Results: Among 4441 children, 2718 (weighted-percentage 58.7%) were clinically assessed. Refractive errors were reported in 43.1% (95% confidence interval 37.6-48.4), 35.2% (32.7-37.6) and 28.4% (25.0-31.8) of children born at 24-26, 27-31, 32-34 WG, respectively. Strabismus was reported in respectively 19.5% (14.6-24.4), 14.8% (12.9-16.7), 8.3% (6.2-10.4). Both impairments presented a significant increase of prevalence while GA decrease ($p<.001$). Among term-born children, refractive errors prevalence was 24.1% (19.1-29.7) and strabismus prevalence was 2.8% (1.0-5.3). Severe/moderate visual deficiencies (<3.2/10) were present in 1.7% (0.2-3.3) of 24-26WG and in less than 1% for other groups. A 10/10 binocular visual acuity was measured for 28.6% (24.0-33.3) of 24-26WG, 35.1% (32.8-37.4) of 27-31WG and 36.0% (32.5-39.5) of 32-34WG Versus 59.7% (53.9-65.4) of reference group. Presence of a Cerebral Palsy at $5^{1/2}$ had a stronger association with visual deficiencies and sub-optimal visual acuity than ROP during neonatal period.

Conclusions: We report in a large cohort of preterm born children high prevalence of refractive errors and strabismus even in children born very and moderate preterm supporting a specific attention for these children. Low prevalence of 10/10 visual acuity, even with glasses, at the age of reading and writing acquisitions could represent an additional challenge.

TITLE: Comparison of peripheral visual field defects on static and kinetic visual field testing in Asian versus Caucasian subjects

SESSION TITLE: Visual Fields and Psychophysics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.D. Hammer, S. Jamali Dogahe, S. Sadegh Mousavi, C. Khanna, Ophthalmology, Mayo Clinic Minnesota, Rochester, Minnesota, UNITED STATES|

Commercial Relationships Disclosure: Jon Hammer: Commercial Relationship: Code N (No Commercial Relationship) | Sepideh Jamali Dogahe: Commercial Relationship: Code N (No Commercial Relationship) | Seyedmostafa Sadegh Mousavi: Commercial Relationship: Code N (No Commercial Relationship) | Cheryl Khanna: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To compare peripheral visual field testing in Asian vs. Caucasian subjects without ocular pathology

Methods: Subjects with no identifiable ocular pathology and normal optical coherence tomography tests were included. A previously validated three-dimensional facial reconstruction model was used to predict peripheral visual field defects. Static 60-4 Humphrey visual field testing and kinetic visual field testing were performed, and results were compared between the Asian and Caucasian groups.

Results: Thirty-four eyes from 17 healthy subjects were enrolled including 12 Asians of Chinese descent (5 males, 7 females) and 5 Caucasians (2 males, 3 females). On kinetic visual field testing, the Asian group had significantly increased mean nasal (62.7 vs 57.2 degrees OD, p=0.02; 62.3 vs 55.2 degrees OS, p=0.005), and inferonasal (59.3 vs 52.4 degrees OD, p=0.02; 60.7 vs 55.6 degrees OS, p=0.01) peripheral field of vision compared to the Caucasian group in both right and left eyes. No significant difference was noted temporally and inferotemporally between the two groups. On static 60-4 testing, the Asian group had higher mean inferonasal quadrant threshold values that did not reach statistical significance (443 vs 380 dB OD, p=0.07; 431 vs 385 dB OS, p=0.18) while the inferotemporal quadrant threshold values were very similar between the two groups (504 vs 508 dB OD, p=0.66; 506 vs 511 dB OS, p=0.71).

Conclusions: Caucasian subjects in this study had a reduction in nasal field compared to Asian control patients, likely due to differences in facial contour, specifically a more prominent nasal contour in Caucasian subjects. This difference in facial contour among races may be relevant in development of normative 60-4 data.

ABSTRACT BODY:

Purpose: The purpose of this retrospective study was to determine if correction of non-strabismic binocular visual dysfunction using the Neurolens® system improves symptoms of patients with multifactorial dry eye disease.

Methods: The Neurolens® system measures eye misalignments as small as 0.1 prism diopters using an electronic eye tracking system, and accordingly fits patients with customizable prescription lenses with a specialized contoured prism. A retrospective review was conducted on all patients treated in the Scheie Eye Institute Dry Eye Clinic at the University of Pennsylvania who were also prescribed lenses using the Neurolens® system. Patients held the diagnosis of multifactorial dry eye disease including meibomian gland dysfunction, tear film insufficiency, and/or Sjogren's disease. All patients also received ongoing traditional treatments for dry eye. Data including patient age, sex, visual acuity, clinical exam findings, and symptoms evaluated by the Ocular Surface Disease Index (OSDI) was collected before and after prescription of the lenses.

Results: Thirteen patients were included in the study, and 14 were excluded due to lack of follow up. The average age of patients was 53.5 years old (SD 16.7). 85% of patients were female and 15% male. The average follow up time was 6.3 months (SD 2.63). There was no significant change in visual acuity on follow up (p=0.46). When asked if they felt if the lenses improved their symptoms, 9 out of 13 (69%) of patients reported improvement after prescription of Neurolens®. This was also evidenced by a statistically significant decrease in average OSDI score from baseline to follow-up after prescription of lenses (47.2 vs 38.0, p=0.03). There was no significant difference in conjunctival or corneal staining on slit lamp examination on follow up (p=0.34).

Conclusions: We conclude that correction of non-strabismic binocular visual dysfunction in patients with multifactorial dry eye disease, along with traditional dry eye treatment modalities, results in a statistically significant decrease in OSDI scores. Improvement in OSDI scores without change in conjunctival or corneal staining suggests that correction of misalignment, rather than any modulation of the ocular surface with additional treatments, improved symptoms. This study helps provide supporting evidence for an innovative non-invasive treatment for dry eye patients.

ABSTRACT BODY:

Purpose: To calculate and compare the average interval between injections of Aflibercept (AFL), Bevacizumab (BEVA), and Ranibizumab (RAN) for patients with diabetic retinopathy (DR).

Methods: A retrospective cohort study was performed at a private retinal practice in Ohio. The Institutional Review Board (Sterling) determined this study consisted of non-human subjects. All data was collected through the practice management of Retina Associates of Cleveland, Inc. Data was collected from patients who received injections of AFL, BEVA, and RAN from July 2020 through June 2021 and includes: patient number, injection service dates, anti-vegf drug injected, procedure codes, and primary diagnoses. The patients were limited to those injected unilaterally and diagnosed with DR, and the number of days between injection service dates was calculated for each injection. The data set was then organized by primary diagnosis and injection type, and the average number of days between injection service dates was determined for DR and each corresponding drug. Statistical analysis included calculating the average interval in days between injections for each medication, standard deviation, and two tailed t-test for comparison between medications.

Results: From July 2020 through June 2021, 14,911 injections were placed unilaterally for any diagnosis. There were 1,313 injections for DR with an average interval between injections of 70 days for all medications. Of the DR injections, the average interval was BEVA 69 days with standard deviation (SD) +/- 56 days, AFL 71 days SD +/- 53 days , and RAN 70 days SD +/- 63 days. In comparing the interval of BEVA versus AFL, the two-tailed t test yields a p value = 0.591; BEVA vs. RAN p = 0.886; AFL vs. RAN p= 0.961.

Conclusions: The results of the study suggest that AFL, RAN and BEVA seem to have similar interval of injections for DR.

TITLE: Pigmented mouse with a tyrosinase mutation as a model for nystagmus

SESSION TITLE: Eye movements and nystagmus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Johnson, L.K. McLoon, Ophthalmology and Visual Sciences, University of Minnesota Twin Cities, Minneapolis, Minnesota, UNITED STATES|

Commercial Relationships Disclosure: Laura Johnson: Commercial Relationship: Code N (No Commercial Relationship) | Linda McLoon: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Infantile nystagmus syndrome (INS) is a gaze-holding disorder characterized by conjugate, uncontrolled oscillation of the eyes that can result in significant loss of visual acuity. However, a large number of INS patients have no known cause in the absence of known sensory afferent defects or previously identified genetic mutations. Using the albino mouse as a model for nystagmus, we tested the optokinetic nystagmus reflexes (OKN) of a mouse strain developed from C57BL6 mice with a mutation in the tyr gene making them phenotypically albino. We performed RNAseq on the extraocular muscles (EOM) and abducens (CN6) and oculomotor (CN3) neurons from B6(CG)-Tyr(c-2J)/J and C57BL6 mice in an attempt to discover molecular differences that may account for nystagmus.

Methods: OKN was measured in C57BL6 and the B6(CG)-Tyr(c-2J)/J mice using an iSCAN system. EOM, tibialis anterior (TA), neuronal populations from CN3 and CN6 isolated en block were dissected from the C57BL6 and B6(CG)-Tyr(c-2J)/J mouse strains. RNA was isolated using a Qiagen kit, and RNAseq analyses were performed. RNA expression levels were compared between the strains to determine genes that were over or under-expressed in the normal compared to the nystagmus mice. We validated candidate genes with a 2-fold difference using PCR and immunohistochemical staining of mouse and surgical waste tissues in children with INS.

Results: All the B6(CG)-Tyr(c-2J)/J mice tested had a nystagmus phenotype when measured with OKN, while the C57BL6 mice had normal OKN. Differential expression analysis from the RNA isolated from the B6(CG)-Tyr(c-2J)/J mice compared to the C57BL6 showed 286 genes differentially expressed in the EOM, 11 genes differentially expressed in the CNs, and 2 genes differentially expressed in all four tissue types: wdfy1 and nnt. Wdfy1 showed decreased immunostaining in rectus muscle samples from human nystagmus subjects compared to controls.

Conclusions: The B6(CG)-Tyr(c-2J)/J mice have nystagmus but, except for the mutation in the tyr gene, are genetically very similar to the C57BL6 mice. Wdfy1 and nnt have been implicated in mitochondrial dysfunction and in maintenance of stem cells in other systems, but their function in the extraocular muscles is unknown. These studies suggest that this mouse model of nystagmus makes them a prime candidate for studying differentially expressed genes between normal and nystagmus mouse groups.

ABSTRACT BODY:

Purpose: To report a series of endophthalmitis cases associated with intravitreal dexamethasone implant injections in a single practice and discuss the clinic findings and visual outcomes associated with each case.

Methods: This retrospective consecutive case series identified all cases of endophthalmitis after intravitreal dexamethasone injection performed from January 1, 2014 to October 20, 2020 using the Wills Eye Hospital / MidAtlantic Retina billing record database. Each case was reviewed to confirm diagnosis of endophthalmitis, demographic and clinical information, and microbiology. Data was analyzed using Excel (Microsoft Excel, Redmond, Washington, USA).

Results: Five cases of endophthalmitis were identified from 3,925 intravitreal dexamethasone injections, resulting in an incidence of 0.13% (1 in 785 injections). Mean age was 82.3 years (range, 63 – 88 years) with a mean of 11.3 intravitreal dexamethasone injections performed (range, 2 – 30 injections) prior to developing endophthalmitis. Cases presented with endophthalmitis a mean (SD) of 3.6 (1.64) days after the causative injection. Three cases grew gram-positive organisms on culture, while the other two cases were culture negative. All five patients responded to a single intravitreal tap and injection of vancomycin and ceftazidime. Mean logMAR visual acuity was 0.44 (20/55) at the time of the causative injection, 2.22 (20/3319) at endophthalmitis presentation, 1.18 (20/303) at three month follow up, and 1.46 (20/577) at last recorded follow up.

Conclusions: Endophthalmitis following intravitreal steroid injections may occur more frequently than after other intravitreal injections. Endophthalmitis following intravitreal dexamethasone implant injection remains an uncommon event. Eyes responded to treatment with intravitreal antibiotics, however the visual outcomes are variable.

ABSTRACT BODY:

Purpose: To determine the incidence and risk factors for rhegmatogenous retinal detachment (RRD) and retinal tears (RT) following cataract surgery.

Methods: Retrospective, cohort analysis of the IRIS Registry was performed. Eyes of patients aged 40 years or older undergoing cataract surgery from 2014-2017 were included. Eyes with history of RRD or RT were excluded. Incidence of RRD and RT, identified using relevant CPT codes, within one year after cataract surgery were the primary outcomes. Multivariable logistic regression was used to evaluate risk factors for RRD and RT after cataract surgery including demographic features (age, sex, race, ethnicity), ocular comorbidities (lattice degeneration, posterior vitreous detachment (PVD), high myopia), and intraoperative factors (hypermature cataract, pseudoexfoliation, floppy iris syndrome, complex surgery CPT code).

Results: Of 3,177,195 eligible eyes (1,983,712 patients), RRD and RT occurred in 6,690 (0.21%) and 5,489 (0.17%) within one year after cataract surgery. Logistic regression odds ratios (OR; 95% CI) showed increased risk of RRD (OR=3.12; 95% CI=2.96-3.28; P<0.001) and RT (OR=1.88; 95% CI=1.78-1.98; P<0.001) for males vs females. Risk was higher in younger patients compared to older patients (ages > 70 yrs), peaking at ages 40-50 yrs for RRD (OR=9.67; 95% CI=8.71-10.74; P<0.001) and ages 51-60 yrs for RT (OR=4.3; 95% CI=3.96-4.66; P<0.001). RRD and RT risk increased in eyes with lattice degeneration (OR=11.09; 95% CI=10.36-11.87; P<0.001 and OR=44.33; 95% CI=41.88-46.92; P<0.001), high myopia (OR=1.35; 95% CI=1.27-1.42; P<0.001 and OR=1.38; 95% CI=1.3-1.46; P<0.001), and eyes with PVD (OR=1.48; 95% CI=1.38-1.6; P<0.001 and OR=1.53; 95% CI=1.42-1.66; P<0.001). Complex surgery CPT code increased RRD risk (OR=1.33; 95% CI=1.23-1.45; P<0.001).

Conclusions: Analysis of the IRIS Registry revealed RRD and RT incidence are low (0.21% and 0.17%, respectively) within one year after cataract surgery. Lattice degeneration, younger age, male sex, PVD, and high myopia conveyed increased risk for RRD and RT. These low incidence rates and risk factors are consistent with prior studies supporting their validity. These data from a large, national database may aid in pre-operative counseling of prospective cataract surgery patients.

TITLE: Mapping the universe of Eph and ephrin transcripts in adult mouse lenses

SESSION TITLE: Cataractogenesis: pathogenesis, prevention and treatment

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S. Murugan, C. Cheng, School of Optometry and Vision Science Program, Indiana University, Bloomington, Indiana, UNITED STATES|

Commercial Relationships Disclosure: Subashree Murugan: Commercial Relationship: Code N (No Commercial Relationship) | Catherine Cheng: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The Eph-ephrin bidirectional pathway involves receptor-ligand interaction to initiate intracellular signaling. Transmembrane Eph receptors are divided into two subclasses, EphAs (9 members, A1-8 and A10) and EphBs (5 members, B1-4 and B6), and the membrane-bound ephrin ligands are classified as ephrin-As (5 members, A1-5) and ephrin-Bs (3 members, B1-3). Mutations in EphA2 and ephrin-A5 have been associated with cataractogenesis in humans and mice. Genetic tests reveal that EphA2 and ephrin-A5 are not a receptor-ligand pair in lens epithelial cells, and thus, other isoforms of ephrins and Ephs must interact with EphA2 and ephrin-A5, respectively to maintain lens epithelial cell homeostasis. We determined which isoforms of Ephs and ephrins are expressed in adult mouse lenses.

Methods: Whole lens RNA samples from adult wild-type (WT), EphA2 knockout (KO), and ephrin-A5 KO mice were tested for the expression of different Eph and ephrin transcripts using reverse-transcription, qualitative PCR, and sequencing. Tissues, such as the brain, lungs, liver, that have previously been shown to express specific Eph or ephrin transcripts were used as positive controls. Primer pairs were designed for each Eph and ephrin isoform and known variant expressed in mouse tissues using the NCBI Primer-BLAST tool.

Results: We verified the presence of transcripts from 6 Eph receptors and 5 ephrin ligands in adult mouse whole lens RNA samples. In addition to EphA2, adult mouse lenses express EphA1, EphB2 (variant 2), EphB3, EphB4 (variant 2), and EphB6. In these samples, we also detected ephrin-A1 (variant 1), ephrin-A2, ephrin-A4, ephrin-A5 (variants 1 and 2), and ephrin-B1. EphA3-A8, EphA10, and EphB1 were detected in other positive control tissues, but not in whole lens WT or KO RNA samples. Ephrin-A3, ephrin-B2, and ephrin-B3 were also not detected in these lenses.

Conclusions: This data confirms that, in addition to EphA2 and ephrin-A5, other isoforms of Ephs and ephrins are also expressed in the adult mouse lens. It is highly likely that ephrin-A1 or -A4 interacts with EphA2 to organize equatorial epithelial cells into hexagonal cells aligned into meridional rows, and similarly, it’s possible that EphA1 interacts with ephrin-A5 to maintain the quiescence of the anterior epithelium. We are currently investigating the localization of these Eph and ephrin isoforms in the epithelial and fiber cell compartments of the lens.

TITLE: Normative exophthalmometry values in Hispanic individuals

SESSION TITLE: Oculoplastics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Cheng, F. Wang, K. Denisova, A. Barmettler, Albert Einstein College of Medicine, Bronx, New York, UNITED STATES|

Commercial Relationships Disclosure: Tiffany Cheng: Commercial Relationship: Code N (No Commercial Relationship) | Fei Wang: Commercial Relationship: Code N (No Commercial Relationship) | Ksenia Denisova: Commercial Relationship: Code N (No Commercial Relationship) | Anne Barmettler: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose:

Orbital anthropometric values vary among ethnic groups. To date, no studies have established normative exophthalmometry values in individuals of Hispanic descent. The purpose of this prospective, observational study was to establish a set of exophthalmometry values and their correlates in the Hispanic population of the Bronx.

Methods:

Two hundred and thirty-eight Hispanic individuals ranging from 9 to 94 years of age recruited at Montefiore Medical Center outpatient clinics from January 2021 to December 2021 were included in the study. Demographic variables including age, sex, ethnicity/race, height, weight, and BMI were collected. The Hertel exophthalmometer was used to determine the degree of ocular prominence (exophthalmometry value, EV) and the inter-orbital distance (Hertel's base, IOD) in each patient. Differences in EV between sexes were evaluated using two sample t tests. Pearson's R was utilized for correlation determination. Multivariable linear regression was utilized to determine the effect of age, sex, and BMI on exophthalmometry values.

Results:

Of the 238 Hispanic patients included, 160 (67.2%) were female and the mean age was 61.1 years (SD=16.3). The mean Hertel's base for all participants was 92.0 mm (SD=4.1), 94.0 mm (SD=3.8) for men and 91.0 mm (SD=3.9) for women. The mean EV for all Hispanic individuals was 16.7 mm (SD=2.4). The mean EV for men was 17.5 mm (SD=2.6) and for women was 16.2 mm (SD=2.1). Exophthalmometry values for men were statistically significantly higher than women's ($p=0.0001$). EV was significantly associated with female sex ($\beta= -1.58$, $p<0.0001$) and BMI ($\beta= 0.091$, $p=0.001$), but not age.

Conclusions:

It is well-established that the degree of ocular prominence varies between ethnic groups. The mean EV in Hispanic individuals is 16.7 mm, higher than that of most Caucasians and Asians, but less than that of Black patients. EV was significantly associated with sex and BMI. This study is the first to create a set of normative exophthalmometry values in the Hispanic population, which may serve as a valuable tool for clinicians to reference when diagnosing and monitoring orbital disease.

ABSTRACT BODY:

Purpose: This study evaluated the relationship between retinal thickness parameters and response to anti-VEGF therapy in patients with diabetic macular edema (DME).

Methods: Patients receiving their first anti-VEGF injection for DME between 1/2016-12/2019 with ≥6 months of follow-up were included. Mean change in logMAR equivalent visual acuity (VA) over 6 months was assessed. Thresholds for VA and central retinal thickness (RT) improvement (Table 1) categorized eyes as “good” (VA and RT response), “VA only” (VA response only), “RT only” (RT response only) or “poor” (neither VA nor RT response) responders. Poor responders that received <3 injections were excluded. Inner (IRL) and outer retinal layer (ORL) thickness on optical coherence tomography (OCT) was measured using automated segmentation software (Figure 1, Heidelberg V6.14, Germany).

Results: For the 126 subjects (151 eyes), mean±SD age was 60±13yrs, diabetes duration 22±11yrs, A1c 8.7±2.0%, 71.5% type 2 diabetes, and 46.4% female. Amongst the whole cohort, 57.0% of eyes met thresholds for VA response and 43.7% for RT response: 32.5% good responders, 21.9% VA only, 11.3% RT only and 34.4% poor responders. Improvement in mean VA was associated with younger age (β=.004; 95% CI 0.001-0.007; P=.01), but not with diabetes duration, diastolic or systolic blood pressure, A1c, lipids or baseline diabetic retinopathy severity (all P>.05). Less vision gain was associated with decreased ORL thickness (β=-.003; 95% CI -0.006 to -0.001; P=.01) and increased IRL thickness at baseline (β=.0004; 95% CI 0.0001-0.0007; P=.02). No baseline demographic characteristics were significantly associated with treatment response group. Baseline ORL, but not IRL, thickness was associated with treatment response group at 6 mo (β=-.018; 95% CI -0.03 to -0.01; P=.006). In general, decreased ORL thickness was more likely to be present in eyes with poorer response to anti-VEGF.

Conclusions: In this cohort of patients with DME, ORL thickness was correlated with mean VA gain and likelihood of both VA and RT improvement in response to anti-VEGF therapy. Decreased baseline ORL thickness was associated with less favorable anatomic and functional outcomes after anti-VEGF therapy. These data suggest that baseline outer retinal thickness in patients undergoing anti-VEGF treatment for DME might be a useful biomarker for treatment response.

ABSTRACT BODY:

Purpose: Lifelong transparency and focusing ability of the lens depends on the precise alignment of equatorial epithelial cells that differentiate into secondary fiber cells during lens development and morphogenesis. During this process, the equatorial epithelial cells transform from randomly packed cells into precisely aligned, hexagonally shaped meridional row cells that elongate to form the hexagonally packed, long fiber cells. Here, we investigate the function of Non-muscle Myosin IIA (NMIIA) (Myh9) in regulating equatorial epithelial cell alignment (meridional row cells) & fiber cell morphogenesis.

Methods: We used genetic knock-in mice to study two Myh9 mutations, R702C in the motor domain and E1841K in the rod domain. The R702C mutation impairs motor function and contractility, while the E1841K mutation disrupts bipolar filament assembly. Images of dissected lenses were acquired using a digital camera to check for cataracts. Lens equatorial cryosections and whole mounts were stained with fluorescent phalloidins (actin filaments; F-actin) and Hoechst (nuclei) and imaged by confocal microscopy to investigate the cellular organization.

Results: Neither mutation causes cataracts or opacities, and no major defects in cell organization are observed in R702C mutant mice. By contrast, the E1841K mutation results in disordered fiber cell packing in equatorial cryosections. Imaging of the equatorial epithelium and peripheral fiber cells in E1841K lenses also reveals meridional row misalignment, and peripheral fiber cell disorder, and variable widths. This indicates that epithelial cells with the E1841K mutation become misaligned during their initial rearrangement into meridional rows, with misalignment persisting during fiber cell elongation.

Conclusions: Disrupted bipolar filament assembly, due to the E1841K mutation, causes misaligned meridional row alignment and disordered fiber cells, while impaired force generation, due to the R702C mutation, does not. Since R702C can still exert tension by cross-linking F-actin, we propose that actomyosin organization, conferred by bipolar filaments' cross-linking F-actin, is important for cell tension and meridional row alignment. These results indicate a novel function of NMIIA in regulating the alignment of lens epithelial cells during their transformation into precisely aligned and hexagonally packed fiber cells.

ABSTRACT BODY:

Purpose: The calculation of the retinal magnification factor (RMF) is a first step towards determining retinal feature sizes in units of length. This is particularly important for the creation of normative databases of adaptive optics (AO) ophthalmoscopy biomarkers, such as cell size, cell density, and vessel diameter. Accurate RMF calculation relies on the individualization of schematic eyes through the incorporation of ocular biometry data. Here we compare four paraxial schematic eyes commonly used in AO retinal imaging, against a new individualized schematic eye, in which each of its four surfaces is estimated from ocular biometry and the media between them is assumed to have homogeneous refractive indices.

Methods: The anterior and posterior surfaces of the cornea and crystalline lens were imaged with an ocular biometer (HP-OCT, Cylite, Notting Hill, Australia), and fitted to a linear combination of ANSI standard Zernike polynomials up to 10th order. Using the optical path length between each surface for each ray returned by the biometer, index-corrected surfaces were generated using real ray tracing. Real ray tracing through these surfaces was then used to calculate the RMF at the preferred retinal locus of fixation (PRL) in individualized four-surface schematic eyes.

Results: Across a sample of 23 eyes of 17 subjects and with spectacle prescription in the -5.5D to +1D, the comparison of the paraxial RMF calculations and the proposed RMF differ by us much as 5.0% (mean 1.5%). Importantly, the incorporation of decentering and tilt of the optical surfaces results in RMF changes with orientation that in our dataset are as large as 2.5%.

Conclusions: A novel RMF calculation method that uses four ocular surfaces estimated using optical biometry is demonstrated and tested in a small subject cohort. The method could be refined by incorporating the refractive index variations within the crystalline lens, whenever these can be experimentally measured in the intact living eye.

ABSTRACT BODY:

Purpose: To review published peer-reviewed reports of massive suprachoroidal hemorrhage (MSCH) between 1990 and 2021.

Methods: We performed a systematic review and meta-analysis of published reports of MSCH, defined as ≥ 2 quadrant involvement, macular involvement, kissing, expulsive, or otherwise defined as “massive” by authors, published between January 1990 and May 2021. The search terms “suprachoroidal hemorrhage”, “choroidal hemorrhage”, “hemorrhagic choroidal detachment”, and “expulsive choroidal hemorrhage” were used to query PubMed, EMBASE, Web of Science, and Google Scholar, and studies with ≥ 3 patients with MSCH and ≥ 3 months follow up were included. Study- and patient-level data including demographics, risk factors, precipitating event, timing of hemorrhage, treatment, pre- and post-treatment best corrected visual acuity (BCVA), anatomic success, and complications were extracted and analyzed using OpenMeta[Analyst] software.

Results: Sixty-four studies including 1423 eyes of 1409 patients with mean (SD) age 62.4 (17.2) years were included. Precipitating event types included 1279/1412 (90.6%) perioperative, 90/1412 (6.3%), traumatic, and 41/1412 (2.9%) spontaneous. The mean (SD) number of quadrants involved was 3.8 (0.4), with 230/330 (71%, 95% CI 60-81%) macular involving, 312/622 (64%, 95% CI 52-76%) kissing, and 160/383 (40%, 95% CI 24-57%) expulsive. 655/1166 (64%, 95% CI 54-74%) eyes were treated surgically, with mean (SD) time until surgery of 9.5 (9.3) days. Patients were followed for mean (SD) 15.0 (9.4) months. Mean (SD) logMAR BCVA was 2.4 (0.3) pre-treatment and 1.6 (0.6) post-treatment. 176/268 (71%, 95% CI 61-80%) eyes achieved improvement in logMAR BCVA (Figure 1) and 136/223 (67%, 95% CI 55-78%) eyes achieved anatomic success (Figure 2) defined as attached macula at last follow up.

Conclusions: In this meta-analysis of published reports of MSCH, the majority of cases were perioperative, with many cases involving the macula, kissing choroidal detachments, or expulsive hemorrhage. Approximately two-thirds of eyes were treated surgically. A majority of eyes experienced some improvement in logMAR BCVA or anatomic success at last follow up, but vision remained limited. Predictors for BCVA improvement and anatomic success are the subject of ongoing analyses.

ABSTRACT BODY:

Purpose: Purpose: To assess and validate a deep learning algorithm to automatically detect incomplete retinal epithelial pigment and outer retina atrophy (iRORA) and complete retinal epithelial pigment and outer retina atrophy (cRORA) in eyes with age-related macular degeneration (AMD).

Methods: Methods: A Resnet18 model was trained to jointly classify the presence of iRORA and cRORA within a given B-scan. The training dataset consisted of OCT B-scans from patients with nonneovascular AMD captured at the Doheny-UCLA Eye Centers were annotated by an experienced grader for the presence of iRORA and/or cRORA: 101 OCT volumes (6,138 OCT B-scans) from subjects with diagnosis of intermediate/late AMD without evidence of macular neovascularization (MNV) and 87 OCT volumes (4,128 OCT B-scans) from 34 subjects with early and intermediate AMD without evidence of iRORA. The algorithm was validated on two separate and independent datasets.

Results: Results: Model performance was quantified in terms of area under the receiver operating characteristic curve (AUROC) and area under the precision-recall curve (AUPRC). On an independently collected test set consisting of 1117 volumes sampled from the general population, the model predicted iRORA and cRORA presence within the entire volume with nearly perfect AUROC performance, and AUPRC scores: iRORA: 0.61, 95% CI (0.45, 0.82), cRORA: 0.83, 95% CI (0.68, 0.95). On another independently collected set of 60 OCT B-scans, which was enriched for iRORA and cRORA lesions, the model performed with AUROC (iRORA: 0.68, 95% CI (0.54, 0.81); cRORA: 0.84, 95% CI (0.75, 0.94)) and AUPRC (iRORA: 0.70, 95% CI (0.55, 0.86); cRORA: 0.82, 95% CI (0.70, 0.93)).

Conclusions: Conclusions: A deep learning model can accurately and precisely identify both iRORA and cRORA lesions within a volume scan, despite the performance not being as good for any single OCT B-scan within volume. Notably, the model can achieve similar or better outcomes compared to human graders, thus potentially obviating a laborious and time-consuming annotation process.

ABSTRACT BODY:

Purpose: The mitochondrial genes TXNRD2 and ME3 are associated with POAG risk in genome-wide association studies (GWAS). These genes may functionally contribute to POAG by altering NADPH levels and oxidative stress response. To assess the impact of these variants, we investigated whether a genetic risk score (GRS) of TXNRD2 and ME3 variants correlates with patient clinical phenotypes.

Methods: 2617 POAG cases from the NEIGHBORHOOD consortium were included in this study. All single nucleotide polymorphisms (SNPs) in the TXNRD2 and ME3 loci associated with POAG ($p<0.05$) were identified using GWAS data. Of these, 20 TXNRD2 and 24 ME3 SNPs were selected for analysis after adjusting for linkage disequilibrium. After aligning alleles for risk, a GRS was constructed for each POAG case using the unweighted sum of POAG risk alleles; this was performed for TXNRD2 SNPs, ME3 SNPs, and TXNRD2+ME3 SNPs combined. The clinical features of individuals in the top 1, 5, 10 and 25% of genetic risk were compared to individuals in the bottom 1, 5, 10 and 25%, respectively. Clinical features examined included age at diagnosis, intraocular pressure (IOP), cup-to-disc ratio (CDR), visual field mean deviation (MD), incidence of paracentral field loss, and need for glaucoma surgery.

Results: Individuals in the top 1% of TXNRD2 GRS had higher mean maximal IOP compared to the bottom 1% (19.9 mmHg in top 1% vs 15.6 mmHg in bottom 1%, $p<0.05$). Individuals in the top 1% of ME3 and TXNRD2+ME3 GRS had greater incidence of paracentral visual field loss (72.7-89% in top 1% vs 14.3-33% in bottom 1%, $p<0.05$ for both). Individuals in the top 5% of ME3 and top 10% of TXNRD2+ME3 GRS had greater mean maximal CDR (0.83 in top 5/10% vs 0.80 in bottom 5/10%, $p<0.05$). There was a trend toward significance for age at diagnosis in the top 10% of TXNRD2+ME3 GRS (63.8 years in top 10% vs 65.6 years in bottom 10%, $p=0.053$).

Conclusions: POAG patients with higher GRS for TXNRD2 and ME3 variants have greater maximal IOP and CDR as well as greater incidence of paracentral field loss. These data suggest that TXNRD2 and ME3 functionally contribute to POAG development and disease severity, potentially through a mechanism that involves NADPH levels. Future prospective clinical studies and translational mechanistic studies will help enable precision medicine approaches to POAG risk stratification and treatment.

ABSTRACT BODY:

Purpose: Presbyopia is an age-related condition in which the eye exhibits a diminished ability to focus on near objects. VUITY^{TM} (pilocarpine HCl ophthalmic solution) 1.25% was recently approved in the US as the first and only prescription eye drop to treat presbyopia. The purpose of this study was to evaluate the systemic pharmacokinetics (PK) of pilocarpine following once daily administration of VUITY for 30 days.

Methods: Steady-state systemic PK of pilocarpine was assessed in 22 participants following bilateral, once-daily topical ocular administration of VUITY for 30 days. PK samples were collected on Day 1 at predose and on Day 30 at predose and 0.25, 0.5, 1, 3, 6, 8, and 10 hours postdose. Plasma concentrations of pilocarpine were quantified using a validated liquid-chromatography mass spectrometry (LC-MS/MS) method with an assay range of 25-5000 pg/mL and PK parameters were calculated using standard non-compartmental analysis methods.

Results: Pilocarpine was rapidly absorbed into systemic circulation with a median $T_{max,ss}$ of 0.334 hours. Plasma concentrations of pilocarpine were measurable in most participants up to 8 to 10 hours postdose. The systemic exposure at steady state was low with mean $C_{max,ss}$ and $AUC_{0\text{-}t,ss}$ of 1950 pg/mL and 4140 pg˙hr/mL, respectively. The mean $T_{1/2}$ following 30 days of dosing was 1.74 hours. For most participants, $C_{trough,ss}$ was below the assay LLOQ (< 25 pg/mL), indicating a lack of systemic accumulation of pilocarpine. Systemic exposure to pilocarpine following administration of VUITY for 30 days was lower than the exposure reported for other pilocarpine products available on the market. Mean plasma C_{max} and $AUC_{0\text{-}6hr}$ achieved with VUITY were approximately 2 times lower than steady-state exposure reported after topical ocular administration of 4% Isopto Carpine. C_{max} achieved with VUITY was 21 times lower than the exposure reported with oral use of 10 mg Salagen.

Conclusions: Systemic exposure in participants administered VUITY once daily for 30 days was low and rapidly cleared from the circulation. Plasma concentrations were lower than those reported for other pilocarpine products on the market.

ABSTRACT BODY:

Purpose: OCT peripapillary retinal nerve fiber layer thickness (pRNFLT) change detection is a standard tool in the management of both human glaucoma and NHP unilateral EG. Here, using a novel approach for consistent anatomical comparisons, we employ quantitative immunohistochemistry (qIHC) to test the hypothesis that retrolaminar myelin-related protein expression alterations correlate to longitudinal OCT structural change in NHP early EG.

Methods: Data from n=4 unilateral early EG NHPs (<30% EG pRNFLT loss) were included. For each EG eye, longitudinal OCT pRNFLT change relative to baseline was quantified within 12 Fovea-BMO (FoBMO axis) 30° sectors (Fig 1). For each NHP, the optic nerve head (ONH) of the EG and Control (C) eye was trephined, (10 mm), 5 µm serial vertical paraffin sections were cut, their clinical location was anatomically estimated (Fig 1a), and n=4 adjacent sections were selected to represent similar FoBMO sectors in both eyes. Sections from all 4 NHPs were deparaffinized and stained with anti 2',3'-Cyclic-nucleotide 3'-phosphodiesterase, (CNPase, a myelin associated enzyme). Localized retrolaminar signal intensity in each section was quantified within the first 4 retrolaminar 50 µm bands of 12 anatomically consistent horizontal regions (Fig 1b). For each NHP, EG vs C eye differences in CNPase intensity within each region and EG vs C CNPase intensity % differences were correlated with longitudinal percent change in OCT pRNFLT in the same OCT sector (Fig 2) using a linear mixed effect model.

Results: CNPase intensity decreased significantly in EG versus C eyes in 26 of 48 qIHC regions where early OCT RNFLT loss had occurred ($p < 0.05$). pRNFLT % change and EG versus C CNPase % intensity difference in the same FoBMO 30° sector were correlated ($p=0.01$, linear mixed effect model, $R^2=0.46$, Fig 2b). EG eyes showed a 49% reduction in CNPase intensity at 0% pRNFLT change.

Conclusions: To our knowledge, this is the first attempt to anatomically link qIHC EG vs C protein expression differences to longitudinally detected OCT pRNFLT change in NHP early EG and demonstrate that myelin loss may occur before RNFLT loss. Linking protein expression change to OCT pRNFLT change may enhance the interpretation of OCT findings and inform our understanding of the pathophysiology of glaucoma.

ABSTRACT BODY:

Purpose: Structural loss often precedes functional loss in cases of primary open-angle glaucoma, thus driving the importance of early detection and monitoring. While established correlations between structure and function in glaucomatous eyes have been studied in various modalities (particularly in traditional narrow field of view (FOV) cameras which assume a constant pixel to distance mapping), it is vital to establish these correlations in widefield (WF) cameras which are widely available, and have not yet been assessed.

Methods: A WF slit-scanning ophthalmoscope (CLARUS™ 500, ZEISS, Dublin, CA) and automated perimeter (HFA3 Model 860 perimeter, ZEISS, Dublin, CA) were used to acquire color fundus photography images and perimetric data respectively. Both healthy (10 eyes, avg. age 56.4 ± 8.9, 44.3 – 73.1 years) and glaucomatous (14 eyes, avg. age 72.5 ± 9.3, 60.9 – 97.9 years) subjects were used as part of a retrospective analysis. Mean deviation (MD) from 24-2 SITA Standard (SS) visual fields (VFs) (extracted from 24-2C) were used to assess global function. Due to the use of a 90° FOV camera, the constant distance assumptions on narrow FOV cameras are not held. The automated measurements with manual annotations are tracked internally. Cup to disc ratios (CDR) from three independent/blind graders were computed and averaged from manual annotations using the default caliper measurement tool in CLARUS software to annotate horizonal and vertical cup and disc lengths; both ratios (hCDR and vCDR) were compared to 24-2 MDs using Spearman correlations.

Results: Structure/functional correlations were observed for both hCDR (ρ = -0.46) and vCDR (ρ = -0.61) measurements as compared with 24-2 MDs. In Fig 1, glaucomatous eyes prove less consistent as compared with normals. Consistent with literature, this study showed CDRs using the standard measurement tool in CLARUS are larger in glaucomatous eyes.

Conclusions: This study demonstrated a capability of providing structure/function comparisons using a WF fundus imager and perimeter. This measurement technique could be useful for enhancing research in the field of glaucoma. The study also confirms the trend that in the early to medium/advanced stages of glaucoma, the vCDR has a stronger correlation than hCDR and that vCDR is traditionally more useful in determining glaucoma severity.

TITLE: Nodal Points and the Eye

SESSION TITLE: Optics: Accommodation, Lens and Ocular Biometry

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Simpson, Simpson Optics LLC, Arlington, Texas, UNITED STATES|

Commercial Relationships Disclosure: Michael Simpson: Commercial Relationship(s);Code E (Employment):Simpson Optics LLC

ABSTRACT BODY:

Purpose: The very concept of “nodal points” probably originated with the eye, because they are only distinct when the refractive index is different on one side. Johann Listing described this in 1845, and the points belong on a paraxial “cardinal point” drawing (Fig 1), though they are often misleadingly sketched alone as the axial intersections of 2 parallel rays. They are meaningful only for small angles, yet it has recently been confirmed that the nodal point can scale the pseudophakic retina at large angles for other reasons. The evaluation is extended here to the phakic eye.

Methods: Raytracing software was used to model an average older eye with a gradient index lens. Input chief ray angles were compared to angles leaving the exit pupil, relative to the visual axis. A 70 year old eye was used because this is a typical age for cataract surgery, where recent questions about “negative dysphotopsia” and “far peripheral vison” have not yet been fully resolved.

Results: The phakic eye was found to have broadly similar properties to the pseudophakic eye, with input chief ray angles being rescaled by a fairly constant factor of 0.81 at the exit pupil over more than 70 degrees (Fig 2). These are actual rays, with angles relative to the visual axis that is rotated 5 degs from the optical axis (angle alpha). They identify image locations on the retina, though the overall image may be slightly defocused and astigmatic. Lines are not drawn to the 2^{nd} nodal point (NP2), to maintain clarity, but a ruler parallel to an input ray can be used to confirm that in addition to the angular rescaling at the pupil, angles from NP2 are approximately the same as input angles to the eye, and that the input angles do not all meet at a single point.

Conclusions: The eye has a remarkably linear relationship between input angle and image location on the retina, with the cornea curving around toward light entering at an angle, and the retina curving around to meet the image. These optical properties have nothing directly to do with the traditional nodal points, which are described for very small angles using a sketch that has only straight lines. At large angles, the relationship comes from ray bundles that pass through the center of the pupil. This discussion also has relevance to fundus cameras, and to wide-field imaging of the retina.

ABSTRACT BODY:

Purpose: RPE65 is an essential enzyme that is required for vertebrate vision. In humans, RPE65 mutations cause severe blinding diseases. Up-to-date D477G is the only known mutation of RPE65 that is dominantly inherited. The pathogenic mechanism by which the heterozygous D477G (WT/KI) mutation impairs retinal function remains unknown. A total of 4 groups, including us, previously reported that when raised under dim light vivarium illumination, the retinal phenotypes in the WT/KI mice were mild non-pathogenic. This study investigated if environmental light influences the onset of D477G pathogenicity in the WT/KI mice.

Methods: Retina function and morphology were evaluated using ERG, OCT, and H&E staining in heterozygous WT/KI and heterozygous RPE65KO (WT/KO) mice maintained under ambient or higher cyclic lighting. Isomerase activity and endogenous chromophore were measured using HPLC. Immunostaining was performed on eyecup flat mounts and retina sections. Levels of visual cycle proteins were analyzed via immunoblotting. In vivo, subcellular fractionation and sucrose density sedimentation were performed to analyze protein mislocalization and aggregation. In vitro, pVITRO expression systems were used to detect protein-protein interaction. Cycloheximide and MG132 were used to determine protein half-life and degradation rate.

Results: When maintained under the physiological light intensity 2000 lux, the WT/KI mice displayed degenerative retina features, including reduced ERG amplitudes and retinal layers thinning, recapitulating that observed in human patients. We also detected increased free opsin levels and upregulated GFAP expression in the same retinas. Molecularly, we found reduced RPE65 and LRAT levels, decreased retinol isomerase activity, and altered subcellular localization and membrane association of RPE65 in the RPE of WT/KI mice. Moreover, the D477G mutant, formed protein complexes with WT-RPE65, leading to a reduction of RPE65 protein stability, which could not be completely rescued by the addition of MG132, a proteasome inhibitor of ubiquitin-dependent protein degradation.

Conclusions: Our results suggested that physiological non-pathogenic illumination played an important role in the manifestation of vision loss in certain forms of monogenetic causes of blindness and uncovered the dominant-negative mechanism of D477G mutation.

ABSTRACT BODY:

Purpose: Microperimetry (MP) is a valuable endpoint in clinical trials for various retinal diseases. Deep learning models that can predict MP from optical coherence tomography (OCT) B-scans may be beneficial given the laborious effort of MP. Transfer learning involves using pre-trained weights on a different but related problem where proficiency in one task may generalize to another. We sought to evaluate a deep learning model pre-trained on OCTs of macular telangiectasia type 2 (MacTel) and fine-tuned on patients with non neovascular age-related macular degeneration (AMD).

Methods: The AMD dataset includes 322 eyes of 161 patients enrolled in the Laser Intervention in the Early Stages of AMD (LEAD) trial at the Centre for Eye Research Australia from 2013 to 2018, partitioned into 110,450 samples for training, 52,858 for validation, and 41,719 for testing. Each sample consists of B-scan window slices and MP sensitivities, for which infrared fundus photos were registered by aligning segmented blood vessels. Three VGGNet models were evaluated: 1) trained on MacTel data (VGG-Mac), 2) trained on AMD data (VGG-AMD), 3) pre-trained with MacTel data and fine-tuned with AMD data (VGG-FT). Primary outcome is the mean absolute error (MAE) of predicted vs. observed MP sensitivity.

Results: All models were evaluated against the same AMD validation set. The fine-tuned model VGG-FT achieved lowest MAE of 2.88 dB (95% CI 2.86, 2.91). VGG-AMD achieved MAE of 3.01 dB (2.99, 3.04), and VGG-Mac achieved MAE of 3.44 dB (3.41, 3.48). Continuous predictions by VGG-FT across B-scan levels were then aggregated to create 2D en-face maps (Figure 2).

Conclusions: The model pretrained on MacTel then fine-tuned on AMD data outperformed the model trained only on AMD data, suggesting that transfer learning between different retinal diseases may increase domain specific performance. Deep learning models to estimate retinal sensitivities using OCTs may be a valuable endpoint in following patients with AMD for clinical trials.

ABSTRACT BODY:

Purpose: To determine if obstructive sleep apnea (OSAS) predisposes patients to glaucoma and macular disease due to vascular compromise by evaluating retinal and optic nerve vasculature and function using optical coherence tomography angiography (OCT-A) and Humphrey visual field testing.

Methods: Forty-five patients undergoing polysomnography ordered per standard of care were enrolled and grouped into three categories based on apnea-hypopnea index (AHI) with control patients having AHI <5 episodes/hr. Medical history, visual acuity testing, 24-2 Humphrey visual field (HVF), intra-ocular pressure measurement, OCT-A studies of the macular and peripapillary retina were obtained. Correlations between polysomnography parameters and imaging data were evaluated.

Results: OCT-A radial peripapillary capillary (RPC) vascular density (VD) demonstrated no relationship to AHI (95% CI (-0.026,0.038)) or severity of OSAS (95% CI: (-0.772, 3.648) for moderate OSAS compared to mild/normal and (-1.295, 3.1421) for severe comparing to mild/normal). OCT-A superficial parafoveal VD (95% CI: (-0.068,0.011), deep parafoveal VD (95% CI: (-0.080,0.009)), and FAZ (95% CI: (-0.001, 0.001)) showed no statistically significant relationship to AHI or OSAS severity after controlling for confounders. OCT retinal nerve fiber layer (RNFL) thickness increased with AHI (p=0.014), but there was no statistically significant correlation with OSAS severity with RNFL thickness (95% CI: (-12.543, 6.792) for moderate comparing to normal and (-2.883, 16.551) for severe comparing to normal). 24-2 HVF parameters were unaffected by OSAS (95% CI: Mean deviation (-0.21,0.29), Pattern standard deviation: (-0.351,0.121), Visual field index: (-0.166, 0.329)). OCT choroidal thickness showed a statistically significant decrease when OSAS was grouped by severity (p=0.0092), but did not correlate with AHI (p=0.129, 95% CI: (-1.210, 0.095))

Conclusions: The severity of OSAS did not show a statistically significant effect on parameters associated with glaucoma or macular vascular disease. Larger cohorts may be required to determine the physiologic consequences of OSAS on the macular and optic nerve vasculature, structure, and function.

ABSTRACT BODY:

Purpose: To characterize the severity of optical coherence tomography angiography (OCTA) artifacts by disease severity in glaucoma suspects and patients.

Methods: 644 OCTA images were included from 409 eyes of 228 healthy, glaucoma suspect and glaucoma patients from the Diagnostic Innovations in Glaucoma Study. Angiovue high-density optic nerve head and macula OCTA images were reviewed for the presence of different subtypes of OCTA artifacts, including eye movement, defocus, decentration, segmentation error, blink, Z offset, and shadow in the superficial vascular layer. The severity of artifacts was quantified based on the percentage of the en-face image or B-scans affected. Artifacts that involved <5% of the OCTA scan were categorized as mild, 5-10% as moderate, and ≥10% as severe. Images with at least 1 severe artifact were classified as poor-quality. Univariable and multivariable mixed effect models were used to evaluate the association of demographic and ocular characteristics with artifact severity.

Results: 31.8% of OCTA images were classified as poor-quality. The prevalence of poor-quality images increased with worsening disease from healthy (13.6%) to glaucoma suspect (23.5%) to glaucoma patients (39.0%). In univariable analyses, diagnosis of glaucoma and worse 24-2 visual field (VF) mean deviation (MD) were significantly associated with poor-quality OCTA images (all P<0.05, Table 1). In the multivariable analysis, older age, male gender, absence of eye tracking and worse 24-2 VF MD were significantly associated with poor-quality OCTA images (all P<0.05). Defocus (21.1%), eye movement (19.6%) and decentration (6.7%) artifacts were the most prevalent subtypes of severe artifacts leading to poor-quality OCTA images. Each was significantly associated with severity of disease including worse 24-2 VF MD (all P<0.05). Compared to healthy subjects, both glaucoma suspect and glaucoma patients were more likely to have moderate to severe eye movement, but only glaucoma patients were more likely to have moderate to severe decentration and defocus artifacts (all P<0.05).

Conclusions: OCTA images of glaucoma patients, particularly those with severe disease, are more likely to be affected by artifacts compared to those of healthy individuals. Quantitative OCTA measurements of glaucoma patients, especially those with advanced disease, must be carefully reviewed to exclude images with artifacts.

ABSTRACT BODY:

Purpose: To assess the efficacy of topical interferon IFN α-2β(IFN) as a primary treatment for ocular surface squamous neoplasia (OSSN) and evaluate factors that impact response to treatment and recurrence of OSSN.

Methods: A retrospective study of 127 OSSN patients treated with topical IFN(1MIU/ml) from January 2009 to June 2021. The diagnosis was based on clinical examination and anterior segment optical coherence tomography. Histologic confirmation was present in 44% of patients. Data on demographics, tumor characteristics, treatment outcome, and side effects were collected. The primary outcomes assessed were tumor resolution frequency and recurrence rate. Secondary outcomes assessed were predictive factors for resolution and recurrence and side effects of treatment.

Results: Participants were mostly older with a mean age of 69 years (SD 12.4, range 29-97), white (92%) males (76%). Complete tumor resolution was achieved in 78% of individuals with a mean time to resolution of 5 months (SD 4.4, range 1.6-36 months). On multivariable analysis, non-Hispanic ethnicity (HR: 0.48, p=0.003, 95% CI: 0.29 to 0.78) and self-reported sun exposure (HR: 0.55, p=0.02, 95% CI: 0.34-0.91) reduced the risk of tumor resolution, while a prior history of OSSN (HR: 4.26, p<0.001, 95% CI: 1.82-9.97) increased the risk of resolution. With a mean follow-up time of 36.3 months (SD 33.8, 0-124 months), the recurrence rate was 1.2%, 3.8%, and 6.2% at 1, 2, and 5 years respectively. Mild hyperemia (18.2%) and pain (12.1%) were the two most common side effects.

Conclusions: Topical IFN is a safe and effective primary treatment modality for OSSN with a reasonable side effect profile.

ABSTRACT BODY:

Purpose: Arcuate-like artifacts seen on deviation/probability (p-) maps of healthy eyes are the most common source of OCT false positives and are the primary basis of so-called “red disease”. To better identify and understand these arcuate-like artifacts we tested a simple model.

Methods: The model: Figure 1A shows the average thickness map of healthy control (HC) eyes from a normative database. The black border, between the yellow and green regions in Fig.1A, is an iso-thickness (75 um) contour encompassing the thickest portion of the RNFL thickness map. Figure 1B&C show the thickness map and p-map of a healthy control with an arcuate-like artifact. Notice that the RNFL thickness (Fig. 1C) of this HC eye is relatively normal, but that the thickest portion no longer falls entirely within the black border. The model predicts that the arcuate-like artifact is due to this misalignment, and it will fall largely within the black contour (red arrow, Fig. 1B). However, arcuate regions that are due to glaucoma will typically extend outside these black borders, and often cross the midline (black vertical line) as shown in Fig. 1D-F. The model was tested by superimposing the black borders on the p-maps of 200 HC eyes. In addition, these borders were also superimposed on the RNFL p-maps of 62 glaucoma eyes with early (EG, MD>-6dB, n=32), moderate (MG, MD<-6dB, >-12dB, n=12), and advanced disease (AG, MD <-12 dB, n=18).

Results: Arcuate-like artifacts were seen on the RNFL p-maps of 8 (4%) of the 200 HC eyes. As predicted, all 8 (100%) of these arcuate artifacts fell within the black borders as shown in Fig. 2A (1st column). On the other hand, only 3 of the 62 patient eyes (2 EG and 1 MG) had abnormal regions restricted to within the black border (Fig. 2B). A post-hoc analysis revealed that these 3 eyes can be distinguished from the 8 HC eyes based upon topographical agreement with the abnormal regions of the RNFL thickness map and/or ganglion cell layer (GCL) p-map, as shown in the 2nd and 3rd columns of Figs. 2A&B.

Conclusions: Arcuate-like artifacts on RNFL p-maps, which can be confused with glaucomatous arcuate damage, fall within the borders of the thick arcuate region of the average RNFL thickness map of healthy eyes. Abnormal arcuate regions falling within these borders should be assumed to be artifacts unless confirmed with GCL p-maps and/or RNFL thickness maps.

ABSTRACT BODY:

Purpose: In this study, experiments were performed to demonstrate ERG recovery in glaucoma-induced mice after generation of new RGCs following PNU-282987 treatment.

Methods: Both sexes of adult mice (3 to 6 months) were injected with 1.2 M hypertonic saline into the episcleral vein to increase IOP. After the procedure, mouse eyes were treated once daily using eye drops containing 1mM PNU-282987/1mg/ml BrdU and weekly ERGs were recorded using the Celeris Diagnosys ERG System. At different time points, animals were euthanized, and retinas were removed, processed immunocytochemically with antibodies against BrdU and Thy 1.2, counterstained with DAPI, and viewed using a Nikon confocal microscope. Data was analyzed with ANOVA and differences were considered significant at $P<0.05$. N's between 3-6 were obtained under each condition.

Results: Hypertonic saline injections elicited a significant increase in IOP four weeks post injection (an average of 15.8 mmHg ±1.2) compared to an average of 11.2 mmHg (±1.8) measured from the same animals before the procedure. Induction of glaucoma also significantly reduced the cell density of Thy1.2+ RGCs by an average of 28.31% (±1.5) four weeks after injection.To illustrate the regenerative potential of PNU-282987, injected animals were treated with BrdU alone or with PNU-282987/BrdU. In the injected mice treated only with BrdU, no BrdU+ cells appeared despite an average loss of 30.88% (±3.4) RGCs. However, after agonist treatment following saline injection, Thy1.2/BrdU+ neurons appeared in the GCL. After 28 days of agonist treatment, PNU-282987 significantly reduced the loss of Thy1.2+ cells associated with the glaucoma procedure to an average of only 12.4% (±0.8) compared to the near 30% average that are typically lost. In ERG recordings, the amplitude of the photopic PhNR decreased by 71.5% (±6.2) after the glaucoma procedure within 1 week. When treated with the agonist for 3 weeks, the amplitude of the PhNR recovered by 90% (±20.5). Scotopic oscillatory potential amplitudes (OP1, 2 and 3) decreased by an average range of between 80.3 and 85.6% (±16.1) after the glaucoma procedure. When treated with the agonist all OPs recovered by an average range of 65 to 85% (±21.7).

Conclusions: Results from these studies support the hypothesis that PNU-282987 can elicit new RGCs and provide recovery of the ERG PhNR and OP amplitudes after inducing glaucoma.

TITLE: A Systematic Review of Electrocautery Use During Ocular and Oculofacial Surgery in Patients with Implantable Electronic Cardiovascular Devices

SESSION TITLE: Oculoplastics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Tauber, J.P. Tingley, A. Barmettler, Ophthalmology, Montefiore Medical Center, Bronx, New York, UNITED STATES|J. Tauber, J.P. Tingley, A. Barmettler, Ophthalmology, Albert Einstein College of Medicine, Bronx, New York, UNITED STATES|

Commercial Relationships Disclosure: Jenna Tauber: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Tingley: Commercial Relationship: Code N (No Commercial Relationship) | Anne Barmettler: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Implantable electronic cardiac devices (IECDs) such as cardiac pacemakers and implantable defibrillators are common life saving devices. Device-related complications can arise in patients undergoing surgical interventions with electrosurgical tools due to electromagnetic interference. Currently, ophthalmologists and oculofacial plastic surgeons rely on inconsistent protocols, which vary by institution, to guide their use of these devices in patients with IECDs. This systematic literature review assesses existing reports on electrocautery use during ocular and periocular surgery in patients with IECDs.

Methods: This review was designed per Preferred Reporting Items for Systematic and Meta-Analysis guidelines. A literature search of published reports was conducted on all Evidence Based Medicine Reviews, Cochrane Databases and Registers, MEDLINE Ovid, Embase.com, Pubmed, and ClinicalTrials.gov. Search terms included “pacemaker” or “implantable cardioverter defibrillator” and “electrocautery” or “cautery”. Inclusion criteria were full text articles, discussing ocular, oculoplastic, or other facial (including dermatologic and head and neck) surgery. Exclusion criteria included non-English language or surgery focused on other parts of the body. Full-text manuscripts of identified articles were reviewed and relevant data were extracted. Data collected included author, publication year, study design, surgery type, electrosurgery type, IECD type, guidelines or findings.

Results: Of 746 publications, twelve studies met inclusion criteria (Figure 1). A summary of these studies can be seen in Table 1. Different safety approaches were taken with pacemakers (such as applying magnets intraoperatively, converting to asynchronous mode, or performing no alterations) and implantable defibrillators (such as disabling prior to electrocautery or no intervention). Precautions such as preoperative device interrogation and limiting duration of current bursts were recommended more often with monopolar cautery.

Conclusions: There is limited original research specifically focused on electrocautery choice during ocular and oculofacial plastic surgery in patients with IECDs. Existing studies suggest bipolar electrocautery and thermal cautery may be safer options compared to monopolar electrocautery in select patients with IECDs.

ABSTRACT BODY:

Purpose: Hereditary eye diseases (HED) affect millions globally. While the field of study of these disorders, Ophthalmic Genetics, has seen major advances, evidence of inclusion and characterization of HEDs in diverse populations is lacking in current literature. This raises questions on the accuracy and applicability of these findings to diverse populations. A literature review was conducted to assess gaps in the representation of African Americans in genomic research surrounding eight HEDs: oculocutaneous albinism, retinoblastoma, congenital aniridia, congenital glaucoma, congenital cataract, Stargardt disease, retinitis pigmentosa, and optic atrophy.

Methods: A two-pronged approach was utilized to gather review sources. 1) An advanced PubMed® search cross-referencing our research population with a predetermined set of search terms for each HED. 2) Exploration of additional databases including Embase®, Web of Science™, and Scopus® by a medical librarian. Sources were then filtered based on predetermined inclusion criteria (to highlight knowledge in the molecular era) and reviewed for significance of contribution to literature.

Results: Out of thousands of studies on each of these diseases, papers clearly reporting disease characterization in African Americans ranged from 14 addressing oculocutaneous albinism to none in aniridia. Analysis of studies that were inclusive of African American patients demonstrated the known utility of diverse genomics research by: reporting novel disease associated variants, challenging classifications of benign and pathogenic variants, proposing previously unreported genotype-phenotype correlations, and expanding documented manifestations of these diseases in more diverse populations.

Conclusions: Genomic research is more likely to be applicable to patients when conducted in populations that share their ancestral background. HED characterization in diverse participants, specifically African Americans, is identified as a knowledge gap area. Addressing this gap will lead to a better understanding of HEDs in broader populations. Greater inclusion of African Americans in Ophthalmic Genetics research is a scientific imperative and is a needed step in the pursuit of the best possible patient care.

ABSTRACT BODY:

Purpose: Although optic nerve (ON) tethering occurs beyond ~26° adduction, the distribution of resulting ocular strain is predicted to vary depending on local tissue properties. We measured peripapillary strain by imaging displacements of embedded vessels using SLO during horizontal duction.

Methods: Using azimuth rotation of Heidelberg Spectalis SLO to achieve 35° ab- & adduction from central gaze, we imaged a 8.9X8.9 mm^2 region centered on the optic disc of young (42 eyes, age 27±5 years, ±SD) and older (39 eyes, 65±9 years) healthy adults. A MATLAB algorithm equalized brightness, corrected torsion, & registered globally across gaze positions. The VLFeat Team scale-invariant feature transform detector was used to quantify displacements of corresponding features that were analyzed in nasal vs. temporal sectors at disc radius increments from the disc center. A vessel mask was used to exclude non-vascular corresponding features from analysis.

Results: Vascular features on the disc were displaced temporally in adduction & nasally in abduction. During adduction, nasal hemi-disc vessels were displaced temporally by similar amount of 11.0±23.0 μm in younger & 10.6±16.7 μm in older subjects. This was significantly more than the temporal hemi-disc was displaced nasally at 4.1±14.0 μm in young & 4.7±11.6 μm in older subjects (P=0.005). During adduction, nasally directed displacement of peripapillary vessels located >3 disc radii from center averaged 3.1±13.5 μm for younger, but only 0.5±12.2 μm for older subjects (P=0.02). Peripapillary features located between 2 & 3 disc radii shifted nasally in abduction by 2.4±13.3 μm in older (P<0.001) but not significantly in young adults at 0.0±8.8 μm. There were no significant vertical displacements in either group.

Conclusions: Consistent with ON tethering, SLO demonstrates greater local disc & peripapillary vessel displacements in add- than abduction that are greater in the nasal than temporal hemi-disc. Since vessels are embedded in other tissues, these displacements represent local strains that are quantitatively similar in both younger & older subjects. Lesser peripapillary strain in older subjects during adduction may be due to scleral stiffening, which would increase associated stress during tethering. Lesser deformation in abduction than adduction is consistent with ON tethering in adduction but not abduction.

TITLE: Deciphering how missense mutations in CRX homeodomain produce distinct dominant retinopathies

SESSION TITLE: Biochemistry and molecular biology of ocular disorders

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: Y. Zheng, C. SUN, X. Zhang, P.A. Ruzycki, S. Chen, Ophthalmology & Visual Sciences, Washington University in St Louis, St Louis, Missouri, UNITED STATES|

Commercial Relationships Disclosure: Yiqiao Zheng: Commercial Relationship: Code N (No Commercial Relationship) | CHI SUN: Commercial Relationship: Code N (No Commercial Relationship) | Xiaodong Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Philip Ruzycki: Commercial Relationship: Code N (No Commercial Relationship) | Shiming Chen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: CRX is a paired-like homeodomain (HD) transcription factor essential for photoreceptor gene expression, function, and survival. This study focused on three human missense mutations within the CRX HD recognition helix, p.E80A, p.K88N and p.R90W, associated with dominant cone-rod dystrophy (CoRD), dominant Leber congenital amaurosis (LCA), and recessive LCA, respectively. The goal was to uncover how each mutation disrupts CRX regulatory activity to inform disease pathogenesis.

Methods: Spec-seq, a high throughput assay for protein-DNA interactions, established quantitative models of CRX HD-DNA binding specificity. pRho-luc reporter assays in HEK293T cells revealed changes in CRX transactivation potential. Knock-in mouse models were generated by introducing p.E80A and p.K88N into the endogenous Crx locus. Previously published p.R90W model was included for comparison. Retinal ChIPseq and RNAseq at postnatal ages detected changes in CRX chromatin binding and subsequent effects on gene expression in each mutation knock-in mouse model.

Results: R90W and E80A maintained WT binding specificity. While R90W significantly lost binding affinity and transactivation activity, explaining rLCA-like phenotype, E80A mutant increased binding affinity and hyperactivated pRho-luc reporter. In accordance with in vitro results, $Crx^{E80A/+}$ and $Crx^{E80A/A}$ mutants showed hyperactivation of rod genes at postnatal age P10. However, cone genes were not activated, and rod differentiation failed to reach mature state at P21, suggesting a path to CoRD-like phenotypes. In contrast, K88N mutant preferred sequences different from that of WT and failed to activate pRho-luc reporter. In agreement with these results, K88N showed reduced binding at WT sites but gained new binding sites in mutant retinas. Both rod and cone genes failed to be activated in $Crx^{K88N/+}$ and $Crx^{K88N/N}$ retinas while some other genes were ectopically activated, explaining the development of LCA-like phenotypes.

Conclusions: We have identified distinct pathogenic mechanisms for two disease-causing mutations in CRX HD: E80A shows hyperactivity, while K88N is antimorphic and alters DNA binding specificity. Thus, HD mutations, through alteration of DNA binding affinity or specificity, can disrupt gene regulation and cause severe dominant diseases. These findings could shed light on the regulatory mechanisms of other HD proteins and associated diseases.

ABSTRACT BODY:

Purpose: Standardized nomenclature facilitates collaboration across specialties and institutions, as well as communication with patients. This study sought to analyze whether there is a predominant nomenclature for thyroid eye disease (TED), to identify possible associations of different terms with author and journal characteristics and trends over time from 2010 to 2020.

Methods: A search in the PubMed database was completed for all articles published in 2010 and 2020 that contained TED related keywords identified by our interdisciplinary research team. Nomenclature, author and journal characteristics were extracted and descriptive as well as comparative statistical analysis was performed to identify associations.

Results: The search yielded 324 and 147 publication results for 2020 and 2010 respectively. 303 of the 2020 publications and 141 of the 2010 publications were included for final analysis. Comparing 2020 to 2010 data, use of the term “Thyroid Eye Disease” (TED) saw the biggest increase from 21.3% to 36.6% (+15.3%) with the U.S. being the leading authorship country. Use of “Graves’ Orbitopathy” saw a moderate increase from 26.2% to 34.0% (+7.8%) Use of “Graves’ Ophthalmopathy” dropped from 27.4% to 19.2% (-8.2%). In 2020, ophthalmology journals saw the highest number of publications of 138 with more than 55.8% utilizing TED as the nomenclature. In contrast, in endocrinology journals as the second leading publishing group (78 articles), only 11.5% of the published articles used the term TED ($p<0.01$). Although the change was not statistically significant ($p=0.23$), both ophthalmology and endocrinology journals have seen upward trends in TED in the past decade from 33.8% to 55.8% (+22%) and 3% to 11% (+8%) respectively.

Conclusions: “Thyroid Eye Disease” was the most commonly used term in 2020 not only by ophthalmologists, but also among almost all medical specialties. It also has the highest increase in the ophthalmology literature over the analyzed 10-year period. Based on our review, we propose that Thyroid Eye Disease (TED) would be the most appropriate term to standardize communication between patients and medical professionals, as well as documentation in the medical record. Our research was conducted by a multidisciplinary team and provides a guideline for authors of future scientific publications that is not rooted in personal preference, but in existing consensus.

