SaCas9 vectors were prepared with either a non-targeting or GFP targeting guide RNA and injected into Nrl.GFP mice at doses of 1E+08, 5E+08 or 1E+09 genome copies per eye. Expression of GFP was assessed by SLO and SaCas9 expression was confirmed by immunostaining and qPCR. Editing rates were assessed by DNA extraction and subcloning analysis.

Results: The PDE6B promoter enabled reporter expression in Y79 cells, human retinal explants and iPSC-derived retinal organoids. Nrl.GFP injected eyes revealed reporter expression was limited to rod photoreceptor cells with 100% of DsRed positive cells also GFP positive. Of 180 randomly selected GFP positive cells, 55% were also DsRed positive and of 92 cone-arrestin positive cells, none were DsRed positive. A dose dependent increase in SaCas9 expression was achieved that coincided with editing rates 1.67%, 5.00% and 8.33% for the doses of 1E+08, 5E+08 and 1E+09, respectively. SLO assessment of GFP revealed a significant difference in mean grey values from F10 injected eyes compared to paired eyes that received the non-targeting gRNA ($p=0.0248$, $n=10$). The middle dose of 5E+08 achieved the biggest difference with a 36.5% reduction in GFP fluorescence relative to paired injected eyes.

Conclusions: With its small size and rod photoreceptor-specific expression profile, the human PDE6B promoter is a viable option for gene therapy vectors, including CRISPR-based editing strategies where restricted expression profiles with effective editing rates will be desired.

ABSTRACT BODY:

Purpose: The eye is an organ attuned to function around the light/dark cycle. Its circadian system fine-tunes this process. Diabetes emerges as a disease that disrupts the overall circadian rhythms. In this study we asked how diabetes affects these daily rhythms in the mouse retina.

Methods: Healthy control and Ins2Akita/J diabetic mice were kept under a physiological 12h:12h light-dark cycle until 4 months of age. Retinas were collected from 4-5 mice every 4 hrs around the day/night cycle. Deep mRNA sequencing was conducted and transcripts were identified. Computational approaches were used for detection of rhythmicity (empirical JTK_Cycle, emp $p<0.05$, FC > 1.2), acrophase prediction (Harmonic Regression with a set period of 24 hrs and normalization set to false), differential rhythmic patterns (DORD analysis BH corrected $p < 0.05$), phase set enrichment analysis (PSEA, BH corrected p-value < 0.01) and upstream regulator predictions (IPA, $p<0.05$).Animal studies were carried out at the institutional animal care facilities at the Indiana University School of Medicine and Queen's University in accordance with institutional and national guidelines for the care and use of laboratory animals (IACUC10604,11167 and PPL2897).

Results: Almost 10% of the retinal transcriptome was identified as rhythmic with a clear 12hr axis of transcriptional activity, peaking at midday and midnight. Although the 12-hour transcriptional axis is retained in the diabetic retina, it was phase advanced by approximately 1-3 hours, however individual genes were phase advanced by up to 10 hours. Phase shifts rather than changes in the amplitude of rhythms of gene expression were more prominent. Interestingly, only mild changes in the circadian rhythms were observed, as those were entrained by the light cycle. However, oxidative phosphorylation and HIF1A and NUPR1 were identified as the major upstream regulators for the phase shifts.

Conclusions: To our knowledge this is the first study mapping the effects of diabetes in the rhythmic output in the retina. Importantly, we identified that much of the daily rhythmicity in the retina is altered and the source of this shift is more related to abnormal metabolic adaptation rather than circadian disruption. This led us to propose that a metabolic shift with an entrained clock within the diabetic retina creates an internal jet lag that contributes to neurodegeneration in diabetic retinopathy.

ABSTRACT BODY:

Purpose: Retinal neurodegenerative diseases (NDs) are comprised of numerous disorders which result in loss of varying cell types. These diseases range from glaucoma, which affects retinal ganglion cells, to age-related macular degeneration, a late onset ND affecting cone photoreceptors and the retinal pigment epithelium, to retinitis pigmentosa and Leber congenital amaurosis, two forms of inherited retinal dystrophies (IRDs) which result in primary cell death of the rod photoreceptors (PRs). In the last two decades, groups have uncovered that most NDs are accompanied by increased release of proinflammatory cytokines and proliferation of active microglia which can expedite the disease course. The purpose of this study is to decipher the inflammatory state of the retina of the BXD32 mouse, a novel, spontaneous IRD model.

Methods: We surveyed for IRD phenotypes using funduscopy with fluorescein angiography (F/FA), electroretinography (ERG), optokinetic nystamography (OKN), optical coherence tomography (OCT), and immunohistochemistry (IHC) for GFAP (glial fibrillary acidic protein) as well as TUNEL staining for apoptosis. We also assessed for inflammation using IHC analyses for macrophages (IBA1, ionized calcium binding adaptor molecule 1), TNFα (tumor necrosis factor alpha) and its downstream pathway components NF-κB p65 (nuclear factor kappa B p65), NLRP3 (NOD-, LRR- and pyrin domain-containing protein 3), STAT3 (signal transducer and activator of transcription 3) along with its phosphorylated forms pSTAT3-Y705 and S727, and the pathway antagonist SOCS3 (suppressor of cytokine signaling 3).

Results: F/FA and OCT found vessel attenuation and a rapid degeneration with most PRs lost before 24 weeks. ERG and OKN showed a steady decreasing loss of vision. IHC for GFAP and TUNEL exposed the highly stressed state of the retina with intense GFAP labeling and apoptosis. Co-labeling TUNEL with IBA1 revealed the presence of phagoptosis (phagocytosis of living cells). IHC confirmed heavy upregulation of all inflammatory markers.

Conclusions: The BXD32 mouse exhibits a rapid and early onset retinal degeneration consistent with expectations of an IRD model. The retinas of these mice also maintain a state of steady and increasing proinflammatory signaling with aberrant phagocytosis by macrophages and dramatic increases in proinflammatory cytokine and signaling pathway proteins.

ABSTRACT BODY:

Purpose: To evaluate a novel, sutureless, and glueless surgical technique using a triple-layer dehydrated amniotic membrane (TLDAM) for pterygia excisions in terms of surgical time and postoperative pain, epiphora, irritation, and foreign body sensation.

Methods: Twenty eyes of eighteen patients with pterygia underwent pterygia excision with mitomycin C. The conjunctival defect was closed with a sutureless, glueless technique with TLDAM placed directly on the dried scleral bed with the edges of the amniotic membrane tucked under the edges of the conjunctival defect. Surgical times were measured from injection of lidocaine to final placement of bandage contact lens.

Immediately postoperatively, a bandage contact lens was placed, and the eye was patched until postoperative day 1. Subsequently, patients graded self-administered questionnaires to rate pain, foreign body sensation (FBS), irritation, and watering on a scale of 1-5 (1-none; 5-most severe) at postoperative day 1 (POD1) and week 1 (POW1).

Results: Surgical times range from 6:55 to 12:00, with a mean of 8:29. Compared with a previous study of also sutureless and glueless methodology, the difference in surgical time means is 11.9 ($p < 0.0001$). Mean questionnaire scores for each postoperative visit were as follows: POD1 Pain 1.8, FBS 2.3, irritation 1.0, and epiphora 2.6; POW1 Pain 1.5, FBS 1.6, irritation 1.6, and epiphora 1.6. Compared to previous studies, this technique showed statistically significant improved pain at POD1 ($p=.0086$, $p<.0001$, $p<.0001$, $p<.0001$) and POW1 ($p=.0354$, $p=.0002$, $p=.0016$, $p<.0001$). Improvement in foreign body sensation was also noted at POD 1 ($p=.0321$, $p<.0001$). See table for full statistical analysis.

Conclusions: The sutureless, glueless technique using Cellularity TLDAM is a safe and effective surgical technique compared to current standard methods. There appears to be a significant benefit regarding surgical time and postoperative pain, irritation, epiphora, and foreign body sensation compared to previous studies.

TITLE: Analysis of Intravitreal Bevacizumab Treatment Response in Eyes with Branch Retinal Vein Occlusion via Optical Coherence Tomography Angiography

SESSION TITLE: Retinal vascular diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Jo, Y. Yoon, Ophthalmology, Asan Medical Center, Songpa-gu, Seoul, KOREA (THE REPUBLIC OF)|

Commercial Relationships Disclosure: Jaehyuck Jo: Commercial Relationship: Code N (No Commercial Relationship) | Young Hee Yoon: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Macular edema secondary to branch retinal vein occlusion (ME-BRVO) is a frequent cause of visual loss, especially when it is refractory to anti-VEGF therapy. The purpose of this study is to identify prognostic factors for response to intravitreal bevacizumab in patients with ME-BRVO by analyzing retinal microvascular integrity using optical coherence tomography angiography (OCTA)

Methods: Medical records of ME-BRVO patients who were treated with bevacizumab and followed at least 12 months were reviewed. On OCTA, the foveal avascular zone (FAZ) and vessel density (VD) of the superficial (SCP) and deep capillary plexuses (DCP) were obtained. Poor response was defined as central retinal thickness (CRT) > 300 μm or a decrease in CRT by < 50 μm after three consecutive bevacizumab injections.

Results: Eighty one eyes from 81 patients were included. Among them, 57 eyes were good responder and 23 eyes poor responder. Mean age of good and poor responders was 59.33 ± 10.36 and 66.17 ± 9.78 years ($p = 0.009$). Compared to good responders, poor responders showed larger DCP-FAZ size (SCP/DCP ratio; 0.92 ± 0.11 vs. 0.86 ± 0.17, $p = 0.045$), less DCP-VD at the most ischemic sector (SCP/DCP ratio; 0.99 ± 0.17 vs. 1.10 ± 0.31, $p = 0.046$), and larger FAZ perimeter (2.59 ± 0.75 vs. 4.10 ± 2.54, $p = 0.010$). In multivariate analyses, age, FAZ perimeter, and DCP-VD of the most ischemic sector were significant risk factors ($p = 0.024$, $p = 0.037$ and $p = 0.035$, respectively).

Conclusions: In ME-BRVO patients, poor response to bevacizumab may be predicted when the patient is older, FAZ is more disrupted, or macular ischemia is more severe in DCP than SCP.

ABSTRACT BODY:

Purpose: Our previous studies have shown that systemic neonatal murine cytomegalovirus (MCMV) infection of BALB/c mice spread to the eye with subsequent establishment of latency in choroid/ RPE, and the development of progressive AMD-like pathologies characterized by loss of choroidal capillaries, basal lamina deposits (BLamD), subretinal deposits (SD), degeneration of RPE and photoreceptors and choroidal neovascularization (CNV)-like lesions. In this study, the RNA sequencing (RNA-Seq) analysis was used to determine the molecular genetic changes and pathways affected by ocular MCMV latency.

Methods: MCMV (50 pfu per mouse) or medium as control were injected intra-peritoneally (i.p.) into BALB/c mice at <3 days after birth. At 18 months p.i., MCMV or medium injected mice were euthanized and eyes were collected and prepared for RNA-Sequencing.

Results: Compared to 3 uninfected control eyes, we identified 321 differentially expressed genes (DEGs) in 6 infected eyes (208 downregulated and 113 upregulated, cutoff with |fold change| ≥ 2 and q≤ 0.05). Using the QIAGEN Ingenuity Pathway Analysis (QIAGEN IPA), we identified 17 affected canonical pathways. 10 pathways function in neuroretinal signaling in which the majority of DEGs were downregulated. This was exemplified by the phototransduction pathway in which all 22 differentially expressed genes were downregulated with a p value less than 10^{-27}. 7 upregulated immune response/inflammatory pathways were also detected. Under the QIAGEN IPA, differentially expressed genes were categorized according to related diseases and functions. Many differentially expressed genes were noted in the categories of Ophthalmic Disease, Organismal Injury, Visual System Function, Cell Death and Survival, Inflammatory Responses, Cellular Movement and Immune Cell Trafficking. Genes involved in activation of retinal degeneration, including degeneration of photoreceptors were identified by activation z scores greater than 2. Cell death of retinal cells and epithelial tissues involving both apoptosis and necroptosis, was also activated.

Conclusions: MCMV ocular latency is associated with upregulation of immune and inflammatory responses and downregulation of multiple neuroretinal signaling pathways. Multiple cell death pathways are activated and contribute to the degeneration of photoreceptors, RPE and choroidal capillaries.

ABSTRACT BODY:

Purpose: To compare tear film osmolarity (TFO) values and matrix metalloproteinase 9 (MMP-9) levels between anophthalmic sockets and healthy fellow eyes and to assess the use of the MMP-9 and TFO as biomarkers for the Dry Anophthalmic Socket Syndrome (DASS).

Methods: In this prospective single-center study, the anophthalmic sockets and healthy fellow eyes of 98 unilateral anophthalmic patients were assessed using the Ocular Surface Disease Index (OSDI) questionnaire, InflammaDry® MMP-9 point-of-care immunoassay, TFO with TearLab™ Osmolarity System, and clinical conjunctival inflammation. MMP-9 concentration and conjunctival inflammation were graded semi-quantitatively. Differences between anophthalmic sockets and the healthy fellow eyes for OSDI scores, MMP-9, TFO values, clinical conjunctival inflammation, and eyelid abnormalities as well as the correlation between these factors and demographic data were evaluated.

Results: Patients had significantly higher OSDI, MMP-9, and TFO values, as well as higher conjunctival inflammation on the anophthalmic side, compared to the healthy side ($p \leq 0.002$, respectively). For anophthalmic sockets, there was a significant positive correlation between OSDI scores and TFO values ($p=0.007$), between the grade of posterior blepharitis and TFO values ($p=0.026$), between the conjunctival inflammation and MMP-9 values ($p<0.001$), as well as between MMP-9 levels and time since eye loss ($p=0.004$).

Conclusions: Measuring MMP-9 and TFO may be helpful tools as efficient, quantifiable biomarkers, disease course parameters, or predictors for treatment response in the clinical management of patients with DASS or in future therapy studies. Ophthalmologists should consider the updated diagnosis criteria including TFO and the definition for DASS proposed in this study.

ABSTRACT BODY:

Purpose: To determine the baseline systemic features predictive of rapid retinal nerve fiber layer (RNFL) thinning over future 5 years in primary open-angle glaucoma (POAG)

Methods: Database in the electronic medical record (EMR) was searched to include patients diagnosed with POAG between 2009 and 2016, and had been followed up for > 5 years with annual evaluation of RNFL thickness using spectral-domain optical coherence tomography (OCT). Systemic data obtained within 6 months from the time of glaucoma diagnosis were extracted from the EMR and incorporated into the model to predict the rate of progressive RNFL thinning. After training and testing a predictive model using a random forest (RF) method, the model was interpreted by the Shapley additive explanation plots (SHAP) method. The features that can explain the rate of progressive RNFL thinning were identified and interpreted.

Results: Data from 1256 eyes of 696 patients and 1107 eyes of 607 patients were included in the training and test sets, respectively. The R square value for the RF model was 0.88. The prediction model showed that higher serum aspartate aminotransferase, lower blood glucose, higher systolic blood pressure, higher high-density lipoprotein were the four most determinant systemic features predicting faster RNFL thinning over 5 years. Partial interaction plots showed interactions between some systemic features influencing the rate of RNFL thinning; the interactions between aspartate aminotransferase and Alkaline Phosphatase, systemic blood pressure and diastolic blood pressure, high-density lipoprotein and low-density lipoprotein, blood urea nitrogen and creatinine were associated features. Among ophthalmic features, higher global RNFL thickness and higher intraocular pressure were the most important factors predicting rapid RNFL thinning.

Conclusions: Baseline systemic features of POAG patients had predictive value in identifying those at risk of faster progression

ABSTRACT BODY:

Purpose: To demonstrate a training tool based on virtual reality technology that will simulate scenes with increasing for patients implanted with a visual
prosthesis. A virtual reality setup can create scenarios with an unlimited field of view that will enable the recipient to practice the scanning techniques needed to gain maximum benefit from the non-natural restored sight.

Methods: A virtual find-the-dot video game was integrated with the Argus II retinal prosthesis system. The game mimics daily use in which the patient is
required to steer the narrow region of interest (ROI) of the array to the target. A small Inertial Measurement Unit (IMU) was mounted on the glasses in order to track head movements in real-time. In the current setup, the regular video camera was disconnected and the video input was based on the visual content from the projection of the ROI of the array (18° x 11°) on the virtual wall based on real-time head position. A single target was presented on the virtual wall in each trial. The patient used a handheld game to indicate that he/she found the target. When the patient reported that the target was found, the trial is ended and the next trial is initiated with a new target at a different location. The application recorded the sub-area of the array

Results: A feasibility test of an Argus II patient shows that only a subset of the array was used to locate the target. OCT scan confirmed that the area of the array that wasn't used in the virtual game was lifted from the retina.

Conclusions: The usability of a virtual reality environment was shown to efficiently monitor the functionality of a retinal implant during scanning in a controlled
environment. The results indicate an issue with the position of the array that couldn’t be detected in regular use of the device. This methodology based on virtual reality technology can be implemented in both retinal and cortical visual implants that aim to restore sight.

ABSTRACT BODY:

Purpose: To characterize the single-cell transcriptome of the adult murine lacrimal gland in wild-type mice and mouse models of Sjogren's syndrome

Methods: Extraorbital lacrimal glands from adult BALB/cJ male (n=4) and female (n=4) mice, as well as adult NOD.B10.H2b male mice (n=2) and adult MRL-lpr female mice (n=2) were dissected and dissociated for droplet-based single-cell RNA sequencing (sc-RNAseq, 10X Genomics). All mice were 4 months of age at the time of experiment. Cell type annotation and differential gene expression analysis were performed using the Monocle R package. Gene set enrichment analysis (GSEA) was carried out using the Molecular Signatures Database (MSigDB) Hallmark gene sets. Cell type markers and other genes of interest were validated using immunofluorescence.

Results: A total of 102,431 cells were profiled by sc-RNAseq and included all known major cell types in the lacrimal gland. There was notable sexual dimorphism in the expression of the secretoglobins, with most secretoglobins being preferentially expressed in male lacrimal glands. Analysis of the immune cell clusters identified cells of monocyte lineage, plasma cells, B cells, T cells, NK cells, mast cells and a cluster of GM-CSF-producing innate lymphoid cells (ILCs). Cells of monocyte lineage exhibited dynamic transcriptional profiles that included a sub-population of Cd163-positive, Pf4-positive macrophages. GSEA revealed significant upregulation of interferon signaling in NOD.B10.H2b and MRL-lpr lacrimal glands.

Conclusions: sc-RNAseq revealed sexual dimorphism in gene expression and diverse immune cell types in lacrimal glands of wild-type mice and mouse models of Sjogren's syndrome. Interferon signaling appeared to be significantly upregulated in two mouse models of Sjogren's syndrome. The role of novel immune sub-populations, including innate lymphoid cells and Cd163-positive macrophages, in lacrimal gland disease remains to be elucidated and warrants further investigation.

ABSTRACT BODY:

Purpose: Positive dyshotopsia (PD) (such as halo, glare, starburst) is one of the main drawbacks of intraocular lenses (IOLs) for presbyopia correction. Adequate assessment of these effects before lens implantation is a valuable tool for both analysis and improvement of currently available IOL designs. This task is non-trivial and can be done by means of different optical setups. In this work we evaluate and compare two see-through setups, designed for simulations of the physical IOL-related visual symptoms.

Methods: Two IOL telescopes, Type 1 (IOL-T1) and Type 2 (IOL-T2) (devices are reported in two separate abstracts), have been objectively compared in their ability to translate visual symptoms from an IOL to an observer. In these systems, an IOL is part of the main ray path, which allows to study PD induced by an actual manufactured IOL. Each setup was evaluated with three different IOL designs: one monofocal, and two multifocals with 2.75 D and 4.00 D add power respectively. All three IOLs had the same base power. A camera was used in place of an observer, and a central glare source was imaged against a black background. The analysis was performed on high dynamic range images obtained from combining several frames (RGB converted to monochrome) with different exposure times. Light scatter data from literature is used as basis for comparison of the level and the field location of the halo of multifocal IOLs.

Results: In both setups, the recorded radial-average scatter function allows to clearly identify the multifocality-related halos and distinguish between the higher- and lower-add IOLs. The scatter levels of monofocal and multifocal IOLs were comparable with earlier reported data (Langeslag et al. JCRS 2014) The location of the IOL-related PD peaks is similar between the two devices and resides below 0.4° in field angle. This is comparable with previously reported theoretical prediction of 0.33° for a 4.00 D add power multifocal IOL (Van der Mooren et al. IOVS2016).

Conclusions: This study compares objectively the PD measured with two see-through setups designed to evaluate actual IOLs. The results show that IOL-T1 and IOL-T2 perform similarly and show data comparable to published pre-clinical data for different IOL designs, allowing objective assessment of PD. Subjective testing with these devices is out of the scope of this work and is reported in two separate studies.

ABSTRACT BODY:

Purpose: To investigate the potential stimulation effect of topical and oral fenofibrate, a peroxisome proliferator-activated receptor α (PPARα) agonist, on corneal nerve regeneration in diabetes mellitus.

Methods: A total of 108 Ins2Akita mice were divided into 4 groups (n=54 eyes/group): negative control (NC), positive control (PC), topical fenofibrate (TF) and oral fenofibrate (OF) treatment groups. All the mice underwent a 2-weekly clinical evaluation including slit-lamp examination, in vivo confocal microscopy (IVCM), corneal sensitivity, and tear enzyme-linked immunosorbent assay analysis. Mice were euthanized after 6-week and 12-week treatment, and were subjected to immunohistochemistry staining; corneal whole-mount staining, and western blot (WB) analysis.

Results: After 12-weeks of treatment, corneal PPARα protein expression evaluated by WB increased by 2.67-folds and 1.52-folds in the TF and OF groups, respectively. IVCM evaluation showed that the corneal nerve fibre density (CNFD) and corneal nerve fibre length (CNFL) significantly improved in the TF (9.2 to 16.8 fibres/mm^2 (p=0.01) and 3.9 to 6.2 mm/mm^2 (p=0.04), respectively) and OF groups (10.3 to 14.7 fibres/mm^2 (p=0.02) and 3.7 to 5.4 mm/mm^2 (p=0.04), respectively; Figure 1). The area of corneal epitheliopathy reduced in the TF (58.7% to 8.9%; p<0.001) and OF groups (37.4 to 6.8%; p<0.001 Figure 2). Corneal whole mount staining with β3-tubulin demonstrated that corneal nerve parameters decreased in diabetic mice, but they improved with fenofibrate treatment. No significant difference was observed in the corneal sensitivity of different groups. The tear substance P and calcitonin gene-related peptide concentrations significantly increased in the TF (115.07 to 163.4 pg/ml (p=0.03) and 149.22 to 215.92 pg/ml (p=0.02), respectively) and OF groups (112.77 to 116.53 pg/ml (p=0.32) and 156.37 to 247.50 pg/ml (p=0.01), respectively).

Conclusions: Topical and oral fenofibrate potentially promote corneal nerves regeneration and enhance ocular surface health in diabetic corneal neuropathy.

ABSTRACT BODY:

Purpose: With increasing emphasis on slowing myopia progression and using axial length to monitor eye growth, normative data for axial elongation in myopic children provide valuable clinical information. Percentile growth curves have been presented but are specific to the population tested and often include myopes and non-myopes, limiting their application. We conducted a meta-analysis to model axial elongation in myopic children with emphasis on the influence of age and race.

Methods: A comprehensive electronic systematic search was performed using Ovid Medline, EMBASE, Cochrane Central Register of Controlled Trials and the following terms: (myopia OR myopic) AND (child OR children) AND (progression OR longitudinal OR follow-up OR shift) AND axial. There were 79 studies with 105 untreated subpopulations and 203 evaluations of the mean axial change from baseline that met the inclusion criteria. Log(mean rate of axial elongation) was analyzed using a weighted multivariable linear mixed effects meta-analysis model. All collected covariates were tested for significance (age, race and baseline axial length selected). The model included three levels of random effects to account for all variability.

Results: Only data without missing observations of significant covariates were included in the final model (118 evaluations). The figure plots modeled annual axial elongation (with prediction intervals) by mean age of evaluation and race. Mean axial elongation decreases as age increases (15.0% decrease per year; 95%CI 11.4–18.5%, P <0.0001) and is greater in Asian children (by 27.9%; 95%CI 7.6–52.2%, P <0.01) compared to non-Asians. No other input variables, including baseline axial length, were statistically significant.

Conclusions: This analysis sets benchmark values for assessing axial elongation and monitoring myopia progression. To our knowledge, this is the first weighted random effects meta-analysis of axial elongation in myopic children. Interpretation is limited by use of aggregated data rather than individual subject data. The large prediction intervals should be borne in mind when interpreting individual rates of axial elongation clinically.

ABSTRACT BODY:

Purpose: To examine the potential impact of baseline imbalances on the 12-month results of OAKS, DERBY, and FILLY.

Methods: This is a post hoc analysis of the OAKS (NCT03525613), DERBY (NCT03525600) and FILLY (NCT02503332) studies. OAKS and DERBY are 24-month, phase 3, randomized studies comparing the efficacy and safety of monthly or every-other-month (EOM) intravitreal pegcetacoplan with sham in patients with GA secondary to age-related macular degeneration. FILLY was a phase 2 study with a similar design. The primary endpoint was change in absolute GA lesion size from baseline to Month 12 in OAKS and DERBY and change in square root transformed lesion size in FILLY. OAKS and FILLY met the primary endpoint while DERBY narrowly missed. In the original, pre-specified analysis, fellow eye CNV (OAKS and DERBY only), time, and baseline lesion size were covariates. To investigate differences in the treatment effect estimate, a systematic covariate analysis was conducted. Eight variables, including 7 baseline characteristics related to GA progression (study eye focality, lesion location, lesion size, pseudodrusen, low-luminance deficit (LLD), intermediate/large drusen number, GA laterality) and region were selected to investigate imbalances between treatment arms within each study. Variables with imbalances

meeting a p<0.2 threshold in any of the studies were included in the common adjusted model and efficacy analyses were repeated.

Results: Four variables with imbalances met the p<0.2 threshold for inclusion in the adjusted model: study eye lesion location (OAKS), study eye intermediate/large drusen number (DERBY, FILLY), study eye LLD (FILLY), and study eye lesion focality (DERBY). Before adjustment, absolute change in GA lesion growth reduction was 22% and 16% (OAKS), 12% and 11% (DERBY), and 31% and 21% (FILLY) for the monthly and EOM arms, respectively, at Month 12. Accounting for imbalanced variables, GA lesion growth reduction was 26% and 18% (OAKS), 16% and 15% (DERBY), and 25% and 18% (FILLY) for the monthly and EOM arms, respectively.

Conclusions: After adjusting for imbalances, results are more consistent across the studies, but this analysis does not fully explain the disparities nor replace the primary analysis. Future studies could consider incorporating additional variables as covariates or pre-specifying a plan for covariate adjustment.

ABSTRACT BODY:

Purpose: Vascular endothelial growth factor A (VEGF) is upregulated in neovascular ocular conditions, including diabetic retinopathy (DR). To study the pathological processes in DR and develop novel treatments, VEGF-induced animal models have been established. Intravitreal injections of recombinant VEGF have been shown to mimic many of the complex DR mechanisms. However, the effects are transient due to the short half-life of injected peptides. The aim of this study was to generate an inducible VEGF expression the human retinal pigment epithelium (ARPE-19) cells.

Methods: ARPE-19 cells were transduced with lentivirus (LV) expressing a SparQ^{TM} all-in-one cumate-inducible plasmid (System Biosciences) expressing VEGF-A$_{165}$ at a multiplicity of infection (MOI) of 20. To induce VEGF expression, cumate (30 µg/ml) was added 3d post-transduction. After 48h, VEGF levels were determined in the culture medium by ELISA (R&D Systems) and by qPCR from cell lysates. Cell viability was evaluated by MTT assay; cell motility was measured by scratch assays. Effects of VEGF expression on ARPE19 permeability were performed in Transwell® inserts (Corning Inc.) using conditioned media and quantified using fluorescent permeability standard, 6-carboxyfluorescein (6-CF).

Results: Cumate induction resulted in a 72% increase in VEGF levels as assessed by ELISA (MOI 20: 2005 ± 270 pg/ml vs. Control: 1165 ± 192 pg/ml, $p < 0.05$). qPCR revealed a 2.5-fold increase of VEGF mRNA levels compared with control ($p < 0.01$). MTT assay showed significantly increased number of cells at MOI 20 (115 ± 5%) compared with Control (100 ± 1%, $p < 0.05$), suggesting increased rate of proliferation. Permeability across the RPE monolayer was significantly increased in LV-transduced cells. Treatment of ARPE19 cells with conditioned media resulted in a significant increase in the apparent permeability coefficients (P_{app}) for 6-CF (0.66 ± 0.08 vs. 1.80 ± 0.41 x 10^{5} cm/s, $p < 0.05$). Scratch assays revealed increased motility and presence of tube-like structures in transduced cells, suggesting the presence of VEGF.

Conclusions: Cumate-inducible VEGF expression is a feasible approach for mechanistic studies evaluating the dose-dependent effects of VEGF on ARPE19 in preclinical drug discovery studies. Future work will generate stably expressing cell lines and evaluate the utility of cumate-inducible VEGF-expressing LV in in vivo systems.

ABSTRACT BODY:

Purpose: Recent studies have suggested that swept-source optical coherence tomography (SS-OCT) may be superior to spectral-domain OCT (SD-OCT) in imaging eyes with pathological myopia. Here, we compare SD-OCT and SS-OCT optic nerve head (ONH) scans in highly myopic (HM) eyes, to determine if one modality is superior to the other in terms of the percentage of usable scans produced (perUSABLE), and if this difference in perUSABLE is correlated with axial length (AL) and the presence of myopic defects, such as staphyloma, peripapillary atrophy and myopic macular degeneration.

Methods: 413 eyes from 212 patients with HM in at least 1 eye (AL 29.1 ± 2.5 mm, range 22.8 to 35.8 mm) were scanned with SD-OCT (Cirrus) and SS-OCT (Triton). Metrics for the quality of each scan were acquired, namely signal strength (SS), centration and motion artifact. Usable scans were defined as having adequate SS (Cirrus: SS≥7; Triton: SS≥30), adequate centration and lack of motion artifact. Paired t-tests and linear regression analysis were performed to compare SD-OCT vs. SS-OCT and evaluate the association between perUSABLE and potential baseline predictor variables (AL, age, gender, lens status, glaucoma diagnosis, myopic macular degeneration presence, peripapillary atrophy presence, disc tilt presence and presence of intrachoroidal cavitations).

Results: On average, ONH RNFL scans resulted in significantly greater likelihood of useable scans in Triton (41.8%p) vs. Cirrus scans (15.0%p, $p<0.001$, paired t-test). Specifically, it was the SS metric that drove this difference. Insufficient SS was found in 1.3%p of Triton scans, but 83.9%p of Cirrus scans ($p<0.001$). After accounting for potential confounders in multivariate analysis in Cirrus scans, every 1 mm of longer AL was associated with a 1.7%p greater likelihood of insufficient SS ($p=0.005$), and presence of MMD with +11.8%p ($p=0.001$). In contrast, in Triton scans, only logMAR VA (worse vision) increased the likelihood of insufficient SS (+1.3%p/ 1.0 LogMAR, $p=0.019$).

Conclusions: SS-OCT appears to be more successful than SD-OCT in providing useable ONH RNFL scans, mainly based on SS differences. In particular, Cirrus SS was affected by longer AL and presence of MMD. Our findings suggest SS-OCT may be more likely to avoid the need for repeated scans to achieve useable ONH RNFL data in HM eyes with MMD.

ABSTRACT BODY:

Purpose: In dry age-related macular degeneration (AMD), immune cells, predominantly macrophages and microglia, migrate to the subretinal space. This is observed in the intermediate stage of disease, prior to retinal pigment epithelial (RPE) atrophy, but the cause of this migration is not clear. Cholesterol, or associated oxidised deposits, accumulate in the subretinal space with age and have been shown to influence microglial migration in vitro. Recently, suppression of claudin-5, the principal tight junction component of the inner blood retinal barrier (iBRB), has been demonstrated to induce a geographic atrophy (GA) like phenotype in mice fed a high cholesterol diet (HCD).

Here, claudin-5 heterozygosity has been induced at the iBRB and mice have been fed HCD for up to 20 weeks, with the aim of elucidating how cholesterol and reduced iBRB integrity may drive the phenotype observed.

Methods: Cldn5 heterozygosity is specifically induced in endothelial cells using the Cre-LoxP system and the endothelial promoter, Tie2. Mice were fed a HCD or normal diet (ND) for up to 20 weeks. Retinal cryosections were examined to determine tight junction composition, cholesterol deposition and immune phenotype, relative to wild-type littermate controls. Serum was extracted from these mice to examine the systemic effect of the HCD.

Results: After 10 weeks of HCD, mice had significantly increased serum levels of cholesterol, as compared to controls fed ND. Filipin and bodipy staining detected an accumulation of cholesterol and lipid deposits in the outer retinal region of these mice. Retinal claudin-5 expression was reduced at the iBRB and increased immunohistochemical signal of macrophage markers, F4/80 and Cd68, suggests an increased presence of macrophages in the retinas of heterozygous mice. Histological analysis also showed greater numbers of cells in the subretinal region that positively stain for Cd68.

Conclusions: These results suggest that the combination of a more permeable iBRB and high dietary cholesterol may influence macrophage recruitment to the retina. Multiple methods of suppressing retinal claudin-5 in mice fed a cholesterol rich diet have now shown to result in RPE atrophy. This study demonstrates another characteristic phenotype of dry AMD, the accumulation of immune cells in the subretinal region, making these animal models an attractive choice for the study of disease progression.

ABSTRACT BODY:

Purpose: Neuroinflammation is triggered by the recognition of damage-associated molecular patterns (DAMPs) by the pattern recognition receptors (PRRs). Toll-like receptors (TLRs)/MyD88 and C-type lectin receptors (CLRs)/Card9 are two major PRR pathways that mediate inflammatory signaling in tissue injury and repair. In the present study, we investigated the respective functions of MyD88 and Card9 in retinal degeneration and neuroinflammation in a mouse model of retinitis pigmentosa (RP).

Methods: Rd10 mice, a RP model harboring Pde6b mutation, were crossed with Myd88$^{-/-}$ or Card9$^{-/-}$ mice to produce rd10; Myd88$^{-/-}$ or rd10; Card9$^{-/-}$ mice. The retinal phenotype was assessed by TUNEL, HE staining and electroretinogram (ERG). Retinal microglia were immunostained with Iba-1. Retinal mRNA profiles associated with neuroinflammation were analyzed by using nCounter Nano String Neuroinflammation panels. Immunostaining for the differential expressed genes was performed on retinal sections.

Results: Mdy88 deficiency in rd10 mice increased the number of TUNEL-positive cells in the outer nuclear layer (ONL) and exacerbated ONL thinning at P21 ($P < 0.01$, each); whereas Card9 deficiency did not influence the retinal phenotype. Consistently, scotopic ERG showed that b-wave amplitudes were decreased in rd10; Myd88$^{-/-}$ mice compared to rd10 mice ($P=0.002$), while there was no difference between rd10; Card9$^{-/-}$ and rd10 mice. Microglial translocation to the outer retina was significantly decreased in rd10; Myd88$^{-/-}$ compared to rd10 mice($P < 0.01$). Retinal mRNA profiling identified increased expression of Ifitm3 and Serpina3n, activation markers of astrocytic glia, in rd10; Myd88$^{-/-}$ mice. Immunostaining confirmed the upregulation of IFITM3 and SERPINA3N in astrocytes and müller cells in rd10; Myd88$^{-/-}$ mice.

Conclusions: TLRs/MyD88 pathway, but not CLRs/Card9 pathway, is a key mediator of neuroinflammation in rd10 mice, and may provide neuroprotection via promoting microglial translocation and regulating astrocyte/müller cell activation in RP.

ABSTRACT BODY:

Purpose: Improved adherence to treatment in the days surrounding clinic visits is a phenomenon known as white coat adherence. White coat adherence can lead to clinical measurements that are not representative of those present outside of clinical encounters. In glaucoma, white coat adherence to prescribed hypotensive therapy may lead to artificially low intraocular pressure readings, which may impact clinical evaluation and treatment decisions. The objective of this study was to assess white coat adherence in glaucoma patients.

Methods: In this cohort study, patients with primary open-angle glaucoma were selected from an ongoing longitudinal NIH-funded study if they used hypotensive eyedrops, had a clinic visit during the parent study, and had adherence data during the 56 days evenly bracketing the clinic visit. Adherence within the implementation phase was measured using Medication Event Monitoring System (MEMS) caps. Wilcoxon tests were used to compare mean adherence between the following periods: $Pre_{1\text{-}3}$ (days 1 to 3 preceding the clinic visit) and $Pre_{4\text{-}14}$ (days 4 to 14 preceding the clinic visit; $Post_{1\text{-}3}$ (days 1 to 3 following the clinic visit) and $Post_{4\text{-}14}$ (days 4 to 14 following the clinic visit). Analyses were performed in the full sample, and in patients with optimal (≥80%, n = 48) and suboptimal adherence (<80%, n = 17).

Results: Sixty-five patients were included, of which 47.7% were male. Mean age was 71 ± 8 years. In the six months bracketing the clinic visit, mean adherence was 86.1% ± 17.9. Overall, mean adherence significantly increased from $Pre_{4\text{-}14}$ to $Pre_{1\text{-}3}$ (85.2% to 88.3%) ($p = 0.04$). No significant change was observed after the clinic visit. In patients with optimal adherence, mean adherence significantly increased from $Pre_{4\text{-}14}$ to $Pre_{1\text{-}3}$ (93.8% to 97.7%) ($p = 0.01$), whereas no significant change was observed in patients with suboptimal adherence.

Conclusions: Our results show the presence of white coat adherence in this cohort of patients. However, this effect was not observed in patients with suboptimal adherence. Due to its potential impact on treatment decisions, providers should remain vigilant for white coat adherence and make this a relevant topic in patient-provider discussions.

ABSTRACT BODY:

Purpose: Interpretable staged transfer learning (iSTL), a pipeline for improving image classification with small sample sizes, was trained to carry out classification of optical coherence tomography (OCT) images. Model attention was visualised using SHAP maps, allowing interpretation of its behaviour.

Methods: A disease classification task using the Inception-v4 convolutional neural network architecture and iSTL training pipeline was carried out. Target OCT images are available under licence (Gholami et al). Normal (n=206), macular hole (MH: n=104), diabetic retinopathy (DR; n=109), and central serous retinopathy (CSR; n=104) scans were used. 50 images were used for data augmentation and training, the remainder were used for validation. The model was pre-trained on ImageNet, given randomly initialised output layers; the early layers frozen. The model was then trained on an intermediate bridge dataset (Kermany et al), output layers replaced, and final training carried out on the target dataset. 10 models were trained, the best performing selected for SHAP attention maps visualisation.

Results: SHAP maps showed both image and disease specific features were allocated importance during prediction. High importance areas have a large impact on the model's prediction, low importance areas have less impact. Classifying CSR, high importance was allocated to areas surrounding posterior epithelial detachment and not to areas of subretinal fluid. With DR, retinal microaneurysms and intraretinal oedema were highlighted but subretinal fluid was not. MH scans saw strong regional importance allocated to the vertical edge of full-thickness holes and surrounding intraretinal cysts when present. Normal images typically presented with medium to high importance on the retinal pigment epithelium adjacent to the macula as well as the inner limiting membrane surface. Many images saw moderate attention within areas of the choroid and vitreous that had no apparent clinical importance. When present in the scan field the optic nerve head was not allocated high importance.

Conclusions: Confounding factors are a concern when training deep learning models, particularly with small datasets. The iSTL model appeared to predominantly use clinically applicable features to make predictions. Further work is needed to determine whether some features used to make predictions are confounds or genuine clinical features related to disease biomarkers.

ABSTRACT BODY:

Purpose: Bioptic telescopic spectacles (BTS) can allow individuals with central vision impairment to obtain driving privileges. Hazard perception is the ability to anticipate potential road hazards to avoid a collision and has been shown to predict collision rates. The purpose of this study was to analyze whether hazard detection is affected by vision loss in bioptic drivers and what role the use of BTS may play.

Methods: ETDRS visual acuity was measured for each eye individually and through the BTS as indicated. Contrast sensitivity testing was performed with the Mars chart. Number of weekly trips and mileage were collected using Driving Habits Questionnaire. Hazard perception testing was conducted using 30 commercially available first-person driving video clips. Subjects signaled when they could first identify a traffic hazard requiring change of speed or direction. Bioptic drivers were tested with and without BTS in alternating blocks. Hazard detection times for each clip were converted to z-scores, converted back to seconds using the average response time across all videos, and then compared among conditions.

Results: Eight visually impaired licensed bioptic drivers and seven normally-sighted control drivers completed the study. There was no significant difference in age (mean±SD = 55±8 years for bioptic drivers vs 52±7 years for controls, P=0.730). Control drivers had significantly better visual acuity (logMAR -0.05±0.04) than visually impaired drivers (logMAR 0.69±0.09, P<0.01), even when these drivers used their bioptic telescope (logMAR 0.13±0.04, P<0.01). Log contrast sensitivity was poorer among bioptic drivers (1.51±0.19 vs 1.80±0.05, P=0.012). There was a trend toward more weekly mileage for bioptic drivers (median of 145 vs 96, P=0.281), but weekly trips were similar (median 9.5 for bioptic vs 10 for control). Standardized mean hazard response times (sec) for each condition were: bioptic with BTS = 5.1±0.9, bioptic w/out BTS = 5.8±1.4, normally-sighted = 3.6±1.9. Hazard response time was improved by about 0.8 sec when bioptic drivers used BTS (P=0.015). Only a low proportion of hazards was missed in all conditions.

Conclusions: Driving hazard response time in bioptic drivers was better with use of bioptic telescopic spectacles on a video-based test, though they still may have reduced response times when compared with normally-sighted drivers. Further work to determine how these findings are related to on-road performance and outcomes is warranted.

ABSTRACT BODY:

Purpose: USH2A mutations are a common cause of autosomal recessive retinitis pigmentosa (RP) and Usher syndrome, for which there are currently no approved treatments. Gene augmentation is a promising therapeutic strategy for treating retinal diseases, however conventional adeno-associated virus (AAV) vectors cannot accommodate cDNAs exceeding 4.7kb, such as the 15.6kb-long USH2A coding sequence. We investigated an alternative non-viral strategy using episomal DNA plasmid vectors containing a scaffold/matrix attachment region (S/MAR) and the human USH2A cDNA.

Methods: USH2A-S/MAR vectors were generated by inserting the human USH2A coding sequence into the pS/MAR backbone in five cloning steps. HEK293 cells and USH2A$^{-/-}$ patient-derived dermal fibroblasts were transfected using the Neon transfection system. Wild-type and ush2a^{u507} zebrafish were microinjected with USH2A-S/MAR vector at the single-cell stage of development. Expression of GFP and USH2A protein (usherin) was assessed in both human cell lines and zebrafish using qRT-PCR, immunostaining and Western blot analysis

Results: USH2A-S/MAR vectors were generated, containing a GFP reporter gene and CAG (pS/MAR-CAG-USH2A) or CMV (pS/MAR-CMV-USH2A) promoters, reaching a size of 23kb. The vectors drove persistent transgene expression in patient fibroblasts and zebrafish with usherin detection, and up to 12 months of GFP expression detected in zebrafish retinal photoreceptor cells.

Conclusions: To our knowledge, this is the first reported vector generating expression of full-length usherin in USH2A models. S/MAR DNA plasmid vectors have shown promise as a novel non-viral retinal gene therapy, warranting further translational development.

ABSTRACT BODY:

Purpose: Triamcinolone acetonide injectable suspension, for suprachoroidal use (SCS-TA) provides targeted drug delivery to the choroid/retina while minimizing steroid exposure in nontarget tissues. Efficacy and safety of SCS-TA in the treatment of macular edema (ME) secondary to noninfectious uveitis (NIU) were demonstrated in PEACHTREE. The objective of these post-hoc analyses was to determine whether baseline disease characteristics impact the efficacy of SCS-TA.

Methods: In PEACHTREE, 96 subjects received SCS-TA at baseline and Week 12; best-corrected visual acuity (BCVA) and central subfield thickness (CST; in μm) were evaluated every 4 weeks for 24 weeks. Mean [SEM] change from baseline (CFB) in BCVA (ETDRS letters) and CST (μm) were calculated among SCS-TA-treated subjects by time since ME diagnosis (n=24 ≤71 days, n=22 >71 days) or NIU diagnosis (n=60 ≤177 days, n=36 >177 days), and by disease onset (n=22 sudden, n=74 insidious) or duration (n=18 ≤3 months, n=78 >3 months). Treatment differences were evaluated using an analysis of variance model with a fixed effect for baseline demographic factors.

Results: Significant BCVA gains and CST reductions from baseline were found in all groups at all visits irrespective of time to diagnosis or disease onset/duration (P≤0.05). At Week 24, BCVA gains were 15.5 [1.48] in subjects with ME diagnosis ≤71 days vs 8.0 [3.37] in those with diagnosis >71 days (P=0.024) and 19.6 [3.13] in subjects with NIU duration ≤3 months vs 12.4 (1.55] with NIU >3 months (P=0.048). In subjects with NIU diagnosis ≤177 days vs >177 days and sudden vs insidious disease duration BCVA gains were 15.5 [1.70] vs 10.8 [2.42] and 18.4 [3.09] vs 12.4 [1.56], respectively at Week 24 (P≥0.075). In subjects with more recent vs earlier ME/NIU diagnoses, changes in CST were -164.2 [20.15] vs -115.3 [24.27] and -163.7 [23.28] vs -133.4 [20.15], while those with sudden vs insidious onset and NIU duration ≤3 vs >3 months had CST values of -165.7 [38.50] vs -148.8 [18.25] and -166.3 [45.29] vs -149.3 [17.49], respectively (P≥0.210).

Conclusions: Significant improvements in BCVA and CST were observed regardless of baseline disease characteristics, with trends towards greater improvements in those with more recent diagnosis and shorter disease duration. These findings suggest that treatment should be initiated promptly upon diagnosis.

TITLE: Evaluating chemical-crosslinking induced microstructural changes in the posterior sclera with high-frequency quantitative ultrasound

SESSION TITLE: Multidisciplinary Ophthalmic Imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Hoerig, J. Mamou, Riverside Research, New York, New York, UNITED STATES|J. Aichele, S. Catheline, LabTAU, Lyon, FRANCE|Q.V. Hoang, Singapore Eye Research Institute, Singapore, SINGAPORE|Q.V. Hoang, Ophthalmology, Columbia University, New York, New York, UNITED STATES|

Commercial Relationships Disclosure: Cameron Hoerig: Commercial Relationship: Code N (No Commercial Relationship) | Johannes Aichele: Commercial Relationship: Code N (No Commercial Relationship) | Stefan Catheline: Commercial Relationship: Code N (No Commercial Relationship) | Quan Hoang: Commercial Relationship: Code N (No Commercial Relationship) | Jonathan Mamou: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Chemical crosslinking (CXL) treatments offer a minimally invasive method of treating corneal ectasia and may also provide a method to halt the progression of myopia by strengthening the posterior sclera. Effective clinical use would require methods to evaluate longitudinal efficacy of CXL. Prior studies revealed the potential of quantitative ultrasound (QUS) to evaluate microstructural changes in the myopic posterior sclera. This study used QUS to monitor changes in sclera microstructure caused by CXL.

Methods: Seven adult ex vivo porcine eyes were procured from a supplier and placed in a -80^{o}C freezer for later use. Prior to data acquisition, eyes were thawed and excess tissue was removed from the posterior pole. Eyes were divided into control (3 eyes) and treated (4 eyes) groups. Control eyes were mounted in the experimental setup and immersed in room temperature phosphate buffered saline whereas treated eyes were immersed in 26mM sodium hydroxymethylglycinate (SHMG), a CXL agent. Eyes were scanned by an 80MHz ultrasound transducer at regular time intervals and the RF echo data were analyzed to compute ten QUS parameters: 5 from backscatter coefficient methods, 4 from envelope statistics, and shear wave speed (SWS) to infer tissue stiffness. Resulting QUS estimates were correlated with immersion time to evaluate the efficacy of QUS to monitor CXL treatment.

Results: Among control eyes, a significant increase in value was measured for spectral intercept (I_0, R^2=0.94, p=0.01), midband fit (R^2=0.91, p=0.01), and effective acoustic concentration (R^2=0.88, p=0.02). When considering treated eyes, positive temporal changes were measured for spectral slope (R^2=0.88, p=0.02) whereas significant decreases were observed for I_0 (R^2=0.86, p=0.02) and effective scatterer diameter (R^2=0.89, p=0.02). SWS estimated by passive elastography showed a significant increase for treated eyes (R^2=0.85, p=0.03) and no significant correlation with immersion time for control eyes (R^2=0.09, p=0.63).

Conclusions: QUS parameters estimated from high frequency ultrasound data are correlated with CXL-induced changes in scleral tissue microstructure. In addition, CXL leads to an increase in tissue stiffness that is measured as an increase in SWS. Results of this study provide preliminary evidence that high frequency QUS may be a useful tool for monitoring CXL treatment in a clinical setting.

TITLE: Golden-yellow fundus reflex and OCT hyper-reflectivity in RPGR retinopathy

SESSION TITLE: Retinal Degenerations, Gene Therapy, Transplantation, and Prostheses

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Benson, A. Agather, D. Blain, R.B. Hufnagel, B.P. Brooks, L. Huryn, W.M. Zein, C.A. Cukras, National Eye Institute, Bethesda, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Matthew Benson: Commercial Relationship: Code N (No Commercial Relationship) | Aime Agather: Commercial Relationship: Code N (No Commercial Relationship) | Delphine Blain: Commercial Relationship: Code N (No Commercial Relationship) | Robert Hufnagel: Commercial Relationship: Code N (No Commercial Relationship) | Brian Brooks: Commercial Relationship: Code N (No Commercial Relationship) | Laryssa Huryn: Commercial Relationship: Code N (No Commercial Relationship) | Wadih Zein: Commercial Relationship: Code N (No Commercial Relationship) | Catherine Cukras: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Pathogenic variants in RPGR represent a common cause of X-linked retinal degeneration and can cause severe vision loss. While a tapetal-like reflex has been demonstrated in female carriers and less commonly in affected males, a more detailed description of this feature is warranted, including evaluation of corresponding OCT findings and genotype-phenotype correlations. To address this, we report a series of patients with RPGR retinopathy who manifested a golden-yellow fundus reflex and corresponding OCT changes, and highlight the clinical, genetic, and multimodal imaging features.

Methods: We performed a single-center retrospective review of patients with disease-causing RPGR variants from 2014-2021. Clinical data including acuity, full-field electroretinography (ffERG), color fundus images, and OCT images were collected. Of 82 total cases, 66 had both fundus and OCT images available for review. An expert examiner, who was masked to participant demographics, clinical evaluations, and pathogenic RPGR variant, assessed bilateral color fundus photos for the presence of a golden-yellow reflex and paracentral OCT B-scans for an abnormally thick hyper-reflective band in the ellipsoid zone area of the outer retina.

Results: Of the total 66 cases, 12 (18.2%; 10 males and 2 females) had a golden-yellow fundus reflex with each demonstrating corresponding OCT outer retinal hyper-reflectivity on macular scans. Eleven out of these 12 (91.7%) had a cone-rod dystrophy (CRD) pattern of retinal dysfunction on ffERG. In addition, 11 out of the 12 (91.7%) cases had RPGR ORF15 (NM_001034853.2) variants located near the distal end of exon 15. One patient had a CRD and a variant in the middle of exon 15. A female carrier had a normal ffERG with a variant near the distal end of exon 15.

Conclusions: We identified a golden-yellow fundus reflex and corresponding hyper-reflective changes on OCT in nearly one-fifth of patients in our study. Intriguingly, the vast majority of these patients were male, had a CRD pattern of retinal dysfunction, and had RPGR ORF15 variants near the distal end of exon 15. By characterizing these imaging features, we hope to improve both diagnostic accuracy and understanding the pathophysiology in patients with RPGR retinopathy.

ABSTRACT BODY:

Purpose: Two hot spots in the RP1L1 gene including amino acid numbers 45 and 1196-1201 have been recently identified in occult macular dystrophy (OMD). Here, we describe the differential clinical effects of these two hotspots.

Methods: 50 participants from 29 families with OMD caused by pathogenic RP1L1 variants (i.e. Miyake's disease) were enrolled in Japan, South Korea, and China. Patients were classified into two genotype groups; patients with p.R45W variant (group A) and subjects with missense variants located between amino acid 1196 and 1201 (group B). Clinical parameters were statistically compared between these two genotype groups, including age of symptom onset, age at examination, visual acuity in the logarithm of the minimum angle of resolution unit (VA) of one randomly selected eye. The morphological features obtained with spectral-domain optical coherence tomography were also investigated.

Results: There are 31 patients in group A and 19 in group B. The median age of onset/examination was 18.8/43.4 years (range, 2-40/11-80) and 39.4/59.5 years (range, 13-70/34-92) in groups A and B, respectively (P= 0.00013). The median duration of 22.0 years (range, 6-64) and 19.0 years (range, 8-42), in groups A and B, respectively (P= 0.9799). The median VA in the right/left eye of groups A and B was 0.70/0.71 (range, -0.08-1.22/0-1.4) and 0.41/0.44 (range, -0.08-1.0/-0.08-0.82) LogMAR unit, respectively (P= 0.0032). The classical photoreceptor findings showing both blurred ellipsoid zone (EZ) and absence of interdigitation zone (IZ) was identified in 27 (27/31, 87.1%) and 15 (15/19, 78.9%) patients in groups A and B; subtle/early photoreceptor changes of local IZ loss and relatively preserved EZ were found in 3 (3/31, 9.68%) and 3 (3/19, 15.8%) in groups A and B (P=0.6583). Comparison analyses revealed statistically significant differences in terms of age of onset, age at the latest examination, and VA. There were no

significant differences with regards to the duration of the disease.

Conclusions: Different clinical severity derived from the two RP1L1 hotspots were identified; the severer phenotype of early onset and poor VA was related with p.R45W compared to 1196-1201. This genotype-phenotype association can be helpful for genetic counselling of patients regarding the visual severity.

ABSTRACT BODY:

Purpose: Multiple sublayers of retina can be visualized with visible light (vis-) OCT.However, image quality can be compromised due to patient movement, cataracts, small pupil size, and light scattering causing haziness and variability in signal to noise ratio in individual A-scans and in entire B-scans.The purpose of this study was to examine the effect of conventional and deep neural network dehazing techniques on the visibility and quantitative assessment of retinal sub-layers on vis-OCT images.

Methods: 9 healthy and 5 glaucoma subjects were scanned 3 times during one session.Scanning was done on the superior nasal side of para-foveal region,1.5 mm from the fovea with a 3D speckle reduction raster scanning protocol(3x3x1.6 mm with 8192x16x1024 samplings) using a prototype vis-OCT system.16 A-scan lines were averaged to reduce speckle noise.Gray-scale image dehazing guided by depth information and pretrained Dehazenet deep model following deep convolutional neural network with residual learning(DnCNN) were applied on original B-scans.Quality improvement were evaluated using quality index(QI) and contrast to noise ratio(CNR) on dehazed B-scans.For each subject, the dehazed B-scan of Dehazenet and DnCNN from a fixed location adjacent to the fovea were selected.The distances between each of 3 bright inner plexiform layers(IPL) and retinal pigment epithelium(RPE) sublayers were segmented manually for thickness measurements using a 8 A-scan averaged profile(Fig.).Coefficient of variations (CVs) were calculated to assess the measurement repeatability of the sublayers on original and dehazed B-scans.

Results: Healthy and glaucoma subjects were age 45.67±11.7and 59.60±13.4($p=0.07$,t-test),visual field mean deviation(MD)-1.55 to1.20 dB,and from -26.42 to -7.70dB($p= 0.003$,Wilcoxon),global mean circumpapillary retinal nerve fiber layer(RNFL)thickness 96.33±12.20 and 59.80±9.09mm($p<0.001$,Wilcoxon),respectively.Dehazed B-scans obtained by deep models have statistically significant better QI and CNR(Table1).Overall intra-subject CVs showed significantly improved reproducibility on all measured sub-layers of dehazed B-scans compared to original scans for all subjects(Tables 2,3).

Conclusions: Vis-OCT image quality can be improved using deep neural network dehazing model resulting in higher reproducible thickness measurements of retinal sublayers within subjects in dehazed B-scans.

TITLE: MMP9 associated with choroidal neovascularization in AMD is expressed in human immune cells

SESSION TITLE: Microglia in AMD and other immune factors in Retinal Degenerative Diseases

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: E.H. Sohn, C. Jiao, A.P. Voigt, T.E. Scheetz, R.F. Mullins, Institute for Vision Research, University of Iowa, Iowa City, Iowa, UNITED STATES|E.H. Sohn, C. Jiao, T.E. Scheetz, R.F. Mullins, Ophthalmology, The University of Iowa Hospitals and Clinics, Iowa City, Iowa, UNITED STATES|

Commercial Relationships Disclosure: Elliott Sohn: Commercial Relationship(s);Code F (Financial Support):Oxford Biomedica | Chunhua Jiao: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Voigt: Commercial Relationship: Code N (No Commercial Relationship) | Todd Scheetz: Commercial Relationship: Code N (No Commercial Relationship) | Robert Mullins: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Immune-mediated mechanisms play an important role in AMD pathogenesis and choroidal neovascularization (CNV), which may explain why many with exudative AMD are incomplete responders to anti-VEGF therapy. The MMP9 gene encodes matrix metallopeptidase 9, aka type IV collagenase, associated with degradation of the extracellular matrix that is implicated in angiogenesis and fibrosis. We recently confirmed that MMP9 increases risk only for exudative AMD. We sought to determine the cell-specific localization of MMP9 gene expression and the levels of MMP9 expressed by human cells.

Methods: Data from single cell RNA sequencing enriched for CD31+ expressing cells of the human posterior segment were analyzed for MMP9 gene expression. THP-1 monocyte cells were differentiated into M0 polarized macrophages with PMA and M2 macrophages with PMA/interleukin(IL)-4/IL-13. THP-1 cells were differentiated into immature dendritic cells (iDCs) with IL-4/GM-CSF, and into mature DCs (mDCs) with IL-4/GM-CSF/TNF-alpha/ionomycin. ELISA for MMP9 was performed on the conditioned media of M0, M2, iDCs and mDCs followed by normalization of the total cell numbers. Zymography was used to detect active and latent forms of MMP9. Immunostaining was performed with CD86 and CD206 to label mDCs and M2 macrophages, respectively.

Results: scRNA-seq of human donor eyes with AMD enriched with CD31+ cells reveal that MMP9 expression is highest in a choroidal DC-like cluster that includes DCs and macrophages with very low to no expression in other cell types or regions of the posterior eye. DCs (mature>immature) expressed higher levels of MMP9 compared to M0 and M2 macrophages (see figure). The band intensity of MMP9 from zymography showed similarly high signal for DCs relative to macrophages. Verification of mature DCs and M2 macrophages was confirmed with immunolabeling.

Conclusions: MMP9 plays a role in CNV through immune cells found in the choroid. Protein expression of MMP9 from dendritic and macrophage cells confirm the plausible mechanism of its role in AMD. Elucidating the disease mechanisms associated with MMP9 is of importance to reveal new targets for therapeutic intervention, the next milestone in exudative AMD.

ABSTRACT BODY:

Purpose: Tauopathies are a family of debilitating neurodegenerative disorders which include Alzheimer's disease, frontotemporal dementia, and more than 20 others. Since the retina is an extension of the CNS, it has attracted significant attention for its use as a biomarker for neurodegenerative diseases. Our previous study has found retinal vascular inflammation and leakage at the very early stage of tauopathic mouse model. Here, we aimed to non-invasively assess the temporal alterations of retinal vasculature and evaluate its potential as the biomarker for the early diagnosis of tauopathy.

Methods: P301S transgenic mice overexpressing human tau with a P301S mutation and age-matched WT littermate mice were used. The alterations of retinal vasculature down to the capillary level were examined by non-invasive imaging technique optical coherence tomography angiography (OCTA) at 3, 6 and 11 months of age. Retinal vasculature of superficial vascular plexus (SVP), intermediate capillary plexus (ICP) and deep capillary plexus (DCP) was analyzed using Angiotool for vessel density, number of branch points and total vessel length.

Results: At the early stage of tauopathy, although retinal vascular features were not greatly altered in the SVP, significant decreases of vessel density, number of brunch points and total vessel length were observed in the ICP and DCP of P301S retinas at 3 months of age. At 6 months of age, moderate decreases in vessel density and length were detected in the SVP of P301S retinas, but they were more significantly decreased in the ICP and DCP of P301S retinas. With aging, vessel density, branch points, and total vessel length in all three vascular plexuses were dramatically decreased in 11-month-old P301S mice compared to age-matched WT mice.

Conclusions: Our results demonstrate that retinal vascular features progressively change during the progression of tauopathy. Vessels in the ICP and DCP may be more susceptible to dysfunction/degeneration than vessels in the SVP. Since changes in retinal vasculature often precede tau pathology in the brain, noninvasive identification of retinal vasculature alterations with OCTA may be a useful biomarker for the early diagnosis of tauopathy.

TITLE: Regional Comparison of MUC1 Expression in the Bulbar Conjunctiva of Dry Eye and Normal Subjects

SESSION TITLE: Dry eye regulators: lacrimal gland, Meibomian gland, basic mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.A. Tichenor, M. Choi, Optometry, Indiana University Bloomington, Bloomington, Indiana, UNITED STATES|

Commercial Relationships Disclosure: Anna Tichenor: Commercial Relationship: Code N (No Commercial Relationship) | Moonjung Choi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To utilize a novel capillary electrophoresis nano-immunoassay system to evaluate and compare regional conjunctival protein expression of ocular surface mucin MUC1 in normal and dry eye subjects.

Methods: Adults with and without signs and symptoms of dry eye disease were recruited. Impression cytology was performed by placing a semicircle of filter paper on the bulbar conjunctiva to collect epithelial cells and membrane associated mucin MUC1 protein. Cells were collected from the temporal, superior, inferior, and nasal bulbar conjunctiva of both eyes, and the lid wiper area of the upper eyelids. After protein extraction using RIPA buffer, two samples from both eyes of a single individual were pooled into one protein sample and expression was analyzed using Jess, a capillary electrophoresis nano-immunoassay system. The chemiluminescence intensity of each single antigen binding signal was calculated using the Compass Simple Western software 6.1 following normalization to the total protein amount. Statistical analyses were conducted using GraphPad Prime 9.

Results: Seven dry eye and seven normal subjects were enrolled. Identifiable antibody binding signals for MUC1 were seen in all samples around 280 kDa as expected. In normal samples, MUC1 protein expression from the nasal bulbar conjunctiva was significantly greater than the superior ($p=0.004$), inferior ($p=0.005$), and eyelid margin ($p=0.008$). While not statistically significant, the MUC1 binding signal intensity was also higher in the temporal bulbar conjunctiva. In the dry eye samples, MUC1 expression was highest in the superior bulbar conjunctiva compared to the inferior ($p=0.01$) and nasal ($p=0.001$) regions. When comparing MUC1 expression between dry eye and normal subjects, MUC1 expression was lower in the nasal ($p<0.0001$) and temporal ($p=0.01$) regions of the dry eye samples.

Conclusions: The Jess system provides numerous advantages over a traditional Western blot especially when analyzing high molecular weight proteins like ocular surface mucins with small sample aliquots. The increased expression of MUC1 in the temporal and nasal bulbar conjunctiva of healthy subjects suggests a functional need for increased lubrication in these areas not normally protected by the eyelids. In addition, the decreased MUC1 expression in dry eye samples, especially temporally and nasally, is consistent with results from previous studies in dry eye patients.

ABSTRACT BODY:

Purpose: To study the relationship between depression and thickness of macular layers.

Methods: From the population-based, age- and sex-stratified LIFE-Adult-Study, reliable (quality ≥20 dB) macular spectral-domain optical coherence tomography (OCT) volume scans (97 B-scans at 512 A-scans) from participants with healthy eyes were selected and segmented into ten retinal layers (Fig. 1A). Each of the 49,664 A-scans of each layer was statistically associated with two measures of depression: First, a lifetime diagnosis of depression as reported by participants in the anamnestic interview (logistic regression; outcome: depression diagnosis, regressors: layer thickness with age as covariate); second, depressive symptoms as evaluated using the Center for Epidemiologic Studies Depression Scale (CES-D), a questionnaire assessing depressive symptoms during the past week (partial Pearson correlation between thickness and CES-D score adjusted for age). P-values were adjusted for multiple comparisons by the false-discovery method.

Results: 11,124 eyes of 6,471 participants were included (mean age: 55.5 years, 53.1% female). Participants who reported physician-diagnosed depression (n=705) had a significantly higher CES-D score (t-test, $p<10^{-15}$, see Fig. 1B). Concerning physician-diagnosed depression, retinal thickness of the ten layers was not significantly related to existing depression diagnosis for any of the examined retinal locations. Regarding current depressive symptoms, the heat maps in Fig. 2 show the partial (age-adjusted) correlations between CES-D and thickness for each of the ten layers. There were significantly correlated locations on each retinal layer, except for IZ and RPE layers, ranging from less than 1% of the retinal area for OPL to over 60% for EZ+OS. While for EZ+OS and the ONL, higher depression scores were associated with a thinner retina over widespread areas, for other layers, particularly GCL and the IPL, specific, localized spatial patterns of associations were found with more pronounced thinning at a ring around the fovea.

Conclusions: In 8 out of 10 retinal layers we found significant correlations between macular layer thickness and depressive symptoms, assessed using the CES-D. Anamnestic physician-diagnosed depression was not significantly associated with thickness.

ABSTRACT BODY:

Purpose: Gene-based therapies for numerous inherited retinal degenerations (IRD) are on the horizon, and current experience with RPE65 gene therapy suggests that treatment given early in life may be most beneficial. We aimed to identify and register all children in the Netherlands with IRD, and determined the genetic cause and risk profile of patients most suitable for future therapies.

Methods: Clinical and genetic data from IRD patients (N=767, 62% male) aged 0-20 years were collected from medical charts from the 5 centers participating in the national RD5000 study group in the Netherlands over a mean follow-up period of 5.95 ± 4.0 years. Patients were stratified in 2 groups: progressive retinal dystrophies and stable retinal dysfunction disorders. Outcome measures were prevalence of diagnosis, causal genes, mean best-corrected visual acuity (BCVA) in LogMAR at age categories 0-5 years, 5-10 years, 10- 15 years and 15 -20 years. Wilcoxon signed Rank Test was used to analyze differences between groups.

Results: Mean age at diagnosis was 6.75 ± 5.0 yrs. Among patients with a progressive retinal dystrophy, retinitis pigmentosa (RP) and Leber congenital amaurosis (LCA) (together N=249; 52%) and X-linked retinoschisis (XLRS; N=63; 13%) were most prevalent. Within the stable retinal dysfunction group, achromatopsia (N= 62; 53%) and congenital stationary night blindness (CSNB; N=49; 41%) were most prevalent. Almost half of the patients (367/767; 48%) were genetically solved. Most frequently reported disease-causing genes for progressive retinal dystrophies were CEP290 (N=33) and RPE65 (N=15) and RS1 (N=29); most frequent disease-causing genes for stable retinal dysfunctions were CNGB3 (N=22) and CACNA1F (N=15). For RP and LCA cases (122 eyes), mean BCVA was 0.73 ± 0.52 at 0-5 years compared to 0.59 ± 0.49 at 5-10 years (p=0.002), 0.40 ± 0.40 at 10-15 years (p=0.014), and 0.32 ± 0.35 at 15-20 years (p=0.028).

Conclusions: In the Netherlands, CEP290 and RS1 are the most frequently identified genetic causes of progressive retinal dystrophies in children, and CNGB3 and CACNA1F the most frequently identified causes of stable retinal dysfunction disorders. The Dutch national RD consortium will be an important source for selection of patients most suitable for future gene-based therapies.

ABSTRACT BODY:

Purpose: Subretinal macular fibrosis occurs in up to 50% of neovascular age-related macular degeneration (nAMD) eyes and is a major cause of anti-VEGF resistance in nAMD. Currently, there are no medications to prevent or treat macular fibrosis secondary to nAMD. The aim of this study was to investigate the role of CC-chemokine receptor 2 (CCR2) expressing monocytes in the development of the fibrovascular phenotype of nAMD.

Methods: Subretinal fibrosis was induced in C57BL/6J mice using the two-stage laser-induced protocol previously described by Little et al (2020). The dynamics of the fibrotic lesion and infiltrating macrophages were assessed by immunofluorescence staining of collagen-1, F4/80 and CCR2, respectively at days 0, 1, 3, 6 and 10 post-second laser. Circulating $CCR2^{+}$ monocytes were depleted using the CCR2 depleting antibody, MC-21, from day 1 to day 5 (acute stage depletion) or from day 5 to day 10 (chronic stage depletion). The level of depletion was confirmed by flow cytometry. Vascular and fibrotic components of the fibrovascular membrane were examined at day 10 post-second laser by immunofluorescence staining of isolectin B4 and collagen-1, respectively.

Results: The fibrotic lesion size reaches its peak 3 days after the second laser. $CCR2^{+}F4/80^{+}$ macrophages were detected in and around the fibrotic lesion and their number increased from day 3 to 10 post-second laser. Depletion of $CCR2^{+}$ monocytes at the acute stage of disease did not affect the size of subretinal fibrosis. However, depletion of $CCR2^{+}$ monocytes at the chronic stage of the disease significantly reduced the vascular and fibrotic components of the fibrovascular membrane.

Conclusions: Our results suggest that $CCR2^{+}$ monocytes play a critical role in the development of the fibrovascular phenotype of nAMD during the chronic stage of inflammation. The underlying mechanism of $CCR2^{+}$monocytes in promoting subretinal fibrosis warrants further investigation.

ABSTRACT BODY:

Purpose: We have demonstrated that a 2-step murine model of phase 1 hyperoxia followed by phase 2 relative hypoxia can induce hypomyelination of the corpus callosum (CC), gliosis, and impaired maturation of pre-myelinating oligodendrocytes consistent with periventricular leukomalacia (PVL). In this investigation, we test whether stabilization of hypoxia inducible factor (HIF) in phase 1, which has been previously shown to prevent oxygen-induced retinopathy, is protective against white matter injury observed in a model of oxygen-induced PVL.

Methods: C57BL/6 pups were placed in 80% oxygen from postnatal day 4 (P4) until P8 and returned to normoxia until P11. Myelination, glial fibrillary associated protein, and capillary density within the CC were quantified using immunofluorescent microscopy and western blotting. Numbers of oligodendrocytes were counted within the CC. Each of these parameters were compared to pups treated with both direct and remote (liver) HIF-1 stabilization in the wild type and hepatic HIF-1 knockout mouse subjected to the oxygen-induced PVL model.

Results: Hyperoxia caused a 3-fold reduction in myelination, a 30% increase in gliosis, a 40% decrease in capillary density, and 50% reduction in oligodendrocytes within the CC. Pharmacological HIF stabilization during hyperoxia resulted in lower HIF-1 levels in hypoxic phase 2 and increased white matter capillary density. While inducing hepatic HIF-1 by DMOG increased CC myelination by 150% compared to hyperoxia alone, direct brain HIF-1 stabilization by Roxadustat suppressed myelination even further than hyperoxia alone (by 50%). The therapeutic effect of remote hepatic stabilization was ablated in the hepatic HIF-1 KO.

Conclusions: PVL can be induced by a 2-step mechanism of oxygen-induced vaso-obliteration that leads to untimely HIF upregulation in phase 2 in synchrony with the oxygen-induced retinopathy model. In this model, remote HIF stabilization during phase 1 results in increased capillary density, decreased evidence of hypoxia within the CNS, and promotion of white matter myelination. These findings support the hypothesis that a unified model of hyperoxia of prematurity results in dysregulation of vasculature development in the eye and brain.

ABSTRACT BODY:

Purpose: Delayed corneal epithelial wound healing is a common complication of diabetes. Our laboratory has found that primary cultured diabetic human corneal epithelial cells show varying levels of mitochondrial depolarization and morphological changes compared to non-diabetic controls. In this study, we characterized mitochondrial and metabolic activity in corneal epithelial cells subject to acute and chronic hyperglycemic stress.

Methods: Telomerase-immortalized human corneal epithelial (hTCEpi) cells were cultured in a defined serum-free keratinocyte growth media containing 6 mM D-glucose. To simulate hyperglycemia, cells were supplemented with additional glucose up to a final concentration of 25 mM. Mannitol was used as an osmotic control. Cells were cultured for 24 hours, 3, 5, 7, 9 or 14 days. Mitochondrial morphology and polarization were assessed using JC-1 and visualized using laser scanning confocal microscopy. Metabolic activity was quantified in real time using a Seahorse metabolic flux analyzer. Oxygen consumption rate (OCR, mitochondrial respiration) and extracellular acidification rate (ECAR, glycolysis) were analyzed using a Seahorse XFp Cell Mito Stress Test kit. Beta oxidation of fatty acids were further measured using a Substrate Oxidation Test kit.

Results: Using JC-1, only cells cultured in high glucose for 14 days showed a loss of polarization and mitochondrial fragmentation. Metabolic activity was unchanged in cells cultured in high glucose for 24 hours. By day 3, cells showed a measurable drop in spare respiratory capacity that remained decreased through day 14. By day 5, glycolysis (ECAR) began to decrease and remained low through day 9. At days 7 and 9, OCR was increased, shifting cells towards a more respiratory phenotype. By day 14, consistent with JC-1 staining, OCR decreased and ECAR increased to normoglycemic levels.

Conclusions: Chronic, not acute, exposure to high glucose negatively impacts mitochondrial structure and function. The decline in mitochondrial activity was associated with a recovery of glycolysis, indicative of metabolic adaptation. The ability of corneal epithelial cells subject to chronic hyperglycemia to rely on glycolysis as the primary energy source would account, in part, for the delayed wound healing seen in diabetes.

ABSTRACT BODY:

Purpose: The optic nerve head (ONH) shows the earliest signs of damage during glaucoma. An imbalance of extracellular matrix (ECM) protein formation and degradation in the human lamina cribrosa (LC) region leads to retinal ganglion cell (RGC) axon damage and eventual apoptosis. ONH astrocytes, LC cells, and microglia have been implicated in glaucomatous ONH damage, with early microglia activation releasing damage associated molecular patterns (DAMPs) that can activate toll-like receptor 4 (TLR4). Current literature shows significant crosstalk between TLR4 and TGFß2 signaling in the development of fibrogenesis and TGFß2 is known to be increased in the glaucomatous ONH. From this, we hypothesize that endogenous DAMPS activate TLR4 and augment TGFß2 signaling, increasing ECM production and pathogenic paracrine signaling between cells of the ONH.

Methods: Normal and glaucomatous human donor eyes were received from the Lions Eye Banks of WI, fixed, cryo-embedded, and processed for immunohistochemistry. Primary ONH LC cells were isolated from fresh normal human donor eyes, cultured, and characterized by western blot and ICC. Immortalized microglia were purchased from ATCC (CRL-3304). Cells were treated with a TLR4 selective inhibitor TAK-242 in the presence or absence of TGFβ2, LPS, or cFN for 48 hours and changes to protein production was assessed by western blot and immunocytochemistry.

Results: The ECM protein fibronectin (FN), as well as the endogenous DAMP fibronectin extra domain A (FN-EDA) were elevated in the LC region of glaucomatous (N=3) human donor eyes compared to normal controls (N=3). Primary human LC cells expressed alpha-SMA and were negative for astrocytic marker GFAP. Treatment with TGFβ2 elevated FN expression and the TLR4 inhibitor, TAK-242, blocked TGFβ2 induced FN expression ($p<0.05$). Immortalized microglia (ATCC CRL-3304) exposed to the TLR4 activator LPS in the presence or absence of TGFβ2 increased FN and Laminin protein expression by western blot and ICC.

Conclusions: These data suggest that multiple cell types within the ONH show significant crosstalk between TLR4 and TGFβ2 signaling during the development of fibrogenesis in the LC region.

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) severity level is evaluated from stereoscopic 7-field color photographs by masked graders at the Wisconsin Reading Center and used as a reference standard for training and validation of AI algorithms. Training data quality influenced by race is understudied relative to standards established for White subjects. Retinal pigmentation is greater in individuals with darker skin tones, and the reduced contrast may affect the detection of DR features by graders. We explored the effect of race-related fundus pigmentation on the grader's ability to document DR.

Methods: All images were acquired by a certified photographer at a single site using the same camera. and evaluated for DR by two experienced graders masked to all demographics. Following our standard protocol for quality assessment, graders determined a confidence score (CS) of high or low (borderline and ungradable) for each image. Graders were permitted to use digital enhancement tools for better visualization. The Red, Green, and Blue (RGB) channel values were also obtained for a representative image of each subject.

Results: Of 183 subjects, 37 (20.2%) were identified as White, 11 (6%) Black and 135 (73.8%) Other with Hispanic ethnicity. DR prevalence was 10.4% in the full cohort (366 eyes), mostly with mild-moderate non-proliferative DR. DR prevalence across the 3 racial/ethnic groups was 12.2%, 0% and 12.2% respectively. CS was high in 93%, 77% and 82%, borderline in 5%, 23% and 16% and ungradable in 1.4%, 0% and 1.5% respectively. There was significant difference between high and low CS across the three groups ($p = 0.029$) and also for the red channel of RGB values: 129 (95% CI 95,105), 85 (77,104), and 94(88,99) ($p < 0.001$).

Conclusions: Grader confidence for evaluating DR features was lower in pigmented retinas which could affect data accuracy from images obtained from darker skinned individuals. It is possible that DR was under called in Black population due to difficulty in detecting early features. This bias can transfer into AI models via training data. Photographer education in image capture techniques and grader training in racially diverse datasets is needed to obtain high quality, categorically delineated data.

ABSTRACT BODY:

Purpose: Rhino-orbital-cerebral mucormycosis (ROCM) is a prevalent manifestation of mucormycosis affecting COVID19 patients with significant morbidity and mortality. Despite sharing a similar set of risk factors, only a subset of patients is affected by ROCM . Hence, we have performed immune-profiling in patients with active COVID19-associated ROCM (Ca-ROCM) to determine their anti-fungal immunity status

Methods: Study includes subjects (i) with COVID19 and ROCM (C^+R^+, n=13), (ii) with COVID19 and no ROCM (C^+R^-, n=9) and (iii) without COVID19 history and no ROCM (C^-R^-, n=7). Proportions of ~50 immune cells subsets (immunophenotyping) and 60 secreted factors (multiplex ELISA) were determined in the peripheral blood of the study subjects using flow cytometry. The COVID subjects included in the study were of non-severe form in C^+R^+ and C^+R^- group

Results: A significant reduction in the natural killer (NK cells), dendritic cells and lymphocytes along with a significant increase in neutrophils was observed in C^+R^+ group compared to the other groups. A significant increase in sIL-1Rs, sTNFRs, sICAM1, IL-6, IL-8, MMP, MPO, NGAL, PDGF-AA/BB, HGF and VEGF, along with significant reduction in angiogenin and IFNα was also observed in C^+R^+ group. Area under the curve and logistic regression analysis demonstrated that proportion of NK cells, Angiogenin and sIL-1R levels were unique in patients with ROCM

Conclusions: The distinct immune profile in patients with Ca-ROCM can be explored as an additional factor in stratifying COVID-19 patients with increased risk of ROCM thereby reducing the morbidity and mortality burden of Ca-ROCM.

ABSTRACT BODY:

Purpose: Prediction of age-related macular degeneration (AMD-)progression based on early imaging biomarkers is currently imprecise, but important for risk-based management and patient selection for clinical trials. Here, we evaluated the impact of drusen on AMD progression based on automated drusen area quantification.

Methods: In total, 7964 participants aged 55+ from the population-based Rotterdam Study were followed up for AMD progression during a study period up to 15 years. Drusen areas within the early treatment diabetic retinopathy (ETDRS) grid on fundus photographs were automatically segmented with a deep learning algorithm at baseline, and were evaluated for their log correlation with consensus annotation by human graders. Associations between drusen area and incident late AMD were determined with cox proportional hazards models, adjusted for age and sex. Optimism-corrected area under the operating receiving curves (AUCs) were constructed for late AMD.

Results: Drusen area quantifications by the deep learning model were highly correlated with consensus annotation by experienced graders ($r = 0.81$, $p < 2.8e\text{-}10$). During a mean follow-up of 6.7 years (SD 1.8), 107 participants developed incident late AMD. A 1 mm^2 increase in deep learning-based drusen area in the ETRDRS grid was associated with a 4.9 times increased risk of incident late AMD (HR 4.9, 95%CI 3.3– 7.2). The prediction model based on automated drusen area quantification reached an AUC of 0.89 (95%CI 0.83-0.95).

Conclusions: The deep learning model was on par with consensus annotation by human graders, and can be used as a quick and objective method for AMD end stage risk prediction. Automated quantification of early and intermediate AMD imaging biomarkers will enhance the investigation of causal relationships and patient selection for clinical trials.

ABSTRACT BODY:

Purpose: E-series resolvins (Rv), derived from the n-fatty acid, eicosapentaenoic acid (EPA), and the D-series Rvs, protectins, and maresins all derived from the n-fatty acid docosahexaenoic acid (DHA), comprise three categories of specialized pro-resolving mediators (SPMs) that actively resolve inflammation in disease. The purpose of this study was to determine if one or more of these SPM families can attenuate the capsaicin-evoked activity of rat trigeminal ganglion neurons indicating a decrease in corneal pain.

Methods: Rat trigeminal ganglia (TG) were extracted and dissociated first in a solution of papain in HBSS for 20 minutes before transferred to a solution of collagenase and dispase for a further 20 minutes. The dissociated cells were then separated using a percoll density gradient. The TG neurons were isolated and plated onto poly-L-lysine and laminin coated glass-bottom dishes and left to grow overnight. The following day, cells were washed with Krebs Ringer Buffer (KRB) and loaded with the calcium-sensitive fluorescent dye fura2. An increase in intracellular [Ca^{2+}] indicated activation of the neuron and pain in the nerve endings. Thirty minutes prior to the experiment cells were treated with one of the following: RvD1, RvD2, RvD3, RvD4, RvD5, or RvE1 at concentrations between 10^{-11}M and 10^{-8}M. The cells were then stimulated with capsaicin (10^{-7}M) and intracellular [Ca^{2+}] were recorded over time.

Results: Pre-treatment with RvD1 10^{-8}M reduced the magnitude of the capsaicin-induced calcium influx by an average of 36.03% (N=7 p=0.013). RvD2 10^{-11}, 10^{-10}, 10^{-9}, and 10^{-8}M reduced the magnitude of the response by an average of 49.29%, 49.57%, 35.64% and 63.58% respectively (N=7, p= 0.001, 0.002, 0.001, and 0.001 respectively). RvD3 10^{-8}M inhibited the response by an average of 25.05% (N=4, p =0.003). RvD5 10^{-9}M inhibited the response by an average of 59.93% (N=4, p= 0.003). RvE1 10^{-10}M significantly reduced intracellular Ca^{2+} influx following capsaicin administration by an average of 19.32% (N=4, p=0.042).

Conclusions: The SPMs RvD1, RvD2, RvD3, RvD5, and RvE1 significantly decrease capsaicin-evoked intracellular [Ca^{2+}] influx in rat TG, with RvD2 being the most potent SPM treatment could decrease ocular surface pain.

TITLE: Measurement of the Refractive Index of the Crystalline Lens in the Human Eye in vivo by Using an Optical Coherence Tomography Equipped Ray-Tracing Scheimpflug Imaging System

SESSION TITLE: New improvements in imaging and development of biomarkers

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. He, Vision Science, New England College of Optometry, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Ji He: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Measurement of the refractive index of the crystalline lens in the human eye in vivo has been a challenge for a long time. The anterior segment optical coherence topography (AS-OCT) and Scheimpflug imaging (SI) technique have been used to access the refractive index in vivo, but need assumption of the lens thickness. Theoretically, a combination of the AS-OCT and the SI could solve the lens refractive index and lens thickness simultaneously. The purpose of this study was to measure the refractive index of the human eye in vivo by using an AS-OCT equipped ray-tracing SI system (RTSI).

Methods: An AS-OCT was constructed to be combined with a RTSI, and mounted on a slit lamp platform together. Both AS-OCT and RTSI shared the same vertically scanning light illumination (about 850nm). The right eyes of five subjects (24 to 62 yr old) were tested. The images were processed to trace the light ray from the cornea to the lens and to accurately solve the lens refractive index and the lens thickness by using a self developed MatLab program. The derived lens refractive index represents the equivalent refractive index in the optical axis direction.

Results: During the image processing, the refractive index of aqueous was first obtained. For the five subjects, the mean aqueous refractive index was 1.3312±0.0013. The mean refractive index of the lens at the center was 1.4032±0.0177, with a range of 0.0366, which was more than 10 times of that for the aqueous (0.0034). The lens refractive index decreased as the distance from the lens center increased, and the rate of reduction in the lens refractive index varied from subject to subject. The mean central lens thickness was 3.93±0.49mm with a range of 1.10mm.

Conclusions: A combination of AS-OCT with RTSI accurately measures the refractive index of the ocular media in the human eye in vivo, and the measurement of the refractive index of the aqueous provides a useful validation of this method. The lens refractive index changes from one eye to another, and reduces from the lens center to the periphery. The rate of the reduction of lens refractive index estimates the gradient refractive index of the lens. With the lens refractive index measured, accurate estimate of the posterior lens shape is achieved.

ABSTRACT BODY:

Purpose: To compare cone-mediated ERG responses to full-field stimuli in children with severe ROP treated with either intravitreal bevacizumab (IVB) or laser photocoagulation.

Methods: Light-adapted responses to a range of red flash intensities were recorded. Cone photoreceptor sensitivity and saturated amplitude were calculated from the a-wave. Post-receptor activity (represented by the b-wave) and inner retinal function (represented by the oscillatory potentials (OPs)) were also analyzed. All response parameters were expressed relative to the mean of the IVB group. Linear mixed effects (LME) modeling was used to determine significant differences between groups. We studied children treated with IVB (n=20; 37 eyes) or laser (n=10; 17 eyes). Twelve patients (22 eyes) receiving IVB required additional laser treatment. Among these groups there was little difference in gestational age, birthweight, or age at ERG test. The gestational age at birth was median 25 (range 21–31) weeks and birthweight was median 572.5 (range 410–1750) g. Corrected age at ERG was median 47.4 (range 8–1,334) weeks. None had retinal detachment.

Results: The first LME model detected a significant difference in function at the various retinal depths ($P < 0.05$). Inner retinal function, represented by the OPs, was higher in laser-treated eyes. Photoreceptor and post-receptor function were similar across the groups. The second LME model detected no significant difference between IVB patients who required subsequent laser and those who did not.

Conclusions: These cone-mediated ERG data identify significant difference between IVB and laser-treated ROP retinas. Specifically, laser may confer relative preservation of the inner retina.

ABSTRACT BODY:

Purpose: To battle the spreading of the COVID-19 virus, all over the world measures like home confinement and nation-wide lockdowns have been implemented at regular intervals. These measures have shown an increase in myopic incidence particularly in China, which applied a very strict lockdown and home confinement. The Netherlands used a so called “intelligent lockdown” which allowed children to go outside. We evaluated the association between COVID restrictions and myopia risk factors in an European cohort of adolescents.

Methods: A total of 1101 participants (mean age 16.3 ± 3.65 yrs) of the population-based prospective birth-cohort study Generation R filled in a questionnaire about their behavior before, during, and after lockdown in the Netherlands. These participants had undergone cycloplegic refractive error measurement at 13 years of age. We evaluated time spent outdoors, time spent online (handheld or other devices), time spent on near work (education and non-educational) from March-October 2020 in myopic (spherical equivalent <-0.5D) and non-myopic children. We used a repeated measures ANOVA to compare differences between these time periods, and logistic regression corrected for age, gender, and ethnicity to evaluate differences between myopic and non myopic children.

Results: During and after lockdown the children spent signicantly more time online (+113 and +59min/day) on both hand held (+64 and +10 min/day) and other devices (+49 and +7 min/day), and on educational nearwork (+73 and +63min/day). Non-educational near work increased only significantly during lockdown (+176 min/day). Time spent outside did not change significantly and was ±2 hours/day. Children of non-European descent spent more time online (235min/day vs 260 min/day, P= 0.004) and on non-educational near work (452 min/day vs 559 min/day, p=0.0002). We found no significant difference in behavior between myopic and non-myopic children.

Conclusions: The Dutch lockdown for COVID increased digitized near work in adolescents, but did not affect outdoor exposure. Children without myopia did not do better than those already myopic. Based on these results, we expect that the COVID pandemic will also lead to an increase in myopia prevalence and progression in European children, but to a lesser extent than in Asia.

TITLE: The risk of psoriasis in patients with uveitis: A population-based cohort study

SESSION TITLE: Clinical Uveitis & Orbital Inflammation: Etiology, Epidemiology & Clinical Assessment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Chen, Department of Ophthalmology, Taichung Veterans General Hospital, TAIWAN|M. Hung, Department of Medical Education, Taichung Veterans General Hospital, TAIWAN|

Commercial Relationships Disclosure: Yu-Yen Chen: Commercial Relationship: Code N (No Commercial Relationship) | Man-Chen Hung: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate whether the risk of subsequent psoriasis and psoriatic arthritis development is increased in patients with uveitis.

Methods: In Taiwan's national health insurance research database, we identified 195,125 patients with new-onset uveitis between 2001 and 2013. We randomly selected 390,250 individuals without uveitis who were matched 2:1 to uveitis cases based on age, sex and year of enrolment. The characteristics of the two groups were compared. Using multivariate Cox regression, hazard ratios (HRs) for psoriasis or psoriatic arthritis corresponding to uveitis were computed after adjustment for age, sex, insurance cost and comorbidities. In subgroup analyses, separate HRs for mild psoriasis, severe psoriasis and psoriatic arthritis were calculated.

Results: The mean age of the study cohort was 50.2 ± 17.2 years. Hypertension, diabetes, hyperlipidaemia and obesity were more prevalent in the uveitis group (all $p < 0.0001$). The hazard of psoriasis or psoriatic arthritis development was significantly greater in the uveitis group than in the non-uveitis group ($p < 0.0001$); this increased risk persisted after adjustment for confounders [adjusted HR = 1.41; 95% confidence interval (CI), 1.33–1.48]. Adjusted HRs showed an increasing trend from mild psoriasis (1.35; 95% CI, 1.28–1.44) to severe psoriasis (1.59; 95% CI, 1.30–1.94) and psoriatic arthritis (1.97; 95% CI, 1.60–2.42).

Conclusions: This nationwide population-based cohort study revealed that patients with uveitis have an increased risk of subsequent psoriasis or psoriatic arthritis development.

ABSTRACT BODY:

Purpose: Glaucoma is an optic neuropathy characterized by progressive death of retinal ganglion cells (RGCs) leading to permanent visual field loss. Existing treatments for glaucoma target lowering the intraocular pressure, laser trabeculoplasty, and surgical interventions. There are no treatments available once RGC death has occurred in the advanced stages of this disease. We investigated induced pluripotent stem cell derived RGC replacement as a therapy to treat for ganglion cell loss in glaucoma.

Methods: Human induced pluripotent stem cells (hiPSCs) were differentiated in vitro using a standardized two-step protocol in 36 days. iPSC-RGCs were characterized for RGC markers by FACS sorting with RGC specific antibodies. Mature iPSC-RGCs were labeled by transduction with AAV2.7m8 SNCG-eGFP. Purified and labeled iPSC-RGCs transplanted intravitreally (5×10^5 cells/2ul) into wild type 4-month-old C57BL/6J mice using a 33-guage needle (n=10). Survival of the transplanted hiPSC-RGCs was assessed at 2, 4 and 6-weeks post-transplantation using Micron III and confocal scanning laser ophthalmoscopy (cSLO). Histological studies were performed 2 and 5 months post-transplantation on retinal flatmounts, retinal and optic nerve sections to study localization and integration of the transplanted hiPSC-RGCs. Functional integration was assessed by electrophysiologic responses to full field photopic stimuli in voltage and current clamp modes under whole cell configuration.

Results: hiPSC differentiation in vitro generates pure populations of iPSC-RGCs. Purified iPSC-RGCs are positive for RGC markers BRN3, SNCG, CD90, and RBPMS. iPSC-RGCs transduced with AAV2.7m8 express eGFP as early as 48-hour post-transduction. eGFP+ve hiPSC-RGCs were detected within the ganglion cell layer of the murine retina as early as 2-weeks post injection and seen as punctate hyperfluorescent foci in the cSLO and color fundus imaging. We detected hiPSC-RGCs integrated in the mouse retina with extensive arborization in 6 weeks following intravitreal injections. hiPSC-RGCs stained positive for BRN3 and RBPMS markers and produced spontaneous firing in response to depolarizing stimuli indicating that the integrated iPSC-RGCs are functional.

Conclusions: Our studies will provide key strategies to enhance the efficiency of stem cell replacement therapy and advance potential treatments for neurodegenerative diseases including glaucoma and optic neuritis.

ABSTRACT BODY:

Purpose: The purpose of this study is to investigate the associations with and surgical outcomes of rhegmatogenous retinal detachments in young adults with three months, one and five years of follow up.

Methods: A retrospective consecutive case series of patients 30 years of age or younger who underwent surgical repair for RRD between 2014 and 2021 at a single practice (12 offices).

Results: 101 patients (109 eyes) were included with at least 3 months of follow up. 67 patients (74 eyes) and 17 patients (19 eyes) were followed for at least 1 year and 5 years respectively. The most common association was myopia 66 eyes (60.1%) followed by trauma 8 eyes (7.3%) and prior ocular surgery 7 eyes (6.4%). Median pre-op Snellen visual acuity was 20/40. The macula was attached in 31 eyes. Five eyes (4.6%) presented with giant retinal tear detachments. The most common method of surgery was Scleral buckle alone (SB) in 71 eyes followed by Vit buckle in 29 eyes and PPV alone in 8 eyes. Single surgery anatomical success was 88.7% for SB, 89.7% for SB/PPV and 75% for PPV. The median final post-operative Snellen visual acuity was 20/30. 12 Patients presented with bilateral retinal detachments and the most common treatment was sequential surgery in 8 patients followed by 4 patients who underwent surgery with laser barricade in the fellow eye. 14 eyes developed a retinal tear or detachment in the fellow eye with a mean interval of 8 months from presentation, the longest interval was 3 years and 11 months. Of the 17 patients that were followed for at least 5 years, 3 patients (17.6%) developed a retinal tear or detachment in the fellow eye. After initial anatomical success 4 eyes (3.6%) developed redetachment with the most common cause being proliferative vitreoretinopathy. The longest interval of redetachment from initial repair was 9 months.

Conclusions: The most common association of rhegmatogenous retinal detachment in this study was myopia. Scleral buckle was the most common surgical intervention. Outcomes were generally favorable. Surgeons and patients should be aware of the risk of bilateral retinal detachment as well as the risk of retinal tear and detachment in the fellow eye. Patients require long term surveillance in both eyes.

ABSTRACT BODY:

Purpose: In this study, we measured the intracellular level of ROS in neutrophils and CD4 T cells in HSK lesions and determined the outcome of manipulating ROS level on HSK severity.

Methods: C57BL/6J (B6) mice were infected with HSV-1 after mild scratching of the corneas. Multi-colored flow cytometry (FCM) was carried out to enumerate the ROS producing cells' frequency in infected mice. qRT-PCR assay measured the transcripts of antioxidant genes and NOX isoforms in uninfected and infected corneas. A slit lamp was used to grade the corneal opacity and angiogenesis in infected corneas of gp91-/-, vehicle and DPI treated groups of B6 mice.

Results: The flow cytometry data showed that approximately 90% of ROS generating leukocytes in HSK lesions were neutrophils. Antioxidant enzymes play an essential role in regulating intracellular ROS levels. Our results showed significant downregulation in antioxidant genes SOD1, GSS, and NQO1 but an upregulation in Hmox1, SOD2, SOD3, and GSR in infected corneas at 10- and 15-day post-infection (DPOI) as compared to uninfected corneas. ROS generation is regulated by flavoenzymes, including NADPH oxidase 2 (NOX2). qRT-PCR studies showed a two to six-fold increase in the expression of NOX2 subunits in infected corneas at 5- and 12-DPOI than uninfected corneas. FCM experiments showed NOX2 (gp91) protein predominance in neutrophils and monocytes in infected corneas at 15-DPOI. The corneal HSV-1 infection of gp91-/- and B6 mice showed no significant difference in the intracellular level of ROS in HSK lesions, suggesting NOX2 does not regulate ROS formation in HSK lesions. To ascertain the functional significance of ROS in regulating HSK, HSV-1 infected mice received a subcutaneous injection of DPI (1mg/Kg /day), a flavoenzyme inhibitor, from 7- through 15-DPOI. Our results showed significantly reduced corneal opacity and angiogenesis in DPI than vehicle-treated mice. Intriguingly, DPI treatment caused an increased level of ROS in neutrophils. An increased ROS level can cause cell death by apoptosis. However, FCM experiments revealed no significant difference in the frequency of apoptotic neutrophils from treated and vehicle groups, indicating the decreased frequency of neutrophils in the DPI treated group is not due to apoptosis.

Conclusions: Together, our results suggest that manipulating ROS level in HSK lesions can play an important role of regulating the severity of HSK.

ABSTRACT BODY:

Purpose: To explore the feasibility of reconstructing and fabricating personalized biosynthetic keratoprosthesis using digital light processing (DLP) 3D bioprinting technique and N-acryloyl glycinamide/gelatin methacrylate-hybrid (PNG) bioink.

Methods: Cornea-mimicking constructs based on synthetically cross-linked PNG bioink were produced by DLP 3D bioprinting. Its characteristics in terms of hydrophilicity, water content, nutrient permeability, stability, optical and mechanical properties were then tested for suitability as corneal replacement tissue. Cytocompatibility was evaluated with human corneal epithelial, stromal, and endothelial cell lines. In-vitro immune response was analyzed with human peripheral blood mononuclear cells by illumina RNA sequencing. In-vivo performance was assessed using an anterior lamellar keratoplasty (ALK) and intrastromal keratoplasty (ISK) model in New Zealand white rabbits.

Results: DLP-bioprinting allows individualization of physical dimensions including thickness and curvature of the PNG keratoprosthesis. The material is superhydrophilic (contact angle 47°), has pre-specified water content (78%), good glucose permeabilization (diffusion coefficient: 2.11*10-6 cm2/s), high stability in PBS, bionic light transmittance (over 90%) and refractive index (≈1.375), and good structural strength (Young's modulus≈0.2MPa). In-vitro evaluation displays that it supports the adhesion and viability (above 90%, over 7 days of cultivation) of corneal epithelial, stromal, and endothelial cells, while maintaining the phenotype and function of keratocytes (positive for Keratocan, CD34 and ALDH1A1). RNA sequencing results indicate that it activates type 2 immunity in macrophage, facilitates tissue regeneration and suppresses inflammation. In-vivo assessment in rabbits showed excellent surgical handling characteristics, and no adverse effects on the host corneal stroma, endothelium or other ocular tissues, although epithelialization was not achieved with the ALK model. Postoperative IOP, corneal sensitivity, and tear formation remains unaffected during the 1-month follow-up.

Conclusions: Our DLP-bioprinted PNG keratoprosthesis is a novel, safe, and effective corneal graft alternative with personalisable physical dimensions which can potentially achieve better clinical outcome and address the current worldwide shortage of donor corneas.

ABSTRACT BODY:

Purpose: Age-dependent processes like extenuated vascular density as well as reduced choroidal blood flow limit oxygen supply to the outer retina. Together with the formation of drusen and thickening of Bruch's membrane this might lead to hypoxic conditions in the ageing retina, linking age-dependent changes to hypoxia. To understand the cellular response of specific retinal cell types upon hypoxic conditions, we performed droplet-based single-cell RNA sequencing (scRNAseq) of mouse retina tissue after hypoxic exposure.

Methods: Droplet-based single-cell RNA sequencing of hypoxic (7% O_2 for 6h) and normoxic male and female mouse retinas (N=2) was performed using the 10X Genomics platform. Data analysis focused on differential gene expression of hypoxic and normoxic cells in each cluster. In-situ hybridization targeting Kif4 was used to confirm the exclusive expression in cone photoreceptors. qPCR was performed to identify Rbm3 and Cirbp isoforms.

Results: 21 retinal cell types and one RPE cluster were identified among the 9410 normoxic and 9033 hypoxic cells in the analysis. Known hypoxic markers including Bnip3, Higd1a and Egln1 were significantly upregulated in various hypoxic clusters, confirming a general response to hypoxia. Interestingly, RNA-binding proteins Rbm3 and Cirbp were differentially expressed across clusters. Remarkably, both genes underwent an isoform switch in hypoxia leading to the preferential expression of short variants. Focusing on photoreceptor-specific responses, we identified a kinesin motor protein (Kif4) to be induced specifically in cones upon hypoxic exposure. In-situ hybridization confirmed the observed cone specific expression.

Conclusions: Our results identified an oxygen-dependent isoform switch in RNA-binding proteins Rbm3 and Cirbp, suggesting functional consequences that might contribute to the pathological impact of reduced tissue oxygenation. Additionally, we identified a hypoxia-induced upregulation of a cone-specific motor protein, Kif4, which needs to be further characterized. Possible functions include axonal transport, cargo-delivery to the cone outer segment and enrichment of transmembrane receptors or channels. Identifying the cargo of this cone-specific kinesin might open the possibility for a new therapeutic target.

ABSTRACT BODY:

Purpose: Contrast sensitivity measurement with sinusoidal patterns (SinCS) is known to have significant variability and influenced by learning effects. Letter contrast sensitivity (LetCS) using a familiar testing process may be better suited in such a case. The purpose of the study was to validate LetCS produced by an iPad application driving a standard 4K screen compared with SinCS produced by two commercial systems (M&S Technologies (M&S) and Vector Vision (VV) by measuring their repeatability.

Methods: The study was a single arm, prospective, repeated measure study. The study population (n=20), a young presbyopic phakic population (43.6 ±2.8 years; range 40 to 49years) attended an initial enrolment / test familiarisation visit and two test visits. CS was measured under photopic (85cd/m2) and mesopic (3cd/m2) conditions, at five spatial frequencies (SF) 1.5, 3, 6, 12 and 18cpd. Repeatability was established by comparing the mean and 95% CI of the difference between the measurements made at the two test visits and the variance between the measurements.

Results: i. Under photopic conditions test variance was lower at all SF for LetCS (Test-retest difference: mean -0.03 to -0.01logCS; 95%CI 0.05 to 0.07logCS) than for SinCS M&S (Test-retest difference: mean -0.14 to -0.04logCs; 95%CI 0.16 to 0.37logCS) ($p \leq 0.001$) and VV (Test-retest difference: mean -0.07 to +0.01logCS; 95%CI 0.12 to 0.18logCS) ($p = 0.020$ to <0.001). ii. under mesopic conditions test variance was lower at all SF for LetCS (Test-retest difference: mean -0.05 to -0.03logCS; 95%CI 0.11 to 0.16logCS) than SinCS M&S (Test-retest difference: mean -0.11 to -0.04logCs; 95%CI 0.21 to 0.34logCS) (p 0.011 to <0.001) and all SF for VV (Test-retest difference: mean -0.08 to -0.01logCS; 95%CI 0.14 to 0.35logCS) ($p = 0.004$ to 0.001) other than 6cpd ($p=0.973$).

Conclusions: Letter contrast sensitivity was shown to be highly repeatable and exhibited significantly lower variance than sinusoidal pattern contrast sensitivity. The implications are that letter contrast sensitivity, needing minimal training, could be well suited for use in clinical studies and its lower variance than sinusoidal contrast sensitivity results in the need for a smaller sample size to achieve the same statistical power than sinusoidal contrast sensitivity.

ABSTRACT BODY:

Purpose: Higher rates of undetected eye disease have previously been identified in older individuals, minority populations, and those with low income and education level. Community-based vision screening may target at-risk populations in urban environments such as Manhattan. This study evaluates the social determinants of health of individuals who failed vision screening and received a referral to ophthalmology in the Manhattan Vision Screening and Follow-up Study.

Methods: We performed a retrospective analysis of preliminary data collected from the Manhattan Vision Screening and Follow-up Study. A total of 382 individuals aged 40 and older and living in affordable housing developments in upper Manhattan were enrolled and screened. Visual acuity, intraocular pressure, and fundus photography are measured. Participants with visual acuity equal to or worse than 20/40, or IOP 23 to 29 mmHg, or unreadable fundus images fail the screening and are scheduled with the on-site optometrist who also refers to ophthalmology. Those with an abnormal image or IOP greater than or equal to 30 mmHg are referred directly to ophthalmology.

Results: Of the 382 individuals enrolled and screened, 256 participants were ultimately referred to ophthalmology, among them 109 after optometry evaluation (Figure 1). Of this population, average age was 70.6 years old, 70.1% female, 50.7% Black/African American, 42.3% Hispanic/Latino, 79.6% unmarried, 67.1% completed less than college education, 39.8% did not speak English as a primary language, 66.3% had Medicare or Medicaid insurance, 87.5% were unemployed, 17.4% were active smokers, and 77.6% had not had an eye exam within the previous year. The most common reasons for referral to ophthalmology were glaucoma suspect (49.2%), retinal abnormality (42.2%), and cataract (14.8%).

Conclusions: This study identified African American and Hispanic race, single marital status, low education level, federal insurance, and unemployment as common epidemiologic characteristics of individuals who needed referral to ophthalmology. Identifying social determinants of health that prevent detection of eye disease may help providers target at-risk populations, and improve access to and utilization of eye care services.

ABSTRACT BODY:

Purpose: An ex-vivo experiment was designed for developing and employing an imaging technique performed with a scanning laser confocal microscope for measuring fluorescent lifetime of endogenous fluorophores of the retinal mice.

Methods: The enucleated eyes of BALBC/c mice are used. They are placed on a slide and observed with a confocal laser scanning microscope, LSM 880 – Carl Zeiss, by a transscleral approach.

This microscope is composed of continuous wave lasers from 405 nm to 613 nm which are used to analyze the intensity and location of the fluorescence signal for each wavelength, and a fluorescence lifetime imaging microscopy (FLIM) system, which is fitted by micropulse lasers of 405 and 440 nm, synchronized with a photomultiplier, and a time correlated single photon counting (TCSPC) device. That system works by exciting fluorophores and measuring their fluorescence lifetime.

Results: We obtained images of a monolayer of autofluorescent hexagonal cells with large nuclei compatible with the retinal pigment epithelium (RPE) using a 488 nm wavelength laser, as is shown in Fig. 1. The mean cell diameter is 5.3 mm and the nucleus diameter is 2.7 mm.

The fluorescence lifetimes measured were 0.8 ns and 2.2 ns, with an excitation wavelength of 405 nm and an emission wavelength range of 465-515 nm, compatible with melanin granules and Flavin adenine dinucleotide (FAD) free, as is observed in Fig. 2.

Conclusions: During the development of this setup for capturing images of the retina ex-vivo it was possible to penetrate sclera and chroroid with the scanning laser until reaching the RPE in the enucleated eyes. Images were taken and the fluorescence lifetime of the endogenous fluorophores was measured.

The next step is to perform in-vivo experiments with anesthetized animals and mouse holders.

TITLE: Birefringence of the retinal nerve fiber layer is reduced in early glaucoma eyes analyzed by polarization-sensitive OCT

SESSION TITLE: Imaging in glaucoma

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S. Steiner, F. Schwarzhans, S. Desissaire, H. Resch, G. Fischer, M. Pircher, C.K. Hitzenberger, C. Vass, Medizinische Universitat Wien, Wien, Wien, AUSTRIA|

Commercial Relationships Disclosure: Stefan Steiner: Commercial Relationship: Code N (No Commercial Relationship) | Florian Schwarzhans: Commercial Relationship: Code N (No Commercial Relationship) | Sylvia Desissaire: Commercial Relationship: Code N (No Commercial Relationship) | Hemma Resch: Commercial Relationship: Code N (No Commercial Relationship) | Georg Fischer: Commercial Relationship: Code N (No Commercial Relationship) | Michael Pircher: Commercial Relationship: Code N (No Commercial Relationship) | Christoph Hitzenberger: Commercial Relationship: Code N (No Commercial Relationship) | Clemens Vass: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To study the circumpapillary birefringence (BIR) of the retinal nerve fiber layer (NFL) in healthy and early glaucoma eyes using polarization-sensitive optical coherence tomography (PS-OCT). The NFL is birefringent, which is caused by intracellular parallel microtubules within the NFL. The number of these microtubules is thought to be reduced as an early sign of glaucoma damage.

Methods: This is a prospective cross-sectional study where we compared circular PS-OCT B-scans in 49 early glaucoma (age: 64 ± 10 years) vs. 49 age-matched healthy eyes (age: 61 ± 9 years). The circular scans (diameter: 3.5 mm) were extracted from volume scans and centered on the optic disc (OD). The BIR value at each virtual A-scan position was the quotient of the retardation (RET) measured at the IS/OS junction divided by the NFL-thickness (NFLT). Early glaucoma was defined by glaucomatous appearance of the OD and repeated pathologic visual field tests with a mean deviation (MD) better than -6 dB. Main outcome parameters were BIR, NFLT, and RET.

Results: Glaucoma eyes showed statistically significantly reduced NFLT (69±13 µm vs. 99±12 µm, $p<0.001$), RET (6.5 ±1.6° vs. 10.5 ±1.9°, $p<0.001$) and BIR (0.108 ±0.008°/µm vs. 0.112 ±0.009°/µm, $p=0.0033$) compared to healthy eyes. Figure 1 shows plots in temporal (T), superior (S), nasal (N), inferior (I) order for NFLT (A), RET (B) and BIR (C). Surprisingly the BIR showed no double-hump pattern as usually observed for NFLT and RET, instead it appeared to have a single dip at the temporal region. This was confirmed in averaged maps shown in Figure 2, whereas: column A-D-G= healthy eyes, B-E-H= glaucoma eyes with superior visual field (VF) impairment (n=27), C-F-I= glaucoma eyes with inferior VF impairment (n=19) and row A-B-C= NFLT, D-E-F= RET, G-H-I=BIR. Glaucoma eyes with both visual field hemispheres affected (n=3) were excluded from the averaged maps.

Conclusions: We report a reduced BIR of the NFL in early perimetric glaucoma, which may be interpreted as a sign of a loss of intracellular microtubules and might contribute to a better understanding of early glaucoma development. Early reduction of BIR in glaucoma models has been shown before in non-human primates. Nevertheless, to establish whether BIR is altered in preperimetric human glaucoma prior to the reduction of NFLT, prospective longitudinal studies are needed.

ABSTRACT BODY:

Purpose: As part of the Clinical Genome Resource (ClinGen), the X-linked Inherited Retinal Diseases Variant Curation Expert Panel (XLIRD VCEP) was established in 2020 to address the need for consistent variant interpretation in inherited retinal disease (IRD) genes with an X-linked inheritance pattern, which account for ~15% of IRD reported in large cohorts.

Methods: The XLIRD VCEP implements the ClinGen variant curation practices that have been recognized by the U.S. FDA to assess individual variants in seven X-linked genes (CACNA1F, CHM, NPD, OFD1, RPGR, RP2 and RS1). By combining expertise in phenotypes and molecular mechanisms of the IRD from clinical and laboratory experts, a set of variant curation rules customized to each gene is specified to assess the pathogenicity of the variants. All reported variants in the seven genes are systematically scored, following the rules and categorized into five classes, including pathogenic, likely pathogenic, variant of uncertain significance (VUS), likely benign, and benign, according to ACMG/AMP guidelines.

Results: We established the XLIRD VCEP, with membership and curation protocols available on the ClinGen website (https://clinicalgenome.org/). Starting with RPGR, in which variants account for 9% of rod-cone and cone-rod dystrophies, gene-specific curation rules are generated. Performance of various computational prediction tools are evaluated, and proper allele frequencies in population databases are selected to determine the pathogenicity of the variant. To facilitate the curation process, in addition to published variants, private variant data from genetic testing laboratories are also collected. Pilot curation exercises being performed will be evaluated to refine the initial rules, which will then be applied to curate variants in the RPGR gene. This process will be repeated for the other XLIRD

genes, and the curations reviewed iteratively to refine the processes further.

Conclusions: Systematic and consistent curation of variants from FDA-recognized gene-specific guidelines supported by sharing genomic data and expertise will evaluate the current classification of variants and decrease the numbers of VUS within these XLIRD genes. This will improve the specificity and accuracy of the molecular diagnoses of patients with variants in these genes and increase the value of genetic testing as a diagnostic tool and guide for patient eligibility for genetic therapies for these IRD.

ABSTRACT BODY:

Purpose: To evaluate the impact of intermittent bright light exposure on ocular growth and refractive error development in a monkey model of form-deprivation myopia.

Methods: Eight infant macaques (21±4 days old) were housed for 210 days under a 12/12h light/dark cycle using standard fluorescent light (SL, 140 lux, 4000K). Macaques were assigned into 2 groups. Animals in group 1 (n=5, 2 rhesus, 3 cynomolgus) were raised under SL, whereas animals in group 2 (n=3, 2 rhesus, 1 cynomolgus) were exposed to an additional 4h/day of intermittent bright light (IBL). IBL consisted of 1h of high intensity LED light (11,066 lux, 4000K) delivered every 2h of SL. Form-deprivation myopia (FDM) was induced monocularly over 154 days using a custom-built 3D-printed helmet fitted with a plano lens and occlusion foil (20/300 VA) covering the form deprived (FD) eye. The fellow (control) eye was covered with a plano lens. Axial length (AL), refractive error and choroidal thickness were assessed fortnightly. Results are expressed as average inter-ocular difference (IOD= FD - control eye) ±SD. Outcome measures were compared between eyes on day 154 (D154) using a paired t-test and between groups using a Mann-Whitney U-test on areas under the outcome measures' curves (AUC) across form-deprivation (D0 to D154).

Results: By the end of form-deprivation (D154), FD eyes exposed to SL had increased AL (IOD = +0.25±0.17 mm; P=0.03) and myopic refraction (IOD= -3.80±0.89 D; P<0.001), and thinner choroids (IOD= -11.8±5.72 µm; P=0.009) compared to control eyes. On the other hand, FD eyes exposed to IBL showed no changes in AL (IOD= +0.02±0.03 mm), refraction (IOD= +0.08±0.14 D) or choroidal thickness (IOD= -1.0±2.64 µm) (all P>0.05). Overall, across the form deprivation period, FD eyes exposed to IBL displayed reduced/abolished IOD in axial elongation, myopic refraction and choroidal thinning compared to the eyes exposed to SL (all P<0.05; Fig.1A-C).

Conclusions: Our preliminary findings suggest that 4h/day of IBL can prevent the development of FDM in infant macaques. Data from 5 additional animals are being collected and analyzed and will be presented at ARVO 2022.

ABSTRACT BODY:

Purpose: Gasdermin D (GSDMD) is a key executor of inflammasome-mediated pyroptotic cell death and inflammation. Previously we demonstrated that global knockout of the GSDMD gene in vivo prevents hyperoxia-induced retinopathy in a neonatal murine model. Here we investigated if depletion of GSDMD expression with single strand AAV9 vector-mediated Crispr/SaCas9 gene editing rescues hyperoxia-induced cell death in murine retinal ganglion cell-5 (RGC-5) and primary retinal microvascular endothelial cells (RMVECs) in vitro.

Methods: Three editing vectors (AAV9-SagRNA-SaCas9-HA) each containing a guide RNA (SagRNA) targeting GSDMD exons 2, 3 or 4 were constructed with a HA tag fused to SaCas9 C-terminal plus a control vector with a scrambled SagRNA. Each of these vectors was transduced into RGC-5 and RMVECs with the helper adenovirus 5. Immunofluorescence and Western blotting for the HA tag were used to confirm transduction. Western blot was used to examine the efficiency of depletion of GSDMD expression. To examine the effects of these vectors on preventing hyperoxia-induced cell death, transduced RGC-5 and RMVECs were incubated in room air (21% O_2) or hyperoxia (95% O_2) for 64 h. Cell survival was detected by cell counting and pyroptotic cell death was assessed by LDH assays.

Results: All GSDMD gene-editing vectors as well as the control vector were effectively transduced in RGC-5 and RMVECs, as evidenced by immunofluorescence and Western blotting. Western blots showed that GSDMD expression was drastically decreased in RGC-5 and RMVECs by the vector containing the guide RNA targeting exon 4. Moreover, DNA sequencing revealed that this vector effectively edited a GSDMD genomic mutation. We found this vector significantly attenuated hyperoxia-reduced cell survival by 40% in RGC-5 compared to controls ($p<0.001$). Similarly, depletion of GSDMD in RMVECs significantly increased cell numbers under hyperoxia compared to controls by 4-fold ($p<0.005$). Furthermore, LDH assay showed that hyperoxia-induced cell death in RMVECs transduced with this vector was significantly decreased by 3-fold compared to controls ($p<0.001$).

Conclusions: Depletion of GSDMD expression by AAV9-mediated Crispr/SaCa9 gene editing markedly rescued hyperoxia-induced cell death in RGC-5 and RMVECs. Thus, this strategy has potential as a novel treatment to prevent oxygen-induced retinopathy in neonatal rodent models as well as in premature infants.

TITLE: RNA Structure-Function Properties of Enhanced Hammerhead Ribozymes with High Catalytic Efficiency

SESSION TITLE: Gene Therapy and Gene Editing for Ocular Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.M. Sullivan, J. Myers, Research Service, VA Western NY Healthcare System, Buffalo, New York, UNITED STATES|J.M. Sullivan, J. Myers, Ophthalmology (Ross Eye Institute), University at Buffalo-SUNY, Buffalo, New York, UNITED STATES|

Commercial Relationships Disclosure: Jack Sullivan: Commercial Relationship(s);Code P (Patent):Research Foundation of SUNY; Veterans Administration; US Patents: 8,450,473 B2, 8,252,5278 | Jason Myers: Commercial Relationship(s);Code P (Patent):Veterans Adminstration; Research Foundation of SUNY

ABSTRACT BODY:

Purpose: Investigate RNA structure/function properties of Enhanced hammerhead ribozymes (EhhRz) to ascertain underlying molecular biophysical properties of log-order kinetic improvements.

Methods: EhhRz-266 attacks full length human rhodopsin mRNA at CUC↓266, a rare position accessible for annealing and cleavage. Minimal substrate RHO-266 RNA is 15 or 14 nt long with 5' FAM and 3' BHQ1 (IDT); cleavage at CUC↓ 266 and product release results in liberation of quenched fluorescence which is quantified optically in real time in a qRT/PCR machine. EhhRzs are transcribed (T7pol) from PCR templates or synthetized (IDT). Mutations in substrate or/and EhhRz assess structure-function relationships in reactions initiated by mixing EhhRz with substrate RNA (100 nM: 1 uM) in buffer (10 mM Tris-HCl, pH 7.5) at 0.5 mM Mg2+ and optically measured at 37°C. Data are analyzed in Origin.

Results: Variation of Stem-II tetraloops (n=24) had marked impact on kinetic turnover activity relative to wild type (GAAA) with both 15-mer (ANOVA, p = 0) and 14-mer (ANOVA, p=0) substrates. Optimal tetraloops are from a class with unique 3D structure. Changes in the 5' end of the EhhRz, base pairing with the 3' end of the substrate, have marked impact on turnover rates at the A7 position (ANOVA, p=0), severe impact at the G6 position (ANOVA, p=0), and less marked impact at the A5 position (ANOVA, p=4.44E-16). Length and composition of Stem-II has a marked impact on turnover rate (ANOVA, p=1.11E-16). The number of G residues at the 5' end of the EhhRz has a marked impact on turnover rate (ANOVA, p=0). Addition of a structured stem at the 5' end of the EhhRz is inhibitory (ANOVA, p=0). Variation of the NUH↓ cleavage site impacts turnover (ANOVA, p=0).

Conclusions: Kinetic efficiency (Vmax/Km) of EhhRzs is on scale of protein RNaseA. EhhRz upstream antisense flank (bound to substrate mRNA) interacts with Stem-II tetraloop to promote catalysis. The optimum Stem-II length (4bp) infers critical distance-dependent interactions. Variation in rate with upstream composition suggests specific nucleotide interactions with Stem-II-tetraloop. Variation in rate with tetraloop infers that these interactions can be highly varied (topological) and dynamic. Outcomes are relevant to establishment of design rules for EhhRzs as nucleic acid therapeutics for arbitrary target mRNAs.

TITLE: Topical application of anti-miR-183/96/182 cluster causes transient, reversible corneal nerve reduction and demonstrates therapeutic potential against bacterial keratitis

SESSION TITLE: Modulation of ocular surface immunity during health and disease

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: N. Gupta, S.A. McClellan, D. Bessert, L.D. Hazlett, S. Xu, Ophthalmology, Visual and anatomical sciences, Wayne State University, Detroit, Michigan, UNITED STATES|

Commercial Relationships Disclosure: Naman Gupta: Commercial Relationship: Code N (No Commercial Relationship) | Sharon McClellan: Commercial Relationship: Code N (No Commercial Relationship) | Denise Bessert: Commercial Relationship: Code N (No Commercial Relationship) | Linda Hazlett: Commercial Relationship: Code N (No Commercial Relationship) | Shunbin Xu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Previously we identified that the miR-183/96/182 cluster (miR-183C) modulates corneal response to Pseudomonas aeruginosa (PA) infection by regulating corneal nerve function and innate immunity[1-3].Local application of anti-miR-183C in a prophylactic regimen causes a transient, reversible reduction of corneal nerve density and protects against PA keratitis[4]. This study is to test whether topical application of anti-miR-183C alone in a therapeutic regimen has similar effects on corneal nerves and PA keratitis.

Methods: 8 weeks old, female C57BL/6 mice were used. Under anesthesia, the cornea of the left eye was scarified by three 1-mm incisions using a 25 5/8-gauge needle. 5.0×10^6 CFU PA (strain 19660; ATCC) in 5 µl was topically delivered. Six or 24 hours after infection and twice daily thereafter, 5 µl of anti-miR-183C or negative-control oligoribonucleotides (NC ORN) in sterile saline (8 µM/each) was topically applied to the infected cornea for 5 days. To test the effect of anti-miR-183C alone on corneal nerves, anti-miR-183C or NC ORNs were topically applied to the cornea 24 hours after a mock infection and twice daily thereafter. At 5 days post (mock) infection (dpi), immunofluorescence (IF) of flat-mounted corneas with bIII-tubulin antibody was done and corneal nerve density was determined.

Results: Topical application of anti-miR-183C resulted in a significant reduction of corneal nerve density. To test whether anti-miR-183C-induced reduction of corneal nerves causes permanent changes to corneal nerves, after the last topical application, another group of anti-miR-treated mice were held for another week without any treatment. Our result showed that their nerve density was fully recovered. Preliminary data on PA-infected corneas showed that topical application of anti-miR-183C significantly reduced the severity of the disease at 3 dpi ($p<0.05$); at 5 dpi, anti-miR-183C treated eyes had slightly decreased severity, however, didn't pass the statistical threshold ($p=0.09$).

Conclusions: Topical application of anti-miR-183C causes transient and reversible corneal nerve density reduction and has a therapeutic potential against PA keratitis. Further studies to optimize the treatment regimen and uncover the molecular mechanisms of the therapeutic effect are warranted.

ABSTRACT BODY:

Purpose: The prevalence of high myopia (spherical refraction [SR] > -6D or an axial length > 26 mm) with a maximum recorded length of 37 mm is projected to increase from 2.7% to 9.8% by 2054. Retinal surgery requires instruments of sufficient length to reach the retina. To assist in the selection of appropriate instruments, modeling was conducted to estimate the length of instruments required for highly myopic eyes.

Methods: A geometric model for a myopic eye was constructed as a guide to determine the length of an instrument required to reach the position of the retina furthest from the point of insertion. The anterior portion of the model included only the cornea, with anterior radius of 7.77 mm drawn to a white-to-white distance of 11.69 mm, and the anterior sclera of radius 13.12 mm extending from this point to a length of 3.5 mm, representing the point of instrument insertion at the pars plana. The posterior portion was comprised of the retinal surface from the posterior pole to +/- 11 mm from the optical axis, parameterized to allow the retinal shape and location to scale with mean SR, according to the model. Matlab code was written to determine the distance to the location on the retina furthest away from the point of insertion.

Results: For the model eye, when axial length increased from 23.6 to 37.3 mm, maximum required instrument reach increased from 23.3 to 33.7 mm.

Conclusions: An instrument with a maximum reach of 34 mm is sufficient to treat an eye with axial length up to 37 mm.

ABSTRACT BODY:

Purpose: To determine the association of the ANGPT2 gene with primary open-angle glaucoma (POAG) in Chinese.

Methods: Six single-nucleotide polymorphisms (SNPs) in ANGPT2 (rs2515487, rs2922869, rs13255574, rs4455855, rs13269021, and rs11775442) were genotyped in a total of 2,601 study subjects from two cohorts. One is a Hong Kong Chinese cohort of 484 high tension glaucoma (HTG) and 537 normal tension glaucoma (NTG) patients, and 496 non-glaucoma control subjects. Another cohort is a Shantou Chinese cohort of 403 HTG and 135 NTG patients, and 543 non-glaucoma control subjects. Subgroup analysis by sex was conducted. Outcomes from different cohorts were combined for a meta-analysis.

Results: SNP rs11775442 showed a nominal association with NTG in the Hong Kong cohort ($P = 0.0498$, OR = 1.24, 95% CI: 1.00-1.55) after adjusting for age and sex. Other SNPs were not significantly associated with NTG, HTG and POAG in individual cohort or in the combined analyses ($P > 0.05$). In the subgroup analysis by sex, SNP rs13269021 in the Shantou cohort was significantly associated with NTG in males ($P = 0.0081$, OR = 1.67, 95% CI: 1.14-2.43; Table 3) but not in females ($P = 0.874$).

Conclusions: For the first time, we identified a sex-specific association of ANGPT2 locus (rs13269021) with NTG in the Shantou cohort, indicating ANGPT2 may have a role in the genetic mechanism of NTG in Chinese males. Further studies are needed to verify the association between ANGPT2 and NTG.

ABSTRACT BODY:

Purpose: Intraocular pressure (IOP) fluctuation is a major risk factor for glaucoma progression and vision loss and is associated with either non-adherence to or poor topical anti-glaucoma drug penetration in patients with POAG. GB-401 is a biodegradable implant formulation containing a beta-adrenergic antagonist prodrug that has the potential to enable sustained IOP reduction with twice-a-year intravitreal (IVT) injections. This study includes in vitro characterization of GB-401 and in vivo evaluation for pharmacokinetics (PK) and ocular toxicity.

Methods: The prodrug was synthesized by conjugating hydrophobic linkers to the parent beta-adrenergic antagonist and loaded in an injectable biodegradable implant. The drug loading, implant injectability and release kinetics were assessed in vitro. Intraocular pharmacokinetics were evaluated in Dutch-belted rabbits at two dose levels. Ocular tissues and blood samples were collected at various timepoints and analyzed for drug concentrations. A repeat-dose GLP toxicity study in minipigs is in progress to evaluate the ocular safety of GB-401.

Results: GB-401 achieved high drug loading and sustained drug release kinetics owing to the modified physiochemical properties of the prodrug. The linkers of the prodrug degrade by hydrolysis, allowing full conversion to the active beta-adrenergic antagonist. The prodrug was previously shown to effectively reduce IOP in an ocular hypertensive rat model (Hoang et al., ARVO 2019). Sustained drug release from GB-401 lasted approximately 120 days in vitro under sink condition. Significant drug levels were achieved in target tissues (iris-ciliary body) from day 3 (180-fold of K_i) and through 4 months (100-fold of K_i), with a maximum concentration >4,000-fold greater than the K_i, whereas no drug was detected in plasma at any timepoint. The implant formulation was well tolerated in the completed PK study in rabbits, as well as the ongoing toxicity study in minipigs, with no signs of ocular toxicity.

Conclusions: GB-401 is an injectable implant formulation containing a beta-adrenergic antagonist prodrug that has the potential to enable a long-term treatment paradigm with sustained IOP reduction achieved via twice-a-year IVT injections in patients with POAG. A Phase 1/2a first-in-human study is planned.

ABSTRACT BODY:

Purpose: Intravitreal anti-vascular endothelial growth factor (VEGF) improves the visual prognosis in myopic choroidal neovascularization at short term, but visual acuity (VA), recurrence rate, and second eye involvement at long-term remain unclear. We performed a longitudinal clinical study with real-world data to learn about the long-term outcomes of anti-VEGF in a large European cohort.

Methods: Up to 12 years of longitudinal data from a tertiary hospital in the Netherlands (2008 – 2018) were analyzed. Patients with high myopia (spherical equivalent (SE) ≤-6D), an active CNV lesion, European descent and no history of anti-VEGF treatment were monitored. A total of 98 eyes (mean SE -14 ± 4D) of 87 patients (mean age 57±14 years) were included. Course of VA during follow-up, recurrence rate and second eye involvement were analyzed as outcomes. Change in VA during follow-up was compared using paired t-tests. Cox proportional hazard models tested the effect of the presence of chorioretinal atrophy (CRA) and lacquer cracks on mCNV recurrence or second eye involvement.

Results: VA significantly improved after a median of 2 anti-VEGF injections ($P<0.001$). At 4 years, the improvement in VA disappeared ($P=0.6$) and continued to deteriorate (Figure 1). The average decrease of VA was 0.05 LogMar per year. The cumulative incidence of recurrent mCNV was 52% at 5 years after the first episode. VA in eyes with recurrent mCNV decreased at a similar rate ($P=0.5$). Diffuse CRA (HR 10.6 95% CI 2.2-51.3, $P=0.003$) and patchy CRA (HR 5.2 95% CI 1.2-22.0, $P =0.027$) were significant predictors for mCNV recurrence. In 22 (25%) patients, the fellow eye developed mCNV after an average of 5.7 years. Age ≤ 40 years at first onset of mCNV significantly increased the risk of bilateral mCNV (HR 4.5, 95% CI 1.4–13.9, $P=0.008$). CRA and lacquer cracks in the fellow eye at baseline did not add significantly to the risk of mCNV in that eye.

Conclusions: This large mCNV study revealed that VA improvement after IVB injections was not maintained at long-term. Recurrences occurred frequently but did not alter the already poor visual prognosis. We advise to closely monitor patients with mCNV since recurrences occur in more than 50%, and pay particular attention to patients younger than 40 years as they are at high risk of second eye involvement.

ABSTRACT BODY:

Purpose: Anterior chamber (AC) depth is a frequently assessed component of the ophthalmic examination, as shallow AC is correlated with risk of acute and chronic angle closure glaucoma or risk of angle closure due to pharmacologic dilation. AC depth can be assessed through gonioscopy or the Von Herick slit lamp evaluation. Telemedicine has recently been employed to enable screening, diagnosis, and management of ophthalmic conditions. In order to evaluate the utility of telemedicine to assess AC depth, we implemented a novel modified slit lamp capable of transmitting stereoscopic images of patients' eyes to remote reviewers. We hypothesized that AC depth assessment using digital stereoscopic slit lamp images would correlate with in-person ophthalmologist assessment of the AC depth.

Methods: We prospectively captured five standardized images of patient eyes (n = 5) using a stereoscopic slit lamp camera. One in-person physician and five remote physicians graded the depth of the AC and graded it on a binary scale as either shallow or deep.

Results: There was 76% agreement (kappa = 0.766) in remote grading of AC depth. The agreement between the in-person and remote graders numbers 1-3 was 100% (kappa =1.0), 50% (kappa = 0.5) for remote grader 4, and 83% (kappa = 0.83) for remote grader 5.

Conclusions: Remote telemedical assessment of the depth of patients' AC using stereoscopic images appears to be feasible according to the results of our small prospective pilot study. Telemedicine may therefore be able to improve access to high quality eye care for patients at risk for shallow AC and associated ophthalmic conditions. Larger future studies are needed to validate the results of this pilot study.

Zigler: Commercial Relationship: Code N (No Commercial Relationship) | Debasish Sinha: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is the leading cause of blindness in the elderly. We have shown that a pro-inflammatory adipokine, Lipocalin-2 (LCN-2), is upregulated in retinal pigment epithelium (RPE) cells in both a mouse model with a dry AMD-like phenotype and in early/dry human AMD donor samples, but only after chronic inflammation has been established. Many elegant studies have shown that LCN-2 exists as either a monomer or a homodimer variant. While the monomer is a potent iron chelator and has anti-microbial effects, the homodimer variant, which has a longer half-life, is unable to chelate iron and has been linked to the onset of several diseases. However, it is not known whether the homodimer variant is also upregulated in AMD nor if it is associated with disease progression. In this study, we evaluated the level of LCN-2 homodimer in AMD and investigated its possible role in inducing retinal degeneration.

Methods: Western blotting (WB) was performed on the RPE cell lysates under reducing and non-reducing conditions to evaluate the levels of the LCN-2 homodimer and monomer variants in our mouse model and human dry AMD donor samples. The levels of the LCN-2 variants were evaluated in spent medium from WT RPE explants overexpressing LCN-2 (RSM-LCN-2). To determine if the homodimer variant can induce retinal degeneration, NOD-SCID mice were injected with RSM-LCN-2, and effects on retinal structure (SD-OCT) and function (electroretinography) were assessed.

Results: WB analysis revealed an increased LCN-2 homodimer:monomer ratio in the RPE lysates from our mouse model and human AMD donors. The presence of the homodimer was confirmed by WB under reducing and non-reducing conditions. RSM-LCN-2 also showed elevated levels of the homodimer variant. Sub-retinal injection of RSM-LCN-2 in NOD-SCID mice, induced significant alterations in retinal structure and function.

Conclusions: Our data suggests that LCN-2 homodimer is the pathogenic form of the adipokine and is involved in AMD pathogenesis. Further, targeting/neutralizing the homodimer variant could be helpful in delaying the onset of retinal degeneration as seen in dry AMD, a multifactorial disease for which there are no treatment options at the present time.

TITLE: Surface softness characterization of a novel biomimetic silicone hydrogel contact lens using an atomic force microscopy indentation method

SESSION TITLE: Contact lens

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: V. Sharma, C.X. Shi, J. Wu, Alcon Research Institute, Fort Worth, Texas, UNITED STATES|

Commercial Relationships Disclosure: Vinay Sharma: Commercial Relationship(s);Code E (Employment):Alcon | Charlie Shi: Commercial Relationship(s);Code E (Employment):Alcon | James Wu: Commercial Relationship(s);Code E (Employment):Alcon

ABSTRACT BODY:

Purpose: An atomic force microscopy (AFM) indentation method was employed to measure the surface softness of a novel reusable biomimetic silicone hydrogel (lehfilcon A) contact lens with surface modification of a cross-linkable bioinspired 2-methacryloyloxyethyl phosphorylcholine (MPC) polymer. The purpose of the study was to measure and compare the surface softness of the lehfilcon A contact lens, the cornea, and other reusable SiHy contact lenses including comfilcon A, senofilcon A, senofilcon C, and samfilcon A.

Methods: An AFM nanoindentation method was developed to test corneas and contact lenses in fully hydrated conditions. The AFM probe used for the indentation experiments had a design (tip size, geometry and spring constant) especially suited to characterize soft materials and biological tissues, and it allowed precise contact-point determination as well as accounted for the fluid-load support effect. Indentation force-curves (FC) were generated for the cornea and contact lens samples at a fixed force, chosen to generate a contact pressure within the physiological range of the upper eyelid pressure on the human ocular surface. These FC were then analyzed to calculate the surface modulus values to conclude relative comparisons in the surface softness.

Results: The improved sensitivity and accuracy of the indentation method allowed precise measurement of the extremely low surface softness for the cornea and lehfilcon A contact lens. The surface modulus of the lehfilcon A contact lens (46±7 kPa) was similar to that of the cornea sample (55±31 kPa), but significantly lower than those of the comfilcon A (231±51 kPa), senofilcon C (251±47 kPa), senofilcon A (257±36 kPa), and samfilcon A (266±39 kPa) contact lenses ($p<0.05$ for all).

Conclusions: A new AFM indentation method with increased sensitivity and accuracy was developed to measure the surface modulus of a novel biomimetic MPC surface-modified SiHy contact lens as well as the cornea and other reusable SiHy contact lenses. The results indicated that the surface of the lehfilcon A contact lens was as soft as the cornea surface and was significantly softer than the comfilcon A, senofilcon A, senofilcon C, and samfilcon A contact lenses. The surface softness of a contact lens might affect the mechanical contact stress on ocular tissues thus its impact on eye comfort.

ABSTRACT BODY:

Purpose: To compare the efficacy of high-dose aflibercept and aflibercept for neovascular age-related macular degeneration.

Methods: This retrospective review included age-matched neovascular age-related macular degeneration (nAMD) patients treated with aflibercept (2mg/0.05ml) and high-dose (HD) aflibercept (3mg/0.075ml). Our current clinical practice patterns are to treat nAMD eyes initially with bevacizumab and transition to aflibercept and HD aflibercept when clinically necessary. Visual acuity, central retinal thickness (CRT), qualitative optical coherence tomography (OCT) data was compared from baseline to 48 months for eyes requiring treatment with aflibercept and HD aflibercept.

Results: A total of 200 eyes of 177 patients were included. Mean visual acuity was similar at baseline for HD aflibercept (logMAR 0.50 ± 0.46 20/63) and aflibercept groups (logMAR 0.51 ± 0.39 (20/64), p=0.20). Mean visual acuity was stable over 48 months in both HD aflibercept (logMAR 0.46 ± 0.37 (20/57), p=0.27) and aflibercept groups (logMAR 0.56 ± 0.48 (20/72), p=0.46). The HD aflibercept group started with a thicker mean CRT (313.7 ± 102.8 µm versus 276.5 ± 68.8 µm, p<0.01) and required more injections than the aflibercept group (34.8 ± 12.5 vs 27.3 ± 9.7 injections respectively, p<0.01). HD aflibercept eyes were also less likely to be extended (27% versus 45%, respectively, p<0.01). Of the 100 eyes who had an incomplete response to monthly bevacizumab and monthly aflibercept, 97% achieved a dry macula with monthly HD aflibercept. Central retinal thickness also improved in HD aflibercept (313.7 ± 102.8 µm to 264.7 ± 52.26 µm, p<0.001) and aflibercept groups (276.5 ± 68.8 µm to 231.0 ± 54.8 µm, p<0.001) over 48 months.

Conclusions: Aflibercept and HD aflibercept are effective at maintaining visual acuity and central retinal thickness in eyes with nAMD over 48 months. Eyes with a suboptimal response to monthly bevacizumab and monthly aflibercept were able to achieve comparable visual acuity and OCT outcomes with high-dose aflibercept. Further studies are necessary to elucidate the real-world applications of standard dose and HD aflibercept.

ABSTRACT BODY:

Purpose: Our labs have demonstrated exercise as a promising intervention in animal models of retinal degeneration (RD). Exercise-induced retinal protection was accompanied by increased levels of brain derived neurotrophic factor (BDNF) and required intact signaling via its high-affinity receptor, TrkB. In the brain, imbalances in astrocytic expression of BDNF and specific TrkB isoform expression, particularly increased TrkB.T1, contribute to neurodegeneration severity. Here, we explore the role of retinal astrocytes in exercise-induced retinal neuroprotection using a light-induced retinal degeneration model (LIRD) that exhibits phenotypes found in patients with RD.

Methods: Adult male BALB/c mice were assigned to active(A)-dim, inactive(I)-dim, inactive(I)-LIRD and active(A)-LIRD groups (n=36 per group). Active mice were treadmill exercised (1hr/d, 10m/min) for two wks, then LIRD was induced (5000 lux/4hrs). Inactive groups were on a static treadmill for the same schedule. At week three, retinal function was assessed using ERG. Retinal flat mounts were stained for astrocytes (GFAP) and density, branching and dendritic arborization were quantified. Magnetic activated cell sorting (ACSA-2) and ddPCR was used to isolate retinal astrocytes and quantify gene expression of BDNF and various TrkB isoforms. Data were analyzed using 2-way ANOVA.

Results: A-LIRD a- and b-wave mean amplitudes were 2.5x and 1.9x greater than I-LIRD means respectively ($p<0.001$), indicating that exercise significantly preserved retinal function. Flat mounts from A-LIRD mice had 50% more astrocytes ($p<0.0001$), 44% more branching ($p<0.0001$,) and 69% more arborization ($p<0.05$). Isolated retinal astrocytes from A-LIRD mice had increased TrkB.FL expression ($p=0.006$), I-LIRD mice had increased TrkB.T1 expression ($p=0.014$) and active groups had increased BDNF expression compared to inactive ($p=0.025$).

Conclusions: Our results indicate exercise influences retinal astrocyte morphology and gene expression. Retinal astrocytes from A-LIRD groups showed increased expression of BDNF and TrkB.FL, the TrkB isoform associated with cell survival. These results suggest exercise can alter retinal astrocyte morphology and restore BDNF-TrkB signaling during RD, providing insight for exercise-based therapies for RD.

ABSTRACT BODY:

Purpose: This observational clinical study was designed to assess the effects of mitochondrial reactive oxygen species (mtROS) scavenger Visomitin (SkQ1 ophthalmic solution) in Leber hereditary optic neuropathy (LHON) patients relative to data demonstrated by prior natural history studies of disease progression and to identify potential primary endpoints for a future double-blind, randomized, placebo-controlled study.

Methods: This was an uncontrolled, open-label, observational study, comprising 6 visits over the course of 30 months. 43 subjects diagnosed with mitochondrial optic neuropathy who were prescribed Visomitin (0.155ug/mL SkQ1 Ophthalmic Solution) for Dry Eye Disease were observed. 26 patients (24 men and 2 women) had genetically confirmed LHON-related mutations in mtDNA. There was no designated primary endpoint. Best Corrected Visual Acuity was assessed using Freiburg Vision Test for low vision.

Results: All 26 subjects with LHON-related mtDNA mutations completed the initial 12-month observation period. Average BCVA of LHON patients significantly improved by 0.37 logMAR ($p=2x10^{-8}$) relative to baseline after 12 months. After 30 months of treatment BCVA change from baseline was 0.42 logMAR ($p=1x10^{-10}$). According to the International Consensus, BCVA improvement of 2 lines (0.2 logMAR) is considered clinically relevant in LHON patients. Studies of natural history of LHON patients carrying the m.11778G>A mutation suggest that over a comparable time frame, BCVA improvement of 0.3 logMAR or more occurs in 18% of patients, and the deterioration of BCVA of the same value (0.3) occurs in 14%. In this study, among patients with m.11778G>A mutation treated with Visomitin an improvement by 0.3 logMAR and more was observed in 56% of patients by the end of the study, while deterioration by 0.3 LogMAR or more was not observed.

Conclusions: Visomitin ophthalmic solution, a drug designed for protection of ocular tissue from oxidative stress at mitochondrial level, demonstrated statistically significant improvement of BCVA relative to baseline in LHON patients. These improvements compare favorably when considering the typical natural history of disease progression. These findings warrant design of a double-masked, randomized, placebo-controlled study of Visomitin efficacy in LHON patients.

ABSTRACT BODY:

Purpose: Mitochondrial DNA (mtDNA) mutations that promote mitochondrial dysfunction have been implicated in age-related retinal diseases. This study used a novel pre-clinical model to test the hypothesis that impaired mitochondrial function due to mtDNA damage results in age-related retinal and retinal pigment epithelium (RPE) degeneration.

Methods: 3-, 6-, 9-, and 12-month-old Polg^{D257A} mutant and wild-type (WT) mice were imaged using optical coherence tomography (OCT) and confocal scanning laser ophthalmoscopy (cSLO)(N=4). In addition, photoreceptor and RPE functions were assessed using electroretinogram (ERG). Histological and immunohistological evaluation of the retinas of Polg^{D257A} mutant and control mice were also performed in cryosections. Cryosections (8 um) were incubated with commercially available antibodies specific to retinal cells and mitochondria. Sections were analyzed using a Leica TCS-SP8. A Student's t-test was used for all statistical analyses.

Results: OCT image analysis revealed a decrease in the size of several retinal cell layers starting at 6 months of age. Most notably, the RPE and photoreceptor (PR) layers were significantly decreased compared to WT mice and accounted for nearly 57% of the total retinal degeneration observed. Analysis of SLO images detected a significant decrease in blue auto fluorescence at 6 months of age. ERG testing displayed a drastic reduction in a-wave, b-wave, and light-adapted response at 12 months of age. Finally, retinal tissue collected for immunofluorescence showed decreases in COX4 and Ezrin proteins compared to WT. Together, this data indicates that mtDNA mutations result in both degenerative and physiological effects in the mouse retina. The degeneration is associated with decreased total retina and RPE thickness, impaired electrophysiological activity from multiple neural retina cell types, and reduced essential proteins implicated in retinal metabolism and integrity.

Conclusions: Polg^{D257A} mutant mice that accumulate mtDNA mutations due to an error-prone exonuclease domain in Polymerase gamma, exhibit an age-related retinal pathology.

ABSTRACT BODY:

Purpose: Retinopathy of prematurity (ROP) is a major cause of blindness in children. The incidence of ROP continues to increase and there is an urgent need to understand the molecular mechanism of ROP development. Immune cells are a source of cytokines and growth factors that may interact with endothelial cells and contribute to retinopathy. We reported that myeloid cells regulated choroidal neovascularization via suppressor of cytokine signaling 3 (SOCS3). However, the role of myeloid cells in ROP is still unknown. We aimed to study the role of myeloid cells and SOCS3 in ROP.

Methods: Socs3 myeloid-specific knockout mice (Socs3 cKO) were generated by breeding Socs3 flox/flox (Socs3 f/f) mice with LysM-Cre mice. Socs3 myeloid-specific overexpression mice (Socs3 cOE) were generated by breeding Socs3 OE flox/flox (Socs3 OE) mice with LysM-Cre mice. Oxygen induced retinopathy (OIR) mouse model was generated by exposing newborn mice to 75% oxygen from postnatal day (P)7 to P12 and to room air from P12 to P17. CD45 positive cells were isolated from retinas with OIR (age-matched normal retina as control) using flow cytometry for single cell RNA sequencing (10x genomics). Retinas were stained with endothelial cell marker Isolectin B4 (Invitrogen) and flat mounted for phenotypical analysis. Results were presented as mean ± SEM and compared using the unpaired nonparametric Mann-Whitney test. Statistical analyses were performed with GraphPad Prism.

Results: Using single cell RNA sequencing data, we applied t-Distributed Stochastic Neighbor Embedding (t-SNE) method to analyze the immune cell profile at steady state and during OIR. All clusters were assigned based on cell markers, which mainly included microglia, macrophages, neutrophils, B cells, T cells, and CD45-positive endothelial cells. A few clusters were identified that only appeared in OIR retinas including subtypes of microglia and macrophages as well as potential myeloid lineage derived endothelial cells. In addition, metabolism, inflammation, and cell proliferation related pathways were ranked on the top based on the pathway analysis using differential expressed genes (DEGs) in clusters that are different from OIR retinas compared with normal retinas.

Conclusions: SOCS3 regulated retinal angiogenesis via modulating myeloid lineage cell recruitment. Manipulating SOCS3 expression in myeloid cells may provide a new way to cure neovascularization in retinas.

ABSTRACT BODY:

Purpose: Considering that differences in the characteristics of ambient light between indoor and outdoor environment may impact myopia development in children, this study investigated the spectral composition of ambient light in different a) outdoor/indoor locations, b) times of a day, and c) seasons.

Methods: The spectral power distribution (SPD) was recorded using a hand-held spectrometer in three outdoor (‘open playground’, ‘under shade of tree’, and ‘canopy’) and three indoor locations (‘room with multiple windows’, ‘closed room’, and ‘closed corridor)’ at five different time points (3-hour intervals between 6:30 and 18:00 clock-hours) on two days, each during summer and monsoon seasons. The pattern and the distribution of SPD across the spectrum, namely the short (380-500 nm), middle (505-565 nm) and long wavelengths (625-780 nm) were further assessed to understand the percentage composition in different locations.

Results: The overall median SPD (IQR [25th-75th percentile] W/nm/m2) across three outdoor locations (0.11 [0.09,0.12]) was 157 times higher than indoor locations (0.0007 [0.0001,0.001]). A considerable locational, diurnal and seasonal variation was observed in the distribution of median SPD value, with the highest value recorded in the ‘open playground’ (0.27 [0.21,0.28]) followed by ‘under shade of tree’ (0.083[0.074,0.09]), ‘canopy’ (0.014[0.012,0.015]), and ‘room with multiple windows’ (0.023[0.015,0.028]). While the spectral power of short, middle, long, and blue wavelengths was significantly lower in indoor compared to outdoor locations, the pattern and the relative percentage composition of short, middle and long wavelengths were similar in both the outdoor and indoor locations.

Conclusions: Irrespective of variation in SPD values with location, time, day and season, outdoor locations exhibited significantly higher SPD than indoor locations. The relative percentage composition of short, middle and long wavelengths of light are similar across all the locations. From a myopia perspective, our findings indicate a possibly greater importance of the spectral power of ambient light rather than its spectral composition, as the latter was similar across outdoor and indoor locations. This finding warrants further research to understand its causal association with myopia.

ABSTRACT BODY:

Purpose: Metabolism plays critical roles in neuronal health and diseases. Sex is an important biological variable, but how sex influences metabolism in the eye and brain remains unclear. This study aims to address the sex difference in metabolites from mouse eye tissues, brain, and plasma in fed and fasted state using targeted metabolomics.

Methods: Three-month-old C57B6/J mice were ad libitum fed or deprived of food for 18 hours. Mouse eye tissues (retina, eyecup, and lens), brain, and plasma were harvested for targeted metabolomics. The steady-state metabolites were analyzed with liquid chromatography mass spectrometry and gas chromatography mass spectrometry. The data were analyzed with both multivariate Partial least squares-discriminant analysis (PLS-DA) and univariate Volcano Plot analysis ($P<0.05$ and fold change >1.3).

Results: Multivariate PLS-DA separated male and female groups in all tissues under either fed or fasted state in scores plots, demonstrating there is sex difference in the metabolome. Volcano Plot analysis showed that 8-47 metabolites were different between males and females under the fed state. The lens and retina had the largest number of changes but the plasma had the least. However, under the fasted state, the changed metabolites were reduced to 5-28, and the profiles of changed metabolites were mostly different from the fasted group. Intriguingly, ATP was reduced in the fasted eye cup, lens and brain, but its level was unchanged in the fasted retina. These results suggest that different sexes have different metabolic flexibility. Remarkably, the CoA precursor, Pantothenate, was the only metabolite that was significantly increased in all the female tissues. The fasting further increased Pantothenate in the female eye cup and lens. We also found tissue-specific changes between sexes. Hypoxanthine was retina-specific, succinate was eye cup specific, and cystine, ascorbic acid, adenine, UTP and UDP-Glucosamine were specific to the lens.