TITLE: Moderate elevation of intraocular pressure induces DNA and RNA oxidative damage in the retina

SESSION TITLE: Glaucoma: biochemistry, biomechanics and omics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Gu, J. Kwong, J. Caprioli, N. Piri, University of California Los Angeles, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Lei Gu: Commercial Relationship: Code N (No Commercial Relationship) | Jacky Man Kwong Kwong: Commercial Relationship: Code N (No Commercial Relationship) | Joseph Caprioli: Commercial Relationship: Code N (No Commercial Relationship) | Natik Piri: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Oxidative stress in the pathogenesis of neurodegenerative diseases is generally associated with damage to cellular macromolecules, including DNA and RNA. This study evaluates the level of oxidized nucleosides 8-hydroxydeoxyguanosine (8OHdG) and 8-hydroxyguanosine (8OHG), biomarkers for oxidative damage of DNA and RNA, respectively, in the retinas of rat experimental glaucoma models

Methods: The experimental glaucoma model was generated by trabecular laser photocoagulation in 3-month-old Brown Norway rats. Apoptotic cells in glaucomatous retinas were detected with TUNEL staining. Spatial distribution of 8OHdG/8OHG in control and experimental retinas was analyzed with immunohistochemistry using DNA and RNA Oxidative Damage Marker monoclonal antibodies. The levels of 8OHdG/8OHG in retinal mitochondrial DNA/RNA samples were measured with DNA/RNA Oxidative Damage ELISA Kit

Results: 8OHdG/8OHG in the retina were predominantly localized to retinal ganglion cell (RGC) somas. The immunostaining intensities for these oxidatively damaged DNA/RNA nucleosides were significantly higher at 1 and 2 weeks after intraocular pressure (IOP) elevation compared to controls. Analysis of different cellular fractions indicates that 8OHdG/8OHG is almost exclusively associated with mitochondrial DNA/RNA, with approximately 65% of oxidized product associated with RNA isolated from mitochondrial fraction and the remaining 35% with mitochondrial DNA. Quantitative analysis of 8OHdG/8OHG in mitochondrial DNA/RNA isolated from retinas of experimental animals 1 and 2 weeks after IOP elevation showed approximately a 3.2 and 2.8 fold increase in the levels of oxidized DNA/RNA, respectively, compared to that of control animals

Conclusions: The observed high levels of 8OHdG/8OHG in RGCs of wild-type animals may lead to mitochondrial dysfunction and contribute to cell damage and progressive loss of RGCs during normal aging. Ocular hypertension is associated with a significant increase in the level of oxidatively damaged mitochondrial DNA/RNA, which in turn could contribute to the increased rate of RGC dysfunction and death in glaucoma

TITLE: FSP1 controls retinal pigment epithelium degeneration: role of ferroptosis

SESSION TITLE: RPE/choroid pathology: oxidative stress, inflammation and neovascularization

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Yang, K. So, A.C. Lo, W. Lam, Department of Ophthalmology, The University of Hong Kong Li Ka Shing Faculty of Medicine, Hong Kong, HONG KONG|K. So, GHM Institute of CNS Regeneration, Jinan University, China, CHINA|

Commercial Relationships Disclosure: Ming Yang: Commercial Relationship: Code N (No Commercial Relationship) | Kwok-Fai So: Commercial Relationship: Code N (No Commercial Relationship) | Amy Lo: Commercial Relationship: Code N (No Commercial Relationship) | Wai-Ching Lam: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal pigment epithelium (RPE) degeneration is central in the pathogenesis of age-related macular degeneration. Ferroptosis is an iron-dependent novel regulated cell death pathway attributed to lipid peroxidation and plays an important role in eye diseases. This study aimed to elucidate the role of ferroptosis suppressor protein-1 (FSP1) in RPE degeneration.

Methods: Primary human retinal pigment epithelial cells (HRPEpiC) and ARPE-19 exposed to sodium iodate (SI) were used as the in vitro RPE degeneration model. C57BL/6J mice receiving intraperitoneal injection of SI were chosen as the in vivo RPE degeneration model. Ferroptosis inhibitors and glutathione peroxidase-4 (GPx-4) silencing RNAs were used to test the involvement of ferroptosis. Levels of intracellular labile iron, lipid peroxidation, glutathione, coenzyme Q_{10} (CoQ_{10}), and nicotinamide adenine dinucleotide hydrogen (NADH) were measured. Protein expressions were assessed by immunohistochemistry and Western blot. Retinal function was assessed by electroretinography (ERG). Statistical analysis was performed using SPSS.

Results: SI triggered RPE cell damage, accompanied by increased levels of intracellular labile iron, glutathione disulfide (GSSG), and lipid peroxidation but decreased amount of cytoplasmic glutathione and GPx-4. Ferroptosis inhibitors significantly alleviated SI-induced cell damage, with the restoration of the aforementioned markers. However, silencing GPx-4 aggravated SI-induced cell damage. Although inhibition of FSP1 aggravated SI-induced cell damage, overexpression of FSP1 ameliorated cell damage with decreased lipid peroxidation accompanied by recovery of CoQ_{10} and NADH. Additionally, SI induced a dramatic reduction in retinal function, retinal thickness, and levels of ferroptosis suppressors, with significantly elevated RPE labile iron, GSSG, and lipid peroxidation in mice. Most notably, ferrostatin-1 markedly restored retinal thickness and ERG function, along with elevated levels of ferroptosis suppressors such as GPx-4 and FSP1. These data further confirmed the distinct role of ferroptosis in RPE degeneration.

Conclusions: FSP1 plays an important role in SI-induced RPE degeneration models in vitro and in vivo. Activation of either FSP1/CoQ_{10}/NADH or GSH/GPx-4 pathway effectively protected SI-induced damages in HRPEpiC cells, ARPE-19 cells, and mouse retina, supporting ferroptosis as a novel target for future AMD treatment.

TITLE: Compliance with hydroxychloroquine screening guidelines at a large academic medical center

SESSION TITLE: Retinal metabolism and physiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Stroman, P. Rao, Retina & Vitreous of Texas, Houston, Texas, UNITED STATES|R. Stroman, Y. Islam, A. Steigleman, Ophthalmology, University of Florida Health, Gainesville, Florida, UNITED STATES|

Commercial Relationships Disclosure: Riley Stroman: Commercial Relationship: Code N (No Commercial Relationship) | Yasmin Islam: Commercial Relationship: Code N (No Commercial Relationship) | Allan Steigleman: Commercial Relationship: Code N (No Commercial Relationship) | Prethy Rao: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Long-term hydroxychloroquine use can result in irreversible maculopathy and vision loss. New screening guidelines to identify early maculopathy were issued by American Academy of Ophthalmology (AAO) in 2016, but limited studies have evaluated compliance with these updated guidelines. This cross-sectional study evaluated compliance with hydroxychloroquine maculopathy screening exams at a large academic institution.

Methods: A retrospective chart review was performed on patients screened for hydroxychloroquine toxicity between 2011-2021. Compliance with AAO screening guidelines was evaluated based on the 2011 guidelines for patients screened between 2011-2015, and with the 2016 guidelines for patients screened in 2016 and later.

Results: A total of 419 patients were included; 239 patients were evaluated between 2011-2015, and 357 patients were evaluated between 2016-2021. Only 60.7% of patients screened before 2016 met the recommended screening exam frequency, while 40.6% received adequate visual field screenings. Amongst patients screened after 2016, 55.3% met the recommended exam screening frequency, 46.4% received screening with macula ocular coherence tomography (OCT) at the recommended interval, and 21.0% of patients received appropriate visual field screening. One-third of patients were prescribed higher than the recommended 5 mg/kg/day of hydroxychloroquine. Ten out of 419 patients developed definite macular toxicity, most of whom had concomitant risk factors for toxicity.

Conclusions: Despite clear guidelines set forth by the AAO in 2011 and 2016, compliance with screening was suboptimal. Hydroxychloroquine prescribers and eye care providers need to collaborate to ensure patients are not overdosed and that they receive appropriate maculopathy screening.

TITLE: PIEZO1 and PIEZO2 pathogenic variants identified in primary congenital glaucoma
SESSION TITLE: Glaucoma Genetics
SESSION TYPE: Paper Session
AUTHORS/INSTITUTIONS: T.L. Young, K. Whisenhunt, S. Martin, S. Tompson, Ophthalmology and Visual Sciences, University of Wisconsin System, Madison, Wisconsin, UNITED STATES|
Commercial Relationships Disclosure: Terri Young: Commercial Relationship: Code N (No Commercial Relationship) | Kristina Whisenhunt: Commercial Relationship: Code N (No Commercial Relationship) | Sean Martin: Commercial Relationship: Code N (No Commercial Relationship) | Stuart Tompson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Primary congenital glaucoma (PCG) is a rare, leading cause of childhood blindness. Increased intraocular pressure (IOP) leads to globe and corneal enlargement, and retinal ganglion cell/optic nerve damage. To date, genetic studies have identified ~25% of PCG molecular etiology. We sought novel variants in glaucoma-implicated genes in a cohort of PCG families lacking mutations in known PCG genes (CYP1B1, LTBP2, TEK, and ANGPT1).
Methods: PCG patients referred to our study were consented, and medical histories and blood samples for DNA extraction were acquired. Probands were exome sequenced using the Sure Select Human All Exon v6 or Roche/Nimblegen SeqCap EZ v2 capture kits on an Illumina HiSeq 2000 platform. Variants that were synonymous, not in coding/splice site regions, or with an allele frequency >0.002 in the gnomAD database were removed using Golden Helix SVS software. Sanger sequencing confirmed the variants in probands and enabled co-segregation analyses in additional family members where available.
Results: Six families with PIEZO1 and/or PIEZO2 variants were identified by exome sequencing. For PIEZO1, two families were identified with compound heterozygous variants (p.Arg351Trp, p.Gln1519Pro; p.Met711Lys, p.Arg1404Trp) and another had a single heterozygous variant (p.Val499Ile). For PIEZO2, two families had a single heterozygous variant (p.Arg2731Gln, p.Val971Ile). Digenic inheritance of PIEZO1 (p.Pro913Ala) and PIEZO2(p.Glu1863Gly) variants were identified in a further family. All variants showed low frequencies in global and all ethnic populations (gnomAD), had CADD scores >20, and involved highly evolutionarily conserved residues, strongly suggesting pathogenicity.
Conclusions: Maintenance of IOP involves regulation of aqueous humor outflow via Schlemm's canal (SC), a unique hybrid vessel in the ocular anterior chamber angle with lymphatic and vascular properties. In mice, PIEZO1 and PIEZO2 proteins form mechanically activated ion channels expressed in lymphatic and vascular endothelial cells. PIEZO1 localizes to SC and is important for lymphatic valve formation in mice. Additionally, PIEZO2 is associated with regulation of aqueous outflow in mice. PIEZO1 expression in human trabecular meshwork cells has also been reported. These findings strongly suggest that PIEZO1 and PIEZO2 are involved in IOP regulation and that rare pathogenic variants are causal for PCG.

ABSTRACT BODY:

Purpose: Early detection of neurodegenerative disease could provide opportunities to prevent irreversible damage. Optical coherence tomography (OCT) allows for noninvasive retina visualization, serving as a potential window for assessment of neurological conditions. For complex multifactorial disease, polygenic risk scores (PRS) involving genetic variants of individual small effects, are associated with disease outcomes. Here we investigate the correlation between retinal layer thickness and neurodegenerative disease, polygenic risk of disease, as well as current and future cognitive performance.

Methods: We utilized OCT images from 50,342 UK Biobank participants to calculate retinal layer thicknesses. We associated these thicknesses with ICD-based diagnosis of Alzheimer's disease (AD) or Parkinson's disease (PD) as well as a Lassosum-derived PRS for each disease. Multivariate Cox proportional hazard models were developed to predict future cognitive decline. All models were adjusted for age, sex, and glaucoma.

Results: AD diagnosis was associated with a thinner outer plexiform layer (OPL) (adjusted OR (aOR)=1.69, p=0.027). AD PRS was associated with thicker inner nuclear layer (INL), choroid-sclera interface (CSI), inner plexiform layer (IPL), and photoreceptor inner segment/outer segment junction layer (ISOS) and thinner retinal nerve fiber layer (RNFL) and ganglion cell layer (GCL) ($p<0.05$ for all) (Figure 1). PD diagnosis was associated with a thinner ISOS (aOR=2.38, p=0.005) and PD PRS was associated with thinner OPL and CSI ($p<0.05$ for both) (Figure 2).

Worse baseline cognitive performance was associated with thinner RNFL (aOR=1.067, $p<0.001$), OPL (aOR=1.017, $p<0.001$) and ISOS (aOR=1.071, $p<0.001$), and thicker INL (aOR=0.948, $p< 0.001$), retinal pigment epithelium (RPE) (aOR=0.977, p=0.033), and GCL (aOR=0.982, p=0.012). In a stepwise Cox model, thinner RNFL (aHR=0.99, p=0.007) and OPL (aHR=0.99, p=0.02) and thicker IPL (aHR=1.04, p=0.002), as well as higher AD PRS predicted future cognitive decline. The model containing retinal thicknesses and PRS improved prediction of future cognitive decline compared to demographic factors alone.

Conclusions: OCT measurements are associated with diagnosis and genetic risk of neurodegenerative disease, as well as cognitive function suggesting that retinal layers may be used as biomarkers for future cognitive disease and decline.

TITLE: Hand Grip Strength and its Ocular Associations: The Ural Eye and Medical Study

SESSION TITLE: Vision Impairment, Visual Function, and Quality of Life

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Panda-Jonas, J. Jonas, G. Kazakbaeva, E. Iakupova, M. Bikbov, Ufa Eye Research Institute, Ufa, RUSSIAN FEDERATION|

Commercial Relationships Disclosure: Songhomitra Panda-Jonas: Commercial Relationship: Code N (No Commercial Relationship) | Jost Jonas: Commercial Relationship: Code N (No Commercial Relationship) | Gyulli Kazakbaeva: Commercial Relationship: Code N (No Commercial Relationship) | Ellina Iakupova: Commercial Relationship: Code N (No Commercial Relationship) | Mukharram Bikbov: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To explore associations between the hand grip strength (HGS) as indicator of general health and ocular parameters and diseases.

Methods: The population-based Ural Eye and Medical Study included 5899 (80.5%) out of 7328 eligible individuals who underwent systemic and ophthalmological examinations including dynamometric HGS measurements.

Results: The study included 5381 (90.4%) individuals (age:58.6±10.6 years;range:40-94 years) with HGS measurements. In multivariable analysis, a higher HGS correlated with better visual acuity (beta:0.05;P<0.001), longer ocular axial length (beta:0.02;P=0.008), higher intraocular pressure (beta:0.03;P=0.001) and lower prevalence of diabetic retinopathy (beta:-0.02;P=0.006) after adjusting for younger age, male sex, Russian ethnicity, higher body height and waist-hip ratio, higher educational level, lower number of smoking package years, lower self-reported salt consumption, higher degree of processing meat, higher physical total score, higher serum concentration of hemoglobin, higher prothrombin index, lower leucocyte cell count, lower prevalence of non-alcoholic fatty liver disease, lower depression score, and lower prevalence of arthritis and previous falls. In that model, HGS was not correlated with the prevalence of any cataract (P=0.24), nuclear cataract (P=0.35), cortical cataract (P=0.88), subcapsular posterior cataract (P=0.87), any glaucoma (P=0.57), open-angle glaucoma (P=0.89), or angle-closure glaucoma (P=0.69).

Conclusions: In addition to parameters such as lower physical activity, higher depression score and worse general health status, a reduced HGS is associated with visual impairment, shorter axial length, lower intraocular pressure and higher prevalence of diabetic retinopathy. HGS dynamometry or a handshake may give additional clinical information for the ophthalmologist about the general health and some ocular parameters of the patient.

ABSTRACT BODY:

Purpose: To evaluate seasonal variation of intraocular pressure (IOP) in non-glaucomatous subjects from records established in two large databases since 1995 and 2005, i.e., the Kyoto Prefectural University of Medicine Glaucoma Registry (KPUM-GR) and the Kyoto Glaucoma Cohort Study (KGC), respectively, for the purpose of glaucoma genome research (i.e., data collected from both glaucoma patients and normal, healthy, non-glaucomatous, control-subject volunteers).

Methods: IOP data meeting the following inclusion criteria extracted from the KPUM-GR or KGC database was obtained: 1) subjects diagnosed as non-glaucomatous with bilateral visual fields within normal limits, 2) applanation (A) IOP (Haag-Streit) of ≤ 21mmHg, and 3) non-contact tonometry (N) (RKT-7700, Nidek) findings measured within 2 hours on the same day with A IOP. In all subjects, right-eye data was used for analysis. IOP seasonal variation was determined via regression-model analysis based on the mean values for each month for both A and N IOP by dividing the data into 12 groups by the month of measurement.

Results: Data-points extracted and later evaluated included 620 from the KPUM-GR and 868 independently derived from and KGC; i.e., a total of 1488 subjects [428 males, 1060 females, mean age: 62.2±11.5 (mean±SD) years]. The A IOP data revealed significant seasonal variation ($P<0.01$), i.e., lower IOP in summer and higher IOP in winter, and the N IOP data also showed significant seasonal variations.

Conclusions: The real-world data of the non-glaucomatous subjects in our two large databases revealed significant seasonal variation of IOP in both A and N.

TITLE: Myopia imaging biomarkers to predict atropine response by optical coherence tomography and fundus photography

SESSION TITLE: Myopia: Clinical Interventions and Diagnostics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Shimizu, T. Yuasa, H. Inoue, T. Imanaka, Santen Seiyaku Kabushiki Kaisha, Osaka, JAPAN|

Commercial Relationships Disclosure: Hiroyuki Shimizu: Commercial Relationship: Code N (No Commercial Relationship) | Takashi Yuasa: Commercial Relationship: Code N (No Commercial Relationship) | Hiroshi Inoue: Commercial Relationship: Code N (No Commercial Relationship) | Takahiro Imanaka: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Atropine is effective for controlling myopia progression in children. Since the response to atropine differs among patients, identification of biomarkers that can predict drug response before treatment is important. Choroidal thickness is reportedly affected by atropine, implying that the drug exerts effects on the posterior segment. However, whether these effects are associated with drug response remains unclear.

Thus, we aimed to predict atropine response by evaluating the relationship between the posterior segment imaging features and drug response.

Methods: We collected optical coherence tomography (OCT) images and fundus photographs (FPs) from our clinical trial “Phase 2 study of STN1012700” (012701LT) (N=99). This study was approved by the Institutional Review Board at Research Committee of Santen Pharmaceutical Co., Ltd. Myopia patients aged 6 to 11 years were included and categorized into three dose groups and a placebo group. The objective equivalent spherical power (SE), axial length (AL), and changes in the SE and AL from baseline to 12 months were evaluated as endpoints. From the OCT data, we extracted the thicknesses of the ganglion cell layer, inner plexiform layer complex (GCL+), and choroid-sclera interface (CSI) at each region, divided in accordance with the Early Treatment of Diabetic Retinopathy Study (ETDRS) grid. From the FPs, we extracted the steepness of the retinal artery (RA) trajectory and the proportion of R layer (Redness) in the RGB layers. A linear mixed model regression analysis was conducted to identify features that were statistically associated with the endpoints. The OCT or FP factors, baseline value, dose groups, and the interaction between the dose groups and factors were included as explanatory variables.

Results: On OCT analysis, the GCL+ thickness in some regions was significantly associated with the change in AL from baseline, depending on the dose group ($P < 0.05$). However, no significant association with the CSI was noted. On PF analysis, while the RA trajectory showed no association with the changes in SE and AL from baseline, the Redness in some regions showed significant association, depending on the dose group ($P < 0.05$).

Conclusions: Therefore, the GCL+ thickness and Redness may be associated with atropine response, suggesting their potential use as biomarkers to predict drug response before treatment.

ABSTRACT BODY:

Purpose: The aim of this study was to compare the efficacy and complications after Tanito microhook ab-interno trabeculotomy (TMH) combined with cataract surgery in one eye and iStent implantation combined with cataract surgery in the fellow eye of a patient.

Methods: Sixty-four eyes of 32 participants (mean age, 75.9 ± 7.6 years; 15 men, 17 women) with primary-open angle glaucoma (65.6 %), exfoliation glaucoma (23.4 %), and other glaucoma types (11.0 %) were included retrospectively. The intraocular pressure (IOP) and number of antiglaucoma medications evaluated preoperatively and postoperatively at 2 weeks, 3, 6, and 12 months were collected by chart review. The postoperative complications including layered hyphema and IOP spike of 30 mmHg or higher also were collected. Comparisons between the two surgical procedures were performed by mixed-effects regression models and followed by Wilcoxon signed-rank test or Fisher's exact probability test.

Results: The preoperative IOP and medications of TMH group (18.8 ± 5.7 mmHg and 3.0 ± 1.2 medications, respectively) were higher than those of iStent group (15.5 ± 3.4 mmHg and 2.7 ± 1.2 medications, respectively) ($p<0.0001$ and $p=0.0437$, respectively); while those of TMH group (12.6 ± 2.3 mmHg and 2.3 ± 0.9 medications, respectively) were identical to those of iStent group (12.8 ± 2.5 mmHg and 2.3 ± 0.9 medications, respectively) ($p=0.0934$ and $p=0.3251$, respectively) at the 12 months postoperatively. By mixed-effects regression analysis, postoperative reduction of IOP and medications were significantly different between the two groups ($p<0.0001$, $p<0.0001$, respectively). At 12 months postoperatively, reduction of IOP in TMH group (6.2 ± 5.6 mmHg, 29.5%) was greater than those in iStent group (2.7 ± 3.2 mmHg, 18.8%) ($p=0.0003$); reduction of medication in TMH group (0.7 ± 1.3, 23.3%) was greater than those of iStent group (0.4 ± 1.1, 14.8%) ($p=0.0437$). Frequency of layered hyphema were significantly higher in TMH group (8 eyes, 25%) than iStent group (0 eye, 0%) ($p=0.0048$); frequency of IOP spike was equivalent between the groups (TMH, 2 eyes, 6%; and iStent, 2 eyes, 6%) ($p=1.0000$).

Conclusions: By fellow-eye comparison, IOP reduction was greater with TMH than with iStent, while achieved levels of IOP was identical between both procedures. The rate of layered hyphema was higher in TMH than iStent.

TITLE: Autoregulatory dynamics of the PERG in mice with induced and rescued mitochondrial dysfunction

SESSION TITLE: Electroretinography: basic mechanisms and disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Chou, H. Yu, A. Lazo, V. Porciatti, University of Miami Health System Bascom Palmer Eye Institute, Miami, Florida, UNITED STATES|R.D. Koilkonda, Lacerta Therapeutics, Inc., Alachua, Florida, UNITED STATES|

Commercial Relationships Disclosure: Tsung-Han Chou: Commercial Relationship: Code N (No Commercial Relationship) | Hong Yu: Commercial Relationship: Code N (No Commercial Relationship) | Rajeshwari Koilkonda: Commercial Relationship: Code N (No Commercial Relationship) | Angelina Lazo: Commercial Relationship: Code N (No Commercial Relationship) | Vittorio Porciatti: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Flickering light around 10 Hz induces rapid dilation of retinal vessels in the inner retina as well as progressive reduction (adaptation) of Pattern Electroretinogram (PERG) amplitude, indicating neuro-vascular-metabolic autoregulation. We measured flicker-PERG adaptation in control mice, in mice with induced mitochondrial dysfunction mimicking Leber Hereditary Optic Neuropathy (LHON) and in mice where induced LHON was rescued with gene-therapy.

Methods: 3-month-old DBA/1J mice were randomly split into three groups and received two intravitreal AAV injections at two-day intervals. The first group (Control, N=17) was injected with AAV/mcherry + AAV/mcherry (4.52 E8 vg/eye); the second group (LHON, N=23) with AAV/mutant ND4 (4.32 E9 vg/eye) + AAV/mcherry (4.52 E8 vg/eye); the third goup (LHON rescue, N=27) with AAV/mutant ND4 (4.32 E9 vg/eye) + AAV/wild-type ND4 (4.4 E8 vg/eye). A group of uninjected mice (naïve control, n=101) was also tested for comparison. In all mice, PERG was recorded from both eyes with superimposed 101 Hz flicker (baseline) and then with 11 Hz flicker (test) and the test minus baseline amplitude was considered as measure of flicker PERG adaptation. Group comparisons were performed using Generalized Estimating Equations (GEE) analysis accounting for the inclusion of both eyes.

Results: In naïve and control groups, the mean PERG adaptation was -4.1 µV (SE=0.42) and -3.2 µV (SE=0.94), respectively; in the LHON group was 0.84 µV (SE=0.89) and in the LHON rescued group was - 2.6 µV (SE=0.94). Multiple comparisons revealed significant ($P<0.05$) differences between control groups and LHON group and between rescued LHON and LHON group but not between control groups and rescued LHON group.

Conclusions: Mitochondrial dysfunction in a mouse model of LHON abolishes the flicker-induced PERG adaptation normally present in control mice. Gene-therapy to rescue mitochondrial function restores, at least in part, PERG adaptation. Flicker-induced PERG adaptation may represent a physiological tool to investigate altered metabolic autoregulation of retinal ganglion cells in optic neuropathies.

ABSTRACT BODY:

Purpose: To investigate the association between macular perfusion density and functional or anatomical impairment in various stages of glaucoma.

Methods: We retrospectively examined 147 medically treated primary open-angle glaucoma eyes. All the patients underwent static perimetry using the Humphrey Field Analyzer program Central 10-2, spectral-domain optical coherence tomography (OCT), and 6 × 6-mm optical coherence tomography angiography (OCT-A) centered on the fovea.

Results: The mean age was 64.0 ± 10.9 years (males: 62, females: 85). The mean intraocular pressure was 13.1 ± 2.1 mmHg. Macular perfusion density was positively correlated with sensitivity corresponding to central visual field and macular thickness in all 8 sectors (all $P < 0.05$; Pearson correlation coefficient). In addition, there was a positive correlation between the averaged macular perfusion density and the averaged thickness of the circumpapillary retinal nerve fiber layer (cpRNFL), as well as between the macular ganglion cell layer and the inner plexiform layer (mGCIPL) ($P = 0.001$ and $P < 0.0001$, respectively; Pearson correlation coefficient).

Conclusions: Macular perfusion density by OCT-A is highly correlated with both functional and structural changes in glaucoma, and thus its assessment might be useful for monitoring glaucoma.

ABSTRACT BODY:

Purpose: Mechanical properties of the peripapillary sclera (PPS) likely influence the vulnerability of optic nerve (ON) axons to glaucomatous damage. Here we investigated eyes and optic nerves of mice with a substantial deficiency in collagen type I, the major structural fibrillar molecule of the sclera.

Methods: Ubi-Cre3 col1a1$^{wt/fl}$ mice lacking one allele of Col1a1 were investigated. Col1a1 encodes for the pro-alpha1(I) chain that is essential for formation of triple stranded collagen type I. Knockdown of Col1a1 mRNA expression and protein synthesis was analyzed via real-time RT-PCR and western blot respectively. Ocular phenotypes of mutant mice and their control littermates were analyzed by histological staining of sagittal sections, including measurement of central corneal thickness (CCT) and retinal thickness. Axial length of enucleated native eyes was measured with a digital caliper. Myelinated ON axons were visualized and counted in PPD-stained ON cross-sections, whereas RGC somata were quantified on retinal whole mounts with an immunofluorescence staining against RBPMS.

Results: At three months of age, mutant mice showed a significant 50 % ($p = 0.02$) reduction in Col1a1 mRNA in scleral RNA that resulted in a 75 % reduction ($p = 0.03$) of translated COL1A1 at five months of age. Axial length and retinal thickness of Ubi-Cre3 col1a1$^{wt/fl}$ mice were not different from that of control littermates, while the cornea of mutant mice was thinner (98.9 µm ± 12.2 versus 86.3 µm ± 4.4, $p = 0.015$). Otherwise, there were no obvious light microscopical differences in ocular morphology. At two months of age, myelinated ON axon number was not different between mutant mice and their control littermates (36,918 ± 4310 versus 39,095 ± 5000). This was different in 5-month-old animals that showed a significant ($p = 0.008$) reduction in ON axons (40,215 ± 4854 versus 33,598 ± 7588). The findings correlated with a reduction of RGC somata (2370 ± 315 per mm^2 versus 1139 ± 277, $p = 0.04$).

Conclusions: We conclude that reduction in collagen type I causes a chronic and continuous loss of ON axons like that seen in glaucoma. The changes are likely induced by alteration of the mechanical properties of the sclera.

ABSTRACT BODY:

Purpose: Wind stimulation is an environmental factor that causes contact lens (CL) discomfort. We investigated the changes in ocular surface temperature and blood flow resulting from wind stimulation in soft CL (SCL) wearers.

Methods: We recruited 21 SCL wearers (21 eyes; mean age, 25.3±4.2 years) who wore two 1-day disposable silicone hydrogel lens (narafilcon A and delefilcon A). We measured the conjunctival blood flow, ocular surface temperature, and non-invasive tear break-up time (NIBUT) with/without SCLs after wind stimulation, which was created by a fan that directed wind at the rate of 3.0 meters/second to the volunteers' faces for 10 minutes while wearing and not wearing SCLs. The blood flow was measured as the mean blur rate (MBR) using laser speckle flowgraphy (LSFG-OAS, Softcare). The temperature and NIBUT measurements were conducted using ocular surface thermography (TG-1000, Tomey) and tear film interferometry (DR-1 Alpha, KOWA), respectively. Dryness was evaluated using the visual analog scale (VAS), with 0 indicating no symptoms.

Results: After wind stimulation, the NIBUT and VAS score for dryness symptoms with the delefilcon A lens (3.7±1.7 seconds and 29.4±16.9, respectively) were significantly ($P<0.01$ for both comparisons, paired t-test) longer and lower than with the narafilcon A lens (2.3±1.7 seconds and 35.9±17.0, respectively). Compared with no SCL, the corneal and bulbar conjunctival temperatures with SCLs decreased significantly ($P<0.01$ for both comparisons). The temperature difference between with/without the delefilcon A lens (-0.36±0.35°C) was significantly ($P<0.01$) lower than with the narafilcon A lens (-0.60±0.42°C). Although the bulbar conjunctival blood flow with the narafilcon A lens increased significantly ($P<0.05$) compared with no SCL (174.3±39.6 vs 158.7±33.2), that with the delefilcon A lens (156±42.3) did not reach significance. The rate of blood flow after wearing the narafilcon A lens (1.11±0.21) was significantly ($P<0.05$) higher than with the delefilcon A lens (0.99±0.19).

Conclusions: CLs with a lower NIBUT and more dryness show significantly greater changes in blood flow and temperature after wind stimulation. The wind stimulation test may be useful as a stress test for CL wear.

ABSTRACT BODY:

Purpose: Geographic atrophy(GA), an advanced form of age-related macular degeneration(AMD), is characterized by degeneration of the photoreceptors and retinal pigment epithelium(RPE). Prior evidence has implicated senescent retinal cells contribute to the pathogenesis of AMD. Increased activation of cyclic GMP–AMP synthase(cGAS)/ stimulator of interferon genes(STING)/Type I Interferon pathway has been reported in GA patients. However, the role of Type-I IFNβ in chronic retinal degeneration remains elusive. This study aims to investigate the role of STING/IFNβ in chronic retinal degeneration and cellular senescence contributing to the pathogenesis of GA.

Methods: STING protein expression in postmortem eyes with various stages of AMD was measured by immunohistochemistry. Luminex was used to determine the IFNβ production in response to STING agonists in primary human RPEs. To elucidate the role of IFNβ in chronic retinal degeneration in vivo, AAV2-CAG-IFNβ(1x10^9 GC/eye, n=12) was used for chronic(20 weeks) expression of IFNβ in the eyes of C57BL/6J mice via intravitreal injection and AAV2-CAG-Null(1x10^9 GC/eye, n= 12) was injected as a control. Optical coherence tomography(OCT) and fluorescein angiography(FA) imaging were performed to monitor leakage and retinal degeneration. Senescence-associated(SA) β-galactosidase assay and immunohistochemistry were used to analyze the retinal cellular senescence and RPE degeneration.

Results: STING protein expression increased in the RPE of AMD patients. In primary human RPEs, STING agonists led to dose-dependent IFNβ production. In the mouse model, an increase of retinal degeneration was observed in AAV2-CAG-IFNβ injected eyes by OCT and fundus imaging, but not in AAV2-CAG-Null injected eyes. AAV2-CAG-IFNβ injected mouse eyes showed a reduction of RPE65 and CRALBP expression and developed degenerated RPEs with features remarkably similar to GA patients. Furthermore, β-galactosidase and p16INK4a positive retinal cells were upregulated in the murine eyes injected with AAV2-CAG-IFNβ, but not in the AAV2-CAG-Null eyes.

Conclusions: STING activation in RPE occurs in postmortem eyes with all stages of AMD. STING agonists drive IFNβ secretion in primary human RPEs. In the murine model, chronic IFNβ expression by AAV2 increases retinal cell senescence and contributes to RPE degeneration. These results suggest that cGAS/STING induced IFNβ may contribute to the pathogenesis of AMD.

TITLE: Macular Pigment Optical Density and Its Determinants in a Russian population. The Ural Eye and Medical Study

SESSION TITLE: Public Health I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Iakupova, S. Panda-Jonas, M. Bikbov, G. Kazakbaeva, J. Jonas, Ufa Eye Research Institute, RUSSIAN FEDERATION|

Commercial Relationships Disclosure: Ellina Iakupova: Commercial Relationship: Code N (No Commercial Relationship) | Songhomitra Panda-Jonas: Commercial Relationship: Code N (No Commercial Relationship) | Mukharram Bikbov: Commercial Relationship: Code N (No Commercial Relationship) | Gyulli Kazakbaeva: Commercial Relationship: Code N (No Commercial Relationship) | Jost Jonas: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess the macular pigment optical density (MPOD) and its associations with ocular and systemic parameters and diseases.

Methods: The Ural Eye and Medical Study included 5899 (80.5%) out of 7328 eligible individuals. As part of ophthalmological and systemic examinations, MPOD was measured by reflectometry.

Results: MPOD data were available for 4889 (82.9%) individuals (mean age:57.8±10.1 years;range:40-94). Mean values for MOPD, maximal MOPD, macular pigment (MP) area and MP volume were 0.13±0.04 d.u. (density units), 0.36±0.09 d.u., 60,791±14,826 pixel, and 8,033±2,888 d.u.pixel, respectively. A higher MP density correlated (regression coefficient r:0.63) with older age (standardized regression coefficient beta:0.59;non-standardized regression coefficient B:0.23;95% confidence interval (CI):0.22,0.23;P<0.001), female sex (beta:0.08;B:0.63;95%CI:0.44,0.83;P<0.001), rural region of habitation (beta:0.13;B:1.02;95%CI:0.0.83,1.22;P<0.001), lower body mass index (beta:-0.04;B:-0.03;95%CI:-0.05,0.01;P=0.004), lower prevalence of chronic obstructive pulmonary disorder (beta:-0.03;B:-0.43;95%CI:-0.79,-0.08;P=0.02), higher erythrocyte sedimentation rate (beta:0.03;B:0.01;95%CI:0.002,0.02;P=0.03), lower leukocyte cell count (beta:-0.04;B:-0.10;95%CI:-0.16,-0.03;P=0.003), thinner temporal parafoveal retinal thickness (beta:-0.06;B:-0.01;95%CI:-0.01,-0.003;P<0.001), thinner central corneal thickness (beta:-0.06;B:-0.006;95%CI:-0.009,-0.004;P<0.001), higher prevalence of previous cataract surgery (beta:0.09;B:2.08;95%CI:1.50,2.65;P<0.001) and reticular pseudo drusen (RPD) (beta:0.03;B:0.56;95%CI:0.13,0.98;P=0.01), and lower stage of open-angle glaucoma (beta:-0.03;B:-0.39;95%CI:-0.74,-0.04;P=0. 03). Prevalence (P=0.44;beta:-0.01) and degree (P=0.70;beta:-0.01) of angle-closure glaucoma, prevalence (P=0.31;beta:0.01) of age-related macular degeneration (AMD) without RPD, and prevalence (P=0.95;beta:0.001) of diabetic retinopathy were not significantly associated with the mean MP density in that model.

Conclusions: After adjusting for age, sex, rural region, body mass index, perifoveal retinal thickness, central corneal thickness and previous cataract surgery, a higher MPOD correlated with a higher RPD prevalence and lower stage of open-angle glaucoma, but not with AMD independently of RPD.

TITLE: Sphingosine 1 Phosphate Signaling Enhances NF-κB Activation and Suppresses Muller Glia Reprogramming in the Injured Retina

SESSION TITLE: Non-neuronal control of retinal neuron regeneration

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: O. Taylor, A.J. Fischer, Neuroscience, The Ohio State University, Columbus, Ohio, UNITED STATES|

Commercial Relationships Disclosure: Olivia Taylor: Commercial Relationship: Code N (No Commercial Relationship) | Andy Fischer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Harnessing the regenerative potential of Muller glia (MG) may lead to the development of novel therapies reversing neuronal cell loss in sight-threatening diseases. In this study, we identify sphingosine 1 phosphate (S1P) as a critical activator of NF-κB, an inflammatory signaling pathway shown to suppress both the proliferation of Muller glia-derived progenitor cells (MGPCs) in chick retinas and the reprogramming of Ascl1-overexpressing MG in mouse retinas. We hypothesize that inhibiting S1P signaling may promote the formation of MGPCs in injured retinas.

Methods: NF-κB-eGFP transgenic mice (n=6, P77-144) received intravitreal injections of 2 µg/dose PF543, a sphingosine kinase 1 inhibitor, with 14.72 µg NMDA (an excitotoxin); the contralateral eye received NMDA + vehicle. Eyes were enucleated, fixed, and sectioned. Retinas were immunolabeled for GFP and Sox2. Co-labeled cells were quantified, and statistical analyses were conducted using a two-tailed paired t-test. A similar paradigm was conducted with SEW2871 (S1PR1 agonist) (2 ug/dose, n=7, P91-96).

Young postnatal chicks (n=6, P7) received intraocular injections of 5 µg/dose PF543 with 73 µg NMDA and 2 µg EdU. Fixed retinal sections were immunolabeled for EdU and Sox2, and co-labeled cells were quantified and analyzed with a two-tailed paired t-test. A similar paradigm was conducted with SEW2871 (5 ug/dose, n=6, P7).

Results: NMDA-damaged mouse retinas treated with PF543 had significantly fewer NF-κB+ MG (5.17±2.14) than control retinas (10.17±4.26, p=0.0035). Mouse retinas treated with SEW2871, without damage, had significantly more NF-κB+ MG (8.21±4.68) than control retinas (2.00±1.85, p=0.0091). Chick retinas treated with PF543 and NMDA showed greater proliferation of MGPCs (78.67±8.09) than control damaged retinas (44.5±13.61, p<0.0001). A decrease in proliferation was observed in injured chick retinas treated with SEW2871 (56.5±8.04) compared to control retinas (69.17±17.38, p=0.0296).

Conclusions: These results suggest that S1P signaling may suppress MGPC formation in part through NF-κB. We previously found that S1PR1 inhibition was not sufficient to decrease NF-κB or enhance MGPC formation; other S1P receptors may be compensatory in the absence of S1PR1 signaling. In this study, we found that S1P synthesis and receptor activation may be a critical inhibitor of MG reprogramming in chick and mouse retinas.

ABSTRACT BODY:

Purpose: To investigate the efficacy of oral administration of Bacillus derived-superoxide dismutase (SOD) in a murine model of experimental dry eye (EDE)

Methods: Mice were divided into 7 groups according to treatment: un-treated, EDE, vehicle, topical 0.05% cyclosporine (CsA), oral 2.5mg/kg SOD, oral 5.0mg/kg SOD, and oral 10.0mg/kg SOD. After exposure to desiccating stress for 5 days except for the un-treated group, tear volume, tear film break-up time (TBUT), and corneal fluorescein staining scores (CFS) were measured at 0, 5, and 10 days after treatment. Ten days after treatment, 2',7'-dichlorodihydrofluorescein diacetate assay (DCF-DA) for reactive oxygen species (ROS) production, enzyme-linked immunosorbent assay for malondialdehyde (MDA) were measured in the cornea, conjunctiva, and lacrimal gland. Flow cytometry for CD4+interferon-γ+ T cells were evaluated in the cornea and conjunctiva. In addition, periodic acid-Schiff staining for conjunctival goblet cells and TUNEL assay for corneal apoptotic cells were performed.

Results: After 5 and 10 days, treatment groups with topical 0.05% CsA, oral 2.5mg/kg SOD, oral 5.0mg/kg SOD, and oral 10.0mg/kg SOD showed increased tear volume and TBUT, and decreased CFS compared with the EDE and vehicle group. ROS production, MDA for oxidative stress, and corneal apoptosis were decreased in the CsA and 3 concentrations of SOD-treated groups. The number of inflammatory T cells of cornea and conjunctiva was decreased and conjunctival goblet cell density was increased in the treatment groups with topical 0.05% CsA, oral 2.5mg/kg SOD, oral 5.0mg/kg SOD, and oral 10.0mg/kg SOD. In addition, compared to the CsA-treated group, the oral 2.5mg/kg SOD groups showed increased TBUT and decreased inflammatory T cells; the oral 5.0mg/kg SOD groups showed decreased CFS and increased conjunctival goblet cells.

Conclusions: Oral administration of SOD could improve clinical parameters, oxidative damage, and inflammation in the murine EDE model.

ABSTRACT BODY:

Purpose: Vascular endothelial growth factor (VEGF) inhibitors provide excellent functional and morphological benefits in treating myopic macular neovascularization (mMNV) in the short term. We longitudinally investigated the real-life visual outcomes and the treatment burden of mMNV over a decade.

Methods: Retrospective electronic record review of adult patients with myopic refraction (<-1.00 D) and active mMNV undergoing at least one anti-VEGF agents' injection between January 2009 and March 2021. Best-corrected visual acuity (BCVA), optical coherence tomography findings, and number of intravitreal anti-VEGF injections administered were extracted at each visit. Factors associated with BCVA change were identified with linear mixed models. Treatment burden was quantified as number of injections to mMNV inactivation and rate of mMNV recurrences. Risk factors for recurrences were identified using recurring-events regression models.

Results: A total of 327 eyes (69% females; median[interquartile range, IQR] refraction -11 D [-14 to -9]) were included; 123 eyes (38%) had ≥5-year follow-up. mMNV presenting with subretinal fluid at baseline (estimate[SE]=0.84[0.40], p=0.03) required a higher number of injections for inactivation. BCVA returned to baseline at 3 years and then worsened (Figure 1). Central macular mMNV location (estimate[SE]= 0.07[0.06] vs. extrafoveal, p=0.01) had the worst prognostic effect on the visual acuity. In 174 eyes (53%), mMNV activity recurred; cumulative number of recurences was 3 at 10 years (Figure 2). Recurring eyes had a faster rate of vision loss (estimate[SE]=0.001[0.002] LogMAR/year for each recurrence, p=0.001) than non-recurring eyes. Older age (HR[95% CI]= 1.10[1.01-1.20] for each 10-year increase, p=0.04), larger mMNV (HR[95% CI]= 1.07[1.01-1.13] for each 1-mm^2 increase, p=0.02), and juxtafoveal mMNV (HR[95% CI]=1.61[1.04-2.51] vs. extrafoveal, p=0.03) were risk factors for recurrences.

Conclusions: mMNV patients progressively lose vision over the long term, despite intravitreal treatments. Older adults with large, central mMNV lesions have a higher risk of mMNV recurrence and faster rates of vision loss.

TITLE: Aflibercept Intravitreal Injection for Myopic Choroidal Neovascularization - 5 years follow up

SESSION TITLE: Macular diseases/Macular edema/Functional testing/evaluation/Laser

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.J. Nassaralla, Retina and Vitreous, Instituto de Olhos de Goiânia, Goiânia, Goiás, BRAZIL|A. Nassaralla, Retina and Vitreous, Centro Oftalmológico de Minas Gerias, Belo Horizonte, Minas Gerais, BRAZIL|

Commercial Relationships Disclosure: Joao Nassaralla: Commercial Relationship: Code N (No Commercial Relationship) | Arthur Nassaralla: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Follow up results of aflibercept intravitreal injecton (AII) in choroidal neovascularization secondary a pathologic myopia (MN) after 5 years.

Methods: 15 eyes wiht MN were trated with 2mg AII. BVVA, macular thickness on OCT and FA were evaluated. Follow-up were 5 years

Results: The mean were: age: 25yrs, refractive error: -10.75D and macular thickness decreased from 352 to 230 micrometers. At 12 months post -treatment mean BCVA increased from 20/100 to 20/50. Only 1 patient lost 35 letters; other 14 increased or stabilized their VA

Conclusions: These short-term results suggest thet AII are effective and safe and useful in patients with MN

ABSTRACT BODY:

Purpose: Rigid contact lenses are the method of choice to optically correct advanced keratoconus. Such lenses may translate and rotate on-eye, changing the resulting Wavefront Error (WFE). This work assesses how this motion affects acuity in normal and keratoconic eyes.

Methods: Previous SyntEyes models were expanded by adding the ability to shift and rotate a sphero-cylindrical rigid contact lens correction with respect to the center of a 5 mm pupil. More specifically, a simulated through-focus experiment of 20 normal and 20 keratoconic SyntEyes first objectively determined the centered sphero-cylindrical correction which optimized the visual Strehl (VSX). The optimal correction was then allowed to misalign ±1 mm in 0.1 mm steps and rotate ±15° in 1° steps, defining an 'alignment space'. This provided 52 111 resultant WFE for each eye, which were used to calculate VSX, changes in which may be used to predict changes in logMAR acuity.

Results: Keratoconic SyntEyes were significantly less tolerant to lens rotation than normal SyntEyes before potentially noticeable changes of more than 2 logMAR letters occur (t-test, $p < 0.01$), which varied considerably between individual eyes. These variations were not correlated with the amount of uncorrected astigmatism ($p > 0.05$) as the contact lenses dampened the corneal astigmatism. Normal SyntEyes had a significantly larger average tolerance to rotation than keratoconic cases (respectively, -14.1° to +13.4° and -10.5° to 10.6°; $p < 0.01$). Similarly, normal SyntEyes were also significantly more tolerant to decentration than keratoconus (0.39 ± 0.15 mm and 0.27 ± 0.13 mm, respectively).

Perfect alignment did not always provide the best possible optical correction, as in 9/20 keratoconic SyntEyes a gain of 1 or more letters was seen for a shifted or decentered lens position (Figure 1). This was also seen in 2/20 normal SyntEyes.

Conclusions: Keratoconic eyes are more sensitive to smaller amounts of misalignment than normal eyes. In many cases, the best possible visual image quality may be obtained with a certain combination of decentration and rotation, rather than with perfect alignment.

TITLE: Comparison of Ocular Health Outcomes Between a Tele-Eye Care Comprehensive Eye Exam and a Gold Standard In-Person Eye Exam

SESSION TITLE: Telehealth

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Blais, F. Brisson, J. Hanssens, School of optometry, Universite de Montreal, Montreal, Quebec, CANADA|

Commercial Relationships Disclosure: Nicolas Blais: Commercial Relationship: Code N (No Commercial Relationship) | Fannie Brisson: Commercial Relationship: Code N (No Commercial Relationship) | Jean-Marie Hanssens: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The lack of data on how tele-eye care comprehensive eye exams compare to the in-person exams in primary eye care settings prevents law makers from clearly outlining the role of tele-eye care. This randomized clinical trial aims to compare the number of ocular health tests results that are outside of clinical norms, compare the confidence level of the eye care provider (ECP) for each of these tests results and compare the eye health diagnoses (Dx) between hybrid tele-eye care and in-person comprehensive eye exam.

Methods: Thirty-five optometry-naïve participants (13 M, 22 F, aged 21-58 years), consulting for routine eye examination were randomly subjected to two comprehensive eye exams. The in-person eye exam was completed by an on-site ECP, while the tele-eye care exam was performed by an in-person technician through DigitalOptometrics™ platform and videoconferencing with a remote ECP. All ocular health tests results were categorized according to their compliance to clinical standards and the ECP scored their confidence level for all exam results. Results of the two modalities were compared with Krippendorff's alpha coefficients (a) and Wilcoxon signed rank tests (p). The number of common and different Dx between both modalities were also analyzed.

Results: No statistically significant difference between both exam modalities was found for all ocular health tests ($a > 0.50$), apart from extra-ocular motilities (EOM) testing ($a = 0.25$; $*p = 0.025$). No abnormal pupils were detected in both modalities. ECP reported significantly better confidence for in-person exams (97 ± 01%) compared to tele-eye care (77 ± 3%) ($p < 0.001$). Twenty-five Dx were found in tele-eye care compared to 23 in-person, among which 14 (29%) did not match between modalities with eight found only in-person and six found only remotely. These had a low morbidity and included conditions such as mild blepharitis and conjunctivochalasis.

Conclusions: Our data suggest that for a sample of people consulting for a routine examination, the levels of confidence of ECP are statistically lower for remote eye exams compared to in-person. However, both exam modalities have a statistically equivalent ability to detect out of standards ocular health findings, apart from EOM testing. To better analyze the difference in total number of ocular health Dx, the ECP should have scored a morbidity level to each Dx they made.

ABSTRACT BODY:

Purpose: Keratoconus (KC) is a progressive corneal thinning disease that manifests in puberty and worsens during pregnancy. The onset and progression of KC is considered to be multifactorial and include: environmental, genetics, and hormonal imbalances; however, the pathobiology remains elusive. This study will reveal recent in vitro and in vivo findings related to sex hormones and their receptors in an attempt to establish a causal and contributory relationship to the KC disease process.

Methods: In vitro: An established 3D in vitro self-assembled extracellular matrix (ECM) model was utilized in order to determine the interplay of major androgens/estrogens and the sex hormone receptors present in Healthy/KC corneal stromal cells via Western Blot analysis. In vivo: Ongoing clinical studies, focusing on sex hormones and KC, are discussed. Androgen/Estrogen ELISA expression was measured in a small cohort of KC patients before and after Collagen Cross Linking (CXL) treatment.

Results: In vitro: Significant changes were observed between Healthy and KC corneas, as well as between males and females in the sex hormone receptors tested; androgen receptor (AR), progesterone receptor (PR), estrogen receptor alpha (ERα), and estrogen receptor beta (ERβ). For example, both estrone (E1) and estriol (E3) stimulation in Healthy-Females showed that AR, PR, and ERβ were significantly upregulated compared to Healthy-Males. In contrast, ERα and ERβ had significantly higher expression in HKC-Females, when compared to HKC-Males. In vivo: Using blood (plasma) levels, the levels of three essential sex hormones (DHEA-S, Estrone, and Estriol) were measured. After CXL, DHEA-S levels were lower but Estrone and Estriol levels were higher, suggesting that CXL not only affects the corneal tissue (i.e., locally), but also modulates hormonal levels in the bloodstream. Variability among patients, and changes due to medication/severity will also be discussed.

Conclusions: Our data suggests that the human cornea is a sex-dependent and a hormone-responsive tissue. We posit that KC is a systemic disease, at least initially, and is heavily dependent on systemic and local hormone alterations.

TITLE: Upregulated YAP activity and histone acetylation modulate glaucomatous trabecular meshwork cell dysfunction

SESSION TITLE: Glaucoma: molecular, biochemical and biomechanical mechanisms

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: H. Li, P.S. Ganapathy, S. Herberg, Ophthalmology & Visual Sciences, SUNY Upstate Medical University, Syracuse, New York, UNITED STATES|D.W. Stamer, Department of Ophthalmology, Duke University, Durham, North Carolina, UNITED STATES|

Commercial Relationships Disclosure: Haiyan Li: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Stamer: Commercial Relationship: Code N (No Commercial Relationship) | Preethi Ganapathy: Commercial Relationship: Code N (No Commercial Relationship) | Samuel Herberg: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The extracellular matrix (ECM) in the glaucomatous trabecular meshwork (GTM) is markedly stiffened. This potent biophysical cue drives progressive cellular dysfunction. Increased Yes-associated protein (YAP) activity is linked to GTM cell pathobiology, and a recent genome-wide study identified YAP1 among novel glaucoma risk loci. Epigenetic modifications such as histone acetylation are further associated with TM failure in glaucoma. Yet, the molecular underpinnings of cellular dysfunction in response to TM stiffening, and the contributions of YAP signaling and epigenetic remodeling remain unclear. Here, we investigate the effects of ECM stiffness modulation on YAP activity and histone acetylation, and how these elements modulate GTM cell dysfunction using ECM hydrogels.

Methods: ECM hydrogels were made by photocrosslinking functionalized collagen type I, elastin-like polypeptide, and hyaluronic acid. Bioinert alginate was incorporated to facilitate stiffening (via Ca^{2+} crosslinking) and dynamic softening (via alginate lyase degradation) of ECM-alginate hydrogels. Donor-derived normal TM (NTM)/GTM cells were plated on/encapsulated in hydrogels and stimulated with histone deacetylase inhibitor trichostatin-A (TSA; 150 nM) or histone acetyltransferase inhibitor garcinol (5 μM). Fibrotic marker level expression, YAP activity, cytoskeletal/nuclear organization, and histone acetylation were quantified.

Results: ECM-alginate hydrogel stiffness was increased ~3-fold upon Ca^{2+} crosslinking ($p<0.001$); alginate lyase treatment restored soft baseline levels. ECM stiffening increased F-actin, alpha-smooth muscle actin, nuclear size/tension, YAP nuclear localization, and histone acetylation in NTM and GTM cells ($p<0.05$). These pathological features were completely reversed in NTM cells by ECM softening, while GTM cells displayed a persistent fibrotic phenotype with elevated histone acetylation. Strikingly, NTM cells in a soft ECM environment treated with TSA showed increased YAP transcriptional activity, nuclear size/tension, and F-actin compared to controls ($p<0.001$). Likewise, GTM cells treated with garcinol exhibited markedly decreased nuclear YAP and expression of fibrotic markers.

Conclusions: Our data suggest that targeting ECM stiffening to interrupt aberrant YAP signaling and histone acetylation is emerging as a promising strategy to permanently restore TM tissue function in glaucoma.

ABSTRACT BODY:

Purpose: To examine whether aberrant macular cone post-synaptic circuitry may underly the decreased best corrected visual acuity (BCVA) seen in albinism.

Methods: Eight patients with albinism underwent multifocal electroretinography (mfERG, VERIS) and retinal imaging with adaptive optics scanning laser ophthalmoscopy (AOSLO). Pearson correlation of peak cone density (CD) with BCVA, mfERG amplitudes, and mfERG “slope” (rate of amplitude decline between the central Ring [R] 2 and peripheral R6) was performed. Parafoveal CDs and their rate of decline were compared to mfERG slope in 4 subjects. Control data was obtained from our previous studies of healthy individuals with peak CD measurements (n=58 [PMC7746960]), parafoveal CD measurements (n=20 [PMC3348369]), or mfERG (n=18 [PMC6754264]).

Results: All subjects had below average peak CD (mean 62,223±34,153; range 22,611-129,576 cones/mm^2 vs. 180,286±25,436; 122,710-247,710 cones/mm^2 in controls), decreased BCVA (mean 20/63; range 20/25-20/150), and flattened mfERG topography (R2-R6 slope: 0.239 vs. 0.312 in controls). Higher peak CD correlated with better logMAR BCVA (r=-0.85, p=0.002) and higher mfERG amplitudes in the periphery (r=0.68, p=0.029), but not centrally (r=-0.08). Parafoveal CDs were low compared to controls within the central 2 degrees, and we did not observe an association between higher CD and steeper mfERG topographies. Interestingly, the 2 subjects with 2 confirmed pathogenic mutations in OCA1 had the steepest mfERG topography and BCVA worse than 20/70 (peak CD: 42,100 and 46,400 cones/mm^2), while the 5 patients with at least one hypomorphic allele had BCVA better than 20/70 despite having flatter mfERG topography (peak CD range 38,399-129,576 cones/mm^2).

Conclusions: Although a wide range of peak foveal cone densities overlapping with the normal range is observed among these patients with albinism, denser cone packing does not result in steeper (more normal) mfERG topography, although it does correlate with better BCVA. Instead, higher cone packing is associated with higher peripheral mfERG amplitudes, suggesting abnormal connections between cone photoreceptors and bipolar cells, which could be similar to the unrefined circuitry seen in fetal retinas. This aberrant post-synaptic circuitry may explain why, even among albinism patients with milder foveal hypoplasia and denser foveal cone packing, optimal visual acuity is often unachievable.

TITLE: Enhanced Antigen-Presenting Cell Maturation in Diabetic Donor Corneas Leads to Heightened Host Allosensitization

SESSION TITLE: Corneal Immunology and Neovascularization

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Liu, T. Blanco, H. Nakagawa, A. Musayeva, S. Wang, T.H. Dohlman, Y. Chen, R. Dana, Ophthalmology, Harvard Medical School, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Catherine Liu: Commercial Relationship: Code N (No Commercial Relationship) | Tomas Blanco: Commercial Relationship: Code N (No Commercial Relationship) | Hayate Nakagawa: Commercial Relationship: Code N (No Commercial Relationship) | Aytan Musayeva: Commercial Relationship: Code N (No Commercial Relationship) | Shudan Wang: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Dohlman: Commercial Relationship: Code N (No Commercial Relationship) | Yihe Chen: Commercial Relationship: Code N (No Commercial Relationship) | Reza Dana: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We have previously shown that a diabetic state induces an altered corneal microenvironment that alters the immune homeostasis of the cornea, leading to increased APC (antigen-presenting cell) maturation. Herein we examine the host alloimmune response to allografts from diabetic donors, in particular the role of graft-borne APC.

Methods: Type I diabetes mellitus (DM) was induced in C57BL/6 mice by injecting streptozocin (STZ). On day 56, corneas were either harvested and assessed through flow cytometry and immunofluorescence or transplanted into non-DM BALB/c recipient mice. Two weeks after transplantation, grafted corneas and draining lymph nodes (DLN) were analyzed by flow cytometry. In addition, IFNγ production by alloreactive CD4+ Th1 cells was quantified by flow cytometry and ELISPOT assay to evaluate the contribution of graft donor APC to host sensitization.

Results: APC ($CD45^+CD11b^+$) in DM corneas showed higher frequency ($p=0.0001$) and enhanced expression of the maturation markers (MHC-II, CD80, CD86, and CCR7) ($p=0.0001$) when compared to APC from non-DM corneas. Following transplantation, the frequency of mature migratory CD45+CD11b+ APC was significantly increased in the DLN of recipients receiving grafts from DM donors as compared to non-DM donors ($p<0.001$). $IFN\gamma^+$ production by alloreactive $CD4^+$ Th1 cells in hosts receiving grafts from DM donors was higher ($p<0.001$) as compared to non-DM donors. DM graft-derived APC were significantly more potent in sensitizing $CD4^+$ Th1 cells (direct pathway of sensitization) ($p<0.001$) compared to host APC (indirect pathway). Finally, DM allografts had a higher failure rate when compared to non-DM allografts (100% vs. 52%, $p<0.001$).

Conclusions: Our results demonstrate that a donor diabetic state leads to increased homing and maturation of corneal APC, and that following transplantation graft-borne APC swiftly migrate to the DLN to increase host sensitization. Together these changes may lead to increased graft rejection / failure when corneal transplants are derived from diabetic donors.

TITLE: Change in Blink Rate Following Botulinum Toxin Injection in Benign Essential Blepharospasm

SESSION TITLE: Oculoplastics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Yazdanpanah, M.T. Yen, S.C. Pflugfelder, Department of Ophthalmology, Baylor College of Medicine, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure: Ghasem Yazdanpanah: Commercial Relationship: Code N (No Commercial Relationship) | Michael Yen: Commercial Relationship: Code N (No Commercial Relationship) | Stephen Pflugfelder: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Benign essential blepharospasm (BEB) is characterized by involuntary twitching of eyelids, increased blinking, and photophobia. Serial injections of botulinum toxin type A (BTX-A) into the eyelid protractors, including the pretarsal orbicularis oculi muscle and corrugator supercili is the core management for BEB. Here, the blink rate was measured objectively to evaluate the effect of BTX-A injection in BEB patients.

Methods: In this prospective case series, 10 subjects with BEB managed with BTX-A injections were included after informed consent. The study was approved by Baylor College of Medicine IRB. Management history was recorded with chart review. Blink rates were measured while watching a video before injection (at least 3 months after last injection) and at follow-up within 4 weeks. The frequency of blinking and the severity of light-sensitivity were self-graded on a visual analog scale. The results are reported as median (range) and Wilcoxon test is used for non-parametric paired comparison.

Results: Nine subjects are female, and median age was 73.5 (49-81) years. The median follow-up time is 21 (14-28) days after BTX-A injection. The duration of treatment is 70 (5-16) months with a total of 27.5 (2-51) injections. Subject graded frequency of blinking (0, normal and 5, constant blinking) was 4.5 (2-5) before BTX-A injection and decreased to 1.75 (0-4.5) at follow-up (p=0.004, Fig1A). Subject reported light-sensitivity (0, none and 5, severe) decreased from 3.5 (0-5) before injection to 2.75 (0-4) at follow-up (p=0.047, Fig 1B). The blink rate before BTX-A injection is 39 (23-64), and significantly decreased to 18.5 (1-60) blinks per minute at follow-up (p=0.004, Fig1C). The average change in blink rate is -45.2±31.2% (mean±SD, Fig 1D). Blink rate change has a significant correlation with both duration of BTX-A injection treatment (r=-0.659, p=0.037) and number of treatments (r=-0.639, p=0.047).

Conclusions: This is the first known report of objective reduction in blink rate after BTX-A injection in BEB patients. BTX-A injection significantly improved photophobia. Higher duration of BTX-A injection treatment or more numbers of past injections significantly correlates with higher decrease in blink rate after each injection.

ABSTRACT BODY:

Purpose: Previously reported data from the phase 1 OPTIC study of ADVM-022 (AAV.7m8-aflibercept) in nAMD patients have demonstrated a single IVT injection gene therapy that durably expresses intraocular aflibercept can reduce the need for frequent anti-VEGF injections and improve visual and anatomical outcomes. The potential impact of baseline levels of neutralizing antibodies (NAbs) to AAV.7m8 on efficacy and safety outcomes are reported.

Methods: OPTIC is an open-label, multi-center, dose-ranging study in treatment-experienced nAMD patients administered a single intravitreal injection of ADVM-022 at 6E11 vg/eye (Cohort C1 n=6; C4 n=9) or 2E11 vg/eye (C2 n=6; C3 n=9). NAbs inclusion criteria were a titer level of <1:5 within 6 months prior to ADVM-022 for C1 and <1:125 for C2-4. The impact of baseline NAbs on treatment burden, aflibercept protein expression levels, central subfield thickness (CST) fluctuations and safety outcomes was evaluated.

Results: As of August 27, 2021, median follow-up was 104 weeks (C1&2), 92 weeks (C3) and 60 weeks (C4). In C2-4 8/9 (89%) and 10/15 (67%) of 6E11 and 2E11 vg/eye patients, respectively, had baseline NAbs to AAV.7m8 <1:125. 12/15 patients receiving 6E11 and 8/15 receiving 2E11 vg/eye ADVM-022 remained supplemental anti-VEGF injection free; mean annualized anti-VEGF injection frequency was reduced by 97% (6E11) and 81% (2E11). 4/7 (57%) 2E11 patients requiring supplemental aflibercept injections had NAbs titres > 1:125. The reductions in mean annualized anti-VEGF injection frequency in patients with baseline NAbs <1:125 were 97% and 93% in the 6E11 and 2E11 vg/eye groups, respectively. Patients with NAbs <1:125 at baseline showed more robust aflibercept protein expression levels and sustained improvements in CST with less fluctuations compared with patients with baseline NAbs >1:125. No correlation between NAbs titer and immune response was observed. ADVM-022 continues to be well tolerated with a favourable safety profile in the nAMD population.

Conclusions: These data suggest patients with baseline NAbs to AAV2.7m8 <1:125 were more likely to demonstrate robust aflibercept protein expression, have sustained improvements in CST with minimal fluctuations, and were less likely to require supplemental aflibercept injections. Baseline NAbs were not associated with occurrence nor duration of inflammation.

ABSTRACT BODY:

Purpose: Reticular Pseudodrusen (RPD) is a critical phenotype in age-related macular degeneration. We trained a deep learning model to reliably segment RPD on optical coherence tomography (OCT) B-scans in participants with intermediate AMD.

Methods: OCT volume scans from 120 participants from the Laser Intervention in the Early Stages of AMD Study were used for model development and internal testing. A total of 60 eyes with RPD and 180 eyes without RPD (with 49 scans per eye) were split at the participant level into 6 folds; 5 folds were used for cross-validation model training and fold 6 was reserved for testing. Each of 5 models consisted of a Mask-RCNN head with ResNeXt-101-32x8d-FPN backbone. The final model is a soft-voting ensemble of the 5 models.

Results: The instance-level Precision-Recall curve for the test fold, which contains 10 eyes with RPD and 30 eyes without RPD, is plotted in Figure 1a. At the instance-level the ensemble achieved precision of 0.64 [95% CI: 0.61,0.67], recall of 0.69 [0.66,0.72], and F1 of 0.66 [0.64,0.68] at the Intersection over Union (IoU) threshold of 0.2 and model probability threshold of 50%. The false positive rate (FPR), defined as the number of negative scans for which at least one RPD was predicted, was 4.4% [3.5%,5.5%]. The predicted vs actual RPD count per scan is plotted in Figure 1b.

For classifying RPD at the eye level, the ensemble achieved precision of 0.56 [0.33, 0.75], 0.83 [0.55,0.95], and 1.00 [0.72,1.00] when thresholding on 1 or more, 5 or more, and 10 or more RPD instances per eye, respectively, in the model prediction of the test fold. The ensemble achieved a recall of 1.00 [0.72,1.00] at those instance thresholds.

Conclusions: We successfully trained a model to segment RPD instances in B-scans and have validated the model on an internal test set.

TITLE:

Ultrasound biomicroscopy correlation with corneal diameter in pediatric patients

SESSION TITLE: Multidisciplinary Ophthalmic Imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Kolosky, A.U. Saga, M.R. Levin, J.L. Alexander, Department of Ophthalmology and Visual Sciences, University of Maryland School of Medicine, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Taylor Kolosky: Commercial Relationship: Code N (No Commercial Relationship) | Anusha Saga: Commercial Relationship: Code N (No Commercial Relationship) | Moran Levin: Commercial Relationship: Code N (No Commercial Relationship) | Janet Alexander: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Prior studies have established ultrasound biomicroscopy (UBM) as a clinically valuable imaging modality for structural anterior segment assessment, but its correlation with standard measures of ocular size, such as corneal diameter (CD), has not been examined. CD evaluation is pertinent to cataract surgery planning, and diagnosis and monitoring for congenital conditions such as microcornea, megalocornea, and congenital glaucoma. CD is typically measured using a ruler, calipers, or gray-scale steps devices. These external CD measurements are subject to error and variability, prompting our investigation of measuring corneal dimensions internally from UBM images.

Using a prospective cohort of healthy controls, we tested the hypothesis that CD correlates with internal corneal span determined from the angle-to-angle (AA) distance measured in UBM images.

Methods:

We collected 45 digital external photos and 86 UBM images of a total of 43 eyes from 24 participants between ages 1 – 12 years without ocular disease. We measured horizontal (H) and vertical (V) CD in each external photo using ImageJ software. We also used ImageJ to measure the internal angle-to-angle (AA) distance in H and V cross-sectional UBM images of each eye.

Results: Horizontal and vertical CD and AA measurements were highly positively correlated, as determined by Pearson correlation coefficients of +0.97 and +0.96, respectively. Bland-Altman plots demonstrated high agreement between methods for both H and V measurements (Fig. 1). Regression analysis revealed a linear relationship between CD and AA for H (Fig. 2A, CD = 0.99 x AA + 0.17, R^2 = 0.94, P<0.0001) and V (Fig. 2B, CD = 0.96 x AA + 0.44, R^2 = 0.92, P<0.0001) measurements.

Conclusions:

UBM image analysis can be used to accurately quantify corneal diameter in children with healthy corneas, as shown by the strong correlation between CD and AA measurements. Given its high resolution and non-invasive nature, UBM may be a useful alternative for determining CD. Further studies are needed to understand the potential to determine CD from AA distance in patients with ocular diseases that may impact the cornea, such as primary congenital glaucoma.

TITLE: Design Concepts for a Myopia Control Soft Contact Lens

SESSION TITLE: Refractive Error: Myopia, Hyperopia, vision and models

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N.A. Brennan, X. Cheng, Johnson and Johnson Vision, Jacksonville, Florida, UNITED STATES|M.J. Collins, School of Optometry, Queensland University of Technology, Brisbane, Queensland, AUSTRALIA|

Commercial Relationships Disclosure: Noel Brennan: Commercial Relationship(s);Code E (Employment):Johnson & Johnson Vision;Code I (Personal Financial Interest):Johnson & Johnson Vision;Code P (Patent):Johnson & Johnson Vision | Michael Collins: Commercial Relationship(s);Code C (Consultant/Contractor):Johnson & Johnson Vision;Code F (Financial Support):Johnson & Johnson Vision | Xu Cheng: Commercial Relationship(s);Code E (Employment):Johnson & Johnson Vision;Code I (Personal Financial Interest):Johnson & Johnson Vision;Code P (Patent):Johnson & Johnson Vision

ABSTRACT BODY:

Purpose: Increasing power in a myopia control treatment zone (MCTZ) of a multifocal soft contact lens can increase myopia control efficacy but negatively impact vision. The basis of vision compromise is explored with simple optical modelling and a novel approach to break the nexus between efficacy and vision.

Methods: The impact of MCTZ power, size and position on visual acuity, contrast and haloes/ghosting were modelled. Optical designs featured annular MCTZs surrounding a central distance vision correction zone (DZ), typical of dual focus (DF) designs such as Acuvue® Bifocal and MiSight®. To overcome limitations of DF designs, the non-coaxial principle described by Yi et al. (ARVO, 2021) was applied to the annular MCTZ. This was tested empirically with an adaptive optics system.

Results: Composite images comprising the clear image from the DZ and blurred images from the DF MCTZ are consistent with Davis et al (ARVO, 2021), showing VA worsening up to a power of +2 to +3 D and improving beyond that level, but with reduced contrast (Fig 1). Rays from a distant point source passing through the DF MCTZ form a halo at the retina (Fig 2), with increasing power in the MCTZ increasing the size of the halo. Convolving for edges shows that ghosting is a major vision limitation of DF designs, with MCTZ power being the main driver of ghost-image size. Forming the MCTZ from a torus rather than a spherical shape generates a ring focus, which can markedly reduce the halo effect (eg. from 3.3° ± 0.1 with a +10D DF MCTZ to 0.11° ± 0.04 with a +10D torus MCTZ). Adding positive power into the torus MCTZ results in short-term (30 min) reduction (± SD) of axial length comparable to that observed with a +3 D full-field lens (11.4 ± 6.2 µm vs 11.0 ± 8.8 µm, N=17 and 18 respectively, p=NS) while maintaining acceptable vision quality.

Conclusions: This is the first optical characterization of vision compromise versus myopia control efficacy with DF lenses to our knowledge. While treatment efficacy of a myopia control soft lens is related to the local power in the MCTZ, the optical method by which treatment is delivered can have a major impact on the extent of vision compromise.

ABSTRACT BODY:

Purpose: Although in vivo confocal microscopy (IVCM) is routinely used in clinics, it is challenging to precisely monitor cornea pathophysiological changes, partially due to the complexity of cornea nerve architecture. Double lacrimal gland removal (DLGR) is commonly employed to establish animal dry eye disease, with a substantial change in cornea nerve morphology and inflammatory cell infiltration. Here we describe a new method for monitoring corneal stroma change using the Heidelberg Retina Tomography III (HRT III) in a murine dry eye model.

Methods: Sprague-Dawley rats (8-9 weeks, male) underwent DLGR to remove the infraorbital and extraorbital lacrimal glands. Male rats were chosen in this study due to a lesser hormonal cycle influence. Up to three stroma nerves per eye were selected to image and re-imaged 2 weeks and 6 weeks post-surgery. Image data were acquired as volume acquisition. The sequential images with selected stromal nerve were manually adjusted and stacked into a 3-D nerve reconstruction by Image J. To validate the result, whole rat cornea was harvested post-mortem and nerve fibers were stained with TUBBIII.

Results: Cornea wholemounts image indicated that the stroma nerve acquired by IVCM matched the nerve architecture map. Due to the curvature of the rat cornea, three IVCM images were located within an area of 30% of the whole cornea (Fig 1A, B). In the rat cornea with dry eye disease, we observed various dendritic cells infiltration along nerve trunks. 3-D reconstruction of the corneal nerve architecture showed the differential spatial distribution of those dendritic cells (Fig 1C, D, triangles). Longitudinal follow-up of the stroma nerve after DLGR indicated that nerve reflection increase (tan arrows), nerve sprouting (white arrows). There was more dendritic cell infiltration (triangles) 6 weeks after the double lacrimal gland compared to 2 weeks post-surgery (Fig2A, B). The 3-D reconstruction of stromal nerve architecture revealed different nerve and cellular changes in the cornea stroma between the anterior side (0^0) and posterior side (180^0).

Conclusions: Here we demonstrated the precise mapping and 3-D reconstruction of stroma nerve architecture in a DLGR dry eye model, revealing that nerve and cellular changes exacerbation after model establishment. This work also suggested that this methodology held potential for development into a clinical diagnostic modality.

ABSTRACT BODY:

Purpose: RP33 is a non-syndromic form of RP caused by mutations in the SNRNP200 gene encoding an essential component of the spliceosome that is required for pre-mRNA splicing. SNRNP200 is expressed in nearly all cells, yet defects are only observed in the retina. To understand the function of SNRNP200 in vision, we generated Drosophila models.

Methods: The Drosophila orthologue of human SNRNP200 is lethal(3)72Ab, which we refer to as dSNRNP200. Human SNRNP200 and fly dSNRNP200 have 74% amino acid identity and 89% similarity. To understand disease mechanisms, we analyzed the developing retina and performed electroretinograms (ERG) of adult Drosophila using RNAi knock-down and patient based CRISPR mutant alleles of dSNRNP200.

Results: RNAi knock-down of dSNRNP200 in the developing eye increased apoptosis in the larval eye discs relative to controls and produced an adult “rough eye” phenotype. Similarly, a CRISPR mutant allele increased apoptosis in larval eye discs relative to controls. ERGs performed on young adults bearing the CRISPR mutant alleles exhibited abnormal waveforms indicative of loss of phototransduction and synaptic transmission that progressed with age, similar to the human disease condition. In addition, loss of prolonged depolarizing afterpotential indicated that the “rod-like” cells of the retina were defective. By contrast, the cone-like cells appeared functional, recapitulating early stages of the human disease.

Conclusions: Globally expressed dSNRNP200 is essential for Drosophila photoreceptor function. Modeling RP33 mutations in the fly recapitulated many aspects of the human disease, which will allow for a molecular dissection of disease mechanisms and genetic and pharmacological screens for potential treatments.

ABSTRACT BODY:
Purpose: To describe the use and trends of virtual care and exam associated factors in Ontario, Canada during the 2020 COVID-19 pandemic.
Methods: Ontario physician billing data from 2017-2020 was analyzed. Virtual care provided by ophthalmologists were identified from fee code and specialty codes. Percentage and adjusted odds ratio (aOR) from logistic regression models were used to assess patients' and ophthalmologists' factors associated with virtual vs in-person visits.
Results: Virtual assessments/consults comprised 0.07%-0.10% of ophthalmology assessments/consults in 2017-2019 and 8.31% in 2020. The weekly uptake of virtual visits increased immediately in the week of the Ontario government's directive to ramp down clinic activities and institution of a new virtual fee code (17.6%, week March 16, 2020), peaked 2 weeks later (55.8%, week March 30, 2020) and reduced immediately after the directive was lifted (24.2%, week May 25, 2020).

During the 2020 pandemic period, use of virtual care was higher in female (11.6%) vs male (10.3%) patients and in patients <20 (16.4%) and 20-39 years (12.3%) vs those aged 40-64 (10.8%) and 65+ (10.6%) years. Patients residing in the poorest/poorer neighbourhood area (10.9%) used virtual care similarly to their counterparts (11.1%). Patients with an acute infectious disease (14.2%) or non-urgent diagnosis (16.2%) had the highest use. Those with a retinal disease diagnosis had the lowest use (4.2%).

Female ophthalmologists provided virtual care more often than male ophthalmologists (15.4% vs 9.9%). Ophthalmologists aged 60-69 (13.1%) provided more virtual care than any other age groups (from 7.7% for 70+ years to 11.3% for <40 years).

Regression analyses indicated a significantly higher chance of virtual care use in female (aOR=1.65) vs male ophthalmologists, in female (aOR=1.13) vs male patients, in patients <20 years (aOR=1.57) and 20-39 years (aOR=1.17) vs 65+, in patients residing in Central (aOR=1.37), East (aOR=1.52) and North (OR=1.13) regions vs those in the Toronto region. Compared with ophthalmologists aged 60-69 years, those in other age groups were less likely to use virtual care (aOR ranged 0.57-0.76).
Conclusions: Virtual care in ophthalmology significantly increased during the initial phase of the pandemic and decreased thereafter. There were significant variations in virtual care use by patient and ophthalmologist characteristics.

TITLE: Trends in retinopathy of prematurity training and future practice intentions among retina and pediatric ophthalmology fellows

SESSION TITLE: Retinopathy of prematurity

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Eton, B. Young, C.G. Besirli, W K Kellogg Eye Center, Ann Arbor, Michigan, UNITED STATES|

Commercial Relationships Disclosure: Emily Eton: Commercial Relationship: Code N (No Commercial Relationship) | Benjamin Young: Commercial Relationship: Code N (No Commercial Relationship) | Cagri Besirli: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinopathy of prematurity (ROP) is a leading cause of blindness among preterm and low-birthweight infants. Improved survival of very preterm and very low birth weight babies has led to increased numbers of patients requiring ROP care; however, studies demonstrate a ROP provider shortage. We sought to better understand the future ROP workforce by identifying trends in ROP training and practice interest among pediatric ophthalmology and retina fellows.

Methods: Lists of vitreoretinal surgery, medical retina, and pediatric ophthalmology fellowship programs participating in the SF Match with Association of University Professors of Ophthalmology compliance as of August 2021 were obtained. Surveys were emailed to fellowship program directors and administrators to be distributed to current fellows and those who graduated in the last year. Survey data were collected and analyzed using Qualtrics software.

Results: Of the 56 respondents, 55.4% were male. Vitreoretinal surgery fellows made up the largest cohort (n=30; 53.6%) with 20 (35.7%) pediatric ophthalmology and 6 (10.7%) medical retina fellows responding. A majority of fellows trained at an academic teaching hospital (n=49; 89.1%). Forty-eight (85.7%) respondents received ROP training, of which 22.0% did screening examinations, 25.0% completed follow-up examinations, 23.2% performed laser therapy, 19.6% administered anti-VEGF injections, and 10.1% performed incisional surgery. Six fellows received ROP telemedicine training. Just under half of respondents (n=26; 46.4%) indicated plans to provide ROP care in the future. Of these, most plan to do screening (n=24; 92.3%) or follow-up (n=22; 84.6%) exams, laser treatment (n=21; 80.8%), or anti-VEGF injections (n=21; 80.8%). Four individuals indicated intention to perform incisional surgery for ROP and 5 plan to do telemedicine screening examinations. Among the 53.6% who did not plan to care for ROP patients or were unsure, the most common reasons cited were lack of interest in the disease process, liability concerns, or time-consuming nature of ROP care.

Conclusions: Despite widespread ROP training in fellowship, a minority of surveyed trainees plan to provide ROP care in future practice. Increasing fellowship telehealth training may expand future ROP telemedicine use and help overcome workforce shortages.

TITLE: Cone location and corneal stiffness in keratoconus

SESSION TITLE: Keratoconus and corneal biomechanics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Bruner, A. Mahmoud, C.J. Roberts, Ophthalmology & Visual Sciences, The Ohio State University, Columbus, Ohio, UNITED STATES|A. Mahmoud, C.J. Roberts, Biomedical Engineering, The Ohio State University, Columbus, Ohio, UNITED STATES|

Commercial Relationships Disclosure: Cameron Bruner: Commercial Relationship: Code N (No Commercial Relationship) | Ashraf Mahmoud: Commercial Relationship: Code N (No Commercial Relationship) | Cynthia Roberts: Commercial Relationship(s);Code C (Consultant/Contractor):Ziemer Ophthalmic Systems AG;Code C (Consultant/Contractor):Oculus Optikgeräte GmbH;Code R (Recipient):Heidelberg Engineering, Inc

ABSTRACT BODY:

Purpose: To investigate the relationship between central corneal stiffness in keratoconic patients as a function of severity of disease and distance of the keratoconic cone from the center.

Methods: Pentacam tomography and Corvis ST biomechanical response metrics were prospectively acquired in 67 eyes of 41 subjects diagnosed with keratoconus. The severity of disease, represented by the magnitude of the 2mm diameter zone around the steepest point of Kmax (Km spot), and the distance of Kmax from the center of the map (Kmax dist) were independently compared via univariate regression analyses to four biomechanical metrics: stiffness parameter at first applanation (SP-A1) and highest concavity (SP-HC), both of which increase with increasing stiffness, as well as deformation amplitude ratio at 2mm (DA Ratio Max) and integrated inverse radius (Int Inv Radius), both of which decrease with increasing stiffness. Statistical analyses were performed in SAS with significant threshold set at $p < 0.05$.

Results: Km spot was found to have a statistically significant negative relationship to both SP-A1 and SP-HC ($p<0.0001$; $R^2 = 0.483$) and ($p<0.0001$; $R^2 = 0.215$), respectively, and a significantly positive relationship to DA Ratio Max and Int Inv Radius ($p< 0.0001$; $R^2 = 0.588$) and ($p<0.0001$; $R^2 = 0.693$), respectively. In terms of Kmax dist, both SP-A1 and SP-HC yielded a weaker, though significantly positive relationship ($p = 0.013$; $R^2 = 0.091$) and ($p = 0.023$; $R^2 = 0.077$), respectively, while DA Ratio Max and Int Inv Radius yielded a significantly negative relationship ($p = 0.002$; $R^2 = 0.137$) and ($p = 0.0002$; $R^2 = 0.190$), respectively.

Conclusions: In keratoconic patients, the corneal stiffness decreases by all biomechanical metrics as severity of disease increases in a continuous manner. In addition, all biomechanical metrics of central corneal stiffness increase as the distance of the keratoconic cone from the center also increases. This is consistent with the focal nature of the biomechanical weakening in keratoconus.

ABSTRACT BODY:

Purpose: Lipid dyshomeostasis has a pathophysiologic role in multiple retinal diseases including age-related macular degeneration and diabetic retinopathy. Cholesteryl ester hydrolases are a family of enzymes found in many tissues, which are needed to convert the biologically inactive cholesteryl esters to their bioactive forms. Our goal was to characterize the role of a specific cholesteryl ester hydrolase (CEH), identified during a forward genetics screen, in retinal physiology.

Methods: We used a semiquantitative scale of fundus spots on retinal photos as a screening tool on a forward genetics pipeline (N-ethyl-N-nitrosourea mutagenesis of C57BL/6J mice). CRISPR/Cas9 technology was then used to generate knockout mice targeting the gene of interest. Fundus photos and Optical Coherence Tomography (OCT) were used to confirm the suspected phenotype. Further characterization of these mice was pursued using light microscopy, immunohistochemistry, in situ hybridization, electron microscopy, electrophysiology and retinal lipid analysis.

Results: We examined 5,793 G3 mice carrying 11,244 coding/splicing mutations in 7,679 genes. This corresponds to a genome saturation of 4.7% when considering predicted damaging mutations occurring in ≥2 mice in the homozygous state. Using the fundus spots scale we were able to identify a specific cholesteryl ester hydrolase as a gene of interest. A CRISPR/Cas9-generated KO mouse line targeting this CEH gene recapitulated the findings from the forward genetics screen. By 4 months of age, these CEH-deficient mice demonstrated accumulation of fundus spots ($p < 0.001$) compared to age and gender matched control mice. By 3 months of age, KO mice showed 7% thinning of the outer nuclear layer on OCT ($p < 0.001$) compared to control mice. These changes increased with aging. We will present anatomical, functional, ultrastructural and biochemical analyses of the retinas of these mice at different time points.

Conclusions: We demonstrate that a CEH enzyme, whose function has not been characterized in the retina before, is essential to retinal homeostasis.

TITLE: Repeatability and reproducibility of optic nerve head optical coherence tomography angiography (OCTA) measurements on glaucomatous and normal eyes

SESSION TITLE: OCT Angiography Clinical Applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Di, S. Yu, P. Sha, Carl Zeiss Meditec, Inc., Dublin, California, UNITED STATES|T. Severin, East Bay Eye Center, San Ramon, California, UNITED STATES|

Commercial Relationships Disclosure: Lung Di: Commercial Relationship(s);Code C (Consultant/Contractor):Carl Zeiss Meditec, Inc., Dublin, CA, United States. | Sophia Yu: Commercial Relationship(s);Code E (Employment):Carl Zeiss Meditec, Inc., Dublin, CA, United States. | Patricia Sha: Commercial Relationship(s);Code E (Employment):Carl Zeiss Meditec, Inc., Dublin, CA, United States. | Todd Severin: Commercial Relationship(s);Code C (Consultant/Contractor):East Bay Eye Center

ABSTRACT BODY:

Purpose: The purpose of this study was to determine the repeatability and reproducibility (R&R) of spectral domain OCTA metrics on optic nerve OCTA en face images in normal and glaucomatous eyes.

Methods: Subjects with glaucoma and healthy controls (both >18 years old) were recruited in this study. If two eyes were eligible, one eye per subject was randomly designated as the study eye. Each eye was imaged using the Angiography 4.5x4.5 mm scan centered on the optic disc on CIRRUS™ HD-OCT 5000 with AngioPlex® OCT Angiography (ZEISS, Dublin, CA). Scans were repeated on 3 devices (by 3 different technicians) 3 times in 1 visit.

Data was processed on the AngioPlex Metrix in CIRRUS 11.0 software, which quantifies the density of vasculature. Two measures of blood vessels were used: Perfusion Density (PD), the area of blood vessels, and Flux Index (FI), the weighted intensity of the perfused vessels per unit area. PD is defined as the total area of perfused microvasculature per unit area, and ranges from 0 (no perfusion) to 1 (fully perfused). FI is defined as total weighted area of perfused microvasculature per unit area in a region of measurement. The weight is the normalized flow intensity corresponding to each pixel. Each scan is segmented into 4 sectors (temporal, nasal, superior, and inferior) for analysis, and a mean coefficient of variance (CV%) is calculated for both R&R. All statistics are estimated from two-way random-effect ANOVA model with random effects operator/device, eye and interaction between operator/device and eye.

Results: 22 control eyes (mean age 44.7 years, SD 14.7) and 21 glaucoma eyes (mean age 68.5 years, SD 8.9) were imaged. Table 1 and Table 2 shows FI and PD mean, standard deviation (both R&R), and coefficient of variance (CV%) for normal and glaucomatous eyes. Across all sectors, R&R CV% are below 5% in normal eyes, and no more than 6.1% in diseased eyes. Mean R&R CV% (both FI and PD) are less than 3% for normal eyes, and they are less than 5% for glaucomatous eyes.

Conclusions: All CV% (FI and PD) for normal and glaucomatous eyes are excellent, and no significant CV% difference is observed across all sectors from the scans. Given the R&R results, these parameters may be useful for monitoring disease progression or early detection of diseases. Future studies are needed to determine the clinical utility of these measurements.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) disease processes are thought to initiate at the Retinal Pigment Epithelial Cell (RPE)/choroid interface. However, how each tissue contributes to disease pathogenesis is not known. We hypothesized that the presence of RPE would reduce gene expression patterns indicative of AMD within 3D bioprinted Outer Blood Retinal Barrier (oBRB) models. Here, we utilized 3D bioprinted oBRB models and single-cell RNA-seq to assess how the presence or absence of RPE affects endothelial cell (EC), fibroblast, and pericyte gene expression patterns within the context of AMD pathogenesis.

Methods: iPSC-derived EC, iPSC-derived fibroblasts, and ocular pericytes were encapsulated in a fibrinogen and gelatin-based hydrogel solution and 3D-printed onto degradable PLGA scaffolds or PET membranes to generate choroid-like tissues. iPSC-RPE were seeded on the apical side of scaffolds 7 days after bioprinting. After 6 weeks of maturation, tissues were digested using dispase, collagenase, and RNAse. Single-cell suspensions were retrieved and fixed to generate barcoded single-cell emulsions and cDNA libraries. The Illumina HiSeq 3000, Cellranger package, the Seurat R package, and the Biowulf computing cluster analyzed single-cell sequencing data. Gene set enrichment analysis was performed using EnrichR and curated using Gene Ontology 2021 ontology sets. EC, fibroblast and pericyte populations were identified within 3D oBRB models using UMAP clustering, EnrichR, and the expression of key signature genes by each cell type.

Results: In EC populations, the presence of RPE in tissues enhanced expression of key choriocapillaris signature genes while the absence of RPE enhanced expression of vascular morphogenesis genes and AMD signature genes. In fibroblast populations, the presence of RPE downregulated senescence and aging genes while enhancing the expression of genes associated with melanin synthesis, phenol synthesis, and retinoid metabolic processes; the absence of RPE enriched genes related to AMD and ECM synthesis. Pericytes demonstrated similar effects on ECM synthesis genes as fibroblasts when RPE were absent.

Conclusions: Combined, these data suggest that the presence of RPE changes EC specification toward choriocapillaris, downregulates senescence and aging in fibroblasts, and downregulates AMD-associated gene expression patterns within oBRB models.

ABSTRACT BODY:

Purpose: Developing a flexible handheld ultra-widefield (UWF) OCT system with two interchangeable lens combinations, a non-contact approach with 105° FOV and a contact approach with 140° FOV, for pediatric peripheral retina imaging.

Methods: We demonstrated a flexible handheld probe for UWF OCT system with non-contact 105° FOV and contact 140° FOV for peripheral retina imaging. The novel optical designs [Figs. 1(a)-1(b)] were compatible with our previously established 55° FOV handheld OCT/OCTA system and shared the same mechanical parts, except for the telescope design after the slow axis of the galvanometer scanner [Fig. 1(c)]. The OCT engine employed a 400-kHz VCSEL (Thorlabs, Inc.) with a center wavelength of 1060 nm and 100 nm bandwidth that provides an imaging depth of 6 mm and an axial resolution of 4.96 μm in air. The working distance for the non-contact system was ~5 mm. The incident power on the cornea was 1.68 mW. A programmed motorized reference arm and an electrically tunable lens were rapidly adjusted during the imaging session to match the imaging subject's axial eye length and fine tune focus. OCT images were acquired and processed by our GPU accelerated software which enabled direct real-time feedback and facilitated alignment process and navigation. A high-speed alignment mode (10Hz volume rate) and an OCT scanning mode (800 × 780 A-scans/Volume and 1.56 seconds) were available for the operator to toggle between them.

Results: 3 healthy adult volunteers (24-34 years old) and 57 pediatric patients were successfully imaged, all the imaging sessions were completed within 5 minutes. Two representative en face OCT images with posterior pole and peripheral retina obtained via non-contact 105° FOV and contact 140° FOV respectively from two neonates with retinopathy of prematurity (ROP) were shown in Fig 2. Peripheral pathologies were fully appreciated in these images without pronounced motion artifacts.

Conclusions: We have demonstrated a flexible 400-kHz handheld UWF OCT system that has two interchangeable eyepieces, a non-contact approach with 105° FOV and a contact approach with 140° FOV, which could acquire images from the posterior pole to peripheral retina in a single shot. The implementation of UWF OCT imaging technology has the potential to facilitate the diagnosis and treatment of retinal diseases such as ROP.

ABSTRACT BODY:

Purpose: Our goal is to identify and study genes essential to retinal development and homeostasis using an unbiased forward genetics approach. Here we characterize a novel association involving a gene with a known role in the ubiquitin–proteasome system (UPS).

Methods: We used a forward genetics screening pipeline (N-ethyl-N- nitrosourea mutagenesis in C57BL/6J mice) to identify, in an unbiased manner, non-redundant genes leading to the accumulation of fundus spots. All G3 mice used in our screening have been pre-genotyped at all mutant loci, making it possible to instantly determine the causative mutation of a given phenotype. We identified a mutation that led to a phenotype of increased fundus spots, that we termed aegean, and used CRISPR/Cas9 mutagenesis to generate mice deficient in the affected gene. We then characterized the retina in these mice.

Results: The aegean phenotype was recapitulated in the CRISPR-generated KO mouse line. This line showed progressive accumulation of fundus spots with age and a statistically significant thinning of the outer retina. We then used serial fundus photos, optical coherence tomography (OCT), immunohistochemistry (of both retinal sections and flat mounts), and electron microscopy to characterize the retinal phenotype. Functional retinal testing with electrophysiology will also be shown.

Conclusions: A forward genetics screening protocol using a semiquantitative fundus spot scale allowed us to identify a novel gene-retinal phenotype association involving a gene important for the ubiquitin proteasome system. This pathway plays a key role in cell cycle control, signal transduction, and removal of toxic/damaged proteins from the cell. Further studies will be needed to further characterize the specific role of this gene in retinal homeostasis.

ABSTRACT BODY:

Purpose: Oxidative stress linked to mitochondrial dysfunction is implicated in the pathophysiology of several retinal pathological conditions. Previous studies have shown that retinal flavoprotein fluorescence (FPF) can be used as a potential biomarker for oxidative stress. Herein, we hypothesize that FPF is higher in conditions mediated by oxidative stress and inversely correlates with best corrected visual acuity (BCVA).

Methods: 10 eyes from 10 healthy subjects, 3 eyes from 3 central serous retinopathy (CSR) patients, 8 eyes from 8 retinal vein occlusion (RVO) patients, 6 eyes from 6 proliferative diabetic retinopathy (PDR) patients, and 12 eyes from 12 chronic exudative age-related macular degeneration (AMD) patients were included in the present observational study (n=39). Eyes were imaged non-invasively using a specialized fundus camera OcuMet Beacon (OcuSciences, Ann Arbor, MI). During each imaging session, the macula was imaged with a blue light in the narrow emission spectra from 520 to 540 nm. Kruskal-Wallis tests were performed to assess differences in FPF values and BCVA between the five groups. Spearman rank correlation coefficient was calculated to assess the relationship between FPF and BCVA. A $p < 0.05$ was considered to be statistically significant.

Results: FPF values and BCVA of all five groups differed significantly (Kruskal-Wallis Tests, $p < 0.001$ and $p = 0.003$, respectively). Mean FPF values of healthy controls, CSR, RVO, PDR, and wet AMD patients were 29.5 ± 7.8, 51 ± 15.6, 60.7 ± 24.4, 64 ± 25.7, and 65 ± 17.7, respectively. Compared to healthy controls, FPF values were significantly higher in conditions such as RVO, PDR, and wet AMD ($p = 0.010$, $p = 0.012$, and $p < 0.01$, respectively). In contrast, there was no significant difference between FPF values of CSR patients compared to healthy controls ($p = 0.912$). There was an inverse correlation between FPF values and BCVA ($r = -0.547$, $p < 0.01$).

Conclusions: FPF values were significantly greater in diseases known to be mediated by oxidative stress compared to healthy controls. Higher FPF values were seen in conditions such as RVO, PDR, and wet AMD as compared to CSR, indicating that there may be varying degrees of oxidative stress in these conditions. The data is consistent with previously published literature on FPF being inversely correlated with BCVA.

ABSTRACT BODY:

Purpose: Pseudo-exfoliation syndrome (PXF) is a systemic disease in which fibrillary proteinaceous material is deposited within the tissues such as the eye, which is thought to arise from dysfunctional matrix turnover and intracellular auto-degradation pathways. In this case-control study setting, we aim to evaluate whether defects in mitophagy specifically have a role in PXF etiology and prognosis.

Methods: The anterior lens capsules obtained in microincisional cataract surgery were collected both from patients with PXF (n=6) and age-matched healthy controls (n=10). The samples were embedded in paraffin blocks and sliced into 0.4 µm slides for analysis. The ABC® IHC detection kit was used to stain the samples for PTEN-induced kinase 1 (PINK1), Parkin and LC3B. Stained images were captured with 20x magnification under confocal microscopy. The expression intensity was measured using color deconvolution plug-in and integrated density value was calculated on Fiji® (U. S. National Institutes of Health, Bethesda, MD). The Mann-Whitney U test was used for statistical analysis and the results were shown on Graphpad Prism (Graphpad, San Diego, CA).

Results: The staining intensity of PINK1 and PARKIN were higher in the epithelia of anterior lens capsule in patients with PXF compared to the control samples, which was only statistically significant for PINK1. (p=0.0002, p=0.999 respectively) LC3B intensity was also found to be increased in PXF patients with statistical significance (p=0.0006). (Images 1 and 2)

Conclusions: This increase in the markers of mitophagy, which is the targeted elimination of dysfunctional mitochondria, may be an important indicator of increased oxidative stress in PXF. It can therefore signal an extensive mitochondrial impairment and higher generation of reactive oxygen species, potentially overburdening the cellular clearance and enhancing faulty protein release. Certainly, further in vitro studies with a larger sample number are needed to compare the actual stress responses dynamically in PXF.

ABSTRACT BODY:

Purpose: To develop a glaucoma staging system based on optical coherence tomography (OCT)-derived retinal nerve fiber layer (RNFL) thickness measurements.

Methods: We developed a glaucoma damage classification system based on unsupervised k-means and Bayes minimum error classifier using 6561 RNFL profiles from 2269 eyes of 1171 subjects. We annotated the discovered clusters to different severity levels based on their respective mean global RNFL thickness. To establish an objective criterion for glaucoma staging, we computed optimal global RNFL thickness thresholds that discriminated different severity levels with highest accuracy using Bayes principle. We evaluated the quality of learning based on the area under the receiver operating characteristic curve (AUC).

Results: The k-means discovered four clusters with 1382, 1613, 1727, and 1839 samples and mean global RNFL thickness of 58.3 µm (±8.9:SD), 78.9 µm (±6.7), 87.7 µm (±8.2), and 101.5 µm (±7.9), respectively. The Bayes minimum error classifier identified optimal global RNFL thresholds of 70 µm, 85 µm, and 95 µm for discriminating the severity levels. The AUC was 0.90 and about 4% of normal eyes and 98% of eyes with advanced glaucoma had either global or quadrant RNFL thickness outside of normal limit.

Conclusions: Machine learning discovered optimal OCT-derived RNFL thresholds of about 70 µm, 85 µm, and 95 µm for staging glaucoma to normal, early, moderate, and advanced stages. The proposed staging system is unbiased with no pre-assumption or human expert intervention in the development process. Additionally, it is objective, easy-to-use, and consistent, which may augment glaucoma research and day-to-day clinical practice.

ABSTRACT BODY:

Purpose: Demodex blepharitis (DB) is present in a significant number of eyecare patients, yet many patients continue to suffer due to improper diagnosis, minimized or underappreciated significance of findings by the eye care professional (ECP), inadequate management, and the lack of FDA-approved treatments. The purpose of this study was to further evaluate (as a continuation of 311 patients presented previously) the clinical impact of DB, impact on patients' quality of life and motivations for seeking care.

Methods: Patients 18 years of age and older were recruited from 12 eye care centers in the US to participate in this DB screening study. The investigators examined patients for objective signs of DB: ≥1.0 mite count, >10 collarettes, and ≥mild lid margin erythema. Patients with all three signs were asked to complete a questionnaire about their symptoms, quality of life, and treatment experience. Impact of DB on contact lens wearers was also collected.

Results: Among 129 patients, 32% made at least two visits to their doctor due to signs or symptoms associated with DB. Unfortunately, 63% of the patients have never been previously diagnosed for DB. The most bothersome symptoms reported in this group were itchy eyes (53%), dry eyes (44%), irritated eyes (31%), foreign body sensation (26%), tearing (23%), and red eyes/eyelids (23%). Approaches to mitigate DB symptoms included warm compresses (46%), lid wipes (29%), artificial tears (48%), antibiotics/steroids (25%), and various tea tree oil preparations (21%). Among those who discontinued aforementioned management approaches, 52% discontinued due to ineffectiveness or intolerability. Among contact lens wearers (11%), 79% of patients complained of discomfort and/or blurry/foggy vision while wearing contact lenses.

Conclusions: Demodex blepharitis is underdiagnosed and often misdiagnosed despite chronically persisting signs and symptoms that often require multiple visits to ECP, typically without resolution. More effective treatments for DB are needed, which will clear the signs of DB and have a positive impact on patients' eyelid health and quality of life. Aggregated data with larger sample size upon study completion, to be presented, will corroborate these findings.

ABSTRACT BODY:

Purpose: To investigate the half maximal effective concentration (EC50) of a novel bispecific protein, RO-634, to Vascular Endothelial Growth Factor-A (VEGF-A) and Angiopoietin-2 (Ang-2) individually versus in tandem. These findings may have important clinical implications for treatment of retinal disease including diabetic macular edema and exudative macular degeneration.

Methods: An Enzyme-linked Immunoassay (ELISA) was utilized to determine the EC50 of the bispecific RO-634 to recombinant human VEGF-A and human Ang-2 analytes independently and in combination. A polyclonal antibody was used to detect when RO-634 bound individually to VEGF-A or Ang-2, while Streptavidin Horseradish Peroxidase (SA-HRP) was used when RO-634 bound both analytes (Figure 1).

Results: The data demonstrate the bispecific RO-634 has an EC50 for solely VEGF-A of 10.04 pM and an EC50 for solely Ang-2 of 136 pM. The bispecific RO-634 demonstrated a lower EC50 to Ang-2 while bound jointly to VEGF-A of 101.9 pM (Figure 2).

Conclusions: Our data suggests EC50 for RO-634 to Ang-2 decreases when the bispecific is also bound to VEGF-A. This synergistic effect could be due to a conformational change that occurs when RO-634 is bound to VEGF-A. Further testing should be done to assess the pharmacokinetics behind the demonstrated synergistic effect.

TITLE: RESULTS OF A PHASE III STUDY OF A NOVEL 0.05% ONCE-DAILY CYCLOSPORINE OPHTHALMIC GEL IN THE TREATMENT OF MODERATE TO SEVERE DRY EYE DISEASE (COSMO)

SESSION TITLE: Ocular surface health and conjunctiva

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P.A. Majmudar, Ophthalmology, Rush University Medical Center, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Parag Majmudar: Commercial Relationship(s);Code C (Consultant/Contractor):Zhaoke Ophthalmology

ABSTRACT BODY:

Purpose: The COSMO study aimed to evaluate the efficacy and safety of a novel 0.05% Cyclosporine Ophthalmic Gel compared with vehicle in the treatment of patients with moderate to severe dry eye disease (DED).

Methods: After a 14-day open-label placebo run in period, 644 eligible subjects were randomized 1:1 to receive treatment with either 0.05% Cyclosporine Ophthalmic Gel or vehicle nightly for 84 days. Evaluation was carried out on baseline, day 14, 42 and 84 consisting of objective measures including corneal and conjunctival staining, Schirmer test and Tear Break Up Time (BUT) and subjective measures including Eye Dryness Score (EDS) and 6 other symptoms using visual analog scale (VAS). The primary efficacy endpoint was the proportion of patients with a ≥1-point decrease in inferior corneal fluorescein staining score (ICSS) from baseline on day 84. Secondary efficacy endpoints evaluated mean change from baseline to day 14, 42 and 84 including VAS scores for EDS and 6 other dry eye symptoms (burning/pinching sensation, itching, foreign body sensation, discomfort, photophobia, and pain), ICSS score, corneal and conjunctival staining rating (Oxford grading), Schirmer test value and BUT score.

Results: The study met the primary efficacy endpoint of a ≥1-point decrease in ICSS in 73.7% of the treatment group vs 53.2% of vehicle group ($P<0.0001$) at day 84. The treatment group showed statistically greater improvement of both ICSS scores and corneal conjunctival staining score over vehicle group on day 14 ($P=0.0011$; $P=0.038$), day 42($P<0.0001$; $P=0.021$) and day 84($P<0.0001$; $P=0.008$). Significant improvement in tear secretion was also observed at day 14($P=0.024$) and day 84($P=0.005$). The EDS scores and stability of tear film (BUT score) at each visit improved significantly relative to baseline, however no significant difference between groups was observed.

Conclusions: 0.05% Cyclosporine Ophthalmic Gel once a day significantly reduced corneal and conjunctival staining and improved tear secretion compared with vehicle in moderate to severe DED. It also significantly alleviated symptoms compared with baseline. 0.05% Cyclosporine Ophthalmic Gel will be a new efficacious, safe and well tolerated therapeutic option that might bring additional benefits of convenience and compliance as a once-a-day treatment for moderate to severe dry eye.

ABSTRACT BODY:

Purpose: In several neurodegenerative diseases such as glaucoma, there is evidence that synapse loss is an early biomarker. Identifying synaptoprotective factors that may prevent synapse loss or even regenerate these connections in the context of degenerating retinas and/or cell-based therapies are of great interest. Thrombospondin is a family of astrocyte-secreted proteins that has been shown to be synaptogenic. Here we hypothesize that thombospondin-1 (TSP1) is synaptoprotective in a mouse retina explant model.

Methods: Retina explants from adult CD-1 mice were cultured in serum free medium for 0, 3, and 7 days. Some of the retinas cultured for 7 days also contained 150 ng/mL of TSP1. After culturing, the tissue was fixed and immunolabeled with CtBP2 and PSD95 to quantify pre- and post-synaptic proteins. Z-stacks were acquired using confocal microscopy (0.1x0.1x0.3mm/voxels). Volume and distribution of puncta was evaluated in the inner plexiform layer (IPL) using VolumeCut and ObjectFinder (https://github.com/lucadellasantina/). Statistics were performed using a Wilcoxon Rank Sum Test.

Results: The average CtBP2 density (puncta/μm^3 ± SE) for the control retinas (N = 3) and 7-day cultured retinas (N = 4) was 0.244 (0.015) and 0.162 (0.004), respectively. The retinas cultured for 7-days with TSP1 (N = 4) had an average CtBP2 density of 0.226 (0.021), which was significantly greater than the 7-day group without TSP1 (P = 0.03) and was not different from the 0-day control (P = 0.63). The average PSD95 density for the 0-day, 7-day, and 7-day with TSP1 was 0.190 (0.008), 0.092 (0.004), 0.113 (0.017), respectively. There was a trend towards a significant increase in PSD95 density in the presence of TSP1 compared to without (P = 0.06), and PSD95 density with TSP1 was not different from the 0-day controls (P = 0.34).

Conclusions: In a retina explant model, our results suggest that TSP1 may be synaptoprotective, specifically for presynaptic ribbons. As we have demonstrated in a previous study, presynaptic ribbons are disassembled prior to postsynaptic component loss in experimental glaucoma, and consequently, TSP1 may be an effective therapeutic target.

TITLE: Diabetic Retinopathy and Nephropathy Have Discordant Progression: A Cross-sectional Case Control Study in a Type 2 Diabetic New Mexican Population

SESSION TITLE: Diabetic Retinopathy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Fitzgerald, S.R. Salazar, C.J. Moezzi, R. Mankad, C.R. Qualls, A. Cabrera, F. Monickaraj, A. Das, University of New Mexico School of Medicine, Albuquerque, New Mexico, UNITED STATES|

Commercial Relationships Disclosure: Ashley Fitzgerald: Commercial Relationship: Code N (No Commercial Relationship) | Savannah Salazar: Commercial Relationship: Code N (No Commercial Relationship) | Cody Moezzi: Commercial Relationship: Code N (No Commercial Relationship) | Rushi Mankad: Commercial Relationship: Code N (No Commercial Relationship) | Clifford Qualls: Commercial Relationship: Code N (No Commercial Relationship) | Andrea Cabrera: Commercial Relationship: Code N (No Commercial Relationship) | Finny Monickaraj: Commercial Relationship: Code N (No Commercial Relationship) | Arup Das: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) and diabetic nephropathy (DN) are the most common microvascular complications of diabetes and are thought to have strong association. The objective of this study was to examine whether these two complications have significant concordance in terms of progression of severity.

Methods: A cross-sectional, case-control study was performed in two cohorts of type 2 diabetic patients in a New Mexican population: the cases had confirmed end-stage renal disease (ESRD; Stage 5, on dialysis, GFR<15, n=163) and the controls had mild DN (Stage 1 or Stage 2, GFR>60, n=114). Systemic parameters including HbA1C, blood pressure (BP), lipid levels, Albuminuria, GFR, serum Creatinine (CR), protein/CR ratio, Hemoglobin (Hb), Hematocrit (Hct), and retinopathy status by dilated fundus exam were collected by retrospective chart review. Statistical analyses were performed with a two-sample t-test for continuous variables and Chi-squared test or Fisher exact test for categorical variables.

Results: The majority (65%) of the ESRD cohort had advanced eye disease (proliferative diabetic retinopathy; PDR), while 18% of patients had no/mild eye disease (No DR/ mild non-proliferative diabetic retinopathy; NPDR). Conversely, the mild DN cohort included a significant number of PDR cases (38%). The development of ESRD was significantly associated with lower HbA1C levels (p=0.001) and higher systolic BP levels (p=<0.001). In the ESRD cohort, development of PDR was significantly associated with younger age (p=0.0002), higher diastolic BP (p=0.03), and higher LDL (p=0.036). No association was found with HbA1C levels, systolic BP, insulin use, HDL, urine albumin/CR between mild DR and PDR groups within the ESRD cohort. Although prediction of ESRD status from advanced retinopathy status has a significant odds ratio (4.033, p<0.001) the analysis of specificity (0.52) determined this to be a poor predictive tool.

Conclusions: Our findings suggest that there is discordance between progression of retinopathy and nephropathy displayed by varying retinopathy statuses within our ESRD and mild DN cohorts. Other factors such as genetic variability may play a role in the divergent pathogenesis and progression of both diabetic micro-vascular complications.

TITLE: Rates of Posterior Capsular Rupture in Ophthalmology Resident Cases after Intravitreal Injections

SESSION TITLE: Cataract surgery 1

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Dodaballapur, M. Desai, Oakland University William Beaumont School of Medicine, Rochester, Michigan, UNITED STATES|V. Govindaraju, J. Chao, C. Gupta, Department of Ophthalmology, Beaumont Health, Royal Oak, Michigan, UNITED STATES|

Commercial Relationships Disclosure: Sneha Dodaballapur: Commercial Relationship: Code N (No Commercial Relationship) | Viren Govindaraju: Commercial Relationship: Code N (No Commercial Relationship) | Jonathan Chao: Commercial Relationship: Code N (No Commercial Relationship) | Maya Desai: Commercial Relationship: Code N (No Commercial Relationship) | Chirag Gupta: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: It has been documented that intravitreal injections (IVI) can increase the rate of posterior capsular ruptures (PCR) during cataract surgery, however this has not been studied in resident cases. This study seeks to investigate PCR rates and potential risk factors for PCR in resident cases.

Methods: A retrospective consecutive cohort study was performed on patients of Beaumont Health, Royal Oak, Michigan. This study was done with the approval of the Institutional Review Board and with the standards delineated in the Helsinki Declaration. Using appropriate ICD-10 and CPT codes, a patient list was generated. Inclusion criteria included prior Beaumont Eye Institute patients 50 years of age or older, had prior history of IVI administered by a resident physician and had an intraoperative complication of PCR. Exclusion criteria included no other intraocular surgery for 3 months prior to the cataract surgery and no patient less than 50 years. Cataract surgery (CEIOL) was performed by third year ophthalmology residents. Data were analyzed using Chi-square analysis, Student t-test, and Relative Risk Ratio with GraphPad Prism. Statistical significance was set at $p<0.05$.

Results: 1,013 eyes were examined in this study of which 46 had PCR as an intraoperative complication of CEIOL (4.53%). Patients with prior IVI had 2.56 times the risk of developing PCR than patients with no history of IVI (RR=2.56, 95% CI=1.066-5.775; p=0.035). In the cohort with a PCR event, 10.87% had prior IVIs. Mean age for PCR complication was higher (68.33yrs, SD: 9.9) than the no PCR cohort (65.45yrs, SD 11.45); p=0.032. There was no significant relationship found between gender, laterality, prior retina surgery, or diagnosis for injection and PCR incidence.

Conclusions: Rates of PCR in resident cases of 4.53% is within the reported range of 0.5-16%. In attending cases without IVI the PCR rate is 0.45-3.6% and is as high as 6% in patients with IVI. Thus, both attending and residents experience relative increases in PCR rate with IVI. This study provides concrete evidence of the 2.56 times increased PCR risk in CEIOL with IVI history in resident cases and adds to the discussion of increased CEIOL complications in older patients. Therefore, along with intraoperative floppy iris syndrome, previous IVI may signal for the CEIOL to be performed by senior level residents and prompt added assistance and equipment in case of complications.

ABSTRACT BODY:

Purpose: Blood pressure (BP) dysregulation is a known risk factor for glaucoma and home BP monitoring is increasingly common. However, little is known about glaucoma patients' ability to use digital health devices. We performed a pilot mixed-methods study with glaucoma patients to evaluate digital health literacy and usability of a commercially available BP smartwatch monitor.

Methods: Adult participants were recruited from the Diagnostic Innovations in Glaucoma Study (DIGS) and/or the African Descent and Data Evaluation Study (ADAGES) and were provided a BP monitor (Omron HeartGuide) to use at home. Baseline digital health literacy was assessed using the standardized eHEALS questionnaire. After one week, participants assessed the usability of the BP monitor and related mobile app using the Post-study System Usability Questionnaire (PSSUQ) and the System Usability Scale (SUS), standardized instruments for usability assessments in information technology. Variations in eHEALS and usability scores across demographic groups were evaluated with ANOVA. Open-ended responses about participants' experience were analyzed thematically.

Results: Among 39 participants, the mean (standard deviation, SD) age was 66.6 (8.7) years. Two-thirds (26, 66.6%) identified as female, 11 (28.2%) as African American, and 2 (5.1%) as Hispanic/Latino. The mean (SD) eHEALS score was 31.5 (4.9), reflecting excellent self-perceived eHealth literacy. Mean (SD) usability scores were 75.9 (17.9) and 2.3 (1.9) for the SUS and PSSUQ, respectively, indicating relatively high levels of usability (70-79th percentile). However, usability scores were significantly lower among older participants ($p=0.009$ for SUS, $p=0.02$ for PSSUQ; Fig. 1). Common themes in open-ended responses included difficulty using the monitor due to lack of technological skill, the watch not fitting properly, and not knowing how to troubleshoot problems.

Conclusions: We identified challenges with using commercially available home BP monitors and mobile apps among glaucoma patients, particularly with increasing age. Glaucoma patients present unique considerations for digital health design, such as older age and visual impairment. Understanding glaucoma patients' digital health literacy and user experience is important for inclusive design and future interventions.

TITLE: Comparison of Visual Outcomes after Combined Phacovitrectomy versus Sequential Vitrectomy and Phacoemulsification for Epiretinal Membrane

SESSION TITLE: Macular diseases/Macular edema/Functional testing/evaluation/Laser

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.A. Sabbagh, J.I. Lim, Illinois Eye and Ear Infirmary, Department of Ophthalmology and Visual Sciences, University of Illinois at Chicago, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Mohammad Sabbagh: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Lim: Commercial Relationship(s);Code F (Financial Support):Aldeyra;Code C (Consultant/Contractor):Aura;Code F (Financial Support):Chengdu;Code C (Consultant/Contractor):Cognition;Code C (Consultant/Contractor):Eyenuk;Code R (Recipient):Iveric Bio;Code C (Consultant/Contractor):Luxa;Code F (Financial Support):NGM Bio

ABSTRACT BODY:

Purpose: To assess the visual outcomes of combined phacoemulsification and vitrectomy versus vitrectomy followed by phacoemulsification for patients with epiretinal membranes.

Methods: A single-center, retrospective chart review of 33 phakic patients who underwent combined phacovitrectomy (COM group) or sequential vitrectomy and phacoemulsification (SEQ group) by a single vitreoretinal surgeon and a total of 6 anterior segment surgeons. Patients were included if they had visually significant ERM and cataracts and excluded if they had other concomitant ocular disease except for mild to moderate correctable refractive errors. Outcome measures included postoperative change in best corrected visual acuity (BCVA) from pre-op BCVA, time to best final BCVA, optical coherence tomography central subfield thickness (CST), and ocular complications.

Results: 25 eyes in the COM group and 8 eyes in the SEQ group were followed a mean of 30 months. The post-operative changes in BCVA and CST between the groups were not statistically significant. 14 of 25 eyes in the COM group achieved a BCVA of 20/30 or better by post-phacovitrectomy month 3 that was sustained through follow up. All 8 eyes in the SEQ group achieved peak vision one month after vitrectomy but had vision decline secondary to cataract development. Average time to phacoemulsification in this group was 9.5 months and 7 of 8 eyes achieved > 20/30 by post-phacoemulsification week 1.

Conclusions: Combined phacovitrectomy for patients with visually significant ERM and cataracts achieves similar results to sequential surgery while providing a more rapid achievement of final BCVA.

ABSTRACT BODY:

Purpose: To compare race-related differences in 1-year outcomes following cataract surgery in individuals of black and white descent.

Methods: A retrospective cohort study was conducted using the TriNetX national database. Patients who underwent cataract surgery were initially stratified into black (n = 40,764) and white (n = 213,657) cohorts. Cohorts were then matched by demographics and comorbidities (age, gender, BMI, history of hypertension, diabetes mellitus, chronic lower respiratory disease, heart failure, nicotine dependence) using 1:1 propensity score matching (PSM). 40,132 patients in each cohort were included in the study for a total of 80,264. Primary outcome measures were vitreous hemorrhage (VH), choroidal hemorrhage, retinal detachment or tear (RD/RT), iridocyclitis, macular edema (ME), cystoid macular degeneration, epiretinal membrane (ERM) toxic maculopathy, ischemic optic neuropathy (ION), glaucoma, strabismus, hemorrhage of orbit, corneal edema, dry eye syndrome (DES), central retinal vein occlusion (CRVO), central retinal artery occlusion (CRAO), vitreous opacities, ptosis, dislocation of lens, endophthalmitis, and retinal vascular occlusions (RVO). Risk ratios (RR) using 95% confidence intervals (CI) were used to compare primary outcomes 1 year after cataract surgery.

Results: 80,264 total patients were included with 40,132 patients in each of the black and white cohorts following PSM. The black cohort had a significant greater risk for developing VH (RR, 1.49; 95% CI, 1.28-1.73), RD/RT (1.17; 1.02-1.33), iridocyclitis (4.67; 4.21-5.18), ME (1.48; 1.34-1.65), cystoid macular degeneration (1.73; 1.59-1.88), ION (1.71; 1.13-2.6), glaucoma (2.14; 1.98-2.31), DES (1.21; 1.13-1.28), CRVO(2.86; 2.01-4.08), dislocation of lens (1.63; 1.24-2.13), endophthalmitis (1.64; 1.31-2.06), and RVO (1.81; 1.47-2.24). The white cohort had a significant risk of developing ERM (0.71; 0.64-0.79), corneal edema (0.64; 0.47-0.87), and ptosis (0.8; 0.7-0.92). No significant difference was seen in choroidal hemorrhage, toxic maculopathy, strabismus, CRAO, and vitreous opacities.

Conclusions: Race should be considered when evaluating long-term outcomes following cataract surgery. Blacks were more likely to develop VH, RD, ME, cystoid macular degeneration, ION, glaucoma, DES, CRVO, lens dislocation, endophthalmitis, and RVO whereas whites were more likely to develop ERM, corneal edema, and ptosis.

TITLE: Longitudinal changes in choroidal optical coherence tomography angiography indices among young adults and children over one year.

SESSION TITLE: Refractive Error: Myopia, Hyperopia, vision and models

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Lal, D. Alonso-Caneiro, S. Read, A. Carkeet, School of Optometry and Vision Science, Queensland University of Technology, Brisbane, Queensland, AUSTRALIA|

Commercial Relationships Disclosure: Barsha Lal: Commercial Relationship: Code N (No Commercial Relationship) | David Alonso-Caneiro: Commercial Relationship: Code N (No Commercial Relationship) | Scott Read: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Carkeet: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Choroidal microvasculature exhibits a significant association with axial length (AL). AL changes with age and as myopia progresses, so long-term changes in choroidal microvasculature might be expected. We conducted a 1-year prospective longitudinal study to investigate changes in choroidal microvasculature indices using optical coherence tomography angiography (OCT-A) among healthy myopic and non-myopic children and young adults.

Methods: Measurements including 3mm×3mm macular OCT-A enhanced depth scans, AL and refraction were collected at baseline and 1-year follow-up for 22 adults (18-30 years,12 myopes,10 non-myopes) and 21 children (6-15 years,11 myopes,10 non-myopes). Choriocapillaris (29 to 49 μm below retinal pigment epithelium (RPE)) and the deep choroidal layer (64 to 115 μm below RPE) en face OCT-A images were analysed to extract magnification-corrected choriocapillaris flow deficit density (FDD_{cc}) and deep choroidal perfusion density (PD_{ch}) for sub-foveal and parafoveal zones. Changes over 1-year were compared between age groups and between refractive groups within the age groups using Mann-Whitney U.

Results: The FDD_{cc} and PD_{ch} did not change significantly over 1-year or differ between age groups ($P>0.05$), however significant differences between refractive subgroups were observed. AL and spherical equivalent refraction underwent significant changes ($P<0.05$), with larger AL changes in children (0.20±0.27mm) than adults (0.04±0.07mm). Parafoveal FDD_{cc} changes were significantly associated with AL changes ($P=0.01$) (Figure 1) and refractive groups ($P=0.01$) and sub-foveal PD_{ch} changes associated with refractive groups ($P=0.01$) in adults but not in children. Between the refractive groups, changes in sub-foveal FDD_{cc} and PD_{ch} and parafoveal FDD_{cc} were significantly different ($P<0.05$) among adults, but not in children (Figure 2).

Conclusions: Longitudinal changes in choroidal OCT-A indices were significantly associated with AL changes and refractive group only in adults, with myopes and non-myopes showing different magnitudes of change. These relationships were not found in children.

TITLE: Comparison of standard versus accelerated corneal collagen crosslinking for keratoconus: 5-year outcomes from the Save Sight Keratoconus Registry

SESSION TITLE: Keratoconus and corneal biomechanics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Kandel, S.L. Watson, Save Sight Institute, Sydney Medical School, Faculty of Medicine and Health, The University of Sydney, Sydney, New South Wales, AUSTRALIA|

Commercial Relationships Disclosure: Himal Kandel: Commercial Relationship: Code N (No Commercial Relationship) | Stephanie Watson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Long term-effectiveness of standard (UVA intensity: 3mW/cm^2, duration: 30 minutes) vs accelerated (UVA intensity: 9mW/cm^2, duration: 10 minutes) corneal crosslinking (CXL) for stabilizing progressive keratoconus is unknown. This study aimed to compare the long-term (5 years) efficacy and safety of these protocols in keratoconus using the real-world data from the Save Sight Keratoconus Registry (SSKR).

Methods: Data from the routine clinical practice (15 sites across Australia, New Zealand and Italy) were captured through a web-based registry system for this observational study. A total of 100 eyes (75 patients) who had standard CXL and 76 eyes (66 patients) who had accelerated CXL, with a follow-up visit at five-year post-CXL were included. The mean age of the participants was 24.2±7.7 (standard 24.3 ± 7.3 vs accelerated 23.7±7.7) years, and 35.0% were female (standard 33.3% vs accelerated 34.8%). The outcome measures included changes in visual acuity, keratometry (maximum keratometry, Kmax; and central steepest keratometry, K2), minimum corneal thickness (MCT), and frequency of adverse events. The outcomes were compared using mixed-effects regression models adjusted for age, sex, visual acuity, keratometry, pachymetry, doctor, practice, and eye laterality.

Results: Both CXL protocols were effective and safe in stabilizing keratoconus and improving outcomes (Fig 1). The adjusted mean changes (95% CI) in outcomes were better in standard than in accelerated CXL [habitual visual acuity gain, 10.2 (7.9 to 12.5) vs 4.9 (1.6 to 8.2) logMAR letters; pinhole visual acuity gain, 5.7 (3.5 to 7.8) vs 0.2 (-2.2 to 2.5) logMAR letters; Kmax, -1.8 (-4.3 to 0.6) vs 1.2 (-1.5 to 3.9)D; K2, -0.9 (-2.2 to 0.3) vs 0.1 (-1.3 to 1.6)D; MCT, -3.0 (-13.7 to 7.7) vs -11.8 (-23.9 to 0.4) μm (p values for visual acuity, pinhole visual acuity, Kmax: <0.05; for K2 and MCT: >0.05)]. The frequency of adverse events at the 5-year follow-up visit was low in both groups [standard, 5 (5%; haze 3; scarring 1, epithelial defect 1) and accelerated 3 (3.9%; haze 2, scarring 1)].

Conclusions: This real-world observational study found that both standard and accelerated CXL were safe and effective procedures for stabilising keratoconus in the long term. The standard CXL resulted in greater improvements in visual acuity and keratometry.

ABSTRACT BODY:

Purpose: Corneal wounding, due to infection, injury or inflammation, heals by stromal scarring and opacification. There is an unmet clinical need for a biomaterial that can prevent the development of corneal stromal scar or as therapeutics to treat these scars. This study reports the possible prophylactic potential of biomimetic hydrogels derived from non-transplant grade human cadaveric and bovine corneas.

Methods: Human (h) and Bovine (b) cornea were decellularized using 1.5M NaCl solution to prepare decellularized corneal extracellular matrix hydrogel (DCMH). In-vitro characterization of retained DNA, sulfated glycosaminoglycans (sGAG) and collagen of native tissue and hDCMH, bDCMH were evaluated. Physical, Chemical and environmental stability of the DCMH was looked into for viscosity profile, shear recovery and gelation property. In-vivo investigation for a scar-free cornea regeneration was conducted by corneal injury model in New Zealand white rabbits (n=6) removal of 200μm depth and 3mm diameter of stromal tissue. DCMH from both sources were topically applied to treat the surgically induced cornea wounds in rabbits, followed by clinical evaluation and comparison with collagen and sham controls. Statistical analyses were performed using ANOVA and Student's t-test.

Results: The total dsDNA, sGAGs and collagen content retained was found to be 2.07 ± 0.23% and 2.12 ± 0.51%; 73.35 ± 7.05% and 66.47 ± 4.01%; 66.47 ± 4.01% and 50.57 ± 4.73% respectively in hDCMH and bDCMH. Viscosity recovered after shear thinning was 307100 mPa.s and 281600 mPa.s for hDCMH and bDCMH. In the in vivo study, the average epithelial thickness recovered was 103.5 ± 12.3 % in the collagen group, 95 ± 11.44% in hDCMH, and 81.95 ± 15.8% for the sham group, significant between collagen and sham control. The central corneal thickness (CCT) regained was 88.85 ± 4.08% collagen group, 78.39 ± 5.059% sham control, 97.07 ± 1.59% hDCMH, 96.52 ± 0.12 % bDCMH with significant difference between hDCMH and bDCMH group.

Conclusions: Our DCMH promotes early re-epithelialization, stromal regeneration, and transparency, indistinguishable from a healthy cornea. These findings suggest that the application of our formulated decellularized corneal matrix hydrogel could be a new promising approach as a minimally invasive and easily performable procedure to prevent scarring followed by traumatic injuries in the cornea.

ABSTRACT BODY:

Purpose: Spontaneously Diabetic Torii (SDT) fatty rat is a novel animal model for obesity and type 2 diabetes. SDT fatty rat develops hyperglycemia, dyslipidemia and other diabetic complications; however, diabetic ocular complications in the animal model have not been fully investigated. Previously, we reported that SDT fatty rats develop diabetic cataract, which well mimics the cataract formation in patients with diabetes. (Kikuchi et al., J Diabetes Res., 2020). In the current study, we further investigated the diabetic retinal complications in SDT fatty rats.

Methods: SDT fatty rats (24 weeks old, male) and age-matched Sprague Dawley (SD) rats were used in this study. Retinal capillaries were isolated by trypsin digestion, and capillary diameter and the retinal capillary pericyte/endothelial cell (P/E) ratio were assessed. Immunostaining for leukocyte adhesion molecules, intercellular adhesion molecule-1 (ICAM-1) and vascular cell adhesion molecule-1 (VCAM-1), was performed.Real-time PCR and Magnetic Luminex assay were performed to investigate the alteration of the inflammation-related molecules, i.e., monocyte chemotactic protein-1 (MCP-1), interleukin-1β (IL-1β), and tumor necrosis factor-α (TNF-α) in the retina of SDT fatty rats.

Results: The retinal capillary diameter significantly increased in SDT fatty rats (7.74±0.16 μm, n=5) compared to SD rats (6.42±0.23 μm, n=5, $p<0.01$). The P/E ratio was significantly lower in the retinal capillaries of SDT fatty rats (0.42±0.04, n=5) than those of SD rats (0.61±0.01, n=5, $p<0.01$). ICAM-1 and VCAM-1 were immunostained in the retinal vessels of SDT fatty rats. mRNA expression levels of Mcp1, Il1b and Tnf were significantly upregulated in the retina of 24-week-old SDT fatty rats (Mcp1, $P<0.01$; Il1b, $P<0.05$; Tnf, $P<0.01$). The protein levels of MCP-1, IL-1β and TNF-α were also significantly increased in the retina of SDT fatty rats than those of SD rats (MCP-1, $P<0.01$; IL-1β, $P<0.05$; TNF-α, $P<0.01$, n=5 each).

Conclusions: The present study demonstrated that SDT fatty rats exhibited early diabetic changes in the retina, indicating that SDT fatty rats serve as a potential animal model in researches on the pathogenesis of human diabetic retinopathy.

ABSTRACT BODY:

Purpose: The chronic sequelae of Stevens-Johnson syndrome (SJS) can progress to various ocular complications and lead to visual impairment. The exact mechanism of the interplay of protein molecules in chronic ocular surface inflammation is not clearly understood. Therefore, this study aims to explore the underlying molecular signaling pathways to understand the disease process and mechanism of ocular damage using a proteomic approach.

Methods: Tear samples were collected from chronic SJS (n=6) with age-gender matched controls (n=6) and analyzed by liquid chromatography-mass spectroscopy for protein profiling and label-free quantification of tear proteins. Highly differentially regulated proteins were selected by z-score normalization followed by t-test significance using abundance values. The candidate proteins were shortlisted based on their presence in at least five patients with exclusive extracellular expression. Also, performed Ingenuity pathway analysis (IPA) to understand the differentially regulated canonical pathways in chronic SJS patients.

Results: The total tear proteins identified were ~1760, of which the t-test revealed 249 were differentially regulated proteins in chronic SJS tears. The results underline that 63 proteins were identified based on the extracellular expression, of which 33 proteins were significantly upregulated, including Neutrophil elastase ($p<0.0001$), Protein S100-A7 ($p<0.0004$), Neutrophil collagenase ($p<0.0016$), Myeloblastin ($p<0.004$), Myeloperoxidase ($p<0.003$), Matrilysin ($p<0.04$). And other 30 proteins were significantly downregulated, mostly related to lacrimal gland secretions. The IPA analysis of the significantly differentially regulated proteins revealed the IL-8 signaling pathway (p-value 1.24E-06) and inflammatory response (p-value 2.64E-04) as a major player in chronic SJS tears and could be correlated with disease conditions. Additionally, 33 proteins were uniquely expressing including Interleukin-36γ in SJS tear.

Conclusions: The findings of this study will contribute to a better understanding of the molecular mechanisms of chronic SJS ocular surface disease and may unravel new biological insights that help identify a potential therapeutic target for an effective treatment strategy.

TITLE: Trends in California ophthalmology surgical volume during the COVID pandemic

SESSION TITLE: Public Health I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Lu, J.D. Bartlett, Stein Eye Institute, University of California Los Angeles, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Amanda Lu: Commercial Relationship: Code N (No Commercial Relationship) | John Bartlett: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Pandemic era restrictions on non-essential travel, redistribution of healthcare resources, and nursing shortages have impacted the ability of ophthalmologists to deliver care. California had among the strictest 2020 restrictions during the pandemic with reallocation of non-essential surgical resources. This study assesses changes in surgical volume of common ophthalmic procedures in California since the COVID-pandemic.

Methods: The California Health and Human Services Agency (Office of Statewide Health Planning & Development) maintains ambulatory and emergency room procedural databases. Common ophthalmic procedures and surgical volumes were extracted for 29 CPT codes from 2014-2020. Procedures with fewer than 100 cases were excluded.

Results: Overall, ophthalmology surgical volume decreased by 19% from 2019 to 2020. Greatest declines were for anterior lamellar corneal transplant (39%) and pterygium with graft (38%). Simple cataract surgeries declined by 29% in 2020, compared to an average annual decline of 3% from 2014-2019. Volume increased only for two surgeries: aqueous shunt with graft (2%) and complex retinal detachment (0.2%). Temporal artery biopsies, historically stable with 0.2% average change from 2014-2019, declined by 28% in 2020. Retinal detachment repairs declined by 20% and 17% (with and without vitrectomy, respectively). In comparison, laparoscopic appendectomy only declined by 2% in 2020. Limitations of this study include role of population changes and changes in annual coding practices.