Conclusions: Sex influences eye and brain metabolism. Different sexes have tissue-specific and metabolic state-specific changes in metabolome. Our findings support that sex should be considered as a biological variable in the design of metabolomics studies.

ABSTRACT BODY:

Purpose: This study aimed to characterize long-term treatment patterns among patients with diabetic macular edema (DME) from a large ophthalmology registry.

Methods: A retrospective analysis was performed among treatment-naïve DME patients (no prior anti-vascular endothelial growth factor (anti-VEGF) intravitreal therapy [IVT] in the past 12 months) initiating IVT from 1/1/2015-12/31/2019 using de-identified electronic medical records (IRIS® Registry). Anti-VEGF agent utilization patterns, including agent type, switches (defined as ≥3 consecutive injections of a different anti-VEGF agent from the original agent), and discontinuations (defined as no anti-VEGF IVT for ≥12 months). Results were stratified by baseline visual acuity (VA) and initial anti-VEGF agent including on-label (ranibizumab and aflibercept) and off-label agent (bevacizumab).

Results: Of 190,345 eyes (147,687 patients), 147,336 eyes (77%) received only 1 anti-VEGF agent over a mean follow-up of 2.3 years, with bevacizumab being the most commonly used agent (53% of eyes). Bevacizumab use decreased by a mean of 5.6% each year and on-label agent use increased by a mean of 6.9% each year (Figure 1). 15% of eyes switched anti-VEGF agents after a mean of 53 weeks, of which 74% switched from bevacizumab to an on-label agent. 52% of eyes discontinued anti-VEGF treatment after a mean of 24 weeks, of which 33% reinitiated after a mean of 91 weeks. Rates of discontinuation, switching, and reinitiation were mostly similar regardless of baseline VA, though discontinuation with no reinitiation of IVT during follow-up was highest in patients with VA ≤20/200 at baseline (Figure 2).

Conclusions: Although a majority of patients with DME discontinue IVT therapy after a mean of 6 months, a third reinitiated. 58% patients initially received bevacizumab, but its use decreased over time with an increased use of on-label agents. Reasons for switching and discontinuation should be further explored.

ABSTRACT BODY:

Purpose: Mitochondrial pyruvate carrier (MPC) transports pyruvate from glycolysis into mitochondria. We recently reported pan-retinal deletion of MPC1 (a major component of MPC) disrupts retinal metabolism and causes retinal degeneration. In this study, we aim to understand the role of MPC in rod photoreceptors

Methods: MPC1 flox/flox mice were crossed with rod photoreceptor cre mice to generate mice with rod-specific deletion of MPC1 ($RMPC1^{-/-}$). We measured visual function by electroretinogram (ERG), retinal thickness by optical coherence tomography (OCT) and H&E, protein expression by immunohistochemistry, ultrastructure by electron microscope (EM), and retinal metabolites by targeted metabolomics and metabolic flux analysis

Results: Immunostaining with a customized antibody confirms the specific deletion of MPC1 in rod photoreceptors in $RMPC^{-/-}$ mice. Scotopic a-wave and b-wave decrease in $RMPC1^{-/-}$ mice starting at postnatal 30 days (P30), and further decline at P60. However, $RMPC1^{-/-}$ mice show a late-onset photoreceptor degeneration after P90. Photoreceptor inner segments are partially damaged in EM but the expression of mitochondrial complexes is normal. Pyruvate and aspartate accumulate, but citrate, glutamate and glutamine remain at normal amounts in $RMPC1^{-/-}$ retinas, suggesting metabolic compensation by other cells and/or nutrients. Consistently, the expression of GFAP and glutamine synthetase is upregulated in Müller glial cells. To study whether an alternative fuel could rescue the phenotype, we fed the mice with a ketogenic diet for 2 months starting at P21. The ketogenic diet significantly improves scotopic ERGs in $RMPC1^{-/-}$ mice in the first month but there is no protection after two months.

Conclusions: Mitochondrial pyruvate transport in photoreceptors is essential for visual function and photoreceptor viability. Although mitochondria have the flexibility to use a variety of nutrients, pyruvate, mostly from glycolysis, is indispensable for normal rod function and survival.

ABSTRACT BODY:

Purpose: Besides the motor deficits, Parkinson’s disease (PD) patients display visual disturbances in the early stages of the disease. One of these symptoms is the impairment of motion perception. Hence, we sought to evaluate if the main cell type involved in motion perception, the starburst amacrine cells, are degenerated in PD and if so, whether this degeneration is related to the degeneration of the dopaminergic system.

Methods: Human eyes from control and PD donors were available for this study. Tyrosine hydroxylase-positive cell density (dopaminergic amacrine cells), choline acetyltransferase-positive cell density (starburst amacrine cell) was evaluated by immunohistochemistry and confocal microscopy in whole-mount retinas. We also quantified the dopaminergic synaptic contacts with starburst amacrine cells using vesicular monoamine transporter-2 (VMAT2) antibodies.

Results: We found a significant decrease in the number of dopaminergic amacrine cells in PD retinas. Moreover, there is a decrease in the density of starburst amacrine cells in the two plexuses where they are located. Importantly, this work describes for the first time that dopaminergic amacrine cells contact with starburst amacrine cells in healthy control retinas and that these connections decrease in PD.

Conclusions: This work shows that there is a degeneration of starburst amacrine cells and their synaptic connections with dopaminergic cells which may explain the motion perception alterations in PD. Hence, these alterations can be used as a biomarker of the pathology using functional tests for motion perception.

ABSTRACT BODY:

Purpose: Intraocular injection is a standard route of administration for the treatment of several eye diseases, including AMD, intraocular inflammation, infection, and gene therapy. In human subjects, intracameral injection is rapid and easy to perform, with minimal discomfort for the patient. However, in the murine model these injections are more challenging due to dimension and anatomy of the eye. Our goal was to develop a semi-automated procedure for safe intracameral injection improving precision and reproducibility in the mouse model.

Methods: A 3D printed plate was developed to safely stabilize the body and immobilize the head of the animal. A color camera and an optical coherent tomography (OCT) system were adapted for injection real-time monitoring. Needles were mounted on a Hamilton syringe fixed on a 4-axis motorized manipulator for precise positioning. In vivo experiments were performed under general anesthesia (IP ketamine 60mg/Kg and Medetomidine 1mg/Kg), while animal's temperature was maintained at 37C. A perforated Tegaderm was applied to the periocular region to recline lashes and partially protrude the globe. Microneedles of various sizes (31-35G) and laser-tailored tip profiles (30 to 14°) as well as different puncture site orientations and speeds of injection were tested. Intracameral injections consisted of 0.4 µL of either BSS or OCT contrast agent. Recorded videos were used to estimate the best injection conditions.

Results: Adult C57Bl/6 mice (20 ex vivo, 6 in vivo) were used. Most successful injections were performed with a custom tri-surface 14° 35G laser-sharpened needle (Fig. 1a). Injections at the iridocorneal angle, tangential to the limbus resulted in effective piercings with less distortion of the globe. By using acute bevel angles facing the endothelium, less damage to the iris and lens, and less bleeding and leaking were reported (Fig. 1b-c). Implementation of a semi-automatic system with real-time monitoring ensued in reproducible results (Fig. 1d).

Conclusions: Implementation of a semi-automatic system under real-time OCT monitoring using tailored needle tip profiles allowed successful and safer intracameral injection in mice. Such setup is suggested to increase precision and reproducibility in murine models.

ABSTRACT BODY:

Purpose: Multiple studies have explored the use of non-invasive brain stimulation (NIBS) to enhance visual function. These studies vary in sample size, outcome measures and NIBS methodology. We conducted a systematic review and meta-analyses to assess the effect of NIBS on visual function in human participants with normal vision.

Methods: We followed the PRISMA guidelines, and a review protocol was registered with PROSPERO before study commencement (CRD42021255882). We searched Embase, Medline, PsychInfo, PubMed and Web of Science using relevant keywords. The search covered the period from database inception until 4th February 2021. Comprehensive meta-analysis (CMA) software was used for quantitative analysis.

Results: Twenty-four studies were included in the meta-analyses. A single session of visual cortex transcranial electrical stimulation (tES; Hedges's g: 0.56, 95% CI: 0.23-0.90, p=0.001) and anodal transcranial direct current stimulation (tDCS; Hedges's g: 0.66, 95% CI: 0.27-1.04, p=0.001) reduced visual crowding. Other pooled analyses showing significant effects included impaired motion perception following cathodal tDCS of the middle temporal area (Hedges's g: 0.46, 95% CI: 0.006-0.92, p=0.047), improved contrast sensitivity (Hedges's g: 0.23, 95% CI: 0.02-0.44, p=0.03), and increased visual evoked potential amplitude (Hedges's g: 0.38, 95% CI: 0.11-0.66, p=0.006) following visual cortex tES. The effects of visual cortex anodal tDCS on visual acuity, motion perception, and contrast sensitivity were not statistically significant.

Conclusions: There are significant effects of visual cortex NIBS on crowding, motion perception, contrast sensitivity and visual evoked potential amplitude among normally sighted individuals.

TITLE: Spata7 is Required for Maintenance of the Retinal Connecting Cilium

SESSION TITLE: Animal models of human ocular disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Lu, K. Xiong, X. Qian, J. Choi, Y. Shim, J. Burnett, G. Mardon, R. Chen, MHG, Baylor College of Medicine, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure: Jiaxiong Lu: Commercial Relationship: Code N (No Commercial Relationship) | Kaitlyn Xiong: Commercial Relationship: Code N (No Commercial Relationship) | Xinye Qian: Commercial Relationship: Code N (No Commercial Relationship) | Jongsu Choi: Commercial Relationship: Code N (No Commercial Relationship) | Yoon-Kyung Shim: Commercial Relationship: Code N (No Commercial Relationship) | Jacob Burnett: Commercial Relationship: Code N (No Commercial Relationship) | Graeme Mardon: Commercial Relationship: Code N (No Commercial Relationship) | Rui Chen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: SPATA7, an early onset LCA3 retinal disease gene, encodes a putative scaffold protein that is essential for the proper assembly of connecting cilium (CC) complex in the photoreceptor cells. Previous studies show that SPATA7 interacts with other photoreceptor-specific ciliary proteins, such as RPGR and RPGRIP1, and maintains the integrity of CC integrity. However, although it is clear that Spata7 is required for the early formation of the CC, whether it is also required for the maintenance of the CC is not clear. This study aims to elucidate the function of Spata7 in the adult retina.

Methods: To investigate Spata7 function in the retina at the adult stage, loss of function mutation is induced in the adult retina upon tamoxifen induction of the inducible Spata7 knockout mouse (Spata7flox/-; UbcCreERT2/+). The phenotype of the mutant mice retina is characterized through a combination of histology, immunohistochemistry, and electroretinogram (ERG).

Results: Spata7 is also essential for maintaining the integrity of the mature retinal CC. Loss of Spata7 in adults causes phenotypes similar to those seen in germline mutant mice, including photoreceptor cell degeneration, defective ERG responses, etc. Close examination of CC reveals that significantly shortened NPHP1 length can be detected when Spata7 is deleted. Consistently, mislocalization of Rhodopsin protein is observed in the outer nuclease layer, which leads to ER stress-mediated apoptosis.

Conclusions: Our results indicate that Spata7 is not only required for the establishment but also for the maintenance of the CC of the photoreceptors. In addition, the approach used in this study will facilitate achieving a mechanistic understanding of CC architecture and function.

ABSTRACT BODY:

Purpose: To produce a high resolution (250μm isotropic), 3-D images of human highly myopic eyes while minimizing eye movements via a novel super-resolution MRI (srMRI)acquisition and processing pipeline with significantly lowered scan times.

Methods: Twenty-two eyes of 11 emmetropic subjects, 25 eyes of 14 subjects with myopia (with vision > 20/40 in >1 eye) with no prior eye medical history or surgeries aside from cataracts underwent IOLMaster biometry and srMRI imaging (3T, 8-channel head coil). A fat-suppressed, axial T2-weighted volumetric scanning sequence with four 90-second scans was acquired using various slice orientations resulting in 4 non-overlapping voxels. Images underwent registration, thresholding, upsampled with tri-linear interpolation producing isotropic voxels (FSL and Matlab). The coronal and axial acquisitions were then co-registered, averaged together and re-registered to achieve a resolution of 0.25 x 0.25 x 0.25 mm. The axial length from the anterior lens surface to the ILM was then calculated. Moreover, in order to quantify motion artifacts, we measured the frequency of blinks and saccades, two measures that indicate that the subject was unable to maintain fixation with eye tracking data over 25 minutes (EyeBrain, NeuroLite, 5-min-blocks with 1-min washout x 5 gazes) that was collected from 11 myopic subjects correctable to 20/20. Ages ranged from 22.5 to 84.7 years old, 60% female with axial lengths ranging from 22.4 to 33.2 mm.

Results: In terms of eye-tracking data, over the course of the 25-minute-long study, there was a steady increase the total time the eyes were closed to approximately 12 sec (40%) of each block. The frequency of saccades similarly increased from ~0.01 to ~0.12 saccades per sec. Both results indicate that MR imaging of the globe would benefit from reduced scan time. Comparing the axial lengths measured by SR-MRI with estimates by IOLMaster, the resulting slope was 1.037 ($p = 4 \times 10^{-29}$), which was not significantly different from a slope of 1 ($p = 0.28$). The residuals were heteroscedastic increasing exponentially with axial length ($p = 2 \times 10^{-5}$) with a rate constant of 5.8 mm.

Conclusions: A novel super-resolution magnetic resonance imaging acquisition and processing pipeline were used to acquire high resolution images of the whole eye with significantly lowered scan times, which is key in reducing motion artifacts.

ABSTRACT BODY:

Purpose: Subthreshold retinal laser therapies (SLT) have vast clinical evidence in the treatment of various retinal disorders, including diabetic macular edema and central serous chorioretinopathy, and also early evidence for age-related macular degeneration. SLTs aim to trigger the heat shock response (HSR), a cellular response to combat stress, in the retinal pigment epithelium (RPE) through laser-induced hyperthermia without causing cell death. However, the therapeutic temperature window for triggering HSR but avoiding apoptosis is narrow, and the same laser exposure produces differing temperature elevations in different patients. Hence, SLT protocols without thermal dosimetry may lead to suboptimal treatment efficacy or safety profile. Here we present a focal electroretinogram (fERG) based method to provide thermal dosimetry for long-pulse SLT to enable personalized treatments.

Methods: Thirty-six laser treatments were delivered to 8 eyes in 4 anaesthetized pigs with 5 mm laser spot diameter and 60 s laser pulse duration. Each treatment was preceded by a laser power calibration protocol, where retinal temperature elevation per unit laser power was determined with a fERG-based method. The obtained value was used to estimate the laser power needed to reach a target temperature between 43.6 and 48.6°C. The treated areas were investigated for visible lesions with fundus imaging and fluorescein angiography. The threshold temperature for lesion generation and the accuracy of the thermal dosimetry were determined by fitting a probit model between the target temperature and damage classification data.

Results: The kinetics of the fERG response was found to accelerate linearly with temperature up to 43°C. At temperatures above 45°C the kinetics of the fERG signal started to decelerate accompanied by a drop in signal amplitude. The fERG-based thermal dosimetry method produced a standard relative error of 7% of the laser-induced temperature elevation. The steady-state threshold temperature for generating a lesion was determined to be 48.0°C for 60 second laser exposures.

Conclusions: fERG responses can be used to estimate laser-induced changes in retinal temperature and to estimate the laser power needed to reach a desired retinal temperature with high accuracy. We conclude that fERG-based retinal temperature determination can enhance the safety and efficacy of SLT with large spot size and long pulse duration.

ABSTRACT BODY:

Purpose: The identification of genetic variants underlying retinitis pigmentosa (RP) and Leber congenital amaurosis (LCA) is challenging as 108 genes are involved. Whole exome sequencing is often used in diagnostic facilities to identify causal variants explaining these phenotypes, but the costs are still prohibiting global applicability. An efficient and cost-effective targeted sequencing method is therefore needed.

Methods: We sequenced the exons and splice sites, and pseudo-exons due to pathogenic deep-intronic variants of 113 genes, and the RP17 autosomal dominant RP locus, using 16,812 smMIPs designed by Molecular Loop Biosciences. Sequencing libraries for 2,000 probands and control cases were prepared in series of 384 samples and analyzed using Illumina NovaSeq 6000. Single nucleotide variants (SNVs) were annotated with an in-house pipeline and prioritized for ≤1.0% allele frequency. Variants with a Franklin-ACMG classification of class 3, 4, or 5 variants were selected for further interpretation.

Results: Across five sequencing runs an average read count per nucleotide of 662x was achieved. All 19 SNVs and 22 copy number variants (CNVs) in control cases were reliably detected. All prioritized variants were evaluated in the first 480 probands. 248 RP and LCA probands (53%) were solved in the initial data analysis encompassing homozygous CNVs, homozygous and compound heterozygous SNVs in genes associated with autosomal recessive phenotypes, and heterozygous variants in genes associated with autosomal dominant or X-linked phenotypes. The 5 most frequently mutated genes were USH2A (12.5%), ABCA4 (11.3%), EYS (10.9%), CRB1 (4.9%), and RPGR (4.1%).

Conclusions: We showed that the smMIPs panel utilized in this study can be used to effectively sequence RP and LCA genes and loci. While the initial solve rate for this cohort of partially prescreened RP/LCA cases is 53%, further analysis will include the analysis of duplications and heterozygous deletions as well as an in-depth analysis of potential splice-site altering variants, adding to this diagnostic yield. We encourage professionals from low- and middle-income countries to contact us for potential patient inclusion.

ABSTRACT BODY:

Purpose: The blood-retinal barrier is maintained by both physical barriers (e.g. intercellular tight junctions) and immunomodulatory molecular signals. Infiltrating leukocytes express various immune checkpoint receptors which regulate activation and effector activity upon engagement with their cognate ligand. We characterized the retinal immunosuppressive milieu under physiological and uveitic states with a focus on immune checkpoint ligand expression by retinal cells.

Methods: Experimental autoimmune uveitis (EAU) was induced in 6-10 week-old female C57BL/6J mice by immunization with 400 µg human IRBP1-20 emulsified with 2.5 mg/mL complete Freund's adjuvant. Age and sex-matched naïve mice were used as controls. Using immunohistochemistry and confocal microscopy (n=4), and cellular indexing of transcriptomes and epitopes by sequencing (CITE-seq), we profiled the expression of a panel of known immune checkpoint molecules in normal and inflamed retinae.

Results: Immunostaining of mouse retinae revealed expression of HVEM (BTLA ligand), CD200 (CD200R ligand) and PD-L1 (PD-1 ligand), but not PVR (TIGIT ligand) during both homeostasis and inflammation (Figure 1). HVEM was expressed in ganglion cell and bipolar cell bodies, and in the photoreceptor layer. CD200 expression was found to be predominantly axonal in the inner plexiform layer, and in the outer plexiform layer at a lower level. PD-L1 expression in healthy retina was seen in the outer plexiform layer and, to a lesser extent, in the ganglion cell and photoreceptor layers. Interestingly, PD-L1 did not colocalize with Iba1+ microglia, and expression levels appeared reduced in EAU. In contrast, expression levels of the other checkpoint ligands appeared similar in the inflamed retina. CITE-seq was performed to validate these findings at the single-cell level in both retinal and immune cells, revealing distinct immunomodulatory gene expression profiles.

Conclusions: Distinct expression patterns of immune checkpoint ligands by different retinal cell types contribute to immunosuppressive homeostasis within the eye. CITE-seq provides the first simultaneous single-cell gene expression profiling and immunophenotyping of healthy versus inflamed retina.

TITLE: Virtual triaging in an Ophthalmic Emergency Department during the Covid-19 pandemic

SESSION TITLE: Telehealth

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Hurley, S. Neary, Ophthalmology, Mater Misericordiae University Hospital, Dublin, IRELAND|

Commercial Relationships Disclosure: Daire Hurley: Commercial Relationship: Code N (No Commercial Relationship) | Simon Neary: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The aim of this audit was to assess the effect of new guidelines on phone triage referrals to an Irish eye emergency department (EED) during the Covid-19 Pandemic. We intended to maximise virtual reviews of non-urgent conditions to reduce footfall within the department.

Methods: A retrospective phone triage referral and clinical note audit was performed to assess outcomes of phone triaging in October. Guidelines for phone triage were formulated with particular regard to what conditions should be seen in EED, treated over the phone or sent straight to outpatients clinic or minor procedures. A prospective phone triage referral and case note audit to assess outcomes after introduction of the guidelines in November

Results: A total of 1,700 patients were referred to the eye emergency department, 861 in October and 839 in November. A total of 617 patients were triaged to EED in November, compared to 692 prior to implementation of guidelines ($p < 0.05$). The number of patients referred straight to outpatients (74 in November vs 51 in October) ($p < 0.05$) and treated over the phone (131 vs 104) ($p < 0.05$) was also significantly reduced. Ultimately, the number of conditions wrongly triaged to EED, as per the guidelines implemented, was significantly reduced (91 vs 240) ($p < 0.05$).

Conclusions: This audit addressed the need to reduce footfall during the Covid-19 pandemic, identified suitable avenues of referrals for certain conditions and demonstrated that these guidelines significantly reduced the number of patients presenting to EED with conditions amenable to phone review or clinic follow-up.

ABSTRACT BODY:

Purpose: Reliability and agreement of an online nurse-assisted eye-screening tool versus manifest tests was investigated in a home healthcare setting.

Methods: Near and distance visual acuity and macular function (Amsler) was tested in patients (mean age 83 years, range 65-97) from home healthcare organizations in the Netherlands. The online Conformité Européenne (CE)-marked eye-screening tool (Easee B.V.) was administered by nurses at the participants' homes using a tablet or laptop and a smartphone as a remote control. Manifest tests were administered within two weeks by a researcher. Bland-Altman's limits of agreement were computed, comparing online and manifest tests. Reliability was analyzed with intraclass correlation coefficients (ICC) and (weighted) kappa. Non-inferiority was set at a difference of less than ±0.15 logMAR.

Results: Forty patients (80 eyes) were included. Between the eye-screening tool and manifest test the following mean differences were found: distance visual acuity 0.02 logMAR, near visual acuity measured with tumbling-E optotypes 0.07 logMAR and 0.03 logMAR with the triangle-circle optotypes. For distance visual acuity 75% of the individual data points were within the non-inferiority threshold. For near visual acuity, 53% and 55% were within the non-inferiority threshold for the tumbling-E and triangle-circle optotypes, respectively. Good reliability between the tests was found for distance visual acuity (ICC=0.78), and moderate for the near visual acuity tests (ICC=0.74 and ICC=0.67) and for detecting macular problems (kappa=0.48).

Conclusions: Nurse-assisted eye-screening seems promising with this online tool in an elderly home healthcare population. Agreement and reliability of the tool was satisfactory. As a next step, acceptability of the tool by the various stakeholders and also cost-effectiveness of eye-screening in home healthcare will be investigated to confirm public support.

ABSTRACT BODY:

Purpose: People with Down syndrome (pwDS) have a high prevalence of early-onset Alzheimer's disease (AD). With the two-fold increase in life expectancy for pwDS, identifying early biomarkers for AD is needed. Previously we have shown that phenotyping using ultra-widefield retinal imaging (UWFI) has the potential to identify peripheral retinal biomarkers for AD in the general population (PMC8377778). Phenotyping peripheral retina in pwDS using this imaging modality has not been reported, therefore we present the feasibility of UWFI in pwDS.

Methods: Our cohort comprises of 24 pwDS with no or early signs of clinical dementia. UWFI was performed using the OPTOS P200DTx laser scanning ophthalmoscope. The peripheral retina was graded by a masked, experienced grader (LC) and ten percent of the images were adjudicated by a senior ophthalmologist (TP). Based on their cognitive scores pwDS were divided into two groups, those without (DSnD, CAMCOG>80) and those with (DSD, CAMCOG<80) clinical dementia.

Results: There was no significant age (DSD 37.09±7.84 vs DSnD 36.43±5.56; p=.849) or sex (males DSD 9[81.8%] vs DSnD 4[57.1%] p=.255) difference between DSD and DSnD groups. All patients required operator assistance to keep their eyes open for acquiring a sufficient quality image. Images could not be taken in 4 cases due to touch phobia and/or lack of compliance, and in 1 case the eyelids obscured the majority of the retina, resulting in 39 gradable images of 20 patients. Peripheral hard drusen were detected on the majority of the images (34 [87.2%]), with 56.7% in DSnD and 43.3% in DSD groups. Most of the images had only a few (<5) hard drusen (24/34). Other peripheral pathologies included: pigmentary changes (8 [20.5%]; DSnD 75%, DSD 25%), haemorrhages (4 [10.3%]; DSnD 25%, DSD 75%). Vitreoretinal degeneration (1), white without pressure (1), RPE atrophy (1) and retinal hole (1) were only detected in DSnD.

Conclusions: This study proved that UWFI is feasible in pwDS. We generated gradable images despite the need for operator assistance. The use of this imaging modality opens up the possibility of detailed phenotyping of pwDS in the peripheral retina where we found a variety of retinal phenotypes, some with high prevalence.

ABSTRACT BODY:

Purpose: Depression is a common mental health problem in people with visual impairment. Exposure to light might influence the onset of depression in this population The aim of this study was to determine if seasonal variation and sunlight are associated with depression in adults with visual impairment, and if effects differ between: 1) adults who are blind vs. adults who have low vision; 2) adults with different eye diseases and; 3) adults who are sensitive to bright light vs. those who are not.

Methods: This study consisted of a quantitative analysis of pre-existing data from seven baseline measurements of studies conducted between 2009-2018. People with visual impairment, aged 18 and above, who were recruited from outpatient low vision rehabilitation organizations in the Netherlands were included. Self-reported data on experienced depressive symptoms was combined with information on season and the amount of sunlight that people were exposed to, retrieved from the Royal Netherlands Meteorological Institute. Logistic regression analyses were performed to analyse the data.

Results: Participants (N=1925) experienced most depressive symptoms in winter (32,8%), followed by summer (27,4%) spring (26,2%), and fall (24,2%). There was a significant difference between the odds to experience depressive symptoms in fall compared to winter (Odds ratio (OR)=0,656, p=0,004). The amount of sunlight was significantly associated with experienced depressive symptoms (OR=0.995, p=0,004). No significant interaction effects were found.

Conclusions: The results of this study support the hypothesis that seasonal variation and the amount of sunlight are associated with depression in people with visual impairment. [HvdA1] It may be interesting to compare these results with people without visual impairment and look at possibilities for treatment[HvdA2] in future research.

ABSTRACT BODY:

Purpose: The current phototoxicity threshold for rodents is set at a retinal dose of 11J/cm^2. It corresponds to the threshold for blue light at 445nm, as the blue component is assumed to be the only responsible for phototoxicity. The other parts of the spectrum such as green or red wavelengths are considered as non-toxic for the retina. In addition, phototoxicity thresholds are defined using acute exposure to light. We previously showed that the phototoxicity threshold for rodents could be overestimated by a factor 50. Here, we aim to evaluate the impact of light exposure on the retinal pigmented epithelium (RPE), the use of acute exposure instead of chronic exposure to assess the phototoxicity threshold and finally the effect of each part of the spectrum on the retina.

Methods: Male Wistar rats were exposed to light-emitting diodes (LED) displaying different wavelengths. We used acute or chronic exposure for 15 days, twice a day and various retinal doses. Light-induced damages were evaluated by immunostaining and TUNEL staining on retina sections or flat mounts of RPE. Protein quantification by western blot on retina samples was also performed.

Results: Exposure to blue and white LED at retinal doses below 11J/cm^2 triggers damages of the RPE with modification of the cell structure and size, and accumulation of albumin and rhodopsin aggregates. We observe that for retinal doses of blue and white LED that were safe in acute exposure, a chronic exposure to these doses induces a significant photoreceptor loss and macrophages invasion of the retina. Finally, addition of a red component to a white LED decreases photoreceptor cell death and modifies the retinal stress response. Meanwhile, decomposition of the white light into blue and green lights highlights the negative impact of the green component that induces photoreceptor loss and an increased expression of several stress markers.

Conclusions: Taken together, these results suggest that light induces damages in the neural retina and the RPE at retinal doses below the current phototoxicity threshold. Moreover, the overestimation of the phototoxicity threshold could be greater than of a factor 50 as chronic exposure should be used to define the threshold. Finally, the protective effect of the red component and the negative impact of the green component underline the importance of each part of the spectrum to evaluate the phototoxicity of a light source.

ABSTRACT BODY:

Purpose: To investigate chronological corneal biomechanical changes in fellow eyes with normal topography from patients with very asymmetric ectasia (VAE) for 3 years.

Methods: The clinical records of patients with VAE were retrospectively reviewed. Patients with VAE were defined as having clinical ectasia in one eye and a fellow eye with normal topography. Corneal biomechanical assessment with high-speed dynamic Scheimpflug-based corneal imaging was performed at baseline and at each follow-up visit in each eye. The deformation amplitude ratio within 2 mm, integrated radius, Ambrósio relational thickness to the horizontal profile, stiffness parameter at the first applanation (SPA1), Corvis Biomechanical Index (CBI), stress–strain index (SSI), and tomographic/biomechanical index were used to investigate the chronological changes in biomechanical parameters. Linear mixed-effects models were used to evaluate changes in biomechanical and clinical parameters over time.

Results: Thirty patients (17 men, 13 women) with VAE met the study criteria. The patients' age at baseline examination was 46.4 ± 14.4 years. Significant changes in SPA1, CBI, and SSI ($p = 0.048$, $p = 0.012$, and $p=0.011$, respectively) were observed during the 3-year period, and only SSI showed a decreasing trend over time. There were no significant changes in other corneal biomechanical parameters and clinical parameters during the 3-year period. A significant association between the SSI and age at initial biomechanical assessment. ($p<0.001$)

Conclusions: Based on corneal biomechanical evaluation over a 3-year period, possible corneal softening in such eyes was observed, highlighting the characteristics of progressive ectatic corneal disorder even in a subclinical status. Future studies using a longer follow-up period are required.

ABSTRACT BODY:

Purpose: HSV-1 can infect the ocular surface and induce the inflammatory disease, herpes stromal keratitis (HSK), which can result in corneal scarring and blindness. Immune regulating cytokines like IL-10 can suppress inflammation and reduce immunopathology. We hypothesize that delivering IL-10 using a genetically modified ocular commensal, Corynebacterium mastitidis (C. mast), will reduce immunopathology associated with HSK.

Methods: For cytokine release from C. mast, functional native secretion signals were identified by creating a phosphatase transposon library. Secretion from positive isolates was quantified using a PNPP assay and the most efficient secretion signal was fused to mIL-10 and transposed into the C. mast genome. mIL-10 production from positive transformant supernatants was analyzed by ELISA, and supernatants were added to T cell cultures to evaluate immune cell proliferation and cytokine production by flow cytometry and ELISA. To assess fitness, transformants were grown 1:1 with WT C. mast (AS1) for 6 hours then plated on agar with and without antibiotic to quantify the survival of the mutant. The ability of transposon mutants to colonize the eye was measured by applying $5x10^5$ and $2.5x10^6$ CFU to the eye every other day for a total of three applications. After 1 week, eyes were swabbed and plated on media containing selecting antibiotics and in vivo immune responses were measured by flow cytometry.

Results: The three best mIL-10 producing isolates caused reduced proliferation ($p<.005$) and INF-γ production ($p<0.01$) in T cells but did not significantly affect IL-17 production. mIL-10 producing isolates were also able to survive alongside AS1 in vitro but only 2 mutants were able to colonize the mouse eye. In vivo immunity was similar between AS1 and the colonizing mIL-10 isolates.

Conclusions: We have demonstrated the potential of genetically engineering ocular bacteria to produce and secrete functional murine IL-10. mIL-10 from C. mast regulates T cell responses by suppressing proliferation and IFN-γ production. Conversely, mIL-10 from C. mast does not affect IL-17, which prevents C. mast from becoming a pathobiont. Together these data suggest that the host should well-control mIL-10 C. mast, and the bacterium may be able to limit HSK in vivo. Overall, this study illustrates the first steps in engineering an ocular bacterium that can control excessive inflammation at the ocular surface.

ABSTRACT BODY:

Purpose: Scleritis is a severe inflammatory ocular disorder with unknown pathogenesis. We investigated sclera affected by non-infectious scleritis as well as healthy sclera for differentially expressed proteins using a mass spectrometry-based proteomics approach.

Methods: We collected scleral samples of eyes enucleated due to severe scleritis (n=3), and control scleral tissues (n=5), all exenterated eyes for eyelid carcinomas without scleral invasion. Clinical data of patients were retrospectively gathered from medical files. Scleral samples were microscopically scraped from tissue slides, and loaded on the LC-MS mass spectrometer after trypsin digestion. In addition, all samples were stained for immuno-histopathological evaluation. Results were analyzed using the proteomics software Scaffold (Proteome Software), and considering the Benjamini-Hochberg method for multiple testing a P-value lower than 0,00016 was considered significant.

Results: Mass spectrometry identified 629 proteins within the healthy and diseased scleral tissues, whereof collagen type I was the most abundantly expressed protein. Collagen type II to XII were also present. Fillagrin-2 was found to be significantly upregulated (P=0.0001) in scleritis, a protein that plays a crucial role in epidermal barrier function. Elongation factor 2 and vinculin were other proteins upregulated in scleritis compared to healthy scleral tissue, however they were not significantly different in this small sample set.

Conclusions: Using this highly powerful and innovative technique, we found that fillagrin-2 was upregulated in scleral samples from patients with non-infectious scleritis. Further research, ideally including more scleritis cases, is needed to validate our findings, and identify the role of fillagrin-2 in the pathogenesis of scleritis.

ABSTRACT BODY:

Purpose: The Veterans Healthcare Administration (VHA) has led the nation's most successful screening program for the detection of diabetic eye disease to date and the demand for such screening continues to increase. While Artificial intelligence (AI) has strived to revolutionize the field of Ophthalmology, actual real-world data has been less than promising, particularly within the VHA setting. We hypothesize that a novel AI-based algorithm created specifically to enhance, rather than replace, the existing standard image analysis by experienced optometrists may be utilized to improve efficiency and patient safety.

Methods: A proof-of-concept AI algorithm based on machine-learning was developed to prescreen patients within the VHA without reducing their quality of care. The algorithm analyzes images for individual image quality, image set completeness, evidence of diabetic retinopathy, and the presence of other ocular pathology. To validate this algorithm, fundus photographs of 100 consecutive Veterans within VISN 8 within a single month (2/2017) were assessed by the algorithm and also reviewed by the optometrists experienced at teleretinal screening. The conclusions of both readings were compared.

Results: 1004 images from 100 patients (~10 images/set) at 17 imaging sites within VISN 8 were included in this study. Quality metrics succeeded in being at least as stringent as the reads of the experienced reviewers. 33% of all patients were found to have image sets of adequate quality (vs. 85% by reviewers). None of the 4 patient image sets that were deemed "abnormal" for retinopathy by the experienced optometrists was passable as "normal" by the algorithm. Of the 33 adequate quality patient image sets, the algorithm detected a total of 14 image sets as "normal." There was a zero false negative rate, supporting the safety of the algorithm. The remaining 19 image sets were subsequently reviewed by a retina specialist. One set, which was previously deemed normal by optometry reviewers, was actually "abnormal" due to the presence of mild nonproliferative diabetic retinopathy.

Conclusions: In this pilot study, the AI algorithm was able to provide adequate screening of fundus images obtained for diabetic screening with a zero false negative rate. Our algorithm serves as an example of a means of increasing efficiency and safety while not sacrificing the quality of care to patients.

ABSTRACT BODY:

Purpose: To determine if there are significant differences in the concentrations of tear proteins in Sjögren syndrome keratoconjunctivitis sicca (SS KCS) compared to healthy controls.

Methods: Tear samples were collected with unmarked Schirmer strips from 15 SS KCS patients and 21 healthy controls. Tear protein was eluted and the concentration measured. Inflammatory mediators were assayed with a Raybiotech L-507 glass slide array and normalized by strip wetting length. All patients underwent an ocular surface exam to evaluate tear-break-up time (TBUT), corneal fluorescein staining, and conjunctival staining. Symptom assessment questionnaire in dry eye (SANDE) scores were collected for all patients.

Results: 57 of the 507 tear proteins analyzed were significantly upregulated in SS patients compared to controls (Table 1). Spearman correlations showed that all 57 upregulated tear proteins were significantly inversely correlated with TBUT and positively correlated with corneal fluorescein staining, conjunctival staining and SANDE scores.

Conclusions: These findings indicate that hundreds of factors can be assayed in tear proteins collected from a Schirmer strip. The results suggest tear protein concentrations are altered in SS KCS compared to controls. The upregulated tear proteins correlated with clinical measures of dry eye symptoms and disease severity. Tear protein concentrations could serve as important biomarkers for studying pathogenesis and in clinical diagnosis and management of SS KCS.

TITLE: Circadian regulation of the inner blood retinal barrier: a paradigm for dry age-related macular degeneration development

SESSION TITLE: AMD: Clinical and translational research/AMD therapies (excluding anti-VEGF)

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F. O'Leary, N. Hudson, J. O'Callaghan, M. Campbell, Smurfit Institute of Genetics Trinity College, Dublin, IRELAND|F. O'Leary, M. Cahill, Royal Victoria Eye and Ear Hospital, Dublin, IRELAND|

Commercial Relationships Disclosure: Fionn O'Leary: Commercial Relationship: Code N (No Commercial Relationship) | Natalie Hudson: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey O'Callaghan: Commercial Relationship: Code N (No Commercial Relationship) | Matthew Campbell: Commercial Relationship: Code N (No Commercial Relationship) | Mark Cahill: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is divided into an atrophic (dry) and neovascular (wet) form. The disease aetiology is yet to be fully elucidated and no effective treatment exists for the end stage of dry AMD, known as geographic atrophy. We have shown that the inner blood retinal barrier (iBRB) cycles in a circadian manner in young healthy adult controls. The tight junction protein claudin-5 which cycles in a circadian manner, is thought to be central to the maintenance of iBRB integrity. We performed a case control study to determine the circadian effect on iBRB kinesis in AMD.

Methods: Participants with dry AMD (n=19) and age matched controls (n=12) were recruited. The Munich Chronotype Questionnaire was used to establish participant chronotype. Participants were assessed using optical coherence tomography (OCT) and fundus fluorescein angiography (FFA). Mid phase fluorescein signal in the macula was quantified using novel Fluorescent Ocular Vascular Analysis Software and analysed as per the Early Treatment Diabetic Retinopathy Study (ETDRS) grid. Fluorescein signal was compared between the morning and the evening for each participant, a proxy for circadian effect on iBRB integrity. Recruitment of participants is ongoing.

Results: There was an increased fluorescein signal throughout all areas of the macula in the evening compared to the morning in young healthy controls (n=30, P =.033). The evening versus morning fluorescein signal differential was reduced and therefore not significant in AMD participants (P =.78). The fluorescein signal appears to persist in the macula longer in AMD participants compared to young healthy controls.

Conclusions: These findings suggest that the iBRB is highly dynamic, with increased fluorescein permeability in the evening compared to the morning in young healthy controls. The circadian associated fluorescein signal differential present in young healthy controls appears attenuated in age matched controls, with no significant difference present in AMD subjects. This suggests that the circadian dependant regulation of iBRB kinesis decreases with ageing and may be arrested in AMD. We suggest that this disruption may be due to decreased or dysfunctional claudin-5 resulting in a more open, "leakier" iBRB, which may be one of the early initiating factors in AMD pathogenesis.

ABSTRACT BODY:

Purpose: To evaluate the ability of the new Standardization of Uveitis Nomenclature (SUN) classification criteria for uveitides to classify patients in an academic uveitis practice.

Methods: A retrospective review of electronic medical records was conducted for all patients attending the uveitis service at the University of Colorado Hospital between January 1, 2013 and December 31, 2020. Patients with scleritis, ocular cicatricial pemphigoid and peripheral ulcerative keratitis were excluded. We attempted to classify each patients' uveitis using the SUN classification criteria. We recorded whether classification was possible as well as their clinical diagnosis by a uveitis specialist.

Results: Of the 1143 patients with uveitis, 50.0% (572/1143) had a disease that was not listed in the SUN classification system, and so no attempt to classify these patients was possible. Of the remaining 571 patients, 522 (91.4%) were able to be classified by SUN and in 94.3% (492/522) of cases their SUN classification matched their clinical diagnosis by a uveitis specialist.

Conclusions: A significant percentage of patients at an academic uveitis practice had a disease for which no SUN classification criteria existed. In cases where classification by SUN could be attempted, the system performed well and agreed with their clinical diagnosis in most cases.

TITLE: OCU410, a Potential Therapeutic for Dry-AMD, Suppresses Inflammatory Cytokine Gene Expression in Retinal Epithelial Cells

SESSION TITLE: Gene Therapy and Gene Editing for Ocular Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D.K. Singh, S.S. Kattala, A.K. Upadhyay, Ocugen Inc, Malvern, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Dinesh Singh: Commercial Relationship(s);Code E (Employment):Ocugen Inc | Sree Kattala: Commercial Relationship(s);Code E (Employment):Ocugen Inc | Arun Upadhyay: Commercial Relationship(s);Code E (Employment):Ocugen Inc

ABSTRACT BODY:

Purpose: In this study, we evaluated role of OCU410 (human RORA) in controlling inflammation, a causative factor for dry age-related macular degeneration (dry-AMD) pathogenesis, in an in vitro assay. While there is no approved therapy for dry-AMD, most therapeutics in clinical trials target the complement system (cell death pathway), inflammation, or oxidative stress. However, these therapies target only one pathway. OCU410 is an orphan nuclear receptor, a transcription factor, that may target multiple pathways, particularly in suppressing inflammatory cytokine gene expression, which can potentially limit damage to the retina due to dry-AMD.

Methods: To assess the effects of OCU410, we created an inflammatory model system using LPS in human immortalized retinal epithelial cells (hTERT-RPE1). Inflammatory cytokine genes for inflammatory cytokines (e.g., IL1b, IL6, CXCL8, etc.) were measured by quantitative reverse transcriptase real time polymerase chain reaction (qRT-PCR). LPS-induced expression of Gluc luciferase was compared in the presence and absence of OCU410 using a robust CXCL8 promoter driven secretory Gaussia Luciferase (GLuc). Secretory Alkaline Phosphatase (SEAP) driven by constitutive strong CMV promoter was used as the internal control for signal normalization. This promoter reporter luciferase system was used to access the direct role of RORA on CXCL8 promoter. In silico analysis also shows that human CXCL8 has a consensus RORA binding site within 1.5kb of the CXCL8 start site.

Results: LPS stimulated the expression of inflammatory cytokines IL1b, CXCL8, and IL6 in a dose dependent manner in hTERT-RPE1 cells treated with OCU410. The expression of inflammatory cytokines in response to LPS was inversely related to the expression of RORA. Furthermore, the GLuc/SEAP luciferase assay on CXCL8 promoter reporter assay demonstrates that the suppression of luciferase activity is mediated through RORA binding on the CXCL8 promoter.

Conclusions: Dry-AMD is characterized by expression of inflammatory cytokines. OCU410 transduction leads to the expression of nuclear hormone receptor RORA upon viral transduction which suppresses inflammatory cytokine gene expression, including CXCL8, in an LPS-induced inflammation model in hTERT-RPE1 cells. Thus, OCU410's ability to inhibit multiple inflammatory cytokines strengthens its potential as a gene therapy molecule for dry-AMD.

TITLE: Surgical Procedure and Applicability of the Orbit Subretinal Delivery System (SDS)™ in the Normal Adult Canine Eye

SESSION TITLE: Novel animal models and neuroprotection in the retina

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.P. Gray, Y. Sato, W.A. Beltran, University of Pennsylvania School of Veterinary Medicine, Philadelphia, Pennsylvania, UNITED STATES|T. Meyer, K. Stoner, Gyroscope Therapeutics, King of Prussia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Alexa Gray: Commercial Relationship: Code N (No Commercial Relationship) | Yu Sato: Commercial Relationship: Code N (No Commercial Relationship) | Tom Meyer: Commercial Relationship(s);Code E (Employment):Gyroscope Therapeutics;Code P (Patent):Gyroscope Therapeutics | Kirsten Stoner: Commercial Relationship(s);Code E (Employment):Gyroscope Therapeutics | William Beltran: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To optimize the surgical procedure and test the applicability of the Gyroscope Therapeutics Orbit SDS™ in normal adult canine retinas. This suprachoroidal approach to subretinal delivery eliminates the need for a vitrectomy and avoids the formation of a retinotomy.

Methods: Right eyes of four adult mongrel dogs (age: ~ 129 weeks; axial globe length: 22 ± 1.3 mm) underwent subretinal injection of an AAV2/5-GRK1-GFP vector with the Orbit SDS™. A 3 mm wide scleral incision located 8 mm posterior to the limbus in the supero-temporal quadrant was performed. The flexible cannula of the device was then introduced into the suprachroidal space and its progression towards the central tapetal fundus monitored under direct visualization through a digital operating microscope with intraoperative OCT. The microneedle was advanced into the subretinal space. A ~10 µL injection of BSS enabled formation of a subretinal bleb which was further expanded by injection of 100 µL of the viral vector solution. cSLO/OCT imaging and OCT angiography (OCTA) were performed with a Spectralis HRA/OCT2 unit at 5 and 9 weeks post injection to monitor GFP expression and integrity of the retinal layers.

Results: All 4 dogs (4 eyes) had successful subretinal injections in the tapetal fundus, and retinas reattached within 48 hours. No adverse effects nor signs of ocular discomfort were seen. cSLO (BAF mode) showed GFP expression that had expanded beyond the bleb borders identified during surgery. A focal dark spot was seen funduscopically in the tapetal area that corresponded to the site of entry of the microneedle. En face OCTA imaging of the choriocapillaris confirmed this was the site of puncture. No evidence of choroidal neovascularization was seen in any of the 4 eyes. OCTA segmentation at the level of the nerve fiber layer confirmed in 1 out of 4 eyes perforation of the neuroretina with the microneedle that had been suspected at the time of surgery.

Conclusions: Preliminary results show that the off label veterinary use of the Orbit SDS™ is a viable surgical approach for subretinal injections in healthy adult canine retinas. The presence of tapetal cells in the canine choroid caused some resistance but did not impair advancement of the microneedle into the SRS. Further histologic examination of the choroid and neuroretina will examine structural integrity of these tissues.

ABSTRACT BODY:

Purpose: Recent studies in our Laboratory have demonstrated that a carbohydrate-binding protein, galectin-8 (Gal-8), plays an important role in the pathogenesis of Pseudomonas Aeruginosa (PA) keratitis. Using a mouse model of PA keratitis, we have shown that: (i) Gal-8 KO mice are resistant to PA keratitis, and that (ii) Gal-8 modulates innate immune response by dampening the TLR4 and inflammasome pathways. These data suggest that inhibiting Gal-8 may improve the outcome of the disease. Therefore, in an effort to find effective strategies to control the disease, the goal of the current study was to test the therapeutic potential of inhibitors of Gal-8 in PA keratitis

Methods: Two groups of Wild type mice (7 – 10 weeks old) were anesthetized, the central corneas of mice were scarified with three parallel 1-mm incisions and a 5 µL drop containing 2000 CFU of bacterial strain PA 6077 was applied to the eye. Immediately prior to infection, control group received a subconjunctival injection of vehicle (10 µL of PBS + DMSO) and the experimental group received a subconjunctival injection of Gal-8 inhibitor, 19a (Hassan et al. Eur J Med Chem, 223:113664, 2021) (10 µL, 5 mg/mL in vehicle). The severity of bacterial keratitis was graded on post-infection day 1, and then corneas were harvested for bacterial enumeration. The experiment was repeated four times. Also, varying concentrations of the inhibitor were tested.

Results: Galectin inhibitor, 19a, at 5 mg/ml concentration, substantially reduced opacity score (Vehicle: 2.7±0.12; 19a: 1.9±0.16; n=40, $p<0.0002$) and the bacterial load (Vehicle: $1.6x10^6$; 19a: $0.6x10^6$ n=40) compared to vehicle.

Conclusions: Targeting Gal-8 is an attractive strategy for the development of novel treatment for blinding immunopathology resulting from bacterial keratitis and possibly other ocular disorders, such as corneal graft rejection and dry eye disease.

ABSTRACT BODY:

Purpose: P2Y receptors (P2YRs) are G protein-coupled receptors activated by nucleotides and are of significance in fluid and mucous secretion in the conjunctiva. Endogenous nucleotides such as UDP are specific to P2Y6R and P2Y14R, while UDP-glucose is specific to P2Y14R, but not P2Y6R. In addition, selective P2Y2 receptor agonists, such as MRS 2768, were developed for treatment of dry eye. The purpose of this study is to elucidate which P2YRs that are functional in rat conjunctival goblet cells (CGCs) by determining their effect on the intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$).

Methods: Conjunctiva from male Sprague-Dawley rats was minced and placed in six-well plates for culture of CGCs. To measure function, first passage CGCs were incubated with the Ca^{2+} specific ratiometric dye Fura2-AM and $[Ca^{2+}]_i$ measured after cells were stimulated with the P2YR selective agonists: UTP (P2Y2R, P2Y4R and P2Y6R), UDP (P2Y6R and P2Y14R), UDP-glucose (P2Y14R) or an agonist specific to P2Y2R (MRS 2768). To investigate $[Ca^{2+}]_i$ response after knockdown of P2Y2R or P2Y6R, cells were treated with siRNA or scsiRNA specific to each receptor or vehicle before incubation with agonist. Calcium experiments were done in duplicate or triplicate and all experiments were performed on CGCs from at least three rats.

Results: Stimulation with UTP 10^{-4} M increased $[Ca^{2+}]_i$ to 897 ± 44 nM, while $[Ca^{2+}]_i$ responses were 817 nM ± 103, 102 ± 26 nM and 262.2 nM ± 60 for UDP 10^{-3} M, UDP-glucose 10^{-7} M and MRS2768 10^{-10} M, respectively. After knockdown of the P2Y2R and P2Y6R, $[Ca^{2+}]_i$ responses were significantly lower after stimulation with UTP 10^{-4} M, MRS 2768 10^{-6} M or UDP 10^{-5} M/UDP 10^{-4} M, respectively.

Conclusions: We conclude that P2Y2R and P2Y6R, but not P2Y14R, are the major P2YRs responsible for conjunctival goblet cell function.

ABSTRACT BODY:

Purpose: To compare corneal transplant failure in patients who have been vaccinated against COVID-19 to a control group of patients who have received an influenza vaccination.

Methods: A retrospective cohort study was conducted using TriNetX, a federated electronic health records research network comprising data from more than 50 health organizations in the United States. Patients who underwent corneal transplantation and either COVID-19 vaccination or Influenza A vaccination were identified by CPT and medication codes and separated into cohorts based which vaccination they had received. COVID-19 vaccination was defined as receiving either 2 doses of Moderna or Pfizer COVID-19 Vaccine or 1 dose of J&J's COVID-19 Vaccine. Cohorts were matched for age, gender, body mass index, and medical comorbidities (essential hypertension, diabetes mellitus, chronic lower respiratory diseases, heart failure, nicotine dependence, and alcohol related disorders). The primary outcome was corneal graft failure at 120 days after corneal transplantation surgery. The relative risk for this outcome was compared between each cohort before and after 1:1 propensity score matching.

Results: A study population of 784 corneal transplant patients who received COVID-19 vaccination and a control population of 1661 patients who received Influenza A vaccination were identified. After propensity matching, 715 matched patients from each cohort were compared. The incidence of corneal transplant failure rate was 1.8% for the COVID-19 vaccine cohort and 1.6% for the Influenza A cohort. While the rate of corneal transplant failure was slightly lower in COVID-19 vaccine recipients in comparison to Influenza vaccine recipients (RR=0.92%, CI 0.42-2.01), this result was not statistically significant (p 0.84).

Conclusions: While there have been several case reports of corneal graft failure after COVID-19 or COVID-19 vaccination, there appears to be no statistically significant impact of the COVID-19 vaccine on corneal transplant failure in this retrospective cohort study. Additionally, corneal graft rejection in vaccinated patients was rare in our study.

TITLE: Fixation Eye Movement Abnormalities, Stereopsis and Inter-ocular suppresion in Amblyopia.

SESSION TITLE: Neurophysiology and Treatments of Binocular Vision Disorders

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: F.F. Ghasia, C. Dulaney, J. Murray, Cole Eye Institute, Cleveland Clinic, Cleveland, Ohio, UNITED STATES|F.F. Ghasia, Director of Visual Neurosciences and Ocular Motility Lab, Cleveland Clinic, Cleveland, Ohio, UNITED STATES|

Commercial Relationships Disclosure: Fatema Ghasia: Commercial Relationship: Code N (No Commercial Relationship) | Cody Dulaney: Commercial Relationship: Code N (No Commercial Relationship) | Jordan Murray: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Amblyopic patients are known to have fixation instability, which arises from alteration of physiologic fixation eye movements (FEMs) and nystagmus. The purpose of the study is to examine the association between amblyopia type and FEM abnormalities on stereopsis and inter-ocular suppression.

Methods: We recruited 34 amblyopes (anisometropic=14, strabismic=12,mixed=8) and 7 controls. Eye movements were recorded using infrared video-oculography during a) Fellow eye viewing(FEV), b) Amblyopic eye viewing(AEV) c) Both eye viewing(BEV), and d) Dichoptic viewing(DcV) at varying FE contrasts. Subjects were classified as having either no nystagmus(n=15), fusion maldevelopment nystagmus (FMN)(n=7), and patients with nystagmus without any structural anomalies that do not meet the criteria of FMN and infantile nystagmus(n=12). An adaptive staircase method was used to measure visual acuities during FEV, AEV and BEV and inter-ocular suppression using Dichoptic Motion Coherence(DMC). The threshold of inter-ocular suppression was determined by the number of dots required to correctly identify the motion coherence at a given FE contrast and area under the curve was computed. Stereoacuity was measured with the Titmus fly test.

Results: Increased fixation instability was associated with greater stereopsis and inter-ocular suppression deficits. Stereopsis deficits were greatest in patients with FMN (Controls: 1.6±0, None:2.1±0.25,Nystagmus no FMN:3.1±0.92, FMN:3.3±0.92,ANOVAp<0.005) and patients with mixed amblyopia(Controls: 1.6±0,Anisometropic:2.1±0.25,Strabismic: 3.1±0.92, Mixed:3.3±0.92,ANOVAp<0.005). AUC for DMC thresholds was greater in amblyopia than controls while controlling for visual acuity deficits. (Controls:415.6± 275.9, Amblyopia:1094.3±884, #ofdots x contrast level, p <0.04). The suppression deficits were dependent on AE visual acuity deficit (p=0.003 and p=0.014) with no significance noted as a function of amblyopia type or FEM abnormalities (p=0.87, p=0.74 respectively).

Conclusions: Neurophysiologic studies have shown that horizontal binocular connections in MT/MST are critical for emergence of stereopsis. Lack of binocular connections in MT/MST drives the development of FMN. We have found that the presence of FMN was associated with greater stereopsis deficits whereas the extent of suppression is primarily driven by severity of amblyopia.

ABSTRACT BODY:

Purpose: Mammals detect light for visual perception, but also for regulation of physiology, cognition, mood, and development. Many of these ‘non-image’ visual functions exhibit extensive integration of light over visual space. Intrinsically photosensitive retinal ganglion cells (ipRGCs), which capture photons with a receptor called melanopsin, are indispensable for many non-image visual functions. Melanopsin is distributed throughout ipRGCs, including in the axon. We hypothesized that phototransduction in axons allows ipRGCs to integrate light over an exceptionally large area.

Methods: We performed electrophysiological recordings from ipRGCs in retinas isolated from transgenic reporter mice. We first determined if ipRGCs detect selective illumination of the distal axon, >1 mm from the soma and dendrites. Next, to measure the axonal contribution to overall photosensitivity, we compared responses elicited by illumination restricted to the soma and dendrites (local) to those elicited by illumination of the entire cell (global). Recording from ipRGCs in the central and peripheral retina permitted a natural comparison of axonal photosensitivity in cells with short and long axons, respectively. Antagonists of synaptic transmission were added to the extracellular medium to isolate melanopsin’s contribution to the light response.

Results: Our observations were consistent with axonal photosensitivity. IpRGCs exhibited excitatory currents and spiking responses to illumination of the distal axon, but not to illumination of an equidistant location on the retina that did not include the axon. Peripheral ipRGCs (1.4-1.8 mm from the optic disk) were ~30% more sensitive to global than local illumination, while central ipRGCs (≤ 0.3 mm from the optic disk) were equally sensitive.

Conclusions: Melanopsin phototransduction within the axons of ipRGCs generates electrical responses to photon absorption far from the cell’s soma and dendrites. The first steps of non-image vision produce greater spatial integration than previously understood.

ABSTRACT BODY:

Purpose: Eye morphogenesis is tightly regulated by a highly conserved genetic network that when disrupted, can result in severe ocular malformation on a spectrum known as microphthalmia, anophthalmia and coloboma (MAC). While over 90 genes are associated with MAC, little is known about disease mechanisms shared between patients with differing genetic diagnoses. This study aimed to identify aberrations to pathways involved in early eye development shared between different causes of microphthalmia. Due to low genetic diagnostic rates, studying shared pathways will critically reveal new candidate genes for future diagnostics.

Methods: Patient-specific (PAX6-associated microphthalmia p.(Asn124Lys) and an unsolved microphthalmia patient) and healthy control iPSC-derived optic vesicles were generated using two clones from each line to model ocular development until day 35. Data on gene and protein expression were generated through RNA-seq, qRT-PCR and immunohistochemistry. Apoptosis, cell proliferation and vesicle diameter were quantified using ImageJ.

Results: At day 35, vesicle diameter was significantly reduced in both microphthalmia models compared to healthy controls. TUNEL staining revealed a significant increase in apoptotic cells in patient vesicles compared to healthy controls while PH3 staining revealed decreased cell proliferation. Using RNA-seq, we detected upregulation of pro-apoptotic genes in microphthalmia optic vesicles. Dysregulation of Notch signalling modulated through an ASCL1 negative feedback loop between the DLL ligand and HES effector families was also common between microphthalmia samples. This resulted in differential expression of Notch target genes such as MITF and HDAC1. Additionally, the increased production of extracellular matrix (ECM) components such as collagen and laminin, resulting in ECM abnormalities, was detected in microphthalmia optic vesicles.

Conclusions: Our study identified reduced size and proliferation, and increased apoptosis in microphthalmia patient-derived optic vesicles possibly contributing to the small eye phenotype. Disruptions to Notch signalling may contribute to a global increase of ECM production and further dysregulation of key early ocular developmental genes. Additionally, abnormally high production of ECM in microphthalmia patients may overly restrict optic vesicle growth, resulting in ocular malformations.

ABSTRACT BODY:

Purpose: To compare differences in outcomes following pars plana vitrectomy (PPV) for retinal detachment (RD) in the postoperative period between individuals on beta blockers (BB) and those who are not using BB.

Methods: A retrospective cohort study was conducted using TriNetX (Cambridge, MA, USA), a federated electronic health records research network comprising multiple large health organizations in the United States. Patients who underwent PPV for RD were identified by CPT code and stratified into BB use and non-BB use. Cohorts were matched for age, gender, and medical comorbidities (essential hypertension, diabetes mellitus, cerebrovascular disease, heart failure, nicotine dependence, alcohol related disorders, and body mass index). The primary outcomes were: Vitreous hemorrhage, choroidal hemorrhage, RD or RD with retinal break, iridocyclitis, retinal edema, cystoid macular edema, macular pucker, toxic maculopathy, intraoperative/postoperative complications, ischemic optic neuropathy, glaucoma, cataract strabismus, hemorrhage of orbit, corneal edema, dry eye syndrome, central retinal vein occlusion (CRVO,) central retinal artery occlusion (CRAO.) One-year outcomes were compared between the cohorts after propensity score matching using logistic regression and greedy nearest-neighbor matching algorithm.

Results: A total of 17,388 patients were included in analysis with 8,694 in each of the BB use and non-BB use cohorts after propensity matching.

The BB cohort had a significant greater risk of developing vitreous hemorrhage (RR, 1.16; 95% CI, 1.1-1.22), and cystoid macular degeneration (RR, 1.11; 95% CI, 1.0-1.22). No significant difference was seen in rate of development of choroidal hemorrhage, RD or RD with retinal break, Iridocyclitis, retinal edema, macular pucker, toxic maculopathy, intraoperative/postoperative complications, ischemic optic neuropathy, glaucoma, cataract, strabismus, hemorrhage of orbit, corneal edema, dry eye syndrome, CRVO and CRAO between the BB and non-BB use cohorts.

Conclusions: Betablocker use is an important consideration when discussing risks during preoperative counseling and evaluating for postoperative complications following PPV for RD. Patients using betablockers were more likely to develop vitreous hemorrhage and cystoid macular edema.

ABSTRACT BODY:

Purpose: Diabetes has been reported to disrupt circadian rhythms with circadian disruption emerging as an important factor in the disease prognosis and treatment success. Endothelial cells are central in the progression of diabetic retinopathy and have a robust circadian clock with rhythms in diverse cellular processes. Thus, we asked whether diabetes alters the expression of circadian genes in these cells and if so, which aspects of the diabetic microenvironment drive these changes.

Methods: Induced pluripotent stem cell derived endothelial cells (iPS-ECs) from healthy and diabetic patients were sequenced and differential analysis was performed, identifying genes related to circadian rhythms. Primary human retinal endothelial cells (hRECs) were cultured in vitro in hyperglycaemia or normoglycaemia for 7 days. Cultures were then synchronised with 50% serum shock and repeated samples collected every 2 hours over 25 hours in either hypoxia or atmospheric oxygen levels. Circadian gene expression was measured with RT-PCR.

Results: iPS-ECs from diabetic patients have 4.03-fold higher Bmal-2 mRNA expression and 5.7-fold less Dec2. Hypoxia, and not hyperglycaemia, affects circadian gene expression in synchronised hRECs. In hypoxia, Bmal1 expression is increased at all time points and phase advanced. The opposite is true of its negative regulator, Per2, which is instead reduced in hypoxia with weakened rhythmicity. Hyperglycaemia alone slightly increases the rhythmicity of Per2 oscillation. Circadian rhythmicity in gene expression persists in all treatments for both Bmal1 and Per2 but is lost in Cry1 expression when cells are treated with hypoxia (normoxia $p=0.02$ vs hypoxia $p=0.18$), as analysed using JTK_Cycle.

Conclusions: Diabetes can alter the expression and rhythmicity of the circadian molecular clock in endothelial cells. In separately testing some elements of the diabetic microenvironment, we have shown that hypoxia alone drives major changes in key core loop genes of the molecular clock. More, hypoxia alters the positive and negative arms of this molecular clock in different ways, with potential implications for the period of the clock and transcription of clock-controlled genes, many of which are immediately relevant to diabetic retinopathy including VEGF. Bmal1, a master transcription factor, appears to have bolstered expression in hypoxia while its negative regulator, Per2, is reduced.

ABSTRACT BODY:

Purpose: Dry eye is a multifactorial disease characterized by a persistently unstable and/or deficient tear film causing discomfort and/or visual impairment, accompanied by variable degrees of ocular surface epitheliopathy, inflammation and neurosensory abnormalities. OC-02 (simpinicline), a novel compound delivered via nasal spray, is a nicotinic acetylcholine receptor agonist that pharmacologically activates the trigeminal parasympathetic pathway to stimulate the lacrimal functional unit to reestablish the natural tear film. This Phase 2 study (PEARL) evaluated the efficacy and safety of OC-02 in the treatment of signs and symptoms of dry eye disease.

Methods: A total of 182 subjects were randomized 1:1:1:1 with OC-02 1.1 mg/mL (n=41), OC-02 5.5 mg/mL (n=41), OC-02 11.1 mg/mL (n=41), or vehicle control (VC, n=42) nasal spray over two visits. Outcome measures were pre- to post-treatment in anesthetized categorical Schirmer's Test Score (STS) outcomes (percentage of ≥10mm) at Visit 1 and Eye Dryness Score (EDS, 0-100 scale) under controlled adverse environment (CAE) exposure at Visit 2.

Results: Subjects treated with 5.5 mg/mL and 11.1 mg/mL OC-02 nasal spray showed statistically significant improvement compared with VC as indicated by a percentage gain in STS ≥10 mm from baseline at Visit 1. The 5.5 mg/mL, 11.1 mg/mL, and VC groups were: 73%, 76%, and 7% ($p<0.0001$), respectively (fig. 1). Correspondingly, improvements in EDS at Visit 2 from pre- to 5 minutes post-treatment in CAE were -16.5 ($p = 0.0067$), -19.0 ($p= 0.0006$), and -6.8, respectively. Of the treated groups, significant improvement in the percentage of eyes was seen with 11.1 mg/mL in baseline EDS <60mm and 5.5 mg/mL and 11.1 mg/mL in baseline EDS >60mm (Fig.2). Most common adverse events reported in >5% of treated subjects was coughing, throat irritation, sneezing, and instillation site irritation.

Conclusions: Compared to VC, OC-02 nasal spray demonstrated improvement in both signs and symptoms of dry eye disease and was safe and well-tolerated under conditions of the study.

ABSTRACT BODY:

Purpose: Macular degeneration is one of the leading causes of blindness in people over the age of 50; the most common being age-related macular degeneration. The pathology can include hyperreflective foci (HRF) detected by spectral-domain optical coherence tomography (SD-OCT) in association with sub-retinal pigment epithelium (RPE) drusen and hyper-pigmentation. Sodium iodate (SI) rapidly induces retinal degeneration in mice that involves RPE pathology modeling some of the characteristics of macular degeneration. The purpose of this study was to determine whether the sodium iodate-induced pathology includes elevated expression of vimentin in the RPE, as well as HRF and other pigmentary changes.

Methods: Twenty C57BL/6J young adult male mice were injected with SI dissolved in PBS at 15, 30, 45, or 60 mg/kg. SD-OCT (Bioptigen) images were acquired pre-injection, and 1, 3, 5, and 7 days post-injection Retinal thickness was measured using Bioptigen software and HRF were counted manually. Frozen vertical retinal cross-sections (12 µm thick) of eyes were processed for H&E staining and IHC. Tissue from each group was also processed for electron microscopy (EM).

Results: HRFs were detected by SD-OCT in the retinas of mice given 30, 45, and 60 mg/kg SI, but not those given 15 mg/kg SI. HRFs were visible as early as post-injection day 1, and became more distinct by day 7. The higher doses of SI caused retinal thickness to be significantly decrease by day 5 post-injection compared to control ($p>0.001$). H&E images showed that the 15mg/kg dose had no apparent effect compared to the control, whereas sections from mice treated with 30, 45, and 60mg/kg contained pigmented lesions in the neural retina. The pigmented lesions in the IS/OS layer and the ONL were also detected by EM. Vimentin expression was increased in the RPE layer of the retina in a dose-dependent manner, detected by IHC.

Conclusions: The results suggest that SI induces HRF and pigment migration into the neural retina of mice. Furthermore, the SI-induced expression of vimentin in the RPE layer suggests a change in phenotype consistent with endothelial to mesenchymal transition (EMT). Overall, the results suggest a causal link between HRF, hyperpigmentation and EMT of RPE cells.

ABSTRACT BODY:

Purpose: In angiogenesis, activation of Flt-1/KDR by ligand binding leads to phosphorylation at intracellular tyrosine residues and activation of downstream signaling cascades. Nevertheless, details of these processes in corneal nerve repair are unclear. VEGF-B has previously been shown to have potent effects in the peripheral nervous system (PNS) possibly due to the existence of receptor heterodimers. The purpose of this study was to investigate Flt-1/KDR tyrosine phosphorylation at specific residues in neuronal cells and characterize similarities and differences with endothelial cells as well as investigate the effects of Flt-1/KDR knockdown on phosphorylation and VEGF-mediated neuronal growth.

Methods: Rat neuronal (PC12), mouse aortic endothelial (MVEC), mouse venous endothelial (MVEC) and human umbilical venous endothelial (HUVEC) cell lines were used. “Receptor Control Group” of cells were acutely stimulated either with VEGF-A or VEGF-B (50 ng/µL) or “vehicle” (PBS; control group). “Receptor Knockdown Group” of cells were treated with siRNA specifically directed against Flt-1 or KDR as per manufacturer’s instructions and then acutely stimulated with VEGF-A or B as described earlier. After treatment, cells were used as follows: (i) One group was fixed in 4% paraformaldehyde and processed for TUBB3 immunostaining and neurite length was visualized using fluorescence microscopy (ii) the second group was harvested in cell lysis buffer (containing anti-protease / anti-phosphatase cocktail), lysed and processed for immunoblotting (IB; LI-COR® Systems) with anti-Flt-1, anti-KDR, anti-phospho-Flt-1 (Tyr1213, Tyr1333), anti-phospho-KDR (Tyr951, Tyr1054, Tyr1175, Tyr1214) antibodies to evaluate receptor tyrosine phosphorylation at specific residues.

Results: Differences in tyrosine phosphorylation at specific residues were observed for Flt1 and KDR in neuronal versus endothelial cells. siRNA-mediated knockdown of Flt1 and KDR caused decreased tyrosine phosphorylation at specific residues in neuronal and endothelial cells. VEGF-A and -B treatment increased neurite outgrowth and branching in PC12 neuronal cells. siRNA knockdown of Flt1 or KDR caused reduction in neurite length and number.

Conclusions: Differences in Flt-1/KDR tyrosine phosphorylation at specific residues may regulate downstream signaling events and influence corneal nerve regeneration.

ABSTRACT BODY:

Purpose: Potency assays for biologicals are complex in nature, and reproducibility, response range, and accuracy depend on various factors such as nature of molecule, mechanism of action, target location, and concentration. Accurate and reproducible potency determination is vital for controlling product quality during manufacture and release. OCU200, a novel fusion biological consisting of human transferrin and tumstatin, is being developed for treatment of DME and wet age-related macular degeneration (wet-AMD). Transferrin facilitates targeting and delivery of OCU200 to the target choroidal endothelial cells through endo/transcytosis. To this end, we developed an enzyme-linked immunosorbent assay (ELISA)-based binding assay and biolayer interferometry (BLI) method to determine binding affinity as a measure of in vitro potency for OCU200.

Methods: In the ELISA, biotinylated transferrin receptor was coated on a streptavidin-coated 96-well plate and varying concentrations of OCU200 were added. A detection antibody (anti-tumstatin-HRP) was applied to measure signal using a UV-visible spectrophotometer, and data was analyzed to determine the dissociation constant. Parallelly, a BLI method was developed to determine the molecular interaction between OCU200 and transferrin receptor. BLI analyzes the interference pattern of white light reflected from two surfaces: the layer of immobilized transferrin receptor on a fiber optic sensor and on the internal reflection surface. Interactions between OCU200 and immobilized transferrin receptor on the biosensor cause a shift in the refracted wavelengths. The shift in the refracted wavelength was measured in real-time, allowing determination of precise and accurate association and dissociation rates.

Results: Dose dependent binding of OCU200 with transferrin receptor was observed in both ELISA and BLI assays. In the ELISA, the dissociation constant was found to be 3.7 ± 0.1 nM. Binding parameters in BLI, i.e. affinity constants (K_D) found to be 0.38 ± 0.01 nM, the association rate (K_{on}) found to be 3.67E+05 (1/Ms), and dissociation rate (K_{off}) found to be 1.43E-04 (1/Ms).

Conclusions: OCU200 binds to the transferrin receptor in a dose dependent manner, supporting our hypothesis that transferrin targets OCU200 to the choroid and retina mediated through the transferrin receptor. Binding affinity with receptor can be used a measure of potency for OCU200.

ABSTRACT BODY:

Purpose: Non-infectious uveitis (NIU) patients are often exposed to high-dose systemic corticosteroids (CS), yet little is known about the risk of osteoporosis/bone fracture in these patients or their adherence to recommended screening protocols. This study assessed the rate of dual-energy x-ray absorptiometry (DXA) monitoring of CS-exposed NIU patients. It also compared the risk of osteoporosis/bone fractures with cohorts of rheumatoid arthritis (RA) patients and normal controls.

Methods: Using data from a commercial and Medicare Advantage claims database, cohorts were created from NIU and RA patients given a cumulative dose of ≥900mg of oral prednisone (or bioequivalent dose of alternative corticosteroids (CS)). Patients were included in the analysis if they had at least 2 years of data prior to the date of reaching the minimum cumulative dose of oral CS, did not have a history of a DXA scan in the previous 18 months, and were ≥18 years old. NIU patients were excluded if they had any diagnosis of infectious uveitis or uveitis associated with systemic inflammatory disease at any time. RA patients were excluded if they were diagnosed with any form of uveitis. Patients were allowed to re-enter the analysis after DXA scan testing if the above criteria were again met. Cox proportional hazard regression estimated the hazard ratio of receiving DXA screening. A separate cohort analysis was conducted to compare the risk of osteoporosis/bone fractures in NIU patients versus matched normal controls, independent of CS use.

Results: 77,630 observations of NIU patients were compared with 80,862 observations of RA patients. During the follow-up period, 17,825 and 24,639 DXA scans were performed in NIU and RA patients, respectively. The adjusted hazard ratio (aHR) of NIU patients to have a DXA scan was 0.64 (95%CI:0.63-0.65; $p<0.001$) with respect to RA patients. After propensity score matching, the aHR of getting osteoporosis or a bone fracture of NIU patients was 0.95 (95%CI:0.93-0.98; $p<0.001$) compared to normal controls.

Conclusions: NIU patients are 36% less likely to receive a DXA scan after high-dose CS exposure compared with RA patients. No elevated risk of osteoporosis for NIU patients was found compared to normal controls.

TITLE: A dual polymer lubricant eye drop containing also osmoprotectants improves ocular discomfort symptoms and tear film stability in patients with dry eye disease

SESSION TITLE: Dry Eye, Clinical

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Giannaccare, M. Borselli, G. Carnovale Scalzo, V. Scorcia, Universita degli Studi Magna Graecia di Catanzaro, Catanzaro, Calabria , ITALY|

Commercial Relationships Disclosure: Giuseppe Giannaccare: Commercial Relationship: Code N (No Commercial Relationship) | Massimiliano Borselli: Commercial Relationship: Code N (No Commercial Relationship) | Giovanna Carnovale Scalzo: Commercial Relationship: Code N (No Commercial Relationship) | Vincenzo Scorcia: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate changes of objective signs and ocular discomfort symptoms in patients affected by dry eye disease (DED) treated with a new commercially available tear substitute.

Methods: A pilot study including 15 patients (6 males, 9 females; mean age 58.4±14.8 years) with mild-moderate DED was conducted. The patients were treated with a new commercially available tear substitute containing two natural polymers (sodium hyaluronate and xantham gum) and osmoprotectants (glycine and betaine). Patients were instructed to instill the study product 4 times daily for 2 months. Non-invasive ocular surface examination was carried out before (T0) and after treatment (T1) by means of Keratograph (Oculus, Germany) for the measurement of: i) tear meniscus height (TMH); ii) non-invasive break-up time (NIBUT); iii) infrared meibography of upper and lower eyelids (Pult scale); iv) ocular redness. During each visit, discomfort symptoms were scored by means of standardized patient evaluation of eye dryness (SPEED) questionnaire. The Wilcoxon test was used to compare changes of ocular parameters from T0 to T1. A P value equal or less than 0.05 was considered statistically significant.

Results: All patients instilled regularly the eye drop reporting a good profile of tolerability. Compared to T0, SPEED score decreased significantly (from 16.0±3.8 to 7.0±3.2; $P<0.001$), while NIBUT value improved significantly at T1 (from 6.3±1.1 to 9.3±3.1 s; $P=0.05$). Furthermore, TMH and Pult score also improved after treatment, but to a lesser extent (respectively, from 0.244±0.028 to 0.332±0.080 mm, $P=0.08$ and from 1.3±0.5 to 1.5±0.6, $P=0.3$). Redness score did not change significantly during the study period ($P=0.2$).

Conclusions: This novel tear substitute containing sodium hyluronate, xantham gum and osmoprotectants improved significantly ocular discomfort symptoms as well as tear film stability in patients with DED. A longer period of treatment could be useful to detect improvement in the other parameters.

ABSTRACT BODY:

Purpose: One of the limiting factors to the broad adoption of medical computer vision is the high cost of annotation. In this work, we introduce the Expert In The Loop (EITL) framework to reduce annotator time requirements with minimal sacrifices to deep model performance.

Methods: We built a cloud native platform based on CVAT (an open source image annotation software) that allows clinicians (i.e. the expert) to annotate medical images (step 1). Upon annotation of subsets of images, a crude deep learning model can be trained. This model can be used to run inference on the unlabeled images (step 2). We then ask the expert to accept or reject the network predictions (step 3), then we retrain our network on our original expert-labeled images and the accepted network-labeled images (step 4). We can repeat steps 2-4 as needed until its accuracy reaches a suitable level.

To validate this pipeline we decided to tackle Optic Disc (OD) segmentation and Vessel Segmentation on Fundus photographs. We use the publicly available Drishti-GS dataset for OD segmentation and High-Resolution Fundus (HRF) dataset for the vessel segmentation. For training, we use supplied ground truth annotation for the baseline network but manually label two images for the EITL experiments. Labeling time for the full dataset has been extrapolated from the annotation time. All reported IoU values are on the Drishti-GS test set and HRF image index 11-15 (fifteen total images for normal, DR, and glaucoma) for each respective dataset. To expedite labeling, the expert in this case is not a clinician but a computer science researcher. We train on a standard U-Net with a combination of cross-entropy and IoU loss.

Results: A full list of network performance can be found in Table 1. For OD segmentation and vessel segmentation, annotating the two images took 79 seconds and saved the expert 32 minutes of time, and 52 minutes, saving the expert over 12 hours, respectively. We see that our network was able to match the performance of an exhaustively annotated dataset after only collecting labels for 2 images.

Conclusions: This study shows that we can employ expert time more efficiently in medical computer vision. By keeping an Expert In The Loop while training we can expand our datasets across more domains while not sacrificing model performance. In the future, we hope to expand our experiments to include model performance where the expert also annotates the most problematic cases.

ABSTRACT BODY:

Purpose: Retinal detachment is a common problem impacting almost 50,000 people annually in the US. If not immediately treated, loss of vision can result but the current state of the art, using synthetic “tamponades”, has serious drawbacks. We hypothesize that a refractive-index match hydrogel with tailored swelling pressure and degradation time will allow normal eye function during healing without significant behavioral changes or secondary surgeries.

Methods: Eighteen (18) male and 18 female New Zealand White rabbits received full baseline ophthalmic exams. Following vitrectomy and subretinal injection of 0.9% NaCl to create a large inferotemporal RD, 24 animals received hydrogel and 12 animals received normal saline as controls. ERG, and OCT were measured at 1, 7, 14, 28, 49 and 84 days post-vitrectomy. IOP, slit-lamp and gross exams were performed at 1 week intervals. Eyes were collected at 14, 28, 49 and 84 days and histology was determined at each time point for one control and one test article. In addition a chromatographic analysis technique developed here was used to determine the evolution and clearance of the hydrogel components as it degraded at each timepoint.

Results: There was no significant increase in intraocular pressure during the length of the study. Chromatographic tracking of the hydrogel components demonstrate that the gel is degrading in vivo over 2-3 weeks, and that the components clear from the eye over time. By the end of the study only trace levels of both components are detected. In addition, histology indicates only minimal differences between the control and test articles. The healing process was also tracked to allow comparison between the control (bleb only) and the test article.

Conclusions: The development of a new hydrogel with tunable properties is demonstrated that can be designed to degrade over a period consistent with the healing process. The gel possesses properties similar to the native tissue and therefore works well as a temporary vitreous replacement. By designing a degradable hydrogel one can leverage the natural fluid flow of the eye to refill the eye after healing has occurred and avoid the need to permanently implant synthetic materials in this space. The preliminary data indicates that the material is well tolerated and the healing process in the presence of the gel is at least as good as the unsupported surgery.

ABSTRACT BODY:

Purpose: Chronic inflammation of the lacrimal gland (LG) is a leading cause of aqueous deficiency dry eye. It results in eye irritation, pain and may lead to severe ocular surface disorders. Visium technology makes it possible to measure the topography of gene expression. Here, we propose to underly the potentials of Visium to compare healthy and chronically inflamed LGs.

Methods: We used the 10X Genomics Visium spatial expression solution on 10µm LG cryosections of 4.5 months old BALB/cJ (control) and NOD.B10Sn-H2b/J (diseased) mice. Each sample was sequenced at a minimal depth of 280 million reads. Raw data was processed with Space Ranger (v1.3.1) to obtain spatial maps of gene expression. Data was normalized and integrated with Seurat (v4.0) to perform clustering and expression analysis.

Results: After integration of data from BALBc and NOD mice, 7 clusters (C0-6) were identified. Overall, we noted in each cluster, an upregulation of immunoglobulins (Ig) and a downregulation of exocrine gland-secreting peptides and secretoglobins (SCGB) in NOD mice. C0 and C1 represented secretory units containing mostly acinar and myoepithelial cells expressing SCGB, which play a barrier function in secretory organs. C2 was characterized by the expression of Ig typical of B cells. In C3, we detected genes expressed by activated lymphocytes and macrophages. In BALBc, it represented 5% of all spots, while in NOD it reached 15% and colocalized with immune infiltrates. C3 is enriched in glycoproteins belonging to the major histocompatibility complex protein family. C4 and C5 were enriched in genes found in ductal cells. C4 likely contained cells releasing mucins and participating in ion exchange. C5 corresponded to excretory ducts. C6 was enriched in fibroblast and macrophage markers.

Conclusions:

We successfully identified the major cellular components of healthy and chronically inflamed LG: secretory units, major ducts and immune cells. Contrary to RNA-seq, Visium indicates which cellular compartment contributes to gene expression changes observed during disease development. Despite the relatively low spatial resolution of this approach, each compartment can be compared between control and diseased LG to evidence local or structure-specific transcriptomic alterations. For example, the downregulation of secreted peptides by the acinar compartment can be related to LG dysfunction and could be involved in immunoregulatory processes.

ABSTRACT BODY:

Purpose: The lacrimal gland (LG) is the exocrine tubuloacinar gland that secretes tears. LG chronic inflammation induced by autoimmune disease or aging impairs tear secretion and causes dry eye disease. Current treatments alleviate symptoms but do not restore LG function, which could be improved by better understanding the mechanisms promoting inflammation. As aberrant inflammasome activation was shown in autoimmunity and age-related diseases, we analyzed the inflammasome pathway in inflammation models and investigated potential modulators.

Methods: We used immunodetection and the R26-CAG-ASC-citrine mouse to detect inflammasomes, a fluorescent reporter of inflammasome complex activation. Acute LG injury was induced by IL-1a injection, and we used RT-qPCR and published RNA-seq data (GSE99093) for gene expression analysis. Chronic inflammation was studied in diabetes-free NOD.B10.H2b (NOD) mice compared to BALBc mice, and their LG transcriptome was analyzed by RNA-seq at 2, 4, and 6 months old. Sequencing data were processed with Rosalind software platform.

Results: The number of ASC specks in LG epithelium was increased by acute or chronic inflammation. Several types of inflammasome sensors were upregulated in inflamed LGs, including Nlrp3, Aim2, and Ifi204. This was associated with an upregulation of the inflammasome effectors Casp1 and Casp4, along with the downstream pro-inflammatory interleukin genes Il1b and Il18, thus suggesting that they are functional. Inflammasome activation following IL-1a-injury preceded epithelial cell death and immune infiltration. We also found that the lipid metabolism pathway genes were upregulated after IL-1a-injury, during the switch from the primary inflammatory response to the tissue repair process. By contrast, Srebf1 and genes involved in fatty acid synthesis were downregulated during chronic inflammation, whereas the expression of lipid transporters and genes promoting the generation of cholesterol was increased.

Conclusions: Epithelial cells can sense tissue injury and may contribute to the development of chronic inflammation by activating the inflammasome signaling pathway. During inflammation, various types of inflammasomes are activated in the LG, thereby illustrating the complexity of the inflammatory response. Altered lipid metabolism might trigger epithelial cell damage that sustains inflammasome activation, promoting LG chronic inflammation.

ABSTRACT BODY:

Purpose: We assessed global cross-trait genetic correlations between glaucoma- and smoking-related traits to gain insights into the pathogenesis of primary open-angle glaucoma (POAG).

Methods: We gathered publicly available genome-wide association study summary statistics from participants of European-ancestry regarding the following glaucoma-related traits: intraocular pressure (IOP; n=139,555), macula retinal nerve fiber layer (mRNFL; n=31,434) thickness, macula ganglion cell-inner plexiform layer (mGCIPL; n=31,434) thickness, vertical cup-disc ratio (vCDR; n=23,899), artificial intelligence-determined vertical cup-disc ratio (AI-vCDR; n=111,724) and POAG (n=216,257). We gathered similar data for the following smoking-related traits: smoking initiation (n=1,232,971; defined as ever having been a regular smoker) and cigarettes smoked per day (CPD; n=337,334). We estimated genetic correlations (r_g) between traits using linkage disequilibrium score regression and tested for causal associations using two-sample Mendelian randomization (MR). The threshold of significance was Bonferroni-corrected for multiple comparisons.

Results: There were positive global genetic correlations between POAG and IOP (r_g=0.68; p<1E-100), vCDR (r_g=0.51; p=4.15E-20) and AI-vCDR (r_g=0.56; p=3.57E-50). There was no global genetic correlation between POAG and mRNFL (r_g=-0.082; p=0.07) or mGCIPL (r_g=-0.03; p=0.55). There were also global genetic correlations between IOP and AI-vCDR (r_g=0.28; p=1.29E-31) and vCDR (r_g=0.19; p=2.16E-6). There were nominal non-significant inverse global genetic correlations between smoking initiation and POAG (r_g=-0.05, p=0.05), IOP (r_g=-0.06, p=0.01), mGCIPL (r_g= -0.07, p=0.03) and AI-vCDR (r_g=-0.04, p=0.03). CPD and IOP also exhibited nominal inverse correlations (r_g=-0.06, p=0.04). Inverse variance weighted MR analyses revealed a significant association between smoking initiation and IOP (-0.18mmHg per standard deviation increase in the smoking initiation instrument, 95% confidence interval: -0.30 to -0.06, p=3.0E-4). A similar significant association was observed with MR-PRESSO, but not with other MR methods.

Conclusions: While shared genetic correlation between smoking- and glaucoma-related traits were nominal, MR analyses demonstrate a possible causal link between smoking initiation and IOP. Further efforts could define shared loci between IOP and smoking initiation that might lead to new drug targets for glaucoma.

ABSTRACT BODY:

Purpose: To investigate sex differences in the frequency of intra- and post-operative complications and visual outcomes following cataract surgery.

Methods: A retrospective chart review (2014 to 2019) was conducted on the medical records of patients who had phacoemulsification cataract surgery at the Sue Anschutz-Rodgers Eye Center, University of Colorado School of Medicine. Data collected included the patient's health history, ocular comorbidities, operative and post-operative complications, and the post-operative best corrected visual acuity (BCVA). The data were analyzed using univariate and multivariable logistic regression with generalized estimating equations to account for the correlation of some patients having two eyes included in the study.

Results: A total of 12,549 eyes from 7,650 patients were included in the study. Ocular comorbidities were different by sex, with males having significantly higher percentages of traumatic cataracts, intraocular injections, prior ocular surgery, mature cataracts, and planned pars plana vitrectomy (PPV). Conversely, females had significantly higher rates of pseudoexfoliation. In multivariable analysis, males had 1.7 higher odds of posterior capsular rupture (PCR) (95% CI:1.0-2.7, p=0.0398) and 1.6 higher odds of vitreous loss (95% CI:1.1-2.5, p=0.0211). Post-operatively, males had a significantly increased risk of retinal detachment, but in multivariable analysis this was no longer significant, and were significantly less likely to undergo Nd:YAG laser capsulotomy for posterior capsule opacification (OR=0.8, 95% CI=0.7-0.9, p=0.002). The best corrected visual acuity (BCVA) was slightly worse for males pre-operatively (mean logMAR 0.376 (Snellen equivalent 20/47) vs. 0.340 (Snellen equivalent 20/44) for females, p=0.002); but post-operatively, both sexes exhibited similar visual acuity of Snellen equivalent 20/25 (p=0.2096) with exclusion of traumatic cataracts, combined surgeries with PPV, and complicated surgeries.

Conclusions: Our study found significant differences by sex in patient presentation and outcomes following cataract surgery. These findings underscore the importance of incorporating sex into studies that investigate cataract surgery outcomes.

ABSTRACT BODY:

Purpose: Diabetes Mellitus is a multisystemic disorder having systemic, ocular and cognitive complications. We studied the changes in visual attention, spatio-visual memory and visual search among diabetic individuals and healthy individuals with family history of diabetes.

Methods: Diabetic and healthy individuals with diabetic family history (N=92, Mean age 45±8.8 years) were included after obtaining informed consent. None of the subjects had any ocular diseases and had best corrected visual acuity of 6/9 or better. Visual attention and processing time (APT) was measured using a Stroop task with congruent and incongruent stimuli, with subjects keying in code for the print color. For Spatio-visual memory, subjects were presented targets sequentially at random locations and the maximum number of blocks the subjects could recall in correct sequence was measured. The difference in processing time for congruent and incongruent stimuli was calculated. Visual search time (VST) was measured as choice reaction time. The time taken for the subject to identify an upright orange colored “T” among 15 distractors was collected. All measurements were performed using PsyToolKit on a calibrated monitor in a normal room setting with the subjects viewing the targets binocularly.

Results: All the visual cognitive parameters were degraded in diabetics compared to healthy individuals. The processing time was significantly higher ($p<0.0001$) for incongruent stimuli ($RTInCon_{DM}$: 1593±198msec; $RTInCon_{HI}$: 1429±112msec) than congruent stimuli ($RTCon_{DM}$: 1312±176msec; $RTCon_{HI}$: 1305±105msec) for both group of subjects. The mean APT longer for diabetics (DM: 281±152msec, HI: 124±91msec; $p<0.0001$) than for healthy individuals. The VST was significantly ($p=0.03$) delayed for diabetic individuals (3156±389msec) than for healthy individuals (3017±316msec). The mean span for spatio-visual memory in diabetic individuals was (3.6±0.8) which was significantly lesser than that for healthy individuals (5±1.3). The reaction time (irrespective of the task) and span of memory was significantly correlated with the age of the patient ($r_{RT}=0.64$, $r_{span}=-0.67$, $p<0.001$).

Conclusions: Diabetics with normal had impaired cognitive functions, when compared to healthy individuals with diabetic family history. Our results imply that cognitive visual impairment can manifest earlier than ocular complications and should be routinely assessed.

ABSTRACT BODY:

Purpose: To present a case of zoster sine herpete (ZSH) manifesting with retinal phlebitis and to examine and compare differences in ZSH diagnosis and treatment patterns among investigators in the Zoster Eye Disease Study Group (ZEDS) in the United States, Canada, and New Zealand.

Methods: Case report, along with a survey of physicians associated with the ZEDS Group in September 2021. Survey participation was voluntary, and participants were surveyed regarding their findings on initial exam, method of diagnosis, treatment undertaken, and overall clinical course.

Results: We report the case of a 55-year-old woman who initially presented with acute anterior uveitis and was diagnosed with ZSH via positive VZV PCR results. The patient also developed iris transillumination defects and retinal phlebitis in her right eye prior to valacyclovir. Her clinical course stabilized after starting oral valacyclovir. At the eight-month follow-up visit, the patient remained on valacyclovir and topical steroid treatment. A total of 28 responses to the survey were collected. Of the 28 respondents, 11 (39.3%) indicated that they had diagnosed ZSH. Methods of diagnosis varied, however clinical exam findings (70%), VZV DNA identification via PCR 14 (50%), and resolution of symptoms following treatment 14 (50%) were most common. Of the 11 respondents who had diagnosed ZSH, three (27.3%) obtained fluorescein angiography and only two (18.2%) diagnosed retinal phlebitis in the setting of ZSH. Oral antivirals were used in all 28 cases (100%) with valacyclovir as most popular with 25 total cases (89.3%). No intravenous or intravitreal treatments were reported. Three (27.3%) of the respondents who had diagnosed ZSH were unable to discontinue antiviral treatment.

Conclusions: Our survey of ZEDS investigators indicates that the majority of ZSH cases are diagnosed via clinical findings and detection of VZV DNA by PCR. Oral antivirals are overwhelmingly the therapy of choice. However, antiviral treatment could not be discontinued in 27.3% of cases. While posterior segment complications were reported in 18.2% of cases, keratitis and uveitis were most common.

ABSTRACT BODY:

Purpose: Mammals sense light for diverse purposes—including perception and the regulation of development, physiology, behavior, mood, and cognition—that require intrinsically photosensitive retinal ganglion cells (ipRGCs). These ocular neurons capture photons with a receptor called melanopsin and send information widely throughout the brain. IpRGCs are evolutionarily conserved, providing an opportunity to compare cell types across ecological niche; indeed, few other retinal output neurons appear to be shared between rodents and primates. Present knowledge indicates that rodent and primate ipRGCs diverge fundamentally in their photosensory mechanisms. However, studies of the latter are few, in large part because their live identification is challenging. We pursue the idea that comparison of rodent and primate ipRGCs will clarify our understanding of how cells are tailored to their tasks.

Methods: We developed an acute, ex vivo method of identifying macaque ipRGCs based on immunotagging of melanopsin's extracellular domain. We performed patch-clamp electrophysiological recordings from macaque ipRGCs, as well as from mouse ipRGCs that expressed macaque melanopsin in lieu of their own. We delivered a suite of visual stimuli and analyzed responses using biophysical methods. To focus on cell-autonomous mechanisms, we added antagonists of synaptic transmission to the extracellular medium.

Results: Our experiments indicate that N-terminal immunotagging is innocuous for melanopsin function. Using this approach, we observed deep conservation between macaque and mouse ipRGCs, from molecular mechanisms that broaden wavelength sensitivity and response lifetime to cellular mechanisms that generate dynamic range for encoding a breadth of environmental light levels. We found one divergence: While the electrical discharges of mouse ipRGCs are irregular, those of macaque ipRGCs are precisely timed.

Conclusions: It appears that many ipRGC mechanisms for sensing environmental illumination are effective enough to stand across the ~70-million-year separation of mice and macaques. Live immunotagging offers a way to identify cell types for functional analysis, and may be especially useful in the study of species that are unamenable to genetic manipulation.

ABSTRACT BODY:

Purpose: Our previous transcriptomic studies on retinal endothelial cells under hyperglycemic conditions have shown the significant upregulation of the chemokine CXCL1. The purpose of this present study is to show the effect of CXCL1 on recruitment of neutrophils and monocytes in the alteration of blood retinal barrier in an in vivo model of diabetic retinopathy.

Methods: The experiment design included the following groups: A) Streptozotocin induced diabetic mice (3 months) vs. diabetic mice treated with neutrophil depleting Ly6G-1A8 antibody (50ug) for 15 days (n=10); B) Wildtype C57BL/6 J mice intravitreally (IVT) injected with recombinant CXCL1 (100 ng/eye) vs. animals pretreated with Ly6G-1A8 antibody (50ug) followed by IVT with recombinant CXCL1 (n=10). Flow cytometry analysis for immune cell infiltration (neutrophils and monocytes) in the retinas. qPCR analysis was used to determine mRNA expression of chemokines and its receptors, proteases and adhesion molecules. Western Blot analysis was used to evaluate the expression of albumin to detect retinal vascular permeability. ELISA was used to measure serum levels of CXCL1 levels in patients with human diabetic retinopathy.

Results: Retinas of both diabetic and intravitreally CXCL1 injected mice showed increased neutrophils ($p = 0.01$) and monocytes ($p = 0.01$) and mRNA expression of proinflammatory chemokines (Ang2, CCL2, CCL5, CCL7, VEGF), chemokine receptors (CCR2, CCR5, CXCR2), proteases (Cathepsin-B,K,L,S, MMP2 and MMP9) and adhesion molecules (ICAM1 and VCAM1). The Ly6G-1A8 antibody treatment had significantly decreased infiltration of both neutrophils and monocytes ($p=0.05$) and decreased expression of these chemokines and proteases. Likewise, western blot analysis confirmed increased extravasation of albumin in retinas of diabetic mice and CXCL1 injected mice ($p=0.01$) and the Ly6G-1A8 antibody treatment significantly reduced the extravasation ($p=0.01$). Also, the CXCL1 level was significantly increased in the serum samples of diabetic retinopathy patients compared to non-diabetic subjects ($p=0.001$).

Conclusions: Overall, we have shown evidence that neutrophil infiltration triggered by CXCL1 plays an important role in the alteration of the BRB in diabetes. A combination therapy of a CXCL1 inhibitor and the anti-VEGF drugs may be a potential therapeutic approach in the management for diabetic macular edema.

ABSTRACT BODY:

Purpose: Glaucoma is a retinal degenerative disease that leads to a progressive loss of retinal ganglion cells (RGCs) and optic nerve degeneration. Atoh7/Math5 is a transcription factor required for RGC competence. In humans, an enhancer deletion was associated with nonsyndromic congenital retinal nonattachment (NCRNA), where patients lack of RGCs and show an aplasia of the optic nerve. Our work aims at utilization a genomic approach to characterize the enhancer structure of Atoh7 and other factors contributing to retinal ganglion cell formation.

Methods: We performed single cell (sc) ATAC-Seq analysis on wild type mouse developing retina at E14.5 to define RGCs regulatory landscape in detail. We investigated the genomic occupancy of PAX6, a transcriptional factor important for RGC genesis at E14.5, using a genomic technique called CUT and RUN. We analyzed transcriptional defects resulting from deleting the Atoh7 enhancer landscape using bulk and sc-RNA-seq at E14.5. We performed anterograde labeling to investigate defects in RGC axons in Atoh7 enhancer deficient mice.

Results: sc-ATAC-Seq analysis captured the cellular heterogeneity and progression from proliferation to differentiation underlying retinal development at E14.5 and revealed the landscape dynamics of Atoh7 enhancer. Genomic profiling of PAX6 uncovers occupancy on cis-regulatory elements nearby genes important for retinal proliferation and RGC differentiation, including Atoh7. Mice harboring CRISPR/Cas9 mediated deletion of an Atoh7 enhancer leads to a profound reduction in Atoh7 expression but did not alter the RGCs formation. RNA-Seq analysis of the KO-mice at E14.5 revealed changes in transcriptional programs related to RGC differentiation and axon formation. Importantly, deletion of Atoh7 enhancer disrupts eye-specific targeting of RGC axons in the dorsal lateral geniculate nucleus (dLGN).

Conclusions: Sc-ATAC analysis reconstructed retinal differentiation trajectories known to exist at E14.5. Genomic occupancy of PAX6 revealed how PAX6 coordinates a complex retinal gene regulatory network important for retinal proliferation and differentiation. Our RNA-Seq analysis of mouse lacking Atoh7 enhancer revealed requirement of this regulatory element to proper axonogenesis. We propose that high levels of Atoh7 expression is required for proper circuit organization of the eye-specific targeting of visual system but is dispensable for RGC formation.

ABSTRACT BODY:

Purpose: To investigate visual outcomes and perceived quality of life of paediatric patients with uveitis treated in a multidisciplinary clinic involving Ophthalmologists and Rheumatologists at a tertiary children's hospital.

Methods: Review of all paediatric uveitis patients presenting to the Children’s Hospital Westmead, Sydney Eye Hospital and Save Sight Institute from 2005-2020. Inclusion criteria includes less than 18 years age of diagnosis, any form of diagnosis of uveitis based on SUN criteria, follow up at least 3 months, WGA paediatric glaucoma guidelines for OHT and glaucoma, ocular morbidities and treatment of the uveitis. Completion of 3 validated instruments for children to assess (1) functional visual ability (FVA) with the Cardiff Visual Ability Questionnaire for Children (CVAQC), (2) VR QoL with the Impact of Vision Impairment for Children (IVI-C), and (3) HR QoL with the Pediatric Quality of Life Inventory (PedsQL) version 4.0.

Results: There were 111 patients (207 eyes) diagnosed with paediatric uveitis 2005-2020. There were 61 female and 48 male patients. The most common aetiological diagnoses was JIA-U (n =65, 59%) followed by Idiopathic uveitis (n = 33, 29.6%) with 84% being anterior uveitis and 16% being non-anterior uveitis. Fifty-three patients were on Methotrexate/Mycophenolate, 30 patients on Adalimumab, 3 patients Infliximab, 3 patients on Tocilizumab and 2 patients Tofacitinib. The mean duration of inflammation prior to commencement of a biological agent was 22.0 months (range: 1-48 months). Over 50% eyes diagnosed with uveitis developed raised IOP at some point, 43/207 eyes (21%) had glaucoma surgery. Mean VA significantly improved after 6 weeks of biological therapy and then was maintained over 12 months. Scores for FVA, VR QoL, and HR QoL were reduced in children with paediatric uveitis. Patients and family members reported improved quality of life being able to be seen by all treating doctors at the same multidisciplinary clinic.

Conclusions: Paediatric uveitis has a marked effect on FVA and QoL. Control of intraocular inflammation is essential in paediatric uveitis. Rapid taper of any steroids crucial as ocular hypertension /glaucoma and cataract is dose and duration dependent. Commencing a step ladder of systemic therapy quickly if steroid treatment not working. Biological therapy reduced intraocular inflammation with maintained visual acuity. Multidisciplinary clinics are gold standard treatment.

ABSTRACT BODY:

Purpose: Uveal melanoma (UM) is a rare, but often lethal, ocular cancer which metastasises to the liver in up to 50% of patients. There are no effective therapies available to treat metastatic UM and as few as 8% of patients survive beyond two years. We previously identified that high expression of $CysLT_1$ is associated with poor UM patient outcomes in a UK cohort, and that $CysLT_1$ antagonists alter the tumorigenic properties of UM cell lines in vitro. This preclinical in vivo and ex vivo research further evaluates the clinical relevance and therapeutic potential of CysLT receptors in UM.

Methods: Immunohistochemical staining was conducted on an independent, primary UM patient cohort from Spain (n=68) to analyse expression of CysLT receptors and their relationship to matched survival data. Primary UM tumours (n=11) were grown as explant cultures and treated with 20 μM 1,4-dihydroxy quininib or vehicle. Following 72 hours of treatment, tumour conditioned media was analysed by ELISA and the secretion of factors was correlated to clinical data. An orthotopic cell line-derived xenograft model of metastatic UM was generated in female athymic Nude-Foxn1nu mice using OMM2.5 metastatic UM cells. 1,4-dihydroxy quininib was administered intraperitoneally at a dose of 25 mg/kg every 3 days, for 3 weeks (n=8). Upon sacrifice, tumour weight was compared to vehicle (n=9) and Dacarbazine (80 mg/kg)(n=8) treated mice and tumours were assessed by immunohistochemistry and digital pathology analysis.

Results: We confirmed that high expression of $CysLT_1$ in primary UM is significantly associated with reduced survival in an independent, validation cohort (p=0.01). Treatment of ex vivo explants derived with 1,4-dihydroxy quininib significantly alters the secretion of IL-13, IL-2 and TNF-α. In an orthotopic xenograft model of metastatic UM, treatment with 1,4-dihydroxy quininib did not significantly decrease tumour weight versus vehicle (p=0.81) but did significantly decreases ATP5B (p=0.03), a marker of oxidative phosphorylation, versus vehicle, mimicking our published in vitro data.

Conclusions: These preclinical data strengthen the importance of CysLT signalling in UM. Our findings suggest that high expression of $CysLT_1$ in UM could act as a biomarker for poor prognosis and that antagonism of $CysLT_1$ may be of therapeutic interest in UM.

TITLE: Ex vivo analysis of mast cell degranulation in human donor choroids

SESSION TITLE: RPE/choroid pathology: oxidative stress, inflammation and neovascularization

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: I.A. Bhutto, T. Niizawa, A. Pado, E. McDonnell, G.A. Lutty, M.M. Edwards, Ophthalmology, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Imran Bhutto: Commercial Relationship: Code N (No Commercial Relationship) | Tomohiro Niizawa: Commercial Relationship: Code N (No Commercial Relationship) | Alexandra Pado: Commercial Relationship: Code N (No Commercial Relationship) | Erin McDonnell: Commercial Relationship: Code N (No Commercial Relationship) | Gerard Lutty: Commercial Relationship: Code N (No Commercial Relationship) | Malia Edwards: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We have previously demonstrated that mast cells are increased in number and there is increased mast degranulation in submacular choroids in all stages of age-related macular degeneration (AMD). We also recently reported ex vivo and in vivo rat models in which a snake venom-like compound, 48/80, stimulates degranulation of choroidal mast cells. Moreover, both oral and topical administration of ketotifen (KTF), a known mast cell stabilizer, reduced mast cell degranulation in the rat model. This study was designed to determine whether human choroid explants can be used as an ex vivo model to study mast cell degranulation and screen potential therapies. In addition, this study investigated the ability of C-reactive protein (CRP), which is elevated in AMD, to stimulate mast cell degranulation.

Methods: Human donor eyes (N=4) were received on wet ice within 30 hrs postmortem. Retinas were isolated from the choroid/RPE complex. The RPE/choroid complex adjacent to the submacula was dissected into pieces. The choroid pieces incubated for 3 hrs at 37°C in either Dulbeccos modified Eagle's media (DMEM) (control), 48/80 (300µg/ml), 48/80 + KTF (300µg/ml), or hCRP (2, 4, and 10 ng/ml). The RPE were then removed with 1% EDTA. Choroids were then fixed in 2% PFA in cacodylate buffer at 4°C overnight and stained for non-specific esterase (NSE) activity. Pigments were bleached with 30% hydrogen peroxide and NSE-stained choroids were imaged. Mast cells were counted using Image J. The percent of degranulated mast cells was calculated in 20x images (4 random fields per piece).

Results: 48/80 stimulated mast cell degranulation in human choroid explants. Moreover, this stimulation was significantly reduced by KTF. CRP also increased mast cell degranulation in a dose-dependent manner, reaching significance at 4 and 10ng/ml. At the 10 ng/ml CRP dose, 43.5% of mast cells were degranulated compared to 15% in the control.

Conclusions: Similar to previous observations in rats, KTF can prevent 48/80-induced mast cell degranulation in human donor eyes. CRP, at physiological concentrations, significantly stimulates mast cell degranulation ex vivo. The ability to study mast cell degranulation ex vivo in human donor choroids may prove useful in testing therapies.

ABSTRACT BODY:

Purpose: Various ocular surface conditions including dry eye disease can present with pain.However,it is challenging to establish etiology and prescribe right treatments due to discordance between patient symptoms and signs.To understand basis of such discordance,we stratified subjects with ocular surface pain based on concordance between severity of signs and symptoms and evaluated corneal structural features and tear molecular factors.We also analysed the various confocal nerve parameters along with systemic and orthoptic parameters in these patients presenting with ocular surface pain using a random forest artificial intelligence(AI) model.

Methods: 300 eyes of 151 patients underwent slit lamp examination,ocular surface disease index (OSDI) scoring,dry eye evaluation and ocular surface staining.Subjects were stratified into -group 1-with no symptoms and clinical signs;group 2-with no symptoms but with signs;group 3-with similar severity of symptoms and signs;and group 4- with symptom severity higher than that of signs.In vivo confocal imaging (IVCM)evaluation was performed in all study subjects.We also evaluated presence or absence of orthoptic issues and connective tissue disorders and in the first step the area under curve (AUC),accuracy,recall,precision and F1-score of the AI model were evaluated.Tear fluid was also collected using Schirmer’s strips and evaluated for soluble factors related to inflammation by multiplex ELISA.

Results: The AI achieved an AUC of 0.736,accuracy of 86%,F1-score of 85.9%,precision of 85.6% and recall of 86.3%.Top 5 parameters used for classification by AI were microneuromas,immature and mature dendritic cells,presence of orthoptic issues and nerve fractal dimension parameter.Patients with higher grade of symptoms and signs showed increased corneal dendritic cells(cDC) density which was more pronounced in subjects with discordant symptoms to signs(group 4).Significantly higher proportion of microneuroma-like structures and cDC were seen in group 4.Higher levels of IL-17A were found in group with more discomfort.

Conclusions: Correlating ocular surface pain and the disparity between signs and symptoms with IVCM and tear molecular factors can help clinicians improve diagnosis and provide targeted treatment for pain and coupled with AI can improve the diagnoses and help better customise treatment of ocular surface pain.

ABSTRACT BODY:

Purpose: To investigate the prevalence of vitreoschisis and the effect of its removal on anatomical outcomes in eyes undergoing pars plana vitrectomy (PPV) for primary rhegmatogenous retinal detachment (RRD) repair.

Methods: Prospective analysis and comparison of preoperative imaging and intraoperative findings in eyes with primary RRD. Before operation, the vitreous status was assessed by means of ophthalmoscopy, ultrasound and optical coherence tomography . Intraoperatively, the presence of vitreoschisis was visualized with the aid of desamethasone; the vitreous cortex remnants were removed with a flex loop as much as possible from the vascular arcades to the periphery. All the operations were performed by a single surgeon.

Main outcome measures were the prevalence of intraoperative vitreoschisis and the rate of post-operative complications at 6 month follow-up (development of macular epiretinal membrane and redetachment)

Results: Eighty-four eyes from 84 patients were enrolled into the study. The primary anatomical success rate was 92.9 %. Intraoperatively, vitreoschisis was found in 40 (47.6%) eyes and extended from the major vascular arcades to the ora serrata in all cases. Age and axial length were independent risk factors associated with the presence of vitreoschisis. Successful removal of vitreoschisis from the detached retina was accomplished in 32 eyes (80%). Redetachments occurred in 6 eyes in which vitreoschisis was not identified or removal was not feasible at the time of operation. The postoperative development of a macular epiretinal membrane causing significant wrinkling and alteration of the foveal profile was found in 7 eyes (8.3%).

Conclusions: The prevalence of vitreoschisis in eyes with primary RRD is almost 50%. The identification and removal of vitreoschisis may have a significant impact on the anatomical success rate in eyes undergoing PPV for primary RRD.

ABSTRACT BODY:

Purpose: Socioeconomic status (SES) and minority racial status are associated with disparities in healthcare quality and disease outcomes.[1] The objective of this project is to assess differences in anti-vascular endothelial growth factor (anti-VEGF) treatment and visual acuity (VA) outcomes of branch retinal vein occlusions (BRVO) across the dimensions of race and SES.

Methods: A retrospective chart review was conducted of all patients with BRVO and cystoid macular edema (CME) treated with anti-VEGF injections at Wake Forest Baptist Health from 2013 to present. Patients were excluded if they had other visually significant visual pathology. Baseline patient characteristics including VA, age, gender, insurance status, phakic status, were recorded. The national percentile of area deprivation index (ADI) was recorded. Anti-VEGF injection type and number of treatments, and final VA outcomes were collected.

Results: 99 eyes of 96 patients were included. 79 patients belonged in the bottom half and 20 belonged in the top half national percentile of ADI. 79 patients identified their race as White and 20 patients identified their race as non-White. The mean presenting logMAR VA of patients in the top 50^{th} and bottom 50^{th} percentile ADI was 0.44 and 0.66 respectively (p=0.06); presenting vision was 0.60 for White patients and 0.71 for non-White patients (p=0.24). The mean final logMAR VA of patients in the top 50^{th} and bottom 50^{th} percentile ADI was 0.27 and 0.47 respectively (p=0.03); final VA was 0.43 for White patients and 0.50 for non-White patients (p=0.27). The number of anti-VEGF injections per year of follow up for patients in the top 50^{th} and bottom 50^{th} percentile ADI was 3.2 and 1.5 respectively, and was 2.5 for White patients and 1.4 for non-White patients. The mean duration of follow up for White patients was 5.2 years and 4.3 years for non-White patients (p=0.16) while it was 4.7 years for the top 50^{th} percentile and 6.6 years for the bottom 50^{th} percentile ADI (p=0.03).

Conclusions: Final VA was worse in patients with lower SES, but did not differ between white and non-White patients. The number of anti-VEGF injections was different between White and non-White patients and across measures of ADI. These results may help increase awareness of barriers to ophthalmic care associated with SES and race.

ABSTRACT BODY:

Purpose: Biguanides have been shown to have amoebicidal activity against Acanthamoeba species. The addition of biguanides in a multi-purpose solution (MPS) may improve protection from Acanthamoeba Keratitis (AK) associated with contact lens wear (CLW). Testing of Acanthamoeba trophozoites and cysts in an investigational triple disinfectant MPS containing Alexidine, a biguanide, Polyaminopropyl Biguanide (PAPB), and Polyquaternium-1 (PQ-1) was conducted to determine Acanthamoeba disinfection efficacy and to further mitigate risk by assessing the potential for encystment.

Methods: A. castellanii (A.c, ATCC 50370) or A. polyphaga (A.p, ATCC 30461) trophozoites or cysts were used to prepare an inoculum of $1x10^7$ organisms/ml. For stand-alone disinfection 10 ml of the MPS (3 lots) was inoculated and incubated for 4 hours. For a regimen test, 6 types of contact lenses were inoculated on each surface and allowed to adsorb for 5 minutes. Each lens (N=4) was rubbed for 10 seconds and rinsed for 5 seconds per side. The treated lens was placed in a lens case well with 3 ml MPS (3 lots) and soaked for 4 hours. Recovery of Acanthamoeba was performed by placing test solution (stand-alone) or lens and soak solution (regimen), separately, into neutralizer broth for 10 minutes. Aliquots were serially diluted in a 96-well microtitre plate containing ¼ strength Ringer's solution. E. coli was added to each well, incubated for 14 days at 26-30^{o}C, and inspected microscopically for recovery. Acanthamoeba recovery values were determined using the Spearman-Karber method and Log_{10} Reduction (LR) was calculated. Encystment was conducted with A.c trophozoites as directed in ISO 19045.

Results: Stand-alone disinfection showed a mean LR of 3.8 and 3.7 for A.c and A.p trophozoites respectively and a mean LR of 3.6 and 1.8 for A.c and A.p cysts respectively after 4 hours of disinfection. Regimen disinfection recovery was <0.5 log for A.c and A.p trophozoites, <1.0 log for A.c cysts, and <0.5 log A.p cysts in all 6 lens types tested. No encystment of A.c was detected after incubation in the MPS for 20-24 hours.

Conclusions: The investigational MPS containing biguanides and polyquaternium-1 showed robust effectiveness of Acanthamoeba trophozoites and cysts in stand-alone, regimen, and encystment testing. Together, these results support that the investigational MPS may reduce the risk of AK associated with CLW.

TITLE: Clinical Characteristics of Dry Eye Patients Diagnosed During Cataract Surgery Evaluation

SESSION TITLE: Dry Eye, Clinical

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Zeng, D. Cui, G. Li, P. Mathews, S. VanCourt, E.K. Akpek, Johns Hopkins Medicine, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Julia Zeng: Commercial Relationship: Code N (No Commercial Relationship) | David Cui: Commercial Relationship: Code N (No Commercial Relationship) | Gavin Li: Commercial Relationship: Code N (No Commercial Relationship) | Priya Mathews: Commercial Relationship: Code N (No Commercial Relationship) | Shanna VanCourt: Commercial Relationship: Code N (No Commercial Relationship) | Esen Akpek: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess the incidence and clinical characteristics of patients diagnosed with dry eye during evaluation for cataract surgery.

Methods: Dry eye patients evaluated by an ophthalmologist between 3/2015 and 7/2021 were identified using international classification of disease codes. A total of 600 of the 1630 identified dry eye patients, randomly selected by a computer software (Microsoft Excel), had their medical records reviewed. Patients diagnosed with dry eye during cataract surgery evaluation were identified, and an equal number of primary dry eye patients were selected as controls. Electronic medical records were reviewed to obtain information regarding demographics, objective dry eye parameters at baseline, dry eye treatments, and dry eye symptoms.

Results: Twenty-six patients (4.3% of total reviewed) received a dry eye diagnosis during cataract surgery evaluation, and an additional 26 patients were selected as controls. More patients from the cataract evaluation group were men (42.3% vs 23.1%, P=.139) and self-identified as racial/ethnic minorities (34.6% vs 19.2%; P=.184), however these differences were not statistically significant (both P>.05). Objective dry eye parameters demonstrated no statistically significant difference (all P>.05) between groups for mean conjunctival lissamine green staining (cataract 2.4 vs control 2.8) and corneal fluorescein staining (cataract 2.1 vs. control 2.2). Fifteen (57.7%) cataract patients and 25 (96.2%) of controls had symptoms of dry eye at presentation (P<.001). Prior to presentation, fewer cataract evaluation patients had used any over-the-counter treatments (53.8% vs 84.6%; P=.016) or prescription treatment (15.4% vs 50.0%; P=.008)

Conclusions: The prevalence of dry eye diagnosed during cataract surgery evaluation is rare, however these represent a greater proportion of asymptomatic patients with no prior dry eye treatment. Objective dry eye parameters and demographic between groups are not statistically significant, however larger studies are warranted to evaluate for clinically and statistically significant differences.

ABSTRACT BODY:

Purpose: To identify and characterize genes associated with primary open angle glaucoma (POAG) in the Ocular Hypertension Treatment Study (OHTS).

Methods: We conducted a genome-wide association study of 1,057 OHTS participants, of whom 374 developed POAG and 683 did not develop POAG after 20 years of follow-up. Participants were typed at 905,636 SNPs that were imputed to 10 million SNPs. We compared allele frequencies with a chi-square test and a genome-wide threshold for statistical significance was set at $p < 5 \times 10^{-8}$. We further evaluated the association with gamma amino butyric acid type A receptor subunit gamma 2 (GABRG2) identified in the OHTS participants by 1) comparing probability for POAG between GABRG2 risk allele carriers and non-carriers using Kaplan-Meier survival analysis; 2) testing a second cohort of POAG patients (n=922) and controls (n=419) for the association with GABRG2; and 3) analyzing human donor eyes with homozygous GABRG2 high-risk alleles (n=4) and homozygous low-risk alleles (n=4) with immunohistochemistry.

Results: We identified a chromosome 5 locus that was highly associated with POAG in the OHTS ($p = 1.9 \times 10^{-8}$). Kaplan-Meier analyses also showed one allele of this risk factor is associated with a 16% increased probability of POAG after 20 years, while two alleles are associated with a 25% increased probability for POAG ($p = 3 .0 \times 10^{-9}$). The chromosome 5 association with glaucoma was confirmed in an independent cohort of POAG patients and controls from Iowa ($p = 3.8 \times 10^{-2}$). GABRG2 is the nearest gene in this chromosome 5 locus. Immunohistochemical analysis of human donor eyes with an antibody directed against GABRG2 demonstrated greatly increased labeling of retinal ganglion cells in eyes with homozygous risk alleles when compared to eyes with no risk alleles.

Conclusions: We have identified a new POAG risk factor locus, GABRG2, that has a significant influence on risk for glaucoma. GABRG2 has a role in gamma amino butyric acid (GABA) signaling / GABAergic activity, which may be an important biological pathway contributing to retinal ganglion cell death in glaucoma.

SUBMITTER (NAME ONLY): Lindsay Chun

TITLE: Utility of 3-0 Prolene ripcord with Baerveldt-350 to partially occlude tube lumen and minimize hypotony-associated complications when ligature dissolves

SESSION TITLE: Surgery & Wound Healing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L.Y. Chun, M. Qiu, Ophthalmology, University of Chicago Division of the Biological Sciences, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Lindsay Chun: Commercial Relationship: Code N (No Commercial Relationship) | Mary Qiu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To retrospectively review a single surgeon's (MQ) experience of using a 3-0 Prolene ripcord in the lumen of Baerveldt 350 Glaucoma Implants (BGI-350) and review of the clinical outcomes of this technique.

Methods: Retrospective chart review was performed on adult patients who received BGI-350s with performed by a single surgeon (MQ) at a single academic center between 10/1/2019 and 6/30/2021. All patients had removable 3-0 prolene ripcords intraoperatively placed in the lumens of BGI-350s. Demographic characteristics, ocular examination findings, and ripcord management outcomes were collected at preoperative and postoperative time points. Outcome variables included intraocular pressure (IOP), number of IOP-lowering medications, and anterior chamber (AC) inflammation at 2 time points: the soonest scheduled visit after the ligature suture dissolved and the postoperative day (POD) of ripcord removal.

Results: 29 eyes of 27 adult patients who received BGI-350s were included in this study. 17/29 [PM1] (58.6%) eyes had prompt ripcord removal at the soonest scheduled visit following ligature dissolution (mean POD 47, IOP 13.1 mmHg on 3.6 meds). The other 13/29 eyes (44.8%) had delayed or no ripcord removal. Among this cohort, 9/13 eyes (69.2%) had low pressure without complications at the time of ligature dissolution (mean POD 47.6, IOP 7.6 mmHg on 3.3 meds). 8 of these eyes (only one of whom had transient AC shallowing) underwent medication de-escalation and subsequent delayed ripcord removal (mean POD 59.9, IOP 14.9mmHg on 2.6 meds). 1 eye had persistent IOP 9 on 0 meds, so the ripcord was trimmed and left in place permanently to prevent hypotony. Furthermore, ripcord removal was delayed due to excessive AC inflammation upon ligature dissolution requiring sustained steroids in 2/13 eyes (15.4%), and due to logistical delays in 2/13 eyes (15.4%) (mean POD 60.1, IOP 13.1 mmHg, 3.2 meds). 0 patients developed choroidal effusions, suprachoroidal hemorrhage, or infections associated with an exposed segment of ripcord in the inferior fornix.

Conclusions: The intraoperative placement of 3-0 Prolene ripcords to partially occlude the lumen of BGI-350s may serve as a useful strategy to safely optimize and sustain postoperative IOP control, prevent hypotony, allow for improved patient outcomes.

ABSTRACT BODY:

Purpose: To determine the efficacy and long-term effects of biological agents in the management of chronic pediatric uveitis

Methods: Retrospective review of medical charts of patients of a single academic referral center.

Results: Included were 48 patients (80 eyes), of whom 33 were females (68.7%). Mean age at time of diagnosis of uveitis was 7.3±4.0 years. At baseline (time when biologic therapy was initiated), all patients had active uveitis: 28 had anterior uveitis (58%), 12 had intermediate uveitis (25%) and 8 had posterior or panuveitis (17%). Uveitis was bilateral in 32 (66.6%) patients. Mean total follow-up was 4.9±2.8 years and mean follow-up after baseline was 39±31.5 months. Complete control of ocular inflammation was achieved with the first biologic medication in 86.2% (n=69) of eyes. 7 patients (14.5%) required to switch to another biologic agent. The most commonly used biologic agent was adalimumab in 43 patients (89.5%). Mean logMAR BCVA at baseline was 0.23 ±0.44 (range 2 to -0.1 logMAR), it was 0.15±0.39 at 12 months of follow- up and remained stable at 24 months, with a mean logMAR BCVA of 0.18±0.41. At baseline, mean dose of prednisone was 13.7±13.4 mg/day and it significantly decreased to 4.4±2.8 mg/day and 2.8±2.8 mg/day at 12 and 24 months of follow-up, consecutively. At baseline, 66.6% (n=32) of patients were dependent on oral corticosteroids and this decreased to 30.2% (n=13) at 12 months and to 21.8% (n=7) at 24 months. At baseline, 34 (42.5%) eyes used topical steroids, at a mean dose of 1.04±1.77 drops/day and this decreased at 12 months to 4 eyes (6.3%), at a mean dose of 0.14±0.47 drops/day and remained stable at 24 months. After starting biologic therapy, 19 eyes (23.7%) experienced flare, at an average time of 10.34±11.76 months (range 5 to 24 months), of which; 14 eyes (73.6%) were treated with adalimumab and 5 eyes (26.4%) with infliximab. Rate of treatment failure was 10.4% (5 patients), 2 treated with adalimumab and 3 with infliximab.

Conclusions: Uveitis was effectively controlled in 86.25% of children. The use of biologic agents enabled stabilization of visual acuity and significantly exerted oral and topical corticosteroid-sparing effect.

ABSTRACT BODY:

Purpose: Increasing evidence suggests that circadian rhythms modulate the development of refractive errors. This retrospective, observational cross-sectional study aimed to uncover the associations between circadian rhythms and refractive errors by analysing the chronotype or morning-evening preference of people with myopia and hyperopia.

Methods: 23,112 participants of the Estonian Biobank who had completed the Munich Chronotype Questionnaire (MCTQ) before the age of 70 were included in the analysis (35% male, aged between 17-69, median age 39 years). Chronotype was defined as the mid-point of sleep on non-working days adjusted for sleep deficit on workdays (MSFsc). The participants' electronic health records were enquired for the diagnoses of myopia and hyperopia (ICD-10 codes H52.1 and H52.0, respectively). The dataset was filtered for participants who had been diagnosed with both refractive errors. Only those who had received one of these diagnoses on at least two separate occasions were considered as having the corresponding refractive error. A logistic regression model was fitted with the outcome as myopia or hyperopia; and MSFsc, age, sex, and time people reported to spend outdoors as covariates.

Results: 4,951 participants with myopia and 2,865 with hyperopia were identified in the study population. The median MSFsc for those diagnosed with myopia was 3.9 (interquartile range, IQR 3.2–4.7), for those with hyperopia 3.3 (IQR 2.6–3.9) and those without myopia or hyperopia 3.7 (IQR 3.0–4.4). After adjusting for age, sex and time people reported spending outdoors, those with higher MSFsc (later chronotype) were more likely to be myopes (OR = 1.16, 95% CI 1.12–1.19, p = 1.53E-18). Interestingly, higher MSFsc was also positively associated with hyperopia (OR = 1.07, 95% CI 1.02–1.12, p = 0.004).

Conclusions: We demonstrate that later chronotype is positively associated with myopia and hyperopia. With access to the genomic information of the Estonian Biobank participants, further genomic analyses will reveal the potential molecular basis for these associations.

Commercial Relationships Disclosure: Kaiyue Teng: Commercial Relationship: Code N (No Commercial Relationship) | Ian Prior: Commercial Relationship: Code N (No Commercial Relationship) | Luminita Paraoan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: PERP (p53 apoptosis effector related to PMP-22) is an apoptosis-specific p53 effector downregulated in uveal melanoma. This study aimed to investigate post translational modifications of PERP and evaluate their effect on PERP regulation in relation to induction of apoptosis.

Methods: Possible phosphorylation sites were predicted by in silico analysis and halo-tag system was used to generate Halo-PERP, Halo-PERP S46A and Halo-PERP S192A constructs. Halo-tagged proteins were pulled-down from transfected human melanoma mel202 cell lysate and analysed by immunoblotting alongside caspase 3 protein forms. Flow cytometry was used to evaluate apoptosis levels in transfected mel202 cells.

Results: Phosphorylation of serine residues of PERP was identified by specific immunoblotting. Two possible phospho-serine sites, S46 and S192, were identified by in silico analysis. Western blotting showed phosphorylated bands were maintained on PERP S192A-transfected mel202 cell lysates pull-downs and not on PERP S46A-transfectants. However, the apoptosis level determined by flow cytometry was lower in Halo-PERP S192A-expressing cells compared with Halo-PERP and Halo-PERP S46A-expressing cells, consistent also with the respective expression levels of caspase 3.

Conclusions: PERP is phosphorylated on S46 residue. However, this mutant does not appear to be involved in regulation of apoptosis. Instead, given its location in the extracellular loop, it is likely to be involved in the stability of the desmosome complex and therefore possibly linked to migratory properties of uveal melanoma cells. Intriguingly, PERP S192A mutant associates with decreased apoptosis suggesting its involvement in the p53 related apoptosis through a different mechanism.

TITLE: The association between pupil diameter and apparent chord mu length value

SESSION TITLE: Cataract surgery 1

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Sella, K. Shouchane-Blum, O. Reitblat, I. Bahar, Ophthalmology, Rabin Medical Center, Petah Tikva, ISRAEL|R. Sella, K. Shouchane-Blum, O. Reitblat, I. Bahar, Tel Aviv University Sackler Faculty of Medicine, Tel Aviv, ISRAEL|

Commercial Relationships Disclosure: Ruti Sella: Commercial Relationship: Code N (No Commercial Relationship) | Karny Shouchane-Blum: Commercial Relationship: Code N (No Commercial Relationship) | Olga Reitblat: Commercial Relationship: Code N (No Commercial Relationship) | Irit Bahar: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Chord mu length represents the distance between the pupil center and the visual axis. It is considered a new reference marker for evaluation before implantation of diffractive multifocal intraocular lenses (IOLs). Previous studies suggested that multifocal IOLs should be well considered in patients with an apparent chord mu length greater than 0.6, as it may be associated with a higher incidence of halos and glare. This value can be measured by a routine biometry prior cataract surgery, using the IOL Master 700 device (Carl Zeiss Meditec, AG). Pupil diameter can vary in different patients and measure differently for the same patient at different light conditions. The purpose of this study was to evaluate the correlation between apparent chord mu length and pupil diameter.

Methods: This prospective study evaluated patients scheduled for an elective cataract surgery at a single tertiary medical center between 2021-2022. Pupil diameter and Chord mu length, in photopic condition, before and after pupil dilatation (by administering a drop of mydramide 0.5% and a drop of cyclophentolate 1%, twice, 10 minutes apart), were measured using the IOL master 700. Exclusion criteria were visual acuity worse than 20/100 and pseudophakia. Wilcoxon signed-rank was used to compare the change in chord mu length.

Results: Forty-nine eyes of 49 patients were included. Mean ± SD pupil diameter, before and after pupil dilatation was 3.11 mm ± 0.83 and 6.66 mm ± 1.14 ($p<0.001$), respectively. Chord mu length increased from 0.322 mm ± 0.22 to 0.44 mm ± 0.25 ($p=0.001$), respectively.

Conclusions: Chord mu length significantly increases after pharmacological pupillary dilatation. This should be taken into consideration in preoperative planning, especially when the apparent chord mu value is taken into account for patient selection in cases of a planned multifocal IOL.

ABSTRACT BODY:

Purpose: APX3330 is a novel, small molecule inhibitor of Ref-1, a transcriptional regulator of key angiogenic (VEGF) and inflammatory signaling pathways relevant to diabetic retinopathy (DR), diabetic macular edema (DME), and neovascular age-related macular degeneration (AMD). In over 300 subjects in 11 prior Phase 1 and Phase 2 clinical trials, oral APX3330 demonstrated a favorable safety and tolerability profile with doses up to 600mg over multiple months in healthy subjects, hepatitis patients, and solid tumor patients. The most common related adverse events (AEs) were mild diarrhea or soft stool (4% with APX3330, 2% with placebo) and mild rash or pruritis (4% with APX3330, 1% with placebo). This abstract reports the masked safety and tolerability of APX3330 in the ongoing 24-week ZETA-1 Phase 2 clinical trial.

Methods: The ZETA-1 trial is a randomized, placebo-controlled, double-masked, multi-center study designed to evaluate the efficacy and safety of oral APX3330 600mg daily dose over 24 weeks in DR patients. Safety data for 35 masked subjects who have been randomized to APX3330 or placebo has been evaluated and summarized, which represents over 1,500 total subject exposure days.

Results: In both trial arms, there have been 28 AEs reported in 16 (46%) of subjects. No adverse events have been thought to be related to the oral study medication, aside from two episodes of diarrhea in the same subject. Five serious AEs have been reported, all designated unrelated to study medication (2 cellulitis, 1 abnormal involuntary movement; before dosing 1 CAD and 1 osteomyelitis). Only 2 subjects have withdrawn from the trial due to non-serious AEs (vasovagal near syncope and worsening diabetic macular edema). With oral administration, no significant organ toxicity (liver, heart, kidney, brain, lung), no vital sign abnormalities (blood pressure and heart rate), and no rash were observed.

Conclusions: Similar to prior trials in healthy subjects, cancer patients, and hepatitis patients, oral administration of APX3330 and placebo have demonstrated a favorable ophthalmic and systemic safety and tolerability profile. Addition safety data from the ongoing ZETA-1 trial will be evaluated to further characterize the efficacy and safety of APX3330 for the oral treatment of diabetic eye diseases.

TITLE: GLAUrious, a multicentre, randomised, controlled non-inferiority study of direct selective laser trabeculoplasty in open angle glaucoma

SESSION TITLE: IOP and laser therapy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Belkin, Eye Research Institute, Tel Aviv University, Tel Aviv, ISRAEL|M. Belkin, Sheba Medical Center, Tel Hashomer, Tel Aviv, ISRAEL|

Commercial Relationships Disclosure: Michael Belkin: Commercial Relationship(s);Code C (Consultant/Contractor):Belkin Vision;Code I (Personal Financial Interest):Belkin Vision;Code P (Patent):Belkin Vision;Code C (Consultant/Contractor):NovaSight;Code I (Personal Financial Interest):NovaSight;Code P (Patent):NovaSight;Code P (Patent):SpringVision;Code C (Consultant/Contractor):SpringVision

ABSTRACT BODY:

Purpose: Effective first-line treatment of open-angle glaucoma (OAG) is currently limited by non-adherence to daily topical hypotensive medication and by lack of access to selective laser trabeculoplasty (SLT). A worldwide need therefore exists for evidence-based, cost-effective, and widely accessible treatment options for OAG, with convenient modes of administration to maximise adherence to treatment and improve long-term outcomes. Direct selective laser trabeculoplasty (DSLT) is a novel, automated, non-contact procedure in which SLT-like laser beams are delivered to the limbus to reduce intraocular pressure (IOP) in patients with OAG, that can be administered within seconds, without the use of a gonioscope and the need for the specialised training required for traditional SLT. GLAUrious (NCT03750201) is a confirmatory clinical trial to assess the safety and efficacy of DSLT, compared with conventional SLT, in patients with OAG.

Methods: In this evaluator-masked, randomised, controlled, non-inferiority study, patients aged ≥40 years with ocular hypertension or OAG, including exfoliative or pigmentary glaucoma, and untreated/washout IOP 22–35 mmHg were recruited between November 2018 and April 2021 at 13 ophthalmology centres in the United Kingdom, Italy, Israel, and the Republic of Georgia. Eligible patients were randomised 1:1 to receive DSLT or SLT. The primary outcome was between-group difference in mean IOP change from baseline to 6 months. Secondary 6-month outcomes were: proportion of patients with ≥20% reduction in unmedicated IOP from baseline; change in mean number of topical hypotensive medications from screening. Rates of adverse events in each treatment group were also evaluated.

Results: A total of 192 patients were randomised to receive treatment, 98 with DSLT and 94 with SLT. Baseline patient and eye characteristics were similar between treatment groups. Primary and secondary endpoints for non-inferiority of DSLT, compared with SLT, at 6-month follow-up will be presented.

Conclusions: The results of the GLAUrious study are expected to support use of DSLT as a widespread, convenient modality that can provide fast, effective laser treatment for OAG across a broad range of clinical settings.

TITLE: Age-Dependent Perception of Ocular Pain and its Differential Impact on Quality of Life Dimensions

SESSION TITLE: Dry Eye, Clinical

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: L. Mirzaee, M. Posarelli, P. Hamrah, Ophtalmology, Tufts Medical Center, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Leyla Mirzaee: Commercial Relationship: Code N (No Commercial Relationship) | Matteo Posarelli: Commercial Relationship: Code N (No Commercial Relationship) | Pedram Hamrah: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Ocular discomfort and pain are one of the most common reasons for ophthalmic consultations. This study aims to assess the age-dependent patient perception of ocular pain and to measure its impact on different health-related quality of life (QoL) dimensions.

Methods: A prospective, single-center, cohort study was conducted with (N= 285) patients with and without corneal and ocular surface pain who completed the multi-dimensional ocular pain assessment survey (OPAS) at an initial and one follow-up visit. The calculation comprises N=127 patients diagnosed with corneal or ocular surface pain who completed at least one item of the pain scales on the OPAS questionnaire. The OPAS comprises somatic (vision-related), social and psychological dimensions of QoL through six items. The age groups were determined as group 1 which includes patients aged 18-40, group 2 comprises ages 41-60 and group 3 considers age 61-80. For the statistical analysis, IBM SPSS Statistics for Windows was used.

Results: The mean age of study patients was 48.42 (± 16.19), ranging from 18 to 80 years. The level of eye pain intensity when it is most was 2 (IQR 0-4) (in the past 24 hours) and 3 (IQR 1-5) in the past 2 weeks. The interference of pain on QoL dimension (0-10 scale) among all ages was 5 (IQR 1-8) for reading/computer use, 4 (IQR 1-8) for driving/TV watching, 2 (IQR 0-6) for general activity, 4 (IQR 0.75-7) for mood, 2 (IQR 0-6) for sleep, and 3 (IQR 0-7) for enjoying life/relationship with other people. The interference of pain on all QoL dimensions was statistically significant: reading/computer ($R= 0.473$; $p< 0.001$), driving/TV watching ($R= 0.459$; $p< 0.001$), general activity ($R= 0.461$; $p< 0.001$), mood ($R= 0.498$; $p< 0.001$), sleep ($R= 0.477$; $p< 0.001$), enjoying life/relationship ($R= 0.477$, $p< 0.001$). Furthermore, the effect of age on pain perception increased in patients of groups 2 and 3, as compared to age group 1. The pain interference on the vision-related dimensions of QoL in age groups 2 and 3 was lower compared to age group 1. Age group 1 was most affected by the psychological (mood) and social dimensions (life relation) of QoL.

Conclusions: The current study demonstrates that ocular pain interferes with all QoL dimensions, particularly with the vision-related QoL dimensions. Older patients report stronger levels of eye pain than younger patients, althouh this has a lower impact on their QoL.

ABSTRACT BODY:

Purpose: Continuous growth of the lens in adulthood produces age-related increase in lens thickness and curvature which impact the lens power. Previous studies on biometry of the aging lens are cross-sectional. In this study, we quantify the longitudinal changes in thickness of the aging human lens using OCT.

Methods: This retrospective study evaluates lens biometry data from 10 eyes of 5 subjects (Age at the initial visit: 21, 26, 30, 34 and 42 years) acquired with a custom-built OCT system at variable intervals between sessions (6.5 months on average) over about 10 years. The system combines a fixation target with adjustable vergence and a SD-OCT system that enables imaging from the anterior corneal surface to the posterior crystalline lens (Ruggeri et al, Biomed Opt Exp 2012). Each OCT dataset consists of at least three images of the lens sequentially acquired across the horizontal meridian of the eye without repositioning the system. All images were acquired with the fixation target adjusted to a vergence of 0 D (distance). For each eye and time point, three consecutive OCT images extracted from the same dataset were processed to manually select the lens surface boundaries and calculate the lens thickness. The processing relies on peak detection of the average reflectivity profile of the lens over the 0.5 mm zone. The lens thickness was obtained from the optical path length assuming a uniform refractive index for the lens (n = 1.415). The average lens thickness across the three measurements was then calculated. Linear regression was used to describe the change in average lens thickness with age. All eyes were included in the analysis.

Results: As expected, the lens increases in thickness with age (Figure A) in all subjects (Age 21: R^2=0.704, P=0.002; Age 26: R^2=0.9996, P=0.039; Age 30, R^2=0.939, P<0.001; Age 34: R^2=0.973, P<0.001 and Age 42, R^2=0.960, P=0.001) of on average 28 µm/year (range 21 to 42 µm/year) (Figure B), which is consistent with findings from cross-sectional studies using Scheimpflug imaging (Dubbelman et al, Optom Vis Sci 2001). The increase in lens thickness was on average greater in the two oldest subjects (36 vs 21 µm/year), suggesting the lens grows faster in incipient presbyopia (Figure A).

Conclusions: We used OCT to quantify the longitudinal increase in crystalline lens thickness over 10 years in 5 adult subjects. The preliminary data suggest a faster growth of the lens in incipient presbyopia.

ABSTRACT BODY:

Purpose: A Light-curable COrnea Matrix (LC-COMatrix) derived from decellularized corneal extracellular matrix was fabricated. LC-COMatrix application to repair corneal stromal defects was evaluated ex-vivo and in vivo.

Methods: The LC-COMatrix was produced from porcine cornea by decellularization, digestion, and methacrylation. The in-situ cross-linking was achieved by combination of LC-COMatrix with a photo-initiating cocktail and curing with visible light (520 nm). The biodegradation, swelling behavior, viscosity, and rheological gelation kinetics of LC-COMatrix were studied. The adhesion-strength, burst-pressure (BP) following perforation repair, and tissue adhesiveness of LC-COMatrix were assessed ex-vivo using human corneas as substrate and compared to fibrin glue (FG) and 20% gelatin methacrylate (GelMA). The potential of LC-COMatrix to repair corneal stromal defects and full-thickness perforations was examined in a rabbit model.

Results: LC-COMatrix has proper swelling behavior, biodegradation, and viscosity for user-friendly corneal repair applications. The storage modulus of LC-COMatrix is 7.8±0.5kPA and is higher than FG (4.8±0.3kPa) and GelMA (5.1±3.2kPa). The adhesion-strength of LC-COMatrix is 21.8±2.3kPa which is significantly higher than that of GelMA (11.1±3.8kPa, $p<0.0001$) and FG (4.9±2.3 kPa, $p<0.0001$). The BP of a 2 mm perforation made by punch-biopsy and repaired with LC-COMatrix is 327±175 mmHg, while this value for GelMA is 151±48 mmHg ($p=0.007$) and for FG is 11±4 mmHg ($p<0.0001$). LC-COMatrix consistently repaired a human corneal stromal defect (10 mm diameter, 300 μm depth) and remained stable for 30 days with a smooth surface and comparable transparency to native human corneas. However, the FG degraded by day 15. In the corneal defects repaired with GelMA, the hydrogel shrank to the center of the corneal stromal defect during follow-up. Moreover, LC-COMatrix successfully integrated and repaired 3-mm lamellar defect in rabbit corneas which the epithelium regenerated, and the defect area remained transparent at 28 days follow-up. Additionally, the corneal macro-perforation (1-mm) in rabbit cornea was repaired with LC-COMatrix with healed epithelium and no subsequent leakage for 28 days.

Conclusions: LC-COMatrix is a natural ready-to-apply bio-integrating adhesive that is representative of the native corneal matrix with potential applications in corneal and ocular surgeries.

ABSTRACT BODY:

Purpose: This study investigated differences in the types and size of giant vacuoles (GVs) at 7 mmHg (physiological pressure in enucleated eyes) and an elevated pressure of 15 mmHg in the inner wall endothelium of Schlemm's canal (SC), using serial block-face scanning electron microscopy (SBF-SEM) and subsequent three-dimensional (3D) reconstruction of GVs.

Methods: Four normal human eyes from four donors were perfused, two at 7 mmHg and two at 15 mmHg, with fluorescent tracers to label the segmental outflow pattern followed by perfusion-fixation. Three radial wedges of tissue including SC from high-, low-, and non-flow areas of each eye based on tracer distribution was processed for SBF-SEM. A similar number of images was analyzed at 7 mmHg (9586) and 15 mmHg (9802). GVs were counted and typed (Type I: no basal opening or I-pore, Type II: basal opening, no I-pore, Type III: I-pore, no basal opening, and Type IV: basal opening and I-pore). A subset of GVs was randomly selected for 3D reconstruction to measure GV volume. For the reconstructed type II GVs, thickness of cellular lining around GVs was measured.

Results: There was a greater number of GVs at 15 mmHg (3302) compared to 7 mmHg (1312). Type IV GVs were more abundant in the high-flow than non-flow areas at both pressures ($P<0.01$). GVs with I-pores were significantly larger than GVs without I-pores in all flow-type areas at both pressures ($P<0.01$). For GV volume across all flow-type areas, GVs with I-pores were not significantly different between pressures. However, GVs without I-pores were significantly larger in volume at elevated pressure ($P<0.01$). Type II GVs had thinner cellular lining at 15 mmHg ($P<0.01$).

Conclusions: SBF-SEM and 3D reconstruction allowed for accurate identification of GV types and size. Comparing both pressures, the volume of GVs with I-pores were similar, while the volume of GVs without I-pores were larger at elevated pressures. This may indicate a threshold size of GVs for pore formation. GVs with I-pores were significantly larger than GVs without I-pores in all flow-type areas at both pressures suggesting that larger size of GVs is a contributing factor for GV-associated I-pores. More Type IV GVs observed in the high-flow areas at both pressures suggest increasing this type of GV may increase the total high-flow area.

ABSTRACT BODY:

Purpose: This study examined conversion rates from non-exudative (dry) to exudative (wet) age-related macular degeneration across different patient populations using real-world data from the AAO IRIS Registry (Intelligent Research in Sight).

Methods: A retrospective cohort analysis was conducted using the IRIS Registry spanning 2016-2019. A total of 2,664,789 patients with dry AMD in at least one eye were included in this study. Observed patient characteristics including age, sex, race, geographic region, and smoking status; dry and wet AMD stage; and conversion time from dry to wet AMD. Descriptive statistics and hazard ratios (HRs) from a Cox proportional hazard model were conducted across these characteristics.

Results: Overall conversion rates from dry to wet AMD were 2.0, 6.1, and 6.7% for early, intermediate, and advanced stages respectively ($p<0.001$). Among those converting to wet AMD, there was decreased risk for males relative to females (HR 0.89, 95% CI [0.88, 0.89]) and Asians (HR 0.52, 95% CI [0.50, 0.54]) or Blacks/African-Americans (HR 0.39, 95% CI [0.37, 0.40]) relative to whites. Relative to patients with bilateral dry AMD, those with wet AMD in one eye and dry in the other eye (HR 5.65, 95% CI [5.56, 5.75] and those with unilateral dry AMD (HR 3.60, 95% CI [3.57, 3.63] had a higher risk of conversion for the eye with dry AMD. Relative to patients with early dry AMD, those with intermediate dry AMD (HR 2.46, 95% CI [2.41, 2.51] and advanced dry AMD (HR 2.69, 95% CI [2.61, 2.77]) had a higher risk of conversion. Among patients with dry AMD in one eye and wet AMD in the other eye, compared with having active choroidal neovascularization in one eye, those with wet AMD with inactive choroidal neovascularization (HR 0.60, 95% CI [0.56, 0.64]) and wet AMD with inactive scar (HR 0.58, 95% CI [0.53, 0.62]) in one eye had a lower risk of conversion to wet AMD in the fellow eye.

Conclusions: In this cohort analysis of the IRIS Registry, females, whites, and smokers had higher risk of conversion from dry to wet AMD. Patients with one eye with wet AMD and one eye with dry AMD and patients with unilateral dry AMD were more likely to convert than patients with bilateral dry AMD. More advanced stages of dry AMD and active choroidal neovascularization in the fellow eye were associated with higher risk of conversion.

ABSTRACT BODY:

Purpose: Beta-adrenergic blockade has been shown in non-human models to have anti-VEGF effects including choroidal neovascularization (CNV) regression. However, previous clinical studies of age-related macular degeneration (AMD) patients have shown conflicting results in the association between beta blocker (BB) use and clinically significant changes in neovascularization or AMD progression. We performed a novel analysis utilizing prospective data to investigate this question.

Methods: We analyzed intermediate AMD (iAMD) patients recruited into the University of Colorado AMD Registry. Grading of AMD stage was performed by two vitreoretinal specialists using multimodal imaging. At enrollment, baseline information was collected including the use of systemic BB medications. We compared the proportion of iAMD patients who were on a systemic BB at enrollment who did progress to advanced AMD with those who did not progress. We also compared the subset of converters to neovascular AMD and geographic atrophy (GA) and performed Kaplan-Meier (K-M) failure analyses to assess the risk of progression by BB use.

Results: 340 iAMD patients were included with a mean age of 75.5 (SD 11.6) and mean follow-up was 33.7 months. Eighty (23.5%) patients were using a systemic BB at time of enrollment. In total, 17.9% of patients converted to advanced AMD, 39 to NV and 24 to GA. There was no significant difference in the proportion of non-converters who were using a BB (24.0%), and those who did convert and were using a BB (21.3%) ($p = 0.652$) (Table 1). Conversion to neovascular AMD or GA was also not associated with decreased BB use (25.6% and 16.7%, $p = 0.741$ and 0.411, respectively). In K-M analysis, BB use was not associated with risk of conversion to advanced AMD ($p = 0.517$) (Figure 1) or to neovascular AMD ($p = 0.863$).

Conclusions: In this prospective AMD cohort, BB use at time of enrollment was not associated with risk of progression from intermediate to advanced AMD.

TITLE: The diversity of genetic testing platforms for inherited retinal diseases

SESSION TITLE: Inherited Retinal Disease Genetics I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Mustafi, J.R. Chao, Ophthalmology, University of Washington, Seattle, Washington, UNITED STATES|D. Mustafi, Ophthalmology, Seattle Children's Hospital, Seattle, Washington, UNITED STATES|

Commercial Relationships Disclosure: Debarshi Mustafi: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Chao: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate genetic testing platforms used to aid in the diagnosis of inherited retinal degenerations (IRDs). As clinical trials for other IRDs progress to treatment, genetic testing will be essential to properly identify patients who may benefit from intervention.

Methods: Data collected regarding targeted genetic panel testing for IRDs offered by different labs were investigated for inclusion of coding and non-coding variants in disease genes. Both large IRD panels and smaller, more focused disease specific panels were included in the analysis. The list of genes assayed by each IRD panel as well as inclusion of any non-coding variants was documented. The genomic location and name of each disease gene was documented across each panel. If non-coding variants were tested it was documented for the gene in question. This curated list was then compared to examine overlapping and unique genes across testing platforms.

Results: Across the three comprehensive IRD panel tests investigated, 404 unique genes are represented, of which 258 genes are tested by all three panels. The top 20 genes known to cause over 70% of all IRDs were represented in the 258 common genes tested by all three panels. In addition, 138 non-coding variants are assayed across the three platforms in 50 unique genes. Focused disease specific panels exhibited significant variability across the 5 testing platforms studied.

Conclusions: Ordering genetic testing for IRDs is not straightforward, as evidenced by the multitude of panels available to providers. It is important that there is coverage of both coding and non-coding regions in IRD genes to offer a diagnosis in these patients. This work details the diversity of testing platforms currently available to clinicians and provides a thorough explanation of genes tested in the different IRD panels. More importantly, this analysis highlights the commonalities and differences that separate these tests. In a time of increased importance for clinical genetic testing of IRD patients, knowledge of the proper test to order is paramount.

ABSTRACT BODY:

Purpose: Vascular endothelial growth factor-C and D (VEGF-C/-D) are angiogenic mediators which may contribute to treatment escape with VEGF-A suppression of retinal disease. The aim of this investigation was to assess combination therapy of OPT-302 (anti-VEGF-C/-D) with ranibizumab (anti-VEGF-A) for the treatment of polypoidal choroidal vasculopathy (PCV).