Conclusions: COVID era declines were noted across almost all ophthalmic surgeries with steep drops in perceived non-urgent procedures such as pterygium and cataract. However, delays in cataracts and other conditions can result in increased disease burden and morbidity for patients. Uniquely, tube shunt procedures increased, perhaps due to progression of glaucoma from delayed routine care. For vision-preserving surgeries such as retinal detachment repair, lack of accessible care during the pandemic is especially concerning.

ABSTRACT BODY:

Purpose: Acute corneal perforations need rapid closure to avoid intraocular infections or suprachoroidal bleeding. The worldwide lack of donor corneas delays the emergency therapy. The current study investigates the efficacy and safety of a fish scale based biomaterial (ologen™ Biocornea) for temporary wound closure for a maximum of 72 hours until a donor cornea is available.

Methods: This is a first-in-human prospective, uncontrolled, interventional, multicenter pilot study (Trial registration number: Eudamed database CIV-15-03-013305). Patients with corneal perforation or laceration with the indication of emergency corneal transplantation were included when a corneal graft was not immediately available. Institutional ethics committee approvals were obtained, the patients provided written informed consent, and the study was performed according to the Declaration of Helsinki and the International Conference on Harmonization Good Clinical Practice guidelines. Ologen™ Biocornea was applied on the recipient's cornea aligning the center of the ologen™ Biocornea with the corneal defect. The ologen™ Biocornea was then fixed onto the cornea by intrastromal 10-0 nylon single sutures. The main outcome measure was effectiveness in closing the perforated cornea until a donor cornea is available. Primary safety endpoints were severe inflammatory anterior chamber reaction, hypotony, suprachoroidal haemorrhage, choroidal detachment, flat anterior chamber, endophthalmitis and wound leakage.

Results: Seven patients (5 m, 2 f) with corneal perforation due to corneal ulcerations were included. A complete success in closing the perforation was achieved in 7 out of 7 patients. In one patient replacement of loose sutures and anterior chamber tamponade with air were needed to complete wound closure. Further adverse events were conjunctival chemosis and hyperemia, foreign body sensation and intracameral fibrin formation in a patient having infectious keratitis at the time of inclusion. Following keratoplasties were regular in all patients.

Conclusions: Using a fish-scale based "biocornea", corneal perforations can be temporarily closed to bridge the time until a human donor cornea becomes available. This approach may alleviate missing immediate access to allogeneic donor corneas and potentially also be an option for complete long-term corneal replacement.

TITLE: Oxidative stress initiates RIPK3/MLKL-mediated corneal epithelial necroptosis and NLRP3 inflammasome signaling during fungal keratitis

SESSION TITLE: Corneal epithelial biology and repair mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Wang, X. Yang, X. Zuo, X. Wang, J. Yuan, Sun Yat-Sen University Zhongshan Ophthalmic Center State Key Laboratory of Ophthalmology, Guangzhou, Guangdong, CHINA|

Commercial Relationships Disclosure: Bowen Wang: Commercial Relationship: Code N (No Commercial Relationship) | Xue Yang: Commercial Relationship: Code N (No Commercial Relationship) | Xin Zuo: Commercial Relationship: Code N (No Commercial Relationship) | Xiaoran Wang: Commercial Relationship: Code N (No Commercial Relationship) | Jin Yuan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess how corneal epithelial necroptosis triggers immune responses against fungal keratitis and determine the underlying mechanisms.

Methods: Immortalized and primary human corneal epithelial cells (HCECs), C57BL/6 (wildtype, WT) mice and RIPK3 knockout (RIPK3-KO), NLRP3 knockout (NLRP3-KO) mice were infected with A. fumigatus to establish fungal keratitis models both in vitro and in vivo. Normal corneas (n = 2) and fungal keratitis corneas (n = 2) from donors and patients were collected separately. Cellular reactive oxygen species (ROS) and mitochondrial membrane potential were detected through flow cytometry. CCK8, LDH assay, TUNEL and PI staining were conducted to quantify cell viability. Morphological changes of necroptotic cell death were observed by electron microscopy (EM). RNA sequencing (RNA-Seq), western blot assay and immunofluorescence staining were performed to investigate the differentially expressed genes. Severity of disease was evaluated via slit-lamp photography, clinical scoring, fungal load and HE staining.

Results: Fungal infection triggered significant corneal epithelial necroptosis in human/mice/in vitro models. Moreover, reduction of excessive ROS release effectively prevent necroptosis. NLRP3 knockout did not affect the occurrence of necroptosis in vivo. In contrast, ablation of necroptosis via RIPK3 significantly delayed recruitment and inhibit NLRP3 inflammasome in macrophages, which enhance the progression of fungal keratitis.

Conclusions: Overproduction of ROS in fungal keratitis leads to significant necroptosis in corneal epithelium. Furthermore, necroptotic stimuli-mediated NLRP3 inflammasome serves as a driving force among host defense against fungal infection.

ABSTRACT BODY:

Purpose: Congenital Hereditary Endothelial Dystrophy (CHED) is a rare form of corneal endothelial dystrophy. Mutations in SLC4A11, an abundant corneal solute transporter, leads to CHED. The purpose of this study is to identify SLC4A11 mutations in familial and non-familial CHED cases and in-silico analysis of the identified mutation.

Methods: The study involved 10 CHED patients (6 females and 4 males) from 2 familial and 5 sporadic cases with mean age around 11 years. Clinical diagnosis of CHED was based on the typical clinical characteristics such as a bilateral ground glass appearance of the cornea with increased corneal thickness assessed clinically and documented using high resolution optical coherence tomography. Blood samples were collected with informed consent, from each participants. Genomic DNA was isolated followed by screening for all coding exons with flanking intronic region of SLC4A11 gene using direct sequencing method. In addition, 80 controls were excluded for the presence of identified variations. Further, in-silico analysis was performed using homology-based modeling (Modeller10.1) for all identified SLC4A11 mutations.

Results: Two familial cases of CHED were identified with novel homozygous c.1514C>G (p.Ser489Trp) and compound heterozygous c.591A>C (p.Arg161Arg) + c.2456insT (p.Val805fs) mutations respectively. Among five non-familial cases, two cases were identified with novel homozygous mutations c.1487G>T (p.Ser480Ile), intronic mutation c.620-2A>G respectively and other with previously reported homozygous c.2653C>T (p.Arg869Cys) mutation. Remaining two cases could not be identified with CHED related pathogenic mutations. Homology modelling based in-silico analysis predicted change in protein stability, protein local flexibility and hydrogen bond interactions caused due to such mutations.

Conclusions: Our study shows a spectrum of SLC4A11 mutations ranging from exonic, intronic, homozygous, heterozygous and compound heterozygous in CHED patients. These mutations showed different grade of deleterious effect in in-silico analysis. In two of the non-familial cases, SLC4A11 mutation was not observed thereby indicating involvement of any other gene or genetic mechanism. Our study aided in the mutational spectrum of SLC4A11 in the pathogenesis of CHED.

ABSTRACT BODY:

Purpose: The oral administration of statins, 3-hydroxy-3-methyl-glutaryl coenzyme A (HMG-CoA) reductase inhibitors, has been associated with beneficial effects on eye conditions due to their pleiotropic effects. The efficacy of its use could be improved if efficient ocular formulations are developed reducing the side effects related with the systemic absorption. The objective of the work was to design contact lenses (CLs) as platforms for the prolonged release of statins (pravastatin sodium). A bioinspired strategy was used to mimic the active site of HMG-CoA.

Methods: Bioinspired hydrogels were prepared from mixtures of 2-hydroxyethyl methacrylate (HEMA), ethylene glycol phenyl ether methacrylate (EGPEM), and 2-aminoethyl methacrylamide hydrochloride (APMA). A physicochemical characterization of the hydrogels was carried out. The hydrogels were loaded by soaking in a pravastatin solution during 48h. Drug release was monitored in simulated lacrimal fluid. Ex vivo porcine cornea and sclera permeability was assessed using vertical diffusion cells. Pravastatin was administered as eye drops and as CLs to male New Zealand white rabbits. The levels of pravastatin in tear fluid were collected using Schirmer test strips. The drug accumulated in cornea, sclera, crystalline, aqueous and vitreous humour, and retina was also quantified.

Results: The incorporation of APMA monomer (E200A40 and E0A40 hydrogels) remarkably increased the amount of pravastatin loaded (7.26±0.6 and 6.70±0.2 mg/g, respectively, Figure 1), without altering the swelling, transmittance, mechanical properties and ocular compatibility typical of soft CLs. The CLs sustained the in vitro release for 1 day. In ex vivo permeability tests, pravastatin was detected in the receptor chamber through transscleral permeation. In in vivo tests, the eye drops resulted in measurable pravastatin levels for 1h. The permanence of the drug in tear fluid was prolonged for more than 8h when it was administered as CLs. Among the ocular tissues evaluated, pravastatin was detected in the cornea (158.5±31.8 ng/g), sclera (1.53±0.6 ng/g), aqueous (108.7±47.5 ng/g) and vitreous humour (2.00±0.6 ng/g).

Conclusions: The design of CLs applying a bioinspired strategy allows the incorporation of pravastatin without altering the properties required as a medical device. Pravastatin-loaded CLs have a great potential to serve as a novel delivery system for the treatment of disorders affecting the anterior and posterior segment of the eye.

ABSTRACT BODY:

Purpose: Corneal collagen crosslinking (CXL) is a commonly used minimally invasive surgical technique to prevent the progression of corneal ectasias, such as keratoconus. Unfortunately, riboflavin and UV-A light-based conventional CXL procedures have not been successfully applied to all patients, and they usually have frequent complications, such as corneal haze and endothelial damage. This study proposes a new method for corneal crosslinking by using ruthenium (Ru) based photoinitiator solution and visible light (430 nm).

Methods: As a ruthenium photoinitiator solution, we applied tris(bipyridine)ruthenium(II) ($[Ru(bpy)_3]^{2+}$) and sodium persulfate (SPS) mixture covalently crosslinks free tyrosine, histidine, and lysine groups under visible light exposure (400-450 nm). Firstly, we demonstrated the effects of the Ru/visible blue light procedure on the viability and toxicity of the human corneal epithelium, limbal, and fibroblast cells via flow cytometry, immunofluorescence staining, and cell toxicity assays. After that, bovine corneas crosslinked with ruthenium mixture and visible blue light were characterized, and their biomechanical properties were compared with the conventional riboflavin/UV-A crosslinking approach.

Results: $[Ru(bpy)_3]^{2+}$ and SPS did not show toxicity under 1 mM in any human corneal cell lines. The crosslinked corneas with the non-toxic ruthenium-based visible light CXL method showed significantly higher Young modulus in the hybrid rheometer, higher mechanical stiffness in uniaxial stress-strain test, and more bonding between collagen fibrils under scanning electron microscopy compared to conventional riboflavin, and UV-A light-based method applied corneas. Additionally, other materialistic characteristics (hydrodynamic behavior, optical transparency, and enzymatic resistance) of ruthenium-based crosslinked corneas were significantly better than riboflavin-based crosslinked corneas.

Conclusions: In all biomechanical tests, the visible light-based crosslinked corneas with non-toxic doses of ruthenium photoinitiator solutions showed better results than conventional UV-A crosslinked corneas. In this way, we prevent UV-A light-induced cytotoxicity in a faster and more effective collagen crosslinking procedure. We foresee that Ru/visible light-based crosslinking treatment could become the standard therapy for all ectatic corneal pathologies because of its superior biocompatibility, safety, and efficiency very soon.

ABSTRACT BODY:

Purpose: Inherited retinal dystrophies (IRDs) are a genetically heterogenous group of disorders for which an early diagnosis may be essential. Approved therapies and clinical trials for many IRDs are most often contingent on a molecular diagnosis. Here, we report our experience with a comprehensive genetic testing strategy for inherited retinal dystrophy using a next-generation sequencing panel in a pediatric population.

Methods: We carried out a retrospective analysis of test results from 1,612 deidentified patients, aged 0 to 12 years, tested consecutively for IRDs using a retinal dystrophy panel at Blueprint Genetics. The molecular diagnoses of IRDs were based on the detection of variants that included mitochondrial variants, copy number variants (CNVs) including small CNVs defined by exon size, and non-coding variants in intron regions +/-20 bps from exon-intron boundaries. Variant interpretation was performed according to American College of Medical Genetics guidelines.

Results: We extracted information from the internal laboratory database. The median coverage of all target regions was 99.9% at >20X while the median sequencing depth was 208X. The median age at testing was 8 years. Males made up 59.7% (962) of the cohort while females made up 39.9%% (643). Sex was not specified for 7 (0.4%) patients. A molecular diagnosis was made in 906 (56.2%) patients while a variant of unknown significance (VUS) favoring pathogenic was identified in an additional 96 (6.0%). Diagnoses were made involving 114 genes; ABCA4, RS1, CNGB3, RPGR, and CEP290 accounted for 37.3% of diagnoses. Mitochondrial variants were responsible for 3 diagnoses. Copy number variants (CNV) contributed to the diagnosis in 71 patients (4.4%); 28/71 (39.4%) patients had CNVs that were 1 or 2 exons in size. Non-coding variants contributed to 171 (10.6%) diagnoses, 45/171 (26.3%) of which were beyond 10 base pairs from the exon-intron boundary.

Conclusions: These results support the clinical utility of genetic testing for IRDs in pediatric patients. Importantly, approved therapies or clinical trials are available for the 5 most common diagnostic genes. Small CNVs, noncoding variants beyond 10 base pairs from the exon-intron boundary, and mitochondrial variants were responsible for the diagnosis in 4.7% of patients, highlighting the importance of a comprehensive testing approach with high sensitivity to detect these variants.

ABSTRACT BODY:

Purpose: Retinoblastoma is the most common primary intraocular tumor in children. Its management is still a challenge. If preclinical models are helpful to evaluate new therapies, current retinoblastoma ones usually fail to represent the entire spectrum of the disease.

We thus aim to develop an orthotopic preclinical model of retinoblastoma using patient-derived tumor cells, mimicking different clinical presentations and available for the evaluation of new therapies.

Methods: Subcutaneous retinoblastoma patient-derived (from enucleation) xenografts were established and maintained on immunodeficient Nude mice. To develop the orthotopic model, a suspension of retinoblastoma cells (from subcutaneous mice tumors) were injected in the subretinal space of Nude rat eyes. Tumor growth was assessed in vivo by retinal photographs and optical coherence tomography (OCT). At the end of the follow-up, histopathology analysis was performed. All experiments were performed in accordance with the ARVO Statement for the Use of Animals in Ophthalmic and Vision Research and the institutional guidelines and local ethics committee regarding animal experimentation.

Results: Forty-nine eyes were grafted. Tumoral growth was observed in 49% of the eyes in a median time of 1,9 weeks. Media remained clear in nearly all eyes, allowing a high-quality observation of fundus during follow-up. OCT documented different patterns of tumoral growth: subretinal, intraretinal or vitreous growth. Interestingly, in some cases the tumors initially located under the retina has migrated secondarily into the inner retina, the usual location of emergence of retinoblastoma in children. Histopathology confirmed the presence of retinoblastoma viable cells.

Conclusions: We develop a preclinical model of retinoblastoma in Nude rat eyes, by grafting under the retina patient-derived tumor cells. The rate of tumor growth must be improved but the model demonstrated subretinal, intraretinal or vitreous tumors and is adapted to new retinoblastoma treatment evaluation.

ABSTRACT BODY:

Purpose: Toxic amyloid-beta oligomers (AβOs) and oxidative stress are hallmarks of dry age-related macular degeneration (dAMD) and can disrupt key homeostatic processes in retinal pigmented epithelium (RPE) cells (Rabin et al. 2013). AβOs disrupt RPE cell function in vivo (Ruozhou et al. 2013) and normal RPE-mediated photoreceptor outer segment (POS) phagocytosis in vitro (Lynn et al. 2021). Sigma-2 receptor (S2R) modulators prevent AβOs from binding to neurons and rescue deficits in neuronal functioning (Izzo et al. 2014). Based on dAMD-related deficits in RPE function and the role of the S2R as a key damage sensor, the hypothesis that S2R modulators could rescue AβO and oxidative stress-induced deficits in the ability of RPE cells to phagocytose POSs was tested.

Methods: A human RPE cell line, ARPE-19 cells, were exposed to AβOs (0.5-2μM) over time (1-8 hr) and AβO binding was assessed via immunocytochemistry (ICC) and high content imaging (n=3-6 experiments). A trafficking assay was used to monitor internalization and degradation of POS over time. ARPE-19s were exposed to AβOs or H_2O_2 in the presence or absence of S2R modulators. The effects of S2R modulators on POS colocalization with lysosomal associated membrane protein 2 (LAMP2) and microtubule-associated proteins 1A/1B light chain 3B (LC3B) were quantified via confocal imaging and unbiased algorithm across time (12-48 hr; n=2 experiments). Statistical significance ($p<0.05$) was determined via Two-Way ANOVA and post hoc Tukey's test.

Results: ICC studies show that AβOs bind to ARPE-19s in time and concentration-dependent manners (EC50=1.86μM). Following exposure of cells to 1μM AβO, POS are retained in LAMP2 positive vesicles and trafficking is diminished to LC3B vesicles when compared to control. S2R modulators from three independent chemical series restored POS trafficking through LAMP2 positive vesicles at 36 and 48 hr ($p<0.0001$) and through LC3B vesicles at 48 hr ($p<0.0001$). The same S2R modulators restored POS trafficking after exposure to 100μM H_2O_2 through LAMP2 positive vesicles at 12 and 48 hr ($p<0.001$) and through LC3B vesicles at 12, 24, and 36 hr ($p<0.001$).

Conclusions: Results point to a role of S2R modulators in rescuing AβO and oxidative stress-induced deficits in RPE cells by normalizing the homeostatic recycling of POSs in RPE cells. These data support S2R modulators as a promising potential therapy for dAMD.

ABSTRACT BODY:

Purpose: Several supervised machine learning models have been proposed to assist in keratoconus (KCN) detection, however, they require numerous well annotated data. Herein, we propose a new unsupervised hybrid artificial intelligence model to detect KCN.

Methods: We have developed an unsupervised model based on the k-means algorithm and adapted flower pollination algorithm (FPA). The proposed model was evaluated using two independent datasets: Pentacam (Oculus Inc., Germany) corneal imaging data collected from 5430 eyes from Department of Ophthalmology and Visual Sciences, Paulista Medical School, Federal University of Sao Paulo, Sao Paulo, Brazil; and CASIA (Tomey, Japan) corneal imaging data of 1531 eyes from Department of Ophthalmology, Jichi Medical University, Tochigi in Japan. Three different clustering scenarios were evaluated: 2 classes (normal vs KCN), 3 classes (normal vs KCN low grade (1-2 stage) vs KCN high grade (3-4 stage) and 5 classes (normal, stage KCN 1, KCN 2, KCN 3 and KCN 4). We compared the proposed method with three other standard unsupervised algorithms including K-means alone, K-medoids, and Spectral cluster (figure 1), following 25 runs. Accuracy (Ac) metrics analyses also included Precision (Pr), Recall (R), F-Score (F), and Purity (Pu).

Results: FPA-K-means outperformed the other algorithms in 2-, 3- and 5-class scenarios, except for Recall and Purity for the 5-class scenario. In the 2-class test, FPA-K-means achieved Ac=96.03, Pr=96.29, R=96.06, F=96.17, and Pu=96.03. When considering a 3-class scenario, FPA-K-means reached Ac=71.02, Pr=53.53, R=75.37, F=64.64, and Pu=80.85. While for the 5-class test, FPA-K-means attained Ac= 75.20, Pr= 35.01, R= 47.70, F= 48.97, and Pu= 53.64, whereas Spectral clustering method achieved R= 55.33 and Pu= 55.12

Conclusions: The proposed model consists of a new unsupervised algorithm that combines two computational learning techniques for detecting KCN from corneal image data. As it is unsupervised, the model is not affected by expert pre-labelling bias. Our study demonstrates that the proposed model can be used in the clinical and scientific setting for detection of KCN. Improvements to this model may be applied in clinics for diagnosing the corneal status of KCN patients.

ABSTRACT BODY:

Purpose: Optical coherence tomography (OCT)-based drusen volume quantification is a relevant biomarker in age-related macular degeneration (AMD). An FDA-approved automated software for quantifying drusen volume using Cirrus (Zeiss Meditec, Dublin, CA) is available, however the comparability with similar approaches on other devices is largely unknown. Hence, we compared drusen volume measured by a newly developed, automated software running on Spectralis OCT data (Heidelberg Engineering, Heidelberg, Germany) against the above-mentioned software on Cirrus.

Methods: We included 306 eyes from 159 individuals with bilateral intermediate (iAMD, n=133) or early (eAMD, n=26) AMD, both reading center confirmed using multi-modal imaging. The Spectralis imaging protocol included a 20°×20°

(25 B-scans) and a 30°×25° macular volume scan (241 B-scans), while the Cirrus protocol included a 200×200 macular cube. We assessed inter-device and inter-scan differences in 3- and 5mm diameter fovea-centered grid with intra-class correlation coefficients (ICCs) and root mean squared error (RMSE). Furthermore, we calculated the agreement based on exceeding a drusen volume cut-off indicating higher AMD progression risk (previously shown at >0.03mm^3 for Cirrus, set at >0.09mm^3 for Spectralis by adding the mean difference between the two devices to 0.03).
Results: Mean age of participants was 71.3±7.4 years. In the 5-mm diameter grid, no drusen were detected in 2 eyes (0.6%) in the Spectralis 241 B-scans, in 13 eyes (4%) in the 25 B-scans and 75 eyes (23.6%) in Cirrus scans. Agreement on drusen volume measurements was high between the two Spectralis scans (ICC 0.993 [0.991-0.994]). Drusen volume measurements between the denser Spectralis scan and Cirrus showed good reliability (ICC 0.803 [0.76-0.84]); the RMSE was 0.007 in eAMD and 0.106 in iAMD. Considering the cut-off mentioned above, agreement (kappa) between the two Spectralis scans was 97.4 (0.94); while with Cirrus it was 89.3 (0.77) for 241 B-scans and 89.4 (0.77) for 25 B-scans, respectively.
Conclusions: Drusen volume measures across the two softwares are not interchangeable. Comparability improves using a binary cut-off. Less dense scan patterns decrease sensitivity of drusen detection in Spectralis OCT scans.

ABSTRACT BODY:

Purpose: The PDS is a US Food and Drug Administration–approved drug delivery system that includes a refillable ocular implant for continuous delivery of a customized formulation of ranibizumab, surgically implanted in the superotemporal quadrant at the pars plana. Key clinical pearls for preoperative evaluation of PDS surgical candidates and patient preference for the PDS versus intravitreal injection are reported.

Methods: The phase 3 Archway trial (NCT03677934) evaluated safety and efficacy of the PDS with ranibizumab 100 mg/mL with fixed 24-week refill-exchanges versus intravitreal ranibizumab 0.5 mg injections every 4 weeks in patients with neovascular age-related macular degeneration (nAMD). Treatment preference was assessed in the PDS arm at week 40 using the PDS Patient Preference Questionnaire.

Results: PDS candidates require careful preoperative evaluation, including thorough review of medical and surgical history to identify factors that may negatively affect conjunctival health and impact suitability for PDS implantation. History of prior conjunctival-based surgery may result in conjunctival scarring or poor tissue integrity. Long-term use of topical medications (eg, for glaucoma) may affect conjunctival quality, causing inflammation, scarring, and decreased thickness. Relevant ocular medical history, such as severe ocular surface disease, scleritis, or concomitant conditions, such as scleroderma, pemphigoid, or Sjogren's syndrome, may also affect conjunctival or scleral integrity.

Examination of the conjunctiva and Tenon's capsule should be performed preoperatively at the slit lamp with a cotton swab to assess mobility, scarring, and translucency/thickness. Eyelid health should be evaluated, with attention to lid hygiene, position, and mobility, which may impact postoperative infection risk and wound healing.

In Archway, 93.2% of PDS-treated patients (n = 234) preferred ranibizumab delivered via the PDS compared with intravitreal injection, with top reasons for preference identified as fewer treatments, less discomfort, and less worry/nervousness.

Conclusions: Careful preoperative evaluation is required to ensure optimal surgical outcomes for PDS candidates. PDS patients demonstrate a marked preference for the PDS over intravitreal injection; consistent attention to the clinical pearls described should help to maintain high levels of patient satisfaction.

ABSTRACT BODY:

Purpose: Mid-day fogging is a common complaint from scleral lens (SL) wearers. We compare self-reported patient fogging to measured fluid reservoir (FR) thickness and central FR optical density after at least 2 hours of continuous wear in established SL patients.

Methods: 22 eyes of 14 patients that had worn SLs for 17 ± 9 months (mean ± SD; range 6 – 33 months) were included in this study. Indication for SL wear was ocular surface disease in 12 eyes and corneal irregularity in 10 eyes. Patients were 53 ± 16 years of age (range: 24-76 years); 8 patients were male. Mean wear time before measurements was 3.6 ± 2 hours (range: 2 – 9 hours). Schleimpflug images were collected by Pentacam (Oculus, Inc). The Pentacam caliper program was used to manually measure central clearance from the 90-degree image. Mid-FR densitometry was recorded from the same image. 7 patients (11 eyes) self-reported fogging, 6 patients (9 eyes) did not. Comparisons were made by t-test.

Results: Average central FR clearance for all eyes (n=22) was 276 ± 115 µm (mean ± SD; range 114 – 560 µm) and average FR densitometry was 6.3 ± 2.4% (range 4.3 – 13.5%). Average FR clearance was not statistically different between foggers 286 ± 124 µm (range 114 -520 µm, n=11) and non-foggers (256 ± 111 µm, range 144 - 560 µm, n=9; P=0.6). FR densitometry was also not statistically different between foggers (8.0 ± 2.7%, range 5.3 to 13.5%) and non-foggers (5.0 ± 0.7%, range 4.3 – 6.7%; P=0.2). When FR clearance was plotted against FR densitometry, no correlation was present for: all eyes (R2 = 0.0003), foggers (R2 = 0.0021) and non-foggers (R2 = 0.008).

Conclusions: No statistical differences in central fluid reservoir clearance or measured fluid reservoir densitometry were found between self-reported foggers or non-foggers wearing scleral lenses. Self-reported scleral lens mid-day fogging is not attributed to central scleral lens fluid reservoir clearance.

ABSTRACT BODY:

Purpose: Rural and urban underserved communities experience lower rates of preventive screening, but factors contributing to variability in diabetic eye screening receipt between these communities have not been systematically analyzed. We used a unique, all-payer database covering over 75% of Wisconsin residents (Wisconsin All-Payer Claims Database) to assess factors associated with screening variability in rural vs. urban underserved and advantaged primary care clinics.

Methods: We included adults with diabetes (18-75 years old) with claims billed throughout the baseline (2012-2013) and measurement years (2013-2014). Patients received screening if they had a claim billed for an exam with an eye care provider or telemedicine-based retinal imaging during the measurement year. We created multivariable logistic regression models to assess the impact of age, gender, hierarchical condition category risk score, health system, primary care clinic rurality, and level of disadvantage (following the Wisconsin Collaborative for Healthcare Quality classification) on screening receipt.

Results: A total of 118,707 adults with diabetes from 143 Wisconsin health systems were included. Most (74%) were over 55 years of age (mean: 61 ± 11 years), male (51%), and obtained care from urban primary care clinics (84%). Screening rates varied widely from 32% to 72%, with the least screening among those obtaining care from urban underserved primary care clinics and the greatest screening among those obtaining care from urban advantaged primary care clinics. Before adjusting for health system in the model, and with urban advantaged primary care clinics serving as the reference, patients who obtained care from rural vs. urban underserved primary care clinics were more likely to obtain screening (OR_{rural} 0.79, 95% CI 0.71-0.88 vs. OR_{urban} 0.60, 95% CI 0.58-0.63). However, patients from urban underserved clinics were more likely than their rural counterparts to obtain screening after adjusting for health system (OR_{rural} 0.72, 95% CI 0.62-0.82 vs. OR_{urban} 0.89, 95% CI 0.84-0.94).

Conclusions: There was significant variability in screening based on primary care rurality and level of disadvantage. Health system contributed substantially to this variability. Health system-focused interventions, particularly those serving patients in urban underserved primary care clinics, may increase screening receipt.

ABSTRACT BODY:

Purpose: Supervision must be documented for every patient encounter during residency training. This is especially indicated when a bill is submitted to a payor for services performed with the involvement of a resident. (1) The teaching physician must include an attestation documenting the level of resident involvement in the patient encounter. (2) When submitted to CMS the GC modifier is also utilized to indicate that a resident, under the direction of a teaching physician, is involved in a patient encounter. We retrospectively reviewed our documentation of the teaching physician in a resident ophthalmology clinic.

Methods: All patient encounters performed by ophthalmology residents over a 5-month period (January thru May 2021) were retrospectively reviewed for appropriate documentation of the teaching physician. All patient encounters were supervised by teaching physicians in an outpatient ambulatory ophthalmology clinic at the Texas Diabetic Institute, San Antonio, TX. Each electronic medical record (EMR) was reviewed for appropriate documentation of the teaching attestation and GC modifier. The data was analyzed using R software.

Results: A total of 1,500 patient encounters were reviewed. All records (100%) documented the teaching attestation. The GC modifier was utilized in 1,388 of patient encounters (92.5%). January (95%) and May (88%) showed the highest and lowest compliance, respectively. The GC modifier was not documented in 7.5% of patient encounters.

Conclusions: All patient encounters included appropriate documentation of the teaching attestation. Residents in clinic have direct supervision by the teaching physician and the EMR sends all notes to teaching physicians to be signed and attested. In addition, all notes are reviewed internally for compliance and are amended if not documented appropriately. Compliance with the GC modifier was significantly lower. This is attributed to inadequate understanding of proper usage and that it may not be required by all payors. With recent increase emphasis on the attestation for all notes, providers are less enthusiastic to also ensure documentation of the GC modifier due to this redundancy. Good practices aim for 100% compliance in documentation. Both teaching and resident physicians should be educated on appropriate supervision and how it should be best documented in the medical record.

ABSTRACT BODY:

Purpose: Oxidative stress is strongly implicated in disease progression of age-related macular degeneration. Oral supplements, including ascorbic acid (AA), target this oxidative etiology, yet efficacy is limited due to insufficient ocular distribution. One possible avenue is restoring the antioxidant potential of the vitreous by improving recycling of the inactive oxidized form of AA, dehydroascorbic acid (DHA), back to its active reduced form. Here, we demonstrate the antioxidant potential of AA to improve common retinal pigment epithelium (ARPE-19) cell viability in the setting of H_2O_2 induced oxidative stress and evaluate osteoblasts as a potential source of antioxidant recycling.

Methods: In vitro evaluation was performed by incubating ARPE-19 in culture media containing .2mM H_2O_2 with and without 100uM AA. MTT assay was performed to assess for cell viability. Osteoblast antioxidant recycling potential was tested by exposing MG-63 osteosarcoma cells to culture media containing 100uM DHA. At each time point from 0 to 80 minutes, media was collected and concentrations of DHA and AA were assessed using HPLC. Statistical comparisons were performed using a student's t-test.

Results: AA successfully attenuated the toxic effects of H_2O_2, with 88% of ARPE-19 cells remaining viable after exposure to both $H_2O_2$and AA, compared to 61% viable after incubation with H_2O_2 alone ($P < .001$). Osteoblast antioxidant recycling of DHA was observed with an increase of AA concentration and a concomitant decrease in DHA levels over time. At 80 minutes, the concentration of AA had a 2-fold increase with a paired 2-fold decrease in DHA levels.

Conclusions: These experiments demonstrate the antioxidant potential of AA to attenuate the effects of oxidative stress and its physiologic importance in managing cellular exposure to reactive oxygen species. Osteoblasts exhibited the potential for antioxidant regeneration of AA outside their biological niche. While preliminary, these results demonstrate the promise of an implantable device that continuously recycles antioxidant, eliminating the need for constant injections.

ABSTRACT BODY:

Purpose: Clinical studies suggest that RPE transplant may delay geographic atrophy progression in AMD patients. Our purpose is to examine a novel device for a novel soft monolayer RPE sheet implantation to the subretinal space in a domestic pig in an in vivo study.

Methods: A novel RPE implant comprised of natural biocompatible scaffold with a printed monolayer of polygonal RPE cells was developed. Implants demonstrate high viability, density, morphology, identity to RPE markers such as PMEL17 and potency by measuring PEDF secretion. For safe delivery of the RPE implant into the subretinal space a novel delivery device has been developed. A patented safe folding of the RPE implant into the device allows to transplant a 2x4 mm RPE implant through a standard 20G trocar. In order to insert the RPE implant into the subretinal space a 25G pars plana vitrectomy performed followed by a retinal bleb formation using a 41G canula. A 25G trocar replaced by a 20G trocar, the device is inserted into the subretinal space and the 2x4 mm RPE implant is released, followed by flattening the retina. Animals were followed for eight weeks, during which, OCT imaging and clinical examination took place.

Results: A total of six eyes of six female domestic pigs were included in this prospective study. Four study eyes underwent subretinal RPE transplant (two with systemic and topical immunosuppression and two with short systemic and full topical immunosuppression) and two control eyes (underwent the procedure without RPE transplant). At the end of the follow up period, all eyes were without inflammation signs, retinas were attached with normal neuroretinal layers and without evidence of proliferative vitro retinopathy, intraretinal nor subretinal fluid nor photoreceptor atrophy on OCT. At the end of the follow up period four eyes had clear crystalline lenses and two eyes developed significant cataract.

Histopathological examination demonstrated the presence of human RPE cell monolayer, with no immune cell activity.

Conclusions: A subretinal transplant of a novel printed RPE sheet implant with the aid of a novel 20G delivery device may be a safe method for RPE subretinal transplantation.

ABSTRACT BODY:

Purpose: Mit in inner segments (IS) of photoreceptors (PR) have optical as well as energy-generating and calcium-buffering functions. They guide light to outer segments (OS). PR Mit are the hypothesized reflectivity source for the border of ORT, a scrolling of photoreceptors by Müller glia in advanced AMD, seen in optical coherence tomography (OCT). We immuno-stained Mit in aged-normal and advanced AMD retinas for cytochrome oxidase 4 (COX4), the terminal oxidase of the electron transport chain, and transmembrane protein 119 (TMEM119), a microglia cell-surface marker.

Methods: Twelve µm-thick sections of maculae from 20 eyes including 4 normal, 7 early-or-intermediate (e-i) AMD, 9 advanced AMD (6 atrophic (a), 3 neovascular (nv)) of white donors >80 years were immuno-stained with COX4 (Invitrogen, #459600) and TMEM119 (Abcam, #ab185333) using red-substrate enzymatic detection and scanned with a 40x objective. Positive controls were surgically excised human liver tissue. Negative control experiments used mouse IgG isotope (COX4) and omitted primary antibody (TMEM119).

Results: In neurosensory retina of normal and e-iAMD eyes, punctate COX4 immunoreactivity localized to inner limiting membrane, ganglion cell layer, PR IS, retinal pigment epithelium and cone pedicles/rod spherules in outer plexiform layer. Staining was moderate in other retinal layers and undetectable in PR OS, Bruch's membrane, and sclera. Of these locations, PR IS was also labeled with anti-TMEM119, in fovea and non-fovea regions, indicating labeling in both cones and rods. In advanced AMD eyes with ORT, both COX4 and TMEM119 specifically labeled PR IS in ORT open and closed configurations. In ORT, immunoreactivity in individual IS of PR lacking OS progressively approached and crossed the external limiting membrane.

Conclusions: Data suggest that PR MIT have a unique molecular composition possibly important for optical properties in health and AMD. The hypothesis that mitochondria are reflectivity sources in OCT, initially shown for ORT using electron microscopy of advanced AMD eyes (PMID 25635579), is further supported by the current demonstration of immunoreactivity for TMEM119 and COX4 at all stages of photoreceptor degeneration. Direct contributions of COX4 and TMEM119 to light transmission and reflectance remain to be determined experimentally.

ABSTRACT BODY:

Purpose: Demodex is a vector for bacteria and the prevalence of bacteria on eyelids has shown to be correlated with Demodex presence. To understand type(s) and/or number of bacteria in those with Demodex blepharitis, the Pandora study evaluated the bacterial flora on the eyelid margin and conjunctival fornices in Demodex blepharitis (DB) and normal or non-Demodex blepharitis (non-DB) patients.

Methods: This is a prospective, observational, multicenter study. Swabs were taken from the eyelid margin and conjunctival fornices of 24 patients with at least 10 collarettes (DB) and 11 patients who have no diagnosis of DB or other forms of blepharitis (patients without collarettes, or signs or symptoms consistent with blepharitis). By study completion, samples from a total of 60 DB patients and at least 40 non-DB patients will be collected. All eyelid/conjunctival swabs were sent for culture on blood, Chocolate and Sabouraud agar plates and gram stain.

Results: Methicillin-resistant Staphylococcus epidermidis (MRSE) were isolated from 29% (7/24) of DB patients while only 2 out of 11 patients (18%) had MRSE in the non-DB group. More than one type of bacteria was found in 63% and 45% of the DB and non-DB patients, respectively. Staphylococcus epidermidis was the most isolated bacteria in both DB and non-DB eyelids but methicillin-sensitive coagulase negative Staphylococcus epidermidis was more commonly isolated in non-DB patients (45% vs 21%).

Conclusions: These preliminary results suggest that more pathogenic (MRSE) and more bacterial strains are found in DB patients compared to normal patients. This signifies the importance of treating Demodex blepharitis to minimize the presence of pathogenic bacteria which can compromise outcomes in patients wearing contact lenses or undergoing refractive or cataract surgery. Larger sample size upon study completion will confirm these preliminary findings.

ABSTRACT BODY:

Purpose: Eye health is influenced by access to eye care. Eye care in the United States is covered by health insurance plans, either private or made available by government. Medicare is provided by government and Marketscan is a private or commercial insurance. Utilization of eye care is impacted by type of insurance a person has. There is lack of data, comparing utilization for infectious and inflammatory eye diseases among those who have Medicare and private insurance. We have conducted a retrospective study, using Medicare and Marketscan to evaluate this comparison

Methods: We have used Medicare and Marketscan data available through National Vision and Eye Health Surveillance System (VEHSS). Medicare is funded by government and covers eye services for nearly the entire US population aged 65 years or older and some < 65 years. The MarketScan Commercial Claims and Encounters (CCAE) data has insurance information from persons with employer-sponsored insurance.

VEHSS uses ICD-10 codes to identify ocular disorders. Each code is categorized in one subgroup and multiple subgroups are combined to form a category. Inflammatory and infectious eye disease category includes subgroups of ocular inflammatory conditions, lacrimal system and orbital inflammation, keratitis, conjunctivitis, eyelid inflammation and infection, and endophthalmitis.

Utilization for Medicare and Marketscan is compared for the year 2016. Utilization for the inflammatory and infectious eye disease category is stratified by age and sex for the two databases

Results: There were 30,423,400 million Medicare beneficiaries and 28,717,700 commercial insurance enrollees in 2016. Annual utilization for Medicare was higher 11% (95% CI: 11.00-11.00) as compared to Marketscan 5.22% (95%:5.21-5.23), and differences remained after stratification by age (data shown in Table).

For both Market scan, females 5.90% (95% CI: 5.89-5.91) vs males 4.50% (95% CI: 4.49- 4.51) and Medicare, females, 13.30% (95% CI: 13.30-3.30) vs. Males, 9.40% (95% CI: 9.30- 9.40), females had higher utilization

Conclusions: Medicare beneficiaries have higher utilization as compared to commercial insurance. This remains when data are stratified by age and sex. Our results are consistent with prior studies that indicate higher utilization in general for Medicare.

ABSTRACT BODY:

Purpose: In vivo biomechanical characterization of the cornea remains a challenge. We have developed a high-resolution ultrasound elastography method to measure corneal axial displacement (CAD) induced by the ocular pulse. Here we compared CAD and a stiffness index derived from CAD between keratoconus patients and normal controls. We also explored the trend of these parameters with keratoconus grade.

Methods: Twenty normal controls (40 eyes) and 20 keratoconus patients (35 eyes) were recruited. Each subject underwent three tests: (1) OCULUS Pentacam for corneal topography; (2) PASCAL Dynamic Contour Tonometry for intraocular pressure (IOP) and ocular pulse amplitude (OPA), and (3) ocular pulse elastography (OPE) for CAD using the Vevo2100 ultrasound system. Corneal topography data was reviewed by a specialist (AH) to determine the presence and grade of keratoconus. Four ultrasound measurements were performed in each eye, and each measurement acquired an 8-second video of the cornea during fixation. This data was processed to obtain the average CAD following published protocols [Kwok et al, TVST, 2020; 9(13):33]. Corneal stiffness index was calculated as OPA/CAD for each eye. Linear mixed models for repeated measures were used to account for association between two eyes of the same subject in data analysis.

Results: Mean CAD (unit: μm) was significantly higher (p=0.0088, Fig. 1A) in keratoconus (46.6, 95% CI: 39.2, 53.9) than normal (34.6, 95% CI: 30.1, 39.1). Mean corneal stiffness (unit: mmHg/μm) was significantly lower (p=0.0068, Fig. 1B) in keratoconus (0.0522, 95% CI: 0.0384, 0.066) than normal (0.0804, 95% CI:0.0666, 0.0942). Age and IOP were not different between groups. Overall, mean CAD increased while corneal stiffness decreased at higher keratoconus grade (p=0.002 and 0.011, Fig. 2).

Conclusions: This study confirmed the biomechanical weakening in keratoconus and suggested that this weakening worsened in more severe cases. Ultrasound elastography may provide a quick (minutes) and safe (no applied forces) biomechanical evaluation of the cornea to aid in keratoconus diagnosis.

ABSTRACT BODY:

Purpose: Information on retinal recovery from oxidative/photo-inflammatory retinal injury is scarce. Retinal light injury models have been used in understanding the various processes involved in retinal degeneration. Our lab developed the FCD-LIRD model and reported evidence of retinal recovery from the original damage caused by intense light. Now using single cell RNA sequencing we performed cell-type specific analyses to identify retinal responses associated with the recovery processes at different time points post light injury.

Methods: C57BL/6J mice (2-4 m) were exposed to FCD-LIRD. Posterior 2mm central retinae were peeled off from eyes collected at 4 h, 48h and 5d after this injury. Unexposed eyes served as controls. Retinal single-cell suspensions were prepared using a Papain Dissociation System and processed using droplet-based single cell RNA-seq (10X Genomics). Sequencing libraries were analyzed using Cell Ranger 3.0.0. Seurat R package (v3.0.0) was used to generate unsupervised cell clusters which were then assigned to specific retinal cell types/sub-types based on expression of known cell-specific gene markers. Differential and specific gene expression patterns, pathway and trajectory analyses were performed.

Results: Twenty-three discrete clusters representing the major retinal cell classes, types and subtypes were identified with a resolution of 0.5 at each time point post retinal injury. Expression patterns of several genes were significantly altered in each cell type at the three time points post light injury. Using IPA analysis, we were able to identify several differentially regulated pathways in several cell types. At 5d post injury, various classes of signaling pathways were differentially upregulated in a Muller cell cluster suggestive of a role in directing retinal recovery from injury.

Conclusions: Differential cell type-specific responses are generated following photo-oxidative/photo-inflammatory retinal injury in the FCD-LIRD model. The differential activation of signaling pathways in Muller cells at 5d post injury may initiate the retinal recovery process suggesting that Muller cells may play important role in cellular recovery earlier than other cell types. Muller cells could be potential targets in a search for therapeutic approaches to maximize retinal recovery from injury.

ABSTRACT BODY:

Purpose: Black populations face higher rates of diabetes (DM) and vision loss from diabetic retinopathy, even after controlling for known risk factors. While we have found differences in OCTA parameters between young healthy black and white subjects, the effect of aging is unknown. The purpose of this prospective cross-sectional study is to use OCTA to determine if there are differences in the chorioretinal capillaries of older black and white non-DM subjects.

Methods: OCTA (Optovue RTVue XR Avanti) was used to image 40 eyes from 27 black non-DM patients (mean age 56.9±14.4y) and 46 eyes from 30 white non-DM patients (mean age 51.7±16.1y). At baseline, there were no significant differences in age (p=.86), gender (p=.17), or image signal strength (p=.45). Subjects had similar baseline systemic comorbidities including hyperlipidemia, heart disease, smoking pack-years, but not hypertension. Built-in software was used to measure vessel density (VD) at the superficial (SCP), middle (MCP), and deep capillary plexuses (DCP); the foveal avascular zone (FAZ) area, perimeter, acircularity index (AI), and FD-300; and the percentage of blood flow area (%BFA) in the choriocapillaris. A mixed-effects regression model, controlling for 2 eyes of the same patient and hypertension, was used to determine the association between race and OCTA parameters.

Results: Within the SCP and MCP, black subjects had lower foveal VD compared to white subjects (15.03±7.54% vs 21.07±8.07%, p=.02) and (28.03± 8.19% vs 35.44±6.51%, p<.001, respectively). No differences were observed at the DCP. Black subjects had a larger FAZ area (.35±.12mm^2 vs .23±.10mm^2, p<.001), FAZ perimeter (2.38±.39mm vs 1.88±.44mm, p<.001) and larger FD-300, a measurement of VD in a 300 µm wide region around the FAZ (51.21±3.76% vs 49.2±3.53%, p=.001). Black subjects had a lower %BFA at the fovea, parafovea, and the 3x3mm area (p=.04, p=.008, p=.006, respectively).

Conclusions: To our knowledge, this is the first report of differences in OCTA parameters between older black and white non-DM adults. Decreased blood flow in the fovea and choriocapillaris, as well as a larger FAZ in older black adults, may contribute to a higher susceptibility to diabetic vascular damage, while highlighting the need for normative databases and racially diverse clinical studies. Further studies are needed to elucidate the role of racial differences in OCTA parameters.

ABSTRACT BODY:

Purpose: Recent studies have demonstrated that pattern electroretinogram (PERG) has the ability to detect early retinal ganglion cell (RGC) dysfunction 8 years before glaucomatous structural changes are detected on optical coherence tomography (OCT) scans, which uses the standard 3.4mm circumpapillary scan diameter for glaucoma diagnosis. A new Glaucoma Module Premium Edition (GMPE) software offers 3 different retinal nerve fiber layer (RNFL) circle scans (3.5, 4.1, 4.7mm) to improve glaucoma diagnosis. From our previous research, we determined that 3.5mm circle scan diameter and PERG parameters had the highest area under the curve (AUC) diagnostic capabilities. The purpose of this study was to assess the ability of PERG parameters to best predict change in the 3 RNFL circle scan diameters.

Methods: 49 eyes (26 patients) were enrolled in the study at Manhattan Eye, Ear, and Throat Hospital, and tested with Humphrey Visual Field Test (24-2), Diopsys NOVA PERG device, and Spectralis spectral domain OCT. Linear regression models were used to assess the contribution of each PERG parameter (Magnitude [Mag], MagnitudeD [MagD], MagnitudeD/Magnitude Ratio [MagD/Mag Ratio]) to the RNFL global thickness variance in the 3 circle scan diameters. Age and spherical error (SE) were entered in Step 1 and one PERG parameter was entered in Step 2 for each OCT circle scan diameter.

Results: In a 2-step linear regression model (Table 1), where the RNFLT circle scan of 3.5mm diameter was the independent variable and after controlling for age and SE, Mag, MagD, and MagD/Mag ratio significantly explained OCT variance by 16.8%, 17.9%, and 13%, respectively. Similarly, when the 4.1mm RNFLT circle scan was the independent variable, Mag, MagD, and MagD/Mag ratio significantly explained OCT variance by 16.3%, 16.6%, and 11.8%, respectively. Lastly, when the 4.7mm RNFLT circle scan was the independent variable, Mag, MagD, and MagD/Mag ratio significantly explained OCT variance by 13.6%, 13.3%, and 8.9%, respectively.

Conclusions: All 3 PERG parameters significantly predicted variance in all 3 circle scan diameters with the 3.5 and 4.1mm RNFL circle scan diameters being most significant. This is in line with previous studies showing that 3.5 and 4.1mm circles have better diagnostic capability at distinguishing normal from PrG. This could be due to a high association between PERG and the 3.5 and 4.1mm RNFL circle scans.

ABSTRACT BODY:

Purpose: Glaucoma is a complex and heterogenous disease with structural and functional variation that might reflect underlying pathogensis. We aim to discover hidden structural patterns of optical coherence tomography (OCT) derived macular ganglion cell complex (GCC) thickness using unsupervised deep learning (DL) among subjects with high polygenic risk (PRS) for primary open angle glaucoma (POAG). Subsequently we used these endophenotypes to discover novel genomic loci.

Methods: POAG PRS was constructed for UK Biobank subjects with LDpred2 using genome-wide association study (GWAS) summary statistics from largest cross-ancestry meta-analysis. Macular OCTs from participants with highest PRS were segmented using Topcon Advanced Boundary Segmentation algorithm to extract GCC layer thickness. A hybrid unsupervised artificial intelligence method that combines deep convolutional autoencoders, manifold learning, and Gaussian Mixture Model (GMM) clustering grouped semantically similar GCC thickness patterns. Optimal number of clusters was determined using probabilistic model selection method (AIC/BIC). We performed GWAS for each GMM-identified feature dimension using linear mixed models adjusted for age, sex, and principal components of ancestry.

Results: We identified 11 optimal macular GCC patterns using 26806 OCT scans from 13403 UKBB participants in the top half of the POAG PRS (Fig1). Among all patterns, P1, 7 and 8 had the highest proportion of subjects with self-report or ICD-code for glaucoma (6.25%, 6.37%, 6.53%) and IOPcc > 24 mmHg (5.83%, 5.70%, 5.84%) while pattern 9 had most myopic refractive error (SE -0.3 ±2.4 D). GWAS was performed with hard-call genotypes for 424155 variants after quality control filters (Fig2). There was no evidence of unaccounted stratification ($lambda_{GC}$ 1.000 to 1.011). We identified numerous genomic regions associated ($P < 1e^{-05}$) with at least one feature dimension related to neurologic disease and development (P1, gene: KIRREL3; P3, genes: DENND4B, ARHGEF28; C7 ZDHHC7), immune system and autoimmune disease (P7 HIVEP3, P8 MARK1, P10 MUSK), metabolomics/obesity (P11 CFAP77) and ocular development (P10 MAF).

Conclusions: Here we demonstrate that DL can be used to identify hidden OCT patterns which in turn can be used to identify unexpected genetic associations. Future work is needed to ensure these patterns are disease specific and further explore the impact of identified genetic variants.

TITLE: Accessibility and cultural inclusivity of online glaucoma-based video content for patient education

SESSION TITLE: Eyecare delivery and economics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Dahshan, Marshall University Joan C Edwards School of Medicine, Huntington, West Virginia, UNITED STATES|N. Johnson, Duke Medicine, Durham, North Carolina, UNITED STATES|K. Muir, Duke University Department of Ophthalmology, Durham, North Carolina, UNITED STATES|

Commercial Relationships Disclosure: Deena Dahshan: Commercial Relationship: Code N (No Commercial Relationship) | Nicholas Johnson: Commercial Relationship: Code N (No Commercial Relationship) | Kelly Muir: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Online video content for glaucoma patient education requires evaluation for understandability and accessibility. This study describes the ease of access, readability, actionability, and cultural inclusivity of glaucoma-specific patient education videos found on websites commonly recommended by glaucoma specialists.

Methods: A survey of glaucoma specialists at the Duke Eye Center identified commonly recommended patient education websites. Materials with content for medical providers, dedicated to research, or affiliated with private practices were excluded. Videos that were not glaucoma-specific or longer than 15 minutes were also excluded. Videos were evaluated by two independent reviewers using the Patient Education Materials Assessment Tool (PEMAT) for understandability and actionability as well as cultural inclusivity and accessibility measures. Agreement analysis with a kappa coefficient (k) over 0.6 was established with the first five videos and scoring discrepancies were resolved via a third independent reviewer.

Results: From 10 recommended websites, 22 videos from the AAO and Glaucoma Research Foundation websites met criteria for evaluation. The average PEMAT score was 68.77% (SD = 18.34) for understandability and 100% (SD = 0.00) for actionability (k=0.63). The average video length was 114.32 ± 120.46 seconds. Only three videos were available in another language (Spanish). With regards to representation among actors and images, there were 42% male and 58% female individuals. Most actors and images were White individuals (68.9%), followed by Black (22.1%), then Asian (5.7%) and other/ambiguous (3.3%). Of note, most physicians (85%) were portrayed by White males.

Conclusions: Current educational videos, while actionable, have room to improve with regards to understandability of materials. Lack of language accessibility may pose as a barrier to care for non-English speaking patients seeking video resources for glaucoma. Improving cultural representation of actors and images may also improve patient receptiveness. Recognizing the readability, accessibility, and cultural inclusivity of glaucoma-specific patient education video content on commonly recommended websites may guide future recommendations to improve patient care.

ABSTRACT BODY:

Purpose: Several deep-intronic variants (DIVs) in ABCA4 have been classified as causative for Stargardt disease. By strengthening a cryptic splice site, ABCA4 DIV c.5197-557G>T determines the retention of an intronic sequence in the mature mRNA, resulting in a premature termination codon. For the first time, we investigated CRISPR/Cas9 genome editing for the potential to correct a splice defect caused by a DIV in ABCA4 - specifically c.5197-557G>T.

Methods: Three CRISPR/Cas9 approaches, implementing Streptococcus pyogenes Cas9 (SpCas9) or SpCas9-nickase were designed: dual gRNA/SpCas9, utilizing two paired gRNAs designed to target regions flanking the c.5197-557G>T DIV, dual gRNA/SpCas9-nickase rescue based on the use of two paired gRNAs coupled to SpCas9-nickase, and (single) gRNA/SpCas9 rescue employing single gRNAs. Minigene splicing assay in HEK293T of the DIV c.5197-557G>T was used for preliminary testing the rescue potential of sixteen strategies. Subsequently, eight most-promising ones were validated in patient-derived heterozygous ABCA4 c.5197-557G>T cone photoreceptor precursor cells (CPCs).

Results: Splicing rescue in the minigene splicing assay ranged from 10±3% to 100±0%. In CPCs, two gRNA combinations each for dual gRNAs/SpCas9, as well as for dual gRNAs/SpCas9-nickase, and four single gRNAs for gRNA/SpCas9 were validated. Due to the partial degradation of the aberrant transcript via nonsense-mediated mRNA decay, CPCs show 28±2% aberrant transcript. The selected strategies reduced the fraction of aberrant transcript up to 5±2%, corresponding to a splicing rescue of 83±5% achieved by a (single) gRNA/SpCas9 strategy. Upon CRISPR/Cas9 treatment, a significant fold increase up to 1.8±0.2 in ABCA4 transcript levels was also detected. Interestingly, when using two paired gRNAs coupled to SpCas9 to target the DIV in CPCs, the level of editing at the ABCA4 target locus quantified 35 days compared to 7 days after treatment revealed a drop in the percentage of edited cells of around 50%, hinting at potential genotoxicity of this design.

Conclusions: In conclusion, we proved CRISPR/Cas9 effective in addressing a splice defects in ABCA4. This study paves the way to the investigation of CRISPR/Cas9 genome editing as a therapeutic tool to correct the several DIVs in the ABCA4 gene, providing initial evidence of possible permanent splicing correction for Stargardt disease.

TITLE: The Effects Of Melanocortin Receptor Agonists On Experimental Autoimmune Uveitis

SESSION TITLE: Uveitis: Translational and Pre-clinical Studies

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.W. Taylor, K. Dawit, T. Ng, Boston University School of Medicine, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Andrew Taylor: Commercial Relationship(s);Code C (Consultant/Contractor):Palatin Technologies;Code F (Financial Support):Palatin Technologies | Kaleb Dawit: Commercial Relationship: Code N (No Commercial Relationship) | Tat Fong Ng: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The melanocortin system plays a vital role in regulating immune activity and retinal cell health within the eye. Augmenting the melanocortin system with α-melanocyte stimulating hormone (α-MSH) during uveitis suppresses inflammation, promotes immune tolerance, and protects the retinal structure. To determine which melanocortin-receptors are important in mediating the beneficial effects of α-MSH-therapy, we assayed different α-MSH-analogs with different functional melanocortin-receptor (MC1r, MC3r, MC4r, and MC5r) specificities.

Methods: Experimental autoimmune uveitis (EAU) was induced in C57BL/6J mice, and the retinas were clinically scored by fundus exam. When the mice reached the chronic stage of EAU, they were injected twice one-day apart with 50 µg of α-MSH (pan-agonist), PL8331 (pan-agonist), PL8177 (potent MC1r-only agonist), PL5000 (same as α-MSH but no MC5r functional activity), MT-II (same as PL5000) or PG901 (MC5r agonist, but an antagonist to MC3r, and MC4r). Clinical EAU scoring was continued until EAU resolution in the α-MSH-treated EAU mice. The eyes were then collected for histology, and spleen cells were collected for retinal-antigen-stimulated IL-17 and IL-10 production.

Results: There was significant EAU suppression with significant retinal structure preservation in EAU mice treated with α-MSH and PL8331. A similar effect was seen in PL8177 treated EAU mice, except the suppression of EAU was temporary. In EAU mice treated with PL5000, MTII, or PG901, there was no suppression of EAU with no preservation of the retinal structure, The stimulated spleen T cells produced IL-10 in mice treated with α-MSH, PL8331, PL8177, PL5000, but continued to produce IL-17 in MT-II, and PG901 treated EAU mice.

Conclusions: In this study, we investigated the effects of α-MSH-analogs in suppressing EAU. Our previous studies showed the importance of the melanocortins in the maintenance of ocular immune privilege and that α-MSH-treatment accelerated recovery and induced retinal-antigen-specific regulatory immunity. Our current results demonstrated that α-MSH-analogs targeting MC1r and MC5r together have a therapeutic potential to suppress uveitis and induce regulatory immunity. Moreover, they can maintain normal retinal structure and prevent retinal cell loss.

Chandrashan, Ophthalmology, Stanford University School of Medicine, Stanford, California, UNITED STATES|R.P. Kowalski, S. Nayyar, V. Jhanji, The Charles T. Campbell Ophthalmic Microbiology Laboratory, University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Sarah Atta: Commercial Relationship: Code N (No Commercial Relationship) | Perera Chandrashan: Commercial Relationship: Code N (No Commercial Relationship) | Keerthana Samanthapudi: Commercial Relationship: Code N (No Commercial Relationship) | Regis Kowalski: Commercial Relationship: Code N (No Commercial Relationship) | Shannon Nayyar: Commercial Relationship: Code N (No Commercial Relationship) | Vishal Jhanji: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Infectious keratitis is a leading cause of ocular morbidity globally, and approximately one-third of all cases are culture-negative. We sought to better understand these cases by investigating risk factors, clinical manifestations, and treatment outcomes.

Methods: This single-center, retrospective case series included all culture-negative infectious keratitis cases at the UPMC Eye Center from January 2016 through December 2020. Cases were reviewed for suspected etiology, ocular and systemic risk factors, visual acuity, symptom duration, management, and outcomes.

Results: 256 cases of culture-negative infectious keratitis were identified (55.08% female, 50.11±20.34 years). 167 cases had complete medical records. Antimicrobial medication was used by 59.88% patients prior to presentation. Majority of cases were presumed to be viral at presentation (45.70%). The most prevalent ocular risk factors were history of ocular surface disease (44.14%), contact lens use (32.34%), and prior ocular surgery (36.84%). Mean presenting VA was 0.91±0.87 logMAR with average defect size of 7.81±12.53 mm^2 and hypopyon in 12.57% cases. Most common initial management was with topical moxifloxacin (26.95%). Management was modified in the majority of cases with 29.34% switched to antiviral therapy. Adjunctive treatment was required in 45.51% cases. Average time to defect resolution was 46.15±65.10 days. Cases with presumed viral etiology had the longest treatment duration and follow-up time. Cases with presumed bacterial etiology had significantly younger age at presentation (41.39±22.10 years) ($p=0.004$). Worse final visual acuity was significantly associated with older age at presentation ($p<0.001$), history of ocular surgery ($p=0.005$), topical corticosteroid use ($p=0.008$), history of corneal disease ($p=0.023$).

Conclusions: Management of culture-negative keratitis relies on clinical suspicion. Viral etiology is commonly suspected in culture-negative keratitis cases, however younger age is significantly associated with bacterial etiology. There is significant variability in presentation and management duration depending on type of etiology. These cases generally have favorable outcomes with prompt intervention.

TITLE: Early Corneal Endothelial Changes Following Transscleral Cyclophotocoagulation

SESSION TITLE: IOP and laser therapy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Khodeiry, P. Monsalve Diaz, P. Gordon, K. Khine, R.K. Lee, Ophthalmology, University of Miami Health System Bascom Palmer Eye Institute, Miami, Florida, UNITED STATES|

Commercial Relationships Disclosure: Mohamed M Khodeiry: Commercial Relationship: Code N (No Commercial Relationship) | Pedro Monsalve Diaz: Commercial Relationship: Code N (No Commercial Relationship) | Phillip Gordon: Commercial Relationship: Code N (No Commercial Relationship) | Kay T Khine: Commercial Relationship: Code N (No Commercial Relationship) | Richard Lee: Commercial Relationship(s);Code F (Financial Support):The Bascom Palmer Eye Institute is supported by NIH Center Core GrantP30EY014801 and a Research to Prevent Blindness Unrestricted Grant. R.K. Lee is supported by the Walter G. Ross Foundation. This work was partly supported by the Camiener Foundation Glaucoma Research Fund and the Gutierrez Family Research Fund.

ABSTRACT BODY:

Purpose: To evaluate the effect of continuous-wave transscleral cyclophotocoagulation (CW-TSCPC) using the slow coagulation parameters on the corneal endothelium in the early postoperative periods.

Methods: A retrospective study of glaucomatous patients who underwent slow coagulation CW-TSCPC (1250 mv power and 4-second duration). The exclusion criteria were previous ocular surgery except for cataract surgery, any corneal disease, the presence of anterior chamber intraocular lens, aphakia, previous ocular inflammation. In addition to intraocular pressure (IOP) measurements, specular microscopy values were obtained using a Konan Noncon Robo Pachy Sp-9000 noncontact-type specular microscope preoperatively, at week 1 (W1), month 1 (M1), and month 3 (M3) after TSCPC. Corneal endothelial cell density (CECD), percent hexagonality, coefficient of variation in cell area (CV), and central corneal thickness (CCT) were assessed in the central corneal area.

Results: The study included 34 eyes of 34 patients. Mean age of the patients was 69.8±11.1 years, 19 (55.9%) patients were females, and 17 (50%) were Hispanic. Primary open angle glaucoma was the most common glaucoma type in 82.4% of the cohort. Twenty-three (67.6%) patients were pseudophakic. Treated patients received 19.1 ± 1.5 laser spots.

After TSCPC, IOP decreased from 19.2±6.5 mmHg at baseline to 13.6±5.2 mmHg at W1 ($p<0.001$), 14.1±3.7 mmHg at M1 ($p<0.001$), and 13.9±5.5 mmHg at M3 ($p<0.001$).

CECD changed from 2517.2±147.1 cell/mm^2 at baseline to 2590.2±151.7 cells/mm^2 at W1, 2443.3±314.3 cell/mm^2 at M1, and 2394.0±560.6 cell/mm^2 at M3 ($p=0.58$, $p= 0.507$, $p=0.882$ respectively). CV values were 38.3±7.4% at baseline, 37.4±6.6% at W1, 53.0±44.9 at M1, and 51.1±40.9 at M3 (all $p>0.05$). No statically significant changes in the percentage of hexagonal cells were noted during the follow up period ($p=0.192$ at W1, $p=0.977$ at M1 and $p=0754$ at M3). CCT changed from 515.9±37.7 µm at baseline to 561.1±56 µm at W1($p=0.006$), 538±48.7µm at M1 ($p=0. 21$) and 532.5±44.8 µm at M3($p=0.356$).

No major complications were reported during the study.

Conclusions: Slow coagulation TSCPC is an efficient and relatively safe procedure with no significant corneal changes noted in patients during the early postoperative period. Studies with longer follow up periods are required for further evaluation of the long-term effect of cyclophotocoagulation treatment on the cornea.

TITLE: Campana cells relay both rod- and cone-mediated visual signals to multiple RGC types

SESSION TITLE: Retinal circuits

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: N. Tian, B.K. Young, P. Wang, Ophthalmology and Visual Sciences, University of Utah Health, Salt Lake City, Utah, UNITED STATES|N. Tian, Research, VA healthcare system Salt Lake City, Salt Lake City, Utah, UNITED STATES|

Commercial Relationships Disclosure: Ning Tian: Commercial Relationship: Code N (No Commercial Relationship) | Brent Young: Commercial Relationship: Code N (No Commercial Relationship) | Ping Wang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We recently described a previously not fully characterized interneuron in the mammalian retina, the Campana cells. The Campana cells share some morphological, physiological, and molecular features with retinal bipolar cells and amacrine cells. Thus, we assume that Campana cells may play atypical roles in vision. To further understand the roles of Campana cells in visual signal processing, we determined the types of RGCs which receive synaptic inputs from Campana cells.

Methods: RGCs are divided into functional groups based on the patterns of their light responses, e.g., rod-, cone-mediated, or mixed ON, OFF, and ON-OFF RGCs. The synaptic connections between Campana cells and RGCs are determined by synaptic responses of RGCs to optogenetic stimulation of a single ChR2-expressing Campana cell. The light/synaptic responses of RGCs are recorded using calcium imaging. Comparison of the light responses of RGCs to the synaptic responses from Campana cells evoked by optogenetic stimulation determines the functional types of RGCs which receive synaptic inputs from Campana cells.

Results: We analyzed the light responses of 88 RGCs from 3 retinas, in which 42 RGCs receive synaptic inputs from Campana cells while 46 RGCs do not receive synaptic inputs from Campana cells. From these 88 RGCs, 4 RGCs only receive rod inputs, 29 RGCs only receive cone inputs, and 55 RGCs receive both rod and cone inputs. 61% RGCs receiving rod-mediated signals receive direct synaptic inputs from Campana cells, while 49% RGCs receiving cone-mediated signals receive direct synaptic inputs from Campana cells ($p = 0.149$, chi test). In the 36 RGCs receiving both rod and Campana cell inputs, 78% are ON cells, 14% are OFF cells, and 8% are ON-OFF cells. This is not different from the RGC type proportion without Campana cell inputs ($p = 0.302$). In the 41 RGCs receiving both cone and Campana cell inputs, 32% are ON cells, 12% are OFF cells, and 56% are ON-OFF cells. This is significantly different from the RGC type proportion of RGCs without Campana cell inputs ($p < 0.0001$).

Conclusions: Campana cells relay rod- and cone-mediated visual signals to multiple functional RGC types. In RGCs receiving rod-mediated inputs, the synaptic connection from Campana cells is independent of the functional types of RGCs. In RGCs receiving cone-mediated inputs, Campana cells preferentially relay synaptic input to ON-OFF RGCs.

Singh, Center for Ophthalmic Bioinformatics, Cleveland Clinic Cole Eye Institute, Cleveland, Ohio, UNITED STATES|S.W. Perkins, Cleveland Clinic Lerner College of Medicine of Case Western Reserve University, Cleveland, Ohio, UNITED STATES|

Commercial Relationships Disclosure: Roshni Kailar: Commercial Relationship: Code N (No Commercial Relationship) | Blanche Kuo: Commercial Relationship: Code N (No Commercial Relationship) | Scott Perkins: Commercial Relationship: Code N (No Commercial Relationship) | Rishi Singh: Commercial Relationship(s);Code E (Employment):OcuSciences;Code I (Personal Financial Interest):Genentech/Roche, Alcon/Novartis, Gyroscope & Asceplix, Zeiss, Bausch and Lomb, Regeneron ;Code F (Financial Support):Apellis, Graybug

ABSTRACT BODY:

Purpose: Patients with Retinal Vein Occlusion (RVO) have differing degrees of response to anti-VEGF treatment. A retrospective comparative study was performed to determine if response to anti-VEGF treatment at 3 months post-initiation of anti-VEGF treatment could predict RVO outcomes, namely Central Subfield Thickness (CST) and Best Visual Acuity (BVA), at the 12-month time point.

Methods: Patients over age 18 with treatment naïve RVO-related macular edema and treated with anti-VEGF injections were included in the study. A machine learning algorithm (Notal Vision Ltd., Tel Aviv, Israel) quantified total retinal fluid (TRF), intraretinal fluid (IRF), and subretinal fluid (SRF). Patients were categorized as early responders (ER) or limited early responders (LER); LER eyes were defined as having CST reduction < 10%, BVA gain < 5 ETDRS letters, or both at 3-months after anti-VEGF initiation. BVA and CST changes over the 12-month period following first anti-VEGF treatment were compared. Statistical analysis involved Levene test, Welch's t-test, and Welch's ANOVA.

Results: 116 eyes met inclusion criteria (74 ER, 42 LER). Baseline VA differed between ER (45.8 letters) and LER (62.9 letters) ($p < 0.0001$). Both 12-month change in BVA and CST varied significantly between early response statuses. Specifically, change in BVA for ER was 21.4 letters and 0.8 letters for LER ($p < 0.0001$), and the change in CST was -187.1 mm for ER and -104.4 mm for LER ($p < 0.05$). VA (+19.9 letters, $p < 0.0001$) and TRF (-613 nl, $p < 0.01$) significantly improved for ER eyes, but only in the initial 3-month period. Changes in VA and fluid compartments were not significant across all other time points and responder categories.

Conclusions: Functional and anatomical improvements at 12-months were more impressive for ER than LER defined at 3 months. Additionally, this study highlights the potential for 3-month TRF reduction as a marker of early response. Most functional and anatomical gains in ER occurred during the initial 3 months of treatment, with no significant improvements in VA or TRF after the first 3 months. Thus, the 3-month response to anti-VEGF treatments may be a useful biomarker to predict the prognosis of eyes with RVO treated with anti-VEGF.

ABSTRACT BODY:

Purpose: Black adults are twice as likely as non-Hispanic whites to become blind and are 50% more likely to develop diabetic eye disease. As few as 30% of Black adults with diabetes obtain yearly eye screening. Thus, there is an urgent need to increase screening to prevent vision loss. We aimed to identify factors influencing eye screening adherence among Black patients with diabetes at an urban federally qualified health center (FQHC) in Milwaukee, WI.

Methods: We conducted semi-structured individual interviews with 25 participants (14 patients with diabetes who self-identified as Black or African-American and 11 clinical personnel). Both inductive and deductive content analysis was performed. All interviews were transcribed verbatim and analyzed using QSR NVivo software.

Results: Patients had a mean age of 54 years (range: 27-72 years) and 57% were female. Clinical personnel included 3 primary care clinicians, 3 medical staff, and 5 administrators. We developed a model to understand factors influencing eye screening adherence among urban Black patients with diabetes adapted from the Socio-Ecological Model of Health and National Institutes of Minority Health and Disparities Research Framework. Factors were categorized as individual, social, and environmental. Many factors, such as limited access to healthcare and transportation, financial tradeoffs, anxiety about diabetes complications, and the burden of diabetes management, were similar to those from our prior qualitative study in a rural FQHC serving predominantly non-Hispanic white patients with diabetes. However, urban Black patients with diabetes reported many additional factors influencing diabetic eye screening adherence, including mistrust and discomfort with healthcare providers, experiences of racism and discrimination in healthcare settings, intergenerational trauma from healthcare experiences, and housing instability. Patients also emphasized the importance of patient self-advocacy in navigating the health care system to manage their medical conditions.

Conclusions: Urban Black patients with diabetes and clinical personnel reported several factors influencing patient adherence with eye screening. The effectiveness of interventions targeting eye screening disparities among urban Black patients with diabetes may be enhanced by addressing these factors.

ABSTRACT BODY:

Purpose: Choroidal neovascularization (CNV) in age-related macular degeneration (AMD) can cause blindness. Increased dietary intake of ω-3 long-chain polyunsaturated fatty acids (LCPUFAs) reduces CNV. ω-3 LCPUFA metabolites from most metabolic pathways (COX, LOX) are anti-angiogenic, but ω-3 LCPUFA metabolites of cytochrome P450 oxidase (CYP)2J, promote angiogenesis. We hypothesized that inhibition of CYP2J activity would augment the protective effects of ω-3 LCPUFAs on CNV.

Methods: We investigated the effects of the CYP2J inhibitor (Flunarizine) in the laser-induced CNV mouse model. The plasma levels of CYP2J metabolites were determined by liquid chromatography and tandem mass spectroscopy. Mouse choroidal and aortic explant sprouting assays were used to investigate the effects of CYP2J inhibition and CYP2J metabolites on angiogenesis ex vivo.

Results: CNV was increased in Tie2-driven CYP2J2-overexpressing mice, associated with increased plasma epoxide: diol ratio ($n \geq 25$, both genders, $p < 0.001$). Inhibiting CYP2J activity with flunarizine augmented the protective effects of ω-3 LCPUFAs on CNV by 20% ($n \geq 26$, both genders, $p < 0.05$). In Tie2-driven CYP2J2-overexpressing mice fed a ω-3 LCPUFA diet, flunarizine suppressed choroidal neovascularization by 39% ($n \geq 33$, both genders, $p < 0.001$) and reduced the plasma levels of CYP2J2 metabolites. In addition, the combination therapy of Flunaridine and Montelukast (CYP2C inhibitor) enhanced the prevention of CNV. The proangiogenic role of CYP2J2 was corroborated in choroid and aortic sprouting assays. Exposure to the ω-3 LCPUFA CYP2J metabolite, 19,20-epoxydocosapentaenoic acid, reversed the suppression of angiogenesis ex vivo by the CYP2J inhibitor flunarizine.

Conclusions: CYP2J Inhibition augmented the protective effects of ω-3 LCPUFAs on pathological choroidal angiogenesis. Flunarizine suppressed angiogenesis by inhibiting CYP2J activity, and Montelukast enhanced the effect. CYP2 inhibition may be a viable approach to inhibit CNV in AMD.

ABSTRACT BODY:

Purpose: Anti–vascular endothelial growth factor (VEGF) treatments for neovascular age-related macular degeneration (nAMD), the leading cause of blindness and visual impairment in the United Kingdom (UK), require frequent intravitreal injections and monitoring. These can pose a substantial burden to patients, caregivers, and health care professionals. This study of routine clinical practice characterized long-term anti-VEGF treatment patterns for nAMD in the UK.

Methods: This was a retrospective analysis of a multicenter electronic medical record (EMR) database that contains data from 9 UK National Health Service ophthalmology sites. A deidentified dataset was constructed from anonymized Medisoft EMR of patients with initial nAMD diagnosis in ≥ 1 eye between January 1, 2014, and December 31, 2018, ≥ 1 anti-VEGF injection (ranibizumab, aflibercept, or bevacizumab), and ≥ 12 months of follow-up. Results are reported by anti-VEGF agent initiated; patients were able to switch anti-VEGF agents.

Results: A cohort of 10,971 patients was analyzed (aflibercept, n = 4908; ranibizumab, n = 5699; bevacizumab, n = 364 [not reported]). In year 1, for patients initiating either aflibercept or ranibizumab, the mean (SD) interval between consecutive injections was 48.4 (21.8) and 46.8 (26.4) days, respectively, and the mean (SD) number of treatment visits was 7.3 (2.5) and 6.4 (2.8), respectively. For aflibercept, the mean (SD; n) treatment interval was 59.0 (27.4; 3523) days in year 2 and 56.6 (26.5; 1812), 55.2 (26.2; 899), and 52.3 (24.6; 409) days in years 3−5, respectively. For ranibizumab, these were 59.9 (29.5; 3128) days in year 2, and 58.7 (27.6; 1791), 58.6 (26.9; 1032), and 56.6 (26.4; 530) days in years 3−5, respectively. The mean (SD) number of treatment visits was also similar for years 2−5 (aflibercept: 5.3 [3.1], 5.5 [3.4], 5.7 [3.5], 5.7 [3.7]); ranibizumab: 5.3 [2.9], 5.5 [2.9], 5.2 [2.9], 4.9 [2.9]) for patients with available data.

Conclusions: Overall, treatment patterns were consistent throughout the follow-up period and data from years 2−5 suggest that patients initiating ranibizumab or aflibercept maintained relatively stable treatment intervals, receiving anti-VEGF injections approximately every 8 weeks.

ABSTRACT BODY:

Purpose: Diet and the gut microbiome are implicated in age-related macular degeneration (AMD). Our team has shown that high-fat diets (HFDs) induce gut dysbiosis, exacerbate laser-induced choroidal neovascularization, and alter retinal transcription in the absence of microbiome. However, the diet-microbiome-transcriptome associations within the choroid/retinal pigment epithelium (RPE) remain unknown. Here, we study how HFDs alter choroid/RPE gene expression and related biological pathways in the absence of microbiome using germ-free (GF) mice.

Methods: RNA was extracted from choroid/RPE tissue (4 mice/group) of 15-weeks old GF C57BL/6J male mice fed normal diet or HFD (23% saturated fat for 8 weeks). RNA was sequenced via paired-end method on NovaSeq6000. Differentially expressed genes (DEGs) were identified (adjusted p-value <0.05) and incorporated in functional enrichment analysis using Toppgene (FDR BH <0.05, logFC >1.5).

Results: After correction of raw data, 1044 DEGs were identified from 24,784 genes. In the GF-HFD cohort, 912 DEGs were upregulated and 132 were downregulated. HFD affected genes involved in inflammation, angiogenesis, immunity, and extracellular matrix (ECM) interactions in the RPE/choroid according to Gene Ontology enrichment. HFD increased expression of Vegfc, Angpt1, Angpt2, Pdgfc, and Pdgfd, which function in concert to regulate angiogenesis and vascular remodeling, and are active targets in clinical trials of AMD. In addition, HFD affected inflammatory and immune-related genes. Some of the most significant DEGs clustered around natural killer T (NKT) cells, including NKT receptors (Cd244a), binding partners (Cd48), cytotoxic effectors (Gzma and Prf1), activators (Cxcl10), and growth factors (IL12b). HFD also upregulated C1qb, C2, C4b, and Cfh of the complement cascade. Finally, ECM components, including collagens Col8a1 and Col10a1, as well as enzymes such as Adamts9, were impacted, all of which correlate with AMD.

Conclusions: This study provides novel data that HFDs alter choroid/RPE biology at the transcriptional level in the absence of gut microbiota. We use the framework of AMD pathogenesis to highlight significant differences in gene expression and pathways, including angiogenesis, inflammation, complement cascade, and ECM interactions. Further studies will help delineate the complex relationships between diet, gut microbiota, and AMD pathobiology.

ABSTRACT BODY:

Purpose: Scleral lenses (SLs) are fit to support the ocular surface in patients with dry eye disease as well as to improve vision in patients with irregular corneal astigmatism or refractive error. Individuals wearing SLs may complain of lens fogging requiring SL removal and reapplication throughout the day.

The purpose of this study was to report indication(s) for SL wear, subjective fogging, mid-day SL removal and reapplication, and clinician observed findings of front surface non-wetting and presence of posterior fluid reservoir (FR) debris.

Methods: Patients who had worn their current SLs for a minimum of 6 months were recruited from 5 sites. After obtaining informed consent, data was collected on patient demographics, indication for SL wear, subjective complaint of fogging, and if SLs were removed and reapplied mid-day. In addition, clinicians recorded the presence or absence of front surface non-wetting, mucus debris, particulate debris, and posterior FR haze.

Results: There were 30 patients enrolled with the following indications for SL wear: corneal irregularity (63.3%), dry eye disease (23.3%), refractive error (10%), and other (3.3%). Slightly more than half complained of lens fogging (56.7%) with 60% reporting removing and reapplying their lenses mid-day.

Of those with subjective fogging 94.1% reported routinely removing and reapplying lenses mid-day compared to only 15.4% of those without fogging complaints.

Clinicians observed SL front surface non-wetting in 34.5% (10/29 eyes) of patients with fogging complaints and only 4.2% (1/24 eyes) of those without.

Particulate debris was noted in 58.6% (17/29 eyes) of those with subjective fogging and 25% (6/24 eyes) of those without which was observed more frequently than mucus debris (10/29 foggers vs 1/24 non fogger eyes) and haze (10/29 fogger vs 0/24 non fogger eyes).

Conclusions: In this series of established SL wearers, most patients with subjective fogging routinely remove and reapply their lenses mid-day. Symptoms described as “fogging” may arise from either front surface non-wetting or post-lens FR debris.

ABSTRACT BODY:

Purpose: To determine molecular pathways facilitating retinal ganglion cell (RGC) dysfunction and death in response to ocular hypertension (OHT)-induced stress. In this study, we sought to establish the contribution of the inflammasome to RGC pathology in a mouse model of OHT-induced glaucoma.

Methods: Glaucomatous degeneration was induced by intracameral injection of the Ad5-MYOC vector that produced a chronic IOP elevation. Inflammasome activation was detected by IL-1β production, changes in casp1, pycard (ASC), nlrp1, and gsdmD gene expression, and protein accumulation using RT-PCR, Western blot, and immunohistochemistry. Wild type and knockout mouse strains were used to determine the role of the inflammasome in ocular hypertension glaucoma. IL-1β cytokine production was assessed by sandwich ELISA in the vitreous fluid; gene expression changes in the retina, by RT-PCR. Changes in RGC functionality were assessed by PERG recordings; RGC loss was assessed at 8 wks post-OHT induction by direct counts in retinal flat mounts.

Results: Activation of the inflammasome became evident in the inner retinal layer and co-localized with $RPBMS^{+}$ RGCs in C57Bl6 (WT) mice at 2-4 wks after glaucoma induction. This correlated in time with RGC dysfunction, where PERG amplitude was reduced 55.8% in WT eyes with chronic OHT glaucoma. RGC density analysis in these animals showed a loss of 32.3±9.2 % in the central and 28.4±9.2 % in the peripheral retina at 6 wks post-OHT-induction. In contrast, mice are deficient in key inflammasome complex proteins NLRP1, Casp1 and GsdmD did not produce statistically significant changes in PERG amplitude. RGC loss was also blocked, averaging 0.7±11.2% increase in the central and no change in the peripheral retina of $NLRP1^{-/-}$ eyes; 7.3± 9.2% decrease in the central and 1.3 ±19.5 % increase in the peripheral retina of $Casp1^{-/-}$ eyes. Immunohistochemistry data in retinal cross-sections showed the absence of Casp1 and a reduction in GsdmD immunolabeling labeling in RGCs in the knockout retinas with induced glaucoma.

Conclusions: Our results show a strong correlation between the elevation of IOP, induction of inflammasome, and RGC pathology in the retina. Our results in mice deficient for inflammasome pathway components revealed the key role of the inflammasome in driving RGC dysfunction and cell death. Drugs inhibitors of inflammasome could protect vision loss in human ocular hypertension glaucoma

ABSTRACT BODY:

Purpose: Childhood cataract is defined as a lens opacity resulting in reduced visual acuity observed in the early years of life. As the most common cause of preventable pediatric vision loss worldwide, early diagnosis is key to achieve good visual function. Literature suggests congenital cataract is associated with altered lens structure, but no quantitative baseline has been established for the difference in lens structure in pediatric cataract versus control eyes. We tested the hypothesis that cataract eyes in children 0-5 years old will have significantly thinner lens thickness compared to age-matched healthy/control eyes by performing a prospective observational case control study.

Methods: 63 subjects, 109 eyes (34 subjects, 53 eyes with cataracts and 40 subjects, 56 eyes as controls) were recruited prospectively at 0-5 years old and imaged using ultrasound biomicroscopy (UBM). Lens thickness was measured using ImageJ and UBM software. Inter-observer agreement of lens measurement techniques was determined by calculating intraclass correlation (ICC) and assessing a Bland-Altman plot. Welch's two-sample two-tailed t-test was used for statistical analysis of lens thickness between groups.

Results: Agreement analysis showed excellent reliability between image measurement tools (ICC = 0.986) and between observers (ICC = 0.989). Cataract eyes had significantly thinner lens (3.17 ± 0.63mm) than control eyes (3.55 ± 0.17mm, p = 0.0008). Stratifying for laterality or prematurity did not yield significant difference in lens thickness within cataract or control groups. Children 0-5 years old with cataracts were 2.9 times more likely to have a lens thickness less than 3.5mm, increasing to 6.6 times if under 7 months of age. Laterality of cataract did not affect odds of having a lens thickness less than 3.5mm. When controlling for age and compensating for correlation between eyes from the same patient, the odds of having cataract decreased by 2.66 for every 1mm increase in lens thickness.

Conclusions: Lens thickness can be measured repeatably and reliably from UBM images in a pediatric population. Cataract eyes in children 0-5 years old have significantly thinner lenses than age-matched control eyes.

TITLE: Drug release kinetics of the Port Delivery System with ranibizumab (PDS): platform technology for continuous retinal drug delivery

SESSION TITLE: AMD and diabetic retinopathy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Horvath, K. Maass, A. Hieb, S. Ranade, Genentech Inc, South San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure: Judit Horvath: Commercial Relationship(s);Code E (Employment):Genentech, Inc. | Katie Maass: Commercial Relationship(s);Code E (Employment):Genentech, Inc. | Aaron Hieb: Commercial Relationship(s);Code E (Employment):Genentech, Inc. | Shrirang Ranade: Commercial Relationship(s);Code E (Employment):Genentech, Inc.

ABSTRACT BODY:

Purpose: The PDS is an FDA-approved drug delivery system designed for continuous delivery of a customized formulation of ranibizumab into the vitreous. The drug is contained within the implant reservoir and released through the porous release control element (RCE) via passive diffusion. In vitro testing was performed to verify modeled drug release kinetics of the PDS implant; effects of varying drug and implant parameters are reported.

Methods: Release rate profiles from the PDS implant were determined by implant loading (drug concentration, implant volume) and device half-life (dependent on RCE porosity and dimensions, drug diffusion coefficient, and implant volume). Drug-filled implants were regularly transferred to new buffer-containing vials to mimic ocular drug clearance and sustain similar release kinetics. A concentration assay (UV-Vis/Bradford) was used to measure released drug concentrations. Release rate data were fit using an exponential model to mimic the expected release kinetics of diffusion and were compared with predicted release rate kinetics.

Results: PDS release rates decreased over time. Changing initial ranibizumab concentration from 10 mg/mL to 150 mg/mL increased starting drug release rates from 1.75 to 25.2 µg/day, with observed ranibizumab release closely following model predictions over a 6-month period.

The PDS implant volume is currently fixed at ~20 µL; however, a range of implant volumes from 10–100 µL have been evaluated. In model predictions for ranibizumab 100 mg/mL, starting drug release is consistent at 13.9–14.5 µg/day across varying implant volumes, with drug release at 6 months ranging from 1 µg/day (10-µL implant) to 11 µg/day (100-µL implant).

The PDS implant is optimized for ranibizumab release, with an RCE release rate index (RRI) of 0.024 mm. Alteration of RCE pore size or drug diffusion coefficient has a significant effect on implant half-life. Decreasing RRI from 0.024 to 0.008 mm increased implant half-life from 14 to 42 weeks in experimental studies with ranibizumab 100 mg/mL.

Conclusions: Drug release from the PDS implant was demonstrated to be highly predictable and tunable based on a simple diffusion model. The Port Delivery System offers a flexible platform technology, with the ability to tailor implant release kinetics by careful selection of the drug molecule, drug concentration, and specific implant parameters.

ABSTRACT BODY:

Purpose: Lacritin non-lytic peptides comprising the protease-released 'N-104' domain are a primary source of natural basal tear bactericidal activity that target Gram-negative inner-membrane proteins FeoB and SpuG (PotH) - in part via the outer-membrane lipoprotein YaiW. While N-104 is highly potent (MIC < 2 μM) against ocular surface pathogen P. aeruginosa (PA14), its efficacy is significantly reduced at physiological conditions - as per many cationic antimicrobial peptides. Here, we searched for peptides or proteins in human normal basal tears that might ligate N-104 thereby synergistically enhancing its bactericidal efficacy.

Methods: Normal human basal tears from 0.5% proparacaine-anesthetized eyes were collected onto Schirmer strips for 5 min. Schirmer strips with ≥ 12 mm of wicked tears were eluted in PBS at 4°C for a pooled tear equivalent of 100 mm, and diluted 5-fold in PBS containing protease inhibitor cocktails (cOmplete Mini, 11836153001). Tears were precleared for 5 hours while rocking at 4°C with 100 μl of Pierce™ Control Agarose beads, and then were added in equal amounts to SulfoLink® immobilized Cys-N-104 or to negative control Cys-C-95 beads (each 100 μl) for overnight incubation at 4°C. C-95 is the inactive N-terminus of lacritin. After collection of flow-through, beads were washed with 100 bead volumes of PBS, eluted via a step gradient of 0.3, 0.5 and 1.0 M KCl for SDS-PAGE/silver staining, and then subjected to MS/MS focusing on the 0.5 M KCl eluate. Mass spectra were analyzed using the Sequest against UniProt Human.

Results: Captured by N-104 and absent from C-95 beads were fifty-eight different proteins above a threshold. Threshold of ≥ 0.24% was defined based on a histogram of the percentage over total values of each hit in the N-104 column. Nine are reported to be antimicrobial including: PIGR, F2, GSN, DMBT1, CST4, IGKC, PRR4, SCGB2A1, and LYZ. Also detected was IGLC2 that although also on C95 beads was 2.6x enriched on N-104.

Conclusions: N-104 appears to target numerous antimicrobial proteins/peptides in normal basal tears under physiological conditions. Whether the relationship might be functionally synergistic has yet to be determined. Given that N-104 is non-lytic, potential synergism may occur via enhancement of N-104’s electrostatic interaction with the bacterial surface and/or with YaiW.

TITLE: Phenotypic characterization of murine models with CRX homeodomain mutations

SESSION TITLE: Modeling inherited retinal degeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. SUN, Y. Zheng, S. Chen, Ophthalmology and Visual Sciences, Washington University in St Louis, St Louis, Missouri, UNITED STATES|

Commercial Relationships Disclosure: CHI SUN: Commercial Relationship: Code N (No Commercial Relationship) | Yiqiao Zheng: Commercial Relationship: Code N (No Commercial Relationship) | Shiming Chen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: CRX is a transcription factor (TF) essential for photoreceptor functional development and maintenance with an important role in the terminal differentiation of photoreceptors. Missense mutations in CRX homeodomain (HD) are linked to variable human retinopathies. We previously reported a murine model carrying the loss-of-function mutation p.R90W that causes recessive Leber Congenital amaurosis (LCA). This study aims to characterize the retinal phenotypes of new murine models for distinct dominant CRX HD mutations, p.E80A and p.K88N.

Methods: Knockin models were generated by introducing E80A or K88N mutations into the Crx locus. Hematoxylin and eosin (H&E) staining of retinal cross-sections revealed morphological defects at various postnatal (P) ages. Immunostaining of cell-type specific markers reported altered localization and relative abundance of affected cell types. Electroretinography (ERG) detected deficits in visual functions. Quantitative PCR (qPCR) determined differential gene expression of CRX-target genes and photoreceptor-specific TFs.

Results: New models showed retinal morphologies different from those found in published animal models. Irregular whorls and rosettes were detected within the outer nuclear layer of all E80A and K88N mutants at P14, worse in homozygotes than in heterozygotes. This phenotypic abnormality appeared within the window of photoreceptor differentiation and the severity progressed over the time of photoreceptor development. At P30, homozygotes of both mutations failed to develop rod outer segments and differentiated cones, thus showing null ERG responses. K88N heterozygotes also showed null ERG responses. E80A heterozygotes had shorter rod outer segments and few detectable cones, resulting in significantly decreased A- and B-wave amplitudes in rod ERG responses and undetectable cone responses. Gene expression analysis at P21 found that overall Crx levels in E80A and K88N mutants were comparable to that in wildtype control, but the expression of CRX-dependent phototransduction components were downregulated.

Conclusions: The murine models of E80A and K88N mutations display dominant Cone-rod dystrophy and LCA-like phenotypes respectively, which match corresponding clinical features in human patients. These models help to understand the underlying cellular and molecular mechanisms of dominant CRX HD mutations, informing treatment windows and strategy designs.

TITLE: Treatment Outcomes of Anti-VEGF Agents for Non-Infectious Uveitic Macula Edema

SESSION TITLE: Clinical Uveitis and Scleritis: Therapies and Outcomes

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Oyeniran, S. Bhandari, H. Sen, S. Kodati, National Eye Institute, Bethesda, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Enny Oyeniran: Commercial Relationship: Code N (No Commercial Relationship) | Sanjeeb Bhandari: Commercial Relationship: Code N (No Commercial Relationship) | H Nida Sen: Commercial Relationship(s);Code E (Employment):Janssen | Shilpa Kodati: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the outcomes of intravitreal anti-vascular endothelial growth factor (anti-VEGF) injections for macula edema secondary to non-infectious uveitis.

Methods: The records of patients that received anti-VEGF injections for uveitic macula edema from January 2017 to August 2021, allowing for at least 180 days of follow-up, were reviewed. Excluded were eyes with a history of infectious uveitis and macula edema secondary to non-uveitic conditions. The primary outcomes were mean change in visual acuity (VA) and central subfield thickness (CST) over 6 months [and 12 months if available] from the start of anti-VEGF treatment. Secondary outcomes were the proportion of eyes that required additional local therapy (including periocular/intraocular steroid injections) or escalation in systemic treatment (including oral steroids or immunomodulatory therapy).

Results: A total of 16 eyes (of 12 patients) met the inclusion criteria. Of these, 63% had panuveitis, 6% posterior uveitis, and 31% intermediate uveitis. Three-fourths of eyes (75%) starting anti-VEGF treatment had a history of elevated intraocular pressure secondary to a steroid response. Aflibercept was the most frequently injected anti-VEGF agent (in 88% of eyes) and the remaining received bevacizumab injections (12% of eyes). The mean VA gain at 6 months was 3.2 letters from a mean VA of 62.3 letters at baseline while mean CST improved by 101 µm from 445 µm at baseline. Three-quarters of eyes (75%) demonstrated a reduction in CST after their initial injection. Fourteen eyes had a 12 month visit from the start of treatment. The mean VA at 12 months remained similar to their baseline while the CST improved by a mean of 83 µm. Eyes received a median of 4 injections from 11 visits over 12 months. Only 1 eye required the addition of a dexamethasone implant in 6 months, with an additional eye requiring it over 12 months. One-tenth of eyes (10%) required an escalation in systemic treatment over 6 months [5% of eyes over 12 months]. IOP remained relatively stable (with a mean change of 0.4mm Hg over 6 months and -3.7 mm Hg over 12 months).

Conclusions: Eyes with non-infectious uveitic macula edema, particularly those intolerant to local steroid injections, may benefit from anti-VEGF injections. Larger studies on the long-term outcomes of VEGF inhibition may establish their role in preventing vision loss in patients with uveitic macular edema.

Commercial Relationships Disclosure: Kimberley Yu: Commercial Relationship: Code N (No Commercial Relationship) | Penny Asbell: Commercial Relationship(s);Code C (Consultant/Contractor):Glia, Senju, Blephex;Code F (Financial Support):Regeneron, Mitotech, Sylentis, Tear Science, MC2 | Roni Shtein: Commercial Relationship: Code N (No Commercial Relationship) | Gui-Shuang Ying: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Dry eye disease (DED) represents a heterogeneous group of conditions with tear film instability and ocular surface irritation. While DED is traditionally classified as aqueous tear deficient vs evaporative, the full spectrum of DED subtypes is poorly characterized. Different etiological subtypes are hypothesized to respond to treatments differently. The DREAM study was a large multi-center randomized clinical trial that did not find omega-3 to be more effective than placebo in treating a broad spectrum of patients with symptomatic DED. We performed secondary analysis of the DREAM data to characterize DED subtypes and their response to omega-3.

Methods: 535 patients with moderate-to-severe DED were 2:1 randomized to receive omega-3 or placebo over one year. We used latent profile analysis to identify subtypes based on baseline DED symptoms, measured via the Ocular Surface Disease Index (OSDI), and 5 DED signs: tear break-up time (TBUT), anesthetized Schirmer's test, corneal staining, conjunctival staining, and meibomian gland dysfunction (MGD). We evaluated the effect of omega-3 on symptom improvement for each subtype using generalized linear regression with false discovery rate (FDR)-adjustment for multiple comparisons.

Results: We identified 5 DED subtypes considered clinically meaningful by dry eye experts (Table 1, Figure 1). Sex ($p<.001$) and race ($p=0.02$) differed significantly among subtypes. Class 1, characterized by the most severe DED signs yet relatively milder symptoms, was significantly associated with a higher proportion of Sjögren's syndrome patients (21%, $p<.001$). Class 5, characterized by severe MGD and TBUT, was significantly associated with rosacea (29%, $p=0.04$). For Class 1 only, the mean OSDI change over one year was greater in patients receiving omega-3 (n=60, -12.2±1.9) than placebo (n=29, -5.3±1.7) (95% CI for difference: [-11.9, -1.9], FDR-adjusted $p=0.03$). However, this was not significant after adjustment for baseline OSDI (-11.3±1.7 vs -7.1±1.9, 95% CI: [-9.2, 0.8], FDR-adjusted $p=0.54$).

Conclusions: Five clinically meaningful DED subtypes identified in the DREAM study differed significantly in demographics, symptoms, signs, and systemic disease associations. Understanding DED subtypes can improve DED classification and targeted management. We did not find omega-3 to be significantly beneficial for the five DED subtypes.

ABSTRACT BODY:

Purpose: We used geometric perfusion deficit (GPD) analysis in OCT angiography (OCTA) to test the hypothesis that early nonperfusion in patients with diabetes mellitus (DM) without diabetic retinopathy (DR) localizes to the deep capillaries near larger vessels.

Methods: After averaging multiple OCTA scans (average 6.7 ± 1.0 scans), we used a semi-automated method to measure GPD, defined as the retinal area located further than 30 μm from the nearest blood vessel, and compared healthy subjects to patients with DM without DR. In the superficial capillary plexus (SCP), deep (DCP) and full retina, we analyzed percent area of GPD in the whole scan as well as in the 100 μm area around arterioles (periarteriolar space), the 100 μm area around venules (perivenular space) and in the area greater than 100 μm from the nearest arteriole or venule (capillary space).

Results: Our initial analysis included 11 eyes of 11 healthy subjects (6 females; age 39.9 ± 11.7 years) and 11 eyes of 11 patients with DM without clinical DR (7 females; age 46.9 ± 16.0 years). The GPD in the DCP was significantly greater in patients with DM without DR compared to healthy subjects (4.0% ± 1.1% versus 3.2% ± 0.8%, respectively; p=0.030), but not in the SCP or full retina (p=0.371 and p=0.094, respectively). Perivenular GPD in the DCP showed the greatest difference (3.0% ± 1.1% in DM versus 2.2% ± 0.7% in healthy; p=0.028), while the periarteriolar and capillary spaces showed no significant difference (p=0.073 and p=0.151, respectively).

Conclusions: We found that perfusion deficits were increased most prominently in the deep capillaries near venules in patients with DM without clinical DR compared to healthy controls. This study suggests that in the macula, early capillary dysfunction in diabetes may preferentially occur in the perivenular compartment of deep capillary plexus.

ABSTRACT BODY:

Purpose: Adherence to recommended annual or biennial diabetic eye exams can prevent vision loss from diabetes. Successful diabetes management including eye care involves a high degree of health literacy and diabetes-specific knowledge. Diabetes-specific health literacy is likely particularly important among older adults who must simultaneously manage other chronic diseases. This study evaluates the role of diabetes-specific health literacy in adherence to diabetic eye exams in a nationally representative sample of older American adults.

Methods: Respondents with self-reported type 2 diabetes mellitus from the Health and Retirement Study (HRS) 2003 Diabetes Study and HRS 2002 Core survey were included. The main outcome was having an eye exam within the past year. The secondary outcome for sensitivity analysis was having an exam within the past two years. The main explanatory variable was diabetes-specific health literacy, an index based on how well respondents understood a series of 10 diabetes care regimen items (e.g., taking insulin, reading nutrition labels). Poisson regression models with robust sandwich variance estimator were constructed to estimate the risk ratio (RR) of diabetes-specific health literacy on adherence to diabetic eye exams, adjusted for age, gender, race and ethnicity, education status, household income, baseline eyesight, and the total illness burden index. Chi-squared tests and Wilcoxon rank sum tests were used to compare groups. All analyses incorporated HRS survey weights.

Results: The analysis included 2060 respondents. Those who had an eye exam within the past year had a higher diabetes-specific health literacy index (mean 3.40 [range 3.00, 3.90] vs. 3.10 [2.80, 3.60], $p<0.001$). On multivariate analysis, having a higher diabetes-specific health literacy index was associated with increased likelihood of an eye exam within the past year (RR 1.14 [95% confidence interval (CI) 1.04, 1.24], $p=0.006$). On sensitivity analysis, the association was borderline (RR 1.05 [95% CI 1.00, 1.10], $p=0.07$).

Conclusions: In an older population of type 2 diabetics, having more diabetes-specific health literacy was associated with increased adherence to diabetic eye exams. This suggests that improving disease-specific health literacy skills could be a means by which to promote vision saving diabetic eye examinations.

TITLE: Change in peripapillary retinal nerve fibre layer thickness from 20 to 28 years old

SESSION TITLE: Glaucoma epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.S. Lee, D.A. Mackey, Centre for Ophthalmology and Visual Science (incorporating the Lions Eye Institute), The University of Western Australia Faculty of Health and Medical Sciences, Perth, Western Australia, AUSTRALIA|A.W. Hewitt, D.A. Mackey, Menzies Institute for Medical Research, University of Tasmania, Hobart, Tasmania, AUSTRALIA|

Commercial Relationships Disclosure: Samantha Lee: Commercial Relationship: Code N (No Commercial Relationship) | Alex Hewitt: Commercial Relationship: Code N (No Commercial Relationship) | David Mackey: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Glaucoma diagnosis almost definitely always lags disease onset by several months if not years. However, it is unclear when exactly does glaucoma start. Moreover, little is known of how the peripapillary retinal nerve fibre layer (pRNFL) thickness change during young adulthood. To address these gaps in our knowledge, we investigated whether pRNFL thinning could be detected at a young age by mapping the 8-year change in pRNFL thickness in a community-based cohort of young adults. We further tested the hypothesis that those with a family history of glaucoma have faster rates of pRNFL thinning than those without a known family history.

Methods: Generation 2 participants from the Raine Study attended an eye examination when they were 20 and 28 years old. The pRNFL thickness globally and at 6 sectors were measured with spectral-domain optical coherence tomography (SD-OCT) imaging. Information on family history of glaucoma was collected using questionnaires administered to the participants and their parents. The 8-year longitudinal change in pRNFL thickness was explored using linear mixed-effect models with random intercept and slope for participants to account for the within-participant correlation between two eyes.

Results: After excluding eyes with pathology and low-quality or erroneous scans, 1,313 eyes of 693 participants were included in the analysis. The pRNFL was thinner at 28 years old than at 20 years globally and at all sectors. The global pRNFL thinned by -0.34µm/year (95% confidence interval= -0.37 to -0.31), with the nasal and superonasal sectors showing the most thinning (-0.46 and -0.45µm/year), followed by the inferotemporal (-0.38µm/year), temporal (-0.29µm/year), superotemporal (-0.22µm/year), and inferonasal (-0.14µm/year) sectors. There was no significant association between family history of glaucoma and rate of pRNFL thinning.

Conclusions: The pRNFL starts to thin at least from the third decade of life, albeit at a very slow rate. There was no evidence that the pRNFL thins at a faster rate in those with a family history of glaucoma. Nonetheless, longer-term follow-up of this cohort is warranted to ascertain the rate of pRNFL thinning in a reference population and in those who eventually develop glaucoma.

TITLE: Indications and Outcomes for Laser Retinopexy in Patients with Lattice Degeneration

SESSION TITLE: Macular diseases/Macular edema/Functional testing/evaluation/Laser

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.S. Kazan, Thomas Jefferson University Sidney Kimmel Medical College, Philadelphia, Pennsylvania, UNITED STATES|R. Mahmoudzadeh, M. Salabati, M. Spirn, Retina Service, Wills Eye Hospital, Philadelphia, Pennsylvania, UNITED STATES|R. Mahmoudzadeh, M. Salabati, M. Spirn, Mid Atlantic Retina, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Adina Kazan: Commercial Relationship: Code N (No Commercial Relationship) | Raziyeh Mahmoudzadeh: Commercial Relationship: Code N (No Commercial Relationship) | Miratoallah Salabati: Commercial Relationship: Code N (No Commercial Relationship) | Marc Spirn: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To examine the characteristics of eyes with lattice degeneration treated with laser retinopexy and to determine the indications, safety, and outcomes of using laser retinopexy in these eyes.

Methods: Single-center, single-surgeon, consecutive retrospective chart review conducted at Wills Eye Hospital between 2014 and 2021. Comprehensive chart reviews documented characteristics and outcomes of these eyes and fellow eyes.

Results: A total of 158 eyes of 139 patients (58.2% female, mean (±SD) age 50 (±17); range 13-79 years) were included in this study. The mean (±SD) follow-up from the lattice diagnosis visit was 880 (±629; range 46-2183) days. The mean time from lattice diagnosis to initial laser was 77 (±263); range 0-2772) days. The mean (± SD) pre-laser logMAR visual acuity was 0.14 (±.27; Snellen equivalent 20/28) and mean post-laser logMAR visual acuity was 0.12 (±.26; Snellen equivalent 20/26, p=0.157). Indications for laser retinopexy were as follows: 54 eyes (35.3%) had retinal detachment of the fellow eye, 69 eyes (45.1%) had an atrophic hole in the lattice, and 36 eyes (23.5%) had an atrophic hole with subretinal fluid. After laser treatment, 20 eyes (12.8%) developed a new posterior vitreous detachment, 13 eyes (8.2%) developed a new epiretinal membrane, and 6 eyes (3.8%) developed a new retinal detachment. Individuals that developed an epiretinal membrane after laser were more likely to be older (60±8 years v 49±17 years, p=0.018). Additionally, eyes that developed epiretinal membranes after laser were also more likely to develop posterior vitreous detachment (OR=6.143 (1.732-21.788, p=0.002). Of eyes that developed a new epiretinal membrane after laser (n=13), no eyes required surgery to fix the epiretinal membrane. Those that developed retinal detachments were more likely to be older (63±5 years vs. 49±17 years) although this did not reach statistical significance (p=0.054). Of eyes that developed retinal detachments after laser (n=6), 4 eyes were treated with laser retinopexy alone, 2 eyes were treated with scleral buckle and pars plana vitrectomy, and all eyes remained attached up to the final visit with one procedure.

Conclusions: Performing laser retinopexy in eyes at higher risk for progression to retinal detachment does not eliminate the risk of further complications, and routine follow-up is recommended. Older patients also tend to have more ERM formation after laser retinopexy.

ABSTRACT BODY:

Purpose: Uveal melanoma (UM) is the most common and lethal eye cancer in adults. Most benign nevi harbor the UM driver mutations in GNAQ/GNA11, suggesting additional genetic insults are required for UM initiation. While ultraviolet light, the major risk factor for skin melanoma, is filtered out by the ocular lens and cornea, the blue light (BL) spectra reaches the posterior of the eye. However, the exact role of BL in inducing uveal melanomagenesis is not well understood. In this study, we investigated the impacts of GNAQ mutation and BL irradiation in UM development.

Methods: Using a solar simulator (TSS-156R, OAI), we analyzed the impact of acute (1 sun (1000 W/m^2), 30 min) and chronic (0.3 sun, 3 hours/day, 4 days) BL exposure (400-500 nm) on UM cell lines, normal choroidal melanocytes (NCMs), and GNAQ-mutant CMs (a precursor cell for UM). NCMs were isolated from human donor eyes, and a GNAQ mutation (c.626A>T) was introduced by lentivirus to generate the mutant CMs. The proliferation rate and clonogenicity potential (i.e. soft agar and spheroid assay; in vitro clue of malignant transformation) of NCMs and mutant CMs were compared. The cell viability (CCK8 assay), reactive oxygen species (ROS, DCFDA assay) levels, and proteomic changes (analyzed by mass spectrometry and DAVID database) post BL exposure were assessed. Statistical analyses were performed by Student's t-test. A P value < 0.05 was considered significant.

Results: GNAQ-mutant CMs maintained the expression of melanocyte markers (Vimentin, MelanA, TRP1, HMB-45, S100) and displayed increased proliferation and clonogenicity potential compared to NCMs. Chronic BL irradiation reduced the viability of NCMs but not UM cell lines (i.e. 92.1, MP46 and OMM2.5). Acute BL exposure generated ~100-fold and 7-fold more ROS in 92.1 and NCMs, respectively, compared to non-treated cells. Proteomic analysis identified that BL caused endoplasmic reticulum stress and reduced DNA repair in NCMs, and significant oxidative stress in 92.1 cells.

Conclusions: We report that BL affected the oxidative status of melanocytes and UM cells, which may lead to DNA damage that can accelerate mutation accumulation, thus initiating or facilitating UM development. In addition, GNAQ mutation and BL exposure trigger central clues involved in uveal melanomagenesis, suggesting that BL may represent an additional hit in the process of GNAQ-mutant nevi transformation.

TITLE: Computationally Efficient Deep Learning Applied to Glaucoma Eye Drop Bottle Detection for Increasing Medication Compliance in Low-Vision Patients

SESSION TITLE: Data science, machine learning, and AI

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Rao, Palo Alto High School, Palo Alto, California, UNITED STATES|H. Fishman MD PHD, Clinical Research, FishmanVision, California, UNITED STATES|

Commercial Relationships Disclosure: Adrit Rao: Commercial Relationship: Code N (No Commercial Relationship) | Harvey Fishman MD PHD: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Compliance in the usage of prescription eye drops is a major limitation in the management of ocular disease regardless of age, medical condition, or sightedness. However, eye drop medication adherence is particularly challenging in low-vision patients who may have difficulty in differentiating among medications because of small font, and similarities in size, color, and shape. Research has surveyed self-administration of medication in low-vision patients and found that a total of 89% of respondents were unable to read the prescription labels and 96% of these patients did not inform healthcare providers when they faced difficulties in handling their medication. The inability to correctly administer eye drops because of low-vision is a significant subset of eye drop medication non-compliance. We propose a deep learning algorithm which can accurately localize eye drop bottles to aid low-vision patients in recognition.

Methods: Our image dataset was collected from the internet and spans the widely prescribed Latanoprost, Timolol, and Alphagan glaucoma eye drop bottle classes (1500 images). Bounding boxes are placed around the bottles in each image by a trained optometrist. Various image augmentations (sheer, zoom, contrast, flip) are applied. The YOLOv4 tiny computationally efficient object detection algorithm is trained on our annotated coordinate dataset.

Results: The algorithm was trained across 300 epochs with a batch size of 16 and image size of 416x416. It recieved a final mean average precision (mAP) score at a 0.5 IoU threshold of 0.85 and at a 0.5:0.95 IoU threshold of 0.49. The algorithm recieved precision of 0.881 and recall of 0.924 across the test set (20% test split). Figure 1 shows box, objectness, and classification loss across epoch progression along with precision, recall, mAP@0.5 and mAP@0.5:0.95 scores. Bottle localization inference on images averaged at 0.008 seconds on a P-100 GPU.

Conclusions: We have proposed a custom deep learning object detection model which can accurately detect and localize three prescription eye drop bottles. With such a tool, patients can potentially identify and use bottles with more ease, lowering the amount of non-compliance. The proposed system is a proof-of-concept and more testing, a larger dataset, and classes are required before deployment onto a mobile phone.

TITLE: Vitreous exposure increases global chromatin accessibility in cis-regulatory elements in lens epithelial explants as they undergo fiber cell differentiation

SESSION TITLE: Lens development and differentiation

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: A. Upreti, J.A. Tangeman, B.D. Wagner, T.J. Jaquish, R. Palko, C. Gantz, M.L. Robinson, Cell,Molecular and Structural Biology(CMSB), Center for Visual Science at Miami University(CVSMU), Miami University, Oxford, Ohio, UNITED STATES|

Commercial Relationships Disclosure: Anil Upreti: Commercial Relationship: Code N (No Commercial Relationship) | Jared Tangeman: Commercial Relationship: Code N (No Commercial Relationship) | Brad Wagner: Commercial Relationship: Code N (No Commercial Relationship) | Tycho Jaquish: Commercial Relationship: Code N (No Commercial Relationship) | Raye Palko: Commercial Relationship: Code N (No Commercial Relationship) | Cameron Gantz: Commercial Relationship: Code N (No Commercial Relationship) | Michael Robinson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The lens epithelial explant system represents a powerful, in vitro approach to understand how extracellular signals coordinate fiber cell differentiation. In this system, growth factors present in the vitreous humor elicit widespread transcriptomic changes resulting in proliferation and the production of proteins characteristic of both inflammation and lens fiber cell differentiation (CD). Here, we document how vitreous treatment changes chromatin accessibility (CA) through time in lens epithelial explants.

Methods: Chromatin extracted from 8-day-old FVB/N mouse lens epithelia was subjected to ATAC-sequencing at 5 different time points: immediately after collection, after 1 day in explant culture, and after an additional explant culture period in 50% bovine vitreous/media for 1, 5 and 10 days. The ATAC data was processed to identify open chromatin regions and associated genomic features. Furthermore, the differentially accessible regions (DARs) between different time points were identified and subjected to GO term analysis. Similarly, DARs were analyzed for over-represented motifs to identify candidate transcription factors (TFs) associated with observed accessibility changes. Finally, the ATAC-seq data was integrated with RNA-seq data to identify novel relationships between CA and transcriptomic changes associated with fiber CD.

Results: Genome-wide analysis of CA indicates a general trend toward increased accessibility of cis-regulatory elements (CREs) for vitreous treatment. GO analysis of genes associated with DARs included eye development, inflammatory response, lens development in camera-type eyes, NIK/NF-kappa B signaling and PI3K signaling. Similarly, some of the top overrepresented motifs associated with DARs in the vitreous treated samples include the transcription factors ATF3, JUN, SOX21, SOX3 and TEAD3. These motifs are consistent with a recent report (Zhao et al. Epigenetics & Chromatin 2019) of these TFs in fiber CD. Fiber cell genes Dnase2b, Cryba4, Crybb1, Crygc, Cryba3 and inflammatory response genes Mmp3, Mmp10, Mmp9, Fn1 exhibit increased accessibility in response to vitreous, consistent with their increased transcription.

Conclusions: Vitreous treatment results in TF-mediated chromatin remodeling in CREs and within gene bodies associated with fiber CD and inflammatory response genes.

ABSTRACT BODY:

Purpose: To assess the rotational stability of toric intraocular lenses (IOL) with and without the use of a capsular tension ring (CTR) in patients undergoing cataract surgery.

Methods: This study is a prospective, randomized clinical trial performed at a military medical center in Las Vegas, Nevada. The eyes of adult patients undergoing cataract surgery with corneal astigmatism greater than or equal to 1.0 diopter were randomized into either the control group or the treatment group. Standard-of-care phacoemulsification cataract surgery was performed using a Tecnis toric lens (Johnson and Johnson Vision) in both groups. In the control group, no CTR was used. In the treatment group, a MORCHER® EYEJET® preloaded single-use CTR was implanted immediately prior to the IOL. Eyes of every axial length were eligible to enroll, and a CTR size 14, 14A, or 14C w used depending on the axial length. Slit lamp photos using retroillumination to document the toric axis were taken on the first day, 1 week, 1 month, 3 months, and 6 months postoperatively. The toric axis was measured by blinded reviewers using computerized image software. The primary outcome was the difference between the preoperative intended toric axis and the measured toric axis on postoperative month 6.

Results: The mean difference between intended and measured toric axis at 6 months postoperatively was 7.4 ± 7.2 degrees in the control group and 4.6 ± 4.7 degrees in the treatment group. The difference was not statistically significant. There were no complications related to the use of the capsular tension ring.

Conclusions: There is a non-significant trend towards fewer degrees of rotation with the addition of the capsular tension ring during cataract surgery. Additional study is needed to determine if this trend will be clinically significant.

BARATHI: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To elucidate the signaling pathway from the retina to sclera (via the choroid), in the regulation of spontaneous axial myopia in an albino guinea pig (GP) model.

Methods: Refraction and biometry measurements were assessed by retinoscopy and Sonomed A-Scan ultrasound respectively. Eighteen Elm Hill albino GPs were divided into two groups, based on post-natal day 14 refraction, as either albino myopia (AM, n=9) or albino hyperopia (AH, n=9). Four GPs from each group were analyzed by RNAseq and the rest were analyzed by proteomics assay. QIAGEN IPA software was used to identify the canonical pathways in the retina, choroid, and sclera from both RNAseq and proteomics data.

Results: The refraction (-5.0±1.5D vs. +3.6±2.4D, $p<0.001$) and axial length (7.4±0.2mm vs. 7.2±0.1mm, $p<0.001$) significantly differed between AM and AH. Around 17,000 gene IDs for GPs were identified from Ensembl, but only 150 genes in the sclera showed significantly different expression between AM and AH with adjusted $p<0.05$. Based on proteomics analysis, >8,000 protein names for GPs were identified from UniProt, and the levels of 274 proteins in the retina, 106 proteins in the choroid, and 125 proteins in the sclera were statistically different between AM and AH with adjusted $p<0.05$. The canonical pathways identified at the gene level were far fewer than at the protein level among all three tissue types.

Conclusions: The combination of differentially expressed mRNA and proteins data can increase the confidence for biological discovery in the spontaneously myopic eye, which can elucidate the genetic basis of individual susceptibility to myopia development and potential pharmaceutical therapeutic targets.

ABSTRACT BODY:

Purpose: To identify a peripheral blood transcriptome that distinguishes Sjögren Syndrome (SS) from non-Sjögren Syndrome. SS is an underdiagnosed condition in patients with dry eye disease.

Methods: Cross-sectional study of participants from Sjögren's International Collaborative Clinical Alliance (SICCA) UCSF sub-cohort returning for up to 15-year follow-up. Participants were classified using the universally accepted American College of Rheumatology/European League Against Rheumatism SS criteria. All participants had slit lamp examination performed including determination of the ocular staining score (corneal staining with fluorescein and conjunctival staining with lissamine green). Additionally, whole peripheral blood was collected into PAXgene RNA tubes (QIAGEN, Germantown, MD) and then submitted for metagenomic sequencing for differential gene expression. Sequenced data were quality filtered and aligned to the ENSEMBL CRCh38 human genome using STAR2. Genes were filtered to include only protein-coding genes that were expressed in at least 25% of the patients. Gene count data were analyzed with DESeq2. Differentially expressed genes with false discovery rate (FDR) <0.01 were considered as notable.

Results: Fourteen participants (10 SS and 4 non-SS) were recruited for up to 15-year follow-up. The ocular staining score remained stable up to 15 years of follow-up in both SS and non-SS groups. However, we identified 6 differentially expressed genes distinguishing SS from non-SS. The genes included OAS3, IFIT1, RSAD2, IFI44L, ISG15, and OASL, all genes that are involved in the canonical interferon pathway.

Conclusions: In those classified as SS, a robust peripheral blood transcriptome distinguishes them from non-SS. The differentially expressed genes, which are related to the interferon pathway, may indicate candidate genes for further study, which could be used as future additional biomarkers of SS and may guide future treatment options.

TITLE: Glaucoma Medication Non-Compliance in a Vietnamese American Population

SESSION TITLE: Glaucoma epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Fan, Loma Linda University Medical Center, Loma Linda, California, UNITED STATES|S. Do, C. Do, Pacific Eye Care Center, Westminster, California, UNITED STATES|

Commercial Relationships Disclosure: Sabrina Do: Commercial Relationship: Code N (No Commercial Relationship) | Cuong Dung Do: Commercial Relationship: Code N (No Commercial Relationship) | Joseph Fan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Higher rates of medication non-compliance in Vietnamese populations have been reported among patients with cardiovascular diseases and diabetes mellitus. Glaucoma medication non-compliance and potential barriers to compliance among Vietnamese Americans have not been reported. This cross-sectional, observational study assesses glaucoma medication non-compliance among a Vietnamese American patient population and identifies the commonly cited barriers which potentially hinder glaucoma medication compliance.

Methods: 206 Vietnamese American patients taking glaucoma medication(s) were recruited from an ophthalmology practice in Westminster, California. All study subjects completed questionnaires on demographics, administration of glaucoma medications, social support, insurances, and commonly reported barriers to medication compliance. Medication non-compliance was determined by criteria established by the MARS-5 questionnaire. Quantitative analyses using descriptive statistics, Chi-square test, t-test, and logistic regression were performed.

Results: 19.4% of the subjects were found to be non-compliant as per the MARS-5 criteria. Decreasing age had a statistically significant association with medication non-compliance (OR=1.05, p=0.02). Increasing frequency of daily administrations of glaucoma medications trended towards non-compliance (OR=1.55, p=0.07). Among non-compliant patients, the most frequently cited barriers were forgetfulness (60%), burning or stinging with drops (47.5%), blurriness from drops (45%), medication cost (32.5%), intolerable medication-induced side effects (32.5%), and busyness with obligations (32.5%).

Conclusions: Non-compliance was found in 19.4% of our survey subjects. Both decreasing age and increasing frequency of administration were correlated with glaucoma medication non-compliance. The most commonly cited barrier was forgetfulness. Knowledge of the factors relevant to non-compliance can guide interventions to improve glaucoma medication compliance.

ABSTRACT BODY:

Purpose: Bacterial keratitis is a prevalent eye infection that causes corneal opacification and purulent discharge, especially among contact lens wearers. Such infections recruit innate immune cells into the cornea, predominately neutrophils (PMN). CD177 is a GPI-anchored protein expressed on ~50% of circulating PMN. Proteinase-3 (PR3) is a serine protease that binds CD177 and is shown to be released from PMN granules upon activation or expressed on the plasma membrane (mPR3). $CD177^{+}$ PMN can be protective or pathogenic in various diseases ranging from IBD to COVID-19. On the other hand, elevated PR3 is found in patients with anti-neutrophil cytoplasmic autoantibody (ANCA)-associated systemic vasculitis. With little known regarding the eye, this study investigates the expression and role(s) of CD177 and PR3 in the cornea following bacterial keratitis.

Methods: This work uses an experimental model of bacterial keratitis carried out in 8-week-old, female susceptible C57BL/6 (B6) and resistant BALB/c mice. The left eye of each mouse was scarified then infected with P. aeruginosa ATCC strain 19660 (5 µL of 1 x 10^{6} CFU). Corneas from naïve, uninfected mice from both strains served as controls. Corneas were harvested at 1, 3, and 5 days post-infection (p.i.). Levels of CD177 and PR3 were determined at the protein level by Western blot and by phenotypic profiling using flow cytometry. In vitro assessment was carried out using HL-60, a human promyelocytic cell line, and siCD177 knockdown.

Results: Results from the in vivo model showed no differences in protein levels at 1 day p.i., but significantly higher levels of both CD177 and PR3 in B6 vs. BALB/c at 3 and 5 days p.i. Flow cytometry data revealed $CD177^{+}$ and $PR3^{+}$ expression on both PMN and macrophages from B6 and BALB/c infected corneas with differential mean fluorescence intensities detected between the strains under normal conditions and following infection. In vitro results indicated that cell activation was altered following CD177 knockdown with differences in downstream signaling.

Conclusions: As one of the first studies to explore the role of CD177 and PR3 in the pathogenesis of bacterial keratitis, our findings reveal strain-specific expression profiles for PMN that may contribute to resistance vs. susceptibility. In addition, we show the presence of $CD177^{+}PR3^{+}$ macrophages. Overall, these findings may uncover novel therapeutic targets to treat bacterial keratitis.

ABSTRACT BODY:

Purpose: Early childhood vision screening remains paramount in the detection of refractive amblyogenic risk factors. However, in resource-constrained environment the limited number of eye care cadres and disproportionate distribution of eye care services mostly lives the rural areas underserved. Photoscreening is a promising technology with increased specificity and sensitivity to identify these refractive anomalies, and with greater propensity to filling this human resource and service gap. Therefore, using plusoptix vision screener A12 we determined the prevalence of amblyopic risk factors among preschool children in rural communities in the Bosomtwi District of Ghana.

Methods: This was a community-based cross-sectional study. Photoscreening was performed for 169/202 children (response rate 83.7%) aged 2-5 years. Referral for comprehensive ophthalmic assessment by an experienced optometrist was dependent on a prespecified amblyopic risk factors criterion by the American Association for Pediatric Ophthalmology and Strabismus (AAPOS). Vision screening was not performed on sleeping and uncooperative children.

Results: The mean age of children was 3.20 (± 0.98) years, with the majority (53.2%) being males. Mean spherical equivalent (S.E.) for the right and left eyes were 0.47 ± 0.42 and 0.68 ± 0.54 diopter respectively. Out of the 14 subjects referred (8.28%) the proportion of amblyogenic risk factors were as follows: 4.14% (7/169) anisocoria, 1.78% (3/169) myopia, 1.18% (2/169) anisometropia, 0.59% (1/169) hyperopia, 0.59% (1/169) gaze asymmetry and 0.0% astigmatism. Anisocoria was more prevalent in females 85.7% (6/7) compared to males 1 (14.3%).

Conclusions: The prevalence of amblyopia risk factors in this study was 8.28%. Anisocoria and myopia were commonly encountered, and female pediatrics were mostly found of unequal pupil size. This results showed undiagnosed amblyogenic risk cases which merits vision screening among children in these rural areas to enhance early detection and management.

ABSTRACT BODY:

Purpose: Recent histomorphometric studies suggested that axial myopic elongation occurs through an equatorial ocular wall enlargement, changing the eye shape from a sphere to a prolate configuration. The equatorial ocular wall enlargement may be achieved by a growth of the equatorial Bruch's membrane (BM), leading to a backward push of the posterior BM and a secondary thinning of the posterior choroid. Since BM is produced by the retinal pigment epithelium, which contains receptors for the epidermal growth factor (EGF) and the in-vitro proliferation of which is supported by EGF, EGF may be a myopic axial elongation-associated messenger molecule. Subsequently, experimental studies in guinea pigs showed that the intravitreal application of blockers of EGF family members and of the EGF receptor led to a decrease in axial elongation, while the intravitreal injection of EGF family members was associated with an increase in axial elongation. The findings suggest that the intravitreal application of EGF receptor blockers such as panitumumab may prevent further axial elongation in adult highly myopic patients. We here examined the safety and tolerability of intravitreally applied panitumumab (Vectibix®).

Methods: The phase 1 study included highly myopic patients with myopic macular degeneration. The eyes received a single intravitreal injection of 0.6 mg (60 µL) panitumumab in a standardized manner.

Results: The study included two patients: Patient #1: male, age: 56 years, best corrected visual acuity (BCVA): 0.05, axial length: 29.10mm, IOP: 12mmHg.; Patient #2: female, age: 68 years, BCVA: 0.12, axial length: 30.86 mm, IOP: 17 mmHg. The examinations performed at one day after the injection did not show any intraocular inflammation or morphological change. Examined at 7 days after the injection, no change was observed in BCVA, retinal electroretinography, perimetry, optical coherence tomography-based clinical histomorphometry of the retina and optic nerve, and intraocular pressure, nor were intraocular signs of inflammation or tissue destruction observed.

Conclusions: The preliminary observations of the first two patients receiving an intravitreal application of the EGF receptor antibody panitumumab do not contradict the assumption of an intraocular tolerability of panitumumab injected in a dose of 0.6 mg.

TITLE: Fat3 deficiency impairs bipolar cell function and fast vision in mice

SESSION TITLE: Photoreceptors and the OPL

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: Y. Xue, C. Cepko, Genetics, Harvard Medical School, Boston, Massachusetts, UNITED STATES|E. Avilés, L. Goodrich, Neurobiology, Harvard Medical School, Boston, Massachusetts, UNITED STATES|V. Kefalov, Ophthalmology & Physiology and Biophysics, University of California Irvine, Irvine, California, UNITED STATES|V. Kefalov, Gavin Herbert Eye Institute & Center for Translational Vision Research, University of California Irvine, Irvine, California, UNITED STATES|

ABSTRACT BODY:

Purpose: Fat3, a member of the Fat family of atypical cadherins, is critical for the development of retinal circuitry. The deletion of Fat3 from the mouse retina impairs amacrine cell migration, neurite retraction, and the proper location of synapses, resulting in the formation of ectopic synaptic layers. However, it is unknown how retinal function is affected by these developmental cellular defects. To investigate this question, we examined retinal function of Fat3-deficienct mice.

Methods: Mice were dark adapted overnight before being anesthetized for in vivo electroretinography (ERG) recordings. Four types of ERG recordings were performed: 1) scotopic test, 2) photopic test, 3) flicker test up to 50 Hz, and 4) three-second step light test. The photopic visual acuity of $Fat3^{-/-}$ mice was measured using the optomotor behavioral assay. In addition, to test if mice can perceive flickered light, a contextual and vision-cued fear conditioning (CVFC) test was designed and applied to $Fat3^{-/-}$ mice. Additional immunohistochemistry and in vivo ERG experiments were performed on $Grik1^{-/-}$, $Grm6^{-/-}$, and $Grik1^{-/-}Grm6^{-/-}$ mice to look for effects due to perturbations in bipolar cells.

Results: $Fat3^{-/-}$ eyes did not show a significant difference in the scotopic ERG, photopic ERG or photopic visual acuity compared to the controls. However, the flicker ERG tests revealed severely decreased amplitude and delayed implicit time from $Fat3^{-/-}$ eyes at the high temporal frequencies (i.e. >20 Hz) compared to the controls. $Fat3^{-/-}$ mice also presented impaired perception of 33 Hz flashes as measured by the CVFC test. $Fat3^{-/-}$ eyes showed diminished d-wave amplitude in the step ERG test, which correlated with decreased GRIK1 expression in OFF-bipolar cells (BC), in which Fat3 mRNA was enriched. $Grik1^{-/-}$ eyes presented a diminished d-wave, slightly decreased 30 Hz amplitude, and advanced 20 Hz implicit time.

Conclusions: These results suggest that Fat3 is critical for OFF-BC function and for retinal processing of visual signals at high temporal frequency. Fat3 is not required for basic light sensation in dark or daylight conditions. Fat3 also appears not to be critical for normal spatial visual resolution in daylight conditions. Additional results from $Grm6^{-/-}$ and $Grik1^{-/-}Grm6^{-/-}$ mice suggest that the function of ON-BCs, in addition to the function of OFF-BCs, might be compromised by Fat3-deficiency, contributing to the unique fast vision phenotype.

ABSTRACT BODY:

Purpose: To overcome the floor effect of OCT measurements, we developed a deep learning model to estimate the functional deterioration directly from 3-dimensional (3D) OCT volumes (segmentation free) and compared the performance with the model trained with 2-dimensional (2D) OCT thickness maps (segmentation dependent) as inputs.

Methods: 8387 24-2 Humphrey visual field (VF) tests were acquired from 1129 patients over multiple visits. 13792 macular and 15026 optic nerve head scans (both 200x200 samplings, Cirrus HD-OCT, Zeiss, Dublin, CA) were acquired within 90 days of the VF visits. To reduce variances caused during imaging, the Bruch's membrane surface was flattened and aligned by adjusting A-scans in the z-direction. Downsampling to 64x64x128 was applied to prevent memory shortage. Two models were trained to estimate the 52 VF threshold values: one was an 18-layer 3D ResNet taking OCT 3D volumes as inputs and the other was an 18-layer 2D ResNet taking 2D macular ganglion cell-inner plexiform layer and retinal nerve fiber layer thickness maps as inputs. A mean square error loss was used to train both models. The 52-point average of the mean absolute error (MAE) and Pearson correlation (PC) between the measured and estimated VF threshold values of each point were used to evaluate the performance.

Results: The MAE was significantly lower in 3D than 2D models (3.41 vs. 3.73 dB, respectively, $p<0.001$, Wilcoxon Signed-rank test). The PC was slightly better in 3D than 2D models (0.76 vs. 0.71, respectively, $p<0.001$, Williams test for equality of correlations). Figure 1 shows the histogram of VF threshold values in the training set with the MAE results. Both models performed better for VF threshold values between 20 and 35 dB, which were most frequently sampled in our dataset. For values under 20 dB, MAE of the 3D model clearly shows a better trend than that of the 2D model, indicating the model using 3D volumes may have less influence from the floor effects.

Conclusions: 3D model shows better accuracy than the 2D model, indicating the possibility of overcoming the floor effects of OCT measurements, although a relatively large error is present due to the under-represented low threshold sensitivity. Further investigation is needed with additional low threshold data.

ABSTRACT BODY:

Purpose: Deep learning is increasingly used for automating tasks in medicine, such as diagnosis of ophthalmic images. However, most previous approaches to this problem have required the use of time-intensive manual labeling of images. We used self-supervised learning to train a network to extract features from a large number of unlabeled optical coherence tomography (OCT) images, and then used this feature extractor as the backbone of a classification system trained on a small set of labeled images.