Methods: Prespecified subgroup analysis of a Phase 2b, randomized, sham-controlled study of OPT-302 administered to treat neovascular age-related macular degeneration (NCT03345082). Participants in the subgroup analysis had PCV identified in the study eye by masked readers at a central reading center. Polyps were identified and defined using multimodal imaging, including fundus photography (subretinal orange nodules), fluorescein angiography (typical primarily occult multifocal lesions) and spectral domain optical coherence tomography (notched, sharply peaked or multi-lobular pigment epithelial detachments with or without a ring of hyperreflectivity along the inner border). Eyes were randomized to receive 6-monthly intravitreal injections of either ranibizumab (0.5 mg) + OPT-302 (0.5 mg or 2 mg) or ranibizumab + sham. Outcomes measures included best-corrected Early Treatment Diabetic Retinopathy Study visual acuity (BCVA), anatomic changes, and safety / tolerability.

Results: Sixty-six participants with PCV were included. OPT-302 with ranibizumab was well tolerated, consistent with the full study population, with no clinically significant safety findings. The mean BCVA change from baseline to week 24 showed a dose response in participants with PCV, who gained 13.5 letters in the 2 mg OPT-302 combination group (n = 22), 10.9 letters in the 0.5 mg OPT-302 combination group (n = 24) and 6.9 letters in the ranibizumab control group (n = 20). The +6.7 letters comparative superiority of 2 mg OPT-302 combination therapy over ranibizumab (p = 0.0253) was accompanied by a greater proportion of participants gaining ≥ 10 or ≥ 15 letters, fewer losing ≥ 5 letters and fewer with retinal fluid at week 24.

Conclusions: OPT-302 combination therapy was well tolerated, with greater improvements in BCVA and less retinal fluid compared to ranibizumab monotherapy in participants with symptomatic macular PCV. Larger studies of dual inhibition of VEGF-C/-D and VEGF-A for the treatment of PCV are warranted.

TITLE: Quantification of Unused Pharmaceuticals for Retrobulbar Blocks in Retina Surgeries at a Tertiary Care Hospital

SESSION TITLE: Eyecare delivery and economics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Toribio, U. Mian, J. Tauber, Montefiore Medical Center, Bronx, New York, UNITED STATES|A. Rai, J. Tauber, Albert Einstein College of Medicine, Bronx, New York, UNITED STATES|

Commercial Relationships Disclosure: Tiana Toribio: Commercial Relationship: Code N (No Commercial Relationship) | Umar Mian: Commercial Relationship: Code N (No Commercial Relationship) | Anvit Rai: Commercial Relationship: Code N (No Commercial Relationship) | Jenna Tauber: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To quantify the impact of unused medications for the administration of retrobulbar blocks during retinal surgeries.

Methods: This prospective observational study of 8 consecutive cases performed by a single vitreoretinal surgeon was performed at Montefiore Medical Center, Bronx, NY in December 2021. Standard retrobular injection medications (single dose vials of 10mL of 0.75% bupivacaine and 5mL of 2% lidocaine) used for preparation of 1:1 10mL retrobulbar block were weighed (ounces) a. prior to opening, b. after medications were drawn up, c. a representative empty bottle was weighed. The quantity of the prepared block that was administered was noted. The quantity of medication that was ultimately used and left unused was quantified by weight and percent. Using the medication purchasing costs, the costs of the unused medications were calculated.

The environmental emissions and impacts from unused medications were calculated using the purchaser price model in the economic input-output life cycle assessment (EIO-LCA) model and the US Environmental Protection Agency's tool for the reduction and assessment of chemical and other environmental impacts (TRACI; version 2.1).

Results: On average, 0.29 oz of 0.75% bupivacaine (74.05%) and 0.11oz of 2% lidocaine (55.79%) were unused per case. On average, 5mL of the prepared 10mL were administered as a retrobulbar block. Costs and environmental emissions of unused medications are shown in Table 1 for a single case, for 100 cases and for 150 cases. Average cost of unused medications per case was $1.29, equating to 0.016 kg CO_2 emissions for pharmaceutical preparation manufacturing. For this surgeon at our institution (estimated 150 surgeries/year) approximately $193.61 for every $294 spent are wasted.

Conclusions: The cost and carbon footprint of unused medications from retrobulbar blocks from a single surgeon are relatively small but meaningful. There are an estimated 300,000 retinal surgeries performed annually in the US (Charles S. Retinal Physician, 2017), so the impact of this waste may be amplified when considered on a larger scale.

ABSTRACT BODY:

Purpose: To develop a machine learning(ML) aided pipeline to automatically confirm geographic atrophy(GA) using real-world fundus autofluorescence(FAF) and infrared reflectance(IR) images linked to the IRIS Registry

Methods: The American Academy of Ophthalmology IRIS® Registry(Intelligent Research in Sight)is the nation's first comprehensive eye disease clinical database, with over 70% of US ophthalmologists contributing. A ML aided pipeline was developed for the IRIS Registry, using a de-identified clinicoimaging dataset with images contributed by 2 large retina practices, patients with a dry age-related macular degeneration(AMD) diagnosis were identified from 2006 to 2019. ML models were developed to assess FAF and IR image quality using features of signal, contrast, noise and sharpness. FAF images with a predicted quality score lower than 0.4[range: 0-1] were excluded. For patients with multiple images at the same encounters, or multiple encounters, the image with the highest quality score was selected. Lastly, training and testing sets were selected using patient-level stratified sampling(age, sex, and race) and labeled by a trained grader. Two deep learning models were developed to classify patients into three categories: no GA, GA without subfoveal involvement, and GA with subfoveal involvement. The models were trained on the training sets with an 80:20 split for training and validation. The trained models were then deployed on the entire cohort

Results: In total, 15,023 FAF and 16,470 IR images from 4,372 eyes of 2,248 patients were identified. After removing low quality images(1,931 FAF images) and multiple images from the same visit(6,825 FAF images, 8,285 IR images), 6,267 pairs of FAF and IR images from 3,372 eyes of 1,872 patients were included. A training set of 442 patients and a testing set of patients(one pair of FAF and IR images per patient) were selected from the cohort. A modified VGG network was developed for GA diagnosis. The model achieved an accuracy of 0.96, 0.96 and 0.94 for training, validation and testing, respectively. The second model for subfoveal involvement is under development

Conclusions: The proposed pipeline demonstrated satisfactory performance confirming GA in AMD eyes using images collected in routine practice. It could potentially be useful in screening patients for GA trials and future GA treatments

ABSTRACT BODY:

Purpose: Corneal blindness due to scarring is treated with cornea transplantation. However, there exists a global challenge of donor material shortage. Preclinical and clinical studies have shown that cell therapies using corneal stromal stem cells (CSSC) suppress scar formation. However, not every CSSC batches achieve stromal regenerative effects. MicroRNA-29 is a “master fibro-regulatory miRNA”, with pivotal roles in regulating tissue fibrosis. Our group identified an upregulated expression of hsa-miR-29a in extracellular vesicles (EV) produced by human CSSC with good healing effects. This work examined miR-29a expression among CSSC batches, and the anti-scarring potency of cells was assessed with a mouse model of corneal injury. We aimed to design a quantitative tool to screen CSSC with healing potency for clinical applications.

Methods: EV fractions from conditioned media of human CSSC cultures (from n=13 donors) were harvested for small RNAs using miRNeasy protocol (Qiagen). The abundance of miR-29a and 16 (housekeeping EV-miRNA) was analyzed with Taqman RT-PCR assay (Thermo Fisher). Corneal stromal wound was induced by Algerbrush burring in Swiss-webster mice (n=18) and treated with human CSSC ($5x10^4$ cells) in fibrin gel. Corneas were examined by Spectral Domain OCT every 4 days and harvested at day 14 for scar evaluation and fibrosis marker expression analysis by qPCR and immunohistochemistry.

Results: The normalized levels of miR-29a expression were upregulated in EV fractions of HC540 and 641 and were low in HC572 and 618 ($P<0.05$, Mann-Whitney U test). On injured mouse corneas, topical treatment using HC540 and 641 (high miR-29a levels) nearly prevented corneal scarring, maintained normal corneal thickness, and lower expression levels of fibrosis genes (mouse collagen III, fibronectin, α-smooth muscle actin, and Thy-1). In contrast, treatment with HC618 and 572 (low miR-29a levels) resulted in thicker corneas with intense scarring, and upregulated fibrosis gene expression, similar to wound controls.

Conclusions: We demonstrated that EV-miR-29a expression could distinguish CSSC with anti-scarring quality, providing a tool to select suitable CSSC for clinical applications.

ABSTRACT BODY:

Purpose: To determine the test-retest repeatability in quantifying macular capillary perfusion density (CPD) using optical coherence tomography angiography (OCTA) in a multi-center setting.

Methods: OCTA data was obtained in self-reported healthy subjects from Bascom Palmer Eye Institute at the University of Miami (UM, N = 18) and the University of Pennsylvania (UPenn, N = 25). OCTA was repeated at an interval of one week for assessment of repeatability (precision) in the same subjects. Analysis of OCTA-derived capillary perfusion density (OCTA-CPD) focused on the macula. Image processing procedures and fractal analysis developed in our lab were used to process OCTA data. Fractal analysis was performed on the skeletonized vascular images to yield vessel densities by box-counting in an annulus to fractal dimension (Dbox) yielding OCTA-CPD. Large vessel and microvessel network densities (D_{box}) as CPD of annuli (0.5-2.5 mm in diameter from 3 mm scans and 0.5 – 5.0 mm from 6 mm scans) in the total retinal vascular network (RVN), superficial (SVP), and deeper vascular plexuses (DVP) were analyzed. Repeatability was assessed by 3 measures: standard deviation (SD), coefficient of variation (CV) of repeated measures, and intraclass correlation coefficient (ICC).

Results: SD, CV, and ICC are listed in table 1. Both sites (UPENN and UM) had similar results. The CV% was about 0.5% which presents high measurement repeatability. However, the ICC was lower than expected, possibly due to the narrow CPD ranges in this healthy cohort. The ICC for the 3 mm scans was higher than that for the 6 mm scans from both sites.

Conclusions: While data collection and analysis are ongoing, our preliminary data showed high repeatability in both research sites, according to the CV. Scans with the 3 mm setting appear to be more repeatable.

ABSTRACT BODY:

Purpose: Corneal neovascularization (CN) is a major cause of vision loss worldwide. Steroids are widely used to treat CN, but the results are highly variable. Glucocorticoids act through binding to both glucocorticoid (GR) and mineralocorticoid receptors (MR). MR overactivation contributes to retinal and choroidal neovascularization, and endothelial MR invalidation reduces CN in mice. In a rat model of CN induced by limbal deficiency, MR antagonism also inhibits CN and upregulates GR expression tilting the GR/MR balance in favor of GR pathway. We thus aimed to evaluate the additive effects of MR antagonism combined with glucocorticoids for CN.

Methods: CN was induced in one eye of Lewis rats by a 360° circumstance total corneal de-epithelialization and limbal cell scratching. Rats were injected with systemic MR antagonist (MRA) spironolactone (SPL, 25mg/kg/day) or vehicle for 14 days alone or in combination with subconjunctival injection of dexamethasone (DEX, 4 mg/ml) at day 3 and 7 or triamcinolone acetonide (TA, 4 mg/ml) at day 3. Corneal morphology and thickness were assessed in vivo at day 3, 7 and 14 using Micron III optical coherence tomography (OCT). Corneal re-epithelialization was evaluated by fluorescein staining under slit lamp at day 3 and 7. Fluorescein (FA) and indocyanine green angiographies (ICG) were performed at day 14 to evaluate the surface of CN. Peripheral cornea and tissues adjacent to limbus were dissected at day 3, 7 and 14 for quantitative PCR and at day 3 and 7 for transcriptomic analysis.

Results: SPL combined with TA showed a greater anti-angiogenic and anti-inflammatory effect compared to SPL alone and improved the corneal re-epithelialization delayed by TA. The effect of combination treatment of SPL and DEX was not different from SPL alone. The transcriptomic analysis identified a greater number of differentially expressed genes in the combined treatment of SPL and TA than SPL or TA alone. Gene set enrichment analysis showed pathways involved in corneal wound healing and differentiation, infectious responses, inflammatory and immune responses, myogenesis, hypoxia, angiogenesis and neuroprotection, suggesting synergetic effects.

Conclusions: The combined treatment of MRA and TA has additive effects on CN and could be a potential therapeutic option for CN.

ABSTRACT BODY:

Purpose: Myopia is a growing public health problem due to its association with sight-threatening conditions. In Africa, the problem is exacerbated by lack of ophthalmic services and spectacle coverage, such that uncorrected refractive error is the leading cause of vision impairment. This study was designed to provide contemporary and future estimates of childhood myopia prevalence in Africa.

Methods: A systematic online literature search (PubMed, Google Scholar, Cochrane Library, Africa Journals Online, Scopus) was conducted for articles on myopia (≤-0.50D or VA≤6/9.5 correctable with minus lenses) from 2001-2021 in Africa. Meta-analysis [OpenMeta (analyst)] was performed to estimate the prevalence of childhood myopia and high myopia. Freeman-Tukey double arcsine transformation was used to minimize the effects of high/low prevalence on the overall pooled estimates. Myopia prevalence from subgroup analysis for urban and rural settings were used as baseline for generating a prediction model using linear regression (SPSS V28).

Results: Forty studies from 19 (of 54) African countries were included in the meta-analysis (N=735400). Overall prevalence of childhood myopia and high myopia was 4.7% (95% CI: 3.8%–5.8%) and 0.4% (95% CI: 0.2%–0.8%), respectively (Fig 1). Prevalence of myopia from 2011-2020 was approximately double that from 2001-2010 for all studies combined and between 2 and 2.5 times higher for ages 5-11 and 12-18 years, for males and females and urban and rural settings, separately. Childhood myopia prevalence is expected to increase in urban settings to 11.1% by 2030, 14.4% by 2040, and 17.7% by the year 2050, marginally higher than expected in the overall population (16.4% by 2050) and noticeably higher than in rural settings (8.4% by 2050) (Fig 2).

Conclusions: Prevalence of childhood myopia has approximately doubled since 2010, with a further 3-fold increase predicted by 2050. This trend has potentially serious implications despite the comparatively low myopia prevalence in Africa. Provision of myopia control treatments is desirable, but implementing basic myopia prevention programs, enhancing spectacle coverage and ophthalmic services as well as generating more data to better understand the changing myopia epidemiology in Africa merit greater attention.

SUBMITTER (NAME ONLY): Abbie Jensen

TITLE: Zebrafish models of Stargardt Disease reveal RPE and cone photoreceptor defects that suggest mechanisms of disease

SESSION TITLE: Macular Diseases excluding AMD

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: A.M. Jensen, Molecular and Cell Biology Graduate Program, University of Massachusetts Amherst, University of Massachusetts Amherst, Amherst, MA, US, academic, Amherst, Massachusetts, UNITED STATES|A.M. Jensen, J. Willoughby, Biology, University of Massachusetts Amherst, Amherst, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Abbie Jensen: Commercial Relationship: Code N (No Commercial Relationship) | John Willoughby: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Juvenile onset macular degeneration, Stargardt (STGD) disease, affects nearly 1:8,000 people and age-related macular degeneration (AMD) is the leading cause of vision loss in people over the age of 50. Both diseases arise primarily from the loss of cone photoreceptors. Recent advances in genome engineering technology and the cone-rich retina of the zebrafish model organism provides the powerful and unique opportunity to create macular degeneration disease models for developing new therapies to slow, prevent, or reverse cone photoreceptor degeneration and prolong vision.

Methods: STGD disease is most commonly caused by mutations in ABCA4. Using CRISPR/Cas9, we created double null mutants for the two zebrafish abca4 homologs (abca4a and abca4b) that also include transgenic fluorescent reporters for retinal pigmented epithelium (RPE) and UV cones. We examined aged retinas labeled with cone subtype specific markers and visualized lipofuscin.

Results: Our analyses of aged (17 month) abca4 double mutants reveals all cone outer segment (COS) subtypes are dysmorphic: green COSs appear longer and thinner, crumpled with ragged outlines; UV COS appear longer and thinner; red COSs are much longer; and blue COSs are distinctly dysmorphic. Rod outer segments appear normal in the mutants. RPE phagocytosis of all COS subtypes is altered, with fewer green, red, and blue phagosomes, but more UV phagosomes present in RPE cell bodies (while none are in wildtype (wt) RPE). abca4 double mutant RPE is dystrophic; showing loss of microvillar alignment and gaps/holes. COS quantification reveals reduced numbers and phagosome quantification (per COS) shows diminished RPE phagocytosis.

Lipofuscin accumulation is observed in STGD disease, but its causal relationship to degeneration is unclear. To examine lipofuscin in the zebrafish Stgd mutants, we used 4-channel laser scanning confocal (LSC) and Fluorescence lifetime imaging microscopy (FLIM). Few, if any, structures in the wt retina are consistent with fluorescence profiles expected for lipofuscin but in the abca4 double mutant, there are several large and bright structures in both the 'lipofuscin' confocal channel and FLIM.

Conclusions: This zebrafish Stgd model provides the unique opportunity to begin to identify and understand the cellular and molecular processes that contribute to cone degeneration in STGD and perhaps to AMD.

ABSTRACT BODY:

Purpose: Retinopathy of prematurity (ROP) is a leading cause of childhood blindness. Infants with ROP receive intense surveillance of their ROP status while they are in the neonatal intensive care unit (NICU). There is, however, a paucity of research regarding the outcomes and treatment of infants with unresolved ROP following discharge from the NICU. Thus, the purpose of our study was to focus on infants who were classified as having unresolved type 2 or low grade ROP at discharge and determine the number of infants who required ROP treatment following discharge.

Methods: This descriptive study was conducted at an academic eye center. Using an ROP registry (2006-2021), we identified infants with type 2 (defined as ROP without plus disease that is stage 1-2 in zone 1, or stage 3 in zone 2) and low grade ROP (defined as ROP not qualifying as type 1 or type 2 ROP) at the time of NICU discharge. We examined the infants' medical records to determine the clinical follow-up and to specifically identify the number of infants who required ROP treatment after discharge.

Results: Our analysis included 114 (21%) infants with type 2 ROP and 433 (79%) infants with low grade ROP whose ROP had not resolved before discharge from the NICU. 337 infants (61.6%) were followed through resolution as an outpatient at our institution. Three (0.9%) of these infants required treatment after discharge. One infant, who was ventilator dependent throughout their first year, received laser treatment for delayed vascularization at 81 weeks post-menopausal age (PMA). Another converted from type 2 to type 1 ROP shortly after discharge, requiring laser treatment at 40 weeks PMA. The third infant received laser treatment for arrested vascularization and signs of reactivity in zone 3 at 68 weeks PMA.

Conclusions: Among infants with type 2 and low grade ROP, we found less than 1% required laser treatment after discharge from the hospital. The majority of infants received outpatient care at our institution. While the percentage of infants who required treatment after discharge was encouragingly low, adequate follow-up remains essential to preventing negative outcomes.

ABSTRACT BODY:

Purpose: With the advance in single-cell omics technologies in the last decade, studies have identified more than 100 different subtypes of retinal cells in the mouse retina. One of the major drawbacks in the current technologies is that they require the dissociation of the tissue, resulting in the loss of spatial information. The purpose of this study is to establish the first single cell spatial atlas of the mouse retina using spatial transcriptome technology.

Methods: To generate the spatial atlas of the mouse retina, we performed single cell spatial transcriptomics analysis on the wild type C57Bl/6J mouse retina using multiplexed error-robust fluorescence in situ hybridization (MERFISH). Based on single cell RNA-seq (scRNA-seq) data from the mouse retina, probes against a panel of 368 cell subtype marker genes were designed and synthesized. To achieve accurate cell segmentation in the highly packed retina, a set of oligo-conjugated antibodies specific to a cell membrane protein was co-stained with MEFISH probes. Deep-learning segmentation algorithms were then used to identify cell boundaries and assign transcripts to single cells. Using single-cell analysis tools such as scVI, tangram, and Giotto, cell type annotation and further downstream spatial analysis were performed.

Results: Six MERFISH experiments each containing 4-9 tissue sections were performed to generate spatial transcriptomic profiles of ~200,000 cells in total. By leveraging scRNA-seq data through data co-embedding, all major cell types and 120 cell subtypes in the retina have been identified. Investigation of the C57Bl/6J single cell spatial atlas revealed that a group of 8 amacrine cell subtypes are mis-localized in the ganglion cell layer, including the previously reported starburst amacrine cells. Spatial proximity analysis has further identified cell subtype pairs that exhibit spatial interaction, such as bipolar cell subtypes 1A and 1B (BC1A and BC1B). Lastly, co-embedding with scRNA-seq data was used to impute gene expression of MERFISH cells, generating spatial expression pattern of the entire transcriptome.

Conclusions: In short, we have generated the first comprehensive spatial single cell reference map of the mouse retina, an essential step toward gaining a comprehensive understanding of the mechanism of retinal function.

ABSTRACT BODY:

Purpose: Allergic eye disease can lead to corneal cicatrisation and vision loss. Topical or systemic dexamethasone and/or cyclosporin A is often required. Topical administration of Nomacopan, a bifunctional recombinant biologic, was shown to effectively attenuate ocular surface inflammation in a model of experimental allergic conjunctival disease (EAC)[1]. The aim of this study was to compare the anti-inflammatory effects of Nomacopan with topical dexamethasone.

Methods: EAC was induced by immunizing 8-10 week old female C57Bl/6J mice (n=8 per group) with ovalbumin (OVA; 1mg)[2] followed, on day 21, with once daily challenges with topical OVA (250ug/mL) for 12 days. Ocular surface inflammation was readily detectable by Day 5 of OVA challenge. Topical Nomacopan at various concentrations (0.063%-0.5%) or dexamethasone (0.1%) was applied twice daily in both eyes from Day 6. Placebo-treated and unchallenged groups were used as controls. All eyes were examined daily and clinical scores assessed from Day 7 post OVA challenge. Animals were euthanised and eyes harvested for histology, flow cytometry and intracellular cytokine expression.

Results: Nomacopan (0.25, 0.5%), but not dexamethasone, significantly downregulated EAC on Day 7 whereas, on Day 10, all three treatments were equally effective when compared to placebo in decreasing EAC clinical scores [p=0.001]. Lower concentrations of Nomacopan were ineffective. Histological findings matched the clinical scores. Conjunctival $CD4^+$T cells were elevated in all treatment groups compared to unchallenged animals. Percentages of conjunctival IL-9^+cells and IL-4^+GATA3^+ $CD4^+$T cells (Th2) were increased in all OVA challenged groups and were significantly inhibited by Nomacopan treatment, but not by dexamethasone. In contrast, IL-4^+IL-9^+CD4^+T cells were significantly decreased [P<0.001] by all three treatments.

Conclusions: Topical Nomacopan suppressed inflammation in EAC by downregulating Th2 and Th9 cells, whereas dexamethasone only decreased Th9 cells, suggesting Nomacopan as an additional treatment option for allergic eye disease.

ABSTRACT BODY:

Purpose: To compare DR severity identified on handheld retinal imaging with UWF and ETDRS photographs.

Methods: Mydriatic images of 225 eyes in 116 diabetic patients were taken with the Aurora (AU) handheld retinal imager and compared with stereoscopic UWF images and standard 7-field ETDRS photos taken at the same visit. Monoscopic 5-field imaging protocol was used for handheld images (centered on macula, optic nerve, and steered superior, inferior, and temporal). Images were evaluated for DR severity by certified graders using the International Classification for DR. Exact and within 1-step agreement between the two imaging modalities were determined, simple and weighted kappa statistics (K/Kw) were calculated. Grading discrepancies were adjudicated to determine the lesions and the sources of error.

Results: Distribution of DR severity by AU/ETDRS photos/UWF images (%): no DR 41.3/33.3/36.0, mild nonproliferative DR (NPDR) 18.7/20.4/17.8, moderate 10.2/14.2/10.7, severe in 16.4/11.6/15.1, proliferative DR (PDR) 13.3/20.4/20.4. All eyes were gradable by all modalities. Agreement between ETDRS and AU images was exact 65.8%, within 1-step 93.8%, k= 0.55 kw=0.75. Agreement between ETDRS and UWF was exact 70.6%, within 1-step 98.7%, k= 0.62 kw=0.81. Agreement between UWF and AU was exact agreement 68.0%, within 1-step 92.9%, k= 0.58 kw=0.76. Table 1 shows the cross-tabulation of DR severity by UWF and AU. Discrepancy of ≥2-steps between UWF and AU was observed in 16 eyes [8(50%) not in AU field, 6(37.5%) poor AU image quality, 2(12.5%) AU grader error) and the lesion causing the discrepancy was intraretinal microvascular abnormalities 5(31.2%), hemorrhages or microaneurysms 4 (25.0%), vitreous/preretinal hemorrhage 4(25.0%, figure 1), new vessels 3(18.8%)]. Using a referral threshold of moderate NPDR, 3(6.5%) eyes with PDR will be missed by AU due to limited field, while for a threshold of severe NPDR, 10(21.7%) eyes with PDR would be missed by AU due to image quality and field discrepancies.

Conclusions: Mydriatic 5-field handheld images using AU had moderate to strong agreement with UWF and ETDRS imaging. However, depending on the referral threshold, substantial levels of vision-threatening disease may be missed, suggesting that lower thresholds of referral are warranted if handheld devices are to be used.

ABSTRACT BODY:

Purpose: Full-field stimulus thresholds (FST) are essential in assessing visual function, especially in patients with severe visual impairment. We describe the distribution of luminance thresholds in subjects with retinitis pigmentosa (RP), aiming to establish a deep phenotyping system.

Methods: Cases with RP who have severe visual acuity decline (counting finger or worse) were enrolled. Comprehensive clinical examinations were performed, including full-field electroretinograms (ffERGs) recorded according to the ISCEV standard. Full-field color stimuli were generated by the Diagnosys Profile ganzfeld ColorDome (Diagnosys, LLC, MA, USA) which utilizes narrow-band LEDs of 448 nm (blue), 530nm (green), and 627 nm (red). FST was performed according to the previously published method (Klein, Birch 2009). The dark-adapted color FST was performed after 40 minutes dark adaptation in the following order: (i) blue; (ii) red; and (iii) white stimulus. The FST data obtained in RP patients were compared with those of seven healthy participants (median age 29, range 23 to 45 years) with no ocular diseases.

Results: The median age of disease onset/age at examination of 28 eyes from 14 cases with RP was 9.0 (range, 0 to 40)/64.0 (36 to 75). The median visual acuity of 28 eyes was 2.7(range, 1.98 to 3.00) LogMAR unit. The full-field ERGs were undetectable both in dark-adapted and light adapted conditions in all 14 RP cases. The median value of thresholds for blue/red/white FST was 7.06(range, -33.1 to 21.8)/10.00(-6.5 to 18.9)/9.37(-25.5 to 24.7) dB. The median value of thresholds for blue/red/white FST was -59.9/-35.8/-54.0 dB in the seven healthy subjects. FST revealed a significant different range of thresholds for each colour stimulus between severe RP patients and healthy subjects.

Conclusions: Distribution of luminance thresholds was demonstrated in 14 cases with severe RP, which was significantly higher than that of healthy participants. Quantitative assessment for patients with severe visual impairment was available with FST, in keeping with previous reports (Roman AJ et al. Prog Retin Eye Res. 2021; Klein et al. Doc Ophthalmol. 2019). Further data from additional affected participants are required to validate the clinical investigation in patients with severe visual impairment.

TITLE: TLR3 and TLR4 regulate complement-induced AMD cellular phenotype in iPSC-derived retinal pigment epithelium

SESSION TITLE: Pathobiology of AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.G. David, C. Zhang, A. Fausey, R. Sharma, M. Farnoodian, K. Bharti, National Eye Institute, Bethesda, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Joys Annika David: Commercial Relationship: Code N (No Commercial Relationship) | Congxiao Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Fausey: Commercial Relationship: Code N (No Commercial Relationship) | Ruchi Sharma: Commercial Relationship: Code N (No Commercial Relationship) | Mitra Farnoodian: Commercial Relationship: Code N (No Commercial Relationship) | Kapil Bharti: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Alternate complement signaling via NF-kB activation is known to regulate subRPE drusen and intracellular lipid deposition in iPSC-derived RPE (iRPE) models of age-related macular degeneration (AMD). Although toll-like receptor (TLR) stimulation is known to culminate in NF-kB activation, whether it is responsible for triggering complement-induced AMD phenotype is less clear. Here, we explore the role of TLR3 and TLR4 in complement-induced cellular responses in AMD pathogenesis.

Methods: Mature iRPE were pretreated with TLR3 or TLR4 inhibitors followed by treatment with either no serum, complement competent human serum (CC-HS) with activated anaphylatoxins, or complement incompetent human serum (CI-HS) with inhibited anaphylatoxin activity as previously described (Sharma et al., 2021). ELISA assays were performed on apical and basal media of cells to quantify cytokine IL-8. Target TLRs were located using immunofluorescent staining and intracellular lipid was detected by BODIPY dye. Additionally, iRPE were treated with TLR3 activator Poly (I:C) and stained for BODIPY and ubiquitin ligase TRIM3 known to mediate polyubiquitination of TLR3. Cells were visualized by fluorescence microscopy.

Results: Inhibitors for TLR3 and TLR4 decreased complement-induced lipid deposition exhibited by reduced BODIPY levels. TLR 4 inhibitor decreased human complement-induced IL-8 secretion in apical media and TLR3 inhibitor decreased IL-8 secretion in basal media. No significant difference in IL-8 secretion was found between CC-HS controls and TLR 4 inhibited cells in basal media or TLR3 inhibited cells in apical media. In iRPE treated with Poly (I:C) at concentrations of 10, 50, and 100 ug/ml, BODIPY and TRIM3 levels increased in a concentration-dependent manner.

Conclusions: In iRPE, complement-induced lipid deposition and activation of NF-kB leading to elevated IL-8 secretion characteristic of inflammation and AMD are mediated by TLR 3 and TLR 4. The regulatory role of these receptors in AMD pathogenesis reflects a possible upstream presence of aberrant RNA and viruses or bacterial endotoxins that trigger the activation of TLR3 and TLR4 respectively.

ABSTRACT BODY:

Purpose: Intraocular pressure (IOP) and blood pressure (BP) are two risk factors in the development and progression of open angle glaucoma (OAG). However, various population-based studies differ for the role that the IOP-BP association has in OAG. To address this, we present a novel approach based on a physiology-informed mathematical model and machine learning (ML) applied to 3 studies conducted in different continents.

Methods: We considered: the Indianapolis Glaucoma Progression Study (IGPS) of 115 OAG eyes; the Singapore Epidemiology of Eye Disease Study (SEED) of 19,625 eyes (283 OAG); and the Thessaloniki Eye Study (TES) of 3,136 eyes (140 OAG). For each study, a validated mathematical model (Guidoboni et al 2014, IOVS) was used to generate 8 hemodynamic variables based on measurements of 4 patient-specific inputs (systolic and diastolic BP, heart rate, IOP). These combined variables form a 12-dimensional physiology-enhanced dataset. An unsupervised ML clustering algorithm, Fuzzy C-Means (FCM), was applied to the 3 enhanced datasets, partitioning eyes into groups with similar hemodynamics.

Results: The FCM algorithm produced 3 clusters on the 12-D data. Fig.1 shows the clustering result from the IGPS study (only OAG eyes) projected onto the IOP-MAP plane (MAP=mean arterial pressure=(2/3)DBP+(1/3)SBP). A wedge-like shape with a tilted boundary between cluster 1 (green) and cluster 3 (blue) is observed, indicating a non-trivial interplay between IOP and MAP. Clustering only the OAG eyes in SEED yielded similar wedge-shaped clusters (Fig. 2a), but with all eyes considered (healthy+OAG) the resulting clusters were vertically stacked (Fig. 2b), indicating they differ only by MAP. A similar phenomenon occurred in TES (Figs. 2c and 2d).

Conclusions: The physiology-informed ML approach revealed a wedge-shaped pattern among OAG eyes that is consistent across studies and continents. When OAG eyes are pooled together with healthy eyes in population-based studies, such as TES and SEED, this pattern is masked by the overwhelming presence of healthy eyes. The pattern

identifies OAG eyes with similar disease biomarkers and may enable individualized OAG management and treatment across populations.

ABSTRACT BODY:

Purpose: Stem cell-derived retinal organoids have uncovered the dynamics of retinal tissue development and pathology caused by inherited retinal degeneration, some of which have suggested potential therapeutics. Yet, the consistency of neuro-retinal architecture is not uniform in suspension cultures as they lack a robust physical scaffold. Therefore, if a physical scaffold that was easy to employ were available, then vitro retinal organoid models may more faithfully recapitulate features of the structure and neuro-retinal maturation found in vivo. Hence, we generated a reproducible and broadly employable synthetic extracellular matrix that improved in vitro retinal organoid generation and maturation.

Methods: A Rx-GFP mouse embryonic stem cell line was used to create retinal organoids. On day three of differentiation, organoids were embedded in polyethylene glycol (PEG) hydrogels containing reactive groups that could be quickly crosslinked with cell-binding and enzymatically sensitive crosslinking peptides that controlled cella adhesion and gel stiffness, respectively. Samples were fixed, stained, and imaged in seven-day intervals until day 32 of differentiation. Evaluation for the presence of retinal progenitor cells, retinal ganglion cells, and cone photoreceptors were done by IHC staining for Chx10, Brn3a, and Thrb2, respectively.

Results: Hydrogels containing less than 5% (weight percent) PEG or more than 7% PEG were either too fragile for handling or unable to be synthesized due to solubility limits, respectively. Compared to suspension culture, the spheroid shape was better maintained in the hydrogel model, producing an even laminar structure of neural retina. The 5% PEG hydrogel had more robust Chx10, Brn3a, and Thrb2 staining compared to the 7% PEG hydrogel and sustaining it through the entire differentiation course. Finally, replacement of standard RGD cell-matrix binding peptides with laminin or basement membrane-binding peptides further enhanced neural retina differentiation.

Conclusions: The creating and screening for a synthetic matrix that embeds retinal organoids improves the efficacy of in vitro retinal stem cell culture. This work can expand to human stem cell-based retinal organoids as well as disease model stem cell lines that not only better understand but also screen for potential therapeutics for retinal diseases with complex genomic heterogeneity.

ABSTRACT BODY:

Purpose: The visual cycle regenerates visual pigments chromophore, 11-cis-retinal, and eliminates its toxic byproducts from the retina, supporting visual function and retinal neuron survival. Unfortunately, during the visual cycle, when 11-cis-retinal is being regenerated in the retina, toxic byproducts, such as all-trans-retinal and bis-retinoid such as N-retinylidene-N-retinylethanolamine (A2E), are produced, which contributes to the pathogenesis of dry form of age-related macular degeneration (AMD) and Stargardt's disease (STGD). To prevent all-trans-retinal mediated retinal degeneration, slowing down the retinoid flow by inhibiting the visual cycle with a small molecule was proposed. The present study describes RPE65-61, a novel, non-retinoid compound, as an inhibitor of RPE65 intended to modulate the excessive activity of the visual cycle to protect the retina from degenerative diseases.

Methods: To determine the inhibition mode of the RPE65-61, we used an adenoviral vector to express chicken RPE65 in 293A cells, and the chicken RPE65 was used in a liposome-based isomerase assay. One hour after the systemic administration of RPE65-61 or vehicle, mice were placed in a light box with white fluorescent tube lights (10,000 lux for 3 hr). The mice were returned to regular housing for five days, and then the light-induced retinal damage (LIRD) was assessed using histology and ERG. Retinoid profiles recovery after the photobleach was assayed using HPLC.

Results: RPE65-61 selectively inhibited retinoid isomerase activity of RPE65 via an uncompetitive mechanism, with IC_{50} of 80 nM. Systemic treatment of mice with RPE65-61 resulted in slower chromophore regeneration after the photobleach and protected the retina from LIRD. Furthermore, RPE65-61 down-regulated the cyclic GMP-AMP synthase stimulator of the interferon genes pathway, decreased the inflammatory factor, attenuated retinal apoptosis caused by LIRD, which led to the preservation of the retinal function.

Conclusions: RPE65-61 potently and selectively inhibited conversion of all-trans-retinyl ester to 11-cis-retinol catalyzed by RPE65. Mice injected with RPE65-61 exhibited delayed chromophore regeneration after photobleach and conferred protection of retina against LIRD. Taken together, these results suggest that RPE65-61 may be used to slow down the visual cycle and to prevent the accumulation of A2E in STGD and AMD.

ABSTRACT BODY:

Purpose: Glucose supports catabolic and anabolic metabolism in the neural retina. It is transported into the retina by the outer (RPE) and inner blood-retinal barrier (BRB) via the glucose transporters GLUT1, encoded by Slc2a1. GLUT1 is highly expressed by Muller glia and photoreceptor cells in the outer retina, while the neurons express GLUT3 in the inner retina. To understand how glucose supports the metabolism and function of the retina, we generated and characterized mouse models with the deletion of the glucose transporter GLUT1 in the neural retina and photoreceptors.

Methods: Mice carrying floxed alleles for Slc2a1 (The Jackson Laboratory, #031871) were crossed with transgenic mice expressing Cre recombinase in the retina (129.B6C3-Tg(Crx-cre)1Tfur), rods Pde6gCre-ERT2 (Tsang lab) and cones (Tg(Opn1mw-cre)1Asw) to generate RetinaΔGlut1, RodΔGlut1, ConeΔGlut1 and GLUT1$^{Flox/Flox}$ (control). Structure and function were assessed by optical coherence tomography (OCT), confocal scanning laser ophthalmoscopy (cSLO) and electroretinograms (ERGs). Immunofluorescence (IF), in-situ hybridization, qPCR, and GC/MS were used to determine changes in the retinas.

Results: In-situ hybridization, IF, and western blot were done to confirm the deletion of GLUT1 in the neural retinas. RetinaΔGlut1 mice showed loss of GLUT1 as early as P3, but exhibited normal retinal lamination at 1 month of age. We found that Slc2a1 and Slc2a3 are the highest expressed glucose transporters in the neural retina. In-situ hybridization of Slc2a1 showed expression in both inner and outer retinal layers, but Slc2a3 was only seen in the inner retinal layers. Scotopic ERGs from RetinaΔGlut1 and RodΔGlut1 were reduced. Photopic ERGs were reduced in RetinaΔGlut1, but not in ConeΔGlut1. OCT scans of RetinaΔGlut1 and RodΔGlut1 only showed ONL thinning and OS shortening. TUNEL positive cells were detected only in the ONL. There were no changes in cone density in RetinaΔGlut1 and ConeΔGlut1. Rhodopsin transcript and protein were severely reduced when normalized to OS length and ONL thickness, consistent with nutrient deprivation. Metabolic measurements confirmed decreased aerobic glycolysis.

Conclusions: GLUT1 expression in the neural retina is required for visual function and the viability of rods, but not cone photoreceptors. Glucose uptake via GLUT1 is necessary for OS renewal. Genetic deletion of GLUT1 does not cause cell death in the inner retina.

ABSTRACT BODY:

Purpose: To evaluate the natural progression of vascular and neurodegenerative alterations using multimodal retinal imaging in patients with MacTel.

Methods: In this retrospective, longitudinal analysis, patients underwent annual ophthalmic examinations including color fundus photography (CFP), fluorescein angiography (FLA), optical coherence tomography (OCT) and OCT-angiography (OCTA). Only treatment-naïve eyes lacking any signs of neovascular membranes/ activity were included, and reviewed for ≥20 months. Eyes were analyzed for the progression of vascular and neurodegenerative changes, including vascular proliferation, perivascular leakage, pigment accumulation, and progression of ellipsoid zone (EZ) loss.

Results: 97 eyes from 57 patients (mean age 63.1 years (range: 39-83); 35 females) were included and followed over a mean period of 22.3 months (range: 20.5-38.2). On OCTA, a proliferation of retinal vessels was observed in 36 eyes (37%). Proliferating vessels were primarily found at the level of the deep retinal plexus and within the temporal parafovea. Seven eyes showed a proliferation of vessels at the level of the outer retina/choriocapillaris layer, possibly involving both choriocapillaris and displaced deep plexus vessels. The latter finding was associated with the development of retinal-choroidal anastomoses in all cases.

In all eyes, the proliferation of intraretinal vessels (PIV) was associated with a focal increase in reflectivity on OCT and increased leakage on FLA. A de novo development of subretinal/sub-RPE neovascular membranes was observed in a single eye only. The progression of EZ-loss did not differ between eyes with or without PIV (0.0017 mm^2/month versus 0.0015 mm^2/month; p=0.09). Eyes with PIV showed a significantly higher frequency of perivascular pigment accumulation compared to eyes without PIV (10/36 (28%) vs 4/61 (7%); chi-square test X^2 (1, N=97) = 8.3, p = 0.004).

Conclusions: The proliferation of intraretinal vessels appears to represent a common finding in MacTel, and can be observed in eyes previously classified as “non-proliferative”. Our results thus indicate the need to reevaluate our current understanding and classification of MacTel into “proliferative” and “non-proliferative” disease stages.

TITLE: Modeling of mitochondrial bioenergetics and autophagy impairment in MELAS-mutant iPSC-derived retinal pigment epithelial cells

SESSION TITLE: Cell biology of retinal diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Bhattacharya, J. Yin, W. Huo, E. Chaum, Ophthalmology and Visual Sciences, Vanderbilt University Medical Center, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure: Sujoy Bhattacharya: Commercial Relationship: Code N (No Commercial Relationship) | Jinggang Yin: Commercial Relationship: Code N (No Commercial Relationship) | Weihong Huo: Commercial Relationship: Code N (No Commercial Relationship) | Edward Chaum: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Mitochondrial dysfunction and mitochondrial DNA (mtDNA) damage in the retinal pigment epithelium (RPE) have been implicated in the pathogenesis of macular degeneration. Elimination of dysfunctional mitochondria through mitochondrial autophagy (mitophagy) is an important quality control mechanism in the RPE. In this study, we model the impact of a prototypical systemic mitochondrial defect, mitochondrial encephalomyopathy, lactic acidosis, and stroke-like episodes (MELAS), in RPE health and homeostasis as a model for impaired mitochondrial bioenergetics.

Methods: We used iPSCs derived from skin biopsies of MELAS patients (m.3243A>G tRNA leu mutation) with different levels of mtDNA heteroplasmy and differentiated them into RPE cells. Mitochondrial depletion of ARPE-19 cells (p^0 cells) was also performed using 50ng/mL ethidium bromide (EtBr) and 50mg/ml uridine. Cell fusion of the human platelets with the p^0 cells performed using PEG-SMEM mixture to generate platelet:RPE “cybrids”. Confocal microscopy, FLowSight Imaging cytometry, and Seahorse XF Mito Stress test were used to analyze mitochondrial function. Western blotting was used to analyze expression of autophagy and mitophagy proteins.

Results: We found that MELAS iPSC-derived RPE cells exhibited key characteristics of native RPE. We observed heteroplasmy-dependent impairment of mitochondrial bioenergetics and reliance on glycolysis for generating energy in the MELAS iPSC-derived RPE. The degree of heteroplasmy was directly associated with increased STAT3 activation, reduced AMPKα activation, and decreased autophagic activity. In addition, impaired autophagy was associated with aberrant lysosomal function, and failure of mitochondrial recycling. The mitochondria-depleted p^0 cells replicated the effects on autophagy impairment and aberrant STAT3/AMPKα signaling and showed reduced mitochondrial respiration, demonstrating phenotypic similarities between p^0 and MELAS iPSC-derived RPE cells.

Conclusions: Our studies demonstrate that the iPSC-derived RPE lines from MELAS patients are useful tools for identifying molecular, cellular, and functional features that contribute to age-related RPE degeneration. We propose that heteroplasmic mitochondrial disease models can be used for the assessment of mitochondrial and cellular dynamics and provide a new experimental model for the RPE in aging and macular degeneration.

TITLE: Stress and sleep deprivation-related biomarkers in tear fluid in Retinitis Pigmentosa. Pilot study

SESSION TITLE: Retinal Degenerations, Gene Therapy, Transplantation, and Prostheses

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E.M. Sobas Abad, M. Mateo-Olivares, C. García-Vazquez, R. Usategui-Martín, J. Pastor, A. Enriquez-De-Salamanca, S. Pastor, Ophthalmology, IOBA, Valladolid, Valladolid, SPAIN|

Commercial Relationships Disclosure: Eva Sobas Abad: Commercial Relationship: Code N (No Commercial Relationship) | Milagros Mateo-Olivares: Commercial Relationship: Code N (No Commercial Relationship) | Carmen García-Vazquez: Commercial Relationship: Code N (No Commercial Relationship) | Ricardo Usategui-Martín: Commercial Relationship: Code N (No Commercial Relationship) | Jose-Carlos Pastor: Commercial Relationship: Code N (No Commercial Relationship) | Amalia Enriquez-De-Salamanca: Commercial Relationship: Code N (No Commercial Relationship) | Salvador Pastor: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinitis pigmentosa (RP) patients commonly experience sleep-related problems and susceptibility towards stress which may be detected by specific biomarkers in tears. We investigated the association between the grade of severity of RP (by clinical assessment), and biochemical stress (by analyzing proposed biomarkers in tears) and determine the impact of psychological factors and sleep disturbances among RP patients

Methods: Seventy-eight RP patients were recruited. The study encompassed administration of State-Trait Anxiety Inventory (STAI), Epworth Sleepiness Scale (ESS) and Pittsburg Sleep Quality Index (PSQI) questionnaires, a complete ophthalmological examination for severity grading of RP and collection of tear samples. The activity of biomarkers (Figure.1) was estimated by 20 Plex-Luminex and statistical analysis was performed to determine associations between perceived stress, sleep quality, sleepiness, and biomarkers activity. To complete the assessment, sampling in healthy controls is being analyzed to compare

Results: At the time of evaluation, 52 (67%) of patients had a severe RP (33 (63.5%- males) and 19 (36.5%) females) with a mean age 53.83 ± 13.17 yrs, and 26 (33%) a mild-moderate grade (14 (53.8%) males) and 12 (46.2%) females) with a mean age 47.12 ± 12.94 yrs (Table.1). The severity of RP tends to be highest in older patients (p=0.036). Fifty-eight (58,9%) patients reported severe-anxiety and 18 (23.,1%) high-anxiety
status measured by STAI. Forty-six (59%) of patients obtained pathological values in PSQI and 43 (55.1%) in EES. Patients with severe and mild-moderate RP (n=38 and 20, respectively) did not show significant differences when sleep quality, and perceived anxiety scores were compared. We found high tear concentrations of EGF, GRO, IL-1Ra, IL-8, and MCP-1. Differences were not significant by age, grade of severity, stress status, and gender between groups, but patients with more severe disease, poor sleep quality, and higher scores of anxiety status showed higher concentrations

Conclusions: Pro-inflammatory cytokines seem to be elevated in tear fluid from RP patients. Present findings reveal that tear fluid biomarkers could be appropriated for the objective assessment of sleep deprivation and stress in RP patients in a non-invasive way

ABSTRACT BODY:

Purpose: Poor image quality can adversely affect the ability of DL algorithms to detect glaucoma. This study evaluates the effect of several common types of image degradation on a DL model that automates quality assessment of fundus photographs.

Methods: 2,815 fundus images from the Diagnostic Innovations in Glaucoma Study and African Descent and Glaucoma Evaluation Study were used to develop a DL model to automate quality assessment. This model was tested on 11,350 photographs from the Ocular Hypertension Treatment Study. Several ablative operations were separately implemented to degrade high-quality images (QS=0) into low quality ones (QS≥0.1). Gaussian blur, brightness (bias) increases and decreases, contrast enhancement factor (gain) decreases, and Gaussian-distributed additive noise were applied. In order to determine the range of degradation values, images were degraded until quality scores peaked at a maximum quality value. For each type of ablation, the maximum degree of degradation was set as the value for which the resulting quality score first surpassed 95% of this peak poor quality value. Within this range, each image was incrementally degraded to create 100 progressively ablated photographs for that ablation form.

Results: While all degradations consistently yielded poor quality scores (Figure 1), each type of ablation yielded different degradation-QS profiles. Noise was the strongest determinant of quality, followed by contrast and focus. The model was more limited in recognizing the extent of degradation for both increased and decreased brightness (max

QS = 0.45 and 0.76, respectively). The model appeared especially sensitive to the Gaussian noise ablation type; random distribution variance of 0.0075 and 0.0125 proved sufficient to degrade an image to a poor quality score.
Conclusions: A DL model to assess fundus photography quality can offer insights into factors influencing DL models for detection of eye disease. Evaluation of the performance of a glaucomatous optic neuropathy model on variably degraded datasets in conjunction with grading by human experts may validate or refute these insights.

ABSTRACT BODY:

Purpose: During the COVID-19 pandemic lockdown, ophthalmology injection clinic volume at the Veteran Affairs (VA) Greater Los Angeles decreased by 50% and it rebounded back to pre-COVID clinic volumes immediately after. The COVID-19 vaccines were introduced for individuals 16 years and older under emergency use authorization by the FDA in December of 2020. The focus of this study is to examine non-ophthalmic characteristics of patients in intravitreal injection clinic during the COVID-19 vaccine era.

Methods: Retrospective chart review study of patients who received intravitreal injections during 7-week period in 2021 (COVID-19 vaccine era) was compared to 2019 (baseline pre-pandemic), and 2020 (peak COVID-19). Electronic medical records were used to obtain patients' demographics, ophthalmic conditions, non-ophthalmic conditions, and COVID-19 vaccine records.

Results: During the 7-week period in 2021, 88.5 % of patients receiving intravitreal injections were vaccinated (n= 263). Of the vaccinated patients, 83.6% received the Pfizer vaccine, 3.8% Moderna, and 1.1% J&J. Of those receiving either the Pfizer or Moderna vaccine, 1.7% were partially vaccinated while all others were fully vaccinated. Patients with a higher BMI were more likely to follow up after vaccination compared to baseline (p=0.019). Hispanic patients were more likely to follow up after vaccination compared to peak COVID-19 period (p=0.026). Cancer patients were more likely to follow up following vaccine compared to baseline (p=0.0001), but no difference compared to peak COVID-19 period. Transplant patients were more likely to follow up following vaccination compared to peak COVID-19 period (p=0.0001), but no difference compared to baseline (p=0.656). Patients with COPD were less likely to follow up even with vaccine (p=0.0001).

Conclusions: The availability of the COVID-19 vaccines impacted intravitreal injection follow up at the VA Los Angeles ophthalmology injection clinic. Most patients receiving intravitreal injection clinic were fully vaccinated. Immunocompromised patients and those with higher BMI were more likely to follow up after the availability of COVID-19 vaccination. Patients with COPD were less likely to follow up even with the availability of vaccines.

ABSTRACT BODY:

Purpose: In uveal melanoma (UM), heavy tumour pigmentation has been associated with a bad prognosis. Microphthalmia-associated transcription factor (MITF) is located on chromosome 3 and it is the master regulator of melanin synthesis and melanocyte development. In cutaneous melanoma, the role of MITF is not completely clear but loss of MITF is associated with epithelial-to-mesenchymal transition (EMT), an increase in stem cell markers and inflammation. In UM, MITF loss is associated with loss of expression of BAP1, which is a negative prognostic marker. We explored the role of MITF in two cohorts of enucleated UM patients: a cohort of 64 UM patients enucleated at the Leiden University Medical Centre (LUMC) and the The Cancer Genome Atlas (TCGA) cohort (n = 80).

Methods: We analysed the relation between MITF expression in UM and clinical-pathological and genetic features and carried out survival analyses on both cohorts. Next, we tested whether MITF expression was related to pigmentation, inflammation and EMT markers in both cohorts and performed a differential expression and gene set enrichment analysis (GSEA) between MITF-low and MITF-high UM in the LUMC cohort.

Results: In the LUMC cohort, MITF expression was lower in dark UM than in light tumours ($p = 0.004$). Moreover, MITF expression was lower in UM with monosomy 3 ($p < 0.001$) and in UM with a high expression of PRAME ($p = 0.01$). However, MITF expression was not significantly related to survival ($p = 0.22$). These results were confirmed in the TCGA cohort. In differential expression analysis, MITF-low UM showed upregulation of the inhibitory receptor TIM-3 and of several genes (such as CXCL16 and HCP5) that have been shown to increase cell proliferation and migration in other cancer types, and in GSEA, MITF-low tumours showed an upregulation of hallmark pathways involved in inflammation.

Conclusions: Since monosomy 3, PRAME expression and inflammation are features of poor prognosis in UM, we propose that MITF loss in UM is related to tumour progression and may have a direct link with the inflammatory state. Further studies are needed to understand if the role of MITF is independent of its relation with chromosome 3 and BAP1 status.

ABSTRACT BODY:

Purpose: Although corneal crosslinking (CXL) was a major breakthrough in keratoconus (KC) management, there has been debate about its efficiency. Cochrane reviews have only found limited, low quality evidence and there is no consensus on which KC cases need CXL, nor on how to establish progression. This is complicated further by noise in the measurements. Some progression criteria may better reflect our clinical knowledge of KC evolution, such as the % of progressive KC based on clinical changes, hence, this study aimed to verify the performance of diverse criteria.

Methods: The retrospective REDCAKE study included data from 743 KC patients measured longitudinally with Pentacam (Oculus, DE). Habitual progression criteria based on (combinations of) the maximum keratometry (K_{MAX}), astigmatism (A_F), and minimum pachymetry (P_{MIN}), or based on ABCD Progression Display were analyzed. For each criterion and cut-off, we calculated the eyes flagged progressive at some point (R_{PROG}), the individual consistency C_{IND} (% of examinations after detection of progression that would still be considered progressive), and the population consistency C_{POP} (% of eyes with C_{IND} > 66%). Finally, we studied more monotonic and consistent variables, such as the front steep keratometry (K_{2F}), the keratometry in a 3 mm area around K_{MAX} ($K_{ZONAL3mm}$), and the mean radius of the back surface (R_{mB}).

Results: Use of a single criterion (e.g. $\triangle K_{MAX}$ >1D) led to rather high values of R_{PROG}, unless the cut-off exceeded the measurement noise. When two criteria were required, (K_{MAX} AND A_F) led to worse C_{POP} and higher variability than (K_{MAX} AND P_{MIN}); alternative criteria ($K_{ZONAL3mm}$ AND R_{mB}) and (K_{2F} AND R_{mB}) obtained the best C_{POP} and the lowest variability (Fig 1; all $p < 0.0001$). ABC, as defined by its authors, obtained a very high R_{PROG} of 74.2%. Using wider 95% confidence intervals (95CI) and requiring two of ABC over the 95CI reduced R_{PROG} to a more realistic 27.9%.

Conclusions: Clinical observation of contact lens parameters, visual acuity, incidence of scarring or corneal transplants suggest 20–35% of KC cases are progressive. This clinical R_{PROG} value should be considered when defining KC progression to avoid overtreatment. By using combinations of alternative variables and wider 95CI for ABC, the R_{PROG} can be brought closer to clinical observations; furthermore, these approaches obtained better longitudinal consistency than current definitions.

ABSTRACT BODY:

Purpose: Retinal angiopathy is a known ocular manifestation of hereditary transthyretin amyloidosis (ATTR). We performed a retrospective, observational clinical study to determine whether vessel density (VD) indices as measured by optical coherence tomography angiography (OCTA) and choroidal vascularity index (CVI) provided insights into retinal and choroidal vascular changes in patients affected by ATTR.

Methods: Twenty-six patients with genetic diagnosis of wild-type ATTR were enrolled to undergo structural optical coherence tomography (OCT) and OCTA. An age-gender-matched control group of twenty-four healthy subjects was selected for statistical comparisons. Swept-source OCT and OCT angiography data from TOPCON DRI OCT Triton were exported using Topcon IMAGENET 6.0 software, and 3D datasets were analysed to determine retinal, choroidal thickness and VD. Images were binarized using the ImageJ software, and total choroid area (TCA), luminal area (LA) and stromal area (SA) were acquired to measure the CVI. Statistical analysis was conducted using MedCalc version 11.5.1 (Medcalc software, Mariakerke, Belgium).

Results: Mean VD was significantly reduced in the superficial capillary plexus (SCP), deep capillary plexus (DCP) and choriocapillaris (CC) in all five Early Treatment Diabetic Retinopathy Study (ETDRS) sectors in the ATTR group compared to controls (P =. 006)

Retinal thickness did not statistically differ between the two groups, while a significantly reduced chororidal thickness was recorded in ATTR patients (P = .008).

The mean CVI was lower in the ATTR group compared to controls (P = .006).

Conclusions: VD resulted reduced at the level of SCP, DCP and CC in ATTR patients, along with choroidal thickness and CVI compared to healthy control.

OCT-A indices and CVI may serve as a noninvasive biomarker to quantitatively evaluate retinal and choroidal vascular involvement in ATTR patients and the possible correlation with systemic parameters.

ABSTRACT BODY:

Purpose: To compare intraocular pressure (IOP) measurements using iCare® PRO rebound tonometry (iCare) and Perkins applanation tonometry (Perkins) in childhood glaucoma suspects and healthy children under protocol-defined general anaesthesia (GA).

Methods: A prospective clinical, case-control study of children who underwent an ophthalmologic examination under GA according to our Childhood Glaucoma Center protocol between April 2019 and March 2021. IOP was taken three times (T1-T3) according to the depth of GA, measured with bispectral index (BIS), which is a continuous form of complex processed electroencephalogram (EEG). IOP measurment was taken three times, alternating, starting with iCare: T1 iCare-Perkins, T2 iCare-Perkins, T3 iCare-Perkins, see Figure 1. Central corneal thickness (CCT) was measured before IOP measurement. Correlation between iCare and Perkins was analysed at each measurement point. CCT was taken into account.

Results: 150 eyes of 75 children were included: 53 glaucoma suspects and 22 healthy controls. Children were 45.45 ± 29.76 months old [mean ± SD]. 54.05% of all children were female. Glaucoma suspects: IOP measured with iCare was 26.8±11.2, 23.2±11.4, 21.7±10.3mmHg and Perkins 18.2±7.7, 16.0±7.1, 16.1±7.4mmHg [mean ± SD] at T1, T2, T3, see Figure 2.

Healthy controls: 14.3±4.7; 10.5±2.5; 10.1±3.0mmHg and 10.2±3.1; 7.4±3.0; 6.9±2.5mmHg, respectively [mean ± SD]. The correlation between iCare and Perkins was good: the intraclass correlation coefficient (r) between the two methods was 0.629 ($p<0.001$). The mean IOP is statistically significantly higher with iCare than with Perkins ($p<0.001$) in both groups. The mean difference (iCare and Perkins) was 6.0±6.1mmHg.

Correlation between IOP and CCT was not statistically significant in both groups.

Conclusions: The IOP were higher in glaucoma subjects than in the healthy ones. iCare leads to higher IOP compared to Perkins in standardized anaesthesia in children. The IOP changes during the course of anesthesia and should be measured at the beginning of anaesthesia according to our protocol, because at this point the IOP is the highest. In our study, IOP was independent of CCT.

ABSTRACT BODY:

Purpose: To investigate the relationship between macular pigment optical volume (MPOV) and contrast sensitivity (CS), microperimetric pointwise sensitivity (PWS) and photostress recovery time (PRT) during 18 months of carotenoid supplementation in patients with open-angle glaucoma (OAG).

Methods: MPOV was measured (central 6°) in one eye using fundus autofluorescence (Spectralis HRA + OCT) in 54 patients with OAG, randomised to receive treatment (10 mg lutein, 10 mg meso-zeaxanthin, 2 mg zeaxanthin, n = 37 [mean age: 66.2 years, range: 48 – 86]) or placebo (n = 17 [mean age: 61.8 years, range: 36 – 76]) supplementation. CS was measured at 1.5, 3, 6, 12 and 18 cycles per degree under photopic (85 cd/m^2) and mesopic (3 cd/m^2) conditions, each with and without glare (Functional Vision Analyzer). Area under log contrast sensitivity function (AULCSF) was calculated for each test condition. PWS at 19 visual field locations (central 10°, MAIA 2) and PRT (MDD-2 Macular Adaptometer) were also measured. All tests were conducted at six monthly intervals from baseline to 18 months. Linear mixed-effects models were used to assess relationships between each visual function measure (response variables: AULCSF, PWS and PRT) and MPOV (fixed effect) over time. Treatment, time and adaptation condition (AULCSF) were included as fixed effects and participant as a random effect to adjust for such factors in the model.

Results: Positive significant relationships were observed between AULCSF (all adaptation conditions) and both MPOV (Beta coefficient [β] = 0.013, P = 0.028, fig. 1a) and time (β = 0.035, P = 0.011). PRT had a significant inverse association with MPOV (β = -0.924, P = 0.045, fig. 1b) and a significant positive association with time (β = 3.78, P=0.019). PWS was not significantly related to MPOV (β = -0.077, P = 0.203, fig. 1c) or time (β = 0.036, P = 0.819).

Conclusions: Patients with OAG and higher MPOV exhibited better CS under mesopic and photopic conditions both with and without glare. PRT was faster in those exhibiting higher MPOV over the supplementation period. Visual function may be improved in glaucoma by increasing MPOV through carotenoid supplementation, but further work is required to determine its longer-term effects on visual function.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is the leading cause of blindness in the elderly and is estimated to affect approximately 8.7% of all individuals between the ages of 45 and 85. In the early or 'dry' form of the disease, protein and lipid deposits, termed drusen, develop between the retinal pigment epithelium (RPE) and the selectively permeable barrier separating the RPE and retina from the choroidal circulation, called Bruch’s membrane, particularly within the macular region of the eye. Apart from aged non-human primates, drusen development is not easily replicated using animal models, however several studies have demonstrated that primary RPE cells, cultured in monolayers accumulate drusen-like deposits. Herein, we assess the accumulation of ‘drusen’ longitudinally in primary porcine RPE cultures and characterize the protein and lipid content of individual drusen to establish their similarity to drusen recovered from human donor eyes with diagnosed AMD.

Methods: Fresh (< 6 hours post mortem) porcine eyes were obtained from a local abattoir and disinfected through immersion in PVP prep solution. On ice, the cornea, lens, vitreous body and retina were removed mechanically before the primary RPE was isolated via enzymatic dissociation using serial incubations in 0.25% trypsin in L-15 media at 37°C. Cells were incubated in 1% DNase I for 2 minutes, purified via centrifugation on a 40% Percoll cushion with 0.01 M Na_2PO_4 and 0.15 M NaCl (pH 7.4), and plated directly on polyethylene terephthalate (PET) transwell membranes. RPE cultures were maintained for up to 26 weeks without passaging. Transwell inserts were fixed in 4% PFA and cryosectioned or flat mounted. Drusen components, size, and quantity were analyzed via immunofluorescence microscopy.

Results: Freshly isolated RPE take approximately 5 – 6 days to fully anchor to the membrane, after which cells no longer slough off with feeding. Throughout the 26 week aging period, approximately 60% of the cultures show no signs of infection. As young as 22 weeks post isolation, primary RPE cultures developed deposits with drusen-like characteristics such as lipid accumulation indicated by Nile Red and positive immunofluorescent staining for known drusen components such as ApoE, vitronectin, and TIMP3.

Conclusions: Through this study, we further verify the efficacy and reproducibility of primary RPE culture as a method of ex vivo modeling of drusen-formation.

ABSTRACT BODY:

Purpose: To determine the feasibility of remote visual field (VF) testing using a virtual reality visual field (VRVF) device with and without assistance.

Methods: Individuals without ocular disease (age ≥ 60) completed a standard automated perimetry (SAP) 24-2 SITA Standard on a Humphrey Field Analyzer and a VRVF (V_0) exam in random order on the same day in clinic with assistance. Participants were taught how to operate the VRVF equipment and given a device to take home. The following day, participants were telehealth-assisted to establish a remote testing environment, confirm proper use, and complete a VRVF exam (V_1). Participants tested remotely and without assistance once a week for 3 weeks (V_{2-4}). A pointwise mean absolute difference and SD between light sensitivity threshold values (LSTV) were calculated (V_0 vs SAP and V_{1-4} vs V_0). Using a normal perimetric database for SAP ages 60-69, the number of points below normal (OD) was graphed. Data input was validated by a second party. Reliability indices were analyzed.

Results: 7 participants (14 eyes) were enrolled and completed reliable VRVF exams in clinic and remotely as determined by mean reliability indices (fixation losses ≤ 0.15, false positives ≤ 0.05, false negatives ≤ 0.06). The mean absolute difference and SD of LSTV between exams appear in Table 1. Excluding an outlier (P2 V_4) and missing data (P7 V_4), the absolute mean difference between V_0 and V_{1-4} generally decreased as the study progressed. Figure 1 displays the number of LSTV below normal (OD), which decreased with weekly, remote self-testing (V_{2-4}) and was greater in those who took V_0 first (x_{V0}=14.5) than SAP first (x_{V0}=1.6).

Conclusions: Variability of LSTV from V_0 and number of points below normal reduced with weekly testing, implying that experience with testing improves results. Initial exposure to SAP may be useful for VRVF testing and could confound comparisons between V_0 and V_{1-4}. VRVF was generally reliable in a telehealth setting for individuals with normal eyes. Further research is needed to assess viability in a glaucoma patient population.

ABSTRACT BODY:

Purpose: Light stimulation decreases oxygen consumption (QO_2) in the photoreceptors, but there is indirect evidence that it increases QO_2 in proximal retina, at least during flickering light. However, in the intact eye, the presence of the retinal circulation makes it difficult to isolate QO_2 of the inner retina from the O_2 supply. Here vascular interference was eliminated by making microelectrode recordings in the isolated retina, permitting us to test the hypothesis that QO_2 changes during flicker in opposite directions in the outer retina (OR) and inner retina (IR).

Methods: Double-barreled O_2-sensitive microelectrodes were used to measure local PO_2 in isolated mouse (C57Bl/6J) retinae. Simultaneously recorded local ERGs assisted in verifying the electrode position. Steady and diffuse white square wave flickering (1 Hz) light of scotopic and photopic intensities was applied. Previous recordings of retinal electrical activity and light-induced K^+ changes demonstrated that 1 Hz stimulation is optimal to evoke metabolic changes in the IR.

Results: Spatial profiles of PO_2 across the retina could be fitted with a 5-layer diffusion model in which the OR was represented, as in vivo, by non-consuming layers for the outer segments and outer nuclear layer (1^{st} and 3^{rd} layers), and a consuming layer for the inner segments (2^{nd} layer). The IR is divided into two more layers, in which the 4^{th} layer represented the OPL through INL and had a QO_2 designated Q4, and a 5^{th} layer, with a QO_2 of Q5, describing the GCL/NFL. In 75% of the profiles, Q5 was negligible, Q5/Q4 =0. The weighted average of QO_2 across the inner retina (Q_{IR}) in many cases was comparable or even larger than the weighted average of QO_2 across the outer layers (Q_{OR}). Flickering light applied while the electrode was stationary at different retinal depths showed that the PO_2 slowly increased over more than 3 min in the OR, reflecting lower Q_{OR}. However, flicker decreased PO_2 in the IR with a faster time course, stabilizing in less than 40 sec, reflecting an increase in Q_{IR}.

Conclusions: Retinal QO_2 can be described by a five-layer model that separates QO_2 in the OR and IR. Using microelectrodes allows a spatial analysis that is not possible with Warburg-type measurements, and we show directly the increase in Q_{IR} underlying neurovascular coupling.

ABSTRACT BODY:

Purpose: Thyroid eye disease (TED) is an autoimmune process with possible vision-threatening manifestations. Little is known about the variability of TED characteristics in different ethnic populations. This pilot study aimed to compare demographic and clinical characteristics of TED and its impact on quality of life among patients at LV Prasad (LVP), Hyderabad, India and Wills Eye Hospital (WEH), Philadelphia, USA and to explore feasibility for a larger longitudinal study.

Methods: TED patients ages ≥18yrs, with active disease (onset ≤18m or Clinical Activity Score (CAS) ≥4) were recruited between 3/2021 -10/2021 at each center. Demographic, medical history, smoking and quality of life data were collected, a comprehensive orbital and ocular evaluation performed, and external eye photographs taken using standard protocols. Data between the WEH and LVP groups were compared using $\chi 2$, Fisher's exact tests, t-tests, or Wilcoxon rank sum tests.

Results: Sixty patients (30/center) were enrolled. WEH and LVP patients did not differ significantly by age (50.7 yrs. vs 45.6 yrs., respectively; p=0.13) or smoking status: % smokers (23% vs 13%; p=0.51). Significant differences between groups were seen by sex (% female: WEH: 86.7% vs LVP: 46.7%; p<0.001) and associated thyroid state (% Graves Disease: WEH: 93% vs LVP: 3%: p<0.0001; and % history of hyperthyroidism: WEH: 80% vs LVP: 50%: p=0.01). Clinical features (corneal and optic nerve status, exophthalmometry), quality of life measures and symptoms of retrobulbar ache and pain with eye movements did not differ significantly between groups (all p> 0.05). However, all (30/30) WEH patients vs. 11% of LVP patients exhibited CAS ≥4. WEH patients also were more symptomatic, e.g. higher CAS scores (mean (SD) 4.17 (1.7) for WEH vs 1.8 (1.7) for LVP), had higher frequencies of chemosis and conjunctival injection and more reported subjective symptoms of ocular irritation and blurry vision (all p values <0.0001).

Conclusions: Significant differences observed in the WEH and LVP patients by sex, underlying thyroid state, clinical activity, signs and some symptoms raise questions about possible variations in underlying pathogenesis, clinical disease expression or other unknown factors that may influence TED and its course in different ethnic populations. A larger study with longitudinal follow up is needed to further elucidate these novel observations.

TITLE: Safety and efficacy of resident performed GATT (gonioscopy-assisted transluminal trabeculotomy)

SESSION TITLE: Surgery & Wound Healing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: I. Patterson, M. Qiu, Ophthalmology, University of Chicago Pritzker School of Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Ian Patterson: Commercial Relationship: Code N (No Commercial Relationship) | Mary Qiu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A variety of literature exists assessing the safety and efficacy of resident-performed laser and traditional glaucoma surgery. In contrast, there is no available literature studying outcomes of resident-performed microinvasive glaucoma surgery (MIGS) due to the novelty of these surgeries. The purpose of our study is to observe the effectiveness and safety of resident performed GATT. Herein, we describe a single surgeon's experience teaching residents GATT.

Methods: Retrospective chart review of patients undergoing resident-performed GATT at an academic medical center from 12/18/19 to 9/30/2021. A resident must have performed more than 50% of the GATT. Patients required at least 90 days of follow-up for inclusion in IOP analysis. Cases of NVG were excluded.

Results: There were 49 eyes from 40 patients (24 POAG, 9 mixed mechanism, 6 chronic angle closure, 5 steroid induced, 2 low tension, 1 trauma, 1 pigmentary, and 1 secondary glaucoma due to ghost cell). Phaco-GATT was performed on 40 eyes. GATT-alone was performed on 9 eyes. Mean follow-up for phaco-GATT was 251 days (range 27-579), and for GATT alone was 369 days (range 48-643). In the phaco-GATT group, 35/40 reached follow-up >90 days. In the GATT alone group, 8/9 eyes reached follow-up >90 days. Both mean IOP and mean number of medications were reduced from baseline at 3, 6, and 12 months postoperatively in both surgical groups (except for mean medications at 12 months in the GATT-alone group), however some timepoints did not reach statistical significance, likely due to small sample size. Complications included 5 hyphemas at postoperative week one (12%), 2 hyphemas at postoperative month one (6%) (all hyphemas <0.5mm in height), 1 Descemet's detachment that resolved with air bubble (2%), 1 choroidal effusion (2%), and 1 cystoid macular edema (2%). GATT-alone took an average of 39 minutes (range 23-77 minutes). Phaco-GATT took an average of 67 minutes (range 31-156 minutes).

Conclusions: GATT is being performed more readily both in the community and at academic centers. As such, physicians in training will be learning how to perform this surgery more readily. Our study has shown that trainees have a similar success and complication rate to that reported in the literature, although operating times may be longer than expected for attending-performed cases.

TITLE: MG53 Maintains Limbal Epithelial Cells to Promote Corneal Regeneration

SESSION TITLE: Corneal Cell and Molecular Biology | Corneal Development

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H.L. Chandler, Q. jiang, T. Tan, H. Zhu, The Ohio State University, Columbus, Ohio, UNITED STATES|

Commercial Relationships Disclosure: Heather Chandler: Commercial Relationship: Code N (No Commercial Relationship) | qiwei jiang: Commercial Relationship: Code N (No Commercial Relationship) | Tao Tan: Commercial Relationship(s);Code E (Employment):TRIM-edicine | Hua Zhu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Corneal wound healing is a complex and coordinated process involving injury repair to the epithelial layer and stimulation of limbal epithelial cell (LEC) migration and proliferation for tissue regeneration. Prevention of excessive stromal myofibroblast activation and vascular ingrowth is imperative to avoid fibrosis and angiogenesis, which can compromise corneal transparency. We hypothesize that MG53 constitutes an active component of corneal healing and regeneration by maintaining the health of LEC.

Methods: An alkaline-induced injury was introduced to the corneas of wildtype (WT) and MG53 knockout (mg53-/-) mice (n=6); healing was monitored for 14 days. Tissue from mice that overexpress MG53 or their littermate controls (n=6) were evaluated for expression of the LEC marker ΔNp63α. Cultured murine LEC were treated with Alexa-647-labeled recombinant human (rh)MG53 to determine protein uptake (n=4). Further, in the presence or absence of rhMG53, LEC underwent a colony formation assay (n=6), a microglass bead injury model followed by an LDH assay to evaluate viability (n=6), and a scratch assay to evaluate migration and proliferation (n=4).

Results: Mice with ablation of MG53 showed reduced expression of ΔNp63α. Further, following injury, the mg53-/- corneas exhibited hallmarks of limbal stem cell deficiency with compromised corneal epithelial regeneration, increased goblet cell infiltration, and pronounced stromal fibrosis and vascularization, compared to WT littermates. Mice with sustained elevation of systemic MG53 circulation show enhanced ΔNp63α expression within the limbus and increased tissue regenerative capacity with enhanced LEC function. Cultured LEC treated with rhMG53 internalized the protein and, when compared to controls, had significantly increased viability following injury ($p<0.001$), more colony forming units ($p<0.01$), and improved migration and proliferation ($p<0.01$).

Conclusions: We demonstrate that the protein MG53 is important in modulating LEC function associated with corneal injury-repair. Based on our data, we conclude that MG53 constitutes an active component of corneal injury-repair and regeneration by maintaining the health of LECs, as well as controlling the stromal fibrotic response.

ABSTRACT BODY:

Purpose: To evaluate the performance of two different white-light emitting diode (LED) confocal imaging systems in diabetic retinopathy (DR) grading.

Methods: In this prospective, instrument validation study, participants with type 1 or type 2 diabetes were scanned consecutively with two different white LED confocal scanners: Eidon and DRSplus (Centervue, Padova, Italy). Two-field retinal photographs were captured for each eye using Eidon (60 degrees, macula-centred and disc-centred fields) and DRSplus (45 degrees, macula-centred and disc-centred fields). Retinal images were randomly submitted to a certified retinal expert for grading in accordance with the DR grading system used in the UK National Health service (NHS). All case were also graded as referable DR (RDR) or not RDR.

Results: One hundred and fifty-five eyes of 78 diabetic patients were included in the analysis. Mean (± standard deviation) age of enrolled patients was 59.2 (± 5.3) years. Images from 5 eyes (3.2%) were classified as ungradable using DRSplus, 3 of these cases were judged as not gradable using Eidon. Among all gradable exams, the level of DR identified on images acquired using DRSplus agreed with those obtained with Eidon in 94% of cases. Cohen's kappa coefficient (κ) was 0.88. There was a 100% agreement when considering RDR.

Conclusions: An excellent agreement between Eidon and DRSplus was reported in determining the DR severity and RDR.

ABSTRACT BODY:

Purpose: Lacrimal gland myoepithelial cells (MEC) play a key role in lacrimal fluid secretion. We recently reported that when MEC are stimulated with oxytocin (OXT), the phospholipase C/calcium pathway is activated, causing these cells to contract. In other tissues, OXT is also known to activate adenylate cyclase to generate the secondary messenger cyclic adenosine monophosphate (cAMP). In this study we aimed to investigate the involvement of cAMP and its downstream effectors in OXT-mediated lacrimal gland MEC contraction.

Methods: Lacrimal gland MEC were isolated and propagated from α-smooth muscle actin (SMA)-GFP mice, in which MEC express GFP making them easily identifiable. RNA and protein samples were prepared to analyze the mRNA and protein expression of adenylate cyclase coupling G proteins (Gαs, Gαo, and Gαi) by RT-PCR and Western blotting, respectively. To increase intracellular cAMP concentration, the following agents were used: forskolin (FKN, a direct activator of adenylate cyclase), 3-isobutyl-1-methylxanthine (IBMX, an inhibitor of the phosphodiesterase that hydrolyzes cAMP), or dibutyryl-cAMP (db-cAMP). In addition, selective inhibitors were used to investigate the role of protein kinase A (PKA) and exchange protein activated by cAMP (EPAC) in OXT-induced MEC contraction. MEC contraction was monitored in real time and changes in cell size were quantified using Fiji software.

Results: The adenylate cyclase coupling G proteins, Gαs, Gαo, and Gαi, are expressed in lacrimal gland MEC at both the mRNA and protein levels. FKN, IBMX and db-cAMP significantly stimulated MEC contraction, and preincubation of cells with either myr-PKI (PKA inhibitor) or ESI09 (EPAC inhibitor) resulted in almost complete inhibition of OXT- and FKN-stimulated MEC contraction.

Conclusions: We conclude that cAMP agonists modulate lacrimal gland MEC contraction via PKA and EPAC and also play a role in oxytocin-induced MEC contraction.

ABSTRACT BODY:
Purpose: Current evaluation of DR relies heavily on grading of secondary vascular effects, such as microaneurysms and hemorrhages, by clinical examination instead of by evaluation of actual vascular changes. VESsel GENeration (VESGEN) is a 2D automated microvascular mapping and quantification software that provides an interactive interface that has been used to map and quantify vascular changes in DR (Parsons-Wingerter, 2010); however, a limitation of the previous study was the lack of comparisons of DR subjects with age-matched controls.
Methods: Type 2 diabetics (n=8; 15 eyes) with an HgA1C of 6.2 to 10.5 and age-matched non-diabetic controls with HgA1C < 5.4 (n=8; 15 eyes) and age range from 25 to 52 years underwent retinal fluorescein angiography (FA). The diabetic cohort was grouped based on their DR level using modified ETDRS criteria and compared to controls. Vessel generations were determined and grouped based on vessel branching and dimeter into large (G1-3), medium (G4-5), and small (G≥6) vessels by VESGEN and output data from FA binary input images were analyzed using GraphPad
Results: Unexpectedly, no age-related changes were observed in arterial and venous tortuosity, density, or a total number of vessels in the controls. Diabetic subjects (mild and moderate) showed significantly less vessel length ($p=0.0047$) and branchpoint density ($p=0.0059$) compared to controls among total vessels (macro and microvessels, arterial and venous). Tortuosity of the total arterial and venous macrovessels (G1-5) were not significantly different in retinas of the controls, mild DR, or moderate DR subjects. However total tortuosity of the arterial but not venous microvessels (G≥6) were significantly increased in both mild ($p=0.0012$) and moderate ($p=0.006$) DR when compared to controls. The total number of arterial but not venous microvessels (G≥6) were increased in both mild ($p=0.001$) and moderate ($p=0.006$) DR when compared to controls. The vessel density of both arterial and venous microvessels in the retina of the mild DR ($p=0.024$ and $p<0.0001$, respectively) and moderate DR ($p=0.001$ and $p<0.0001$, respectively) subjects were statistically significantly increased compared to controls.
Conclusions: This study suggests that in microvessels (>G-5), vascular changes begin at mild DR. VESGEN with FA imaging may serve as an additional clinical tool for monitoring the small changes in progression of DR.

ABSTRACT BODY:

Purpose: Retinal vascular morphology provides valuable information for both ophthalmic disease and systemic disease (termed 'oculomics'), e.g., atherosclerosis and diabetes mellitus, in a rapid and non-invasive way. To help recognise high risk cases of ophthalmic and systemic disease through observing the changes of retinal vascular morphology, we propose a deep learning pipeline to automatically analyse the vascular morphology (AutoMorph) which measures 12 kinds of metrics, such as vessel calibre and tortuosity.

Methods: AutoMorph consists of four functional modules: image pre-processing, image quality grading, anatomical segmentation, including binary vessel, artery/vein, and optic disc/cup segmentation, and vascular morphology feature measurement. Image quality grading and anatomical segmentation use the most recent deep learning techniques and are trained on 12 public datasets, such as DRIVE, STARE, and CHASEDB1. We employ model ensemble strategy to achieve robust results and analyse the prediction confidence to rectify false gradable cases in image quality grading. We quantitatively validate module performance on 6 external publicly available datasets including EyePACS image quality dataset (EyePACS-Q), DDR, AV-WIDE, DR-HAGIS, IOSTAR-AV, and IDRID datasets.

Results: The EfficientNet-b4 architecture used in the image grading module achieves comparable performance to the state-of-the-art method in EyePACS-Q, with an F1-score of 0.86. The confidence analysis reduces 76% of false gradable images. The binary vessel segmentation module achieves an F1-score of 0.73 on AV-WIDE and 0.78 on DR-HAGIS. The artery/vein module scores 0.66 on IOSTAR-AV, and optic disc/cup module achieves 0.94 in disc segmentation in IDRID. These results verify that AutoMorph performs well in external validation, being quantitatively on par or even better than some recent work in internal validation.

Conclusions: AutoMorph performs well even when the external validation data shows significant difference to the training data, e.g., validation on ultra-wide field retinal photography. The fully automatic pipeline integrates recent technical work to facilitate 'oculomics' research.

TITLE: The effect of L-NAME on outflow facility in whole porcine eyes.

SESSION TITLE: Aqueous humor dynamics, IOP, corneal disease, cytokines and growth factors

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R.A. Kelly, F.S. McDonnell, W.D. Stamer, Duke University Department of Ophthalmology, Durham, North Carolina, UNITED STATES|D.R. Overby, Imperial College London, London, London, UNITED KINGDOM|

Commercial Relationships Disclosure: Ruth Kelly: Commercial Relationship: Code N (No Commercial Relationship) | Fiona McDonnell: Commercial Relationship: Code N (No Commercial Relationship) | Darryl Overby: Commercial Relationship: Code N (No Commercial Relationship) | William Stamer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: N(ω)-nitro-L-arginine methyl ester (L-NAME), a nitric oxide synthase (NOS) inhibitor, has previously been shown to decrease outflow facility in human anterior segments and murine eyes, but not in enucleated whole globes of porcine eyes. The aim of the present study was to test the effects of L-NAME on outflow facility in enucleated whole globes of porcine eyes.

Methods: Paired porcine eyes (n=5) were used within 24 hours of death. Eyes were perfused at constant pressure of 15 mmHg. Following a 1 hour baseline, one eye of each pair was exchanged with 50 μM of L-NAME in Dulbecco's Phosphate-Buffered Saline with 1 mg/mL D-glucose (DBG), and then perfused for 3 hours, while the contralateral control eye was perfused with DBG for 3 hr.

Results: Over the course of the perfusion, control porcine eyes displayed a “washout” rate of 5.2 [-23.1, 33.6] % increase in outflow facility (mean [CI], p = 0.6354, one sample t-test to theoretical mean of 0, n=5). In contrast, outflow facility in contralateral eyes that were treated with L-NAME significantly decreased by 12.2 [-23.0, -1.3] % over time of perfusion (mean [CI], p = 0.0361, n=5), with a net decrease of 17% compared to control (p = 0.1101, paired t-test, n=5).

Conclusions: Results showing that L-NAME significantly decreases outflow in porcine eyes are consistent with those observed previously in mouse and human eyes and suggests that basal levels of endogenous NO production by endothelial cells of Schlemm’s canal is an important mediator of outflow resistance, and thus IOP.

TITLE: KPI-287 Demonstrates Superior Efficacy Over Axitinib in a VEGF-induced Retinal Leakage Model

SESSION TITLE: AMD and diabetic retinopathy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W. Ong, P. Baciu, E. Enlow, Kala Pharmaceuticals, Inc., Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Winston Ong: Commercial Relationship(s);Code E (Employment):Kala Pharmaceuticals, Inc. | Peter Baciu: Commercial Relationship(s);Code E (Employment):Kala Pharmaceuticals, Inc. | Elizabeth Enlow: Commercial Relationship(s);Code E (Employment):Kala Pharmaceuticals, Inc.

ABSTRACT BODY:

Purpose: Anti-VEGF therapeutics that provide both reliability of administration and durability of action are critical for patients suffering from neovascular disease. Small molecule pan-VEGFR inhibitors hold great promise to meet this unmet medical need. However, the ability to deliver small molecule VEGFR2 inhibitors to posterior ocular tissues is hindered by unfavorable solubilities and dosing limitations. These shortcomings are addressed by KPI-287, an investigational NCE that potently inhibits VEGFR family members with a superior pharmacokinetic/pharmacodynamic (PK/PD) profile relative to compounds currently undergoing clinical trials.

Methods: In vitro kinase pharmacological profiles of KPI-287 and axitinib were evaluated against a panel of 97 kinases distributed across the kinome (Eurofins DiscoveRx, USA). IC_{50} for VEGFR-2 and PDGFR-β were determined in HUVEC and NIH3T3 cell lines, respectively (ProQinase, Germany). PK/PD profiles of both compounds were evaluated in Dutch-belted rabbits following topical administration and intravitreal (IVT) challenge with rhVGEF.

Results: Both KPI-287 and axitinib demonstrate comparable inhibitory profile against VEGFR and PDGFR kinases (FLT1, KDR, FLT4, PDGFR-α and PDGFR-β). However, the two compounds exhibited differing secondary pharmacology, with KPI-287 showing activity at EGFR, ALK and TGFβ1. Despite the similar activities at VEGR subtypes, KPI-287 showed superior in vivo efficacy compared to axitinib in the rabbit rhVEGF challenge model despite more frequent dosing of axitinib. The superior efficacy of KPI-287 correlated with a greater solubility and higher tissue levels achieved in the retina and choroid of Dutch-belted rabbits compared to those for axitinib. PK/PD profiling of KPI-287 demonstrated that efficacy can be achieved at retinal concentration >250 nM, supporting administration of KPI-287 by intravitreal and suprachoroidal routes.

Conclusions: Relative to axitinib, the most potent VEGFR2 inhibitor currently in the clinic for the treatment of wet AMD, KPI-287 demonstrated comparable in vitro potency and superior efficacy in the rabbit VEGF challenge model. The favorable efficacy profile was associated with greater solubility and ability to achieve higher tissue levels. These data support the development of KPI-287 for the treatment of choroidal neovascular disease using IVT and suprachoroidal routes of delivery.

ABSTRACT BODY:

Purpose: Threshold-level spatial vision (e.g., contrast sensitivity, logMAR visual acuity) is known to be deteriorated in keratoconus. However, suprathreshold spatial visual performance in this disease condition remains largely unknown. This study assessed the suprathreshold contrast perception in keratoconus using the well-known contrast constancy paradigm. The study hypothesized that suprathreshold contrast matches for keratoconus will show deficiencies that may be predicted from the pattern of loss in their contrast sensitivity function (CSF).

Methods: Apparent contrast matches were determined at 10% and 50% stimulus contrast in 10 unilateral keratoconic cases (24 – 29yrs) and 10 age-similar controls using an adaptive staircase procedure with 8 reversals. Contrast matches were determined between a “standard” Gabor grating, with spatial frequency corresponding to the peak of the subject’s CSF, and “test” gratings with frequencies at one-third, one-half, twice or thrice that of the standard grating.

Results: Contrast sensitivity of keratoconic cases showed significant deterioration (mean±1SD area under CSF: 1.25±0.37log units), relative to controls (2.23±0.24log units) ($p<0.001$). For both cases and controls, the matching contrasts of test gratings for both suprathreshold contrast levels were within ±20% of the standard grating contrast for spatial frequencies greater than the peak CSF ($p=0.12$ for both). In comparison, the contrast matches of test gratings were significantly higher (~40 – 60%) for spatial frequencies lower than the peak CSF ($p<0.05$ for both frequencies).

Conclusions: Suprathreshold contrast perception appears to remain unaltered in keratoconus for spatial frequencies higher than the peak of the CSF, even though contrast sensitivity is significantly deteriorated. Suprathreshold contrast losses may however be perceived in both keratoconics and controls for spatial frequencies lower than the peak of the CSF.

ABSTRACT BODY:

Purpose: To apply a 3D ultrasound elastography technique to map and evaluate the through-depth and regional variation of tissue deformation in the optic nerve head (ONH) and the surrounding peripapillary sclera (PPS) during intraocular pressure (IOP) elevation.

Methods: Inflation tests were performed in 15 normal human donor (20-78 years old) globes while IOP was raised from 15 to 30 mmHg. A 3D volume of the posterior eye centered at the ONH (10 mm × 10 mm) was scanned at each pressure step using a 50MHz ultrasound probe (MS700, Vevo2100, VisualSonics). A correlation-based 3D speckle tracking algorithm was used to compute tissue displacements. Radial, circumferential, meridional and shear strains in spherical coordinates were obtained. ONH and PPS were manually segmented on 3D ultrasound images and divided into equal anterior and posterior layers. Average strains at 30 mmHg were calculated for each region and compared using linear mixed models with unconstrained covariance matrix to account for associations of different regions of the same eye.

Results: Strain maps (Figure 1) showed higher magnitudes of radial (ε_{rr}) and out-of-plane shear ($\varepsilon_{\varphi r}$) strains in the anterior ONH and PPS. Quantitative analysis showed that ε_{rr} and $\varepsilon_{\varphi r}$ were significantly greater in the anterior PPS than posterior PPS (-4.80±0.84% vs -1.42±0.74% and 1.53±0.43% vs 0.76±0.21%, p's<0.001; Figure 2). Similarly, ε_{rr} and $\varepsilon_{\varphi r}$ were significantly greater in the anterior ONH than posterior ONH (-4.15±0.83% vs -0.10±0.61% and 2.45±0.93% vs 1.30±0.42%, p's<0.001). Anterior ONH had larger shear but smaller radial strain compared to anterior PPS (p=0.0003 and 0.0001).

Conclusions: Despite a small total thickness, the ONH and PPS exhibited significant depth-dependent variation in IOP-related mechanical deformation. Radial and shear strains were largely concentrated in the anterior region, possibly underlying glaucomatous damage such as tissue tear and disc hemorrhage in this region.

ABSTRACT BODY:

Purpose: To determine the diagnostic accuracy of iPad perimetry using the visualFields Easy (VFE) application for glaucoma screening.

Methods: This was a prospective, cross-sectional study that enrolled patients undergoing their first Humphrey Field Analyzer (HFA) visual field test at the glaucoma clinic at a tertiary eye hospital in India between October 2014 and September 2015. Patients were excluded if they had undergone intraocular surgery within 2 weeks of enrollment. Participants received 24-2 SITA Standard HFA testing followed by iPad perimetry with the visualFields Easy application. The diagnostic accuracy of iPad perimetry was assessed for visual field defects relative to HFA results and for glaucoma relative to ophthalmologist diagnosis.

Results: iPad perimetry showed an area under the receiver operating characteristic (AUROC) curve of 0.67 (0.61-0.74) for visual field defect detection. This is in contrast with 0.86 (0.81-0.91) using 24-2 HVF. For detection of any glaucoma, VFE had an AUROC of 0.66 (0.58-0.73) while HVF had 0.89 (0.84-0.93). Sensitivities for glaucoma detection were 66.7% (48.7-78.5) and 80.2% (69.6-90.1) for VFE and HVF, respectively.

Conclusions: Our findings suggest that iPAD perimetry using the VFE application is inferior to 24-2 Standard HVF testing in detecting any visual field defects and glaucoma. The limited sensitivity of VFE minimizes its utility as an optimal tool for a glaucoma screening.

ABSTRACT BODY:

Purpose: Regulated, cyclical peaks of outer segment phagocytosis (OSP), by the retinal pigmented epithelium (RPE), maintain healthy photoreceptors. Defective OSP is implicated in inherited and age-related blindness˙ However, the mechanisms instigating OSP in photoreceptors, particularly in cones, remains poorly characterised, leaving a knowledge gap in retinal biology and disease. This study investigates extrinsic environmental and intrinsic molecular regulators of OSP in zebrafish.

Methods: Real-time PCR was carried out on cDNA generated from 15 dpf zebrafish eyes collected under normal light-dark (14h:10h) or following 1 day under dark-dark conditions. For TEM analysis of shed OS, phagosomes were manually counted, and the density calculated as phagosomes per µm of RPE (n=3). Proteomic profiling of sibling eyes collected at ZT 4, ZT 9 and ZT 17 was performed by mass spectrometry (MS) (n=3).

Results: Real-time PCR identified candidate OSP regulators including cerkl, mertka and abcf1 to maximise expression prior to one or both OSP peaks under a regular light-dark cycle (n=3). Dark:dark environmental conditions revealed the number of RPE phagosomes at circadian time (CT) 4 (0.12 phagosomes/um RPE) was significantly ($p=0.003$) reduced compared to the peak number (0.18 phagosomes/um RPE) at ZT 4 under a normal light dark cycle, suggesting an absence of circadian regulation. Preliminary data (n=2) suggests that the absence of light alters the transcription profiles of several known OSP regulators. Potential novel regulators of OSP were uncovered using proteome profiling of the zebrafish retina at ZT 4, ZT 9 and ZT 17 and these are being validated by immunostaining.

Conclusions: The data provides a model for insights into the regulators of OSP in a cone-rich retina. In summary, the results shown here identify transcript and proteomic profiles of known and putative OSP regulators, revealing highly upregulated expression levels at time-points correlating to both dawn and dusk peaks of OSP. Exposure to light:dark transition is necessary to fully initiate the burst of OSP at peaks in the zebrafish retina, and may be involved in controlling expression profiles of molecular regulators. This data also holds biomedical significance as defective OSP may be part of the disease pathway for many retinal and macular degenerations.

ABSTRACT BODY:

Purpose: The aim was to assess the effect of eye movements on intraorbital cables of retinal implants using dynamic computer tomography (CT) scan series during gaze changes that can cause mechanical forces leading to movements of subretinal electronic arrays in patients.

Methods: In 27 datasets of patients with Retina Implant Alpha IMS (Retina Implant AG, Reutlingen, Germany) the displacements of the microchip were investigated relative to the optic disc and major blood vessels. Additionally, three techniques for intra-orbital cable routing were analyzed (straight cable route, para-bulbar loop and encircling band). The bending radius of the intra-orbital cable was measured as indicator for mechanical stress; additionally, gaze restrictions were analyzed.

Results: Chip position remained stable in 12/27 cases (44%) whereas in 15/27 (56%), displacement occurred. The mean ± SD displacement in those 15 eyes was 0.66 ± 0.35 mm (range, 0.24–1.67 mm); similar data were obtained in 8 patients who had received Alpha AMS implants. CT-investigation of average bending radius variation of intra-orbital cables was 87% for straight cable route, 11% for para-bulbar loop routing and 16% for encircling band technique. The analysis of eye motility showed a restriction in the up-gaze and gaze to the temporal side directly after surgery in 8/9 Implant Alpha AMS patients. The degree of motility restriction decreased continuously with recovery during the observation time.

Conclusions: In patients with Retina Implant Alpha, firstly, the majority shows slow implant displacements in the subretinal space (mean ± SD 0.66 ± 0.35 mm), developing without major sequelae; secondly, arcuate routes with large bending radius of intra-orbital cables significantly reduce cable movement and thereby mitigate mechanical forces; thirdly, short intra-orbital cable lengths are mainly restricting up-gaze and gaze to the temporal side. There are several mechanical forces, related to eye movements and cable properties, including breaks, that need careful consideration of engineering techniques, selection of cable routes and surgical procedures.

ABSTRACT BODY:

Purpose: To determine the incidence and risk factors for developing treatment-warranted diabetic macular edema (TW-DME) within 5 years after diagnosis of type 2 diabetes (DM2). This may aid identification of patients at increased risk of vision loss who may benefit from additional interventions.

Methods: We performed a retrospective longitudinal cohort study using the Optum's de-identified Clinformatics® Data Mart Database from 2007 to 2015. Individuals 18 years of age and older with a diagnosis of DM2 and continuous insurance enrollment of 6 years (1 pre, 5 post-diagnosis) were identified. The cumulative incidence of TW-DME within 5 years was determined using medical claims data. Associations between TW-DME and sociodemographic and clinical factors were tested with multivariable logistic regression. Statistical significance was evaluated with a p-value of 0.05.

Results: Of 72,067 patients newly diagnosed with DM2, 540 (0.75%) patients had developed TW-DME at 5 years after DM2 diagnosis. Patients who developed TW-DME were more likely to be of older age at diagnosis (age 65-74, OR 1.58, p=0.009) and to have other systemic complications of DM2, including renal disease (OR 2.59, p<0.001), neurological disease (OR 2.40, p<0.001), and peripheral circulatory disorders (OR 2.15, p=0.007). In addition, insulin use (OR 4.11, p<0.001) was more common, and max A1c was higher (9.7 ± 2.5 vs 7.6 ± 2.0, p<0.01) in those developing TW-DME. Young age at diagnosis (age 18-34, OR 0.36, p=0.005), Medicare insurance (OR 0.47, p<0.001), morbid obesity (OR 0.62, p=0.001), smoking (OR 0.77, p=0.046), and dyslipidemia (OR 0.80, p=0.034) were identified as protective factors. African-Americans and Hispanics had a higher incidence of TW-DME, 0.84% and 0.79% respectively, while Asians had a lower incidence of 0.64%.

Conclusions: Patients with a history of A1c > 9%, insulin use, renal disease, neurologic disease, and peripheral circulatory disease, and advanced age at diagnosis are at a higher risk for early development of TW-DME. These patients may require additional and earlier screening after diagnosis of DM2.

TITLE: Astrocytes of the optic nerve head in pig and human eyes have no aquaporin channels

SESSION TITLE: Neuron/Glia Interactions in Retinal Health and Disease

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: H.A. Quigley, C. Keuthan, M. Pease, E. Kimball, Johns Hopkins Medicine, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Harry Quigley: Commercial Relationship(s);Code F (Financial Support):Heidelberg,Topcon,Sensimed,Equinox;Code C (Consultant/Contractor):Sensimed,IDx,Equinox,Gore,Injectsense | Casey Keuthan: Commercial Relationship: Code N (No Commercial Relationship) | Mary Pease: Commercial Relationship: Code N (No Commercial Relationship) | Elizabeth Kimball: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: It has been proposed that glaucoma's optic nerve (ON) injury is related to glymphatic pathway fluid movement and thus would be dependent on astrocytic aquaporin (AQP) channels [1]. We have reported that AQPs are absent in the astrocytic lamina of rodent optic nerve head (ONH) [2]. This study quantified regional AQP channel expression in astrocytes of the porcine and human retina, ONH and myelinated ON (MON).

Methods: In pig and human post mortem eyes, we immunolabeled sections containing retina, ONH and MON against AQP1, 4, and 9, myelin basic protein, glial fibrillary acidic protein (GFAP) and α-dystroglycan (αDG). AQP label was quantified in each region [2] and quantitative gene expression data were analyzed in retina, ONH and MON tissues separately by qPCR in pig eyes. Human eyes were confirmed to have no retinal or ON disease histologically and by pre-mortem history.

Results: Pig and human eyes had abundant AQP4 in Müller cells, retinal astrocytes, and MON astrocytes, but minimal expression in the ONH lamina cribrosa. AQP1, 9 were present in retina, but not in ONH. Immunolabeling of GFAP and αDG were present and had similar staining patterns in ONH and MON. Quantitative AQP4 labeling was at background level in ONH, but substantial in MON (ONH vs MON, $p \leq 0.01$). AQP4 mRNA expression was minimal in ONH, but significantly higher in MON ($p=0.0001$). GFAP mRNA expression was uniform in ONH and MON.

Conclusions: The absence of AQP4 channels in ONH astrocytes is evolutionarily conserved in all mammals studied. Aqp4 knockout mice have no beneficial or detrimental outcomes in experimental glaucoma. The regionally specific lack of AQP channels in ONH astrocytes is likely to be a protective mechanism against swelling in the narrow ONH region. The glymphatic pathway is unlikely to play a role at the site of damage in glaucoma.

ABSTRACT BODY:

Purpose: Variance of the probability mass function (PMF) for sensitivity estimation is an important measure for visual field (VF) testing algorithms, as a smaller variance indicates that the algorithm is more confident that the PMF represents the true sensitivity. We developed and tested a variance reduction technique to optimize the initial sensitivity estimation, thereby improving the overall performance of visual field testing algorithms.

Methods: The Zippy Estimation by Sequential Testing (ZEST) algorithm was simulated on our visual field dataset with 504 normal and 784 glaucomatous visual fields with a 24-2 testing pattern. Visual fields were divided into multiple VF regions and fixed the testing locations of the first batch of light stimuli to be inside the nasal and arcuate region. After obtaining the sensitivity estimations from these testing locations, a gradient boosting decision tree classifier was used to determine whether the visual field is from a normal or abnormal group. Then, the initial PMFs of the remaining locations were set to be the empirical distribution obtained from a normal or abnormal group based on prediction outcomes. Finally, these locations were tested with the adjusted initial PMFs.

Results: By adopting the proposed variance reduction approach, ZEST becomes 4.57% faster and 4.17% more accurate ($p<0.01$). Meanwhile, the gradient boosting decision tree classifier achieves a 97% average classification accuracy.

Conclusions: Our results indicate that using a carefully designed testing sequence can effectively reduce the variance in sensitivity estimation and greatly improve the quality of visual field tests, leading to shortened testing time, higher testing accuracy, and improved patient’s satisfaction.

ABSTRACT BODY:

Purpose: To develop an automatic method to find the external limbal transitions points between the cornea and the sclera based on anterior topography obtained from ultrawide-field anterior segment optical coherence (OCT) images.

Methods: An ultrahigh-speed (325 kHz) ultrawide-field swept-source OCT prototype was used to obtain corneo-scleral (CS) images of the left and right eyes from four subjects. The imaging depth range is 15.5 mm with an axial resolution of 12.2 µm (in air). The scan pattern consisted of 16 radial scans of 20 mm width. This scan pattern was centered on the pupil and repeated three times consecutively in each acquisition. The CS profile, segmented from the OCT cross-sectional images, was corrected for the field distortion inherent to the OCT scans. For each meridian, the second central moment of the OCT signal was projected to obtain a radial profile on which the anterior CS junction [DH1] and pupil can be identified by sharp transitions. The anterior corneal surface inside the CS junction was fitted with a 4^{th} degree polynomial and the anterior conjunctival surface over the sclera outside the CS junction was fit with a 2^{nd} degree polynomial. The external limbus was identified as the point where these best-fit corneal and scleral surfaces intersected. The external [DH2] limbal positions from the 16 meridians were combined and modelled with a best-fit ellipse.

Results: The average ± standard deviation radial distance from the pupil center to the limbal transition was 6.16 ± 0.24 mm. Further, the limbus was modeled with an ellipse which average ± standard deviation minor and major axes of 11.87 ± 0.70 mm and 13.01 ± 0.48 mm, respectively.

Conclusions: Ultra-fast swept-source OCT provides high-resolution CS images. Using the central moment of the OCT signal, the CS transition and the pupil can be identified automatically. The external limbus defined by the shape of the anterior surface is different to the WTW distance and therefore an automatic method, as the one proposed, would be more suitable to define the external limbus which is needed for scleral lens fitting.

TITLE: Separately Imaging Zeaxanthin and Meso-zeaxanthin in the Human Fovea with Polarized Resonance Raman Microscopy

SESSION TITLE: Biochemistry and Molecular Biology of the Retina/RPE

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Giauque, F. Chang, Z. Wan, B. Li, P.S. Bernstein, Department of Ophthalmology and Visual Sciences, The University of Utah School of Medicine, Salt Lake City, Utah, UNITED STATES|

Commercial Relationships Disclosure: Nathan Giauque: Commercial Relationship: Code N (No Commercial Relationship) | Fu-Yen Chang: Commercial Relationship: Code N (No Commercial Relationship) | Zihe Wan: Commercial Relationship: Code N (No Commercial Relationship) | Binxing Li: Commercial Relationship: Code N (No Commercial Relationship) | Paul Bernstein: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Zeaxanthin and meso-zeaxanthin are the dominant carotenoids in the human fovea. These two carotenoids are stereoisomers, sharing the same molecular formula but differing from each other only in the orientation of the hydroxyl group at the C3' of the β-ionone ring. Conventional resonance Raman microscopy cannot distinguish zeaxanthin from meso-zeaxanthin. Here, we investigated whether zeaxanthin and meso-zeaxanthin can be separately measured using polarized resonance Raman microscopy.

Methods: Our XploRA Plus confocal resonance Raman microscope is equipped with three polarized laser modes (vertical, horizontal, and circular) and three polarized Raman detection modes (vertical, horizontal, and non-polarized), generating nine polarized test conditions. To determine the optimal condition for the separation of zeaxanthin and meso-zeaxanthin, 100 μM zeaxanthin and 100 μM meso-zeaxanthin solutions in methanol were mixed with ratios of 1:0, 3:1, 2:1, 1:1, 1:2, 1:3, and 0:1, respectively, and tested at nine polarized conditions with excitation of a 473 nm laser. Using the optimized condition, we further measured the carotenoid in the fovea of an 87-year-old female donor eye. A total zeaxanthin map was created by mapping the intensity of the V1 peak at 1528 cm^{-1}. Separate maps of zeaxanthin and meso-zeaxanthin were generated by LabSpec6 software's Classical Least Squares(CLS) fitting algorithm.

Results: The compositions of zeaxanthin and meso-zeaxanthin in the mixed carotenoid solutions measured under two polarized conditions: horizontal laser vs vertical Raman (H-V), and circular laser vs vertical Raman (C-V), were significantly correlated to the known ratios of the mixed carotenoid solutions. The Raman signals of carotenoids under C-V condition were stronger than the H-V condition, serving as the optimized condition to measure carotenoids in the human fovea. The retinal distribution of total zeaxanthins exhibits a circle with a dot at its center. Further analysis revealed that zeaxanthin was localized mainly at the central dot area, whereas the meso-zeaxanthin was allocated on the circle.

Conclusions: This demonstrates that zeaxanthin and meso-zeaxanthin can be separately measured under polarized Raman conditions, which might offer new knowledge to understand the physiological role of macular carotenoids in the prevention of retinal disease.

ABSTRACT BODY:

Purpose: It is emerging that there are early changes of visual function in association with Alzheimer's disease (AD). In this work, we propose to test the potential changes and when the changes start to appear in the retinas o AD mice, using the triple transgenic mouse model (3×Tg-AD).

Methods: We carried out a longitudinal study in AD (3×Tg-AD) mice at 2, 4, 6, 12 months of ages. Age and sex-matched wild-type mice were used as controls. Visual acuity and contrast sensitivity were assessed by optomotor response (OMR). Retina functional changes were evaluated by electroretinography (ERG) to record the ganglion cell dominated positive scotopic threshold response (pSTR) that were elicited with the dimmest flashes (0.0001765 cd/m^2). Outer retinal layer functions were recorded by ERG maximum scotopic response (Xenon lamp, 2cd. cd/m^2), light-adapted photopic (Xenon light, 600 cd/m^2), S cone test (green light, 13 cd.s/m^2), and M cone test (blue light, 13 cd.s/m^2).

Results: Significantly reduced visual contrast sensitivity (CS) was detected in 3xTG-AD mice at as early as 2 months (2M) of age compared to age-matched wild-type control mice. Notably, female AD mice showed better CS than male mice when examined at 2M of age. Starting from 6M old, there was significant reduction of visual acuity (VA) in 3xTG-AD mice comparing with age-matched WT control mice. The ERG pSTR amplitude in 3xTg-AD mice was also significantly reduced at 4M of age comparing to WT, and this difference persisted throughout the later ages examined (4M, 99.308+/-7.194 vs 107.307+/-6.986, $p < 0.01$; 12M, 56.39+/-15.56 vs 78.77+/-16.89, $p < 0.05$ by two-way ANOVA). 3xTg-AD mice also revealed a significantly higher scotopic b-wave amplitude and light-adapted photopic response than WT mice starting from 6M of age. The a-wave amplitude and S cone test or M cone test in AD mice were not significantly different from the WT at all time points.

Conclusions: Our results suggest visual function deficit at a very early-stage of AD. Sex differences in the spatial frequency threshold should be considered. The pattern of neuronal dysfunction in AD mice occurs primarily in the inner retina and probably progresses to encompass the outer retina with age.

Commercial Relationships Disclosure: Palak Gupta: Commercial Relationship: Code N (No Commercial Relationship) | Sinem Beylergil: Commercial Relationship: Code N (No Commercial Relationship) | Jordan Murray: Commercial Relationship: Code N (No Commercial Relationship) | Jonathan Jacobs: Commercial Relationship: Code N (No Commercial Relationship) | Aasef Shaikh: Commercial Relationship: Code N (No Commercial Relationship) | Fatema Ghasia: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Vergence insufficiency, impaired saccades contribute to depth perception deficits, poor navigation, and increased fall risk in PD patients. 1/3rd of PD patients also have strabismus and disabling double vision. DBS is becoming increasingly common for improving general motor symptoms of PD. In this study we examined the effects of bilateral STN DBS on the binocular coordination of saccades in PD.

Methods: We measured binocular eye positions during gaze-holding and saccades using high-resolution video-oculography (Eyelink1000™) in twenty PD patients and seven healthy controls. Saccades were quantified by placing LED targets at 150 cm distance on an isovergence circle with angle of ±10° and ±20°. Subsequently, clustering was performed to analyze gaze-holding performance. Saccades were identified and analyzed using the Engbert algorithm.

Results: Binocular coordination in PD was significantly better with DBS switched ON, as compared to OFF ($p<0.05$). Supervised clustering was applied to gaze fixation data in order to assess performance. Controls had a mean of maximal deviation (Horizontal: 1.9±0.56°, Vertical: 1.94±0.6°) significantly different from PD DBS OFF (Horizontal: 3.08±2.98°, Vertical: 1.54± 1.40°), but not from PD DBS ON (Horizontal: 1.71± 1.28°, Vertical: 1.27± 1.4°). This was also reflected in saccade tasks with fusion maintenance. Post saccade drift variance in controls (Mean:0.01±0.03°; $p<0.05$) was found to be different from PD with DBS OFF (Mean:0.19±0.76°). Meanwhile, there was no difference in post saccade drift variance between controls and PD DBS ON (Mean:0.01±0.02°). The difference in latency of controls (Mean:0.244±0.029msec), PD DBS ON (Mean:0.50±0.47msec) and PD DBS OFF (Mean:0.32±0.11msec) approaches statistical significance ($p=0.09$).

Conclusions: Objective analysis of gaze-holding and saccadic eye movements suggest that saccadic abnormalities and strabismus are prevalent, significant, and interrelated in PD. The results suggest that STN-DBS affects the neural pathway common to both vergence and saccades, possibly by acting on the STN–substantia nigra pars reticulata–superior colliculi pathway. These findings provide novel insights into the pathophysiology of Parkinson's disease and may yield better treatment strategies for strabismus, including using STN DBS.

ABSTRACT BODY:

Purpose: To examine tissue quality resulting from manipulation to form double scroll (DS) DMEK grafts during and after graft preparation.

Methods: DS during preparation: Grafts prepared from 10 pairs of donor corneas (age 39-66) were floated in BSS and allowed to spontaneously scroll. Controlled bursts of BSS were used to promote DS formation in one member of each pair. Grafts were subsequently stained with Calcein-AM, imaged, and analyzed for endothelial cell loss (ECL) by FIJI segmentation. Cell loss from manipulated and unmanipulated mate grafts was compared using unpaired Student's t-test. Double scrolling preloaded grafts: Grafts from 18 pairs of donor corneas (split into 'young' (age 48-64) and 'old' (age 66-80) cohorts) were prepared and loaded into a Straiko modified Jones tube. One member of each pair was induced to DS by applying repeated push-pull action on a BSS-filled syringe attached to the injector tube. Manipulated and unmanipulated mate grafts were analyzed and compared as described above.

Results: An eye bank processing technician was able to successfully form a DS during graft preparation in 9/10 attempts. There was no difference in ECL in manipulated compared to unmanipulated mate grafts (15.2%±3.3% vs 15.2%±4.4%, P=0.99). For preloaded DMEK grafts, the old cohort could form a DS in 9/9 attempts while the young cohort could only form DS in 6/9 attempts. The additional tissue manipulation resulted in a significant difference in ECL in the old cohort (manipulated: 17.4%±3.5% vs unmanipulated: 13.0%±4.2%, P=0.03), but not the young cohort (15.5%±4.4% vs 13.0%±4.5%, P=0.24).

Conclusions: DS DMEK grafts can be successfully formed during or after graft preparation. In older donor grafts, additional manipulation required to form a DS results in increased ECL; but this cell loss is within the acceptable range for transplant tissue. In younger donor grafts, additional manipulation using either technique does not result in increased ECL. For older donor grafts, surgeons should weigh the advantage of an easily opened DS against the risk of higher ECL. These two techniques may encourage the use of younger donor grafts, as neither technique produced an increase in ECL in younger donors. These techniques may also prove useful with both young and old donor tissue in more complex surgical cases, as they yield easily opened DS grafts that may reduce the difficulty of DMEK surgery.

ABSTRACT BODY:

Purpose: Glaucoma is a widespread neurodegenerative disease affecting the retinal ganglion cells, optic nerve, distal visual pathways and beyond. Recent studies suggest that cerebrospinal fluid (CSF) plays a role in clearing wastes from the brain and that CSF dynamics may be altered in neurodegenerative diseases. Since CSF dynamics can be facilitated by the global brain activity, in the present study, we investigated how the dynamics of CSF and its coupling with global brain activity may be altered in glaucoma using functional magnetic resonance imaging (fMRI).

Methods: 19 early glaucoma patients (62.3±1.7 yrs) (mean±SEM), 19 advanced glaucoma patients (64.7±2.4 yrs), and 19 healthy subjects (59±2.4 yrs) underwent anatomical MRI and resting-state fMRI with eyes closed. Age did not differ across groups (P=0.188). We extracted the CSF signal time profiles from the fourth ventricle (Fig. 1A) and the global brain activity [blood-oxygenation-level-dependent signal time profiles] from the entire gray matter (Fig. 1B). Following previous literature (Han F, et al. PLOS Biol 2021;19), the coupling between the CSF signals and the global brain activity (CSF-BOLD coupling) was examined via cross correlation at the 4s time lag, where more negative values indicate stronger coupling. We also associated these correlations with the volumes of the anterior visual pathway in anatomical MRI.

Results: A significant group difference was observed in the power (i.e., strength) of the low frequency (0.01-0.03Hz) in the CSF signals (P=0.013; Fig.1C). Specifically, early glaucoma patients showed significantly greater power than advanced glaucoma patients (Bonferroni P=0.010). The power of the global brain activity showed similar trends but did not reach significance (P=0.390; Fig.1D).

The CSF-BOLD coupling at the 4s lag differed significantly across groups (P=0.007; Fig. 1E). Early glaucoma patients had significantly stronger coupling than advanced glaucoma patients (Bonferroni P=0.025) and healthy controls (Bonferroni P=0.013).

Further, CSF-BOLD coupling was correlated with the volumes of optic nerve (right: R=-0.342, P=0.009; left: R=-0.344, P=0.009, Fig. 2D,E) and optic chiasm (R=0.264, P=0.047, Fig. 2F).

Conclusions: Our observations of the altered CSF dynamics and CSF-BOLD coupling provide physiological evidence to support the recent hypothesis of widespread brain involvements in the early stage of glaucoma.

ABSTRACT BODY:

Purpose: To compare the accuracy and generalizability of Vision Transformer, a new deep learning (DL) technique, to a traditional convolutional neural network, ResNet-50, for detecting primary open-angle glaucoma (POAG) using Ocular Hypertension Treatment Study (OHTS) fundus photographs and 5 external datasets.

Methods: 66,715 photographs of 1,636 participants in the OHTS were used to compare the best-performing Vision Transformer model (Data-efficient image Transformer, DeiT) to ResNet-50 for detecting the OHTS Endpoint Committee determinations of POAG attributable to optic disc changes (ENPOAGDISC), visual field changes (ENPOAGVF), or both (ENPOAGANY) and OHTS Optic Disc Reading Center (RCPOAGDISC) and Visual Field Reading Center (RCPOAGVF) determinations. The accuracy of Vision Transformer and Resnet-50 DL models also were compared in 5 external international test datasets of fundus images labeled as glaucoma or healthy: 1) Diagnostic Innovations in Glaucoma Study (DIGS) and African Descent and Glaucoma Evaluation Study (ADAGES, United States) datasets, 2) the ACRIMA (Spain) dataset, (3) the Large-Scale Attention-based Glaucoma (LAG, China) dataset, (4) the Retinal IMage database for Optic Nerve Evaluation (RIM-ONE, Spain) dataset, (5) The Online Retinal Fundus Image Dataset for Glaucoma Analysis and Research (ORIGA, Singapore) dataset. Areas under receiver operator characteristic curves (AUROC) were used to measure model accuracy.

Results: The Vision Transformer models demonstrated similar performance to the ResNet-50 on the OHTS test sets for all 5 ground truth POAG labels (Figure: panel a). The diagnostic accuracy of Vision Transformer was consistently

higher than Resnet-50 on the independent external fundus photograph datasets (Figure: panels b-f). For example, the DeiT model AUROC for ENPOAGANY was between 0.08 and 0.20 higher than the ResNet-50 model AUROC.
Conclusions: Vision Transformer has the potential to serve as a critical tool to reduce biases and improve the generalizability of DL models for the detection of glaucoma from fundus photograps.

ABSTRACT BODY:

Purpose: To validate the role of an artificial-intelligence (AI) based quantification of most relevant OCT biomarkers in assessing disease activity and treatment response in eyes affected by center-involved diabetic macular edema (DME).

Methods: After adequately training the deep learning algorithm using normal and diabetic OCT images, a specific tool for automatically detect and quantify: intraretinal and subretinal fluids (IRF and SRF), hyperreflective retinal foci (HRF), the integrity of external limiting membrane (ELM) and ellipsoid zone (EZ), and the area of retinal exudates (AHE) was developed, trained and then validated versus two blinded experienced examiners. Three-hundred eyes affected by center-involved DME were consecutively enrolled to validate the automatic tool, and 100 DME treated eyes were used to quantify each parameter over time (at least three follow-up examinations). Fluid volumes (IRF and SRF) and AHE were measured for three concentric circles with diameters of 1, 3 and 6 mm (fovea, paracentral ring and pericentral ring). HRF were measured in the central 3 mm, whereas the integrity of ELM/EZ was quantified in the central 1 mm. ICC was calculated for each parameter between the two human examiners, and versus the automated tool.

Results: The agreement for any OCT biomarkers detection and quantification, at any time point, between operators was complete (ICC: 1.0), as versus the AI tool (ICC: 0.99). In all DME eyes most intraretinal fluid per square millimeter was present at the fovea, followed by the paracentral ring and pericentral ring ($p<0.0001$). And this was also the case for subretinal fluid ($p<0.0001$). In the follow-up eyes, at every time point, this observation was confirmed. HRF significantly decreased after treatment ($p<0.001$), recovey of ELM/EZ integrity was reached ($p<0.005$) and the area of hard exudates slowly reduced in all rings ($p<0.005$).

Conclusions: Accurate, repeatable location and quantification of major OCT biomarkers of DME, namely: individual macular fluids (IRF and SRF), HRF, integrity of ELM/EZ, and area of hard exudates, are currently mandatory to adequately diagnose and prognosticate treatment response over time. A fully validated AI based tool, as reported, allows the clinicians to routinely identify and quantify the most relevant OCT biomarkers offering an objective way of planning and following DME eyes.

ABSTRACT BODY:

Purpose: The recently developed visible-light OCT (vis-OCT) enabled an axial resolution of 1.3 μm, enhanced tissue scattering contrast, and introduced new functional imaging capabilities. These capabilities are increasingly desirable in the clinic. However, its clinical translation is limited by supercontinuum light sources with high relative-intensity noise (RIN), which degrades image quality and limits imaging speed. Therefore, we seek to develop a high-speed vis-OCT by eliminating RIN.

Methods: We developed a vis-OCT, which uses two subpixel calibrated spectrometers in a Mach-Zehnder interferometer (MZI) to achieve balanced detection and RIN cancelation. We first coupled a supercontinuum light source (NKT Photonics, 78 MHz repetition rate) into a 10:90 fiber coupler. We delivered 10% of the light to the eye (200 μW) and 90% of the light to a transmission-based reference arm. Light backscattered from the eye was transmitted to a second 50:50 fiber coupler and was simultaneously detected by two well-calibrated spectrometers (Blizzard, Opticent Health).

Results: Compared with the previous vis-OCT influenced by RIN, balanced detection achieved nearly shot-noise-limited imaging in humans, reduced the noise floor by 20.5 dB, increased the peak signal to the noise floor ratio from 16.1 dB to 31.8 dB, and increased the contrast to noise ratio from -9.7 dB to 3.8 dB (Figs. 1a&1b). We performed all imaging at a 125 kHz A-line rate with a field-of-view up to 10 mm × 4 mm (1024 A-lines × 256 B-scans) as shown in Fig. 1c, the fastest ever for ophthalmic vis-OCT.

Conclusions: We developed the first subpixel-calibrated balanced detection MZI for significant RIN suppression in retinal vis-OCT. RIN suppression enabled the highest speed vis-OCT imaging at 125 kHz and the largest field-of-view in humans.

ABSTRACT BODY:

Purpose: Glaucoma is a neurodegenerative disease that affects the retina, resulting in the degeneration of retinal ganglion cells (RGCs) and subsequent loss of vision. While RGCs are the primary cell type affected in the disease state, previous studies have demonstrated that blood brain barrier (BBB) properties may be compromised in glaucoma. However, the factors responsible for BBB disruption have remained elusive and thus, the goal of the study was to explore how changes in paracrine signaling within the BBB may be responsible for certain aspects of glaucoma using human pluripotent stem cell (hPSC)-derived cells.

Methods: To model aspects of barrier dysfunction in glaucoma, hPSCs with a glaucoma-specific Optineurin (E50K) mutation, as well as isogenic controls, were directed to differentiate into cells of the BBB, including RGCs, astrocytes, and microvascular endothelial cells (MVECs). Subsequently, MVECs were seeded into the top of an established in vitro barrier transwell model, while RGCs and astrocytes grown in the bottom. The ability to recapitulate characteristic properties of the BBB were then tested, including trans-endothelial electrical resistance (TEER), permeability and rhodamine transport. Further, RNA sequencing and ELISA identified factors responsible for changes observed.

Results: The establishment of the barrier model with RGCs, astrocytes, and MVECs resulted in a significant enhancement of barrier properties compared to MVECs grown alone. However, when the barrier model was assembled with cells with the glaucoma OPTN(E50K) mutation, barrier integrity was compromised, including reduced TEER and increased barrier permeability along with reduced efflux transporter activity and/or localization. An increased expression of certain secreted factors were identified from OPTN(E50K) astrocytes, and addition of exogenous factors applied to healthy cultures resulted in barrier dysfunction similar to the glaucoma barrier model.

Conclusions: The results of this study will expand our understanding of the mechanisms by which glaucoma affects the BBB. Overall, the in vitro glaucoma barrier model demonstrated characteristic functional deficits, mimicking some aspects of the phenotypes observed during the progression of glaucomatous neurodegeneration, with strong implications for the use of this model for disease modeling and drug development to rescue neurodegenerative phenotypes.

TITLE: Automated detection of Drusenoid Pigment Epithelial Detachments (DPEDs) on OCT's in patients with Age related Macular Degeneration (AMD)

SESSION TITLE: Imaging of posterior segment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Mukherjee, T. de silva, C. Duic, A. Thavikulwat, K. Hess, H. Wiley, T.D. Keenan, E.Y. Chew, C. Cukras, National Eye Institute, National Institutes of Health, Bethesda, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Souvick Mukherjee: Commercial Relationship: Code N (No Commercial Relationship) | Tharindu de silva: Commercial Relationship: Code N (No Commercial Relationship) | Cameron Duic: Commercial Relationship: Code N (No Commercial Relationship) | Alisa T Thavikulwat: Commercial Relationship: Code N (No Commercial Relationship) | Kristina Hess: Commercial Relationship: Code N (No Commercial Relationship) | Henry Wiley: Commercial Relationship: Code N (No Commercial Relationship) | Tiarnan Keenan: Commercial Relationship: Code N (No Commercial Relationship) | Emily Chew: Commercial Relationship: Code N (No Commercial Relationship) | Catherine Cukras: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: DPEDs in AMD appear as large yellowish mounds on stereoscopic examination. DPEDs are an important risk factor for progression to late AMD and vision loss. Spectral Domain OCT (SD-OCT) is an important imaging modality in the evaluation of retinal diseases. Automated detection of DPEDs on SD-OCT may help understand the pathophysiology of AMD progression and be useful for clinical trial screening.

Methods: 131 patients (294 eyes) enrolled in a longitudinal study of dark adaptation (NCT01352975) with a range of AMD severities from no AMD to eyes with advanced atrophic disease were imaged using both color fundus imaging (Topcon) and SD-OCT imaging (Heidelberg, Germany). Color fundus images were graded by the Wisconsin Reading Center and assigned AMD severity scores (AMDSC) of 0-10.

SD-OCT imaging consisted of a volumetric macular scan (30°x25°, 496×768×121 voxels). A 3D-UNet trained to segment the Retinal Pigment Epithelium (RPE) and Bruch's membrane (BM) layers was used to contour all 294 macular volumes. The $6x6mm^2$ region representing the grid centered around the fovea was considered for calculating the mean ± std of the maximum width (W) and maximum elevation (H) between the RPE and BM layers in eyes with DPEDs. The layer contours were screened to identify measures satisfying the requirements of distinct elevations (>50μm) in the RPE Drusen Complex region with minimum diameter (>433μm), defining a DPED.

Results: Out of 76 eyes with no AMD (AMDSC 0-1), 111 with early AMD (AMDSC 2-5), 96 with intermediate AMD (AMDSC 6-8), and 11 with Geographic Atrophy (GA) (AMDSC 9-10)- 12/329 (eyes/B-scans) in the intermediate AMD group (W=1168.48±598.19μm, H=143.85±56.62μm) and 4/81 (eyes/BScans) in the GA group (W=715.92±279.52μm, H=113.53±40.28μm) met the DPED criteria. These occurred in 1/27 (eyes/BScans) AMDSC-6, 10/269 AMDSC-7, 1/33 AMDSC-8, and 4/81 AMDSC-10, with no DPEDs identified in eyes with AMDSC 0-5.

Conclusions: Segmentation of RPE and BM layers by a 3D-UNet can subsequently be used for automated and objective detection of DPEDs on B-scans within the macular volume. Eyes with DPEDs are of special interest with some studies targeting this phenotype. By automating this process using OCTs, more quantitative and reproducible DPED detections are possible leading to more efficient clinical trial designs.

TITLE: Ocular surface mast cells delay regression of pathological corneal blood vessels

SESSION TITLE: Corneal Immunology and Neovascularization

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: W. Cho, E. Elbasiony, Y. Guan, A. Singh, S. Mittal, S. Chauhan, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: WonKyung Cho: Commercial Relationship: Code N (No Commercial Relationship) | Elsayed Elbasiony: Commercial Relationship: Code N (No Commercial Relationship) | Yilin Guan: Commercial Relationship: Code N (No Commercial Relationship) | Aastha Singh: Commercial Relationship: Code N (No Commercial Relationship) | Sharad Mittal: Commercial Relationship: Code N (No Commercial Relationship) | Sunil Chauhan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Corneal angiogenesis, induced by various ocular insults, compromises corneal transparency. Our previous studies have shown that activation of ocular surface mast cells directly promote the development of new blood vessels. Here we investigated whether mast cells contribute to the stability of inflammatory blood vessels and impede vessel regression.

Methods: Neovascularization was induced by placing a single figure-8 intrastromal suture in the cornea using 11-0 nylon. On day 9, the suture was removed upon establishment of mature blood vessels. Corneas were harvested and stained with avidin^{+} (mast cells) and CD31^{+} (vascular endothelial cells) for immunohistochemistry (IHC) analysis. Real-time vessel regression was followed by capturing slit-lamp pictures. To investigate the direct effect of mast cells on vessel regression, suture was placed in mast cell deficient cKit$^{w\text{-}sh}$ and their wildtype (WT) C57BL/6 controls. To evaluate the effect of pharmacological blockade of mast cells on the reversion of mature blood vessels, corneas were treated one day prior to suture removal with mast cell inhibitor, cromolyn (2% in PBS). Slit lamp images were analyzed using ImageJ software. Corneas were harvested on day of suture removal and 2 days post-suture removal and expression of angiogenic factor, VEGF, was quantified to assess vessel regression at the molecular level.

Results: IHC analysis demonstrated an abundance of mast cells surrounding the new corneal blood vessels on day 9 post-suture. By 48 hours following suture removal, a significant 51.3% (± 0.67%) regression of blood vessels were observed in cKit$^{w\text{-}sh}$ mice, compared to 11.5% (± 2.15%) regression in WT controls ($p=0.002$). Established vessels completely regressed in cKit$^{w\text{-}sh}$ mice by day 7 post-suture removal. Moreover, cromolyn treatment promoted faster regression of inflammatory blood vessels, as demonstrated by complete regression of pathological vessels by 24 hours post-suture removal, compared to PBS treatment resulting in no significant change in the inflammatory vessels. Furthermore, molecular analysis of vessel regression showed a 59% lower expression of VEGF in the cromolyn-treated corneas, relative to PBS-treated groups ($p=0.03$).

Conclusions: Our data demonstrate that deficiency of ocular surface mast cell function results in faster regression of pathologic corneal blood vessels, suggesting mast cells promote the stability of inflammatory vessels.

TITLE: In vitro modelling of autosomal dominant TGFBI corneal dystrophies and development of a targeted therapeutic approach

SESSION TITLE: Development of molecular therapies for inherited ocular disease

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: O. Rezek, B. Sanchez-Pintado, M.E. Cheetham, A.E. Davidson, A.J. Hardcastle, Institute of Ophthalmology, University College London, London, London, UNITED KINGDOM|S. Tuft, Moorfields Eye Hospital NHS Foundation Trust, London, London, UNITED KINGDOM|

Commercial Relationships Disclosure: Olivia Farah Rezek: Commercial Relationship: Code N (No Commercial Relationship) | Beatriz Sanchez-Pintado: Commercial Relationship: Code N (No Commercial Relationship) | Michael Cheetham: Commercial Relationship(s);Code C (Consultant/Contractor):ProQR;Code C (Consultant/Contractor):Alia Therapeutics;Code C (Consultant/Contractor):PYC | Alice Davidson: Commercial Relationship: Code N (No Commercial Relationship) | Stephen Tuft: Commercial Relationship: Code N (No Commercial Relationship) | Alison Hardcastle: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: TGFBI corneal dystrophies are autosomal dominant inherited diseases with distinctive phenotype-genotype correlations, characterised by the accumulation of TGFBI protein (TGFBIp) positive deposits in the sub-epithelial, Bowman and/or stromal layers of the cornea. Current surgical treatments do not target the underlying genetic cause of the disease, with disease symptoms frequently reoccurring. In order to generate disease models, patient derived induced pluripotent stem cells (iPSCs) were differentiated towards corneal epithelial-like cells to study the pathophysiology of TGFBI corneal dystrophies, and explore the use of targeted antisense oligonucleotides (ASOs) as a potential therapy.

Methods: Fibroblasts obtained from patients harbouring heterozygous hotspot mutations c.370C>T, p.R124C or c.371G>A, p.R124H were reprogrammed to iPSCs by nucleofection with the pluripotency factors Oct3/4, Kfl4, Sox2, L-Myc, Lin28 and mir302/367. iPSCs were differentiated towards a corneal epithelial-like cell lineage, in parallel with control iPSC, and characterised for expression of epithelial markers using quantitative reverse transcriptase PCR and immunocytochemistry. ASOs were designed to reduce expression of TGFBI mutant alleles and treatment effects were explored by reverse transcriptase (RT)-PCR, Sanger sequencing and quantitative RT-PCR.

Results: Immunofluorescence confirmed the expression of the stem cell markers Oct4, Nanog, SSEA4 and Tra-1-81 in all iPSC lines. Characterisation of the iPSC derived model confirmed a corneal epithelial-like phenotype with endogenous expression of markers KRT3, KRT14, P63, ABCG2 and E-cadherin at transcript and protein level. Following ASO treatment, a reduction of TGFBI transcript levels was observed by RT-PCR. Sanger sequencing demonstrated a specific reduction of the mutant allele in comparison to the wild type allele.

Conclusions: We have established a patient iPSC derived in vitro model to investigate the molecular mechanisms of TGFBI corneal dystrophies and test therapeutic approaches in an appropriate genomic and cellular context. Preliminary investigations indicate that ASO treatment targeting mutations at position p.R124 may be effective in reducing the expression of the mutant allele. Further investigations are required to further characterise the molecular mechanisms of disease and the effect of ASOs on TGFBIp.

TITLE: Ocular surface mast cells promote nerve damage and trigeminal ganglion inflammation following corneal injury

SESSION TITLE: Corneal Immunology and Neovascularization

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Guan, W. Cho, E. Elbasiony, A. Singh, S. Mittal, S. Chauhan, Department of Ophthalmology, Harvard Medical School, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Yilin Guan: Commercial Relationship: Code N (No Commercial Relationship) | WonKyung Cho: Commercial Relationship: Code N (No Commercial Relationship) | Elsayed Elbasiony: Commercial Relationship: Code N (No Commercial Relationship) | Aastha Singh: Commercial Relationship: Code N (No Commercial Relationship) | Sharad Mittal: Commercial Relationship: Code N (No Commercial Relationship) | Sunil Chauhan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Nerve damage following injury has been associated with impaired wound healing. We have previously shown that corneal injury leads to increased activation of ocular surface mast cells. Here, we investigated whether mast cells interact with corneal nerve and contribute to nerve degeneration and neuroinflammation.

Methods: Corneal injury was induced by mechanical removal of the epithelium (3 mm) and one-third of the anterior stroma in C57BL/6 mice using an Algebrush II. To evaluate the proximity of mast cells and damaged nerves, corneas were harvested 6 hours post-injury and stained with β-tubulin III (corneal nerves), and avidin (mast cells), for immunohistochemistry (IHC) analysis. Trigeminal ganglions (TGs) were harvested post-injury and lysates were prepared to measure levels of tryptase (mast cell activation marker), CD11b and Substance P (SubP), using colorimetric assay and PCR analysis. To assess direct interaction between mast cells and inflamed corneal nerves, primary TGs were co-cultured with bone marrow-derived mast cells for 24h. Brightfield images were captured, and neurite length was quantified using ImageJ software. TGs harvested from co-cultures were assessed for expression of nerve activation marker SubP and CGRP. To assess the in vivo effect of mast cell activation on nerve damage, injured corneas were treated with mast cell inhibitor cromolyn (2% in PBS) and hyperactivation of nerves were measured using eye wipe test.

Results: IHC analysis demonstrated that ocular surface mast cells infiltrated into the injured cornea in close proximity to the damaged corneal nerves. Corneal injury resulted in a significant activation of TG mast cells and inflammation, as indicated by increased levels of tryptase ($p=0.003$), CD11b ($p<0.001$) and SubP ($p=0.009$). Co-culturing of TGs with mast cells resulted in an approximate 13-fold upregulation in CGRP ($p<0.001$), and ~1.5-fold increase in SubP ($p=0.008$), compared to TGs cultured alone. Moreover, mast cells resulted in significant neuronal degeneration, as indicated by 50% decrease in neurite length compared to control TG cultures ($p<0.001$). Pharmacological inhibition of ocular surface mast cell activation resulted in a significant decline in TG inflammation and hyperalgesia, as shown by decreased eye wipes ($p=0.005$).

Conclusions: Ocular surface mast cells exacerbate nerve degeneration and promote inflammation in the trigeminal ganglion.

ABSTRACT BODY:

Purpose: The mouse laser-induced choroidal neovascularization (CNV) model is the most popular experimental model to mimic the wet form of age-related macular degeneration (AMD). In this study we aimed to compare the differences in CNV pathology between C57BL/6J mice from different vendors.

Methods: 8-week-old male C57BL/6JRj mice from Janvier Labs (France) and C57BL/6JRccHsd from Envigo (Netherlands) were used in the study. CNV was induced by using a 532 nm laser and the development was monitored in vivo by fluorescein angiography (FA) and spectral domain optical coherence tomography (SD-OCT) on days 0, 3, 7 and 14. The lesions were qualitatively graded from FA images for vascular leakage (non-leaky or leaky). FA scans were analysed by a proprietary algorithm, where the neural network was trained to recognize and quantify CNV lesions using transfer learning approach. Choroidal flat mounts (D7 n = 5-6/group or D14 n = 6/group) were immunolabelled with isolectin B_4, anti-iba1 and anti-collagen I antibodies, scanned using Leica THUNDER 3D microscope and manually analysed using FIJI/ImageJ (NIH). The data were statistically analysed with Mixed-effects model (FA) or Mann-Whitney U test (histology).

Results: There was no difference in the CNV grading (% of leaky lesions) in Janvier mice compared to Envigo (p=0.96). While absolute values of FA leakage area were overall lower in Janvier mice in all time points, this study was not sufficiently powered to detect that difference (area in mm^2, mean ± SD, Janvier vs. Envigo: 0.04±0.042 vs. 0.056±0.054 on D3; 0.014±0.028 vs. 0.043±0.092 on D7; 0.008±0.015 vs. 0.035±0.067 on D14). Isolectin area was larger in Envigo mice lesions on D7 ($p < 0.05$) and on D14 ($p < 0.0001$) as compared to Janvier mice. Iba1 area was bigger in Envigo mice as compared to Janvier mice on D7 ($p < 0.001$). There was a trend towards bigger Collagen I area in Envigo animals compared to Janvier mice on D7 ($p = 0.077$).

Conclusions: Envigo C57BL/6JRccHsd mice show more severe CNV pathology than Janvier C57BL/6JRj mice. These data suggest strain-specific differences in neovascular and fibrotic processes after laser CNV induction. These

differences should be considered when selecting animal strains for IND-enabling studies in wet AMD.

ABSTRACT BODY:

Purpose: Patients with primary open angle glaucoma (POAG) deteriorate despite intraocular pressure (IOP) reduction, suggesting other factors confer susceptibility. Evidence from our group and others implicates systemic mitochondrial (mt) function in glaucoma pathogenesis. We wanted to establish whether systemic mt function is associated with the rate of visual field (VF) progression in patients with POAG treated with IOP-lowering

Methods: Mt function parameters (Basal, ATP-linked, Maximal, Reserve), expressed as oxygen consumption rate (OCR) pmol/min/100,000 cells (XFe24 Analyzer), were measured in lymphocytes of 168 treated white-European POAG patients. Inclusion criteria: ≥6 reliable VFs and ≥3 years follow up. Exclusion criteria: secondary and narrow angle glaucoma, systemic conditions / drugs potentially affecting mt function. Both eyes of the same patient were included if eligible. Mixed-effect linear models were used to investigate the association between VF Mean Deviation (MD) rate of change and mt function, after adjusting for baseline age, central corneal thickness (CCT) and IOP during the observation period; separate IOP models for mean, peak, % reduction and standard deviation (SD) were generated

Results: A total of 211 eyes were included. Mean (±SD) age, IOP, and CCT were 72.6 (±10.0) years, 14.9 (±2.8) mmHg and 538 (±41) μm, respectively. Mean (±SD) rate of VF MD progression was -0.61 (±0.53) dB. In all models and for each measure of OCR, lower mt function was highly significantly associated with faster rates of VF progression. Table 1 shows results of the 'SD IOP' multivariable model; IOP mean, peak and % reduction were not significantly associated with VF progression. Figure 1a shows Basal OCR and SD IOP were significantly associated with MD rate of progression. Fig. 1b shows the relationship between basal OCR and VF progression rate. The model total marginal R^2 was 0.084. Semi-partial R^2 (proportion 'variance accounted for') was 0.020 and 0.074 for SD IOP and Basal OCR, respectively

Conclusions: Systemic (lymphocyte) mt function is highly significantly associated with the rate of VF loss in POAG patients treated with IOP lowering. Our findings suggest that measurement of mt function may help identify patients at high risk of more rapid progression. Mt function may be a new target for glaucoma treatment

ABSTRACT BODY:

Purpose: Pathogenic variants in the Crumbs homolog 1 (CRB1) gene are associated with autosomal recessive, early-onset retinal degeneration. The most common pathogenic CRB1 variant c.2843G>A, pCys948Arg occurs in the first nucleotide of exon 9, and is widely classified as a missense mutation. The single nucleotide variant (SNV) c.2842+5G>A is a common CRB1 splice site variant which is positioned in the splice donor site of intron 8. A dual luciferase assay utilising an out-of-frame CRB1 intron-exon hybrid was designed, validated and used to functionally evaluate these two common CRB1 mutations.

Methods: The out-of-frame CRB1 exon-intron hybrid sequence was inserted into the SGDLuc3.0 backbone between the Renilla and firefly luciferases. Correct splicing, which would result in an in-frame sequence and correlate with firefly luminescence was predicted in-silico. Site-directed mutagenesis introduced the above-mentioned SNVs into the wild-type plasmid. Luciferase assays measuring Renilla and firefly luminescence were performed on transfected HEK293T cells. Splice products were analysed with Sanger sequencing.

Results: A 7.4-fold increase (SD ± 3.1) in firefly luminesce from baseline Renilla expression was detected in cells transfected with the intron-exon hybrid sequence. Correct splicing of the hCRB1.IE.8.9 hybrid sequence was confirmed with Sanger sequencing. The plasmid containing the SNV c.2842+5G>A resulted in a loss of firefly luciferase luminescence. Sanger sequencing confirmed a read-through of splice donor site. Firefly luminesce fold increase from the plasmid containing the SNV c.2843G>A was significantly reduced (3.31 (SD ± 0.46)) compared to the wild-type plasmid (6.16 (SD ± 1.74)). Sanger sequencing the splice products confirmed a read-through of the splice acceptor site 60% of splice products, while 36% of splice products exhibited correct splicing.

Conclusions: Due to the location of the most common CRB1 pathogenic variant at the first nucleotide of exon 9, it is plausible that this SNV might affect splicing in addition to causing a missense change. The data generated from the dual luciferase assay is the first to implicate the c.2843G>A SNV as a splice site mutation. A common splice site mutation, c.2842+5G>A, was validated to cause a splice defect in this assay. In future experiments, this dual luciferase assay could be used to screen guide RNA in CRISPR-Cas based therapies.

ABSTRACT BODY:

Purpose: Mutations in CLRN1 cause Usher syndrome type 3A (USH3A), a recessive inherited disorder leading to combined hearing and vision loss. In this study, we created and characterized a novel zebrafish model lacking clrn1 to investigate the pathophysiology of USH3A.

Methods: CRISPR/Cas9 was used to delete 90% of the zebrafish clrn1 coding sequence. High-intensity light (3500 lux) exposure experiments were performed in 5-7dpf larvae, along with phalloidin and TUNEL staining. In 4 to 20-month adults, we assessed the retinal structure and the cone photoreceptor mosaic using spectral-domain optical coherence tomography. We also analyzed photoreceptor morphology using hematoxylin and eosin staining, and cell death and regeneration using staining for activated caspase-3, and BrdU incorporation assays.

Results: High-intensity light treated clrn1 mutant zebrafish presented with a significant increase in the number of TUNEL positive photoreceptor nuclei and regions of absent or disrupted phalloidin staining, indicating that the absence of Clarin1 sensitizes photoreceptors to stress. In adult clrn1 mutant zebrafish raised under normal lighting, we observed progressive alterations of the photoreceptor mosaic from 4 to 20-months of age, suggesting a loss of photoreceptor integrity. Histological analysis of clrn1 mutant zebrafish retinas showed gross changes at 20 months compared to wildtype. Specifically, we observed a significant thinning of the outer nuclear layer (ONL) in the central retina, an indication of photoreceptor cell death. At the time points investigated, we did not observe a significant increase in activated-caspase 3 staining. However, there was a small but significant increase in BrdU incorporation at 4-months, suggesting regeneration and therefore loss of photoreceptors at an early age. BrdU incorporation decreased with age, potentially as a consequence of losing regenerative potential in older adults.

Conclusions: The clrn1 mutant zebrafish represents the first model of USH3 disease that displays photoreceptor disorganization and degeneration. Collectively, our data indicates that the loss of Clarin1 function in zebrafish induces a slow, progressive retinal degeneration. We will utilize this model, along with cell-specific clrn1 re-expression and RNAseq analysis, to investigate the mechanisms promoting retinal degeneration in USH3A.

ABSTRACT BODY:

Purpose: Prior animal studies have shown that T cell specific for heat shock proteins (HSPs) play an important role in glaucomatous neurodegeneration. Given the high incidence of glaucoma in patients with Boston keratoprosthesis type I (KPro), we investigated the levels of HSP specific $CD4^+$ T-lymphocytes in the peripheral blood of patients with KPro.

Methods: Adult patients with KPro and healthy control subjects were prospectively enrolled. Patients with any autoimmune or immunodeficiency diseases were excluded. Peripheral blood monocytes (PBMC) were isolated from the blood of each participant and stimulated with HSP-27 or another member of the small HSP family, α-crystallin. Both interferon gamma+ helper T cells (Th1) and transforming growth factor beta+ regulatory T cells (Treg) were quantified by flow cytometry and presented as percentage of total PBMC counts. Retinal nerve fiber layer thickness (RNFLT) was measured for all. Ophthalmic data were collected for the KPro eye for KPro patients and worse eye (based on RNFLT) for controls.

Results: KPro patients (n=6) with an average of 9.2±5.0 years from their first KPro surgery and healthy controls (n=13) were similar in age, gender, body mass index and intraocular pressure (IOP) ($p>0.22$ for all; Table 1), although all KPro patients were treated for IOP. Best corrected visual acuity, cup to disc ratio and average RNFLT were worse for KPro patients (0.4±0.3 LogMAR, 0.7±0.3 and 63.5±33.5 μm, respectively) compared to controls (0.05±0.09 LogMAR, 0.3±0.1 and 95.1±11.7 μm respectively; $p\leq0.002$ for all). Total unstimulated Th1 and Treg cell counts were similar in KPro (2.6±6.5% and 0.8±0.9%) and controls (3.3±1.9% and 1.7±1.7%, $p>0.25$ for both; Figure 1A). After stimulation with HSPs, Th1 cells specific for HSP-27 and α-crystallin were more abundant in KPro patients than controls (10.1±6.6% vs 2.5±2.2%, $p=0.001$; 8.9±3.1% vs 2.4±0.8%, $p<0.001$ respectively; Figure 1B), whereas Treg cells specific for HSP-27 and α-crystallin did not differ between the groups (2.2±1.4% vs 0.9±1.7%, $p=0.10$; 1.0±0.3% vs 0.6±0.8%, $p=0.42$, respectively; Figure 1B).

Conclusions: Although our findings are preliminary and larger cohorts of patients are being recruited to validate the results, the data suggest robust systemic HSP-specific Th1 responses were induced in patients with KPro. The elevated level of these T-cells may contribute to the prevalent and severe glaucomatous neurodegeneration in these patients.

ABSTRACT BODY:

Purpose: The progressive death of cones ultimately causes loss of vision in patients with retinal degenerative diseases, and there is currently no treatment available. Differentiation of human-induced pluripotent stem cells (hiPSCs) into a cone-rich cell population represents a potential therapy for cone/retinal degeneration. COCO is a multifunctional antagonist of the WNT, TGF-β, and BMP pathways and has been shown to promote cone differentiation from hiPSCs. NRL and NR2E3 are key transcription factors for photoreceptor differentiation. Thyroid hormone is known to orchestrate cone development. This work investigated the potential of differentiating hiPSCs into a cone-rich cell population by targeting these different regulatory pathways.

Methods: Wild-type iPS(IMR90)-4 cells and mutant iPS(IMR90)-4 cells with deletion of NRL or NR2E3 were used. NRL or NR2E3 knockout cell lines were generated using Synthego Gene Knockout Kit V2 and confirmed by Sanger sequencing. Embryonic bodies generated from the wild-type and mutant cells were cultured in a retinal induction medium containing COCO (30 ng/ml) for 4 weeks. Neuronal retinal vesicles formed were then transferred into bioreactors (Synthecon) and cultured in the COCO differentiation medium containing triiodothyronine (T3, 5 nM) for another 2-3 months, followed by evaluation of the expression of photoreceptor genes and differentiation of cones using qRT-PCR and immunofluorescence labeling.

Results: Treatment with COCO enhanced differentiation of IMR90-4 cells into cones and increased expression of the photoreceptor precursor genes (PAX6, CRX, and RXR) and the cone-specific genes (OPN1SW, ARR3, and GNAT2). Deletion of NRL or NR2E3 further enhanced the gene expression and cone differentiation. COCO plus thyroid hormone induced differentiation of IMR90-4 cells into M-cones and increased expression of OPN1MW, compared with cells treated with COCO only.

Conclusions: COCO induces differentiation of IMR90-4 cells into retinal/photoreceptor precursors and cone photoreceptors. Deletion of NRL or NR2E3 promotes cone differentiation. Thyroid hormone promotes differentiation of M-cones from IMR90-4 cells. These findings highlight the potential of differentiation of hiPSCs into a cone-rich cell population by targeting multiple regulatory pathways.

ABSTRACT BODY:

Purpose: The impact of missed appointments for anti-vascular endothelial growth factor (anti-VEGF) injection treatment for macular edema due to retinal vein occlusion (MERVO) on visual acuity (VA) is unknown. We performed a secondary analysis of Study of COmparative Treatments for REtinal Vein Occlusion 2 (SCORE2) data to evaluate the association between patients' adherence to clinical trial visits and VA in patients with central retinal vein occlusion (CRVO) or hemiretinal vein occlusion (HRVO).

Methods: The SCORE2 protocol included a visit every 4 weeks (every 28-35 days) during the first year. Visit adherence was measured as: number of missed visits, average (avg days) and longest (max days) visit interval, average (avg missed days) and longest (max missed days) unintended visit interval. Avg and max missed days were categorized as on time (0 days), late (>0-60 days), and very late (>60 days). Primary outcome was change in Early Treatment Diabetic Retinopathy Study (ETDRS) VA between baseline study visit and last attended visit during Year 1, using multivariate linear regression models controlling for baseline VA, baseline central subfield thickness, age, gender, race, ethnicity, study eye disease type, prior anti-VEGF in study eye, disease duration at baseline, history of diabetes, coronary artery disease or hypertension, whether or not patient was re-randomized at Month 6, and total number of injections.