Methods: A total of 94,847 OCT volumes from 16,710 patients obtained from University of Washington were used. These were split into an unsupervised training set of 88,834 volumes (15,716 patients), a training set of 4490 volumes (795 patients), and a validation set of 1523 volumes (199 patients). Diagnostic labels were used for the training and validation sets, but not the unsupervised training set. Unsupervised training was done using the DINO framework. The resulting models produced feature vectors from B-scans. The models were then frozen and used to extract features from the labeled training set. Linear regressors were fit on the extracted features to predict age and logMAR, and a k-nearest neighbor (kNN) classifier was fit to diagnose age-related macular degeneration (AMD), diabetic eye disease, and glaucoma (Figure 1).

Results: The OCT-trained network had an R2 of 0.61 for age and 0.32 for LogMAR. Its Average Precisions (AP) for AMD, diabetic eye disease, and glaucoma were 0.87, 0.70, and 0.56, respectively. The age R2 and all three diagnostic scores were higher than for the ImageNet-trained model, and the diagnostic scores for both models were significantly higher than the baseline prevalence (Figure 2).

Conclusions: Here we leverage unlabeled images to perform feature extraction with deep learning and then use a small set of labeled images to train simple algorithms using these features. This approach may be useful for training deep learning models with few labeled examples. Pretraining on ophthalmic images without labels can improve model performance on labeled datasets.

ABSTRACT BODY:

Purpose: Paracrine supportive effects of MSCs are thought to be at least partially accomplished by TNTs which allow direct intercellular communication and cargo transfer. This study aims to demonstrates formation of TNTs between AdMSCs and RPE-1 and their alterations in response to experimental stress conditions.

Methods: Serum starvation and oxidative stress were used as stress conditions to induce TNTs. Texas Red™-X Phalloidin for binding F-actin of tunneling tubes, anti β-tubulin for cell structure, DAPI for nuclei were used for immunofluorosence staining. Scanning electron microscopy (SEM) imaging determined the average thickness of TNTs. CTG (CellTiter-Glo®) assay determined cell survival due to TNTs. Reactive oxygen species (ROS) quantification within the cells group was performed. Fluo-4AM staining was used to determine Ca^{2+} concentrations.

Results: Fluorescence microscopy revealed that TNTs, which are not anchored to the substratum, regularly connect between cultured RPE-1 and AdMSCs in stress environments and contain F-actin but no microtubules. SEM showed the ultrastructure of TNTs were straight connections between cells with a diameter ranging from 35 to 200 nm and a length of up to 120 mm. We observed that RPE-1 have lower cell viability when seeded under stress without AdMSCs than in the group co-cultured ($p=0.0015$). Decreased total ROS production in RPE-1 under stress conditions was observed with coculture ($p=0.017$) and it suggested that TNT-mediated mitochondrial transport may have occurred. In hypoxic condition, TNTs was determined more widely than in serum starvation ($p=0.0001$). Ca^{2+} imaging has been shown that calcium signals are transmitted by intercellular communication via TNTs and increase in stress environments ($p=0.0001$).

Conclusions: Our observations demostrated the signal trafficking via TNTs between RPE-1 and AdMSCs. This communication may support the ability to survive in response to stress conditions. These results can provide a new perspective on stem cell-based therapy in ophthalmologic diseases that may help develop a new strategy to manipulate direct signal, organelle, or molecule transfer for retinal pigment epithelial damage.

ABSTRACT BODY:

Purpose: To investigate the optical coherence tomography (OCT) measured retinal thickness (RT) and best-corrected visual acuity (BCVA) in eyes with different types of astigmatism.

Methods: This retrospective, case-control study was conducted at the Optometry Clinic of Hong Kong Polytechnic University. Subjects were stratified into with-the-rule (WTR), against-the-rule (ATR) and control groups by noncycloplegic subjective refraction. Inclusion criteria were: age between 18-45 years, spherical-equivalent refraction (SE) ≥ -10.00 D, cylindrical power (Cyl) ≤ -0.75 D with cylindrical axes of 0-30°/150-180° for WTR and 60-120° for ATR, and Cyl ≥ -0.25 D for the control group. Those eyes with any ocular disease that may cause retina defect, previous history of ocular surgery, BCVA > 0.1 LogMAR or poor imaging quality were excluded. BCVA were determined with Snellen charts and converted into LogMAR. The fovea-centred 6-mm scan was performed by SD-OCT (Spectralis OCT, Heidelberg), and RT was measured automatically by the inbuilt Heidelberg software, then manually checked and corrected by an experienced operator. Both corneal curvature and SE were used to adjust the magnification factor in OCT imaging.

Results: In total, 101 subjects met the inclusion criteria and only right eyes were analysed (WTR, n=41; ATR, n=25; Controls, n=35). There were no significant differences in age, gender, SE, corneal curvature and intraocular pressure across three groups (all P > 0.05). One-way ANOVA showed a significant difference in both BCVA (P = 0.046) and global RT in 6-mm macula (P = 0.031) among the three groups. Bonferroni's post hoc tests showed that the between-group difference in BCVA (WTR vs Controls, P = 0.041), as well as those differences in RT at inner-nasal (WTR vs ATR, P = 0.034) and outer-temporal (WTR vs Controls, P = 0.042) were statistically significant. BCVA was positively correlated with global RT (r = 0.310, P = 0.002) after adjusting for age, gender, SE, and corneal curvature.

Conclusions: A thicker RT and poorer BCVA were found in eyes with WTR astigmatism in Chinese young adults, compared with the ATR and control groups. Our findings suggest that the effect of astigmatism on ocular morphological and functional characteristics may vary depending on not only magnitude but axes of astigmatism.

ABSTRACT BODY:

Purpose: When fixating a target, small eye movements (drift, microsaccades and tremors) cause the eyes to move. We have devised a novel fixation target (a radial sine wave grating) that, when drifting, recruits optokinetic-like responses. We predict that these drift-induced eye movements will either stabilize (contracting) or destabilize (expanding) fixation.

Methods: Five typical observers with normal vision were asked to fixate four different fixation targets for 90s each in random order. The target was either a radial sine wave luminance grating (3° diameter; 1 cpd; 100% contrast) that contracted (2Hz), expanded (2Hz) or was stationary (0Hz). As a control condition, observers fixated a 'bull's eye and cross hair' target (0.6° outer diameter; 0.2° inner diameter) previously reported to improve fixation performance (Thaler et al. 2013). All stimuli were presented against a 53 cd/m^2 mean luminance grey background. Observers viewed the targets binocularly and eye movements were recorded at 1000Hz from the eye with better acuity. Saccades and blinks were excluded from eye movement traces and a bivariate probability density function of target-relative eye position was calculated. The accuracy and precision of gaze were derived from the 68% isocontour that encompassed the eye position data.

Results: There was a significant main effect of stimulus type on the accuracy of eye position [$F(3,12) = 5.979$, $p = 0.010$, $\eta^2 = 0.599$]. The contracting stimulus resulted in more accurate fixation than the typical bull's eye and crosshair stimulus ($p_{bonf} = 0.009$). There were no other significant differences among the different stimuli for fixation stability. Despite our novel fixation target being larger in diameter, there was no significant change in precision compared to the conventional target.

Conclusions: Our results suggest that our novel contracting concentric fixation targets improve the accuracy of fixation over an extended epoch. The constant level of precision with this target further suggests that functional benefits of fixational eye movements (Tulunay-Keesey, 1960) are preserved. We envision that our novel fixation target may be useful in applications where maintaining gaze over long durations is critical, for example during visual field testing, experiments in vision science, or for individuals with impaired central vision (e.g. age-related macular degeneration) when viewing with an eccentric retinal locus.

ABSTRACT BODY:

Purpose: Modern autorefractors have demonstrated high accuracy and higher repeatability than manifest refraction in adults yet are not considered precise enough to substitute the gold standard, even in low-resource settings where there is a severe shortage of experienced refractionists. This work evaluates a novel approach that combines dynamic wavefront aberrometry data, acquired using an affordable portable autorefractor, with the analysis of retinal image quality metrics (IQMs) to predict subjective refraction.

Methods: 56 subjects (34±14 years) were recruited for the analysis. Each participant underwent standard clinical refraction followed by a 10-second video acquisition using a QuickSee (QS) wavefront aberrometer (PlenOptika, USA). Shack-Hartmann images of each video for the right eye were processed to obtain Zernike coefficients up to the 4^{th} order. Coefficients obtained for each image were mathematically corrected with the closest sphero-cylindrical correction and the residual wavefront error was used to calculate the Point Spread Function (PSF) and IQMs (e.g., Strehl Ratio) describing some performance parameter of the corrected eye. Since each IQM is part of a dynamic sequence, it is possible to build a dynamic signal for each metric which contains information about fluctuations in image quality during the measurement. The final refraction is obtained as the average of the refractions corresponding to the images whose IMQs provided optimal performance.

To assess this method, we compared the results of the QS with those obtained by the new algorithm (using 6 different IQMs, Table 1) against the standard clinical refraction. Figures of merit were mean bias error (MBE), 95% limits of agreement (LOA), mean absolute error (MAE), and the percentages of agreement (0.25 and 0.5D thresholds) between refractions.

Results: The proposed method reduced the differences between QS and manifest refraction. Specifically, for spherical equivalent refraction (M) (Table 1) a 79% average reduction in MBE together with moderate average improvements for MAE (10.3%), LOA (5%), and percentage of agreement within 0.25D (8.8%) and 0.5D (6.3%) were found for all IQMs evaluated.

Conclusions: The proposed algorithm behaves as an efficient filter which selects those measurements within the dynamic sequence that are more representative of the manifest refraction of the patient.

ABSTRACT BODY:

Purpose: Previous evidence suggests that the time for visual recovery after exposure to glare is commonly slowed in age-related macular degeneration (AMD), even among patients with normal visual acuity, varying by age and extent of disease. However, systematic data from epidemiological studies is lacking. We thus set out to assess photoreceptor function and recovery following photostress in a population-based study of individuals aged 70+ (AugUR), to investigate the association of photostress recovery time (PRT) with age and AMD status.

Methods: Presence and severity of AMD was assessed via manual grading of color fundus images applying the Three Continent AMD Consortium Severity Scale. After assessing visual acuity via ETDRS charts in 4m distance, the full macular region was bleached tor 30 seconds via a bright direct ophthalmoscope and PRT was measured as the seconds of the participants' recovery to regain their visual acuity. The participant's AMD status was derived as their most severe eye-specific AMD status (worse eye), PRT was then analyzed for this worse eye, or a random eye if both had the same AMD stage. As cataract can potentially influence PRT, status after cataract surgery was determined via interview-based questionnaire.

Results: Baseline data on AMD status as well as PRT was available for 1391 AugUR participants, aged 70-95 years (mean age 78.3±4.9), 42.5% male. A total of 289 individuals had early (moderate, mild, severe) and 49 had late AMD. PRT ranged from 2 to 239 seconds (mean 94.6±48.1), increased by age and particularly early AMD (Figure 1A,B). Logistic regression adjusted by age and sex revealed a highly significant association of increasing PRT with any AMD (Odds Ratio [OR]=1.091 per 10 seconds, P-value=$3.2*10^{-11}$). The same association was found when focussing on early AMD (OR=1.091, P=$3.0*10^{-10}$), and when only including participants with cataract surgery (n=483; e.g. any AMD: OR=1.088, P=$7.7*10^{-5}$).

Conclusions: PRT is easy to assess, thus potentially applicable broadly in epidemiological studies and worthwhile for further evaluation longitudinally. In addition to providing unique PRT values for an older population, we demonstrate a significant association with particularly early AMD cross-sectionally, indicating the potential of PRT as a functional biomarker.

TITLE: Characterization of refractive error progression in patients with blue cone monochromacy

SESSION TITLE: Quality of Life Outcomes, Rehabilitation and Training Programs

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T.H. Khuu, A.D. Igelman, P. Yang, M.E. Pennesi, Casey Eye Institute, Oregon Health & Science University, Portland, Oregon, UNITED STATES|T.H. Khuu, Elson S. Floyd College of Medicine, Washington State University, Spokane, Washington, UNITED STATES|

Commercial Relationships Disclosure: Thomas Khuu: Commercial Relationship: Code N (No Commercial Relationship) | Austin Igelman: Commercial Relationship: Code N (No Commercial Relationship) | Paul Yang: Commercial Relationship: Code N (No Commercial Relationship) | Mark Pennesi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Blue cone monochromacy (BCM) is associated with a high prevalence of myopia. However, data on the natural history of refractive error in BCM are scarce. The aim of this study is to investigate the refractive error changes in patients with BCM to better characterize its natural progression.

Methods: A retrospective, single-center study of patients with BCM confirmed by genotypic analysis was conducted. Study variables included age, refractive error, and genotype. Refractive error is reported as spherical equivalent of refraction (SER). Patients with at least two SER evaluations measured under 25 years of age and 2 or more years apart were included in the analysis.

Results: Six patients met the study inclusion criteria. The mean patient age ± SD in years at the first and last measurements was 7.00 ± 5.92 (range 0.42–15.00) and 15.50 ± 7.71 (range 7.00–25.00), respectively. The mean SER ± SD at the first and last measurements was -0.58 D ± 7.76 D (range 7.75 D – -13.19 D) and -5.05 D ± 9.61 D (range 3.88 D – -22.94 D), respectively, with an average change in refraction of -4.47 D (range 0.875 D– -9.75 D). Five patients had genotypes consistent with previously described OPN1LW and OPN1MW mutations associated with BCM. One patient had a novel R151T inactivating mutation; this particular mutation demonstrated the highest myopic average SER at the first and last measurements of -13.19 D and -22.94 D, respectively, and the highest average change in refraction of -9.75 D.

Conclusions: Although BCM is commonly associated with myopia, refractive error in this population may vary, with some patients exhibiting hyperopia. However, refractive error generally trended towards increased myopia as patients aged. The R151T variant demonstrated the most severe myopic changes, suggesting that specific genetic mutations may contribute to the degree of myopic progression in BCM.

ABSTRACT BODY:

Purpose: Average retinal sensitivity measured by microperimetry may be a more sensitive measure of disease progression than standard visual acuity in patients with dry age-related macular degeneration (AMD). Several optical coherence tomography (OCT) structural parameters have been associated with decreased retinal sensitivity across all stages of AMD. However, limited longitudinal work has been published to date. This study aimed to evaluate associations between baseline OCT structural parameters and changes in average retinal sensitivity over three years.

Methods: Prospective, longitudinal study. At baseline and 3 years later, AMD patients and controls (>50 years old) were imaged with color-fundus photographs used for AMD staging (Age-Related Eye Disease Study scale) and spectral domain OCT (Spectralis, Heidelberg, Germany). OCT features were graded by two independent graders using a pre-established protocol. MAIA microperimetry (Centervue, Italy) was used to assess retinal sensitivity, using a full-threshold 37-point protocol (10 degrees diameter). Univariable and multivariable mixed-effect linear regression models were utilized for data analysis.

Results: We included data from 43 eyes with AMD and 22 eyes from age-matched controls. A diagnosis of early AMD at baseline was associated with decreased average retinal sensitivity three years later (p=.03). No associations were found between baseline intermediate or late AMD stages and changes in average retinal sensitivity at three years. Accounting for confounding factors, among the baseline OCT features assessed, the presence of ellipsoid disruption was associated with decreased average retinal sensitivity at three years (p= .04, β= -5.33).

Conclusions: Among several OCT features commonly seen in patients with AMD, the presence of ellipsoid zone disruption at baseline was associated with a decrease in average retinal sensitivity at three years. These results support retinal sensitivity measured by MAIA microperimetry as a potentially useful functional measure in the care of patients with AMD. Longitudinal structure/function correlations like these may improve our ability to provide prognostic information in AMD.

TITLE: Long-term results of postoperative viscoelastic installation after trabeculectomy for hypotension management

SESSION TITLE: Surgery & Wound Healing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. von Medem, M. Saeger, B. Noelle, J. Roider, Christian-Albrechts-Universitat zu Kiel Medizinische Fakultat, Kiel, Schleswig-Holstein, GERMANY|

Commercial Relationships Disclosure: Constantin von Medem: Commercial Relationship: Code N (No Commercial Relationship) | Mark Saeger: Commercial Relationship: Code N (No Commercial Relationship) | Bernhard Noelle: Commercial Relationship: Code N (No Commercial Relationship) | Johann Roider: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Anterior chamber viscoelastic installation is a common procedure for postoperative hypotension after trabeculectomy with mytomycin C (TET). It increases the intraocular pressure (IOP) by reducing flow through the scleral flap. However, it could be supposed that this reduced flow within the critical postoperative healing phase could negatively affect the overall outcome. Therefore, we investigated long-term outcomes.

Methods: Retrospective study of 71 eyes with postoperative viscoelastic filling (cohesive viscoelastic, Healon) and 89 eyes (control group) that underwent TET between 2008-2016. We compared Best-Corrected Visual Acuity (BCVA), IOP, number of antiglaucomatous eye drops and the potential need of an additional operation at seven different times (pre-op, post-op, year 1-5). Failing criteria were defined as the occurrence of one or more of the following: IOP greater than 21mmHg, IOP lower than 5 mmHg, less than 20% reduction of the IOP compared to baseline or the need of an additional IOP-lowering intervention.

Results: The average IOP at baseline was 27.3 mmHg in the Healon group and 24.8 mmHg in the control group (p=0.082). One year after TET, the IOP was reduced to 14.1 mmHg in the Healon group and to 15.0 mmHg in the control group (p=0.365). The number of failed TET (see above-mentioned criteria) at year 1 was n=7 (14%) in the Healon group and n=26 (33.8%) in the control group (p=0.013).

At year 5, the mean IOP was 14.3 mmHg in the remaining 15 patients of the Healon group and 14.1 mmHg in the remaining 33 patients in the control group (p=0.868). The number of failures at year 5 was n=3 (20.0%) in the Healon group and n=11 (33.3%) in the control group (p=0.346).

The need of topic antiglaucomatous medication after operation was reduced from 3.0 to 0.6 (year 1) and 1.4 (year 5) in the Healon group and from 3.0 to 1.0 and 1.4 in the control group (p=0.07 year 1, p=0.851 year 5).

Conclusions: This data shows that the postoperative installation of Healon is a safe way to treat hypotension after TET. Also during a 5 year follow-up no significant difference in BCVA, IOP, antiglaucomatous eyedrops and re-operations could be found between the two groups. Additionally, the number of failures defined due to the above mentioned criteria do not show a significant difference between both groups. Based on this data, Healon does not have a negative effect on the long-term outcome of TET.

ABSTRACT BODY:

Purpose: Swept-source optical coherence tomography (SS-OCT) was used to investigate choroidal changes after anti-vascular endothelial growth factor (anti-VEGF) therapy in eyes with exudative age-related macular degeneration (eAMD) that contained three types of macular neovascularization (MNV).

Methods: Treatment-naïve eyes with eAMD undergoing anti-VEGF therapy were included. SS-OCTA images (PLEX® Elite 9000; Carl Zeiss Meditec, Inc, Dublin, CA) were obtained at the first treatment and after anti-VEGF injections. Mean choroidal thickness (MCT) and choroidal vascularity index (CVI) measurements in both 5mm and 11mm foveal centered circles were obtained from the 12X12mm scans. If the choroidal signal was blocked from overlying retinal pigment epithelial detachments (PEDs) or hemorrhage, then these areas were excluded from the CVI measurements. If more than 10% of the 5mm circle region was blocked, then these eyes were excluded from the CVI analysis.

Results: A total of 41 treatment-naïve eAMD eyes from 37 patients were included: 24 eyes with type 1 MNV, 4 eyes with type 2 MNV, and 13 eyes with type 3 MNV. All eyes had two visits that included the day of the first treatment and the first visit after treatment. Seven eyes were excluded from the CVI analysis. For all eyes, the MCT and CVI decreased in both the 5mm and 11mm circles after treatment ($P<0.05$) compared with the first treatment visit. In eyes with both type 1 and type 2 MNV, the decrease in the MCT within the 5mm ($P<0.05$) and 11mm circles ($P<0.05$) were statistically significant, but in eyes with type 3 MNV, the decrease in the 5mm circle MCT was not significant ($P=0.32$), while there was a significant decrease in the 11mm circle after treatment ($P<0.05$).

Conclusions: Due to the decrease in the central MCT observed in eyes with type 1 and type 2 MNV, but not type 3 MNV, we propose that at baseline, the type 1 and type 2 MNV lesions serve as high-volume arteriovenous shunts between the choroidal arterial and venous circulations. Anti-VEGF therapy causes a decrease in exudation and a decrease in flow within the arteriovenous shunt that would exist in any type 1 or type 2 MNV while this type of central choroidal arteriovenous shunt would not exist in the intra-retinal type 3 MNV.

ABSTRACT BODY:
Purpose: To evaluate the safety and efficacy of APP13007 0.05% twice daily (BID) after cataract surgery in a Phase 2 double-masked, placebo-controlled study.
Methods: Subjects with inflammation on the first post-operative day (POD1) following routine, uncomplicated cataract surgery were randomized (1:1) to receive 1 drop of APP13007 0.05% or placebo BID (morning and evening) in the study eye for 21 days. Subjects were evaluated on PODs 4, 8, 15, 22 and 28.
Results: Forty-five (45) male/female subjects (mean age 67.7 yrs, 71.1% females and 73.3% white) were randomized to receive APP13007 (APP) (N=22) or placebo (PBO) (N=23). Subject demographics were comparable between the two groups. Seven (7) subjects discontinued the study before POD22: 1 on APP was withdrawn due to an AE (moderate photophobia and eye pain); 3 on PBO were rescued and 3 on PBO were withdrawn for other reasons.

APP was well-tolerated with a safety profile similar to placebo. There were no treatment-emergent SAEs. The most common AEs were ocular disorders commonly reported after cataract surgery (mild to moderate severity; more frequent in the PBO group). There were no AEs related to IOP elevations, no individual IOP was > 21 mmHg and no IOP elevations were > 10 mmHg while on APP13007.

A higher percent of subjects receiving APP achieved ACC count/Grade = 0 at POD8 sustained through POD22 when compared to PBO. Subjects reporting ocular pain at POD1 had rapid resolution on treatment. When compared to PBO, a higher percent of subjects receiving APP had complete resolution of ocular pain at POD4 sustained through POD22. In addition, visual acuity appeared to improve more rapidly in subjects receiving APP compared to PBO.

Number (%) of Subjects with ACC Count/Grade = 0 at a Visit Sustained to POD22:
POD1 (Baseline): APP = 0; PBO = 0
POD4: APP = 0; PBO = 0
POD8: APP = 7 (31.8%) *; PBO = 1 (4.3%)
POD15: APP = 15 (68.2%) *; PBO = 7 (30.4%)

Number (%) of Subjects with Ocular Pain Grade = 0 at a Visit Sustained to POD22:
POD1 (Baseline): APP = 6 (27.3%); PBO = 6 (26.1%)
POD4: APP = 16 (72.7%); PBO = 11 (47.8%)
POD8: APP = 18 (81.8%); PBO = 13 (56.5%)
POD15: APP = 21 (95.5%) *; PBO = 15 (65.2%)

* $p < 0.05$ (Pearson Chi-Square test)
Conclusions: These data support the development of APP13007 0.05% BID to treat inflammation and pain following ocular surgery.

ABSTRACT BODY:

Purpose: Norrin/Frizzled4 signaling plays an important role in the development of retinal blood vessels, blood-retina barrier (BRB) function, and ultimately retinal function. We recently reported that the antibody-based Norrin mimetic F4L5.13, a novel agonist for Frizzled4 and LRP5, promotes angiogenesis and BRB function in the Tspan12 KO model of impaired Norrin/Frizzled4 signaling. Here, we sought to define the pharmacodynamic effects of the agonist in the presence or absence of vascular malformations, determine if the agonist restores visual function, monitor gene expression responses in multiple retinal cell populations, and determine the duration of its barrier promoting effects after intraperitoneal or intravitreal administration.

Methods: ERG, fluorescein angiography, single cell RNA-sequencing, immuno-staining of vascular endothelial cells, and staining with pimonidazole/hypoxyprobe were performed after F4L5.13 administration to Tspan12 systemic KO mice. In addition, Tspan12 endothelial-cell-specific KO mice (ECKO) were generated by activation of Cdh5-CreERT2 at P28, resulting in a BRB disease model without vascular malformations. Effects of F4L5.13 on BRB function in Tspan12 ECKO mice were monitored longitudinally using fluorescein angiography.

Results: Administration of F4L5.13 from P6-28 fully restored the ERG b-wave in Tspan12 KO mice, restored angiogenesis and BRB function, alleviated hypoxia, and largely restored gene expression profiles in the neuroretina of Tspan12 KO mice. Administration after P28 did not restore the ERG b-wave, revert vascular malformations, or establish normoxia, but it resulted in substantial restoration of BRB function. In adult Tspan12 ECKO mice without vascular malformations, F4L5.13 restored BRB function efficiently, and a single intravitreal injection suppressed BRB phenotypes for 2-4 weeks.

Conclusions: Vascular malformations in Tspan12 KO mice, once developed, cannot be resolved by F4L5.13, yet, the agonist partially promotes BRB function even in the malformed vasculature. When F4L5.13 is administered before vascular malformations have formed, it induces the development of a normal vasculature, restores the ERG, and normalizes gene expression profiles. In the Tspan12 ECKO model of BRB dysfunction without vascular malformations, F4L5.13 demonstrates excellent efficacy in promoting BRB function, even after a single intravitreal injection.

ABSTRACT BODY:

Purpose: Biallelic pathogenic variants in the ABCA4 gene cause a significant proportion of inherited retinal disease worldwide. High allelic heterogeneity partly explains the wide variability in visual outcomes in affected patients. Understanding the pathogenicity of individual alleles is confounded by the co-occurrence on one chromosome of two or more rare variants. Such ‘complex alleles’, due to linkage disequilibrium, often occur in many unrelated probands. Here we explore this phenomenon in a large cohort of molecularly solved and phased probands.

Methods: Patients with genetically confirmed ABCA4-retinopathy seen at a single centre were included. We sought those with 3 or more rare variants; either variants with proven pathogenicity or else rare missense variants, including those scored individually as variants of uncertain pathogenicity (VUP). The reported complex alleles that comprise c.5603A>T, p.(Asn1868Ile) (allele frequency 4%) are the subject of a separate study and not included here.

Results: The full cohort comprised 925 patients. Of these, 106 patients (11.4%) carried 3 protein altering rare variants, and 12 (1.3%) carried 4, such alleles comprising 7% of all disease-associated chromosomes, occurring in 118/925 probands. The most common was c.[1622T>C;3113C>T] (p.[Leu541Pro;Ala1038Val]) accounting for 39 alleles in 36 probands. The allele c.[634C>T;5882G>A] (p.[Arg212Cys;Gly1961Glu]) occurred on 10 alleles of 10 patients of African descent, c.[4222T>C;4918C>T] (p.[Trp1408Arg;Arg1640Trp]) and c.[2588G>C;1715G>A] (p.[Gly863Ala;Arg572Gln]) occurred in 9 and 6 alleles in European patients, respectively, and did not include c.5603T.

Conclusions: Our results show that a significant proportion of patients have complex alleles in which two or more disease-associated variants may be found together. The reporting of such alleles, will help in the scoring of genotypes by clinical labs, reducing those instances in which two variants might be assumed to be in trans, particularly when relatives are unavailable for phasing. The modification of some variants by others occurring in cis will become evident with increasing phased genotypic data from affected patients.

TITLE: Prostanoids are elevated and serve as inflammatory stimuli in diabetes-relevant retinal inflammation in vitro

SESSION TITLE: Cell biology of retinal diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.K. Stark, J. Penn, Pharmacology, Vanderbilt University, Nashville, Tennessee, UNITED STATES|J. Penn, Ophthalmology and Visual Sciences, Vanderbilt University Medical Center, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure: Amy Stark: Commercial Relationship: Code N (No Commercial Relationship) | John Penn: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Evidence since the 1960s indicates retinal inflammation may drive early diabetic retinopathy (DR) progression in a cyclooxygenase (COX)-dependent manner. However, trials of nonsteroidal anti-inflammatory drugs (NSAIDs) as DR treatments have failed largely due to severe cardiovascular and gastrointestinal side effects associated with chronic, broad-spectrum COX inhibition by NSAIDS. Prostanoids, signaling lipids downstream of COX, may offer specific targets for DR therapies that circumvent NSAID side effects. We investigated the prostanoids elevated by DR-relevant inflammation and determined their effects as inflammatory stimuli in select human retinal cells.

Methods: Human Müller cells (hMC) and retinal microvascular endothelial cells (hRMEC) were treated with 1ng/ml IL-1β or control for 24hrs, then media were harvested for mass spectrometry of prostaglandins PGD_2, PGE_2, $PGF_{2\alpha}$, prostacyclin PGI_2, and thromboxane TXA_2. hMC and hRMEC were treated with 1nM-10μM doses of PGE_2, $PGF_{2\alpha}$, or cicaprost (PGI_2 analog) with controls for 6hrs before lysis for qRT-PCR analysis of cytokine or adhesion molecule gene expression.

Results: Mass spectrometry demonstrated increases of 2124% for PGE_2 ($p<0.001$), 615% for $PGF_{2\alpha}$ ($p=0.001$), and 375% for 6-keto-$PGF_{1\alpha}$ (PGI_2 metabolite; $p<0.001$) in IL-1β-treated hMC vs. control. In IL-1β-treated hRMEC, $PGF_{2\alpha}$ increased 288% ($p<0.001$) and 6-keto-$PGF_{1\alpha}$ decreased 66.7% ($p=0.007$) vs. control. 10nM treatments of PGE_2 ($p=0.042$), $PGF_{2\alpha}$($p=0.041$), or cicaprost ($p<0.001$) significantly elevated IL1B expression in hMC. IL6 and CXCL8 also increased dose-dependently. Elevation of ICAM1 in hRMEC was elicited by 1μM $PGF_{2\alpha}$ ($p=0.035$) or 10μM PGE_2 ($p=0.015$), similar for VCAM1 and SELE (E-selectin). Notably, 1μM cicaprost decreased SELE 42.1% ($p=0.035$) while VCAM1 and ICAM1 were not altered.

Conclusions: Our results indicate that IL-1β-induced inflammation of hMC and hRMEC alters the secretion of prostanoids PGE_2, $PGF_{2\alpha}$, and PGI_2. In hMC, stimulation by these prostanoids elevates proinflammatory cytokine gene expression. In hRMEC, PGE_2 and $PGF_{2\alpha}$ elevate gene expression of adhesion molecules, whereas PGI_2 reduces SELE expression, potentially yielding an anti-inflammatory effect. Specific modulation of PGE_2, $PGF_{2\alpha}$, and/or PGI_2 signaling in the retina may be beneficial in slowing early DR progression in a targeted manner, eliminating adverse effects of broad-spectrum COX inhibition.

ABSTRACT BODY:

Purpose: Marfan syndrome (MFS) is a connective tissue disorder with manifestations in the cardiovascular, musculoskeletal and ocular systems. MFS affects approximately 1:3,000 people; it is inherited in autosomal dominant fashion, caused by mutations in the FBN1 gene on chromosome 15. The ocular features consist of lens dislocation, increased axial length, presenile cataract formation, open angle and phacolytic glaucoma, and retinal detachments. The purpose of this study is to evaluate the utility of ultrasound biomicroscopy (UBM) in quantifying lens subluxation and zonular stability.

Methods: We conducted a retrospective review of UBM exams of 8 eyes of 4 patients with MFS aged 21-43 years; diagnosis was confirmed using Ghent II criteria. Eight eyes of 4 age-matched normal patients in our database were measured for comparison. Examinations were performed using Quantel Aviso UBM system with 50 MHz probe. We measured anterior chamber (AC) depth, lens thickness, anterior radius and displacement from the pupil center as well as appearance of the zonules.

Results: Central AC depth averaged 2.59±0.39 mm in MFS versus 2.92±0.38 mm in controls. Lens thickness averaged 4.3±0.6 mm in MFS patients versus 3.9±0.4 for controls and the anterior radius of curvature averaged 6.3±2.1 mm in MFS versus 9.8±1.5 mm in controls. The difference in anterior lens radius from controls was statistically significant (p=.002). The lens was displaced superonasally in 3 eyes, superotemporally in 1 eye and inferotemporally in 2 eyes. There was no displacement in 2 eyes. Zonules were enhanced in all MFS eyes compared to normals, particularly in the quadrant opposite to the direction of lens displacement or herniation.

Conclusions: MFS patients on average showed decreased central AC depth. The lens tended to be greater in thickness than in age-matched controls and its anterior radius was significantly reduced. Ectopia lentis is a diagnostic criterion of MFS and many patients will undergo lens extraction, which may be complicated by weakened zonular support. UBM can be a useful adjunct in evaluating zonular stability and lens size and subluxation.

ABSTRACT BODY:

Purpose: βA3/A1-crystallin (encoded by Cryba1) plays a structural role in the lens but has non-structural functions in the retinal pigment epithelium (RPE). Several isoforms of βA3/A1-crystallin exist, including two peptides (A3 and A1) produced from the same full-length mRNA by leaky ribosomal scanning and a truncated isoform produced from mRNA lacking exon 4. We hypothesize that such isoform plasticity represents a unique mechanism of precise regulation of βA3/A1-crystallin function.

Methods: Phylogenetic analysis of the βA3/A1-crystallin sequence was performed using GeneTree (Ensembl, ENSGT00940000159685). NetPhos3.1 was used for predicting phosphorylation sites. RPE flatmounts and whole lenses (from C57Bl/6J mice) and HPV16 E6/E7 cells were incubated with 100 mg/mL cycloheximide for 3 hours followed by qPCR using Taqman probes designed against different exon junctions of Cryba1 mRNA.

Results: The analysis of the Cryba1 coding sequence (CDS) revealed a CCACC sequence upstream of the second translation initiation site that is used to produce the shorter A1 isoform. This sequence might represent a KOZAK sequence that is “hidden” within the Cryba1 CDS to drive leaky ribosomal scanning. Strikingly, this “hidden” KOZAK translates into threonine residues, which are predicted to be phosphorylated by protein kinase C (PKC, NetPhos score 0.835) and are highly conserved in mammals, except for Marsupials. We also found that the truncated peptide translated from mRNA lacking exon 4 might be produced only to be degraded by nonsense-mediated decay (NMD). Treatment of immortalized mouse RPE cells (but not freshly extracted RPE or lens) with NMD inhibitor cycloheximide, resulted in a reduced proportion of Cryba1 mRNA transcripts that include exon 4, suggesting that NMD may be a primary mechanism involved in shutting down Cryba1 expression as occurs in RPE cell lines.

Conclusions: The finding that the “hidden” KOZAK might not only be responsible for the emerging of a shorter, functionally different A1 isoform but also translates into potentially phosphorylatable threonines may reveal an elegant way to regulate protein function at multiple levels. NMD might offer an additional layer of regulation of Cryba1 expression, however, its mechanism and possible benefits are yet to be studied.

ABSTRACT BODY:

Purpose: Single cell resolution provides insight into a cell's biology. Current methods that provide high throughput isolation of cells are limited to dissociated cells, often at the cost of important morphological features. Thus, methods that allow for the rapid isolation of single cells according to their morphological phenotype are valuable. Previously, our lab successfully isolated and cultured adult retinal ganglion cells (RGCs) from mice and found a wide range of neurite outgrowth capacity. To understand the molecular mechanisms by which certain RGCs inherently regenerate, we have implemented a magnetic microraft array system (QIAscout) to efficiently isolate cells according to morphology.

Methods: Retinas from 6-12-week old transgenic mice expressing tdTomato in Vglut2-Cre+ cells were dissociated and incubated with CD90.2-APC antibody. Cells were sorted using Fluorescence-Activated Cell Sorting (FACS) to isolate RGCs. Following FACS, cells were stained with RBPMS, an RGC-specific marker, to determine purity. Sorted RGCs were seeded onto 96-well plates and onto 200μm^2 microraft arrays, where they were cultured in RGC medium for 7 days. Prior to collection of RGCs, viable cells were stained with Calcein-AM and imaged to identify their distinct morphologies. Each microraft, carrying a single Calcein-AM+/tdTomato+ cell, was extracted using the QIAscout system and subsequently placed in a lysis buffer and stored at -20°C. Images were captured of each raft before, after, and during collection.

Results: FACS collected cells were highly enriched for RGCs, and 99.3% of tdTomato+/APC+ cells were immunolabeled with RBPMS. Additionally, these cells were successfully cultured and showed neurite outgrowth. Using the QIAscout system, viable RGCs were collected at a rate of 1 cell per 3 minutes. Morphologically distinct groups of RGCs were collected according to four general patterns of neurite extension: 1. No neurite outgrowth; 2. Single neurite; 3. Multiple neurites; 4. Complex/branching neurites.

Conclusions: Using the QIAscout system, our lab has successfully collected individually cultured RGCs by their morphological phenotype at an efficient and reproducible rate. Further single cell transcriptomic profiling can be performed on our morphologically distinct populations to provide insight as to why certain cells are more resilient and capable of higher levels of innate neurite outgrowth.

ABSTRACT BODY:

Purpose: Topically administered lubricants are fundamental for treating dry eye syndrome (DES). In this study, the protective mechanism conferred by the Thealoz® Duo eye drops was investigated in dry eye patients by longitudinal clinical examination and, subsequently, the tear proteome changes were characterized employing the mass spectrometry-based proteomics approach.

Methods: A total of 58 participants underwent thorough DES diagnostic steps, namely the ocular surface disease index (OSDI) and, were divided into dry eye (DRY, N=35) and healthy (CTRL, N=23). Only participants in the DRY were subjected to administration of the Thealoz® Duo (hyaluronic acid 0.15% and trehalose 3%). All participants in both groups were scheduled for clinical investigation before the application (day 0, T1) of the Thealoz® Duo and after day 28 ± 4 (T2) and day 56 ± 4 (T3). Descriptive statistical analysis of all the clinical attributes of the participants were investigated. Next, 174 individual tear samples from both groups at three time-points were subjected to proteomics and in-silico bioinformatics analyses.

Results: Application of Thealoz® Duo significantly improved the OSDI score in DRY at T2 vs. T1 ($p=4.1E-3$) and T3 vs. T1 ($p=2.0E-5$) as well as many visual analogue scale parameters. Proteomics analysis resulted in identification of 649 tear proteins (FDR<1%) and 144 were found to be significantly ($p<0.05$) differently abundant between the designated groups. Bioinformatics analysis revealed that in DRY vs. CTRL at T2 due to the usage of the Thealoz® Duo resulted in heightened molecular processes involved in glycolysis ($p=2.3E-5$), cellular homeostasis ($p=2.4E-3$), acute phase response ($p=4.9E-3$), actin cytoskeleton signaling ($p=8.5E-3$) and inhibition of apoptosis ($p=4.1E-4$). The hallmark of this study was that the activated inflammatory process in DRY vs. CTRL at T1 ($p=9.7E-4$) and T2 ($p=8.7E-4$) was inhibited at T3 of Thealoz® Duo use.

Conclusions: In summary, this clinical investigation ascertained that the continual application of Thealoz® Duo significantly improved vision-related functions in DES patients. Notably, for the first time, the proteomics analysis unraveled novel mechanistic changes and expression of specific markers attributed to the efficacy of Thealoz® Duo in breaking the vicious cycle of inflammation and promoting the restoration of homeostasis on the ocular surface of DES patients.

TITLE: Filtering blue light mitigates the deleterious effects induced by the oxidative stress in primary human retinal pigment epithelial cells

SESSION TITLE: AMD - Biochemical and molecular disease mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Abdouh, M. Lu, Y. Chen, A.A. Goyeneche, J.V. Burnier, M.N. Burnier, Research Institute of the McGill University Health Centre, Montreal, Quebec, CANADA|

Commercial Relationships Disclosure: Mohamed Abdouh: Commercial Relationship: Code N (No Commercial Relationship) | Melissa Lu: Commercial Relationship: Code N (No Commercial Relationship) | Yunxi Chen: Commercial Relationship: Code N (No Commercial Relationship) | Alicia Goyeneche: Commercial Relationship: Code N (No Commercial Relationship) | Julia Burnier: Commercial Relationship: Code N (No Commercial Relationship) | Miguel Burnier: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is a major cause of blindness in the elderly population. It is characterized by the loss of central vision due to damaged retinal pigment epithelium (RPE) cells and photoreceptors. Blue Light (BL) exposure was proposed as a risk factor for AMD progression as it triggers RPE cell loss. We undertook this study to determine the effects of BL on the behaviour of RPE cells and their potential mitigation by BL-filtering intraocular lenses (IOL).

Methods: A2E-loaded ARPE-19 cells and human eye-isolated primary RPE cells were exposed or not to BL (400 – 500 nm) under a Solar Simulator (TSS-156R, OAI) set at 100 mW/cm^2, in the absence or presence of either clear ultraviolet (UV)-filtering intraocular lenses (CIOL), or a yellow UV- and BL-filtering IOL (YIOL). RPE cells were analyzed for (i) their oxidative stress by measuring both total cellular and mitochondrial reactive oxygen species (ROS), and (ii) their viability. The involvement of ROS in the cytotoxic effects of BL was investigated following the pre-treatment of RPE cells with the antioxidant N-acetyl cysteine (NAC). All experiments were performed at least 3 times, and data were compared using an ANOVA followed by the Dunnett post-hoc test for multiple comparisons with one control group. A P value < 0.05 was considered statistically significant.

Results: We observed that RPE cells exposure to BL significantly increased the levels of both total cellular ROS ($P < 0.001$) and mitochondrial superoxide anion ($P < 0.001$). While these increases were not affected by placing the CIOL in the BL beam, YIOL decreased the levels of both ROS reservoirs ($P < 0.01$; compared to BL-exposed cells). Increased ROS production induced following BL exposure was accompanied by a significant increase in cell death ($P < 0.001$). Similarly, in contrast to CIOL, YIOL reversed the effects of BL on RPE cell viability ($P < 0.001$). Notably, pre-treatment of cells with NAC abolished the increased cell death, suggesting that the cytotoxic effects of BL on RPE cell were mainly due to increased levels of ROS.

Conclusions: Our data indicate that BL is cytotoxic to RPE cells due to increased oxidative stress. These effects were mitigated by filtering these radiations. The use of BL-filtering devices may represent a strategy to reduce the BL harmful effects on RPE cells and delay the onset of AMD.

ABSTRACT BODY:

Purpose: There is little data characterizing ophthalmic illness among individuals experiencing homelessness, who face health hazards distinct from the general population. We quantified rates of hospitalization for ophthalmic disease and injury among individuals experiencing homelessness in the United States, using the National Inpatient Sample(NIS) database.

Methods: We conducted a retrospective cross-sectional analysis using recent data from the NIS database(2016-2018). This database is the largest all-payor inpatient care database and provides a stratified random sample representing 97% of discharges in the United States. Individuals with primary ophthalmic illness were identified by filtering for those with an ICD-10 code related to disease of the eye or adnexa, excluding diabetic eye disease. Housing status was identified using ICD-10 codes for homelessness. Data analysis was conducted using R software.

Results: The most common diagnoses among homeless individuals hospitalized for ophthalmic disease are: corneal ulcer(16.8%), orbital floor fracture(13.4%), laceration of the eyelid(9.1%), orbital cellulitis(5.9%), and endophthalmitis(2.5%). This distribution differs from the most common diagnoses among the general population. Our results show higher rates of trauma-related diagnoses among homeless individuals(38%) when compared to ophthalmic hospitalizations among the general population(23%). In addition, there is a lower proportion of optic neuritis(7.1% to 1.2%), and diplopia/visual disturbances(9.2% to 2.8%) in the homeless population compared to the general population.

Conclusions: This is the first published data on ophthalmologic illness requiring hospitalization among homeless individuals. Our study shows trauma-related hospitalizations at an increased rate among the homeless population, with lower rates of illness with neurological cause. This is attributable to homeless individuals facing greater risk of trauma and infection. An effective intervention might be the development of education materials and programs teaching causes and signs of eye trauma and infection, to enable prevention and quicker treatment.

TITLE: Scleral Buckle Removal: Long-term Patient Outcomes

SESSION TITLE: Vitreoretinal surgery/VR Interface/PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Patel, A. Shepherd, V. Chaturvedi, Ophthalmology, Rush University Medical Center, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Palak Patel: Commercial Relationship: Code N (No Commercial Relationship) | Annie Shepherd: Commercial Relationship: Code N (No Commercial Relationship) | Vivek Chaturvedi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Scleral buckling has been a successful course of management for repairing primary rhegmatogenous retinal detachments. Occasionally, patients require their removal. While outcomes in this subset of patients have been investigated, there have not been any large patient series to be able to reach any conclusions. Long term sequelae of scleral buckle (SB) removal is debated in the literature, specifically around the risk of re-detachment. We performed a retrospective observational study evaluating the clinical indications for and outcomes following scleral buckle removal.

Methods: A retrospective chart review of 87 patients with history of SB removal between June 1st, 2000 and January 1st, 2021 at a large academic center and associated private retina practice in Chicago, IL was completed. Exclusion criteria included unplanned or self-explanted scleral buckle removal. Primary outcomes measured include patient symptoms prior to SB removal, indications for removal, resolution of symptoms following removal, rate of redetachment, rate of additional ocular surgery, and changes in visual acuity and intraocular pressure. Secondary outcomes will include identifying factors associated with poorer outcomes.

Results: A total of 87 eyes with history of SB removal were included with an average follow-up of 4 years. About 60% were males and the mean age at the time of SB removal was 58 years. The leading indications for removal were exposure (53 eyes, 60.9%), infection (18 eyes, 20.7%), and diplopia/strabismus (17 eyes, 19.5%). The average time from SB placement to removal was 12.1 years (SD ±11.2). Most patients presented with symptoms, specifically of pain and discomfort (57 eyes, 65.5%), diplopia (19 eyes, 21.8%), and drainage/discharge (16 eyes, 18.4%). Of these patients, 92.7% experienced symptom resolution following SB removal. Notably, only 5.75% of all eyes (5 eyes) experienced a re-detachment requiring surgery. Within this subset, the average time from SB placement to removal was 1.87 years (SD ±1.78) and time to re-detachment following removal was 13.0 months (SD ±23.2 months). Nine percent of all eyes required additional strabismus or oculoplastic surgery.

Conclusions: Overall, our review demonstrates that the removal of scleral buckle provides a high rate of symptomatic relief and low risk of subsequent detachment. Nonetheless, close monitoring is warranted to monitor for a recurrent retinal detachment.

ABSTRACT BODY:

Purpose: Patients undergoing intravitreal injections experience pain as the needle courses through the unanaesthetised sclera and choroid. We describe the design, development and in-vivo testing in a rabbit model of a titanium implant that allows for intravitreal injections through the implant to minimize patient discomfort.

Methods: Computer aided design of the novel implant was rendered using Solidworks®. Anodized Grade 5 titanium alloy (TiAl6V) implants were machined by conventional turning of blank rods. The holes and slots were machined using a drill press while the conical end of the implant was created by shaping tool. The implant was hand polished using 500 grit sandpaper followed by 1000 grit sandpaper. Both ex-vivo testing of the implant in enucleated goat's eye as well as in-vivo validation in 4 rabbit eyes was carried out. The implant was placed through the pars plana via a minor surgical procedure and was sutured to the sclera and covered with conjunctiva. Subsequent intravitreal injections were administered under topical anaesthesia with a 30 gauge needle through the implant, thus delivering the drug directly into the vitreous cavity. Repeated intravitreal injections were administered every 2 weeks via the implant for 3 months in 4 rabbits. The implants were removed at 5 months and the scleral wound was sutured. One eye was enucleated for histopathological evaluation.

Results: There was no complication during the implantation. Post-implantation, eye opening of rabbits was normal. Subsequent intravitreals were easy to administer. No efflux was observed during injection. Focal cataract adjacent to the implant was observed in 1 rabbit. Complications such as vitreous haemorrhage, retinal detachment or endophthalmitis were not observed. There was no focal erosion of conjunctiva. Following explantation the sclera and overlying conjunctiva healed well. Histopathological analysis did not reveal any inflammation or necrosis.

Conclusions: The current work shows the successful design and implantation of an intraocular device that can be used repeatedly for painless minimally invasive drug delivery. The in-vivo evaluation of the implant shows promising results for future animal and human studies.

ABSTRACT BODY:

Purpose: 57.5 million people worldwide are affected by glaucoma. However, 50% of those with glaucoma are unaware, and 80% of those identified for follow-up in community screenings (CS) fail to do so. Current standards of visual field testing are usually limited to the clinic. As such, a wearable perimetry headset was used to perform Virtual Reality Visual Field Acuity (VRVFA) examination for suspected visual field loss in the community minimizing exposure to COVID-19 and the need for follow-up.

Methods: 31 subjects from 4 CS were screened by an onsite certified telemedicine reader (CR) who considered family history, visual acuity, intraocular pressures, cup-to-disc ratio, nerve fiber layer defects, and ganglion cell complex captured by non-mydriatic photography and ocular coherence tomography (OCT-B). Cataracts were also graded. Supervised VRVFA testing with a multilingual Palmscan VF2000 Analyzer (Fig.1) was performed in 6 minutes on average. Eyes with fixation losses >20% or false positive/negative ratios >0.375 were excluded. Visual field index (VFI), mean deviation (MD), pattern standard deviation (PSD), and mean sensitivity (MS) from VRVFA were compared to CR glaucoma referral and cataract grading. Descriptive statistics, independent samples t-tests, and Mood's median tests were performed. Subjects with positive findings underwent same-day robotic glaucoma specialist telepresence evaluation.

Results: 37 eyes from 31 subjects met inclusion criteria (mean age 51.42 ± 14.57 years, 56.76% male, 94.59% Hispanic). 7 (18.92%) eyes were referred for glaucoma evaluation. Glaucoma referrals had significantly different VFI (66.86% vs 86.40%, p=0.027), MD (-9.60 vs -4.04, p=0.031), and MS (19.94 vs 26.01, p=0.027) (Fig. 2). 30 (81.08%) eyes were 0-1+ in cataract grading, 5 (13.51%) were 2-3+, and 2 (5.41%) were intra-ocular lenses (IOL); respectively, these subgroups were not significantly different in VFI (84.20% vs 92.80% vs 35.00%, p=0.147), MD (-4.70 vs -2.11 vs -18.41, p=0.147), PSD (3.52 vs 2.25 vs 9.69, p=0.053), or MS (25.38 vs 27.75 vs 9.91, p=0.147) (Fig. 2).

Conclusions: VRVFA testing yielded valuable information on the extent of vision loss as a supportive screening tool for glaucoma congruent with referrals. Expanded testing is needed. Future studies may evaluate VRVFA utility in evaluating other peripheral vision threatening diseases.

ABSTRACT BODY:

Purpose: To evaluate the effect of a systemic multidrug immunosuppressive protocol on the survival and integration of hESC-derived photoreceptor precursor cells (PRPCs) transplanted into the subretinal space (SRS) of normal and degenerated canine retinas.

Methods: Stage 2 retinal organoids (day 104-151 of differentiation) were generated from a CRX-tdTomato reporter line (WA09 CRX+/tdTomato, WiCell, Madison, WI) and dissociated to produce cell suspension containing fluorescent PRPCs for subretinal injection in 7 normal (12 eyes) and 3 mutant (rcd1/PDE6B) dogs (6 eyes) using a modified subretinal injector (RetinaJect, SurModics, CA). Seven dogs were placed under an immunosuppressive (IS) regimen (prednisolone, cyclosporine A, mycophenolate mofetil), 2 dogs were not medicated, and 1 dog had IS halted after 20 weeks. Survival of PRPCs was monitored by non-invasive multimodal imaging including color and fluorescence photography, cSLO (NIR and BAF modes), cross-sectional and en face OCT. Following termination, survival and integration of PRPCs and involvement of innate and adaptive cellular immune responses were assessed by IHC.

Results: In dogs under IS, loss of transplanted donor cells was seen within the first week post-injection (PI) but remaining cells survived up to 20 weeks PI. In normal retinas, most donor cells remained in the SRS, while in degenerated retinas clusters of cells were found to have migrated into the host's ONL and inner retina. IHC analysis showed that most PRPCs expressed cone markers (hCA, M/L opsin) and some formed neurites and pedicle-like structures. In dogs that were not under IS, or that had IS halted, there was a rapid loss of transplanted cells. In these dogs, IHC revealed a mixed inflammatory infiltrate composed mostly of macrophages ($CD18^+$) and resident microglia ($Iba1^+$) and to a lesser extent of helper (CD4+) and cytotoxic (CD8+) T-cells as well as B-cells ($CD20^+$).

Conclusions: Our triple drug IS regimen provided long-term (up to 5 months) survival of xenotransplanted hESC-derived PRPCs into the canine retina. Additionally, our results confirmed that degenerating retinas are more suitable for integration of donor PRPCs.

ABSTRACT BODY:

Purpose: It has been suggested that individuals with a fragmented foveal avascular zone (FAZ) have altered foveal photoreceptor distributions which would impact visual function.[1] Here we sought to compare adaptive optics (AO) corrected visual acuity in individuals with fragmented FAZs to those with normal FAZ morphology.

Methods: We recruited five individuals with fragmented FAZs (2M, 3F; Age range: 12 to 45 years, Avg = 27 years) and 16 individuals with normal FAZ morphology (6M, 10F; Age range: 11 to 67 years, Avg = 28 years). Stimuli (black Snellen E's of varying sizes and orientations) were presented using a custom-built AOSLO (mean illumination wavelength 790nm, mean wavefront sensing wavelength 850nm). Individuals were asked to identify the orientation of each E in a four alternative forced-choice task. The orientation of each E was random, and the gap size of the E was driven by the individual's responses by using two interleaved QUEST procedures. Prior to initiating each measurement block, the AO operator specified the number of E's to be presented (typically 30-40 E's per block). After 7-30 (Average = 13) blocks were performed, a psychometric function was fit to the data (using the Palamedes toolbox in MATLAB). The acuity threshold was defined as the log minimum angle of resolution (logMAR) in arc minutes from the psychometric fit function which corresponded to where individuals responded with the correct orientation for 62.5% of the E's presented. Statistical analyses were performed using GraphPad Prism 9.

Results: The mean logMAR acuity for individuals with fragmented FAZs was -0.21 (0.62 MAR, 20/12.5 Snellen) with a standard deviation of 0.063 (range: -0.29 to -0.13). The mean logMAR acuity for individuals with a normal FAZ was -0.23 (0.59 MAR, 20/12 Snellen) with a standard deviation of 0.054 (range: -0.34 to -0.13). No significant difference in AO-corrected acuity estimates (defined as the psychometric fit threshold) was found between control eyes and eyes with a fragmented FAZ. (unpaired t-test; $p = 0.33$)

Conclusions: AO-corrected acuity measured at the fovea does not appear to differ between individuals with and without fragmented FAZs. Our findings are inconsistent with individuals with fragmented FAZs having altered photoreceptor distributions.

ABSTRACT BODY:

Purpose: A major challenge in the treatment of retinal eye diseases is the delivery of therapeutic agents to the target site. Traditional intravitreal injection is based on the random, passive diffusion of molecules. Topical drug delivery to the retina is an even more complex challenge. The major hurdle for all medication or drug delivery systems is the narrow macromolecular matrix of the different ocular tissues, which act as a barrier and prevent the penetration of particles and drugs. In order to address specific cells or layers of the retina, the use of micro- or nanoparticles from biomaterial research promises targeted, biocompatible and safer applications. Previously published nanopropellers (NPs) that can be actively controlled through the vitreous body to reach the retina present a chance to reach desired targets in the retina. The propulsion takes place through the spiral shape of the magnetic NPs.

Methods: In the present study, the biocompatibility and degradability of the NPs were adjusted by using different chemical materials. The biocompatibility was evaluated with several ocular cells and cell lines, including primary porcine Müller and RPE cells as well as the 661W, Mio-M1, and ARPE-19 cell line. The changes in the chemical composition of the NPs demand a revaluation of the delivery properties. To this end, the magnetic NP function was assessed with the prior mentioned primary cells and cell lines, porcine retinal organ cultures, and eyes. To investigate the propulsion of the NPs, they were labeled with fluorescent agents for imaging and analyzed with confocal microscopy in vitro, ex vivo, and after histological preparation.

Results: Our studies on retinal cells and retinal organ cultures resulted in excellent biocompatibility of the NPs. Furthermore, since the NPs were now formed out of different degradable materials, the time of degradation could be customized. The still-intact propulsion properties were confirmed with OCT and confocal microscopy. The NPs could be controlled to and into the retina or retinal cells. Histological examinations confirmed that only the magnetic NPs arrived at the region of interest.

Conclusions: The biodegradability and the active navigation of the nanopropellers to aimed positions in the retina promise new possibilities for targeted forms of delivery and therapy.

ABSTRACT BODY:

Purpose: The COVID-19 pandemic led to changes in glaucoma care to ensure patient and provider safety. In this qualitative interview study, we aimed to identify changes perceived as improvements in care that have persisted, even following vaccine rollout and uptrending patient volumes after the pandemic's initial surges.

Methods: From July-December 2021, 20 of 45 (44%) NYC glaucoma specialists contacted were interviewed through semi-structured interviews, utilizing a 15 question guide while allowing for exploration of new topics. Interviews were audio-recorded, transcribed, and thematically analyzed with NVivo qualitative software.

Results: Thematic saturation was reached after 15 transcripts. Participants included 12 women and 8 men from 9 institutions, in practice for 6-41 years. When asked to rate the change their practice experienced during the pandemic's first surge on a scale of 1 to 5 (5 being the most change), physicians reported a 4.26 ± 0.94. Certain changes have persisted [Figure 1]. Almost all physicians reported that infection prevention protocols (e.g. hand washing, mask donning) remain and may persist after the pandemic subsides. 9 [45%] reported that increasing the follow-up window for stable patients (e.g. from every 4 months to 6 months) was also a persistent change. While practices initially switched to disposable tools (e.g. tonometer tips, gonioscopy lenses), 9 of 17 [53%] physicians who reported on disposable tools have continued their usage. While disposable tool usage has declined since the first wave [p value=0.003; Figure 2], physicians who continued their usage shared positive views on safety and efficiency. 8 [47%] discontinued their usage, reporting negative sentiments around inaccuracy and waste. Telemedicine was not a persistent change, with only 1 provider continuing to use telemedicine. Reported rationale for discontinuation was the inability to collect data such as intraocular pressure, visual field testing and ophthalmoscopy.

Conclusions: COVID-19 continues to impact glaucoma care. Persistent practice changes include infection prevention, extended follow-up windows and disposable tool usage, while telemedicine has largely been discontinued. As glaucoma care continues to evolve, these changes have lasting implications for continuity of care, patient safety and care delivery.

ABSTRACT BODY:

Purpose: We developed a geographic atrophy (GA) segmentation model for OCT data based on deep learning. One of the main obstacles for clinical application of this automated algorithm is understanding for which specific cases we can expect reliable results and when it is likely to fail. This work proposes an approach to estimate the regional uncertainty of a deep learning segmentation model.

Methods: We generated uncertainty maps for GA segmentation using a model ensemble trained through cross-validation. As each model in the ensemble was trained with different data, observing the variance in results across them can be used to estimate epistemic uncertainty (unseen manifestations). Data augmentation in the test phase simulating different signal level conditions can estimate the aleatoric uncertainty (signal levels the model is unfamiliar with). Analyzing both sources of uncertainty, we generated maps that relate to model confidence. These maps were evaluated by analyzing the segmentation performance at different levels of uncertainty compared to two expert graders (R1 and R2), excluding from the analysis those regions with uncertainty higher than a chosen level (Figure 1).

Results: We processed 180 OCT scans (PLEX® Elite 9000, ZEISS, Dublin, CA) from GA eyes and 45 from non-GA AMD eyes. Regions of segmentation disagreement between the automated method and each grader had significantly higher values of uncertainty (Figure 2A). Automated segmentation accuracy (Dice Index) increased with lower uncertainty thresholds (excluding larger image regions from the analysis) while the comparison between two graders did not improve (Figure 2B), showing the ability of the uncertainty maps to indicate regions where the algorithm was not confident. Choosing a threshold producing a segmentation performance similar to the intergrader agreement (Dice=0.91) deemed as uncertain approximately 6% of the image on average while maintaining detection sensitivity. Uncertain regions corresponded primarily to locations without GA where the algorithm might make a false positive decision (Figure 2C).

Conclusions: We introduce a method to generate uncertainty maps for an automated GA segmentation model. These maps inform about segmentation confidence and can be used as feedback for manual review.

ABSTRACT BODY:

Purpose: Myopia is a significant public health concern because of its rapidly increasing prevalence and the ocular complications associated with myopia progression. Multifocal soft contact lenses (MFCLs) are used for myopia management, but with variable effectiveness, potentially caused by reduced accommodative responses during MFCLs wear (see Kang 2016 and Gong 2017). In this study we investigated the accommodative response in children during early MFCL wear for myopia management and measured the change in refractive error (RE) and axial length (AL) over one year.

Methods: Ten myopic children (mean age 10.8 ± 2.3 yrs; 5Ms/5Fs) with no history of myopia control and normal binocular functions were fit with Biofinity MFCLs with a +2.00 D ADD. MFCLs were worn for at least 10 hrs/d and 5 d/wk. At the beginning of treatment, accommodative responses to 2, 2.5, and 4 D stimuli, were measured monocularly with a Grand Seiko open field autorefractor while the subjects wore the MFCLs. The gains of the accommodative stimulus-response functions were estimated by the slopes of linear regressions fit to each subject's data. Wet autorefraction and AL were measured at baseline, 6 months, and 12 months using a Grand Seiko autorefractor and Lenstar Biometer, respectively.

Results: The mean (± SEM) wet RE was OD –2.94 ± 0.27 D, OS –2.88 ± 0.37 D at baseline and was –3.35 ± 0.38 D and –3.28 ± 0.47 D one year later, respectively. Greater axial elongation caused more myopia progression in both eyes after wearing MFCLs for one year (R^2, OD 0.65 and OS 0.78; $p < 0.01$ for both). Accommodative gain measured during MFCL wear varied at baseline (OD 0.80 ± 0.14, OS 0.90 ± 0.12) and was a significant predictor of myopia progression and axial elongation: Lower accommodative gain during MFCL wear at baseline was correlated with more myopia and greater axial elongation at 1 yr (see fig for details).

Conclusions: These data support the hypothesis that children with higher accommodative gains during MFCL wear experience more ADD power leading to more effective myopia management. To improve the effectiveness of MFCLs for myopia management, we speculate that accommodative biofeedback training during MFCL wear may be helpful (see Wagner 2020).

ABSTRACT BODY:

Purpose: Development of the retina is under precise temporal and spatial regulation. Although it has been observed that the chromatin state changes dynamically during retinal development, how it changes and its relationship with transcriptomics are unclear. Therefore, we aim at applying the latest single-cell multi-omics and spatial transcriptomics tools to gain insights into this complex development process.

Methods: Samples from foveal and peripheral human fetal retina between 10- and 23-weeks gestational age were collected and subjected to single nuclei multiome profiling using the 10X Genomics platform to generate transcriptomic and open chromatin data from the same nuclei. Batch corrected data obtained from all samples were analyzed together to identify cell types and subtypes. Transcription factors (TFs) and gene regulatory networks (GRNs) that correlate with the developmental process were analyzed based on the multiome dataset. Finally, the single-cell spatial developmental maps will be generated using the massively multiplexed single-molecule RNA in situ hybridization (MERFISH) technology.

Results: In total, single nuclei multiome profiling of 280,000 nuclei has been generated from 24 samples of the peripheral and foveal retina. All major cell types and over 30 cell subtypes have been identified in our dataset. Consistent with the idea that cell differentiation starts from the central retina and progresses toward the periphery, delayed development onset of the peripheral retina was clearly observed. Furthermore, based on pseudotime analysis, the trajectory matched well with the established birth order of all cell types. By analyzing cells close to the branch points among trajectory, known and novel TFs, GRNs that correlate with the developmental process were identified. Both concordant and discordant regulations of transcripts and open chromatin were observed, providing insights on different modes of regulatory switch during development. Finally, the generation of a single-cell spatial developmental map of the retina is underway.

Conclusions: Our study produces a spatial-temporal multi-omics map of the human developing retina. Integrative analysis of this multi-omics dataset reveals candidate TFs and GRNs controlling the developmental process. Comparison between transcriptome and open chromatin profiles reveals the complex dynamics of gene regulation between genomic and epigenomics during retinal development.

ABSTRACT BODY:

Purpose: To demonstrate that application of the alpha7 nicotinic acetylcholine receptor selective agonist, PNU-282987, elicits new neurons in a blast damaged retina and recovery of retinal function.

Methods: Ocular blast damage was induced in adult mice (3-8 months old; both sexes) after exposure to a single blast of 35 psi to the left eye. Blast exposed transgenic mice expressing TdTomato Müller glia, were treated daily with an eyedrop solution containing 1mM PNU-282987 post-blast for 4 weeks. Antibody staining studies were performed to study regeneration of new neurons derived from Müller glia and ERGs were obtained each week to examine functional recovery. ERG recordings were obtained from control, blast damaged and mice exposed to blast followed by 4 weeks of PNU-282987 treatment. Recordings were obtained using the Celeris Diagnosis system. Data was analyzed with ANOVA and significant differences were indicated as $P<0.05$. N's between 4-6 were obtained under each condition.

Results: Blast exposure caused a significant loss of cells in all retinal layers after 4 weeks, ranging between 15 and 40% (+/- 8.2) compared to unblasted eyes. Immunohistochemical analysis demonstrated double labeled TdTom positive photoreceptors, bipolar cells, amacrine cells and retinal ganglion cells in blast exposed mice treated with PNU-282987. Scotopic ERG recordings from blast exposed mice had significantly decreased amplitudes in a-waves, b-waves, and oscillatory potentials (OP1,2,3) (between 35 and 47% +/- 6) compared to ERGs obtained from the same mice prior to blast exposure. Significantly decreased amplitudes were also seen from scotopic flicker frequency recordings at 5, 10, 20 and 30 Hz (between 31 and 52% +/-11) following blast exposure. Animals treated with PNU-282987 for 4 weeks after blast showed a significant recovery in a-wave amplitudes by 45% +/-12, in b-waves by 35% +/-11, and in OP1,2 and 3 waves (between 43 to 82% +/-25). Recovery of flicker amplitudes of 5, 10, 20 and 30 Hz were measured between 20 and 48% +/-10 when compared to responses from the same mice under control conditions.

Conclusions: Blast exposure caused a significant loss of cells in all retinal layers and a reduction in ERG waveform amplitudes. After treatment with PNU-282987 for 1 month, newly generated neurons derived from Müller glia were found in all retinal layers, which corresponded with recovery of ERG responses.

ABSTRACT BODY:

Purpose: To study real-world nAMD patients' characteristics in two BROL regimens.

Methods: A retrospective cohort study at Retina Associates of Cleveland, Inc. (extracted on December 1, 2021) analyzed two nAMD groups, BROL alone and BROL alternating with other anti-VEGFs. BROL alone switched from a previous anti-VEGF, had at least 12 months follow-up post switch and at least 3 BROL injections and no other anti-VEGF in first 12 months of treatment post switch. BROL alternating switched from a previous anti-VEGF, had at least 12 months follow-up post switch and at least 3 BROL and 1 other anti-VEGF injection in first 12 months of treatment post switch. Injection intervals, visual acuity (VA), and central macular thickness (CMT) were analyzed at baseline (first BROL injection) and last follow-up, along with follow-up times distribution post first BROL injection. Inflammatory events were reported.

Results: BROL alone identified 172 eyes from 152 patients (53.3% females) with mean±standard deviation (SD) age, VA and CMT of 80.7±7.8 years, 1.14±0.87 logMAR and 300.7±118.1 µm respectively at baseline. BROL alternating identified 56 eyes from 49 patients (65.3% females) with similar baseline mean age, VA and CMT (77.5±9.0 years,1.04±0.75 logMAR and 299.3±91.0 µm respectively).

Alternating eyes had shorter pre-switch intervals (33.2±11.9 days) than BROL alone (48.8±25.8 days), and could extend interval by 8.4±20.5 days at last follow-up compared to 32.7±61.1 days for BROL alone (Table 1). Follow-up time (from first BROL injection) in BROL alternating and BROL alone was 564.3±107.0 days and 552.5 ±104.4 days, respectively. BROL alternating had no inflammatory events, 1.7% of BROL alone eyes did.

Mean change from first BROL injection to last follow-up in VA was a gain and CMT reduction in both groups (Table 1). BROL alone group saw largest CMT reduction (-39.6 µm) compared to alternating group (-28.5 µm) (Table 1), consistent with fluids volume reduction within retinal layers (Table 2).

Conclusions: Both regimens had similar baseline characteristics. Alternating group had history of shorter intervals pre-switch and extended interval by fewer days with at least a year follow-up.

ABSTRACT BODY:

Purpose: While increasing evidence from patients and animal models suggests that early diabetic retinal neurodegeneration may precede the retinal vascular abnormalities that currently define diabetic retinopathy (DR), the underlying pathophysiology and relevant cell types affected in early diabetic retinal disease (DRD) remain poorly understood. In order to identify molecular pathways dysregulated in specific retinal neuronal cell types in early DRD, we performed single-nuclei RNA sequencing of the retina in diabetic mice at two time points following disease onset.

Methods: To induce diabetes, male C57BL/6J mice were treated with five daily intraperitoneal injections of 60mg/kg streptozotocin (STZ) or vehicle. Animals with random glucose >250 mg/dL were considered diabetic and the early retinal phenotype was confirmed at 6 weeks after treatment using optical coherence tomography and dark-adapted electroretinogram. At either 6 or 36 weeks following STZ treatment, retinas from control and diabetic mice (n=8 mice per group per time point) were dissected and separated into two batches for methanol fixation, homogenization, and nuclei preparation. Nuclei were subjected to sequential combinatorial labeling using HiFseq and library sequencing was performed using the Illumina NovaSeq6000 S4 platform.

Results: After preprocessing, we selected cells with >300, <2,000 UMIs (unique molecular identifiers) and <5% mitochondrial counts, then normalized the count matrix in the Seurat package. In total, 18,328 and 3,643 cells were identified at the 6- and 36-week time points, respectively. Unsupervised cell-type annotation analyses yielded 6 clusters representing all retinal neuronal cell types, though relative proportions differed from expected likely due to the use of nuclear rather than whole cell transcripts. The most highly differentially-expressed genes were dysregulated across multiple cell types at the early time point. Integration of gene regulatory networks and our dataset to infer transcription factor activity for each cell suggested unique transcriptional programs at different stages of DRD.

Conclusions: Single-nuclei RNA sequencing of the retina in the STZ-induced diabetes mouse model reveals patterns of gene dysregulation in retinal neurons that may underlie the pathogenesis of early diabetic retinal neurodegeneration and contribute to subsequent progression of DR.

TITLE: Optical coherence tomography imaging quality in patients with retinitis pigmentosa without mydriatic eye drops

SESSION TITLE: Retinal Degenerations, Gene Therapy, Transplantation, and Prostheses

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Mejia-Freire, M. Mateos-Olivares, F.J. Valentín Bravo, S. Pastor, Ophthalmology, Hospital Clinico Universitario de Valladolid, Valladolid, Castilla y León, SPAIN|E.M. Sobas Abad, R. Usategui Martin, J. Pastor, S. Pastor, Instituto de Oftalmobiologia Aplicada, Valladolid, Castilla y León, SPAIN|

Commercial Relationships Disclosure: Santiago Mejia-Freire: Commercial Relationship: Code N (No Commercial Relationship) | Milagros Mateos-Olivares: Commercial Relationship: Code N (No Commercial Relationship) | Francisco Valentín Bravo: Commercial Relationship: Code N (No Commercial Relationship) | Eva Sobas Abad: Commercial Relationship: Code N (No Commercial Relationship) | Ricardo Usategui Martin: Commercial Relationship: Code N (No Commercial Relationship) | Jose-Carlos Pastor: Commercial Relationship: Code N (No Commercial Relationship) | Salvador Pastor: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Many factors influence the acquisition and interpretation of optical coherence tomography (OCT) and OCT angiography (OCT-A) images, including the state of the pupil. The aim of this observational prospective study was to determine the effect of non-mydriasis when obtaining and interpreting the images in patients with retinitis pigmentosa (RP).

Methods: Seventy-six patients with a diagnosis of RP were enrolled and classified by severity, and 30 healthy individuals were used as controls. All of them underwent a complete ophthalmological examination. Zeiss PLEX Elite 5000® High Definition-OCT was used for imaging, which was performed without pharmacological mydriasis. Main measured parameters were vessel (VD) and perfusion density (PD), foveal avascular zone area (FAZ), signal strength, macular and ganglion cell (GCL) layer thickness, presence and type of artifacts found.

Results: Seventy-nine eyes with RP and 60 eyes as controls were analyzed. Statistically significant differences were observed in most OCT-A parameters between both groups, with a reduction in complete VD (-5.98 mm/mm^2; $p<0.001$), and PD (-16.32%; $p<0.001$) and an increase in FAZ (+ 0.11 mm^2; $p<0.001$) which was measured manually in 76 patient images and 21 of controls. Signal strength was significantly lower in the patient group (7.86 ± 1.79 ($p < 0.002$)), as well as in structural OCT images (central macular thickness: -42.88 µm ($p < 0.001$); GCL thickness: -33.18 µm ($p<0.001$)). Artifacts were found in 76 of the 79 patient images (96%) and in 47 of the controls (78%). Projection artifact was the most frequent in both groups. Seventeen images of the patient group and fourteen images of patients with severe RP had between 3 to 4 artifacts ($p <0.001$).

Conclusions: Non-mydriasis is not a limiting factor for a correct acquisition and interpretation of images in patients with a mild-moderate stage of RP, considering that in severe stages pupillary dilation may be necessary to improve the image quality and reduce artifacts, despite increased glare and photophobia in these patients.

TITLE: Gender Disparities in Mental Health and Social Support among Glaucoma Patients during the COVID-19 Pandemic

SESSION TITLE: Glaucoma epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Delavar, J. Bu, B. Radha Saseendrakumar, S. Baxter, Viterbi Family Department of Ophthalmology and Shiley Eye Institute, University of California San Diego, La Jolla, California, UNITED STATES|

Commercial Relationships Disclosure: Arash Delavar: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Bu: Commercial Relationship: Code N (No Commercial Relationship) | Bharanidharan Radha Saseendrakumar: Commercial Relationship: Code N (No Commercial Relationship) | Sally Baxter: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The mental health burden of the COVID-19 pandemic is thought to be substantial. Glaucoma patients are especially vulnerable considering prior reports of higher rates of anxiety and depression than the general population at baseline. In this study, we explore how measures of mental health and social support during the pandemic varied by gender among those diagnosed with glaucoma.

Methods: We obtained a cohort of patients diagnosed with glaucoma (any type) from the NIH All of US Research Program. Answers from the latest COVID-19 Participant Experience (COPE) survey were used. Logistic regression was used to evaluate the association between reported depression (using Patient Health Questionnaire-9 (PHQ-9) scores), stress associated with social distancing, and measures of social support if one became sick with COVID-19 by self-reported gender (male, female, other). Multivariable models were adjusted for age, race/ethnicity, health insurance status, education, and income, with males as the reference group. Observations with missing values for covariates used in the models were dropped.

Results: Of 3,675 glaucoma patients, 56.1% were female, 83.4% were non-Hispanic White, and 95.0% had insurance plans other than Medicaid or none. Many patients had a PHQ-9 score >4 (33.5%), indicating mild, moderate, or severe depression, and 74.4% experienced “a lot” or “some” stress during the pandemic from social distancing. After adjusting for covariates, females were more likely to report depression (OR: 1.40, 95% CI: 1.20-1.62) and stress associated with social distancing (OR: 1.34, 95% CI: 1.14-1.57) than males. Further, females were less likely to report having help if they were sick with COVID-19 and needed someone to prepare meals (OR: 0.78, 95% CI: 0.67-0.92) or help with daily chores (OR: 0.79, 95% CI: 0.67-0.91).

Conclusions: Females with glaucoma were more likely to experience depression, stress due to social distancing, and were less likely to have social support if sick with COVID-19 than their male counterparts. As measures of mental wellbeing and social support are associated with better medication adherence and health outcomes, glaucoma patients identifying as female may represent an especially vulnerable population. Efforts should be made to identify glaucoma patients experiencing hardship during the COVID-19 pandemic.

ABSTRACT BODY:

Purpose: Adipocytes have lipid droplets in their organelles specialized in fat storage. Free fatty-acids (FFAs) are released from lipid droplets to provide energy substrates. Since some FFAs such as docosahexaenoic acid cannot be synthesized de novo in mammals, adipose tissue is indispensable as a long-term depot of these FFAs. Considering that several FFAs have essential roles in retinal homeostasis, we hypothesized that adipocyte deficiency would promote retinal dysfunction and senescence. We investigated this hypothesis in two genetic mouse models where adipocytes are ablated.

Methods: C57BL/6J expressing an inducible diphtheria toxin receptor (Lox-Stop-Lox-ROSA-DTR) and adiponectin-Cre (DTR^{ADQ}) were used. DTR^{ADQ} mice were treated with diphtheria toxin intraperitoneally to eliminate adipocytes selectively. FAT-ATTAC (fat apoptosis through targeted activation of caspase 8) mice were treated with a dimerizer as another model to induce adipocyte apoptosis. Retinal responses were recorded by electroretinogram (ERG) using littermates that received the same treatments as controls. Transmission electron microscopy (TEM) was used to visualize photoreceptor structure. Senescence-associated (SA) β-galactosidase (Gal) staining was utilized to detect senescent cells which produce acid lysosomal β-Gal in retinal tissue.

Results: Both DTR^{ADQ} and FAT-ATTAC lost fat by postnatal adipocyte ablation. Fat-ablated mice demonstrated significantly decreased a- and b-wave amplitudes measured by ERG, indicating that adipocyte ablation induced retinal dysfunction. TEM images revealed that DTR^{ADQ} had sparse outer disc membrane compared to control suggesting an abnormality in outer segment synthesis. Furthermore, disc membranes at the base of photoreceptor outer segments were disorganized by adipocyte ablation. SA β-Gal staining revealed the increased level of β-Gal in the inner segment of photoreceptor in DTR^{ADQ}mice, where lysosome localizes in photoreceptors.

Conclusions: Adipocytes play an essential role in retinal function and photoreceptor disc membrane synthesis. Ablation of adipocytes causes retinal dysfunction as measured by electrophysiology, and induces photoreceptor senescence.

TITLE: Corneal Endothelial Mosaic of the Descemet Membrane Tears (Haab Striae)

SESSION TITLE: Corneal Endothelium

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F.C. Abib, Anatomy, Univerisdade Federal do Paraná, Curitiba, Paraná (PR), BRAZIL| F.C. Abib, Córnea, Clínica de Olhos Prof. Dr. Fernando Abib, Curitiba, Paraná (PR), BRAZIL|

Commercial Relationships Disclosure: Fernando Abib: Commercial Relationship(s);Code P (Patent):Fernando C Abib

ABSTRACT BODY:

Purpose: Otto Haab (1850–1931), Swiss ophthalmologist that contributed with pathological anatomy of the eye, one of than was used to describe tears in the Descemet membrane, thus originated the eponymous Haab striae. The Haab striae are found in congenital glaucoma, trauma as birth injury, contusion, acute hydrops, megalocornea, conical cornea, and with marked AP diameter.

Purpose: to demonstrate the behavior of endothelial mosaic in corneas with Haab striae using contact specular microscopy and compare with normal eye.

Methods: Ten patients with Haab striae: female 6 and male 4, right eye 6 and left 4, age 6 – 54 and mean 27.7±15 years old. BioOptics contact specular microscope and Bambi 2500 software was used.

Haab striae group (HSG) - eyes with Haab striae (central, near of the HS, further of the HS areas); Control group (CG) - contralateral eyes without striae (central area).

The sampling process of the specular microscopy (images and endotelial cells) was guided by the Cells Analyzer software (USA Patent) to obtain a sampling error smaller than 5% for each especular microsocpy exam.

Descriptive cell data from the sample of the endotelial mosaic acquired by specular microscopy exams: image number, total cell number, and calculated sampling error.

Morphometric data of the endothelial cells: endothelial cell density (ECD), coefficient of variation (CV), and percentage of hexagonal cells (HEX).

Descriptive statistics were used to demonstrate endothelial data and the comparison between the studied groups and areas will be compared by the Student t test at 95% significance level.

Results: Endothelial samples: CG: 2.8±1.6 images with 328±169 cells per exam and sampling error 3.12±0.86; HSG: 7.2±2.2 images with 393±90 cells per exame and sampling error 2,87±0.50.

Endothelal data of the studied groups (Figure 1A).

Endothelial mosaic areas compared in eyes with Haab Striae (Figure 1B).

The Figure 2 shows the specular microscopy images of the one of the studied Haab stria due to birth injury.

Conclusions: Haab striae cause continuous and significant loss of endothelial cell density, it's highier at the margins of the Haab striae. The endotelial cell density gradually decreases as it approaches the margins of the Haab striae. Coefficient of variation and percentage of hexagonal cells did not show changes.

ABSTRACT BODY:

Purpose: Acute injury to the retina or choroid can mobilize hematopoietic cells to the sites of injury and vascular repair can be performed by a BM population termed myeloid angiogenic cells (MACs). Hematopoietic cells are derived from the bone marrow (BM) present in both long and flat bones such as the tibia and calvarium, respectively. However, whether this injury-induced mobilization of hematopoietic cells to the damaged eye occurs specifically from one BM source or the other is not known. In this study, we investigated the differential contribution of tibial (long bone) and calvarial (flat bone) BM cells to the areas of injury using the mouse model of choroidal neovascularization (CNV).

Methods: BM-derived hematopoietic cells were isolated from the calvarium of adult Rosa-mTmG mice and from the tibia of adult C57BL/6-EGFP mice to obtain td tomato-fluorescent (td^+) calvarial cells and green-fluorescent (gfp^+) tibial cells, respectively. The BM cells were enriched for hematopoietic stem and progenitor cells using EasySep Mouse Hematopoietic Progenitor Cell Isolation Kit (Stemcell Technologies). Adoptive transfer of cells ($1x10^5$) was performed in C57BL/6J wild type. Recipient mice were then subjected to laser photocoagulation in one eye to induce CNV. Uninjured eyes were used as control. Mice were euthanized 24 hours post-injury and their rpe/choroids were harvested for flow cytometry.

Results: CNV resulted in a significant increase in total $CD45^+$ hematopoietic cells in the choroid compared to untreated eyes (0.7% vs. 0.43%, p=0.0143). We observed that the injured choroid recruited more gfp^+ (tibial) monocytes compared to td^+ (calvarial) monocytes (0.36% vs. 0.039%, p=0.0022). However, there were more td^+ neutrophils (0.867% vs 0.1179%, p=0.029) compared to gfp^+ neutrophils in the injured choroid. The injured choroid recruited more td^+ MACs compared to gfp^+ MACs (0.80% vs. 0.01310%, p=0.0022). There was no significant difference in the contribution of tibial or calvarial cells to macrophages 24 hours after CNV injury.

Conclusions: Our study supports dynamic recruitment of hematopoietic cells into the rpe/choroid during acute injury. Our data suggests that mobilization of cells from the hematopoietic system into the injured rpe/choroid is not homogenous. Calvarial marrow cells may provide the optimal source of cells for generating vascular reparative cells in vivo.

TITLE: Visual field score decline in eyes with untreated diabetic retinopathy: historical data from the Diabetic Retinopathy Study (DRS) randomized clinical trial

SESSION TITLE: Diabetic retinopathy epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Vitale, D. Lee, E. Agron, T.D. Keenan, E.Y. Chew, Division of Epidemiology and Clinical Applications, National Eye Institute, National Institutes of Health, Bethesda, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Susan Vitale: Commercial Relationship: Code N (No Commercial Relationship) | Debora Lee: Commercial Relationship: Code N (No Commercial Relationship) | Elvira Agron: Commercial Relationship: Code N (No Commercial Relationship) | Tiarnan Keenan: Commercial Relationship: Code N (No Commercial Relationship) | Emily Chew: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Recent studies have shown visual field (VF) loss to be greater in eyes treated with pan-retinal photocoagulation (PRP) than in those treated with anti-VEGF for proliferative diabetic retinopathy (PDR); reasons for VF loss in eyes treated with anti-VEGF are yet unknown. To better understand VF loss that occurs after various PDR treatments, studying VF changes in untreated eyes may be helpful. However, after establishment of PRP as standard of care, eyes with PDR are rarely left untreated. This study used data from the Diabetic Retinopathy Study (DRS) to investigate the natural history of VF changes in untreated eyes with nonproliferative diabetic retinopathy (NPDR) or PDR.

Methods: The DRS (1971-1979) was a randomized clinical trial evaluating the efficacy of PRP in persons with PDR in ≥ 1 eye or severe NPDR in both eyes. Participants had one eye randomized to PRP; the fellow eye was assigned to deferred treatment. VF data (Goldmann perimetry, IV4e test stimulus) were collected at baseline, 4 months, and then annually until 6 yrs. VF score was the sum of 12 meridian scores (for each meridian, peripheral extent of the field in degrees minus width of any scotomas). VF scores were analyzed over time among untreated eyes and for the paired difference between (argon)PRP-treated and fellow untreated eyes. Eyes that developed PDR with high-risk characteristics (HRC) in the deferral arm were treated with PRP and subsequently censored in the analyses.

Results: 1660 eyes (18% NPDR, 40% PDR/HRC) of 830 persons (44% female, age 43±14y) were included. Baseline VF score was 729±80. Among untreated eyes, VF score declined 30 /yr (95% CI, -35, -26) after adjustment for age, sex, and baseline PDR status and VF score. Difference in VF score between treated and untreated eyes was negative at 4 months, 1 yr, and 2 yrs (-32, -22, -20, $p<.001$ for all) (i.e., PRP-treated eyes had significantly lower VF scores than untreated eyes). After yr 3, differences were not statistically significant (yrs 3 through 6: 0.5, 11.4, 32.9, 18.4; p-values .96, .31, .05, .68).

Conclusions: VF scores declined significantly in untreated eyes in the DRS, suggesting VF loss progresses over the natural history of PDR. VF loss was initially greater after PRP than in untreated eyes, but this difference diminished after yr 3.

TITLE: Role of non-canonical Wnt signaling in Retinal Ganglion Cell (RGC) neurite growth and optic nerve regeneration

SESSION TITLE: Retinal ganglion cells

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Musada, T. Carmy-Bennun, G. Dvoriantchikova, D. Ivanov, A. Hackam, Bascom Palmer Eye Institute, University of Miami Miller School of Medicine, Miami, Florida, UNITED STATES|

Commercial Relationships Disclosure: Ganeswara Rao Musada: Commercial Relationship: Code N (No Commercial Relationship) | Tal Carmy-Bennun: Commercial Relationship: Code N (No Commercial Relationship) | Galina Dvoriantchikova: Commercial Relationship: Code N (No Commercial Relationship) | Dmitry Ivanov: Commercial Relationship: Code N (No Commercial Relationship) | Abigail Shoshana Hackam: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A primary challenge during optic neuropathies is to promote Retinal Ganglion Cell (RGC) survival and axon growth during or after axon degeneration. Although the role of canonical Wnt ligands such as Wnt3a was studied in RGC axon regeneration, the effect of non-canonical Wnt ligands such as Wnt5a on RGC protection and axon growth and regeneration was not analyzed. In the current study, we explored the role of Wnt5a in RGC protection and optic nerve regeneration in a mouse model of traumatic optic neuropathy.

Methods: Primary RGC cultures were treated with different concentrations of recombinant Wnt5a to identify its effect on RGC neurite growth and complexity. Optic nerve crush mouse model was used to identify the effect of intravitreal injections of Wnt5a on RGC protection and optic nerve regeneration after 2 weeks of injury. Western blots and IHC were performed with Wnt5a intravitreally injected retinal lysates and retinal sections respectively, to identify the induced signaling mechanisms in retinal cells. PERG was used for the functional assessment of RGC.

Results: Primary RGCs treated with 20ng (Average neurite length (ANL); 138±11.6 mean±SD, $p=0.0003$), 50ng (ANL; 236.5±11.9, $p<0.0001$) and 100ng (ANL; 407.6±29.5, $p<0.0001$) concentration of Wnt5a protein showed significantly increased average neurite length and neurite complexity compared to BSA treated RGCs (ANL; 35.16±2.63). The optic nerve sections also showed significant increase in axon length and axon number in Wnt5a injected eyes compared to saline injected eyes. The western blots showed a significant increase in phosphorylation of CamKII ($p<0.0001$), phosphorylation of JNK ($p=0.0007$) and phosphorylation of STAT3 ($p<0.0001$) in Wnt5a 20ng and 50ng injected eyes in comparison with PBS injected eyes. The IHC of retinal sections identified the activation of CamKII and JNK in RGCs.

Conclusions: For the first time, this study identified Wnt5a, a non-canonical Wnt ligand as a regulator of RGC protection, neurite growth and optic nerve regeneration. The induced CamKII and JNK/STAT3 signaling mechanisms in RGC and other retinal cells such as Muller glia by Wnt5a could be responsible for RGC protection and optic nerve regeneration. This study identifies the importance of Wnt5a and non-canonical Wnt signaling mechanisms to induce RGC protection and RGC axon regeneration that could be useful as therapeutic targets.

TITLE: Treatment of Ocular Infections: Consideration for Antibiotic Drug-Drug Interactions

SESSION TITLE: Anti inflammatory agents, antibiotics and antivirals

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Wozniak, W. Johnson, E. Dunster, Ophthalmology, University of Rochester, Rochester, New York, UNITED STATES|

Commercial Relationships Disclosure: Rachel Wozniak: Commercial Relationship: Code N (No Commercial Relationship) | William Johnson: Commercial Relationship: Code N (No Commercial Relationship) | Elianna Dunster: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In the treatment of ocular infections such as conjunctivitis, keratitis and endophthalmitis, it is common practice to use more than one antibiotic to achieve broad spectrum coverage as well as overcome circulating antibiotic resistance. However, there is the potential for individual compounds to either potentiate or antagonize one another with respect to antimicrobial efficacy when used in combination. Thus, we studied drug-drug interactions using a suite of common ophthalmic antibiotics to aid clinicians in selecting appropriate combination therapies.

Methods: Using standard in vitro microbiologic growth conditions, we measured the minimum inhibitory concentrations (MICs) of 8 ophthalmic antibiotics (vancomycin, tobramycin, gentamicin, moxifloxacin, polymyxin B/trimethoprim, ceftazidime, cefazoline and erythromycin) towards Gram-positive Staphylococcus aureus and Gram-negative Pseudomonas aeruginosa. Next, each drug was systematically tested in combination with each other using standard checkerboard Fractional Inhibitory Concentration (FIC) testing. The formula: [(MIC Drug A in combination/MIC Drug A alone) + (MIC Drug B in combination/MIC Drug B alone) = FICI] was used to classify drug-drug interactions as antagonistic (FICI>4), indifferent (FICI=1-4), additive (FIC=0.5-1) or synergistic (FIC<0.5).

Results: 56 combinations were evaluated for drug-drug interactions (28 in S. aureus and 28 in P. aeruginosa). Towards S. aureus, 19 combinations were indifferent (efficacy was similar alone or in combination). However, 8 combinations demonstrated additive activity (improved efficacy in combination), and 1 displayed synergistic activity (improved activity beyond what may be expected). Similarly, against P. aeruginosa, 20 combinations proved indifferent, 7 were additive and 1 was synergistic. No antibiotic drug combinations were found to be antagonistic towards either S. aureus or P. aeruginosa.

Conclusions: Drug-drug interactions are well known in medicine yet have not been specifically studied with a relevant set of ophthalmic antibiotics. Our data suggest that while the majority of ophthalmic antibiotics had no change in efficacy when used alone vs in combination, there were combinations that displayed improved antimicrobial efficacy. These combinations may represent an improved treatment modality for ocular infections.

ABSTRACT BODY:

Purpose: Regulatory $FoxP3^+$ T cells (Tregs) are critical in maintaining corneal allograft tolerance. The highly vascularized inflammatory microenvironment in corneal transplantation adversely affects the suppressive function of Tregs. Emerging evidence indicates the functional crosstalk between $CD11b^+Gr\text{-}1^+$ myeloid-derived suppressor cells (MDSCs) and Tregs, but little is known about the impact of $CD11b^+Gr\text{-}1^+$ MDSCs on the rescue of inflammation-induced Treg dysregulation. The purpose of this study is to determine the rescue effect of $CD11b^+Gr\text{-}1^+$ MDSCs on IL-6-mediated Treg dysregulation, and to further elucidate the underlying mechanism by which this rescue occurs.

Methods: BALB/c bone marrow cells were cultured in complete RPMI medium in the presence of IL-6 (20ng/ml) and GM-CSF (20ng/ml) for 4 days to differentiate MDSCs. $CD4^+CD25^+$ Tregs ($2.5x10^5$) were co-cultured either with $CD11b^+Gr\text{-}1^+$ MDSCs or with $CD11b^+$ cells at a ratio of 1:1 in the absence or presence of IL-6 (40ng/ml) for 48 hours. IL-10 knockdown (KD) $CD11b^+Gr\text{-}1^+$ MDSCs were generated by IL-10 siRNA (10nM) transfection for 6 hours prior to co-culture with Tregs. FoxP3 expression and IL-10 secretion of Tregs were analyzed by flow cytometry and immunoblotting.

Results: Flow cytometric quantification showed Tregs cultured with IL-6 had significantly reduced expression of FoxP3 (12.5±0.3% vs. baseline 15.97±0.6%, p=0.0318) and modestly decreased secretion of IL-10 (5.16±1.2% vs. baseline 10.7±1.9%, p=0.0495) as compared to culture without IL-6. Addition of $CD11b^+$ cells to culture partially preserved FoxP3 expression (18.2±0.3%) and IL-10 production (32.63±12.3%) by Tregs in the presence of IL-6. In contrast, addition of $CD11b^+Gr\text{-}1^+$ MDSCs to culture led to significantly higher FoxP3 (32.93±1.9%, p=0.0035) and IL-10 (60.03±13.3%, p=0.0238) expression by Tregs than addition of $CD11b^+$ cells. Furthermore, Tregs co-cultured with IL-10 KD $CD11b^+Gr\text{-}1^+$ MDSCs exhibited significantly reduced $FoxP3^+$ Tregs (23±1.8%) and IL-10-secreting $FoxP3^+$ Tregs (55.93±4.4%) as compared to those co-cultured with WT $CD11b^+Gr\text{-}1^+$ MDSCs (32.3±2.4% and 82.53±3.4%, respectively, p=0.0403 and p=0.0015, respectively).

Conclusions: Our data show that in vitro generated MDSCs are effective in preventing inflammatory cytokine-induced impairment of Treg function, which can be explored as a novel therapeutic approach in ocular alloimmune disorders, including high risk corneal transplantation.

ABSTRACT BODY:

Purpose: Background: Despite being primarily a respiratory disease, COVID-19 can lead to non-respiratory complications, including myocardial infarction and acute ischemic stroke. Moreover, COVID-19 spike protein (SP) was reported in the retina of deceased patients with COVID-19. Retinal microvascular abnormalities as loss of microvasculature and distinct thinning of the microcapillaries were reported in patients who recovered from COVID-19. We are still in the midst of the COVID-19 pandemic, with more deaths and cases every day. Therefore investigating the impact of COVID-19 on the retinal neurovascular environment and the long-term effect of this virus on vision is of great interest.

Purpose: To study the contribution of COVID-19 SP to retinal inflammation and vascular death.

Methods: Methods: COVID-19 SP, a highly glycosylated protein that allows the virus to penetrate the cell and cause infection, was injected intravitreally in 6-8 weeks global h-ACE2 knock-in mice and wild-type mice. Mice were sacrificed after 14 days, then vascular cell death and inflammation were evaluated by the presence of acellular capillaries and the expression of inflammatory and apoptotic markers. To complement our in-vivo studies, Human Microvascular Endothelial Cells (HMEC) were treated with 100 nM COVID-19 SP for 48 hours. The expression of inflammatory and apoptotic markers was assessed by PCR western blot.

Results: Results: Our results showed that HMEC exposed to COVID-19 SP for 48 hours displayed an increase in inflammatory and apoptotic markers expression including TNF-α, IL-1β, IL-6, and cleaved caspase-3 compared to control conditions. Additionally, COVID-19 SP enhanced the oxidative stress in HMEC, evident by the increase in nitro-tyrosine formation, superoxide dismutase, and NADPH oxidase complex 1 (NOX1 and NOX5) expression. The in-vivo findings came in agreement with our in-vitro studies. We found that intravitreal injection of the COVID-19 SP-induced 1) strong activation of the retinal glial cells, assessed by GFAP radial staining, and 2) increased vascular death, assessed by acellular capillaries formation 14 days after the injection.

Conclusions: Conclusions: Our findings highlight the possible role of COVID-19 SP in inducing retinal inflammation and vascular death. Further studies are required to reveal the impact of COVID-19 SP on visual acuity and the possibility of causing visual impairment using various animal models.

ABSTRACT BODY:

Purpose: Segmentation of regions of nonperfusion (RNP) with an automated algorithm enables detection of these regions by personnel that have not been trained in interpreting OCTA scans.

The procedural, or conventional, algorithm uses vessel binarization and image processing to detect areas without vessels. This algorithm is subject to error in regions with noise or low signal. The alternative algorithm is a convolutional neural network (CNN) that has been trained with OCTA retina projections and OCT reflectance images as inputs and annotations made by expert clinicians as targets.

Methods: The CNN was trained using 60,000 patches obtained from 14 15x15 and 46 12x12 OCTA scans (PLEX® Elite 9000, ZEISS, Dublin, CA) of eyes having significant areas of ischemia, along with expert segmentations of RNPs. 21 scans not used for the training were segmented using the procedural and DL algorithms. Outputs were compared against annotations of these scans made by expert clinicians. Dice coefficients were calculated for each output vs the expert segmentation for each acquisition.

Results: For the 21 scans in the test dataset, the CNN outperformed the procedural algorithm. Undesired segmentation of the FAZ as RNP was reduced but not eliminated in the CNN output, and some regions of low signal were incorrectly segmented. This may be improved by modifying the CNN training dataset and architecture.

Conclusions: A CNN algorithm for segmentation of RNP compares favorably with one based on binarization and thresholding of OCTA scans.

ABSTRACT BODY:

Purpose: Hyalocyte-like cells (HLC), also known as macrophage-like cells, are cells located at the vitreoretinal interface. Recently, HLCs have been imaged in human subjects by averaging several acquisitions of optical coherence tomography (OCT) volumes. In this study, we investigated whether multiple acquisition averaging of OCT volumes could visualize HLCs in patients with epiretinal membranes (ERM).

Methods: Five patients with ERM and three control subjects were recruited for the study. OCT angiography (OCTA) and OCT volumes were simultaneously acquired using the RTVue XR Avanti (Optovue, USA). For each eye, we performed 3x3 mm2 scans at two locations: (1) ~7 degrees temporal to the fovea and (2) ~7 degrees nasal to the fovea. At each location, ten scans were serially acquired for averaging. Rigid followed by non-rigid of the volumes was performed using MATLAB (MathWorks, USA). The B-scans of were then cross-correlated and averaged. OCT volumes were then inspected in ImageJ. A projection of a 3 um slab above the inner limiting membrane (ILM) was used to isolate the HLCs from the underlying retina. Cell counting was performed manually.

Results: Fig. 1A shows a composite image from a control subject's left eye. En face OCTA is shown in red, while the projection of the 3 um slab above the ILM is shown in green. HLC's were numerously observed with a star-shaped appearance and regular spacing (Fig.1B). Fig. 2A shows a composite image from a the right eye of a subject with ERM. The shape of HLCs in ERM eyes appeared more elongated, stretched, and spindle-shaped compared to controls (yellow arrows, Fig. 2B). Additionally, HLCs were far less abundant than in controls (1.92 +/- 1.9 cells/mm2 vs. 50.5 +/- 22 cells/mm2) and irregularly spaced.

Conclusions: Using serial acquisition, image registration, and averaging of OCTA and OCT volumes, we observed HLCs on the surface of ERMs. HLCs were less numerous in patients with ERM than controls and possessed a more elongated, spindle-shaped appearance. Imaging of HLCs with OCT could potentially provide biomarkers for the management of ERMs.

TITLE: Diagnostic Accuracy of Trained Image Graders in Screening for Retinopathy Among Youth with Diabetes

SESSION TITLE: Diabetic Retinopathy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Zhou, Baylor College of Medicine, Houston, Texas, UNITED STATES|L. Eltemsah, L. Prichett, R. Wolf, Department of Pediatrics, Johns Hopkins Medicine, Baltimore, Maryland, UNITED STATES|A. Liu, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|M. Bahrainian, R. Channa, UW Health, University of Wisconsin-Madison, Madison, Wisconsin, UNITED STATES|

ABSTRACT BODY:

Purpose: There is a growing prevalence of diabetes mellitus in the pediatric population, which increases the importance of regular screening for complications such as diabetic retinopathy (DR). The use of digital fundus photography and trained image graders can help increase access to DR screening. Our aim was to assess the diagnostic accuracy of trained image graders (with no prior experience in ophthalmology) in detecting retinopathy from digital fundus photos of pediatric patients with diabetes.

Methods: This cross-sectional analysis compared DR evaluations from two fellowship trained retina specialists and two non-ophthalmologist trained graders. The graders evaluated 90 nonmydriatic fundus photos obtained from pediatric patients with type 1 and type 2 diabetes seen at a multidisciplinary pediatric diabetes center. Trained graders took an online course on DR grading and underwent two hours of training with the retina specialists. A reference standard was determined by agreement between the retina specialists, with discrepancies adjudicated by a third fellowship-trained retina specialist and/or in-person eye exam if there continued to be a question regarding presence of DR. The main outcomes measured were percent agreement with the reference standard, and sensitivity and specificity of detecting DR for trained graders and retina specialists.

Results: Among the 90 patients from whom the retinal images were taken, the average age was 13.8 years old, 52% were non-Hispanic white, 52% were female, and 76% had type 1 diabetes. The prevalence of DR was 13% in this sample. Sensitivity for DR detection varied between 83-91% among trained graders compared to 91-92% for retina specialists. Specificity varied between 67-92% for trained graders compared to 71-83% for retina specialists. Agreement with reference standard varied between 70-91% for trained graders and 74-84% for retina specialists.

Conclusions: After undergoing a standardized training program, trained graders (with no prior experience in ophthalmology) can detect DR with high sensitivity from fundus photos of pediatric patients with diabetes, comparable to that of retina specialists. The use of trained graders in teleretinal screening networks for pediatric diabetes may be a feasible option to improve access to DR screening.

ABSTRACT BODY:

Purpose: Uncorrected Refractive Errors (UREs) is a reversible condition that can be treated with appropriate eyeglasses. UREs affect over 1 billion people globally, with 90% of this population living in low-and-middle-income countries where vision exams can be highly inaccessible due to a shortage of experienced eyecare professionals. This work aims to assess if a machine learning (ML) approach, when applied to data obtained with an affordable handheld autorefractor, could increase access to clinical-quality subjective refraction (SR) when operated by non-experts.

Methods: Data used for this analysis was obtained from a clinical study performed at Aravind Eye Hospital in Madurai, India, using a low-cost portable wavefront aberrometer, an early prototype of the QuickSee (QS) (PlenOptika, Inc., USA). A total of 669 participants were enrolled with ages ranging between 15 and 70 years (35.2 ± 13.7) and spherical equivalent error between -6.0 D and 3.5 D (-0.7 ± 1.67 D). Four ML regressor models were trained and tested for each power vector M, J0 and J45: random forest (RF), gradient boosting (GB), extreme gradient boosting (XGB), and a custom assembly model (ASB) that averages the predictions of RF, GB, and XGB. Algorithms were trained on a dataset of 1,244 samples using as input features: age, gender, Zernike coefficients up to 5th order, and measurement quality related metrics provided by the autorefractor. A smaller subset of 518 unseen samples was used to test the agreement of the predictions against SR using Bland-Altman analysis, overall prediction error in terms of mean absolute error (MAE) and root mean squared error (RMSE), and the percentage of agreement for 0.25 D and 0.5 D thresholds.

Results: All models improved the agreement with SR compared to the baseline autorefraction, but ASB obtained the best results (Table 1). Bland-Altman analysis showed a decrease in the 95% limits of agreement of ±0.63 D, ±0.14 D, and ±0.08 D for M, J0 and J45, respectively. The wavefront-aberrometry related variables had the biggest impact on the prediction, while demographic and measurement quality-related features showed a heterogeneous but consistent predictive value.

Conclusions: These results suggest that ML is effective for improving precision in predicting patient's SR from objective measurements taken with a low-cost portable device.

TITLE: Spatial distribution of VEGF-A isoforms in macular retinas with or without wet AMD

SESSION TITLE: RPE/choroid pathology: oxidative stress, inflammation and neovascularization

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.T. Demirs, T.R. Vollmer, C.W. Wilson, S. Poor, D.S. Rice, C.L. Grosskreutz, Ophthalmology, Novartis AG, Cambridge, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: John Demirs: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Vollmer: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Wilson: Commercial Relationship: Code N (No Commercial Relationship) | Stephen Poor: Commercial Relationship: Code N (No Commercial Relationship) | Dennis Rice: Commercial Relationship: Code N (No Commercial Relationship) | Cynthia Grosskreutz: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Recent innovations in in-situ hybridization technologies allows for the distinction between alternatively spliced transcripts of the same gene. VEGF-A is a driving force in choroidal neovascularization and promotes new vessel growth into the sub-retinal and sub-RPE space, but it is unclear if the spatial distribution or expression levels of specific VEGF-A isoform transcripts are a major contributor to pathogenesis. Here, we evaluated the gene expression and distribution of three VEGF-A isoforms (VEGF-A 121, VEGF-A 165, VEGF-A 189) in cross sections of postmortem eyes using BASEscope technology for any wet AMD-associated alteration in VEGF isoform expression levels and spatial distribution.

Methods: Human postmortem globes were collected (< 6 hours post-mortem) in accordance with the Declaration of Helsinki, fixed and processed. AMD grading was performed on H&E sections. Specificity of BASEscope probes was confirmed by in situ hybridization of Calu6 cells transiently transfected with cDNAs encoding the VEGF-A isoforms. In-situ hybridization of probes against donor tissue was performed to assess VEGF mRNA distribution and expression levels in the posterior regions of eyes from control (n = 10) and wet AMD donors (n = 5). Probes against PPIB and POLR2A were used for normalization of VEGF-A expression. Quantification was performed using HALO software.

Results: After quantitation and normalization, no statistically significant difference in VEGF-A isoform transcript expression was observed in the macular regions of sections from wet AMD donor eyes. The spatial distribution of VEGF-A isoforms, throughout the retina layers, was unchanged in sections from both wet AMD and control donor eyes. Similar results were observed in the peripheral retina.

Conclusions: There was no statistically significant difference in the levels of VEGF isoforms between the two study groups. Confounders for this study are age and treatment history of lesions. VEGF synthesis may be transient and highly focal. Evaluating these lesions posthumously may not fully capture the relevant dynamics of the disease. Alternatively, differential regulation of VEGF isoforms that are involved in wet AMD may not be at the level of transcript, and thus there may be differences in protein levels. Isoform specific antibodies are not well characterized and were not tested in this study.

ABSTRACT BODY:

Purpose: To develop an interpretable statistical model involving optimally selected spectral-domain optical coherence (SD-OCT) imaging biomarkers related to conversion time from non-neovascular to neovascular age-related macular degeneration (AMD)

Methods: The HARBOR dataset, with 686 fellow eyes and time-varying SD-OCT images, was used for this study. Twenty-one drusen imaging features were extracted at each visit.

A multivariable joint model was implemented which consists of two parts fitted jointly- (1) nonparametric mixed effect models using natural cubic splines of ‘time’ and demographic factors to smoothen longitudinal trajectories of standardized imaging biomarkers, (2) a time-to-conversion model with 5 selected single nucleotide polymorphisms (fixed covariates) and smoothened trajectories of the longitudinal biomarkers (time-dependent covariates). For (2), 3 different models were considered: (a) a model with longitudinal biomarker values, (b) rate of changes in biomarker trajectories, (c) and area under trajectory (AUT).

A Bayesian regularized approach was used for selection among the 21 biomarkers in this multivariable model. A variable importance (VI) measure was defined as the probability of being over .25 in the absolute magnitude of the regularized coefficients of longitudinal variables in the standardized scale.

Results: The top drusen biomarkers based on VI for 3 models were as follows (posterior mean, VI):

(a) value: area (.21, .33) and volume (.16, .26) within 3mm of fovea;

(b) rate of change: area within 3mm (-4.2, 1) and 5mm (-1.5, .54), volume within 3mm (5.8, 1) of fovea, total area within the field of view (FOV) (-.28, .5);

(c) AUT: area within 3mm of fovea (.12, .18), mean area in FOV (.08, .13).

Conclusions: High values and high AUT of drusen area and volume within 3mm of the fovea expedite the conversion to neovascular AMD. However, variations in time for area and volume yield opposite interpretations. Low variations in drusen area over time expedite the conversion, whereas high variations in drusen volume do not. Additionally, as the distance from fovea increases, the impact of drusen area and volume dies out as we observe at 5mm distance, where only drusen area has an impact through its variations over time. Lastly, aggregate and mean area in FOV delay the conversion with higher variations and lower AUT, respectively.

ABSTRACT BODY:

Purpose: To compare hypocyanescent lesions on Indocyanine Green Angiography (ICGA) to choriocapillaris flow deficits on Optical Coherence Tomography Angiography (OCTA) in eyes with posterior and panuveitis.

Methods: En-face 6x6 OCTA images of the choriocapillaris and mid-phase ICGA images from patients with posterior and panuveitis were retrospectively reviewed and images were quantitatively compared using ImageJ. Using feature-based image registration, the OCTA image was mapped to the ICGA image. Each lesion was outlined, binarized and then overlapped to determine the Dice similarity coefficient (DSC). Bland-Altman analysis was used to compare measurements of lesion morphology including four primary features: lesion number (LN), lesion density (LD%), lesion circularity (LCi) and mean lesion size (MLS). Lastly, eyes were divided into clinically quiet group and an active group and subgroup comparison of DSC values were conducted.

Results: A total of 36 eyes from 26 patients were analyzed. The overall agreement between lesions from ICG and OCTA was classified as good (mean DSC = 0.744; 95% confidence interval [0.679, 0.809]). No significant differences between the mean LN, LD%, LCi, and MLS were noted. LN and LCi were slightly higher in ICGA compared with OCTA. LD% and MLS were slightly higher on OCTA compared with ICGA. Eyes with active disease (0.642 ± 0.175, n = 12) had a significantly lower DSC compared to those eyes with quiet disease (0.789 ± 0.183, n = 24) (P = 0.028).

Conclusions: OCTA appears to be a reasonably accurate measure of choriocapillaris flow deficits in patients with posterior and panuveitis compared to hypocyanescent lesions on ICGA.

ABSTRACT BODY:

Purpose: Glaucoma has been associated with retinal ganglion cell (RGC) damage and their dysfunction, as well as with thinning of the inner retinal thickness layers; but to the best of our knowledge, no such data is available regarding the involvement of the photoreceptor thickness layer, especially in glaucoma suscepts (GS). The aim is to evaluate the relationships between steady state pattern electroretinogram (ssPERG) with inner and outer retinal layer thicknesses in GS.

Methods: Forty eyes from twenty glaucoma suspects were enrolled in this cross-sectional study conducted at Manhattan Eye Ear Throat Hospital. Subjects underwent comprehensive eye examination, as well as Humphrey visual fields, SD-OCT thickness measurements, and ssPERG testing. Spearman, Pearson, and partial correlation analyses were used.

Results: Spearman's rho analysis showed PERG parameters were significantly correlated with almost all the sectorial retinal thickness measurements ($r_s > 0.352$, $p < 0.03$). As expected, Pearson correlation analysis revealed significant associations between all PERG parameters and the ganglion cell layer (GCL) ($r > 0.352$, $p < 0.041$) and inner plexiform layer (IPL) ($r > 0.356$, $p < 0.039$) thicknesses independently. Additionally, partial correlation showed that Magnitude (Mag) and MagnitudeD (MagD) PERG parameters were significantly and negatively correlated with foveolar outer nuclear layer (ONL) ($r = -0.572$, $p = 0.004$). No other associations between PERG parameters and parafoveal ONL and outer plexiform layer (OPL) were found.

Conclusions: In GS, retinal ganglion cell (RGC) dysfunction, assessed by means of PERG testing, was associated with not only thinning of the ganglion cell layer and inner plexiform layers independently, but also with simultaneous swelling of the foveolar outer nuclear layer demonstrating a possible combined and simultaneous glaucomatous morphological change to the photoreceptors (cone swelling, infiltration of glial cells, and increased extracellular matrix deposition) as well as to the RGCs (reductions in the size of cells, axons, and dendritic tree, apoptosis). More studies are needed to investigate the electrophysiology of the retinal neuronal pathway in glaucoma as well as to determine the possible breakdown of the neurovascular coupling in GS.

ABSTRACT BODY:

Purpose: To describe spectral-domain optical coherence tomography (SD-OCT) morphological features of patients with cone dystrophy and to determine the relationship between these findings and visual acuity.

Methods: Forty-two patients (84 eyes) with the diagnosis of cone dystrophy based on clinical findings and electroretinogram (severely reduced or non-recordable cone response with preserved rod function) were included in our study. SD-OCT imaging was performed and images were evaluated regarding the integrity and pattern of hyper-reflective outer retinal bands and other findings. The relationship between these findings, age, central retinal thickness (CRT), and best-corrected visual acuity (BCVA) was assessed.

Results: SD-OCT images of 82 eyes showed outer retinal abnormalities. Five SD-OCT morphological categories were found (figure 1): Outer retinal atrophy (24.4%), undifferentiated outer retinal layers (22.0%), ellipsoid zone (EZ) disruption (19.5%), outer foveal defect (17.1%), and prominent outer retinal layers (17.1%). Also, five isolated OCT findings were found (figure 2) including, foveal hypoplasia (14.6%), trans-retinal hyperreflective dots (THD) (29.3%), outer plexiform layer (OPL) schisis (11.3%), pseudodrusen (9.8%), and EZ bowing (13.4%). Age and CRT were significantly different across the morphological categories ($p<0.001$). Eyes with prominent outer retinal layers and outer retinal atrophy had the best and worst visual acuity, respectively.

Conclusions: SD-OCT imaging shows extensive morphologic findings in cone dystrophy, which can be utilized to evaluate/diagnose these patients and may serve as predictive biomarkers of visual acuity.

ABSTRACT BODY:

Purpose: Interferon β (IFN-β), a subtype of type I IFNs, has an anti-viral effect as part of a response to viral double-stranded RNA (dsRNA) through the Toll-like receptor (TLR) 3 and retinoic acid-inducible gene I (RIG-I) pathways. We previously evaluated the response of synthetic dsRNA stimulation on immortalized human corneal limbal epithelial (HCLE) and conjunctival epithelial (HCjE) cells and found an increased barrier function in those cells. In this study, we investigated the effect of type I IFNs on ocular-surface barrier function in cultured HCLE and HCJE cells.

Methods: HCLE and HCjE cells were cultured on 12-mm Transwell® inserts (Corning®) and stimulated with 0ng/mL (control) and 0.25, 2.5, and 25ng/mL IFN-β, and transepithelial electrical resistance (TER) was measured before stimulation and every 3 hours up until 24-hours post stimulation. Tight junction [claudin (CL)-1, CL4, and CL7] and glycocalyx [mucin (MUC)-1, MUC4, and MUC16] protein expressions were then evaluated via real-time polymerase chain reaction (PCR), western blotting, and immunohistochemistry examinations.

Results: At 24-hours post stimulation with 2.5 and 25ng/ml IFN-β, a significant TER increase of 25.0% and 34.6%, respectively, in the HCLE cells and 10.9% and 15.0%, respectively, in the HCjE cells was observed compared with that in the control cells ($P<0.05$). The TER increase began at 3 hours post stimulation, and remained up until 24 hours. Post stimulation with 2.5ng/mL IFN-β, real-time PCR ($P<0.05$), western blotting ($P<0.05$), and immunohistochemistry findings revealed increased expression of CL1, CL4, MUC1, MUC4, and MUC16, yet no change of CL7 expression, in both the HCLE and HCjE cells compared with the control cells.

Conclusions: In this study, the evaluation of tight junction and glycocalyx protein expression in HCLE and HCjE cells post stimulation with IFN-β revealed that IFN-β stimulation increased the barrier function of those cells, thus illustrating that it plays a significant beneficial role of promoting an anti-viral effect on the ocular surface.

TITLE: Generation of an inducible, photoreceptor-specific model of oxidative stress in zebrafish

SESSION TITLE: Photoreceptors and disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R.A. Hutto, K.M. Rutter, S.E. Brockerhoff, Biochemistry, University of Washington, Seattle, Washington, UNITED STATES|S.E. Brockerhoff, Opthalmology, University of Washington, Seattle, Washington, UNITED STATES|

Commercial Relationships Disclosure: Rachel Hutto: Commercial Relationship: Code N (No Commercial Relationship) | Kaitlyn Rutter: Commercial Relationship: Code N (No Commercial Relationship) | Susan Brockerhoff: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Oxidative stress is considered a hallmark of aging and is purported to play a role in many retinal diseases. However, many in vivo models of oxidative stress and damage are limited due to systemic effects or a lack of inducibility. This study aimed to generate an inducible zebrafish model of cone photoreceptor-specific oxidative stress using the KillerRed protein, which generates reactive oxygen species when photobleached.

Methods: We injected plasmid containing mitochondrially-targeted KillerRed under the cone gnat2 promoter into embryos to generate Tg(gnat2:mito-KillerRed) zebrafish. For live imaging of cone mitochondria, Tg(gnat2:mito-KillerRed) fish were crossed with Tg(gnat2:mito-TagBFP) fish and stimulated with 561 nm laser.

An optogenetic stimulus array was constructed using 565nm LED Stars, an aluminum heatsink, an LED driver, and a power supply. LEDs were attached to the heatsink in an array to fit under the 12 wells of a standard 48-well plate fitted to 3D-printed housing. Zebrafish larvae were subject to 15 minute intervals of stimulation from 4 to 6 days of age.

Results: Confocal timelapse stimulation of gnat2:mito-KillerRed in fish co-expressing gnat2:mito-BFP shows an induction of cone mitochondrial migration, a previously reported response to mitochondrial stress (FigA). LED stimulation similarly increases the total number of mislocalized mitochondria in gnat2:mito-KillerRed fish relative to control fish lacking KillerRed and unstimulated gnat2:mito-KillerRed fish (FigB). LED stimulation of gnat2:mito-KillerRed fish caused a specific disruption in mitochondrial morphology in cones while normal morphology of photoreceptors and other retinal cells was maintained (FigC).

Conclusions: Our results demonstrate that the Tg(gnat2:mito-KillerRed) zebrafish model can be used as an inducible tool for monitoring photoreceptor responses to mitochondrial oxidative stress. Future work with this model will evaluate its potential for studying chronic oxidative stress as animals age.

ABSTRACT BODY:

Purpose: To describe OCT findings in pediatric uveitis patients and analyze visual acuity changes over time.

Methods: A retrospective chart review of pediatric patients (0 to 18 years old) seen at the Emory Eye Center between 2008 and June 2020 with a diagnosis of uveitis and OCT imaging available was conducted. Data collected included demographic data, uveitis etiology, anatomical uveitis location, best-corrected visual acuity (BCVA), findings on OCT, and treatment.

Results: There were 204 patients and 327 eyes with a diagnosis of pediatric uveitis and at least one OCT on record. The average age was 11.5 years with 57% females (116), 43% Black (87) and 33% Caucasian (68). 137 (67%) patients had bilateral uveitis with the majority, 194 (95%), with a non-infectious etiology. Anatomical location of uveitis was anterior, intermediate, anterior/intermediate, posterior, or panuveitis in 42%, 24%, 9%, 10%, and 15% respectively. At baseline on OCT, there were 222 normal eyes, 19 eyes with an epiretinal membrane (ERM), 53 eyes with macular edema, 14 eyes with both macular edema and ERM, and 19 eyes with subretinal fibrosis. On mixed model analysis controlling for the correlation that exists between eyes of the same subject, the worst initial BCVA was seen in eyes with epiretinal membrane and macular edema, followed by macular edema eyes, subretinal fibrosis, and eyes with an ERM with a logMAR BCVA of 0.95, 0.75, 0.73, and 0.50 respectively ($p<0.0001$). Notably, with most abnormal OCT findings, BCVA improved over 24 months except for ERM eyes, which showed a logMAR BCVA change of 0.50 to 0.60 ($p<0.0001$). In a sub-analysis of patients with macular edema with or without subretinal fluid (SRF), there was no difference between baseline clinical characteristics or BCVA in patients who had SRF.

Conclusions: OCT imaging in pediatric uveitis is important for diagnosis and monitoring progression of sight-threatening complications. Pediatric uveitis cases show a high proportion of bilateral involvement and prevalence of complications leading to worse BCVA, which demonstrates that prompt treatment and continued monitoring via OCT imaging can prevent ocular sequelae leading to blindness.

ABSTRACT BODY:

Purpose: Decrease in retinal vessel diameters (VD) has been well established in glaucoma, but no such relationships were reported in glaucoma suspects (GS) yet. This study hypothesized that decreased VD had a significant relationship with changes in steady-state pattern electroretinography (ss-PERG) and in the ganglion cell layer - inner plexiform layer (GCL-IPL) in GS.

Methods: Thirty-one eyes (20 patients) were enrolled in the study at Manhattan Eye Ear and Throat Hospital, based on normal Humphrey 24-2 visual field test, suspicious optic nerve head, and glaucoma stage 0. Each subject underwent full ophthalmologic examination, optical coherence tomography (OCT), OCT-angiography (OCTA), and ss-PERG. The OCTA images were analyzed in ImageJ. A linear regression analysis was used.

Results: In the linear regression model controlling for age, race, spherical equivalent (SE), and central corneal thickness (CCT), VD explained a 4.7% variance in Magnitude (Mag) ($p = 0.169$), 9.2% variance in MagnitudeD (MagD) ($p = 0.021$), and 16.9% variance in MagD/Mag ratio ($p = 0.009$).

After controlling for age, signal strength, and CCT, the linear regression model with GCL-IPL as the dependent variable found VD significantly associated with the average GCL-IPL (AvGCL-IPL) ($p = 0.006$), minimum GCL-IPL (MinGCL-IPL) ($p = 0.002$), superior sector (S) ($p = 0.007$), superonasal sector (SN) ($p = 0.014$), inferior sector ($p = 0.023$), and inferonasal (IN) sector ($p = 0.014$). In an identical linear regression model, Mag was significantly associated with S ($p = 0.005$), SN ($p = 0.047$), superotemporal (ST) sector ($p = 0.01$), and IN sector ($p = 0.02$). MagD had a significant relationship with AvGCL-IPL ($p = 0.015$), MinGCL-IPL ($p = 0.006$), superior sector ($p = 0.003$), ST ($p = 0.009$), and IN ($p = 0.05$). MagD/Mag ratio was significantly associated with the AvGCL-IPL ($p=0.003$), MinGCL-IPL ($p < 0.001$), and S ($p = 0.046$).

Conclusions: Retinal VD reductions were significantly associated with a decrease in MagD and MagD/Mag ratio as well as with specific GCL-IPL parameters in GS. These findings add evidence to the vascular theory of glaucoma indicating the possible presence of a breakdown of neurovascular coupling in GS, where high demands of retinal ganglion cells in energy are not met by adequate blood supply.

ABSTRACT BODY:

Purpose: To investigate the association between the neutrophil-to-lymphocyte ratio (NLR) and human corneal endothelial cells (CEnCs).

Methods: A total of 307 eyes from 307 subjects who underwent specular microscopy were included. Corneal endothelial cell density (CECD), hexagonality (HEX), central corneal thickness (CCT), coefficient of variation (CV), and cell area were measured using specular microscopy. Whole blood samples were obtained to measure the complete blood cell count. The NLR was calculated, and its relationship with CEnCs was evaluated.

Results: CV was positively correlated with the percentage (%) of neutrophils ($r = 0.120$, $p = 0.037$) and absolute neutrophil count ($r = 0.131$, $p = 0.022$) and negatively correlated with the % of lymphocyte ($r = -0.131$, $p = 0.022$). HEX was correlated with the % of neutrophil ($r = -0.156$, $p = 0.006$), % of lymphocyte ($r = 0.141$, $p = 0.014$), % of basophil ($r = 0.142$, $p = 0.013$), NLR ($r = -0.129$, $p = 0.024$), and the mean corpuscular volume ($r = 0.121$, $p = 0.035$). The prevalence of diabetes did not show a statistically significant correlation with various indicators of corneal endothelial cells.

Conclusions: CV and HEX, which indicate the stability of CEnCs, are associated with NLR in the peripheral blood, suggesting that systemic inflammation and immunity may implicate the pathology of CEnCs. In addition, glycemic control may affect the corneal endothelial cells rather than the presence of diabetes.

ABSTRACT BODY:

Purpose: The increasing myopia prevalence globally is a relatively recent social health problem. Outdoor activity is an evidence-based environmental factor that protects against myopia progression. The purpose of the current study was to study the positive ocular effects of intensive outdoor activity for only 1 week.

Methods: Children aged 10 to 13 years participated in an intensive outdoor activity program, i.e., more than 2hours on the first day, 3 hours on the second day, and 6 hours daily on subsequent days for a total of 6 days during the 2021 summer vacation at the National Akagi Youth Friendship Center. Eye examinations included measurement of the refractive error using the HOYA iTrace Surgical Workstation (Tracey Technologies) and axial length and corneal thickness using swept-source optical coherence tomography (SS-OCT) biometry (IOLMaster700, Carl Zeiss Meditec AG), choroidal thickness using SS-OCT (Xephilio OCT-S1, Canon), tear fluid volume (Schirmer test and strip meniscometry test), and a questionnaire. These parameters were analyzed at the start and end of the program using the paired-t test. Data from the left eyes were analyzed.

Results: Seventeen children (mean±standard deviation age, 12.0±1.0 years; 47.1% female) were included. The baseline and final choroidal thicknesses were, respectively, 359.5±121.7 and 397.4±122.1 μm ($p < 0.001$). The respective central corneal thicknesses also differed significantly, i.e., 579.0±45.6 and 584±44.6 μm ($p < 0.002$). The refractive errors and axial lengths did not differ significantly, -1.69±1.48 diopters (D) vs -1.83±1.87 D ($p = 0.201$) and 24.15±0.97 mm vs 24.15±0.96 mm ($p = 0.463$). The tear fluid volume did not differ significantly between the start and end of the program.

Conclusions: Our results suggested that intensive outdoor activity even for 1 week increased the choroidal thickness in Japanese schoolchildren. Further studies are needed to assess the effects in more subjects and thelong term.

ABSTRACT BODY:

Purpose: A multicohort investigation of the association between physical activity and longitudinal structural thinning in a cohort of early manifest primary open-angle glaucoma and between self-reported physical activity and total macular thickness in a population-based cohort.

Methods: In the discovery phase, 402 participants from the Progression Risk of Glaucoma: RElevant SNPs with Significant Association study wore a tri-axis accelerometer for a continuous seven-day period. Participants were split into tertiles based on the mean number of daily steps. The retrospective rate of Spectral-Domain Optical Coherence Tomography (SD-OCT) macular ganglion cell-inner plexiform layer (mGCIPL) was compared between tertiles. For the replication phase, self-reported exercise data from 29,708 individuals from the UK Biobank were cross-sectionally correlated with total macular thickness using SD-OCT imaging.

Results: Following adjustment for ocular and demographic covariates, the most active tertile was associated with a thicker cross-sectional mGCIPL (multivariate P=0.013) and demonstrated a 0.23µm/year slower rate of mGCIPL thinning (beta: 0.07µm/year/SD 95% CI 0.02-0.12 P=0.004). The most active tertile also exhibited a 2-fold lower risk of Guided Progression Analysis detected event based mGCIPL progression compared to the least active tertile (hazard ratio: 2.01 95% CI: 1.06-3.34; P=0.027). The magnitude of this association strengthened after adjusting for relevant cardiovascular and systemic comorbidities (0.08µm/year/SD 95% CI 0.03-0.13 P=0.003). A secondary analysis of cross-sectional visual fields demonstrated a higher daily step count was also associated with a higher mean deviation (less visual field damage) at time of accelerometer acquisition (beta: 0.24dB/SD 95% CI: 0.05-0.43 P=0.013). Assessment of the UK Biobank cohort revealed a positive correlation between self-reported days per week of exercise and total macular thickness (0.01SD/day 95% CI: 0.005-0.13 P<0.001).

Conclusions: Greater physical activity was associated with both a thicker cross-sectional mGCIPL and slower rate of mGCIPL thinning in primary open-angle glaucoma. Furthermore, greater physical exercise was associated with a thicker total macular thickness in the UK Biobank. These results implicate physical activity as a relevant covariate for neuroretinal degeneration, which may be relevant to glaucoma disease progression.

ABSTRACT BODY:

Purpose: One commonly utilized color vision deficiency test is the Hardy-Rand-Rittler (HRR) Pseudoisochromatic plates; however, its scoring is categorical and has limitations in detecting subtle deficiencies and disease progression. Cone Contrast Threshold (CCT) has demonstrated sensitivity and specificity in identifying color vision deficit with a numerical score. We sought to correlate the categorical results of the HRR test with quantitative CCT test results.

Methods: Patients initially underwent HRR pseudoisochromatic plate and then CCT testing (ColorDx CCT, Konan Medical, Irvine, CA). They were grouped by their HRR score as either “Normal” (n=44) or “Unclassified” red/green deficit (n= 26). Subjects were first tested with 10 screening plates, and if they incorrectly read any HRR screening plate, they were directed to read specific plates to determine severity of deficit. Subjects with “Unclassified” red/green deficits read all severity plates correctly but scored a 9 out of 10 or lower on the screening plates. CCT scoring between “Normal” and “Unclassified” HRR groups were compared using an independent samples t-test. Subjects that were diagnosed with glaucoma, glaucoma suspect, or any retinal pathologies were excluded from analysis.

Results: Normal subjects had significantly higher CCT scores in red (96.25) and green (91.34) testing than Unclassified subjects, who scored 69.11 and 63.11 respectively (Table 1). Lower CCT scores were related to greater deficits in color vision. Subjects with Unclassified HRR test results showed larger standard deviations in red (SD= 45.82) and green (SD= 42.08) sensitivity scores on CCT, compared to subjects with Normal HRR test results in red (SD= 18.00) and green (SD= 19.40) sensitivity scores on CCT.

Conclusions: Subjects with normal HRR scores had significantly different CCT scores than subjects with unclassified HRR scores. Granular numerical scoring with CCT may enable clinicians to monitor subtle changes in patients’ color vision. Further delineation and analysis of “mild, medium, and strong” HRR categories could be made to allow for improved correlation between HRR and CCT scoring.

TITLE: Engineering an affibody to modulate angiogenesis via Ang2/Tie2 signaling pathway

SESSION TITLE: RPE/choroid pathology: oxidative stress, inflammation and neovascularization

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Q. Luong, K. Trempy, A. Galindo, H. Uehara, B.K. Ambati, University of Oregon, University of Oregon, Eugene, OR, US, academic, Eugene, Oregon, UNITED STATES|

Commercial Relationships Disclosure: Quyen Luong: Commercial Relationship: Code N (No Commercial Relationship) | Kieley Trempy: Commercial Relationship: Code N (No Commercial Relationship) | Alycia Galindo: Commercial Relationship: Code N (No Commercial Relationship) | Hironori Uehara: Commercial Relationship: Code N (No Commercial Relationship) | Balamurali Ambati: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Angiopoietin-2 (Ang2) along with VEGF signaling have been implicated in abnormal angiogenesis of ocular diseases, including wet age-related macular degeneration (AMD). Ang2 antagonizes Angiopoietin-1 (Ang1) stabilizing effects while promoting vascular destabilization. Antibody therapies targeting both Ang2 and VEGF lead to reduced vascular permeability with noninferior outcomes compared to anti-VEGF therapy alone. Here, we engineered affibodies, high-affinity proteins that are 10-fold smaller than antibodies, to test the hypothesis that inhibiting the binding of Ang2 to its receptor, Tie2, modulates their interaction and signaling.

Methods: Using yeast surface display, we sorted through a library with 10^8 unique affibody-bearing S. cerevisiae via streptavidin magnetic and fluorescence activated cell sorting (FACS), and identified 20 candidate colonies. Colonies were sequenced, inserted into expressing vector pET-28b+, expressed in BL21(DE)3 E. coli, and purified using Cobalt resin/His-Tag affinity chromatography. The identity of the affibodies were confirmed on protein immunoblot. Binding and inhibitory kinetics of affibodies on the yeast surface and purified affibodies were assessed with FACS and ELISA, respectively. Structure binding were computationally predicted and validated.