Results: Of the 362 patients enrolled in SCORE2, 358 were included in the study. Only 48 patients missed a visit during the initial year of follow up, and only 12 missed more than 1 visit. After adjustment, for each visit missed, patients lost 3.0 letters (95%CI: -6.2, 0.2) of vision (p=0.07). On average, the 48 patients who missed at least 1 visit lost 9.4 letters (95%CI: -14.4, -4.3, p<0.001) of vision after adjustment. Average days and maximal interval between visit were not associated with changes in VA (p>0.22) for both comparisons). However, when a visit was missed, the average missed days between missed visits and the max missed interval were both associated with loss of VA (both variables: 0 days missed as reference, late [1-60 days] -10.8 letters [95%CI: -16.9, -4.7], very late [>60 days] -7.3 letters [95%CI: -14.5, -0.2]; p=0.003 for both). See Table 1 for additional results.

Conclusions: Visit adherence is associated with VA outcomes during Year 1 in SCORE2 participants.

ABSTRACT BODY:

Purpose: The symmetry of macular fundus features in the two eyes of the same patient with age-related macular degeneration (AMD) was investigated using swept-source optical coherence tomography (SS-OCT).

Methods: AMD patients were enrolled in a prospective SS-OCT natural history study from April 2016 to June 2021. SS-OCT imaging was performed at the time of their first visit. Two graders diagnosed the presence of drusen, geographic atrophy (GA), and exudative AMD (eAMD) in each eye. Medical records were reviewed to assess prior exudation. Validated algorithms were used to measure the area and volume of drusen. To assess asymmetry, one eye of each patient was randomly selected as the index eye and compared with the fellow eye. The kappa statistic (κ) was used to assess the symmetry of diagnosis. The intraclass correlation coefficient (ICC) was used to assess the symmetry of the drusen area and volume.

Results: A total of 1310 patients with AMD were included. The average age was 78 years old (range, 50-102) with 60% women. Of the 1310 subjects, 54% (701) presented with symmetric disease; 20% with bilateral drusen, 11% with bilateral GA, and 22% with bilateral eAMD. Only 0.5% of subjects had both GA and eAMD in both eyes. Of the randomly selected index eyes, 825 (47%) were right eyes. Overall, limited interocular agreement was observed between index and fellow eyes (54%; $\kappa = 0.29$). Kappa coefficients were poor (<0.4) for index eyes diagnosed with drusen ($\kappa = 0.27$), eAMD ($\kappa = 0.17$), and mixed disease ($\kappa = 0.03$). There was moderate agreement between index and fellow eyes for GA ($\kappa = 0.50$). Of the 265 patients with bilateral drusen, the symmetry of drusen area measurements had moderate ICC values of 0.70, 0.71 and 0.70 in the 3 mm and 5 mm diameter circles centered on the fovea and in the total scan area, respectively. The ICC for the drusen volume was slightly lower with ICC values of 0.65, 0.66 and 0.64 respectively.

Conclusions: Interocular symmetry was poor for eyes with drusen, eAMD, and mixed, but moderate for GA. While the diagnosis of drusen was not appreciably symmetric between eyes, the drusen area and volume measurements were moderately symmetric in patients with bilateral drusen.

ABSTRACT BODY:

Purpose: Uncontrolled T cell activation can result pathological conditions including autoimmunity and graft rejections. Our group has previously shown that mesenchymal stem cells (MSCs) inhibit activation of innate immune cells including neutrophils and macrophages. Here, we investigate whether MSCs regulate T cell responses by secreting interleukin-11 (IL-11).

Methods: Human bone-marrow derived MSCs (hMSCs) were purchased and phenotypically characterized for their expression of CD45- CD34- CD73+ CD90+. CD4+ CD25- T cells (purity: >95%) were magnetically sorted from human peripheral blood mononuclear cells for the MSC-T cell co-culture assays. Expression and secretion of IL-11 by hMSCs were evaluated using real-time PCR and ELISA, respectively. Expression of IL-11 receptor was confirmed in activated CD4+ CD25- T cells using flow cytometry. CD4+ CD25- T cells stimulated with anti-CD3/CD28 beads (1:1 ratio) were co-cultured with MSCs at 1:1 ratio for 24 hours (for early activation) and 66 hours (for proliferation) in the presence and absence of hIL-11 neutralizing antibody (20 µg/ml). Early T cell activation was assessed by evaluating expression of CD40L and CD69 (Median Fluorescence intensity; MFI) using flow cytometry. For proliferation, CD4+ CD25- T cells were stained with CFSE prior to co-culture and their proliferation was quantified by measuring CFSE dilution via flow cytometry.

Results: hMSCs constitutively express high levels of IL-11 at both mRNA and protein levels. Naïve CD4+ CD25- T cells showed the expression of IL-11 receptor, which was upregulated by 2-fold following CD3/CD28 stimulation. hMSCs significantly suppressed early activation of naive T cells, as indicated by an approximate 70% reduction in expression of both CD69 (p=0.025) and CD40L (p=0.011). This MSC mediated reduction in early T cell activation was not observed following the neutralization of IL-11. Furthermore, our CFSE dilution assay demonstrated that hMSCs significantly prevented the proliferation of CD4+ CD25-T cells (p=0.006); however, this MSC-mediated suppression of proliferation was abrogated following IL-11 neutralization.

Conclusions: IL-11 secretion by human mesenchymal stem cells is critical for inhibition of early T cell activation and proliferation.

ABSTRACT BODY:

Purpose: Small fiber neuropathy is known to be associated with Sjögren Syndrome (SS) and in-vivo corneal confocal microscopy can identify features of a small fiber neuropathy. Here we performed a descriptive study to identify features of a short fiber neuropathy of the corneal sub-basal nerve plexus using in-vivo confocal microscopy in participants from the Sjögren's International Collaborative Clinical Alliance (SICCA) returning for up to 15-year follow-up compared to healthy controls.

Methods: We recruited 14 participants from the SICCA, the largest SS cohort in the world and funded by the National Institutes of Health, and 22 healthy controls. Eleven participants met SS classification based on updated 2016 American College of Rheumatology/European League Against Rheumatism criteria. All participants underwent slit-lamp examination and in vivo confocal microscopy of the central cornea's sub-basal nerve plexus centered about the central vortex to create a 30-image montage. Each image was analyzed with automated software (ACCmetrics, Manchester, United Kingdom) to produce seven nerve metrics. We performed t-tests to make comparisons of nerve metrics between SS (from SICCA cohort) and healthy controls (recruited from outside SICCA cohort) as well as SS and non-SS (both from SICCA cohort).

Results: Most nerve metrics were significantly lower in SS participants compared to healthy controls. Mean corneal nerve fiber density was found to be 3.5 mm/mm^2 in SS participants compared to 10.6 mm/mm^2 in healthy controls (95% CI: 0.48 to 6.46, $p<0.001$). Mean corneal nerve branch density was 2.7 main fiber branch points/mm^2 in SS participants compared to 15.2 in healthy controls (95% CI: -0.5 to 6.0, $p=0.001$). Mean corneal nerve fiber length was 4.3 mm/mm^2 in SS participants compared to 9.9 in healthy controls (95% CI: 2.6 to 6.1, $p<0.001$). When we compared SS (n=10) and non-SS (n=4) returning SICCA participants, mean nerve metrics were generally higher in those classified as non-SS, though these findings did not achieve statistical significance.

Conclusions: SS exhibits lower corneal nerve metrics compared to healthy controls. These findings suggest that a short fiber neuropathy can distinguish SS from healthy controls and may serve as a potential novel biomarker in identifying SS.

TITLE: A PCO Predictive In Vitro Model to Examine the Role of Fibronectin and IOL Surface Property on PCO formation

SESSION TITLE: Cataractogenesis: pathogenesis, prevention and treatment

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: L. Tang, J. Roy, A. Jaitli, A. Chatila, Bioengineering, The University of Texas at Arlington, Arlington, Texas, UNITED STATES|

Commercial Relationships Disclosure: Liping Tang: Commercial Relationship(s);Code C (Consultant/Contractor):Progenitec Inc;Code S (non-remunerative):Progenitec | Joyita Roy: Commercial Relationship: Code N (No Commercial Relationship) | Arjun Jaitli: Commercial Relationship(s);Code E (Employment):Alcon | Amjad Chatila: Commercial Relationship(s);Code E (Employment):Alcon

ABSTRACT BODY:

Purpose: The occurrence of posterior capsule opacification (PCO) is due to the residual lens epithelial cells to infiltrate at the interface between lens capsule (LCs) and IOLs. IOL material adhesiveness is believed to affect cell infiltration and PCO formation. Extracellular matrix (ECM) proteins, particularly fibronectin (FN), have been suggested to play an important role in PCO formation. While many studies have examined the interaction of FN with IOLs, the role of adsorbed FN on influencing PCO is yet to be investigated. Using a PCO predictive in vitro model based on IOL:LC adhesive force, we investigated the influence of FN adsorption and IOL surface hydrophilicity on cell infiltration and PCO formation at IOL:LC interface.

Methods: To mimic cell infiltration at IOL:LC interface, an in vitro model was established with simulated LC and a custom-designed micro-force tester. By adding various amounts of FNs onto the simulated LCs prior to placing commercially available IOLs, including acrylic foldable, PMMA, and silicone IOLs, the influence of FNs on adhesion force between IOLs and LCs was examined. In addition, such influence on cell infiltration at the interface was examined by analyzing the amount of dye infiltration in a macromolecular dye imaging system. Finally, the influence of surface hydrophilicity on IOL:LC adhesive force and cell infiltration was examined using acrylic foldable IOLs coated with hydrophilic polymer- Di(ethylene glycol) (Diglyme).

Results: We observed that IOLs show different adhesiveness with LCs in the following order: acrylic foldable>silicone>PMMA. FN plays a significant role in increasing the adhesion force of acrylic foldables, but not PMMA & Silicone IOLs. As expected, FN significantly reduced dye penetration at the interface between acrylic foldable IOLs (~50% reduction) and LCs. However, Diglyme coating significantly reduced the IOL:LC adhesive forces while increased dye penetration compared to acrylic foldable controls. The presence of FN had an insignificant influence on the adhesive forces and dye penetration.

Conclusions: The results support the overall hypothesis that FN adsorption may increase the IOL:LC adhesive force and reduce cell infiltration at the interface (Fig. 1). By increasing surface hydrophilicity, Diglyme coating significantly reduced IOL:LC adhesive force and increase dye infiltration while demolished the influence of FN.

ABSTRACT BODY:

Purpose: Archaea are prokaryotic members of the Third domain. Although usually missing or ignored in human microbiome studies, they are emerging as intimate and influential immune/disease modulators of the human microbiome in collaboration but distinct from bacteria and or other microbiota. To date, there are 5, but still increasing number of phyla; Crenarchaeota, Euryarchaeota, Korarchaeota, Nanoarchaeota and Thaumarchaeota. They have been recovered from mucosal surfaces including the gastrointestinal tract (GIT), nose, lung, vagina, and also skin. Our purpose was to investigate and document the presence and diversity of archaeal signatures in contact lens case ecosystems collected from the ocular surface of patients presenting with microbial keratitis.

Methods: We used whole genome sequencing (WGS) to document and compare the prevalence and diversity of archaeal signatures in 30 contact lens systems (CTLS) of 15 patients presenting with bacteria keratitis (BK), n=6, Acanthamoeba keratitis (AK), n=6, microbial keratitis (MK), n=2 and or fungal keratitis (FK), (n=1).

Results: A total of 3 phyla, 55 genera and 86 species were detected during the WGS survey. At least one archaeal signature was found in all patients' contact lens cases, but relative abundance for all ecosystems was low (<1%, 9244 tags). Two of the five phyla were detected in 96.7% (n=29/30) of CLTS. These included Euryarcheota (n=78.3%, n=7240 tags, 96.7% of CTLS) and Crenarchaeota, 21.7%, n=2003 tags, also 96.7% of cases. Thaumarchaeota was detected in only 1 patient (6.7%) in 3.3% of cases. Archaeal signatures (tags) were more frequently detected in cases of patients with AK (n=5648, 61.09%) than in cases of patients with BK (n=3527, 38.15%, p<0.0001), FK, n=28, 0.30%, p<0.0001), and or microbial keratitis, n=41, 0.44%, p<0.0001). Methane-producing species (n=39/77, 50.6%) were the dominant members detected among the Euryarchaeota phyla.

Conclusions: Archaea may be present on the ocular mucosa surface. The role these unique prokaryotes may play in ocular surface immune defense or disease disorders is unknown.

TITLE: Ultrasonic vitrectomy device-tissue interaction characterization

SESSION TITLE: Vitreoretinal surgery/VR Interface/PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Higgins, A. Papour, Surgical R&D, Bausch and Lomb, Saint Louis, Missouri, UNITED STATES|

Commercial Relationships Disclosure: Grant Higgins: Commercial Relationship(s);Code C (Consultant/Contractor):Bausch & Lomb;Code E (Employment):EASI | Asael Papour: Commercial Relationship(s);Code E (Employment):Bausch & Lomb

ABSTRACT BODY:

Purpose: Electrical signatures of ultrasonic vitrectomy devices during tissue interaction have not been fully characterized and are not well understood as a theoretical model does not exist. Electrical measurements in BSS and pig vitreous show the ultrasonic energy-tissue interaction behavior and reveal high sensitivity of the ultrasonic probe to tissue type and sub-type. This is a first demonstration of ultrasonic vitrectomy tissue detection capability that may detect tissue type in real-time during surgery.

Methods: Measurements: Electrical data of Vitesse 25 gauge vitrectomy probe, driven by Stellaris Elite^{TM} (Bausch & Lomb, LLC) was measured using voltage and current probes on a mixed signal oscilloscope (Tektronix MSO 4054) with 1MS/s high resolution acquistion rate. The vitrectomy probe was operated in BSS and two forms of pig vitreous with 60 um stroke and 100 mmHg vacuum. Vitreous was harvested from a fresh pig eye and separated into two samples; viscous liquid (water and hyluronan) and thick gel-like (with collagen matrix).

Results: Vitesse shows an average power increase of 70% when operated in thick gel-like vitreous (Vit Base) compared to BSS with a 36% increase in voltage, a 16% increase in current, and a 20% increase in impedance. When operated in the viscous liquid (thin vitreous), Vitesse shows an average power increase of 47% when compared to BSS with a 23% increase in voltage, an 18% increase in current, and a 6% increase in impedance. A two sample unpaired t-test of the electrical parameters in tissue vs BSS with a significance level of 0.01 show extremely high statistical significance ($p < 0.001$).

Conclusions: There is a substantial difference in the electrical characteristics required to operate on posterior tissue types and BSS. With all four electrical parameters showing statistically significant results, this displays proof of concept that ultrasonic devices may be able to sense changes in tissue interaction during surgery in real-time.

ABSTRACT BODY:

Purpose: To investigate filtration bleb vascularization after ab-externo implantation of the Santen Preserflo microshunt using anterior segment OCT-angiography

Methods: 9 patients underwent Preserflo microshunt implantation according to the standard protocol recommended by Santen. The pre- and postoperative drug regimen was according to department standards. At 1 week, 2 weeks, 1 months, 2 months, 3 months and 6 months postoperatively, OCT-A images of the filtration bleb were acquired using a Zeiss Plex Elite 9000 angio-OCT. A 20D add-on lens enabled anterior segment imaging with the device. A 3x3 mm rectangle (posterior pole scale, equals approx. 6x6 mm on the anterior surface) was imaged. Vascularization was assessed by calculating the perfusion density using algorithms provided by Zeiss (ARI network)

Results: Perfusion density in the filtration bleb was 30.82, 26.33, 29.09, 29.06 and 25.09 respectively (1w, 2w, 1m, 2m, 3m, 6m) (p=0,432). IOP decreased from 21,85 ± 6,80 mmHg to 7,69 ± 1,77 mmHg, 8,54 ± 1,98 mmHg, 10,84 ± 2,71 mmHg, 11,92 ± 4,21 mmHg, 11,08 ± 4,66 mmHg and 13,40 ± 8,99 mmHg.

Conclusions: The present study demonstrates that the perfusion density algorithm on the Zeiss Plex Elite can be used to monitor filtration bleb vascularization longitudinally. Larger cohorts are needed to gain insight in the relationship between bleb vascularization and surgical outcome

ABSTRACT BODY:

Purpose: Microelectronic retinal prostheses have been implanted to restore the vision of individuals blinded by outer retinal degenerative diseases but showed considerable performance variations across users. Given that retinitis pigmentosa has the numerous genotypes which have distinct phenotypes, there is a possibility of different characteristics in electrically-evoked responses across those genotypes. However, the past prosthetic researches have typically used retinal degeneration 1 (rd1) and 10 (rd10) models which have Pde6b gene mutation. To extend our understanding to another type of degenerate retinas, we studied electric responses of retinal ganglion cells (RGCs) in rd8 mice which have Crb1 gene mutation for the first time.

Methods: We used cell-attached patch clamping method to record spikes from RGCs in the wild-type (wt, C57BL/6J; n = 6 and n = 7 for ON and OFF RGCs, respectively) and rd8 mice (C57BL/6N; n = 7 and n = 9 for ON and OFF RGCs, respectively). First, ON and OFF RGCs were identified by their responses to 1-sec-long stationary white spot flash on a gray background. Second, an electric stimulus (4 ms duration, -100 μA) was applied to evoke network-mediated responses. Similar to our previous works, the electrically-elicited spiking responses were divided into two parts: first burst and delayed response.

Results: Both peak firing rate and spike count of delayed responses arising in rd8 RGCs were considerably lower compared to those of wt RGCs. For example, in the wt mice, the peak firing rates of ON and OFF RGCs were 277.4±122.4 and 361.5±209.5 Hz; however, those were decreased in the rd8 mice to 162.7±149.4 and 260.1±177.3 Hz, respectively. Also, the average spike counts of both ON and OFF types were smaller in rd8 than wt: 49.1±26.3 vs. 17.1±13.4 (wt vs. rd8 for ON RGCs), and 12.2±9.6 vs. 8.3±4.4 (wt vs. rd8 for OFF RGCs), respectively.

Conclusions: In summary, we characterized the electrically-evoked responses of ON and OFF RGCs in rd8 mice. In addition to our recent publication regarding network-mediated responses of rd10 mice, systematic comparison of results from rd8 vs. rd10 will enhance our understanding of electrically-elicited responses of RGCs in different forms of retinal degeneration. These researches are likely to contribute in reduction of performance variations across prosthetic users.

TITLE: Report of a rare mild phenotype of retinitis pigmentosa in a family with distal USH2A mutations predicted to result in truncated protein

SESSION TITLE: Inherited Retinal Disease Genetics I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.L. Hu, S. Rehman, L.E. Fry, M.E. McClements, R.E. MacLaren, K. Xue, University of Oxford Nuffield Laboratory of Ophthalmology, Oxford, Oxfordshire, UNITED KINGDOM|S. Rehman, R.E. MacLaren, K. Xue, Oxford Eye Hospital, Oxford, Oxfordshire, UNITED KINGDOM|

Commercial Relationships Disclosure: Monica Hu: Commercial Relationship: Code N (No Commercial Relationship) | Salwah Rehman: Commercial Relationship: Code N (No Commercial Relationship) | Lewis Fry: Commercial Relationship: Code N (No Commercial Relationship) | Michelle McClements: Commercial Relationship: Code N (No Commercial Relationship) | Robert MacLaren: Commercial Relationship: Code N (No Commercial Relationship) | Kanmin Xue: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Mutations in USH2A, encoding usherin, are the most common cause for non-syndromic autosomal recessive retinitis pigmentosa (RP) and Usher syndrome type 2. Here we report two siblings with extremely mild forms of retinitis pigmentosa without hearing impairment, each confirmed to be compound heterozygous for an USH2A c.6590C>T missense variant and an exon 70 deletion.

Methods: Each patient underwent clinical examination, microperimetry, OCT, fundus autofluorescence (FAF) imaging, and genetic testing by targeted next generation sequencing.

Results: Two sisters, aged 50 and 48 years, presented with slow, progressive peripheral visual field loss and nyctalopia beginning in their 30s. They were otherwise clinically well, had no hearing deficit on audiology testing, and no family history of any vision problems. Cancer-related retinopathy had been excluded. Visual acuities were 6/5 OD 6/6 OS in the elder and 6/6 OU in the younger, both retaining sufficient visual fields for driving. FAF in both patients showed a hyperautofluorescent ring surrounding the macula bilaterally. OCT demonstrated well-preserved retina within the ringed areas, but ellipsoid zone loss outside the ring. Genetic testing of the older sister initially found a heterozygous missense variant of uncertain significance, USH2A c.6590C>T (Thr2197Ile). Multiplex ligand-dependent probe amplification (MLPA) analysis revealed heterozygosity for an exon 70 deletion, predicted to result in a frameshift. Genetic testing of the younger sister showed identical mutations. Further segregation analysis confirmed bi-allelic inheritance.

Conclusions: Compound heterozygosity of a missense mutation and a 3’ exon deletion in USH2A is associated with a very mild form of RP with preserved central vision and hearing. USH2A c.6590C>T was previously reported as a variant of uncertain significance with conflicting evidence of pathogenicity. Deletion of the penultimate exon 70 is predicted to cause read-through of the terminal splice site into terminal exon 72 before reaching a stop codon. While this transcript may evade nonsense-mediated decay, disruption of the C-terminus may affect the PDZ-binding motif (PBD) and its interaction with harmonin. While there remains some uncertainty regarding the pathogenicity of c.6590C>T variant, the mild phenotypes observed would be compatible with partially retained protein function.

ABSTRACT BODY:

Purpose: To determine the retinal capillary function (the efficiency of blood flow transferring capacity of retinal capillary network) in patients with multiple sclerosis: 2-year follow-up.

Methods: A total of 22 patients (22 eyes) with RRMS were followed for a period of 27 ± 6 months. One eye of each subject was imaged at baseline and at follow-up. Retinal blood flow (RBF) was measured using a Retinal Function Imager and retinal capillary density (RCD, expressed as fractal dimension Dbox) was measured using optical coherence tomography angiography. The efficiency of blood flow transferring capacity of retinal capillary network retinal capillary function (RCF) was defined as the ratio of RBF to RCD.

Results: RCF was 1.36 ± 0.26 nl/s/Dbox (mean ± SD) at baseline and significantly increased to 1.61 ± 0.36 nl/s/Dbox after training (P = 0.03), reflecting an increase of 19%. There were 15 study subjects without clinical and radiological disease activity during the follow-up period, while there were 8 subjects with disease activity. Further analysis showed that the significant increase of RCF (i.e. change 0.33 nl/s/Dbox' P = 0.042) occurred only in the subgroup without disease activity. The change in the subgroup with active disease was 0.08 nl/s/Dbox (P = 0.50).

Conclusions: This is the first prospective study to demonstrate an increased RCF in MS patients with stable disease at 2-year follow-up, suggesting a possible recovery of RCF which may be associated to an enhanced blood flow to the retina in these patients.

ABSTRACT BODY:

Purpose: There is variable data regarding the frequency of germline MBD4 variants in patients with uveal melanoma (UM). The frequencies of pathogenic/likely pathogenic (P/LP) variants range from ~0.7% (8/1099) in a French cohort to 0.23% (1/432) in a Finnish cohort with no loss of function variants detected in the Finnish cohort. This casts doubt on the association of germline MBD4 variants and UM predisposition. Therefore, the goal of this study was to evaluate the frequency of MBD4 variants in a cohort of UM patients with strong personal and/or family history of cancer.

Methods: Germline variants in MBD4 were assessed in 182 UM patients with strong personal and/or family history of cancer including 27 patients with familial UM. Screening was carried out by next generation sequencing of individual or pooled samples (8 samples/pool) and all detected variants were confirmed by Sanger sequencing. Mutation burden was available in one patient that was included in The Cancer Genome Atlas (TCGA) project.

Results: Three patients (1.65%), all females, had germline P/LP variants in MBD4, which was significantly higher than in the European, Non-Finnish, general non-cancer population (Fisher's exact 2-tailed p =0.001, RR 95% CI: 15.96 (5.1-50.4)). The ages of these patients were 41, 58, and 71 years. The 41-year-old female had multiple family members affected with breast and colon cancer. She was recurrence free at 91 months after enucleation of her large monosomy 3 (M3) tumor, with very high mutation burden. The 58-year-old female died shortly after diagnosis and treatment of her UM from an unrelated cause. She reported a family history of throat cancer in her father and unknown cancers in her maternal and paternal cousins. The 71 year-old-female, had a history of two additional relatives on the same side of the family with UM. Germline DNA was available on one of them and he tested negative for the MBD4 pathogenic variant.

Conclusions: Our results support a role for MBD4 P/LP variants in predisposition to UM, likely through modifying the effect of other cancer predisposition genes. Further studies of the clinical phenotype of subjects with germline pathogenic variants are warranted.

ABSTRACT BODY:

Purpose: To investigate specialized pro-resolving lipid mediator (SPMs) as neuroprotective interventions to ameliorate neuroinflammation caused by blast exposure. We hypothesized that early administration of the SPMs, NPD1 or MaR1, will mitigate neuroinflammation, preserving retinal and optic nerve tissues after blast exposure in a blast-induced eye injury model.

Methods: A compressed-air driven shock tube was used to expose anesthetized adult male Long-Evans rats to shock waves simulating an open-field blast exposure. Blast waves of peak overpressure of 133 ± 4 kPa and a positive phase duration of 3.34 ± 0.05 ms were used. Approximately 30 minutes after blast exposure, rats were treated with either 1.0 µg/kg MaR-1, 0.1 µg/kg NPD1 or vehicle (0.9% saline) delivered via tail vein injection and treated daily thereafter until day 7. Unexposed rats were included as controls. Rats were euthanized at 9, 23, and 33 days after blast exposure. The retina and optic nerve tissue were subjected to immunohistochemistry and Western Blots analyses for glial fibrillary acidic protein (GFAP) and for ionized calcium-binding adaptor 1 (Iba1) as indicators of gliosis. Tissues were evaluated for relative levels of positive signals compared to the unexposed controls.

Results: An increase in GFAP-immunostaining was detected throughout the Müller cell processes traversing the inner plexiform layer and in retinal ganglion cells of vehicle blast-exposed rats compared to controls. Immunolabeling of Iba-1 showed an increase in microglia reactivity in the retinas and optic nerve at 9, 23, and 33 days post blast of vehicle-treated blast rats compared to controls. Western Blot analysis showed a ~1.5-fold increase in GFAP protein levels in optic nerve homogenates from vehicle-treated blast exposed rats as compared to the control group. MaR1 and NPD1 treatment reduced GFAP upregulation and mitigated microglial reactivity in the retina and optic nerve up to 33 days after blast injury.

Conclusions: Blast wave exposure resulting in retinal damage, manifested by increased expression of proteins involved in gliosis, was reduced by either MaR-1 and/or NPD1 intervention. Thus the treatments of MaR1 or NPD1 suggest an effective strategy to reduce or halt retina and optic nerve glia cell activation due to blast wave exposures.

ABSTRACT BODY:

Purpose: Previous studies by our group and others have shown a significant role of bile acids (BA) in various retinal diseases. Gut microbiota has been shown to profoundly affect BA metabolism and systemic composition due to bacterial bile salt hydrolases (BSH). Dysregulated BA-gut microbiome axis (BGA) contributes to various pathologic conditions, including diabetic retinopathy. In addition, exogenous administration of the BA ursodeoxycholic acid (UDCA) has been shown to balance gut microbiota and, from our studies, to ameliorate oxygen-induced retinopathy (OIR), an experimental model of retinopathy of prematurity (ROP). Here, we have investigated whether OIR in mice alters the BGA and whether treatment with UDCA could normalize it.

Methods: Seven days-old mice pups (P7) were subjected to OIR. A group of OIR mice was treated with 50 mg/kg/day of UDCA administered ip. from postnatal days 7 to 17 (P7–P17). Age-matched fully untreated (RA) mice were used as control. BA and microbiome composition was assessed in cecal samples of mice at P17 in all experimental groups, using LC-MS/MS and 16S sequencing, respectively. Spearman's rank correlation coefficient was assessed to determine the specific association of altered BA profile with relative microbiome composition. In addition, levels of BSH activity and systemic insulin-like growth factor 1 (IGF-1) were analyzed in all experimental groups.

Results: BA composition in cecal samples of OIR mice at P17 showed increased levels of unconjugated BA in OIR mice and decreased glycine and taurine conjugated BA, indicating dysregulated BA metabolism. In addition, microbiome composition in OIR mice was significantly disrupted with higher levels of Proteobacteria and lower composition of BSH-producing phyla such as Firmicutes and Bacteroidetes compared to control mice (RA). Furthermore, Spearman's rank correlation coefficient analysis confirmed a significantly dysregulated BGA in OIR. Finally, UDCA treatment of OIR mice corrected the BA-gut microbiome dysregulation. These changes were further associated with a significant decrease in serum IGF-1 levels and increased cecal BSH enzymatic activity in OIR+UDCA mice compared to OIR mice.

Conclusions: Our experimental data evidence a potential correlation between dysregulated BGA and ROP and suggest UDCA as an effective therapy to correct BA-gut microbiome dysregulation in ROP.

ABSTRACT BODY:

Purpose: Melanopsin-expressing intrinsically photosensitive retinal ganglion cells (ipRGCs) survive late in dominant optic atrophy (DOA), long after other RGC sub-types (and vision) have been lost: the underlaying mechanism is unclear. Our purpose here was to optimise a pathway for the preparation and enrichment of single RGC suspensions from an experimental mouse model of DOA and wildtype retinas. This will facilitate single cell RNA sequencing (scRNAseq) approaches to determine if differentially upregulated neuroprotective genes or pathways in ipRGCs are the source of this resistance.

Methods: Retinas of C57/BL6J (P21) mice of both sexes were compared: four groups underwent papain enzyme treatment for 20, 30, 40 or 45 minutes respectively while a final group underwent mechanical disruption [N=3 mice (n=6 retinas) / group]. Fluorescence Assisted Cell Sorting (FACS) on the resulting single cell suspensions was used to enrich the samples for viable RGCs [CD90(thy1.2)$^{+}$,CD48^{-},CD57^{-},CD15^{-},DAPI^{-}]. This was validated by FACS-post-sort-purity-check, RGC marker (SNCG) immunocytochemistry (ICC) & RT-qPCR for RGC specific genes (Thy1, Brn3a, Sncg). This optimised protocol was used to isolate RGCs from both Opa1$^{+/TTAG_del}$ mice and littermate (wildtype) controls (5 months old, N=18 mice per group) for subsequent scRNAseq analysis.

Results: Viability post papain digestion was (mean±SEM) 60.8±2.4%, 54.4±4.3%, 60.2±5.9%, 59.3±3.3% at 20,30,40,45 minutes respectively with no difference between timepoints (one- way ANOVA $F_{(1.28, 2.56)}$=1.84 p=0.30)). Mechanical dissociation led to lower viability (10.41±2.90%; t-test p<0.0001 vs. papain (30m) group). Following FACS processing, papain (30m) suspensions showed RGC enrichment of 78.0±6.6% on post-sort-purity-check and viability of 96.5±3.2% maintained (90.1±1.8%) 5 hours later. ICC showed 75.2±10.6% of cells in the RGC enriched sample staining for SNCG, compared to 13.1±3.1% in the remaining suspension (t-test p<0.0001); across the same comparison, expression of RGC specific genes demonstrated logfold increases by RT-qPCR of: Thy1 25.3±0.9, Brn3a 61.4±0.8, Sncg 7.5±0.9.

Conclusions: This optimised protocol has allowed for enrichment of RGCs from wildtype and DOA model retina for use in scRNAseq. Such investigations will contribute to a greater understanding of the disease resistance of ipRGCs, potentially opening the way for novel neuroprotective therapies for DOA.

SUBMITTER (NAME ONLY): C Ethier

TITLE: A Novel Image-Based Method to Determine Iris Biomechanics in Angle-Closure Glaucoma

SESSION TITLE: Biomechanics and ocular blood flow

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: C.R. Ethier, B. Safa, Biomedical Engineering, Georgia Institute of Technology, Atlanta, Georgia, UNITED STATES|C.R. Ethier, M. Bahrani Fard, Mechanical Engineering, Georgia Institute of Technology, Atlanta, Georgia, UNITED STATES|

Commercial Relationships Disclosure: C Ethier: Commercial Relationship: Code N (No Commercial Relationship) | Mohammad Reza Bahrani Fard: Commercial Relationship: Code N (No Commercial Relationship) | Babak Safa: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Established risk factors for primary angle-closure glaucoma (PACG) include anatomical deficits (e.g., anterior chamber crowding), age, and genetic background, yet only a small percentage of people classified as high-risk progress to PACG (ZAP trial), indicating that current risk factors are incomplete. Here we consider iridial biomechanical properties as a risk factor, and specifically describe an imaging-based technique to determine such factors in vivo.

Methods: We repurposed an existing public biometric database [Konnison+, 2019 Int Conf Biometrics; 163 near-infrared videos from 42 subjects] depicting both eyes during the pupillary light reflex (PLR). Pupil size was determined in darkness and at maximal constriction by segmenting the pupillary margin, and iridial surface features were automatically tracked to determine iridial deformations. Deformations were fit using engineering inverse finite element modeling (iFEM), thereby determining T_s, the magnitude of the sphincter muscle traction; and E and v, the modulus and Poisson ratio of the stroma.

Results: Pupillary segmentation was reliable, repeatable in a test-retest paradigm, and symmetric between eyes in this ostensibly normal cohort (Figure). Stromal feature tracking was less reliable. iFEM fitting of pupillary contraction showed a strong linear correlation between T_s and E, with a mean T_s:E value of 5 (range 4-13, depending on assumed sphincter muscle size).

Conclusions: Our methodology to estimate iris biomechanical properties from near-infrared videos is fast and inexpensive and may aid in understanding additional risk factors for PACG, complementing OCT anatomic measurements. Our estimate of sphincter muscle stiffness is greater than previous estimates [Pant+, IOVS 2018; Panda+, IOVS 2021], possibly due to different patient populations in our study (European descent) vs. previous studies (Asian), of interest due to differential incidence rates of PACG in these populations. Better methods for determining sphincter muscle size in vivo and iridial feature tracking are needed to improve the methodology.

ABSTRACT BODY:

Purpose: The purpose of the study is to quantitatively analyze the choriocapillaris alterations using SS-OCTA in eyes presenting with angioid streaks and to compare these alterations with control eyes.

Methods: Macular 6x6 mm SS-OCTA scans were retrospectively analyzed in eyes with angoid streaks and in control eyes. The choriocapillaris en face slabs (structure and flow) were extracted from the SS-OCTA device after a manual segmentation. En face choriocapillaris flow images were compensated with en face choriocapillaris structure images, followed by Phansalkar local thresholding method using both using a window radius 4 and 8 pixels, respectively. Quantitative analysis was performed in the 4 peripheral 1X1mm corners of the OCTA 6x6mm image in order to include equidistant and comparable regions in all eyes outside of the area of MNV, if present. The percentage of flow deficits (FD%), the number and size of the flow deficits and the total area of FDs were then computed for comparison.

Results: 54 eyes of 31 patients were included in the analysis: 27 eyes diagnosed with angioid streaks (14 patients) and 27 controls (17 patients). Macular neovascularization was associated in 21 of the eyes with angioid streaks. Analysis of the 4, 1X1mm peripheral corners of the 6X6mm OCTA image showed that eyes with angiod streaks had a higher FD% compared to the control group (47.62+/-8.06 versus 38.90+/-6.38 using radius 4 pixels ($p<0.001$); 48.37+/-7.65 versus 39.66+/-6.51 using radius 8 pixels ($p<0.001$).The average size of FDs as well as the total area size of the FDs were significantly higher in eyes with angioid streaks compared to control eyes ($p<0.001$)

Conclusions: Angioid streaks eyes present a reduced choriocapillaris flow compared to control eyes using SS-OCTA. A reduced choriocapillaris perfusion may contribute, among other factors, to development of neovascularization and atrophy in patients with angioid streaks.

TITLE: Evaluating access to laser therapy by driving distance using Medicare data and Geographic Information Systems mapping

SESSION TITLE: Health Economics and Health Care Delivery

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J. Shaffer, A.Y. Lee, C.S. Lee, Ophthalmology, University of Washington Department of Medicine, Seattle, Washington, UNITED STATES|D.D. Miller, Ophthalmology, Mayo Clinic, Jacksonville, Florida, UNITED STATES|

Commercial Relationships Disclosure: Jamie Shaffer: Commercial Relationship: Code N (No Commercial Relationship) | Darby Miller: Commercial Relationship: Code N (No Commercial Relationship) | Aaron Lee: Commercial Relationship(s);Code C (Consultant/Contractor):Genentech, Roche, and Johnson and Johnson;Code E (Employment):US Food and Drug Administration;Code F (Financial Support):Santen, Regeneron, Carl Zeiss Meditec, and Novartis | Cecilia Lee: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To address concerns about regional variation in access to eye care, several states allow optometrists to perform laser procedures previously limited to ophthalmologists, including selective laser trabeculoplasty (SLT) and Nd:YAG laser procedures. We evaluated access to care for residents of three such states by comparing driving distances to optometrists versus ophthalmologists.

Methods: Medicare Fee For Service Data was obtained from the Centers for Medicare & Medicaid Services for 2016 to 2020 for Oklahoma, Kentucky, and Louisiana. Nine digit zip codes for the offices where YAG and SLT were performed were geocoded into GPS coordinates using GEODATA from Melissa (Rancho Santa Margarita, CA) matched by the year of service. Using TomTom historical traffic data, isochrones for 10, 20, and 30 minute driving times were generated for each office location. Population weighted centroids at the census block level from the US Census 2020 data were then used to measure the proportion of the population within 30 minutes of an optometrist or ophthalmologist performing YAG and SLT procedures.

Results: Isochrones for optometrists and ophthalmologists show that optometrists cover an area similar to that covered by ophthalmologists for SLT (Figure 1) and YAG (Figure 2) laser procedures. For SLT, the percent of population covered within 30 minutes of driving time by optometrists was 73.40% (95% CI 73.38 - 73.42), compared to 84.05% (95% CI: 84.03 - 84.07) for ophthalmologists. For YAG, the percent of population covered by optometrists was 84.77% (95% CI 84.75 - 84.79), compared to 85.25% (95% CI: 85.23 - 85.27) for ophthalmologists. For both laser procedures, the percent of the population covered exclusively by optometrists was 5.63% (95% CI 5.62 - 5.64), compared to 6.06% (95% CI: 6.05 - 6.07) by ophthalmologists. The odds ratio for coverage by optometry was 0.92 (95% CI: 0.92 to 0.93).

Conclusions: Despite expansion of laser privileges to optometrists in Oklahoma, Kentucky, and Louisiana, ophthalmologists continue to serve a statistically significant higher percentage of the population for both laser procedures. The expansion of laser privileges to optometrists has not resulted in a statistically significant increase in access to laser procedures.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is a leading cause of vision loss globally. A single nucleotide polymorphism Y402H in Complement factor H, a key negative regulator of complement activation, has been shown to increase an individual's risk of developing AMD. The CFH gene is located on chromosome 1 in the regulator of complement activation gene cluster. Factor H related proteins 1-5 are encoded downstream of CFH. In contrast to FH, FHR-4 acts to promote complement activation and has been suggested to compete with FH for ligand binding. Recently FHR-4 levels have been shown to be elevated systemically in the plasma and serum of AMD patients, however the abundance of FHR-4 protein in RPE choroid tissue from genotyped AMD donors and age-matched controls has not been assessed.

Methods: We studied FH and FHR-4 protein expression in genotyped human donor eyes by both western blot and immunohistochemistry. Western blots were performed on serially extracted aqueous soluble (circulating) and detergent soluble (tissue bound) protein fractions from 2 YY control, 2 YY AMD, 2 HH control and 2 HH AMD donors. Macular tissue sections from 4 YY control, 4 YY AMD, 3 HH control and 3 HH AMD donors were incubated with goat-anti-FH and mouse anti-FHR-4 antibodies.

Results: We found that serum FH protein levels were similar in all donors whereas FHR-4 was elevated in AMD donor serum, consistent with previous reports. We next assessed the relative abundance of FH and FHR-4 in choroid and detected FH protein in both soluble and insoluble RPE/choroid fractions, whereas low levels of FHR-4 were observed only in the soluble fraction. Immunohistochemically we observed robust labeling for FH in all samples, most notably in extracellular domains surrounding the choriocapillaris. In contrast, labeling for FHR-4 protein was variable and relatively weak.

Conclusions: Individuals homozygous for Y402H polymorphism who have increased risk of developing AMD have elevated levels of FHR-4 in their serum, however, no alterations are observed in the local choroidal concentrations of FHR-4. FH, but not FHR4, was found in the detergent soluble, ECM bound protein fraction. Thus, FH is the most abundant member of the FH/FHR family in the choroid, highlighting its importance in AMD pathogenesis.

ABSTRACT BODY:

Purpose: To report visual outcomes, survival rate and short-term complications in patients treated with Lucia KPRO.

Methods: All eligible patients were included. Suitable patients for keratoprosthsis surgery were those who weren't candidates for conventional PKP, including severe bilateral limbal stem cell disease, history of repeat corneal graft failure, ocular surface chemical burns or immune mediated ocular surface disease. Analyzed variables include diagnosis prior to transplantation, age, gender, BCVA, IOP, and postop complications. Descriptive analysis was performed using Excel (Microsoft, Redmond, WA) and statistical analysis was performed using StatPlus (StatPlus, Version 6, AnalystSoft Inc., Walnut, CA). Chisquare test was used to analyze categorical data. Normality test was performed to determine if a data is normally distributed.Preop and postop LogMAR VA were determined to be normally distributed. Then, paired two-tailed t-test was used to compare VA. Statistical significance was set at $p < 0.05$. Log-rank test was performed on Kaplan-Meier survival curves for maintenance of VA and device retention.

Results: 20 eyes of 19 patients were included . Mean age 53.85±17.25 yo. Average follow up 95.3±69.89 days. Previous transplants were performed in 13 eyes (65%), in 7 eyes (35%) KPRO implant was the primary procedure. Mean preop VA 2.40±0.38 logMAR, immediate postop VA was 1.08±0.67 logMAR and 0.98±0.99 logMAR at end of follow up (6 mo) having a statistically significant improvement ($p<0.05$). Most frequent complication was ocular hypertension in the immediate postoperative 25%, retroprothesic membrane formation 5%, sterile vitretiis 10% and corneal thinning around the optic 10%. 11 eyes (55%) had prior diagnosis of glaucoma and 1 eye had corneal dehiscence secondary to trauma. 5 patients required a second surgical intervention to address complications: 2 amniotic membrane grafts, 1 vitrectomy and cyclodestructive procedure for uncontrolled IOP, 1 antibiotic/steroid intravitreal inyections for sterile vitreiitis, and 1 KPRO re-suturing for dehiscence. Device retention throughout the follow-up period was 100%.

Conclusions: First short-term study reporting Lucia KPRO outcomes. All patients improved VA and 100% retention rate. Results are comparable with type I Boston KPRO with the undoubtable advantage of reaching a higher quantity of patients because of its costs, especially in our population.

ABSTRACT BODY:

Purpose: Accurate detection and quantification of fluid in SD-OCT images can assist with treatment decisions and prognostic evaluations in exudative retinal diseases. This study evaluated the performance of a fully-automated, machine learning (ML)-augmented OCT segmentation platform in quantifying macular fluid volumes in wet age-related macular degeneration (AMD) and diabetic macular edema (DME).

Methods: A total of 120 volumetric SD-OCT scans (60 wet AMD and 60 DME) from both Cirrus and Spectralis devices (1:1 ratio for both diseases) were included. A previously developed ML segmentation platform provided fully-automated segmentation of intraretinal fluid (IRF) and subretinal fluid (SRF). Two trained readers (R1 & R2) independently reviewed and corrected the baseline ML segmentation (semi-automated segmentation) while two senior readers collaborated to create a gold-standard (GS) semi-automated segmentation for reference. Central macular fluid volumes (i.e., central 2 mm foveal-centered zone) from ML, R1, and R2 were compared to GS volumes. Agreement was assessed using intraclass correlation coefficients (ICC) and Bland-Altman plots.

Results: In DME, ML achieved an ICC of 0.976 for IRF compared to reader values of 0.992 for both R1 and R2. In wet AMD, ML achieved an ICC of 0.895 for IRF compared to values of 0.971 and 0.970 for R1 and R2, respectively. For SRF volumes in wet AMD, ML achieved an ICC of 0.988 compared to reader values of 0.997 for both R1 and R2. Bland-Altman plots with mean volume differences and 95% limits of agreement are shown in figure 1.

Conclusions: The ML automated platform demonstrated excellent agreement with the gold-standard achieving performance comparable to the readers in IRF quantification in DME and SRF quantification in wet AMD validating its potential use in future disease characterization. The fully-automated segmentation platform allows for quick and accurate measurements of fluid volumes in SD-OCT scans of DME and wet AMD from two widely used OCT devices.

ABSTRACT BODY:

Purpose: We are developing a cone-based optogenetic vision restoration approach that aims to resensitize dormant cone photoreceptors in patients with low vision. In a subset of patients with inherited retinal dystrophies (IRDs), cones lose their light-sensitive outer segments but remain alive in a dormant stage. This creates an opportunity to resensitize them through targeted optogenetic tools. However, the true proportion of low vision patients harboring dormant, non-functional cones, is currently unknown. The worldwide multicenter retrospective study (EyeConic) aims to estimate the proportion of low vision patients with remaining cone cell bodies for the first time.

Methods: We have enrolled 276 eyes of 174 patients with generalized IRDs (study patients) from 7 centers, 15 patients with Stargardt macular dystrophy (STGD) and 15 healthy individuals. Eyes of patients with generalized IRDs and best-corrected visual acuity (BCVA) less than 20/400 were included. We developed a machine-learning-based algorithm to segment total retina in study participants based on macular optical coherence tomography (OCT) scans and calculated the volume of the central foveolar hypercylinder (350 µm diameter). This value is used as a proxy for the remaining cone mass and is expressed as normalized z scores of healthy outer nuclear layer volume.

Results: Foveal hypercylinder volumes of study patients followed a normal distribution and were highly variable ranging from complete atrophy to normal volumes. We found that 31% and 39% of study patients had foveolar hypercylinder volumes within 2 and 3 z scores (indicating 2 and 3 standard deviations from the normal), respectively. There was no correlation between foveolar hypercylinder volume of study patients and BCVA (r=0.04). The highest z-scores were observed in patients harboring biallelic mutations in CEP78, IFT140, CEP290, CRX and TULP1.

Conclusions: A substantial number of patients with generalized IRDs show a foveal hypercylinder volume that is within the range of a healthy cone volume. Such structure-function dissociation provides an opportunity for cone-based optogenetic vision restoration. A significant fraction of patients with low vision are thus candidates for cone-

based optogenetics therapy.

ABSTRACT BODY:

Purpose: To evaluate PRP vs IVR effects on choroidal thickness, and retinal thickness and integrity in eyes with proliferative diabetic retinopathy (PDR) requiring treatment.

Methods: This is a post hoc analysis of Protocol S participants randomized to PRP or IVR to treat PDR. The data source is the DRCR Retina Network, but the content and conclusions presented herein are solely the responsibility of the authors and have not been reviewed or approved by the network. Zeiss Cirrus map and Heidelberg Spectralis raster line OCT images at baseline, 2 and 5 years were evaluated. Choroidal thickness (between Bruch's membrane and the choroid-sclera junction) was manually measured at a single point using calipers in the devices' software at the fovea, and the superior and inferior outer ring center points. The images were evaluated for foveal central subfield (FCS) thickness, total retinal volume (TRV), disorganization of retinal inner layers (DRIL), external limiting membrane (ELM) integrity and ellipsoid zone (EZ) integrity.

Results: Choroidal thickness was graded in 159 of 177 PRP and 143 of 166 IVR eyes at baseline, 135 PRP and 119 IVR at 2 years, and 67 PRP and 62 IVR at 5 years. Mean change from baseline choroidal thickness at the fovea (-3 vs -6 and -8 vs -11 um), superiorly (-4 vs -6 and -15 vs -11 um), and inferiorly (-13 vs -14 and -27 vs -19 um) for PRP vs IVR at 2 and 5 years were not significantly different between treatments (all p>.05). The decreases compared to baseline were significant in both groups superiorly at 5 years (both p=.03), and inferiorly at 2 and 5 years (both p = .003 at 2 years; p<.001 for PRP and p=.003 for IVR at 5 years). Mean change from baseline FCS (8 vs -39 and -4 vs -39 μm) and TRV (-.03 vs -.79 and -.39 vs -1.07 mm3) for PRP vs IVR at 2 and 5 years were significantly different between treatments (p<.001 and p=.04 for FCS; p<.001 and p=.01 for TRV). Rates of DRIL (52% vs 39% and 58% vs 56%), ELM (58% vs 64% and 52% vs 46%), and EZ (53% vs 58% and 52% vs 49%) for PRP vs IVR at 2 and 5 years were similar.

Conclusions: In this randomized cohort, we did not find differences in choroidal thickness changes between PRP and IVR from baseline to 2 or 5 years. Both study arms had significant decreases in superior and inferior choroidal thickness at 5 years. IVR had greater FCS thickness and TRV reductions than PRP.

TITLE: Encapsulation of epalrestat in niosomes
SESSION TITLE: Drug delivery
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: A. Kattar, C. Alvarez-Lorenzo, A. Concheiro, Pharmaceutical Technology, Universidade de Santiago de Compostela, Santiago de Compostela, Galicia, SPAIN|
Commercial Relationships Disclosure: Axel Kattar: Commercial Relationship: Code N (No Commercial Relationship) | Carmen Alvarez-Lorenzo: Commercial Relationship: Code N (No Commercial Relationship) | Angel Concheiro: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The increase of diabetic patients leads to an increase of ocular diabetic diseases as diabetic retinopathy. This occurs when the retina degrades due to osmotic pressure and oxidative stress caused by the polyol pathway, activated in high glycemic conditions. This pathway is blocked by epalrestat, a drug already used in the context of diabetic neuropathy, but the epalrestat molecule is very hydrophobic. It is hypothesized that the formation of a niosomal complex as a carrier for epalrestat will display physicochemical properties and have an encapsulation efficiency that points towards the molecule being able to reach the posterior segment of the eye, which is the therapeutic site.

Methods: Formulation of the niosomes was done using different molar ratios of surfactant:helper lipid:charge modifier/Tween80:cholesterol:DOTMA. The reagents were dissolved in ethanol, dried with a rotavapor, then hydrated with MilliQ water. The flask was ultrasonicated, and then sonified with a probe sonifier. Dialysis was performed to remove unencapsulated drug. The niosomes formed were characterized in terms of size, polydispersity, surface charge and morphology using DLS, zeta-potential and TEM. Quantification of epalrestat in subsequent experiments was done by HPLC. The encapsulation efficiency and release profile were measured by dialysis, in 14 000 kDa cellulose tubing.

Results: Loaded niosomes were formed with the physicochemical properties and encapsulation efficiency as described below. The morphology was spherical.

T60CD0ef: 84 nm, 0.541 PDI, -23.34 ± 5.341 mV zeta-potential, 99.86 ± 0.24% encapsulation efficiency.

T60CD5ef: 69 nm, 0.460 PDI, +17.27 ± 10.29 mV zeta-potential, 99.75 ± 0.35% encapsulation efficiency.

T60CD10ef: 75nm, 0.279 PDI, +40.39 ± 10.29 mV zeta-potential, 99.64 ± 0.13% encapsulation efficiency.

The release profile showed better release with lower DOTMA percentage, up until 10 days, when the niosomes with 5% DOTMA released more than niosomes without charge modifier. (Image 1)

Conclusions: The hypothesis was confirmed and niosomal particles were prepared using a robust protocol. To confirm the viability of such particles tissue permeation experiments will be performed. The effect of surface charge on the ability of epalrestat to escape the niosomes should be explored in more detail.

ABSTRACT BODY:

Purpose: To identify the cause of autosomal dominant retinitis pigmentosa (adRP) in a cohort of families without mutations in known adRP genes and consequently to characterize a novel, dominant-acting mutation in ZBED1, a gene in the pseudoautosomal region 1 (PAR1) of the X and Y chromosomes.

Methods: Families from the University of Texas and the Ocular Genomics Institute (OGI) cohorts were screened using whole-exome NGS. Following identification of a novel ZBED1 variant in two families, UTAD076 and UTAD1013, a second cohort from the Ocular Genomics Institute (OGI) at Harvard was screened for the variant. Genealogies were established by interviews of family members; additional samples were collected and sequenced. Haplotypes segregating with the mutation were determined using STR and SNV polymorphisms and LOD scores were calculated in two large families from the University of Texas. Blood samples were obtained from an affected/unaffected sib pair and were used to create iPSCs. Whole genome sequencing was performed in both families to rule out additional, co-segregating pathogenic variants.

Results: A novel variant in ZBED1 (c.754T>A, p.Tyr252Asn) was the only segregating, potentially pathogenic, coding variant identified by exome sequencing in two large adRP families. We subsequently identified an additional two patients in the OGI cohort carrying the same heterozygous variant. One patient overlapped with the UTAD1013 family but the other could not be definitively placed in either family. Using the variant as a marker, LOD scores of 3.6 (UTAD1013) and 4.5 (UTAD076) were calculated. The location of the gene in the pseudoautosomal region confounds haplotype analysis, but genealogies suggest an Irish founder.

Conclusions: A novel, dominant-acting gene mutation in a pseudoautosomal gene is the likely cause of retinitis pigmentosa in two large Irish-American families. The phenotype in both families is similar, with relatively late onset in females and earlier onset in males. Genes in the PAR1 escape X-inactivation but still have lower total expression in females. The ZBED1 gene is thought to function as a transcription factor and is ubiquitously expressed. In retina, ZBED1 is expressed in both rod and cone photoreceptors with even higher expression in bipolar and amacrine cells.

TITLE: The Effects of Negative Periocular Pressure on Biomechanics of the Optic Nerve Head (ONH) and Cornea: A Computational Modeling Study

SESSION TITLE: Structure-Function Relationship

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Safa, C.R. Ethier, Biomedical Engineering, Georgia Institute of Technology, Atlanta, Georgia, UNITED STATES|J. Berdahl, Equinox Ophthalmic, Inc, North Dakota, UNITED STATES|

Commercial Relationships Disclosure: Babak Safa: Commercial Relationship: Code N (No Commercial Relationship) | John Berdahl: Commercial Relationship(s);Code O (Owner):Equinox Ophthalmic, Inc;Code P (Patent):Equinox Ophthalmic, Inc | C Ethier: Commercial Relationship(s);Code C (Consultant/Contractor):Equinox Ophthalmic, Inc

ABSTRACT BODY:

Purpose: Decreasing intraocular pressure (IOP) is the only approved treatment for glaucoma. The Multi-Pressure Dial system (MPD; Equinox Ophthalmic) is a medical device consisting of goggles connected to a programmable vacuum pump that delivers a negative periocular pressure (NPP; Swan+, 2020 Transl Vis Sci Technol). Experimental data show that IOP is reduced during goggle wear, yet the effects on ONH and corneal biomechanics are unknown. Our objective was to evaluate the effect of NPP on ONH and corneal biomechanics by using finite element (FE) modeling.

Methods: An axisymmetric FE model of the eye was developed based on the existing model from Sigal et al. (IOVS 2005; Fig. 1A). At baseline, we imposed the following pressures: IOP = 15.8 mmHg, NPP = 0, retrolaminar pressure (RLTP) = 8 mmHg. During goggle wear (NPP = -7.9 mmHg), we imposed a lowered IOP = 11.5 mmHg (based on experimental data Swan+, 2020), and unchanged RLTP. IOP was uniformly applied on the interior surface of the corneoscleral shell; NPP was applied uniformly from the apex to ~2.5 mm posterior to the limbus and then decreased linearly to zero at the edge of the peripapillary sclera (ppSC). Tissues were modelled as incompressible neo-Hookean materials, with the ppSc including circumferential collagen fibers. To validate our model, we compared the computed compliance of the corneoscleral shell to literature data.

Results: Our model had a predicted ocular compliance of 3.1 μL/mmHg, in agreement with literature values of 1.4-3.9 μL/mmHg (McEwen&Helen, 1965 Ophthalmologica). Application of NPP increased the average first principal Lagrangian strain (Ξ, a measure of tissue stretching) at the corneal apex by 27.3%, and at the limbus by 23.4%. Importantly, NPP decreased ONH strain by 54.5% (Fig. 1B).

Conclusions: Imposing a negative periocular pressure is predicted to increase corneal and limbal strains but reduce the mechanical strain in the ONH. ONH strain reduction occurs because the effects of IOP lowering seem to outweigh the effects of globe expansion, which in theory should be beneficial for glaucoma patients.

ABSTRACT BODY:

Purpose:

During the COVID-19 pandemic, regulatory changes in the United States allowed physicians to practice telemedicine across state lines. Data on the use of interstate ophthalmic telemedicine during the pandemic are limited. We aimed to evaluate the geographic characteristics and interstate utilization of telemedical care as compared to in-person care at a tertiary eye care center during the pandemic.

Methods:

In this single-center, retrospective, cross-sectional study at Massachusetts Eye and Ear (MEE) from January 1 to December 31, 2020, clinical encounters were reviewed to extract patient and visit characteristics. In-person versus telemedical visit types were identified based on institutional categories and billing codes. Residential zip codes were used to estimate geographic characteristics of patients including distance from MEE and in-state versus out-of-state status. Pearson chi-squared tests were used to compare telemedical and in-person care groups.

Results:

A total of 1911 telemedical patients (2262 encounters) and 65763 in-person patients (147211 encounters) were included. The median (interquartile range; IQR) age of telemedicine patients was 61 (43-72) years, 62% of which were female. The median (IQR) age of in-person patients was 63 (49-72) years, 58% of which were female. Telemedicine patients included 14.7% (n=281) out-of-state patients, as compared to 12.0% (n=7876) out-of-state in-person patients ($p<0.001$). Regarding distance, 42.5% of telemedicine patients and 47.5% of in-person patients lived <10 miles ($p<0.001$), 41.9% and 41.3% lived 10-50 miles ($p=0.611$), 8.8% and 7.0% lived 51-100 miles ($p=0.002$), 3.9% and 2.5% lived 101-250 miles ($p<0.001$), and 3.0% and 1.8% lived >250 miles ($p<0.001$) away from MEE, respectively.

Conclusions:

A significantly greater proportion of telemedical care, as compared to in-person care, was provided to out-of-state patients at a large eye care center during the pandemic. Moreover, a significantly greater proportion of telemedical care was utilized by patients living further away from the eye center. Proposals to revert to pre-pandemic policies requiring in-state telemedicine could set back forward progress made during the pandemic, including negative impacts on access to care and continuity of care for established patients. Expanded telemedicine licensure and scope could help advance the efficiency and deployment gains seen during the pandemic.

ABSTRACT BODY:

Purpose: LCA10 is a severe, inherited retinal disease (IRD) resulting in early blindness, with no treatments available. Current validated endpoints to assess vision may show some limitations in individuals with profound visual impairment. To address this need, new endpoints such as a mobility course (MC), are being assessed. The aim of the study was to assess the novel Ora MC as an efficacy endpoint to evaluate functional vision in individuals with a phenotype representative of LCA10.

Methods: This was a prospective non interventional study testing the Ora MC composite score (MCCS) based on participants' ability to navigate through two sets of MCs of decreasing difficulty: The Low-Contrast Visual Navigation Challenge® (LCVNC) and the High-Contrast Visual Navigation Challenge® (HCVNC), each with eight increasing luminance levels (range 0.35 to 500 lux). Participants navigated both MCs 3 times during each of 3 separate visits assessing each individual eye and both eyes. The MCCS was derived from the most difficult course a participant was able to navigate, and the scores were provided by a masked central reading center (a more difficult MC passed meant a better MCCS). Visual assessments including best corrected visual acuity (BCVA), were performed at the same visit in all participants.

Results: 48 participants (mean age 27.3, range 6-57, 23 females) with LCA10 (n=39) or other LCA or IRD with phenotype representative of LCA10 (n=9) underwent complete assessments and were included in the final analysis. Mean BCVA was 1.14, range 0 to 4. The test-retest reliability of the MCCS, as assessed by the intra-class coefficient, was high (ICC 0.97, 95% CI: 0.93 – 0.99), demonstrating the high reproducibility of this tool as an endpoint for clinical trials. There was a high negative correlation between the MCCS and BCVA, as demonstrated by a Pearson correlation coefficient of -0.75 (95% CI: -0.84, -0.56) for the better eye, -0.75 (95% CI: -0.85, -0.59) for the worse eye and -0.73 (95% CI: -0.83, -0.54) for both eyes.

Conclusions: Ora MCCS was highly reproducible and had a strong negative correlation with BCVA, showing that a decrease in logMAR values was correlated with an increased MCCS and vice-versa. This novel tool can be used as an efficacy endpoint to assess functional vision in clinical trials in individuals with a phenotype representative of LCA10.

TITLE: Characterization of cone structure and function in a mouse model for blue cone monochromacy patients with a C203R mutation

SESSION TITLE: Photoreceptor Biology, Protection and Degeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Sechrest, W. Deng, Ophthalmology and Visual Sciences, West Virginia University, Morgantown, West Virginia, UNITED STATES|X. Ma, Ophthalmology, University of Florida, Gainesville, Florida, UNITED STATES|W. Deng, Biochemistry, West Virginia University, Morgantown, West Virginia, UNITED STATES|

Commercial Relationships Disclosure: Emily Sechrest: Commercial Relationship: Code N (No Commercial Relationship) | Xiajie Ma: Commercial Relationship: Code N (No Commercial Relationship) | Wen-Tao Deng: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Blue cone monochromacy (BCM) is a severe vision disorder caused by severely reduced or absence of function in L- and M-cones. Presence of a C203R missense mutation in a single OPN1LW/MW hybrid gene or in multiple OPN1LW/MW genes is the most common cause of BCM. In this study, we seek to dissect the disease mechanism of a C203R mutation through characterizing the structure and function of cone photoreceptors in a knock-in mouse model carrying a corresponding mutation.

Methods: Opn1mw^{C198R} (OPN1L/MW^{C203R} equivalent) knock-in mice were generated using CRISPR/Cas9 genome editing technology and were bred into an Opn1sw$^{-/-}$ background to eliminate interference from endogenous S-opsin. Retinal whole mounts of Opn1mw^{C198R} mice were labeled with peanut agglutinin (PNA) to assess cone viability at 1, 3, 6, and 9 months of age. Quantitative RT-PCR was used to evaluate mRNA levels of Opn1mw^{C198R} at P5, P15, and P30. In tandem, cross-sections from Opn1mw^{C198R} retinas were examined by immunohistochemistry (IHC) using antibodies against L/M-opsin, PDE6α', and GNAT2. Finally, M-cone mediated retinal function was analyzed at P30 by electroretinography (ERG). Age-matched C57BL/6J mice were used as controls.

Results: Ventral and dorsal regions of Opn1mw^{C198R} retina display significantly reduced cone viability by 3 months and cones continue to degenerate with age. By 6 months, Opn1mw^{C198R} cones in the dorsal and ventral regions of the retina are reduced by 60.0% and 43.9%, respectively, compared to those at 1 month of age ($P < 0.05$). While qRT-PCR shows that Opn1mw mRNA is comparable between WT and mutant at P5, mutant mRNA levels drop 44% by P30 ($P<0.05$). Surprisingly, OPN1MW^{C198R} protein was not detected by IHC at P5, P15, or P30. GNAT2 staining appeared brighter at P5 compared to WT, but was mislocalized to the cone cell body and inner segment. Furthermore, GNAT2 staining dissipates by P15 and P30, suggesting cone outer segments are absent or significantly shortened in Opn1mw^{C198R} mice. Moreover, ERG demonstrates that Opn1mw^{C198R} eyes have no M-cone mediated retinal function at P30.

Conclusions: Cone structure and function in Opn1mw^{C198R} mice appear to phenocopy BCM patients with C203R mutations, demonstrating that this model can be adequately used for characterization of the disease mechanism behind a C203R mutation and in development of therapy.

TITLE: TRPV4 involvement in inflammation and tissue damage in corneal epithelium

SESSION TITLE: Corneal epithelial biology and repair mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Lapajne, M. Lakk, D. Krizaj, Department of Ophthalmology and Visual Sciences, The University of Utah School of Medicine, Salt Lake City, Utah, UNITED STATES|L. Lapajne, M. Hawlina, Eye Hospital, University Medical Centre Ljubljana, Ljubljana, SLOVENIA|

Commercial Relationships Disclosure: Luka Lapajne: Commercial Relationship: Code N (No Commercial Relationship) | Monika Lakk: Commercial Relationship: Code N (No Commercial Relationship) | Marko Hawlina: Commercial Relationship: Code N (No Commercial Relationship) | David Krizaj: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Corneal epithelium is subjected to biological, chemical, and physical stressors from the environment, many of which are known activators or modulators of TRPV4 channel. TRPV4 signaling has been linked to nociception and release of inflammatory molecules which might contribute to tissue damage but the role of TRPV4 in corneal epithelial pathophysiology is not understood well. Here, we investigate the involvement of TRPV4 in ultraviolet light-mediated injury, G-protein receptor-dependent signaling and cytokine release.

Methods: Corneas from C57BL/6 and TRPV4$^{-/-}$ mice were enzymatically detached from the stroma and used for in situ experiments. They were subjected to assorted agonists and antagonists as well as to UVB radiation, mimicking UVB damage inflicted to the cornea. For cytokine release assay, epithelial cells were dissociated, subjected to the UV stimuli or the selective TRPV4 agonist GSK1016790A and supernatants were evaluated by chemiluminescence reaction. Optical imaging assessed the properties of Ca^{2+} homeostasis under different experimental conditions.

Results: UVB radiation reversibly elevated $[Ca^{2+}]_i$ in mouse corneal epithelial cells, an effect that was slightly attenuated by TRPV4 ablation or inhibition. UV-evoked increases in $[Ca^{2+}]_i$ principally reflected release of calcium from the pool stored intracellularly within the endoplasmic reticulum. Pharmacological activation of the protease-activated receptor-2 (PAR-2) sensitized TRPV4 for agonist activation. UVB radiation and TRPV4 activation evoked stimulus-specific release of proinflammatory cytokines and inflammatory substances, effects that were antagonized by pharmacological blockade of TRPV4.

Conclusions: Our data suggest that corneal epithelial cells respond to harmful UVB radiation with parallel and additive activation of TRPV4 channels and release of calcium from intracellular stores. It is possible that substances residing in tears contribute to PAR-2-mediated TRPV4 regulation in corneal epithelial cells under pathological conditions. In addition, the corneal milieu is likely to be influenced by TRPV4- and/or UVB-dependent release of cytokines and inflammatory substances, with potential effects on transparency, would healing and nociception. Overall, this study identifies TRPV4 as a potential target of ocular surface inflammation and tissue damage.

ABSTRACT BODY:

Purpose: To evaluate the evolution of MA in patients with neovascular AMD (nAMD) treated with anti-vascular endothelial growth factor (anti-VEGF) agents, compared with their fellow eyes exhibiting dry AMD.

Methods: This retrospective study included 124 patients from three centers with neovascular AMD treated with anti-VEGF intravitreal injections in one eye and dry AMD in the fellow eye. We analyzed data from two groups of patients: 91 patients without MA at baseline in order to study time to first MA development in treated and fellow eyes, and 47 patients with a total of 4 years of follow-up in order to study time course and growth rate of MA in treated and fellow eyes. MA was evaluated using NIR images, while all available OCT images were used to confirm that the atrophic area fulfilled the criteria proposed by the Classification of Atrophy Meetings (CAM) group.

Results: MA first detection in treated eyes (TE) increased in significant levels from year 2 to year 6 in comparison with fellow eyes (FE). Presence of MA during the 4-year of follow up was recorded in 50% of TE and in 18% of FE. Repeated measures ANOVA revealed significant time, eye and time eye interaction effects. MA in treated eyes exhibited a steady significant increase up to year 6, whereas in the FE the significant increase is halted at year 4. The annual increase in the TE was 0.275 mm/y [0.10 mm/y for year 1, 0.23 mm/y for year 2, 0.37 mm/y for year 3, and 0.49 mm/y for year 4]. The respective annual increase for the FE was 0.110 mm/y; [0.09 mm/y for year 1, 0.14 mm/y for year 2, 0.11 mm/y for year 3 and 0.10 mm/y for year 4].

Conclusions: In this study we documented a significant difference in MA incidence and progression in eyes with nAMD treated with anti-VEGF agents compared to fellow eyes exhibiting dry AMD. Treated nAMD eyes tend to develop more often MA; moreover, MA progresses in a faster rate in these eyes compared to fellow dry AMD eyes.

ABSTRACT BODY:

Purpose: Early postnatal hyperglycemia (phase I retinopathy of prematurity (ROP)) is a significant risk factor for proliferative retinopathy of prematurity (phase II ROP), a leading cause of blindness in children. Abnormalities of glucose and lipid metabolism affect development and progression of retinal vascular growth (Phase I ROP). Fibroblast growth factor 21 (FGF21), a metabolic regulator of lipid and glucose usage, may improve Phase I ROP metabolism. FGF21 effects on lipid metabolism in retina were addressed in hyperglycemia-associated retinopathy (HAR) in C57BL/6J mice with delayed vascular growth, a model of phase I ROP.

Methods: Hyperglycemia-associated retinopathy (phase I ROP) was induced with intraperitoneal (i.p.) injection of streptozotocin administered from postnatal day (P) 1 to 9. At P10, retinal vessel growth was evaluated in FGF21 vs. vehicle-treated mice (i.p. from P7 to P9) (n=14-16). Co-treatment of HAR mice with FGF21 plus intravitreal siRNA Acaca (de novo fatty acid synthesis enzyme) (n=8-9), or i.p. etomoxir (CPT1A inhibitor) (n=8-9) vs. controls was also conducted. Lipid and proteins were assessed in retina of FGF21- vs. vehicle-treated mice (n=5 each). A transcriptome array was assessed in retina of FGF21- vs vehicle-treated mice (Affymetrix (Santa Clara, CA).

Results: In the phase I ROP mouse model with hyperglycemia-induced delayed retinal vascular development, FGF21 administration increased retinal vascularization (with increased deep vascular coverage ($P=0.0007$)). Inhibition of CPT1A greatly decreased ($P<0.01$) FGF21 protection of hyperglycemia-induced delayed retinal vascular growth. Mild changes were observed in phospholipids between FGF21- vs. vehicle-treated HAR mice. Proteomics analysis showed an increased level of antioxidant enzymes in HAR mice treated with FGF21. Transcriptome analysis suggests the involvement of transforming growth factor beta (TGF-β), Integrin and p53 signaling pathways with FGF21 prevention of hyperglycemia associated phase I ROP.

Conclusions: FGF21 promotes normal vascularization during hyperglycemia associated vessel growth delay in phase I ROP, associated with regulation of retinal lipid metabolism. Preventing vessel growth cessation in phase I ROP prevents phase II ROP.

TITLE: Selective oligodendrocyte ablation alters optic nerve conduction and retinal ganglion cell layer density

SESSION TITLE: Retinal ganglion cells

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Balraj, R. Miller, Anatomy, The George Washington University School of Medicine and Health Sciences, Washington, District of Columbia, UNITED STATES|

Commercial Relationships Disclosure: Annika Balraj: Commercial Relationship: Code N (No Commercial Relationship) | Robert Miller: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Successful signal propagation along axons is important for the survival of neural networks. In the optic nerve, oligodendrocytes produce the myelin sheath which provides insulation for retinal ganglion cell (RGC) axons. Optic neuritis (the demyelination and inflammation of the optic nerve) results in visual deficits and thinning of retinal nerve fiber and ganglion cell layers. Demyelination can induce functional deficits; however, the impact of demyelination on upstream network connectivity is not well understood. This study evaluates the effect of local optic nerve demyelination on axonal conduction and retinal connectivity.

Methods: In the MBP-iCP9 transgenic mouse, the myelin basic protein (MBP) promoter drives expression of an inducible caspase 9 (iCP9) sequence and a DsRed reporter. Eye injection of the chemical inducer of dimerization (CID) results in the selective apoptosis of MBP+ oligodendrocytes and subsequent demyelination. MBP-iCP9 mice were injected at P14 with either CID or vehicle for three consecutive days. After two weeks, immunohistochemistry was used to quantify oligodendrocyte loss and retinal layer density and identify RGC subtypes. Optic nerve compound action potentials (CAPs) were measured using extracellular recordings. Axon populations were identified as axons with similar conduction speeds. Within-nerve controls used tetrodotoxin to isolate and remove the stimulus artifact during analysis.

Results: CID-treated nerves had a significant loss of DsRed+ CC1+ oligodendrocytes ($n>5$, $p=0.04$). Average CAP area (a measure of functional axons) was reduced in CID-treated mice ($n<5$). CID-treated nerves retained the fastest-conducting axon populations but lost slow-conducting axons. Average ganglion cell layer density was significantly lower in CID-treated retinas ($n>4$, $p=0.03$), while inner and outer nuclear layer density were unaffected ($p>0.05$). Analysis of the ganglion cell layer found a significant loss of RBPMS+ ($p=0.03$) and Brn3a+ ($p=0.02$) cells in CID-treated retinas and a non-significant reduction of ChAT+ amacrine cells ($p=0.06$).

Conclusions: These results suggest that partial demyelination of the optic nerve can induce a significant conduction deficit and disrupt retinal connectivity through the loss of alpha-RGCs. This provides valuable insight into the regulatory role of myelination in the maintenance of upstream neural networks.

SUBMITTER (NAME ONLY): Omar Shareef

TITLE: Validating the Usefulness of a Random Forests Classifier as an Alternative to SCORTEN in Predicting Mortality for Individuals with SJS/TEN

SESSION TITLE: Ocular surface health and conjunctiva

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: O. Shareef, J.T. Kwan, S. Lau, H.N. Saeed, Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|O. Shareef, Harvard College, Cambridge, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Omar Shareef: Commercial Relationship: Code N (No Commercial Relationship) | James Kwan: Commercial Relationship: Code N (No Commercial Relationship) | Sarina Lau: Commercial Relationship: Code N (No Commercial Relationship) | Hajirah Saeed: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The SCORTEN scoring system was developed in 2000 as a severity-of-illness score for Stevens Johnson syndrome and toxic epidermal necrolysis (SJS/TEN) and has since been used for predicting mortality for individuals with SJS/TEN. Survivors of SJS/TEN can develop blinding ocular surface disease, and a higher SCORTEN score can be a predictor of worse ocular complications. However, certain predictors required for the SCORTEN scale can be difficult to assess accurately, particularly total body surface area (TBSA) involvement. An alternative method that uses laboratory results can serve as a simpler way to predict mortality and severity of ocular disease and can be easily implemented into existing electronic health record (EHR) systems.

Methods: A random forests classifier (RFC) model to predict mortality was trained on laboratory data from 156 patients. The test dataset included 36 patients. Missing values in the training data were handled using k-nearest neighbors imputation and categorical data were split using one-hot encoding. Cross-validation was used to determine that an RFC was the most robust in predictive power. Several RFCs were trained on the data using the full set of predictors (n=97). The top five predictors were found from the most accurate model and a final RFC was trained using only this subset of predictors on an upsampled dataset.

Results: On the testing data, the accuracy and the area under the receiver operating characteristic curve (AUROC) for the SCORTEN model were 0.833 and 0.688, respectively. For the RFC model, the accuracy and AUROC were 0.889 and 0.842, respectively. The differences in both accuracy ($p = 0.32$) and AUROC ($p = 0.488$) were not statistically significant. The five predictors used to train this algorithm in order of importance were: Bilirubin (total), PT, RBC, WBC, and NRBC.

Conclusions: The similar performance between the SCORTEN and RFC models indicates that the RFC model can be utilized as an alternative to SCORTEN and may be more easily calculated. The RFC model does not share any of the predictors used by the SCORTEN model including TBSA involvement, which can be notoriously difficult to calculate. This alternative model can be easily implemented in existing EHR systems by simply pulling from lab tests and may serve as a useful tool in predicting ocular morbidity.

ABSTRACT BODY:

Purpose: We have shown that global deletion of the mitochondrial arginase isoform arginase 2 (A2) limits retinal ganglion cell (RGC) death in various models of retinal neurodegeneration. Herein, we examined the mechanisms of this neuroprotection and show that neuron-specific deletion of A2 is sufficient to prevent optic nerve crush (ONC)-induced neurodegeneration.

Methods: Wild type (WT), $A2^{-/-}$ global knockout (A2KO), and Calbindin2-specific ($Calb2\text{-}cre^{+}$ $A2^{f/f}$) KO mice on the C57BL/6J background were subjected to ONC. Stress-activated calcium signaling and mitochondrial dysfunction were assessed by changes in activation status of p38 MAPK, calcium/calmodulin-dependent protein kinase II (CAMKII), and the mitochondrial fission marker dynamin-related protein 1 (Drp1), respectively at 6 and 24 h post ONC. Survival of RGC was quantified with NeuN immunostaining of retina flat-mounts at day 14 and TUNEL labeling of retina sections at day 5 post ONC. Pattern ERGs, spectral domain-optical coherence tomography (SD-OCT), and OptoMotry responses (OMR) were measured at day 21 post ONC. Axonal sprouting was determined by anterograde transport of Cholera Toxin B (CTB).

Results: Early increases in A2 expression, phosphorylation of stress-activated proteins p38 and CAMKII, and the mitochondrial fission protein DRP-1 at ^{616}Ser, (n=4-7; $p<0.05$) were detected in WT retinas, and this was abrogated by deletion of A2. IHC showed increased A2 and phospho p38 immunoreactivities within RGC of WT mice. Further, the number of NeuN positive RGC was significantly reduced in $A2^{f/f}$ mice post ONC (39% of sham controls). This RGC loss was reduced in Calb2 A2 KO mice ($p=0.07$; n=5). Calb2 A2 KO mice also showed fewer TUNEL positive RGC neurons compared to $A2^{f/f}$ ($p=0.02$; n=4). PERG and visual acuity were decreased in $A2^{f/f}$ mice and improved in Calb2 A2 KO mice (n=4-7; $p<0.05$). OCT and CTB analysis of retinal thickness and axonal sprouting, respectively, showed improved responses in the Calb2 A2 KO mice after ONC as compared with the $A2^{f/f}$ (n=4-7; $p<0.05$).

Conclusions: Our data indicate that A2 is neurotoxic in RGCs after injury, and deletion of A2 in Calb2 expressing RGCs limits ONC-induced retinal neurodegeneration and thereby improves visual function. Based on our preliminary findings, stress-activated Calcium signaling via CaMKII/p38 and mitochondrial dysfunction are probable mechanisms involved in A2-mediated RGC cell death.

Commercial Relationships Disclosure: Marilyn Marquez: Commercial Relationship: Code N (No Commercial Relationship) | Luis Haddock: Commercial Relationship: Code N (No Commercial Relationship) | Jorge Fortun: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the utility of near-infrared imaging (NIR) of the optic disc, obtained as part of routine optical coherence tomography (OCT) of the macula during evaluation in a retina clinic, as a screening to tool to identify eyes with possible glaucomatous optic neuropathy.

Methods: A series of consecutive patients seen in the retina clinic underwent optic nerve-head OCT with RNFL analysis, in addition to routine macular OCT. The NIR images of the optic disc acquired during the macular OCT were evaluated by two different masked graders (both retina specialists) to determine whether the images were suspicious for glaucomatous optic neuropathy and would warrant further evaluation or referral to a glaucoma specialist. An unmasked glaucoma specialist then evaluated the optic disc RNFL analysis of each eye to determine whether there was a glaucomatous optic nerve damage or a suspicion of glaucomatous optic neuropathy

Results: Of 216 eyes (108 patients) who had imaging in the retina clinic, 15 % of those eyes were unable to be assessed by the IR image. From the eyes that were able to be assessed, 14% of the images had a discrepancy between the results of the unmasked grader and the masked graders, and 86% of images had a coincidence between the masked and unmasked grader.

Conclusions: NIR obtained as part of routine OCT of the macula during evaluation in a retina clinic, can serve as a useful screening tool to identify eyes with possible glaucomatous optic neuropathy.

ABSTRACT BODY:

Purpose: Elevated intraocular pressure (IOP) is the primary risk factor of primary open-angle glaucoma (POAG). TGFβ2 and Wnt signaling pathways are associated with POAG. Excessive TGFβ2 induces pathological changes in the trabecular meshwork (TM). Also, TGFβ2 elevates IOP in mouse and human eyes. In contrast, inhibition of Wnt signaling contributes to POAG. We reported that an elevation of sFRP1 and Dkk1, the Wnt inhibitors, in the POAG TM and/or aqueous humor. Overexpression of either sFRP1 or Dkk1 elevates IOP in mouse and/or human eyes. There is also a cross-inhibition between TGFβ2 and Wnt signaling pathways. Here, we determine the mechanism of this cross-inhibition and if the activation of the canonical Wnt signaling inhibits TGFβ2 signaling and its related pathological changes in the TM.

Methods: HTM cells were treated with or without TGFβ2, Wnt3a, and/or GSK3β inhibitors. Cytosolic and nuclear fractions were co-immunoprecipitated (Co-IP). Some of the nuclear fractions were used for electrophoretic mobility shift assay (EMSA). Förster resonance energy transfer and fluorescent live imaging (FRET-FLIM) was used to study protein-protein interaction using pHTM cells transduced with Ad5-SMAD4-GFP with or without Ad5-β-catenin-mCherry. Human donor eyes were used for perfusion cultures.

Results: We treated pHTM cells with TGFβ2 with or without Wnt3a/GSK3β inhibitors and found that in single or in combination, they promoted SMAD4 and β-catenin nuclear translocation. Co-immunoprecipitation assays showed that Smad4 was associated with β-catenin in pHTM cells. FRET-FLIM assays showed a shortening of the fluorescent lifetime of Smad4-GFP in the presence of β-catenin-mCherry in pHTM cells, indicating a direct binding between the two proteins. EMSA assays showed that the Smad4-β-catenin complex did not interfere with DNA binding. Western immunoblotting and immunofluorescence studies showed that the activation of Wnt signaling using Wnt3a or GSK3β inhibitors inhibited TGFβ2-induced TGFβ signaling as well as ECM proteins in pHTM cells. Topical application of CHIR inhibited TGFβ2-induced ocular hypertension in perfusion culture human eyes.

Conclusions: The activation of either signaling pathways promotes the nuclear translocation of both β-catenin and Smad4 and they form a complex in the nucleus via direct binding. Also, the activation of Wnt signaling inhibits TGFβ2-induced pathological changes in the TM.

ABSTRACT BODY:

Purpose: Cumulative Dissipated Energy (CDE) is the amount of ultrasound energy used during phacoemulsification (PHACO). We carried out a cross-sectional study to prove that the higher the number of PHACOS, the less CDE was used by the ophthalmic surgeon.

Methods: We conducted a cross-sectional, data was obtained from a training residency program from August 2020 to November 2020. Patients undergoing surgery with LOCS III nuclear opalescence, grades 2 and 3 (NO2 and NO3), were consecutively included. Exclusion criteria included patients with one functional eye, zonular weakness, congenital and traumatic cataracts. Three groups were created: group 1, less than 80 surgeries performed, group 2 between 80 and 160 surgeries, and group 3 more than 160 surgeries.All patients were operated on the same PHACO platform, the Alcon Centurion system. Statistical analysis was performed with SPSS (Ver. 22. IBM Corp. Armonk, USA). The CDE between the groups was compared with the Bonferroni post hoc analysis.

Results: One hundred and thirty-five eyes of 135 patients were included, 45 eyes per group, 54.1% (n = 73) were right eyes. The median CDE was 11.5, 10.4, and 7.4 in groups 1, 2, and 3, respectively. The interquartile range, the minimum and maximum values of CDE per group are shown in Table 1. When comparing the three groups, it was found that the surgeon with more experience used less CDE ($p = 0.014$). (Figure 1) When comparing groups, there were no significant differences between group 1 vs. group 2 ($p=0.61$) or when comparing group 2 vs. group 3 ($p = 0.2$). Nevertheless, there was a significant difference when comparing group 1 with group 3 ($p=0.006$).

Conclusions: The final amount of CDE may be helpful to measure surgical progress in trainee residents, as it may be directly related to the efficacy of the surgical technique and could be a reliable parameter to predict future outcomes of postoperative inflammation. More than 160 surgeries are required to achieve CDE reduction compared to more experienced surgeons. Most training centers consider this parameter and provide residents with the number of surgeries required to achieve a benchmark for the PHACO learning curve. The CDE is an important variable to evaluate the progress of an ophthalmologist in training, so it would be a valuable parameter to evaluate the progress that he has during his surgical training.

TITLE: Intercellular material transfer following retinal ganglion cell transplantation

SESSION TITLE: Gene and Cell Therapy for Retinal Disease

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: K.Y. Zhang, E.A. Aguzzi, A. Nagalingam, C. Keuthan, X. Chang, D.J. Zack, T.V. Johnson, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Kevin Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Erika Aguzzi: Commercial Relationship: Code N (No Commercial Relationship) | Arumugam Nagalingam: Commercial Relationship: Code N (No Commercial Relationship) | Casey Keuthan: Commercial Relationship: Code N (No Commercial Relationship) | Xiaoli Chang: Commercial Relationship: Code N (No Commercial Relationship) | Donald Zack: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Johnson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Notable transplantation studies demonstrated intercellular transfer of cytoplasmic material including fluorescent labels between donor and host photoreceptors (PR). This phenomenon, material transfer (MT), confounds cell tracking analyses. We examined whether MT is PR-specific by conducting rigorous assessments for MT after retinal ganglion cell (RGC) transplantation.

Methods: Organotypic retinal explants from B6 ACTb-EGFP mice were cocultured with tdTomato$^+$ (tdT$^+$) human embryonic stem cell derived RGCs (hRGCs) on the vitreous surface for 1 week. We assessed MT by inspecting for tdT labeling and human-specific lineage markers colocalized to host GFP$^+$ retinal cells. We compared the incidence of MT in retinas with intact and enzymatically disrupted internal limiting membrane (ILM) using Pronase. We also assessed MT rates following in vivo intravitreal hRGC transplantation.

Results: 3D reconstructions of tiled confocal retinal flatmounts revealed tdT$^+$GFP$^+$ cells in the host inner nuclear layer (INL) with distinct Müller glial (MG) morphology. Immunostaining confirmed GFAP and tdT colocalization throughout the soma and radial processes in 85% of the atypical cells sampled (n=20). tdT$^+$GFP$^+$ cells were in contact with tdT$^+$ hRGCs and retained a nuclear heterochromatin structure that was specific to mouse INL cells and distinct from hRGCs. We assessed recipient retinas for human-specific donor-derived nuclear antigen (HuNu) and mitochondrial antigen (HuMito), and found 92.7% of tdT$^+$GFP$^+$ MG were HuNu$^+$ (n=68) and 72.7% were HuMito$^+$ (n=11). Fluorescence activated cell sorting of tdT$^+$GFP$^+$ cells demonstrated greater expression of human-specific RGC transcripts, including BRN3B, RBPMS, and TUBB3, compared to tdT$^-$GFP$^+$ cells. We found 6.7% of BSS (n=15) and 35.5% of Pronase-treated (n=31) retinal explants exhibited tdT$^+$GFP$^+$ cells (p=0.037). Following in vivo transplantation, we observed tdT$^+$GFP$^+$ MG within the host INL exclusively in retinas with ILM disruption (0% in BSS-treated, n=32; 9.7% in Pronase-treated, n=31; p=0.071).

Conclusions: We identified that hRGC xenografts into mouse retinas transferred donor-derived material, including cytoplasmic, nuclear, and organelle proteins and mRNA. The primary recipient cell type is MG, and MT is dependent on ILM disruption. We demonstrated that retinal MT is not unique to PRs and must be emphasized when interpreting hRGC transplantation results.

ABSTRACT BODY:

Purpose: To investigate the efficacy of retinoschisin (Rs1) gene rescue in a mouse model (Rs1-KO) of juvenile X-linked retinoschisis (JXLR) through administration of low dose AAV2/4 – RS1 with an Ef1α promoter.
Methods: An AAV2/4-RS1-Ef1α promoter vector was delivered by subretinal 2 ul injections of 2E9/ml in Rs1-KO mice (N=7). Injections occurred on postnatal days 18-26. Full field Electroretinogram (ERG), Optical coherence tomography (OCT), and a visually guided swim assay (VGSA), were chosen as endpoints to assess efficacy. ERGs were completed at one, two-, and five-months post injection (PI). OCTs were completed at 3 weeks, 2 months, and 4 months PI using a masked retinoschisis severity score. Mice underwent a VGSA performed in light and dark conditions to assess functional vision at six months of age. Experimental eyes were compared to untreated fellow eyes as well as eyes of untreated Rs1-KO mice (N=13).
Results: ERG: At one-month PI, treated eyes showed significantly higher b-wave amplitudes ($p=0.0187$) than untreated eyes on light adapted 3.0 cone ERG, which persisted until 5 months PI ($p=0.0029$). For the 5 Hz flicker, a pure cone response, treated eyes showed higher amplitude at one and two months than untreated eyes ($p=0.0014$ and $p=0.0002$), but lost significance by 5 months PI. Dark adapted rod amplitudes were not significantly different between treated and untreated eyes at any time point; however, the b/a ratio of the standard combined response was significantly higher in treated eyes than untreated eyes at 1- and 2-months PI ($p=0.0092$, $p=0.0063$). OCT: Treated Rs1-KO eyes had less severe retinoschisis at 3 weeks and 2 months PI ($p=0.022$, $p<0.0001$) compared to untreated eyes, but significance was lost at 5 months PI. VGSA: at five months after treatment, treated mice had a significantly faster time to platform than untreated mice under light adapted (cone) conditions ($p=0.0024$) but not in dark adapted (rod) conditions ($p=0.755$).
Conclusions: Subretinal gene therapy delivering 2E9/ml AAV2/4-RS1-EF1α promoter resulted in improved cone ERG, reduced retinoschisis observed by OCT, and functional vision measured by VGSA, but no effect in rod ERG or rod mediated visual function. Patients with JXLR lose central cone function over time; our study suggests cones may be rescued separately from rods using subretinal gene therapy.

ABSTRACT BODY:

Purpose: The Clinical Genome Resource (ClinGen) has established a Retina Gene Curation Expert Panel (GCEP) to evaluate the clinical validity of more than 200 genes implicated in inherited retinal disorders (IRD). The ClinGen clinical validity framework requires (1) defining the disease entity for gene curation, and (2) finding an appropriate standardized term (Mondo identifier). IRD nomenclature includes a variety of pathologic, morphologic, gene locus, and eponymous terms. These challenges are exacerbated by variable expressivity, locus heterogeneity, and allelic disorders among IRDs. Thus, the Retina GCEP has sought to revise the Mondo ontology and terminology for IRDs to capture the phenotypic spectrum in a standardized nomenclature.

Methods: The Retina GCEP is using the ClinGen gene-disease clinical validity framework (version 8.0) to evaluate the clinical validity of over 200 IRD-implicated genes. The group follows ClinGen guidance (clinicalgenome.org). Subsequently, a Mondo ID is used to label the disease entity (mondo.monarchinitiative.org).

Results: To date, the ClinGen Retina GCEP has finalized the clinical validity of over 30 gene-IRD relationships. For many genes currently under review, identification and systematic merging or splitting of multiple overlapping retinal phenotypes into unified disease terms is required to capture the phenotypic spectrum for causal genotypes and observed inheritance patterns. To name these disease entities, the Retina GCEP proposes a gene-first nomenclature system with the gene first followed by a disease descriptor (e.g. TSPAN12-related vitreoretinopathy). For genes associated with IRD with multiple inheritance patterns, or distinct genotype-phenotype relationships, the disease entities can be split (e.g. RPE65-related dominant retinopathy, and RPE65-related recessive retinopathy). Disease terms are periodically updated in the Mondo disease ontology database. Historical names of the lumped disease entities are included as synonyms for improved search purposes.

Conclusions: Due to the significant locus heterogeneity and the broad, overlapping spectrum of clinical presentations linked to many genes implicated in IRD, a unified nomenclature system is optimal for capturing the spectrum of IRD gene:disease relationships. We anticipate that these efforts will clarify clinical indications for gene augmentation and similar gene-based therapies as they emerge.

ABSTRACT BODY:

Purpose: In vivo cellular imaging with transscleral optical imaging (TOI) (Cellularis®, prototype Version 2.0) allows studying retinal structure and function. We currently conduct a prospective clinical validation study assessing retinal pigment epithelium (RPE) and photoreceptor (PR) cells with the TOI in subjects referred to the tertiary care eye clinic. Here we report on our observations of using this new technology.

Methods: Adult subjects (>18 years of age) with visual acuity <0.3logMAR and absence of pregnancy and epilepsy qualify for inclusion. Participants undergo full clinical examination including Optical Coherence Tomography (OCT) scanning followed by TOI imaging. If possible both eyes of a participant are imaged in 5 macular zones of 2mm x 2mm (Figure 1). Both RPE and PR layer images are acquired.

Results: By the end of 2021, we analyzed 206 eyes of 116 of participants (54% women; 46% men; mean age 59±18 years). RPE and PR images were acquired in at least 1 zone for all 206 eyes (Figure 2). For 75% (n=154) of the eyes, RPE and PR images were acquired in all 5 zones. Alignment and acquisition time was on average 1 minute per zone. When comparing the group of eyes where all 5 zones could be imaged to those where this was not the case, the proportion of participants with e.g. myopia ≤-2D or cataract was significantly higher (64% vs. 90%, $p<0.001$). However, especially with cataract, it depended on the type; image acquisition was easily feasible with myopic cataract for example. In subjects with darker colored eyes examination was easier than in those with light eyes (51% vs. 29%, $p=0.008$). Other factors, including insufficiently dilated pupils, higher degrees of astigmatism jeopardized complete image acquisition and quality. No adverse events were observed, only two subjects complained about slight discomfort during the examination.

Conclusions: Due to its good handling properties and quality of the presentation of RPE and PR cells, TOI has the potential to become a significant tool in the evaluation of retinal diseases.

ABSTRACT BODY:

Purpose: Antisense Morpholinos ologoneucleotides (MO) has been routinely used in genetic functional studies in zebrafish embryos. However, it's well known that MO activate p53-associated genes to induce apoptosis. This study was aimed to generate transgenic zebrafish models using CRISPR Interference (CRISPR-i) to interrogate gene functions during eye development.

Methods: Zebrafish-codon-optimized dCas9 was generated from a zebrafish-codon-optimized Cas9 through mutagenesis of D10A and H840A in HNH and RuvC domains respectively. The dCas9 was linked to a synthesized zebrafish- codon-optimized Krab domain and reporter. Using Gateway cloning technology, we generated the following three TolII plasmid systems, Ubi-dCas9-Krab-GFP, Ubi-GFP, and Hsp70-dCas9-Krab-GFP and coinjected these recombinant plasmids and transposes mRNA into zebrafish embryos and screened for founder fish by reporter expression and genotyping. We studied the eye phenotypes in these transgenic embryos expressing dcas9-Krab-GFP by injecting chemically modified-sgRNAs specific for the genes important for eye morphogenesis.

Results: With repeated experiments, we verified that there was no detectable cutting activity of both HNH and RuvC domains of zebrafish-codon-optimized dCas9, and further verified the repressive activity of the synthesized zebrafish-codon-optimized dCas9-Krab system in cultured HEK293 cells using sgRNAs targeting Pax6 and Otx2. rx3 sgRNA injected transgenic embryos expressing dcas9-Krab-GFP developed microphthalmia and/or coloboma at as early as 24 hour post fertilization (hpf) compared to uninjected control transgenic embryos. The microphthalmia and colobama persisted through the observations after 48 hours post fertilization (hpf).

Conclusions: Our experiments indicated that CRISPR-i can be used as a transgenic system in zebrafish and this system is of great value in the investigation of gene functions in ocular morphorgenesis, given the ease of use, versatility for the targets and the short period of time (~24 hrs) needed for induction of ocular phenotypes. This system will allow more rapid ascertainment of phenotypes associated with gene expression screens and paves the way for generating a model system to knock down gene expression in a spatiotemporally regulatable manner.

TITLE: Assessment of filtering bleb morphology after Gel-Stent-Implantation (XEN^{TM}) with anterior segement OCT

SESSION TITLE: OCT Clinical Applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Thieme, R. Burk, Ophthalmology, Universitat Bielefeld, Bielefeld, Nordrhein-Westfalen, GERMANY|

Commercial Relationships Disclosure: Claudia Thieme: Commercial Relationship: Code N (No Commercial Relationship) | Reinhard Burk: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The success of a filtrating operation depends on the maintenance of the filtering bleb (FB). The purpose of this study is to illustrate the persistance of the FB after Gel-Stent-Implantation (XEN^{TM}) in different types of open angle glaucoma by anterior segment OCT (asOCT).

Methods: 78 eyes of 78 patients (32 women, 46 men, age 69 ± 12 years, perimetry: median MD 7,9dB, Min. -11,7dB Max. 20,9dB; median sLV: 6dB, Min. 1,7dB Max.11,5dB) have been examined by asOCT (HRA OCT II Spectralis), at timepoints T1: 97 days (± 53 days) and T2: 699 days (± 242 days): primary open-angle glaucoma (pOAG) (n=50), secondary open-angle glaucoma (sOAG) with pseudoexfoliation (PEX) (n=20) and sOAG with pigmentdispersion (n=8). The FB was morphologically classified as microcystic (m), mixed (mx) and absent (a). The correlation between FB, intraocular pressure (IOP) and medical therapy (TX) was analyzed with IBM SPSS Statistics Version 21.

Results: At T1 bleb classification was: n=61 (m), n=8 (g), n=9 (a), at T2 the bleb classification was: n=31 (m), n=24 (g), n=23 (a). Surgery resulted in a significant IOP reduction from preoperative (21 ± 8 mmHg) to postoperative IOP at T1 (15 ± 5 mmHg) and T2 (14 ± 4 mmHg) ($p<0.01$), the difference between IOP-T1 and IOP-T2 is not significant ($p>0.01$). The number of medications was preoperative 3 (±1) and significantly reduced compared to TX-T1: 0,5 (±1) and T2: 1 (±1) ($p<0.01$). The need for bleb revision was as follows: no revision n=45, 1 revision n=23 (pOAG n=15, sOAG with PEX n=6, sOAG with pigmentdispersion n=2), two revisions n=7 (pOAG n=6, sOAG with PEX n=1) and 4 revisions n=3 (pOAG n=2, sOAG with PEX, n=1). The revisions included a second stent implantation (n=20), third stent implantation (n=1), needling (n=11), viscocanalostomy (n=1), cyclophotocoagulation (n=2), cyclocryocoagulation (n=1), tenoncyst exzision (n=1).

Conclusions: FB classification reveals a microcystic structure. FB-revisions are not dependent on glaucoma classification. Further studies with longer follow-up time and larger patient cohorts are necessary to evaluate the effect of glaucoma type and FB persistance.

TITLE: Effects of Carotenoid Supplementation on the Lipid Profile of the Serum of a Transgenic Mouse

SESSION TITLE: Biochemistry and Molecular Biology of the Retina/RPE

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F. Chang, A. Ranganathan, B. Li, P.S. Bernstein, Department of Ophthalmology and Visual Sciences, The University of Utah School of Medicine, Salt Lake City, Utah, UNITED STATES|

Commercial Relationships Disclosure: Fu-Yen Chang: Commercial Relationship: Code N (No Commercial Relationship) | Arunkumar Ranganathan: Commercial Relationship: Code N (No Commercial Relationship) | Binxing Li: Commercial Relationship: Code N (No Commercial Relationship) | Paul Bernstein: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Lipoproteins deliver lipids and macular carotenoids to the eye. The lipid contents of lipoproteins in the circulation are associated with the risk of the progression of age-related macular degeneration (AMD). We investigated the effects of carotenoid supplementation on the serum lipid profile of a transgenic mouse line that takes up carotenoids.

Methods: BCO2 knockout mice with expression of RPE-Cre ($Bco2^{-/-}$ Transgenic) were kept on vitamin A deficient chow for one month to increase the bioavailability of carotenoids. They were then divided into four groups (3 mice/group) and fed with zeaxanthin, lutein, β-carotene, and the control chow (no carotenoid) for one month. The contents of HDL, LDL, and triglycerides (TG) in the serum of these mice were analyzed using a CURO L7 Lipid Analyzer. Briefly, 35 µL of serum from each animal was loaded on a lipid profile test strip for a 3-minute measurement. T-test was used for statistical analysis, and $p<0.05$ was considered statistically significant.

Results: Supplementation with zeaxanthin, lutein, and β-carotene significantly increased the HDL cholesterol in the serum of the $Bco2^{-/-}$ transgenic mice, and the contents of HDL cholesterol in the mice fed with carotenoids were increased about twofold relative to the control. Zeaxanthin significantly reduced ~ 50% of the serum TG, whereas no significant alteration was detected from lutein or β-carotene supplementation. Interestingly, the contents of LDL cholesterol were not detectable because they were below the detection limit.

Conclusions: Our data show that supplementation with zeaxanthin, lutein, and β-carotene can increase serum HDL cholesterol in mice, while zeaxanthin may reduce serum TG. Our finding demonstrates that carotenoid supplementation might alter the lipid profile in the circulation, offering new insights into AMD prevention using carotenoids.

ABSTRACT BODY:

Purpose: Many professional athletes undergo laser assisted in situ keratomileusis (LASIK) during their careers, though no study has shown improved performance following the surgery. The objective of this study is to determine how LASIK impacts Major League Baseball (MLB) player batting performance.

Methods: MLB players who underwent LASIK during their careers and had greater than 130 at-bats in the seasons before and after surgery were identified via public records. Seasonal changes in individual player batting performance were measured with batting average (BA), slugging percentage (SLG), on-base plus slugging percentage (OPS), and wins above replacement (WAR). Batting statistics were compared across seasons for individual players.

Results: Thirty-seven unique MLB players with mid-career LASIK were identified. In the season prior to LASIK, players experienced an average change of -0.014 in BA ($p = 0.024$), -0.023 in SLG ($p = 0.073$), -0.032 in OPS ($p = 0.089$), and -1.09 in WAR ($p = 0.004$). In the season after LASIK, players experienced an average change of 0.009 in BA ($p = 0.109$), 0.017 in SLG ($p = 0.221$), 0.018 in OPS ($p = 0.343$), and 0.68 in WAR ($p = 0.088$). 66% percent of players experienced an increase in BA, 63% an increase in SLG, 55% an increase in OPS, and 55% an increase in WAR. Each of the batting statistics followed a similar trend across the four seasons, where the mean drops in the season prior to LASIK before rebounding back towards the baseline for the two seasons after LASIK.

Conclusions: Our study demonstrated that professional baseball players have a significant drop in batting performance in the season prior to LASIK, likely motivating some to seek surgery. While performance improved on average after LASIK, the change was not statistically significant, and may be related to regression to the mean. Ophthalmologists and athletes should have an individualized informed discussion regarding the potential risks and benefits of refractive surgery and have tempered expectations for the magnitude of performance benefit from the procedure.

ABSTRACT BODY:

Purpose: Hyaluronan (HA) is a key component of the corneal limbal extracellular matrix and is upregulated after injury, playing an important role in corneal wound healing. Excess reactive oxygen species (ROS) are toxic to cells and HA is susceptible to oxidation by ROS, yet the precise chemical structures of oxidized HA (oxHA) and their physiological properties remain unknown. The aim of this study was to characterize the molecular weight and structure of oxHA generated using different ROS, and to compare the effects of oxHA and unoxidized HA of different molecular weights on cellular responses of corneal epithelial cells that are related to wound healing.

Methods: High molecular weight HA (HMWHA - 2670kDa) was oxidized using increasing molar ratios of hydrogen peroxide (H_2O_2) and hypochlorous acid (HOCl). Thereafter, the oxHA was purified using chromatography by Sephadex PD 10 columns. The size of oxHA was characterized by agarose gel electrophoresis and gel filtration high-pressure liquid chromatography. The structure of the oxHA was characterized by ^{1}H and ^{13}C NMR at 500 MHz. Human corneal epithelial cells (HTCEs) were treated with oxHA, or size-matched unoxidized HA, and cell viability, proliferation, and migration assayed.

Results: Smaller HA fragments were generated with increasing molar ratios of both H_2O_2 and HOCl. Chlorinated HA was detected after treatment with HOCl, according to ^{1}H NMR spectra. HMWHA significantly promoted corneal epithelial cell viability when compared to LMWHA, ULMWHA and oxHA. LMWHA and oxHA promoted cell migration, while HMWHA and ULMWHA did not.

Conclusions: HA fragmentation by ROS alters its physiological activity on corneal epithelial cells.

ABSTRACT BODY:

Purpose: Glaucoma leads to the loss of retinal ganglion cells (RGCs). Cell transplantation has been proposed to restore RGCs; however, current attempts show limited donor RGC integration. We previously used stromal cell-derived factor-1 (SDF1) to direct mouse RGCs into the retina, but the migration mechanisms have not yet been studied.

Methods: To improve clinical relevance, human RGCs were differentiated from Brn3b-tdTomato hESC in organoid cultures. RGCs were isolated by magnetic microbeads against CD90.2 at day 38-46 of differentiation. We studied RGC migration kinetics and modes in response to SDF1 gradient in vitro and in vivo using transwell setup and subretinal transplantation, respectively. For loss-of-function studies, we have applied: 1) small-molecule inhibitor of CXCR4 receptor on RGCs – AMD3100; 2) somal translocation inhibitor – CK666; 3) multipolar migration inhibitor – roscovitine.

Results: Expression of CXCR4 on hESC-derived RGCs was confirmed by transcript- and proteomics, with ~83% of RGCs being CXCR4+. AMD3100, an SDF1 antagonist, treatment decreased the RGC recruitment in response to SDF1 from 42.2±10.5% to 12.7±1.8% (n=3; $p<0.01$) in vitro. Time-lapse studies in vitro show that inhibiting somal translocation decreases migration speed from 5.64±2.18 to 4.69±2.01μm/s (n=3, $p<0.01$), whereas inhibiting multipolar migration decreases speed to 3.20±1.52μm/s (n=3, $p<0.01$) in vitro – demonstrating hESC-RGCs migration via both modalities.

The short-term transplantation studies confirmed our previous observations that an SDF1 gradient significantly improves the migration and integration of human RGCs within three days after subretinal delivery. Blocking CXCR4 in donor RGCs also led to decrease in transplantation outcome: transplantation score (TS) of 3.3±0.3 (n=3, m=15) vs 1.3 (n=1, m=6).

Lastly, transplantation experiments with inhibitors suggest that multipolar migration is the major contributor to donor RGC migration in the retina, with donor RGCs migrating via multipolar migration having a TS of 3.2 (n=1, m=6) and RGCs migrating via somal translocation having a TS of 2.8 (n=1, m=5).

Conclusions: Establishing an SDF1 gradient across the host retina enhances donor hESC-RGCs integration primarily through multipolar migration, and SDF1 acts through the CXCR4 receptor – suggesting the possibility that RGCs selected for these features before transplantation will improve donor cell integration.

ABSTRACT BODY:

Purpose: The slope of the second component of rod-mediated dark adaptation (RMDA), rod-intercept time (RIT), and, more recently, the area under the dark adaptation curve (AUC) are metrics used in characterizing RMDA. Associations among all 3 measures have yet to be examined by AMD status and severity in the same persons.

Methods: RMDA testing at 5° eccentricity was completed in the ALSTAR2 baseline visit using the AdaptDx (83% equivalent bleach). Testing terminated once RIT was calculated by the AdaptDx or stopped at 45 minutes in cases where sensitivity did not recover. The slope of the second component was obtained from a linear model fit for all data points > 2.5 log sensitivity. AUC was calculated using the trapezoidal rule for all sensitivities < 3 log units for the full test time, and with test data truncated at 20, 12, and 6 minutes. The AREDS 9-step classification was used to determine AMD status and severity. Spearman correlations were used to associate the measures.

Results: Among 481 participants (mean age 71.8 years, 60% female, 91% white), there were 239 normal, 139 early AMD, and 103 intermediate AMD eyes. Slope of the second component, RIT, and all AUC measures were significantly associated among participants. Slope of the second component was more strongly associated with RIT (r_s=0.65) than the AUC measures (r_s=0.44 or less) (Table). As AUC measures were based on increasingly shorter test times, correlations with RIT and slope decreased. Compared to early and intermediate AMD, RIT and AUC associations were lower among normal eyes. The slope and AUC measures were not associated among normal eyes. The strongest associations of RIT with slope and the full AUC measure were among those with intermediate AMD (r_s =0.75 and 0.94 respectively).

Conclusions: All RMDA measures are associated with each other when examined among all participants. As AUC decreases at shorter test times, it becomes less correlated with RIT. This suggests that reductions in test time, specifically < 12 minutes, for faster screening do not produce measures that are good substitutes for RIT. The lack of association between the slope and AUC among normal eyes suggests that AUC is insufficient in conveying RMDA results for older adults without AMD. Slope and AUC based on 12 minutes or more are acceptable surrogates of RIT among those with early and intermediate AMD.

ABSTRACT BODY:

Purpose: Adeno-Associated Virus (AAV)-based gene therapies have been developed for various anterior segment diseases involved cornea, trabecular meshwork and iris. Intracameral injection is the appropriate procedure to deliver AAV to transduce anterior segment. Self-complementary AAV (scAAV) can bypass the rate-limiting step of second-strand synthesis and has shown to mediate a rapid onset and higher level of transgene expression compared to the parent vector. However, the transduction profile of different scAAV serotypes following intracameral injection has not been established. This study aims to evaluate transduction of scAAV2, 3b, 6, 8 and 9 in anterior segment tissues.

Methods: EGFP gene was packaged in conventionally used AAV serotypes 2, 3b, 6, 8 and 9, with the chimeric CMV–chicken ß–actin (CBA) promoter. In 8-week old C57BL/6J mice, 1.0µl scAAV-CBA-EGFP solution for one serotype was injected into the anterior chamber of right eye for each mouse (n=6). The formulation buffer injected eyes serve as the negative control (n=6). Four weeks post injection, the intracameral injected eyes were enucleated and subjected to immunohistochemistry. The anterior segment including cornea, anterior chamber angle, ciliary body and iris was imaged and evaluated for the transduction efficiency and tropism using EGFP as a surrogate marker. EGFP-positive cells/structures in the anterior segment was analyzed for distribution and EGFP-signal was quantitated.

Results: The self-complementary AAVs resulted in the transduction of corneal endothelium, corneal keratocyte, trabecular meshwork and ciliary body but with varied distribution, transduction efficiency and cell specificity. The inflammatory cells infiltration was observed in different levels for serotypes studied.

Conclusions: Our results provides the dataset applicable to the development of AAV-based therapy, targeting the ocular diseases involved the anterior segment. In addition, this data generated from this study may also be applied to the appropriate AAV vector selection for the gene therapy for glaucoma and corneal diseases, which can be targeted by intracameral administration.

ABSTRACT BODY:

Purpose: Eye models generally represent the lens as a homogenous thick lens with an equivalent index calculated to match the known lens power. Studies have found that the equivalent index decreases with age. In parallel, lens growth is associated with the progressive formation of a central plateau in the refractive index gradient profile. The purpose of this study is to determine the relation between lens gradient parameters and equivalent index and evaluate the impact of the plateau formation on lens optics.

Methods: A paraxial model of the lens with gradient was developed. The gradient is characterized by the axial variation of the index, n(z), and radius of curvature of isoindicial surfaces, R(z). n(z) was a power function with three parameters: surface and equatorial indices and power coefficient (p). The surface (1.371) and equatorial (1.418) indices were independent of age. The power coefficient was age-dependent. A linear variation was assumed for R(z) in the anterior and posterior lens. An expression of lens power in terms of gradient parameters was derived by integrating the incremental gradient power over the thickness of the lens. Comparison with the formula for the equivalent lens power produced a relation between gradient parameters and equivalent index. The model was used to predict the age-dependence of p corresponding to equivalent index data from three studies: 1.441-0.00039*Age (Dubbleman et al, Vis Res 2001), 1.4506-0.00035*Age (Atchison et al, J Vis, 2008) and 1.4483-0.0007*Age (Chang et al, Biom Opt Exp, 2018). The calculated value of p was compared with values obtained from MRI (Kasthurirangan et al, IOVS 2008) and OCT (De Castro et al, J Mod Opt 2011).

Results: Power coefficient (p) and equivalent index (neq) are related by p = (neq - 1.371) / (neq - 1.418). At age 20, p ranged from 2.8 to 4.1, consistent with MRI and OCT data (Figure 1). With all three datasets, the decrease in neq with age is correlated with an increase in p, consistent with the formation of a refractive index plateau.

Conclusions: The model produces results that are consistent with experimental data. The formation of a central refractive index plateau is associated with a decrease in lens equivalent index.

Jittayasothorn, Laboratory of Immunology, Immunoregulation Section, National Eye Institute, Bethesda, Maryland, UNITED STATES|

ABSTRACT BODY:

Purpose: To evaluate the role of 4-aminoantipyrine (ampyrone) in improving pigmentation in a mouse model of oculocutaneous albinism type 1B (OCA1B).

Methods: We used high-throughput screening (HTS) to identify potential activators and inhibitors of the intra-melanosomal domain of human tyrosinase (hTyr). Activators were investigated by in vitro enzymology. C57BL/6J-Tyr $^{c\text{-}h/c\text{-}h}$ mice (a model of OCA1B) were intraperitoneally (i.p.) injected with three doses of ampyrone for thirty days and evaluated for increased melanin pigmentation in the fur and eyes using clinical/biochemical methods and light/electron microscopy.

Results: High-throughput screening of ~34,000 unique compounds identified 115 candidate inhibitors and 9 candidate activators of hTyr enzymatic activity. Among the activators, ampyrone increased the in vitro catalytic efficiency of the OCA1B-related hTyr variant P406L by ~40%, suggesting a partial recovery of function. Treating OCA1B mice with ampyrone up to 48 mg/kg/day i.p. for 30 days resulted in a mild improvement of melanin deposition in fur, as determined by spectrophotometric analysis. However, data on changes in pigmentation of iris and retinal pigment epithelium upon treatment were inconclusive.

Conclusions: Our data support the use of HTS for the identification of candidate compounds to modulate tyrosinase activity. The limited effect of ampyrone on pigmentation, especially in eye tissues, suggests the need to expand the pool of candidate activators through alternative screening strategies and to combine in vitro with in vivo testing for the identification of promising candidates.

ABSTRACT BODY:

Purpose: In the mammalian retina, daily renewal of light-sensitive photoreceptor outer segments involves coordinated shedding of distal outer segment tips and their engulfment by adjacent retinal pigment epithelial (RPE) cells. Exposure of the anionic membrane lipid phosphatidylserine (PS) at the outer leaflet of photoreceptor outer segment tips promotes shedding and subsequent phagocytosis by RPE cells. The mechanisms underlying this PS exposure remain to be understood. Anoctamin-6 (also known as TMEM16F) is a calcium-activated lipid scramblase that can promote PS exposure. Here we investigated whether anoctamin-6 has a role in PS exposure by photoreceptor outer segments in mouse retina in vivo.

Methods: ano6$^{+/-}$ mice were extensively backcrossed to 129T2/SvEmsJ (WT129) and then bred to yield ano6$^{-/-}$ mice. For experiments, ano6$^{-/-}$ and control WT129 mice were housed in strict 12 h light/dark cycles and sacrificed at 4-5 months of age at time points relative to light onset. Retinas were immediately dissected and incubated photoreceptor side up with PS detection reagent pSIVA (polarity-sensitive indicator of viability and apoptosis). X-y image stacks were obtained using a Leica TSP8 laser scanning confocal microscopy system. Maximum projections were analyzed using ImageJ. Data sets of n≥4 were analyzed using two-tailed Student's t-test.

Results: Anoctamin-6 knockout mice (ano6$^{-/-}$) are not viable in C57BL6/J genetic background. We found that ano6$^{-/-}$ mice in 129 background are viable and have no obvious gross abnormalities up to 6 months of age. Moreover, ano6$^{-/-}$ mice breed with fecundity similar to WT129 mice. Ano6 protein was detected in WT129 but not ano6$^{-/-}$ retina. ano6$^{-/-}$ retina behaved similarly to WT129 tissue in dissections. In WT129 mice, outer segment PS tips elongate and change in frequency in a characteristic diurnal rhythm. Here, we found that at light onset, when outer segment PS tip length in WT129 peaks, PS tip length in ano6$^{-/-}$ was significantly less than in WT129 ($p<0.05$). One hour after light onset, the peak of frequency of outer segment PS tips in WT129 retina, PS tip frequency in ano6$^{-/-}$ was significantly less than in WT129 ($p<0.05$).

Conclusions: Lack of anoctamin-6 leads to loss of rhythmic outer segment PS tip elongation and change in frequency. To our knowledge, anoctamin-6 is the first scramblase to be linked to PS exposure of photoreceptor outer segment tips.

ABSTRACT BODY:

Purpose: P23H rho is a common genetic cause of retinitis pigmentosa and encodes for misfolded P23H rhodopsin protein. The mechanisms by which rods recognize and target misfolded rhodopsin for degradation are not well understood. Here, we performed mass spectrometry on P23H rhodopsin immunopurified from $rho^{P23H/P23H}$ mice retinas to identify interacting proteins and compare with wild-type (WT) rhodopsin from $rho^{+/+}$ mice.

Methods: Monoclonal anti-rhodopsin antibody 1D4 (Santa Cruz Biotechnologies) was used to immunoprecipitate 5mg of WT or P23H rhodopsin protein and its interacting proteins from retinal protein lysates of postnatal day 15 $rho^{+/+}$ (24 retinas) or $rho^{P23H/P23H}$ (40 retinas) mice. Liquid chromatography with tandem mass spectrometry (LC-MS-MS) was performed on 3 independent samples of WT or P23H rhodopsin protein (LTQ-Orbitrap mass spectrometer, Thermo Finnigan, Waltman, MA). As a negative control, LC-MS-MS was also performed on immunoprecipitates from mouse embryonic fibroblasts. Spectral counts from WT, P23H, and MEF LC-MS-MS experiments were collected and analyzed by Gene Ontology (GO), Kyoto-Encyclopedia of Genes and Genomes (KEGG), Reactome, and CytoScape.

Results: We found 276 proteins that bound to WT rhodopsin, and 286 proteins bound to P23H rhodopsin of which 173 proteins were unique to P23H rhodopsin. GO, KEGG, and Reactome analysis identified enrichment of multiple unique pathways such as ER-associated protein degradation and ubiquitinoylation in the P23H rhodopsin interactome compared to WT. By contrast, phototransduction and visual perception terms were less enriched for P23H rhodopsin. GO-cellular compartment analysis showed decrease in outer segment, cilium, and inner segment proteins but increase in axonal/synapse proteins in the P23H interactome.

Conclusions: Proteomic analysis reveals numerous differences between P23H and WT rhodopsin protein interactome. The P23H rhodopsin interactome is enriched in translational and post-translational quality control processes. The P23H rhodopsin interactome differs throughout all regions of the rod photoreceptor cell. These proteomic and subcellular changes could correspond to mechanisms rods use to eliminate misfolded rhodopsin. These molecular alterations may contribute to pathogenesis of retinitis pigmentosa caused by P23H rhodopsin.

ABSTRACT BODY:

Purpose: Non-neovascular age-related macular degeneration (NNAMD) is associated with loss of ellipsoid zone (EZ) on optical coherence tomography (OCT). Geographic atrophy (GA) in NNAMD can be identified and measured using sub-RPE (retinal pigment epithelium) illumination area (IA) on commercially available software. In this study we compare sub-RPE IA changes using a commercial software program to changes in EZ loss on OCT identified by machine learning analysis with manual correction in patients with NNAMD with GA.

Methods: This is a retrospective review of patients diagnosed with NNAMD and GA with growth. IA was measured by the Advanced RPE Analysis feature of FORUM Viewer (Carl Zeiss Meditec, Inc.) which measures the area (mm^2) exhibiting sub-RPE hyper-reflectance within a 2.5-mm radius from the fovea on OCT due to loss of outer retina. IA was manually corrected where needed. OCTs were also analyzed by machine learning algorithms followed by manual correction of layer segmentation using custom software. EZ loss was measured by the percentage of the 6x6-mm scan where EZ thickness was zero µm. Correlation was calculated using Pearson correlation coefficient.

Results: 60 eyes of 60 patients were included in the study with a mean follow-up length of 5.1 years. At baseline, mean age was 79 and mean IA was 3.0 mm^2. Mean EZ loss measured 1.67 mm^2 after machine learning analysis and 5.3 mm^2 after manual correction. IA strongly correlated to EZ loss measured by machine learning ($r = .85$) and manual correction ($r = .93$) on 60 OCTs. Area where EZ measured 10 or less microns was 3.4 mm^2 after machine learning and 6.1 mm^2 after manual correction. Mean annual growth of IA was 1.15 mm^2/yr while mean annual change in EZ loss on manually corrected OCTs was 1.4 mm^2/yr.

Conclusions: EZ measurements on OCT can be used to estimate GA in NNAMD. IA correlates strongly to EZ loss measured by machine learning and manual segmentation. GA area measures smaller than area of EZ loss and can take several years of growth to reach the area of EZ loss. IA and OCT layer segmentation should be compared to measurements of GA on fundus autofluorescence to determine their potential as outcomes measures in clinical research.

TITLE: Nocardia scleritis masked as post-operative inflammation
SESSION TITLE: Antimicrobial Resistance, Epidemiology and New Antimicrobials
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: M. Schulgit, K. Baynes, A. Hamdan, D. Mammo, S.K. Srivastava, Cole Eye Institute, Cleveland Clinic, Cleveland, Ohio, UNITED STATES|M. Schulgit, Cleveland Clinic Lerner College of Medicine of Case Western Reserve University, Cleveland, Ohio, UNITED STATES|
Commercial Relationships Disclosure: Matthew Schulgit: Commercial Relationship: Code N (No Commercial Relationship) | Kimberly Baynes: Commercial Relationship: Code N (No Commercial Relationship) | Abel Hamdan: Commercial Relationship: Code N (No Commercial Relationship) | Danny Mammo: Commercial Relationship: Code N (No Commercial Relationship) | Sunil Srivastava: Commercial Relationship(s);Code C (Consultant/Contractor):Gilead, Eyevensys, Jcyte, Regeneron, Eyepoint, Zeiss, Bausch and Lomb, Sanofi, Allergan, Abbvie, Novartis;Code R (Recipient):Gilead, Eyevensys, Eyepoint, Regeneron, Bausch

ABSTRACT BODY:

Purpose: Nocardia scleritis is rare and can mimic other infectious species, needing specific medication which delays resolution. Early identification is integral to avoid permanent damage. This report describes two patients presenting with Nocardia scleritis that masked as post-surgical inflammation and were exacerbated by local steroids.
Methods: A retrospective chart review of patients with Nocardia scleritis. Demographics, clinical history, and outcomes were reviewed.
Results: Two cases were identified:

Case 1: A 71-year-old female s/p conjunctival biopsy with cryotherapy presented with eye pain, blurred vision. Oral corticosteroid and moxifloxacin initially resolved discomfort. Periocular steroids were delivered during corticosteroid taper. After several weeks, symptoms and visual acuity worsened leading to referral. Upon evaluation, visual acuity was counting fingers with scleral necrosis and ovoid dense hypopyon. Right eye anterior chamber paracentesis elucidated Nocardia, prompting initiation of systemic, topical, and intravitreal antibiotics (bactrim, topical linezolid and amikacin, and intravitreal amikacin). Clinical symptoms and exam significantly improved with antibiotic course with resolution of scleritis. Visual acuity remains poor due to cataract formation 4 months after diagnosis.

Case 2: A 62-year-old female presented for evaluation of chronic postoperative inflammation after a trabeculotomy with mitomycin 3 months prior. Postoperative course was complicated by persistent scleral and anterior chamber inflammation. A systemic workup revealed a positive HLA B27 antigen. Corticosteroids including systemic, IV, and periocular steroids were administered to control postoperative inflammation. Upon presentation, the visual acuity was hand motions with multiple ovoid hypopyons. Aqueous paracentesis revealed Nocardia species. Multiple intravitreal amikacin antibiotics were administered. Despite aggressive intravitreal and systemic antibiotics, the eye worsened and was enucleated.
Conclusions: Clinical presentation of Nocardia scleritis can be masked and exacerbated by local steroids. In cases of post-operative scleral inflammation, caution is advised prior to the use of local steroid injections. The indolent nature of Nocardia infection can lead to diagnostic delay. As surgical trauma can precede infection, early consideration of Nocardia is important when postoperative patients present with scleritic symptoms.

ABSTRACT BODY:

Purpose: To determine the time to effectiveness of intravitreal clindamycin in patients with toxoplasmosis chorioretinitis.

Methods: This is a retrospective review of patients with toxoplasmosis chorioretinitis who had fundus imaging. All patients received intravitreal clindamycin (1mg) as therapy. For this analysis, a masked physician qualitatively marked the first sign of improvement based on fundus appearance. The time from injection to first sign of improvement was calculated for each individual, and averaged amongst the patients. The time to inactivity was calculated as well. Those who were lost to follow-up were excluded.

Results: 19 patients were identified with 276 fundus photos reviewed. 5 patients were treated with clindamycin monotherapy, 2 patients were given oral Bactrim only, and 12 patients were given oral Bactrim and clindamycin therapy. On average, patients showed observed first improvement 20.67 days after their injection (range 7 to 42 days). The fastest time to response was 7 days after treatment with intravitreal clindamycin. 5 patients time to response was within 8-15 days. The average time to complete inactivity was found to be 9.37 weeks (1-35 weeks). The average time to respond for those on oral Bactrim and intravitreal clindamycin was 18.71 days (3 days to 47 days). Average number of injections to signs of improvement was 1.44. Two patients worsened despite intravitreal injections. 6 patients resolved with intravitreal clindamycin only. 5 patients had optic nerve or macular lesions and were treated with oral Bactrim and intravitreal clindamycin.

Conclusions: In this series, intravitreal clindamycin shows a photographic response lesion improvement on average of 3 weeks after injection. Compared to oral regimens that can take from 4 weeks to several months to reduce activity, intravitreal clindamycin potentially works faster. Intravitreal clindamycin can be considered a first line of therapy for active toxoplasmic chorioretinitis especially in those with macular and nerve threatening disease.

ABSTRACT BODY:

Purpose: We evaluated the tolerability and efficacy of the topical rho-kinase inhibitor netarsudil in the treatment of canine corneal endothelial degeneration (CED).

Methods: Eighteen eyes of 14 client-owned dogs with CED were enrolled in a prospective, randomized, placebo-controlled clinical trial. The patients received topical netarsudil 0.02% (Rhopressa©, Aerie Pharmaceuticals) or vehicle control twice daily for the initial 4 months, then all patients received netarsudil for the final four months. Ophthalmic examination with measurement of Schirmer tear test I (STT), intraocular pressure (IOP), anterior segment photography, ultrasonic pachymetry (USP), Fourier-domain optical coherence tomography (FD-OCT), and in-vivo confocal microscopy was performed prior to and at 1, 2, 4, 6 and 8 months throughout treatment. The effect of treatment on corneal thickness, corneal stromal thickness, percentage of cornea affected by edema, and endothelial cell density (ECD) was evaluated by repeated measures ANOVA.

Results: Seven dogs (9 eyes) received placebo during the first 4 months, while 7 dogs (9 eyes) received netarsudil for 8 months. During netarsudil treatment, conjunctival hyperemia (n = 13), reticulated intraepithelial bullae (n = 1), and corneal stromal hemorrhage (n = 1) were identified were identified at one or more timepoints; one patient with stromal hemorrhage required temporary cessation of netarsudil for 1 month. Five eyes treated with netarsudil had decreased tear production at one or more timepoints during the study and required immunomodulatory treatment. No significant differences in corneal thickness, corneal stromal thickness, ECD, and percentage of the cornea affected by edema were observed between treatment groups or over time ($p>0.05$).

Conclusions: Netarsudil is generally well-tolerated in dogs with endothelial degeneration but may result in dry eye thus tear production should be closely monitored. While improvement was not observed in canine CED patients treated with topical netarsudil, interim analysis suggests stable disease after 4 or 8 months of treatment. Enrollment of more patients is required to fully evaluate the efficacy of netarsudil for canine CED.

TITLE: Instrument-Based Vision Screening: Integration into Primary Care with Referral and Follow-Up at Vision Center

SESSION TITLE: Amblyopia

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Hartmann, Vision Center and Research Institute, Akron Children's Hospital, Akron, Ohio, UNITED STATES|I. Boydstun, R.W. Hertle, Vision Center, Akron Children's Hospital, Akron, Ohio, UNITED STATES|

Commercial Relationships Disclosure: E Eugenie Hartmann: Commercial Relationship: Code N (No Commercial Relationship) | Ian Boydstun: Commercial Relationship: Code N (No Commercial Relationship) | Richard Hertle: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate the relationship between screening outcomes using the SPOT Vision Screener at 3-, 4- and 5-year-old Well Child Checks (WCC) in general pediatric offices and comprehensive eye examination follow-up in the Vision Center specialty care clinics at Akron Children’s Hospital.

Methods: Staff and providers in pediatric offices were systematically trained on the use of the SPOT Vision Screener. This instruction included the importance of identifying amblyogenic risk factors in the preschool age group as well as hands on demonstration and practice with the device. Two primary care clinics were selected as initial sites for launching this project. Electronic charting was designed to automatically order and report instrument-based vision screening for all 3-,4- and 5-year-old WCCs. Results from SPOT screening were compared with findings from comprehensive eye examinations during the first four months of this new protocol.

Results: Of the 177 referrals resulting from 724 WCCs that included instrument-based vision screening, 87 patients (49% of referrals) presented for comprehensive eye examinations in the Vision Center. The SPOT results for one of these patients did not detect any abnormality, however, the provider had observed exotropia OD, which resulted in an accurate referral. Of the remaining 86 referrals based on the SPOT, 82 (95%) were identified as having astigmatism (unilateral, bilateral or with other potential conditions). A summary of the SPOT results by condition compared with the number of patients who were prescribed refractive error correction is shown in Table 1. Only 4 patients were identified by the SPOT as having a potential condition other than astigmatism. Patients identified with potential bilateral astigmatism only were twice as likely to be prescribed glasses based on the findings from their eye examination as patients identified with potential unilateral astigmatism only.

Conclusions: Understanding the effectiveness of instrument-based vision screening in pediatric offices requires tracking referrals, as well as outcomes of eye examinations. The preponderance of referrals we observed for astigmatism was not surprising based on the inherent design of these devices. Correlation of refractive errors obtained by our eye-care providers along with their treatment protocols will provide greater understanding of the strength and weaknesses of these devices.

ABSTRACT BODY:

Purpose: Mutations in the RPE expressed gene Mfrp (membrane-type frizzled related protein) results in early-onset retinal degeneration (RD) in human and mice. The goal of this study is to identify the cell type-specific transcriptional and gene-regulatory events in the retina that lead to RD using Mfrp gene knock-out (KO) mice.

Methods: Retina + RPE tissue from Mfrp$^{-/-}$ and Wild type (WT) mice at 28 days and 2.5 months were analyzed via single nucleus (sn) RNA-seq and ATAC-seq (n=3) followed by experimental validation.

Results: Cluster analysis of the snRNA-seq data (~140,000 nuclei) revealed >30 clusters encompassing known retinal cell-types. To identify the transcriptional changes associated with RD, we performed differential expression analysis (WT vs. Mfrp$^{-/-}$) with a focus on RPE cells, Rods, and Cones. Notably, more than 50 significantly differentially expressed genes (DEGs) ($p < 0.05$, Wilcoxon Rank-Sum) in RPE cells, rods, and cones are involved in Mfrp related RD. Among these, ~21 genes are differentially expressed in RPE cells, and about 35 are differentially expressed in rods and cones. In photoreceptors, a majority of DEGs are observed at 28 days, the exception being rhodopsin - which was significantly down-regulated at 2.5 months ($P< 0.05$) in rods. These DEGs include transcription factors, structural proteins, and members of visual transduction. In RPE cells, we observed more DEGs at 2.5 months than at 28 days. These DEGs with $P\leq 0.02$ by snRNA-seq are involved in visual transduction and phagocytosis pathways and include Rdh10, Rpe6, Lrp2, Cralbp, Mertk, Igtav which were validated by qRT-PCR ($P< 0.05$). Genes involved in lipid metabolism (Hmgcs2 $P< 0.05$ and Slc16a1 $P< 0.05$) and glucose transport (Slc2a1 $P< 0.05$) are also downregulated in RPE cells at 2.5 months by qRT-PCR. Lastly, our snRNA-seq analysis revealed downregulation of genes associated with PI3K-AKT pathway in RPE cells at 2.5 months. We further validated that AMPK and mTOR pathways show altered activation in Mfrp$^{-/-}$ mice.

Conclusions: The snRNA-seq data revealed that RPE cells show progressive changes in regulation of key pathways with age while photoreceptors show more prominent alterations in transcriptional regulation at 28 days in Mfrp$^{-/-}$ mice. Analysis of changes in additional cell types as well as analysis of snATAC-seq data is in progress to understand the mechanism underlying Mfrp related RD pathology.

TITLE: An improved method for OCT-based, murine laser-induced choroidal neovascularization lesion quantification

SESSION TITLE: RPE/choroid pathology: oxidative stress, inflammation and neovascularization

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Jensen, N. Lambert-Cheatham, G.D. Hartman, A. Muniyandi, B. Park, K. Sishtla, T.W. Corson, Ophthalmology, Indiana University School of Medicine, Indianapolis, Indiana, UNITED STATES|N. Jensen, The University of Utah School of Medicine, Salt Lake City, Utah, UNITED STATES|

Commercial Relationships Disclosure: Nathan Jensen: Commercial Relationship: Code N (No Commercial Relationship) | Nathan Lambert-Cheatham: Commercial Relationship: Code N (No Commercial Relationship) | Gabriella Hartman: Commercial Relationship: Code N (No Commercial Relationship) | Anbukkarasi Muniyandi: Commercial Relationship: Code N (No Commercial Relationship) | Bomina Park: Commercial Relationship: Code N (No Commercial Relationship) | Kamakshi Sishtla: Commercial Relationship: Code N (No Commercial Relationship) | Timothy Corson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The laser-induced choroidal neovascularization (L-CNV) murine model provides quantifiable data to evaluate efficacy of therapeutic treatments and genetic effects. We previously validated lesion quantification from optical coherence tomography (OCT) images as a reliable assessment of CNV lesion size. However, the existing method is time consuming, and the subjective nature of defining lesion borders led to variability between evaluators. We therefore investigated if OCT lesion quantification could be simplified, streamlined, and made more reliable among evaluators.

Methods: The rate-limiting step in analysis is defining the borders of a given lesion. We developed a workflow where the lesion borders are specified using the multi-point tool in ImageJ. The lesion borders were pinpointed to the pixel coordinates in the x-plane and y-plane. These coordinates were imported to a custom Excel template and converted to μm, adjusting for the different degrees of scaling in the OCT x and y planes. Volume was calculated as previously described. This streamlined method was compared against the prior method to evaluate reliability and quantification time per lesion. To evaluate the interrater reliability, 10 OCT images of lesions were scored by 6 trained evaluators and superimposed to assess consistency.

Results: The new process demonstrated improved time efficiency and precise quantification of OCT lesion volume. The time to calculate the volume of a lesion previously was 2 minutes, 56.9±16.4 seconds (mean±SD). The new method averaged 22.0±1.9 seconds, or ~8 times faster (paired t-test, $p<0.0001$, $n=5$). Subjectively, evaluators noted that the new method allowed for greater reliability in lesion border identification. Some lesions had near unanimous agreement with only minor differences between volume measurements while others had larger differences. The largest discrepancy between evaluators was the determination of the superior-most coordinates. Expert consensus demonstrated the importance of identifying the lesion as an ellipsoid shape and avoiding edema or a bleb as the superior coordinate of the lesion.

Conclusions: A new method of evaluating L-CNV lesion size greatly reduced analysis time, and subjectively allowed for more precise lesion border identification. Inter-evaluator discrepancies exist but may be minimized by group discussion and training.

ABSTRACT BODY:

Purpose: The blood-retinal barrier (BRB) mediates movement of molecules from the blood to the inner retina, protecting the neural retina from potentially harmful molecules and maintaining retinal homeostasis. We previously demonstrated that retinoic acid (RA) signaling is necessary for BRB integrity in the zebrafish model. RA signaling is known to induce expression of RA-metabolizing enzyme Cyp26a1 in a sensitive feedback mechanism. The purpose of this study was to investigate the cellular mechanisms by which RA maintains the BRB by examining the expression patterns of cyp26a1 in the retina.

Methods: To visualize the BRB in vivo, we utilized the transgenic Tg(l-fabp:DBP-EGFP) zebrafish model that expresses vitamin D binding protein (a member of the albumin gene family) tagged to GFP. This model displays the integrity of the BRB with GFP-tagged protein localized within the retinal vasculature by 3 days post-fertilization. Breakdown of the BRB is visualized as “leaking” of GFP outside the vasculature. To disrupt RA signaling, zebrafish embryos, larvae, and adults were treated with varying concentrations of DEAB and BMS493, antagonists of retinal dehydrogenase and the RA receptor, respectively. To visualize the Müller cells and endothelial cells, gfap:GFP and kdrl:GFP transgenic fish were used, respectively. RNAScope analysis was used to detect and quantify the expression of cyp26a1 in retinas of zebrafish at different developmental stages.

Results: Treatment with DEAB or BMS493 resulted in a non-functional disrupted BRB in up to 95% of embryos and adults. In the retina, cyp26a1 was primarily detected in the Müller cells starting at 3 dpf, and treatment with pharmacological RA signaling inhibitors significantly decreased Müller cell cyp26a1 expression.

Conclusions: The gene encoding RA-metabolizing enzyme Cyp26a1 is primarily expressed in the Müller cells of the retina, indicating that Müller cells may play a critical role in RA-mediated BRB maintenance.

TITLE: Clusterin modulates IOP homeostasis by regulating the actin cytoskeleton and attenuating profibrotic responses in TM

SESSION TITLE: Aqueous humor dynamics & Trabecular Meshwork

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: A. Soundararajan, P.P. Pattabiraman, Ophthalmology, Indiana University Purdue University Indianapolis, Indianapolis, Indiana, UNITED STATES|

Commercial Relationships Disclosure: Avinash Soundararajan: Commercial Relationship: Code N (No Commercial Relationship) | Padmanabhan Pattabiraman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Clusterin is a secretory chaperone protein known to regulate cell-matrix interactions. Altered cytoskeletal rearrangement and excessive extracellular matrix (ECM) deposition in the trabecular meshwork (TM) outflow pathway results in increased AH outflow resistance and elevated IOP. This study evaluated the role and mechanism of clusterin in regulating IOP.

Methods: Immunoblotting (IB) was used to analyze the effect of– a) adenovirus-mediated clusterin expression (AdCLU) on proteins related to actin organization, ECM and fibrosis; b) effect of recombinant clusterin (rhCLU) on TGFβ2-mediated ECM changes in TM. Immunofluorescence (IF) and live-cell imaging using SiR-actin was used to analyze the effect of clusterin on ECM and actin fibers, respectively. The effect of clusterin on TGFβ2-mediated IOP elevation was studied using human anterior segment perfusion cultures by perfusing with TGFβ2 followed by rhCLU in the presence of TGFβ2. Students t-test was used for statistical analyses with significance of $p<0.05$.

Results: The IB analysis showed AdCLU significantly reduced- a) actin-cytoskeleton associated proteins- PRK2(p=0.0006), LIMK1(p=0.04); b) Integrins- INTαV(p=0.04), INTβ5(p=0.01); c) tight junction protein Zo-1(p=0.007) d) ECM- COL1A(p=0.04), FN(p=0.03), ELN(p=0.005), and secretory FN(p=0.002); e) pro-fibrotic proteins- TGFβ2(p=0.03), TSP-1(p=0.005), and secretory PAI-1(p=0.007) and TSP-1(p=0.05). rhCLU treatment significantly reduced pro-fibrotic effect of TGFβ2, evidenced by significant reduction in COL1A(p=0.002) and TSP1(p=0.01), and secretory TSP1(p=0.01) and PAI-1(p=0.02). IF showed reduced COL1A and FN distribution in AdCLU. Live cell imaging showed reduction in F-actin distribution with rhCLU, which was initially increased by TGFβ2 treatment. Perfusion of TGFβ2 in the human anterior segment increased IOP significantly (n=5, p=0.006) by the third day which was significantly reduced on day eight (p=0.008) due to rhCLU perfusion.

Conclusions: For the first time, we show importance of clusterin in lowering actin-based tension and attenuating profibrotic ECM accumulation in TM, possibly facilitating the increase in AH outflow and, thereby regulating IOP homeostasis. Further understanding of the functional role of clusterin and its binding partners in mediating cell-matrix interactions in TM will pave way for novel therapeutic approaches for lowering elevated IOP.

ABSTRACT BODY:

Purpose: Better translational models are urgently needed for many retinal degenerative diseases to facilitate understanding pathogenetic processes and test potential therapies. Usher syndrome presents a particularly compelling need for such models, due to the devastating nature of the disease and the lack of rodent models showing retinal degeneration. Usher 1B is a primary target due to its rapid onset and prevalence among Usher subtypes. Nonhuman primates best mirror human retina anatomy and function by having a macula and fovea, as well as photoreceptor calyceal processes that are a major site of dysfunction in Usher syndrome but are absent in rodents.

Methods: We used CRISPR-Cas9 editing to create rhesus monkey embryos with mutations in exon 3 of MYO7A. Custom guide RNAs and Cas9 mRNA or protein were injected into zygotes 16 hours after in vitro insemination. Trophectoderm biopsies from day 8 blastocysts were genotyped, and those with desired mutations were selected for transfer to surrogate dams. Infant PBMCs, skin and cheek cells were sequenced to confirm infant genotype. Infant audition was assessed by auditory brainstem responses (ABR) and distortion product otoacoustic emissions (DPOAE). Retinal structure and function were evaluated by multimodal retinal imaging and ERG.

Results: In the first live infant, genotyping of skin and buccal cells and single-cell sequencing of PBMCs showed a mosaic pattern with half of cells possessing a homozygous single base insertion in exon 3 resulting in a premature stop codon, while half were homozygous for wild type MYO7A. ABR and DPOAE responses were attenuated at one month of age but were normal in subsequent tests through 2 years of age, and normal retinal structure and function were present at all ages. A second infant born in November 2021 showed a compound heterozygote pattern with 1bp and 63bp deletions in exon 3. Auditory testing at 4 weeks of age showed no detectable ABR or DPOAE responses. Retinal imaging at 6 weeks detected no significant abnormalities. Development of the auditory and retinal phenotypes will be followed longitudinally.

Conclusions: This study showed the ability to induce mutations in the MYO7A gene in rhesus macaques, resulting in absence of auditory function in early infancy. Continued confirmation of an USH1B phenotype will set the stage for studies of gene therapy in this first gene-edited nonhuman primate model of Usher syndrome.

ABSTRACT BODY:

Purpose: It is crucial for animals to accurately judge the depth of moving objects. During observer translation, the relative image motion between stationary objects at different distances, known as motion parallax (MP), provides important depth information. However, when an object also moves relative to the scene, the computation of depth from MP is complicated by the object's independent motion. Previously, we demonstrated that humans show systematic depth biases during self-motion that depend on object motion in the world. Here, we propose and compare two distinct perceptual mechanisms by which object motion may induce depth biases.

Methods: Naïve human subjects viewed a virtual 3D scene consisting of a ground plane and stationary background objects, while lateral self-motion was simulated by optic flow. A target object, lying above the ground plane, could be either stationary or moving laterally at different velocities. In a dual report task, the subjects were asked to judge the depth of the target object relative to the plane of fixation, as well as whether they thought the object was moving independently relative to the scene.

Results: We constructed Bayesian ideal observer models for two proposed perceptual mechanisms: (incomplete) flow parsing (FP) and causal inference (CI). In the FP model, some fraction of image motion resulting from object motion can be attributed to self-motion, but the model assumes that a moving object is always present. In the CI model, the ideal observer can probabilistically attribute image motion to two separate causes: scene-relative object motion and self-motion. Both models predict systematic depth biases that depend on object motion relative to the scene, but only the CI model captures biases that depend on subjects' belief about object motion. By the Akaike information criterion, the CI model provides a consistently better fit than the FP model across 6 subjects.

Conclusions: We demonstrate that both incomplete flow parsing and causal inference are feasible explanations for the substantial depth biases that are induced by scene-relative object motion. However, the component of depth bias that depends on a subject's belief about object motion is consistent with involvement of a causal inference process that adjudicates whether image motion is caused by a combination of object motion and self-motion.

ABSTRACT BODY:

Purpose: Ophthalmic services are facing unprecedented pressures. Telemedicine has emerged as a potential solution to increase healthcare accessibility to a greater number of patients. This has been particularly emphasised by the COVID-19 pandemic, where digital health facilitated the provision of ophthalmic services in the face of strained resources, widespread service cancellations and social distancing restrictions. Thus, telemedicine has proven itself to be an invaluable resource. However, greater reliance on digital technology may further exacerbate healthcare inequalities faced by certain populations. The purpose of our study was to determine factors associated with non-attendance at asynchronous tele-ophthalmic clinics.

Methods: This was a retrospective cohort study that reviewed all patients newly referred to Moorfields Eye Hospital (MEH) in London, United Kingdom, between January 1st 2019 and October 31st 2021. Electronic healthcare records were used to extract sociodemographic information, clinical variables and appointment details. The primary outcome measure was attendance at asynchronous clinics. 'Asynchronous' is the approach in which the patient attends for in-person assessment and/or imaging by technician with subsequent review of results by a clinician. Multivariable logistic regression modelling was used to examine attendance status against sociodemographic, clinical and operational exposure variables.

Results: A total of 8878 eligible patients (median age 57±20 years, 52% female) attended asynchronous clinics across all MEH sites in the defined time period. Non-attendance was 11.7%. All asynchronous clinics were either medical retina (n=2740) or glaucoma (n=6138). Medical retina patients had 61% less odds ($p<0.001$) of attending their appointment compared to those attending the glaucoma service. Patients with diabetes (adjusted OR 2.16, CI 1.70-2.75) and registered sight impairment (OR 1.53, CI 0.35-6.60) were more likely to attend. Male sex (OR 0.78, CI 0.68-0.89) and greater levels of socioeconomic deprivation (OR 0.92, CI 0.90-0.95) were associated with increased rates of non-attendance.

Conclusions: Male sex and socioeconomic deprivation are associated with greater rates of non-attendance at asynchronous teleophthalmic clinics. Further study into the identified factors associated with poor attendance may determine potential solutions and improve healthcare provision in these populations.

ABSTRACT BODY:

Purpose: Earlier we optimized an in vitro model for studying hydrogen sulfide (H_2S) toxicity to the human cornea. This study examined if H_2S toxicity to corneal stromal fibroblasts is due to (a) changes in inflammatory and apoptotic parameters and (b) whether the effects are concentration-dependent using an established in vitro model.

Methods: Healthy donor human corneas (n=30) were obtained from the eye bank and used to generate primary human corneal stromal fibroblasts (hCSFs) following our standard protocol. Sodium hydrosulfide (NaSH) was used as a source of H_2S. Primary hCSFs were exposed to different concentrations of NaSH (1 mM - 10 mM) for 24h. The changes in inflammatory and apoptotic parameters were assessed using quantitative real-time PCR, mitochondrial membrane potential ($\Delta\Psi m$), and TUNNEL assays.

Results: H_2S toxicity to hCSFs is dose-dependent. Exposure to lower concentrations (1 - 4 mM) of NaSH showed alteration of inflammatory genes IL-1α, IL-1β, and TNF-α ($p \leq 0.05$). However, higher concentrations (5 - 10 mM) of NaSH exposure leads to alterations in inflammatory genes IL-1α, IL-1β, and TNF-α as well as apoptotic genes caspase 8 and FADD and showed loss of mitochondrial membrane potential and significantly increased TUNEL positive cells as compared to the non-H_2S exposed hCSFs ($p \leq 0.05$).

Conclusions: H_2S causes dose-dependent toxicity and changes in inflammatory and apoptotic mediaters in hCSFs in vitro. Onging studies will provide additional mechanistic information.

ABSTRACT BODY:

Purpose: Previously, eccentric fixation was reported in children with residual amblyopia who had an interocular difference [IOD] of visual acuity ≥0.2 logMAR after treatment (glasses, patching, atropine). Using OCT, we measured eccentric fixation (called OCT fixation shift) in children with residual amblyopia (Jin et al, 2020). We found that OCT fixation shift is significantly higher in amblyopic eyes than in fellow eyes and control eyes, especially in children with strabismic amblyopia where 78% of had measurable OCT eccentric fixation. We ask how common OCT fixation shift is present in children without residual strabismic amblyopia (IOD of visual acuity improved to <0.2 logMAR with treatments). Here, we report OCT fixation shift in strabismic amblyopic children without residual amblyopia and compare it with those with residual amblyopia.

Methods: Children aged 4 to 16 years (mean±SD = 9.7±3.3 years) with non-residual strabismic amblyopia (n=23), with residual strabismic amblyopia (n=28), and normal controls (n=75) were studied. Spectral-domain OCT was used to estimate fixation shift. We asked the child to focus on the internal blue dot fixation target of the OCT. OCT fixation shift, i.e. the distance between the foveal center and the fixation point, was measured, adjusted for axial length, and converted into visual degrees. OCT fixation shifts in the amblyopic eye in two amblyopic groups and the right eye of the control group were compared by ANOVA.

Results: OCT fixation shift was 0.17±0.29° for control eyes, 1.54±1.48° for residual amblyopic eyes, and 0.43 ± 0.44° for non-residual amblyopic eyes ($F=34.2$, $P<0.001$). Fixation shift between the non-residual amblyopic group and control group did not differ ($P=0.31$), and fixation shift for the non-residual amblyopic group was significantly lower than the residual amblyopic eyes ($P<0.001$). Fifteen (65%) in the non-residual group had the measurable fixation shift, which is not significantly different from that (78%) in the residual group (chi-squared=0.56, p=0.45).

Conclusions: Eccentric fixation, assessed by OCT fixation shift, is measurable in about 2/3 of children with strabismic amblyopia (both residual and non-residual). Although the occurrence of OCT fixation shift shows similar frequency in both groups, the magnitude of OCT fixation shift is less in children without residual strabismic amblyopia than those with residual strabismic amblyopia.

TITLE: COVID-19 impact on delayed clinical visits in diabetic retinopathy patients

SESSION TITLE: Diabetic retinopathy epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Willis, The University of Tennessee at Chattanooga College of Arts and Sciences, Chattanooga, Tennessee, UNITED STATES|E. Willis, A. Brock, D. Reichstein, Tennessee Retina, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure: Ethan Willis: Commercial Relationship: Code N (No Commercial Relationship) | Anderson Brock: Commercial Relationship: Code N (No Commercial Relationship) | David Reichstein: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The COVID-19 pandemic created an unprecedented setback for diabetic retinopathy (DR) patients receiving routine anti-vascular endothelial growth factor (VEGF) injections. In this retrospective clinical study, we assessed visual and anatomical outcomes of “late follow-up" appointments cancelled or rescheduled during an 11-week quarantine period from March 15th- June 1st, 2020, due to the urgency to limit non-emergent clinical visits. This study tested the hypothesis that strict frequency of treatment is a requisite for successful therapy.

Methods: To meet “late follow-up" requirements, all study patients had appointments scheduled within the quarantine period that were delayed past their previous physician recommended interval, beyond June 1st, 2020. Of the 7042 delayed patients, 5137 returned for examination. 2764 were injection patients, of which 616 were delayed beyond the quarantine period. These 616 patients were subsequently categorized by diagnosis. We then analyzed the electronic medical record (EMR) for 300 eyes with treatment-requiring diabetic retinopathy to establish baseline anatomical and visual status prior to the delayed clinical visit. The EMR of the follow-up appointment was subsequently viewed for comparison. Best-corrected visual acuity (BCVA) and retinal examination findings were recorded from both visits. All eyes received at least 1 anti-VEGF injection prior to March 15th, 2020.

Results: 300 eyes were delayed beyond their previously scheduled interval an average of 14.04 weeks. Upon return, 37 eyes (12.3%) had improved BCVA, 169 (56.3%) remained stable, and 94 (31.4%) had worsened. Of the 300 eyes, there was an average of 2.2 lines lost (p=0.03). 29 delayed eyes (9.7%) returned with improved macular edema, 121 (40.3%) remained stable, and 143 (47.7%) had worsened upon examination. Due to vitreous hemorrhage, edema progression in 7 eyes (2.3%) was unknown. 290 eyes (96.7%) remained with non-proliferative DR, while 10 (3.3%) progressed to proliferative DR. 23 (7.6%) returned with new or worsened vitreous hemorrhages. No patients developed a retinal tear or detachment during this period.

Conclusions: COVID-19 had a severe impact on routine clinical visits. Prolonged frequency of anti-VEGF treatment for DR is associated with increased risk for BCVA decline and negative anatomical outcomes. Effective therapy requires strict compliance with intravitreal injections and routine clinical appointments.

ABSTRACT BODY:

Purpose:

Overexpression of runt-related transcription factor 1 (RUNX1) has been recently linked to aberrant angiogenesis in proliferative diabetic retinopathy and choroidal neovascularization. Topical delivery of small-molecule inhibitors of RUNX1 such as Ro24-7429 could lead to a novel and non-invasive treatment for a wide variety of angiogenic diseases of the eye. This study evaluated the in vitro effect of a nanoemulsion loaded with Ro24-7429 on migration and proliferation of human retinal endothelial cells (HRECs).

Methods: Ro24-7429 dispersed in the oil phase was homogenized and subsequently sonicated to fabricate an oil in water nano-emulsion. Dynamic light scattering (DLS) measured the drop size of the nanoemulsion. In vitro cytotoxicity and proliferation assays of unloaded (eNanoV), loaded (eNanoRo24) nanoemulsions, and Ro24-7429 in DMSO were used to test several concentrations. Scratch wound assay was performed for the evaluation of cell migration. Immunofluorescence staining (IF) for RUNX1 and delta-like four (DLL4) was carried on to assess the tip and stalk morphology of HRECs.

Results: We confirmed that the nano-emulsion constitutes lower than 200 nm in drop size. eNanoV and eNanoRo24 were not toxic for the HRECs even at the highest concentration tested of 8% v/v at 48h. A significant reduction (P-value<0.5) of proliferation and migration were observed after treatment. eNanoRo24 had higher reduction of proliferation than Ro24-7429 in DMSO. IF described a reduction of RUNX1 as well as DLL4 on treated HRECs. DLL4 is a protein-related to the tip phenotype of endothelial cells in sprouting angiogenesis.

Conclusions: eNanoRo24 reduced the proliferation and migration of HRECs in vitro. We did not observe any toxicity with application of eNanoRo24 in HRECs. Also, eNanoRo24 may improve the activity of the Ro24-7429. The inhibition of migration may be mediated by a change in the tip/stalk morphology. The reduction of both migration and proliferation strongly suggests that eNanoRo24 modulates the activity of endothelial cells and the angiogenic process, thus demonstrating the therapeutic potential of this drug delivery system.

ABSTRACT BODY:

Purpose: The recent 24-2C SITA Faster visual field (VF) test increases sensitivity of central field defects by adding 10 test locations from the 10-2 pattern to the end of the 24-2 test. However, some clinicians prefer to test glaucoma patients with the SITA Standard strategy. The purpose of this ongoing clinical study was to compare the 24-2C SITA Standard to the 24-2C SITA Faster in healthy and glaucomatous eyes.
Methods: 24-2C SITA Standard (SS) and 24-2C SITA Faster (SFR), as well as 10-2 SS, and 10-2 SITA Fast VFs were acquired on an HFA3 Model 860 perimeter (ZEISS, Dublin, CA) at each of two visits on one eye for healthy and glaucomatous subjects. 24-2 SS VFs were extracted from 24-2C SS as a reference for disease severity. Data from last qualified visit were used for analyses; 10-2 VFs were not used for these analyses.

Bland-Altman and scatter plots were used to assess agreement for the Mean Deviation (MD), Visual Field Index (VFI), and Pattern Standard Deviation (PSD) global parameters. The sum of any total deviation (TD) and pattern deviation (PD) points flagged for the VFs were totaled and compared using paired equivalence t-tests ($\alpha = 0.05$). Limits of equivalence were chosen as 5% of total test points.
Results: Mean age was 57.3 (standard deviation, SD: 7.6; range: 44.3 to 74.7) years for 28 healthy eyes and 71.3 (SD: 9.0; range 54.0 to 97.9) years for 28 glaucoma eyes. Mean 24-2 SS MD was 0.38 (SD: 1.17; range: -1.89 to 2.62) dB and -7.92 (SD: 7.72; range: -23.42 to 1.63) dB in healthy and glaucoma eyes, respectively.

MD, VFI, and PSD values were similar between both strategies across all eyes, with linear correlations ranging from 0.98 to 0.99 (See Fig. 1). For healthy eyes, mean difference (SD) for TD was -0.9 (SD: 3.9) points and 1.1 (5.1) points for PD while glaucoma mean difference was -0.1 (8.8) for TD and 1.2 (5.9) points for PD (see Table 1).
Conclusions: 24-2C SITA Standard showed comparable sensitivity to detect visual field defects as 24-2C SITA Faster in this study, with mean differences between the number of any flagged TD and PD points ranging from -0.9 to 1.2 defects. Thus, the 24-2C test pattern with the reference SITA Standard strategy may offer clinicians a similar ability to detect central visual field loss as SITA Faster without the need to run a supplementary SITA 10-2.

ABSTRACT BODY:

Purpose: This study was conducted to assess differences in oculomotor characteristics of high and low skill level video game players as it has been suggested that the efficiency saccadic eye movements is enhanced with video game play.

Methods: Forty-six collegiate video game players (41 male, 5 female) participated in a combine event in which the game Overwatch was played competitively. Participants consented to complete various tests and questionnaires before and after playing in the competition, including oculomotor testing using a RightEye Vision System, and answering questions about their playtime (hours per week) and skill level in the game. Dynamic visual acuity reaction time, dynamic visual acuity speed, reaction time processing speed, overall reaction time, reaction time saccadic latency, horizontal saccade efficiency, and vertical saccade efficiency from the RightEye was compared for the high skill (Diamond level or higher) and low skill players with a student t test. Oculomotor data were also compared to playtime using linear regression. calculated. Visual acuity and ocular health was assessed at all visits.

Results: Twelve participants were classified as high skilled and 34 were low skilled players in Overwatch. There were no statistical differences ($P>0.05$) when comparing distance visual acuity reaction time, reaction time processing speed, overall reaction time, reaction time saccadic latency, or horizontal saccade efficiency for the high and low skill levels. Dynamic visual acuity speed was 81.5mph in the high skill group and 82.0 in the low skill group, which was significantly different ($P=0.01$). These values are at or close to the maximum tested velocity (82mph). Vertical saccade efficiency, the distance of the eye from the ideal path, was 8.1mm in the high skill group and 6.58mm in the low skill group, ($P=0.047$). Regression analyses found no significant correlations between any of the oculomotor tests and the amount of playtime per week.

Conclusions: Most of the oculomotor skills tested in this study were not related to skill level or the amount of playtime per week in these college video game players.

ABSTRACT BODY:

Purpose: An unmet medical need exists for treatments for blepharitis, as well as for additional treatments for dry eye disease (DED) which is reported in some 70 to 80% of patients with blepharitis. We performed a post hoc analysis of a prospective, randomized, double-masked phase 2 clinical trial that evaluated the safety and efficacy of NCX 4251 (fluticasone propionate ophthalmic suspension) 0.1% for the treatment of acute exacerbations of blepharitis.

Methods: A total of 224 subjects with a documented history of blepharitis and exhibiting an acute exacerbation of blepharitis in both eyes (based on minimum scores for eyelid redness, eyelid debris and eyelid discomfort at the Screening and Baseline Visits) were randomized in a 1:1 ratio to NCX 4251 or its vehicle. Subjects performed current standard of care (i.e., daily lid scrubs with dilute baby shampoo) and administered NCX 4251 or its vehicle once daily for 14 days, followed by an additional 14 days of lid scrubs only. Signs and symptoms of blepharitis and DED, as well as safety parameters were assessed. A post hoc analysis was performed on a subgroup of subjects (123 of the 224 subjects) with baseline scores ≥2.0 on a scale of 0 (none) to 4 (severe) for inferior cornea fluorescein staining.

Results: The analysis demonstrated a statistically significant difference between NCX 4251 versus vehicle for change from baseline in eye dryness score as assessed on a Visual Analog Scale (VAS) at Day 8 (earliest timepoint assessed; $p=0.0085$), Day 11 ($p=0.0020$) and Day 15 ($p<0.0016$). Statistically significant differences versus vehicle were also observed in other symptoms of dry eye disease (photophobia, blurred vision, burning/stinging, foreign body sensation, ocular itching, pain) at all timepoints during treatment (Day 8, Day 11 and Day 15). In some symptoms statistically significant treatment effects persisted up to two weeks after the end of treatment. At Day 15, the difference in reduction from baseline in inferior cornea fluorescein staining reached a p-value of 0.0524. NCX 4251 was well tolerated. There were no serious or treatment-related adverse events.

Conclusions: NCX 4251 Ophthalmic Suspension, 0.1% was effective, safe and well tolerated. NCX 4251 has the potential to provide a safe and efficacious short-term treatment for DED. The encouraging findings from this post hoc analysis must be confirmed in larger prospective clinical trials.

ABSTRACT BODY:

Purpose: To assess safety and efficacy of topically administered 0.4% ripasudil ophthalmic solution (Glanatec®; Kowa Pharmaceuticals), a topical Rho-kinase inhibitor, in dogs with ADAMTS10-open-angle glaucoma (ADAMTS10-OAG).

Methods: Eleven three-year old Beagle dogs with ADAMTS10-OAG (five males and six females) were used. The four-week study included a baseline period (week 1), q24h administration (week 2), q12h administration (week 3), and washout period (week 4). Left and right eyes were randomly assigned to receive either balanced salt solution (BSS) sham or ripasudil treatment. Efficacy assessments consisted of diurnal intraocular pressure (IOP) and pupil diameter measurements. Safety was assessed by diurnal conjunctival hyperemia, routine eye examinations, central corneal thickness, and gonioscopy. The linear Gaussian model was used to evaluate the differences in least square means of quantitative outcome measures between eyes that received BSS and ripasudil.

Results: There were no significant differences in mean IOPs between ripasudil- and BSS-treated eyes (baseline period: ripasudil 27.9 ± 1.5 mmHg vs. BSS 27.0 ± 1.5 mmHg; q24h-treatment: ripasudil 28.8 ± 1.7 mmHg vs. BSS 27.7 ± 1.7 mmHg; q12h-treatment: ripasudil 30.8 ± 2.8 mmHg vs. BSS 29.7 ± 2.8 mmHg; washout period: 34.7 ± 2.7 mmHg vs. BSS 32.9 ± 2.6 mmHg). There was also no effect on diurnal pupil diameter. Mild to moderate conjunctival hyperemia developed in both ripasudil- and BSS-treated eyes during the treatment periods (weeks 2 & 3). No other adverse effects were observed.

Conclusions: Due to lack of efficacy, these results do not support future use of ripasudil ophthalmic solution as treatment for canine glaucoma.

ABSTRACT BODY:

Purpose: Optic nerve trauma induces retinal microglia (RMG) activation and causes irreversible retinal ganglion cells (RGC) loss in mammals. Since aldose reductase (AR) is an inflammatory response mediator and is highly expressed in RMG, we investigated the effects of AR inhibition on RMG activation, RGC survival, and axon regeneration in an optic nerve crush (ONC) model.

Methods: BV2 microglia were utilized to study the effects of AR inhibition on cytokine secretion, cell migration, and microglia-retinal organoid co-culture with LPS exposure. Adult animals underwent ONC (OS) or sham (OD) and were treated with AR inhibitor- Sorbinil or DMSO by intraperitoneal injection. Total protein of ONs and retinae was collected for Western blot probing with Iba-1, AR, GFAP, and GAPDH. Cryosections of ONs and retinae were stained with Iba1, Cleaved Caspase 3, GFAP, and DAPI. RGC survival and regenerating axons were observed 1 and 2 weeks post-ONC (pONC). Flatmount retinae were stained with RBPMS for RGC counting. Regenerative axons were visualized by CTB-555. RGC function was detected by pattern ERG. The study was conducted in compliance with ARVO Statement for the Use of Animals in Ophthalmic and Vision Research and approved by IACUC at University of Pittsburgh. All experiments were performed in independent triplicate and considered significant if $P < 0.05$.

Results: In-vitro, results show that Sorbinil attenuates LPS-induced BV2 activation, migration, and retinal organoid apoptosis in the BV2-organoid co-culture. In-vivo, we observed that Iba-1 and AR protein expression was elevated by ONC and attenuated by Sorbinil in the retina and ON. However, GFAP protein expression was only altered in the retina and reduced by Sorbinil. Detected by cryosection staining, Iba-1+ cells and GFAP+ cells were elevated by ONC and attenuated by Sorbinil. In addition, Sorbinil reduced apoptotic marker expression in the ONC retina. Although experiments of 2 weeks pONC display no change, we did observe that Sorbinil promoted RGC survival, restored RGC function and displayed a trend towards delaying axon degeneration 1 week pONC.

Conclusions: This is the first study to explore the effects of AR inhibition on RMG and RGC in the ONC model. AR inhibition promotes RGC survival, restores RGC function and delays axon degeneration by attenuating RMG activation, which provides a potential therapeutic strategy against ocular inflammatory diseases.

ABSTRACT BODY:

Purpose: To identify cell type-specific and age-related changes in gene expression and gene regulation in the mouse retina.

Methods: Retina and RPE tissue were isolated from 2.5 month-old (n=3) and 21 month-old (n=3) mice and analyzed via single-nucleus RNA-seq and single-nucleus ATAC-seq.

Results: Cluster analysis of the snRNA-seq data (~62,000 nuclei) revealed >30 clusters encompassing known retinal cell-types such as photoreceptors, horizontal cells, RPE, and RGCs. To identify differences in gene expression in the retina between young and old mice, we performed differential expression (2.5 months vs. 21 months) for each cell cluster. Overall, we identified several age-related gene expression patterns across retinal cells. To further investigate these changes, we compared age-related retinal genes to those that have previously been reported in the brain. Strikingly, 168 genes that were identified in retinal tissue were also reported in the brain. 67 of these genes followed the same trends of being up or down regulated with age in both the mouse retina and brain tissue, although there was variation in expression among cell types in both tissues. Among the 67 genes in common between the retina and brain, 10 are known to be associated with retinal disease. Notably, Ahi1, Son, Ubb, Cst3, and Gngt2 were all significantly up-regulated ($p < 0.01$, Wilcoxon Rank-Sum) with aging in the retina via snRNA-seq. These findings were further confirmed by qRT-PCR. Ahi1 was up-regulated in RGCs, (p=8.92E-09) and Gngt2 was up-regulated in cones (p=5.49E-94). Son and Cst3 were both up regulated in all cell types with age with p-values ranging from 1.32E-84-0.015 and 3.12E-132-1, respectively. Ubb was up regulated in all cell types except for rods (P = 1.25E-75 to 1). Out of these 5 genes, only Cst3 did not show the same pattern of expression in the retina and brain.

Conclusions: In the retina, horizontal cells, RPE, and RGC cells showed most of the age-related differences. Several genes that matched the aging pattern in both mouse brain and retina are found to have a significant role in apoptosis and regulation of the apoptotic pathway. Analysis of additional genes/pathways and cell types as well as snATAC-seq data is in progress. This study provides key insight into genes that show altered regulation with age in retinal tissue and contribute to aging.

ABSTRACT BODY:

Purpose: The purpose of this study was to identify complications and subjective rates of improvement in a patient population that received Neodymium-doped Yttrium Aluminum Garnet (Nd:YAG) vitreolysis for symptomatic vitreous floaters.

Methods: All patients who underwent Nd:YAG vitreolysis for symptomatic floaters were retrospectively identified from January 1, 2015 to October 31st, 2019 at the University of Minnesota Medical Center. Primary outcomes were adverse events and patient reported subjective symptomatic changes following treatment. Secondary outcomes included visual acuity and intraocular pressure (IOP) before and after treatment. A standardized questionnaire was used to rate floater symptoms on a scale of 1 to 10 after treatments were completed (1=unnoticeable, 10=unbearable). Patients were also asked if they would choose to have another laser treatment for floaters if symptoms return. The paired t-test was used to compare pre- and post-procedure visual acuities, IOP, and questionnaire ratings ($P<0.05$).

Results: 129 treatments in 80 eyes of 62 patients were identified. Twelve (15%) eyes were referred for possible pars plana vitrectomy. Six (7.50%) eyes were lost to follow-up since their last treatment. Three (3.75%) eyes experienced adverse events consisting of a transient IOP increase, posterior subcapsular cataract formation, mild vitreous hemorrhage, and an episode of vasovagal syncope. No complications were visually significant. 53 (85%) patients indicated that they would repeat the laser treatment if symptoms return. Pre- and post-treatment visual acuity was not statistically different. Pre- and post-treatment IOP was statistically different, with lower IOP after treatment. Symptomatic improvement was found to be statistically significant ($p<0.0001$) (Table 1).

Conclusions: Our findings demonstrate high rates of subjective symptomatic improvement with rare complications necessitating regular peri-operative follow-up. None of the encountered complications were visually significant. These results increase the available evidence that Nd:YAG vitreolysis for floaters is a reasonable treatment option for persistently symptomatic syneresis. Future prospective and larger sample size studies are needed to define the incidence of complication with Nd:YAG vitreolysis and the effect on IOP.

ABSTRACT BODY:

Purpose: When pupil size reduces, defocus blur and peripheral aberration decrease to improve vision, while diffraction blur increases and retinal illumination decreases to reduce vision. Since reduced pupil size might have a different impact on distance and near vision for people with presbyopia, this exploratory analysis investigated an optimal range of pupil size that improves near vision while minimally impacting distance vision, based on pooled data from individuals who received AGN-190584 for presbyopia in the GEMINI studies.

Methods: The randomized, double-masked, multicenter, vehicle-controlled, phase 3 GEMINI 1 and GEMINI 2 studies (N=750 total) evaluated safety and efficacy of AGN-190584 (once daily ophthalmic formulation of pilocarpine HCl 1.25% optimized in a proprietary vehicle [now FDA-approved as Vuity™]) in individuals with presbyopia. At 8 prespecified timepoints on Day 30, distance corrected near visual acuity (DCNVA) at 40 cm, corrected distance visual acuity (CDVA) at 4 m, and pupil diameter for the nondominant eye (per Neuroptics' pupillometer) were assessed in mesopic conditions (10-11 lux at target). Analyses were conducted on pupil size when individuals gained ≥3 lines in DCNVA or lost >5 letters in CDVA from baseline on Day 30, by pupil diameter (using measurements at all 8 timepoints).

Results: At day 30 in individuals who received AGN-190584, a trend suggesting a negative correlation between the change in DCNVA from baseline and pupil size was noted; smaller pupil sizes produced greater DCNVA improvement, with 50.6% (n=40/79), 24.0% (n=116/483), 16.6% (n=63/379), and 12.4% (n=73/588) of individuals gaining ≥3 lines for pupil sizes ≤1.5 mm, >2 to ≤2.5 mm, >3 to ≤3.5 mm, and >4 mm, respectively. However, when the pupil size was ≤2 mm, mesopic CDVA appeared to become compromised, with 4.4% (n=11/250) and 10.7% (n=6/56) of individuals losing >5 letters in CDVA for pupil sizes >1.5 to ≤2.0 mm and ≤1.5 mm, compared with 2.1% (n=7/335), 1.7% (n=5/296), and 4.1% (n=20/483) for pupil sizes >2.0 to ≤2.5 mm, >3.0 to ≤3.5 mm, and >4 mm, respectively.

Conclusions: An optimum pupil size should consider both NVA and DVA as a smaller pupil size benefits NVA, while too small a pupil size can compromise DVA. Our study findings suggest that the optimum pupil size should be between 2.0 and 2.5 mm.

ABSTRACT BODY:

Purpose: Glaucoma is one of the leading causes of blindness worldwide. The outflow pathway, especially fibrosing trabecular meshwork (TM), plays an essential role in this disease, and the availability of TM cells is crucial for in vitro research. To date, extracting TM cells from mice is complex and relies on injecting magnetic microbeads in the anterior chamber of living mice with subsequent isolation. Therefore, a cost-effective and animal experiment-reducing strategy for the extraction of mouse TM cells is required.

Methods: After Enucleation, eyes were cut in half anterior-to-posteriorly. Lens and posterior segment were removed, Iris and the attached ciliary body were gently pulled backwards and disconnected from the remaining tissue to expose the TM. Cuts anterior and posterior the TM allowed for removal of the TM region. Tissue was cultured facing down in a 6-well filled with Eagle`s Minimum Essential Medium supplemented with 10% FBS. Phagocytotic properties were assessed using fluorescent microbeads, and Immunocytochemistry (ICC) analysis was performed for different markers present in TM cells.

Results: An outgrowth of cells could be observed after 4-7 days. These cells were able to phagocytize fluorescent microbeads and were positive in ICC for collagen IV, fibronectin 1, vimentin and α-smooth muscle actin. Also, typical cross-linked actin networks (CLANs) were expressed after one-week TGFB2 exposure. As previously reported for TM cells, treatment of the isolated cells with 100 nM Dexamethasone for one week led to increased Myocilin expression.

Conclusions: The isolated cells show phagocytotic properties and specific expression of markers reported in TM cells. Therefore, our presented dissection-based method is an inexpensive, reproducible method for isolating TM cells in mice.

TITLE: Quantitative Autofluorescence in patients with central serous chorioretinopathy

SESSION TITLE: Posterior Segment Imaging

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: R. Liegl, I. Stasik, B. Lahme, F.G. Holz, C. Weber, Ophthalmology, Universitatsklinikum Bonn, Bonn, Nordrhein-Westfalen, GERMANY|

Commercial Relationships Disclosure: Raffael Liegl: Commercial Relationship(s);Code C (Consultant/Contractor):Novartis;Code C (Consultant/Contractor):Allergan;Code R (Recipient):DORC | Isabel Stasik: Commercial Relationship: Code N (No Commercial Relationship) | Bastian Lahme: Commercial Relationship: Code N (No Commercial Relationship) | Frank Holz: Commercial Relationship: Code N (No Commercial Relationship) | Constance Weber: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate characteristics of fundus autofluorescence in patients with central serous chorioretinopathy (CSC). CSC belongs to the spectrum of pachychoroid disease. These are associated with a thickened choroid and a dysfunctional RPE. Quantitative fundus autofluorescence (qAF) is a scanning laser device that is able to measure autofluorescence signals quantitavely. In acute CSC autofluorescence is typically decreased while in chronic forms an increased signal can be found.

This study was performed to quantify the alterations in qAF signals in patients with CSC and in their fellow-eye in comparison with a healthy control group.

Methods: Patients clinically diagnosed with CSC were recruited prospectively. All patients received a full clinical examination including best corrected visual acuity (BCVA), EDI-OCT and qAF. EDI-OCT was acquired using a Spectralis OCT (Heidelberg Engineering) and choroidal thickness was measured in each eye at four different localizations. QAF images were taken with a confocal scanning laser ophthalmoscope (Heidelberg Engineering). QAF values were subsequently assessed using a Delori-grid and mean values of the inner eight ring (IN8) and the middle ring (MID) were collected. Data was collected in an Microsoft Excel spreadsheet and statistical analyses were performed using SPSS statistics.

Results: In total, 66 eyes from 33 patients suffering from CSC were included. Among these 45 eyes had a manifest CSC while 21 fellow eyes did not show signs of CSC. QAF values between these two groups did not show significant differences neither in the IN8 ring ($p=0.46$) nor in the MID ring ($p=0.23$). Mean qAF units in the CSC eyes were 194 (IN8) and 224 (MID) and 182 (IN8) and 205 (MID) for the fellow eyes. We compared our CSC group to a healthy cohort comprising of 18 eyes from 12 patients. QAF units differed significantly compared to both CSC manifest and fellow eyes.

Conclusions: QAF is a useful technology to assess alterations of the RPE. Our data show that patients with CSC have increased qAF values in comparison to healthy controls. In fellow-eyes of CSC patients, qAF signals do not differ significantly from manifest CSC eyes. This finding suggests that RPE alterations might be present not only in the manifest CSC eyes, but also in their fellow-eyes, even though these are clinically unremarkable.

ABSTRACT BODY:

Purpose: Glaucoma is one of the leading causes of irreversible blindness worldwide. Drainage devices are among the most popular surgical procedures to lower intraocular pressure (IOP) in order to prevent glaucoma progression. The Paul Glaucoma Implant (PGI) is an innovative device with a smaller size and internal diameter compared to more “traditional” tubes such as the Ahmed and Baerveldt. It was developed to overcome typical drawbacks of these tubes, including early failure in the former and post-operative hypotony and delayed function in the latter. In theory, a smaller tube should also result in reduced corneal endothelial cell loss over time. This large descriptive case series shows the one-year results of the very first patient cohort receiving a PGI in Germany.

Methods: A prospective database of patients undergoing PGI implantation at the University Eye Hospital in Bonn was created in a Microsoft Excel spreadsheet. Data of preoperative and follow-up visits have been collected until now and the database is continuously updated at every visit. Major outcomes were IOP, number of glaucoma medication, best corrected visual acuity (BCVA), visual field results, corneal endothelial cell count and complications. Statistics were obtained with SPSS statistics for Windows.

Results: A total of 60 eyes from 58 patients were included. The mean review period was 8 months (range from 1-13 months). The mean IOP at baseline was 26 mmHg. The PGI led to a mean IOP reduction of 64%. The mean IOP was 9 mmHg at 6 weeks, 11 mmHg at 3 months and 12 mmHg at 6 months postoperatively. Complication rates were low, with 5% (n=3) of patients having a temporary hyphema postoperatively whilst another 5% (n=3) developed a numerical hypotony postoperatively that resolved without an additional intervention. Only 3 % (n=2) needed topical glaucoma medication at six months postoperatively.

Conclusions: The PGI is a safe and effective new glaucoma drainage device that reduces IOP effectively with a low complication rate. Thus, it represents an innovative new treatment modality. Further studies are necessary to evaluate its long-term effect.

ABSTRACT BODY:

Purpose: Burkina Faso, in West Africa, is one of many countries that experience frequent seasonal outbreaks of presumed infectious conjunctivitis of unknown etiology. This study leverages the hypothesis free diagnostic tool of metagenomic deep sequencing (MDS) to determine the local causes of infectious conjunctivitis

Methods: Inclusion criteria required acute conjunctivitis symptoms for less than 14 days. Sterile polyester applicators (Puritan) were used to swab the lower conjunctival fornix of each eye. All swabs were immediately placed in DNA/RNA-Shield (Zymo Research). Details of sequencing, library preparation, and bioinformatics analyses have been previously described.

Results: Samples were obtained from 19 participants. 47% were female. The average age was 9 years. Both eyes were affected in 15/19 cases (79%). The predominant ocular presenting symptom was purulent discharge, present in 17/19 (89%) cases. MDS identified a virus as the causative pathogen 53% (10/19) of cases. Bacterial pathogens were identified in 16% (3/19) of cases. A mixed bacterial and viral infection was noted in 2/19 (11%). Of the 10 viral etiologies identified, an adenoviral species was identified in 2 cases. This represents 20% of all viral pathogens and 11% of all cases. Other viruses identified as pathogenic include rhinovirus, influenza A and herpes viridae including herpes simplex virus (HSV), varicella zoster virus (VZV), Epstein Barr virus (EBV) and cytomegalovirus (CMV). The five bacteria identified as causative etiologies were Streptococcus pneumonia, Corynebacterium mastiditis, Moraxella catarrhalais, Neisseria meningititis, and Hemophilus influenza

Conclusions: Causative pathogens of patients presenting with acute, mostly purulent, clinically presumed infectious conjunctivitis in Burkina Faso are surprising. Adenoviridae were isolated in only two cases (11%). Bacterial pathogens only were identified in three cases. This study suggests that clinicians' clinical suspicions of causative etiologies for infectious conjunctivitis may not be accurate. Similarly, classic teaching for what clinical findings predict which pathogen (viral vs bacterial) may need to be critically re-evaluated. Local surveillance with pathogen identification of seasonal and epidemic conjunctivitis outbreaks is necessary to determine definitive etiologies determine appropriate treatment strategies and inform region-specific public health initiatives.

ABSTRACT BODY:

Purpose: X-linked Retinoschisis (XLRS) is an early onset degenerative retinal disease that causes cystic lesions in the middle layers of the retina, a loss of visual acuity, and decreased contrast sensitivity. XLRS is caused by mutations in Retinoschisin 1 (RS1) which encodes the secreted protein retinoschisin (RS1). Rs1-mutant mouse models develop key hallmarks of XLRS including intraretinal schisis and reduced ERG b-waves. The disease phenotype is present at early ages leading to the question of whether retinal development is ever normal. Here we explore the early ERG properties of Rs1 mutant mice, using an ex vivo system and pharmacological blockade to isolate ERG components generated by photoreceptors, depolarizing bipolar cells (DBCs) and Müller glial cells (MGCs).

Methods: We recorded light evoked responses from WT and two Rs1-mutant strains $Rs1^{KO}$, $Rs1^{C59S}$ at P13, an age where Rs1 mutants have developed intraretinal schisis. After dark adaptation, mice were sacrificed and retinae were isolated and mounted on a custom ERG chamber. ERGs were evoked by 1-4 ms pulses from a LED band-passed at 505±20 nm in triplicate. Photon intensity was varied from 5-50,000 photons/um^{-2}. ERGs were recorded while retinae perfused by normal Ringers, Ringers contains barium chloride (100 µM) and then also LAP-4 (14 µM). Response components reflecting MGCs and DBCs were estimated by waveform subtraction.

Results: In comparison to WT, ERGs of Rs1 mutant mice had comparable b-waves, and a tendency toward larger a-waves, while MGC responses were only larger in $Rs1^{C59S}$ mice.

Conclusions: These results indicate that Rs1 mutations have less impact on the rod pathway at P13 than at later ages. Ongoing studies will determine the ERG phenotype at still younger ages.

ABSTRACT BODY:

Purpose: Although many integrins have been previously identified in native corneal endothelium, integrin expression between native and cultured cells remains incomplete. The goal of this study is to compare the integrin expression profile of native corneal endothelium and of cultured corneal endothelial cells (CECs), using both primary cultures and an immortalized cell line.

Methods: Human CECs were isolated from healthy eye bank corneas (n=1) and cultured on plastic until first passage. Immortalized CECs (HCEnC21T; P26) and primary cultures of CECs were seeded on glass coverslips at an initial seeding density of 10,000 cells per cm^2 and cultured for 7 days before fixation (90% acetone). Fixed cells, and fixed native cornea (n=1), were immunostained against integrins subunits (α1, α2, α4, α5, α6, α10, α11, αv, β1, β4 and β5), and photographed (Zeiss LSM-800 confocal microscope).

Results: Collagen-binding integrin subunit α1 was expressed in CEnC21T cells, whereas α1 and α2 were present in primary cultures of CECs and native corneal endothelium. Subunits α10 and α11 were absent from CEnC21T, native CECs and native endothelium. Laminin-binding integrin subunits α6 and β4 were absent from cultured CECs, in both the cell line and the primary cultures, but were expressed in native endothelium. For the RGD-binding integrin subunits, α4, α5, αv and β5 were absent in cultured CECs (in both the cell line and the primary cultures), whereas native corneal endothelium expressed the four of them. Integrin subunit β1, which can pair with a variety of different α subchains to form 12 different known integrins, was expressed in cultured CECs as well as in native corneal endothelium.

Conclusions: The integrin expression profile of cultured CECs was different from the profile of native corneal endothelium, namely the loss of α4, α5, α6, αv, β4 and β5 with cultured CECs, demonstrating that cell culture conditions affect integrin expression. While much has been learned about integrins, additional knowledge on the roles of integrins in the adhesion of CECs is needed, as loss of adhesion may be implicated in corneal diseases.

ABSTRACT BODY:

Purpose: Doxycycline is a known treatment for meibomian gland disease (MGD), which is a major risk factor for the development of dry eye syndrome (DES) and recurrent corneal erosion (RCE). The degree to which pre-existing corneal conditions pose a risk for complications after keratorefractive surgery (KRS) is as yet undetermined. This study compared differences in outcomes in the 1-year postoperative period following KRS between patients with and without a 1-year history of doxycycline use.

Methods: A retrospective cohort study was conducted using TriNetX, a real-time, national, federated research network. Patients who underwent KRS were identified by Current Procedural Terminology (CPT) code and stratified into two cohorts based on their history of doxycycline use. Each subject was then matched to a control via 1:1 propensity score matching based on age, gender, BMI, and medical comorbidities such as essential hypertension, diabetes mellitus, and chronic lower respiratory diseases. The primary endpoint of the study was the comparative 1-year postoperative incidence of the following outcomes: DES, RCE, secondary corneal edema, corneal scar or opacity, corneal ectasia, acute conjunctivitis, diffuse lamellar keratitis, corneal neovascularization, vitreous degeneration, ischemic optic neuropathy, vitreous hemorrhage, retinal detachment or break, retinal edema, and cystoid macular degeneration.

Results: A total of 2,056 patients were included in the analysis with 1,028 patients in each cohort after propensity matching. The doxycycline cohort had a statistically significant higher risk of developing DES (RR 1.46, 95% CI 1.2-1.78; RD 6.32%, 95% CI 3.1-9.55) and RCE (RR 2.8, 95% CI 1.37-5.73; RD 1.75%, 95% CI 0.59-2.91) within 1 year of undergoing KRS compared to matched controls. No significant differences were detected between the two cohorts for the other 1-year postoperative outcomes.

Conclusions: Dry eye syndrome and RCE are commonly seen in the postoperative period of KRS and can impact the quality of life in patients. In this study, patients with a history of doxycycline use were significantly more likely to develop DES and RCE following KRS. All other assessed clinical outcomes revealed no significant difference. The severity of pre-existing corneal conditions should be considered when evaluating patients for KRS and discussing outcomes with patients both pre- and post-operatively.

TITLE: Comparing distance-center and near-center multifocal soft contact lenses for myopia control

SESSION TITLE: Myopia epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Singh, E. Tian, Vision Science, University of California Berkeley, Berkeley, California, UNITED STATES|

Commercial Relationships Disclosure: Sarah Singh: Commercial Relationship(s);Code C (Consultant/Contractor):CooperVision Specialty Eye Care, Euclid Systems | Emmy Tian: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Studies have shown that multifocal soft contact lenses (MFSCLs) are effective in slowing myopia progression. While distance-center (DC) lenses are used more commonly and have been investigated in multi-center clinical trials, near-center (NC) lenses have not, despite having more commercially available and daily disposable options. This retrospective study was designed to compare the myopia controlling effect of DC and NC lenses.

Methods: A retrospective analysis of patient data from the UC Berkeley Myopia Control Clinic, captured between 2013 and 2019, was performed to compare rates of myopia progression between patients using NC and DC MFSCLs. Participants had between -0.25D and -6.00D spherical equivalent refraction at baseline and were patients in the clinic for at least 4 months. We included participants that had < 1.50D of anisometropia and < -1.75D of cylinder at any axis. Patients were excluded if they were concurrently using another method of myopia control, such as topical atropine. Additional exclusion criteria were a strabismus observed during a visit in clinic, history of amblyopia, or pathology such as retinopathy of prematurity. Myopia progression rates were estimated using linear regression of autorefraction measurements.

Results: 56 DC and 24 NC subjects were analyzed. There was no significant difference between the right and left eyes, so only right eye data is reported. At baseline, mean [SD] age was 10.9 [2.6] for the DC group and 11.3 [2.2] for the NC group. 32 [54.1%] were female in the DC group, and 13 [54.2%] in the NC group. After treatment, the estimated monthly progression rates were -0.032 D/month (95% CI, -0.054 to -0.0095, SD 0.082) for the DC group and -0.054 D/month (95% CI, -0.090 to -0.018, SD 0.017) for the NC group. There was no significant difference ($p = 0.2859$) between monthly progression rates between the two groups, which can be extrapolated to annual progression rates of (-0.032 x 12) = 0.38 D/year for the DC group and (-0.054x12) = 0.65 D/year for the NC group.

Conclusions: NC and DC MFSCLs slow myopia progression at a similar rate. With more commercially available and daily disposable options, near center lenses could be considered to slow progression in young myopic patients. While the exact mechanism of how MFSCLs slow myopia progression is unknown, these results suggest that competing hyperopic and myopic defocus across the entire retina is important.

ABSTRACT BODY:

Purpose: Macular neovascularization (MNV) vessel density (VD) has been traditionally measured by manually delineating the borders of the MNV lesion on en face OCTA and processing with software for automatic thresholding, skeletonization, and VD calculation. This area-dependent method might be inaccurate as the MNV lesion size changes with treatment (Figure 1). We propose a new, quicker, area-independent method to measure MNV VD that gives comparable results to the traditional method.

Methods: A retrospective analysis was performed to measure the VD of 30 MNV lesions using en face OCTA images across four quarterly visits (N=120) using both methods. The new method consisted of drawing a fixed pattern around the MNV lesion only once, registering both the pattern and image for subsequent visits, and finally calculating the respective VD. (Figure 2) Ten OCTA volumetric scans of MNV lesions were selected from three different OCTA machines (Angiovue®, Cirrus5000®, and PLEX® Elite). For optimal MNV lesion display, different OCT slabs were selected for all images belonging to each of the OCTA machines: choriocapillaris slab for Angiovue®, RPE-RPE fit slab for Cirrus5000®, and custom global slab for PLEX® Elite. The OCTA Analysis Toolbox software was used for manual delineation of the MNV lesion, skeletonization, and VD calculation.

Results: Median area-independent MNV VD was significantly lower than area-dependent MNV VD for all visits and across all devices ($p \leq 0.005$) except for visit 3 ($p=0.052$) and visit 4 ($p=0.052$). Spearman's rank-order correlation showed a strong relationship between MNV VD measured using both methods ($\rho > 0.5$) in all cases across all visits except the Angiovue cases at 3 months follow-up ($\rho = 0.3$). On Bland-Altman analysis, all measured values for all three OCTA devices fell between the upper and lower limits of agreement.

Conclusions: Area-independent MNV VD measurements were reliable and comparable to results obtained via the more traditional, area-dependent VD measurement. Moreover, these measurements were easier and less time-consuming to perform as the fixed pattern used to delineate the MNV lesion at initial visit is registered for subsequent visits.

ABSTRACT BODY:

Purpose: To investigate the relationship between dry eye disease (DED) and work functioning, unemployment, absenteeism, and worry about job loss in a general population.

Methods: 89,215 subjects (18–96 years, 59.5% female) from the Dutch population-based Lifelines cohort were included. DED was assessed using the validated Women's Health study (WHS) questionnaire (either a clinical diagnosis of dry eye or both dryness and irritation symptoms often or constantly present). Unemployment, absenteeism, and worry were assessed with single-item questions. Work functioning was assessed in 36,399 working participants using the validated work role functioning questionnaire (WRFQ) 2.0. The relationships between DED and work functioning, unemployment, absenteeism, and worry about job loss were assessed with logistic regression models, corrected for age, sex, body mass index (BMI), income, education, smoking, and 48 comorbidities associated with dry eye.

Results: 9.1% of participants were defined as having DED: 8.5% had a previous clinical diagnosis of dry eye and 1.9% had highly symptomatic dry eye. Participants with DED had impaired overall work functioning compared to those without DED (49.4% vs 41.1%, OR 1.24, 95% CI 1.14-1.35, P=0.002, corrected for everything). Absenteeism was only slightly increased in DED participants (OR 1.10, 95% CI 1.01-1.20, P=0.04). DED carried a similar risk of impaired work functioning as rheumatoid arthritis and COPD. For participants with highly symptomatic dry eye (often or constant symptoms) impaired work functioning was even higher (60.3%) and at the level of obstructive sleep apnea syndrome and depression. The impaired work functioning scores seen with increasing symptom load were greater for undiagnosed subjects than for diagnosed subjects (interaction term 'clinical diagnosis * dry eye symptoms' P=0.002). After correction for comorbidities, DED was not associated with unemployment (OR 1.07, 95% CI 0.94-1.21, P=0.32), but remained tied to increased worry about job loss (OR 1.23, 95% CI 1.10-1.36, P<0.0005).

Conclusions: In this large population-based study, DED was particularly linked to a substantially impaired work functioning, and less to unemployment and absenteeism. The impact of DED on work functioning is comparable to that of other severe chronic disorders, and undiagnosed subjects may be more affected. This highlights the importance of recognizing DED as a severe disorder and providing a diagnosis.

TITLE: Educate. Participate. Innovate: Training and empowering patients living with rare, degenerative retinal diseases as active stakeholders in medicines research, development, and policy.

SESSION TITLE: Vision care training and education

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F. Waters, Retina International, IRELAND|

Commercial Relationships Disclosure: Fiona Waters: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: There is an increasing demand for patient involvement in medical innovation at research, industry, and policy levels. Retina International (RI) has observed an unmet need amongst its community, where the knowledge and skills to effectively engage in an advisory or advocacy capacity are not developed. As the demand for patient expertise increases, so must our panel of informed patient advocates.

Methods: RI developed a 3-month training programme. 11 globally representative trainees, consisting of 9 patient representatives and 2 PhD candidates were selected following application. The curriculum was co-created with subject matter experts (SMEs) and patients. Three learning streams were designed: 1) Education: Genetic Testing, Patient Registries, PROMs, Clinical Trials, and Regulation & HTA; 2) Participation: Ethics, Advisory Boards, and Health Futurism; and 3) Innovation: Rare Disease Policy, Data Generation, and the Student Project, where trainees were tasked with generating data via surveys and designing their own advocacy strategies. A blended learning approach consisting of independent e-learning, interactive seminars led by an SME, and skills development workshops was used.

Results: Analysis of the programme is underway. 9 of 11 participants completed the programme on schedule. Preliminary findings highlight increased understanding of the scope, processes, and role of patients in medicines R&D for retinal diseases, and the policy actions that support them. The breadth and depth of topics covered, as well as the side-by-side learning of patients and researchers was of high value to both groups. The student project was also reported as a practical, confidence-building experience. As a result of the skills developed, 5 graduates have enrolled in RIs 2022 policy action taskforces to date.

Conclusions: This pilot has demonstrated the potential impact of a tailored and education programme, that develops advisory and advocacy skills in retina patients. Results of this programme by way of increased engagement of graduates with RI projects is already evident. This engagement is predicted to yield broader representation of effective retina patient experts at a global and national level, leading to patient-centred innovations in medicines R&D and health policy.

ABSTRACT BODY:

Purpose: To evaluate the diagnostic accuracy of a multi-modality deep learning (DL) classifier using wide optical coherence tomography (OCT) optic nerve head (ONH) cube scans in eyes with and without axial high myopia.

Methods: This cross-sectional study included 371 primary open-angle glaucoma (POAG) eyes (mean (95% CI) visual field MD -3.78dB (-4.16, -3.41)) and 86 healthy eyes without axial high myopia (axial length (AL) <26 mm) and 92 POAG eyes (mean (95% CI) visual field MD -4.05dB (-4.85, -3.26)) and 44 healthy eyes with axial high myopia (AL≥26mm) from the Diagnostic Innovations in Glaucoma Study (DIGS). We used OCT cube scans of 30deg x 25deg (8.7 x 7.3mm) centered on the ONH, which was formed by 121 horizontal B-scans. The multi-modal DL classifier combines the output features of 3 individual VGG16 models applied on the Spectralis ONH cube scans as follows: 1) texture-based enface image, 2) circumpapillary retinal nerve fiber layer (cpRNFL) thickness map image and 3) scanning laser ophthalmoscope (SLO) image. Area under the receiver operating curves (AUROC) adjusted for both eyes, AL, age, Bruch's membrane opening area and image quality were used to compare different approaches.

Results: Adjusted AUROCs were 0.91 (95% CI = 0.87, 0.95) for the multi-modal DL model, and significantly higher (p-value ≤0.05 for all comparisons) than individual VGG16 model: 0.83 (0.79, 0.86) for texture based en-face image, 0.84 (0.81, 0.87) for cpRNFL thickness map, and 0.68 (0.61, 0.74) for SLO image. A subset analysis of high myopic eyes with AL ≥26mm showed significant higher diagnostic accuracy (AUROCs (95% CI)) of multi-modality DL model 0.89 (0.86, 0.92) compared to texture based en-face image 0.83 (0.78, 0.85), cpRNFL 0.85 (0.81, 0.86) and SLO image 0.69 (0.63, 0.76) with p-value ≤ 0.05 for all comparisons.

Conclusions: Combining the cpRNFL thickness map with texture based en-face images showed higher ability to discriminate between healthy and glaucoma in high myopic eyes than thickness maps alone. While more work is needed, it is likely that texture based en-face images have a role in differentiating high myopic eyes with glaucoma from those without glaucoma.

SUBMITTER (NAME ONLY): Ana Villaplana Velasco

TITLE: Decreased retinal vascular complexity is an early biomarker for myocardial infarction during the next 5 years after ophthalmic examination

SESSION TITLE: Macular diseases/Macular edema/Functional testing/evaluation/Laser

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Villaplana Velasco, J. Englemann, K. Rawlik, O. Canela-Xandri, T. MacGillivray, K. Rannikmae, A. Tenesa, M. Bernabeu, E. PAIRO-CASTINEIRA, The University of Edinburgh College of Medicine and Veterinary Medicine, Edinburgh, Edinburgh, UNITED KINGDOM|M. Rama Krishnan Mookiah, E. Trucco, University of Dundee, Dundee, Dundee, UNITED KINGDOM|

ABSTRACT BODY:

Purpose: There is increasing evidence that retinal vascular complexity (D_f) might offer earlier insights into myocardial infarction (MI) progression. Our recent study indicates that D_f predictive power is as important as systolic blood pressure and body-mass index in predicting MI risk. We present here a study analysing D_f utility period on predicting MI over the past 8 years succeeding the ophthalmic examination.

Methods: We used a subset of 516 incident MI cases and 516 random and age-matched controls from UK Biobank (UKB) that had good quality images from both eyes. We obtained D_f from this imaging subset with VAMPIRE 3.1 software and calculated a polygenic risk score for coronary artery disease (PRS_{CAD}) for each participant using the summary statistics from the CArdioGRAM consortium and PRSice2 software. We developed a MI predictive model combining sex, body-mass index, SBP, smoking, both eyes D_f, PRS_{CAD} and a random forest algorithm. Predicted MI risk obtained through internal cross-validation was next used to separate individuals at high and low MI risk(high MI-risk>0.5 and low MI-risk=<0.5). We investigated potential survival rate differences between these by completing Kaplan-Meier curves and a Log-rank test. We assessed D_f utility period by comparing in time windows of three years the MI risk accuracy of our model with the one from a reproduction of an established risk model named SCORE, based only on epidemiological variables

Results: There is a significant survival rate difference(Log-rank Test P-value<10^{50}) between high vs low MI risk groups. Longitudinal analysis on the timeline of these MI events suggest that our model yields the greatest accuracy during the first 5 years since the ophthalmic examination($Accuracy_{0\text{-}2}$=0.749, $Accuracy_{3\text{-}5}$=0.787, and $Accuracy_{6\text{-}8}$ =0.732). Time-matched comparisons between our MI risk predictions and SCORE-based estimations shows that our approach achieves a higher accuracy during the first 5 years(Accuracy-$SCORE_{0\text{-}2}$=0.697, Accuracy-$SCORE_{3\text{-}5}$= 0.734). Afterwards, the accuracy between both MI risk models is similar(Accuracy- $SCORE_{6\text{-}8}$=0.708).

Conclusions: This study discloses a promising holistic strategy that can prevent MI incidence and triage those with an elevated hazard. Our project highlights the value of easily accessible vascular imaging phenotypes and their promising application in personalised medicine.

ABSTRACT BODY:

Purpose: Hydrogel-based, intracameral travoprost implant (OTX-TIC) is designed to deliver sustained-release travoprost to the anterior chamber for the treatment of glaucoma and is currently in a Phase 2 clinical trial. The purpose of this study was to evaluate the safety, tolerability and pharmacodynamic (PD) profile of repeated OTX-TIC administrations in a canine model.

Methods: Normotensive female beagle dogs received either one placebo vehicle implant (Group 1), one 26 µg OTX-TIC (Group 2), two 26 µg OTX-TIC (Group 3) or one 13 µg OTX-TIC (Group 4) implant injected intracamerally into the right eye (n = 8/group). Groups 1, 2 and 3 were dosed on Days 1 and 127, and Group 4 was dosed on Days 1, 57, 113, and 169. Group 2 represented an intended clinical dose and Group 3 provided a 2X dose multiple and 2X implant safety factor for travoprost drug and implant biomaterial. Group 4 used a shorter persisting hydrogel with a daily travoprost dose comparable to Group 2. Intraocular pressure (IOP), endothelial cell count and corneal thickness were collected. Ocular exams were performed with slit lamp and graded using a modified Hackett-McDonald Scoring System which included conjunctival hyperemia (0 = normal to 3 = severe) and pupillary reflex (0 = normal to 3 = miotic pupil).

Results: OTX-TIC was well-tolerated following repeated administration through 30 weeks. No signs of intraocular inflammation (aqueous cell or flare, vitreous cell) were observed in any eyes of all groups during the study. Mean reduction in IOP (standard deviation) compared to baseline was 7.7% (10.2), 25.7% (13.4), 25.3% (16.2), and 31.0% (12.0) for Groups 1, 2, 3 and 4, respectively throughout the study period. Conjunctival hyperemia and miosis, both known PD responses to travoprost in dogs, were observed in OTX-TIC treated eyes for 30 weeks. Mean conjunctival hyperemia scores and pupillary reflex scores were higher in OTX-TIC treated eyes (Groups 2, 3 and 4) compared to placebo vehicle (Group 1) at all study timepoints.

Conclusions: Multiple, repeated OTX-TIC administrations were generally safe and well-tolerated with no signs of inflammation observed and produced a clinically meaningful reduction in IOP through 30 weeks in beagles. OTX-TIC is currently being investigated in a Phase 2 clinical trial in the US.

ABSTRACT BODY:

Purpose: To design a deep learning (DL) model for detection of glaucoma progression with longitudinal series of macular optical coherence tomography angiography (OCTA) images.

Methods: Two-hundred and two eyes of 134 patients with open angle glaucoma were included. Eligible eyes were required to have 4 visits and 2 years of follow up of OCTA. Glaucoma progression was defined as having 24-2 visual field (VF) mean deviation (MD) rates of < 0 and P value < 0.05 during the follow-up. The data were split with 80% in the training dataset and 20% in the testing dataset. The baseline and final macular OCTA images were aligned according to the center of fovea avascular zone automatically, by checking the correlation of the two images on vector space (Figure 1). To improve the generalizability of the model, data augmentation such as random cropping and resizing were used to increase the training data. For the classification model, a customized convolutional neural network (CNN) with a multi-layer perceptron (MLP) classifier was used. The baseline and final images for each eye were concatenated along the color channel and then sent into the CNN for classification. The cross entropy was used as the loss function for training and a weight of 0.13 was assigned to the non-progressing samples and 0.87 for progressing samples. The performance of the model was evaluated using the area under receiver operating characteristics (AUC), sensitivity, specificity and accuracy. As a comparison method, a logistic regression model was performed to evaluate the performance of whole image vessel density (wiVD) loss on detection of glaucoma progression.

Results: The average (range) follow-up time was 3.5 (2.4-5.5) years and average (standard deviation) baseline VF MD was –3.4 (±5.0) dB. Twenty-eight (14%) eyes demonstrated glaucoma progression. The AUC for detection of progression from macular OCTA images of the DL model was 0.81and for the logistic regression model 0.66 (Figure 2). The sensitivity, specificity and accuracy of the DL model on the testing dataset was 67%, 83% and 80%, respectively.

Conclusions: The optimized DL model detected glaucoma progression based on longitudinal macular OCTA images with high performance. Implementation of this DL model, after external validation, could enhance detection of glaucoma progression.

TITLE: Elucidating endothelial caspase-9 signaling pathways in retinal vein occlusion.

SESSION TITLE: Retinal vascular diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.M. Potenski, Molecular Pharmacology and Therapeutics, Columbia University, New York, New York, UNITED STATES|C.M. Troy, M. Choi, J. Smart, Pathology, Columbia University, New York, New York, UNITED STATES|C.M. Troy, Neurology, Columbia University, New York, New York, UNITED STATES|

Commercial Relationships Disclosure: Anna Potenski: Commercial Relationship: Code N (No Commercial Relationship) | Carol Troy: Commercial Relationship(s);Code P (Patent):Columbia University | Monica Choi: Commercial Relationship: Code N (No Commercial Relationship) | Jade Smart: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Non-apoptotic induction of endothelial caspase-9 by retinal vein occlusion (RVO) sets off a signaling pathway causing edema, BRB breakdown, and eventual neuronal loss, however the exact mechanism of this pathway is still unknown. Previous studies by our lab have shown that knocking out endothelial caspase-9 diminishes the amount of edema and neuronal damage after RVO, suggesting that the endothelial caspase-9 is motivating the signaling pathway. Since this large induction of caspase-9 seems to be non-apoptotic which is atypical of the normal function, we are determining if the upstream activation of caspase-9 by Apaf-1 is the driving force behind the non-apoptotic signaling. These experiments will be carried out using inducible endothelial cell Apaf-1 knock out mice (Apaf-1 iECKO) and WT littermates who are injured with retinal vein occlusions.

Methods: 2-month-old Apaf-1 iECKO and WT littermate mice will undergo the RVO procedure previously described in Avrutsky, et al. Live imaging readouts will be used to track the pathology of the animals and compare to previous data from the caspase-9 iECKO mice. Immunohistochemistry and western blotting will be used to determine the presence of a known downstream target caspase-7, other caspases, and proteins known to be associated with other cell death pathways. TUNEL staining will be used to measure the amount of cell death present after injury in knockout and wild type littermates.

Results: Apaf-1 iECKO mice show less edema after injury than Apaf-1 WT littermates measured using total retinal thickness. They also do not show the same level of thinning 8 days post injury suggesting that there is more neuronal death in the WT animals than the KOs. Apaf-1 iECKOs have lower expression of caspase-9 and direct target caspase-7 as well as less TUNEL staining, indicating less neuronal death.

Conclusions: The activation of caspase-9 specifically in endothelial cells seems to be different than its canonical function however we see that Apaf-1 iECKO is protective in many of the same ways that caspase-9 iECKO is. This suggests that although endothelial caspase-9 is not leading to cell death within the endothelial cells, it is still being activated by Apaf-1. This suggests that the activation of caspase-9 is not driving the non-apoptotic function in endothelial cells and may instead be due to the downstream signaling.

TITLE: Capillary velocimetry on human retina---a preliminary study

SESSION TITLE: New perspectives in technology

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: Q. Zhang, X. Zhou, R.K. Wang, University of Washington, Seattle, Washington, UNITED STATES|

Commercial Relationships Disclosure: Qinqin Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Xiao Zhou: Commercial Relationship: Code N (No Commercial Relationship) | Ruikang Wang: Commercial Relationship(s);Code F (Financial Support):Carl Zeiss Meditec;Code C (Consultant/Contractor):Carl Zeiss Meditec;Code P (Patent):Carl Zeiss Meditec

ABSTRACT BODY:

Purpose: To investigate the capillary blood flow velocity on human retina with various pathologies in vivo based on commercial OCTA device with modified scanning protocols

Methods: A 1060 nm SS OCTA engine (PLEX® Elite 9000, ZEISS, Dublin, CA) with 200 kHz A-line rate and motion tracking mechanism was utilized in our study. New scanning protocol with 200 A-linesx200 B-scans covering ~ 2mmx2mm with 10 repetitions was designed and implemented on the device for capillary velocimetry estimation. The time interval between the adjacent B scans was ~1ms that gives a distinguishable velocity range from 0 mm/s to ~0.5mm/s according to the theorical analysis. The mean frequency (MF) of signal was calculated by eigen-decomposition (ED) approach representing the mean velocity of blood flow within the scanned tissue volume. Depth-resolved retinal and choroidal layers were segmented to investigate the speed variations in different plexus, including the superficial retinal layer (SRL), deep retinal layer (DRL), and choriocapillaris (CC) layers. Color images were utilized to demonstrate the flow speed with red-ish color indicating the fast flow, and blue-ish color indicating the slow flow. To keep the consistency, a fixed display range ([0, 700 Hz]) was applied to all the color images, which was only determined by the time interval of the scanning protocol.

Results: Ten normal eyes (mean age 27.7±3.3), twelve NPDR eyes (mean age 57.2±5.9) and twenty PDR eyes (mean age 56.2±16.6) were recruited in this preliminary study. The MF has shown the capability of differentiating the flow speed at capillary level (Fig.1) in human retina. Overall, the capillaries in retinal layers (SRL&DRL) showed a larger mean MF compared with the flow in CC layer both in normal and DR eyes. A significantly deceased flow speed was observed in PDR eyes by one-anova test among the three groups. However, the ages were not age-matched among the three groups which may introduce bias in the flow speed comparison. Age-matched normal eyes are required for further comparison.

Conclusions: The modified scanning protocol in PLEX Elite with a time interval of ~ 1ms has the capability to differentiate the blood flow speed of capillaries in human eyes with various ocular pathologies using the ED-based capillary velocimetry approach. The results showed the velocimetry may play a role not only in the investigations of ocular disease but also in developing endpoints for therapeutic clinical trials.

ABSTRACT BODY:

Purpose: To evaluate a deep learning classifier for the automated classification of optical coherence tomography angiography images from diabetic retinopathy (DR) eyes with and without macular ischemia (MI).

Methods: In this study, 241 3x3 mm superficial vascular complex (SVC) OCTA images of DR patients with and without MI, as well as healthy controls were used to train a multi-layer deep convolutional neural network (DenseNet121) to differentiate between healthy versus DR with and without MI. A two-class (DR versus healthy controls) and a three-class classification system (DR without MI, DR with MI, and healthy control) were implemented. In order to evaluate classification performances overall in the dataset, a 5-fold cross-validation method was used. Visualization of the output of the DL classifier on OCTA images was performed using two different methods: Smoothed Saliency Maps and GradCAM++.

Results: The accuracy of the binary classification (DR versus healthy controls) was 90.87%, along with a sensitivity of 88.96% and a precision of 96.48%. The three-class classification (DR with MI, without MI, and controls) showed an accuracy of 85.89%. Healthy controls and DR with MI obtained the highest sensitivity, of 94.25% and 93.98%, respectively.

Conclusions: This study describes the use of a deep learning-based model to automatically classify DR with/without MI on central 3x3mm OCTA images. Thus, this model may be a useful screening tool and help improve the clinical management of DR patients.

ABSTRACT BODY:

Purpose: Retinoic acid receptor-related orphan receptor alpha (RORα) is a lipid-sensing nuclear receptor and transcription factor expressed in many retinal cell types including photoreceptors, ganglion cells and bipolar cells. It plays a crucial role in regulating expression of target genes involved in diverse physiological processes in the eye, such as those in lens and photoreceptor development. Genetic variations of RORα have been linked to development of age-related macular degeneration. In this study, we investigated the role of RORα in retinal bipolar cell function during aging using mice with spontaneous RORα deletion mutation ($RORα^{sg/sg}$).

Methods: $RORα^{sg/sg}$ and age-matched wild-type (WT) mice were assessed at various time points during aging for functional and phenotypical analysis. The distribution of RORα in retina was analyzed using single cell RNA sequencing (scRNA seq) database and its localization was monitored by immunohistochemistry, along with evaluation of changes in bipolar cell morphology using PKCα, a rod bipolar cell selective marker. Further, visual function was assessed by scotopic full-field electroretinography (ERG), and retinal expression of genes involved in signal transmission through bipolar cells was determined in $RORα^{sg/sg}$ and WT mice.

Results: RORα expression was found in retinal bipolar cells in scRNA seq analysis and its localization was confirmed in retinal sections. Compared with WT, $RORα^{sg/sg}$ mice showed substantial impairment of visual function with significant attenuation (P=0.0002) of b-wave ERG amplitude at 5 month, with greater reduction (P=0.04) at 12 month, suggestive of bipolar cell dysfunction. However, ERG a-waves, which originate in photoreceptors, were comparatively normal. $RORa^{sg/sg}$ mice revealed significant degeneration and progressive loss of bipolar cells upon aging, with notable loss of rod bipolar cells at 5 months followed by more conspicuous loss and severely disrupted morphology upon aging (9 months and >12 months old), with respect to WT. Furthermore, $RORa^{sg/sg}$ retinal tissues revealed significant dysregulation of genes involved in glutamate and calcium signaling.

Conclusions: These findings suggest that RORα deficiency results in progressive, age-related rod bipolar cell degeneration with associated visual dysfunction, indicating a crucial role of RORα in regulating rod bipolar cell integrity and function in aging eyes.

TITLE: Impact of Glare Strength on Contrast Sensitivity in Pseudophakes

SESSION TITLE: Vision Impairment, Visual Function, and Quality of Life

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Lee, Clinical Operations, Johnson & Johnson Vision, Inc., Irvine, California, UNITED STATES|C. Sefton, Self, California, UNITED STATES|

Commercial Relationships Disclosure: Katherine Lee: Commercial Relationship(s);Code E (Employment):Johnson and Johnson Vision, Inc. | Cameron Sefton: Commercial Relationship(s);Code E (Employment):Johnson & Johnson Vision, Inc.

ABSTRACT BODY:

Purpose: Evaluation of contrast sensitivity (CS) in clinical trials of intraocular lenses (IOLs) has long been used as a supplemental measure of image quality. Factors such as IOL design and lighting/glare conditions are known to degrade image quality and reduce CS. While general parameters for CS testing are outlined in ANSI/ISO standards, glare strength (illuminance) is not. ANSI/ISO recommend a level of glare that reduces mean mesopic CS by 0.1 log units at 6 cpd, determined through a pilot study of young, healthy adults. In a previous pilot study, researchers demonstrated that the manufacturer's standard glare (150 lux) on the Clinical Trial Suite (CTS, M&S Technologies) as well as two attenuated settings (69 and 110 lux) sufficiently reduced the mean CS at 6 cpd by at least 0.1 log units. This study was conducted to compare the effect of the lower glare level on CS for pseudophakic subjects.

Methods: This was a prospective, non-interventional, multi-center clinical study in adults previously implanted with a TECNIS 1-piece monofocal IOL, Model ZCB00 (at least two months postoperative). Subjects with BCDVA worse than 20/20, posterior capsular opacification, or other adverse ocular/lens findings were not eligible for enrollment. Monocular mesopic CS at 6 cpd with and without standard and attenuated glare (150 and 69 lux, before 1.5 ND filter) was measured using the M&S CTS.

Results: Monocular data from 88 subjects were evaluated. Mean (SD) mesopic CS without glare was 1.669 (0.288) log units. Under standard and attenuated glare conditions, mean mesopic CS was 1.393 (0.308) and 1.519 (0.324) log units, respectively. This represented a 0.28 and 0.15 log unit decrease in mean mesopic CS under standard and attenuated glare, respectively. This study showed that two different glare levels can both satisfy ANSI/ISO criteria for CS testing. Testing under approximately 50% lower glare illuminance resulted in a near 50% gain in mesopic CS at 6 cpd in monofocal patients.

Conclusions: ANSI/ISO criteria for CS testing can be met with standard and attenuated glare conditions, based on this study. These findings suggest that CS is highly dependent on glare illuminance, and CS loss due to glare in pseudophakic patients should be carefully interpreted.

ABSTRACT BODY:

Purpose: The aim of this study is to determine if there is a difference in the rate at which symptoms are reported at diagnosis in the first versus second eye to develop neovascular age-related macular degeneration (nAMD).

Methods: A retrospective chart review identified patients who developed nAMD sequentially (defined as a >30-day gap in diagnosis of each eye). Demographic and clinical characteristics were abstracted from the medical record. Symptoms relatable to nAMD included reduced central vision, visual distortion, increased difficulty adapting to low light levels, needing more light to read or to perform close work, increased difficulty reading printed words, decreased intensity of colors, difficulty recognizing faces, and/or a well-defined blurry spot or blind spot in the central field of vision. In cases where patients could not determine, or did not specify which eye was affected, symptoms were attributed to both eyes. For comparison, patients with sequential nAMD were matched to those who had unilateral nAMD, controlling for age, gender, vision, observation period, and treatment agent.

Results: 47 patients with sequential nAMD were matched with 47 patients with unilateral nAMD. Both groups were equally likely to present with symptoms at the time of diagnosis of their first eye (60% vs. 55%, X^2=0.369, p=0.543), but very few patients reported symptoms in their fellow eyes (6.4% vs. 0%, X^2=1.044; p= 0.307). Among patients who went on to develop bilateral nAMD, fewer symptoms were reported at diagnosis of the second eye compared with the first eye (34% vs. 60%, X^2=6.153, p=0.0131). For comparison, at an equivalent time after the diagnosis of nAMD in unilateral nAMD patients, few patients reported symptoms in their fellow eyes (4.3% vs. 34%, X^2=17.1716; p<0.001). And both groups of patients rarely reported symptoms in their fellow eyes at the preceding visit (6.5% vs. 4.3%, X^2 =0.212; p=0.646).

Conclusions: Patients with nAMD more commonly present with symptoms at the diagnosis of their first eye. Despite being taught to monitor and report symptoms concerning for nAMD, fewer patients reported symptoms at the time that their second eye was diagnosed with nAMD. This underscores the importance of regular examinations to monitor the fellow eyes of patients with unilateral nAMD to permit early detection of treatable disease.

TITLE: Intergenerational utility in parents of children with amblyopia
SESSION TITLE: Amblyopia
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: G. van der Sterre, E. van de Graaf, H.J. Simonsz, Ophthalmology, Erasmus MC, Rotterdam, Zuid-Holland, NETHERLANDS|H. van der Meulen-Schot, E. Abma-Bustraan, Ophthalmology, Reinier de Graaf Gasthuis, Delft, Zuid-Holland, NETHERLANDS|
Commercial Relationships Disclosure: Geertje van der Sterre: Commercial Relationship: Code N (No Commercial Relationship) | H.M. van der Meulen-Schot: Commercial Relationship: Code N (No Commercial Relationship) | E. Abma-Bustraan: Commercial Relationship: Code N (No Commercial Relationship) | E.S. van de Graaf: Commercial Relationship: Code N (No Commercial Relationship) | Huibert Simonsz: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:
Purpose: We measured the loss of disease-related quality of life in parents whose child was treated for amblyopia.
Methods: Eligible were the parents of children age three to six who were first treated for amblyopia with occlusion therapy.
Interviews took on average 20 minutes and were conducted by telephone after 6 weeks of occlusion therapy.

Parents were asked how many years of their life they would be willing to give up (Time Trade-Off) in exchange for a completely cured amblyopia with their child. Answers were obtained using a staircase forced choice procedure. Options were 1 day, 1 week, 1 month, 3 months, 6 months, 1, 2, 5, 10, 20, 30 years.

Secondly, they were asked how much risk of unilateral blindness they are willing to take (Standard Gamble) in exchange for a completely cured amblyopia with their child. This question asked participants to imagine they could give their child good vision in both eyes, by themselves undergoing a hypothetical procedure that would accomplish this, but also carried the risk of blinding one of their own eyes.
Results: So far, we have been able to interview 19 parents.

For TTO, widely differing options over the entire range from 0 to 30 years were chosen. The average was 4.8 years, median 5 years, standard deviation 6.8 years.

For SG, 5 out of 12 parents presented with this question were willing to risk the sight in one eye (10% and 1%), 4 opted for risks of 0.01% or 0.005%, 3 for no risk.

No correlation existed between these scores and the clinical variables of the child. However, parents who had amblyopia themselves were willing to take a higher risk in SG, and parents who had a family member with amblyopia were willing to sacrifice more life years with TTO.
Conclusions: It is surprising to see how much of their life or vision parents are willing to give up for a healthy child. These results may seem trivial as most parents wish the best for their child anyway. However, parents and not their children vote and thereby decide on the availability of screening programs and amblyopia treatment. Hence, intergenerational utility should be included as a component in their cost-effectiveness analysis.

TITLE: Detecting glaucomatous loss in the photopic full-field electroretinogram (ERG): influence of chromatic contrast, flash duration and flicker frequency

SESSION TITLE: Structure-Function Relationship

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Dunn, G. Cull, J. Reynaud, D. Jennings, T. Holthausen, B. Fortune, Discoveries in Sight Research Laboratories, Devers Eye Institute, Legacy Health, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure: Michaela Dunn: Commercial Relationship: Code N (No Commercial Relationship) | Grant Cull: Commercial Relationship: Code N (No Commercial Relationship) | Juan Reynaud: Commercial Relationship: Code N (No Commercial Relationship) | Dawn Jennings: Commercial Relationship: Code N (No Commercial Relationship) | Trinity Holthausen: Commercial Relationship: Code N (No Commercial Relationship) | Brad Fortune: Commercial Relationship(s);Code F (Financial Support):Heidelberg Engineering, GmbH, Perfuse Therapeutics, Inc.;Code C (Consultant/Contractor):Perfuse Therapeutics, Inc., Perceive Biotherapeutics, Inc.

ABSTRACT BODY:

Purpose: The ERG photopic negative response (PhNR) is reduced in glaucoma; generally detected best using a red stimulus flash on a blue background (R/B). Longer duration flashes separate the ERG "on" (increment) and "off" (decrement) responses, which also combine to shape flicker responses in a manner that depends on stimulus frequency, and possibly also sensitivity to glaucoma. Here we compare brief (4.5 ms) R/B flashes, long (200 ms) R/B and white-on-white (W/W) flashes, and varied W/W flicker frequencies for their ability to detect early functional loss in a non-human primate (NHP) model of experimental glaucoma (EG).

Methods: Photopic ERGs were recorded (UTAS BigShot, LKC, Gaithersburg, MD) at an early stage of unilateral EG (defined by OCT structural changes, PMID: 27564522) in 6 anesthetized adult rhesus monkeys (Macaca mulatta, 5F/1M ages 4.7-16.5 y) with dilated pupils after 10 min adaptation to 30 cd/m^2 blue light, then scotopic ERGs after 20 min dark adaptation. All photopic stimuli were 560 cd/m^2, including 4.5 ms R/B, 200 ms R/B and W/W flashes, and 4.5 ms W/W flicker at 5, 10, 20, 30.3, 40, and 50 Hz; scotopic W flashes ranged -3.6 to 2.4 log cd-s/m^2. Amplitude and implicit time (IT) of a-wave, b-wave and d-wave peaks were measured, along with PhNR amplitude 65 ms after flash onset and 80 ms after long flash offset. Flicker amplitude and IT were measured by peak-trough and harmonics by Fourier analysis (latter not shown). ANOVA and paired t-tests were used for statistical analysis.

Results: Peripapillary retinal nerve fiber layer thickness in EG and fellow control (FC) eyes was 86.0 ± 11.3 and 101.2 ± 7.4 µm, respectively. Significant ERG differences between EG and FC eyes were found only for the PhNR amplitude of the R/B brief flash ($p = 0.031$) and the “on” PhNR of the R/B long flash ($p = 0.042$, Table/Fig). D-wave latency ($p < 0.0001$) and IT ($p = 0.003$) were delayed by 10-15 ms for R/B relative to W/W long flashes, but did not differ between EG and FC eyes.

Conclusions: At this early stage of NHP EG, full-field ERG changes were limited to reduction of the PhNR for brief R/B and the “on” PhNR of long R/B flashes. Thus, R/B stimuli were better than W/W for detecting early functional loss and separating “off” responses offered no benefit. The chromaticity-dependent timing of the d-wave has some precedent but requires further investigation.

TITLE: Deep learning-based fovea localization in low-cost OCT using macular thickness and corresponding principal curvatures

SESSION TITLE: Machine Learning: Segmentation and Classification

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Salehi, H. Bagherinia, S.A. Bello, L. Ramirez, Carl Zeiss Meditec, Inc., Dublin, California, UNITED STATES|

Commercial Relationships Disclosure: Ali Salehi: Commercial Relationship(s);Code E (Employment):Carl Zeiss Meditec, Inc. | Homayoun Bagherinia: Commercial Relationship(s);Code E (Employment):Carl Zeiss Meditec, Inc. | Simon Bello: Commercial Relationship(s);Code E (Employment):Carl Zeiss Meditec, Inc. | Luisa Ramirez: Commercial Relationship(s);Code C (Consultant/Contractor):Carl Zeiss Meditec, Inc.

ABSTRACT BODY:

Purpose: Macular Thickness Analysis (MTA) is a widely used tool for diagnosing and monitoring patients with ocular pathologies. The robustness of MTA is directly connected to the location of the fovea, which is used to place the ETDRS grid on the macular thickness (MT) map. The fovea localization based on OCT data becomes problematic when the OCT data is generated by a low-cost OCT system due to low contrast in the data. We developed a deep learning-based algorithm to localize the fovea using MT maps for low-cost OCT.

Methods: Scans from one or both eyes of 562 subjects (with one or more scans) were used for training and validation. In each case, the resulting OCT volumes over 6×6 mm using PLEX® Elite 9000 (ZEISS, Dublin, CA) and CIRRUS™ HD-OCT 5000 with/without AngioPlex® OCT Angiography (ZEISS, Dublin, CA) were segmented to delineate the inner limiting membrane (ILM) and the retinal pigment epithelium (RPE). The prototype segmentation was used to generate MT maps with 512x512 pixels over an area of 5.78×5.78 mm. The principal curvature maps (min and max) were calculated using the MT map (Figure 1). One grader manually selected the center of fovea used as the ground truth. This resulted in 1020 samples, from which 816 are used for training and 204 for the first test set (i.e., high-quality set). Additionally, 492 samples (extracted from multiple scans, one or both eyes of 82 subjects) from a prototype low-cost device formed a second test set. No samples from this low-cost device are used for training. The MT map and corresponding curvatures maps were input to a MobileNetV2, trained to estimate a single point. Various geometric and photometric augmentations were used during the training to increase the model's generalization.

Results: The difference between ground truth and estimation was 65±71 microns for the first test set of 204 samples from the same devices as training data. Error on test data from the low-cost device was 100±138 microns (see Figure 1-d). Figure 2-a shows the error distribution on low-cost OCT data and other mentioned devices. Figure 2-b shows the model's accuracy for various error thresholds. Processing time was 40 ms on an Intel Xeon CPU and 15 ms using a GTX 1080Ti GPU.

Conclusions: The result showed the effectiveness and robustness of the method to locate the fovea from MT maps obtained using low-cost OCT data.

ABSTRACT BODY:

Purpose: Occlusive retinal vasculitis is the most common ocular manifestation of Behçet's Disease (BD). In such cases, OCT-angiography (OCT-A) evaluates the retinal vascular plexus and microperimetry can assess macular sensitivity. We performed a cross-sectional structural and functional study of the parafoveal retina in Behçet's uveitis (BU) patients, comparing them to age- and sex-matched non-ocular BD (NOBD) and healthy subjects (HS).

Methods: Of 151 potentially eligible patients that met the International Criteria for Behçet's Disease (2014), 45 presented ocular involvement. We enrolled 75 eyes from 14 patients with BU (mean age 40.6 ± 11.7 years), 13 with NOBD (41.2 ± 8.7), and 13 HS (39.9 ± 11.1) in this study. Thirty-one patients were ineligible by refusal, inability to acquire OCT-A images, or neuro/retinopathies. All BU patients had inactive retinal vasculitis evaluated on fluorescein angiography. We analyzed foveal avascular zone (FAZ) area and vessel density (VD) in superficial vascular plexus (SVP), intermediate capillary plexus (ICP), and deep capillary plexus (DCP) with Spectralis® (Heidelberg Engineering, Heidelberg, Germany) (Figure 1A). They were measured using ImageJ (NIH, Maryland, USA) (Figure 1B). The MP-3 microperimeter (Nidek, Tokyo, Japan) evaluated macular sensitivity (MS). In addition, we also compared the groups' retinal nerve fiber layer (RNFL), ganglion cell layer (GCL), and full-thickness retina (FTR). This study had Institutional Ethics Committee approval.

Results: Variance analysis showed reduction ($p < 0.05$) in parafoveal VD in DCP in BU patients (Figure 1C), especially in the nasal quadrant (~ 20%) (Figure 1D). There was thinning in nasal (< 25.5%) and inferior (< 17%) GCL thickness, as well as in superior (< 6.8%), nasal (< 13.8%), and inferior (< 7.9%) FTR (Figure 2A). FAZ area and VD in the SVP and ICP did not differ between the groups (Figure 2B). MS was generalized reduced with a predilection to the nasal quadrant (~ 40%) (Figure 2C). Non-perfusion areas (34.8%) and microvascular abnormalities (78.2%) were observed in all plexuses and were more visible in the DCP (Figure 2D-F).

Conclusions: In patients with BU, vasculitis primarily affects the DCP, structural and functional macular changes are more critical in the nasal quadrant, MS loss may occur even if there is no structural damage, and qualitative vascular findings seem to be a promising diagnostic biomarker.

ABSTRACT BODY:

Purpose: Phenotypic alterations of retinal pigment epithelium (RPE) cells are central in age-related macular degeneration (AMD). Shape descriptors for individual RPE cells based on RPEs cytoskeleton may help to delineate healthy from AMD affected cells, even in early stages of disease. Here, we quantified differences in RPE morphology between donors with unaffected macula and with AMD.

Methods: Twenty-two human RPE flatmounts (7 AMD, mean age 85 ± 3 yrs (early: 3, geographic atrophy: 1; neovascular: 3;); 15 unaffected (≤51 yrs, n = 8; >80 yrs, n = 7)) were imaged at different locations (fovea, perifovea, near periphery) using a laser scanning confocal fluorescence microscope (exc. 488 nm; emission: 490-695 nm; z-stack: 390 nm steps). Hypoautofluorescent gaps between adjacent RPE cells were formed by the absence of lipofuscin/melanolipofuscin granules between the F-actin cytoskeletons. These gaps were manually marked with computer-assistance and considered borders between cells. Shape descriptors including form factor (measure for circularity), area, solidity, convexity, and roundness for each cell were calculated using customized software. Total autofluorescence (AF) per cell was defined as the integrated density of intensity from all pixels within the cell. Statistical analysis was performed using an ensemble classifier based on logistic regression.

Results: Comparing young vs healthy aged eyes, there was a trend to increased area and reduced form factor. In AMD eyes, RPE shape was significantly altered at all locations with area, solidity and form factor being the most discriminatory descriptors. In samples from healthy donors, with increasing distance to the fovea, area, solidity, and convexity increased, while form factor decreased. Finally, reduced RPE cell AF in AMD was significantly associated

with decreased roundness and solidity of the RPE.

Conclusions: Morphological RPE cell alterations in presence of AMD can be accurately quantified using cell shape descriptors. Enlarged and deformed cells in AMD are assumed to be indicative of structurally and functionally impaired RPE cells. The results of this study may help guide the interpretation of RPE morphology in in vivo studies utilizing high-resolution single cell imaging, e.g., adaptive optics scanning laser ophthalmoscopes or transscleral optic phase imaging.

ABSTRACT BODY:

Purpose: Diabetic retinopathy is preceded by subtle functional neurodegenerative changes, including reduced light sensitivity "lower retinal sensitivity". It is not yet understood if potentially modifiable risk factors may be determinants of retinal sensitivity (RS). Using cross-sectional data from a cohort study, we investigated whether those risk factors were associated with RS.

Methods: We used data from The Maastricht Study, up to 5,255 participants, 50.5% men, age 59.7±8.7 years, and 22.6% with type 2 diabetes (T2D). We determined HbA1c (mmol/mol) and total cholesterol (mmol/L) in fasting plasma samples. We assessed dietary intake and alcohol consumption with a validated food frequency questionnaire, and smoking status via a questionnaire. We measured cardiorespiratory fitness, defined as the maximum power output adjusted for body mass. We measured 24-hour ambulatory blood pressure (mm Hg). We assessed waist circumference (cm) and physical activity (hours/day). We estimated the RS using Heidelberg Edge Perimeter and defined RS as the mean (peri)macular RS of both eyes. We used linear regression analyses with adjustment for potential confounders and tested for interaction by sex and T2D.

Results: After full adjustment, greater HbA1c, lower healthy diet score and cardiorespiratory fitness, and current versus never smoking were significantly associated with lower RS, per SD-β[95% CI], -0.05[-0.08; -0.02], -0.06[-0.09; -0.03], -0.05[-0.08; -0.01], and -0.14[-0.22; -0.06], respectively; greater 24-hour ambulatory systolic blood pressure was

significantly associated with lower RS in individuals with, but not in individuals without, T2D -0.06[-0.12; -0.04]. In contrast, greater total cholesterol was significantly associated with greater RS 0.05[0.02; 0.08]. Alcohol consumption, antihypertensive medication use, lower physical activity, and greater waist circumference were not associated with RS. Sex did not modify the associations.

Conclusions: In this study, higher levels of glycemia or systolic blood pressure, lower adherence to a healthy diet, or cardiorespiratory fitness, and smoking were associated with a lower RS. Hence, early-stage prevention of these factors may contribute to the prevention of loss of RS and, ultimately, diabetic retinopathy.

ABSTRACT BODY:

Purpose: To achieve the highest transduction levels, AAV administration to the eye has traditionally been performed by subretinal injection between the neural retina and underlying retinal pigmented epithelium. While this method provides the benefit of positioning the vector directly next to its cellular target, it requires retinal detachment, an operating room, and a trained retinal surgeon. A therapy that is administered directly into the vitreous of the eye could provide a safer and more feasible approach. Previously, we characterized a novel AAV capsid, AAV204, which facilitates transduction of both the inner and outer retina after intravitreal administration in mice and non-human primates. We hypothesized that using this capsid with a modified intravitreal injection, termed para-retinal injection, may produce more robust transduction levels, particularly in the macula and optic nerve.

Methods: Para-retinal administration was performed by layering the virus on top of the retina between the vitreous and the inner limiting membrane, thus not creating a subretinal detachment. 100 µL of viral suspension (1×10^{11} total vector genomes) of AAV204.CBh.GFP or AAV8.CBh.GFP were administered to four non-human primate eyes. GFP expression was monitored using scanning laser ophthalmoscopy (SLO). 28 days post-injection, eyes were collected, processed, and analyzed by immunohistochemistry.

Results: SLO imaging of AAV204.CBh.GFP dosed eyes showed intense GFP expression in the macula, papillomacular bundle, and retinal nerve fibers. Immunohistochemistry imaging confirmed SLO analysis results, revealing high levels of GFP expression in the macula and foveal pit, as well as retinal ganglion cells and the associated retinal nerve fibers extending to the optic nerve. Alternatively, AAV8.CBh.GFP-injected animals showed little to no GFP expression in the macula or optic nerve. Of note, the dose used in this study was at least 10-fold lower compared to intravitreal AAV injections commonly used in the field.

Conclusions: These results suggest that para-retinal injection of AAV vectors, and more specifically using our novel AAV204 capsid, may be an efficient route of administration for drugs that target the macula or optic nerve/retinal ganglion cell layer.

ABSTRACT BODY:

Purpose: Standard-of-care optical coherence tomography (OCT) systems are manually-aligned tabletop instruments that require strict patient cooperation and careful head stabilization with chinrests. These requirements limit imaging of pediatric patients, who are frequently unwilling or unable to cooperate, and of bedbound or hospitalized patients, who cannot use a tabletop OCT system. Compensation for variation in both position and orientation of the patient's head is necessary for successful imaging under such circumstances.

Methods: We extend our previous robotically-aligned OCT (RAOCT) scanner to support face tracking without assumptions on head orientation (Fig. 1). Two scanner-integrated depth cameras replaced previous fixed-mount cameras, and we generated an artificial frontal face view for subject tracking from their composite face surface maps. Our control software then maneuvered the robot to position the scanner's pupil pivot at the subject's pupil and to match the subject's head orientation. We evaluated this approach through IRB-approved imaging of human subjects in varied head orientations. Subjects were either freestanding or seated upright facing the system and were asked to orient their head with non-zero pitch and yaw. An operator then triggered the system to perform semi-automatic alignment and imaging of the desired eye, after which the system returned to its starting configuration. We conducted imaging in this fashion for multiple positions and head orientations for each subject.

Results: The RAOCT system successfully obtained motion-stabilized OCT images in widely varying subject positions and head orientations (Fig. 2a). For each subject, OCT volumes obtained with different positions and orientations captured the target retinal anatomy (Fig. 2b). The time to first images after initiation of alignment was routinely under 30 seconds.

Conclusions: Robotically-aligned OCT with scanner-integrated head tracking enables reliable imaging of subjects with arbitrary head orientations. This approach promises to facilitate imaging of pediatric and hospitalized patients.

ABSTRACT BODY:

Purpose: AdRP is an inherited retinal disease that affects ~400,000 people worldwide. In the United States, ~2500 people have a proline to histidine substitution at codon 23 (P23H) in rhodopsin (RHO). It is believed that misfolded mutant Rho protein contributes to rod photoreceptor (rod) death. Wave Life Sciences has previously reported that stereopure antisense oligonucleotides (ASOs) bind to RNA via complementary base pairing that promotes RNase H–mediated degradation of mutant RNA. Here we evalutated the efficacy of stereopure ASOs targeting P23H hRHO mRNA injected into the vitreous of transgenic P23H hRHO (TgP23H hRHO) pigs on retinal structure and function.

Methods: Four neonatal TgP23H hRHO pigs received bilateral intravitreal (IVT) injections (50 uL) of ASOs targeting the P23H hRHO mutation at 10 µg (n=2) or 25 µg (n=2). Controls included: TgP23H hRHO eyes injected with PBS (n=1), or non-targeting ASO (n=3; 25 µg), and uninjected age-matched WT and TgP23H hRHO eyes. Presence of ASO in retina (retinal exposure), aqueous, vitreous and RPE were assessed by hybridization ELISA. We conducted regular ocular exams, fundus imaging, full-field ERGs and OCTs to assess tolerability and efficacy of ASOs on retina structure and function. Animals were euthanized at 8 (n=5) or 16 (n=3) weeks post injection (wpi). Morphological assessments were conducted in immunohistochemically labeled frozen sections.

Results: PK analysis found dose and time dependent retinal exposure (25 µg dose: 5 and 2 µg/g at 8 and 16 wpi, respectively; 10 µg dose: 0.7 and 0.2 µg/g at 8 and 16 wpi, respectively). ASOs did not induce inflammation and rejuvenated rod structure and function in treated retinas. Naïve and PBS injected TgP23H hRHO pigs had no scotopic ERG b-wave (flash intensity; 0.01 $cd*s/m^2$). At 16 wpi, all Tg retinas treated with 25 µg of targeting ASO had scoptopic b-waves of whose amplitudes were ~40% of WT. Rod morphology and rhodopsin expression were preserved compared to untreated Tg littermates.

Conclusions: InTgP23H hRHO pigs, a single IVT injection of an ASO targeting P23H hRHO is well tolerated, preserves rod morphology and rhodopsin expression, and rejuvenates rod function for at least four months after administration. This represents a strong resolution of rod photoreceptor degeneration.

ABSTRACT BODY:

Purpose: RPE65 association with RPE smooth endoplasmic reticulum (sER) is required to regenerate 11-cis retinal. How RPE65 binds to sER is unclear as it lacks transmembrane motifs, but a crystallographically unresolved “missing loop” (ML) at residues 107-125 is proposed to be involved. This contains a highly conserved PDPCK motif. Our previous studies reveal that C112 in the missing loop region is palmitoylated and partly important for RPE65-membrane binding and visual cycle function. To elucidate the mechanism of RPE65-membrane binding, we targeted the functional significance of the crystallographically unresolved region in RPE65 membrane binding.

Methods: Secondary structure analyses of the ML were studied using web-based servers (I-TASSER and HELIQUEST). Circular dichroism (CD) spectroscopy and gel filtration chromatography (GFC) was performed using synthethic peptides corresponding to the ML of RPE65. Extensive mutational analyses, palmitoylation detection, subcellular fractionation, and isomerase assays were done. We made a GFP-RPE65$^{107\text{-}125}$ construct for immunofluorescence (IF) studies. We predicted the orientation of RPE65 containing the modelled ML and employed molecular dynamic (MD) simulations to study binding.

Results: In silico analysis of the ML predicts this region to form an amphipathic alpha (α)-helical (AH) structure. CD and GFC analyses of unpalmitoylated synthetic peptide confirmed the capacity of the disordered loop to fold into α-helices upon association with lipid-like molecules, while the palmitoylated synthetic peptide was always α-helical. Mutagenesis revealed that most of the residues forming the AH significantly affect the palmitoylation level of RPE65 and membrane association of RPE65. Moreover, we found that mutation of almost all residues in the hydrophobic face and some charged/polar residues in the hydrophilic face have severe (>50% reduction) to total loss of RPE65 isomerase activity. IF studies reveal that this sequence functions as a membrane sensor and a membrane targeting motif. MD simulations clearly show AH-membrane insertion, strongly validating our experimental findings.

Conclusions: We conclude that the AH plays a major role in the regulation of RPE65 palmitoylation and sER membrane interaction and, thus, the catalytic function of RPE65. Taking all these findings into consideration, we propose a hypothetical working model for RPE65-membrane binding.

ABSTRACT BODY:

Purpose: PCED results from the failure of rapid epithelialization and closure within 10-14 days after a corneal injury, even with standard supportive treatment. If left untreated, PCEDs can result in stromal scarring, perforations, secondary infections, ulcerations, and vision loss. KPI-012 topical ophthalmic solution is a novel, bone marrow derived mesenchymal stem cell (MSC) secretome with a multifactorial mechanism of action that has the potential to treat PCED of various etiologies. In preclinical studies KPI-012 has demonstrated the ability to accelerate corneal wound healing and reduce scarring, inflammation, and angiogenesis. The purpose of this Phase 1b trial was to evaluate the safety and efficacy of twice daily (BID) KPI-012 for the treatment of PCED.

Methods: A prospective, single-arm, Phase 1b trial enrolled 12 subjects at two independent sites in Mexico. The initial safety cohort consisted of 3 subjects with low vision and no active corneal disease. KPI-012 was administered BID for 1 week and subjects were followed for 1 week. The efficacy cohort consisted of 9 subjects with PCED of various etiologies. In this cohort, KPI-012 was administered BID for up to 8 weeks and followed for up to 18 weeks. The key efficacy endpoint was complete healing of corneal defects evaluated by corneal staining. Other efficacy endpoints included reduction in defect size, visual acuity, corneal neovascularization, and opacity. The safety measures included tolerability/pain, intraocular pressure, vital signs, and adverse events.

Results: In the efficacy cohort, 6 of the 8 subjects had complete healing of their PCED. There was one early withdrawal unrelated to the KPI-012 treatment in the efficacy cohort. Among the 6 completely healed subjects, four achieved complete healing after one week of treatment, one after two weeks, and one after four weeks of treatment. Improvement in PCED was observed in one subject but complete healing was not achieved. All subjects with complete PCED resolution remained healed through end of their follow-up periods. KPI-012 was well-tolerated with favorable safety profile in both the safety and efficacy cohorts.

Conclusions: KPI-012 topical solution administered twice daily for up to 8 weeks appeared safe, well-tolerated, and effective in the treatment of PCED with various etiologies.

ABSTRACT BODY:

Purpose: To identify distinct populations expressing homeostatic and regulatory genes and specific identity markers based on gene expression profiles.

Methods: Female C57BL/6J (B6) mice aged 6–8 weeks were allowed to house in 50–75% relative humidity before the experiments. The CD45+ cells were sorted from the conjunctiva of B6 mice using the Aria-II cell sorter. Single-cell gene expression libraries was prepared using the Chromium Single Cell Gene Expression 3v3.1 kit and sequenced on the NovaSeq 6000 Sequencing System using the S2 v1.0 Flowcell. Raw sequence reads in the FASTQ format were aligned to the mouse reference genome using Cell Ranger Count v6.0.1 and analyzed with Seurat v3.1. Cell-cell interactions were analyzed by Cell Chat and Gene pathway analysis using Qiagen IPA. Immunofluorescence staining in whole-mount conjunctival tissue samples was visualized using laser scanning confocal microscope.

Results: Sixteen distinct clusters were identified, including myeloid cells (neutrophils, monocytes, macrophages), dendritic cells (DC), and lymphoid cells (B, T, gdT, ILC2, and NK) lineages. Novel neutrophil [lipocalin (Lcn2) high and low), MHCIIlow macrophage (MP), and Retnla DC2 clusters were identified. Approximately half of the cells map to myeloid and dendritic cell populations with differential expression profiles that include genes with homeostatic and regulatory functions. Serpinb2 (MHCIIlo macrophage), Apoe (monocyte), Cd209a (macrophage), Cst3 (cDC1), and IL4i1 in migratory DC (mDC). Suppressed inflammatory and activated anti-inflammatory/regulatory pathways were observed in certain myeloid and DC populations. Confocal immunolocalization of identity markers showed cDC2 and mDC located on or within the conjunctival epithelium. Monocyte, macrophage, cDC1 and IL-13/IL-5+ ILC2 were located below the conjunctival epithelium and goblet cells.

Conclusions: This study provides valuable information that can be used for more specific cell identification and cell-specific gene expression profiles that can be compared with those in ocular surface inflammatory diseases, such as dry eye where there is recruitment and activation of immune cells. It provides biomarkers that can be used to determine factors, such as diet and microbiome, that maintain the production of the homeostatic and regulatory factors by the conjunctival immune cells.

ABSTRACT BODY:

Purpose: Primary cilia are microtubule-based organelles that transduce extracellular cues into intracellular signals critical for diverse processes including proliferation and tissue repair. Defective ciliary function results in multisystemic diseases known as ciliopathies in humans. Many ciliopathies in the eye, such as Bardet-Biedl Syndrome, share a common feature of atrophy of the retinal pigment epithelium (RPE). Mutation in genes involved in cilia formation, including IFT88 or BBS4 which cause Bardet-Biedl Syndrome, result in loss of or shortened cilia. However, the roles for RPE cilia in vivo remain unknown. This study investigates the role of primary cilia in the proliferative and reparative responses of mouse RPE after targeted laser-injury.

Methods: RPE flatmount from Bbs4$^{-/-}$ mutant mice and wildtype controls from pups on the day of birth (P0), were obtained and immunostained for cilia markers. Transgenic mice were generated with RPE-selective loss of primary cilia (RPE-cKO mice) by crossing IFT88$^{flox/flox}$ mice and BEST1-cre mice. Using a laser-induced injury model in vivo, primary cilia formation was assessed by ciliary markers on RPE flatmounts in response to injury using fluorescence microscopy. Anti-Ki67 antibody was used as a proliferative cell marker. The re-epithelialization was analyzed for wound size measurement with anti ZO-1 antibody and phalloidin. Statistical analyses were performed using Student's t-test or One-way ANOVA, $p<0.05$ was considered statistically significant.

Results: Ciliation in Bbs4 mutant RPE cells is disrupted early during eye development. RPE cilium were reassembled after laser injury, followed by rapid disassembly when repair is completed (n=4 mice). Consequently, faster repair is observed with loss of cilia in RPE-cKO mice than control eyes. Additionally, the removal of cilia by RPE-cKO mice improved wound healing by enhancing cellular proliferation in mouse RPE (n=6-10 eyes, Student's t-test, $P<0.05$).

Conclusions: This study supports a novel role for primary cilia in RPE repair and provides insights into potential cilia-based therapeutic targets for RPE degenerative diseases.

ABSTRACT BODY:

Purpose: Controversy exists concerning the possible association of exfoliation syndrome and abdominal aortic aneurysms due to conflicting evidence in prior studies. A retrospective, electronic medical records (EMR) study was performed using the statewide Utah Population Database (UPDB) to investigate the relationship of exfoliation syndrome and exfoliation glaucoma (XFS/XFG) in abdominal aortic aneurysm (AAA) patients.

Methods: A population-based, retrospective study was undertaken using the Utah Population Database (UPDB). Patients ages ≥40y identified with an AAA diagnosis from 1996-2015, based on International Classification of Diseases (ICD) version 9/10 codes, were included (n=7167). An XFS/XFG outcome in AAA patients and in 5:1 sex- and age-matched controls (n=35,923) was determined from a patient population identified with XFS/XFG (n=3,582) based on ICD 9/10 codes. A hazards model with a competing risk of death was used to determine the risk of XFS/XFG in AAA patients compared with controls. A chart review was conducted to confirm a clinical diagnosis of AAA in XFS/XFG patients.

Results: Of AAA patients, 20 (0.3%) developed XFS/XFG, while in controls, 118 (0.3%) developed XFS/XFG. We found no increased risk of XFS/XFG in AAA patients compared with controls (HR=0.99, 95%CI 0.6-1.6). Of the XFS/XFG patient cohort, 9 patients had a clinical diagnosis of AAA (0.3%) upon chart review. Of chart-review patients confirmed to have both conditions, 50% were male and, on average, had: AAA presentation at age 76y; initial AAA size, 3.9 cm; and XFS/XFG presentation age, 77y.

Conclusions: Exfoliation syndrome is a multifactorial, age-related systemic disorder with genetic and environmental influences associated with various clinical comorbidities. Although prior studies have shown a relationship between XFS and AAA, these findings, from a large UPDB investigation, do not support an association between AAA and the development of XFS/XFG.

TITLE: Disrupting the ciliary gradient of active Arl3 affects rod photoreceptor nuclear migration

SESSION TITLE: Biochemistry and molecular biology of ocular disorders

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: A.M. Travis, S. Manocha, J.R. Willer, J.N. Pearring, Ophthalmology and Visual Sciences, University of Michigan Michigan Medicine, Ann Arbor, Michigan, UNITED STATES|

Commercial Relationships Disclosure: Amanda Travis: Commercial Relationship: Code N (No Commercial Relationship) | Samiya Manocha: Commercial Relationship: Code N (No Commercial Relationship) | Jason Willer: Commercial Relationship: Code N (No Commercial Relationship) | Jillian Pearring: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Human mutations in the small GTPase Arl3 cause a variety of inherited retinal dystrophies that can present as either autosomal recessive or autosomal dominant; however, the underlying pathobiological mechanism of these mutations remains unexplored. Transgenic expression of constitutively active Arl3-Q71L in wild type mouse rods was shown to cause rod nuclei to be displaced to the inner nuclear layer. We hypothesized that dominant mutations in Arl3 would cause a rod nuclear migration defect leading to a possibly divergent disease mechanism.

Methods: FLAG-tagged Arl3 constructs with either autosomal dominant or well characterized GTPase cycle mutations were exogenously expressed in mouse rod photoreceptors via in vivo electroporation. Positively expressing eyes were collected at P21 and then sectioned and immunostained with FLAG antibodies and Hoechst to visualize the location of Arl3-overexpressing rod nuclei. The 3D location of each nucleus within the nuclear layers was then graphed as a function of distance from the outer plexiform layer. In addition, the GTPase activity of each mutant was studied by overexpression in AD293 cells using GST-effector pulldowns and in vivo crosslinking with the cell membrane permeable crosslinker DSS.

Results: Expression of the autosomal dominant mutations D67V and Y90C resulted in nuclei positioned more basally within the outer nuclear layer or even mislocalized to the inner nuclear layer, similar to the GTP-locked Q71L. We found that while Arl3-D67V behaves as a constitutively active mutant, Arl3-Y90C behaves as a fast-cycling mutant. Fast cycling Arl3-Y90C has increased binding to the guanine exchange factor, Arl13B, as well as aberrant GEF-independent Arl3 activity. Finally, we show that the Y90C-dependent nuclear migration defect can be rescued by the overexpression of Arl3 effectors or the ciliary cargo of Arl3 effectors, the disruption of Y90C-Arl13B binding, or the disruption of GTP binding to Y90C.

Conclusions: Our results are consistent with the hypothesis that dominant mutations in Arl3 cause a defect in the migration of rod photoreceptor nuclei by disrupting the ciliary Arl3-GTP gradient. We found that either removing Arl3-GTP or restoring the ciliary Arl3-GTP gradient is sufficient to rescue the nuclear migration defect. Further studies will be necessary to find the ciliary signal underlying this phenotype.

ABSTRACT BODY:

Purpose: For high-resolution prosthetic vision, pixels should be small, and crosstalk should be low. However, shallow penetration of the electric field with planar bipolar pixels prevents sufficient neural stimulation within the safe charge injection limit for pixels under 40μm. To overcome such limitation, we developed 3D arrays with deeper penetrating field and investigated the functional integration of these structures with the retina in vivo.

Methods: 3D implants were constructed by polymerizing honeycomb-shaped 25μm tall walls on planar photovoltaic arrays of 40μm and 20μm pixels, with a common return electrode on the edge of each device. Following subretinal implantation in rats with degenerated retinae (RCS rats), visually evoked potentials (VEPs) were measured in response to pulsed NIR (880nm) activation of the implants. Stimulation threshold was measured with full-field illumination, while visual acuity was assessed using alternating gratings, utilizing current steering-based field confinement. To verify the long-term effects, the VEP performance was followed up for at least 32 weeks post-op.

Results: Bipolar, horizontal and glial cells migrated into the honeycomb-shaped wells of both sizes. The full-field stimulation threshold with 3D implants was around 0.06mW/mm^2 with 10ms pulses - the same as with their flat counterparts, independent of the pixel size. The threshold remained nearly constant over the follow-up period. The VEP amplitude at high irradiances (2-5mW/mm^2) usually exceeded 100μV on the day of implantation, dropped drastically to a few tens of μV after a week, and gradually recovered to the initial level, if not greater, in approximately 15 weeks. Grating acuity matched the row pitch with 40μm pixels. With 20μm pixels, the prosthetic acuity matched the natural resolution of rats: 27.9 +/- 2.8μm.

Conclusions: Retinal integration with 3D implants did not adversely affect its electrical excitability. The stimulation threshold and visual acuity with 3D arrays were not different from those measured with flat arrays, utilizing current steering-based field confinement. If successful in human patients with atrophic macular degeneration, 3D honeycomb-shaped implants with 20μm pixels may enable prosthetic visual acuity as high as 20/80.

ABSTRACT BODY:

Purpose: Danio rerio (zebrafish) are often used as a model to study visual physiology. Previous methodologies utilize an analog system to assess binocular and monocular visual acuities using the optokinetic response (OKR); however, an analog device presents with disadvantages, such as being multi-step, inefficient, and containing paper components prone to water damage. Thus, we have developed a digital system to observe the optokinetic response in zebrafish and effectively measure visual acuity.

Methods: Adult zebrafish were maintained under standard conditions and visual acuity was measured using an analog OKR device. Similarly, visual acuity was measured using a new digital OKR device. Acuity measurements were measured using high contrast, black-and-white stripes as well as colored stripes. A comparison between the measured visual acuities was completed using a paired t-test.

Results: The average analog visual acuity obtained using black-and-white stripes was 0.74 cycles per degree (cpd), while the average digital visual acuity was 0.48 cpd, as demonstrated in Figure 1. The analog system yielded significantly higher visual acuity in comparison to the digital system ($p<0.05$, $n=10$; Student's T-test). Likewise, visual acuity using red, blue and green produced similar results—the analog system had an overall higher visual acuity threshold in comparison to the digital system. Despite these differences, the analog and digital systems show a similar trend in visual acuity measurements, as seen in Figure 2.

Conclusions: Here, we demonstrate that visual acuity trends are consistent among analog and digital systems in both black-and-white and colored stimuli. Thus, an improved digital model can be beneficial for quickly evaluating visual response in adult zebrafish and facilitating disease-related research.

ABSTRACT BODY:

Purpose: To predict visual acuity (VA) in patients with microbial keratitis (MK), at 90-day after diagnosis and at presentation, from data at the initial clinical ophthalmic encounter.

Methods: Patients with MK were identified in the University of Michigan electronic health record between August 2012 and February 2021. VA was extracted for the affected eye in MK patients with a unilateral infection, or for the better seeing eye in patients with bilateral infections, at the time of diagnosis and at day 90 (final). Random forest (RF) models were used to predict initial and final VA (iVA and fVA) that were <20/40. Predictors included age, gender, iVA (for the 90-day prediction model), and information documented in the clinical notes at presentation but excluding the assessment and plan. Model diagnostics are reported with 95% confidence intervals (CI) for area under the curve (AUC), misclassification, sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV).

Results: 1791 MK patients were identified. Patients averaged 48.0 years old (standard deviation, SD=20.3) with 1734 (96.8%) unilateral infections and 57 (3.2%) bilateral infections. LogMAR iVA was on average 0.85 (Snellen equivalent=20/142; SD=1.25) in the affected or better eye and was <20/40 in 43.0% of patients. fVA was <20/40 in 26.6% of patients. The RF model for predicting fVA of <20/40 had an AUC of 0.95 (CI, 0.94- 0.97) and a misclassification rate of 11% (8-13%). The sensitivity, specificity, PPV, and NPV were 91% (86-95%), 89% (86- 91%), 73% (65-79%), and 97% (95-98%), respectively. Older age, worse presenting VA, and more mentions of “hypopyon,” “PKP,” and “OS” in the clinical note were found to be associated with 90-day VA <20/40. The RF model for predicting iVA of <20/40 had an AUC of 0.88 (CI, 0.85-0.91) and a misclassification rate of 17% (14- 20%). The sensitivity, specificity, PPV, and NPV were 77% (71- 82%), 88% (84-91%), 83% (78- 88%), and 83% (79-87%), respectively. Older age, less mentions of the term “quiet” in the clinical note, and more mentions of “hypopyon,” “OD,” and “BID” were associated with iVA of <20/40.

Conclusions: RF models showed strong performance in predicting fVA and iVA. The model identified morphologic features, past ocular surgery, and indirect measure of medication use as key risk factors associated with poor VA outcomes. Predicting fVA can inform clinicians when risk stratifying patients with MK.

ABSTRACT BODY:

Purpose: Ultra-wide field retinal imaging has become a useful tool for diagnosing and monitoring pediatric retinal diseases especially those affecting the retinal periphery. Recently, wireless retinal camera system has been used for ultra-wide field imaging mostly in pediatric population. This study investigated its additional feature, fundus fluorescein angiography (FFA) in diagnosing, treatment and follow-up monitoring of pediatric retinal conditions.

Methods: In this pilot, consecutive case series, the eyes with various retinal diseases were imaged at three sites: Moorfields Eye Hospital Abu Dhabi, Danat Al Emarat Hospital for Women and Children an d Kanad Hospital in al Ain, United Arab Emirates. PanoCam wireless hand-held retinal camera with built-in LED screen (Visunex, San Ramon, CA, U.S.A.) was used. Photos were taken of the posterior pole, including the optic nerve and macula and extended to 130° to include superior, inferior, nasal, and temporal retinal fields. Full control of illumination and image sharpness was achieved by finger control and focusing on working area and not on the screen. Weight calculate dose of fluorescein dye was injected intravenously and individual frames were captures. Images with significant artifacts were removed.

Results: Ultra-wide field fundus image acquisition and analysis was carried out in a total of 42 eyes of 21 children during the period from January and December 2020. Eight patient (16 eyes) had ultra-wide field FFA. All examination were uneventful. Patients were aged between 0 - 50 months, with mean age of 4.7 months. Of all 21 children, 11 were male and 10 were female. The diagnoses included retinopathy of prematurity, Coat’s disease, familiar exudative vitreoretinopathy, retinoschisis and others. Case management between different sites was made easy by sharing on Cloud.

Conclusions: By providing high quality fundus fluorescein angiograms the wireless hand-held retinal camera system is a suitable platform for diagnosis, treatment and follow-up monitoring of pediatric retinal diseases.

ABSTRACT BODY:

Purpose: Choroideremia is an inherited retinal degeneration in which asymmetric retinal deterioration occurs with greater temporal preservation. This correlates with higher retinal sensitivity nasal to central fixation, which we have previously documented. A key question is whether visual acuity (VA) in constricted visual fields measured with the Early Treatment Diabetic Retinopathy Study (ETDRS) chart is impacted by a neglecting of letters temporally compared to nasally. To investigate this further, we assessed whether choroideremia patients made errors more on the temporal than nasal side of the ETDRS chart in each eye under test conditions.

Methods: Monocular VA for right (RE) and left (LE) eyes was measured with a standard ETDRS chart at 4 metres. Letter columns were labelled from nasal (N) to temporal (T) visual field: N2, N1, C (central), T1 and T2 (Figure 2). Total errors per column in the chart were counted until 1 row below the “threshold” row (lowest row with no more than two errors). The distribution of column errors for each group was analysed with the X^2 test.

Results: Sixty eyes from 30 choroideremia patients (median age 44.9 years [IQR 39.1-58.9]) and 86 eyes from 43 healthy controls (median age 20 years [IQR 20-21]) were examined. Median VA was 72 for patients and 93 for controls. Results showed greater errors in T2 compared to N2 in the RE of choroideremia patients (p=0.045). However, there was no significant difference in the LE of patients (p=0.26), or in either eye in controls (RE p=0.77, LE p=0.32).

Conclusions: Choroideremia patients seem less able to read the right compared to the left side of the EDTRS chart with the right but not left eye. Since the left side is read first with each row, this may represent difficulties in tracking saccades in the right eye since the more sensitive temporal retina is not aligned with any letters along the row being read. Conversely, this surviving temporal retina in the left eye may provide a clearer view of the entire row, which may facilitate correct identification of subsequent letters. The ETDRS chart may not therefore be optimal for patients with asymetrically constricted visual fields so alternative approaches, such as reading rows backwards, may provide more consistent results.

ABSTRACT BODY:

Purpose: Quantitative metrics derived from OCT images could help detect hydroxychloroquine (HCQ) toxicity, which can be especially challenging in early (mild) disease. This project aims to investigate the generalizability of OCT metrics from different OCT instruments in their ability to discriminate early toxicity cases from unaffected eyes.

Methods: Participants enrolled in a case-control study (NCT01145196) underwent multimodal screening tests including SD-OCT imaging using both the Spectralis (Heidelberg Engineering, Heidelberg, Germany) (30^{o}x25^{o}, 60 µm spacing) and Cirrus (Carl Zeiss Meditec, Inc., Dublin, CA, USA) (6mmx6mm, 48 µm spacing) and were classified into unaffected or affected eyes. Forty-four participants (mean age 55, 91% female) included participants without any evidence of toxicity (99 eyes) and those with mild HCQ toxicity (14 eyes), defined as ≤100 µm Ellipsoid Zone loss on the foveal B-scan. Quantitative metrics computed from OCT images included total retina thickness (TRT), outer retina thickness (ORT) and minimum intensity (MinI) in both the TR and OR. OCT metrics were averaged across Early Treatment Diabetic Retinopathy (ETDRS) sectors. Bland-Altman plots assessed the agreement of metrics computed from the two instrumentation. The area under the receiver operating characteristic curves (AUC) were used to evaluate the ability of each metric from each OCT platform to discriminate between eyes with and without HCQ toxicity.

Results: Bland Altman analysis demonstrated minimal differences between the instruments for TRT (0.015 mm, 95% CI -0.019 mm to 0.039 mm) and ORT (0.005 mm, 95% CI -0.013 mm to 0.022 mm) measurements. However, minimum intensity measures had comparatively less agreement between instruments (t-test for TR p=0.0008, OR p=0.04861). For both instruments, ORT and TRT afforded excellent ability to discriminate between unaffected and mildly affected eyes with highest AUC values for ORT> 0.98 in the inner ETDRS subfields. OR MinI metrics from both instruments demonstrated good discrimination in the inner subfields (Heidelberg 0.95, Cirrus 0.91) but with larger differences between the instruments.

Conclusions: OCT metrics such as ORT, TRT and MinI derived from both instruments demonstrated successful generalizability in discriminating early/mild HCQ toxicity eyes from unaffected eyes. This bolsters the potential utility of OCT metrics to aid HCQ screening.

ABSTRACT BODY:

Purpose: Retinal ganglion cells (RGC) are vulnerable to damage in diseases and injuries that cause blindness and cannot repair themselves. One promising approach is to reapply developmental mechanisms that form visual circuits, to promote repair. During development, target-derived cues and neural activity are required in both, the RGCs and target cells, to connect RGC axons with their synaptic partners in the brain. While many studies have identified events occurring in the RGCs to promote repair, far less is known about the role of target cells in RGC axon regeneration. Here we are testing a novel idea that post-synaptic target cells in the retinofugal pathway can be leveraged to promote regeneration of visual circuits.

Methods: We performed a distal injury to sever the optic tract of adult mice anterior to the pre-tectum. We increased neural activity broadly in the distal optic pathway using a chemogenetic approach; injury-only animals served as controls. To identify the specific contribution of target cells, we used synaptotagmin17::cre (Syt17::Cre) mice to precisely activate cells in the nucleus of the optic tract (NOT), a subcortical visual target. We used the rabies viral tracing system to identify inputs to cre-labeled cells in the NOT. We assessed RGC degeneration through immunohistochemistry, and axon regeneration through intravitreal injection of fluorophore-conjugated cholera-toxin subunit β.

Results: We observed significant regeneration of RGC axons ($p=0.0007$, Mann-Whitney, $n=10$) in the group that received increased neural activity, with significant regeneration within pre-tectum targets. We confirmed that cre-labeled cells in the NOT are bonafide retinorecipient cells. We also observed significant regeneration of RGC axons ($p=0.03$, Mann Whitney, $n=7$) in Syt17::Cre mice in which only the retinorecipient target cells were activated.

Conclusions: Our data shows that increasing electrical activity of neurons in the distal optic pathway can promote regeneration of RGC axons, and that specific activation of retinorecipient targets is sufficient to promote RGC axon regeneration in a distal injury model. These results suggest that target-derived cues are important to promote robust, accurate rewiring of injured visual circuits. These experiments will address the role of post-synaptic cells in CNS repair and have widespread relevance for treating blinding diseases, stroke and traumatic brain injury.

ABSTRACT BODY:

Purpose: Distance visual acuity (VA) testing is commonly performed in children to screen for significant refractive error; however, the diagnostic value of distance VA remains unclear. We examined associations between VA and different types of cycloplegic refractive error in children.

Methods: Unaided distance VA (logMAR) was assessed monocularly in 234 children using single-surround ATS-HOTV (5-6 years) or eETDRS (7-9 years) protocols. Better-eye VA was used for analyses. Cycloplegic refractive error was determined using the Grand Seiko WR-5100K autorefractor. Refractive error was classified as emmetropia (EMM; -0.75D< sphere (sph) <+0.75D & cylinder (cyl) <0.75D), simple myopia (SM; sph≤-0.75D & cyl<0.75D), simple hyperopia (SH; sph≥+0.75D & cyl<0.75D), compound myopic/hyperopic astigmatism (CMA/CHA; both meridians myopic/hyperopic & cyl≥0.75D), simple myopic/hyperopic astigmatism (SMA/SHA; one myopic/hyperopic & one emmetropic meridian), or mixed astigmatism (MA; one hyperopic & one myopic meridian). Receiver operating characteristic (ROC) analysis was conducted to identify optimal logMAR VA thresholds for the detection of each refractive error type (if N>10) using the Youden Index.

Results: VA ranged from -0.3 to 1.2 logMAR (median=0.0, IQR=0.3), SE from -3.15D to +10.45D (mean=+1.00D, SD=1.79D), and astigmatism from 0.03D to 4.24D (mean=0.75D, SD=0.75D). Refractive error distribution was SH (N=90), EMM (N=52), SHA (N=27), CHA (N=26), SM (N=16), SMA (N=13), CMA (N=7), and MA (N=3). Analyses found low optimal logMAR VA thresholds across refractive error types (SM=0.15, SMA=0.05, SH=-0.25, SHA=-0.05, CHA=0.05), with high sensitivity (SM=94%, SMA=85%, SH=100%, SHA=85%, CHA=81%) but low specificity (SMA=63%, SH=1%, SHA=39%, CHA=66%) except for SM (79%). Analyses were repeated with clinically significant hyperopia (sph≥+2.00D; SH: N=13, CHA: N=13), also yielding low optimal thresholds (SH=-0.25, CHA=0.05), high sensitivity (SH=100%, CHA=92%), and low specificity (SH=2%, CHA=55%). ROC analysis on any clinically significant refractive error type showed a low optimal logMAR threshold (0.05) with 78% sensitivity and 87% specificity.

Conclusions: Distance VA had poor diagnostic value in the detection of clinically significant refractive error in children 5 to 9 years of age. Optimal logMAR VA thresholds based on the Youden Index were not informative in discriminating refractive error type.

ABSTRACT BODY:

Purpose: The choroid is the dense vascular layer present posterior to the outer retina, serving various metabolic functions such as supplying oxygen and nutrients to the retina layers. Studies indicate that choroidal structural changes are related to several vision-threatening posterior segment disorders. Clinicians hypothesize that early manifestations of retinal diseases may be localized to specific regions of choroidal vasculature. However, studies so far were based on gross choroidal biomarkers including the thickness, volume, and vascularity index but not based on finer vasculature quantification. In this regard, to enable early diagnosis, clinicians seek to have biomarkers at the level of blood vessels in 3D. In response, we proposed and validated an end-to-end methodology to quantify choroidal Haller's sublayer vasculature in 3D using wide-field SS-OCT volumes.

Methods: This is a retrospective study performed using healthy and diseased wide-field SS-OCT volume scans taken from the Carl Zeiss Plex Elite 9000 device. We proposed an end-to-end algorithm to quantify Haller's sublayer vasculature. Firstly, we employ previously validated 3D residual U-Net, binarization based on exponential and non-linear enhancement, and 3D smoothing to segment the vasculature. Secondly, we employ TEASAR, 3D tensor voting, and geometrical modeling to estimate centerline (CL) and cross-sectional (CS) radius (Figure 1(a)). The accuracy of CL and CS estimates was validated based on subjective grading, performed on both synthetic and choroidal (of one healthy and two diseased eyes) vasculature. In each session (total 3 sessions), the grader graded CS at 5 randomly picked CL points (Figure 1(b)) to measure various parameters (Figure 1(c)).

Results: For each of the four parameters under consideration, we achieved an average grading score above 92%, demonstrating the efficacy of the proposed methodology. 3D heatmaps depicting relative CS radius as well as histograms of the representative healthy and diseased eyes facilitate quantitative visualization of the vasculature (Figure 2).

Conclusions: The proposed methodology is accurately quantifying choroidal Haller's sublayer vasculature in 3D.

AUTHORS/INSTITUTIONS: K. Narain, J. Revashetti, S. Limaye, South Bay Retina, California, UNITED STATES|
Commercial Relationships Disclosure: Keshav Narain: Commercial Relationship: Code N (No Commercial Relationship) | Janhavi Revashetti: Commercial Relationship: Code N (No Commercial Relationship) | Siddharth Limaye: Commercial Relationship: Code N (No Commercial Relationship)
ABSTRACT BODY:
Purpose: Vitamin B12 is a water-soluble essential micronutrient required for the development, myelination, and function of the nervous system. Absorption of vitamin B12 occurs via the GI tract and is impaired with age and certain medication. Deficiency in serum vitamin B12 is more common over age 60 and is known to impact optic nerve function and testing.

Serum B12 levels are considered normal above 250 pg/mL. 3% of men and 8% of women were found to have suboptimal B12 intake in the 2013-2016 National Health and Nutrition Examination Survey. Vitamin B12 deficiency is known to directly impact optic nerve function.

Our working hypothesis was that lower levels of B12 would be more likely to demonstrate abnormalities in optic nerve function, resulting in misdiagnosis of glaucoma or other conditions.
Methods: We retrospectively examined the impact of low, suboptimal, and normal B12 levels on optic nerve function using perimetry, visual evoked potential, and pattern electroretinography within a population of patients at increased risk for glaucoma.
Results: We found no correlation between the level of B12 (above 300mg) and electrophysiologic parameters. Due to small numbers, it was not possible to draw conclusions regarding the correlation between various parameters. Of the patients with sub-optimal B12, a majority had concurrent diagnoses of glaucoma or other optic nerve diseases.
Conclusions: Our data is limited and demonstrates that vitamin B12 deficiency may impact optic nerve function in a way that resembles more common diagnoses such as glaucoma. Our numbers were insufficient to define any correlation between latency, amplitude, phase, or other electrophysiologic parameters. We propose a further study to include larger numbers of patients with a randomization strategy to identify electrophysiologic parameters that may be specifically affected by various ranges of B12 deficiency.

Patients with characteristics of optic nerve disease including glaucomas should be evaluated for B12 deficiency. Not only could the deficiency result in worsening optic nerve function, but it may also influence the ability of the tissue to regenerate and heal. Neurogenesis, like other cytoproliferative events, requires B12. Suboptimal levels of B12 can both impair the diagnosis and also the treatment of glaucoma.

ABSTRACT BODY:

Purpose: It is currently inconclusive how the newer generation intraocular lens (IOL) power formulas perform on eyes undergoing combined phacovitrectomy. We performed a retrospective, clinical study to assess the refractive accuracy of 4 newer generation formulas in eyes which underwent combined phacovitrectomy.

Methods: Preoperative optical biometry and postoperative outcomes were obtained from 61 eyes which underwent combined phacovitrectomy from 2017 to 2020 at the Johns Hopkins Wilmer Eye Institute. Inclusion criteria were postoperative best corrected visual acuity of 20/40 or better within 6 months and IOL implantation in the capsular bag. Exclusion criteria include eyes with any history of ocular surgeries, intraoperative complications, or evidence of corneal pathology. The Barrett Universal II, Kane, EVO v2.0, and Hill-RBF v3.0 were compared for their accuracy in predicting postoperative spherical equivalents (SE). Correlations between biometric parameters and errors were also assessed. A Wilcoxon rank sum test and Pearson's correlation coefficient were used for statistical analyses.

Results: Errors ranged from -2.36 to 2.97 diopters (D), mean absolute errors (MAE) ranged from 0.47 to 0.50 D, and median absolute errors (MedAE) ranged from 0.28 to 0.34 D. The Barrett formula had the lowest mean error (-0.035), MAE (0.469) and MedAE (0.275). The Barrett formula also had the highest percentage of eyes with predicted error within ±0.25 D (49.2%) and ±0.5 D (72.1%). Based on the MedAE, however, the Barrett formula had a comparable accuracy to other formulas (p ranged from 0.46-0.75). No other pairwise comparisons resulted in statistically significant differences. The anterior chamber depth (ACD) was found to have a weak negative correlation with error for all formulas. (correlation coefficients: -0.29 to -0.32, p: 0.011 to 0.026) The axial length (AL), mean keratometry (Km), and IOL power did not have a statistically significant correlation with error for all formulas.

Conclusions: All 4 newer generation formulas had a comparable accuracy in predicting refractive outcomes in eyes undergoing combined phacovitrectomy. Because the ACD had a statistically significant correlation with error in all formulas, this may serve as a target for improving the accuracy of newer formulas.

ABSTRACT BODY:

Purpose: Lysyl oxidase-like 1 (LOXL1) and fibrillin-1 (FBN1) are abundant proteins in exfoliation material (XFM), a hallmark of exfoliation syndrome (XFS). LOXL1 is associated with XFS and many mutations in FBN1 cause Marfan syndrome (MFS). LOXL1 and fibrillin-1 also co-exist in normal lens zonules. Zonule weakness is a common ocular feature shared by XFS and MFS. Here we sought to uncover their involvement in ocular health and disease.

Methods: $Loxl1^{-/-}$ and $Fbn1^{C1039G/+}$ mice on a 129 background were gifts from Drs. Tiansen Li and Hal Dietz and were used to create a double mutant (dbm) line, $Fbn1^{C1039G/+}/Loxl1^{-/-}$. Survival and systemic phenotypes were monitored and anterior segment morphology was measured by SD-OCT. Immunohistochemistry (IHC), transmission electron microscopy (TEM), atomic force microscopy (AFM) and biochemistry approaches were employed.

Results: $Fbn1^{C1039G/+}$ mice survive more than 1 year, consistent with being a mild MFS mouse model. Likewise, $Loxl1^{-/-}$ mice survive beyond 1 year of age. However, dbm mice do not survive beyond 3 months of age due to aorta dilation. Dbm mice also exhibited more pelvic floor organ prolapse. SD-OCT demonstrated thin central corneal thickness (CCT) and increased anterior chamber depth (ACD) in both $Fbn1^{C1039G/+}$ and $Loxl1^{-/-}$ mice. Thinning of CCT and deepening of ACD were more pronounced in dbm mice with normal axial length, indicating compromised zonules, which was confirmed by IHC for MAGP-1. Compared to wt, $Loxl1^{-/-}$ mice had fewer and abnormally formed elastic fibers, and enlarged and less defined collagen fibrils in their peripapillary sclera (PPS) revealed by TEM. Interestingly, by AFM we observed lower Young's modulus of cornea in all 3 lines compared to wt. Conversely, $Loxl1^{-/-}$ mice demonstrated higher Young's modulus of PPS than wt did. To investigate such differential biomechanical effects due to LOXL1 absence in the cornea and sclera, we used acetic acid collagen extraction which revealed differential collagen solubility and post-translational modification. Lastly, we also observed the differential influence of aging on collagen crosslinking in cornea and sclera.

Conclusions: The phenotypic and mechanistic investigations of our mouse models demonstrated their potential as an invaluable resource for further understanding and treatment of ocular and systemic manifestations of connective tissue disease.

ABSTRACT BODY:

Purpose: Mean retinal sensitivity (MS) from microperimetry (MP), and ellipsoid zone (EZ) area and central subfield thickness (CST) from optical coherence tomography (OCT) are quantitative measures that provide insight to functional and structural function in inherited retinal degenerations (IRDs). There are few available estimates for their rates of change in IRDs. Here we provide estimates of change over 2 years from the Rate of Progression in USH2A-related Retinal Degeneration (RUSH2A) study based on these measures using mixed effects models.

Methods: In this prospective multicenter study, participants with visual acuity ≥20/80, stable fixation, and kinetic visual field of ≥10° in the study eye had MP and OCT testing at baseline, 1, and 2 years. MP was performed only in centers that had available equipment, while OCT was performed in all participants. Summary measures were MS from MP, and EZ area and CST from OCT. CST values were excluded when intraretinal cystoid spaces were detected. Mixed effects models were used to estimate the annual rates of change and percentage rates of change using log transformed data with 95% confidence intervals (CI). Models were applied to all eyes and to a restricted group of eyes with baseline levels above specific thresholds: >2 dB for MS and >1 mm^2 for OCT EZ area to mitigate floor effects. A model down-weighting outlier rates of change was also applied.

Results: 102 eyes were included. The average decline in MS [N=85] was 0.42 (0.27, 0.57) dB/year (Table 1) or 8.8 (6.2, 11.3)%/year (Table 2) in the entire cohort, and 0.51 (0.32, 0.69) dB/year or 8.8 (6.1, 11.5) %/year in the restricted cohort [N=69]. The average decline in EZ area for the entire cohort [N=100] was 0.11 (0.02, 0.20) mm^2/year or 1.2 (-1.1, 3.6) %/year vs 0.15 (0.03, 0.27) mm^2/year or 0.8 (-1.0, 2.6) %/year in the restricted cohort [N=72]. The decline in CST was 2.05 (1.07, 3.02) µm/year or 0.8 (0.4, 1.2) %/year in the entire cohort [N=63] when no cystoid spaces were detected. Down-weighting outliers reduced the estimated decline of MS and EZ, but not CST, compared to the unadjusted model.

Conclusions: Based on 2 years of follow-up in RUSH2A, estimates of the annual rates of decline in MP and OCT measures were affected by the baseline values of the eyes included in the analysis. Down-weighting outliers reduced the estimated decline of MS and EZ, but not CST.

TITLE: Dual patch-clamp recording of synaptic transmission between morphologically and physiologically characterized cone bipolar cell types and a diffused ganglion cell in wholemount mouse retina

SESSION TITLE: Retinal circuits

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: Y. Xue, S. Lee, J. Zhou, Yale University Department of Ophthalmology and Visual Science, New Haven, Connecticut, UNITED STATES|Y. Xue, Yale University Graduate School of Arts and Sciences, New Haven, Connecticut, UNITED STATES|

Commercial Relationships Disclosure: Yao Xue: Commercial Relationship: Code N (No Commercial Relationship) | Seunghoon Lee: Commercial Relationship: Code N (No Commercial Relationship) | Jimmy Zhou: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: While bipolar cells have been successfully studied with imaging, connectomic, and transcriptomic methods in recent years, the output synaptic physiology and functional circuitry of bipolar cell types remain poorly understood, except in the case of rod bipolar cells. This study is to characterize the physiology and synaptic transmission of identified cone bipolar cell (CBC) types in the mouse retina.

Methods: Patch-clamp recordings were made with two-photon microscopy from various morphological types of CBCs in the wholemount mouse retina. Receptive field properties were characterized using visual stimuli of various sizes and patterns. Dual patch-clamp recording was used to characterized synaptic transmission from CBC types to an ON-OFF small-field ganglion cell (tentatively termed XGC), which was brightly labelled in a transgenic line used.

Results: Receptive-field properties, baseline synaptic inputs, and major voltage-gated currents were characterized for 12 out of the 14 known morphological types of CBCs in the wholemount mouse retina. A catalog was generated to correlate physiological properties with morphological types of CBCs. Almost every CBC type showed distinctive physiological characteristics that distinguished one type from other types of CBCs. When the physiological and morphological features were analyzed together, all CBC types could be unambiguously defined. Dual patch-clamp recordings were then made from pairs of physiologically and morphological identified CBC types and XGCs in the whole-mount retina. Two distinctive kinetic patterns of signal transmission were found, suggesting differential temporal encoding of spatial visual integration. The results revealed an intriguing synaptic organization involving both chemical and electric synapses.

Conclusions: This study correlated distinct receptive-field and intrinsic physiological properties with morphologically identified CBC types and revealed new patterns of synaptic transmission from CBC types to XGCs, which may enhance spatiotemporal encoding of visual information.

TITLE: Assessment of Bifoveality in Adults with Retinal Polarization Scanning

SESSION TITLE: Strabismus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.K. Kulwin, J.M. Holmes, The University of Arizona Department of Ophthalmology and Vision Science, Tucson, Arizona, UNITED STATES|

Commercial Relationships Disclosure: Jeremy Kulwin: Commercial Relationship: Code N (No Commercial Relationship) | Jonathan Holmes: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Simultaneous binocular retinal polarization scanning has been successfully used to distinguish bifoveal fixation from monofixation as a means of screening for amblyopia in children. Although device performance is known to be degraded by spectacles and relies on accommodation (originally designed for screening children), we evaluated the ability of retinal polarization scanning to distinguish bifoveal fixation from monofixation in adults.

Methods: We studied 36 adults, ages 18 to 85y, presenting to an adult strabismus referral clinic. The gold standard for bifoveality was defined as at least 60 seconds of arc (arcsec) on the Randot Preschool stereoacuity test (StereoOptical, Chicago IL) performed at 40cm. Sensory monofixation was defined as 200 arcsec or worse, and indeterminate as 100 arcsec. To minimize potential confounding from poor VA, only subjects with 20/40 or better VA in each eye were included. Retinal polarization scanning was performed using the blinqPro (Rebion, Boston, MA), yielding a binocularity score from 0% to 100%. Analogous to children, we defined bifoveality by retinal polarization as a blinqPro binocularity score of 60% or better. Testing was performed through spectacles if worn. We compared assessments of bifoveality versus monofixation using kappa statistics.

Results: Of 36 adults, 7 (19%) were classified as bifoveal based on Randot Preschool near stereoacuity testing, 8 (22%) as indeterminate and 21 (58%) as monofixational. Only 3 (8%) of subjects were classified as bifoveal by the blinqPro. Agreement in bifoveality, between Randot Preschool and blinqPro was poor (kappa = -0.07, 95% CI -0.20 to 0.06, excluding subjects indeterminate on stereoacuity testing). No adults identified as bifoveal on Randot Preschool testing were identified as bifoveal on blinqPro testing.

Conclusions: In contrast to application of the blinq to children, where it is very useful in screening for amblyopia, the current device does not reliably distinguish bifoveality from monofixation in adults. The blinq manufacturers had already identified limitations in detecting bifoveality in adults; inadequate accommodation, attempting to scan through spectacles where coatings and reflections interfere with the signal, and image degradation from less than clear media. Further modification of methods to identify bifoveality are needed for adults.

ABSTRACT BODY:

Purpose: Modeling of complex, polygenetic and environmentally-modulated diseases such as age-related macular degeneration (AMD) presents the need for a nuanced approach to accurately mimic the disease that is found in humans. To tackle this problem, we mined the BXD family of recombinant inbred lines of mice for polygenetic models of AMD using a systems genetics approach. Our goal is to provide the vision community with one or more spontaneous polygenetic pre-clinical models of AMD.

Methods: Based on the literature, we identified 27 genes associated with human AMD, 11 of which have polymorphisms in the BXD family of mice that are predicted to change the function of the gene product in a similar manner to that predicted in humans. We chose 6 strains of mice with various combinations of the 11 genes with the goal of selecting mice with various presentations of AMD. BXD strains and C57B/6J controls are being aged from 6 to 18 months and are evaluated clinically every three months. Optical coherence tomography (OCT), full field electroretinogram (ERG), funduscopy/fluorescein angiography (FA) and optokinetic nystagmus (OKN) measurements are used to document any pathophysiology. Histological and ultrastructural analyses are being performed upon euthanasia at 18 months.

Results: Here we present preliminary data from our two most promising polygenetic AMD mouse strains. BXD34 presents with functional deficits documented as lessened ERG amplitudes along with reductions in visual acuity and contrast senstitivity by 9 months of age. Subretinal deposits are evident by OCT analyses and ultrastructural analyses reveals marked basal linear and basal laminar deposits. Moreover, there are numerous vesicles filled with debris present in the cytoplasm of the retinal pigment epithelium (RPE). In contrast, BXD38 presents with no functional deficits up to 9 months of age despite the presence of subretinal deposits that were detected using OCT. These strains are continuing to be aged and phenotyped.

Conclusions: Currently, BXD34 exhibits the most similarities to an atrophic AMD-like phenotype by exhibiting drusen-like deposits and both anatomical and physiological declines in retinal health. BXD38 presents with more mild functional deficits coupled with the presence of subretinal deposits. These strains are continuing to be evaluated up to 18 months of age at which time ultrastructural and immunohistochemical analyses will performed.

ABSTRACT BODY:

Purpose: To engineer a micorphysiologic system that more accurately recapitulates the vascularized outer retina suitable for evaluating AMD pathology and development of novel therapeutics.

Methods: A hydrogel library based on poly (ethylene glycol) (PEG), poly-L-lysine (PLL) and poly(allylamine) (PAA) was generated using succinimide and free amine reaction chemistry. Cellular compatibility was evaluated using a rat endothelial cell line and human iPSC-derived choroidal endothelial cells generated via directed differentiation and CD31 magnetic bead immunopanning. Cell health and identity was evaluated using a series of live dead assays and immunofluorescence staining.

Results: A library of 12 synthetic, chemically crosslinked, hydrogels with tunable mechanical and degradation properties were developed. Hydrogels with a lower amine content were found to have superior endothelial cell compatibility. We hypothesize that this is due to the cell surface disrobing characteristics of the polycations presents in the gels. Hydrogels with a higher polycation concentration showed relatively poor endothelial cell compatibility. Gels with optimal compatibility were found to promote endothelial cell spreading, migration, and capillary network-like formation.

Conclusions: In this study novel hydrogels with unique mechanical and degradation properties were generated via chemical crosslinking of PEG, PLL and PAA. Low amine hydrogels were found to be superior for promoting endothelial cell spreading, migration and vascular tube formation. To create in vitro models that more accurately recapitulate the choriocapillaris, optimized hydrogels will be used as a bioink for screen-based printing of rat and human vascular endothelial cells.

ABSTRACT BODY:

Purpose: Amacrine cells (ACs) are the most abundant inhibitory interneurons in the retina yet remain the least understood retinal cell class. The great diversity of ACs has been a major obstacle to access individual cell types for systematic studies. The development of genetic tools that allow for cell type-specific targeting and manipulation would be an important step towards the characterization of AC types. In this study, we aim to use new mouse intersectional genetic tools combined with functional imaging and electrophysiology recording to morphologically and functionally dissect AC circuits.

Methods: We created intersectional strategies by using a combination of Cre and tTA expression to discover new AC types and to target these cells with increased specificity. After that, we focused on a new AC type for functional analysis. We characterized its light response properties by imaging Ca^{2+} responses at the sites of neurotransmitter release, and then identify its post-synaptic RGCs with intersectional ChR2 activation. Finally, we developed a chemogenetic mouse line to inactivate the AC and examine its functional roles in different circuits.

Results: With Slc32a1-iCreER/ CaMK2a-tTA intersectional strategy combined with temporally controlled Cre induction, we discovered a narrow-field AC subtype (named CK2-AC1) in the mouse retina and achieved single AC type targeting. Two-photon Ca^{2+} imaging revealed that CK2-AC1 received synaptic inputs from OFF bipolar cells and responded strongly to local motion but not to global motion. Optogenetic stimulation showed that CK2-AC1 provided glycinergic inputs to several RGC types stratified in the middle of the IPL, such as HD1-RGC and HD2-RGC. Chemogentic inactivation experiments further demonstrated that CK2-AC1 provided suppression to several RGC types during local stimulation and shape the object motion sensitivity (OMS) of these RGCs.

Conclusions: This study introduced a workflow based on Cre/tTA intersectional strategies for systematically analyzing AC types and examining their circuit roles in visual processing. With this workflow, we discovered a new AC type and revealed its functional roles in the OMS circuits. We propose that CK2-AC1, together with other ACs in the OMS circuits, controls the objective motion sensitive signals RGC send to the brain.

Commercial Relationships Disclosure: Assylbek Zhylkibayev: Commercial Relationship: Code N (No Commercial Relationship) | Ritesh Srivastava: Commercial Relationship: Code N (No Commercial Relationship) | Mohammad Athar: Commercial Relationship: Code N (No Commercial Relationship) | Marina Gorbatyuk: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Corneal tissue damage is often associated with exposure to arsenicals, which are highly toxic chemical warfare agents (CWAs), including lewisite (LEW). However, the difficulties associated with accessing the posterior ocular tissues in CWA-affected individuals and the technical challenges of using CWAs in laboratory settings make it necessary to use relatively less toxic arsenicals in eye research. Similar to LEW, phenylarsine oxide (PAO) activates a pro-inflammatory response, oxidative stress, and a cell death program in the lung, liver, and skin tissues. We hypothesized that arsenical exposure results in corneal injury and retinal tissue damage.

Methods: Human corneal epithelial cells (HCEC), keratocytes (HCK), and retinal endothelial cells (HREC) were incubated with 200 nM PAO for 6, 12, and 24 h. Cytokine expression was detected using qRT-PCR. Direct ocular exposure of C57BL/6 mice to PAO was conducted at doses of 5 and 50 µg for 3 min using the patch method. Cytokine gene expression, retinal functional, and histological analyses of PAO-treated mice were performed 1 day and 14 days after exposure using qRT-PCR and ERG, respectively.

Results: Treating human corneal and retinal cells with PAO resulted in a significant elevation of Il-1β (HREC 2.7-fold; HCEC 2-fold), Cox2 (HCK 3.7-fold; HREC 15.5-fold; HCEC 4.6-fold), and Ifn α (HCK 349.3-fold; HREC 11.5-fold; HCEC 33.7-fold). Similar to the in vitro results, the in vivo findings showed that there was a marked increase in cytokine gene expression in both the corneal and retinal tissues of exposed mice. Mice treated with 5 µg PAO per eye showed significant increases in Il-6 (cornea 13-fold; retina 106-fold), Il-1β (cornea 7-fold; retina 22-fold), and Cox2 (cornea 11-fold; retina 109-fold). Mice exposed to 50 µg PAO per eye showed a remarkable elevation of Il-6 (cornea 1,337-fold; retina 134-fold), Il-1β (cornea 1,213-fold; retina 2,705-fold), and Cox2 (cornea 82-fold; retina 80-fold) mRNA. In addition, PAO exposure resulted in diminished scotopic a- and b-wave ERG amplitudes at 2 weeks after exposure.

Conclusions: These findings establish a foundation for future mechanistic ocular toxicity studies of arsenical exposed populations, demonstrating that not only the corneal tissue, but also the retina may be damaged depending on the severity of exposure.

ABSTRACT BODY:

Purpose: Manual measurements of retinal flow deficits (RFDs) in eyes with proliferative diabetic retinopathy (PDR) imaged with widefield swept-source OCT (SS-OCT) were compared with measurements from an automated algorithm.

Methods: In a retrospective review of patients enrolled in a prospective SS-OCT (PLEX® Elite 9000, Carl Zeiss Meditec, Dublin CA) imaging study, a consecutive case series of eyes with PDR were imaged using a foveal-centered 12x12mm scan pattern underwent manual segmentation of areas with RFDs. Total retinal vasculature slabs were used for analysis of RFDs. A previously published algorithm was used to assess RFDs by converting a 2-dimensional en face SS-OCTA image to a vessel binary image using MATLAB. The areas of RFDs identified using the manual and automated methods were compared.

Results: A total of 19 eyes with PDR from 15 patients over 62 visits were compared. All scans were evaluated. The average RFD area measurements were not significantly different between manual (16.72 ± 17.27 mm^2) and algorithm (17.64 ± 15.33 mm^2) (p=0.15). 75% of the manual and algorithm measurements were within 5 mm^2 of each other, with total measurements ranging from 0-80 mm^2. There was also no significant difference between areas of RFDs detected only by the manual approach (5.14 ± 3.94 mm^2) compared with the algorithm approach (6.06 ± 3.91 mm^2; p=0.15). Examples of the scans and RFD outlines are shown in Fig. 1.

Conclusions: On average, the two techniques yielded similar results for total RFD area measurements with no disparity in areas detected by only one technique. This suggests that the automated approach might be useful for grading and monitoring RFDs in eyes with PDR.

ABSTRACT BODY:

Purpose: The topography of rod and cone photoreceptor cells shapes the patterns of outer retinal loss observed in progressive cone-rod and rod-cone dystrophies. To better understand these diseases, we modeled the OCTs observed in progressive photoreceptor degenerations by simulating differential survival of rod and cone cells.

Methods: We assumed that the thickness of the outer retina is proportional to the topographic composition of living rod and cone photoreceptor cells. Consequently, the death of rods or cones will reduce the thickness of the outer retina proportionally to the baseline composition of these cells. By definition, 100% of rods and 100% of cones survive in eyes unaffected by disease. Using this framework, we imaged the maculas of an unaffected control using a Heidelberg Spectralis OCT, segmented the retinal layers using the Iowa Reference Algorithms, and located the fovea and the optic nerve within these volumes. We registered these volumes to published densities of photoreceptor cells (Curcio et al. J Comp Neurol 1990), interpolated the cell densities at every A-scan, and computed the expected proportion of rod and cone photoreceptor cells at every A-scan. To simulate the death of photoreceptor cells, we reduced the thicknesses of the outer retinal layers as a function of the contribution of rods and cones, reconstructed the segmentation, and resampled the voxels within each layer.

Results: When more cones are lost than rods, our model reproduces the basic pattern of a cone-rod dystrophy, such as autosomal recessive Stargardt disease. When more rods are lost than cones, our model reproduces the basic pattern of a rod-cone dystrophy, such as USH2A-associated retinitis pigmentosa. Users can explore the interactive model at https://observablehq.com/@barefootbiology/simulating-rod-and-cone-loss.

Conclusions: Clinicians can infer the approximate proportions of surviving rods and cones by comparing the simulated output to B-scans of actual patients. Computational biologists can use the model to communicate with clinicians by translating mathematical models of cell survival into the visual idiom of the clinic.

ABSTRACT BODY:

Purpose: To extract vascular features in the superficial (SVC) and deep (DVC) vascular complex using optical coherence tomography angiography (OCTA), and to compare them among subjects with mild to moderate diabetic retinopathy without macular edema (DR), diabetics without retinopathy (DnoR), and normal controls (NRL)

Methods: En face OCTA images of the SVC and DVC were generated after scanning the 3 × 3 mm^2 macular regions. Twenty subjects were imaged, including 5 NRL, 10 DnoR, and 5 DR, and only the right eye was included in the analysis. The quantification defines the region of interests (ROIs) as 45° equal-area sectors namely NS, SN, ST, TS, TI, IT, IN, and NI (N = nasal, S = superior, T = temporal, I = inferior), in addition to the whole circular zone centered at the macula. The microvascular morphologic features were analyzed using fractal dimension (FD) and vascular orientation pattern curve (Ma et al, Sci Rep, 2021). FD is a metric to characterize global vessel anatomical complexity. Vascular orientation pattern captures local variations in the vessel orientation ranging from 0 to 180°, and the area under the curve indicates the vessel area density (VAD). An analysis of variance (ANOVA) and post hoc Tukey's test was performed to detect the difference in FD and VAD in each ROI among the three groups.

Results: For the whole macular zone, significant differences in FD and VAD were observed between NRL and DR (Fig1). Different sectoral ROIs exhibited different abilities to differentiate DR from the other two groups. Sector ST showed no difference among the three groups in FD nor VAD, although n is too low to be conclusive; whereas sector IN showed significant difference not only between NRL and DR, but also between DnoR and NRL in VAD (p=0.0060 for SVC; p=0.0225 for DVC), and between DnoR and DR in FD (p=0.0033 for SVC; p=0.0401 for DVC). In addition, the vascular orientation pattern in DR shows greater difference from NRL or DnoR in sector IN than in the whole macular zone (Fig2).

Conclusions: Retinal vascular features were extracted from OCTA images for multi-dimensional quantification using layer- and sector-based ROIs. DR-associated microvascular deterioration is not uniform in all sectors. Sector IN detected the microvascular difference between DnoR and DR, and its sectoral analysis holds promise for DR detection at the earliest stage.

ABSTRACT BODY:

Purpose: Studies suggest delayed rod-mediated dark adaptation (DA) is a diagnostic indicator of age-related macular degeneration (AMD). We assessed if DA differences (estimated by rod-intercept time [RIT]) are more discernible between AMD severity grades using an OCT-based criteria (including subretinal drusenoid deposit [SDD] presence) over a Colour Fundus Photography (CFP)-based classification.

Methods: Data was acquired from two related cross-sectional population based studies - Northern Ireland Sensory Aging studies (NISA;NISA-2). Participants with RIT data (AdaptDx [Maculogix,USA]) and both CFP (Canon CX-1 Digital Fundus Camera [Canon,USA]) and spectral domain OCT (SD-OCT;Heidelberg Spectralis SD-OCT [Heidelberg Engineering, Germany]) images were used. SDD presence was identified and images graded by Beckman and OCT-based classifications. Age-corrected time-to-event analysis assessed the magnitude of differences in RIT and plotted using Kaplan Meier curves (Fig 1).

Results: 459 eyes (mean [standard deviation; SD] age 66[8] years) were stratified into Beckman0-3 and then OCT0-2. Uncorrected mean(SD) RIT for Beckman groups was 7.5(5.3), 8.0(4.3), 7.3(4.7) and 15.6(11.9) mins, respectively. Uncorrected mean(SD) RIT for OCT groups appeared more distinct between gradings: 7.4(5.5), 10.0(7.2) and 15.3(21.0) mins respectively. After age-correcting, eyes in B3 had statistically significantly worse average RITs compared to the other groups (B0-2; p=<0.005 all) but there were no differences in RIT between the other Beckman groups. Eyes in OCT2 had worse RITs compared to controls (OCT0) (p=<0.001) and eyes in OCT1 (p=0.009). No statistically significant difference was found between OCT0 and OCT1 (p=0.195). SDD presence significantly worsened RIT within OCT2 (p=0.002) but not within OCT1 (p=0.285). In OCT0 the presence of SDDs gave better RIT values(p=0.012).

Conclusions: There is some evidence of differences in RIT being more apparent between AMD severity grades using an OCT-based rather than a CFP-based classification, but differences were less clear once corrected for age. OCT classifications including SDDs, may be useful for clinical trials in AMD. A highlight of our enriched population study is a uniquely large SDD sample (n=109) not regularly reported in recent DA research.

ABSTRACT BODY:

Purpose: Artificial intelligence (AI) methods have become an indispensable part of ophthalmology in recent years. A variety of AI methods are available to analyze visual fields (VFs) and to detect or predict vision loss progression. Nearly all of the recent deep learning VF models have been implemented in the Python language, which provides numerous readily available algorithms and techniques for this purpose. At the same time, the vast majority of VF analytic tools have been implemented in the R language. Here, we aim to bridge this gap by providing a Python-wrapped package to make numerous previously developed R libraries and functions for VF analysis available in the Python language.

Methods: In a first step, we analyzed existing R libraries for visual fields, most notably the vfprogression [1] and the visualFields [2] libraries for overlaps as well as distinct functionality. Based on this, we conceptualized a Python package combining the functionality of the existing R libraries and harmonizing their data structures. Finally, with help of the wrapper library rpy2, we translated this functionality and the according data structures into Python.

Results: The developed Python package is available as open-source software at the GitHub repository: https://github.com/mohaEs/PyVisualField. In the same repository, we demonstrate the capabilities of the new Python package in the categories of presenting data, plotting, scoring and progression as well as normalization analysis. For each category, we provide function descriptions and examples and the function output in Jupyter notebooks. Fig. 1 shows examples of demonstration from the functionality from the original vfprogression R library and, analogously, Fig. 2 shows examples from the visualFields R library.

Conclusions: To make the considerable VF analysis functionality of existing R libraries available to the Python AI community, we developed a Python package and demonstrate its functionality to support ophthalmic researchers in VF statistical analysis, plotting, and progression prediction.

ABSTRACT BODY:

Purpose: Macular telangiectasia type II (MacTel) is a late onset macular disease leading to progressive vision loss. Previous work determined that low circulating levels of serine in MacTel patients is associated with retinal dysfunction. Whole exome sequencing studies found that rare variants in PHGDH, the rate limiting enzyme in serine synthesis, account for a significant fraction of the disease. The purpose of this study was to determine the potential impact of reduced PHGDH function on retinal health.

Methods: To test the rate of serine and glycine biosynthesis in the retina, as well as uptake of these amino acids from the circulation, we used heavy carbon (C^{13}) labeled glucose, serine or glycine coupled with mass spectrometry. To determine the consequences of reduced PHGDH activity on retinal health we used mice heterozygous for PHGDH and monitored their retinal function and metabolite levels.

Results: We determined that the neural retina and RPE/choroid exhibit high de novo serine synthesis, comparable to that in the brain. Additionally, a large portion of retinal serine originates in the circulation. Mice with reduced PHGDH function have altered circulating, retinal and RPE metabolite levels. Electroretinogram (ERG) measurements in mice indicate visual impairment with reduced PHGDH activity.

Conclusions: The high rate of serine biosynthesis, as well as uptake from the circulation, suggests that the serine pool in the retina is highly dynamic. Variants in PHGDH that impair enzyme function, as observed in a subset MacTel patients, are sufficient to generate metabolite defects and drive retinal dysfunction.

ABSTRACT BODY:

Purpose: T cell costimulation has been implicated in the pathogenesis of autoimmune uveitis. Acazicolcept (ALPN-101) is an Fc fusion protein of the human inducible T cell costimulator ligand (ICOSL) and a variant immunoglobulin domain (vIgD™) designed to inhibit the CD28 and ICOS T cell costimulatory pathways. Here we evaluate the efficacy of systemic administration of acazicolcept in experimental autoimmune uveitis (EAU).

Methods: EAU was induced on Study Day 0 (SD0) in female Lewis rats using IRBP peptide R16 in complete Freund's adjuvant. Rats were treated with acazicolcept (100 mg/kg), an Fc control protein (50 mg/kg), or triamcinolone acetonide (0.8 mg/kg) once by subcutaneous injection on SD7. Masked clinical scores, body weights, and ocular histologies were assessed through SD14. Aqueous and intraocular contents collected on SD14 were analyzed by multiplex cytokine analysis and flow cytometry.

Results: Compared to Fc control, acazicolcept significantly reduced the number of eye-infiltrating CD45+ cells and IL-17A+ and IFNγ+ CD3+ T cells and tended to decrease intraocular aqueous cytokines including leptin, IL-1β, RANTES, IFNγ, IL-17A, VEGF, CXCL5, and IP-10, as effectively as steroid treatment (though not always statistically significantly). From SD10-13, Fc control-treated rats demonstrated a significantly higher average masked clinical score than the steroid or acazicolcept-treated groups (AUC, $p<0.01$). Histology scores of eyes from steroid- (4.7 ± 4.9, $p<0.05$) or acazicolcept-treated rats (4.2 ± 5.2, $p<0.05$) were also significantly lower than Fc-treated rats (19.1 ± 10.39) on SD14. Steroid-treated animals lost a significant amount of body weight during treatment between SD7-14, as compared to acazicolcept- ($p=0.0003$) or Fc control-treated ($p=0.0071$) animals.

Conclusions: Systemic treatment with acazicolcept significantly suppresses EAU in rats, as evidenced by reduced clinical and histological scores, and correlated with reduced eye-infiltrating IL-17A+ and IFNγ+ T cells. Acazicolcept was well-tolerated without the weight loss induced by steroid treatment. Due to species- and disease-related differences, the dose regimen used in this study is not predictive of the effective dose in humans. However, these data suggest acazicolcept may be a safe and effective alternative to corticosteroids for use in treatment of autoimmune uveitis.

ABSTRACT BODY:

Purpose: Ocular pathologies are understudied sequelae of multiple sclerosis (MS) and other autoimmune diseases. Current treatments are expensive, highly immunosuppressive drugs that increase infections and cause other adverse effects but are only partially efficacious. The goal of this study was to test the hypothesis that a well-formulated ketogenic diet (WF-KD) can reduce optic neuritis and preserve vision in a mouse model of MS called experimental autoimmune encephalomyelitis (EAE).

Methods: Male and female C57BL/6J mice were fed the WF-KD (77.1% fat, 22.4% protein, 0.5% carbohydrate) or a nutrient-matched control diet (10.4% fat, 20.4% protein, 69.3% carbohydrate) and 2 weeks later immunized with a myelin oligodendrocyte glycoprotein peptide antigen to induce EAE. Motor deficits, visual acuity, as well as glucose and ketone levels in blood were measured longitudinally. Post-mortem, retinal ganglion cells (RGCs) were quantified and splenocytes were immuno-profiled. Circulating cytokines and fatty acid content were also analyzed.

Results: Unlike obesogenic western diets containing pro-inflammatory fats and high carbohydrate content, EAE mice fed a WF-KD did not gain weight. The WF-KD conferred resistance to EAE motor deficits and preserved RGCs and visual acuity. Analysis of plasma showed that the WF-KD decreased circulating C-reactive protein and proinflammatory cytokines, reduced pro-inflammatory omega-6 fatty acids (e.g., arachidonic acid), and increased anti-inflammatory omega-3 fatty acids.

Conclusions: These findings demonstrate that a diet enriched in healthy fats and restricted for carbohydrates promotes a systemic anti-inflammatory milieu that mitigates autoimmune-induced visual and motor deficits, further supporting ongoing clinical trials testing this dietary strategy to treat MS patients.

ABSTRACT BODY:

Purpose: The choroid plays a crucial role in the health and function of the outer retinal layers, yet little is known about the impact of perinatal systemic health factors on its development. There is some evidence that suggest hyperoxia is associated with a thinner choroid in preterm infants. We hypothesize that higher oxygen support during the intensive care period is associated with a thinner subfoveal choroid in preterm infants.

Methods: Preterm infants were imaged using handheld swept-source optical coherence tomography (SS-OCT) as a part of the prospective, observational, IRB approved BabySTEPS (STudy of Eye imaging in Premature infantS) clinical study. Choroidal thickness (SFCT) was measured across the central 1mm at 36±1 weeks postmenstrual age (PMA) and averaged between eyes. Highest, mean, and lowest oxygen saturation (SpO2) and fraction of inspired oxygen (FiO2) values in a 24 hour interval on day of ROP screening at 31±1 and 36±1 weeks PMA were recorded and correlated with SFCT at 36±1 weeks PMA. For statistical analysis, FiO2 and SpO2 were categorized with low FiO2 binned as room air equivalent “FiO2=21%” or requiring extra support “FiO2>21%.”

Results: Mean (+/- standard deviation) SFCT was 199.4 ± 64.7 μm from 53 eyes (27 infants) at 36 weeks PMA. After univariable analysis, infants with higher FiO2 need (lowest value in 24 hours; FiO2=21% vs FiO2>21%) at 31 and 36 weeks PMA had a thinner choroid at 36 weeks (31 weeks: 205.9±12.5 vs 126.4±2.6 μm; 36 weeks:201.3±12.8 vs 162.2±3.7 μm, p=0.003 for all). SpO2 and other FiO2 measures at 31 and 36 weeks PMA were not associated with SFCT or could not be correlated due to limited sample size. Higher FiO2 need (lowest value) remained significant in the multivariable analysis at both 31 weeks and 36 weeks PMA (p=0.001 and p=0.002 respectively).

Conclusions: Preterm infants requiring higher levels of oxygen support, reflected by increased FiO2 needs at both 31 and 36 weeks PMA, had thinner subfoveal choroid measurements at 36 weeks. Understanding how higher FiO2 exposures effect the developing choroid and influence choroidal thickness measurements could help explain poorer visual outcomes in preterm infants with a thinner choroid. Further investigations are necessary.

ABSTRACT BODY:

Purpose: Progressive photoreceptor loss and resultant thinning of the outer nuclear layer (ONL) is an important feature of age-related macular degeneration (AMD). However, ONL thickness measurements cannot be obtained clinically in standard optical coherence tomography (OCT) because of the oblique-orientation of the Henle's fiber layer (HFL). This observational study uses a novel volumetric directional OCT (VD-OCT) prototype, and a custom spoke-circular scanning pattern to clearly differentiate the two layers over the entire macular area with a single OCT volume.

Methods: Previously, we discovered that imaging the retina at an oblique angle can provide better contrast to differentiate the HFL and ONL. However, measuring the thickness of ONL and HFL over the entire macular required acquisition of OCT volumes at several different pupil entry positions, which is only possible with high level of patient cooperation and complex image processing. In this study, we built a novel OCT prototype that incorporates two sets of optical scanners in the sample arm to synchronously scan the imaging beam on both the pupil and retina. By synchronization of the two scanners, we can precisely control the OCT beam entry positions and maintain optimum beam incident angles on the retina to generate sufficient optical contrast for the HFL over the entire macular area.

Results: Five healthy adult volunteers were imaged upon dilation with the VD-OCT prototype for about five minutes in this study. The thickness of the true ONL can be assessed objectively on the cross-sectional scans acquired from the VD-OCT prototype (Fig. 1(a-c)). The volumetric ONL thickness heat maps can be calculated and plotted as demonstrated in Fig. 1(d) (spoke-circular scanning pattern) and Fig. 1(e) (regular spoke scanning pattern). The global and local ONL thickness variations are apparent in comparison with the heat maps: HFL became hyper-reflective in the macular region with the spoke-circular scanning pattern.

Conclusions: VD-OCT was used to visualize the otherwise invisible HFL with the aid of synchronous imaging beam scanning at both the retina and pupil planes. The VD-OCT prototype provides sufficient contrast to delineate the directionally reflective HFL tissue over the macular volume. True ONL thickness can be measured for the characterization of photoreceptor loss and its consequent thinning of the tissue.

ABSTRACT BODY:

Purpose: The corneal endothelium plays an important role in maintaining corneal health and transparency. Glaucoma is a widely prevalent disease which can be managed medically, surgically, and/or with laser treatment, yet the effects of glaucoma treatments on the corneal endothelium is unknown. We performed a retrospective, observational clinical study to describe the characteristics of the corneal endothelium of glaucomatous eyes by specular microscopy. Our goal was to compare the health of the corneal endothelium of glaucomatous eyes treated with various treatment modalities.

Methods: The central cornea of 121 eyes consisting of normal control and glaucoma-affected eyes were imaged using the Konan NSP-9900 specular microscope. Any eyes with corneal pathology (other than dry eye disease), keratoplasty, or cataract or glaucoma surgery within the past 6 months were excluded. Glaucomatous eyes were divided into those treated by topical medication only, or those who received two or more treatment types: glaucoma drops, laser, or incisional surgery. The Konan CellChek software was used to perform analysis of endothelial cell density (ECD).

Results: The mean ECD was significantly decreased in glaucomatous eyes compared to normal control eyes ($p<0.001$). Glaucomatous eyes treated with topical medication had lower average ECD compared to controls. A one-way ANOVA performed comparing the ECD of control, medically treated, and eyes that received 2 or more treatment types showed a statistically significant difference between groups ($p<0.0005$). Glaucomatous eyes that had undergone 2 or more treatment types (laser, surgery, and medication) had a significantly decreased ECD compared to those which received medication alone ($p<0.05$).

Conclusions: Eyes with glaucoma, particularly those receiving 2 or more treatments, have a lower corneal ECD than controls. Lower ECD suggests that corneal endothelial cell loss is associated with glaucoma treatment and/or the disease process itself. Eyes that had undergone multiple treatments had significantly lower ECD than eyes treated with medication alone, indicating that cell loss in the corneal endothelium likely increases with additional glaucoma treatments. Further studies are needed to explore the underlying mechanism for this decrease in corneal endothelial cell density in patients with glaucoma, and to characterize which treatments have the most impact on the health of the corneal endothelium.

ABSTRACT BODY:

Purpose: Apurinic/apyrimidinic endonuclease 1/reduction-oxidation factor 1 (APE1/Ref-1) is both a DNA repair enzyme and a redox (reduction-oxidation) signaling protein. We have identified Ref-1 as a potential therapeutic target for neovascular age-related macular degeneration (nvAMD) and other neovascular eye diseases; Ref-1 inhibitor APX3330 is currently in Phase II trials for diabetic retinopathy. Ref-1's redox-sensitive transcription activation modulates angiogenesis and inflammation as it stimulates transcription factors including HIF1-α, NF-κB, and STAT3. We previously showed that inhibiting Ref-1's redox function reduces angiogenesis in vitro and in murine laser-induced choroidal neovascularization (L-CNV). This study aimed to analyze Ref-1 expression during the progression of L-CNV in mice and in human nvAMD and control eyes.

Methods: L-CNV was induced in 7-week old, wild-type female C57BL/6J mouse eyes to simulate features of nvAMD, and eyes harvested at 1, 3, 5, 7, 10, and 14 days after laser treatment. De-identified paraffin sections of human nvAMD and age-matched control patients were acquired from the National Disease Research Interchange (NDRI). Ref-1 expression was analyzed by confocal microscopy on immunostained retinal and choroidal flat-mounts and frozen cryosections from mouse eyes, and on human nvAMD vs control sections.

Results: In L-CNV, Ref-1 was highly expressed in and around the lesions, especially soon after the laser treatment on days 1, 3, and 5. The higher expression of Ref-1 was seen in the ganglion cell layer, inner and outer nuclear layers, inner and outer segments of photoreceptors in the retina and in the retinal pigment epithelium (RPE)/choroid. Expression was lower in lesions at later time points on days 7, 10, and 14. The human eye immunostaining showed that Ref-1 is predominantly highly expressed in the RPE layer in nvAMD compared to healthy eyes.

Conclusions: High expression of Ref-1 in L-CNV mice eyes at different time points and in the eyes of human nvAMD patients further supports a functional role of Ref-1 in CNV. Overall, this study provides further insight into the importance of Ref-1 for nvAMD pathogenesis and highlights the potential of this novel drug target for nvAMD.

ABSTRACT BODY:

Purpose: Quantitative and qualitative fundus autofluorescence (FAF) analysis strongly depends on the clearness of the optical media. Especially the lens status is crucial in FAF imaging since the aging lens has both light blocking and AF properties that impact and distort image analysis. Here, we report both lens opacification and lens autofluorescence (LAF) to aid the development of a lens correction factor for adequate FAF analysis.

Methods: Seventy-four subjects (18-95 years, mean of 9.2 +/- 4.1 per decade, 28 females) received quantitative LAF (using laser scanning ophthalmoscope), Scheimpflug, as well as blue FAF, green FAF, and infrared (IR) imaging. LAF values were determined following the protocol as recently proposed (PMID: 28973367). The Pentacam nucleus staging (PNS) score was extracted from Scheimpflug images to estimate lens opacification. Mean opinion scores (MOS) of FAF and IR image quality (focus, illumination, symmetry, zoom, centering) were compiled by two medical readers. Linear regression analyses between PNS/LAF and age were calculated, and the coefficient of determination (r^2) was reported. Finally, a Pearson's correlation coefficient (r) between PNS/LAF and the respective MOS was determined.

Results: Mean LAF for the third and seventh life decade were 4.2 +/- 2.1 and 13.5 +/- 7.2 [a.u]. Both PNS and LAF showed a significant age-dependent increase ($p < 0.01$) with an r^2 of 0.28/0.38. LAF was associated with a significantly reduced MOS ($p=0.04$) only for blue FAF with an r of 0.2. Similarly, PNS was associated with a reduced MOS ($p= 0.02$) for blue FAF with an r of 0.3.

Conclusions: Age only explained a limited fraction of the variability in both lenticular autofluorescence and opacification. Retinal image quality, especially in the shorter wavelengths, deteriorated slightly with lenticular remodeling. These results question the current practice of simple age-based opacification correction in quantitative FAF imaging. Individualized measures of lens remodeling have the potential to characterize the influence of the optical media more precisely. We propose LAF and PNS as novel methods to correct for lenticular autofluorescence and opacification.

ABSTRACT BODY:

Purpose: Adaptive optics (AO) has enabled visualizing cellular structure in the retina, yet its clinical usability has been hampered by small field-of-view and bulkiness of instrumentation. We developed a compact imaging system with a multiscale optical architecture that delivers large views of the retina as well as highly-magnified AO-corrected images. This study explored imaging performance in human eyes.

Methods: The prototype included three imaging modalities: confocal scanning laser ophthalmoscopy (SLO) based on 786 nm super-luminescent diode scanned at 8 kHz, optical coherence tomography (OCT) based on a 1050 nm swept-source at 200 kHz, and OCT angiography (OCTA). Each modality could be operated with a field-of-view of either 40 x 30 deg or 4 x 3 deg. In the latter case, ocular wavefront aberrations were corrected by AO operating in closed loop at 13 Hz. During OCT/OCTA examinations, head and eye movements were compensated by automated pupil and retinal tracking at 100 Hz. The ability to visualize microscopic retinal structure was experimented in 35 healthy volunteers and 39 patients affected by various fundus pathologies, including diabetic retinopathy, age-related macular degeneration and inherited retinal dystrophies.

Results: The overall dimensions of the system were 49 x 50 x 50 cm. Large-field SLO and OCT provided quick overviews of the retina while both AOSLO and AOOCT enabled the visualization of parafoveal cone cells, nerve fiber bundles, capillaries, and microscopic lesions. Multiple-averaged AOOCT B-scans revealed Müller-cell-like structures. AOOCTA could image capillaries and choriocapillaris with minimal shadowing artifacts. In pathological cases, AOSLO showed the distribution and lateral extent of microscopic lesions like micro-aneurisms, micro-exudates, atrophic region borders, pigment clusters, and photoreceptor losses. AOOCT scans completed these observations with information on depth location and axial extent of these alterations.

Conclusions: The multimodal multiscale imaging architecture enabled in-depth retinal examinations through a straightforward process: 1) acquire an overview image, 2) identify regions of interest, 3) examine these regions with near-histology 3-D resolution. When confirmed by further investigations, this technology should offer new possibilities for retinal phenotyping and clinical research in new therapies.

ABSTRACT BODY:

Purpose: We previously established that Ossabaw mini pigs exposed to the western diet develop the metabolic syndrome (MetS) and acquire type 2 diabetes (T2DM), resembling the human phenotype. In this study, we sought to elucidate the structural and histological characteristics of the Ossabaw pig retina.

Methods: Six-month-old Ossabaw pigs were fed on a western diet for six weeks. At the end of the study, blood profiling was performed to confirm type 2 diabetes and metabolic syndrome. The retina was dissected and cryosectioned for light microscopy and immunohistochemistry. Retinal sections were immunostained using specific antibodies for ganglion cells, synapses, bipolar cells, and retinal photoreceptors and imaged on a confocal microscope.

Results: The Ossabaw mini pigs had elevated fasting blood glucose concentrations and dyslipidemia. Ossabaw pig retinas showed disrupted cellular architecture across neural layers, with numerous large vacuoles seen in the inner nuclear layer's cell bodies and the ganglion cell layer. The immunostained retina showed degenerative neuronal cells and loss of synapses that are vital to retinal function.

Conclusions: The present study described the early degenerative and neuronal changes in the retina caused by the western diet-induced metabolic abnormalities in the Ossabaw mini pigs.

TITLE: Pain following cataract surgery is impacted by objective and patient perceived surgical duration

SESSION TITLE: Cataract surgery II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Lemdani, H. Choudhry, A. Patel, M. Jaffry, M. Dastjerdi, Rutgers New Jersey Medical School, Newark, New Jersey, UNITED STATES|

Commercial Relationships Disclosure: Mehdi Lemdani: Commercial Relationship: Code N (No Commercial Relationship) | Hassaam Choudhry: Commercial Relationship: Code N (No Commercial Relationship) | Aman Patel: Commercial Relationship: Code N (No Commercial Relationship) | Mustafa Jaffry: Commercial Relationship: Code N (No Commercial Relationship) | Mohammad Dastjerdi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Previous research suggesting some agreement between patients' perceived duration (PSD) of cataract surgery (CS) and objective duration (OSD) also explored the pain perception. We performed retrospective data analysis to explore the relationship between a patient's perception of pain following CS.

Methods: Retrospective data analysis was carried out on data published in the Dryad database and collected CS cases between 17 May 2011 and 22 July 2011 in the Department of Ophthalmology of Hôpital Cochin, a teaching university hospital located in Paris, France. Multivariate regression analysis was also run to assess significant associations of various factors, including age, gender, operative duration, and complication rate, with both objective and patient percieved duration of cataract surgery.

Results: 356 total cases were collected between 17 May 2011 and 22 July 2011 in the Department of Ophthalmology of Hôpital Cochin. 151 patients were male and 205 were female. In males, OSD and PSD significantly predicted the pain level perceived, with each minute in objective and percieved surgery duration corresponding with increases in log odds of .082 (95% CI .022 to .141, p=.007) and .064 (95% CI .012 to .115, p=.016). In females, only PSD significantly predicted pain, with each minute corresponding to .49 increase in experienced pain level (95% CI .008 to .090, p=.020). Age groups were stratified into <60, >=60 and <69, >=69 and <79, and >=79. In the youngest age stratification for each minute of OSD there was a predicted increase of 0.64 in experienced level of pain (95% CI 0.16 to 1.12, p=0.009*). However for every minute in PSD, there was a predicted decrease of 0.25 in the experienced pain level (95% CI -0.49 to -0.01, p=0.039). In ages >=60 and <69 and >=69 and <79 , each minute of PSD corresponded to an increase of .10 (95% CI 0.02 to 0.18, p=.019) and 0.06 (95% CI 0 to 0.11, p=.036) in experienced pain level. In the oldest age group, only an increase in OSD significantly predicted patient perceived pain, where each minute corresponded to an increase of 0.12 in experienced pain level (95% CI 0.04 to 0.20, p=.003).

Conclusions: These findings suggest variation in OSD and PSD impact on pain across age groups and gender. However, our study also suggests that OSD and PSD are more likely to predict patient perceived pain than other factors such as postoperative complications.

ABSTRACT BODY:

Purpose: The mechanisms underlying retinal ganglion cell (RGC) vulnerability and dysfunction in glaucoma are poorly understood. Here, we used two-photon laser scanning microscopy to investigate alterations in real-time light-evoked RGC calcium (Ca^{2+}) responses during ocular hypertension (OHT) damage.

Methods: Transgenic mice carrying the Ca^{2+} indicator GCaMP6f (Thy1.GCaMP6f) received an intracameral injection of magnetic microbeads to induce OHT. Two weeks following induction, prior to cell loss, retinae were two-photon imaged through the sclera of anesthetized mice or acutely dissected for ex vivo imaging. Next, ROIs were drawn on response movies using ImageJ or using suite2p to extract RGC signals and custom code (Rstudio/MATLAB) used to compute: i) rise time, ii) decay time, iii) amplitude, and iv) ON-OFF index, which indicates ON-OFF preference. For ex vivo recordings, computational methods (PCA/UMAP) were used to divide sham data into 7 functionally defined RGC types. Student's t-test or ANOVA methods were applied to detect significant differences (significance: $P \leq 0.05$).

Results: In vivo and ex vivo RGC Ca^{2+} transients were significantly altered and showed abnormalities consistent with a change in Ca^{2+} clearance in the mouse glaucoma model. Specifically, trans-scleral imaging showed a several-fold increase in Ca^{2+} decay time in ON RGC (sham: 0.93 ± 0.09 sec, OHT: 3.53 ± 0.57 sec, N=7-8 mice/group, n=74-89 cells/group, $p<0.01$) and Ca^{2+} rise time in OFF RGC (sham: 2.92± 0.42 sec, OHT: 6.60 ± 1.19 sec, N=4 mice/group, n=8-14 cells/group, $p<0.05$) leading to sustained Ca^{2+} accumulation. Data obtained with explant imaging were consistent and showed an increase in mean Ca^{2+} decay time for OHT RGC (sham: 0.97± 0.058 sec, OHT: 1.85± 0.197 sec, N>5 mice/group, n>400 RGC/group, $p<0.05$). We also observed a decrease in the proportion of OFF-RGCs as seen by a shift in the mean of the ON-OFF index (Sham: -0.05 ± .015 ON-OFF index, OHT: +0.03 ± .012 ON-OFF index).

Conclusions: Our study reveals major alterations in light-evoked RGC Ca^{2+} dynamics under OHT conditions, notably abnormal Ca^{2+} clearance. These findings suggest significant defects in the mechanisms that regulate Ca^{2+} efflux which can lead to RGC dysfunction and increased vulnerability in glaucoma.

TITLE: Interphotoreceptor matrix proteoglycans IMPG1 and IMPG2 undergoes intramolecular proteolysis and reveal localization interdependency

SESSION TITLE: Photoreceptor Biology, Protection and Degeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E.M. SALIDO, C. Coulter, B. Mitchell, Biochemistry, and Ophthalmology and Visual Sciences, West Virginia University, Morgantown, West Virginia, UNITED STATES|

Commercial Relationships Disclosure: EZEQUIEL SALIDO: Commercial Relationship: Code N (No Commercial Relationship) | Chloe Coulter: Commercial Relationship: Code N (No Commercial Relationship) | Benjamin Mitchell: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The interphotoreceptor matrix (IPM) is a specialized extracellular matrix that surrounds the photoreceptors inner and outer segments. Two major constitutes of the IPM are the interphotoreceptor matrix proteoglycan 1 and 2 (IMPG1 and IMPG2). Both proteoglycans possess SEA domains (Sperm protein, Enterokinase and Agrin) which are linked to self-cleave intramolecular proteolysis in proteoglycans. Mutations in the SEA domains of IMPG1 and IMPG2 are associated with vision loss. This work studies the possible proteolysis of IMPG1 and IMPG2 and its relevance to vision physiology

Methods: We used protein alignment computational tools, and classical Wester blot and immunohistochemistry techniques

Results: The amino acid sequence alignment of IMPG1 and IMPG2 against established proteolytic sequences predicted that one of the two SEA domains on both proteins are likely to undergo proteolysis. Western blot analysis of IMPG1 confirmed protein proteolysis independently of IMPG2 presence. On the other hand, western blot and immunohistochemical analysis confirmed IMPG2 proteolysis involving the generation of two IMPG2 subunits, a membrane attached and a free extracellular peptide. These experiments revealed that the extracellular portion of IMPG2 migrates from the IPM inner segment to the IPM outer segment by a mechanism dependent on IMPG1.

Conclusions: Overall, this work demonstrates that IMPG1 and IMPG2 proteolyzed as part of their maturation process and revealed the IPM outer segment localization of the extracellular portion of IMPG2.

ABSTRACT BODY:

Purpose: Small bistratified ganglion cells are proposed to carry S-ON signals required for color vision. However, to the contrary, the ON signals from cones to bipolar cells including S-cone bipolar cell input to small bistratified cells are interrupted in patients with mutations in the gene encoding mGluR6 yet they have normal color vision and cone vision is little disturbed in general (Dryja et al. 2005, PNAS, 102, p. 4884). This suggests that there is a second principle ON pathway whereby signals including those involved in conscious color vision are relayed to bipolar cells. To begin testing the hypothesis that it's based on GABA mediated feedforward via horizontal cells, we have used an ex vivo ERG system in mice which allows recording of signals transretinally in the presence and absence of GABA antagonists.

Methods: Pieces of mouse retina from defined locations were placed in an ex vivo ERG chamber and perfused with Ames' solution at 37°C. ERG responses were recorded transretinally to on-off stimuli. Light arriving from the photoreceptor side was from a Gooch & Housego OL 490 Agile Light Source that has an incorporated diffraction grating and Digital Light Processor; it was controlled by custom ERG hardware and software to deliver programmable spectral output capable of producing cone isolating stimuli and narrowband lights for measuring spectral sensitivity functions.

Results: High signal-to-noise ratio responses could be recorded for several hours from a single preparation. We compared responses before and after application of the glutamate agonist, L-AP4, and GABA antagonists, gabazine and TPMPA; recordings before and after washout of the drugs were reproducible. ERG waveforms in the presence of gabazine and TPMPA could be subtracted from the control to reveal a GABA mediated waveform or "GABAwave". This was compared to responses mediated by glutamate signaling that were obtained by subtracting the waveform after application of L-AP4 from the control ERG.

Conclusions: The ERG ON waveform attributable to GABA signaling had a faster onset than the ON response mediated by the G-protein-coupled receptor mGluR6 which was blocked by application of L-AP4, demonstrating the outer retina as the source of the GABAwave. The GABAwave constituted a major component of the ERG b-wave indicating that GABA mediated feedforward is a major ON signaling pathway in the outer retina.

ABSTRACT BODY:

Purpose: The role of intraocular pressure (IOP) fluctuation in glaucoma progression remains controversial. We investigate whether IOP fluctuation is independently associated with the rate of visual field (VF) progression.

Methods: Participants from the UKGTS with ≥5 VFs were included. Associations between IOP metrics and the mean deviation (MD) rate of progression (RoP) were tested with mixed models. The variables of interest were mean ocular pulse amplitude (OPA), and standard deviation (SD) of diurnal IOP (diurnal fluctuation) and of IOP at all visits (long-term fluctuation). The effect of correlated IOP metrics (Fig1) and multicollinearity were controlled with a principal component analysis of peak and mean IOP during the trial, and baseline (untreated) IOP. The first principal component (PC1) was included as a model covariate. Interactions between variables of interest and time from baseline modelled the variables' effect on the RoP. Analyses were conducted separately in the two arms.

Results: 213 patients in the placebo arm (mean±SD age: 66.5±10.3 years) and 217 patients in the treatment arm (mean±SD age: 65.2±10.4 years) were included. The median [IQR] of mean IOP, diurnal and long-term fluctuation were, respectively, 18.4 [16.0-21.9], 1.4 [0.9-2.0] and 2.1 [1.6-2.9] mmHg in the placebo arm, and 15.2 [13.2-17.1], 1.3 [0.8-1.7] and 1.9 [1.4-2.6] mmHg in the treatment arm. Mean±SD RoP were -0.32±0.65 and 0.03±0.58 dB/year in the placebo and treatment group, respectively. In the univariable analysis, diurnal and long-term IOP fluctuations were significantly associated with RoP in the placebo arm ($p<0.001$), and long-term fluctuation in the treatment arm ($p=0.047$). PC1, combining information of baseline, mean and peak IOPs, were significantly associated with RoP in the placebo ($p=0.029$) but not in the treatment arm ($p=0.95$). In the multivariable model, diurnal (placebo estimate: 0.047 dB/year, $p=0.60$; treatment estimate: 0.046 dB/year, $p=0.63$) and long-term IOP fluctuations (placebo estimate: -0.124 dB/year, $p=0.16$; treatment estimate: -0.119 dB/year, $p=0.63$) were not significantly associated with the RoP (Fig2). OPA was also not associated with RoP ($p\geq0.11$).

Conclusions: This study confirms that IOP fluctuation is not an independent factor for glaucoma progression and other aspects of IOP may be more informative.

ABSTRACT BODY:

Purpose: Reduction of ocular blood flow in glaucoma is thought to be related to upregulation of the endothelin system. Our purpose here was to determine the time course and dose dependency of ONH tissue blood flow in response to a single administration of PER-001.

Methods: LSFG (Softcare Co., Ltd.) was used to measure ONH tissue blood flow (as previously described in detail, PMID: 23737471) in 6 anesthetized adult rhesus monkeys (Macaca mulatta, 4F/2M ages 7-12 y) with unilateral experimental glaucoma (EG). Three LSFG scans were obtained for each eye and averaged at each time point, starting 30 min prior to bilateral intravitreal administration of 50 µL of PER-001 or vehicle, and thereafter every 15-30 min for 6 hr. The dose of PER-001 was varied in random order between 0.001, 0.01, 0.1 mg or vehicle for each subject. The effects of dose, time after administration and eye (EG vs fellow control, FC) were assessed using repeated measures ANOVA, mixed-effects models and generalized estimating equations to include effects of an array of vital signs.

Results: At the beginning of the series of 4 weekly PER-001 assays, ONH neuroretinal minimum rim width in EG and FC eyes, respectively was 155 ± 74 vs 291 ± 39 µm ($p=0.005$); peripapillary retinal nerve fiber layer thickness was 77 ± 21 vs 100 ± 8.5 µm ($p=0.04$); and mean blur rate (MBR) from LSFG was 12.3 ± 3.0 vs 14.2 ± 4.9 ($p = 0.18$); thus, representing a moderate stage of EG damage. Following administration of PER-001 (Figs.1,2), LSFG MBR increased significantly in EG eyes with time after injection ($p<0.0001$), indicating increased flow; there was a significant time-dose interaction ($p<0.0001$) and effect of dose ($p=0.0006$). Whereas, in FC eyes, only the effect of time after injection was significant ($p<0.0001$). The effect of PER-001 on ONH blood flow was relatively greater in EG eyes such that blood flow increased to a level comparable to FC eyes after ~4 hr, for the mid and high dose. This pattern held after controlling for end-tidal CO_2, the only vital sign significantly associated with MBR.

Conclusions: ONH tissue blood flow increased in a dose-dependent manner after administration of PER-001. The effect was more prominent in EG compared to FC eyes, consistent with the hypothesis that upregulation of the endothelin system contributes to reduction of blood flow in glaucoma.

ABSTRACT BODY:

Purpose: Reduction of ocular blood flow in glaucoma is thought to be related to upregulation of the endothelin system. The purpose of this study was to characterize the effect of PER-001 on the macro and microvasculature of the ONH in glaucomatous and control eyes.

Methods: OCTA (Spectralis, Heidelberg Engineering GmbH) was used to quantify the ONH vasculature in 6 anesthetized adult rhesus monkeys (Macaca mulatta, 4F/2M ages 7-12 y) with unilateral experimental glaucoma (EG, PMID: 27564522). OCTA scans were 15 x 15 deg (768 x 768 A-lines) centered on the ONH and registered to the original baseline in real time during acquisition. ONH rim was defined by Bruch's membrane opening laterally and posteriorly and by the internal limiting membrane anteriorly; the integral of all voxels within these boundaries (scaled for lateral magnification of the rhesus eye) defined ONH rim volume, while the same voxels weighted by the OCTA signal defined the ONH rim vascular volume. Large vessels and microvascular-capillaries were also analyzed separately. OCTA scans were recorded for each eye, starting 15-30 min prior to bilateral intravitreal administration of 50 µL of PER-001 or vehicle, and thereafter every 30 min for 6 hr. Statistical analysis included repeated measures ANOVA, linear regression and t-tests.

Results: At the point PER-001 assays were conducted, ONH neuroretinal minimum rim width in EG vs fellow control (FC) eyes, respectively, was 155 ± 74 vs 291 ± 39 µm (p=0.005); peripapillary retinal nerve fiber layer thickness was 77 ± 21 vs 100 ± 8.5 µm (p=0.04); thus, representing a moderate stage of EG damage. Following administration of PER-001, ONH volume increased significantly more in EG than FC eyes, which was explained almost entirely by an increase in total vascular volume, including an increase for both large vessel and microvascular-capillary volume (Figs. 1,2). Subtle effects of vehicle alone were far exceeded by those of PER-001.

Conclusions: Administration of PER-001 elicited an increase of ONH vascular volume, including dilatory effects on both large vessels and ONH tissue microvasculature. These effects were stronger in EG compared to control eyes and consistent with the hypothesis that upregulation of the endothelin system contributes to vascular compromise in glaucoma. Further studies of PER-001 in glaucoma are warranted.

ABSTRACT BODY:

Purpose: The vertebrate photoreceptor cell's outer segment is a highly modified primary cilium filled with hundreds of disc-shaped membranes known as "discs" which serve to efficiently capture light. To cope with light stress of disc membranes, photoreceptor cells constantly renew them. This is accomplished by the daily formation of new discs at the outer segment base and the engulfment of old discs from outer segment tips by the retinal pigment epithelium (RPE). The formation of each new disc begins at the base of the outer segment where Arp2/3 driven actin polymerization pushes out the ciliary membrane to form a membrane evagination. To drive actin polymerization, the Arp2/3 complex is known to require the activity of a nucleation promoting factor. Here, we sought to identify the nucleation promoting factor working with Arp2/3 during disc formation. Defects in disc morphogenesis underlie many blinding retinal diseases and understanding the basic molecular mechanism of the process lays the foundation for the development of future therapies.

Methods: We conducted a series of proteomic experiments to identify proteins potentially interacting with Arp2/3 at the site of disc formation. We identified protein isoforms representing all five members of the WAVE regulatory complex, including the nucleation promoting factor, Wasf3. We next analyzed the retinas of Wasf3$^{-/-}$ mice by Western blotting, light microscopy and electron microscopy.

Results: We found that the WAVE complex serves as the nucleation promoting factor for Arp2/3 at the site of disc formation. We identified the major protein isoforms of the WAVE complex present in rod outer segments, and showed that the absence of one of them, Wasf3, results in the complete loss of actin at the site of disc morphogenesis. Without the action of actin to initiate disc formation, the membranes delivered to the outer segment in Wasf3$^{-/-}$ mice grossly overgrow and their photoreceptors degenerate having disorganized membrane whorls emanating from their cilia rather than normal outer segments.

Conclusions: These data establish the WAVE complex as an essential component for photoreceptor disc morphogenesis and vertebrate vision.

TITLE: Protein kinase C regulates hypoxia-induced effects on NMDA receptor-mediated retinocollicular neurotransmission

SESSION TITLE: Neuroprotection, blood flow and ischemia

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Dumanska, N. Veselovsky, Department of Neuronal Network Physiology, Institut Fiziologii imeni O O Bogomolca Nacional'na akademia nauk Ukraini, Kiiv, Kiiv, UKRAINE|

Commercial Relationships Disclosure: Hanna Dumanska: Commercial Relationship: Code N (No Commercial Relationship) | Nickilai Veselovsky: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Hypoxia is the main factor in the pathogenesis of numerous retinal and optic nerve diseases. The retinocollicular projections are part of a fundamental set of structures in visual attention. We have previously reported that hypoxia-induced pathological long-term potentiation (LTP) of NMDA retinocollicular transmission is associated with a decrease of the current decay time. Such a decrease reflects an increase in NR2A/NR2B ratio and subsequent decrease of calcium influx and is a protective cellular mechanism in response to hypoxic injury. In this study, we tested the hypothesis that the protein kinase C (PKC) pathway is involved in hypoxia-induced LTP of NMDA retinocollicular transmission as well as in changes in NMDAR subunits ratio.

Methods: We developed the in vitro model of the visual retinocollicular pathway - a coculture of dissociated retinal cells and superficial superior colliculus (SSC) neurons. Using paired patch-clamp technique, we recorded pharmacologically isolated evoked NMDA postsynaptic currents in SSC neurons by generation action potentials in presynaptic retinal ganglion cells. Spontaneous postsynaptic currents we recorded in absence of presynaptic stimulation. The method of fast local superfusion was used for the application of hypoxic solutions on the pairs of neurons. We tested effect of chelerythrine chloride (ChC, 5 μM) - an inhibitor of PKC. The decay time constants were determined from a single exponential fit of the decay phase of currents.

Results: The presence of ChC completely blocked LTP of NMDA transmission induced by hypoxia. The ChC also abolished the hypoxia-induced increase of spontaneous NMDA currents amplitudes but did not affect the increased occurrence frequency. Moreover, we observed that ChC blocked the decrease of the decay time of evoked and spontaneous currents (for example control 48.2 ± 4.6ms; hypoxia 13.5 ± 5.4ms; hypoxia in presence of ChC 45.8 ± 5.5 ms; reoxygenation in presence of ChC 46.2± 4.8ms; reoxygenation 43.8 ± 5.6ms).

Conclusions: The results obtained are consistent with our hypothesis. Inhibition of PKC pathway completely blocked LTP of NMDA retinocollicular transmission and lead to the offset of associated changes in NMDA receptor subunits. The revealed electrophysiological basis of plasticity and protective mechanism in response to hypoxic injury might be targeted to prevent lesions of the retinocollicular pathway.

TITLE: Compounding of low-concentration atropine for myopia control
SESSION TITLE: Myopia epidemiology
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: E. Tomiyama, M.A. Bullimore, K. Richdale, College of Optometry, University of Houston, Houston, Texas, UNITED STATES|
Commercial Relationships Disclosure: Erin Tomiyama: Commercial Relationship(s);Code F (Financial Support):Paragon | Mark Bullimore: Commercial Relationship(s);Code C (Consultant/Contractor):Alcon, CooperVision, CorneaGen, Essilor, Euclid Systems, Eyenovia, Genentech, Johnson & Johnson, Novartis, Oculus, Paragon Vision Sciences, Presbia | Kathryn Richdale: Commercial Relationship(s);Code F (Financial Support):Alcon, Vyluma, Paragon;Code C (Consultant/Contractor):CooperVision, Euclid, Paragon, SightGlass, Novartis

ABSTRACT BODY:

Purpose: Low-concentration atropine is commonly prescribed to slow myopia progression in children but is not FDA-approved for that indication and is only available in the US from compounding pharmacies. The purpose of this study was to ascertain the most common procedures used to compound low concentration atropine.
Methods: US compounding pharmacies were identified via a survey of myopia management doctors in practice and at optometry schools, via social media, conferences, email, and web search. Based on this screen, a total of 28 pharmacies were contacted via telephone and asked a standard set of questions about their pharmacy practices regarding the preparation and storage of their compounded atropine product.
Results: Twenty-six pharmacies across 19 US States provided answers to at least three questions. The most frequently reported bottle size was 5 ml (IQR: 3.5-10). For storage, 7 of 18 pharmacies (39%) recommended refrigeration and 11 (61%) stated room temperature was sufficient. The median beyond use date provided was 60 days (IQR: 45-180).

For preparation, 14 pharmacies (54%) used commercially available 1% atropine solution, 9 (34%) used powdered atropine, 2 (8%) used either, and 1 (4%) stated their approach was proprietary. For the added inactive ingredients, 10 pharmacies (42%) used commercially available artificial tears only, 6 (25%) added saline only, 6 (25%) used more than one ingredient, and 2 (8%) were proprietary. Only two pharmacies mentioned adding Boric acid and one mentioned “pH adjusted” saline.
Conclusions: There were a wide variety of methods used to compound low-concentration atropine, which may alter the pH and affect its stability and potency. Whether these differences ultimately affect the efficacy and safety of low-concentration atropine is not known. Further research is needed to assess how these variations may affect the outcomes of myopia management.

ABSTRACT BODY:

Purpose: Most studies of retinol binding protein 3 (RBP3) have focused on its role in the vitamin A cycle or transport of lipids in the retina. RPB3 is the major protein component of the interphotoreceptor matrix (IPM) and plays a role in maintaining the health and integrity of the retina. However, studies have detected RPB3 in other compartments of the eye, and this study seeks to further explore its presence in the humors of the eye as a step in determining extra-retinal function.

Methods: Intact human globes were used with postmortem times from 3-12 hrs. Aqueous was obtained by inserting a 30-gauge syringe through the cornea into the anterior chamber. Vitreous was obtained via a syringe after removing the anterior structures by a circumferential incision at the level of the ciliary body. 7 vitreous and 7 aqueous samples were collected from 14 different individuals without history of ocular disease. To challenge human sample data, aqueous and soluble IPM fractions were collected from wildtype (WT) and RBP3-/- adult albino Sprague Dawley rats reared under cyclic dim light. Aqueous was collected by the same methods as human eyes. To collect IPM, retinas were detached under chilled PBS and gently agitated. The extract was centrifuged to remove cell fragments. Western blot analysis used rabbit monoclonals directed against human and rat RPB3s.

Results: RBP3 (124 kDa) was easily detected in human aqueous and vitreous. Minor immunoreactive bands were detected, particularly in vitreous, at 100, 75 and 60 kDa. Intensity of bands did not correlate with postmortem interval. In the aqueous, RBP3 was 65% less concentrated vs. vitreous and typically lacked lower bands. Western blot analysis showed an immunospecific full-length 140 kDa band in the WT IPM which was not seen in RBP3-/- animals. Minor bands were not detected. In the aqueous, RBP3 was detected by Western blot and appeared to be the most prominent protein overall, although its level corresponded to ~2% of that in the IPM.

Conclusions: RBP3 is not restricted to the IPM but is a prominent component of the aqueous and vitreous. Our data indicates that there is a gradient in RBP3's concentration, with levels decreasing from the IPM to vitreous, with the lowest in aqueous. These distribution patterns across species suggest extra-retinal roles and merit further investigation of RBP3's expression and function throughout the eye.

ABSTRACT BODY:

Purpose: The laminar region of the eye is continuously exposed to intraocular pressure (IOP) and cerebrospinal fluid pressure (CSFP) on its anterior and posterior surfaces, respectively. Body position-dependent changes in IOP and CSFP also changes translaminar pressure (TLP=IOP-CSFP), which has been hypothesized as a risk factor in glaucoma. However, there have been few studies of the resultant stresses and strains within the lamina cribrosa beams (LC) and interspersed laminar neural tissues (NT) with TLP change. This study aimed to calculate the influence of postural change (sitting vs. supine) on the resultant stresses and strains in the optic nerve head (ONH), LC, and NT, under simultaneously applied IOP and CSFP.

Methods: Three eye-specific posterior eye finite element models were constructed, including the LC/NT microstructure, and cable elements representing anisotropic collagen fibers embedded in the peripapillary sclera and pia via a fully coupled, mesh-free, penalty-based cable-in-solid algorithm. The FE models were then subjected to three combinations of IOP and CSFP loadings consistent with postural changes; results were then interpreted in relation to the postural role in the resultant ONH, LC, and NT deformations, stresses, and strains.

Results: Moving from sitting to supine body position caused a larger tensile, compressive, and shear stresses and strains in the ONH (Figure). IOP was the dominant ($p<0.05$) factor in the resultant stresses and strains in the LC and NT compared to CSFP. IOP also was the dominant factor ($p<0.05$) driving deformation of the anterior and posterior scleral canal openings as well as anterior and posterior laminar insertions (~ 3 times larger than CSFP) while CSFP played a pivotal role in controlling posterior laminar deformation. The cable elements representing the collagen fibers in the peripapillary sclera experienced a larger axial force in the supine compared to the sitting position, with IOP being the dominant factor compared to CSFP.

Conclusions: Postural changes in the stresses and strains in the LC and interspersed laminar NT could improve our understanding the pathogenenic mechanisms of glaucoma, the ocular effects of idiopathic intracranial hypertension, and visual impairment in astronauts in long-duration spaceflight.

ABSTRACT BODY:

Purpose: To examine the contribution of retinal venous congestion in selected retinal diseases where it is suspected of being a unifying pathogenic factor.

Methods: In cases of unilateral retinal vascular disease, comparison of vessel and blood flow characteristics between the affected and unaffected eye was made using noninvasive assessment of linear capillary blood flow velocity by motion contrast fundus photography, retinal blood oxygen saturation by spectrophotometry, retinal hyperreflectivity and thickness by optical coherence tomography (OCT), capillary perfusion by OCT angiography and fluorescein angiography, and disc vessel pulsation by infrared videography.

Results: In 9 patients with unilateral central retinal vein occlusion (CRVO), diabetic retinopathy (DR) or paracentral acute middle maculopathy (PAMM), retinal arterial oxygen saturation in the affected eye was elevated by 1.9% in CRVO, reduced by 4.2% and 4.4% in DR and PAMM, respectively, while venous oxygen saturation was reduced by 15.9%, 15.4% and 2.2% in CRVO, DR and PAMM, respectively. Mean arterial capillary perfusion velocity in affected eye were reduced by 67%, 83% and 15% in CRVO, DR and PAMM, respectively, while venous capillary perfusion velocities were reduced by 76%, 22% and 21% lower in CRVO, DR and PAMM, respectively. Intravenous reflectivity patterns were blurred in most of the affected eyes. Venous pulsation was absent in 7 out of 9 affected eyes, but only in 3 out of 9 unaffected eyes.

Conclusions: Intra-patient comparison of retinal vessels and blood flow contrasting findings, in agreement with the assumption that flow reduction secondary to venous congestion is a unifying characteristic of unilateral CRVO, DR and PAMM.

ABSTRACT BODY:

Purpose: Gene editing is a powerful tool to eliminate expression of mutant proteins. Before any editing approach goes to the clinic, targeted and "off target" editing must be evaluated, preferably in the same animal in situ. The P23H mutation in rhodopsin (RHO) is a common cause of human adRP and a frequent target for gene editing approaches. To evaluate genome editing of an ARCUS meganuclease, RHO1-2, we created humanized mice that harbor WT and mutant P23H hRHO near the P23H mRho locus. One line harbors two humanized WT hRHO alleles (hRHO KI Hz), the other, two humanized P23H hRHO alleles (P23H hRHO KI Hz). When crossed the progeny harbor one WT and one P23H hRHO allele (hRHO KI/P23H hRho KI). We To characterized retinal structure and function in all three mouse lines to define the optimal time frame for evaluation of RHO1-2 gene editing.

Methods: We compared dark and light adapted full field electroretinogram (ffERG) responses in all three genotypes to C57Bl6/J mice. Responses were evoked using a standard ISCEV protocol. b-wave amplitudes at all flash intensities were compared across genotype x age. Morphological assessments were conducted in immunohistochemically labeled frozen sections. Outer nuclear layer (ONL) thickness - DAPI labeled somata and rod morphology - rhodopsin and REEP6.

Results: Retinal structure/function in hRHO KI Hz is similar to C57Bl6/J through P65. At P40, P23H hRHO KI Hz retina has no scotopic ERG and the ONL is a single layer of nuclei with clumped chromatin, emblematic of cones. hRHO KI/P23H hRho KI retinal structure shows time dependent ONL thinning. At P20, hRHO KI/P23H hRho KI retina is similar to hRHO KI Hz. At P30 and P60, hRHO KI/P23H hRho KI ONL thins significantly, albeit not as severe as P23H hRHO KI Hz. hRHO KI/P23H hRho KI scotopic b-wave amplitudes are reduced compared to hRHO KI (~ 60% at P20 and 50% at P75). Across all genotypes, photopic b-wave amplitudes are similar through P70. We continue to track changes in retinal structure and function in older mice.

Conclusions: hRHO KI/P23H hRho KI retina has a broad window for genome editing. Early treatment (first postnatal week) will determine maximum editing capability and late treatment will define efficacy in late stage disease. P23H hRHO/hRHO mice are a valuable resource for in situ evaluation of targeted and "off target" editing of P23H and WT hRHO alleles.

ABSTRACT BODY:

Purpose: To evaluate the corneal biomechanics using Corvis ST® in different stages of Fuchs Endothelial Corneal Dystrophy (FECD), and to compare with healthy subjects.

Methods: Cross-sectional retrospective study that included FECD eyes without edema (n=54, Group 1), with subclinical edema (n=47, Group 2), and with clinically definite edema (n=17, Group 3), and healthy controls (n=53). All eyes were submitted to Scheimpflug tomography and Corvis ST® in the same day. The exclusion criteria were history of previous corneal transplantation, other corneal diseases, high refractive error and ocular hypertension or glaucoma. All biomechanical corneal parameters provided by the updated version of Corvis ST® were analyzed. For statistical purpose, study groups were compared with the use of ANOVA (parametric) and Kruskall-wallis (nonparametric) tests followed by post-hoc analysis.

Results: Comparing with controls, all FECD groups had lower time at highest concavity (HC, all p=0.001); Groups 1 and 2 had higher deflection amplitude at HC (p=0.018 and p=0.044), but also higher peak distance (p<0.001 and p=0.022); Group 1 had higher time at second applanation (A2, p=0.003); Group 2 had lower time at first applanation (A1, p0.001), and stress-strain index (p=0.027); Group 3 had higher deflection length at A1 (p=0.012); Groups 2 and 3 had higher corvis biomechanical index (CBI, p=0.013 and p=0.04). Comparing with Group 1, Group 3 had higher deflection length at A1 (p=0.047), and lower integrated radius (p=0.04).

Conclusions: FECD eyes in all severity stages had different corneal biomechanical behavior compared with controls. Overall, FECD corneas without edema or with subclinical edema were more deformable than controls, while FECD corneas with clinically definite edema were less deformable compared with those without edema and controls. CBI was higher in FECD corneas with subclinical and clinically definite edema.

ABSTRACT BODY:

Purpose: Visible-light optical coherence tomography (vis-OCT) is an emerging imaging modality that can provide retinal imaging with an axial resolution of ~1.2 microns. Accurate retinal layer segmentation has yet to be established for vis-OCT. In this study, we built an end-to-end, deep learning-based segmentation algorithm to obtain boundaries for 12 retinal layers in human vis-OCT images.

Methods: The dataset consisted of 96 Vis-OCT B-scan images of the macula from human participants collected using the Aurora X2 vis-OCT system (Opticent Health, Evanston IL). Fourteen areas of the retina (12 layers + 2 backgrounds) were manually annotated. The images were resized to a height of 512 pixels and divided into strips of 32 pixels in width for training. The images were augmented with linear contrast, scaling, rotation, and translation. The final augmented dataset was split into training, validation, and test sets at a ratio of 60:20:20, respectively. A four-level U-net was then constructed with 5x3 pixel kernel sizes. The deep learning model was trained for 60 epochs with an Adam optimizer.

Results: Fig. 1A shows an example vis-OCT image from the testing dataset. The image was used as an input to the deep learning model, which produced as a segmented image with 14 labels as output. The boundaries of each layer segmentation were determined and plotted in Fig. 1B. The combined average dice coefficient for the segmented layers was 0.90 +/- 0.06 (max: 0.98, min: 0.76).

Conclusions: We successfully created an automatic retinal layer segmentation algorithm that utilized an end-to-end deep learning approach for vis-OCT images. We characterized the accuracy of the modelmodel's accuracy on our testing dataset and demonstrated its utility in investigating the sub-laminae of the inner plexiform layer. This study serves as the foundation for future work on automatic segmentation of vis-OCT images.

TITLE: Expected Visual Field Outcomes Following Boston Keratoprosthesis Type I and II in Eyes without Glaucoma

SESSION TITLE: Refractive and non-refractive corneal surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Crist, Tufts University School of Medicine, Boston, Massachusetts, UNITED STATES|C.H. Dohlman, J. Chodosh, T.C. Chen, Massachusetts Eye and Ear Department of Ophthalmology, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Charlotte Crist: Commercial Relationship: Code N (No Commercial Relationship) | Claes Dohlman: Commercial Relationship: Code N (No Commercial Relationship) | James Chodosh: Commercial Relationship: Code N (No Commercial Relationship) | Teresa Chen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine if the aperture of the Boston keratoprosthesis (Kpro) type I and II device causes visual field defects on standard white-on-white perimetry in eyes without glaucoma. It is critical to know what should be expected for baseline visual field testing in Kpro eyes without glaucoma, in order to accurately assess for any progressive restriction in peripheral vision, which may herald the onset of glaucoma, one of the leading causes of irreversible blindness in Kpro patients.

Methods: We performed a retrospective chart review and analyzed the Humphrey visual field 24-2 testing (HVF Swedish Interactive Threshold Algorithm standard 24-2 test, Humphrey visual field analyzer Carl Zeiss Meditec, Inc., Dublin, CA) of patients aged 18 and older who had undergone Boston Kpro I or II surgery from January 1, 1990 to June 1, 2021 and who did not have glaucoma at the time of visual field testing. Patients were included if their central vision was 20/40 or better with correction. Patient were excluded if they had poor reliability indices (i.e. more than 33% fixation losses, false positives, and/or false negatives) or if they had any other non-glaucomatous disease that could independently affect their HVF test results.

Results: Out of 414 Kpro I eyes (of 389 patients) and 90 Kpro II eyes (of 78 patients) analyzed, 9 patients (4 Kpro I and 5 Kpro II) met the inclusion and exclusion criteria. We analyzed 36 HVFs of these 9 patients: 14 HVFs of 4 Kpro I patients and 22 HVFs of 5 Kpro II patients. Of the 14 Kpro I HVFs, 9 (64.3%) were full fields, 3 (21.4%) had a rim artifact, and 2 (14.3%) had a borderline superior nasal step. Of the 22 Kpro II HVFs, 10 (45.5%) of the Kpro II HVFs were full fields, 9 (40.9%) had a rim artifact, 2 (9.1%) had a rim artifact with borderline inferior nasal step, and 1 (4.5%) had a significant lid artifact. Seven of 9 patients had at least one full field, with the last two patients having a rim artifact and a rim artifact with a borderline inferior step.

Conclusions: Kpro I and II devices do not significantly affect peripheral vision on HVF SITA standard 24-2 testing in eyes without glaucoma. The most common artifact in Kpro patients was the rim artifact, affecting only the outermost testing points.

ABSTRACT BODY:

Purpose: Vascular endothelial growth factor (VEGF) inhibitors are standard of care first-line treatment for diabetic macular edema (DME) and wet type age-related macular degeneration (wAMD) although moderate frequency of intraocular administration and the substantial inadequately responding population limit the utility of these treatments. Variants of IGT-427 were designed to address both limitations of the current therapies. The dual function of VEGF inhibition and Tie2 activation is designed to improve the quality of the retinal vasculature and the longer vitreous half-life designed to reduce the frequency of administration compared to the current standard of care. This study set out to evaluate variant's biological and biophysical characteristics.

Methods: The binding affinity was assessed by SPR analysis and the potency in regulating target signaling pathways was assessed in mammalian cell-based assays. Laser-induced choroidal neovascularization (CNV) model in rabbits was employed to examine its in vivo mode of action. In addition, its vitreous pharmacokinetics was measured in a rabbit model.

Results: IGT-427, a bispecific antibody, simultaneously suppressed VEGF signaling and activated Tie2 signaling pathways in heterologous CHO cells and vascular endothelial cells. IGT-427 bound human Tie-2 with Kd < 1 nM in a bivalent interaction, analogous to the cellular surface interaction, and bound human VEGF with a Kd < 10 pM. It displayed comparable high affinities toward rabbit orthologs. Intravitreal IGT-427 reduced vascular leakage in the rabbit CNV model. Engineered variants of IGT-427 were site-specifically PEGyated to increase the apparent molecular weight of the bispecific antibody by > 3-fold. While these variants had slightly reduced apparent affinity for Tie-2 and VEGF, they were similar in activity blocking VEGF and activating Tie-2 in cell-based assays. The extended ocular half-life in rabbit eyes compared to unmodified IGT-427 and Aflibercept will be presented.

Conclusions: IGT-427 has potential as best-in-class therapeutics with superior efficacy compared to agents that only inhibit VEGF, have more potent agonist activity on Tie-2 compared to Ang2 inhibiting agents, and have reduced frequency of intravitreal administration.

ABSTRACT BODY:

Purpose: Fuchs' endothelial corneal dystrophy (FECD) is characterized by progressive changes in Descemet's membrane (DM). Its pathophysiology is only partially elucidated and involves certain genetic backgrounds, an abnormal response to oxidative stress, abnormal production of extracellular matrix and endothelial apoptosis. However, despite these similarities, there is heterogeneity in the clinical course. Objectives: To describe and characterize the different lesions of DM to determine whether there are subgroups of FECD

Methods: Study on operative residues, approved by an ethics committee. DMs of approximately 8 mm in diameter were obtained by Descemetorhexis from patients undergoing endothelial transplantation in one of 23 participating French and French-speaking centers (French Fuchs Study group). They were stored either in water to remove residual cells and allow analysis of the MD surface or fixed in 0.4% paraformaldehyde to allow analysis of residual cells. MDs were flat-mounted on glass slide, dehydrated, and then observed by brightfield and phase-contrast light microscopy with manual classification and image analysis.

Results: DM were procured from 500 patients (63% female) aged 71+/-11 years. 65% of the MD were in perfect condition, in one piece, allowing analysis of its entire surface without loss of information. Several elementary lesions were described: 1/ Guttae (constant) of different shapes, diameter, and with differences in organization (between central and peripheral areas but also from one patient to another), in particular radial alignments; 2/ fibrillar and curly structures (inconstant) more or less covering the most central Guttae; 3/ intra- or extracellular pigment (inconstant); 4/ other reliefs "imprinted" in the DM (constant); 5/ several populations of residual cells of normal or dystrophic appearance. Some associations were more frequent than others, allowing to define subgroups of FECD.

Conclusions: This unique and large collection allows, for the first time to our knowledge, to describe with great precision all lesions constituting DM at the stage when patients are transplanted in France. It highlights an unsuspected diversity of the histology of FECD. This first study will be followed by a prospective study to establish correlations between elementary lesions, possible subgroups, clinical characteristics and genetic background

ABSTRACT BODY:

Purpose: Vesicant injuries have been associated with chronic corneal pathology, including persistent inflammation and neovascularization. We and others have shown non-IgE-mediated activation of mast cells upon tissue injury leads to piecemeal release of inflammatory mediators. Here, we investigated the effect of alkylating agent exposure on mast cell activation and secretion of various inflammatory and chemotactic factors.

Methods: Human mast cells (LAD2) were maintained in culture medium containing hSCF (100 ng/ml). To assess the direct effect of alkylating agents, mast cells were exposed directly to 10 μM of nitrogen mustard (NM) for 2 hours. To delineate whether NM-exposed human corneal epithelial cells (HCEC) activate mast cells, HCECs were pretreated with 10 μM of NM for 2 hours and the harvested supernatant were added to LAD2 cultures for additional 2h. To evaluate the continuous effect of NM exposure, mast cells were washed and incubated for another 6h in fresh media. Mast cell activation was evaluated by measuring level of β-hexosaminidase in the culture supernatant. Expression of inflammatory (TNFα, VEGF) and chemotactic factor (IL-8) were quantified in mustard-exposed mast cells. To evaluate the efficacy of mast cell inhibitor-cromolyn, NM-exposed mast cells were treated with 0.2% cromolyn.

Results: Direct nitrogen mustard exposure of mast cells resulted in a 2-fold increase in levels of β-hexosaminidase, compared to media alone ($p<0.001$). Supernatants harvested from NM-exposed corneal epithelial cells also resulted in mast cell activation as evaluated by a significant upregulation of β-hexosaminidase levels (6-fold; $p<0.001$). Cromolyn treatment substantially suppressed the observed NM-induced mast cell activation ($p=0.009$, $p=0.01$, respectively). A significant increase in inflammatory factors TNFα (3-fold; $p=0.029$) and VEGF ($p=0.005$), and chemotactic factor IL-8 (>10-fold; $p<0.001$) was observed in mast cells following NM exposure. Moreover, inhibition of mast cells by cromolyn treatment significantly abrogated expression of both inflammatory and chemotactic factors ($p<0.05$).

Conclusions: Our data demonstrate that direct exposure of nitrogen mustard and NM-exposed corneal epithelial cells activate mast cells to secrete inflammatory and chemotactic molecules, suggesting blockade of mast cells as a potential therapeutic strategy in attenuating alkylating agent-induced ocular inflammation and tissue damage.

TITLE: Non-hemostatic role of Factor X in corneal herpes simplex virus-1 (HSV-1) infection

SESSION TITLE: Corneal Immunology and Neovascularization

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Setia, P.K. Suvas, M. Rana, A. Chakraborty, S. Suvas, Ophthalmology, Visual and Anatomical Sciences, Wayne State University, Detroit, Michigan, UNITED STATES|

Commercial Relationships Disclosure: Mizumi Setia: Commercial Relationship: Code N (No Commercial Relationship) | Pratima Suvas: Commercial Relationship: Code N (No Commercial Relationship) | Mashidur Rana: Commercial Relationship: Code N (No Commercial Relationship) | Anish Chakraborty: Commercial Relationship: Code N (No Commercial Relationship) | Susmit Suvas: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The focus of current study is to explore the non-hemostatic role of Factor X (FX), clotting factor, in HSV-1 infected mice.

Methods: The corneal HSV-1(McKrae) infection was carried out on anesthetized C57BL/6J (B6) mice after mild corneal scratching. qRT-PCR assay was performed on uninfected and HSV-1 infected corneas to measure the expression of FX, protease activated receptors (PARs), and Tissue factor (TF). FX protein level was determined by ELISA. Immunohistochemistry (IHC) staining for FX, PAR-1, and PAR-2 molecules was carried out on frozen corneal sections. The cellular expression of FX, PAR-1, and PAR-2 was investigated using flow cytometry (FCM). Viral plaque assay measured the amount of infectious virus in infected tissue.

Results: qRT-PCR analysis showed an average 38-fold increase in FX transcript in infected corneas at 13DPOI than 5DPOI. ELISA results also showed higher levels of FX protein at 13DPOI compared to 5DPOI. Furthermore, qRT-PCR analysis of separated corneal epithelium and stroma showed the higher expression of FX in stroma than in epithelium. IHC staining revealed FX localization in the anterior stroma of infected corneal sections at 15DPOI. The flow cytometry data showed the significantly higher expression of FX (both membrane-bound and intracellular levels) in myeloid (CD11b+) than CD4 T cells in infected corneas. Tissue factor (TF) converts FX to an active FXa product. Intriguingly, qRT-PCR results depicted significant downregulation in TF transcripts in infected than uninfected corneas. FXa exerts its effect by binding to PARs. Our results showed no significant change in PAR-1 and PAR-2 mRNA levels in infected than uninfected corneas. To evaluate the role of FX in regulating HSV-1 induced inflammation, oral Rivaroxaban (10mg/kg/day) treatment was given to HSV-1 infected mice. We observed an increased encephalitis incidence in drug than vehicle-treated groups of mice. Viral plaque assay showed the presence of infectious virus in the brainstem of the drug than vehicle-treated groups of infected mice at 10DPOI, suggesting the role of FXa in regulating HSV-1 clearance. The ongoing experiments are ascertaining the outcome of manipulating factor X signaling in HSK lesions.

Conclusions: Together, our results showed that FX expression in HSV-1 infected corneas is localized in myeloid cells and systemic inhibition of FXa signaling increased the incidence of HSV-1 induced encephalitis.

ABSTRACT BODY:

Purpose: The primate retina contains ~20 anatomically identified retinal ganglion cell (RGC) types and >10 polyaxonal amacrine cell (PAC) types. However, only 7 RGC types and 1 PAC type have been studied functionally in detail. Our goal is to understand the diversity of visual processing in the RGC and PAC types of the macaque and human retina.

Methods: Large-scale multi-electrode recordings were performed from the peripheral retina. The spike-triggered average of each cell was calculated from responses to flickering checkerboards and used to summarize its spatial, temporal and chromatic properties. Cell types were identified by clustering their functional properties. Substantial errors due to spike sorting were ruled out by stereotypical properties of cells across the electrode array, refractory periods, spatiotemporal structure of electrical footprints, and mosaic organization of receptive fields (RFs) within each type.

Results: In every recording, the well-known ON & OFF parasol, ON & OFF midget, ON & OFF smooth monostratified, and small bistratified RGCs, and A1 PACs, were identified. In 12 macaque retina recordings, at least 15 new RGC and 12 new PAC types with distinct RF properties were identified (Fig. 1A). Each new cell type was observed in several retinas. Most of the novel cell types exhibited one or more unusual properties: 1) inhomogeneous spatial RFs composed of multiple spots or branches; 2) spatially segregated ON and OFF inputs, driven by L/M cones or S cones, not in a center-surround arrangement (Fig. 1B); and 3) sparse spiking in response to checkerboards and naturalistic movies. In 4 human retina recordings, ~20 putative homologs of macaque RGC and PAC types were identified (Fig. 1B). One human PAC type exhibited double the spatial density of its macaque homolog, and one had no obvious homolog.

Conclusions: Most novel RGC and PAC types in the primate retina exhibited unusual spatial and spectral RF properties and firing patterns, suggesting specific functions in visual processing. While most human cell types appear to have macaque homologs, a few cells and properties may be unique to the human retina.

ABSTRACT BODY:

Purpose: Selenium is an essential trace element, which once ingested is incorporated into antioxidant enzymes that prevent cellular damage. However, clinical studies have identified excess selenium levels in plasma and aqueous in patients with glaucoma. Given reported benefits of selenium supplementation in thyroid-associated ophthalmopathy, we aimed to evaluate whether dietary selenium, iodine, and prescribed medication for thyroid dysfunction were associated with glaucoma-related endophenotypes in the general population.

Methods: Participants from the TwinsUK registry were recruited. Firstly, energy-adjusted selenium and iodine intake from 1,977 individuals was estimated through a validated food frequency questionnaire(FFQ). Secondly, self-reported prescribed thyroid medication use was recorded for 1,234 twins. Endophenotypes evaluated included intraocular pressure (IOP), retinal nerve fibre layer (RNFL) thickness and vertical cup to disc ratio (VDCR) adjusted for disc area. Linear mixed models investigated associations of individual nutrients and endophenotype after stratifying intake into quartiles. Logistic regression modelling evaluated use of thyroid hormone medication and IOP > 21mmHg, VCDR > 0.7 and RNFL< 90µm. All models were adjusted for age, sex, spherical equivalent (SE) and family structure.

Results: Mean(SD) age was 62.1(12.25). Mean endophenotype values were IOP: 13.3mmhg(2.82), VCDR: 0.4(0.14) and RNFL: 95.1µm(10.10). Dietary iodine was not associated with any endophenotypes. Multivariate regression models evaluating lowest versus highest quartiles of dietary intake of selenium identified an effect of high selenium intake on VCDR (β=0.02,p=0.04) and a trend towards a thinner RNFL(β=-1.28, p=0.068). IOP was not associated with selenium uptake(β=0.23, p=0.279). The use of oral thyroid hormone medication was associated with a greater risk of having an RNFL thickness less than 90µm (odds ratio (OR):1.67,p=0.001), and non-significant odds ratios of having an IOP>21mmHg (OR:1.30,p=0.80) or a VCDR >0.7(OR:1.26,p=0.83).

Conclusions: In a healthy population, higher levels of dietary selenium appear to be related to a larger VCDR and oral thyroid medication is associated with a greater risk of having a thin RNFL. Larger longitudinal studies are required to replicate these results and determine whether hypothyroid patients and individuals with high selenium intakes are at greater risk of glaucoma.

ABSTRACT BODY:

Purpose: To evaluate the management of nAMD, visual outcomes at 1 year, factors predicting sufficient treatment, and the impact of treatment sufficiency on visual outcomes in routine clinical practice.

Methods: This retrospective analysis of the Intelligent Research in Sight (IRIS)® registry included treatment-naïve eyes diagnosed with nAMD between Jan 2013 and Dec 2019 with best-corrected visual acuity (BCVA) ≥20/400, anti-VEGF treatment within 3 months of diagnosis, and 1 year of follow-up. Eyes were considered sufficiently or insufficiently treated if they received ≥7 or <7 anti-VEGF injections in Year 1, respectively. Logistic regression identified factors associated with visual outcomes and treatment sufficiency, and the impact of treatment sufficiency on BCVA.

Results: Of 295,561 eligible eyes, 206,517 eyes were treated and 88,990 eyes were not actively treated. Of 184,258 treated patient-eyes, 109,696 (59.5%) received sufficient and 74,562 (40.5%) insufficient treatment. Baseline characteristics were largely comparable across treated groups; mean baseline BCVA was ~61 letters. Mean number of injections was 8.9 vs 4.0 with sufficient vs insufficient treatment, respectively. Asian, African American, Hispanic; Medicaid insured; or non-retina specialist treated patients were less likely to receive sufficient treatment (all P<0.001). Mean BCVA change from baseline at 1 year was significantly greater with sufficient vs insufficient treatment (3.5 vs –0.3 letters; P<0.0001), with larger gains in eyes with baseline BCVA of 20/100-20/200 (10.2 vs 3.1 letters) and <20/200-≥20/400 (19.9 vs 8.9 letters). Sufficiently treated eyes had higher odds of gaining ≥15-letters (odds ratio [OR], 1.7; 95% confidence interval [CI], 1.6, 1.7) and lower odds of losing ≥15-letters (OR, 0.7; 95% CI, 0.6, 0.7) compared to insufficiently treated eyes. Older age, Medicaid insured, and/or better BCVA were associated with worse visual outcomes in both sufficiently and insufficiently treated eyes (all P<0.05).

Conclusions: A substantial number of eyes diagnosed with nAMD were insufficiently treated over 1 year, with worse visual outcomes compared with sufficiently treated eyes. Patient race, ethnicity, insurance type, and treating physician speciality impacted nAMD management. Such findings can identify gaps in care leading to suboptimal outcomes during management of nAMD.

ABSTRACT BODY:

Purpose: Corneal blindness is the fourth leading cause of blindness. Currently, corneal transplantation is the only remaining therapeutic option as pharmacotherapy remains limited. As the cornea has several physiological and anatomical barriers, direct delivery of therapeutics into the eye remains highly challenging. This work will study corneal penetration of carbon quantum dots (CQDs) as a function of size and charge. Highly positively charged spermidine-derived CQDs, have shown to allow the opening of the tight junctions of the corneal epithelium, the major barrier for drug delivery into the anterior segment of the eye.

Methods: Synthesis of CQDs was achieved in a microwave reactor from solutions of glucosamine hydrochloride and capping agent at different temperatures. CQDs with hydrodynamic diameter varying between 1-389 nm were obtained. Zeta potential varied between -24 and +32 mV. The influence of size, surface properties and composition of CQDs on corneal permeation and the ability to reach deeper layers in the eye was investigated. CQDs were topically instilled on a bovine ex vivo eye model. Confocal microscopy imaging of the cornea was performed to determine the presence of CQDs in the corneal epithelium and endothelium.

Results: Negatively charged CQDs synthesized from glucosamine hydrochloride and b-alanine show poor penetration into the corneal epithelium. Positively charged CQDs prepared from glucosamine hydrochloride and ethylenediamine as a passivating agent penetrated through the tight junctions of the corneal epithelium. The same was observed for positively charged formed using spermidine as capping agent at 200°C. Decreasing the reaction temperature results in positively charged CQDs of very small size(1.5±0.55nm) shown to reach even the corneal endothelium.

Conclusions: We have shown that CQDs could cross the corneal epithelium and the corneal endothelium. We found that size is the most critical factor for permeation into the cornea. The corneal epithelium is a major barrier for the penetration of nanostructures > 20 nm, while particles < 10 nm could cross the endothelium. Also, the charge influences penetration efficacy. It was observed that positively charged particles could more easily penetrate the epithelium and reach the subsequent layers of the cornea. In contrast, negatively charged particles can barely cross the epithelium. This can be explained by the negative charge of the corneal epithelium.

ABSTRACT BODY:

Purpose: The role of rod photoreceptors, the most numerous cells in the retina, in proliferative diabetic retinopathy is unknown. This study aims to investigate if, upon exposure to elevated glucose, rod photoreceptors produce pro-angiogenic mediators and can trigger the retinal vascular endothelial cell angiogenic responses of proliferation, migration and branching.

Methods: Primary cultures of mouse rod photoreceptors and retinal microvascular endothelial cells (RMECs) were generated and used for all experiments. The mediators produced by rod photoreceptors exposed to physiologically relevant levels of high glucose were analyzed by multiplex ELISA. Angiogenic responses of RMECs treated with photoreceptor-produced mediators, or with control stimuli, were evaluated by proliferation, migration, and tube formation assays. Transcriptomic shifts in RMECs stimulated with photoreceptor-produced mediators were assessed by qRT-PCR.

Results: Rod photoreceptors treated with 25 mM D-glucose (high glucose) produced higher concentrations of VEGF (2.5-fold increase, $p<0.05$), TNF-α (2.4-fold increase, $p<0.05$), and IL-6 (2-fold increase, $p<0.05$) compared to rod photoreceptors treated with 5 mM D-glucose (normal glucose), or with 25 mM L-glucose (osmotic control). Conditioned media produced by photoreceptors treated with high glucose elicited a 2.5-fold increase in RMEC proliferation ($p<0.001$) and a 2-fold decrease in the time required for scratch closure by migrating RMEC ($p<0.001$). Photoreceptor-produced mediators had proangiogenic effects on RMEC branching and maximum RMEC tube lengths increased 1.9-fold after incubation with media from photoreceptors treated with high glucose ($p<0.001$). Conditioned culture medium produced by photoreceptors in high glucose conditions induced the expression of matrix metalloprotease 9 (MMP-9) (10-fold increase, $p<0.001$) and of MMP-2 (2.3-fold increase, $p<0.001$) in RMEC.

Conclusions: Rod photoreceptors under elevated glucose conditions produce mediators that increase RMEC proliferation, migration, and branching and induce a proangiogenic transcriptomic shift in endothelial cells.

ABSTRACT BODY:

Purpose: Increased retinal vascular tortuosity has been quantified in retinal images of humans with retinopathy of prematurity (ROP). The oxygen-induced retinopathy (OIR) model of ischemic retinopathy mimics hallmark features of ROP, including initial ischemia followed by neovascularization. The purpose of this proof-of-concept study was to develop a semi-automatic deep learning algorithm that can be used to investigate whether there is a correlation between retinal vascular tortuosity and disease activity in OIR mice, analogous to what is observed in infants with ROP. Application of this algorithm to images of OIR retinas aimed to characterize vascular tortuosity as a novel outcome measurement in the OIR model.

Methods: OIR was induced in C57BL/6J mice via hyperbaric oxygen exposure from postnatal day 7 (P7) to P12. Retinal flat-mounts of P17 OIR mice were manually segmented for superficial vessels by 4 graders and validated using a subset of images. The optic disc of each image was manually demarcated prior to algorithm input. Using a previously pre-trained DL algorithm for calculating tortuosity index (TI) in retinopathy of prematurity (iROP-Assist), each segmentation and its corresponding disc center was used to generate a TI. Statistical significance between groups was defined as $p \leq 0.05$ and determined using a Student's T-Test.

Results: 50 flat-mount images representing normoxic (NOX) mice and 50 flat-mount images representing untreated P17 OIR mice were included in this analysis. The median tortuosity index for NOX and OIR images was 1.01 [IQR 0.0] and 1.04 [IQR 0.02] respectively (Figure 1), which represented a statistically significant difference ($p < 0.01$). Examples of paired real and segmented NOX and OIR images are shown in Figure 2.

Conclusions: The tortuosity index of retinal vasculature can be semi-automatically calculated for retinal images of OIR mice using a deep learning algorithm. Application of this algorithm to compare the TI for NOX and OIR mice at P17 demonstrated significantly greater tortuosity in OIR mice. Future studies may employ this tool to rapidly assess the effects of therapeutic interventions on the TI of the OIR phenotype.

ABSTRACT BODY:

Purpose: Retinal degenerative diseases frequently involve photoreceptor cell (PRC) death. We have observed dramatic rescue of cone PRCs in the rd10 mouse model of retinopathy when administered (+)-pentazocine ((+)-PTZ), a high affinity SIG1R ligand. The molecular mechanisms of SIG1R-mediated neuroprotection are under investigation. We previously reported that NRF2 may be central to SIG1R-mediated PRC rescue in rd10 mice. CUL3 is a component of the NRF2-KEAP1 pathway and facilitates NRF2 ubiquitination. CUL3 is critical to caspase-8 ubiquitination which regulates cellular apoptosis. Here, we asked whether SIG1R co-localizes with CUL3 and whether its activation alters CUL3 expression.

Methods: 661W cone cells were treated with (+)-PTZ. We used qRT-PCR to investigate Cul3 gene expression, immunoblotting to detect protein levels, CellROX assay to assess oxidative stress and reactive oxygen species (ROS) levels. Small interfering RNA (siRNA), targeting Sig1R or Cul3, was transfected into cells using lipofectamine RNAiMAX reagent to knockdown protein expression. Proximity ligation assay (PLA), co-immuno-EM and co-immunoprecipitation (co-IP) were used to detect the extent to which SIG1R co-localizes and interacts with CUL3.

Results: Treatment of 661W cells with (+)-PTZ [20 μM] significantly increased the expression of Cul3. With increasing concentrations of (+)-PTZ, CUL3 protein levels increased in a dose-dependent manner (~5 fold [3 μM], ~13 fold [10 μM], 18 fold [20 μM] & 18 fold [50 μM]). After silencing SIG1R using siRNA, Cul3 expression decreased dramatically. In Müller cells isolated from $Sig1R^{-/-}$ mice, we observed a significant decrease of CUL3, similar to that observed in 661W cells. In Cul3-siRNA-transfected 661W cells, cellular ROS levels increased significantly. Using PLA and EM immunogold labeling we observed co-localization of SIG1R and CUL3 in 661W cells. The proteins were co-localized in mouse retina tissue as well. Co-IP verified the interaction of SIG1R with CUL3.

Conclusions: Our data provide first evidence that SIG1R co-localizes/interacts with CUL3, a key player in the NRF2-KEAP1 antioxidant pathway. Furthermore, activation of SIG1R modulates Cul3 expression, which may be relevant to its retinal neuroprotective properties. Future studies will investigate comprehensively the role of CUL3 in SIG1R-mediated cone PRC rescue.

TITLE: ASSESSMENT OF SAFETY IN THE CORNEAL DONATION PROCESS DURING THE COVID-19 PANDEMIC

SESSION TITLE: Refractive and non-refractive corneal surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: I.C. José, A.M. Casella, A. Pelaquim, B.I. Santos, R.C. Feijó, A.P. Oguido, Universidade Estadual de Londrina, Londrina, PR, BRAZIL|

Commercial Relationships Disclosure: Isadora José: Commercial Relationship: Code N (No Commercial Relationship) | Antonio Casella: Commercial Relationship: Code N (No Commercial Relationship) | Andressa Pelaquim: Commercial Relationship: Code N (No Commercial Relationship) | Beatriz Santos: Commercial Relationship: Code N (No Commercial Relationship) | Rodolfo Feijó: Commercial Relationship: Code N (No Commercial Relationship) | Ana Oguido: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the impact of the covid-19 pandemic and the safety of the corneal donation process in an Eye Bank in Southern Brazil.

Methods: This is a cross-sectional, observational, retrospective study involving 771 potential corneal donors and their respective RT-PCR COVID-19 results. The tests were performed by collecting secretions from the oropharynx and nasopharynx and processed in a laboratory at the University Hospital of Londrina-PR, from March 2020 to November 2021. The individuals were submitted to a complementary check list to the traditional one for clinical and epidemiological screening of potential corneal donors against coronavirus (SARS-Cov2). Patients not tested for COVID-19 in this first step were excluded using the main clinical screening criteria already routinely used. The criteria used for further validation of potential donors were: donor who had COVID-19 with complete remission of symptoms for more than 28 days, donor with no clinical suspicion, and no suspected or confirmed contact of COVID-19. Donors diagnosed with COVID-19, donor with COVID-19 suspected by clinical and epidemiological evaluation, contacts of suspected or confirmed COVID-19 less than 14 days ago, and donor with clinical suspicion less than 28 days ago but negative molecular test were discarded in this evaluation.

Results: Among the 771 potential corneal donors, 710 individuals performed the RT-PCR test. A total of 689 (97.04%) individuals tested negative for COVID-19. The average age of suitable donors was 52.52 ± 18.10 years, 289 (41.9%) were female and 400 (58.1%) were male. However, 21 (2.96%) individuals tested positive for COVID-19 and were discarded, even after the complementary screening implemented due to the coronavirus pandemic. Among the positives, 9 (1.2%) cases were female and 12 (1.6%) were male; the average age was 55.10 ± 23.10.

Conclusions: Despite the complementary exclusion criteria for potential organ and tissue donors in the pandemic, the use of RT-PCR for COVID-19 proved to be essential to maintain safety in the corneal donation process.

ABSTRACT BODY:

Purpose: Diabetic macular ischemia (DMI) is a complication of diabetic retinopathy (DR) that can result in irreversible vision loss. There is no approved treatment for DMI. The non-randomized, open-label, single rising dose (SRD)/multiple dosing (MD) HORNBILL study (NCT04424290) is investigating the safety and efficacy of intravitreal BI-X, an anti-ischemia modulator, in patients with DMI.

Methods: Patients with DR treated with pan-retinal photocoagulation who have evidence of DMI are eligible for inclusion in both parts of the study, defined (using optical coherence tomography angiography) in the completed SRD part as any degree of disruption in retinal vascularity within the superficial and/or deep retinal plexus, and in the ongoing MD part as a foveal avascular zone (FAZ) size of ≥0.5 mm^2. The SRD part comprised three dosing cohorts (0.5, 1.0, and 2.5 mg of BI-X), and the primary endpoint was the number of dose-limiting events; secondary endpoints were the number of drug-related adverse events (AEs) and number of ocular AEs. The primary MD endpoint is the number of patients with drug-related AEs; secondary endpoints include change from baseline of best-corrected visual acuity (BCVA), FAZ size, and central retinal thickness.

Results: The SRD part enrolled 12 patients. Half of the patients were female, and the mean age was 61.8 years. The mean time since reported onset of DMI was 4.8 years, and mean BCVA was 30.8 letters. In total, 8 AEs were reported; 5 were ocular (conjunctival hemorrhage, ocular hyperemia, procedural pain, temporary intraocular pressure increase, vitreous detachment), all of which were deemed procedure-related other than hyperemia and vitreous detachment. There were no dose-limiting events, or drug-related AEs reported. Preliminary signs of efficacy were observed; BCVA improved by 5.3 and 4.0 letters in the 1.0 mg and 2.5 mg groups, respectively. The maximum feasible dose in the SRD part was 2.5 mg, which is now being used in the ongoing MD cohort, into which two patients have been enrolled.

Conclusions: Single doses of BI-X were well tolerated by patients with DMI, with no dose-limiting events or drug-related AEs reported. The ongoing single-masked, randomized, MD study will further examine the efficacy of BI-X in patients with DMI.

ABSTRACT BODY:

Purpose: Depth-resolved visualization and quantification of hyper-reflective foci in the entire 3D OCT scan corresponding to intraretinal pigment migration and pigmentation along the retinal pigment epithelium (RPE) were achieved using an OAC-based algorithm.

Methods: Subjects with intraretinal hyper-reflective foci and increased reflectivity along the RPE were imaged using a SS-OCT (PLEX® Elite 9000; ZEISS, Dublin, CA) 6×6 mm macular scan pattern. Inner limiting membrane (ILM), RPE, and Bruch's membrane (BM) were segmented using the manufacturer's software. OCT scans were converted to images contrasted by OACs in linear space (Fig. 1A, B). Hyper-reflective foci judged by OACs within a slab from the ILM to 10 μm above the RPE were labeled in green as intraretinal pigmentary deposits. The RPE was color-coded from yellow to red to demonstrate OAC values in which foci of increased reflectivity were highlighted in red. The total pigment burden was segmented from the en face sum projection of an OAC slab from the ILM to BM using an adaptive thresholding method. En face areas of hyper-reflective foci identified by the algorithm were compared with manual segmentations.

Results: A total of 49 eyes from 42 patients were recruited. Visualization of these hyper-reflective lesions was successfully accomplished, and intraretinal hyper-reflective foci were distinguished from increased reflectivity along the RPE (Fig. 1D, E). Hyper-reflective lesions from 24 eyes were manually segmented by identifying intraretinal lesions on B-scans and choroidal hypo-transmission defects on sub-RPE slabs extending 64 to 400 μm below BM. A significant correlation was found in area measurements of the total pigment burden between automated and manual segmentations ($P<0.001$, Fig. 1C).

Conclusions: An automated algorithm based on OACs was able to visualize, localize and quantify hyper-reflective foci in the retina and along the RPE, and the automated quantifications were successfully validated against manual segmentations.

ABSTRACT BODY:

Purpose: The aim of this study is to detect optic nerve head (ONH) changes with swept-source optical coherence tomography (SS-OCT) evaluated with the hypotenuse of the ONH cupping (HOC) after intraocular pressure (IOP) lowering procedures.

Methods: Subjects with progressing glaucoma presenting typical ONH and SS-OCT findings that were referred to IOP-lowering glaucoma procedures were included. Patients underwent 24-2 perimetry (SITA standard; Humphrey Field Analyzer; Zeiss) and SS-OCT (DRI-Triton; Topcon) using the wide-field 9mmx12mm raster scan. IOP and SS-OCT scans were obtained at the preoperative period (pre-op), up to 7 days (PO1) and between 30 to 90 days post-operatively (PO2). A B-scan at the center of optic disc and an average of five central B-scans were used to calculate the ONH parameters. HOC was calculated using the Pythagorean theorem: $hypotenuse^2 = leg1^2 + leg2^2$ using the length and depth of the cupping as the legs of a right triangle (figure 1). We also evaluated the change of the BMO-to-BMO extension. Statistical analysis was performed using Generalized estimating equations (GEE).

Results: Fifteen eyes (12 subjects) qualified for the study and underwent the 3 visits. The average age was 70±11.04 years. At the baseline, the average circumpapillary retinal nerve fiber layer (cRNFL) was 60.13±23.21 µm and the visual field (VF) mean deviation (MD) was -13.29±8.5 DB. The mean IOP on each visit (pre-op, PO1 and PO2) were: 20.5±4.99; 11±4.95 and 15.7±5.04, respectively ($p<0.01$). Average HOC decreased significantly after the IOP-lowering procedures ($p=0.001$), markedly between pre-op to PO1. The average components of HOC, depth and lenght, and the BMO-to-BMO extension also decreased significantly (table 1). There was no significant change from PO1 to PO2 in all parameters.

Conclusions: HOC evaluated with SS-OCT significantly decreased after IOP-lowering surgeries to treat progressing glaucoma. This biomarker may be useful to evaluate short-term ONH changes. Notwithstanding, a longer follow-up is needed to determine the persistence of these changes.

ABSTRACT BODY:

Purpose: The purpose of the current study was to investigate the size, cargo, and function of extracellular vesicles (EVs) derived from healthy ARPE-19 cells expressing wild-type (WT)-Fibulin-3 (WT-RPE-EV) compared to diseased ARPE-19 cells expressing the R345W-Fibulin-3 mutation (R345W-RPE-EV).

Methods: ARPE-19 cells were infected with luciferase-tagged WT-Fibulin-3 or luciferase-tagged R345W-Fibulin-3 using lentiviruses. EVs were isolated from the media of ARPE-19 cells by conventional ultracentrifugation or density gradient ultracentrifugation. The amount and size distribution of EVs was determined by Nanoparticle Tracking Analysis (NTA). EV protein concentrations were quantified using the DC^{TM} Protein Assay (Bio-Rad). Transmission and cryogenic electron microscopy (EM) were used to image the morphology of the EVs. EV markers were validated using western blot analysis. EV cargo was analyzed by unbiased proteomics using LC-MS/MS with subsequent pathway analysis (Advaita). The EV-associated transforming growth factor-beta 1 (TGF-β1) protein was measured by enzyme-linked immunosorbent assay. EV uptake was investigated by using PKH67-labeled vesicles and was analyzed by confocal imaging. Migration ability was evaluated in ARPE-19 cells using scratch assays in the presence or absence of EVs. mRNA expression levels of endothelial-mesenchymal transition (EMT) markers were measured in ARPE-19 cells after EV treatment, by RT-PCR.

Results: NTA analysis showed that the particle size distributions of R345W-RPE-EV were smaller than those of the WT-RPE-EV, however, there was no difference between EV protein concentrations. Similarly, EM revealed spherical and concave-appearing EVs with two subpopulations of diameters: 30 nm and over 100 nm. Pathway analysis revealed that primary cilia and sonic hedgehog pathways were found to be 3- to 5-fold more abundant in WT-RPE-EV. In contrast, EMT drivers, lysosome components, and ribosome components were found to be 3- to 7-fold more abundant in R345W-RPE-EV. We also found higher levels of TGF-β1 associated with R345W-RPE-EVs compared to WT-RPE-EVs ($p<0.001$). Incubation with R345W-RPE-EVs caused enhanced migration and elevated EMT marker expression in ARPE-19 cells.

Conclusions: These results suggest that R345W-RPE-EVs potentially induce EMT in RPE cells, which may be significant to RPE disease progression.

TITLE: Re-entrainment of retinal circadian clock rescues retinal function after the environmental circadian disruption

SESSION TITLE: Photoreceptors and disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Baba, I. Roberts, H. Duong, G. Tosini, Pharmacology/Toxicology, Morehouse School of Medicine, Atlanta, Georgia, UNITED STATES|

Commercial Relationships Disclosure: Kenkichi Baba: Commercial Relationship: Code N (No Commercial Relationship) | Imani Roberts: Commercial Relationship: Code N (No Commercial Relationship) | Hao Duong: Commercial Relationship: Code N (No Commercial Relationship) | Gianluca Tosini: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The circadian clock plays important roles in the regulation of retinal functions. Previous studies have indicated that removal of the clock gene, Bmal1, from the retina alters photosensitivity, spectral identity and cone viability. We have previously reported that environmental circadian disruption (ECD) also affected circadian clocks in retina and retinal pigment epithelium (RPE). ECD also affected retinal function by altering peripheral retinal circuitry. In this study we investigated whether the re-exposure to stable light cycle is able to re-entrain circadian clocks in the eye and rescue retinal function after ECD.

Methods: PER2::LUC and C57BL/6 mice were placed in a light tight isolated chamber and expose to ECD light cycles by advancing the time of light-on at 6 hours/week for 4 weeks. For control group, mice were exposed to a 12/12 Light/Dark (LD) cycle without any shifts. After the end of ECD cycle, mice were re-exposed to a 12/12 LD cycle for two to four weeks. Then after two or four weeks, PER2::LUC mice (3-4 mo. old) were sacrificed and the retina and the RPE were isolated and cultured for bioluminescence measurement. C57BL/6 mice (3-4 mo. old) were also subjected to both scotopic and photic electroretinogram (ERG).

Results: The circadian rhythm in PER2::LUC bioluminescence revealed that re-exposure of stable light cycle for two weeks re-entrained circadian clock in the retina and RPE. Two weeks of re-exposure to a 12/12 LD cycle did not rescue the amplitude of scotopic b-wave after ECD, but after four weeks of re-exposure to a 12/12 LD the amplitude of scotopic b-waves did not show any difference with respect to control group.

Conclusions: Our data indicates that two weeks of exposure to a 12/12 LD after ECD re-entrains circadian clocks in retina and RPE and the re-entrainment ocular clock rescues the retinal functioning. Thus, our results suggest that ECD induced visual impairment can be reversed by the stable light cycle.

ABSTRACT BODY:

Purpose: Uveal melanomas (UM) are the most common primary intraocular malignancy in adults. Using gene expression profiling (GEP), UMs can be prognostically categorized as either Class 1 (low risk) or Class 2 (high risk) tumors. Most high risk metastatic UMs harbor a deactivating mutation BRCA1 associated protein-1 (BAP1) gene. A BAP1 mutation leads to loss of nuclear BAP1 expression which strongly correlates with a Class 2 GEP. Recent investigations have shown that the digital morphometry of tumor nuclei correlates with BAP-1 status. Here, we performed a retrospective cohort analysis between BAP1 status and nucleolar features, a relationship that remains unexplored.

Methods: 10 H&E stained slides composed of 5 BAP1-mutant and 5 BAP1-wildtype UMs were scanned by Phillips IntelliSite Scanner and uploaded as whole slide images to the Phillips Intellisite Suite for morphometric analysis. The longest nucleolar diameter (in μm) and nucleolar organizing region (NOR) number was determined for 200 consecutive tumor nuclei in one high-powered field for a total of 2,000 tumor cells. A Student t-test was performed to determine possible statistical differences between mean nucleolar diameter and NOR number in BAP1-mutant and BAP1-wildtype UM groups.

Results: The BAP1-mutant group had a mean nucleolar diameter of 2.43 μm (range 1–9.1) and mean NOR number of 1.4 (range 1–5). The BAP1-wildtype group had a mean nucleolar diameter of 2.15 μm (range 0.5–6) and mean NOR number of 2 (range 1–6). A strong statistical difference between mean nucleolar diameter (P = 7.65E-24) and mean NOR number (P = 4.68E-47) was observed between BAP1-mutant and BAP1-wildtype UM groups.

Conclusions: BAP1-mutant UMs have larger nucleoli and fewer NORs than BAP1-wildtype UMs. This finding supports previous research regarding the prognostic relevance of nucleolar size and number of NORs in Class 1 and Class 2 UMs but suggests that BAP1 alteration may account for these observations. With use of advanced whole slide image analytical techniques, further investigation of this phenomenon should be pursued to determine if standard H&E stained slides can be used to predict GEP Class in UM.

ABSTRACT BODY:

Purpose: Cytokines are inherently prone to proteolytic degradation and thus conclusions drawn from collection and storing of the ocular samples could potentially result in misled clinical decisions. This study aimed to determine the effects of sample collection and storage duration on the levels of various cytokines in the human aqueous humor and vitreous samples.

Methods: Samples were obtained from 27 human eyes that underwent pars plana vitrectomy for various diagnoses. Undiluted samples (0.1-0.3ml) were aliquoted into 3 tubes and stored at -80^{O}C for analysis within 1-week, 3-month and 9-month duration since collection. All 27 cytokine analytes were analyzed with the Bioplex Pro-Human cytokine 27-plex assay kit. An ANOVA was run to assess the impact of storage time and sampling location for each biomarker. Cytokine profiles were embedded using principal component analysis (PCA) to view the proximity between timepoints for each sample. A p-value less than the Bonferroni corrected threshold of 0.05 was considered significant.

Results: Four of the 27 biomarkers were significantly impacted by storage duration at both 3- and 9-month timepoints (Interleukin 2 [IL-2], IL-10, IL-12, and Platelet-derived growth factor [PDGF-BB]), whereas 11 were significantly influenced by sampling location of anterior chamber versus vitreous within the same eyes (Granulocyte-macrophage colony-stimulating factor [GM-CSF], IL-2, IL-5, IL-6, IL-7, IL-8, IL-9, IL-12, IL-15, PDGF-BB, and vascular endothelial growth factor [VEGF]). Amongst biomarkers where sample duration was significant, the relative abundance tended to decrease with time. For biomarkers where sampling location of anterior chamber versus vitreous was significant, cytokine concentrations tended to be higher in aqueous humor, with the exception of IL-7. Neither sampling location offered a significant advantage of mitigating deterioration in storage. Separability of patient-specific cytokine profiles at all 3 timepoints in the PCA remained relatively the same over time.

Conclusions: Although there is degradation amongst specific cytokine analytes over 9 months of sample storage, sampling between aqueous humour and vitreous specimens within the same eyes shows much more variation than individual sample deterioration. In all cases, the overall patient-specific cytokine profiles remained relatively the same over time.

TITLE: Topical instillation of Metformin Prevents Oxidative Stress-Induced Eye Lens Opacity Through Induction of AMPK-Nrf2-Mediated Antioxidant Pathway

SESSION TITLE: Cataractogenesis: pathogenesis, prevention and treatment

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: D.P. Singh, B. Chhunchha, R.R. krueger, Ophthalmology and Visual Sciences, University of Nebraska Medical Center College of Medicine, Omaha, Nebraska, UNITED STATES|E. Kubo, Department of Ophthalmology, Kanazawa Medical University, Kanazawa, JAPAN|

Commercial Relationships Disclosure: Dhirendra Singh: Commercial Relationship: Code N (No Commercial Relationship) | Bhavana Chhunchha: Commercial Relationship: Code N (No Commercial Relationship) | Ronald krueger: Commercial Relationship: Code N (No Commercial Relationship) | Eri Kubo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Oxidative stress amplification due to dysregulation of antioxidant pathway with advancing age is a major cause of aging diseases. Metformin (Met), an antidiabetic, has been found to be a potent inducer of Nrf2 (NFE2-related factor 2) antioxidant pathway. Using C57BL/6 mice as a model system, herein we showed that topical application of Met in the eye internalizes in lenses and prevents lens opacity ex-vivo through activation of AMPK-Nrf2/antioxidant-mediated defense pathway.

Methods: 18-month-old mice (n=18) were used for study and anaesthetized with an oxygen-isoflurane pump before Met topical application. Buffered saline (n=6) or 5mM/5µl (n=6) of Met in buffered saline (pH7.4) or Met blocker, atropine (3.5mM) followed by Met (n=6) was instilled once daily in the eyes for 7 days and lenses were collected. To assess Met penetration, lenses were isolated and lens extract was processed and analyzed by Acquity UPLC with Waters triple-quad Xevo TQS. Also, total RNA and protein were isolated and processed for qPCR and Western analyses to assess levels of Nrf2 and its target genes, like Prdx6 and phaseII enzymes expression using specific probes. In another set of ex-vivo experiments, the isolated lenses were exposed to 0-100µM of H_2O_2 for variable times to assess lens opacity. The lenses were photographed (Nikon SMZ 745T) and lens opacity was determined using densitometry. H2DCF-DA dye measured reactive oxygen species (ROS) levels. Two-tailed Student's t-test and one–way ANOVA were used for statistical analysis.

Results: Data analyses revealed that Met could internalize in the lenses, and the lenses displayed upregulation and activation of AMPK. These lenses showed significantly increased expression of Nrf2 and its target antioxidant genes mRNA and protein like Prdx6 and PhaseII enzymes ($p<0.001$) with dramatic reduction in ROS levels compared to untreated lenses. Untreated lenses developed H_2O_2-induced lens opacity ex-vivo, while treated showed significantly less opacity; 81% at 48h and 68% at 120h of H_2O_2 exposure.

Conclusions: All together, our results demonstrate that topically applied Met internalizes in eye lenses and prevents oxidative stress-evoked the lens opacity through activation of AMPK-Nrf2- antioxidant defense pathway, thus raise the possibility of Met-based interventions to delay/prevent aging-related cataract.

ABSTRACT BODY:

Purpose: It is of interest to determine how aberrations across the wide visual field and eye shape change over time in children. The study aims to demonstrate the following features of a scanning Shack-Hartmann wavefront sensor (WFS): (1) compact size, (2) natural open-view central fixation, (3) invisible laser and (4) rapid scanning speed.

Methods: We have designed an innovative scanning mechanism with compact motorized stages to achieve scanning along horizontal, vertical, and diagonal meridians. Scanning the horizontal meridian uses the rotary stage only, while scanning in the vertical direction is achieved by translating the x-z linear stage and tilting the hot mirror. Diagonal scanning involves both operations. A high sensitivity CCD sensor ensured each scan was completed within a blink interval, and an invisible 980 nm laser minimized visual distractions. An open-view design allows participants to maintain their central fixation while minimizing instrumental myopia and providing accommodation control without cycloplegia. The accuracy of the WFS was tested by comparing an optical ray-tracing simulation in Zemax to horizontal scan measurements from a model eye. The model eye consisted of a 25 mm focal length doublet with a diffuser at its focal point. Optical ray tracing was performed at 0 to 30° degrees in 5° steps and compared with the measured aberrations.

Results: Zernike coefficients from the Zemax simulation for vertical astigmatism (z5) and horizontal coma (z8) were plotted against data from wavefront measurements collected with the sensor and the model eye. The r^2 values from linear regression were 0.9835 (z5) and 0.9805 (z8), representing a good correlation. As expected, z5 and z8 increased in magnitude with eccentricity, while z12 remained stable at 0.008 ± 0.006 μm (mean ± stdev) across the horizontal meridian. A single scan, up to ±30°, was completed in less than 3 seconds.

Conclusions: We have demonstrated a new version of a compact scanning WFS covering up to ±30°, ±35°, and ±20° along horizontal, diagonal, and vertical meridians, respectively. The WFS can be easily transported to measure the children's eye's aberrations across the visual field in a clinical or school setting.

ABSTRACT BODY:

Purpose: To characterize retinal vein occlusion (RVO)-related macular edema (ME) treatment patterns and its impact on 12 and 24-month best visual acuity (BVA) and central subfield thickness (CST).

Methods: A retrospective cohort study of patients diagnosed with RVO in a tertiary ophthalmic center was performed. Patients who developed RVO-related ME and received their first anti-vascular endothelial growth factor (anti-VEGF) injection between 2003-2020 were included. Treatment patterns analyzed included steady-state anti-VEGF injection interval, time between diagnosis and treatment of ME, and steroid usage. Linear regression analyzed the relationship between treatment patterns and 12 and 24-month BVA and CST, adjusting for sociodemographic factors and systemic comorbidities.

Results: Analysis included 215 eyes with branch RVO (BRVO) and 185 eyes with central RVO (CRVO) or hemiretinal RVO (HRVO). 50.2% of BRVO patients received anti-VEGF injections ≤q8 weeks, 25.6% received injections q8-12 weeks, and 24.2% received injections >q12 weeks. 44.3% of CRVO/HRVO patients received anti-VEGF injections ≤q8 weeks, 31.9% received injections q8-12 weeks, and 23.8% received injections >q12 weeks. There was no significant difference in BVA and CST at baseline, 12, or 24 months in all injection interval subgroups in BRVO and CRVO/HRVO patients. 8.4% of BRVO and 9.2% of CRVO/HRVO patients were treated with steroids. In BRVO patients, steroid usage was associated with a 6.61 (95% CI=0.27-12.96, p<0.01) letter loss in BVA at 12 months and a CST increase of 58.32 (95% CI=9.66-106.97, p=0.02) and 68.47 (95% CI=12.42-123.51, p=0.02) μm at 12 and 24 months, respectively (Tables 1 and 2). Delay between diagnosis and treatment of ME was 35.8±130.5 days in BRVO patients and 10.7±34.2 days in CRVO/HRVO patients. In BRVO patients, every day of delay was associated with a 0.03 (95% CI=0.01-0.05, p=0.01) letter loss of BVA at 24 months. CST was found to be increased by 0.18 (95% CI=0.04-0.31, p=0.01) and 0.79 (95% CI=0.22-1.36, p=0.01) μm for every delayed day at 24 months in BRVO and CRVO/HRVO patients, respectively.

Conclusions: Treatment delay and steroid usage were associated with worse improvements in long term BVA and CST. Steady-state anti-VEGF injection interval was not found to be significant predictor of patient outcomes.

ABSTRACT BODY:

Purpose: To determine corneal elastic modulus with optical coherence elastography (OCE). The OCE technology is eventually aimed to determine efficacy of a novel corneal collagen crosslinking (CXL) protocol by measuring corneal elastic modulus.

Methods: Ex-vivo experiments on three enucleated adult rabbit eyes were performed. A custom benchtop 100 kHz, 5-μm axial resolution swept-source optical coherence tomography (SS-OCT) system operating at 1060 nm wavelength was built. Corneoscleral discs were mounted on an artificial anterior chamber with closed-loop intracameral pressure control using a micro-infusion pump and pressure sensor. A speckle tracking method was used by locating the maximum cross-correlation between multipixel kernels. Local tissue displacements were tracked during a stepwise quasistatic mechanical loading with a intracameral pressure increment from 17 to 25 mmHg (Figure 1). B-M mode OCT scanning was used to obtain 2-D cross-section scan from central 6-mm of cornea. Corneal axial strain tensor (perpendicular to the corneal surface) was calculated as, $E_{zz}(x,z) \equiv dU_z(x,z) \div dX$ where $U_z(x,z)$ represents the local axial displacements. Using the assumptions of homogeneity and uniform thickness, compressive (known as out-of-plane) Young's modulus was calculated.

Results: The average central corneal thickness of all three eyes was 480 microns. The axial strain profile was plotted (Figure 2) and the compressive Young's modulus was measured as 23.4 kPa, 48.1 kPa and 49.1 kPa for all three corneas.

Conclusions: The measured compressive Young's modulus is within the literature range of approximately 35 to 80 kPa. The OCE will be crucial for post-CXL biomechanical efficacy on intact corneal tissue under normal physiological pressure of 10 to 18 mmHg.

ABSTRACT BODY:

Purpose: Chronic inflammation is now regarded as a major pathogenic pathway common in retinal degenerative diseases. Current studies suggest that antioxidant therapies for chronic inflammation treatment are a feasible objective to stop disease progression and represent a promising strategy to improve the therapeutic benefits of regenerative medicine. In this line, nanoceria has been added to the group of antioxidant/anti-inflammatory substances with therapeutic properties. Nanoceria has a unique electronic structure that when reduced to the nanoscale behaves as an oxygen radical scavenger. Here, we developed a new generation of functional nanomedicine which integrates single and combined therapeutic functions involving nanoceria, specially designed for an eye drop formulation, together with retinal pigment epithelial (RPE) cell therapy for retinal degeneration.

Methods: Subretinal implantation of hiPSC-derived RPE cells in RCS rat model of retinitis pigmentosa was performed in the presence or absence of nanoceria eye drops. Four study groups were created: group 1 received subretinal injection of RPE cell suspension (10^5 cells/eye) under continuous nanoceria treatment; group 2 only received subretinal injection of RPE cell suspension; group 3 was injected with vehicle and treated with nanoceria; group 4 was injected with vehicle. Animals were tested at 1, 2, and 4 weeks after cell injection/treatment by OCT, FAF, and ERG to evaluate: 1) conservation of retina; 2) retinal function; 3) survival and integration of the implanted cells. After 4 weeks, animals were euthanized and eyes analyzed by ICP-MS, immunohistochemistry, qPCR, and western-blot.

Results: Ocular administration of nanoceria eye drops in the RCS rats reaches all eye parts without translocation inside the body. Nanoceria preserved the retina structure and RPE viability after transplantation and decreased the infiltration of activated microglia and reduced reactive gliosis. Transplanted RPE cells in presence of nanoceria expressed higher levels of specific markers bestrophin 1, MITF, and RPE65, and reduced glial activation. Moreover, transplanted RPE with nanoceria better preserved ONL compared to vehicle treatment

Conclusions: The combined therapy with RPE cell transplantation and the antioxidant and anti-inflammatory effect of the nanoceria eye drops is a potentially better therapeutic approach to protect the retina from degeneration.

ABSTRACT BODY:

Purpose: To investigate whether reclassifying eyes with intermediate (i)AMD by additional imaging-based biomarkers identifies sub-phenotypes of iAMD with reduced visual function (VF).

Methods: People with no AMD and Beckman defined iAMD in the MACUSTAR study performed Best Corrected Visual Acuity (BCVA), Low Luminance Visual Acuity (LLVA), Moorfields Acuity Test (MAT), Pelli Robson Contrast Sensitivity (CS), International Reading Speed Test (IReST), Mesopic (MesAT) and Scotopic (ScoAT) average thresholds (S-MAIA microperimetry) and AdaptDx Rod Intercept Time (RIT), followed by multimodal imaging (colour fundus and confocal infrared photography, fundus autofluorescence and spectral domain optical coherence tomography). Images were graded by a central reading centre for presence of the following features: pigmentary abnormalities (PA), reticular pseudodrusen (RPD), incomplete and complete retinal pigment epithelium and outer retinal atrophy (iRORA and cRORA). Pairwise complete VF data were compared across three structurally defined

groups; no AMD, iAMD feature absent(-) and iAMD feature present(+) using nonparametric Kruskal-Wallis, followed by pairwise Wilcoxon tests. Being a signal seeking exploratory analysis, multiple testing correction was not applied.
Results: 224 people (n=56 no AMD [33F; mean age 68 yrs]; n=168 iAMD [106F; 71 yrs]) were included in this analysis. Of those with iAMD, 96(57%) had PA, 37(22%) had RPD, 18(11%) had iRORA and 7(4%) had cRORA. With the exception of IReST, those with iAMD and absent structural features had worse median VF than those with no AMD on all measures ($p<0.01$). LLVA, CS, MesAT, ScoAT and RIT were worse in those with iAMD+RPD compared to iAMD–RPD ($p<0.04$). LLVA, CS, MAT, MesAT and ScoAT were worse in those with iAMD+cRORA compared to iAMD–cRORA ($p<0.05$). CS was worse in those with iAMD+PA compared to iAMD–PA ($p=0.01$). There were no median differences between presence or absence of iRORA in any VF measure.
Conclusions: Though ascribed the same AMD disease stage, eyes with iAMD+RPD and iAMD+cRORA had poorer low luminance and contrast vision than other iAMD eyes. As the number of eyes with observed structural features is small, we aim to confirm our findings in a large longitudinal cohort and examine whether additional structural or functional features should be accounted for in AMD disease classification or used as entry criteria in treatment trials.

ABSTRACT BODY:

Purpose: The PDS is an innovative drug delivery system for the continuous delivery of a customized formulation of ranibizumab (RBZ) into the vitreous, approved for nAMD in the US. The Portal extension trial (NCT03683251) is evaluating long-term safety and efficacy of the PDS with RBZ 100 mg/mL (PDS 100 mg/mL) in patients (pts) with nAMD who completed the Ladder (NCT02510794) or Archway (NCT03677934) trials, or will complete the Velodrome (NCT04657289) trial. Interim efficacy data from Portal and long-term pooled safety data from Ladder, Archway, and Portal are reported.

Methods: In Ladder, pts received PDS (10, 40, or 100 mg/mL) with pro re nata (PRN) refills, or monthly intravitreal RBZ 0.5 mg injections (monthly RBZ). In Archway, pts received PDS 100 mg/mL with fixed 24-week refill-exchanges (PDS Q24W) or monthly RBZ (every 4 weeks). Once moved to Portal, pts receive PDS Q24W from day 1. Efficacy outcomes were assessed for Ladder-to-Portal pts treated with prior PDS 100 mg/mL PRN or prior monthly RBZ. Long-term safety was analyzed using pooled data from all pts who received PDS via optimized surgery procedure in Ladder, Archway, or Portal.

Results: For Ladder-to-Portal pts, BCVA remained stable from baseline (BL) to month 48 in prior PDS 100 mg/mL PRN (n=59) and prior monthly RBZ (n=41) arms; mean change from BL (letters; 95% CI) was 0.1 (–6.6, 6.8; n=31) and 2.3 (–9.4, 14.1; n=15), respectively. Center point thickness was also stable through month 48. ~95% of pts did not need supplemental treatment before each refill-exchange procedure. The PDS Patient Preference Questionnaire showed that 92% of Ladder-to-Portal prior monthly RBZ pts preferred PDS at week 40 over injections. In the all PDS safety population (n=555; mean follow-up 111 weeks), 137 (24.7%) pts had ≥1 ocular adverse event of special interest (AESI); most common ocular AESIs were cataract (11.4%), vitreous hemorrhage (6.1%), and conjunctival bleb/conjunctival filtering bleb leak (6.3%). Endophthalmitis occurred in 11/555 (2.0%) pts. Most AESIs were mild/moderate in severity.

Conclusions: Interim results from Portal suggest 48-month maintenance of visual/anatomical outcomes with PDS 100 mg/mL, with PDS preferred to monthly injections. The long-term safety profile of PDS is well characterized, manageable, and reveals no new safety signals.

ABSTRACT BODY:

Purpose: To study the expression of CB2 receptor in the posterior segment of the eye and its response to intraocular inflammation (IOI).

Methods: EAU was induced in 53 C57BL/6J mice as previously published using the uveitogenic 161-180 amino acid fraction of human intra-retinal-binding-protein (hIRBP). Clinical and histopathological grading were performed on days 4, 10, 17, 21 and 24 post induction using indirect ophthalmoscopy and H&E staining respectively. CD4+ T Cells and CB2 receptor were stained in ocular sections and retinal whole flat mounts using immunofluorescence. Perfusion of Fluorescein isothiocyanate dextran conjugate (MW 500k, Sigma) was used for retinal blood vessels staining in flat retinas. Analysis was performed at different time points for cell volume and number using Confocal 3D microscopy and Imaris software.

Results: IOI occurred in 44 out of 53 (83%) mice with induced EAU. Clinical signs of inflammation appeared at 10 days, peaked at 17 to 21 days, and declined at 24 days, post EAU induction. Mice with high clinical scores exhibited more CD4+ cells and higher CB2 receptor positive cells in the vitreous, retina and choroid compared to mice with low grades of inflammation. In retinal flat mounts analysis, CB2 receptor was present in the retina of control mice and significantly upregulated on day 10 ($p<0.05$). CD4+ cells were located outside the retinal blood vessels, peaked on days 10-21 and diminished on day 24 post induction ($p<0.05$).

Conclusions: EAU proved to be a robust and reproducible model in our laboratory. CB2 receptor peaked in the retina earlier than the appearance of CD4+ cells which paralleled the clinical appearance of IOI. These preliminary results suggest that cannabinoids may have a potential effect on EAU.

ABSTRACT BODY:

Purpose: Retinal photoreceptors are neurons generating electrical signals in response to light excitation. This function is performed by a set of phototransduction proteins localized in photoreceptor outer segments. Despite their well-known functions, the information about their absolute amounts is often conflicting, which impedes our deeper understanding of the relevant molecular mechanisms. In this study, we used a recently developed mass spectrometry-based protein quantification method, called “MS-Western”, for measuring absolute amounts of key functional proteins residing in rod outer segments.

Methods: MS Western quantifies proteins after co-digestion of a sample containing proteins of interest combined with a heavy-isotope labeled protein chimera composed of tryptic peptides representing each of these proteins and a reference protein (typically BSA). It relates the molar abundance of all analyzed peptides to a single reference protein (BSA) added to the sample as a standard. Our chimeric construct contained 3-5 reliably identifiable tryptic peptides representing 20 rod outer segment proteins along with 6 peptides representing BSA.

Results: By comparing the ion intensities of “light” and “heavy” peptides measured in a single mass spectrometry experiment, we simultaneously measured the absolute amounts of all 20 proteins of interest. The method’s accuracy was validated by confirming the equimolar amounts of protein subunits within the known stoichiometric complexes: PDE6α/PDE6β and RGS9/Gβ5/R9AP. The ratios of PDE holoenzyme and the RGS complex to rhodopsin in mouse rods were 1:120 and 1:450, respectively. Another example of this quantification is the 6:1 molar ratio between guanylyl cyclase 1 and 2, and their respective molar ratios to rhodopsin of 1:510 and 1:2,970. Altogether, this analysis provided an accurate quantification of 20 phototransduction and other functionally important outer segment proteins and resolved several discrepancies on their quantifications previously reported in the literature.

Conclusions: MS-Western is an accurate method for quantification of multiple proteins in a single mass spectrometry experiment. This approach is by far superior to a traditional Western blotting technique, which requires high quality antibodies and purified protein standards. MS-Western can be used to accurately measure the amounts of multiple proteins in any ocular tissue

TITLE: Molecular Event in HRP Apoptosis

SESSION TITLE: Biochemistry and Molecular Mechanisms of Diabetic Retinopathy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L.L. Valdez, Molecular Science, The University of Texas Rio Grande Valley School of Medicine, Edinburg, Texas, UNITED STATES|

Commercial Relationships Disclosure: Laura Valdez: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Human retinal pericytes (HRP) are contractile cells adjacent to and provide support for endothelial cells (EC) of capillaries, which are essential in the regulation of retinal vasculature. Early stages of DR are characterized by the loss of HRP, which leads to the development of advanced-stage pathology including angiogenesis. Although much is known about the etiology of DR, the apoptotic pathway that incites HRP loss remains unclear. Our preliminary studies reveal that monocyte-derived macrophages secrete TGF-β1, which induces the expression and secretion of a TGF-β1-Induced, pro-apoptotic BIGH3 protein (TGF-β–Induced Gene Human Clone 3) leading to apoptosis of HRP Eye, 30(12), 1639-1647Based on a preliminary study in renal cells (unpublished data), CTP (c-terminal peptide) with an RGD domain is released from BIGH3 by proteolysis leading to renal cell apoptosis. In the present study, we employed Western Blots to determine if a similar molecular event also takes place in the BIGH3 protein to induce HRP apoptosis.

Methods: HRP cells were obtained from Cell Systems and were cultured in complete media with 10% FBS, 1% penicillin/streptomycin, in a humidified 5% CO_2 incubator with a temperature of 37°C. Cells were harvested from passages 5-8 until reaching confluency. HRP were starved for 24hrs with media composed of only DMEM and 1% penicillin/streptomycin prior to getting treated 24hrs with and without 15ug/mL of TGF-β, 50ug/mL of Leupeptin (a protease inhibitor), and with both TGF-β and Leupeptin. Conditioned media was collected after 24hrs and stored in -80C until protein concentration assay and probed with an anti-BIGH3 polyclonal antibody, an in-house generated rabbit antibody generated against full-length recombinant BIGH3. Western blot analyses of the cleaved BIGH3 protein band were quantified using ImageJ.

Results: Western blots show two BIGH3 protein bands: un-cleaved protein (60kD) and cleaved (or truncated). Image analyses of band intensity of the cleaved proteins was significantly reduced (by five-fold) in the presence of Leupeptin (a protease inhibitor). Similarly, a two-fold reduction of the cleaved protein was also observed when Leupeptin was added to the cell media in conjunction with TGF-β.

Conclusions: Consistent with our previous observation, cultured HPR secret BIGH3 protein. Thus, our results are consistent with prior observations in renal cells that CTP release (by proteolysis) from BIGH3 is a molecular event in the HRP apoptosis.

ABSTRACT BODY:
Purpose: The absence of clinical tools to evaluate individual variation in the pace of aging represents a major impediment to understanding aging and maximizing health throughout life. The lens is an ideal tissue for quantitative assessment of molecular aging in vivo. Long-lived proteins in lens fiber cells are expressed during fetal life, do not undergo turnover, accumulate molecular alterations throughout life, and are optically accessible in vivo. The study purpose was to measure age-dependent signals in vivo in lenses of both healthy human subjects and wild-type C57BL/6 mice. We hypothesize that cumulative alterations in the lens may constitute an in vivo biomarker of molecular aging.
Methods: Quasi-elastic light scattering (QLS) was used to measure age-dependent changes in vivo in lenses of 34 healthy human subjects without history of eye disease (18 males, 16 females; ages 5–61), and in unanesthetized wild-type C57BL/6 mice aged 3–22 months-old. We also examined time-dependent effects of in situ oxidation on QLS signals obtained from water-soluble human lens protein extract (hLPE) during long-term incubation in vitro.
Results: Our results indicated that aging related QLS metrics can be acquired noninvasively in human subjects and in unanesthetized mice. Age-dependent QLS signal changes detected in vivo in humans and mice recapitulated time-dependent changes in hydrodynamic radius, protein polydispersity, and supramolecular order of human lens proteins during long-term incubation (~1 year) and in response to sustained oxidation (~2.5 months) in vitro.
Conclusions: Our findings demonstrate that QLS analysis of lens proteins provides a practical technique for noninvasive assessment of molecular aging in vivo.

ABSTRACT BODY:

Purpose: The number of endothelial grafts precut by corneal banks increases. Their shelf life is limited to a few days. We previously demonstrated the superiority of an active storage with the corneal bioreactor (BR) over organ culture (passive) for whole corneas. Aims: Measure endothelial viability of precut DMEK after 3 and 10 days of storage in our BR in a preclinical study.

Methods: Human pairs of corneas were included. The endothelial cell density (ECD in cells/mm^2), thickness and transparency of corneas were measured before graft preparation. Descemet's membrane (DM) was peeled using the no-touch technique leaving the graft attached to the center of the cornea (on approx. 1/mm^2). After randomization, one cornea was kept in organ culture (OC) and the other in the BR (21 mmHg, 2.6 µL/min) in the same medium (CorneaMax, Eurobio). The final viable ECD was determined using the triple staining with Hoechst-Ethidium-Calcein-AM. In addition, the expression of CD166 and NCAM (lateral membranes), ZO-1 (apical junctions), Na^+/K^+ATPase (endothelial pump function) and COX-IV (mitochondrial content) was studied by immunostaining to characterize endothelial cells after the storage.

Results: Initial ECDs were comparable: 2185±232 cells/mm^2 in BR versus 2276±328 cells/mm^2 in OC for the 3-day period and 2680±416 cells/mm^2 in BR versus 2644±420 cells/mm^2 in OC for the 10-day period. The DMs did not fold back in either BR or OC. Viable ECD did not differ significantly between BR and OC for either storage period: 2378±501 cell/mm^2 in BR versus 2342±503 cell/mm^2 in OC for the 3-day period (n=8 pairs and p=0.6238) and 2482±288 cell/mm^2 in BR versus 2579±315 cell/mm^2 in OC for the 10-day period (n=5 pairs and p=0.1756). Corneas were more transparent and thinner in BR than in OC after 3 days (916±86 versus 1193±136µm with p=0.0001) and 10 days (957±128 versus 1220±105µm with p=0.0625). The functional and structural markers studied were expressed in both groups after 3 and 10 days, some better preserved in BR.

Conclusions: The storage of precut DMEKs seems to be possible in BR and OC for at least 10 days. Interestingly, a precut endothelium continues to partially exert its pump function in the BR. In practice, this could allow the anterior part to be used for DALK. In addition to improving the storage of whole grafts, the BR allows the storage of precut DMEKs for up to 10 days with excellent endothelial survival.

ABSTRACT BODY:

Purpose: Tauroursodeoxycholic acid (TUDCA) is neuroprotective in retinal degeneration models. Cucurbitacin I has a chemical structure similar to TUDCA and has been shown to be protective in models of CNS neurodegeneration. Therefore, we sought to test whether systemic treatment with Cucurbitacin I is protective in a light induced retinal degeneration (LIRD) model.

Methods: Adult male (n=15) and female (n=14) BALB/cAnNCrl mice received two injections of either vehicle (10% DMSO+PBS, n=13) or Cucurbitacin I treatment (1.3 mg/kg; 10 µl/gram of mouse weight, n=16). After the first injection, mice were dark-adapted overnight and injected again 30-60 min prior to LIRD. Mice were either exposed to 2500 lux, to induce LIRD, or dim light (50 lux) for 4 hours. One week after light exposure, retinal function was assessed by electroretinograms (ERG) and eyes were collected for histology. Outer Nuclei Layer (ONL) counts were assessed in retinal sections stained with hematoxylin and eosin. Retinal sections were stained for GFAP and IBA1 to assess retinal glial inflammatory response. Two-way ANOVA was conducted to analyze data (mean±SD).

Results: Exposure to toxic light diminished scotopic ERG at 1 cd s/m^2 a- and b-wave amplitudes, compared to dim light exposure (-118µV±43.2 vs -256µV±57.9 and 370µV±130 vs 558µV±158, respectively; $p<0.04$). ONL nuclei counts were diminished to 70% in comparison to dim light exposed mice ($p<0.003$). Systemic treatment with Cucurbitacin I prevented the losses in ERG a- and b-wave amplitudes (-228µV±33.2 vs -256µV±57.9 and 526µV±91 vs 558µV±158, respectively; $p>0.28$) and ONL nuclei count ($p>0.5$), with outcomes statistically indistinguishable from dim light exposed groups. Retinal sections from vehicle-treated mice undergoing LIRD showed increased labeling of both GFAP ($p<0.03$) and IBA1 ($p<0.03$) compared to dim groups or mice undergoing LIRD but treated with Cucurbitacin I.

Conclusions: Systemic treatment with Cucurbitacin I protects against retinal degeneration. Injections of Cucurbitacin I protected both retinal function and structure of adult BALB/cAnNCrl mice model of LIRD. The suppression of inflammatory responses likely occurred in microglia and Müller glial cells. As CNS neuroprotection by Cucurbitacin I treatment is mediated by inhibiting JAK2-STAT3 signaling and preventing microglial overactivation, we plan future studies to examine these potential mechanistic pathways in retina.

ABSTRACT BODY:

Purpose: Vision loss is a prominent feature of neuronal ceroid lipofuscinosis Type 2 (CLN2) Batten disease, yet cognitive, motor, and language impairments prevent reliable measurement of visual acuity (VA) using standard methods. We previously described a novel VA test using optokinetic nystagmus (OKN) detection technology (Threshold Visual Acuity Test, University of Auckland, NZ), demonstrating high correlation between central retinal thickness (CRT) and VA-OKN as well as symmetrical VA-OKN between eyes in children with CLN2 disease. Here, we report longitudinal data for the same children, as well as test-retest variability.

Methods: Six to 10 months after initial VA-OKN measurement, binocular and monocular VA-OKN testing was performed at two consecutive visits two weeks apart in 23 children ages 3 to 9 years with classic CLN2 disease.

Results: Longitudinal data were available for binocular VA-OKN (OU) in 14 children, and for monocular VA-OKN in the right eye (OD) in 11 children and the left eye (OS) in 10 children. Eight of nine children (89%) who initially cooperated with monocular testing in both eyes did so at the second and third visits. Binocular VA-OKN ranged from 0.3 to 1.4 logMAR. Monocular VA-OKN remained highly symmetric between right and left eyes. Mean longitudinal change in VA-OKN over the 6 to 10-month testing period was 0.06 logMAR OU, 0.03 OD, and -0.05 OS. The 95% CI for test-retest limits of agreement on Bland-Altman analysis were 0.24 to -0.26 (mean difference = -0.01) OU, 0.30 to -0.30 (-0.03) OD, and 0.13 to -0.31 (-0.09) OS, with Pearson correlation coefficients of 0.93 OU, 0.88 OD, and 0.91 OS.

Conclusions: In children with the profound neurocognitive impairments associated with CLN2 disease that prevent use of standard VA methods, the novel, OKN detection-based Threshold Visual Acuity Test appears to be a valid measure, demonstrating satisfactory test-retest variability. More longitudinal data are needed to characterize the pattern and progression of VA loss in CLN2 disease.

TITLE: Retinal changes seen on OCT and OCTA for diabetic subjects compared with cone distribution and vascular changes from AOSLO

SESSION TITLE: Applications of adaptive optics and advanced imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.E. Elsner, T.J. Gast, B. Walker, R.N. Gilbert, V. Parimi, S.A. Burns, School of Optometry, Indiana University, Bloomington, Indiana, UNITED STATES|

Commercial Relationships Disclosure: Ann Elsner: Commercial Relationship(s);Code I (Personal Financial Interest):Aeon Imaging, LLC;Code O (Owner):Aeon Imaging, LLC;Code P (Patent):Aeon Imaging, LLC, Indiana University, 6,640,124;7,331,669;7,781,106;8,488,895iana University;Code R (Recipient):Aeon Imaging, LLC;Code F (Financial Support):Aeon Imaging, LLC | Thomas Gast: Commercial Relationship: Code N (No Commercial Relationship) | Brittany Walker: Commercial Relationship: Code N (No Commercial Relationship) | Robert Gilbert: Commercial Relationship: Code N (No Commercial Relationship) | Vamsi Parimi: Commercial Relationship: Code N (No Commercial Relationship) | Stephen Burns: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Diabetic patients have a wider range of cone densities than controls and have capillary remodeling on AOSLO, even with normal total retinal thickness on OCT. To probe the relation of retinal vs. subretinal changes to cone distribution, we used OCT to localize lesions and OCTA for vessel remodeling and decreased flow.

Methods: Cone density and retinal vessels were imaged as previously for 10 diabetic subjects (29-79 yr, 54.5 +/- 12.7 yr). All subjects were consented and tested as approved by the Indiana University Institutional Review Board, which adhered to the Declaration of Helsinki. We performed OCT and OCTA (Heidelberg Spectralis II), then imaged cones and retinal microcirculation with AOSLO, using confocal and multiply scattered light images. We used reflectance mode and motion mapping for vessels, montaging images for the 6 x 6 deg central retina and temporal retina to 7 deg. Graders assessed OCT B-scans for cysts, exudates, microaneurysms, layer disruptions, subretinal fluid, and subretinal deposits and OCTA for lower flow and vessel remodeling. A 2-parameter exponential model of cone density, ln(cone density) = a * microns eccentricity + b, estimated total cones within the central 14 deg.

Results: Both total cones, 173,000 – 283,000, and vascular findings differed among subjects. All subjects had retinal microaneurysms and capillary remodeling seen shadowing cone maps and seen in inner retinal images on AOSLO. Retinal OCTA localized lesions in all subjects, but less capillary remodeling than AOSLO. Significant subretinal OCT or OCTA findings were not seen in either younger subject, with total cones 176,000 and 189,000, < the 95% CIs for age-similar controls. Similarly, no significant subretinal OCT findings were seen in the 3 older subjects with the lowest total cones. In contrast, there were subretinal deposits, indistinguishable from drusenoid deposits, in a 62 yr old with 273,000 total cones, the second highest of diabetics and within 95% CIs of controls. No subject had subretinal fluid on OCT.

Conclusions: Diabetic subjects with retinal thicknesses within normal limits can nevertheless have numerous retinal lesions, visible on OCT B-scans. Retinal vessel remodeling is visible on OCTA but to a lesser extent than with AOSLO. Our findings are inconsistent with early subretinal changes being necessary for low cone densities.

ABSTRACT BODY:

Purpose: To determine the causative organisms, antimicrobial susceptibility patterns, and demographic differences of microbial keratitis (MK) infections at a Midwestern tertiary eye center.

Methods: MK patients were identified in the University of Michigan electronic health record from August 2012 to February 2021. Laboratory tests (culture, stain, smear, polymerase chain reaction, antibody, antigen) from 7 days before to 90 days after MK diagnosis were identified and classified as lab-positive (any positive result) or lab-negative. Lab-positive infections were categorized as bacterial (gram-positive, gram-negative, acid-fast bacilli [AFB]), fungal, viral, Acanthamoeba, or polymicrobial. Antimicrobial susceptibilities were obtained. Patient demographics were compared between lab-positive and negative cases and between MK organism types using t-, Kruskal-Wallis, Chi-square, or Fisher exact tests.

Results: Of 2990 MK patients, 966 (32.3%) had labs performed, of which 517 (53.5%) were positive (289 females; 442 White, 45 Black, 9 Asian, 11 other races). Infections were bacterial in 72.7% (n=376) of patients, fungal in 6.6% (n=34), viral in 2.1% (n=11), Acanthamoeba in 0.8% (n=4), and polymicrobial in 17.8% (n=92). Of the bacterial infections, 72.1% (n=271) were gram-positive with coagulase-negative Staphylococcus (CoNS; 28.7%) and Staphylococcus aureus (S. aureus; 25.5%) as the most common pathogens. Bacteria were gram-negative in 26.1% (n=98) of cases, with Pseudomonas aeruginosa as the predominant pathogen (46.3%), and AFB in 1.9% (n=7). Methicillin-resistance occurred in 37% of S. aureus and 71% of CoNS; 100% were susceptible to vancomycin. Lab-positive patients were significantly older than lab-negative patients (mean ± standard deviation, 57.5 ± 20.5 years vs. 54.3 ± 20.3, p=0.015). White patients represented a larger percentage of bacterial, fungal, or polymicrobial infections than viral infections (87.0%, 97.1%, 88.9% vs 45.5%, all $p<0.05$). Black patients represented a larger percentage of viral infections than bacterial, fungal, or polymicrobial infections (45.5% vs 9.0%, 2.9%, 6.7%, all $p<0.05$).

Conclusions: Bacterial keratitis accounted for most MK cases. Gram-positive bacteria were the most common isolates, followed by gram-negative. CoNS and S. aureus were universally susceptible to vancomycin. Patients with positive labs were significantly older. There were significant differences between MK types with respect to race.

ABSTRACT BODY:

Purpose: To evaluate the baseline and longitudinal higher order OCT features in the Phase III VISTA diabetic macular edema (DME) clinical trial based on race.

Methods: This was a post-hoc analysis of the Phase III VISTA-DME clinical trial, which included patients randomized 1:1 to receive 2mg IAI every 4 weeks or 8 weeks after 5 initial monthly doses. Higher-order OCT analysis conducted with a machine learning-enhanced feature extraction and multi-compartment segmentation platform enabled evaluation of volumetric fluid features and compartmental retinal integrity (e.g. EZ integrity). Specific features included mean central subfield thickness (CST), intraretinal fluid (IRF) volume, EZ-RPE panmacular volume and total EZ attenuation. Retinal anatomic dynamics and BCVA changes were compared and stratified by reported race. Patients self-reported as White (n=198), Black/African American (n=25), Asian (n=5), American Indian/Native Alaskan (n=1) and Not Reported (n=3). Only White (W) and Black/African American (B/AA) patients were included in analysis due to subject quantity.

Results: At baseline, age and clinical characteristics such as systolic blood pressure, BMI, duration of diabetes and BCVA were similar between W and B/AA (all $p>0.05$) (Table 1). Diastolic blood pressure was higher in B/AA (74.4 vs 77.7 mmHg, $p=0.033$). At Baseline and at Week 100, CST, IRF volume, EZ-RPE volume, EZ total attenuation and BCVA were similar between W and B/AA (all $p>0.05$).

From Baseline to Week 100 (Table 2), W and B/AA showed significant improvement in CST (-191.6±156.2µm, -236.8±200.5µm respectively, $p<0.01$ from baseline) and IRF Volume (-1.2±1.4 mm^3, -1.2±2.5 mm^3, $p=0.021$ from baseline). However, while W showed significant improvement in EZ-RPE volume (+1.3±0.2mm^3, $p<0.01$) and EZ total attenuation (-0.7±4.0%, $p=0.016$), B/AA demonstrated a nonsignificant improvement in both ($p=0.20$, $p=0.65$ respectively). W and B/AA showed significant improvement in BCVA during that period ($p<0.01$).

Conclusions: Higher order OCT DME features and longitudinal response to IAI demonstrated similar features and findings when comparing based on race. Both groups demonstrated significant anatomic and functional improvements with IAI.

TITLE: Arginine and citrulline induce angiogenic mechanisms and increase intracellular nitric oxide production in human retinal endothelial cells

SESSION TITLE: Biochemistry and Molecular Mechanisms of Diabetic Retinopathy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Warden, M.A. Brantley, Ophthalmology, Vanderbilt University Medical Center, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure: Cassandra Warden: Commercial Relationship: Code N (No Commercial Relationship) | Milam Brantley: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Purpose: We previously observed elevated plasma levels of both arginine and citrulline in patients with diabetic retinopathy compared to diabetic controls. Intracellularly, citrulline is converted to arginine, which serves as a substrate for both arginase and endothelial nitric oxide synthase (eNOS). In the current study, we tested whether arginine and citrulline could induce an angiogenic response in human retinal microvascular endothelial cells (HRMEC) and if arginine and citrulline activate arginase and/or eNOS in HRMEC.

Methods: Methods: HRMEC were treated with 30 μM citrulline, 70 μM arginine, or citrulline + arginine, and the angiogenic response was measured with cell proliferation, cell migration, and tube formation assays. To determine if citrulline and arginine activate arginase or eNOS in HRMEC, arginase activity was quantified by measuring urea, a product of arginase, and DAF-FM DA was used to stain for intracellular nitric oxide, a product of eNOS. Western blots were used to measure protein expression of arginase-1, arginase-2, total eNOS, and phosphorylated eNOS.

Results: Results: Individually, neither citrulline nor arginine resulted in an angiogenic response in HRMEC, but citrulline + arginine induced proliferation by 39.6% ($p = 0.018$), cell migration by 57.7% ($p = 0.011$), and resulted in tubes that were 36.2% longer ($p = 0.0042$) compared to untreated controls. There was no change in arginase activity or arginase-2 protein expression in HRMEC treated with citrulline and/or arginine, but citrulline + arginine resulted in lower protein expression of arginase-1 compared to untreated cells ($p = 0.0046$). Citrulline ($p = 0.012$), arginine (0.0029), and citrulline + arginine ($p = 0.025$) all increased NO production compared to controls. Arginine ($p = 0.028$) and citrulline + arginine ($p = 6.3 \times 10^{-4}$) led to greater total eNOS expression than in controls, and citrulline + arginine resulted in higher protein expression of phosphorylated eNOS compared to controls ($p = 0.029$).

Conclusions: Conclusions: These data demonstrate that arginine and citrulline together can induce an angiogenic response, increased nitric oxide production, and increase eNOS expression and phosphorylation with no effect on arginase activity in HRMEC. This suggests that elevated plasma arginine and citrulline could potentially contribute to progression of diabetic retinopathy.

TITLE: Consequences of eliminating ^{52}LFRTVL^{57} residues from the N-terminal domain of αA-crystallin on structure and function of the protein

SESSION TITLE: Lens proteins and cataracts

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. MAHALINGAM, G. Shankar, P. Santhoshkumar, K. Sharma, Department of Ophthalmology, University of Missouri, Columbia, Missouri, UNITED STATES|K. Sharma, Department of Biochemistry, University of Missouri, Columbia, Missouri, UNITED STATES|

Commercial Relationships Disclosure: SUNDARARAJAN MAHALINGAM: Commercial Relationship: Code N (No Commercial Relationship) | Goutham Shankar: Commercial Relationship: Code N (No Commercial Relationship) | Puttur Santhoshkumar: Commercial Relationship: Code N (No Commercial Relationship) | Krishna Sharma: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We previously reported that deletion of ^{54}FLRAPSWF^{61} sequence from αB-crystallin results in gain of function. Since αA- and αB- have significant (~54%) sequence homology, we hypothesized that deletion of ^{52}LFRTVL^{57} from αA- will result in a gain of function. Thus, the present study was undertaken to see the effect of deleting 52-57 region on the structure-function of αA-crystallin.

Methods: Chaperone activities of the purified recombinant αA-wt and the deletion mutant (αAΔ52-57) were evaluated using one μM luciferase and 100 μg alcohol dehydrogenase (ADH) substrates. The ability of the proteins to inhibit $A\beta_{1-42}$ oligomerization and fibril formation in-vitro was examined under TEM. Cell integrity and ROS detection assays were performed to access the cytoprotective activity of the crystallins in sodium iodate-challenged ARPE-19 cells. The molecular size, hydrophobicity, and stability of the WT and mutant proteins were compared by standard methods.

Results: The average molar mass of αA oligomers increased from 710 kDa to 1036 kDa in αAΔ52-57. The hydrodynamic radii (Rh) of the mutant also showed a similar increase in size. The αAΔ52-57 mutant exhibited a 7-fold and 5-fold increase in chaperone activity compared to αA-wt with the unfolding luciferase and ADH, respectively. αA-mutant also suppressed $A\beta_{1-42}$ fibril formation in-vitro and showed 11 ± 0.39 % higher protection against $A\beta_{1-42}$-induced cytotoxicity in ARPE-19 cells compared to WT. Sodium iodate-induced cytotoxicity and ROS detection studies showed that the mutant αA protein has 20 ± 1.06 % greater anti-apoptotic activity than WT with equal concentration of chaperone tested and also showed 15 ± 0.68 % higher anti-oxidative activity than the wild-type in oxidatively stressed cells.

Conclusions: Our findings suggest that the residues 52-57 in αA-crystallin modulate oligomer size and chaperone activity. The deletion of the conserved 52-57 residues activates αA-crystallin. Further studies are required to understand the molecular basis for the activation of αA-crystallin after deletion of 52-57 sequence.

TITLE: Netrin-4 modulates corneal wound healing by enhancing corneal epithelium and nerve regeneration in vitro and in vivo.

SESSION TITLE: Corneal epithelial biology and repair mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Xiao, D. Lara, Q. Zhou, T.T. Nguyen, M. Rosenblatt, V.H. Guaiquil, Illinois Eye and Ear Infirmary, Department of Ophthalmology and Visual Sciences, University of Illinois at Chicago, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Cissy Xiao: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Lara: Commercial Relationship: Code N (No Commercial Relationship) | Qiang Zhou: Commercial Relationship: Code N (No Commercial Relationship) | Tara Nguyen: Commercial Relationship: Code N (No Commercial Relationship) | Mark Rosenblatt: Commercial Relationship: Code N (No Commercial Relationship) | Victor Guaiquil: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine the functional effects of Netrin-4, a known modulator of axon guidance, tumorigenesis, and angiogenesis, on corneal epithelium and nerve regeneration.

Methods: The endogenous expression of Netrin-4 was evaluated by immunofluorescent staining (IFS) in mouse cornea and trigeminal ganglia (TG) and human corneas. The recovery of Netrin-4 expression after corneal epithelium injury was confirmed by IFS and RT-qPCR. In vitro, human corneal limbal epithelial (HCLE) cells and freshly isolated TG neurons were treated with recombinant Netrin-4 in a dose-response manner. HCLE cells were cultured until confluency, and scratch assays were measured with time-lapse microscopy. TG neurons isolated from Thy1-YFP mice (N=3/treatment) were treated with medium only, NGF, or Netrin-4. Neuronal growth and neurite extension were then quantified with Neurolucida software. The in vivo effects of Netrin-4 were tested on mice (N=6/condition) using a corneal epithelial debridement model. Post-injury, mice were treated with topical drops of PBS or Netrin-4. Epithelial healing was evaluated with a slit lamp microscope and analyzed in Fiji. The corneas were flat mounted and stained on day 10 to assess subbasal nerve regeneration. Student’s t-test and ANOVA were used for statistical analyses.

Results: Netrin-4 was highly expressed in the mouse and human corneal epithelium and the neuronal cell bodies of TG. After injury, Netrin-4 was initially downregulated in these tissues and slowly returned to baseline levels of expression. The scratch assays on HCLE cells show that Netrin-4 at 25ng/mL induced significantly faster wound closure than control. Similarly, the in vivo data showed that mice receiving topical Netrin-4 had accelerated wound healing compared to control mice. The average neurite length was greater in isolated TG neurons treated with 25ng/mL Netrin-4 ($p=0.02$) and 50ng/mL NGF ($p<0.0001$) compared to the control. In vivo, the average length of subbasal nerves was greater for mice treated with Netrin-4 than for those treated with vehicle.

Conclusions: Netrin-4 was normally expressed in the corneal epithelium, and after injury, its expression slowly recovered to basal levels. Netrin-4 increased corneal epithelium and nerve regeneration both in vitro and in vivo. Ongoing studies aim to establish the optimal route of administration for Netrin-4 in corneal wound healing.

ABSTRACT BODY:

Purpose: Cornea is susceptible to accidental/intentional chemical injury. Chlorine (Cl_2) exposure to the eye causes corneal damage, redness, tearing, itching, and blurred vision. Autophagy and lysosomal biogenesis play a vital role in corneal homeostasis, repair, and transparency maintenance. This study tested if mTORC1-mediated dysfunctional autophagy and lysosomal biogenesis is associated with Cl_2 induced corneal damage.

Methods: Primary human stromal fibroblast cultures (hCSF) and ex vivo organ culture model using donor human corneas were used. hCSF cultures were exposed to +/- Cl_2 (0.5ppm liberated from 0.001% NaOCl) for 72h (n=6). Thereafter, cultures were fixed in 4% paraformaldehyde and generating protein lysates and mRNA and cDNA. The changes in autophagosomal and lysosomal signature genes (ATGs, LC3, SQSTM1/p62, LAMP1, mTORC1, and TFEB) were measured with qRT-PCR and proteins levels and distribution with western blotting and/or immunofluorescence. Ex vivo human corneas were exposed to 0.5ppm Cl_2 for 30 minutes and incubated for 2 months (n=3). mRNA and protein levels of autophagy markers (LC3, Beclin1, and p62) were analyzed with qRT-PCR, western blotting, and immunofluorescence.

Results: hCSF exposed to Cl_2 had decreased phosphorylated mTORC compared to vehicle. Cl_2 exposure to hCSF significantly increased mRNA and protein levels of LC3 ($p=<0.01$, $p=<0.01$), Beclin1 ($p=<0.01$, $p=<0.01$), and p62 ($p=<0.01$, $p=<0.01$) compared to vehicle. ICC of hCSF exposed to Cl_2 had higher levels of LC3 and Beclin1 with increased levels and accumulation of p62. Further, ICC showed TFEB distribution is greater in cytosol when exposed to Cl_2 compared to vehicle. LAMP1 is decreased in Cl_2 exposed hCSFs. IHC of ex vivo cultures showed increased protein levels of LC3, Beclin1, and p62 after Cl_2 exposure compared to vehicle.

Conclusions: Autophagy mechanism is involved in Cl_2 mediated toxicity to the cornea. Further ongoing studies are expected to offer additional mechanistic information regarding the role of autophagy in corneal injury, repair and homeostasis.

ABSTRACT BODY:

Purpose: To develop an algorithm and scripts to combine disparate multimodal imaging modalities and show its use by overlaying en-face optical coherence tomography angiography (OCTA) images and Optos ultra-widefield (UWF) retinal images using the Fiji (ImageJ) plugin BigWarp.

Methods: Optos UWF images and Heidelberg en-face OCTA images were collected from various patients as part of their routine care. En-face OCTA images were generated and ten (10) images at varying retinal depths were exported. The Fiji plugin BigWarp was used to transform the Optos UWF image onto the en-face OCTA image using matching reference points in the retinal vasculature surrounding the macula. The images were then overlayed and stacked to create a series of ten combined Optos UWF and en-face OCTA images of increasing retinal depths. The first algorithm was modified to include two scripts that automatically aligned all the en-face OCTA images.

Results: The Optos UWF image could easily be transformed to the en-face OCTA images using BigWarp with common vessel branch point landmarks in the vasculature. The resulting warped Optos image was then successfully superimposed onto the ten Optos UWF images. The scripts more easily allowed for automatic overlay of the images.

Conclusions: Optos UWF images can be successfully superimposed onto en-face OCTA images using freely available software that has been applied to ocular use. This synthesis of multimodal imaging may increase their potential diagnostic value. Script A is publicly available at https://doi.org/10.6084/m9.figshare.16879591.v1 and Script B is available at https://doi.org/10.6084/m9.figshare.17330048.

ABSTRACT BODY:

Purpose: Regular physical activity is important in healthy aging and is known to positively influence the retina and visual function. In order to elucidate the effect of physical activity on the retina we assessed the acute chorioretinal changes in senior athletes following short intense physical strain as assessed by optical coherence tomography (OCT).

Methods: Seventeen eyes of 17 healthy senior sportsmen (mean age 67.9 ± 7.4 years, 11 males and 6 females) were recruited for the study conducted at Semmelweis University, Department of Ophthalmology. The subjects performed a stepwise incremental exercise trial until exhaustion (vita maxima) or reaching a peak of maximum physiological age-related systolic blood pressure (calculated as 220/min - age) on a cycle ergometer. Macular scanning with a spectral domain (SD) OCT device was performed before and 1, 5, 15, 30 and 60 minutes following the exercise. The SD-OCT images were exported and segmented by our custom-built OCTRIMA 3D software and the thickness of the choroid and 7 retinal layers was measured. One-way ANOVA analysis was performed followed by Dunnett post hoc test. The level of significance was set at 5%.

Results: A significant thinning of the total retina was observed 1 minute post exercise which was followed by a significant thickening at 5 minutes (-1.56±1.1µm, p=0.000 and +1.05±1.0µm, p=0.012, respectively), with thickness values returning to baseline afterwards. The same significant trend was observed at the composite layer of the outer retina consisting of the outer plexiform and outer nuclear layer and the outer segment (-0.7±0.3µm, p=0.000 and +0.7±0.5µm, p=0.000 for 1 and 5 minutes, respectively). The outer region of the GCL+IPL complex showed also a significant thinning at 1 minute (-0.5±0.4µm, p=0.000). There was neither any significant change in choroidal thickness nor any correlation with the thickness changes of the intraretinal layers.

Conclusions: We could observe acute changes in senior sportsmen after strong physical strain involving the entire macula. These changes seem to be mainly present in the outer retina, independent of the choroidal vasculature. The observed trend is somewhat less pronounced, although seemingly similar to our previous observations in young sportsmen and warrants further research regarding its role in the healthy ageing of the retina.

ABSTRACT BODY:

Purpose: Proliferative diabetic retinopathy (PDR) is the leading cause of blindness among working-age adults. Photoreceptors are the most common and metabolically demanding cells in the retina thus oxygen is vital for retinal function. Hypoxia induced metabolic stress leads to photoreceptor atrophy and retinopathy. Furthermore, photoreceptor cell death is known to occur mainly via apoptosis. However, the protection of hypoxia-induced-cytotoxicity in cone photoreceptor cells has not been investigated extensively. The aim of this study was to determine whether co-treatment of insulin and the N-Acetyl-L-Cysteine (NAC) efficiently protects against hypoxia-induced cytotoxicity in 661W cells.

Methods: 661W were cultured at 5% CO2 at 37 C in DMEM with 10% FBS, 1% a penicillin/streptomycin. Cobalt (II) Chloride hexahydrate ($CoCl_2$) was used to induce hypoxia. Insulin was suspended in sterile water, and NAC was diluted in the culture medium. For recovery experiment, cells were pretreated with $CoCl_2$ for 24hrs, followed by replacing of medium with 100nM insulin and 3mM NAC alone, or with a combination of the two reagents for another 24hrs. Cell viability was determined by MTT assay in a 96 well plate. Morphological changes of the cells were observed and photographed under phase-contrast microscope and protein expression was measured by Western blot analysis. Statistical analysis was undertaken using independent two-tailed Students t-test using SPSS Statistics software.

Results: Treatment with $CoCl_2$ significantly inhibited cell proliferation, reduced the number of viability cells, and induced apoptosis, initiated PARP cleavage, and increased caspase 3 activation. In addition, $CoCl_2$ treatment led to oxidative stress, autophagy, and ubiquitination in the 661W cells. These effects, including cell proliferations were significantly reversed by the combination treatment of Insulin and NAC. In contrast, treatment with Insulin alone did not result in a similar protective effect and NAC partially protects against hypoxia induced toxicity.

Conclusions: Hypoxia induces significant apoptosis, oxidative stress, and protein ubiquitination in 661W cone photoreceptors. A combination treatment of Insulin and NAC completely reversed such hypoxia-induced cytotoxicity. Additional research on a combination therapy employing insulin and NAC may provide a promising therapeutic strategy for hypoxia-mediated cone photoreceptor cell damage.

Williams: Commercial Relationship: Code N (No Commercial Relationship) | Monica Jablonski: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Glaucoma is a multifactorial, neurodegenerative disease characterized by the progressive loss of retinal ganglion cells (RGCs), optic nerve (ON) damage, and subsequent vision loss. Current treatments focus on lowering intraocular pressure (IOP); however, it is known that some patients continue to experience RGC death despite adequate IOP reduction. Our study aims to identify genes associated with ON health using systems genetics to provide insight for the development of neuroprotective agents.

Methods: A large cohort of the BXD family were aged to >13 months-of-age. ONs from 75 strains and the DBA/2J (D2) parent were harvested, sectioned, and stained with p-phenylenediamine. Numbers of healthy axons per ON cross-section were counted from 1–10 replicates per stain. Phenotype values were averaged per sex, and data were uploaded to GeneNetwork2 for mapping and systems genetics analyses. The trait was mapped using a linear mixed model utilizing the leave-one-chromosome-out method. Genome-wide significance levels ($P<0.05$) were obtained from 5,000 permutations of the data. Gene-phenotype correlations were performed and considered significant with a Pearson correlation coefficient <0.05.

Results: The number of healthy axons per ON varies 2.1-fold between the extremes and ranges from 30,000 in BXD98 to 62,000 in BXD20. QTL analysis identified a peak on Chr 9 ranging from 94.66Mb to 105.70 Mb with a logarithm of odds score of 4.27. This region of accounted for 424 positional candidate genes, 213 from the eye database and 211 from the retina database. Five candidates—armadillo repeat containing 8 (Armc8); mitochondrial ribosomal protein L3 (Mrpl3); Eph receptor B1 (Ephb1); Propionyl coenzyme A carboxylase, beta peptide (Pccb); nephronophthisis 3 (Nphp3)—passed stringent criteria and are high priority candidates. These genes were significantly correlated with higher numbers of live axons per ON (R^2= 0.38 – 0.46, P= 2.0e-3 – 9.26e-5).

Conclusions: A genomic region linked to ON health was located on Chr 9 in the BXD family of mice. Using stringent selection criteria, we identified 5 novel gene candidates associated with ON health. Further analysis is necessary to understand each candidate’s role as a plausible therapeutic target and would provide insight for development of future neuroprotective glaucoma treatments.

ABSTRACT BODY:

Purpose: Cellular senescence has been reported in human glaucoma patients and in a glaucoma mouse model. Mechanisms of senescence in the retina, and cell types implicated in this detrimental phenotype and propagation, remain incompletely understood. We aim to investigate the implication of senescence and identify the cells involved using the experimental model of retinal ischemia-reperfusion (I/R) injury in mice with the goal to prevent retinal degeneration.

Methods: Intraocular pressure (IOP) was increased in mice for 60 minutes by doing intracameral injection of elevated saline solution. In vivo and ex vivo measurements have been performed at different time points, up to 14 days post I/R injury. Visual acuity was evaluated using optokinetic response (OKR) tracking. Structural changes were assessed using optical coherence tomography (OCT). Retinal ganglion cell (RGC) degeneration was quantified on retinal flatmounts by counting BRN3A immunostained positive cells. qPCR on retinal lysates and immunohistochemistry was utilized in order to assess spatiotemporal patterns of senescence. For all analyses, the contralateral eye has been used as control and statistics have been performed using paired t-test.

Results: We observed a visual acuity dysfunction using OKR of the injured eye compared to control (-0.111 cycle/degree, p=0.016, n=4) at day 6. Despite being insignificant, thinning of the inner retinal layer after 14 days was noticed using OCT. RGC degeneration was measured with a loss of 59.24% at day 7 (p=0.018, n=4) and 36.28% at day 14 (p=0.030, n=6). We observed upregulation of senescence related genes in injured retinas compared to control at day 2: Cxcl1, Cdkn2b, Cdkn1a and day 7: Cxcl1, Il-1a. Using immunostaining, senescence markers were detected in injured retinas at day 2: P16INK4A and PAI1 were expressed in microglia and/or macrophages and Y-H2AX in RGCs and photoreceptors.

Conclusions: Evidence of cellular senescence is detectable in the retina following I/R insult. Several retinal cell types appear to be involved. However, what are the specific cell types that express and/or propagate the phenotype remain unclear. Therefore, to elucidate this we are planning to do single cell RNA sequencing to address these questions. In future steps will attempt to rescue the I/R senescent phenotype to improve visual acuity, with an ultimate goal of targeting cellular senescence in glaucoma patients for neuroprotection.

ABSTRACT BODY:

Purpose: To introduce an axon-centric approach to determine IOP-induced neural tissue insult in the optic nerve head (ONH).

Methods: Optical coherence tomography (OCT) images of a normal monkey ONH were acquired at IOPs of 10 and 40mmHg (Figure 1). IOP-induced ONH deformations were tracked using digital volume correlation (DVC). The non-collagenous ONH volume incorporating lamina cribrosa (LC) beam and pore details was formed by combining manual reconstructions from OCT images and polarized light microscopy of cryosections. The large blood vessels were later removed from the non-collagenous ONH volume. Axon paths from the retinal nerve fiber layer to the optic nerve were approximated by a custom fluid tracing technique. Experimental deformations were combined with local axon paths to determine the IOP-induced stretch along the axons (longitudinal) and the compression perpendicular to the axons (transverse). The largest longitudinal stretch and transverse compression over the whole axon were assigned as the “worst-case” insults for the axon. For analysis, the axons were grouped into six regions.

Results: The largest longitudinal stretch insult in the temporal region (range 5% to 21%) was 2.5x that in the superior (ST, SN) and nasal (IN, N) regions. The peak value of transverse compression insult in the inferior nasal region (7%) was 16% higher compared to all other regions.

Conclusions: Longitudinal stretch and transverse compression represent distinct mechanisms of potential axon damage. The presented approach has the potential to help identify the link between IOP-induced deformation and neural tissue damage and glaucoma.

ABSTRACT BODY:

Purpose: Noninfectious uveitis is highly associated with immune-mediated diseases; however, its association with polyautoimmunity (PolyA) or familial autoimmunity is unknown. Therefore, this study aimed to analyze those phenomena in patients with noninfectious uveitis.

Methods: Cross-sectional study. Means and standard deviations were reported for the quantitative variables and absolute and relative frequencies for qualitative variables. Data were analyzed using hierarchical agglomerative cluster analysis. We first compared the collected variables with the “Index disease” and showed the p-value to find which variables had a statistical relationship to perform the clustering using the Gower coefficient. Then, we performed multivariate analysis and built a multinomial linear regression model. This model had “Index disease” as a dependent variable. The association measure was the β weights obtained. Next, to identify disease co-occurrence patterns to define PolyA spectra in uveitis, the R function “pheatmap” was used; this function allows heat maps to be drawn with the variables most related to PolyA. From the 218 recorded blocks of patients, it produces hard clusters, which were then used to study the co-occurrence of diseases.

Results: We analyzed 218 patients with noninfectious uveitis. Most patients were females (69.3%). The most common clinical characteristics were recurrent course (51.8%), persistent duration (60.6%), and insidious onset (62.4%). Anterior and panuveitis were the most common anatomical locations. Additionally, 36 patients (16.5%) had latent PolyA, and 100 patients (45.9%) had overt PolyA and, of which 22 (10.1%) had Multiple Autoimmune Syndrome. We found 22 index diseases and 28 diseases that coexist grouped in six hard clusters (Fig 1). Patients with PolyA had a mean of 2.3 diseases. One patient had 5 autoimmune diseases together documented. The most common index diseases were Idiopathic uveitis, Autoimmune uveitis, Sjögren’s syndrome, Juvenile idiopathic arthritis, and Ankylosing spondylitis. PolyA was associated statistically with epiretinal membrane (p:0.015) and optic disk edema (p:0.049).

Conclusions: PolyA is a common phenomenon among patients with noninfectious uveitis that can contribute as a risk factor in developing complications.

ABSTRACT BODY:

Purpose: Pathological angiogenesis is the hallmark of proliferative diabetic retinopathy (DR) at the advanced stage of this ocular disease. In response to prolonged tissue injury, human retinal microvascular endothelial (HRMEC) cells form new blood vessels to ensure the supply of oxygen and nutrients to the eye; however, progressive fibrovascular proliferation can eventually lead to retinal detachment and blindness. Caspase-8, the responsible protease for apoptosis has also been shown to modulate pathological and developmental angiogenesis but whether it exerts this role in a hyperglycemic environment has not yet been explored.

Methods: HRMEC were propagated using Complete Classic Medium with 1% Antibiotic-Antimycotic and 10% FBS. Conditioned medium was harvested from cells seeded into 24 well plates at a density of 800K and stored at -20°. HRMECs were treated with 5.5mM or 30mM of glucose, and the Casp-8 Glo assay was performed 24hrs following treatment. Cells were transfected with siRNA at 80% confluent. With a final concentration of siRNA solution 600pmol, samples were probed with p38 MAPK Antibody and Phospho-p38 MAPK. After transfected cells were confluent, they were starved in 2% FBS DMEM medium overnight. A wound was induced by scratching the cell monolayer with a P200 pipette tip. Cell migration was observed under the light microscope 24hrs after treatment.

Results: After 24 hours of glucose treatment, there were 232.5K viable cells in 5.5mM compared to 119K in 30mM glucose. Additionally, high glucose also increased VEGF secretion after 24hrs of glucose treatment (5.5mM of glucose 16.30pg VEGF/mL, 5.5 mM vs 22.41pg/mL 30mM). Hyperglycemic conditions also resulted in increased Pro-Caspase 8 expression, as the concentration of Pro-Caspase 8 expression from 1.25 fold change at 5.5mM to 2.5 fold (compared to 18S RNA). Western blots showed near-complete blocking of p38 phosphorylation in HRMEC with Caspase 8 KD.

Conclusions: In conclusion, caspase 8 activity was confirmed by Caspase-Glo assay in HRMEC when treated at both 5.5mM and 30mM of glucose, specifically at a luminescence of 1.75 RLU and 1.90 RLU, respectively. In addition, Caspase-8 KD resulted in a significant reduction of protein expression from 2.1-fold change to 1.1 along with an inhibition of cell migration.Taken together, our data strongly suggest that Caspase-8 promotes HRMEC migration via MAPK pathway involving p38 phosphorylation.

ABSTRACT BODY:

Purpose: Extracellular vesicles (EV) are detectable in aqueous humor (AH) from adult patients in previous studies. However, the presence of EVs in AH from pediatric diseased eyes has not been explored. Also, the expression profile of tetraspanins (CD9, CD63 and CD81) on AH EVs remains unclear. Herein, we measure the concentration of the pediatric diseased eye-derived AH EVs and analyze their size distribution and determine the phenotypic expression levels of tetraspanins of AH EV at single vesicle resolution.

Methods: Twenty-seven AH samples were obtained from 4 congenital cataract (CAT), 6 congenital glaucoma (GLC), 4 pediatric retinal disease (PRD) and 13 retinoblastoma (Rb) eyes. Rb eyes were further divided into treatment-naïve (Rb_Tn) and treatment-active (Rb_Tx) subgroups. Unprocessed AH samples were subjected to Nanoparticle Tracking Analysis (NTA) (Nanosight NS300) for size distribution and concentration, and to Single Particle-Interferometric Reflectance Imaging Sensor (SP-IRIS) (Exoview R100) for interferometric sizing and fluorescent-based immunophenotyping of EV marker expression (CD63, CD81, and CD9).

Results: By NTA analysis, the concentration of AH EVs is within 3.11×10^{9}~1.38×10^{10} vesicles per mL with a major population in an average modal size of 76.8~103 nm across pediatric disease states. SP-IRIS analysis revealed that tetraspanins, $CD63^{+}$, $CD81^{+}$ and $CD9^{+}$ EVs were detectable across all AH samples using the Exoview R100 platform. In addition, we identified a significant enrichment of CD63 single positive EV subpopulation in AH across 4 disease states (CAT + GLC + PRD + Rb_Tx): 54.9% of mono-$CD63^{+}$ EV among all fluorescent positive EVs. However, a mono-$CD63^{+}$ EV population composed only 28.3% of the AH EV population from Rb_Tn eyes ($P = 0.007$ when compared to 4 other disease states) suggesting a higher population of tumor-derived EVs in these eyes.

Conclusions: Small EVs are readily detectable in unprocessed AH with a dominant mono-$CD63^{+}$ EVs in AH regardless of pediatric eye disease states. Tetraspanin colocalization analysis indicates the clearance of tumor-derived EV heterogeneity by chemotherapy in Rb. This suggests an AH specific role of mono-$CD63^{+}$ EVs. These novel findings uncover a new direction in AH EV biomarker research.

ABSTRACT BODY:

Purpose: The number of military soldiers experiencing single or repeated blast injuries has increased with the development of explosive devices. Many of them suffer from visual deficits resulting from blast-induced eye and brain injury. The importance of studying visual deficits has been noticed due to their significant lifelong effects. However, the blast-induced visual deficit mechanism, which helps to diagnose and treat, is not fully understood because of its difficulty mimicking an open-field blast environment. In this study, we evaluated retinal pathophysiology following repeated blast exposure to the eye and brain using a custom-built advanced blast stimulator (ABS) reproducing an open-field blast environment.

Methods: The left side of the eye and head of WT mice (C57BL/6J, 12 weeks old) were exposed to three consecutive air blast shocks with a peak overpressure of 138 KPa using a custom-built ABS, and unexposed age-matched mice served as control. At 3 days after blast injury, the left eyes of blast-exposed and control mice were harvested, and TUNEL assay was performed. At 6 weeks after blast exposure, visual function was examined by visual acuity, pattern-evoked electroretinography (PERG) and positive scotopic threshold response (pSTR), and retinal sections were prepared for immunohistochemistry.

Results: At 3 days after blast injury, increased TUNEL positive cells in the ganglion cell layer were observed in blast-exposured retina. At 6 weeks after blast injury, there were significant reductions of visual acuity, PERG, and pSTR in blast-exposed mice compared to those in control mice, accompanied by a significant reduction of retinal ganglion cells.

Conclusions: Our study demonstrates that repeated blast exposure on the eye and brain results in severe pathophysiological damage in the retina. The blast injury model with ABS mimicking open-field blast is reproducible and may facilitate the study of biomarkers for diagnosis and neuroprotective mechanisms to explore therapeutic targets in sodiers suffering from blast injuries.

ABSTRACT BODY:

Purpose: The inner blood-retinal barrier (iBRB) mainly comprises of retinal microvascular endothelial cells (RMECs) regulating the transport of molecules such as ions, proteins and water required for the maintenance of retinal homeostasis. Small leucine rich proteoglycans, such as decorin, constitute an integral component of the endothelial cell extracellular matrix (ECM). Since decorin can elicit diverse molecular signals to modulate cell permeability, migration, and survival of RMECs, the present study aims to study the role of decorin in restoring hypoxia-induced damage to the endothelial cell integrity in the retina.

Methods: Human retinal microvascular endothelial cells (HRMECs) were cultured to confluency and subjected to hypoxia +/- 200 nM human recombinant decorin for 24 h. Cells were analysed in real time using xCELLigence system for 7 days. iBRB was evaluated using FITC-dextran permeability and tight junction proteins, including ZO1 by immunohistochemistry and western blotting. Cellular proliferation and scratch wound migration assays were also performed. Cell media was collected to measure the decorin levels using ELISA.

Results: Biochemical and immunoassays characterized the localization and release of decorin by HRMECs. Furthermore, decorin treatment to HRMECs exposed to hypoxia effectively reduced cell permeability and restored tight junction function. Additionally, decorin prevented aberrant endothelial cell proliferation and migration.

Conclusions: Decorin may counteract the hypoxia-induced iBRB disruption in the retinal microvascular endothelial cells, thereby presenting new therapeutic strategies for the management of retinal vascular disorders.

ABSTRACT BODY:

Purpose: To determine the effect of supplementation with Lutein (L), Zeaxanthin (Z) and Meso-Zeaxanthin (MZ) on multisensory integration (MSI) performance among individuals with open-angle glaucoma (OAG).

Methods: The European Nutrition in Glaucoma Management study (ENIGMA, ClinicalTrials.gov id: NCT04460365) is a placebo-controlled, double-masked randomized trial evaluating the effects of 18 months of carotenoid supplementation in OAG. 62 participants (24 female) with a diagnosis of OAG were enrolled, of whom 42 were randomized to active treatment (10 mg L, 10 mg MZ, 2 mg Z [MacuShield®]), and 20 to placebo. Macular pigment optical density (MPOD) was measured in the study eye using dual-wavelength autofluorescence (Heidelberg Spectralis OCT). MSI was assessed using the sound induced flash illusion (SIFI), where participants indicated the number of visual flashes observed on screen, while simultaneously presented with a congruent or incongruent number of auditory beeps. Participants susceptibility to the SIFI illusion, where individuals misperceive the number of flashes displayed in the incongruent condition, was assessed as an indicator of MSI efficiency.

Results: Mean MPOD increased by 60% in treated participants over the study duration, indicating effective carotenoid tissue deposition. A 2 (treatment: active and placebo) by 2 (time: baseline and 18 months) mixed repeated-measures ANOVA revealed a statistically significant interaction of treatment and time ($F(1,48) = 4.518$, $p = 0.039$) for the incongruent SIFI condition, indicating improved MSI performance following supplementation in those treated with carotenoids, but not placebo.

Conclusions: MSI performance improved significantly in response to supplementation with L, Z and MZ in people with OAG. MSI deficiencies have been reported in older individuals prone to falling, an issue known to affect people living with glaucoma. This finding indicates that MSI performance, a factor potentially linked to daily life issues affecting people with glaucoma such as risk of falls, driving safety concerns and general impact on quality of life, may be improved by supplementation with a mix of L, Z and MZ carotenoids.

ABSTRACT BODY:

Purpose: Lymphangiogenesis is critically involved in immune responses and corneal graft rejection. Recently tyrosinase has been identified as a novel regulator of developmental and inflammation-induced lymphangiogenesis. However, the underlying mechanisms are still unknown. Here we analyze the influence of tyrosinase on proliferation and expression of vascular growth factors in vitro and in vivo and test whether tyrosinase influences graft survival.

Methods: Proliferation of human dermal lymphatic endothelial cells (HDLEC) with/without tyrosinase was measured by using IncuCyte Zoom. Expression of vascular endothelial growth factors was quantified in HDLECs in vitro and in central cornea in vivo by using qRT-PCR. Balb/c mice were subjected to corneal transplantations and received a 1.5 mm graft from C57B/6 mice or albino C57BL/6 (B6N-Tyr^{cBrd}) mice. Graft survival was determined over 8 weeks and immune cell frequencies in draining lymph nodes were analyzed 3 days and 8 weeks post-transplantation.

Results: Treatment of HDLECs with recombinant tyrosinase inhibited proliferation in a dose-dependent manner. The treatment of HDLECs with recombinant Tyrosinase resulted in a significantly reduced mRNA expression of VEGF-D, VEGF-R2, and -R3 in vitro.

In order to further analyze the influence of tyrosinase on lymphangiogenesis in vivo, the limbal lymph vessel architecture of naive C57BL/6 and B6N-Tyr^{cBrd} mice was compared. B6N-Tyr^{cBrd} mice showed a significant increase in lymph vessel area and a significantly higher number of endpoints and branch points. The quantitative RT-PCR of isolated central corneal RNA showed a significantly higher expression of VEGF-A, -C, VEGF-R2, and -R3 in B6N-Tyr^{cBrd} mice compared to C57BL/6 animals. BALB/c mice receiving grafts from B6N-Tyr^{cBrd} mice showed significantly reduced graft survival compared to animals grafted from C57BL/6 mice. No significant differences in the infiltration of immune cells into draining lymph nodes could be observed between the two groups.

Conclusions: In this study, we identify tyrosinase as a novel regulator for the expression of vascular endothelial growth factors in vitro and in vivo. Furthermore, tyrosinase seems to be a key player in regulating limbal lymphatic vessel architecture and corneal graft survival. A potential mechanism of how tyrosinase is involved in corneal graft rejection is this novel lymphangiogenesis modulating activity.

TITLE: IRBP in Diabetic retinopathy – Cell Culture & Ophthalmic Pathology Studies

SESSION TITLE: Biochemistry and Molecular Mechanisms of Diabetic Retinopathy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.E. Martinez, L.L. Valdez, A.T. Tsin, Molecular Science, The University of Texas Rio Grande Valley, Edinburg, Texas, UNITED STATES|

Commercial Relationships Disclosure: Jose Martinez: Commercial Relationship: Code N (No Commercial Relationship) | Laura Valdez: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Tsin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Interphotoreceptor-Retinoid-Binding-Protein (IRBP) is restricted to the subretinal space by the external limiting membrane and RPE zonulae occludens. Its expression is reduced in diabetic retinopathy (DR) and increased expression is protective. Hypoxia decreases viable cone-like photoreceptors (661W) but increased VEGF, suggesting a role of photoreceptors in proliferative DR (PDR) (Rodriguez et al, Arch Clin Exp. Ophthal 3:23,2021). Here, we investigated the effects of high glucose and VEGF on IRBP expression by 661W and rod-like Y79 cells and distribution of IRBP and albumin in human globes with PDR and NPDR.

Methods: 661W and Y79 cells were cultured in DMEM or RPMI respectively with 10% FBS to 80% confluency and passaged to 65,000 cells/well for 24hrs prior to treatment and treated with 5.5mM and 30mM glucose with 10ng/mL of VEGF for 24 hrs. ELISA measured IRBP in the media. The expression of IRBP and albumin in human globes were examined by immunohistochemisry.

Results: During the 24hr treatment period, neither high glucose nor exogenous VEGF changed viable cell number. High glucose decreased of IRBP concentration in the media of 661W after the 24hrs (127+5nM IRBP in 5.5mM versus 69+5nM in 30mM glucose). VEGF also decreased in IRBP in the cell media (28+ 5nM IRBP in 5.5mM versus 0nM in 30mM glucose). Glucose and VEGF did not induce a similar decrease IRBP expression in Y79 cells (133nM in 5.5mM glucose, 133nM in 5.5mM with VEGF, 133nM in 30mM and 133nM in 30mM with VEGF). ANOVA showed significant treatment effects in 661W cells but not in Y79 ($F=0.83$ for 661W and $F=0.41$ for Y79). In control eyes IRBP was prominently expressed within the interphotoreceptor matrix (IPM); IRBP expression was markedly reduced in NPDR and PDR retina. Albumin was not detected in the IPM of control globes but was present in those with PDR.

Conclusions: High glucose and exogenous VEGF decreased IRBP expression in 661W but not Y79 cells. The decreased expression of IRBP in DR globes and entry of albumin into the subretinal space in PDR suggests a breakdown of the blood retinal barrier. Taken together, our data suggests that the mechanisms controlling the expression of IRBP are complex involving decreased IRBP transcription, and changes in the integrity of the junctional complexes normally restricting IRBP to the subretinal space.

ABSTRACT BODY:

Purpose: To identify candidate systemic proteomic factors which may modulate the choroidal neovascularization (CNV) activity and subsequently determine the need for intravitreal anti-VEGF injections (IAI) in patients with neovascular AMD.

Methods: Cohort study on 46 patients with neovascular AMD, treated with anti-VEGF injections. The cohort was stratified by treatment need. One group (N=25) received regular IAI at intervals of 6 weeks or less, while still having signs of CNV activity (high frequency group – HF). The second stratum (N=21) included subjects with a treatment interval of 10 weeks or longer and having no signs of CNV activity (low frequency group – LF). Full ophthalmological profiling has been done and EDTA blood samples were collected. Proteomic factors were analyzed using Hyper Reaction Monitoring (HRM) mass spectrometry. Welch's two sample t-test was performed on log2-transformed data for statistical analysis. Proteins which were differentially expressed between HF and LF at a ratio of >1.5 and $p<0.05$ were considered as candidate proteins for further analysis.

Results: Both strata were well balanced with regards to age (HF 78.4±8.14; LF 79.7±7.00 years), gender (HF: 40% LF: 61.9% female) and BCVA (HF 61.4±15.7; LF 65.0±12.4). Central retinal thickness differed HF 352.2±98.0 vs. LF 274.8±45.7µm. 1'182 proteins represented by 20'826 peptide ion variants were quantified across all samples. Nine of these met the criteria. Six were up- and three downregulated in HF vs. LF. Up-regulated proteins: complement c1q subcomponent subunit b (C1QB) (95% CI HF 18.69-19.52; LF 18.09-18.66; ratio HF/LF=1,84; p=0.0068), cytosol aminopeptidase (LAP3) (95% CI HF 14.41-15.21; LF 14.16-14.66; ratio HF/LF=1.54; p=0.0318), and insulin-like growth factor-binding protein 3 (IGFBP3) (95% CI HF 13.44-14.90; LF 12.64-13.39; ratio HF/LF=4.1496; p=0.0106). Down-regulated proteins: Acidic leucine-rich nuclear phosphoprotein 32 family member A (ANP32A) (95% CI HF 8.19-12.63; LF 11.33-14.09; ratio HF/LF=0.67; p=0.0482).

Conclusions: Nine protein candidates were identified, which were differentially expressed between HF and LF. Factors with angiogenic potential such as C1QB, LAP3 and IGFBP3 were elevated in the high frequency treatment group, while factors with anti-angiogenic potential were increased in the low-frequency group. The data suggest a potential for systemic modulation of CNV activity.

TITLE: Postoperative Complication Rates by Haptic Fixation Distance From Limbus in Sutureless Intrascleral Intraocular Lens Fixation

SESSION TITLE: Cataract surgery II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Zheng, G. Tsougranis, G. Sanchez, D. Mantopoulos, D.M. Miller, Ophthalmology, Dartmouth-Hitchcock Medical Center, Lebanon, New Hampshire, UNITED STATES|

Commercial Relationships Disclosure: Heavenly Zheng: Commercial Relationship: Code N (No Commercial Relationship) | Gregory Tsougranis: Commercial Relationship: Code N (No Commercial Relationship) | George Sanchez: Commercial Relationship: Code N (No Commercial Relationship) | Dimosthenis Mantopoulos: Commercial Relationship: Code N (No Commercial Relationship) | Donald Miller: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Flanged haptic intrascleral intraocular lens (IOL) fixation, commonly known as the Yamane technique, is a relatively new method of sutureless IOL fixation in patients who lack proper capsular support for traditional posterior chamber IOLs. We examined whether the distance of haptic fixation from the corneal limbus affected clinical outcome with particular attention drawn to the post-operative development of cystoid macular edema (CME), iris chafing, and intraocular inflammation.

Methods: Retrospective cohort study encompassing all patients who underwent secondary IOL placement via Yamane technique at Dartmouth-Hitchcock Medical Center from June 2015 to September 2021 was performed and totalled 60 procedures completed by two ophthalmologists. Data collected included gender, procedure laterality, age, sclerotomy distance (i.e. 2, 2.5, or 3 mm from the limbus), and postoperative incidence of CME, pigment dispersion, and inflammation. Rates of these postoperative complications were assessed by distance from the limbus. Inclusion criteria included (1) minimum follow-up time of two months and (2) no prior history of CME, pigment dispersion, and intraocular inflammation at the time of secondary lens implantation.

Results: Twenty-eight out of the total 60 patients met the inclusion/exclusion criteria and were further examined. The cohort's mean age was 68.1 ± 16.6 years with a mean follow-up time of 9.9 months. Overall, the incidence of postoperative CME, intraocular inflammation, and iris chafing at ≥2 months follow-up time was 29%, 54%, and 18%, respectively. The incidence of CME significantly increased with haptic fixation distance farther from the limbus, with a rate of 0%, 24%, and 66% at 2, 2.5, and 3 mm, respectively ($P = 0.043$). On the other hand, the incidence of both iris chafing ($P = 0.578$) and intraocular inflammation ($P = 0.424$) increased with haptic fixation closer to the limbus; however, these differences were not significant.

Conclusions: Presently, the placement of the haptics during Yamane IOL fixation has largely been a matter of surgeon preference and has ranged from 2 to 3 mm from the limbus. However, the distance from the limbus may hold clinical significance and should be considered given that differing rates of CME, iris chafing, and intraocular inflammation are seen due to these distances.

TITLE: Time-Course of Retinal Function during Zebrafish Retinal Regeneration
SESSION TITLE: Retina Development and Regeneration
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: L. Morey, D. Mitchell, D.L. Stenkamp, University of Idaho, Moscow, Idaho, UNITED STATES|P. Meighan, M.D. Varnum, Washington State University, Pullman, Washington, UNITED STATES|
Commercial Relationships Disclosure: Lindsey Morey: Commercial Relationship: Code N (No Commercial Relationship) | Diana Mitchell: Commercial Relationship: Code N (No Commercial Relationship) | Peter Meighan: Commercial Relationship: Code N (No Commercial Relationship) | Michael Varnum: Commercial Relationship: Code N (No Commercial Relationship) | Deborah Stenkamp: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Zebrafish regenerate their retinas following damage, resulting in restoration of function (McGinn et al., 2018 J Neurosci). Behavioral measures of visual function are restored more rapidly following a lesion that destroys inner retinal neurons and spares photoreceptors (PR) and glia (selective lesion; SL), than following a lesion that destroys all retinal neurons and spares only glia (extensive lesion; EL) (Sherpa et al., 2014 Dev Neurobiol). Here we evaluate recovery of visual function through characterization of the electroretinogram (ERG) over time following each type of retinal damage.

Methods: Right eyes of zebrafish (6mo–1.5yrs, both sexes) were lesioned with intravitreal injection of 10μM (EL) or 2μM (SL) ouabain, with left eyes as unlesioned controls. Function of retinal circuitry was analyzed at selected recovery times using ERG recordings in live zebrafish (n=3-13/timepoint). Eyes were then harvested for histological analyses of PKCα+ ON bipolar cells (BP) and parvalbumin (PARV)+ amacrine cell (AC) processes within the deep sublaminae of the inner plexiform layer (IPL), which receive input from ON BPs.

Results: A qualitative study of ERG waveforms focused on the “post-photoreceptor response” (PPR) to assess BP function and PR-BP connectivity, which in a healthy retina is dominated by the b-wave or ON BP response. There was a rapid reduction in amplitude of the PPR after both EL and SL, though the reduction was greater for EL. During early stages of functional recovery after each lesion type, we observed a deviated waveform, consistent with emergence of a d-wave (OFF BP response) elicited at light termination. At later time points (EL: 45 days post-injury (DPI), SL: 21DPI), the PPR amplitude increased and peaked sooner after the light stimulus compared to earlier DPIs, suggesting emergence of the b-wave. Later sampling times (EL: 60-90DPI, SL: 80DPI) continued to show PPRs with reduced amplitude and deviated waveforms, suggesting physiological abnormalities may persist. PKCα+ ON BP terminals and PARV+ AC processes became more reliably positioned within the deep sublaminae of the INL over recovery time after each lesion type.

Conclusions: ERG waveform topography suggests that PR-OFF BP component/connectivity may functionally recover and mature earlier during regeneration compared to the PR-ON BP component. Analysis with cell-specific markers suggests the gradual restoration of ON BP circuitry during regeneration.

ABSTRACT BODY:

Purpose: To develop an automated Random Forest (RF) machine learning model for evaluating Spectralis (Heidelberg) SD-OCT image quality.

Methods: This analysis utilized 52 SD-OCT Spectralis SD-OCT scans for training. Each scan was reviewed by two expert graders on a slice-by-slice basis. Each slice was assigned to one of three quality categories (Good, Moderate, Poor), with Good being defined as an image with no quality defects, Moderate being a gradable image with noticeable quality defects, and poor being an ungradable image. Following initial assessment, 4 additional limited quality scans were introduced to provide greater representation of “Poor” quality slice examples. Image features including intensity mean, median, variance, skew, kurtosis, and homogeneity were extracted. In addition to these features, a set of machine learning layer segmentation confidence scores were included in the feature vector for each image.
The computed features were used to train a series of random forest classifiers. To assess the impact of class imbalance on feature training, excess good and moderate scans were filtered from the training folds until a desired class balance (2:2:1) was achieved. Mean AUC scores for each class were computed via One vs. Rest binarization and micro-averaging over 10 independent runs of 5-fold cross validation.

Results: Following initial training, micro-averaged AUC scores of 0.90 ± 0.03, 0.85 ± 0.05, and 0.82 ± 0.12 for Good, Moderate, and Poor, respectively were achieved. Using the expanded dataset with increased representation of poor quality scans, the performance of the classifier on was improved (Good: 0.91 ± 0.06, Moderate: 0.82 ± 0.07, Poor: 0.90 ± 0.06). Class balancing the training sets via a filtering algorithm and including machine learning confidence scores resulted in similar but slightly improved mean AUC metrics (Good: 0.93 ± 0.03, Moderate: 0.84 ± .07, Bad: 0.90 ± 0.05) with more balanced confusion matrices.

Conclusions: The random forest model enabled reliable automated classification of “Good” and “Poor” quality Spectralis OCT images with minimal cross-over between these two classes. This tool has the potential to act as an image quality-gating system by providing rapid feedback during clinical trial image acquisition and advanced image analysis programs.

ABSTRACT BODY:

Purpose: Tumor regression of uveal melanomas (UM) after radiotherapy has been confirmed as a strong prognostic factor for metastatis. The main and most commonly used diagnostic tool to control uveal melanoma response to brachytherapy treatment is A/B scan ultrasound. Changes in tumor height and internal reflectivity are the main outcomes for monitoring uveal melanoma regression after brachytherapy. Radiomics represents an innovative way of high throughput extraction of quantitative information from medical images to describe the heterogeneity of the lesions such as tumors.The purpose of this study was to determinate possible variations in the texture of the ultrasound imagines that could be correlated with the different pattern of regression of uveal melanoma after Ruthenium-106 or Iodine-125 plaque brachytherapy.

Methods: The dataset involved 50 eyes of 50 patients that underwent Ruthenium-106 or Iodine 125 plaque brachytherapy for uveal melanoma at the Ocular Oncology Unit of “Fondazione Policlinico Gemelli” in Rome. Each eye was classified in one of two regression pattern :“favourable” (progressive decrease in height and increase in internal reflectivity after brachytherapy) and “unfavourable” (stability or increase in size after brachytherapy and stable internal reflectivity). For the analysis, we selected and compared the same transversal and longitudinal ultrasound scans with greater tumor thickness at baseline, after 1 year and 3 years from treatment. The scans were performed by the same operator, with years of experience in the acquisition of ultrasound images for oncological purposes. These standardized images were put into a texture analysis program (Aliza) where a hand drawn region of interest (ROI) was created around whole tumor margins or in subregions of it. Furthermore, the ROI was analyzed both for semantic and agnostic features, such as intensity, shape, size or volume.

Results: Using features extracted from US images a deep learning-based model for the evaluation of pattern of regression of uveal melanoma after brachytherapy treatment was created An area under ROC curve (AUC) was generated to calculate sensitivity, specificity and accuracy of the model.

Conclusions: Deep learning-based radiomics analysis can be applied to quantify regression after brachytherapy treatment for uveal melanoma and can represent a decision support for retreatment and its timing.

ABSTRACT BODY:

Purpose: Neurotrophic factors play a key role in neuroprotection and regeneration of retinal ganglion cells (RGCs) as shown in rodent models of optic neuropathies. However, advancement towards clinical application has been limited by lack of data from large animal models. Here we tested the hypothesis that brain-derived neurotrophic factor (BDNF) and 8-(4-chlorophenylthio) (CPT)-cAMP together promote RGC survival in a porcine model of traumatic optic neuropathy.

Methods: Optic nerve crush (ONC) was surgically performed in Yucatan minipigs (5.5-6 months old) under general anesthesia. The contralateral optic nerves served as uncrushed controls. At the end of surgery, BDNF and CPT-cAMP (or 0.9% NaCl for vehicle control) were intravitreally injected into both eyes. Fundus exams, intraocular pressure measurements, and flash visual evoked potential (fVEP) recordings were performed prior to and 2 and 4 weeks after ONC. At week 3, eyes were injected with cholera toxin B subunit (CTB) to anterogradely label RGC axons in the optic nerve. At week 4, eyes and optic nerves were harvested and fixed. Retinas were dissected and immunostained for RBPMS (RGC marker), mounted, imaged by confocal microscopy, and quantified for RGC survival. Optic nerves were cryosectioned, imaged by fluorescent microscopy, and analyzed for RGC axon survival and regeneration.

Results: Fundus exam revealed edema of optic nerve head in the crushed eye and bilateral vascular attenuation after unilateral ONC. No change was observed in intraocular pressure. fVEP after ONC exhibited lower peak amplitude compared to uncrushed controls, and BDNF plus CPT-cAMP-treated eyes had decreased variation in peak latency compared to vehicle control. RBPMS immunofluorescence revealed increased RGC survival in retinal flatmounts treated with BDNF plus CPT-cAMP, and increased axon survival was observed in optic nerve sections from treated animals.

Conclusions: BDNF and CPT-cAMP treatment resulted in improved functional and histological outcomes for RGCs in a large animal injury model. This combination of neurotrophic factors has therapeutic potential for neuroprotection after optic nerve injury.

ABSTRACT BODY:

Purpose: In 2020 the injection of Poly(3-hexylthiophene-2,5-diyl) (P3HT) nanoparticles (NPs) in retinitis pigmentosa model rats has proved to treat degenerative blindness (Maya-Vetencourt et al. 2020). Despite the effectiveness of this approach, the working principles are still matter of debate and any experimental investigation has not led to a conclusive interpretation. In this work we address the theoretical study of the interaction among the P3HT-NPs, the retinal electrolytic environment and a neuron membrane, aiming at highlighting the main working principles of such a complex system

Methods: The model takes into account 3 main blocks, shown in Fig.1: (1) model of photoactivation and transport phenomena in the bulk of NP (2) study of redox and capacitive phenomena at the NP-retinal oxygenated electrolyte interface, where superoxide O_2^- anion is produced;(3) model of neuron interaction with the NP-modified electrolytic environment. The description is performed through the Drift-Diffusion and Poisson-Nernst-Planck equations. Model calibration has been performed through electrochemical experiments of P3HT in oxygenated environment.

Results: Fig.2 shows neuron depolarization(left) and superoxide concentration c_{O2-}(right) as a function of oxygen partial pressure (Panel A) for two values of cleft thickness(10 and 100 nm) and as a function of the cleft thickness(Panel B). Predicted curve behaviors indicate that neuron depolarization and c_{O2-} production are strongly coupled mechanisms: as O_2^- is formed, it accumulates in the cleft region, inducing a significant neuron depolarization which may trigger action potential firing. As the cleft increases(Panel b), the superoxide is able to redistribute and the depolarization decreases

Conclusions: The proposed theoretical model has been used as a virtual laboratory to investigate biophysical mechanisms which are hardly accessible with experiments. Model predictions seem to suggest a correlation between the presence of superoxide ion and retinal neuron depolarization and highlight the crucial role played by the molecular oxygen and by the cleft size, thus helping shed light on the controversial working principles of the retinal prosthesis

ABSTRACT BODY:

Purpose: Google Cloud Platform (GCP) empowers clinicians to explore Artificial Intelligence (AI) via its code-free user interface. This, however, is associated with a low level of transparency and control over algorithm design. As a solution, the GCP Explainable AI features can produce saliency heatmaps with minimal coding, highlighting regions of model interest to guide clinician's understanding.

We present a qualitative evaluation of these explanations through a user survey, comparing them to the same saliency technique produced from a bespoke model.

Methods: We trained two algorithms for the binary classification of referrable vs non-referrable Diabetic Retinopathy (DR), using the same 60,133 fundus images from publicly available datasets. The AutoML and bespoke models reached accuracies of 93.7%, and 96.5% respectively, sufficient for our purposes of saliency map assessment.

12 test images were selected to represent varying degrees of AutoML prediction confidence. For each image, an XRAI saliency map was produced for both the AutoML and bespoke algorithms. The prior involved minimal coding, whereas the latter required a fully coded Jupyter notebook.

These maps were provided to a consultant ophthalmologist with 20 years of experience, who answered a survey of three specified questions per image, via a 5-point Likert scale. These focused on the map's localisation ability, clarity of information, and overall quality.

Results: Paired t-tests showed no statistically significant difference between the AutoML and bespoke map scores (3.25±0.75 vs 3.58±0.51) when comparing quality, however localisation ability and clarity of information were significantly higher for the bespoke model (2.75±1.14 vs 3.92±0.51, and 2.67±1.07 vs 3.83±0.58). A combined score for the three questions also showed a significant difference with a mean of 11.3±2.9 for bespoke and 8.67±1.44 for AutoML.

Conclusions: Our results showed that utilising the same saliency method and dataset in two different models can lead to significantly differing maps. Our qualitative evaluation depicted superiority of bespoke saliency maps in localisation and clarity when compared to the AutoML explainability tools.

ABSTRACT BODY:

Purpose: Neovascular retinal diseases may be responsive to tyrosine kinase inhibitors (TKIs) which have a broader anti-angiogenic profile than anti-vascular endothelial growth factor agents alone. OTX-TKI is a novel, hydrogel-based, biodegradable, intravitreal implant designed to deliver the TKI axitinib for up to 6-9 months for the treatment of neovascular retinal diseases. The purpose was to evaluate the toxicology profile of OTX-TKI for 6 months in non-human primates (NHP).

Methods: Six cynomolgus monkeys were injected intravitreally with an OTX-TKI 700 µg implant in the right eye and saline in the left eye (control). Experimental dose represents a human equivalent dose of 1400 µg axitinib and 2.3x ocular dose safety margin when normalized to the vitreous volume between human and monkey. Ophthalmic exams with slit lamp biomicroscopy, intraocular pressure (IOP), optical coherence tomography (OCT) and confocal scanning laser ophthalmoscopy (cSLO) images were collected throughout the 6-month study period.

Results: Aqueous cell and flare, and vitreous cell and haze were graded a score of 0 at all timepoints through 6-months in all OTX-TKI and control eyes. No abnormalities were observed by ophthalmic exams. No clinically significant differences in IOP were observed between OTX-TKI and control eyes through 6-months. OCT imaging showed no clinically significant changes. Implants appeared idle and fully visible in the inferior vitreous up to 5-months. At Month 6, cSLO images showed implants in a majority of animals (4/6) had completely degraded and the implants in the remaining two animals were beginning to degrade.

Conclusions: OTX-TKI was generally well-tolerated with a favorable safety profile following administration in NHPs. No signs of intraocular inflammation or clinically significant changes in IOP and OCT images were observed. The safety and efficacy of OTX-TKI 600 µg intravitreal implant is currently being evaluated in humans for the treatment of wet age-related macular degeneration in a U.S.-based Phase 1b study.

ABSTRACT BODY:

Purpose: The iris-claw Artisan is an iris-fixated intraocular lens (IOL) used to correct aphakia in eyes without adequate capsular support. Limited long term follow-up data on efficacy and safety is available in Canada. In this study, we evaluate long term visual outcomes and complications following implantation of this secondary IOL.

Methods: This is a retrospective chart review including data of patients that underwent implantation of the Artisan IOL at a tertiary Canadian centre between January 2013 and December 2021. Clinical outcomes were assessed at standard of care post-operative follow-up visits at 1 day, 1 week, 1 month, and 3 months. Key outcomes assessed include uncorrected distance visual acuity (UCDVA), best corrected distance visual acuity (BCDVA), and complications.

Results: A total of 51 eyes from 47 patients were evaluated (49.0% male, 51.0% female). Mean patient age was 68 years (range 27-96). Retropupillary fixation was performed in 50 eyes and prepupillary fixation in 1 eye. Mean follow-up duration was 12 months (range 1-63 months). The most common indications for Artisan implantation were IOL dislocation (n=33; 64.7%), followed by aphakia (n=11; 21.6%), and IOL subluxation (n=7; 13.7%). The underlying causes to the above indications were surgical complications (n=13, 25.5%), pseudoexfoliation (n=8, 15.7%), trauma (n=3, 5.9%), and Marfan syndrome (n=2; 3.9%). Zonular weakness was regarded as the cause in 25 eyes (49.0%) with no other pertinent ocular history. The average LogMAR of the UCDVA prior to implantation and at 3-month follow-up was 1.053 (range; -0.1 to 2.8) and 0.413 (range; 0 to 2.3), respectively, and BCDVA was 0.658 (range: 0 to 2.3) and 0.602 (range: -0.02 to 2.8), respectively. Intraocular pressure increased from an average of 15.6 mmHg to 17.5 mmHg at 3-month follow-up. Visual acuity improved in 37 eyes (72.6%), remained the same in 4 eyes (7.8%), and decreased in 10 eyes (19.6%) after surgery. The most common complication at 3-month follow-up was pupil ovalization (n=8, 15.7%), followed by iris atrophy (n=3, 5.9%). Other complications included cystoid macular edema (n=1), cornea decompensation (n=1), and hyphema (n=1).

Conclusions: This is the largest study of patients that have undergone Artisan implantation in Canada. Iris-claw Artisan IOL is an effective and safe option for implantation in eyes without sufficient capsular support.

ABSTRACT BODY:

Purpose: Mice deficient in Wwtr1, the gene that encodes transcriptional co-activator with PDZ-binding motif (TAZ), have a softer Descemet's membrane and decreased corneal endothelial cell (CEnC) density. To explore the underlying pathophysiology in TAZ deficient mice, single cell-RNA sequencing (scRNA-seq) was performed in wildtype (WT) and homozygous TAZ ($Wwtr1^{-/-}$) and heterozygous TAZ deficient ($Wwtr1^{+/-}$) mice at 2, 6, and 11 months of age.

Methods: Six corneas from 3 mice were pooled together and single cell suspensions were prepared for each genotype and age group. Cell suspensions were submitted for 10X Chromium Single Cell 3' library preparation and HiSeq 4000 sequencing. scRNA-seq analysis was carried out with Seurat using R. A cluster of CEnC was identified based upon the expression pattern of known marker genes for CEnC. Differential gene expression analysis was performed within the CEnC cluster to investigate the transcriptomic alterations between ages and genotypes. Differentially expressed (DE) genes were defined as genes with adjusted P-values < 0.05. Gene ontology (GO) term enrichment analysis was performed using ShinyGO v0.741; a false discovery rate (FDR) < 0.05 was applied.

Results: scRNA-seq revealed the presence of 13 cell clusters; cluster 11 showed higher expression of known marker genes (Col4a2, Col8a2, and Cdh2) for murine CEnCs. Within cluster 11, broader gene expression changes were observed between 2 and 11 months old $Wwtr1^{-/-}$ mice than between WT and $Wwtr1^{-/-}$ mice at the same age. GO analysis revealed (1) enrichment of ribosomal subunit assembly in 2-month-old $Wwtr1^{-/-}$ mice versus age-matched WT mice and (2) depletion of glycolysis and ribonucleotide metabolism in late endosome in 11-month-old $Wwtr1^{-/-}$ mice versus 2-month-old $Wwtr1^{-/-}$ mice. 11-month-old $Wwtr1^{-/-}$ mice had significantly higher expression of Plekhf1 gene versus age-matched WT and $Wwtr1^{+/-}$ mice, which is responsible for autophagosome transport and fusion with late endosomes.

Conclusions: Transcriptomics demonstrated that homozygous TAZ deficiency is associated with excessive autophagy in CEnCs. These results provide insights into the importance of TAZ signaling in the autophagy related degeneration of CEnCs.

ABSTRACT BODY:

Purpose: Standard optical coherence tomography (OCT) retinal imaging methods do not clearly distinguish outer nuclear layer (ONL) from Henle's fiber layer (HFL). HFL can be visually distinguished from ONL by de-centering the OCT beam pupil entry position, but this process requires operator skill and involves manual adjustment for every B-scan. Robotically-aligned OCT (RAOCT) automatically optimizes the pupil entry position per B-scan to acquire retinal volumes that offer complete radial visualization of HFL.

Methods: We mounted a custom swept-source OCT (1060nm) system on a collaborative robot with face and pupil tracking cameras (Fig. 1B) to enable real-time pupil tracking of imaging subjects. As seen in Figure 1A, a 2D fast steering mirror (FSM) conjugate to the retinal image plane modifies the pupil entry position of the OCT beam. Our custom software acquired retinal OCT volumes with radial B-scans and automatically adjusted the pupil entry position for each B-scan in an optimal path to visualize the HFL (Fig. 1C). With these B-scans, we reconstructed full retinal volumes that include HFL data throughout. We acquired such retinal volumes from consented subjects under an IRB-approved protocol.

Results: Figure 2 shows B-scans from retinal volumes acquired with and without the automated pupil entry adjustment. Fig. 2A shows a B-scan from a standard volume taken through the pupil center, and Fig. 2D shows a B-scan from the reconstructed volume, combining data from the B-scans in Fig. 2B and 2C. Arrows indicate areas of increased contrast due to reflectance from HFL.

Conclusions: We developed a technique for automated volumetric HFL visualization using a pupil entry adjusting RAOCT system. With this method, retinal volumes that distinguish HFL and ONL can be readily acquired, allowing for the investigation of ONL measurements as potential biomarkers in leading ophthalmic diseases.

ABSTRACT BODY:

Purpose: Metallothionein 1 (MT1) is a metal transporter and antioxidative protein that is essential in maintaining cellular physiological and redox balance. While the oxidative stress-related neuroprotective effect of the MT1 in central nervous system disorders has been investigated, the role of MT1 in the retina is still not clear.

Methods: Macular explants and peripheral retinal explants from four human donors were exposed to intense light stress (32k lux, left eye) or dim light (5 lux, right eye of the same donor). We first used single-cell RNA sequencing technology to compare the different transcription profiles of different types of retinal cells in the human macula and peripheral retina in response to photic stress. We identified one of the top differentially expressed genes, MT1, expressed more in the peripheral-dominant Müller cells in response to stress than the Müller cells that dominate the macula. We explored further the expression pattern of MT1 in the macula and temporal mid-periphery. We stained the MT1 protein together with the Müller cell-specific marker, cellular retinaldehyde–binding protein (CRALBP). We also assessed the topographic protein expression of MT1 in retinal punches (2mm diameter) from the macula, including the fovea, to the periphery by Western blot. The changes of MT1 expression in Müller cells in response to retinal stress was explored further in a mouse model of subretinal neovascularization, the JR5558 mouse. To understand the protective roles of MT1 in Müller cells, we used siRNA to knock down the MT1 in human primary Müller cells in vitro and evaluate their response to photic stress. The viability of huPMCs with or without knockdown under photic stress was assessed by an AlamarBlue viability assay and LDH cell toxicity assay.

Results: The MT1 protein was specifically expressed in Müller cells and expressed more in the peripheral retina than the macula. The peripheral Müller cells upregulated their MT1 transcription levels in response to stress much more than the macular Müller cells. MT1 expression was also activated in the JR5558 mouse. MT1 knockdown in vitro significantly reduced the viability and increased cell cytotoxicity of human primary Müller cells under stress.

Conclusions: Increased levels of MT1 in Müller cells may protect the peripheral retina and help explain why the macula is more prone to develop certain degenerative conditions than the peripheral retina.

ABSTRACT BODY:

Purpose: Accurate and automated segmentation of geographic atrophy (GA) assists in disease detection, clinical decision-making, and clinical trial enrollment. In this study, we apply a deep learning approach to segment GA on fundus autofluorescence (FAF) images, assess algorithm accuracy, and identify GA features influencing algorithm performance.

Methods: A deep learning-based semantic segmentation model using DeepLabv3+ architecture was developed to automatically segment GA area on FAF images. The model was trained on 296 FAF images (163 eyes, multiple visits) from Age-Related Eye Disease Study 2 (AREDS2) with manually segmented GA areas. The performance was first validated on 47 FAF images after independently defining ground truth and subsquently on 620 FAF images (197 eyes, multiple visits) after manual verification of algorithm output. In both test sets, algorithm segmentation was compared to manual segmentation to quantify the accuracy of pixel area overlap, absolute percent error (PE), and area difference (AD). Algorithm performance was also evaluated on different GA features: configuration (e.g. horseshoe, ring, central solid); GA at center of macula, GA proximity to fovea, and variations in autofluorescence (AF).

Results: Evaluation of 47 test images exhibited GA pixel overlap accuracy = 0.94 and intersection over union = 0.86. Further validation in 620 test images indicated a mean PE of 9.56% (stdev=38.0%). A total of 414 images (66.8%) required no correction and 470 (69.1%) images demonstrated PE of ≤5%. Only 60 (8.8%) images had PE ≥25%. Bland-Altman comparison of the contours revealed bias of 0.26 mm^2 with 95% limits of agreement (-9.81, 10.32 mm^2). Segmentation error was highest in the presence of: decreased AF at the center of the macula (PE 48.41%, AD 2.79mm^2), decreased AF with halo of increased AF (PE 48.57%, AD -4.18mm^2), and area of decreased AF within the grid (PE 39.74%, AD 2.02mm^2). Segmentation error was lowest in solid GA with central involvement (PE 0.02%, AD -0.00mm^2). However, no statistical significance was observed in area differences amongst any GA features.

Conclusions: Deep learning models can reliably and accurately segment GA on FAF images. Although decreased AF near the fovea and decreased AF within the grid confounded the algorithm in some cases, it did not show any significantly diminished accuracy for different features analyzed.

ABSTRACT BODY:

Purpose: The management of patients with aphakia and/or lack of capsular support remains debated. The sutureless posterior chamber IOL (PCIOL) fixation is a very useful surgical option. The purpose of the study was to compare the one-year outcomes as well as post-operative best corrected visual acuity, refractive errors and complications of two different techniques of sutureless PCIOL secondary implantation.

Methods: Patients who underwent secondary implantation from December 2019 to January 2022 in the Department of Ophthalmology of Creteil Hospital were retrospectively included. Eyes implanted with the iris claw lens (Artisan Aphakia IOL model 205, Ophtec BV, Groningen, The Netherlands) were included in group 1, and eyes implanted with a newly developed sutureless trans-scleral plugs fixated lens (STSPFL, Carlevale lens, Soleko, Pontecorvo, Italy) were included in group 2.

Results: Twenty-five eyes of 25 patients were enrolled in group 1, and twenty eyes of 20 patients in group 2. No difference was found in visual acuity between two groups (0.38 +/- 0.24 logmar for group 1 and 0.26 +/- 0.54 logmar for group 2) ($p = 0.18$) at mean post-operative follow up (12.19 +/- 3.44 months for group 1 and 12.42 +/- 3.96 months for group 2) ($p = 0.13$). Both the mean refractive error (MRE) and induced astigmatism (IA) were greater in group 1 compared to group 2, respectively: the MRE was 0.99 +/- 0.57 vs. 0.46 +/- 0.36 ($p < 0.01$), and IA was 1.72 +/- 0.96 vs. 0.72 +/- 0.52 ($p < 0.01$). The most common complications in group 2 were conjunctival erosion (10%) and breakage of the plugs (10%).

Conclusions: No significant differences in terms of the recovery of visual acuity were found between the two groups. Group 2 (STPFL) gives better results in our sample due to less post-operative induced astigmatism and less refractive error.

ABSTRACT BODY:

Purpose: The culture of purified retinal ganglion cell (RGC) cultures has been a vital tool in the study of glaucoma and neural regeneration. Traditionally, RGCs are isolated from early postnatal animals using a two-step immunopanning (IP) technique, a procedure limited to RGCs of a specific maturity. This study aimed to develop a method using a low-pressure cell sorting protocol that will allow for the sorting of RGCs and their subtypes using optogenetic markers while maintaining the RGCs survival and electrophysiological properties, which can be affected using traditional fluorescence associated cell sorting (FACS).

Methods: Using a combined IP-FACS protocol that initially depletes macrophage and photoreceptors using IP before enriching for RGCs using low-pressure FACS against Thy-1 expression. RGC viability was compared against a two-step IP using a live/dead analysis. Cell phenotype was compared using immunohistochemistry for RBPMS and β-III-Tubulin, while properties such as axon outgrowth and neurite branching were also measured. Further, RT-qPCR was carried out to verify the purity of isolated cells. Functionality was compared using calcium imaging to determine isolated RGC response to both potassium chloride (KCl) and glutamate.

Results: RGCs purified by the IP-FACS method remained viable with no evident cytotoxicity and similarly extended their neurites to those purified by the IP method. RGCs isolated from both methods showed similar expression of RGC-specific proteins and similar gene expression levels. IP and IP-FACS methods resulted in no significant difference ($p > 0.05$) in a total number of neurites of 2.14 ± 0.3 and 2.47 ± 0.5, longest neurite length of 1098.14 ± 205.5 µm and 1184.15 ± 111.3 µm, total neurite length of 1765.5 ±367.7 µm and 2117.6 ± 23.3 µm and the average neurite length of 890.9 ± 148.9 µm and 882.2 ± 157.1 µm, respectively. Calcium imaging revealed that both populations respond to KCl and glutamate stimuli, confirming that cells are functional to standard calcium stimulus.

Conclusions: Our results showed that low-pressure FACS can isolate RGCs from rodents with comparable viability, phenotype, and function compared to the traditional method of immunopanning. This method opens the possibility of isolating embryonic RGCs or subtype populations by combining FACS isolation with optogenetically labeled transgenic rodents.

ABSTRACT BODY:

Purpose: DM1 is a growing pathology whose management is still under development. The age of diagnosis is usually between 10 and 14 years old, so early diagnosis is very important; We propose microperimetry (MP) as a part of this process and its correlation with the structure of the ganglion cell complex (GCC) evaluated by optical coherence tomography (OCT).

Methods: A descriptive, cross-sectional and comparative study was carried out in type 1 diabetic patients without signs of diabetic retinopathy (DR). Structural OCT was performed using a 9 mm macular cube with the Nidek RS 3000 Advanced 2 equipment (Nidek, Gamagori, Japan) and retinal sensitivity (RS) values were obtained by micropermitry in 13 specifically located points in scotopic and photopic mode using the Nidek MP3s (Nidek, Gamagori, Japan). Finally, the statistical analysis was carried out using SPSS version 25 (IBM, Armonk, NY, USA).

Results: 148 eyes of 75 subjects were analyzed, 36 diabetic patients without diabetic retinopathy and 39 healthy volunteers, the photopic mean retinal sensitivity (MRS) in the diabetic group was 30.5 +/- 1.98 dB, lower than the mean in the healthy group (31.12 +/- 1.27 dB, p = 0.05). In scotopic mode, MRS was lower (14.53 +/- 1.21 dB) than the mean of the control group (14.64 +/- 1.45 dB), however, they were not statistically significant (p = 0.063). Correlation between retinal sensitivity (RS), and GCC thickness has been found both in diabetics (0.279; p = 0.022) as well as in the control group (0.238; p = 0.007), however, it has not been seen that the group of diabetics present a significant decrease in the GCC thickness compared to the healthy group.

Conclusions: The average photopic MRS of diabetic patients is 30.68 +/- 1.92 dB, lower than the MRS in healthy volunteers with similar characteristics. Despite showing correlation between RS and GCC thickness in both groups; it has not been significantly lower in patients with DM1 without diabetic retinopathy signs, compared to healthy population.

ABSTRACT BODY:

Purpose: The goal of our lab is to understand the pathophysiology of Fuchs endothelial corneal dystrophy (FECD) and why it is more common in women than men. Damage from ROS and decreased ATP production are prominent in FECD pathophysiology. The purpose of this study was to characterize the role of chronic hyperoxic stress (room air + 5% CO_2, $[O_2]_A$) vs. physiologic oxygen conditions (2.5% O_2 + 5% CO_2, balance N_2, $[O_2]_{2.5}$; environmental chamber, Billups-Rothenberg, Inc., Del Mar, CA) and estradiol (E2) on ROS and ATP levels in human corneal endothelial cells (HCEnCs). We hypothesized that $[O_2]_{2.5}$ would have lower ROS and higher ATP than $[O_2]_A$ and E2 would restore physiologic ROS and ATP levels under $[O_2]_A$.

Methods: Primary HCEnC cultures were prepared at $[O_2]_A$ and $[O_2]_{2.5}$. Cells were grown in growth medium until confluence and then matured for 7-10 days in minimal medium with 10 nM E2 in half of the cell samples. Cell lysates were analyzed for ROS levels (Cell Biolabs In Vitro ROS/RNS Assay, San Diego, CA) compared to an H_2O_2 standard curve and normalized to total protein concentration. ATP levels in cell lysates were measured with a luminescent ATP detection kit (Abcam, Cambridge, MA). Mean data were compared using ANOVA. Significant differences were explored with Tukey post hoc test with significance at $p<0.05$.

Results: There were no significant differences in ROS levels amongst O_2 and E2 conditions (p=0.53), and no differences were observed when data were analyzed separately for male (p=0.42) and female (p=0.40) donors (Table). E2 also had no effect on ATP levels. However, ATP levels were significantly different by O_2 condition (p= 0.01). ATP was significantly higher for cells at $[O_2]_{2.5}$−E2 than $[O_2]_A$−E2 (p=0.02). When data were stratified by sex, male HCEnCs had no significant differences in ATP levels in any condition (p=0.77), but female HCEnCs had significantly higher ATP levels at $[O_2]_{2.5}$−E2 than at $[O_2]_A$−E2 (p=0.01) (Table).

Conclusions: Our data show that O_2 and E2 do not regulate ROS in HCEnCs, but O_2 does affect ATP levels in a sex-specific manner. Alterations in HCEnC energetics may contribute to the pathophysiology of the sex difference in the prevalence of FECD.

TITLE: The role of CD80 and HSV-1 ICP22 interaction on HSV-1 pathogenicity and latency-reactivation in infected mice

SESSION TITLE: Infection and Immunity

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Matundan, U. Jaggi, H. Ghiasi, Surgery, Cedars-Sinai Medical Center, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Harry Matundan: Commercial Relationship: Code N (No Commercial Relationship) | Ujjaldeep Jaggi: Commercial Relationship: Code N (No Commercial Relationship) | Homayon Ghiasi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Previously we have shown that CD80 and not CD86 is suppressed in the corneas of mice ocularly infected with wild type (WT) HSV-1. This suppression of CD80 was mediated by binding of HSV-1 ICP22 to CD80 promoter. In addition, we found that ocular infection of mice with a recombinant HSV-1 expressing CD80 virus exacerbated eye disease in infected mice. In the current study, we investigated if any specific region of ICP22 is involved with the suppression of CD80 by using recombinant viruses lacking ICP22 gene or lacking ICP22 binding site to CD80 promoter.

Methods: BALB/c mice were scarified and ocularly infected with $2x10^5$ pfu/eye of a recombinant virus lacking ICP22 (D22) or lacking CD80 binding region (KOS-ICP22Δ40). Parental avirulent HSV-1 strain KOS (WT) was used as a control. Viral replication in the eye, corneal scarring, latency-reactivation, and exhaustion markers were determined in infected mice. Flow cytometry analysis was done to evaluate the expression of immune infiltrates into the cornea. CD80 promoter activity was monitored by luciferase assays after infection.

Results: Luciferase analysis of D22 and KOS-ICP22Δ40 infected cells compared with WT virus shown that ICP22 is involved in down-regulation of CD80 promoter in vivo and in vitro. At a functional level, both D22 and KOS-ICP22Δ40 viruses enhanced levels of effector CD8 T cell population and affected infiltrates in cornea of infected mice in a time-dependent fashion compared to WT virus. Suppression of CD80 in DCs was blocked in the absence of ICP22. The absence of ICP22 binding to CD80 promoter using both D22 and KOS-ICP22Δ40 viruses increased eye disease but latency and reactivation were not affected compared with WT virus.

Conclusions: Our results suggest that inhibiting the binding of HSV-1 ICP22 to CD80 promoter leads to increased HSV-1 pathogenicity. This is of particular interest, because it indicates that the absence of ICP22 leads to increased CD80 and CD8 expression in the eye of infected mice resulting in more eye disease. Thus, our data signifies that HSV-1 uses CD80 suppression by ICP22 as a mechanism of immune escape in order to protect the host from increased pathology.

ABSTRACT BODY:

Purpose: Sustained release implants composed entirely from novel prodrugs have the potential to improve the safety and compliance of ophthalmic medications. The prodrug implants are non-swelling, exhibit surface erosion-based drug release, and avoid polymer-associated pro-inflammatory degradation products. The purpose of this work was to evaluate the preclinical ocular safety and pharmacokinetics of a prostaglandin prodrug intracameral implant (RTC-1119 IC implant) with >6 mo sustained release of latanoprost acid for primary open angle glaucoma and ocular hypertension.

Methods: RTC-1119 IC Implants were prepared by extrusion of RTC-1119, a prodrug of latanoprost acid, without the inclusion of a polymer carrier. Tolerability and surface erosion of RTC-1119 IC Implants was evaluated following IC administration in New Zealand white rabbits (4 rabbits, 7 eyes) for a duration of 7.5 months. Implants were visualized by gonioscopy. Safety was assessed through ocular exams, anterior segment optical coherence tomography, and histopathology. Quantification of latanoprost acid in aqueous humor and iris-ciliary body was assessed by liquid chromatography-mass spectrometry (Days 7, 28).

Results: The RTC-1119 IC Implant was well tolerated, with ocular exams indicating no adverse findings. No change in corneal thickness or implant associated inflammation was observed. Gonioscopy showed implants becoming smaller in diameter over time, supporting the surface erosion mechanism of drug release, and completely biodegrade without leaving behind any remnants due to the absence of a carrier system (Figure 1). Consistent levels of latanoprost acid were observed in the aqueous humor and iris-ciliary body at Day 7 and Day 28 (Figure 2).

Conclusions: The present study indicates that the RTC-1119 IC Implant is well tolerated in the rabbit eye, where it undergoes surface erosion to provide controlled release of latanoprost acid. Gonioscopic visualization of implants indicate that duration of drug release is >6 mo. Ongoing work is evaluating the IOP lowering effect of the RTC-1119 IC Implant in a canine model. This data supports the further development of the RTC-1119 IC Implant towards first-in-human clinical trials.

ABSTRACT BODY:

Purpose: Despite an increasing incidence of skin cancer over the last decade, studies have reported a decline in the diagnosis and treatment of skin cancer during the COVID-19 pandemic. We performed a retrospective cohort study using a large population-based cohort from the Veterans Health Administration (VHA) to determine how the pandemic has affected tumor size and morbidity in veterans with periocular non-melanoma skin cancer.

Methods: Electronic health records from all VHA sites were accessed through the VA Informatics and Computing Infrastructure (VINCI). Data were stored in the Observational Medical Outcomes Partnership (OMOP) model and queried via SQL Server. ICD-10 and current procedural terminology codes were used to identify patients who received Mohs surgery for periocular basal cell carcinoma (BCC) or squamous cell carcinoma (SCC) between 08/01/2018 and 09/10/2021. A combination of structured algorithms and manual review were used to extract patient demographics, lesion characteristics, and surgical outcome at three time points, ie. pre-COVID, early, and late COVID. Unpaired t-tests were used to assess statistical significance.

Results: Patient characteristics were similar between pre- and post-COVID cohorts in terms of gender, age, race, and tumor type. The average number of Mohs periocular surgeries performed per week were 23.1% (7.31 vs 5.62) and 13.1% (7.49 vs 6.51) lower in the early and later pandemic, respectively, compared to similar pre-COVID timeframes by month (Figure 1). Mean lesion size (maximum diameter) was 1.35 cm larger post-COVID compared to pre-COVID (95% CI 0.19 2.51, P=0.022); however, the defect size remained similar (Figure 2). Stratifying by tumor type, the same trends were noted in BCC, particularly early in the pandemic. However, mean SCC lesion and defect sizes did not vary over time.

Conclusions: Periocular Mohs surgery rates declined in the COVID pandemic across VHA. Lesions were larger particularly in the earlier phase of the pandemic for BCC. Future analyses using this cohort will attempt to determine if telehealth and travel time were associated with distinct outcomes.

TITLE: The Impact of Hyperglycemia on Cognitive Function and Vision

SESSION TITLE: Biochemistry and Molecular Mechanisms of Diabetic Retinopathy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. McCarthy, Biology, American University, Washington, District of Columbia, UNITED STATES|

Commercial Relationships Disclosure: Elizabeth McCarthy: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Type II diabetes (modeled in this research with hyperglycemia) has been shown to cause cognitive deficits and lead to retinopathy. Here, we looked at adult zebrafish to see if breakdowns in the blood-brain barrier and the blood-retinal barrier would be correlated with dysfunction on vision- and/or memory-guided behavioral assays. We hypothesized that our glucose-treated fish would have increased inflammatory markers (Rel-A) and decreased tight junction protein (Claudin-5) in the brain and retina, and that these markers would be consistent with glucose-treated fish having inferior performance on vision- and memory-guided assays.

Methods: To test our hypothesis, we maintained three groups of fish (roughly 10 per group), water-treated (stress control), mannitol-treated (osmotic control) and glucose-treated, in hyperglycemic conditions (or control) for 8 or 12 weeks while we collecting behavioral data. Every four weeks, fish were run through a three-chamber choice task (3CC) to assess cognition and, at the end of exposure, visually guided optomotor responses (OMR) were assessed and tissue samples were collected to determine changes in brain and retinal protein levels.

Results: At 8 weeks, no significant changes to memory were observed in glucose-treated fish. At 12 weeks, glucose-treated fish had significantly improved memory relative to water-treated fish ($p < 0.001$), though they were not significantly different from mannitol-treated fish. OMRs at 8 weeks revealed that glucose-treated fish performed better than both mannitol- ($p = 0.0166$) and water-treated fish ($p = 0.0394$). At 12 weeks, significantly more glucose-treated fish displayed positive OMRs compared to mannitol-treated controls ($p = 0.0166$). Preliminary molecular results show increased Rel-A and decreased Claudin-5 in both the brain and the retina of glucose-treated fish at both time points.

Conclusions: These results suggest that hyperglycemia-induced deficits in vision and cognition are controlled by different pathways; one involving osmotically-induced alterations and the other initiated by glucose specific mechanisms. Overall, hyperglycemia induced inflammation and decreased tight junction proteins seemed to be correlated with better performance on vision and memory guided behavioral assays.

ABSTRACT BODY:

Purpose: To characterize patches of fluorescently labeled cone photoreceptors detected in female carriers of choroideremia (CHM) following intravenous injection of indocyanine green (ICG) dye using adaptive optics (AO) imaging (PMID:33796365).

Methods: Patches of fluorescently labeled photoreceptors (>50 cones) were identified using AO-ICG following multimodal AO imaging in 11 eyes from 6 carriers of CHM. Co-registered non-confocal split detection AO images were used to evaluate whether fluorescent patterns corresponded to cone photoreceptors, and outer retinal length (ORL) measurements were performed in AO-OCT volumes. For comparative purposes, histology of the outer retina from mice was obtained using custom-modified microscopes. Murine photoreceptors and retinal pigment epithelial (RPE) cells were assessed following both systemic injection of ICG as well as ex vivo incubation with ICG.

Results: In mice after systemic injection with ICG, RPE cells were labeled with ICG (PMID:27564519) but there was no observable ICG fluorescence in the photoreceptor layer. Photoreceptors were however readily labeled when detached from the RPE and incubated with ICG ex vivo, suggesting that the outer blood-retinal barrier function of the RPE prevents labeling of photoreceptors during normal physiologic conditions. In carriers, in addition to the ICG fluorescence pattern observed in the RPE mosaic, patches of ICG-labeled cone photoreceptors were also observed (23 distinct patches identified across 10 eyes). The excellent correspondence between fluorescently labeled photoreceptors visualized using AO-ICG and simultaneously acquired split detection images confirmed that these were indeed cones. There were no apparent differences in spacing, density, or ORL measurements of cones within these patches.

Conclusions: The discovery of ICG-labeled cone photoreceptors in patients, together with mouse histology data, suggests that there are focal disruptions to the outer blood-retinal barrier in carriers of CHM. These photoreceptors appear to be structurally normal and may be associated with interspersed enlarged RPE cells seen in CHM (IOVS 2021; 62:1900). These results demonstrate a possible novel application of AO-ICG as a functional assay for assessing the integrity of the outer blood-retinal barrier function of the RPE.

ABSTRACT BODY:

Purpose: Establishing the relationship between photoreceptors and visual function in the normal population is crucial for understanding the effects of progression and/or treatment of retinal disease. By using highly sensitive measures of photoreceptor structure and function, we aim to determine if there is a correlation between cone density, rod/cone function, and color vision in a group of healthy individuals.

Methods: Monocular data from ten healthy individuals were examined (6M, 4F, mean age: 29 years, range: 24-36 years). Functional assessment was carried out using Advanced Vision & Optometric Tests (AVOT), and included rapid flicker sensitivity, measured with cone- and rod-enhanced stimuli (at the fovea and in 4 quadrants located at 5 degrees eccentricity), as well as colour vision, measured using the Colour Assessment and Diagnosis (CAD) test. The CAD test yielded both red-green (RG) and yellow-blue (YB) chromatic discrimination thresholds. Photoreceptor structure was assessed using nonconfocal split-detection Adaptive Optics Scanning Light Ophthalmoscopy (AOSLO). Cone density was measured at 0.5, 1 and 5 degrees along the temporal meridian, using 55 x 55 μm regions of interests (ROIs). Three ROIs at each location were quantified twice by two independent graders.

Results: Measurements fell within the normal range for all AVOT and AOSLO assessments (Table 1). Agreement between cone density measurements of the two graders was excellent (intraclass correlation coefficient = 0.988, 95% confidence interval = 0.980-0.993). There were no statistically significant correlations between central cone density (0.5 or 1 degree) and either CAD or foveal cone-mediated thresholds (Pearson, $p > 0.05$). Nor were there any significant correlations between cone density at 5 degrees and peripheral rod- or cone-mediated thresholds (in the upper and lower temporal quadrants) (Pearson, $p > 0.05$).

Conclusions: Despite their current use as outcome measures in clinical trials for gene therapy, this is the first time the CAD, rod- and cone-mediated flicker tests and AOSLO have been validated against each other. Our data suggest that, in healthy individuals, natural variation in cone density does not have a significant effect on visual function.

ABSTRACT BODY:

Purpose: Usher syndrome (USH) is a rare genetic autosomal recessive (AR) disorder characterized by sensorineural hearing loss and retinitis pigmentosa. We performed prospective observational natural history clinical trial to clarify genotype-phenotype correlation of Usher syndrome patients in Russia for possible further treatment application

Methods: 118 syndromic RP patients with hearing loss of AR and sporadic inheritance were included under NCT03901391 and NCT03319524 protocols. Complete ophthalmic and audiology examinations were conducted in all the study subjects. DNA samples were extracted from patients' peripheral blood for whole exome sequencing (WES) analysis. Sanger sequencing was conducted for validating the identified mutations and cosegregation pattern in the families, MLPA was done for deletions borders clarification.

Results: USH patient group data is in Table 1. USH1 patients with biallelic mutations in MYO7A (14 cases), USH1C (1 case), CDH23 (2 cases), PCDH15 (2 cases) and CIB2 (1 case). USH2 patients with biallelic mutations in USH2A (71 cases), 15 of them are newly reported mutations in USH2A gene and are provided in Table 2. 7 patients had W3955X USH2A mutation – 3 homozygous and 4 – in compound heterozygous state with another confirmed pathogenic mutation, which are considered to be of founder effect from eastern Europe, one of the patients had deletion of 38 exon of USH2A c.7121-?_7303+? del, mutations in GPR98 (1 case), DFNB31 (2 cases). In 6 patients biallelic CLRN1 gene mutations were confirmed of USH3 group, 3 of those patients have known ancestors from Baltic region including Finland. Partially solved cases included USH2A: 1 heterozygous mutation, no second mutation found (3 cases), POC1B (1 case), EYS (1 case) – two compound heterozygous mutations, PRGR hemizygous mutation – but no genetic causes of hearing loss is found in these cases. GJB2 hearing loss genetically confirmed, but no genetic causes of vision loss found (3 cases). There were USH phenotype patients with confirmed another genetic disease: NIPBL (Cornelia de Lange syndrome 1), LOXHD1 (Deafness, autosomal recessive 77), PRGR (X-linked retinitis pigmentosa), PEX6 (Zellweger spectrum disorder). No any mutations found in 4 USH patients.

Conclusions: This study clarified main genetic causes of Usher syndrome and its phenocopies in Russian patients, 15 novel variants in USH2A gene were identified.

ABSTRACT BODY:

Purpose: To model the rapidity with which surface charge and consequent local near-surface voltage patterns change on a phase-separating globular protein, and to compare mean times for pattern change with characteristic times for translational diffusion to a neighboring protein, and for rotational diffusion to substantially different orientations in solution.

Methods: Our published, calibrated grand-canonical partition function model for the equilibrium charge regulation of bovine gammaB-crystallin indicates that to account for 95% of the coexisting charging patterns, approximately 400 distinct surface charge patterns are needed. Because of detailed balancing at equilibrium, such a model also gives ratios of rate constants describing protonation and deprotonation of each of the charged sites. We combine these ratios with existing literature data on typical rate constants for each type of titratable amino acid side chain and chain termini. By doing so we estimate individual rate constants for the rapidity of transitions between charging patterns connected by single protonation or deprotonation steps.

Results: The typical transition times between charging patterns range in general from microseconds to milliseconds, and in concentrated solutions can be orders of magnitude longer than typical times for translational diffusion to a neighboring protein (a few nanoseconds to microseconds), or for rotational diffusion through an angle of one radian, which is typically about 10 nanoseconds for this protein.

Conclusions: The implication of this kinetic model is that individual protein molecules that have a given charging pattern encounter many other protein molecules before their surface voltage patterns have a high likelihood of substantially changing. Because of this relative slowness of surface charge pattern changes, accurate modeling of the degree to which individual types of pairs are in close proximity, as well as how both direct energetic and hydrodynamic interactions affect their close-range mutual motion, can thus be accomplished, to a first approximation, by considering each such surface charge pattern pair independently.

TITLE: Spatial transcriptomics of human pluripotent stem cell derived retinal organoids offers new insight in retinal development

SESSION TITLE: Retina Development and Regeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Dorgau, J. Collin, R. Queen, A. Rozanska, M. Lako, Bioscience Institute, Newcastle University, Newcastle upon Tyne, Tyne and Wear, UNITED KINGDOM|

Commercial Relationships Disclosure: Birthe Dorgau: Commercial Relationship: Code N (No Commercial Relationship) | Joseph Collin: Commercial Relationship: Code N (No Commercial Relationship) | Rachel Queen: Commercial Relationship: Code N (No Commercial Relationship) | Agata Rozanska: Commercial Relationship: Code N (No Commercial Relationship) | Majlinda Lako: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Although scRNA-Seq enables identification of distinct and changing cell populations during retinal development, the spatial resolution of those cell populations is missing. Spatial transcriptomics (ST) enables the visualisation and quantitative analysis of the transcriptome in spatial location, providing a novel tool for detailed studies of human retinal development. In this study ST is used for the first time on pluripotent stem cell derived retinal organoids to examine the spatial resolution of retinal cell-types during development.

Methods: Retinal organoids were cultured until day 210 of differentiation and collected at day 10, 20, 35, 45, 60, 90, 150 and 210 for ST and scRNA-Seq. experiments. ST experiments were performed using the 10xVisium Spatial Gene Expression Kit (10x Genomics). For this purpose, retinal organoids were fresh frozen and stored at -80°C. Cryosections of each sample were collected on individual 10xVisium Gene Expression slides and processed according to manufacturer's protocol. Whole transcriptome libraries were sequenced, analysed, and visualized using Space Ranger and Spaniel R package. For scRNA-Seq. retinal organoids were dissociated followed by cell capture and library generation using the Chromium Single Cell 3′ Library & Gel Bead Kit (10x Genomics). Uniform manifold approximation and projection plots were used to visualise the clusters.

Results: Early retinal organoids (day10) were dominated by a cell cluster expressing eye-field marker genes whereas later stages (day20/35) showed several progenitor cell clusters including retinal progenitor cells. Additionally, ocular surface epithelium and lens/cornea cells were found at these stages. Retinal ganglion cells appeared at day 35 and were detected throughout differentiation. Mid stages of retinal development revealed photoreceptor precursor expression at day 90, which matured to rods and cones in late developmental stages (day150/210), where also a bipolar cell cluster was evident. The comparison of ST and scRNA-Seq. data indicated comparable cluster distribution in development.

Conclusions: ST provides a powerful tool to investigate the spatial resolution changes within a tissue during development, demonstrating here for the first time on human retinal organoids. Thus, ST offers significant insights in normal retinal developmental and/or disease pathological mechanisms.

ABSTRACT BODY:

Purpose: To offer early ophthalmology exposure to underrepresented minority (URM) premedical undergraduate students through clinical, research, and mentorship opportunities in an effort to increase URM trainees in the ophthalmology pipeline.

Methods: An ophthalmology mentorship program for URM undergraduate students was launched in the spring 2021 semester and continued through the fall 2021 semester. The program offered clinical experience through virtual shadowing sessions, research opportunities, and mentorship for applying to medical school and supporting career development. Twenty-two undergraduate students (including 13 returning students from the first session) were paired with 13 mentors composed of medical students, residents, and post-doctoral fellows. As part of the Virtual Shadowing Series, 8 ophthalmology faculty hosted 1-hour sessions during which they presented patient cases and surgical videos and shared their career paths.

Results: In a survey, respondents reported increased interest in ophthalmology (17/19, 90%), medicine (15/19, 83%), and research (13/19, 68%). Students attended an average of 3.5 (median 3) of the 8 virtual shadowing sessions offered. All respondents met with their mentor or attended a virtual shadowing session at least once, and all respondents indicated an interest in continuing to participate in the program. In addition to virtual shadowing, 3 students shadowed in the operating room for a half day, observing vitreoretinal surgery through a heads-up 3D surgery platform.

Conclusions: A program offering mentorship, research opportunities, and virtual shadowing experiences for URM undergraduate students increased interest in ophthalmology, medicine, and research for the majority of students, and may serve as a model for other institutions.

ABSTRACT BODY:

Purpose: COVID-19 has disrupted provision of and access to healthcare. Children newly diagnosed with uveitis are particularly vulnerable to these disruptions. We aimed to describe the impact of the pandemic on the experiences and perceptions of care use for families of children newly diagnosed with uveitis.

Methods: UNICORNS-C19 is a cross-sectional study embedded within the Uveitis in Childhood National Prospective Cohort Study (UNICORNS), which is recruiting UK children with non-infectious uveitis in order to understand the sociodemographic, clinical and biological determinants of disease and treatment outcomes and quality of life.
We distributed (postally and electronically) a modified Health Foundation / Ipsos Mori survey, which comprises 13 questions (closed and open) around health and social care. Quantitative data were analysed using descriptive statistics, free text responses were analysed using qualitative thematic analysis. A framework was developed to index and chart data into themes through an iterative process.

Results: Response rate to date is 42 of the 95 UNICORNS families approached (44%). Of those who participated, 61% expressed concern over the impact of the pandemic on their health, with a third (31%) expressing difficulties in accessing essential medication, and 56% finding it harder to get basic food stuffs. Despite this, the majority expressed a positive experience with NHS services, with 72% being comfortable using their specialist hospital during the pandemic. Key themes identified in analysis included positive experiences of safety procedures and the adoption of digital health tools across different levels of care (primary to quaternary); negative experiences of poor co-ordination of care, or of delivery of synchronous telemedicine care of rare disease from primary / secondary health teams, and negative perceptions around the use of immunosuppression during the pandemic.

Conclusions: The UNICORNS study is well placed to provide useful data on patient experience for those starting a rare, chronic childhood disease care pathway during a global pandemic. Our findings suggest that primary and secondary care teams require additional support in delivering / co-ordinating care for those with rare disease. UNICORN C-19 findings will inform recommendations for future service planning.

ABSTRACT BODY:

Purpose: To report the clinical and genetic characteristics of autosomal recessive bestrophinopathy (ARB) in Egyptian patients who are offspring to consanguineous parents. ARB is a rare inherited retinal disorder.

Methods: Prosepective study aiming to characterize the clinical picture, multimodal imaging and genetic findings in 13 patients with ARB from 11 consanguineous Egyptian families. All patients underwent complete ophthalmological examination and multimodal imaging including fundus photography, fundus autofluorescence (FAF) and optical coherence tomography (OCT). Full-field electroretinography (ERG) and electro-oculography (EOG) were performed as well as genetic testing of the BEST1 gene for biallelic mutations.

Results: The patients were comprised of 11 females and 2 males. The visual acuity ranged from counting fingers to 20/32. All patients exhibited retinal findings on multimodal imaging classically-described with ARB. These findings include hyperautoflourescent retinal flecks in the posterior pole and retinal midperiphery with corresponding hyperreflective RPE deposits on OCT, subretinal fluid in the fovea with overlying elongated photoreceptors in a stalactite-like arrangement and intraretinal cysts. One patient showed diffusely thinned neurosensory retina and RPE, but she had extinguished ERG and absent light rise on EOG. Her old retinal imaging demonstrated classic ARB findings. Another patient showed a large scar in the fovea markedly compromising vision. On electrophysiology, there was moderate reduction in ERG and absent light rise on EOG. Sequencing of BEST-1 gene revealed 2 previously-reported mutations c.122C>T, p.P41L, g.5952 C>T and c.424C>T- chr11:61724438C>T, p.R142W, and 2 novel mutations; c.245insCAG in a single patient and c.185G>C, p.R62P in 4 patients

Conclusions: Autosomal recessive bestrophinopathy is a recognizable phenotype caused by inherited mutations in the BEST1 gene. In this study, we present the clinical spectrum as well as a novel mutation found in 6 Egyptian patients from various regions. The novel mutation was not associated with a significant impact on retinal clinical picture.

ABSTRACT BODY:

Purpose:

To assess the safety and tolerability of magnetic cell therapy as treatment for subjects with corneal edema secondary to Fuchs' endothelial corneal dystrophy (FECD) or pseudophakic bullous keratopathy (PBK).

Methods: Human corneal endothelial cells were isolated from donor corneas, expanded in vitro and labeled with biocompatible magnetic nanoparticles to formulate EO2002, magnetic human corneal endothelial cells.

The safety and tolerability of a single intracameral injection of magnetic human corneal endothelial cells (EO2002) with and without endothelial brushing (EB) or Descemet stripping (DS) will be assessed in a phase 1, open-label, dose-escalating multicenter study. In total, 18 subjects with corneal edema will be enrolled in the study and will receive a single dose of EO2002 followed by the application of an external magnetic eye patch. Half of the subjects will only receive an injection of EO2002 and the other half will undergo EB or DS followed by EO2002 injection. Three doses will be studied over a 6-month follow-up period. The primary endpoints are the absence of inflammation and a stable intraocular pressure. The secondary endpoints will assess changes in corneal thickness and in best corrected visual acuity (BCVA).

Results:

Study enrollment for pseudophakic subjects that are surgical candidates for DSEK with BCVA <20/40 is ongoing. To date, 9 subjects were enrolled and treated with EO2002 with and without DS. No product-related SAEs have occurred.

Conclusions:

EO2020 injection in subjects with symptomatic corneal edema is well-tolerated, with no significant adverse events or changes in intraocular pressure. Forthcoming data from the remainder of the study should provide valuable information on the safety of all doses as well as essential data on secondary endpoints in this patient population.

ABSTRACT BODY:

Purpose: The link between the gut microbiome and age-related macular degeneration (AMD) is not completely understood, but gut dysbiosis has been implicated in AMD pathogenesis. Our team previously showed that high-fat diet (HFD) intake induces changes in gut microbiota composition (gut dysbiosis), alters the retinal and choroidal transcriptome, and exacerbates choroidal neovascularization in mouse models. However, little is known about how HFD changes the functional profiles of microbes. The purpose of this study is to use shotgun metagenomics to determine the effect of HFD consumption on microbial metabolic pathways, thereby clarifying the link between HFD-induced gut dysbiosis and AMD.

Methods: C57BL/6 mice were placed on either a ND or 23% HFD for 8 weeks (4 mice/group). For shotgun metagenomic analysis, DNA was extracted from fecal pellets and Illumina compatible libraries were generated using the QIAseq FX Library Kit. Sequencing runs were performed on the Illumina NextSeq platform. Abundant microbial genes were identified and biological pathways associated with these genes were determined using the Kyoto Encyclopedia of Genes and Genomes.

Results: Between HFD and ND mice, we identified 29 significantly altered microbial metabolic pathways based on the Kruskal-Wallis Rank Sum Test (p-value < 0.05). The most significantly upregulated pathway in HFD mice was the biosynthesis of heparan sulfate (implicated in AMD pathogenesis due to its interaction with complement factor H). In contrast, significantly down-regulated pathways in HFD mice include N-glycan biosynthesis (important for intestinal barrier function), primary/secondary bile acid (BA) biosynthesis (BAs inhibit AMD features in vitro), polyphenol biosynthesis (protects against oxidative stress), glycerophospholipid metabolism (similarly altered in AMD patients), and sucrose/galactose metabolism (key for maintaining retinal homeostasis). Compared to HFD mice, ND mice exhibited significantly decreased degradation of terpenoids (eg, geraniol), a group of compounds with geroprotective properties.

Conclusions: HFD intake significantly dysregulates microbial metabolic pathways involving the metabolism of lipids, carbohydrates, amino acids, glycans, and terpenoids. Therefore, a HFD not only modulates gut microbiome composition, but is also associated with alterations in key microbial metabolic pathways that overlap with AMD pathogenesis.

TITLE: How the use of dim red-light pre-recording affects ERG responses of mice with long-wavelength shifted opsin

SESSION TITLE: Electroretinography: basic mechanisms and disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Joachimsthaler, N. Stallwitz, J.J. Kremers, Ophthalmology, University Hospital Erlangen, Erlangen, Bavaria, GERMANY|A. Joachimsthaler, N. Stallwitz, Animal Physiology, Friedrich-Alexander-Universitat Erlangen-Nurnberg, Erlangen, Bayern, GERMANY|

Commercial Relationships Disclosure: Anneka Joachimsthaler: Commercial Relationship: Code N (No Commercial Relationship) | Nina Stallwitz: Commercial Relationship: Code N (No Commercial Relationship) | Jan Kremers: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We investigated, how the ERGs of (LIAIS) mice, expressing a human L*-opsin instead of the native M-opsin, are affected by the use of visible red light, that may lead to photoisomerizations in the L*-opsin, during the preparations prior to ERG recordings.

Methods: Recordings were done on LIAIS mice, using wildtype (WT) littermates as control. Mice were dark adapted overnight and further handling was done either under dim red light or IR light with IR sensitive goggles performed in two separate sessions that were 2 weeks apart.

Anesthetized animals were placed on a heated platform in the Ganzfeld bowl and were dark adapted for 10 min before scotopic flash ERGs were recorded. Flash strengths increased from -3.7 to 0.8 log cd.s/m^2, with stimulus frequencies decreasing from 1 to 0.5 Hz and interstimulus intervals increasing from 10 to 120 sec.

For the following photopic flash ERG recordings the animals were adapted for 2 min to a 1.4 log cd/m^2 white background, before flashes with flash strengths increasing from -0.2 to 1.2 log cd.s/m^2 were presented upon the background.

All flash ERG responses were analyzed with regard to amplitudes and latencies of the prominent wave components.

Results: Preparation was substantially longer under IR light.

Responses to scotopic flash ERGs using red light were ≈14% smaller in LIAIS compared to WT mice. For both genotypes the use of IR light resulted in larger amplitudes of the scotopic a- and b-wave. This effect was stronger for LIAIS mice, where amplitudes increased by 22% (a-wave) and 28% (b-wave). In WT mice, a- and b-wave increased by 16% and 13%, respectively. OPs and implicit times did not depend on the light source used for preparation.

For the photopic flash ERGs, after the use of red light pre-recording the WT b-wave was 17% larger and 11% faster compared to LIAIS mice. The effect of IR light usage pre-recording was less pronounced. B-wave amplitudes were about 13% and 17% larger after IR preparation for WT and LIAIS mice, respectively.

Conclusions: The use of red light for mouse handling pre-recording has a slightly stronger effect on the red sensitive LIAIS mice compared to WT mice. However, the use of IR light resulted in larger ERG responses for both genotypes. Even though the use of IR light seems to ensure a more dark adapted state for the animals, handling is quite challenging and prolonged the total time of the experiment substantially.

ABSTRACT BODY:

Purpose: Diabetic Retinopathy (DR), a retinal microvascular disease, is the major cause of preventable vision loss globally and is expected to affect ~191 million individuals by 2030. A major challenge in treating DR is its 'Clinical Silence'; wherein, the disease progression is not accompanied with easily observable symptoms. Currently, diabetic patients are annually examined using fundoscopy for onset or progression of vision threatening DR. However, fundoscopy, the gold standard for DR screening is time-consuming, expensive, uncomfortable, requires expertise and instrumentation. To overcome these limitations and to prevent DR-associated vision loss, we focused on identifying DR-associated biomarkers in urine, which would help in developing an alternative, rapid, and point-of-care (POC) screening procedure to predict the onset and progression of DR.

Methods: A total of 96 diabetic patients were recruited in a clinical study approved by the University of Missouri (MU) IRB committee. Four biomarkers that are related to onset of DR, 8-hydroxydeoxyguanosine (8-OHdG), Angiopoeitin-2, Membrane attack complex (C5b-9), Placental growth factor (PLGF), were chosen for evaluation. Urine samples were collected and the levels of four biomarkers were determined for various stages of DR as identified from the Fundus examination.

Results: The urinary biomarker levels were compared between mild and moderate stages of DR as this transition represents the clinically significant inflection point of disease. The average levels of three biomarkers (8-OHdG, Angiopoietin, and C5b-9) were found to be increased during mild to moderate transition, while for the PLGF the levels decreased. Classification into Low-risk and High-risk DR groups based on severity of the disease shows significantly higher levels of C5b-9 in high-risk groups compared to low-risk.

Conclusions: The change in the levels of the biomarker from mild to moderate stage of DR suggests their role as potential biomarkers for identifying progression of DR. Further analysis based on different demographic factors can provide crucial cues on onset of DR. However, it is important to validate the combination of biomarkers with larger sample set and subsequently integrate them into a single panel for a sensitive and reliable screening of DR. The design of POC lateral flow devices for the biomarkers is in progress.

Commercial Relationships Disclosure: Salil Lachke: Commercial Relationship: Code N (No Commercial Relationship) | Shaili Patel: Commercial Relationship: Code N (No Commercial Relationship) | Deepti Anand: Commercial Relationship: Code N (No Commercial Relationship) | Hozumi Motohashi: Commercial Relationship: Code N (No Commercial Relationship) | Fumiki Katsuoka: Commercial Relationship: Code N (No Commercial Relationship) | Masayuki Yamamoto: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The small Maf transcription factors (TFs) Mafg and Mafk belong to the basic leucine-zipper (bZIP) protein family. Previous data showed that Mafg$^{-/-}$:Mafk$^{+/-}$ compound knockout (KO) mice develop cataract from age 4-month onward. Interestingly, Mafg$^{-/-}$:Mafk$^{-/-}$ double KO mice exhibit lens defects significantly early, prior to birth. However, the role of Mafg and Mafk in embryonic lens development has not been examined. Therefore, we sought to characterize lens defects in embryonic stages in Mafg$^{-/-}$:Mafk$^{-/-}$ double KO mice.

Methods: Appropriate crosses were set-up to generate Mafg$^{-/-}$:Mafk$^{-/-}$ mice and immunostaining and fluorescence microscopy was used for characterization of lens markers. High-throughput RNA-sequencing (RNA-seq) was performed on embryonic day (E) 16.5 Mafg$^{-/-}$:Mafk$^{-/-}$ and control lenses in biological triplicates. Differentially expressed genes (DEGs) in E16.5 Mafg$^{-/-}$:Mafk$^{-/-}$ lenses were validated using RT-qPCR or immunostaining.

Results: At E16.5, the anterior epithelium of the lens (AEL) in Mafg$^{-/-}$:Mafk$^{-/-}$ animals appears abnormally multilayered. Further, Mafg$^{-/-}$:Mafk$^{-/-}$ lenses exhibit abnormal abundance of F-actin near the “fulcrum” region. To gain insights into the molecular basis of these defects, RNA-seq of Mafg$^{-/-}$:Mafk$^{-/-}$ E16.5 lenses was performed. Over 200 DEGs were identified in Mafg$^{-/-}$:Mafk$^{-/-}$ lenses. These DEGs were further prioritized based on iSyTE analysis, gene ontology (GO) analysis and relevance to lens biology. Among the prioritized candidates, Epha5 (Eph receptor A 5) is found to be significantly reduced in Mafg$^{-/-}$:Mafk$^{-/-}$ lenses but not in control or Mafg$^{-/-}$:Mafk$^{+/-}$ lenses. Because deletion of ephrin-A5 (Efna5), an established ligand of the Epha5 receptor, is shown to cause lens epithelial cell adhesion defects, it is possible that Epha5 reduction contributes to the multilayered AEL defect in Mafg$^{-/-}$:Mafk$^{-/-}$ lenses. Further, other candidates with functional relevance to the cytoskeleton, cell cycle and extracellular matrix were also among the DEGs in Mafg$^{-/-}$:Mafk$^{-/-}$ lenses and may contribute to the lens defects.

Conclusions: These data demonstrate that Mafg and Mafk are necessary for proper development of the lens during embryogenesis. Further, these data uncover new downstream regulatory targets of Mafg and Mafk in the lens. Because these TFs are expressed beyond the lens, these new regulatory relationships may inform on small Maf-based control in non-lens tissues.

ABSTRACT BODY:

Purpose: Inherited retinal disease is a major cause of blindness worldwide. The most common disease-causing mutation in patients with RHO-associated retinitis pigmentosa (RP) is a dominant gain-of-function missense variant at amino acid residue 23 (Pro23His). Treatment for this disease and other dominantly inherited retinal dystrophies will require knockdown or ablation of mutant allele expression. To that end the purpose of this study was to develop a CRISPR-Cas9-mediated transcriptional repression strategy capable of suppressing RHO expression.

Methods: We created CRISPR-Cas9 transcriptional knockdown reagents using catalytically inactive S. aureus Cas9 (dCas9) fused to the Krüppel associated box (KRAB) transcriptional repressor domain and evaluated four guides targeted to transcriptional regulatory elements in the promoter region of RHO. Using a reporter construct carrying GFP cloned downstream of the RHO promoter fragment (nucleotides -1403 to +73), we assayed GFP knockdown in cells treated with our RHO promoter-targeted CRISPR-dCas9 reagents. Following functional confirmation, reagents were packaged into AAV5 vectors and delivered to human retinal explants (N=3) and Pro23His mutant retinal degenerative swine (N=4). RHO knockdown was demonstrated via Western blot analysis and immunocytochemistry.

Results: Quantitative RT-PCR analysis of cells treated with CRISPR-dCas9 and reporter plasmids demonstrated ~74%-84% reduction in GFP expression when compared to control cells treated with reporter plasmid only. The guide with the greatest knockdown in this assay (sag94) was cloned into AAV5 cassette plasmids along with dCas9-KRAB and used in downstream ex vivo and in vivo experiments. Western blot analysis demonstrated significant RHO knockdown (50%) in human retinal explants treated with AAV5-RHOpCRISPRi vector compared to untreated controls. When we extended these studies into the Pro23His rhodopsin mutant swine model, we observed a 20% knockdown of rhodopsin in CRISPRi-treated retinae compared with untreated contralateral control retinae at two-weeks post injection.

Conclusions: We have generated a dCas9-KRAB gene repression system suitable for suppressing RHO expression in vivo. This work may provide a paradigm from which to develop CRISPR-dCas9 therapies to treat dominantly inherited retinal dystrophies.

ABSTRACT BODY:

Purpose: The purpose of this study was to evaluate thickness of retinal layers in Leber hereditary optic neuropathy(LHON) compared to non-mitochondrial optic neuropathies in atrophic stage with the aim to see if in LHON any specific patterns can be found.

Methods: 14 patients(24 eyes),10 males/4 females,mean age 37.5 years, with confirmed LHON (LHON group) were compared to 13 patients(23 eyes)with optic neuropathy, mean age 46 years, 7 males/6 females, with LHON-negative genetic testing(mtDNA+WES) and without identified aetiology of the bilateral optic atrophy (nonLHON group). Seven eyes were excluded due to confounding factors. Peripapillary RNFL (pRNFL) measurement and segmentation analysis of macular region retinal layers was performed using the Heidelberg Engineering Spectralis SD-OCT. Published normal segmentation data were used for controls.

Results: In LHON group RNFL, GCL and IPL layers were thinner in all ETDRS fields compared to nonLHON group, except for the central circle where LHON group had significantly better preservation of these layers (p=0.012,p=0.006 and p=0.011). The LHON group RNFL was significantly thinner in the pericentral middle ring (p=0.005), whilst IPL was significantly thinner in both middle and outer ring (p=0.019 and p=0.04). LHON group had thicker INL even compared to controls in the central circle (p=0.008) and the outer ring (p= 0.024), whilst the INL layer in nonLHON group was not significantly thicker than in controls. The LHON group also had thicker INL in the central circle (p=0.004) compared to nonLHON group. The ratio between the middle ETDRS ring and the central circle for RNFL (0.83–2.62), GCL (0.76-2.88) and INL (0.84-3.16) thicknesses were lower in LHON group compared to non LHON group (1.45-3.46, 1.72-3.57 and 1.14–3.30). Interestingly, in 3 LHON patients with VA improvement, the ratios were similar to results of nonLHON group. This may represent a new LHON biomarker. The two groups also significantly differed in temporal (p=0.045) and temporal superior region (p=0.001) pRNFL thickness.

Conclusions: The retinal ganglion cell complex thickness (RNFL-GCL-IPL) is relatively preserved in central ETDRS circle in LHON compared to non-mitochondrial optic nerve atrophies. LHON patients also showed thickening of INL layer compared to healthy controls. Our findings might represent novel biomarkers and the structural basis for possible recovery in some LHON patients.

ABSTRACT BODY:

Purpose: To investigate possible changes in peripapillary retinal nerve fibre layer (RNFL) after successful surgery for rhegmatogenous retinal detachment (RRD).

Methods: Forty eyes, which underwent surgery for primary RRD, were included in the study. Successful surgery was performed either by pars plana vitrectomy, retinopexy and SF6 gas tamponade or pneumatic retinopexy. Exclusion criteria were known conditions that can cause changes to the RNFL (e.g. history of glaucoma) or surgery that demanded extensive manipulations. Spectral-domain optical coherence tomography (SD-OCT) was used for the measurement of the peripapillary RNFL. Values calculated by the device in 6 peripapillary sectors were used. Pre-operative measurements and at 1, 3 and 6 months time post-operative were compared. Control eye was the fellow eye at each time point. Demographic and clinical characteristics of patients were also recorded. Eighteen patients have completed the 6 month follow up .

Results: 18 patients have completed the six month follow up and were compared. Initially, the peripapillary RNFL values of the 18 affected (detached) eyes were measured in each follow up (at 1, 3 and 6 month post operatively). Only segments that are corresponding to the detached area were compared. Analysis was performed with one-way Anova and post-huc Tukey test. 17 eyes. Statistically significant changes were noticed in 15 eyes at least in one segment related to the detached area. Out of these, 5 eyes had statistically significant change in all RNFL segments corresponding to the detached area and 10 eyes at least in one segment. Finally, RNFL segments related to the detached retina were compared in each follow up between the two eyes. Two-tailed T-test was used for the analysis. 14 out of 18 eyes showed statistically significant difference in each follow up, 2 had no significant difference and 2 had statistical differences only in some time points.

Conclusions: The peripapillary RNFL values in the segments related to the detached retina seem to be affected over time despite successful retinal detachment repair.

TITLE: A Phase 1/ Phase 2 Study Evaluating the Safety and Efficacy of TTHX1114 on the Regeneration of Corneal Endothelial Cells in Patients with Corneal Endothelial Dystrophy

SESSION TITLE: Corneal Endothelium

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Eveleth, T. Tremblay, Trefoil Therapeutics, Inc, California, UNITED STATES|

Commercial Relationships Disclosure: David Eveleth: Commercial Relationship(s);Code E (Employment):Trefoil Therapeutics, Inc;Code P (Patent):Trefoil Therapeutics, Inc;Code S (non-remunerative):Trefoil Therapeutics, Inc. | Thomas Tremblay: Commercial Relationship(s);Code E (Employment):Trefoil Therapeutics, Inc.

ABSTRACT BODY:

Purpose: To assess the safety and tolerability of TTHX1114.

Methods: Protocol was reviewed/ approved by the IRB and informed consent obtained from all subjects. TTHX1114 was administered as a weekly 10mcL IC injection at doses of 1ng, 3ng, or 10ng or vehicle x 4 weeks. The study included patients with Fuchs endothelial corneal dystrophy (FECD), central endothelial cell (CEC) density < 2000 mm^2 in the study eye; adequate function in the fellow eye; and no other co-morbid conditions that would interfere with the assessment of safety or efficacy. 22 subjects were enrolled/randomized; 17 subjects received TTHX1114 (1ng [7], 3ng [3], or 10ng [7]) and 5 received placebo. Assessments included specular microscopy, slit-lamp examination, BCVA, central corneal thickness (CCT), and IOP.

Results: Of the subjects enrolled, 19/22 (86.4%) were female, 100% were White, with a mean age of 74.5. All subjects received all injections and completed the study. There did not appear to be any meaningful changes in slit-lamp, BCVA, CCT, or IOP. A total of 88 10mcL injections were administered and the mean and median change from pre-injection IOP was -1.9 and -2, respectively; the highest increase was 4mmHg. There were no deaths, SAEs, or DLTs. No AEs were considered related to TTHX1114 by the Investigator, but 4 AEs were considered related to the IC injections procedure; these events were all mild, reported only in 1 subject each, and included conjunctival hemorrhage, eye irritation, foreign body sensation in eye, and photophobia. Analysis of specular microscopy is ongoing.

Conclusions: Standard ocular assessments were sufficient to assess the safety and tolerability of TTHX1114 and an injection volume of 10mcL which appeared to be safe and well-tolerated. The MTD was not exceeded and the RP2D was determined to be 10ng/10mcL delivered by IC injection. The study was originally designed to also obtain a preliminary estimate of efficacy by assessment of CEC densities but this was confounded by the presence of guttae and the inability to reproducibly image the same geographic location at subsequent visits. Further dose/volume escalation should be conducted and exploration of relevant efficacy endpoints which may include eligibility criteria requiring significantly abnormal baseline measurements and/or more reliably imageable patients in additional studies.

ABSTRACT BODY:

Purpose: In 2019, a novel teleretinal imaging program was implemented at the Veteran Affairs (VA) Greater Los Angeles Healthcare System providing remote OCT evaluation with prompt retinal specialist evaluation. The purpose of this study was to determine how the COVID-19 pandemic affected the tele-OCT screening program in its second year of implementation.

Methods: Retrospective chart review study of patients evaluated by a retina specialist through asynchronous tele-OCT evaluation in 2019 and 2020. Electronic medical records were used to obtain patients' demographic and clinical characteristics, tele-OCT consult results, and patient adherence to tele-OCT follow-up plans.

Results: There were 108 tele-OCT consults in 2020 compared to 158 tele-OCT consults in 2019, a 32% decrease. There was no significant difference in overall patient adherence to follow-up between the two years. In 2020, patients who had diagnosed anxiety were less likely to be adherent compared to 2019 (37.5% v. 71.4%, $p=0.023$). In 2020, the retinal diagnosis was less likely to be changed after teleretinal consultation compared to 2019 (12.96% v. 29.1%, $p<0.01$).

Conclusions: The decrease in tele-OCT use reflects the decrease in patients presenting to referring clinics that utilized the consult mechanism during the COVID-19 pandemic. Patient anxiety should be considered when addressing compliance. The teleretinal program is providing an education benefit to referring providers.

ABSTRACT BODY:

Purpose: The retinal pigment epithelium (RPE) is susceptible to regional atrophy in several retinal degenerative diseases, such as age-related macular degeneration (AMD). Variations of RPE phenotype and function with retinal location influence the development of Geographic Atrophy, a late stage of AMD. Understanding the precise location and the nature of RPE phenotypic and molecular differences will be invaluable to study retinal diseases. In this work, we provide a detailed and comprehensive morphometric map of the entire human RPE and show how it changes in AMD.

Methods: RPE/choroid flatmounts were generated from more than 20 human non-AMD and AMD eyes. The entire flatmounts were stained for RPE cell borders and imaged. An open-source software for image analysis, based on machine learning, was developed to quantify RPE morphometry. Spreadsheets with raw data and heatmaps were generated to compare regional RPE differences.

Results: RPE cell area analysis of non-AMD eyes revealed the presence of 5 statistically different subpopulations, which we named as P1 to P5. P1 corresponded to fovea and parafovea (median: 147.2 ± 15.4 μm^2 sd), while P5 corresponded to far-peripheral RPE (median: 331.9 ± 27.2 μm^2 sd). Interestingly, a peripheral ring of smaller RPE cells (P4) was discovered (median: 176.8 ± 18.7 μm^2 sd) that is closer in size to perifoveal RPE cells (median: 177.6 ± 15.7 μm^2 sd). RPE aspect ratio increased gradually with retinal eccentricity, while hexagonality decreased correspondingly. The morphometric differences between RPE subpopulations, seen in non-AMD eyes, decreased in AMD eyes. Each subpopulation had greater variability compared to non-AMD (30-70% higher standard deviation). Analysis of RPE atrophies in AMD eyes and ultra-widefield retinal images of patients with Late-Onset Retinal Degeneration (L-ORD) and Choroideremia (CHM) showed that P1, P4 and P5 were most affected in AMD, while mid-peripheral subpopulation P3 was the most affected in L-ORD and CHM.

Conclusions: Overall, the study provides the first exhaustive morphometric map of the human RPE and a geographic reference of RPE subpopulations for future studies. The analysis of AMD eyes will help to predict disease progression using RPE morphometry progression. Future studies will focus on finding molecular markers for RPE subpopulations to understand the etiology of retinal diseases.

ABSTRACT BODY:

Purpose: Stevens Johnson Syndrome/Toxic Epidermal Necrolysis (SJS/TEN) are mainly drug-induced severe cutaneous adverse reactions with increased morbidity and mortality. It also involves the eyes causing ocular surface disease leading to visual impairment and blindness. The pathogenesis is not completely understood. HLA-E-specific activating receptor CD94/NKG2C is reported to trigger T-cell receptor-independent cytotoxicity in cytotoxic T cells. Several cytokines are known to play a role in the pathogenesis of this condition. The role of IL-6 and NKG2C in causing ocular surface disease and keratinocyte apoptosis is not fully explored. Determination of the expression of IL-6 and NKG2C studied by immunofluorescence microscopy will enable better understanding of their potential roles in the pathogenesis of SJS/TEN. It is hypothesized that IL-6 and NKG2C play a crucial role in the pathogenesis of SJS/TEN and may correlate with the degree of severity of skin detachment and ocular surface disease.

Methods: In order to validate this hypothesis, the specific aim is to determine the expression of IL-6 and NKG2C in the skin of patients with biopsy confirmed SJS/TEN compared to the lichen planus controls by immunohistochemistry and correlation with severity of skin detachment. Under a current, Loyola IRB approved protocol, 12 collected and archived unstained slides of skin and blood plasma samples from patients with biopsy confirmed SJS/TEN will be used for this study. Deconvolution Immunoflourescence (IF) will be performed using IL-6 and NKG2C antibodies using a Delta Vision microscope equipped with a digital camera.

Results: Deconvolution immunofluorescence performed on skin biopsy confirmed SJS/TEN slides showed expression of IL-6 and NKG2C using a DeltaVision microscope.

Conclusions: IL-6 and NKG2C may be involved in the pathogenesis of SJS/TEN. Further studies are warranted to establish their roles in the severity of disease.

ABSTRACT BODY:

Purpose: To present data on long-term (10 years) follow-up of visual acuity results in participants with age-related macular degeneration (AMD) enrolled in the Age-Related Eye Disease Study 2 (AREDS2), a clinical trial of oral supplementation for the treatment of AMD

Methods: Participants (n=4203) 50 to 85 years with bilateral large drusen or unilateral late AMD were enrolled in the AREDS2 study from 82 retinal specialty clinics in the US between 2006–2008 and followed until the conclusion of the clinical trial in 2012. After the end of the trial, an additional 5-year of follow-up was conducted in a subset (2923 participants) via telephone every 6 months until 2018. A subset of the AREDS2 participants (709 participants[1418 eyes]) was also evaluated in a final in-clinic study visit (at 10 years) to collect data on best-corrected visual acuity (VA), AMD status evaluated with color fundus photographs(CFP) and optical coherence tomography that were graded centrally by the reading center (AMD progression assessed with AREDS severity scale for AMD), and treatment. Late AMD was defined as the presence of neovascularization or geographic atrophy on CFP.

Results: The mean (SD) age of the 709 participants at baseline was 70 (7.5) years. The mean (SD) VA of 76.6 (16.8) letters (Snellen equivalent of 20/30) at baseline remained stable in the initial five years but dropped to a mean of 63.1 (24.8) letters (Snellen 20/60) at the 10-year visit (Table 1, Figure 1A). The proportion of eyes with VA≥20/40 dropped from 85% at baseline to 57% over 10 years while those with VA<20/200 increased from 4% to 15% (Table 1, Figure 1B). Late AMD increased from 18% at baseline to 74% at 10 years. Another analysis showed that at year 10, 650 of 1414 eyes (46%) had ≥10 letters loss compared with baseline. Of all the participants with vision loss, 293/650 (45%) had developed late AMD by year 5 that increased to 471(72.7%) over 10 years.

Conclusions: Half of the cohort followed had maintained good VA (20/30 on average) over 10 years. The mean VA dropped by year 10 with 72% progressing to late AMD. Only a small proportion of eyes experienced severe vision loss.

ABSTRACT BODY:

Purpose: To evaluate potential performance improvements from using varying levels of global information in deep learning layer segmentation.

Methods: All models were trained with a dataset of 141,000 annotated OCT B-scans, and trained where full images were compressed into 128x128 patches. First, a lowmag model considered the internal limiting membrane (ILM) segmentation alone. A second model used both the ILM and Brooks Membrane (BM) as segmentation targets (two-line model). This focused the model on global OCT architecture. The third model was trained on ILM to BM region of interest (ROI), which then applied the segmentation to the top of the identified region. These models were evaluated on a high-pathology holdout test set of 451 annotated images, and performance was compared using the average deviation away from manual annotations in pixels.

Results: The single line lowmag model had an average offset of 25.38 pixels, heavily impacted by blank sections where the model was unable to detect any ILM line (Figure 1). The two-line model performed better on average than single line segmentations, with an average offset of 2.18 pixels, potentially due to more robust segmentations in high pathology samples. The two-line model also performed better than the ROI model, which had an average offset of 5.65 pixels. Interestingly, the ROI model was less precise than the two-line model, which suggests that there is something useful about both identifying the specific boundaries in the image relevant to the segmentation goal, as well as information regarding the broader context.

Conclusions: Both global and local information are important for making accurate annotations of biological structures which are impacted by pathology and unusual circumstances. This work examines the effect of different levels of global information on deep learning model segmentation performance.

ABSTRACT BODY:

Purpose: We aim to determine the effects of implementing an artificial intelligence (AI) diabetic retinopathy (DR) screening system on the rate of patient follow-up and time to follow-up in patients of the North Philadelphia community with more-than-mild (MTM) DR.

Methods: A retrospective chart review of patients screened for DR with Eyenuk's (Los Angeles, CA) EyeArt software at three primary care offices between 10/1/2020–12/31/21. Inclusion criteria were diabetics 18 or older who had a DR screening. Photos were taken on a non-mydriatic fundus camera. EyeArt interpretation was based on the International Classification of Diabetic Retinopathy (ICDR) criteria. Results were reported as “referable” for uninterpretable images or MTM DR (ICDR 2-4 +/- evidence of macular edema) or “not referable” (ICDR 0-1 and no evidence of macular edema). Temple ophthalmology office staff reviewed the EyeArt database to schedule follow up appointments for referrable patients. Screening outcomes and time to follow up exams were recorded and compared to a control group that were interpreted by an optometrist without AI between 3/2018 and 3/2020.

Results: 41 patients were screened for DR at 3 clinic sites after implementing AI. 24/41 (58.5%) were referable by EyeArt. 17/41 (41.4%) patients were not referable. Of the referable patients, 3/24 (12.5%) were contacted by office staff, and all 3 completed a follow up exam. The average time to a follow-up exam was 126 +/- 25.7 days after the screening exam. Of 1902 screening exams prior to implementing EyeArt, 688 (35.1%) were referable. 157/688 (22.8%) had an appointment scheduled, and 133/157 (85.7%) showed up to their appointment. The average time from screening to interpretation was 30.5 +/- 43.2 days, and the average time from interpretation to appointment was 158.6 +/- 123.3 days. There was no significant difference between protocols for time to appointment (p=0.40).

Conclusions: We found no difference in time to follow up exam after AI implementation, due to delays at the appointment scheduling step. AI interprets the images immediately, but the follow-up exam is not scheduled until the ophthalmology office staff are notified. To effectively utilize AI, involving PCP office staff in scheduling follow up exams immediately after EyeArt interpretation is crucial.

ABSTRACT BODY:

Purpose: Retinal detachment is a sight-threatening ophthalmic emergency and timely repair is critical to optimize long-term visual outcomes. Sex and race/ethnicity health disparities have been previously identified in many fields but data for retinal detachments is limited. The purpose of this study is to investigate differences in rhegmatogenous retinal detachment (RRD) repair by race, ethnicity, and sex.

Methods: A retrospective study of a nationally representative claims database (Clinformatics^{TM} Data Mart Database [OptumInsight, Eden Prairie, MN]) for patients with an incident RRD between 2003-2019 was performed. Patients with pre-existing ocular conditions, discontinuous coverage, less than a year of coverage prior to the index diagnosis of RRD, and less than 30 days of follow-up after the index diagnosis were excluded. Two diagnoses of RRD were required for the primary outcome model. Models were adjusted for age, year of diagnosis, ocular comorbidities, systemic comorbidities. Primary outcomes were adjusted odds of receiving surgery, time to repair, and type of surgery.

Results: Among 10,339 eligible cases of incident RRD, 44% (n=4536) were women, 72% (n=7450) were White, 11% (n=1111) were Hispanic, and 11% (n=1137) were Black. The primary outcome model had 2755 confirmed RRD cases and 95% (n=2622) of these patients received surgery. Women had 20% reduced odds of receiving an RRD repair after adjustment (odds ratio [OR]: 0.80, 95% CI 0.74-0.87). Asian (OR 0.71, 0.57-0.90), Black (OR 0.83, 0.73-0.95), and Hispanic patients (OR 0.79, 0.69-0.90) also had lower odds of repair. Delays in RRD repair were not observed by sex, but Hispanic patients were more often delayed relative to their White counterparts (16 days, p=0.009).

Conclusions: In a retrospective national claims-analysis, women and racial/ethnic minorities were found to have significantly lower odds of rhegmatogenous retinal detachment repair relative to men and White patients, respectively. Hispanic patients experience delays in care relative to their White counterparts. While the reason for these differences is likely multi-faceted, health disparities and delays in care are known to have devastating implications on patient outcomes and warrant further investigation.

SUBMITTER (NAME ONLY): Annastelle Cohen

TITLE: Developmental and adult estradiol signaling disruption alters expression of estrogenic pathway components in the zebrafish retina

SESSION TITLE: Biochemistry and Molecular Biology of the Retina/RPE

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.L. Cohen, V.P. Connaughton, Biology, American University, Washington, District of Columbia, UNITED STATES|L. Cassidy, Neuroscience, American University, Washington, District of Columbia, UNITED STATES|

Commercial Relationships Disclosure: Annastelle Cohen: Commercial Relationship: Code N (No Commercial Relationship) | Lauren Cassidy: Commercial Relationship: Code N (No Commercial Relationship) | Victoria Connaughton: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We previously reported that developmental manipulation to estradiol (E2) signaling causes long-term visual deficits in adult zebrafish. Here, we hypothesize that developmental exposure to environmentally relevant concentrations of bisphenol-A (BPA), an estrogen mimic, will cause long-term molecular changes in E2 signaling components within retina, including expression of estrogen receptors (ERs) and neural aromatase (cyp19a1b), similar to what has been well-established in the brain.

Methods: Zebrafish larvae and adults were transiently exposed to either low BPA (0.001μM), high BPA (0.1μM), vehicle control (DMSO, 0.003%), or water for 24 hours. Larval fish were returned to control conditions and reared until adulthood; adults were immediately sacrificed after exposure. Total RNA was extracted from adult retina and brain (N=2-3/treatment) and used in quantitative reverse transcription PCR (RT-qPCR) to quantify changes in mRNA expression of E2 transcriptional targets. Relative gene expression was determined with the comparative Ct method ($2^{-\Delta\Delta Ct}$).

Results: Preliminary results show upregulation of cyp19a1b and ERβ mRNA in retina and brain of adults exposed to BPA. Upregulation was concentration dependent in retina whereas low BPA caused the greatest expression in brain tissue, and at a greater overall relative expression than in retina (~300%). Adults developmentally exposed to low BPA, but not high BPA, exhibited upregulation of cyp19a1b (~600%) and ERα (250%) in retina; changes in ERβ expression were not detected in retina at either concentration. Larval exposures did not alter the expression of adult brain ERs or cyp19a1b.

Conclusions: Our results suggest that developmental disruption to E2 signaling through BPA exposure can have long-term molecular effects in retinal tissue. These differences were also observed in adults acutely exposed, suggesting that the effects of BPA both occur rapidly and sustain. The tissue-dependent differences observed suggest that retinal E2 signaling and regulation is unique to mechanisms well-studied in the brain, highlighting the significance of retinal-specific research on estrogenic pathways and the effects of disruption.

ABSTRACT BODY:

Purpose: Approximately 70% of long-duration crewmembers develop signs of optic disc edema (ODE), a finding of spaceflight-associated neuro-ocular syndrome (SANS). The severity of ODE differs across individuals subjected to similar environmental factors on the International Space Station (ISS). Understanding the sources of this variability is of high priority because the incidence and severity of ODE may increase as mission durations are extended, potentially causing irreversible vision loss. We therefore tested the hypothesis that having crowded optic nerve head (ONH) morphology prior to flight confers a predisposition to spaceflight-induced ODE development.

Methods: Radial and circular OCT scans centered on the ONH were collected preflight and on flight day ~150 from both eyes of 31 crewmembers completing missions on the ISS. ODE was quantified as the change in total retinal thickness (TRT) from the annular region extending 250 μm from Bruch's membrane opening (BMO). ONH metrics included minimum rim width (MRW), cup volume, and cup-to-disc ratio. For each radial B-scan (≥24 per scan), the optic cup was defined as the region bounded by the internal limiting membrane and a cup reference line that was 200 μm anterior to a disc reference line connecting the BMO points. Circumpapillary retinal nerve fiber layer (RNFL) thickness and choroid thickness were also measured. Associations between the preflight variables and inflight changes in TRT were assessed using a linear mixed-effects model.

Results: Mild ODE was observed across the cohort during spaceflight, as evidenced by a mean (SE) increase in TRT of 38.3 (6.4) μm from baseline (392.0 (5.8) μm, $P < 0.001$). A greater increase in TRT during spaceflight was associated with shallower preflight optic cup depth (slope = -0.11 ± 0.03, $P < 0.001$) and smaller preflight optic cup volume (slope = -62.8 ± 18.9, $P = 0.002$). TRT changes were not associated with preflight cup-to-disc ratio ($P = 0.31$), MRW ($P = 0.14$), RNFL thickness ($P = 0.81$), or choroid thickness ($P = 0.38$).

Conclusions: Crowded ONH morphology represents a possible risk factor for the development of spaceflight-induced ODE. However, variables outside of the optic cup (MRW, RNFL, choroid thickness) do not have an association with ODE. Crewmembers with small and/or shallow optic cups may benefit from additional ophthalmic monitoring during spaceflight and use of countermeasures against SANS.

ABSTRACT BODY:

Purpose: Current anti-VEGF therapy for wet age-related macular degeneration (wet AMD) is rapidly cleared from the vitreous and requires injections every 1-2 months. OTX-TKI is a novel, hydrogel-based intravitreal implant designed to deliver a tyrosine kinase inhibitor, axitinib, for up to 6-9 months for the treatment of neovascular retinal diseases. Here we characterize the ocular distribution of axitinib from OTX-TKI implant following a single intravitreal injection in non-human primates.

Methods: Cynomolgus monkeys received intravitreal injections of either three 200 µg- (group 1, n=8), one 300 µg- (group 2, n=8) or one 600 µg- (group 3, n=8) OTX-TKI implant(s) bilaterally on Day 0. Experimental doses were selected to study the effects of dose and number of implants on distribution of axitinib. Ocular exams with slit lamp, intraocular pressure (IOP), confocal scanning laser ophthalmoscopy (cSLO) images and plasma samples were collected throughout the 9-month study. Subsets of eyes were enucleated at 3, 6 and 9 months to collect retina, choroid/retinal pigment epithelium (RPE), vitreous and aqueous humor tissue samples and analyzed for axitinib levels.

Results: OTX-TKI was well tolerated in all groups. No significant inflammatory response to OTX-TKI or clinically significant changes in IOP were observed. High axitinib levels in retina tissue were measured at Month 3 (>900 IC_{50}) and Month 6 (>16,000 IC_{50}) for all groups (Figure 1). Drug distribution in retina and choroid/RPE was higher in group 1 at Month 3, but comparable across all groups at Month 6. By Month 6, groups 1 and 2 implants released ~50% and group 3 implants released 35% of the dose in the vitreous. Daily release rates in group 1 implants were higher than groups 2 and 3 likely due to the larger surface area with the three implants used in group 1 only. Implant degradation was observed around Month 6 and released axitinib particles were visible in the vitreous at Month 9 (Figure 2). Plasma samples at Month 3 from all groups were below the level of quantification of axitinib (0.1 ng/mL) indicating minimal systemic exposure.

Conclusions: OTX-TKI delivered high levels of axitinib to retinal tissue and was generally well tolerated in non-human primates with no signs of significant inflammation. OTX-TKI is currently being investigated in humans for the treatment of wet AMD in a U.S.-based Phase 1b clinical trial.

ABSTRACT BODY:

Purpose: The optic nerve head (ONH) is the initial site of optic nerve damage. ONH-derived astrocytes and lamina cribrosa (LC) cells synthesize proteins to support the ONH. However, ONH cells are adversely affected in glaucoma and cause detrimental changes to the ONH. Previous studies have shown increased expression of the profibrotic cytokine transforming growth factor-beta 2 (TGFβ2) in the glaucomatous ONH. In glaucoma conditions, TGFβ2 promotes dysregulated signaling through the canonical and non-canonical pathways. The purpose of this study was to determine the differential gene expression profile between control and TGFβ2 treated ONH astrocytes and LC cells using RNA sequencing (RNA-seq).

Methods: Primary human normal ONH astrocytes (n=3 strains) and LC cells (n=3 strains) were derived from human donor eyes. ONH cells were grown to confluency and treated with or without TGFβ2 (5ng/ml) for 24 hours. Total RNA was extracted from ONH cells and RNA sequence libraries were prepared and sequenced on an Illumina Miseq2000. RNA seq analysis was performed to identify significant differentially expressed genes and was tested for pathway enrichment analysis using WEB-based Gene SeT anaLysis Toolkit.

Results: RNA-seq and pathway analysis identified several significant enriched gene sets (FDR<0.05) for ONH astrocytes and LC cells. These differential expressed genes were involved in the extracellular matrix and ECM structural constituents such as disintegrin and metalloprotease family members, collagens, and periostin. Other gene sets included metabolism and steroid hormone biosynthesis such as alcohol dehydrogenase, aldehyde dehydrogenase, and cytochrome P450.

Conclusions: TGFβ2 modulates the expression of several genes in cultured human ONH astrocytes and LC cells that may be responsible for pathogenic remodeling of the optic nerve head in glaucoma. New therapeutic targets or small molecule inhibitors may be identified that stop or slow the pathogenesis of glaucoma.

TITLE: Selectively disrupting connexin-36 in rod photoreceptor cells alters light adaptation in photopic ERG amplitude

SESSION TITLE: Electroretinography: basic mechanisms and disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.A. Dixon, S. Modgil, S. Zhang, P. Iuvone, Ophthalmology, Vision Science, Emory University, Atlanta, Georgia, UNITED STATES|C. Ribelayga, Vision Sciences, University of Houston System, Houston, Texas, UNITED STATES|S. Zhang, Beijing Tongren Eye Center, Beijing Tongren Hospital, Capital Medical University, Beijing, CHINA|

Michael Iuvone: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: When presented with a rod saturating background light, photopic ERG flash response amplitudes gradually increase as a function of time. This light-adapted response is disrupted when connexin-36 (Cx36) is knocked out in cone photoreceptors with b-wave amplitudes at a maximal level as soon as the background light is applied (Zhang et al., IOVS 2020;61(6)24). It is unknown if this response is due to eliminating cone-cone gap junctions or rod-cone gap junctions. To answer this question, we investigated the response to rod-specific disruption of Gjd2, the gene that encodes Cx36.

Methods: Mice of either sex aged 90 to 120 days were entrained to a 12h light/12h dark cycle. Three genotypes of mice were studied: Rho-iCre75; $Gjd2^{fl/fl}$ (rod-Cx36KO); $Gjd2^{fl/fl}$ (Cre-negative control); Rho-iCre75 mice with no floxed allele. Scotopic and photopic ERGs were recorded as described in Zhang et al. (2020) at mid-subjective night following dark adaptation. Optomotor responses were recorded under photopic conditions to assess visual acuity (spatial frequency threshold) and contrast sensitivity.

Results: There were no significant differences in scotopic ERG a-wave or b-wave amplitudes between rod-Cx36KO mice and controls (Rho-iCre and $Gjd2^{fl/fl}$ mice). The photopic b-wave amplitude of rod-Cx36KO mice was significantly higher than that of both control groups at all light-adaptation times ($p<0.01$). In contrast to the gradual increase in photopic b-wave amplitude of the control groups as a function of light-adaptation time, in the rod-Cx36KO mice, there was an immediate and constant increase in amplitude with little or no change over time. There was no significant difference in contrast sensitivity nor visual acuity between the groups ($p=0.06$ and $p=0.83$, respectively).

Conclusions: Our results show that mice with rod specific disruption of Cx36 appeared to enter a fully light adapted state immediately after the introduction of background light, which phenocopies the results observed in cone-specific Cx36KO mice. Thus, rod-cone gap junctions, rather than cone-cone gap junctions, regulate the photopic ERG light-adaptive response.

TITLE: Can SLT safely delay surgery in presurgical primary open angle glaucoma?

SESSION TITLE: IOP and laser therapy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Johal, H. Hamze, S. Sharma, A. Mohite, Ophthalmology, New Cross Hospital, Wolverhampton, Wolverhampton, UNITED KINGDOM|

Commercial Relationships Disclosure: Manpreet Johal: Commercial Relationship: Code N (No Commercial Relationship) | Hisham Hamze: Commercial Relationship: Code N (No Commercial Relationship) | Shivam Sharma: Commercial Relationship: Code N (No Commercial Relationship) | Abhijit Mohite: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Selective laser trabeculoplasty (SLT) has been widely used as both a primary and adjunct treatment in glaucoma. Glaucoma surgery was significantly affected during the Covid-19 pandemic due to reduced theatre and clinic capacity. We looked at SLT as a temporary alternative to safely delay surgical intervention in presurgical primary open angle glaucoma (POAG).

Methods: This is a retrospective study that included 104 patients who had a diagnosis of POAG and received SLT treatment, with at least 1 year follow-up. Primary outcomes included: reduction in intraocular pressure (IOP), and number of glaucoma medications (NGM). The endpoint was defined as time to be listed for glaucoma surgery. All eyes that had progressive or advanced visual fields and were on 2 or more medications were included. Eyes with previous glaucoma filtration surgery or argon laser trabeculoplasty, diagnosed with normal tension glaucoma or that had significant angle closure disease (peripheral anterior synechiae >180) were excluded.

Results: The mean patient age was 73.4 ± years. At baseline, the mean IOP and NGM were 20.5 ± 4.9 and 2.8 ± 0.9 mmHg, respectively. At 12 months, the mean IOP was 16.5 ± 3.3 mmHg and the NGM was 2.7 ± 1.0. The IOP reduction was 3.7 ± 5.8 mmHg (14.5%, $p<0.01$) at 12 months follow-up, 3.4 ± 4.7 mmHg (15.5%, $p<0.01$) at 24 months follow-up, 3.7 ± 5.2mmHg (15.2%, $p<0.01$) at 36 months follow-up and 2.5 ± 5.9 mmHg (10.1%, $p=0.04$) at 48 months follow-up. No surgical intervention was needed in 96% of eyes within the first year of SLT. There was no significant difference in the NGM pre- and post- SLT.

Conclusions: With the current pandemic limiting the surgical capacities of eye hospitals, SLT can safely delay the need for glaucoma surgery for at least 1 year by reducing the IOP. This is particularly apparent in elderly patients or those poorly compliant to medical therapy. In addition, this could increase ophthalmology clinic capacity by reducing the number of post-operative follow ups.

TITLE: Effect of the ATP-sensitive potassium channel opener diazoxide on retinal vessel diameter of C57BL/6J mice

SESSION TITLE: Blood flow and ischemia

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: U. Roy Chowdhury, M.P. Fautsch, Ophthalmology, Mayo Foundation for Medical Education and Research, Rochester, Minnesota, UNITED STATES|

Commercial Relationships Disclosure: Uttio Roy Chowdhury: Commercial Relationship: Code N (No Commercial Relationship) | Michael Fautsch: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: ATP-sensitive potassium (K_{ATP}) channel openers (e.g., diazoxide) are known to increase blood flow in various non-ocular organ systems through vasodilation. K_{ATP} channel openers can also lower IOP, presumably by increasing aqueous humor outflow through the episcleral venous system. To determine if diazoxide could influence the retina vasculature, we evaluated retinal vessel diameter (RVD) in vivo.

Methods: RVD was measured by fluorescein angiography. Fundus images of retina from C57BL/6J mice treated intravitreally (single treatment, n=5) or topically once daily for 7 consecutive days (n=5) with diazoxide (5 mM) or vehicle, were captured by Phoenix Micron IV OCT. Predetermined retinal vessels were each measured at three separate locations in all retinas and averaged to obtain mean vessel diameter per retina. Imaging was performed in anesthetized mice at 15 min post treatment for intravitreal group and at 1 h and 23 h after the last topical treatment (day 7). Post treatment RVD was measured at 7 days after termination of diazoxide treatment in the topically-applied group.

Results: RVD increased by 30.0 ± 7.1% (n=5, $p<0.001$) from baseline, within 15 minutes of intravitreal diazoxide injection, while injection with vehicle caused no significant change (-4.1 ± 4.0%, n=5, p=0.07). When diazoxide was applied topically once daily for 7 days, RVD at 1 h after day 7 treatment was 20.0 ± 10.7% (n=5, p=0.007) greater than baseline values, with no change observed in vehicle treated eyes (-0.4 ± 3.2%, n=5, p=0.84). At 23 h after the Day 7 dose, RVD was 19.0 ± 5.2% (n=5, $p<0.001$) greater than baseline values with no significant change in the vehicle treated eyes (1.7 ± 1.6 %, n=5, p=0.07). Seven days following the last topical treatment, RVD returned to baseline levels (1.7 ± 3.5%, n=2, p=0.66).

Conclusions: Treatment with diazoxide causes dilation of retinal vessels and may influence blood flow to this region. This may have beneficial effects for some retinal pathologies.

ABSTRACT BODY:

Purpose: To confirm the usefulness of a novel orphan pediatric retinal disease panel for detecting variants in the NDP (Norrie Disease Protein) gene. Familial Exudative Vitreo Retinopathy (FEVR) and Norrie Disease (ND) can be caused by variants of the NDP gene (Norrin). A cohort of 76 subjects diagnosed with FEVR/ND and close relatives were sequenced using a custom Ampliseq panel that includes NDP and seven other genes linked to FEVR/ND and Retinoschisis (CTNNB1, TSPAN12, KIF11, FZD4, LRP5, ZNF408, RS1).

Methods: A custom Ampliseq targeted panel (180 amplicons) for 8 genes was designed with Illumina's DesignStudio Sequencing Assay Designer. The targeted panel was distributed into three pools (PCR reactions) per patient sample for complete coverage of 83 exons with 25 bp adjacent intron sequence. Target Genes were: NDP (ChrX), RS1 (Chr10); CTNNB1 (Chr3); TSPAN12 (Chr7); KIF11 (Chr10), FZD4 (Chr11), LRP5 (Chr11), and ZNF408 (Chr11). Ampliseq libraries were quality controlled by capillary electrophoresis and sequenced on the Illumina iSeq-100 platform at a scale of up to 50 samples per run. Variant impacts and allele frequency data were determined from ClinVar and The Genome Aggregation Databases (gnomAD).

Results: A total of 33 protein-altering variants were found in six FEVR/ND-related genes. Of note, 1/33 (3%) of the variants was present in the NDP gene. This patient was heterozygous for the NDP: His42Arg variant, pathogenic for ND. This mutation was found in a patient with a clinical FEVR grade of 4, indicating the diagnosis being ND rather than FEVR. The sequencing data revealed 95.5% of the base reads were > Q30 quality, the percent on-target bases passing filer was 92.2%, and the average sequencing depth coverage was 978.

Conclusions:

The custom Ampliseq targeted-sequencing Orphan Pediatric Retinal Disease panel was developed with the intention to detect genes associated with FEVR/ND and Retinoschisis. The panel's sequencing coverage was of sufficient depth to detect protein-altering variants in the NDP gene, the primary gene for ND.

ABSTRACT BODY:

Purpose: Adeno-associated virus serotype 2 (AAV2) is a promising gene therapy platform for glaucoma and other optic neuropathies. However, pre-existing serum neutralizing antibodies (Nab) may significantly inhibit effective transduction and gene transfer. To investigate the effects of serum Nab on viral transduction in a large animal model, we delivered AAV2 to retinal ganglion cells (RGCs) in the porcine visual system at two timepoints and assessed transduction while monitoring serum Nab over time.

Methods: Yucatan minipigs (5.5-6 months old) were pre-screened for serum Nab titers, and animals with a positive titer were excluded. On day 0, AAV2-CMV-eGFP was intravitreally injected into the nasal and temporal aspects of the right eye, while the left eye served as a negative control. On day 14, the right eye was re-injected with AAV2-CAG-TdTomato in a similar fashion. On day 28, eyes were harvested and fixed in 4% PFA. The retinas were dissected, stained by immunofluorescence for RBPMS, flatmounted, imaged by confocal microscopy, and analyzed. To determine Nab titers, pig serum was collected on days 0, 3, 7, 14, and 28. Serial dilutions of pig serum were incubated with AAV2-Luciferase and subsequently with human embryonic kidney (HEK293) cells. Luciferase activity was measured and used to establish anti-AAV2 Nab titers.

Results: RGCs were transduced by viral administrations at both timepoints (AAV2-CMV-eGFP, day 0; AAV2-CAG-TdTomato, day 14) as evidenced by colocalization of eGFP and TdTomato with RBPMS immunofluorescence. In the negative control eye, the absence of eGFP and TdTomato expression was confirmed. Transduction efficiency was highest at the temporal and nasal retina near injection sites. Serum anti-AAV2 Nab levels increased over time beginning at day 7.

Conclusions: AAV2 can be successfully readministered over a short interval to porcine RGCs despite systemic production of anti-AAV2 Nab. Nab were produced in response to AAV2 exposure and increased over the study time course.

TITLE: Non-classical center-surround antagonism in the retina controls spatial and temporal filtering in scotopic light

SESSION TITLE: Retinal circuits

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: N. Ingram, F. Rieke, Physiology and Biophysics, University of Washington, Seattle, Washington, UNITED STATES|

Commercial Relationships Disclosure: Norianne Ingram: Commercial Relationship: Code N (No Commercial Relationship) | Fred Rieke: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Center-surround antagonism(CSA) alters retinal ganglion cell(RGC) sampling of spatial inputs in bright light conditions but has appeared to be absent in scotopic light. While we confirm classical CSA in primate retina, we also observed non-classical effects due to surround input in dim light. Here, we investigated the non-classical spatial and temporal filtering properties of RGCs in dim light and probed the potential mechanisms mediating surround-dependent effects.

Methods: Electrophysiological recordings were made from ON parasol RGCs in RPE-attached, flat-mounted macaque retinas. RGCs were stimulated with spatially- and temporally-defined patterns with scotopic to low-photopic light. CSA was probed using spot-annulus stimuli to independently control the stimulation of the center vs surround. Short contrast steps and noise sequences were used to explore the temporal dependence on surround inhibition.

Results: Classic CSA was confirmed in RGC spatial receptive fields in mesopic and photopic conditions and was absent in scotopic conditions. Despite this, the center dimensions continued to narrow as background intensity increased. Pharmacology confirmed that the decreases in center persist without horizontal cell feedback. Subunits were also substantially larger in dim light and narrowed with increasing intensity. The time required for the receptive field to stabilize after the light was increased from 0.1 to 10 R^*/rod/s was ~30s. We found that surround activation shaped the kinetics of RGC responses in dim light. The responses to contrast steps and the noise-derived linear filters reached a peak more quickly when surrounds were illuminated. We simulated the responses to the steps by convolving the appropriate linear filter with the step stimulus. The predicted responses showed most of the surround-dependent differences in the time to peak of the recorded waveforms, but they did not fully explain the transience of the response following step onset.

Conclusions: CSA mechanisms drive temporal and spatial filtering in dim light. Alterations in kinetics are particularly notable in dim light since rod photoreceptor signaling is notoriously slow, providing ample opportunity for significant temporal filtering in downstream circuits. Modulation of inputs in the spatial and temporal domains are likely to determine threshold sensitivity for complex tasks like motion detection in dim light.

ABSTRACT BODY:

Purpose: Recent studies justify the rise of late onset myopia in young people due to unhealthy digital habits (too much near work time, too near face-device distance, too low ambient illumination). University students are an especially vulnerable group due to the high volume of near vision tasks they normally perform in indoor illumination conditions. We performed a study to collect objective digital habits data in a university population and investigate their potential correlation with clinical subjective refraction.

Methods: 70 subjects aged 21±3 years, in their first or second year of university completed a clinical optometric examination, and used their own personal smartphones to install an app that continuously (at 1 Hz) measured their digital habits: face-device distance, ambient light level, daily screen time (measured only while looking at the screen); daily number of times the device was looked at (minimum interval between events of 20”. A statistical inference analysis was performed to know the relation between digital habits and the spherical equivalent of their refraction (SER), axial length (AL), and smartphone reading distance (SRD).

Results: A total of 60M of data points corresponding to 15M seconds, with at least 3600 s of data per subject, were obtained. Average daily screen time was 1.4±1.2h, with a maximum of 6.2 h, while the daily number of times the device was looked at was 74±59. The average intersubject face-device distance was 363±56 mm, while the SRD was significantly, ($p<10^{10}$) smaller, 296±59 mm. Mean+SD illuminance was 311±225 lux. The mean standard deviation of the intrasubject distance was 83 mm and illuminance was 714 lux. Lower SER values (larger myopia) and larger AL values correspond to a nearer face-device distance of lower ambient illumination, but the correlation was very weak ($R^2<0.03$).

Conclusions: Face-device distance and ambient illumination varied among subjects but also within the individual subjects’ data, indicating that a continuous measurement is needed to sample and estimate the real accommodating effort and illuminance. Within the context of the cohort size and study duration it was not possible to predict a strong correlation between SER or AL, with high variability in the digital habits data between subjects. A longitudinal study of several years would be needed to learn the effects of digital habits on myopia.

ABSTRACT BODY:

Purpose: Aging leads to visual deterioration. Little is known about the molecular changes correlated with vision decline. Heterogeneity of retinal layers creates a challenge for isolated assessment. We aimed to identify age-related functional decline in mouse vision and examine aging impact at the molecular level.

Methods: Visual function was tested in 3-month and 18-month old mice using a comprehensive approach: 1.Visual acuity was assessed with Optomotor response (OMR) assay. 2.Rod and cone photoreceptor function was measured with scotopic and photopic electroretinography (ERG). 3.Visual system physiology was tested by performing recordings of Visually Evoked Potentials (VEPs). 4.RGC activity was assessed with recording of pattern ERG (PERG). For molecular analysis, the bulk RNAseq was performed. Gene set enrichment analysis was applied for differential expression comparisons between two groups of RNA-Seq samples.

Results: Optomotor response and ERG responses were significantly decreased in 18 month old animals in both scotopic and photopic conditions in comparison to 3-month old animals (p-value<0.0001). We observed a significant reduction of VEPs amplitudes recorded in the superior colliculus and the primary visual cortex. Interestingly pattern ERG recordings showed no statistical significance between young and old animals. Analysis of molecular changes revealed 1451 genes up-regulated (log2 fold>=1, FDR<0.05) and 2394 genes down-regulated (log2 fold<=-1, FDR<0.05) upon natural aging. Upregulated pathways in aged animals included inflammation, TNFa signaling and apoptosis. Downregulated pathways included DNA repair and fatty acid metabolism pathways.

Conclusions: Aging leads to a reduction in vision in mice. Significant decrease in photoreceptor function measured by ERG is coherent with behavioral measurements (OMR). Visual information processing is affected by aging; however, RGC function is preserved in old mice. The analysis of age-related molecular changes reveals transcriptional pathways impacted in aged retinas. Connecting functional and molecular approaches will lead to a better understanding of age-related diseases and may lead to novel therapies in the future.

ABSTRACT BODY:

Purpose: To train and validate a convolutional neural network (CNN) to segment retinal anatomic layers and drusen in age-related macular degeneration (AMD) on volumetric optical coherence tomography (OCT) and quantify drusen area.

Methods: Study participants with non-exudative AMD were enrolled and underwent 6x6-mm central OCT scans on one eye with a 70-kHz commercial system (RTVue-XR Avanti; Optove, Inc.) A deep CNN takes OCT B-scans as input and outputs retinal layer boundaries (ILM, NFL/GCL, IPL/INL, INL/OPL, OPL/ONL, EZ, and RPE/BM. ILM - Inner limiting membrane; NFL – Nerve fiber layer; GCL – Gangling cell layer; IPL – inner plexiform layer; INL – inner nuclear layer; OPL – outer plexiform layer; ONL – outer nuclear layer; EZ – Ellipsoid Zone; RPE – retinal pigment epithelium; BM – Bruch's Membrane) [Fig. 1B]. In addition, a hybrid CNN [Fig. 1 G, H], which combines 3D and 2D convolutional layers to segment drusen, takes the thickness map, the minimum en face projection, and the volume data of the RPE slab as inputs and outputs the drusen distribution map. Image graders (Y.G., M.G.) manually graded the ground truth for these networks based on the B-scans and en face images. Five-fold cross-validation was used to evaluate our method on the entire dataset.

Results: We included 120 participants: 82 with nonexudative AMD and 38 healthy eyes. On the test sets, the networked achieved average Dice coefficients of 0.92 ±0.05 (mean±standard deviation) and 0.78±0.15 on the retinal layer and drusen segmentation, respectively. Since the network achieves accuracy in both of these tasks it represents an end-to-end approach and eliminates the need for graders to make subjective processing decisions such as manual correction of retinal layer boundaries. The proposed method showed high accuracy, even on small drusen [Fig.2, blue arrow] and did not produce false drusen segmentation in healthy eyes.

Conclusions: A CNN can accurately segment seven retinal layers and quantify drusen in nonexudative AMD eyes on volumetric OCT scans.

ABSTRACT BODY:

Purpose: To evaluate the clinical outcomes of retinal arterial macroaneurysm (RAM) with vitreous hemorrhage (VH).

Methods: Retrospective analysis of eyes with RAM and VH seen between July 2013 and October 2021. Clinical and demographic data were reviewed including best corrected Snellen visual acuity (BCVA), treatment, comorbidities, and anticoagulation use. Treatment options included observation, intravitreal anti-VEGF injections (IVI), and pars plana vitrectomy (PPV). Patients with other retinal vascular pathologies requiring treatment were excluded.

Results: Of 50 eligible eyes analyzed, 33 underwent observation, 5 received IVI, and 12 underwent PPV. The mean number of injections in IVI group was 3.6±2.8 (range, 1-8). In IVI group, 100% were treated with bevacizumab. The incidence of subretinal hemorrhage was 18.2% in observation group, 25.0% in surgery group of which 8.3% had treatment with subretinal TPA, and 60.0% in IVI group. The mean time to intervention was 13±15.3 days for PPV and 38±69.9 days for IVI. There was no significant difference in age, gender, lens status, final BCVA, and duration of follow-up between the three groups (Table 1). All eyes showed a significant improvement in BCVA, but IVI and PPV groups had worse presenting BCVA and greater visual improvements compared to the observation group. There was no correlation between the number of injections and final BCVA (r=0.13, p=0.83). IVI and PPV groups used significantly more anticoagulants than observation group. However, there was no significant difference in final BCVA between patients using anticoagulant agents (0.52±0.53, Snellen 20/68) compared to those who were not (0.55±0.65, Snellen 20/71, p= 0.87).

Conclusions: Patients with RAM and VH are elderly and demonstrated significantly improved BCVA from baseline in all treatment groups and similar final visual outcomes. Improved BCVA was not impacted by the number of injections or anticoagulant use, suggesting that these factors may play a less important role in the treatment of RAM with VH.

ABSTRACT BODY:

Purpose: Inherited retinal degenerations (IRDs) are the primary cause of working age blind registration in Western countries. These rare disease are genetically heterogeneous (>300 known genetic loci) and genetic diagnosis is required for many novel therapies (e.g., gene therapy). First-tier genetic testing of IRDs with panel-based next generation sequencing (pNGS) has a diagnostic yield of ~70-80% leaving the remaining more challenging cases to be resolved by second-tier testing methods.

Methods: Patients on a large hospital-based IRD register in Ireland were clinically and genetically assessed. 84% of this cohort was genetically resolved from 1st tier pNGS (250 genes). Non-resolved cases (n=69) were clinically reassessed with 26% (n=18) being reclassified as non-IRD disease. 34 patients were available for further genetic testing, all providing informed consent. Autosomal recessive cases with 1 candidate variant underwent single gene testing (introns and exons). Cases with inadequate pNGS coverage had repeat pNGS (250 genes) while those with adequate initial panel coverage had an expanded panel (351 genes) or trio whole exome sequencing (WES).

Results: Removing non-IRD cases from consideration and utilizing case-appropriate 2nd-tier genetic testing techniques, we genetically resolved 56% of previously unresolved pedigrees bringing the overall resolve rate to 92% (388/423). Resolution rate by test was pNGS 100% (n=5), single gene test 44% (n=4/9), trio WES 25% (1/4). 4 novel variants were found, 1 each in ABCA4, EYS, FLVCR1, and RPGR . 15.6% of the cohort resolved by 2nd line testing approaches are eligible for current gene therapy clinical trials (RPGR).

Conclusions: Though novel techniques like WGS will supersede current techniques, at present pNGS remains the most cost effective first-tier approach for molecular assessment of diverse IRD populations (€600 for NGS vs mean €1,222 for all other test types per positive result). Second-tier genetic testing should be guided by clinical (i.e., reassessment, multimodal imaging, electrophysiology) and genetic (i.e. single alleles in autosomal recessive disease) indications to achieve a genetic diagnosis in the most cost-effective manner. See Figure 1.

ABSTRACT BODY:

Purpose: To study the visual impairments associated with multiple sclerosis (MS), experimental autoimmune encephalomyelitis (EAE) is a standard animal model induced by immunizing mice with myelin oligodendrocyte glycoprotein peptide (MOG_{35-55}). However, this form of EAE idoes not involve B cells, in contrast to MS. The present study aimed to characterize the visual symptoms in a B cell-dependent EAE to better mimic human MS.

Methods: B cell-dependent EAE was induced with an antigen called bMOG. After the induction of EAE with bMOG in C57BL/6J male mice, changes in visual function were followed by electroretinography and optomotor acuity tests. Motor deficits were monitored in parallel with a standard clinical scoring method. Retinal neuron survival, gliosis, microglia activation, optic nerve demyelination and opsin expression were examined by histological and Western blot analyses. Gene expression changes were determined by RNA sequencing.

Results: bMOG EAE mice showed persistent loss of visual acuity. In contrast, the electroretinogram (ERG) and the motor function spontaneously recovered after deficits culminating in the inflammatory disease phase. Visual acuity loss was associated with retinal inflammation, gliosis and synaptic impairments, as suggested by histological observations and transcriptomic results. Interestingly, chromatic ERG recordings revealed significant alterations in the M-cone pathway.

Conclusions: The visual changes induced by bMOG in mice present similarities to those reported in multiple sclerosis and neuromyelitis optica. Therefore, bMOG EAE offers a new model to test experimental treatments for MS in the visual system.

ABSTRACT BODY:

Purpose: To explore poorly understood mechanisms that maintain IOP within a normal range. The trabecular meshwork (TM) consists of ECM embedded with collagen and elastin fibers and studies have shown that TM stiffness is considerably higher in glaucoma eyes. Emerging data indicates that the TM moves dynamically with transient IOP fluctuations, resulting in dynamic aqueous outflow. Soft biological tissues exhibit time-dependent/viscoelastic behavior under dynamic loading, but little is known about time-dependent TM behavior. We calculated the viscoelastic mechanical properties of the TM in n=2 healthy and n=2 glaucoma eyes obtained within 72 hours postmortem.

Methods: A quadrant of the anterior segment was mounted and submerged in a saline bath inside a pressure chamber to maintain 4 mmHg simulated episcleral venous pressure. A cannula connected to an adjustable saline reservoir was inserted into one end of Schlemm's canal (SC), with the other end open. A series of cross-sectional scans of the TM/SC complex were captured at 30 frames/second at two locations in each eye during pressure oscillation from 0 to 30 mmHg. A segmentation program delineated the TM boundaries in the OCT images to construct a 20-μm-thick volume finite element (FE) mesh of the TM/SC complex. Collagen and elastin fibrils were embedded in the model using our mesh-free penalty-based cable-in-solid algorithm (Fig). A pre-tension in the collagen and elastin fibrils and a pre-stress in the ECM of the TM were induced to mimic ciliary muscle contraction at the relaxed stage. The model was subjected to a normal optimized pressure function from 0 to 30 mmHg from the SC and the other boundaries were subjected to floating boundary conditions. An FE optimization algorithm was used to adjust the ECM/fiber mechanical properties such that TM/SC model and OCT imaging data best matched over time.

Results: Significantly higher short- and long-time ECM shear moduli, and collagen and elastin fibril elastic moduli, were present in the glaucoma eye TM compared to normal controls ($p<0.05$). The external region of the TM in glaucoma eyes (Fig) showed lower stresses versus the internal region.

Conclusions: Mechanical alterations are challenging to monitor clinically. We characterized the alterations in ex vivo healthy and glaucoma eyes. Our findings may contribute to enhanced understanding of glaucoma pathophysiology, diagnosis, and treatment.

ABSTRACT BODY:

Purpose: To evaluate the current practices, knowledge and needs of ophthalmologist at various clinical settings in Turkey regarding inherited eye diseases. Also, we aimed to understand the need for a subspecialty of ophthalmic genetics in a country where the rate of consanguinity and inherited eye diseases is higher.

Methods: A 29-question self-administered survey with branching algorithm was developed through Google forms and the survey link was sent to 2983 ophthalmologists practicing at various clinical settings in Turkey during February to June 2021. The survey assessed participants' occupational characteristics, current practices and preferences, knowledge about available diagnostic and therapeutic options, proposals to improve continuing education and healthcare services related to the inherited eye diseases.

Results: 414 (20.8%) ophthalmologists completed the survey, 236 of which (57%) were specialist, 178 (43%) were academic faculty. Of the respondents, 107 (25.9%) were in private practice, 71 (17.1%) in state hospitals, 129 (31.2%) in training and research hospitals, and 107 (25.8%) in university hospitals. 192 (46.4%) respondents were general ophthalmologists and 222 (53.6%) were subspecialist. Only 43.2 % of ophthalmologists reported presence of medical geneticist in their facility. Majority of the respondents reported being uninformed about genetic diagnostic tests (82.4%), available genetic tests in or near their facility (78.5%), and which genetic diagnostic tests were covered by health insurance system (93%). There was statistically significant difference in responses about management strategies of inherited eye diseases between subgroups with respect to affiliation ($p<0.05$, Table 1). Nearly 90% of ophthalmologists thought that training after residency was inadequate and 94% expressed the need for a subspecialty of ophthalmic genetics.

Conclusions: In the current era of next-generation genetic diagnostic tests and gene therapies, practice patterns and needs of ophthalmologists were revealed for the first time in a setting of higher disease rates due to consanguinity and fewer specialists interested in inherited eye diseases.

TITLE: Determining Patient Preferences at an Academic Ophthalmology Clinic: a Discrete Choice Experiment

SESSION TITLE: Vision care training and education

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Kubsad, A. Chen, Department of Ophthalmology, University of Washington School of Medicine, Seattle, Washington, UNITED STATES|

Commercial Relationships Disclosure: Sanjay Kubsad: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Chen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Eliciting patient perspectives can help inform in the design and improvement of an ophthalmology service to provide care that is respectful of and responsive to individual patient preferences, needs, and values. A discrete choice experiment is a survey technique where scenarios are presented for respondents to make trade-offs between two attributes by weighing the relative importance of each.

Methods: This study evaluated patient preferences at two academic ophthalmology clinics in Seattle, Washington. A discrete choice experiment was used to evaluate the relative importance of the following variables: out-of-pocket costs, expertise, wait times, appointment numbers, face-to-face times, and continuity of care. Forty-three patients were recruited from two ophthalmology clinics. Demographic data was collected. Patients were asked to rank the importance of each variable for their care. Additionally, eight choice-tasks were presented in random order and forced-choice preferences were elicited. The survey was translated into Spanish by the Harborview Interpreter Services, and telephonic or in-person interpreters were used when necessary. Ranked data was visualized. Choice data were analyzed using a binomial sign test.

Results: The relative importance of one attribute to another was measured first via a self-rank of attributes and second a discrete-choice questionnaire. Patients showed a wide variety of preferences across the different attributes. A self-ranking of attributes revealed high preferences for improved continuity of care, increased physician experience and increased face to face time. Discrete choice testing revealed that patients strongly preferred continuity of care ($P<0.05$). Face to face time was also the least preferred option when in conflict with other attributes ($P<0.05$).

Conclusions: Self-ranking and discrete-choice questionnaire matched in their evaluation of patient preferences for most attributes in terms of relative importance. In the latter, continuity of care was the most important attribute. Patients over-estimated the importance of face-to-face time with the provider when compared with a discrete-choice questionnaire evaluation. One limitation of this study was the small sample size. Future work with a larger study population could provide additional insight into attributes important for patient-centered care and help guide improvements to how care is delivered.

TITLE: The Oculoplastic Selfie – is age a barrier to success?

SESSION TITLE: Public Health II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Guevara, H. Kandola, S. Kang, Adnexal, Moorfields Eye Hospital NHS Foundation Trust, London, London, UNITED KINGDOM|

Commercial Relationships Disclosure: Gabriella Guevara: Commercial Relationship: Code N (No Commercial Relationship) | Hardeep Kandola: Commercial Relationship: Code N (No Commercial Relationship) | Swan Kang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess if patients of all ages were able to submit self-generated photographs of presumed benign eyelid pathology. Still photographs supplement synchronous video consultations in the virtual oculoplastic clinic by providing superior resolution images to allow enhanced assessment of small eyelid lesions.

Methods: New patients referred with benign eyelid lesions were asked to submit self-captured photographs to a designated email inbox prior to a video consultation. Photographs for 300 consecutive patients between 29th April and 6th May 2021 were reviewed by two independent observers (GG and HK).

Each patient's submitted photographs were independently graded as either inadequate, adequate or excellent based on a previously agreed standard. Furthermore, observers also noted whether the images were adequately focussed and well lit.

Results: 300 patients submitted 895 photographs to the shared inbox in the time period. 57.3% (172) of participants were female and patient mean age was 42.5 years old (SD=16.37) ranging from 16 to 90. Mean number of photos submitted per patient was 2.98 (SD = 1.84) ranging from 1 to 15 images. 84.5% of photographs were graded as excellent (40.5%) or adequate (44.0%). There was no statistical difference in overall quality in different age groups (Chi Square test p-value = 0.79). There was also no statistically significant difference in ability to submit adequately focussed (Chi Square test p-value = 1.02) or well lit patients (Chi Square test p-value =0.78) among patients in different age groups. There was a weak correlation between age and number of photos submitted with younger patients more likely to submit a higher number (Pearson correlation -0.12 p = 0.03)

Conclusions: Age alone is not a barrier to successful patient generated photography of benign eyelid lesions. Quality improvement work is in progress to further improve image quality through patient education.

ABSTRACT BODY:

Purpose: We hypothesized that high cholesterol levels leading to the formation of cholesterol crystals in the diabetic retina contribute to DR pathology and vision loss. Alpha-cyclodextrin, a cyclic oligosaccharide lowers cholesterol levels and improves atherosclerotic lesions. In this study, we investigated the effect of alpha-cyclodextrin on cholesterol crystals-induced retinal damage in DR.

Methods: Four-month-old db/db mice were given either oral alpha-cyclodextrin incorporated in their diet (21g/kg body weight) or a control diet. Mice were euthanized after 4 months of treatment. Measurement of Electroretinograms (ERG) and Optomotor kinetic (OKN) responses were undertaken to determine the retinal neural function and visual response respectively before euthanization. Eyes were collected for Scanning Electron Microscopy (SEM) and Immunohistochemistry for macroglia reactivity using Glial fibrillary acidic protein (GFAP).

Results: We observed the removal of cholesterol crystals from the retinas of diabetic mice with oral alpha-cyclodextrin treatment. GFAP reactivity was significantly reduced in the retinal macroglia cells of diabetic mice with oral alpha-cyclodextrin treatment (677.70 ± 204.51 vs 888.65 ± 218.29, $p<0.05$) compared to that of standard chow-fed diabetic mice. The a-wave in the ERG photopic response in alpha-cyclodextrin treated db/db mice was significantly improved compared to db/db mice (133.81 ± 20.58 vs 73.51 ± 36.6, $p<0.05$), and OKN responses were also improved in alpha-cyclodextrin treated db/db mice (0.41 ± 0.02 vs 0.37 ± 0.03, $p<0.05$) compared to the control diet treated db/db mice.

Conclusions: We demonstrate that cholesterol crystal-induced retinal pathology occurs in diabetes and contributes to DR which is improved by the use of oral alpha-cyclodextrin. We show that in addition to the reduction in retinal inflammation, treatment can preserve retinal neural cells, and subsequently retinal visual function and response can be restored using this therapy.

ABSTRACT BODY:

Purpose: Children with the cancer predisposition syndrome Neurofibromatosis type 1 (NF1) are prone to the development of optic pathway gliomas, where nearly 50% of affected individuals will exhibit vision deficits. These visual impairments are caused by axonal injury to, and potentially the eventual death of, retinal ganglion cells (RGCs), yet little is known how the NF1 gene/protein product, neurofibromin, contributes to RGC biology. This study was designed to investigate the effects that different NF1 mutations have on human RGC differentiation and survival.

Methods: Human iPSCs carrying various heterozygous (het) and homozygous (hom) NF1 mutations, and autologous control cells, were modified to contain a previously described BRN3B/tdTomato/Thy1.2 knock-in reporter/purification tag. NF1 wild-type (control) and mutant cells were then differentiated into 2D hRGC cultures and 3D retinal organoids using established protocols. Gene expression analysis was performed by qPCR and bulk RNAseq at time points throughout differentiation. Additionally, the differentiated hRGCs generated from the various NF1 mutant and control lines were purified and the effects of exogenous stressors on cell survival and neurite outgrowth were quantified by high-content image analysis.

Results: NF1 het iPSCs differentiated into tdTomato+ hRGCs similar to control lines, while NF1 hom cells differentiated with the same protocol showed reduced BRN3B/tdTomato/Thy1.2 reporter-expressing cells. Despite a decrease in pluripotency gene expression (e.g. POU5F1, NANOG) during 2D hRGC differentiation, NF1 hom iPSCs failed to express many early retinal development markers (e.g. LHX2, RAX, SIX3, SIX6). In preliminary attempts to differentiate NF1 cells into retinal organoids, NF1 mutant iPSCs successfully formed embryoid bodies, but some NF1 lines did not resemble control retinal organoids following neural induction. hRGCs differentiated from NF1 het lines were more sensitive to cell stressors, such as rotenone, in a mutation-specific manner.

Conclusions: NF1 mutant cell lines exhibit differences in RGC and retinal development, which are being further characterized. A high content screening approach, to identify compounds that can protect hRGCs from NF1-associated phenotypes, is currently underway. Together, this work provides a better understanding of potential cell autonomous mechanisms of NF1-associated vision loss.

ABSTRACT BODY:

Purpose: Inflammatory bowel disease (IBD) is known to cause extraintestinal manifestations in at least a third of patients and is especially more common among the geriatric population. The purpose of this study is to estimate the lifetime risk of retinal disorders among patients with inflammatory bowel disease above the age of 55 years.

Methods: A retrospective cohort study was conducted using TriNetX (Cambridge, MA, USA), a federated research network composed of electronic medical records from over 80 million patients across 57 healthcare organizations. Individuals over the age of 55 with and without the diagnosis of inflammatory bowel disease (IBD) were identified using validated ICD-10 codes. Then, 1:1 propensity score matching (PSM) was utilized to create two same-sized cohorts balanced for comorbidities and demographics. After PSM, the lifetime outcomes of retinal disorders were compared with matched controls. A subgroup analysis was also conducted comparing Crohn's disease and Ulcerative Colitis.

Results: A total of 188,516 patients over the age of 55 were identified on TriNetX with a diagnosis of IBD. Subjects showed a statistically significant higher risk of having vitreous opacities (RR 2.01, 95% 1.86-2.18), puckering of macula (RR 1.78, 95% 1.63-1.95), macular degeneration (RR 1.64, 95% 1.56-1.73), retinal detachment or break (RR 1.53, 95% 1.37-1.7), cystoid macular degeneration (RR 1.53, 95% 1.30-1.80), retinal vascular occlusions (RR 1.46, 95% 1.28-1.65), central retinal vein occlusion (RR 1.45, 95% 1.14-1.84), retinal edema (RR 1.44, 95% 1.23-1.68), and vitreous hemorrhage (RR 1.26 95% 1.08-1.48) compared to controls. A subgroup analysis showed a statistically significant higher risk of vitreous hemorrhage (RR 1.32, 95% 1.03-1.69), puckering of macula (RR 1.18, 95% 1.04-1.34), and vitreous opacities (RR 1.15, 95% 1.03-1.28) in patients with Ulcerative Colitis compared to Crohn's Disease. Patients with Ulcerative Colitis were less likely to have retinal edema compared to Crohn's disease (RR 0.76, 95% 0.60-0.95).

Conclusions: Patients with IBD over the age of 55 years are at a significantly higher risk of developing retinal disorders compared to patients without IBD. Increased awareness of retinal disorders in this patient population could lead to improved patient care.

ABSTRACT BODY:

Purpose: To report risk factors for retinal detachment (RD) following open globe injury (OGI) and the outcomes of RD repair following OGI.

Methods: Retrospective chart review of all OGI occurring between January 2000 and July 2017 at the University of Michigan. 587 eyes with OGI were surgically managed at our center with at least 30 days of follow-up. All eyes diagnosed with RD following open globe injury were included in this study. Multivariable regression was performed to identify risk factors for RD following open globe injury and predictors of poor vision following RD repair.

Results: 170/587 eyes (29.0%) were diagnosed with RD after OGI. The majority of patients were young males, 129/170 (75.9%) with mean age was 41.7 ± 24.2 years. Mean presenting logMAR visual acuity was 2.5±0.7, Snellen equivalent between hand motion and light perception. 25/170 eyes (14.7%) were diagnosed with RD on presentation, 79/170 eyes (46.5%) within 1 week, and 132/170 eyes (77.6%) within 1 month. Predictors of RD in multivariable regression included zone 3 injury (OR = 2.96, $p < 0.0001$), lens disruption (OR 1.54, $p = 0.0398$), vitreous hemorrhage (OR = 2.96, $p < 0.0001$), and presenting acuity worse than count fingers (OR = 2.37, $p=0.0023$). 105/170 eyes (61.8%) eventually underwent RD repair with 34 eyes (32.4%) re-detaching following repair. Of those eyes that underwent RD repair, mean final logMAR visual acuity was 1.95±0.95, Snellen equivalent between count fingers and hand motion. 40/105 eyes (38.1%) achieved vision count fingers or better vision at last follow-up. Predictors of poor vision, defined as worse than count fingers, following RD repair in multivariable modeling included aphakia (OR = 3.67, $p = 0.0190$), PVR at time of surgery (OR 4.38, $p = 0.0154$), and re-detachment (OR 2.78, $p = 0.0278$).

Conclusions: Retinal detachment commonly occurs within the first month following OGI. Posterior injuries, those with vitreous hemorrhage, lens disruption, or poor presenting acuity are more likely to develop retinal detachment after ocular trauma. Anatomic success was achieved in most patients who underwent repair, with just under half of these patients achieving ambulatory vision, suggesting surgery is worth attempting in many cases of retinal detachment following OGI.

ABSTRACT BODY:

Purpose: Two-photon excited fluorescence (TPEF) of the eye's fundus is a new imaging modality that has been recently demonstrated on humans. Using near-infrared fs laser pulses and two-photon excitation it is possible to probe retinal fluorophores with excitation spectra in the UV spectral range, impossible with one-photon imaging. This study was designed to verify the applicability of the newly developed instrument and imaging method with healthy volunteers without prior experience with this technique.

Methods: The study was performed using a TPEF scanning laser ophthalmoscope schematically shown in Fig. 1a. Fluorescence was excited with laser light at 780 nm, 76 fs pulse duration, pulse repetition rate of 6 MHz, and average power of 0.3 mW. Imaging was performed in a dark room with no prior dark adaptation or pupil dilation. Typically, 90-120 frames were recorded per eye and averaged in post-processing. We investigated a group of 13 healthy subjects with no history of ocular diseases in two age groups, 20-30 (n = 9) and 50-53 (n = 3) years old.

Results: In all cases, the recorded TPEF signal was significantly higher than the instrument noise and sufficient to reconstruct fundus images. With the first group of subjects, the mean fluorescence photon count per pixel was 45.8 x 10^{-3}, SD = 7.4 x 10^{-3} (n = 9). With the second group, mean fluorescence photon count per pixel was 48.7 x 10^{-3}, SD = 9.4 x 10^{-4} (n = 3). There was no significant difference between the two groups (Fig. 1b). Selected examples of images on naïve volunteers are shown (Fig. 1c). These results are comparable to those obtained on a trained eye (1 subject with substantial experience with this imaging modality, 10 sessions). Here, the mean photon count was slightly higher (89.9 x 10^{-3}, SD = 5.8x10^{-3}).

Conclusions: The results show that our novel imaging method is applicable to imaging untrained subjects and could be used clinically. The TPEF signal was significantly higher than the instrument's noise, and of the same order of magnitude as for an experienced subject; sufficient to reconstruct the TPEF image.

ABSTRACT BODY:

Purpose: Accurate measurement of the neural rim based on optic disc imaging is an important aspect of glaucoma severity grading, often performed best by a trained glaucoma specialist. We aim to improve upon existing partially automated tools by building a fully automated system (RimNet) for direct rim segmentation and rim-to-disc ratio (RDR) calculation in glaucomatous eyes with images obtained in a retrospective observational study.

Methods: An database of 857 glaucomatous funduscopic images of 695 eyes were used for training, validation, and testing divided by an 80%/10%/10% random split. All rims were manually delineated by glaucoma specialists. The dataset consists of 591 patients (242 male, 349 female). Mean age was 60.4 years (±14.2). Any images deemed of insufficient quality by a glaucoma specialist were excluded. RimNet consists of a deep learning rim segmentation model and a computer vision RDR measurement tool. A random search algorithm was used to identify the best performing deep learning architecture for rim segmentation, as determined by intersection-over-union with the clinician segmentations. The measurement tool uses the model-generated rim segmentation to identify the thinnest section of the rim and calculate the RDR. The Drishti-GS dataset was used for an external validation of RimNet performance (Sivaswamy 2015).

Results: RimNet achieved a mean average error (MAE) of 0.06 (±0.04) for RDR on the test set. Figure 1 demonstrates training, validation, and test RDR results. An MAE of 0.13 (±0.09) was achieved for rim-to-disc area ratio (RDAR) on the test set. Bland Altman plots are shown in Figure 2. On the Drishti-GS dataset an MAE of 0.06 (±0.04) for RDR and 0.12 (±0.08) for RDAR was observed.

Conclusions: RimNet efficacious rim segmentation and RDR calculations, as demonstrated by the low MAEs and good agreements on both our test and DRISHTI-GS datasets. Such an automated algorithm would be a valuable component in an automated RDR-based glaucoma grading system. Further improvements could be made by improving the deep learning algorithm and expanding the variety of glaucomatous training images.

ABSTRACT BODY:

Purpose: The Port Delivery System with ranibizumab (PDS) is a drug delivery system approved in the United States for neovascular age-related macular degeneration (nAMD). Following surgical implantation via the pars plana, the PDS allows for continuous intravitreal delivery of a customized formulation of the anti–vascular endothelial growth factor (VEGF) ranibizumab. In the phase 3 Archway trial of the PDS for nAMD (NCT03677934), aqueous humor (AH) samples were collected to characterize pharmacokinetics and pharmacodynamics of ranibizumab delivered via the PDS and intravitreal injection.

Methods: Archway assessed PDS 100 mg/mL and fixed refill-exchanges every 24 weeks (wks) vs monthly intravitreal ranibizumab 0.5 mg injections. All patients had ≥ 3 anti-VEGF intravitreal injections before screening and an intravitreal ranibizumab 0.5 mg injection at end of screening, 21–28 days before baseline (BL). Optional AH samples, each collected predose, were obtained and analyzed at BL and wks 24, 28, 48, and 52. Ranibizumab and free VEGF AH concentrations were measured using validated enzyme-linked immunosorbent assays with lower limits of quantitation of 20 ng/mL and 1.46 pg/mL, respectively. Significance was tested via Wilcoxon rank test with Bonferroni multiplicity correction.

Results: Optional AH samples were available for 102/248 and 65/167 patients at BL in the PDS and monthly ranibizumab arms, respectively. At BL, median AH ranibizumab and free VEGF concentrations (Table 1) were similar in both arms. At post-BL visits, ranibizumab concentrations were higher and free VEGF concentrations were lower in the PDS arm at 4 and 24 wks since dose, versus 4 wks since ranibizumab injection (PDS vs monthly ranibizumab, $P<0.01$ at each timepoint). In the PDS arm, free VEGF concentrations were similar at 4 and 24 wks since dose, indicating sustained free VEGF suppression throughout the 24-wk refill interval with the PDS. No correlations were observed between free VEGF concentrations and maintenance of BL best-corrected visual acuity or central subfield thickness at wk 36/40 in either arm.

Conclusions: The PDS delivered a more sustained concentration of ranibizumab versus monthly injections, resulting in improved longitudinal suppression of VEGF in AH.

TITLE: Temporal and Spatial Expression of G Protein-Coupled Estrogen Receptor 1 (Gper1) in Developing Mouse Retina

SESSION TITLE: Retina Development and Regeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W. Teal, J. Ogilvie, Biology, Saint Louis University, Saint Louis, Missouri, UNITED STATES|

Commercial Relationships Disclosure: Wendy Teal: Commercial Relationship: Code N (No Commercial Relationship) | Judith Ogilvie: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Gper1 is a G-protein-coupled estrogen family receptor known for rapid, non-genomic signaling with differential subcellular localization compared to the classic alpha and beta estrogen receptors. It has been demonstrated to be important for sensory system development and highly expressed in the developing zebrafish retina and optic nerve. The goal of this study is to determine Gper1's expression profile and localization in the developing mouse retina, which has not previously been elucidated.

Methods: We analyzed single-cell RNA-seq (scRNA-seq) data (Clark, et al. 2019, Neuron 102:1111-1126) using the R package Seurat to determine Gper1's expression profile. We used immunohistochemistry and western blot to determine Gper1 protein expression from P0-P21, using liver tissue and hippocampi as negative and positive controls, respectively.

Results: scRNA-seq analysis showed that Gper1 is expressed transcriptionally from E14-P8 in the mouse retina, with a transcriptional peak around P2. The transcript expression was most abundant in retinal progenitor and neurogenic cells with a subset of ganglion and other cell types also identified. The overall expression level was relatively low. Immunohistochemical data shows Gper1 protein localized to a subpopulation of cell bodies in the ganglion cell layer as early as birth, with Gper1 protein abundance peaking around P8 and then declining.

Conclusions: scRNA-seq analysis showed that Gper1 is expressed early in mouse retinal development, consistent with immunohistochemistry and western blot observations. Together, the data suggest that Gper1 may be expressed widely at low levels in neurogenic and retinal progenitor cells, but that gene and protein expression may become concentrated in a subpopulation of retinal ganglion cells around P2. Determining Gper1's temporal and spatial expression throughout development may provide insight into its function.

ABSTRACT BODY:

Purpose: Individuals with central vision loss, for example, those in macular degeneration (MD), primarily use their peripheral for navigation and other daily living activities. Previously, we reported that peripheral attentive motion tracking, which is critical for navigation, can be improved by perceptual learning (PL) in individuals with MD. In this study, we investigated whether transcranial random noise stimulation (tRNS), a form of non-invasive brain stimulation, can enhance this perceptual learning effect.

Methods: 10 participants (42-65y, 6 males), including 6 with unilateral macular degeneration (UMD) and 4 with bilateral macular degeneration (BMD), were assigned into treatment (tRNS) and control (sham stimulation) groups using a stratified random sampling (3 UMD and 2 BMD in each group). Participants in both groups completed 5 x 40-min PL sessions across consecutive days, while tRNS/sham stimulation was delivered to the motion-sensitive extrastriate area MT+ (3 cm above and 5 cm to the left/right of inion). MOT speed thresholds (8 elements, starting speed 4°/s, partial report procedure) were measured for both hemifields separately during the preliminary baseline visit, pre- and post-intervention on each stimulation day, and then every 24h for 3 days after the stimulation day. tRNS/sham stimulation was applied on the MT+ contralateral; while MOT training was conducted in the hemifield ipsilateral to the affected eye (UMD) or eye with poorer visual acuity (BMD).

Results: MOT task performance improved in both the trained and untrained hemifield in all participants following perceptual learning. However, the tRNS group exhibited a larger improvement in both the trained (tRNS: 37 ± 18%, sham stimulation: 28 ± 11%; $p = 0.008$) and untrained (tRNS: 21 ± 9%, sham stimulation: 15 ± 11%; $p = 0.02$) hemifield than the sham group. In addition, the improvement in MOT performance in both hemispheres was sustained in the tRNS group for at least 72h (trained hemifield: 22 ± 10%, untrained 13 ± 8%, $p = 0.03$) after the final perceptual learning session. For the sham stimulation group, the improvement was sustained only for 48h in the trained hemifield and for 24h in the untrained hemifield.

Conclusions: These initial results suggest that tRNS boosts the efficacy of perceptual learning in enhancing peripheral attentive motion tracking in individuals with macular degeneration.

ABSTRACT BODY:

Purpose: Many optical coherence tomography (OCT) systems incorporate IR fundus imaging for retinal preview and tracking. The acquisition reliability of OCT data depends on the quality of the IR fundus images' focus. This technique demonstrates a real time image focus measurement using a fast method which can aid an operator during patient alignment. The real time focus measurement is also essential for an automated acquisition system.
Methods: Our method first computes a focus value for each IR image by calculating the sum of the gradient magnitude above the 95th percentile of the gradient image as the focus value. Prior to the image gradient calculation, stripe artifacts are removed from IR images using a real time algorithm.

To test the algorithm, prototype software was used to collect a series of IR images (768x624 pixels over 11.52×9.36 mm2 with a pixel size of 15 μm/pixel) from a CLARUS^{TM} 500 (ZEISS, Dublin, CA) at a frame rate of 50 Hz, using normal and small pupil acquisition modes.

Sequences of roughly 700-800 images each were collected from 10 subjects (some of which had multiple sequences). Images with artifacts, such as blinks, were removed from the database, leaving roughly 5000 total images. The images that remained in the database could be in-focus or out of focus. The algorithm then determines a "Focus Value" for each image. The focus values are converted to probabilities by transforming the focus values using a cumulative distribution function (CDF) (Fig 1) determined from 5,005 IR images. This plot shows the probability that an image is in focus for a given focus value as determined by the algorithm.
Results: To evaluate the algorithm's performance, approximately 100 images were randomly selected from each of the 10 sequences for evaluation. 1,016 independent images (486 out of focus and 530 in-focus) were evaluated subjectively by an expert grader using large vessel sharpness as a measure of focus using two grades (in-focus vs out of focus). We used the grader's evaluation and the focus measurement calculated by the algorithm to compute receiver operating curves (ROC) (Fig 2). The area under the curve (AUC = 0.97) showed great performance of the algorithm with the test data.
Conclusions: We demonstrated a functional real time IR image focus assessment algorithm that can help operators with patient alignment and automated acquisition.

ABSTRACT BODY:

Purpose: A hallmark of inherited photoreceptor degenerations is the development of aberrant spontaneous activity in retinal ganglion cells (RGCs). This activity can degrade the signal-to-noise ratio of residual visual signals as well as signals introduced by therapeutic interventions. We previously found that blocking calcium-permeable AMPA receptors (CP-AMPARs) reduces aberrant activity in AII-ACs and On-alpha RGCs in rd10 retina, likely by blocking rod-bipolar to AII-AC signaling. Our goal was to further investigate the mechanisms underlying aberrant activity during late-stage degeneration and determine whether specific cell types were differentially affected.

Methods: We studied rd10 mice at postnatal day 45-55, an age when rods have degenerated but some cones remain. We used two-photon calcium imaging (Cal520 AM) to record spontaneous calcium fluctuations from somas in the ganglion cell layer (GCL) in regions lacking residual light responses. Signals were measured for 1-5 minutes before and after applying the CP-AMPAR antagonist, IEM-1460 (IEM, 50 μM). Some retinas were later immunolabeled with cell-type specific markers (RBPMS, SMI-32, calbindin) to distinguish amacrine cells from RGCs, and to classify different alpha-RGC types. Data are mean ± 1 s.d.

Results: A subset of amacrine cells and RGCs displayed spontaneous, sustained (>10 sec) calcium fluctuations that were reversibly abolished by IEM-1460. The loss of the spontaneous fluctuations in sustained On-alpha RGCs reduced the signal variance by 48.0±11% (n=9 cells). Other alpha RGCs showed significantly less suppression (18±15%, n=15 cells, $p<0.0001$, unpaired t-test, 4 retinas). Overall, in 1423 ACs and GCs in 6 retinas, IEM reduced calcium-signal variance by 21.3±5.1% ($p=0.0007$, one sample t-test). The amplitude of the sustained fluctuations was positively correlated amongst the On-alpha RGCs in the same retinas, but anticorrelated between On-alpha sustained RGCs and putative Off-alpha RGCs.

Conclusions: A CP-AMPAR antagonist can suppress sustained aberrant activity in amacrine and ganglion cells after complete rod degeneration. The presence of anti-correlated activity in On-alpha sustained and putative Off-alpha RGCs is consistent with the involvement of AII-ACs. Our results suggest that CP-AMPARs may be a therapeutic target for suppressing aberrant activity in late stage retinal degeneration.

ABSTRACT BODY:

Purpose: The Alabama Screening and Intervention for Glaucoma and eye Health through Telemedicine (AL-SIGHT) program was developed to engage at-risk populations living in rural Alabama who have limited access to eye care. AL-SIGHT utilizes remote optic nerve assessment to identify glaucoma and other eye diseases in patients seen at federally qualified health centers (FQHCs). This study aims to evaluate the satisfaction of participants enrolled in the first year of the AL-SIGHT program.

Methods: Three FQHCs in rural, underserved communities in Alabama enrolled participants with one or more risk factors: Black or Hispanic ≥ 40 years, White ≥ 50 years, diabetes, a pre-existing glaucoma diagnosis, and/or a family history of glaucoma. After demographic surveys and a brief eye health education program were administered, participants received visual acuity and IOP measurement, autorefraction, visual field testing, fundus photos, and optic nerve and macular optical coherence tomography. A satisfaction survey was then administered to the participant at the conclusion of the encounter with the research coordinator. Survey responses were analyzed with frequencies and percentages.

Results: Among the 340 participants enrolled, 297 (87.4%) were very satisfied and 42 (12.4%) were satisfied with the telemedicine program. 287 (84.4%) were very satisfied and 53 (15.6%) were satisfied with the time spent for the program. 312 (92%) found the location of screening very convenient and 27 (7.9%) found it convenient. 323 (95%) were very likely and 17 (5%) were somewhat likely to recommend the program to others.

Conclusions: The AL-SIGHT program had near total participant satisfaction. Participants also found the program location in the FQHCs where the participants also receive their primary care to be convenient. High satisfaction levels can be used to promote telemedicine programs to patients and increase access to eye care services especially in rural areas.

TITLE: Association of health literacy and utilization of ocular hypotensive medication among adults with glaucoma

SESSION TITLE: Glaucoma epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B.T. Cheng, A.P. Tanna, Department of Ophthalmology, Northwestern University Feinberg School of Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Brian Cheng: Commercial Relationship: Code N (No Commercial Relationship) | Angelo Tanna: Commercial Relationship(s);Code C (Consultant/Contractor):Bausch & Lomb, Ivantis, Sandoz, Zeiss

ABSTRACT BODY:

Purpose: Previous studies have shown patients with glaucoma and low health literacy have increased difficulty with eye drop administration and greater risk of disease progression. However, the association of low health literacy and utilization of ocular hypotensive medications is not well-delineated. We conducted a retrospective, cross-sectional analysis to test the hypothesis that patients with low health literacy utilize more glaucoma medications and have higher rates of polypharmacy.

Methods: Data were analyzed of adults (≥18 years) enrolled in the Medical Expenditure Panel Survey (MEPS) from 1996-2017. The MEPS is an annual, representative survey of individuals, families, their healthcare providers, and pharmacies in the United States. National Assessment of Adult Literacy (NAAL) score was used to stratify into low (NAAL <226) and high health literacy (NAAL ≥226). Multivariable regression models adjusted for insurance type were constructed to examine the impact of literacy on prescription medications, health expenditures, and polypharmacy (≥3 medications prescribed for glaucoma).

Results: There were 7846 adults enrolled in the MEPS who self-reported diagnosis of glaucoma. There were increased rates of low health literacy associated with self-reported glaucoma (23.9% vs 9.7%, adjusted OR [95% CI]: 2.43 [2.25-2.62], P<.0001). Among adults with glaucoma, low health literacy was associated with a greater number of glaucoma prescription medications (adjusted risk ratio: 1.06 [1.01-1.12], P=0.03) and increased healthcare spending on these medications (adjusted β: $57.05 [$30.22-83.87], P<.0001). Moreover, adults with low health literacy were more likely to report polypharmacy (adjusted OR: 1.28 [1.11-1.47], P=0.0005).

Conclusions: Self-reported diagnosis of glaucoma was associated with low health literacy. Moreover, low health literacy was associated with a greater number of glaucoma prescription medications, increased expenditures, and higher likelihood of polypharmacy. Glaucoma patients with low health literacy may benefit from careful patient education and close treatment monitoring.

ABSTRACT BODY:

Purpose: Low dose of systemic doxycycline (LD-OD) has been proven to produce antiangiogenic effects and to inhibit both the expression and activation of matrix metalloproteases (MMP)-2 and MMP-9, whose expression is particularly relevant to pterygium progression.The aim of the study is to assess the outcome of both primary and recurrent clinically significant pterygium after surgical excision and conjunctival graft apposition in a cohort of patients undergoing chronic treatment with LD-OD for chronic refractory blepharitis.

Methods: Retrospective analysis of patients that underwent surgical excision and conjunctival graft apposition was conducted.Included patients were under LD-OD treatment before surgery and were affected by pterygium involving > 5 keratoscopic rings.Patients were divided in two groups: primary pterygium and recurrent pterygium.Rate of recurrence in both groups 1 year postoperatively was registered.Surface regularity, visual quality and dry-eye symptoms at 1-month, 3-months and 6-months follow-up were also monitored.

Results: In primary pterygium group 1/36 patients (2.77%) showed recurrence at 1-year follow-up.Best corrected visual acuity(BCVA) improved at 6-weeks follow-up (p=0.037), with a significant decrease in astigmatic refractive error (p = 0.021). Surface asymmetry index(SAI) and corneal total root mean square (RMS) were significantly lower at 1-year follow-up (p=0.042 and p =0.039 respectively).Ocular surface disease index (OSDI) score significantly reduced at 6-weeks follow-up (p=0.025).In recurrent pterygium group clinical relapse was detected in 1/24 patients (4.16%) at 1-year visit. BCVA significantly increased (p<0.001) and astigmatic refractive error significantly decreased (p=0.002) at 6-weeks examination. They also experienced a decrease in SAI(p=0.004), longitudinal spherical aberration (LSA)(p=0.021), Symmetry Index of Curvature (IC)(p=0.043), RMS(p=0.036), high-order aberrations (HOAs)(p=0.041) and OSDI score (p=0.005).

Conclusions: LD-OD treated patients with primary or recurrent pterygium show a lower rate of recurrence at 1-year follow-up compared to data in literature. Surface regularity and symptoms also improve in these patients after surgery.Prospective studies on a larger population are encouraged.

ABSTRACT BODY:

Purpose: Aim of our research was to develop an ophthalmic eye drops (MDV1601) able to intervene in any event of “dry eye cascade” as defined by DEWS II, by employing two endogenous molecules, Palmitoylethanolamide (PEA) and Docosahexaenoic acid (DHA), showing well documented neuro-regenerative and anti-inflammatory activities and which are very difficult to stabilize in a safe eye drops.

Methods: MDV1601 shelf-life stability studies were performed in two different final packaging: LDPE bottle (10mL) with ODS system and single-dose pouches (0.5 mL) according to International Conference on Harmonization (ICH) stability guidelines: 25°C (±2°C/ NMT 60% R.H) and 40°C (± 2°C/ NMT 75% R.H). Safety of the new patented formulation was evaluated by cellular viability using an in vitro human corneal cells model (HCE-SkinEthic), through MMT assay.

Results: MDV1601 is an isotonic and safe eye drop solution preservative free. PEA and DHA are highly stable for 6 months at 40° and for at least 24 months at 25°C, meeting ICH stability requirements for the storage at room temperature. The MMT results after 30 min (irritation test) and 24h (cytotoxicity test) of MDV1601 contact time suggested absence of direct toxicity and no epithelial surface damage (viability >98% versus negative control-PBS).

Conclusions: MDV1601 is the first formulation based on two very active endogenous molecules (PEA and DHA) potentially able to stabilize tear film and to protect ocular surface in dry eye syndrome, in line with the DEWS II definition of dry eye. The presence of PEA+DHA combo links anti-inflammatory and neuro-regenerative activity potentially able to improve signs and symptoms of the disease. Moreover, the absence of preservatives may result in improved ocular safety. MDV1601 could represent the “ideal artificial tear” for physiological restoration of ocular surface in dry eye syndrome.

ABSTRACT BODY:

Purpose: RPE cells and their interaction to photoreceptor OS are the first microconnectome of the visual system yet our understanding of the morphology relies on limited data from electron microscopy (EM). Our goal was to use volume EM to provide a detailed and unprecedented description of human RPE cells and their contact with OS.

Methods: A parafoveal retinal volume from a 28-year-old male Caucasian with an unremarkable macula was prepared by serial block-face scanning EM. The RPE cell membrane was reconstructed manually using TrakEM2 software (ImageJ). The cell body organelle content was reconstructed using advanced automated image segmentation methods (Dragonfly, Object Research Systems).

Results: Surface area and volume of a single complete RPE cell was 16898 μm^2 and 6042 μm^3, respectively. AP (n=808) originate from the apical part of the CB and comprised 85% and 21% of the total RPE surface area and volume. AP are elongated (mean length±SD: 6926±4353 nm) and form specialized interactions with overlying OS of cones and rods. Diameter of an AP ranged from 135 to 615 nm. The cell contained 546 pigment granules (lipofuscin/ melanolipofuscin/ melanosome), with a total surface area and volume of 5028 μm^2 and 734 μm^3. Details of volume coverage percentage of organelles are listed in the Table. We identified 438 mitochondria in the cytoplasm with a surface area and volume of 3607 μm^2 and 271 μm^3. The nucleus showed a total surface area and volume of 274 μm^2 and 375 μm^3. Membranous tubules and sacs in the cytoplasm resembling endoplasmic reticulum, yet to be confirmed by histochemical analysis, showed a total surface area and volume of 5321 μm^2 and 988 μm^3.

Conclusions: The apical surface of RPE and its relationship to photoreceptor OS is more extensive and complex than previously appreciated from light microscopy and single section EM studies. The surface area for molecular exchange vital for vision is vast. Cytoplasmic organelles are important clinical imaging signal sources. Our data will assist the interpretation of clinical high-resolution optical coherence tomography in early detection of neurodegenerative retinal diseases including age-related macular degeneration, for explicating the viral vector route in subretinal gene therapy, and benchmarking cells used for cell-based therapy and disease modeling.

ABSTRACT BODY:

Purpose: Mitochondrial dysfunction is implicated in optic neuropathies such as normal-tension glaucoma (NTG) and a missense mutation in the mitophagy gene Optineurin ($OPTN^{E50K}$), has a strong association (17% prevalence) with NTG. To date, mechanism to improve mitochondrial homeostasis in human RGC neurons for developing RGC neuroprotection is unclear. Here, using human stem cell differentiated RGC neurons and cutting-edge cell biology approaches, we set out to identify RGC protection mechanism by improving mitochondrial homeostasis

Methods: Small molecule-based stem cell differentiation and immunopurification (MACS) was done to obtain pure, well characterized RGCs (originally developed in Don Zack lab). CRISPR mutated human embryonic stem cells with $OPTN^{E50K}$ mutation was used for glaucoma modeling. Mitochondrial damage was inflicted by potent stressor, CCCP. Literature evidence suggests Tank-binding kinase1 (TBK1) inhibits mitochondrial biogenesis and we tested if TBK1 inhibition by a potent inhibitor BX795 could promote mitochondrial biogenesis. Mitochondrial mass was measured by immunofluorescence (Tom20), western blot (Tom70) and flow cytometry. Activation of mitobiogenesis was measured by qPCR and western blot of biogenesis genes (AMPK, PGC1a). Statistical comparison between two independent data sets was done using student's t-test.

Results: Mitochondrial homeostasis or Mitochondrial quality control (MQC) process is maintained by biogenesis of healthy mitochondria, fission/fusion, and degradation of damaged mitochondria (mitophagy). Our data shows hRGCs promote mitochondrial biogenesis under mitochondrial stress. Aggregates of $OPTN^{E50K}$ are dissolved by TBK1 inhibitor, BX795, ($p<0.05$, 24hrs; <0.005, 48hrs) treatment. Furthermore, TBK1 inhibition also enhanced mitochondrial mass (<0.05, WT and <0.01, E50K hRGCs) by activating biogenesis pathway and improved cell viability ($p<0.01$, WT and <0.05, E50K hRGCs) with reduction in caspase activity ($p<0.01$, WT).

Conclusions: Protein aggregates are often found in neurodegenerative conditions and increased mitochondrial biogenesis is often seen as a stress response. TBK1 inhibition leads to dissolution of $OPTN^{E50K}$ aggregates, with increased mitochondrial biogenesis resulting in neuroprotection of both WT and E50K hRGCs. Our study, for the first time, shows RGC neuroprotection mechanism by improving MQC, which is applicable for multiple optic neuropathies.

ABSTRACT BODY:

Purpose: Intravitreal delivery of gene therapy vectors to the retina carries lower risk of adverse events compared to subretinal injections, but has thus far exhibited less therapeutic potential in animal studies. We developed a new adeno-associated virus (AAV) vector for intravitreal delivery of genes to cone photoreceptors. The virus carries an expression cassette with a cDNA encoding an engineered opsin fused to the gene for green fluorescent protein (GFP) under the control of regulatory elements directing expression to long- and middle-wavelength (L/M) cone photoreceptors. The purpose of this study was to evaluate the expression pattern of the opsin-GFP fusion protein after intravitreal injection of the vector in a primate eye.

Methods: The expression cassette was packaged in the 7m8 AAV capsid and 8.5×10^{10} viral genomes in a volume of 50 microliters was injected into the vitreous of an adult macaque eye. The eye was harvested 5 weeks after the injection and retinal cryosections were labeled with antibodies against short-wavelength (S) and L/M opsin. Following confocal imaging, volumes of fovea (400 µm wide, 20 µm deep) were analyzed in TrakEM2 to count individual GFP-expressing, S, and L/M cones.

Results: GFP fluorescence was confined to the fovea. Across the fovea around 25% of cones expressed GFP, with expression highest at the center. GFP was localized primarily in the outer segments, and diffusely along the plasma membrane. While the majority of transduced cones were L/M, surprisingly a small fraction (~5%) were S cones.

Conclusions: A gene therapy vector designed for intravitreal delivery directed robust expression of an engineered opsin to foveal cones in a primate. This finding is promising for the next phase of ocular gene therapy in humans.

ABSTRACT BODY:

Purpose: To examine endothelial cell loss (ECL) associated with DSAEK grafts preloaded in the Tan EndoGlide Ultrathin or a circular glass Jones tube.

Methods: Twenty-seven donor corneas (age 42-73) were pre-cut for DSAEK with a microkeratome, trephinated, and loaded into either a Tan EndoGlide or glass Jones tube. Grafts were stored in a Life4C filled Krolman viewing chamber for 24 hours and then removed from their carriers using retina forceps (Tan EndoGlide) or via ejection (Jones tube) onto a bed of calcein AM-supplemented viscoelastic. Grafts were then imaged and analyzed for ECL by FIJI segmentation. ECL was determined for DSAEK grafts in the different cohorts and statistical significance was determined using one-way ANOVA and Tukey's post-hoc analysis.

Results: There were no significant differences in donor characteristics (including age, pre-processing endothelial cell density, death-to-preservation, lens status or diabetes status) for grafts loaded into a Tan EndoGlide or Jones tube. The EndoGlide is oval-shaped with a 3.5mm x 2.2mm opening, while the Jones tube has a 3mm diameter round lumen. ECL for grafts loaded into a Tan EndoGlide was 10.3% ± 2.3% (graft thickness: 60 – 189μm, n = 9). ECL for thin grafts (34 – 69μm, n = 9) loaded into the Jones tube was 24.0% ± 5.0%, while ECL for thick grafts (92 – 119μm, n = 9) was 34.2% ± 6.1%. ECL for grafts loaded into the Tan EndoGlide is significantly less than those loaded into the Jones tube ($P<0.001$). Thin grafts loaded in the Jones tube also had significantly less ECL than thick grafts loaded into the Jones tube ($P<0.001$).

Conclusions: The size and shape of the carrier can influence the cell viability of preloaded DSAEK grafts. The Tan EndoGlide and Jones tube differ in both internal shape and diameter. The higher ECL in the grafts loaded into the circular Jones tube was likely produced by endothelial-to-endothelial surface contact as well as excessive stromal folds inside of the carrier. Thinner grafts had less ECL when loaded in the Jones tube, but still showed characteristic patterns of cell loss along tissue folds.

ABSTRACT BODY:

Purpose: The inability to predict the outcome of micro-invasive glaucoma surgeries (MIGS) on lowering intraocular pressure (IOP) is a critical barrier to providing safe and effective interventions for patients. To address this critical barrier, our goal is to advance knowledge on the dynamic mechanisms of the distal aqueous humor drainage in the aqueous veins in the perilimbal sclera. We have developed an optical resolution photoacoustic (PA) microscopy system for resolving the deformation of aqueous veins and perilimbal sclera in porcine and human eyes in three dimensions (3D) as a function of IOP. In this study, we will induce variations of the biomechanical properties in whole eye globes by crosslinking and examine the performance of our methods.

Methods: Whole porcine eyes were treated with 5% genipin for crosslinking. During the imaging experiment, the globes were first pre-conditioned to a physiological state, then perfused at a constant flow rate with 0.25% indocyanine green (ICG) to steadily increase the IOP under continuous monitoring. PA images were taken at 5 mmHg IOP intervals at 790 and 1200 nm wavelengths, targeting the ICG-perfused aqueous veins and collagen-rich perilimbal sclera, respectively. The displacement of the spatial features within the tissue components were tracked throughout the image series. Strain fields in each tissue components were calculated using a finite element analysis (FEA) method.

Results: The biomechanical tensile tests on perilimbal tissue samples determined that the genipin crosslinking procedure results in moderately altered tissue stiffness (tangent modulus) and viscoelastic relaxation times. Results from preliminary whole globe experiments show strain gradients at the vein-sclera interface in untreated whole globes. Studies are ongoing to examine the performance of the PA and strain analysis methods to discern biomechanical differences in the observed tissue components of the untreated and crosslinked globes.

Conclusions: PA imaging combined with data driven FEA will advance understanding of the tissue biomechanics of the complex aqueous veins-perilimbal scleral system and role in IOP regulation. Advancing this knowledge on biomechanics and aqueous humor dynamics will enable clinicians to improve MIGS outcomes by choosing the appropriate surgery for a given patient based on characteristics of the distal outflow system.

ABSTRACT BODY:

Purpose: Bacterial keratitis is a vision threatening infection of the cornea. Serratia marcescens causes contact lens associated bacterial keratitis and experiences a hostile environment on the ocular surface. Mutation of the stress regulator gene gumB in S. marcescens strongly reduces the bacteria's ability to induce corneal inflammation. The goal of this study was to gain insight into the mechanisms responsible for this conserved stress response system protein in regulating ocular microbial pathogenesis.

Methods: Transcriptomic analysis of S. marcescens contact lens isolate K904 and an isogenic gumB mutant. RNA-sequencing, NanoString, and qRT-PCR were used to measure RNA from bacteria grown in lysogeny broth and in New Zealand White rabbit corneas. Proteomics on surface fraction from cultures grown in lysogeny broth was performed. Cytotoxicity was measured with PrestoBlue and Calcein AM staining. Genes for individual candidate cytotoxic factors were cloned and expressed from plasmids. Protease activity was measured from normalized culture filtrates using azocasein. Surface proteins and type I pili were assessed using PAGE and yeast agglutination analysis. Biofilm formation was assessed by the microplate-crystal violet assay.

Results: Approximately 15% of the S. marcescens genome had significantly altered expression in the gumB mutant ($p<0.05$). Of interest, major changes include reduction of toxic and host-pathogen regulator genes including flagella, pili, hemolysins, and serralysin metalloproteases. The gumB mutant secretomes were defective in protease activity (down 65±5% verus WT, $p<0.001$) and cytotoxicity to ocular surface cells (down 50±10% versus WT, $p<0.01$). Expression of serralysin, but not the ShlA cytolysin, PhlA phospholipase, or FlhDC virulence regulator restored cytotoxicity to the gumB mutant indicating that serralysin protease expression could complement the gumB mutant defect. Biofilm formation by the gumB mutant was defective (down 87±7% versus WT, $p<0.05$) and data suggest that this was due to loss of pilus biosynthesis rather than extracellular polysaccharide levels.

Conclusions: This study indicates that GumB is a major regulator of virulence genes and bacterial interactions with ocular cells through transcriptional control of secreted metalloproteases and biofilm promoting adhesins.

ABSTRACT BODY:

Purpose: Blue light hazard refers to potential retinal phototoxicity from short-wavelength “blue” light exposure. Blue light is ubiquitous in both natural and artificial light sources, including, most notably, sunlight. Light emitting diodes (LEDs) are a common source of artificial blue light. Speculation exists whether blue light from LED-backlit electronic devices may lead to retinal toxicity. The purpose of this study was to determine the effects of long-term exposure to narrowband short-wavelength ambient lighting on retinal function in rhesus monkeys that were part of experiments examining the effects of blue light on refractive development (Hung et al., 2021).

Methods: Infant rhesus monkeys were reared under short-wavelength “blue” light (n=7; 465 nm, 20 nm half-max bandwidth;183±28 lux) on a 12-hour light/dark cycle starting at 26±2 days of age. Age-matched control monkeys were reared under broadband “white” light (n=8; 504±168 lux). Light- and dark-adapted full-field flash electroretinograms (ERGs) were recorded in anesthetized monkeys at 330±9 days of age. Photopic stimuli were brief duration (<5 ms) red flashes (0.04-5.68 cd.s/m^2) on a rod-saturating blue background and the ISCEV standard white flash (3.0 cd.s/m^2 on a white 30 cd/m^2 background). Monkeys were dark-adapted for 20 minutes and scotopic stimuli were ISCEV standard white flashes of 0.01, 3, and 10 cd.s/m^2. A-wave, b-wave, and photopic negative response (PhNR) amplitudes were measured.

Results: For ISCEV standard light-adapted ERGs, there were no significant differences in a-wave (43.1±9.6 vs. 39.9±4.4 μV; P=0.35), b-wave (176.1±40.1 vs. 160.1±30.6 μV; P=0.49), and PhNR (16.4±8.7 vs. 8.7±10.0 μV; P=0.15) amplitudes between control and blue light reared monkeys. For red flashes on a blue background, there were no significant differences in a-wave, b-wave, and PhNR amplitudes between groups for all flash energies (P>0.05 for all). Similarly, dark-adapted a- and b-wave amplitudes were not significantly different between groups (P>0.05 for all). There were no significant differences in a- and b-wave implicit times between groups for all ISCEV standard stimuli (P>0.05 for all).

Conclusions: Long-term exposure to narrowband blue light did not affect photopic or scotopic ERG responses in infant monkeys. Findings suggest that exposure to 12 hours of daily blue light for approximately 10 months does not result in altered retinal function.

ABSTRACT BODY:

Purpose: To evaluate if there is a difference in the geographical pattern of non-invasive tear film rupture in healthy patient's vs with evaporative dry eye (DED).

Methods: Retrospective, cross-sectional and observational study. Patients with evaporative dry eye and healthy individuals who had dry eye assessments included Ocular Surface Disease Index questionnaire, meibum expressibility, lid margin abnormality, ocular staining, non-invasive tear film break-up time, and meibography were included.

Healthy patients were defined as OSDI<13, NIKBUT>10 seconds, and no ocular staining. Patients with DED were included according to the criteria of the International Workshop on MG Dysfunction (OSDI score>12 points, NIKBUT<10 seconds, degrees of expressibility 1 to 3, and liquid secretion score MGYLS>3).

The NIKBUT was calculated using the Antares topographer according to the manufacturer's protocols. The topographic definition of the tear film rupture was carried out by dividing the 12 rings projected into 6 central and 6 peripherals. In addition, for the definition of the lower and upper quadrants, and line was drawn from 1 to 180 grades of the tear rupture map, as well as from 90 to 270 grades for the identification of the nasal, and temporal quadrant. The evaluation was made by two independent observers.

Results: Seventy-two eyes of 72 patients were studied, with an average age of 34.94 ± 25.07 (range 18 to 77), 51.4% of the male sex, 36 with DED, and 36 healthy patients. 100% of the patients with DED had some rupture vs 50% of the healthy patients. We found that the initial rupture of the tear film in the lower temporal quadrant is more frequent in patients with DED compared to healthy patients. (22 vs 9, p=0.003), with an OR of 4.17 (95% CI 1.75,13.15). In addition, there was a difference in the initial NIKBUT (13.83±3.84 and 5.43 ± 2.13, p = 0.003), age, (40.44 ± 16.89 vs 29.42± 13.13 years, p= 0.003), thickness of the tear film (67.08 ± 18.80 vs 82.92 ± 31.97 microns, p=0.005), loss of meibomian glands in the upper eyelid (21.89±9.17 vs 16.43±6.33%, p=0.005) and lid margin abnormality (1.77±0.86 vs 1.00±0.75, p=0.0003) between the patients with DED and the healthy ones respectively

Conclusions: In our population, the tear film ruptured more frequently in the lower temporal quadrant in patients with evaporative dry eye than in healthy patients.

ABSTRACT BODY:

Purpose: Galectin-3 (Gal-3), is a β-galactoside-binding protein is purported to be a prognostic biomarker in patients with severe disease (e.g., heart failure or depression). We hypothesized that manipulation of the Vitamin A cycle during light-induced retinal damage (LIRD) could reveal whether increased Gal-3 expression is a predictor of microglia/macrophage deposition within the RPE during damage resolution.

Methods: High activity Rpe65 (L450 ($^{L/L}$)) and the low activity variant (M450 ($^{M/M}$)) were bred to Cx3CR1-GFP-mice on C57Bl/6J background. Light damage was conducted at 50,000 lux for 5 h during the dark phase of the circadian cycle. Mice were imaged and sacrificed at days 1, 3, & 7 after damage (age= P60-P365, n=3-4/group). Retinal thickness and morphology were measured via SD-OCT, cSLO, and histopathology. Tissue was collected for RPE flat mounts. GFP+ (microglia/macrophages) and Gal-3+ cells were counted and classified. ZO-1 spatial patterns were measured with CellProfiler and Imaris.

Results: Differences in damage patterns and kinetics between RPE 65 $^{M/M}$ and RPE65$^{L/L}$ mice were evident in both functional and morphological outcomes. On days 1 & 3 post LIRD, GFP^{+} cells were not significantly different in number between genotypes. Later, on day 7, more GFP^{+} cells were observed in the RPE 65 $^{L/L}$ mice compared to RPE65 $^{M/M}$ and no damage controls [BJ1] ($p<0.0001$). Notably, the RPE65$^{L/L}$ mice lost most of their ERG a-, b-, and c-wave amplitudes within the first 24-72 hours post LIRD induction compared to RPE65$^{M/M}$ mice ($p<0.005$). This phenotype worsened by day 7 post LIRD induction ($p<0.001$). Retinal detachments occurred earlier in RPE65$^{L/L}$ animals than in the RPE65$^{M/M}$ mice. Expression of Gal-3 in RPE65$^{M/M}$ mice was comparable to RPE65 $^{L/L}$ during early stages of damage (up to day 3 post LIRD induction); however, at day 7, RPE65$^{M/M}$ mice exhibited low levels of Gal-3 while RPE65$^{L/L}$ animals continued to express high levels of the protein heterogeneously in both RPE cells and CX3CR1-GFP^{+} cells. The distribution of GFP^{+} cells was correlated with Gal-3 expression patterns in RPE cells in a time-dependent manner after LIRD induction

Conclusions: Changes in subretinal expression of Gal-3 correlate to CX3CR1-GFP^{+} cell deposition and correspond to functional and morphological damage. Significance: Galectin inhibitory drugs may therapeutically modulate sub-retinal damage via microglia/macrophage-RPE interactions

TITLE: Impact of government-imposed lockdown due to the COVID-19 Pandemic on admissions and severity of retinal detachments in a referral eye hospital in Germany.

SESSION TITLE: Vitreoretinal surgery/VR Interface/PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Strzalkowski, C. Reiter, S. Dithmar, Ophthalmology, HELIOS Dr Horst Schmidt Kliniken Wiesbaden, GERMANY|

Commercial Relationships Disclosure: Piotr Strzalkowski: Commercial Relationship: Code N (No Commercial Relationship) | Constantin Reiter: Commercial Relationship: Code N (No Commercial Relationship) | Stefan Dithmar: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To analyze the patient characteristics and severity of retinal detachments (RDs) in a referral eye hospital during the COVID-19 pandemic with a corresponding timeline a year before.

Methods: Retrospective cohort study based on electronic patient records of all patients with confirmed diagnosis of RD from February 22, 2020 (lockdown imposed by German Government) to May 4, 2020 (end of lockdown) and following 2 weeks after lockdown period (LP) in the Department of Ophthalmology, Helios Dr. Horst Schmidt Klinikum (HSK), Wiesbaden, Germany, were analyzed and compared to the equivalent pre-COVID-period (p-Cp) from February 22, 2019, to May 4, 2019).

Results: During LP 26 patients were diagnosed with RD compared to 60 patients in the p-Cp (-56.7%, $p<0.01$). Within 2 weeks after LP a total of 13 with RD were admitted. A year before, two weeks after p-Cp 26 patients with RD were admitted, respectively (-50%, $p<0.01$). There was no statistical difference in age between LP group and p-Cp group (65.3±11.5 vs. 69.1±12.3 years ($p>0.05$)). Time between initial symptoms and ophthalmological examination was significantly longer in LP group ($p<0.01$). While usage of gas tamponade and silicone oil tamponade was similar in both LP and p-Cp group, there was a significant increase of proliferative vitreoretinopathy (PVR) RD needing silicone oil tamponade within two weeks after LP ended in Germany (LP 53.8% vs. p-Cp 23.1%) ($p<0.01$).

Conclusions: During government-imposed lockdown caused by COVID-19 pandemic, the rate of patients admitted with RD dropped significantly compared to the same p-Cp. Time between initial symptoms and ophthalmological examination was significantly longer in LP group, with consecutively more PVR-RD needing silicone oil tamponade within the following two weeks after lockdown period ended. While policymakers have focused primarily on containing chains of infection with SARS-CoV-2, it has had a massive impact on the medical care of ophthalmic emergencies with worsening prognosis after retinal detachment.

Commercial Relationships Disclosure: Frederick Collison: Commercial Relationship: Code N (No Commercial Relationship) | Ed Kopidlansky: Commercial Relationship(s);Code E (Employment):Precision Vision LLC | J Jason McAnany: Commercial Relationship(s);Code P (Patent):University of Illinois at Chicago College of Medicine, Patent application ID number 16768493

ABSTRACT BODY:

Purpose: To determine the effects of age and simulated optical abnormality on contrast sensitivity (CS) in luminance noise using a novel booklet-based letter CS test.

Methods: Sixty-eight subjects with no known visual deficits who recently underwent a comprehensive eye exam participated in this study (age range 18-85, with at least 10 subjects per decade between ages 20 and 70 years). Subjects were tested using the right eye only and asked to identify letters that spanned a broad range of Weber contrast (0.001 to 0.56) printed in a novel booklet-based test. The letters were presented against a uniform gray background (no-noise condition) and in the presence of static spatial luminance noise (noise condition), which consisted of light and dark checks. A subset of 5 subjects (age range 26-35 years) performed the same test under three additional conditions: (1) simulated cataract (Simuspecs Blur/Glare Cataract filter #20776), (2) +2 diopters (D) of blur, and (3) low room luminance (illuminance reduction of approximately 20x). CS for these three conditions was compared to the standard condition using paired t-tests with Bonferroni correction ($p = 0.05/3$).

Results: In the no-noise condition, contrast sensitivity was independent of age (mean log CS of 1.7) until approximately 54 years, and declined linearly for older subjects (CS loss of 0.1 log unit/decade). CS measured in noise was independent of age across the range of ages tested (mean log CS of 0.9); the slope of a linear regression function fit to these data was not significantly different from 0. Manipulations of simulated cataract and +2D blur significantly reduced CS in the no-noise condition (both $p < 0.05/3$), whereas these optical manipulations did not significantly affect CS in noise. Reduced room illumination did not significantly affect CS in the presence or absence of noise.

Conclusions: The results suggest that measurements of CS in luminance noise may be valuable, as these measures appear to be independent of age and certain forms of optical degradation. Furthermore, the results support CS measurements in noise in patients with retina or optic nerve disease, as noise may minimize possible artifacts arising from optical effects such as media opacities or defocus.

ABSTRACT BODY:

Purpose: Spatial variation in vitreous collagen fiber density may play a role in vitreous aging. Methods for quantifying fiber density across the eye are not well developed. Our objective was to evaluate the performance of different image segmentation methods for detecting variation in vitreous collagen fiber density in confocal reflectance images.

Methods: Four right fresh young adult porcine eyes were sectioned in the sagittal plane at the nasal limbus. Two-dimensional 70um x 70um confocal reflectance images were obtained every 1mm along an anterior-posterior axis originating at the nasal limbus. Three methods were used to quantify fiber density: 1) manual fiber counting by a single grader; 2) automated fiber counting using the Fiji ridge detection plugin; 3) automated pixel thresholding using the Fiji moments algorithm. Pearson correlation was used to compare methods. Simple linear regression was used to evaluate anterior-posterior density trends.

Results: Confocal reflectance images of porcine vitreous demonstrated a network of linear fibers with a diameter of 1.18 ± 0.51um (mean ± SD). Manual fiber counting yielded an average density of 0.019 ± 0.006 fibers/um^2, whereas automated fiber counting yielded an average density of 0.032 ± 0.014 fibers/um^2. Automated pixel thresholding resulted in an average of 23 ± 9% of pixels occupied by signal. There were strong correlations between manual fiber counting and automated fiber counting (R-squared=0.80, $p<0.0001$) and between automated fiber counting and automated pixel thresholding (R-squared=0.85, $p<0.0001$). All three methods demonstrated a significant trend of decreasing density from anterior to posterior. The density was found to vary by 7.1% per mm (95%CI 4.0-10.2%; $p<0.0001$) by manual fiber counting and 8.2% per mm (95%CI 3.9-12.6%; $p=0.0005$) by automated fiber counting, and 7.1% per mm (95%CI 3.3-10.9%; $p=0.0006$) by automated pixel thresholding.

Conclusions: High correlation was observed between three methods for quantifying fiber density in vitreous confocal reflectance images. By all three methods, collagen fiber density was greater anteriorly, near the vitreous base, which is consistent with prior research. These results support the use of these methods for assessing relative differences in vitreous collagen fiber density.

Song: Commercial Relationship: Code N (No Commercial Relationship) | Lauren P. Daskivich: Commercial Relationship: Code N (No Commercial Relationship) | Brandon Wong: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate risk factors for in-person follow-up compliance and diagnosis of glaucoma in patients with glaucomatous findings via teleretinal diabetic retinopathy screening (TDRS).

Methods: Retrospective chart review was conducted on diabetic patients with large or asymmetric cup-to-disc ratios identified by teleretinal screening in Los Angeles County's primary care-based TDRS program between 1/1/2016 to 12/31/2018. Demographic and clinical information were extracted from medical records. Risk factors for in-person visit compliance and diagnosis of glaucoma were analyzed with multivariable logistic regression in compliant patients.

Results: 837 patients with optic discs suspicious for glaucoma on teleretinal screening were included. 542 patients (64.8%) successfully completed an in-person visit with 87.6% of those diagnosed with glaucoma-related pathology (60.8% as glaucoma suspect and 26.8% as glaucoma). Patients 50-65 years old were 1.52 times as likely of being compliant with in-person visits compared to those <50 years old (p=0.048). Caucasian patients were 3.04 times as likely to be non-compliant compared to Latino patients (p=0.041). For every $10,000 increase in zip-code median income, patients were 10% less likely of being complaint (p=0.019). Those screened at sites with associated ambulatory optometry clinics were seen in-person faster than those at tertiary care medical centers, with 8% fewer days between screenings and initial in-person visits (p=0.046). Patients >65 years old were more likely to have confirmed glaucoma than those <50 years old (p <0.001). Compared to Latino patients, African American and Caucasian patients were 3.18 (p<0.001) and 7.32 times (p=0.024) as likely to have confirmed glaucoma, respectively.

Conclusions: In this safety net patient population with suspected glaucoma on teleretinal screening, patients who were younger, Caucasian, or from higher-income neighborhoods were less likely to follow up for an in-person evaluation. Compared to Latino patients, African American patients and Caucasian patients were at higher risk for confirmed glaucoma diagnosis.

ABSTRACT BODY:

Purpose: To evaluate whether repeated intravitreal injections are associated with glaucomatous progression in eyes with glaucoma spectrum diseases.

Methods: Retrospective longitudinal study of patients with ocular hypertension (OHT), glaucoma suspects (GS) or definite glaucoma that received ≥8 total intravitreal injections per eye and had ≥2 SD-OCT RNFL thickness measurements at least 12 months apart, having received ≥1 intravitreal injection during the study period. We excluded eyes with poor OCT quality and if the baseline global RNFL thickness was < 50 µm. Our primary outcome was the variation in RNFL thickness. Linear mixed effects models were constructed, including a multivariable model.

Results: 118 eyes from 104 patients were included. Average baseline age was 70.75±10.90 years with a follow-up of 39.91±23.14 months. 41% of eyes had primary open angle glaucoma (POAG), 36% OHT or GS, 16% secondary OAG and 6% angle-closure glaucoma (ACG). 40% had exudative AMD, 26% venous occlusion, 25% diabetic macular edema and 9% other retinal disorders. Average number of intravitreal injections during the study period was 22.10±14.19. RNFL thickness decreased significantly (85.97±20.14 to 79.70±20.69 µm; p<0.001; -2.10±7.36 µm/year), with no significant changes found in visual fields MD (p=0.382). There was a significant difference in RNFL variation among glaucoma spectrum diseases, with more thinning in eyes with secondary OAG (-11.24±16.95 µm; -3.79±6.19 µm/year), followed by POAG (-8.64±14.39 µm; -3.35±6.23 µm/year), ACG (-8.13±11.08 µm; -3.78±5.64 µm/year) and OHT/GS (-0.94±15.69 µm; -0.04±8.74 µm/year) (p<0.001). A higher number of study time injections was significantly associated with higher RNFL thinning (p=0.008). The proportion of eyes under glaucoma medical treatment increased from 73.7% to 82.2% (p=0.049), as well as the average number of glaucoma medications per eye (p=0.018); more eyes underwent selective laser trabeculoplasty (p<0.001) and surgical implantation of tube shunts (p=0.002). IOP decreased significantly from 18.64±7.10 to 15.05±4.04 mmHg (p<0.001). In a multivariable linear mixed model, higher baseline RNFL thickness (p<0.001), higher baseline IOP (p<0.001), lower central corneal thickness (p<0.001) and type of glaucoma spectrum disease (p=0.017) significantly predicted higher RNFL thinning.

Conclusions: Routine optic nerve evaluations should be performed in patients undergoing regular intravitreal injections.

ABSTRACT BODY:

Purpose: Topical prostaglandin analogues are first line therapy for the treatment of open-angle glaucoma (OAG). Although effective if dosed properly, patient adherence with eyedrops is poor and worsens in proportion to increased medication (med) burden in terms of both number of bottles and frequency of dosing. Additional drawbacks include ocular surface disease and cosmetic side effects. To address these drawbacks, two travoprost-eluting intraocular implants (iDose) were developed. We conducted a Phase 2, randomized, double-masked, multicenter trial to compare the safety and efficacy of these implants to timolol 0.5% BID in reducing IOP in OAG or ocular hypertension. This submission provides analysis of the subset of patients on the same or lesser topical IOP-lowering therapy at 36 months vs screening.

Methods: Randomized patients on 0 to 3 medications at screening received iDose-FE (fast eluting; n=51), iDose-SE (slow eluting; n=54) or underwent sham procedures and received timolol BID (n=49). iDose patients received placebo eyedrops. Additional topical IOP-lowering meds were added per protocol for patients with IOP >18mmHg at any visit. In this analysis, the proportion of patients on the same or lesser number of topical IOP-lowering meds at month 36 vs screening were evaluated. Mean change from 8AM baseline IOP was evaluated at month 36 in this population. Adverse events and safety parameters were evaluated.

Results: iDose-FE and iDose-SE demonstrated a clinically relevant IOP-lowering effect of 8.3 and 8.5mmHg, respectively, vs 8.2mmHg for timolol control. 70% of iDose-FE and 68% of iDose-SE subjects were well controlled on iDose with the same or lesser topical med burden at 36 months vs screening, vs 46% of subjects on timolol. iDose was generally well tolerated with no adverse events of conjunctival hyperemia, periorbital fat atrophy, clinically significant endothelial cell loss, and only a single adverse event of iris color change.

Conclusions: Robust, sustained IOP-lowering was achieved with both iDose models. The therapy was generally well tolerated over a period of 36 months. A responder analysis demonstrates substantial reduction in topical med burden for iDose-treated eyes, thus making iDose an attractive alternative to topical IOP-lowering therapy. iDose is currently being evaluated in two Phase 3 pivotal trials with results expected in late 2022.

TITLE:

Long-term comparison of Kahook Dual Blade excisional goniotomy and Gonioscopy-assisted Transluminal Trabeculotomy

SESSION TITLE: Surgery & Wound Healing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Chen, Z. Zhang, Tulane University School of Medicine, New Orleans, Louisiana, UNITED STATES|O. Adeleye, Tulane University, New Orleans, Louisiana, UNITED STATES|

Commercial Relationships Disclosure: Michael Chen: Commercial Relationship: Code N (No Commercial Relationship) | Olufunke Adeleye: Commercial Relationship: Code N (No Commercial Relationship) | Ze Zhang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Kahook Dual Blade (KDB) Goniotomy and gonioscopy-assisted transluminal trabeculotomy (GATT) both target the trabecular meshwork to increase aqueous outflow. We aimed to compare the efficacy and safety of KDB and GATT in patients with open angle glaucoma (OAG) with at least one year of follow-up.

Methods: A retrospective chart review was performed of adult patients at two centers who underwent KDB or GATT (with or without phacoemulsification) for treatment of OAG with at least one year of follow-up. Data collected included visual acuity, intraocular pressure (IOP), glaucoma medications, visual field results, diagnosis, adverse events, and additional glaucoma procedures. The primary outcome included surgical success (defined as 20% or more IOP reduction). T-test and chi-squares were used for analysis.

Results: Forty-four eyes were enrolled in the study, with 22 eyes in each group. Age, gender, and other demographics were similar in both groups. The mean preoperative IOP was 17.9 + 7.1 mm Hg and 22 +7.8 mmHg ($p= 0.041$) on 2.6 + 0.9 and 3.8 +0.8 medications ($p<0.001$) in the KDB and GATT groups, respectively. At 1 year, the mean IOP reduction 0.5 ± 7.1 mm Hg and 8.4 ± 7.7 mm Hg ($p=0.05$) in the KDB and GATT group, respectively. KDB eyes had 38.5% success while GATT eyes had 84.6% success. At 6 months, the mean medication reduction was 0.47 + 1.07 and 1.32 + 1.14 ($p=0.02$) in the KDB and GATT groups respectively. At 1 year, mean medication reduction was 0.568± 1.56 in the KDB group and 0.15± 0.55 ($p=0.088$) in the GATT group. There was no statistically significant difference in adverse events between the two groups.

Conclusions: Our study showed both KDB and GATT are safe and can effectively lower IOP and reduce medication burden. At one-year follow up, GATT appears to be show greater IOP reduction and more likely to achieve at least 20% reduction in IOP at 1 year despite a higher preoperative IOP and medication burden than KDB. There was no significant difference in medical reduction between the two groups, though it is notable the GATT group had a higher preoperative drop burden. This is the first study to show a significant difference in IOP reduction and surgical success between GATT and KDB with one year of follow up. A more extensive study is warranted to study this difference further.

SUBMITTER (NAME ONLY): Jeremy Bohl

TITLE: Blockade of alpha7-nicotinic acetylcholine receptors decreases calcium signaling in starburst amacrine cells in the mouse retina

SESSION TITLE: Retinal and central processing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Bohl, Z. Sharpe, M. Ayub, T. Ichinose, Ophthalmology, Visual and Anatomical Sciences, Wayne State University School of Medicine, Detroit, Michigan, UNITED STATES|

Commercial Relationships Disclosure: Jeremy Bohl: Commercial Relationship: Code N (No Commercial Relationship) | Zachary Sharpe: Commercial Relationship: Code N (No Commercial Relationship) | Mahnoor Ayub: Commercial Relationship: Code N (No Commercial Relationship) | Tomomi Ichinose: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal motion detection is dependent on the excitatory and inhibitory outputs of the starburst amacrine cell (SAC), Acetylcholine (Ach) and GABA respectively. We recently found that blockade of alpha-7 nicotinic acetylcholine receptors (α7-nAChRs) decreased the direction selectivity of on-off direction-selective ganglion cells, which was attributable to cholinergic feedback to bipolar cells. To examine whether the direction selectivity of SACs is controlled by cholinergic feedback to bipolar cells, we carried out two-photon calcium imaging on light-evoked responses from SACs in the presence and absence of Methyllycaconitine (MLA).

Methods: Oregon Green BAPTA (OGB-1) or GCaMP6m was used for calcium imaging. Electrophoretic injection of OGB-1 was conducted with a sharp electrode placed onto tdTomato labeled SACs. Recording of calcium responses in labeled SACs took place 1-2 hours after injection of OGB1. For GCaMP6 introduction, AAV9-GCaMP6M was injected into the intravitreal space of ChAT-Cre mouse eyes. Distal dendrites of SACs were imaged, and a 180° bidirectional moving bar stimulus was projected onto the photoreceptors on the ventral half of the retina by a UV LED. After calcium imaging was captured in a control solution, MLA (100 nM) was bath applied. Two-photon imaging occurred at 15 frames per second in a recording window of 256x124 pixels. Calcium fluorescence was analyzed using Fluoanalyzer in MATLAB.

Results: In response to two-directional stimulation, we observed brighter responses to preferred motion, centripetal direction, and dimmer responses during null, centrifugal direction. The application of MLA decreased the calcium responses in both directions for the SAC. After washout of MLA, preferred directional response increased to near control conditions, but null directional responses remained dimmer. These results indicate decreased synaptic output from the SACs, which is consistent with our previous observation of reduced direction selectivity in on-off direction-selective ganglion cells.

Conclusions: Our results show that α7-nAChR blockade by MLA decreases the overall calcium response in distal SAC dendrites. These new results confirm our previous work that cholinergic feedback to bipolar cells from SACs plays a role in SACs' direction selectivity, resulting in a reduced direction selectivity in on-off direction-selective ganglion cells.

SUBMITTER (NAME ONLY): Hanieh Mirhajianmoghadam

TITLE: Axial length changes in response to myopic defocus under different ambient light intensities

SESSION TITLE: Refractive Error: Myopia, Hyperopia, vision and models

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Mirhajianmoghadam, L.A. Ostrin, College of Optometry, University of Houston, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure: Hanieh Mirhajianmoghadam: Commercial Relationship: Code N (No Commercial Relationship) | Lisa Ostrin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Studies have shown that axial length (AL) changes in response to myopic optical defocus in young adults. However, the range of myopic defocus used has been limited (≤ +3 D). Moreover, the interaction between myopic defocus and ambient light intensity on AL is not well-studied. The goal of this study was to assess AL change in response to increasing increments of myopic defocus under three different ambient light conditions.

Methods: Healthy participants (ages 28.5±6.1 years, n=15) underwent three experimental sessions in a randomized order. At each session, participants first viewed a movie at 2 meters for 10 minutes. The room light was then adjusted to one of the three ambient light intensities (dim: <50 lux, moderate: ~500 lux, bright: ~2000 lux) and after 15 minutes, a Lenstar biometer was used to measure baseline AL. +2D was then added to the left eye. Participants continued to watch the movie, and AL was measured in both eyes after 15 minutes. Each 15 minutes, the defocus was increased to +4D and +6D, and Lenstar repeated. Upon removal of the final lens, recovery was assessed at 15 minutes. For each eye, the AL difference between the baseline measurement and each time point was calculated. The difference in AL between experimental and control eyes was analyzed with repeated measures ANOVA for sequential time points (four 15-minutes intervals) and light intensity (dim, moderate, bright).

Results: Spherical equivalent refractive error and axial length were comparable between right and left eyes (control: -0.6±1.3 D and 23.56±1.00 mm; experimental: -0.6±1.3 D and 23.57±0.96 mm; P=0.49 and P=0.76, respectively). There was no significant AL change across the four time points (P=0.96) or between the three light intensities (P=0.83). Additionally, there were no significant interactions between time point and light intensity (P=0.81).

Conclusions: Axial length did not significantly change in experimental eyes compared to control eyes following 15 minute intervals of monocular myopic defocus from +2D to +6D, regardless of ambient light intensity. Our results suggest that if axial length changes occur in response to myopic defocus, they may not be detectable with a Lenstar biometer.

ABSTRACT BODY:

Purpose: Purpose: Endoplasmic reticulum (ER) stress is linked with several retinal degenerative diseases including age-related macular degeneration (AMD). Chronic ER stress during ageing leads to retinal pigment epithelium (RPE) dysfunction, which is a hallmark of AMD. However, the role of mitochondria in ER stress-induced RPE dysfunction remains poorly investigated. Therefore, the objective of the present study is to explore the crosstalk between the ER and mitochondria (MT) in ER stress-induced RPE dysfunction and cell death.

Methods: Methods: A human RPE cell line (ARPE-19) was treated with an ER stress inducer (tunicamycin (TM), 1µg/mL,) for 48 h. Protective effect of various pharmacological inhibitors and mitochondrial targeted antioxidant, MitoQ, were assessed. Mitochondrial ROS (mt-ROS), membrane potential (Δψm), and intracellular ATP level were measured by Mitosox, JC-1, and ATP assays, respectively. Cell death was determined by lactate dehydrogenase (LDH) leakage. Barrier integrity was assessed by electric cell-substrate impedance sensing (ECIS) system. qPCR and western blot were performed to determine ER stress and apoptotic markers expression. Statistical analysis was performed using ANOVA or Student's t test.

Results: Results: Treatment of ARPE-19 cells with TM significantly upregulated several ER stress markers gene, including XBP1s, ATF4, CHOP and PDI. Furthermore, TM-treatment resulted in an increase in mt-ROS, decreased Δψm, less ATP, and cell death. Interestingly, JNK kinase inhibitor pretreatment attenuated TM-induced cell death. Bid, a mitochondrial proapoptotic protein, was also increased in TM-treated ARPE-19 cells and pretreatment with BI-6C9, an inhibitor of Bid, reduced TM-induced cell death. Finally, MitoQ pretreatment attenuated disruption of membrane integrity and cell death induced by TM.

Conclusions: Conclusions: Our results demonstrate that ER stress induces apoptosis in ARPE-19 cells by causing mitochondrial damage. We further show that blocking mitochondrial apoptotic pathway or addition of mitochondria-targeted antioxidant have a protective effect against ER stress-induced cell death.

ABSTRACT BODY:

Purpose: Optical coherence tomography (OCT) has the potential to provide objective diagnosis of ROP, however, integration of OCT into ROP diagnosis has been limited. We investigate whether an investigational 140 degree field of view OCT has the potential to assist with ROP diagnosis in awake neonates.

Methods: We review our experience imaging 35 unique patients, more than 100 imaging sessions, in the neonatal intensive care unit (NICU) who met criteria for ROP screening (birthweight ≤ 1500g or gestational age ≤ 30 weeks). Patients underwent ophthalmoscopic exam and OCT imaging using a 400-kHz, portable, contact swept-source system with a real-time feedback display, following placement of an eyelid speculum and pharmacological dilation. RetCam imaging was performed in some cases for comparison. Experience with OCT-based diagnosis versus ophthalmoscopic diagnosis was qualitatively compared by a single, unmasked examiner.

Results: The full ICROP classification could be made in all imaging sessions unless research imaging was deferred for medical reasons. The field of view of the contact-based design appeared wider than Retcam 130 degree lens (Figure 1). In addition to documentation of the extent of peripheral stage, in some cases, it was possible to visualize the ora serrate and document full vascularization of the retina (Figure 2). Anecdotally, it was easier to visualize the peripheral stage through small pupils compared to ophthalmoscopy, and while not formally measured, the exam seemed to be faster and better tolerated by the babies.

Conclusions: Early experience with an investigational contact-based UWF-OCT suggests that OCT-based screening may provide objective documentation and diagnosis of the full spectrum of Zone, Stage, and Plus disease in ROP. Although not formally studied here, our experience suggests that OCT-based screening also has the potential to be faster, less stressful to the neonate (and preferred by NICU nurses) compared to the ophthalmoscopic examination or standard fundus imaging.

ABSTRACT BODY:

Purpose: Alzheimer's disease (AD) is the major cause of dementia in the world with increasing evidences of the retina being affected. Since no cure exists, there is an urgent unmet need to find new treatments. Resveratrol, a natural polyphenol found in dark chocolate and red wine, has been advocated as a potential neuroprotectant in this disease. However, resveratrol has a low solubility and bioavailability limiting its clinical translation. In this study, we assessed a novel formulation of resveratrol in vitro and in vivo in a triple transgenic Alzheimer's disease (3xTg-AD) mouse model.

Methods: Resveratrol nanoparticles (RNs) were formulated using a thin rehydration technique. They were assessed in vitro on R28 cells against glutamate excitotoxicity and cobalt chloride induced hypoxia. Next, 3xTg-AD mice received intranasally either RNs (n=7) or an equivalent vehicle (n=6) 5 days a week for 3 months. After 3 months of treatment, animals were imaged using Detection of Apoptosing Retinal Cells (DARC). DARC count was defined as the number of fluorescent spots counted by a masked investigator. After sacrifice, their brains were harvested and immunostained for amyloid-beta (Aβ) and phosphorylated tau (pTau). Retinas were immunostained with Brn3a, a retinal ganglion cell (RGC) marker.

Results: RN formulation incorporating over 10 mg/ml resveratrol was stable over 90 days. RNs were able to protect R28 cells exposed to glutamate compared to the vehicle (IC_{50} 25.1±0.4 vs 14.4±1.0 mM, $p<0.0001$) but did not show any neuroprotection against cobalt chloride induced hypoxia compared to the vehicle (260.3±16.5 vs 200.7±22.3 μM, $p>0.05$). In vivo, DARC count was reduced with RN treatment compared to the vehicle (7.7±2.1 vs 49.1±13.3, $p<0.01$). However, these results did not correlate with a higher RGC density compared to the vehicle (1205±203 vs 1015±100 cells/mm^2, $p>0.05$). Interestingly, Aβ and pTau depositions in the brain were reduced with RN treatment compared to the vehicle (3.6±0.2 vs 4.5±0.2 Aβ score, $p<0.01$ and 2.1±0.5 vs 6.6±1.9 pTau score, $p<0.05$). No adverse effects were seen in vivo either systemically or in the eye.

Conclusions: These promising results show that RN is non-toxic and neuroprotective in vitro and in vivo when administered intranasally. However, DARC imaging failed to show a correlation with RGC density. Further studies are needed to confirm these results.

ABSTRACT BODY:

Purpose: Recently, we performed global metabolomics and transcriptomic analyses to determine key signaling pathways perturbed during experimental S. aureus endophthalmitis. We observed dysregulation in purine metabolism with a significant decline in “adenosine” levels. Here, we sought to determine the role of adenosine signaling in the pathobiology of bacterial endophthalmitis.

Methods: Bacterial endophthalmitis was induced in C57BL/6 mice by intravitreal (IVT) injection of S. aureus (SA) strain, RN6390. Retinal tissue was used for metabolomics and transcriptomic studies. The physiological role of adenosine was determined by IVT injection 6 h post-SA infection. Disease progression was evaluated by a daily eye exam and ERG analysis and assessment of bacterial burden and inflammatory cytokines. Mechanistic studies were performed using cultured human retinal Müller glia, mouse bone marrow-derived macrophages (BMDMs), and challenging them with S. aureus in the presence/absence of adenosine or specific inhibitors/activators.

Results: Our temporal metabolomics and transcriptomic analyses revealed a time-dependent decrease in adenosine levels and its signaling pathway genes in S. aureus-infected mouse retina. Interestingly, intravitreal administration of adenosine significantly reduced bacterial burden and intraocular inflammation resulting in preserved retinal functions. The supplementation of adenosine enhanced the expression of its signaling pathway genes CD73 and ADORA1. Moreover, adenosine treatment enhanced the expression of antimicrobial peptides viz. S100A7/A8 in Muller glia and BMDMs, resulting in increased bacterial phagocytosis and killing. Adenosine treatment exhibited anti-inflammatory properties in SA-infected cells.

Conclusions: Our study demonstrates reduced adenosine and impairment of its downstream signaling during bacterial endophthalmitis. Adenosine derivatives could be used as an anti-inflammatory/anti-bacterial therapy to improve visual outcomes in endophthalmitis.

ABSTRACT BODY:

Purpose: To develop an automatic method to count specifically-labeled mouse retinal ganglion cells (RGCs) with improved accuracy and efficiency. This method can be used to assess the status of RGC degeneration in glaucoma mouse models.

Methods: An automated algorithm was developed based on improved YOLOv5. Five channels instead of a single channel with the Squeeze-and-Excitation block added was used to improve the accuracy of counting. The complete number of RGCs in an intact mouse retina is obtained by dividing the retina into small overlapping areas and counting followed by merging all divided areas together using the Non-Maximum Suppress algorithm. The degeneration of RGCs was induced by intravitreal injection of NMDA. RGCs were labeled with an anti-BRN3A antibody.

Results: The automated quantification result shows a very strong correlation (mean Pearson correlation coefficient approximately equal to 0.993) with that of manual counting for both normal mice and a glaucoma mouse model. Our model achieves a mean average precision of 0.981. Furthermore, the GPU calculation time for each mouse retina is less than one minute.

Conclusions: We have developed a new automatic RGC counting technique with great accuracy and speed. It will provide a convenient tool for researchers who are engaged in glaucoma research using mouse models to understand the pathogenesis of glaucoma and develop potential therapeutic drugs.

ABSTRACT BODY:

Purpose: Pseudomonas aeruginosa (PA) is a major cause of infectious keratitis. Extracellular vesicles (EVs) are membrane bound nanovesicles secreted by cells that play a key role in cell communication. The purpose of this study is to characterize the biomolecular cargo in corneal epithelial-derived EVs released during PA infection in the corneal epithelium.

Methods: Telomerase-immortalized human corneal epithelial cells were infected with a standard invasive test strain of PA (strain PA01) for six hours. EVs were isolated from cell culture supernatants by size exclusion chromatography. Pooled fractions F1/F2 contained EVs and pooled fractions F4/F5 contained secretory proteins. Uninfected cells and planktonic PA were used as controls. Immunoblotting was performed for EV markers CD63, CD9, CD81, TSG101 and flotillin; size and concentration were determined by nanoparticle tracking analysis (NTA). Mass spectrometry was performed by the Proteomics Core at UTSW. Protein abundance values were log2 transformed and analyzed using a two-tailed t-test. Proteins with $p<0.05$ were subject to analysis using functional enrichment analysis tool (FunRich) software.

Results: All of the tested EV markers were detected in EVs. Protein concentration was lower in EVs than the secretory fraction. Using NTA, the average EV particle size was 30 ± 150 nm. PA infection did not alter EV particle number. Comapring protein abundance, 132 proteins in EVs released from PA-infected cells were significantly different than EV released from non-infected cells. Of these, 72 proteins were upregulated in response to PA-infection. Gene enrichment analysis indicated that among the 132 differentially expressed proteins, most genes belong to energy and metabolic pathways. Of the 72 upregulated proteins, gene enrichment analysis showed that the highest percentage of genes were related to G alpha and IL-8 signaling, energy pathways, signal transduction, metabolism, and hydrolase activity.

Conclusions: While PA infection does not alter the number of EVs released by corneal epithelial cells, it does alter the proteomic profile. Bioinformatics analysis indicates that proteins related to critical biological process including immune signaling, energy metabolism and cell communication pathways are enriched in corneal epithelial EVs released during PA infection.

TITLE: Two-color full-field stimulus thresholds under scotopic and photopic conditions in inherited retinal degenerations

SESSION TITLE: Fundamental and Applied Psychophysics and Color Vision

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Kevin III, University of Mississippi, University Park, Mississippi, UNITED STATES|D. Kevin III, J.C. Park, N. Sabbia, J. McAnany, R.A. Hyde, Ophthalmology and Visual Sciences, University of Illinois at Chicago, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Dion Kevin III: Commercial Relationship: Code N (No Commercial Relationship) | Jason Park: Commercial Relationship: Code N (No Commercial Relationship) | Nicole Sabbia: Commercial Relationship: Code N (No Commercial Relationship) | J Jason McAnany: Commercial Relationship: Code N (No Commercial Relationship) | Robert Hyde: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The full-field stimulus test (FST), a measure of visual sensitivity typically obtained under dark-adapted conditions, is correlated with the most sensitive location of the visual field measured by dark-adapted static perimetry. The purpose of this study was to perform a comprehensive analysis of the FST under dark-adapted (DA) and light-adapted (LA) conditions with red and blue light, and to determine their relationship with visual field area assessed by kinetic perimetry.

Methods: Eleven subjects with a known diagnosis of an inherited retinal degeneration (IRD) participated. Visual field area was determined using an Octopus 900 kinetic perimeter with three target sizes (V4e, III4e, and I4e). Area of scotomata, if present, were subtracted from the recorded field area. FST thresholds were obtained with photopically matched (cd/m^2) red (632 nm) and blue (468 nm) stimuli under LA and DA conditions. DA-FST (red and blue) thresholds were compared with LA-FST (red and blue) thresholds. DA-FST (red and blue) and LA-FST (red and blue) thresholds were also compared with the visual field areas.

Results: FST thresholds for red and blue stimuli were highly correlated under DA ($r = 0.94$, $p < 0.001$) and LA ($r = 0.95$, $p < 0.001$) conditions. For 9 of the 11 subjects, DA-FST threshold was approximately 2.2 log units higher for the red stimulus than for the blue stimulus. The remaining 2 subjects had equal red and blue DA-FST thresholds, consistent with their clinically apparent lack of rod function. LA-FST threshold was approximately 0.2 log units higher for the red stimulus than for the blue stimulus. For subjects with nearly normal visual fields (where $\log_{10}$ (visual field area [$degrees^2$]) > 3.5), FST values varied widely, with no measurable dependence on visual field area. In contrast, for subjects with reduced visual field areas, FST thresholds increased as visual field area decreased.

Conclusions: FST threshold differences between red and blue stimuli were consistent with predictions based on the scotopic and photopic spectral sensitivity functions, allowing the quantification of full-field rod- and cone-pathway sensitivity in this cohort of IRD patients. For subjects with marked field loss, FST thresholds were associated with kinetic field area.

TITLE: Long-term effects of anti-VEGF therapy versus panretinal photocoagulation (PRP) on retinal vessel caliber in eyes with proliferative diabetic retinopathy (PDR)

SESSION TITLE: Diabetic Retinopathy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K.L. Josic, Jaeb Center for Health Research, Tampa, Florida, UNITED STATES|S. Shen , J.W. Pak, S. Meuer, A. Domalpally, B.A. Blodi, Wisconsin Reading Center, Department of Ophthalmology and Visual Sciences, University of Wisconsin-Madison, Madison, Wisconsin, UNITED STATES|

Commercial Relationships Disclosure: Steven Shen: Commercial Relationship: Code N (No Commercial Relationship) | Kristin Josic: Commercial Relationship(s);Code F (Financial Support):Genentech;Code F (Financial Support):National Eye Institute (NEI);Code F (Financial Support):National Institutes of Health (NIH) | Jeong Pak: Commercial Relationship: Code N (No Commercial Relationship) | Stacy Meuer: Commercial Relationship: Code N (No Commercial Relationship) | Amitha Domalpally: Commercial Relationship: Code N (No Commercial Relationship) | Barbara Blodi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The DRCR Retina Network Protocol S trial was a non-inferiority study that compared ranibizumab (RBZ) to PRP in eyes with high-risk PDR. To better understand the long-term effects of anti-VEGF therapy, we performed a post-hoc evaluation of retinal vasculature in PDR eyes treated with RBZ versus PRP.

Methods: Fundus photographs of study eyes were evaluated for retinal vessel caliber at Baseline (BL), 2-Year (Y2), and 5-Year (Y5) time points. The Integrative Vessel Analysis (IVAN) software was used to measure Central Retinal Artery/Vein Equivalents (CRAE/CRVE) and the arteriovenous ratio (AVR) of vessels at 1 disc diameter from the optic nerve. Changes in CRAE, CRVE, and AVR over the 3 time points were analyzed between the RBZ and PRP groups using mixed linear regression models. Sensitivity analyses included censored eyes in each randomization group that received the alternate treatment.

Results: 107 eyes (83 participants) with gradable images for all 3 timepoints were analyzed: 48 eyes (35 participants) in the RBZ group and 59 eyes (48 participants) in PRP group. CRAE decreased significantly more in the PRP versus (vs) RBZ arm at Y2 (mean (SD) = -12 (17) μm vs. -2 (12) μm p=0.003), and there was a trend towards greater decrease in the RBZ arm between Y2 and Y5 (-1 (17) μm vs. -8 (18) μm, p = 0.13) with no difference between the groups at Y5 (-13 (18) vs. -9 (17), p = 0.22). CRVE decreased consistently in the PRP vs. RBZ arm at Y2 (-19 (25) vs. -14 (22), p = 0.26), with a larger decrease in the PRP arm at Y5 (-28 (27) μm vs. -18 (21) μm, p = 0.01). However, this decrease was not sustained following sensitivity analysis. In the RBZ group, the mean (SD) number of injections was 22.0 (11.4) at Y5 with no difference between BL/Y2 and Y2/Y5. In the final models, inclusive of ocular factors, BL demographics and randomization stratification factors, the only additional factor associated with changes in CRAE and CRVE was BL diabetic retinopathy.

Conclusions: Decreases in arteriolar and venular caliber were seen over 5 years in both the RBZ and PRP groups. While most of the arteriolar narrowing occurred within the first 2 years for the PRP group, it occurred after 2 years in the RBZ group, suggesting that these treatments may affect the retinal vasculature at differential rates.

ABSTRACT BODY:

Purpose: To evaluate the value of IHC staining for BAP1 and PRAME in a routine clinical setup

Methods: Patients treated for uveal melanoma from 2017 to 2021 were included in the study. IHC stainings were performed on both cytospin, enucleated eyes and cell blocks using self-clotting technique

Results: A total of 222 patients were diagnosed with uveal melanoma at the Copenhagen University clinic. 143 patients were treated for Choroidal melanoma, 13 for ciliary body melanoma and 66 for iris melanoma. One patient with iris melanoma chose not to be operated.One Patient was treated for bilateral uveal. melanoma.Of the 65 Patients with iris melanoma 64 were treated with local resection and one patient was enucleated. Of the 156 patients with posterior melanoma, 45 had TransVitreal-RetinoChoroidal biopsy (TVRC) followed by enucleation of the eye and.4 patients had only enucleation. A total of 103 patients with posterior melanoma had TVRC and Brachytherapy and 1 patients was only treated with brachytherapy..

55 of 65 Iris patients had BAP1 IHC performed.. One patient had too little material for analyses and one sample was inconclusive, leaving 53 (96%) sample diagnostic. 47 of 49 enucleates eyes were analysed for BAP! IHC and only 1 was inconclusive leaving a total of 46 samples diagnostic (98%). For the TVRC this number was only 55% (73 of 133 patients)

Conclusions: BAP1 IHC yields a high outcome when "true" histology is availble, but is not very stable in cytological preparations.

ABSTRACT BODY:

Purpose: Rhodopsin mediates light detection by activating the G protein transducin, a heterotrimeric complex of G_{α}, G_{β} and G_{γ} subunits. Upon activation, G_{α} dissociates from $G_{\beta\gamma}$ and initiates downstream signaling to produce the photoresponse. Proper G_{α} function is required for light detection, while dysregulated $G_{\beta\gamma}$ signaling could lead to neurological and carcinogenic conditions. Recently, a llama-derived nanobody (Nb5) was shown to bind the $G_{\beta\gamma}$ heterodimer, covering the G_{α}-binding site and potentially modulating G-protein signaling. Here, we investigated the function of rods in transgenic mice expressing the Nb5 nanobody.

Methods: We generated transgenic mice expressing Nb5 under the rhodopsin promoter. To facilitate detection, Nb5 was flanked by a FLAG domain. The animals were bred on a C57Bl/6 background, maintained on a 12hr light/dark cycle, and dark-adapted overnight for experiments. The Nb5 effects on rod function were studied by scotopic in-vivo electroretinography (ERG), ex-vivo transretinal recordings, and optokinetic behavior experiments. Retina histology was studied by FLAG and peanut agglutinin immunohistochemistry. Nb5 expression in the retina was quantified by western blotting.

Results: In-vivo ERG revealed a 50% reduction in maximal a-wave response amplitude in mutant mice versus controls. Dark-adapted fractional sensitivity, estimated from dim flash transretinal responses, was reduced by 30% in the mutants versus controls. Scotopic visual acuity and contrast sensitivity both were reduced by 30% in the mutants versus controls. Western blots showed robust Nb5 expression in the mutants, and immunohistochemistry confirmed Nb5 expression in rods. The presence of Nb5 down-regulated G_{α} subunit expression by 75% in the mutant retinas. Histological studies did not reveal any retinal degeneration in the mutants up to 5 months relative to controls. However, the immunohistochemistry revealed a non-uniform Nb5 expression in the outer nuclear layer of mutant retinas.

Conclusions: We conclude that the transducin nanobody likely remains bound to the $G_{\beta\gamma}$ complex, leading to reduced rod sensitivity and visual acuity, but without inducing degeneration. Together, our results demonstrate that expression of Nb5 in rods partially suppresses their function without adverse effects on their long-term survival, advancing development of new types of G protein-coupled receptor targeting drugs.

ABSTRACT BODY:

Purpose: The Pelli-Robson (PR) chart measures contrast sensitivity by presenting letters of decreasing contrast to determine a patient's threshold contrast. The purpose of this study is to demonstrate the comparability of a contrast sensitivity application developed for a wearable augmented reality platform to the PR contrast sensitivity test.
Methods: Fourteen participants with and without contrast sensitivity deficits were recruited to complete the Heru contrast sensitivity (HCS) application and PR chart test. Randomization determined which eye, OD or OS, was tested for each participant. The PR chart test was administered to participants with full refractive correction. The Heru contrast sensitivity application (HCS) was installed on a Magic Leap 1, size 2 headset, and uses a tumbling E presentation on a light background with a shrinking staircase thresholding strategy. Trial lenses were inserted into the headset to correct using the distance spherical equivalent. To improve our sampling of the lower end of the contrast sensitivity range, participants repeated HCS and PR tests using neutral density filters with 2x and 3x attenuation (ND2 and ND3). Contrast sensitivity values were compared between the two tests using Bland Altman analysis.
Results: Our study included 14 eyes, 79% female, with an age range of 24-80 years old (mean age of 49 years). Fourteen eyes from 14 subjects were independently tested with both methods using no filter and using a neutral density filter with an attenuation factor of 2 (ND2). Eleven of those eyes were also tested with a neutral density filter with an attenuation factor of 3, but two of the results were invalid because the subject could not see the PR chart. The overall mean difference was -0.08 dB with limits of agreement from -0.7 to 0.75 dB, showing significant variability. The mean difference and total number of outliers increased with the use of a neutral density filter (-0.03 with no filter, -0.14 with ND2, and -0.08 with ND3 (Figure 1), with outliers of 7%, 21% and 22% respectively.
Conclusions: It is possible to implement a contrast sensitivity test on a wearable device, and for the tested population the mean log contrast sensitivity matches well on average to the Pelli-Robson.

ABSTRACT BODY:

Purpose: To quantitatively evaluate the efficacy of anti-tubercular therapy (ATT) in tubercular uveitis (TBU) patients.

Methods: In this systematic review and meta-analysis, a search of PubMed, EMBASE and Cochrane Library was conducted for articles on ATT outcomes in TBU published between 1st January 2000 and 1st August 2021. Study details, demographics, clinical features, investigations that led to a diagnosis of TBU, treatment regimen (ATT, corticosteroids and immunosuppressants), and information on target treatment outcomes was extracted independently by three reviewers. A meta-analysis of proportions was performed. Main outcome measures include inflammation recurrence; inflammation reduction; complete resolution of inflammation; improved visual acuity (VA); ability to taper corticosteroids to < 10 mg/day without inflammatory progression; use of adjunctive immunosuppressants while on ATT. This review is prospectively registered in PROSPERO (CRD42020206845)

Results: Forty-nine studies reporting data for 4,017 TBU patients were included. In comparative studies, the odds ratio (OR) of inflammatory recurrence was 0.33 (95%CI: 0.19-0.60) for TBU patients treated with ATT versus no ATT. For TBU patients treated with ATT, the pooled absolute incidences of inflammatory recurrence, inflammatory reduction, complete resolution of inflammation and of visual acuity improvement were 13% (n=310/2,216; 95%CI: 9-18), 81% (n=217/276; 95%CI: 62-95), 83% (n=1,167/1,812; 95%CI: 77-89), and 65% (n=347/542; 95%CI: 51-78) respectively. Corticosteroids were tapered to <10 mg/day without inflammatory progression in 91% (n=326/395; 95%CI: 78-99) of patients, 9% (n=121/1,376; 95%CI: 6-13) of whom were administered concomitant immunosuppressive agents alongside ATT.

Conclusions: Treatment of TBU with ATT is associated with a high level of control or improvement of inflammation, followed by a two-thirds improvement in the risk of inflammatory recurrence in TBU patients; only one-seventh of TBU patients have recurrences during follow up. Visual acuity improved in most patients. However, more prospective studies with detailed reporting of ATT regimens, patient subgroups and outcomes are required to elucidate the effectiveness of ATT about other outcome measures.

TITLE: Analyzing the effect of the COVID-19 pandemic on patient outcomes following keratorefractive surgery

SESSION TITLE: Refractive and non-refractive corneal surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Sohal, B. Murdock, D. Belyea, Ophthalmology, The George Washington University, Washington, District of Columbia, UNITED STATES|H. Pakhchanian, I. Ali, The George Washington University School of Medicine and Health Sciences, Washington, District of Columbia, UNITED STATES|R. Raiker, West Virginia University School of Medicine, Morgantown, West Virginia, UNITED STATES|

Commercial Relationships Disclosure: Preet Sohal: Commercial Relationship: Code N (No Commercial Relationship) | Haig Pakhchanian: Commercial Relationship: Code N (No Commercial Relationship) | Rahul Raiker: Commercial Relationship: Code N (No Commercial Relationship) | Issa Ali: Commercial Relationship: Code N (No Commercial Relationship) | Braedon Murdock: Commercial Relationship: Code N (No Commercial Relationship) | David Belyea: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the impact of the COVID-19 pandemic on keratorefractive surgery outcomes by comparing rates of post-operative complications prior to and during the pandemic.

Methods: A retrospective cohort study was conducted using TriNetX (Cambridge, MA, USA), a federated electronic health records research network comprising multiple large health organizations in the United States. Patients were identified based on using validated CPT procedure codes for keratorefractive Surgery and were separated into two cohorts based on if they received their procedure before the pandemic protocols (Jan 1, 2019-Mar 17, 2020) or during the pandemic (Mar 18, 2020 to Dec 1, 2020). Then, 1:1 propensity score matching was utilized to create two same-sized cohorts which matched for various demographic and medical conditions. Subsequently, the relative risk for 11 specific post-operative complications between was compared between the two cohorts. Relative risks between cohorts were calculated and outcomes with $p<0.05$ were considered statistically significant.

Results: A total of 2,626 patients were included in analysis with 1,313 in each of the pre-pandemic and pandemic cohorts after propensity matching. Dry eye had a greater risk (RR 1.29; 95 CI, 0.94, 1.77) among the pandemic cohort, however the results were not statically significant ($P>0.113$). Similarly, retinal detachment was observed to have a lower risk (RR 0.83; 95% CI, 0.36, 1.92) among the pandemic cohort but the results were not statistically significant either ($P >0.663$). No statistically significant differences in the remaining post-operative complications were observed including recurrent corneal erosion, secondary corneal erosion, corneal scar/opacity, diffuse lamellar keratitis, corneal neovascularization, vitreous degeneration and hemorrhage, retinal edema, and cystoid macular degeneration.

Conclusions: The COVID-19 pandemic undoubtedly affected surgical practice of many ophthalmologists, and many operating rooms adopted new protocols after safety concerns for surgeons and ancillary staff. The results show that there was no statistically significant difference in the rate of post-operative complications for patients undergoing keratorefractive surgery before and during the pandemic. This suggests that despite the new safety protocols implemented in operating rooms, the quality-of-care patients received during the pandemic was not impacted.

ABSTRACT BODY:

Purpose: Purpose: With few exceptions, analysis of eye injuries, has been limited to relatively small-scale studies and currently there is no internationally adopted registry to collect data on eye injuries. This study reports analysed data collected from a new international eye injury registry.

Methods: Data was collected from 18 participating centers across 8 countries; Indonesia, India, USA, Iran, Nepal, Mexico, Guatemala and Pakistan utilizing a freely accessible online platform, the International Globe and Adnexal Trauma Epidemiological Eye Study (IGATES) registry. The mechanism and location of injury, clinical management and visual outcomes were analyzed. All data were anonymized and participating sites obtained ethics from their local ethics review board.

Results: 1988 eyes (representing 1922 patients) with a male to female ratio of 3.7 and mean age of 30.6 years were included in the analysis. The male to female ratio was highest in Guatemala (7.1) and lowest in Mexico (2.0). More than 9/10 injuries (93%) were accidental/unintentional with 52.9% occurring in the home and 23.9% in the workplace. Iran had the highest rate of workplace injuries (53.7%) and the USA and Mexico the highest rate of domestic eye injuries, 63.0% and 67.0%, respectively. Eye protection was reported as worn in 7/1859 (0.4%) of all patients.

Conclusions: The majority of eye injuries were accidental and occurred at home, there were significant differences found amongst the surveyed countries. This may have implications for public health interventions such as education of the public in regards to the risks in the home. IGATES will provide an opportunity to use big data to analyze eye injuries, to help improve outcomes and ultimately reduce their incidence with real-time, informed prevention strategies.

TITLE: Combined Intense Pulsed Light and Low Level Light Therapy Vs. Oral Azithromycin for the treatment of moderate to severe hypersecretory meibomian gland disfunction.

SESSION TITLE: Dry eye regulators: lacrimal gland, Meibomian gland, basic mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.Y. Arteaga Rivera, D. Jimenez-Collado, N. Macriz-Romero, A. Ramírez-Miranda, C.A. Müller-Morales, A. Navas, E.O. Graue-Hernandez, Cornea, Instituto de Oftalmologia Fundacion Conde de Valenciana IAP, Mexico City, Mexico City, MEXICO|

Commercial Relationships Disclosure: José Arteaga Rivera: Commercial Relationship: Code N (No Commercial Relationship) | David Jimenez-Collado: Commercial Relationship: Code N (No Commercial Relationship) | Nicole Macriz-Romero: Commercial Relationship: Code N (No Commercial Relationship) | Arturo Ramírez-Miranda: Commercial Relationship: Code N (No Commercial Relationship) | Carlos Müller-Morales: Commercial Relationship: Code N (No Commercial Relationship) | Alejandro Navas: Commercial Relationship: Code N (No Commercial Relationship) | Enrique Graue-Hernandez: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To compare subjective and objective clinical outcomes in patients treated with oral azithromycin or intense pulsed light (IPL) + low level light (LLLT).

Methods: This is a retrospective observational study in 20 patients with moderate to severe hypersecretory meibomian gland disfunction (MGD). Twelve patients were treated with oral azithromycin 1g once a week for 3 weeks, and 11 patients with IPL+LLLT using the Eye-Light® and My Mask® (Espansione Marketing S.p.A, Bologna, Italy) respectively, following the eye-light treatment protocol once a week for 3 weeks. Both groups were reevaluated 1 month after finishing treatment.

Patients with any medication or condition that could modify the ocular surface, macrolide hypersensitivity, pregnant and breastfeeding women were excluded. Variables analyzed were: non–invasive tear break-up time, meibography, tear meniscus height (TMH) and conjunctival redness (OCULUS Keratograph® 5M, Wetzlar, Germany). Uncorrected and corrected visual acuity, tear break-up time (TBUT), Schirmer I test, Oxford scale for fluorescein staining and OSDI scores were also recorded.

Results: Mean patient age was 57.65±10.43 years. All pretreatment variables were similar in both groups ($p>0.05$). When compared to their baseline measurements the group treated with IPL+LLLT showed statistically significant differences ($p<0.05$) in TMH (0.34±0.26 to 0.40 ±0.28)), Oxford score (1.32±1.04 to 0.55±0.59), dry eye sensation (3.18±1.60 to 1.55±1.63), eyelid redness (1.82±2.27 to 0.73±1.34), eyelid telangiectasia (1.27±1.00 to 0.27±0.46), eyelid edema (1.09±0.83 to 0.27±0.46), ocular mucus secretion (0.64±0.80 to 0.00) and OSDI scores (44.09±20.29 to 19.09±17.86). The azithromycin group showed significant differences ($p<0.05$) in TBUT (5.79±4.41to 9.88±10.52), dry eye sensation (3.25±1.48 to 1.75±1.76), eyelid hyperemia (1.41±0.66 to 1.08±0.66) and OSDI scores (36.5±18.68 to 22.25±13.63). When comparing IPL+LLLT group with the azithromycin group, no significant differences were observed.

Conclusions: Both treatments confer improvement in the subjective and objective parameters studied. Despite the fact that no significant differences were observed when comparing both groups, patients treated with IPL+LLLT showed improvement in more variables suggesting that it might be superior for the treatment of hypersecretory MGD.

TITLE: Inorganic polyphosphate-collagen complexes improve corneal epithelial cell function under glucose starvation and enhance corneal wound healing

SESSION TITLE: Corneal epithelial biology and repair mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G.M. Rogers, D. Myung, Ophthalmology, Stanford University, Stanford, California, UNITED STATES|D. Myung, Ophthalmology, VA Palo Alto Health Care System, Palo Alto, California, UNITED STATES|

Commercial Relationships Disclosure: Gabriella Rogers: Commercial Relationship: Code N (No Commercial Relationship) | David Myung: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Corneal injuries collectively represent a major global human health challenge, affecting hundreds of millions of people each year. Thus, there is a critical need for treatments that drive proper corneal wound healing. Polyphosphate (PolyP) is a biocompatible inorganic linear polymer composed of phosphate units. In the past few years, studies have shown that PolyP functions as a storage reservoir for ATP, regulates cell responses to stress, and increases cell proliferation. In this study we hypothesized that collagen crosslinked via electrostatic interactions using PolyP will form complexes that can support corneal wound healing by providing additional energy to facilitate cellular growth and normal cell function.

Methods: PolyP-collagen complex was formed by adding PolyP45 to bovine collagen type 1. The presence of PolyP in the complexes was confirmed by adding DAPI and reading the fluorescence intensity using excitation/emission settings of 350/550 nm. Corneal epithelial cells (CECs) were seeded on PolyP-collagen complexes. Cell phenotype and morphology were evaluated via staining with CK3, ZO-1 and phalloidin. The intracellular content of PolyP and mitochondrial morphology was evaluated using DAPI and TOM 22 respectively, after 16 hours of cell starvation. Corneal wound healing was evaluated using an ex vivo model of organ culture. A lamellar keratectomy was performed in rabbit corneas followed application of PolyP-collagen. Corneal wound size was monitored daily using fluorescein.

Results: CECs seeded on PolyP-collagen expressed CK3, ZO-1 and were able to proliferate forming a monolayer. Serum and glucose-starved CECs that were not treated with PolyP-collagen exhibited reduced intracellular PolyP and fragmented mitochondria morphology. Starved CECs treated with PolyP-collagen showed increased intracellular PolyP and normal tubulated mitochondrial morphology. PolyP-collagen treated rabbit corneas had 75% of the wounds healed by day 5 compared to 0% from the untreated group.

Conclusions: CECs showed normal phenotype and biocompatibility in the presence of PolyP-collagen complexes. In addition, CECs were able to uptake PolyP-collagen that may have helped supply ATP to maintain normal mitochondrial function under starvation conditions. We suggest that intracellular PolyP levels may contribute to enhanced corneal wound healing and tissue regeneration

TITLE: Unraveling how Corneal Schwann cells Affect Axonal Regeneration

SESSION TITLE: Corneal stromal biology, wound healing modulators and regeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Paramo, R. Mohan, P. Bargagna-Mohan, Neuroscience, UConn Health, Farmington, Connecticut, UNITED STATES|R. Paramo, R. Mohan, University of Connecticut School of Medicine, Farmington, Connecticut, UNITED STATES|

Commercial Relationships Disclosure: Ricky Paramo: Commercial Relationship: Code N (No Commercial Relationship) | Royce Mohan: Commercial Relationship: Code N (No Commercial Relationship) | Paola Bargagna-Mohan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Corneal Schwann cells (cSCs) are glial cells that ensheath axons and provide trophic support for axons. Surgical procedures that lesion stromal axons often result in aberrant axonal regeneration with impaired sensation. This study aims to illuminate temporal and regio-specific changes in myelinating (m) and non-myelinating (nm) cSCs during injury by exploiting the proteolipid protein 1-enhanced green fluorescent protein (Plp1-egfp) mouse.

Methods: Anesthetized adult male and female Plp1-egfp mice were subjected to stromal micropocket injury. Corneas were harvested 7, 14, and 30 days post-injury and processed for whole mount immunohistochemistry using antibodies against L1CAM (nm-cSCs), beta III-Tubulin (bIIITub), and NF-200 (m-SCs). Samples were analyzed by epifluorescence microscopy. NeuronJ (FIJI software) was used to quantify axonal and cSC network from high-resolution tiled images. The limbus-to-limbus corneal diameter was set at 3.8 mm and an internal 1.6 mm diameter for the central cornea. Statistical analysis was performed using ANOVA with Tukey's multiple comparison test and results were considered significant with $P < 0.05$.

Results: Comparisons of the L1CAM, NF200, and eGFP staining in control corneas for both total and central networks revealed significantly higher density for L1CAM and eGFP over NF200 in the central cornea. Upon injury, all markers were reduced significantly at 7 d, but returned at 14 d post-injury and exceeded controls levels. The network of eGFP cells in the central cornea at 14 d exceeded that of NF200. At 30 d post-injury, the total network of eGFP cells remained the highest. In the central cornea, the eGFP network was equivalent to L1CAM but significantly greater than NF200 cells. At 30 d the eGFP network was greater than that of NF200 and bIIITub at the peripheral cornea, identifying regional differences in the regeneration of SCs and axons.

Conclusions: Our data suggest that differential expression of L1CAM and NF200 during SC restoration could contribute to aberrant axonal regeneration in the repairing central cornea. Regenerating cSCs apparently also initiate a pro-myelination repair program. This immunolocalization study examining the temporal and regio-specific changes in different cSC biomarkers could help advance our understanding of how these critical glial cells influence axonal growth and restore sensory function in injury and disease paradigms.

TITLE: Differences in acute chemical injury severity grading between Cornea specialists and non-Corneal specialists

SESSION TITLE: Ocular surface health and conjunctiva

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F.C. Figueiredo, Biosciences Institute, Newcastle University Faculty of Medical Sciences, Newcastle upon Tyne, Newcastle upon Tyne, UNITED KINGDOM|F.C. Figueiredo, B.L. Teh, M. Shaw, J. sandhu, Ophthalmology, Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle Upon Tyne, Newcastle upon Tyne, UNITED KINGDOM|

Commercial Relationships Disclosure: Francisco Figueiredo: Commercial Relationship: Code N (No Commercial Relationship) | Boon Teh: Commercial Relationship: Code N (No Commercial Relationship) | Michael Shaw: Commercial Relationship: Code N (No Commercial Relationship) | Jaswant sandhu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Ocular chemical injuries (OCI) require prompt medical attention, including immediate assessment with appropriate treatment, as they are potentially blinding. Severity grading assessment of OCI on presentation is important both for management and prognosis.

This study aimed to look at inter-rater reliability between Cornea specialists and non-Corneal specialists in grading acute chemical injury severity.

Methods: This is a prospective study in a United Kingdom (UK) tertiary hospital in two different time periods: September 2017–June 2018 and September 2021–December 2021.

Consecutive patients presenting to the Eye Emergency Department (EED) with a history of acute OCI within those two time periods were included. Patients were initially assessed by non-Corneal specialists of different grades (specialty trainee to consultant) using Roper-Hall classification, with treatment initiated as per local protocol. They were then assessed by Cornea specialists within 24 hours of presentation to compare the chemical injury severity grading.

Results: Forty eyes of 31 patients had acute OCI. Most of the patients were male (77%; n=24) with mean age of 42 (range:19-84; SD:18). The majority (55%; n=17) had alkali injuries and 65% (n=20) of them were accidents at workplace or home.

Thirty-five eyes (87%) had a mild chemical injury (Grade 1 and 2) and carried a good prognosis. Seven eyes with mild chemical injury and four eyes with moderate-severe chemical injury of Grade 3 and 4 were due to assault.

There was a 70% (n=28 eyes) agreement between Cornea specialists and non-Corneal specialists. The remaining 10% (n=4 eyes) were under-graded and 20% (n=8 eyes) were over-graded. Of those under-graded eyes, there was no change in management in 3 eyes, including two which required perilimbal conjunctiva resection and human amniotic membrane transplant. One had additional topical therapy and had a full recovery.

For the over-graded eyes, six eyes had their topical therapy regime simplified. Two eyes were admitted to hospital for treatment and discharged earlier following re-grading of the injury.

Conclusions: There is good inter-rater reliability between Cornea specialists and non-Corneal specialists in grading OCI severity. Over-grading may increase treatment cost with avoidable admission whilst under-grading may compromise patient care. Further data collection is needed to allow for two comparable time period.

ABSTRACT BODY:

Purpose: Epigenetic factors play dynamic roles in neuronal development, progenitor cell proliferation, differentiation, and neural regeneration. Histone modification by histone deacetylases (HDACs) represents a key mechanism by which neurons regulate transcriptional profile during proliferation and differentiation. Accumulative studies have highlighted the therapeutic potential of HDACs inhibitors in neurological disorder. Therefore, we aimed to find HDAC that correlates with retinal ganglion cells (RGCs) development, which may provide a target of HDAC inhibitor in retinal degenerative diseases.

Methods: HDACs (members 1-6, 8-11) mRNA levels in retinal ganglion cells (RGCs) isolated from mouse at embryonic (E16) and postnatal (P0, P10) stages were analyzed by quantitative polymerase chain reaction (qPCR). PC12 cells were transduced with lentivirus carrying shRNA against HDAC11. Over 25 different transductants were generated with HDAC11 mRNA level knockdown ranged 20% to 70%. The transductants were subjected to proliferation assay, evaluated by 5-ethynyl-2'-deoxyuridine (EdU) incorporation before and after treatment of nerve growth factor (NGF; 30 ng/ml). Neurite outgrowth was quantitatively assessed 3 days after NGF-induction of neural differentiation.

Results: Initial screening of HDACs mRNA revealed a unique temporal increase of HDAC11 from E16 to P10, indicating an inhibitory contribution of HDAC11 to RGC growth capacity. To test this hypothesis, we established HDAC11 knockdown cell lines using neuron-like PC12 cells and examined their performance in proliferation and differentiation. In the absence of NGF, transduced cell line with about 50% knockdown in HDAC11 showed significantly increased number of dividing cells compared to naïve control PC12 cells while it also showed significantly more neurite outgrowth following NGF treatment, suggesting HDAC11 deficiency can enhance both proliferation and differentiation.

Conclusions: Our data show that HDAC11 may play a role in mediating neural progenitor cell proliferation and neuronal differentiation. These findings may suggest a novel target for promoting neuronal regeneration.

TITLE: c-Fos regulates retinal angiogenesis through modulating photoreceptor-released inflammatory proteins

SESSION TITLE: Retinal vascular diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Sun, S. Kaneko, T. Wang, D.I. Tsirukis, E. Lam, Ophthalmology, Boston Children's Hospital, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Ye Sun: Commercial Relationship: Code N (No Commercial Relationship) | Satoshi Kaneko: Commercial Relationship: Code N (No Commercial Relationship) | Tianxi Wang: Commercial Relationship: Code N (No Commercial Relationship) | Demetrios Tsirukis: Commercial Relationship: Code N (No Commercial Relationship) | Enton Lam: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Pathological proliferative angiogenesis causes irreversible blindness in vascular eye diseases such as retinopathy of prematurity (ROP). Inflammatory mediators are known key regulators in retinopathy and inflammation is often thought to come from infiltrating inflammatory cells, but we recently found that photoreceptors also can signal for blood vessel growth through inflammatory signals via c-Fos in a mouse model of retinal angiogenesis. However, the underlying molecular and cellular mechanisms of photoreceptor control in ROP via c-Fos remain to be determined.

Methods: Photoreceptor specific c-Fos knockout mice (c-Fos cKO) wss generated by crossing c-Fos flox/flox mice with rod photoreceptor specific Rhodopsin improved Cre mice (Rho-iCre). The oxygen induced retinopathy (OIR) mouse model was generated as a ROP preclinical mouse model. RNA Isolation, real-time PCR, western blot and immunohistochemistry were used to analyze gene expression and protein localization. Confocal imaging, fundus fluorescein angiography and HE staining were used to identify phenotypes. Adeno associated virus (AAV) was used to modulate gene expression. CUT&Tag sequencing was used to examine the targets of c-Fos. GraphPad Prism (v8.0) was used for statistical analysis.

Results: c-Fos expression was significantly induced and robustly activated in OIR retinas including photoreceptor layer at postnatal (P) 13. c-Fos deficiency in rod photoreceptors significantly reduced NV by 30% (p=0.007, n=16-26) without influencing VO (p=0.33) compared to littermate floxed controls. Pharmacologic treatment with c-Fos (AP-1) inhibitor (SR11302) and photoreceptor specific AAV shRNA subretinal delivery targeting c-Fos significantly suppressed retinal neovascularization in OIR model. CUT&Tag sequencing data showed that over 200 genes potentially bind to c-Fos at P14 only in retina with OIR not in normal control. In contrast, there were over 150 genes potentially bind to c-Fos at P14 only under normal condition but not in OIR condition.

Conclusions: These data suggest that c-Fos in photoreceptors mediates neovascularization through modulating photoreceptor-released inflammatory proteins in OIR retinas. Targeting c-Fos protected against neovascularization and may be a potential therapeutic for treating retinal angiogenesis.

ABSTRACT BODY:

Purpose: Sulfur mustard (SM) gas exposure to the eye causes severe toxicity to the cornea called mustard gas keratopathy (MGK). This study investigated delayed/chronic corneal toxicity and clinical manifestations at 1-, 2-, and 4-months in rabbit eyes in vivo exposed to SM.

Methods: The study was approved by the institutional animal care and use committee and followed ARVO guidelines. New Zealand White rabbits (n = 36) were exposed to SM vapor at a target concentration of 200 mg-min/m^3 for 8 minutes. Clinical eye manifestations in live rabbits were performed with the slit-lamp microscope, confocal HRT3 microscope, Fante's grading system, fluorescein staining, Schirmer’s tests, pachymetry, applanation tonometry, and optical coherence tomography. At the endpoints, rabbits were humanely euthanized, and corneas were collected for histological, molecular, and cellular analyses.

Results: SM exposed rabbit corneas showed a significant corneal haze (Fante’s scores 2-4; $p<0.0001$), central corneal thickness (749-560 ± 40.7; $p<0.0001$), tear flow (18-21± 2.3 $p<0.0001$), and corneal edema, decreased in keratocyte density, loss of endothelium cell number and corneal neovascularization (NV) compared to naïve untreated control corneas up to 2-month post-SM exposure. At 4-month post-SM exposure, rabbit corneas developed additional pathologies including severe ulcer of varying sizes, epithelial defects, and NV at the peri-limbal plexus regions. Also, few of the SM-exposed rabbit eyes showed ruptured cornea with iris plugged the hole and prolapsed. In these rabbits, significantly decreased central corneal thickness ($p<0.001$) and severe epithelium-erosion were observed. The clinical quantitative analyses matched typical delayed/chronic corneal pathology. Histological and molecular studies are underway.

Conclusions: Mustard gas exposure to eyes cause severe delayed/chronic corneal toxicity in rabbits in vivo. Additional analysis is warranted.

TITLE: Comparison of Combined Phacoemulsification with Ahmed Glaucoma Valve implantation and Combined Phacoemulsification with Xen Gel Stent Implantation in Patients with Primary Open Angle Glaucoma

SESSION TITLE: Surgery & Wound Healing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Rahmatnejad, F.J. Gross, Ophthalmology, Eastern Virginia Medical School, Norfolk, Virginia, UNITED STATES|N. Chaganty, Mathematics and Statistics, Old Dominion University, Norfolk, Virginia, UNITED STATES|

Commercial Relationships Disclosure: Kamran Rahmatnejad: Commercial Relationship: Code N (No Commercial Relationship) | Fredric Gross: Commercial Relationship: Code N (No Commercial Relationship) | N Rao Chaganty: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the effect of combined phacoemulsification with Ahmed glaucoma valve implantation and combined phacoemulsification with Xen gel stent implantation on intraocular pressure (IOP) of patients with primary open angle glaucoma (POAG)

Methods: In this retrospective study, we enrolled 12 patients who underwent combined phacoemulsification with Ahmed glaucoma valve implantation (group 1) and 15 patients who underwent combined phacoemulsification with Xen Gel stent implantation (group 2). All 27 patients had preoperative IOP of 18 mm Hg or higher. We compared the IOP and number of IOP-lowering medications at baseline and postoperative month 3 (POM3) between the two groups.

Results: The age mean +/- standard deviation (SD) was 64.08+/-13.50 years for group 1 and 65.53+/-9.73 for group 2. Male composed 58% in group 1 and 60% in group 2. White gender composed 41.7% and 46.7% in group 1 and 2, respectively. After confirming the normality assumption, two sample t-test was performed for the difference between the two groups. At POM3, mean IOP decreased to 14.33+/-3.45 mm Hg (44% decrease) in group 1 and 18.53+/-8.38 (26.8% decrease) in group 2 (P=0.11). The number of IOP-lowering medications decreased from 3.08+/-0.90 to 1.33+/-1.16 in group 1, and from 3.13+/-1.30 to 1.27+/-1.39 in group 2 at POM3 visit (P=0.91).

Conclusions: In this study, phacoemulsification combined with Ahmed glaucoma valve implantation was more effective at lowering IOP in comparison to phacoemulsification combined with Xen gel stent implantation, although this difference did not reach a statistically significance level. Further studies with a larger sample size might be able to show a statistically significant difference between the two procedures.

TITLE: Anti-Inflammatory and Anti-Fibrotic Activities of Human Corneal Stromal Stem Cells and Their Extracellular Vesicles Measured by in vitro Assays

SESSION TITLE: Corneal stromal biology, wound healing modulators and regeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Le, R. Knight, S. Robertson, S.X. Deng, Ophthalmology, University of California Los Angeles, Los Angeles, California, UNITED STATES|B. Le, Drexel University College of Medicine, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Bryan Le: Commercial Relationship: Code N (No Commercial Relationship) | Rob Knight: Commercial Relationship: Code N (No Commercial Relationship) | Sarah Robertson: Commercial Relationship: Code N (No Commercial Relationship) | Sophie Deng: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Human Corneal Stromal Stem Cells (CSSC) have been shown to promote regeneration of transparent stromal tissue and suppress inflammation in wounded mouse corneas. Small extracellular vesicles (sEV) secreted by these CSSC have been implicated to play a crucial role in this process. It is important to identify those CSSC that display high regenerative capacity. This study investigated the capacity of CSSC and their sEVs to suppress inflammation and fibrosis using in vitro assays.

Methods: Conditioned media of primary human CSSC were collected for sEV isolation and assay analysis. Anti-inflammatory response was evaluated using a RAW 264.7 cell assay, in which osteoclast differentiation was induced by receptor activator of nuclear factor kappa-B ligand (RANKL) and Concanavalin A. Cell morphology and mRNA level of matrix metalloproteinase 9 (MMP-9), Tartrate resistant acid phosphatase (ACP5), and Cathepsin K (CTSK) was quantified by qRT-PCR. Anti-fibrotic activity was assessed by a differentiation protocol in which primary human corneal fibroblasts differentiated into myofibroblasts after TGF-β1 treatment and were assayed for pro-collagen I alpha-1 (pro-COLIa1) level via ELISA and the protein expression of myofibroblast markers, α-smooth muscle actin (αSMA) and fibronectin extra domain-A (EDA-FN) by immunohistochemistry.

Results: Conditioned media and sEVs from primary CSSCs were capable of significantly reducing gene expression of MMP-9 (5.37 folds and 2.07 folds, respectively, $p<0.05$), CTSK (2.1 and 3 folds, $p<0.05$), and ACP5 (2.2 and 2.1 folds, $p<0.05$) compared to the positive control in the RAW 264.7 cell assay. CSSC conditioned media potency correlates with their sEVs' potency to prevent monocyte-to-osteoclast differentiation. In anti-fibrotic assays, sEVs from CSSC reduced pro-COLIa1 level by 40.9% relative to the positive control and lowered αSMA-positive cells by 32% ($p<0.001$). Among these different CSSC derived from multiple donors, one distinct donor CSSC produced sEVs that repeatedly demonstrate a higher anti-inflammatory and anti-fibrotic capacity than other CSSC ($p<0.001$).

Conclusions: The anti-fibrotic activity of sEV could be quantified using in vitro assays. There is donor variation among CSSCs and their sEVs in respect to their anti-inflammatory and anti-fibrotic capacity. The factors didact the activities of sEV remain to be elucidated.

ABSTRACT BODY:

Purpose: This study aims to 1) understand the IOP performance of 25+® Gauge (Ga) dual-cutting, 20K cuts per minute (cpm) beveled vitrectomy probes used for vitreous removal during a vitrectomy; 2) understand the operation time of vitreous removal during a vitrectomy.

Methods: 25+® HYPERVIT® beveled 20K cpm vitrectomy probes were driven by a CONSTELLATION® Vision System (Alcon Vision, LLC.) to aspirate vitreous in a hollow acrylic eye model. A digital transducer (OMEGA, PX409-001GUSBH) was connected to the bottom of eye model to detect IOP change during aspiration. 4cc of fresh porcine vitreous was filled into the eye model per testing. Six samples were tested under core duty cycle, vacuums of 250mmHg, 450mmHg and 650mmHg and cut rate of 20,000cpm. Both system IOP control enabled and disabled were used with 30mmHg as the initial IOP setting. Average IOP fluctuation during aspiration, final stable IOP, average operation time of vitreous removal were calculated for each test setting. Statistical analyses were performed on average IOP fluctuation rate using Welch's t- test with $p<0.05$.

Results: Without IOP compensation, the average fluctuation rate was -0.035 ± 0. 006mmHg/s for 250mmHg, -0.105 ± 0.008mmHg/s for 450mmHg and -0.175 ± 0.021mmHg/s for 650mmHg, which showed significant differences between each vacuum setting($p<0.05$). After enabling IOP compensation, average IOP fluctuation rate significantly reduced to 0.001±0. 005mmHg/s, 0.004 ±0.007 mmHg/s and 0.005±0.010 mmHg/s at vacuums of 250, 450 and 650mmHg($p<0.05$). There was no significant difference of IOP fluctuation rate between vacuum settings ($p>0.05$). Without IOP compensation, the final stable IOPs after removing vitreous at vacuum settings of 250mmHg, 450mmHg and 650mmHg were 22.11±1.80mmHg, 15.12± 0.41mmHg and 7.11± 1.20mmHg. With IOP compensation, the IOP level maintained at 30.75 ± 0.24 mmHg, 30.72 ± 0.84mmHg, and 30.52 ± 0.92 mmHg for the same vacuums. Corresponding operation times of complete removal of vitreous were 206s, 145s and 129s respectively.

Conclusions: During vitreous removal at the maximum cut rate, 25+® Ga 20K cpm vitrectomy probes with IOP compensation maintain IOP at improved levels with less fluctuations compared with no compensation. Using IOP compensation and 20K cpm vitrectomy probe in a 25G vitrectomy procedure can help surgeons to achieve a stable and efficient vitreous removal process.

ABSTRACT BODY:

Purpose: Ebola virus disease (EVD) survivors are at increased risk of uveitis and sequelae including cataract, which can lead to vision disability. Prior work in the EVICT study explored the short-term outcomes of cataract surgery in survivors but the long-term outcomes and the potential for Ebola virus to reside in cataract materials requires further study.

Methods: We performed a long-term analysis on EVD survivors who were enrolled in the EVICT study underwent manual small incision cataract surgery (MSICS). Patients underwent anterior chamber taps for Ebola virus (EBOV) RNA RT-PCR; those who tested negative were eligible for MSICS. Follow-up data on visual acuity (VA) and ocular complications at 3–4-months, 6 months, and 12 months post-surgery were analyzed. Histology and In situ hybridization (ISH) for EBOV RNA were performed on lens and capsular material from MSICS surgery.

Results: Clinical outcomes of 34 EVD survivors who underwent MSICS surgery were analyzed. Median preoperative logMAR (VA) was 2.65 (VA Counting fingers - Hand motions). Post-operatively, median logMAR VA improved to 0.18 at 3-4 months ($p < 0.01$) but showed slight worsening to 0.48 ($p < 0.01$) at 6 months and 0.60 ($p < 0.01$) at 12 months. Nine patients underwent an additional YAG capsulotomy procedure. Ocular adverse events within 1-3 months included recurrent uveitis (n=1, 3%). Adverse events observed at 3-4 months included vitreous opacity (n=3, 8.8%), epiretinal membrane (n=1, 3%) and panuveitis (n=1, 3%). Recurrent uveitis was observed between 6-12 months in 11 patients (32%). Other findings observed included vitreous opacity (n=5, 14.7%), epiretinal membrane (n=1, 3%), tractional retinal detachment (n=1, 3%) band keratopathy (n=1, 3%), Histopathology of cataracts and cataract nuclei (n=7) showed lens fiber vacuolation and morgagnian globules, Anterior capsules (n=2) showed mineralization and thickened capsule. Further ISH analysis of 7 lens samples showed no evidence of EBOV RNA within lens or capsular material.

Conclusions: Twelve month outcomes from the EVICT study showed that cataract surgery is safe and restored vision with no evidence of EBOV RNA within lens or capsular tissues. Secondary cataract, recurrent uveitis and retinal findings were observed although our analysis was limited by patient dropout and sample size. MSCIS surgery in EVD survivors was well-tolerated but patients required ongoing monitoring.

TITLE: The Effect of Injector Tip Shapes on Insertion During Intraocular Lens Implantation.
SESSION TITLE: Cataract surgery II
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: Y. Inoue, T. Hishida, T. Sobajima, S. Nagasaka, Kabushiki Kaisha Nidek, Gamagori, Aichi, JAPAN|
Commercial Relationships Disclosure: Yota Inoue: Commercial Relationship: Code N (No Commercial Relationship) | Takahiro Hishida: Commercial Relationship: Code N (No Commercial Relationship) | Tatsuya Sobajima: Commercial Relationship: Code N (No Commercial Relationship) | Shinji Nagasaka: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: At ARVO 2021, our team reported on the effect of differing tip shapes on IOL injectors. The study indicated resistance during insertion could be affected by shape, size, material, and surface roughness of the injector. The current study investigates the effect on insertion due purely to tip shapes using three parameters, bevel angle, slit length, and diameter of the nozzle .

Methods: We prepared a sample that was scaled up from the actual injector.
The study evaluated a control sample consisting of a round polypropylene bar (6 mm in diameter). The treatment samples included:
(1) Slit length (3, 4, 5 mm *slit width 1.2 mm) (6 mm in diameter)
(2) Bevel angle (35, 45, 55°) (6 mm in diameter)
(3) Diameter of the nozzle (4 mm from the tip – 7.0, 7.5, 8.0 mm)

The following testing procedure was used:
A silicone sheet (thickness=0.4 mm) was used to simulate a cornea. After making an incision of 6.5±0.1 mm, the injector tip was inserted in the silicone at a speed of 2 mm/sec with a universal material testing machine (AGS-50NX). (1) and (3) were inserted for 4.6 mm depth to pass common use . (2) was inserted for 9 mm depth to pass the bevel root.
The maximum value of the resistance during insertion was measured 17 times for each master model injector. The resistance values were compared between control and treatment samples. $P<0.05$ was considered statistically significant.

Results: The maximum value of insertion resistance (N) was significantly lower at all bevel angles compared to the control group as reported below:

Control group: 6.88 ±0.564 N
Bevel angle: 35 degree = 5.11 ±0.587 N ($P < 0.05$), 45° = 3.81 ±0.337 N ($P < 0.05$), 55° = 2.77 ±0.316 N ($P < 0.05$)
Slit length: 3 mm = 6.73 ±0.728 N ($P = 0.25$, t-test), 4 mm = 7.34 ±0.660 N ($P < 0.05$),
5 mm = 7.91 ±0.769 N ($P < 0.05$)
Diameter of the nozzle : 7 mm = 7.00 ±0.513 N ($P = 0.26$), 7.5 mm = 7.82 ±0.839 N ($P < 0.05$),
8 mm = 8.13 ±0.517 N ($P < 0.05$)

Conclusions: The outcomes of this study suggest that the bevel angle had the greatest effect on the ease of injector insertion. With a sharp bevel tip, the bevel root angle is more obtuse, and sudden resistance on the injector is less likely, reducing the chances of the bevel root being stuck in the incision. Therefore, injectors with a sharp bevel tip experienced significantly lower resistance when the bevel root passed through the silicone sheet.

TITLE: Predicting progression to proliferative diabetic retinopathy

SESSION TITLE: Epidemiology of Diabetic Retinopathy

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: C. Sun, Y. Guo, S. Yonamine, Ophthalmology, University of California San Francisco, San Francisco, California, UNITED STATES|C. Sun, FI Proctor Foundation, University of California San Francisco, San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure: Cathy Sun: Commercial Relationship: Code N (No Commercial Relationship) | Yian Guo: Commercial Relationship: Code N (No Commercial Relationship) | Sean Yonamine: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To develop a prediction model for progression of non-proliferative diabetic retinopathy (NPDR) to proliferative diabetic retinopathy (PDR) and to determine if incorporating additional clinical time points improves model performance.

Methods: Using de-identified electronic health records from an academic medical center, we identified a cohort of patients with NPDR at the index date. This cohort included patients with age ≥18 years, presence of type 1 or 2 diabetes mellitus, and no prior diagnosis of PDR. Patients who progressed to PDR or were lost to follow-up (censored) ≤6 months from the index date were excluded. Figure 1 illustrates our study design. Four types of models were compared: Cox proportional hazards, Cox with backward selection, Cox with lasso regression, and Random Survival Forest (RSF). Covariates were included in the models if they were significant (p-value <0.05) in the univariable Cox models or clinically relevant. For each model, three sets of covariates were compared: covariates at the index date (static model 1), covariates updated at 6-month follow-up (static model 2), and covariates at the index date plus change of time-varying covariates during the 6-month observation period (dynamic model). The data were split into 80% training and 20% testing. The model performance was evaluated by the concordance index (0-1; perfect prediction= 1).

Results: The cohort of 1107 patients had a median age of 66 years (IQR 56-74) and 547 (49%) were female. The cohort consisted of 32% white, 30% Asian, 14% Latinx, 11% black and 11% other races. The insurance types included 48% Medicare, 23% PPO/HMO, 15% Medi-Cal/Self-Pay and 14% other. 89 (8.0%) patients progressed to PDR with a median event time of 22.8 months (IQR 11.7-40). The concordance index of the trained models assessed on the test dataset are shown in Table 1. The dynamic model using RSF had the best predictive performance at a concordance index of 0.848. In this model, the variables ranked as most important were insurance, age, number of outpatient visits before the index date, mean Systolic Blood Pressure (SBP) and change in mean SBP during the observation period.

Conclusions: We developed a set of prediction models for progression of NPDR to PDR that achieved high performance (concordance index >0.7). The dynamic model that incorporated the change in clinical variables during the 6-month observation period had the best performance.

ABSTRACT BODY:

Purpose: To give an update on our recent progress in measurements and interpretation of the optoretinograms (ORGs) i.e., detection of light-evoked functional retinal responses using Optical Coherence Tomography. To present the design and implementation of mouse retinal Full Field Swept Source Optical Coherence Tomography (FF-SS-OCT) system for high-speed measurements of mouse retinal ORGs.

Methods: Albino mice were imaged in vivo with a custom mouse retinal FF-SS-OCT employed with a light stimulation channel to allow measurements of high-speed mouse retinal ORGs. For comparison, the same mice were evaluated using our standard ORG probing setup using Scanning Light Ophthalmoscopy / Optical Coherence Tomography (SLO/OCT) retinal imaging system. Before the ORG experiments, mice were dark-adapted. Both intensity-based ORG analysis (time-dependent changes of the depth scattering profiles of retinal layers), and phase-based ORG analysis (time-dependent changes of the phase difference (path length) between retinal layers) have been extracted from the ORG data sets.

Results: The depth scattering ORG profiles extracted using the SLO/OCT system and FF-SS-OCT reveal similar correlations between depth positions and intensity of different retina bands. The phase-based ORG signals extracted from the same data sets, although more sensitive to retina motion and more computationally demanding, provided an order of magnitude higher sensitivity of detecting changes in retina layer positions. The application of FF-SS-OCT system allowed observation of the fast ORG responses in mouse retina with much higher precision if compared to the ORGs extracted using raster scanning SLO/OCT retinal imaging system.

Conclusions: Successful implementation of phase-based ORG signal analysis in mice for data acquired with the SLO/OCT system and FF-SS-OCT allowed direct comparison of the results. Implementation of FF-SS-OCT for extraction of ORG signals opens the possibility of future studies of the fast ORG response in mice, potentially allowing separation of Cone and Rod-based ORGs and direct correlation of the ORGs with the ERGs (electroretinograms). However, slow ORG signals connected with light-evoked water movements between different compartments of the retina can still be more efficiently studied with our standard raster scanning SLO/OCT retinal imaging system.

ABSTRACT BODY:

Purpose: The MerTK tyrosine kinase receptor is a key element of the retinal pigment epithelial (RPE) phagocytic machinery required for photoreceptors (PRs) survival. Recently, we showed this receptor is subjected to the cleavage of its extracellular domain as a way of finely controlling its function. We thus investigated the ocular phenotype of MerTK cleavage-resistant ($MerTK^{CR}$) mice devoid of the cleavage site.

Methods: $MerTK^{CR}$ and control mice were monitored between the ages of 3 and 18 months using fundus photography (FP), autofluorescence (AF) detection, optical coherence tomography (OCT), electroretinography (ERG), optokinetic behavioral tests as well as paraffin-embedded and electron microscopy (EM) tissue sections. Survival of bone-marrow macrophages (BMMs) was assessed in pig primary RPE co-cultures. Mitochondrial activity and energy sources use were evaluated with the Seahorse technology on freshly-dissected RPE/choroid and retina tissues.

Results: Our first cohorts showed large degenerative areas in the central retina associated with AF, in males and then in females, only when followed monthly by OCT plus FP/AF but not by OCT alone. We thus hypothesize that $MerTK^{CR}$ mice might be light-sensitized by the FP and AF lamp bulbs. Besides thinning of the photoreceptor layer, macrophages infiltration was observed by OCT. Though, $MerTK^{CR}$ BMMs do not survive more than controls in primary RPE co-cultures, suggesting that observed macrophages could be linked to decreased RPE immunosuppressivity rather than to increased BMMs survival potential. At the EM level, RPE anomalies were detected including phagosomes retained in the apical area and abnormal mitochondria. Accordingly, mitochondrial function and energy production are reduced in RPE/choroid tissues.

Conclusions: Current experiments are testing which cell type carries the light sensitivity, assessing macrophages infiltration after laser impacts and exploring in vivo BMMs survival after adoptive cross-transfers between $MerTK^{CR}$ and control mice. As well, the RPE phagocytic profile is being explored both in vitro and in vivo. All together, this new mouse model displays a novel phenotype that could prove useful to understand the interplay between RPE and PRs in inflammatory retinal degenerations and highlight a new role for MerTK in the maintenance of the immune privilege in the retina.