Results: DNA sequencing showed distinct sequences for all 20 colonies. Western blot confirmed the successful expression of affibody proteins in E. coli. Out of the 20 candidates, 2 colonies showed high affinity to Ang2 proteins on yeast-surface and ELISA. Colony 2 had high affinity (Kd: 8.2 nM) to Ang2 and partial affinity to Ang1 (Kd: 4.4 nM), with IC50 values equal to 65 and 87 nM in inhibiting Ang1/Tie2 and Ang2/Tie2 interactions, respectively. Colony 4 can bind only to Ang2 (Kd: 12.4 nM), with IC50 value equals to 124 nM. Top docking poses from each program showed points of contact with the active site of Ang2.

Conclusions: We demonstrated the binding and inhibitory effects of affibodies that modulates Ang2/Tie2 interactions on yeast-surface, in ELISA, and in silico, which potentially eliminates the Ang2-antagonism on Ang1 signaling and enhances Ang1 stabilizing effects. These findings will be confirmed on cell cultures and animals. With the ability to prevent Ang2-induced permeability and angiogenesis of AMD, affibody is a potential small therapeutic agent for future treatment of AMD.

ABSTRACT BODY:

Purpose: Objectively evaluate the efficacy of BTA in the treatment of abducens nerve palsy/paresis in 10 patients, analyzing ectoscopy, decrease in diplopia and patient's satisfaction.

Methods: The method consists of applying BTA to the medial rectus muscle, 10 mm away from the limbus, measured with a surgical compass, without opening the conjunctiva, with an insulin syringe and needle.

In eyes with palsy 7 units were applied and in eyes with paresis 5 units were applied.

The medication used was Botox (Allergan,100 U bottle diluted in 2 ml of 0.9% saline solution).

Thirty days after application, results were objectively evaluated and patients were asked about their satisfaction.

Results: Seven had lateral rerctus muscle paresis and three had palsy.

The age of patients ranged from 35 to 70 years (mean 55 years) and 60% were male.

Three patients were diabetic and hypertensive, two were only hypertensive, two had hypercholesterolemia and three had no comorbidities.

At the time of treatment, 4 patients reported having the diagnosis for more than a year, 6 patients sought care within the first 15 days of the disease and were treated with BTA one month after the onset of the condition.

Seven patients had objective improvement of diplopia, five of which had paresis and two had palsy of the medial rectum. After a year of follow-up, only one patient among the seven required a new application of BTA, 6 months after the first, obtaining again a good result. The others continued without diplopia.

Among the 4 patients who performed the BTA application after 1 year of diagnosis, 2 (50%) had improved diplopia and 2 had not. Only 1 patient (25%) was satisfied with the result.

Among the 6 patients with less than three months of evolution, five (83.4%) were satisfied and showed improvement in diplopia and one was dissatisfied (16.6%) and did not show improvement in diplopia.

As for satisfaction with the procedure, the 6 patients who presented paresis said they were satisfied and 4 said they were dissatisfied (one with paresis and three with palsy).

Conclusions: Our results show that the application of TBA was more effective in cases of paresis with 15 days to three months of evolution.

Paresias had a much stronger improvement in diplopia and satisfaction with the treatment, compared to palsies.

The method of injecting BTA without a microscope use or opening the conjunctiva, was simple, safe and effective.

TITLE: A Nonrandomized Phase 2 Trial of EG-Mirotin, a Novel, First-in-class, Subcutaneously Delivered Peptide Drug for Non-Proliferative Diabetic Retinopathy

SESSION TITLE: Diabetic Retinopathy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Lee, Soonchunhyang University Hospital, Yongsan-gu, Seoul, KOREA (THE REPUBLIC OF)|

Commercial Relationships Disclosure: Sung Jin Lee: Commercial Relationship(s);Code C (Consultant/Contractor):EyeGene INC

ABSTRACT BODY:

Purpose: EG-Mirotin, which includes an active ingredient; EGT022, targeting Non-Proliferative Diabetic Retinopathy (NPDR), the early stage of retinopathy. EG-Mirotin is a drug that is used before capillary damage progresses to an irreversible stage. Safety and efficacy of EG-Mirotin were investigated in subjects with Type 1 or 2 diabetes and NPDR with the degree from moderate to severe.

Methods: Subjects (n=10, 20 eyes) satisfying the selection criteria through the screening test were administered EG-Mirotin once a day (3 mg in 1.5 ml of sterile saline) for 5 days, 5 times in total, and were evaluated of the Ischemic index changes and safety. End-of-study (EOS) is performed approximately 8 weeks ± 1 (57 days ± 7) from the first dose.

Results: A total of 4 Treatment Emergent Adverse Events (TEAE) were observed in 2 subjects out of 10 (20.00%) who received the investigational drug. Among them, no subjects were reported experiencing a TEAE related to the investigational drug. All injections were well tolerated (3 mg in 1.5 ml of sterile saline) with no dose-limiting adverse events, deaths, serious adverse events. The overall average percent change in ischemic index at each evaluation point compared to baseline was statistically significant (Greenhouse-Geisser $F=9.456$, $p=0.004$ for the main effect of time), and a larger change was observed when the baseline ischemic index value was high (Greenhouse-Geisser $F=10.946$, $p=0.002$ for the time*group interaction).

Conclusions: EG-Mirotin was well tolerated and found to reverse the ischemia and leakage of capillaries in the retina caused by diabetes.

TITLE: Optical Coherence Tomography Characteristics in Neovascular Age-Related Macular Degeneration with 20/40 or Better Visual Acuity

SESSION TITLE: AMD: Clinical and translational research/AMD therapies (excluding anti-VEGF)

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Ong, B. Nawash, University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania, UNITED STATES|J. Chhablani, Department of Ophthalmology, UPMC, Pittsburgh, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Joshua Ong: Commercial Relationship: Code N (No Commercial Relationship) | Baraa Nawash: Commercial Relationship: Code N (No Commercial Relationship) | Jay Chhablani: Commercial Relationship(s);Code C (Consultant/Contractor):Novartis;Code C (Consultant/Contractor):Abbvie;Code C (Consultant/Contractor):Salutaris

ABSTRACT BODY:

Purpose: Most clinical studies have described imaging characteristics of neovascular age-related macular degeneration (nAMD) with 20/40 or worse visual acuity (VA). Considering the lack of literature on nAMD eyes with 20/40 or better, we aim to describe the OCT characteristics in eyes with this unique presentation at baseline and through 1 year follow-up during anti–vascular endothelial growth factor (anti-VEGF) monotherapy.

Methods: Retrospective study involving nAMD patients with 20/40 or better VA from 2011 to 2021 from a single hospital system. Eyes that had anti-VEGF injections from an outside hospital; previous history of associated ocular disease; or did not have 1 year of follow-up were excluded. Monthly OCTs were analyzed for imaging characteristics such as subretinal fluid (SRF), intraretinal fluid (IRF), subretinal hyperreflective material (SHRM), pigment epithelial detachment (PED), choroidal neovascularization (CNV), central macular thickness (CMT), and subfoveal choroidal thickness. Statistical analysis was conducted for differences through 1 year follow-up.

Results: Forty-nine eyes from 45 patients were included and a total of 331 OCT visits were analyzed. Mean age was 75.4±8.2 years. At baseline, 39 eyes (79.6%) had SRF, 24 eyes (49.0%) had IRF, and 20 eyes (40.8%) had both. CNV location was 33 subfoveal (67.4%), 11 juxtafoveal (22.5%), and 5 extrafoveal (10.2%). A total of 29 eyes (59.1%) had findings of SHRM. PED classification was 32 drusenoid (65.3%), 11 fibrovascular (22.4%), 5 flat irregular (10.2%), 1 serous (2%), and no eyes had hemorrhagic PED. CNV type was 32 mixed (34.7%) and 17 type 1 (65.3%). During the first year of follow-up, mean anti-VEGF injection/year was 6.1±2.7. Mean CNV length at baseline was 1112.0±451.4μm, and at 1 year follow-up was 1132.3 ± 506.9μm (p=0.705). Mean subfoveal choroidal thickness was 156.9±32.9μm at baseline, and at 1 year follow-up was 153.9 ± 32.9μm (p=0.606). Mean CMT was 288.8±54.8μm at baseline, and at 1 year follow-up was 274.32±45.4μm (p=0.199).

Conclusions: Among the eyes with nAMD with 20/40 or better, 1/3rd of the eyes presented with non-subfoveal location of CNV with majority being type 1. There was minimal change in CMT and CNV length during the first year of anti-VEGF monotherapy. Further analysis of the area under the curve for various imaging parameters and correlation with visual outcome is underway.

ABSTRACT BODY:

Purpose: Brain pathology in chronic traumatic encephalopathy (CTE) includes the accumulation of hyperphosphorylated tau (p-tau), as well as TAR DNA binding protein 43 kDa (TDP-43) in late stages. Visual abnormalities including photophobia, visuospatial perception defects, and hallucinations have been described in CTE; however, retinal pathology and its contribution to visual defects in CTE are unknown. In this retrospective study, we examined the retinal histopathology from patients with autopsy-confirmed stage IV CTE.

Methods: Enucleation specimens from 8 control patients (6 males and 2 females; ages 61-81; mean: 69.6; SD: 6.9) and 8 patients with stage IV CTE (8 males; ages 62-93, mean: 77.5, SD: 9.9) were collected. Control patients had no known history of traumatic brain injury and no evidence of CTE at autopsy. CTE patients were former contact sport athletes (football, rugby, or boxing). Pupil-optic nerve cross sections were prepared and stained with hematoxylin and eosin (H&E). Immunohistochemistry was performed using anti-p-tau (AT8, Thermo Fisher; 1:1000), anti-pTDP-43 (Cosmo Bio; 1:1000), and anti-TDP-43 antibodies (Proteintech; 1:6000).

Results: Retinal anatomy including retinal lamina thickness was comparable between CTE and control by H&E. No p-tau pathology was observed in either CTE or normal retinas. pTDP-43 staining was commonly found in CTE retinas (7/8) but rarely seen in controls (1/8). Staining was limited to a small subset of inner nuclear layer (INL) interneurons at the junction between INL and outer plexiform layer. TDP-43 staining also revealed a small subset of INL interneurons with cytoplasmic TDP-43+ inclusions and loss of nuclear TDP-43 expression. The location of these cells in INL is most consistent with retinal horizontal cells. TDP-43 pathology was not identified elsewhere in the retina.

Conclusions: This study identified that stage IV CTE is associated with novel retinal TDP-43 and pTDP-43 neuropathology in a discrete subset of retinal INL interneurons consistent with horizontal cells. Additional studies in larger cohorts are needed to define the role of TDP-43 in normal and diseased horizontal cells. Our findings suggest that abnormalities in horizontal cell functions (e.g., light/dark adaptation, contrast sensitivity) secondary to pTDP-43 accumulation may be possible clinical symptoms in CTE patients.

ABSTRACT BODY:

Purpose: Although the depolarization of iris pigment epithelium (IPE) is one characteristic property in polarization-sensitive optical coherence tomography (PS-OCT) images of the anterior eye segment, it received limited attention and has not been investigated to date. This study aims at exploring quantification standards to assess potential properties of the quasi-IPE region in PS-OCT images.

Methods: This cross-sectional, observational study is based on PS-OCT images from 101 healthy eyes observed under identical environment and machine setting. For the quantitative analysis of depolarization in IPE, we use depolarization metric polarimetric entropy that is known to be associated with density of melanin granules. Three PS-OCT images (intensity, grey-scale entropy, and false-colored entropy) at horizontal cross-section of each eye are shown in Fig. 1.

Scleral Spur (SS) is identified using custom-developed model on the intensity image. The highlighted area under iris is manually segmented from grey-scale entropy images as quasi-IPE region. Thickness of the quasi-IPE is measured at a distance of 2000μm from the SS and defined as T2000. The area of the quasi-IPE is defined as IPE-Area. Melanin concentration rate 0.5(MCR0.5) is defined as a ratio of the entropy over 0.5 compared to the total area in IPE-Area. For each variable, differences in gender and age groups were analyzed through student t-test or one-way ANOVA at its temporal or nasal regions separately.

Results: The 101 participants included 79 male and 22 female with mean age of 39.0±11.3yrs, ranging from 18-64yrs. Among the three quantification values, IPE-Area (averages at temporal or nasal (T/N): 1.52±0.25 or 1.34±0.24 mm2) showed significant difference between gender groups. (T/N: p=0.010 or 0.016). While T2000(T/N: 0.27±0.03mm or 0.27±0.04 mm) and MCR0.5 (T/N: 0.79±0.065 or 0.81±0.04.9) were not significant in both age and gender groups.

Conclusions: Quantitative results suggest a stable structural region under the iris. The quasi-IPE structure that has high depolarization might be a combination of melanin concentrated IPE layer and fuzzy area caused by scattering of light by melanin granules.

To the best of our knowledge, this is the first attempt made on quantification of the quasi-IPE region in PS-OCT images. Future work may involve laboratorial examinations on diseased eyes or anatomy-based research.

TITLE: Deep Learning Facilitated Study of the Relationship between Visual Field Sensitivity (VFS) and Photoreceptor Outer Segment (OS) Metrics in Retinitis Pigmentosa (RP)

SESSION TITLE: Retinal Degeneration

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: Y. Wang, K. Juroch, T. Luu, D.G. Birch, Retina Foundation of the Southwest, Dallas, Texas, UNITED STATES|Y. Wang, D.G. Birch, Ophthalmology, The University of Texas Southwestern Medical Center, Dallas, Texas, UNITED STATES|

Commercial Relationships Disclosure: Yi-Zhong Wang: Commercial Relationship: Code N (No Commercial Relationship) | Katherine Juroch: Commercial Relationship: Code N (No Commercial Relationship) | Tein Luu: Commercial Relationship: Code N (No Commercial Relationship) | David Birch: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: It is known that VFS correlates with ellipsoid zone (EZ) width or area in RP. However, fewer studies reported the relationship between VFS and OS volume. Here we examined the association between VFS and 3D OS metrics with the assistance of a deep learning model (DLM) for automatic segmentation of retinal layers in OCT images.

Methods: Twenty-five patients with RP participated the study. Octopus spot size III VFS were obtained from both eyes of each patient (10-2 for EZ limited in the macula and 30-2 for EZ extended beyond macula). Spectralis high-resolution 9mm 121-line macular volume scans were obtained for all eyes. EZ and apex RPE were automatically segmented by a DLM (Wang et al., TVST 2021). Two graders performed manual correction of DLM segmentation to serve as a reference. The 3D OS map from a volume scan was reconstructed by interpolating the discrete 2D B-scan OS layers defined by EZ and apex RPE over the scan area. OS metrics, including mean OS length, EZ area and OS volume, were computed from the 3D OS maps generated from both DLM (fully automatic) and the reference (manual grading). A regression analysis was conducted to examine the relationship between the mean VFS in dB over the scan area and log OS metrics. Bland-Altman and correlation analyses were employed to compare OS metrics determined by DLM to the reference.

Results: Mean VFS, average OS length, EZ area, and OS volume ranged from 3.1 to 30.2 dB, 7.4 to 31.4 mm, 0.26 to 66.7 mm^2, and 0.0019 to 1.98 mm^3, respectively. Mean VFS was significantly correlated with log average OS length (r = 0.45), EZ area (r = 0.84) and OS volume (r = 0.84) determined by DLM. The model performed similarly to the reference as shown in the Table. Bland-Altman analysis showed a close agreement between the OS metrics determined by DLM and the reference. EZ area and OS volume measured by the model was highly correlated with the reference (r=0.992 and r=0.996, respectively).

Conclusions: Resembling to EZ area, OS volume significantly correlates with retinal sensitivity. The large dynamic range of OS volume may render it being an effective biomarker to assess RP progression. The close agreement between OS metrics determined by DLM and the reference suggests that deep learning may provide efficient tools to facilitate the study on the structure and function relationship in RP.

Commercial Relationships Disclosure: Somaye Jafari: Commercial Relationship: Code N (No Commercial Relationship) | Joseph Park: Commercial Relationship: Code N (No Commercial Relationship) | Joseph Demer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Prior models of extraocular mechanics have artificially constrained globe translation either by rigidly fixation eye center, or suspending it with unphysiological virtual springs. In order to clarify the role connective tissues on globe rotation & translation, we developed an FEM of incremental adduction induced by active contractility of extraocular muscles (EOMs), including the suspensory tissues & optic nerve (ON).

Methods: The model implemented hemisymmetric geometries of bilaminar EOMs, ON, orbital wall, & orbital fat were obtained from MRI of 5 healthy adults, and measured constitutive tissue properties. Active & passive strain energies of EOMs were defined using ABAQUS (Dassault Systemes) software. The eye was rotated by EOM deformations caused by twitch activation. Ocular center was not fixed, but the globe was instead suspended by Tenon's fascia and an anatomically realistic pulley system, including orbital layer insertions. Starting from 26° adduction, the medial rectus was commanded to incrementally contract, and the lateral rectus to relax. We alternatively modeled absence of orbital fat, versus fat with Young's modulus ranging up to 7 KPa.

Results: During incremental adduction from 26 to 32°, EOM, ON & connective tissue tensions were physiologically plausible, and stress & strain were concentrated at the optic disc. Maximum principal strain was 6% in peripapillary sclera, lamina cribrosa, & ON sheath, while minimum principal strain was -6% in peripapillary sclera, lamina cribrosa, & disc. Von mises stress averaged 30MPa in lamina cribrosa. Without orbital fat, the globe translated 0.1mm nasally but 1.2mm posteriorly, which is non-physiological. With 7KPa stiffness orbital fat, translation was 0.17mm nasally but only 0.33mm posteriorly, which is physiologically realistic.

Conclusions: This physiologically plausible method of simulating EOM activation along with an anatomically realistic suspension system can provide realistic input to model biomechanical behavior of active and passive tissues in the orbit to clarify biomechanical consequences of ON traction during adduction.

TITLE: A novel homozygous nonsense mutation in the PDE6C gene discovered in a patient with achromatopsia

SESSION TITLE: Inherited Retinal Disease Genetics I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Seraly, J.M. Sullivan, Ophthalmology (Ross Eye Institute), University at Buffalo Jacobs School of Medicine and Biomedical Sciences, Buffalo, New York, UNITED STATES|J.M. Sullivan, Research Service, VA Western NY Healthcare System, Buffalo, New York, UNITED STATES|

Commercial Relationships Disclosure: Mark Seraly: Commercial Relationship: Code N (No Commercial Relationship) | Jack Sullivan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To report a case of autosomal recessive achromatopsia in a child with a novel homozygous nonsense mutation in PDE6C.

Methods: A retrospective chart review was performed with over 4 years of clinical follow up. Investigators reviewed the patient's visual acuity, optical coherence tomography (OCT), full field electroretinography (ffERG), and serial comprehensive ophthalmologic exam results to ascertain patient's clinical phenotype. The patient underwent genetic testing with an Inherited Retinal Disorders panel (NGS, 248 genes) by Invitae-Spark Therapeutics. Genetic results and counseling were disclosed to the patient's parents in person during a subsequent clinic visit by an inherited retinal disease specialist.

Results: A six-year-old male presented with severe photophobia and pendular nystagmus. The patient was born at full term from a consanguineous marriage of two first cousins. Patient's cycloplegic refraction showed high myopic astigmatism with best corrected visual acuity of 20/150 in both eyes (OU). Dilated fundoscopic examination revealed a mild blunting of the foveal light reflex with subtle subfoveal granular pigmentary changes OU. OCT revealed severe attenuation of the subfoveal outer nuclear layer and punctate disruptions in the ellipsoid zone, both consistent with cone photoreceptor loss. Paucity of panretinal cone photoreceptor function was corroborated by ffERG (sedated), which revealed nonrecordable response to the 30Hz flicker photopic stimuli and severe attenuation of photopic amplitudes; scotopic and maximum combined responses were within normal limits. Due to age, color vision could not yet be performed. Genotyping (NGS) revealed a novel pathogenic nonsense mutation (homozygous) in the PDE6C gene [exon 13, c.1669C>T; p.Arg557*]. The patient has remained clinically stable with serial examination every 4-6 months with no evidence of progression of retinal degeneration by serial OCT imaging.

Conclusions: The novel homozygous nonsense (null) mutation in PDE6C (p.Arg557*) is consistent with an achromatopsia phenotype. Marked loss of PDE6C protein solely in cone photoreceptors is expected to severely attenuate cone phototransduction and perhaps challenge cone vitality. Replacement gene therapy (prior to cone loss) would be a reasonable approach for null PDE6C-induced achromatopsia phenotype in future clinical trials.

ABSTRACT BODY:

Purpose: Recent studies suggest that diabetes affects retinal neurons before onset of more noticeable vascular anomalies. Using cultured neurons and adult retinal explants, we tested the hypothesis that Cell Adhesion Molecules (CAMs) regulate growth of neuronal processes or neurites. We also investigated glucose-sensitive transcriptional regulation of neuronal CAMs and CAM interactions within retinal layers.

Methods: Caspr1 KO was created using CRISPR-Cas9 in Neuro2a and 661W cell lines. Cells were labelled with F-actin and microtubule probes (n=4). Live imaging was done up to 12 hours, and neurite length measured from randomly chosen fields. To check transcriptional regulation of Caspr1, cells were treated with Actinomycin D for 4-6 hours (10µg/ml, n=6). Luciferase reporter assay was performed in cells transfected with Caspr1 promoter reporter construct (n=6). Retinal explants from 10-week old male chicken were cultured in 5mM or 25 mM glucose up to 6 days, cryosectioned 10µm and stained using CAM-specific antibodies for IHC (n=4).

Results: Caspr1 KO cells show significantly increased neurite lengths (23.4±1.5, 22.2±2.6, 25.6±1.3µm) compared to WT (6±1, 11.2±1.1, 12.8±1µm, $p<0.01$) at 1, 2 and 3 hours respectively. Neurite lengths converged in WT (22.8±4.1µm) and KO (26.2±1.4µm, $p=0.47$) after 4 hours up to 10 hours (26.2±4.3µm WT Vs. 27±1.2µm KO, $p=0.87$). Transcriptional regulation of Caspr1 was confirmed by treating cells with Actinomycin D, which effectively blocked Caspr1 mRNA expression ($p=0.002$). Luciferase assay shows that hyperglycemia significantly reduces Caspr1 promoter activity ($p=0.0004$). Retinal explants show partial colocalization of Caspr1 and Contactin1 (Pearson's coefficient>0.7). Hyperglycemia visibly alters intensity and distribution of CAMs across retinal layers.

Conclusions: Previously we showed that hyperglycemia affects neurite growth and CAM expression in primary adult retinal neurons. We now show that Caspr1 negatively regulates initiation of neurite outgrowth, and hyperglycemia leads to transcriptional downregulation of Caspr1 and altered distribution of CAMs in the retina. Neuronal CAM interactions and their regulation will be explored further using studies in an animal model of diabetic retinopathy.

ABSTRACT BODY:

Purpose: Lumican is a small leucine rich proteoglycan present in the human amniotic membrane (AM) that promotes corneal epithelialization. The aim of the present study was determining whether lumican can be extracted from AM and evaluating its stability as AM extract (AME) stored at different temperatures, which could help design epitheliazing-eye drops.

Methods: One-hundred mg of AM were incubated with dispase II at 37°C for 30 min and mechanically de-epithelialized. The de-epithelialized AM was washed and immersed in liquid nitrogen for 40 min, then crushed until a fine powder was obtained, which was solubilized with 2.5 ml of saline buffer with protease inhibitors and centrifuged. Supernatant was collected and stored at -20°C, 4°C and room temperature (RT) for 6, 12, 20 and 32 days until lumican quantitation. Lumican was calculated in each sample according with: [ng/ml lumican / mg of AM tissue].

Results: We obtained similar protein concentrations among all the AME at basal protein quantification. There was no significant difference between protein concentration and time of storage; however, we found significant differences ($p<0.05$) between the AME of 32- and 20-days with respect their basal protein concentration. After that, we analyzed protein concentration with storage temperature, and found significant differences ($p<0.05$) in the AME of 32 days at 4°C and -20°C respect the RT condition, similarly the AME of 20 days had significant results at -20°C respect other temperature conditions. The quantification of lumican in AME showed that the concentration was affected by time of storage and temperature conditions. Lumican in the AME of 12 days was significantly higher ($p<0.05$) in comparison with the AME of 32, 20 and 6 days. There was no differences between lumican in the AME of 32 and 20 days with respect the temperature conditions of storage. Interestingly, when we analyzed the AME of 12 days we significantly ($p<0.05$) observed a high proportion of lumican in temperature conditions of -20°C and 4°C with respect of RT and -70°C. Similarly, we found a significant difference of lumican in the AME of 6 days stored at -20°C, respect other temperatures.

Conclusions: Lumican can be extracted from AM and stored for 12 days as AME, at both temperature conditions of -20°C and 4°C. Further studies are needed to determine AME lumican's function on corneal epithelial cells.

ABSTRACT BODY:

Purpose: To compare 1-year post-operative outcomes after cataract surgery in patients with and without a 1-year history of Vancomycin use.

Methods: A retrospective cohort study was done using TriNetX (Cambridge, MA, USA), a federal electronic medical database including 69 million records from multiple large health organizations in the United States. Patients who underwent cataract surgery were identified by CPT code and stratified into two cohorts: those with and without a 1-year history of vancomycin use. Cohorts were controlled for age, gender, and medical comorbidities (essential hypertension, diabetes mellitus, chronic lower respiratory diseases, heart failure, nicotine dependence, and body mass index) using a 1:1 matched propensity score analysis. The 1-year outcomes measured were: vitreous hemorrhage (VH), choroidal hemorrhage (CH), retinal detachment (RD) or break, iridocyclitis, retinal edema (RE), corneal edema (CE), cystoid macular edema (CME), epiretinal membrane (ERM), toxic maculopathy (TM), ischemic optic neuropathy (ION), glaucoma, strabismus, dry eye, central retinal vein occlusion (CRVO), central retinal artery occlusion (CRAO), vitreous opacities, ptosis, endophthalmitis, and retinal vascular occlusions (RVO).

Results: A total of 32,716 cataract surgery patients were included in analysis with 16,358 in each cohort with and without a 1-year history of vancomycin use. The cohort with history of vancomycin use had a significant greater risk of RE (RR, 1.24; 95% CI, 1.04-1.49), CME (RR, 1.23; 95% CI, 1.08-1.4), ERM (RR, 1.28; 95% CI, 1.1-1.48), ION (RR, 2.17; 95% CI, 1.1-4.3), glaucoma (RR, 1.23; 95% CI, 1.09-1.3), dry eye (RR, 1.26; 95% CI, 1.14-1.39), ptosis (RR, 1.27; 95% CI, 1.06-1.53), and endophthalmitis (RR, 2.02; 95% CI, 1.47-2.76), whereas the cohort with no history of vancomycin use had a significant greater risk of vitreous opacities (RR 0.77; 95% CI, 0.64-0.93). No significant difference was seen in the rate of development of VH, CH, CE, RD or break, iridocyclitis, TM, strabismus, CRVO, CRAO, or RVO between the two cohorts.

Conclusions: Medication history, specifically vancomycin antibiotic use, is an important factor to consider when evaluating postoperative complications of cataract surgery. A 1-year history of vancomycin use increased the risk of developing potentially sight-threatening ocular disorders such as endophthalmitis, glaucoma, and ION, but decreased the risk of vitreous opacities.

ABSTRACT BODY:

Purpose: Since the retina cells are non-regenerating neuronal cells, detection at the early stage of cell degeneration is important. We developed an in-vivo optical imaging system incorporated with adaptive optics to obtain photoreceptor images in real time.

Methods: To image photoreceptors, we adopted differential interference contrast (DIC) microscopy composed of a polarizer, DIC prism, and analyzer. Also, to reduce the optical aberration from the eye, adaptive optics (AO) was combined with DIC microscopy. Light sources with the wavelengths of 623nm for cell detection and 840nm for AO were used. We performed in-vivo retina imaging in female adult marmosets (5y and 2y). The pupil in marmoset' eye was dilated to obtain the stable optical path in in-vivo imaging. As imaging the retina cell layers, the marmosets were kept under anesthesia via 1-5% isoflurane inhalation. The photoreceptors in marmoset eye were imaged by charge-coupled device (CCD) detector [2752 x 2192 pixels]. Through a real-time AO feedback loop, the improved image was obtained every 0.5 to 1 second.

Results: The figure 1 is the image of the in-vivo photoreceptor layer of retina in the marmoset eye. The photoreceptor layer with circle shape photoreceptors in a mosaic pattern as reported in a previous study[1] was clearly observed by our system. From the size and pattern of photoreceptor, we could expect that the bright parts are cone cells. The curvature of eyes made the blurred area in the image around the outside. The field of view in the image was calculated about 14,000 μm^2. We observed that photoreceptors were densely and uniformly distributed in photoreceptor layer for the normal marmosets.

Conclusions: Conclusions: We imaged marmoset photoreceptors in-vivo with the DIC imaging system incorporated with AO. Retina layers were imaged in real-time in the feedback of AO correction.

ABSTRACT BODY:

Purpose: Microglia modulate inflammation and neurodegeneration in common neurodegenerative diseases. However, the signalling systems that induce dysregulation of microglial homeostasis are incompletely understood. We have recently identified that tropomyosin 1 (TPM1), an actin binding protein, regulates inflammation and neuronal remodelling in the aging retina. Here, we further investigated the role of TPM1 in regulating microglia activity in BV2 cells, a murine microglia cell line.

Methods: To study the role of TPM1 in inflammation, we first transfected BV2 cells with TPM1 overexpressed plasmids for two days, and then the molecular and morphological alterations of cells were evaluated by qRT-PCR, Western blotting and immunohistochemistry. To study if inhibition of TPM1 could reverse LPS-induced inflammation, we treated cells with TPM1 specific siRNA for one days followed by LPS treatment, and then the inflammatory cytokines were detected. To further study the PKA/CREB signaling pathway, we treated cells with dbCAMP (an activator of PKA) in TPM1 plasmids treated cells, or H89 (an inhibitor of PKA) in siTPM1 treated cells following LPS treatment.

Results: TPM1 overexpression in BV2 cells significantly activated microglia and promoted the release of pro-inflammatory cytokines TNF-α, IL-1β and IL-6 and chemokines COX-2 and iNOS, and downregulated phosphorylated PKA and CREB. TPM1 overexpression failed to regulated p-CREB after treatment with dbCAMP in BV2 cells. When transfecting with TPM1 siRNA in BV2 cells following LPS treatment, we found that TPM1 knockdown remarkably inhibited microglia activation and inflammatory cytokines release, and reversed the decrease of PKA/CREB signaling pathway which was induced by LPS treatment. By applying H89 in BV2 cells, we found that TPM1 knockdown failed to upregulate p-CREB in LPS-treated cells.

Conclusions: Our data demonstrated that TPM1 mediated microglia activation and inflammation by regulating PKA/CREB signaling pathway. The therapeutic approaches targeting the inhibition of TPM1 could be a potential strategy to study microglia homeostasis and inflammation-related diseases.

TITLE: Effect of COVID-19 lockdown on refractive errors in children aged 5 – 12 years: a retrospective study

SESSION TITLE: Myopia epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Pacella, E. Trovato Battagliola, M. D'Andrea, P. Mangiantini, M. Malvasi, A. Comberiati, R. Migliorini, Sense Organs, Universita degli Studi di Roma La Sapienza Facolta di Medicina e Odontoiatria, Roma, Lazio, ITALY|

Commercial Relationships Disclosure: Elena Pacella: Commercial Relationship: Code N (No Commercial Relationship) | Edoardo Trovato Battagliola: Commercial Relationship: Code N (No Commercial Relationship) | Mattia D'Andrea: Commercial Relationship: Code N (No Commercial Relationship) | Pietro Mangiantini: Commercial Relationship: Code N (No Commercial Relationship) | Mariaelena Malvasi: Commercial Relationship: Code N (No Commercial Relationship) | Anna Maria Comberiati: Commercial Relationship: Code N (No Commercial Relationship) | Raffaele Migliorini: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To explore whether the COVID-19 lockdown increased the incidence of myopia among age-school children.

Methods: Retrospective study recruiting children aged 5 – 12. Selection: random. Inclusion criteria: healthy children presenting for an eye exam since 2016. Exclusion criteria: presence of ocular comorbidities other than refractive error, spherical equivalent (SE) less than -4D or greater than +4D, BCVA less than 20/20, blepharoptosis, media opacities, corneal or retinal dystrophies, strabismus, amblyopia, nystagmus, or concurrent therapy with atropine 0.01%. Outcome measure: age measured in months, SE of the right eye (RE) measured in diopters (D) under cycloplegia (cyclopentolate 1%). Statistical analysis: ANOVA, Chi-square, Tukey's test. Significance: $p < .05$.

Results: A total of 803 children. In the years prior to COVID-19, the mean SE ± SD diopters in the RE: 0.54 ± 1.49 D in 2016 (n = 160), 0.43 ± 1.84 D in 2017 (n = 145), 0.34 ± 1.41 D in 2018 (n = 152), 0.35 ± 1.75 D in 2019 (n = 166) (ANOVA, p = .659) (Fig. 1). In 2021 (n = 180), the mean SE was -0.08 ± 1.44 D (ANOVA, p = .005). Using the Tukey's test, the mean SE of 2021 changed by -0.619 D 95% CI [-1.091, -0.147] and -0.501 D 95% CI [-0.986, -0.016] as compared to the SE of 2016 and 2017, respectively (Fig. 2). Mean age was comparable in all groups (ANOVA, p = .307). The decrease of the mean SE of the 2021 group corresponds to an increase in the percentage of myopes (≤-0.5D) and a decrease in the percentage of hyperopes (≥ 2D). Myopes represent the 24.10% of children aged 60 – 96 months, and 63.86% of children aged 97 – 144 months. Hyperopes represent 9.64% of children aged 60 – 96 months, and 6.02% of children aged 97 – 144 months. This represents a statistically-significant increase in the number of myopes (Chi-square, p = .016) and decrease in the number of hyperopes (Chi-square, p = .001), as compared to the previous years (2016-2019).

Conclusions: This retrospective study shows a statistically-significant decrease in the mean SE in children aged 5-12 in the year following the COVID-19 lockdown (2021). The percentage of myopes has increased significantly, while the percentage of hyperopes has decreased. Children aged 8 - 12 years showed the greatest refractive change. The lifestyle changes imposed by the lockdown were likely responsible for the increased prevalence of myopia observed in 2021.

ABSTRACT BODY:

Purpose: To report the prevalence of Ocular Surface Dysfunction in Patients Presenting for Refractive Surgery Evaluation in The United Arab Emirates.

Methods: Consecutive patients presenting for refractive surgery evaluation were included. Patient information including demographics and current eye drop use were collected. The Dry Eye Questionnaire 5 (DEQ-5) was administered. Slit-lamp findings, Oxford grading of the corneal and conjunctival staining, tear-break-up time (TBUT), Schirmer test, and tear matrix metalloproteinase-9 (InflammaDry) positivity were recorded.

Results: 38 Emirati patients were included. The mean age was 26±8 years (range 17-45) and 22 (57.9%) were female. Ten (27%) patients were using artificial tears, none used other eye drops such as cyclosporine. The mean DEQ-5 score was 5.05±3.90, with 14 (36.8%) scoring more than 6. 13 (36.1%) right and 18 (50%) left eyes had a score>0 on the Oxford scale. There were no other pathologic findings on slit-lamp examination. Mean TBUT was 4.2±3.4 for the right and 4.1±3.3sec for the left eyes, and mean Schirmer score was 17.5±5.4 and 17.7±5.6mm for the right and left eyes, respectively. 11 (29.7%) right and left eyes tested positive for MMP-9.

Conclusions: Subjective and objective findings of ocular surface dysfunction were common among Emirati patients presenting for refractive surgery. Screening for dry eye in this population is important as it may impact the outcome of refractive surgery.

ABSTRACT BODY:

Purpose: Refractive errors produce image defocus and may alter quantitative metrics extracted from en face optical coherence tomography angiography (OCTA) images. Up to date it is possible to correct the sphere in commercialized devices using manual or auto-focus, but astigmatism remains uncorrected. This cross-sectional study assessed the qualitative effect of astigmatism on OCTA images and its quantitative analysis.

Methods: Patients undergoing comprehensive ophthalmic examination, including OCTA, were included. We recruited subjects with a measured astigmatism of 0.5 diopters (D) or more. OCTA scans were acquired with and without astigmatism correction on a single visit using SPECTRALIS HRA-OCT2 (Heidelberg Engineering, Heidelberg, Germany) with follow-up mode activated. Astigmatism correction was applied to either the first or second OCTA image in random order using cylindrical lenses adapted to the OCTA device, with values from -1 to -5. The primary outcome measure was vessel density index (VD) in the nasal macular area of the superficial vascular plexus before and after astigmatism correction. A paired t-test was used for total analysis and a two-way ANOVA test for grouped analysis including astigmatism diopters (0.5-1.25, 1.5-2.25, 2.5-3.25 and >3.5) and axis intervals (with the rule, against the rule or oblique).

Results: Ninety-one eyes of 91 subjects were included in our cohort, showing a mean astigmatism of 1.25D (95% CI 1.09-1.41) with a mean age of 63.6 years. Mean VD was significantly higher with astigmatic correction (mean 0.308 (95% CI 0.294-0.322) vs. 0.274 (95% CI 0.259-0.288) $p<0.0001$). Subgroup analysis suggested consistent effects of astigmatism correction depending on the amount of diopters ($p=0.047$) and regardless of the axis ($p=0.119$).

Conclusions: Our data suggest that astigmatic correction increases VD values in OCTA images. Astigmatism correction should therefore be considered in studies that include analyzing quantitative parameters obtained by OCTA. However, further studies will be needed in order to assess the clinical significance of these changes.

TITLE: Early-onset X-linked Retinoschisis: Clinical Presentation and Outcomes

SESSION TITLE: Pediatric ophthalmology and imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. PIQUIN, Y. Abdelmassih, G. Martin, C. Edelson, F. Metge, G. Caputo, T. Chapron, La Fondation Adolphe de Rothschild, Paris, Île-de-France, FRANCE|

Commercial Relationships Disclosure: Gwendoline PIQUIN: Commercial Relationship: Code N (No Commercial Relationship) | Youssef Abdelmassih: Commercial Relationship: Code N (No Commercial Relationship) | Gilles Martin: Commercial Relationship: Code N (No Commercial Relationship) | Catherine Edelson: Commercial Relationship: Code N (No Commercial Relationship) | Florence Metge: Commercial Relationship: Code N (No Commercial Relationship) | Georges Caputo: Commercial Relationship: Code N (No Commercial Relationship) | Thibaut Chapron: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To describe clinical characteristics and outcomes of children with early onset X-linked retinoschisis (XLRS).

Methods: In this retrospective consecutive case series we included children diagnosed with XLRS before the age of 2. Presenting signs, clinical characteristics, treatments and outcomes were recorded.

Results: Eight patients (16 eyes) with a mean age of 17.25+/-5.82 months were included. Strabismus was the most common presenting symptom (6 patients, 75%). Clinical signs at first diagnosis included peripheral retinoschisis in 14 eyes (88%, 8 patients) of which 6 (43%) were bullous, vitreous haemorrhage in 3 eyes (19%) and retinal detachment in 3 eyes (19%). The macula was involved in all the eyes. Six eyes (38%) received surgery. At last follow-up, visual acuity, when available, ranged from no light perception to 20/32, no children had persistent retinal detachment.

Conclusions: Children with early-onset X-linked retinoschisis have severe forms. All children had macular involvement and peripheral retinoschisis. Peripheral retinoschisis can be bullous and often extends to the macula. Diagnosis can be often clinical but handheld OCT can be helpful in atypical forms. Complications requiring surgical management are frequent.

TITLE: Two-dimensional eye velocity distributions of foveal fixation at different gaze angles

SESSION TITLE: Eye movements and nystagmus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Mcilreavy, V.V. Nedelchev, F.A. Ennis, Optometry and Vision Sciences, Cardiff University, Cardiff, Wales, UNITED KINGDOM|

Commercial Relationships Disclosure: Lee Mcilreavy: Commercial Relationship: Code N (No Commercial Relationship) | Viktor Nedelchev: Commercial Relationship: Code N (No Commercial Relationship) | Fergal Ennis: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Small eye movements (drifts, microsaccades and tremors) keep the eye in continuous motion, even as observers attempt to fixate a target. In this study we examine eye velocity distributions from typical observers as they fixate targets presented at different gaze angle. We hypothesise that the mechanics of the oculomotor plant will bias eye velocity towards primary position.

Methods: Twelve typical observers with normal vision were asked to fixate a target (0.4° green dot) presented for 12s at either 0° (primary position) or at eccentricity of ±16° horizontal or ±16° vertical. The targets were presented in a random order against a black background in an otherwise dark room. Observers viewed the targets binocularly and eye movements were recorded at 1000Hz from the eye with better visual acuity. Saccades and blinks were excluded from eye movement data and a bivariate probability density function of target-relative eye velocity was calculated after filtering eye position data. The centroid of the isocontour that encompassed the highest 68% of data was examined to determine any directional bias.

Results: Preliminary results show the mean x coordinate of the centroid has a leftward bias (-0.030 ± 0.092°/s) during right-gaze (+16°), and a rightward bias (+0.039 ± 0.120°/s) during left-gaze (-16°). This difference (0.072°/s) was statistically significant [$t(11) = 2.697$, $p = 0.010$, $d = 0.779$]. In contrast, the mean y coordinate of the centroid had a downward bias during up-gaze (-0.217 ± 0.310°/s) and down-gaze (-0.230 ± 0.281°/s). This difference (0.012°/s) was not statistically significant [$t(11) = 0.101$, $p = 0.461$, $d = 0.029$]. There were no significant differences between any of the eccentric gaze positions and primary position (i.e. 0°).

Conclusions: We have demonstrated that eye velocity during foveal fixation is dependent on gaze angle. Eye velocity is biased towards primary position during horizontal gaze, and downward during vertical gaze. These findings may relate to differences underlying horizontal and vertical oculomotor control. We speculate that the magnitude of the horizontal differences observed will increase with larger gaze angles (i.e. beyond 16°). Our results may have implications for aspects of foveal vision that are critically dependent on eye velocity, e.g., visual acuity, with thresholds potentially varying as a function of horizontal gaze angle.

ABSTRACT BODY:

Purpose: To assess safety and tolerability of intraocularly applied cetuximab as an epidermal growth factor receptor antibody.

Methods: The experimental study included a group of adult rabbits (body weight: 2.4kg) and a group of young rabbits (body weight: 1.6 kg). All rabbits received three intravitreal injections of 0.5 mg cetuximab (Erbitux®) (0.10 mL) (in a concentration of 5mg cetuximab / mL) into their right eyes in 4-week intervals, while the contralateral eyes received intravitreal injections of Ringer's solution in the same volume at the same time points. After each injection, the intraocular pressure was measured in both eyes. All animals underwent regular ophthalmological examinations at baseline and at two-week intervals, including inspection of the external eye, ophthalmoscopy, tonometry, fundus photography and ocular biometry.

Results: The study included 10 adult rabbits with a mean age of 12 months (range: 10 - 14 months) and 8 young rabbits with a mean age of 6 months (range: 5 to 7 months). Neither in the young animal group nor the adult rabbit group did the biometric measurements of axial length, anterior chamber depth and lens thickness and the IOP readings differ significantly between the right (study) eyes and the left (control) eyes (Table 1). None of the eyes showed an intraocular inflammation during the study period or peculiarities of the fundus such as retinal inflammatory infiltration or retinal hemorrhages. Comparing photographs of the anterior segment and of the fundus taken at the study end and at baseline in a masked manner did not reveal any detected difference.

Conclusions: The repeated intravitreal application of cetuximab did not result in any detected intraocular toxic or destructive effect. The results do not contradict the assumption of intraocular tolerability of cetuximab.

ABSTRACT BODY:

Purpose: To study the cytokeratin profile and keratinization-related genes expression in keratinized lid margins of chronic Stevens-Johnson syndrome (SJS) patients.

Methods: Posterior eyelid margins from 24 chronic SJS patients undergoing mucous membrane grafting, and six healthy margins retrieved from orbital exenteration specimens were studied using immunofluorescence staining (CK10, CK1, filaggrin, transglutaminase 1 (TGM1), CK19, MUC5AC) and quantitative PCR (differential mRNA expression of keratinization-related genes- PTEN, HBEGF, KGF, EGF, TGFA, TGFB and TNFA). The staining as well as gene expression was studied separately in the lid margin epidermis (LME, from eyelash root to meibomian glands opening), and lid margin conjunctiva (LMC) segments of eyelid margins.

Results: The expression of CK 1/10, filaggrin, TGM1 in the LMC was similar to the LME in SJS patients. Expression of CK19 was confined to the basal epithelial layer of the LMC in SJS compared to full-thickness expression in normals. MUC5AC expression was absent in LMC of SJS patients. Increased expression of PTEN ($p \leq 0.0001$), KGF ($p \leq 0.056$), TNFA ($p \leq 0.02$), TGFA ($p \leq 0.01$) was observed in the LME of SJS patients compared to normal LME. LMC of SJS patients showed an increased expression of PTEN ($p \leq 0.002$), HBEGF ($p \leq 0.002$), EGF ($p \leq 0.002$), KGF ($p \leq 0.02$), TNFA ($p \leq 0.04$), TGFA ($p \leq 0.003$), and TGFB($p \leq 0.001$) compared to normal LMC. No significant differences were observed in the expression of these genes between LME and LMC of SJS patients. These genes were also validated using String analysis which also revealed the positive regulation of keratinization.

Conclusions: In lid margins of SJS, there is an increased expression of keratinization-related genes compared to normal lid margin. Keratinized LMC shares similar cytokeratin profile and keratinization genes expression as seen in cutaneous epithelium of SJS patients, indicating the possibility of the cutaneous epithelium as a source for keratinized LMC.

ABSTRACT BODY:

Purpose: Retinal arteriolar and venular calibers have been proposed to be surrogate measures of systemic microvascular health. We evaluated the associations of deep-learning based retinal vessel caliber measurements with incidence of fatal and non-fatal myocardial infarction (MI) using data from the UK Biobank.

Methods: Prevalent and incident MI was defined with an algorithm developed by UK Biobank, combining information from self-reported medical conditions, operations and medications, hospital admissions and death registries before and after the code date of baseline assessment respectively. Fully automated measurements of central retinal artery and vein equivalents (CRAE/CRVE) from retinal fundus photographs in the area 0.5-2.0 disc diameters away from the optic disc were estimated with a recently validated deep-learning system (SIVA-DLS). Hazard ratios (HR) and area-under-the-curve (AUC) were calculated for evaluating the association and improvement in discriminative performance between CRAE/CRVE with incident MI.

Results: After excluding individuals with prevalent MI and ungradable retinal photographs, 34,841 subjects at risk of incident MI were included in the final analysis. Baseline assessment was conducted from 2009 to 2013, with subjects at risk of MI followed up to March 2020. A total of 375 subjects developed incident MI. Persons with narrower CRAE were more likely to have incident MI (HR 1.67 [95% CI: 1.19-2.36], comparing 1st to 4th quartile, and HR 0.86 [95% CI: 0.75-0.98], per SD increase in CRAE), adjusting for age and gender. When further adjusted for total cholesterol, high-density lipoprotein cholesterol, systolic blood pressure, and other risk factors, the association between CRAE and incident MI persisted (HR 1.64 [95% CI: 1.16-2.32], 1st vs. 4th quartile). CRVE was associated when adjusted for age and gender (HR 1.51 [95% CI: 1.06-2.13]) but not in multivariable models. AUC increased significantly from 0.718 to 0.724 (adjusted for age and gender, $p = 0.030$) when CRAE/CRVE is included in the models.

Conclusions: Narrowed retinal arteriolar caliber, reflecting systemic microvascular damage, was associated with incident MI. Deep-learning based retinal vessel caliber measurements from retinal photographs may be a useful biomarker of cardiovascular disease in clinical and epidemiological studies.

ABSTRACT BODY:

Purpose: To compare the outcomes at one year between the first and second eyes in patients who develop sequential age-related neovascular macular degeneration (nAMD).

Methods: Treatment-naive patients who sequentially developed nAMD between March 2015 and March 2020 were identified. Outcomes at one-year were compared between the first and second eyes to develop nAMD. All patients were treated with an initial series of 3 monthly loading doses of anti-VEGF agents, followed by further intravitreal injections (IVI) as required. Outcomes included visual acuity (VA), central macular thickness (CMT), as well as evidence for geographic atrophy (GA) and/or pigment epithelial detachment (PED) on optical coherence tomography (OCT) imaging.

Results: Fifty-six patients who sequentially developed nAMD were identified. The mean age was 81.5 ± 7.9 (range 60-94) and 66% were female. The average time to diagnosis of nAMD in the second eye was 474 ± 369 days. The mean number of IVI for the first eye before second eye conversion was 7.8 ± 6.2 (range 1-33). There was no difference in the number of IVI in the first compared with the second eye at one year (8.4 ± 2.6 injections versus 9.0 ± 2.0, P=0.269). VA at diagnosis and after 12 months were better for the second eye compared with the first eye to develop nAMD (0.72 ± 0.53 logMAR vs. 0.41 ± 033 logMAR, P<0.001, and 0.67 ± 0.63 logMAR vs. 0.42 ± 0.36 logMAR, P=0.008). CMT at diagnosis was thicker for the first eye compared with the second eye to develop nAMD (381 ± 120 µm vs. 335 ± 94 µm, P=0.017), but was similar at one year (296 ± 100 µm vs. 278 ± 82 µm P=0.193). At diagnosis, PED height was thicker for the first eye compared with the second eye to develop nAMD (236±208 µm vs. 154±155 µm, P=0.009), but was similar at one year (195±170 µm vs. 141±139 µm, P=0.053). Finally, 3 eyes (5.4%) had GA at the time of nAMD diagnosis in the first eye, whereas 8 eyes (14%) had GA at the time that the second eye developed nAMD (χ^2=2.520, P=0.112). There was a correlation between presence of GA in the first eye and the development of GA in the second eye by the time of its diagnosis (r=0.356, P=0.007).

Conclusions: At diagnosis the second eye to develop nAMD tends to have better vision and thinner CMT. Although these eyes had better anatomical outcomes at one year, this did not translate into better vision nor a lower disease burden requiring less treatment

ABSTRACT BODY:

Purpose: Subtle structural changes in the outer retina may be associated with physiological aging and age-related macular degeneration (AMD) pathology. We previously reported that basal laminar deposit (BLamD), an established histological marker for AMD, can be visualized clinically in early AMD eyes using ultrahigh resolution OCT (UHR OCT).

However, OCT images are degraded by speckle noise and sharpness is reduced by the acquisition process, making fine features including outer retinal layers and BLamD difficult to visualize directly. Merging multiple volumes can reduce noise and improve contrast, but requires motion correction accuracy below the scanner resolution, which is challenging due to fixational eye motion.

Using our scanner-independent framework for advanced computational motion correction and signal reconstruction (MoReOCT), we correct for involuntary saccadic motion and blinks, and improve signal-to-noise ratio and sharpness to enhance the visualization of thin outer retinal features.

Methods: Retrospective image processing was performed on OCT scans of a prospectively enrolled cohort of AMD patients (53 eyes / 39 subjects), as well as a cohort of healthy adult subjects (63 eyes / 39 s.) using a prototype UHR OCT instrument (2.7 μm axial resolution). For each eye, we acquired 6 volumetric scans over a 6 x 6 mm field centered at the fovea, with alternating horizontal and vertical B-scan direction. The eye motion trajectory of each scan was estimated from the data in a joint optimization such that the consistency of orthogonally scanned volumes was maximized.

To compensate image blur inherent in the acquisition process, we applied deconvolution at the scale of the measured PSF in the axial direction. While deconvolution increases speckle noise when applied to individual OCT acquisitions, this effect can be mitigated by jointly using all volume data in a 3-D iterative reconstruction with total variation denoising. The visualization setup uses moderate denoising, whereas the processing setup, intended for algorithmic analysis, uses more.

Results: The figures compare unprocessed B-scans to virtual B-scans resampled at identical A-scan locations from the MoReOCT volumes.

Conclusions: Volume merging and signal reconstruction can improve visibility of fine retinal structures and could aid in understanding AMD pathogenesis.

ABSTRACT BODY:

Purpose: To study if nAMD patients switching from one anti-Vascular Endothelial Growth Factor (VEGF) to BROL prolonged injection intervals.

Methods: A retrospective cohort study at Retina Associates of Cleveland, Inc. (extracted December 1, 2021) analyzed nAMD patients who switched from one anti-VEGF to BROL, had at least 3 BROL injections, 12 months follow-up or more and no other anti-VEGF in first 12 months post switch.

Injection intervals, visual acuity (VA), and central macular thickness (CMT) were analyzed at baseline (first BROL injection) and last follow-up, along with follow-up distribution post first BROL injection. Inflammatory events were reported.

Subgroup analyses were based on last interval at baseline,< 56 days and ≥ 56 days, to study previous anti-VEGF and BROL intervals; and on highest to lowest quartile of baseline VA, to study initial VA at switch effects on BROL intervals.

Results: Study identified 172 eyes from 152 patients (53.3% females), with baseline age of 80.7±7.8 years, VA of 1.14±0.87 logMAR and CMT of 300.7±118.1 µm. Quantities reported as mean±standard deviation (SD).

Last interval pre-switch was 48.8±25.8 days. Last post-switch interval follow-up period extended 32.7±61.1 days. First BROL injection follow-up period was 552.5±104.4 days. VA and CMT change from baseline to last follow-up was 0.13±0.75 logMAR (vision gain) and 39.6±112.1 (thickness reduction) respectively (Table 1). Post switch, 1.7% of eyes developed inflammatory events.

For subgroup of intervals < 56 days pre-switch, intervals extended 40.2±50.8 days post-switch and higher VA gain than in main group. Lower interval extension and VA gain for ≥ 56 days subgroup compared to < 56 days subgroup and main group (Table 1). All groups saw similar CMT reduction.

Lowest quartile baseline VA interval extension was much larger compared to other quartile and main groups. Highest quartile VA at baseline saw largest CMT reduction. Vision gain was seen post BROL switch in all quartile subgroups (Table 2).

Conclusions: Treated for a year or more, 172 nAMD BROL switch eyes extended intervals, maintained vision and saw CMT reduction, strengthening real-world BROL use literature findings.

ABSTRACT BODY:

Purpose: The purpose of this study was to compare the ability of Scheimpflug tomography and anterior segment optical coherence tomography (OCT) in detecting subclinical corneal edema in patients with Fuchs endothelial corneal dystrophy (FECD) without clinical corneal edema.

Methods: In this single-center, consecutive case series, 47 eyes of 29 patients with FECD were analyzed. The main outcome measures were anterior/posterior keratometry and central/thinnest corneal thickness. The criteria for subclinical corneal edema were loss of regular isopachs, displacement of the thinnest point of the cornea, and presence of posterior surface depression. Tomographic analyses were performed using Scheimpflug imaging (Pentacam HR) and OCT (anterior segment swept-source optical coherence tomography).

Results: The measurement of the continuous variables revealed a significant difference between the 2 devices. The anterior curvature was steeper and the posterior curvature was flatter when measured with OCT (P = 0.001). The OCT showed a lower central corneal thickness and thinnest corneal thickness (P = 0.001). The agreement between both devices to detect subclinical corneal edema was high. The interdevice reliability for loss of parallel isopachs as measured by Cohen kappa coefficient was 0.84; for the displacement of the thinnest point of the cornea, it was 0.6, and for the focal posterior corneal surface depression, it was 0.62. Subclinical corneal edema was detected in 72.3% of the patients with both devices. In only 2 cases (4.3%), subclinical corneal edema was detected by one of the devices.

Conclusions: Scheimpflug and OCT imaging were both able to detect tomographic patterns of subclinical corneal edema. Therefore, both devices can help decision-making, favoring early endothelial keratoplasty in symptomatic patients with FECD without clinical corneal edema.

ABSTRACT BODY:

Purpose: Long-term low levels of serum Insulin-like growth factor-1 (IGF-1) in premature infants have been reported to increase the risk of retinopathy of prematurity and maintaining high serum IGF-1 levels early in life in premature infants may be a way to prevent postnatal complications.

We previously reported a small for gestational age model (SGA-rat) in which pregnant rats were fed a protein-restricted diet to induce intrauterine growth failure of the fetuses and were born with low birth weight (Saito et al. 2014 ARVO). Serum IGF-1 in SGA-rats at day 8 (P8) was significantly lower than that in rats born to pregnant rats fed a normal diet. In this study, we investigated the effect of IGF-1 administration on SGA-rats of Oxygen-Induced Retinopathy (OIR).

Methods: Pregnant Sprague-Dawley rats were purchased and fed a normal diet (20% protein) (control group: Cnt-rat) or a low-protein diet (10% protein) (SGA-rat) with equivalent calories from day 13 of gestation. For OIR, OxyCycler was used for oxygen loading for 7 cycles (from birth to P14) with 50% O_2/24h and then 10% O_2/24h as one cycle, and the rats were kept in ambient air until P18.

Experiment 1: After weighing the pups at P18, the blood was collected from the heart, and the removed right eye was fixed to prepare retinal flatmounts. From these retinal flatmounts, we assessed the severity of retinopathy (Clock Hours: CH) and measured the percentage of avascular area to total retinal area (%AVA). In the left eye, the retina was homogenized and measured the intraretinal vascular endothelial growth factor (VEGF) and IGF-1 concentrations by ELISA. Serum IGF-1 concentration was also measured by ELISA, and the endpoints were compared between SGA-rat and Cnt-rat.

Experiment 2: To exogenously supplement IGF-1 to SGA-rat, IGF-1 (2ug/g body weight) was subcutaneously administered once daily from P4 to P14 (SGA-IGF1-rat), and the same endpoints as in Experiment 1 at P14 and P18 were compared with the control group (SGA-PBS-rat) that received PBS.

The results obtained are presented as mean ± standard deviation, and statistical analysis was performed using Wilcoxon test with p-value < 0.05 as significant difference.

Results: The results are shown in Table 1.

Conclusions: In SGA-rat, low IGF-1 levels immediately after birth did not contribute to the worsening of retinopathy, but rather IGF-1 administration worsened retinopathy.

ABSTRACT BODY:

Purpose: Contrast sensitivity function (CSF) is a visual function metric that might be of clinical value when evaluating intraretinal changes in patients with epiretinal membrane (ERM). Inherent limitations of existing contrast sensitivity tests have prevented its adoption into practice thus far. Employing a novel active learning quantitative CSF (qCSF) device, we aim to investigate structure-function associations between central foveal thickness (CFT) visual acuity (VA) and contrast sensitivity.

Methods: This prospective cross-sectional study included 115 eyes of 88 patients with idiopathic ERM. Patients underwent complete ophthalmic examination and spectral-domain OCT imaging (SD-OCT, SPECTRALIS® Heidelberg). CFT values were obtained from SD-OCT images. Contrast sensitivity (CS) was measured using the Manifold Contrast Vision Meter (Adaptive Sensory Technology, San Diego, CA). Outcomes included Area under the Log CSF (AULCSF), contrast acuity (CA) and CS thresholds at 1, 1.5, 3, 6, 12, and 18 cycles per degree (cpd). Pearson's correlations and mixed-effects multiple linear regression models were performed to evaluate structure-function associations between CFT, LogMAR VA and CSF outcome measures.

Results: Median LogMAR VA was 0.21 (0.19) and median AULCSF was 0.86 (0.21). Median CFT was 345 (106.2) μm. CFT was moderately correlated with VA (R=0.435, p<0.001), AULCSF (R= -0.489, p<0.001), CA (R=-0.492, p<0.001), and CS thresholds at cpd3 (R=-0.450, p<0.001), cpd6 (R=-0.494, p<0.001), and cpd12 (R=-0.418, p<0.001). CFT showed weak correlation with CS threshold at cpd1.5 (R=-0.291, p=0.002). In the mixed-effects regression models, CFT was positively associated with LogMAR VA (ß=0.0009, p<0.001), and negatively associated with AULCSF (ß=-0.001, p <0.001), CA (ß=-.0009, p<0.001) and CS thresholds at 1cpd (ß=-0.0004, p <0.031), 1.5cpd (ß=-0.0005, p<0.001), 3cpd (ß=-0.001, p<0.001), 6cpd (ß=-0.002, p<0.001), 12cpd (ß=-0.001, p<0.001).

Conclusions: Our results suggest that CFT is more strongly associated with qCSF than VA in patients with ERM. qCSF method may serve as a valuable visual function metric for assessing patients with ERM.

ABSTRACT BODY:

Purpose: To assess the lifetime associations between various ocular conditions in patients with substance use disorders, including alcohol, cannabis, opioid, and nicotine related disorders, from the time of diagnosis.

Methods: We conducted a retrospective cohort study using TriNetX, a national, federated database that provides aggregate electronic health record data from 80 million unique patient files within 56 healthcare organizations. Patients diagnosed with substance use disorders (SUD) were identified using ICD-10 diagnostic codes and followed for subsequent diagnoses of 27 ocular conditions over the span of a patient's lifetime after initial diagnosis of substance use disorder. The primary outcomes were incidence, as listed in Table 1. Patients with pre-existing ocular disease were excluded from this analysis.

Results: A total of 7,546,278 patients were included with 1,460,831 diagnosed with alcohol use disorders (AUD), 775,891 with cannabis use disorders (CUD), 573,583 with opioid use disorders (OUD), and 4,753,973 with nicotine dependence (ND). 37% (10/27) of ocular diagnoses had the same incidence between each SUD cohort. AUD had the most diagnoses with the highest incidence (48%) and CUD had the most diagnoses with the lowest incidence (63%). AUD had the highest incidence of disorders of refraction and accommodation (3.1%), glaucoma (1.4%), and cataract (1.4%). CUD had the lowest incidence of cystoid macular degeneration (0%), puckering of macula (0.1%), and retinal vascular occlusion (0.1%). OUD had the highest incidence of strabismus (0.3%) and dry eye syndrome (1.5%) and lowest incidence of retinal vascular occlusion (0.1%). ND had the highest incidence of conjunctivitis (2.1%), glaucoma (1.4%), and cataract (1.4%). The incidence of glaucoma, cataracts, macular degeneration, blindness, and disorders of refraction and accommodation were higher among patients with alcohol and nicotine use disorders than cannabis and opioid use disorders. The incidence of dry eye syndrome was highest among patients with opioid use disorders while the incidence of conjunctivitis was highest among those with nicotine use disorders.

Conclusions: This the first national-scale study that sheds light on the associations between substance use disorder and the most common ocular diseases. These findings can be useful when examining a patient with a history of SUD.

ABSTRACT BODY:

Purpose: Computer Vision Syndrome (CVS) is a form of asthenopia that manifests with symptoms such as eye pain/discomfort, headache, and blurred vision, among others. Early identification of CVS is especially relevant during the COVID-19 pandemic, which has led to an increase in virtual schooling and digital screen time among children worldwide. This study seeks to evaluate differences in etiologies of eye pain, treatment recommendations, and the relationship between refractive errors and eye pain in the pediatric population before and during the COVID-19 pandemic.

Methods: After IRB approval, we retrospectively reviewed the records of patients who visited our tertiary care institution between 2018 and 2021 with a chief complaint of eye pain, determined by the encounter's primary ICD-10 code. Patients who visited before 03/11/2020, when the WHO declared COVID-19 a pandemic, were classified as the pre-pandemic group (PPG), while patients who consulted after this date were classified as the during-pandemic group (DPG). Demographics, symptoms, refractive error, treatment, and schooling method were recorded as covariates and analyzed using a Chi-square and Fisher's exact test.

Results: 38 patients were included in the study (21 PPG; 17 DPG). The mean age was 10.1 ± 3.2 years, and the majority were African American (44.7%). Virtual school attendance for the PPG and DPG was 4.8% and 58.8%, respectively ($P<0.05$) (Table 1). There was a higher prevalence of reported blurry vision, headaches, eye redness, eye swelling, and rubbing among DPG patients (Table 1). Counseling on screen time minimization was more likely to be documented in the DPG (Table 2). A greater proportion of patients were prescribed new glasses in the DPG though there was no significant relationship between eye pain and refractive error or anisometropia in either group ($P>0.05$).

Conclusions: The increased prevalence of CVS symptoms in the DPG suggests an association between virtual schooling and CVS in children. There is a role for ophthalmologists to improve rates of counseling for the prevention of eye pain-related symptomatology with digital device usage. Further studies will survey parents to assess their awareness of conservative treatments for eye pain such as artificial tears and decreased screen time.

ABSTRACT BODY:

Purpose: To measure the strain response to intraocular pressure (IOP) decrease produced in the lamina cribrosa (LC) after suture lysis surgery and analyze for the effects of glaucoma damage.

Methods: Twenty-nine suture lysis procedures after trabeculectomy were performed on 27 eyes from 26 glaucoma patients, average age = 68 years, IOP decrease = 12mmHg, and mean deviation (MD) range = -0.17 to -29.2dB. iCare IOP and radial scans by optical coherence tomography (OCT) of the optic nerve head were captured before and 20 minutes after suture lysis (Midgett et al. 2019). Images were enhanced (Fig. 1) and the anterior LC border manually marked. Digital volume correlation (DVC) was applied to the OCT images to calculate the strain response. Compliance of the strain response (strain/ΔIOP) and retinal nerve fiber layer (RNFL) were averaged overall and in four LC quadrants (inferior, superior, nasal, temporal). Linear regression was used to analyze relationships between strain, compliance, IOP, RNFL, MD, and visual field index (VFI).

Results: A larger IOP decrease produced larger tensile anterior-posterior strain (E_{zz}), maximum principal strain (E_{max}), and maximum shear strain (Γ_{max}) ($p<0.01$). Anterior lamina depth (ALD) did not consistently increase or decrease with IOP decrease; 24% of eyes had posterior ALD change. Eyes with thinner RNFL had a more compliant E_{max}, Γ_{max}, and torsional shear strain ($E_{\theta z}$) response to IOP change ($p<0.04$) (Fig. 2). A more compliant E_{max}, $E_{\theta z}$, and E_{rz} response was found for eyes with worse MD ($p<0.05$), and a more compliant $E_{\theta z}$ and E_{rz} for lower VFI ($p<0.05$). Analyzing quadrant averages showed that the association between thinner RNFL and more compliant E_{max} and Γ_{max} response occurred in the nasal quadrant and also in the inferior quadrant for Γ_{max} ($p<0.05$).

Conclusions: IOP decrease predicted tensile strain, but not ALD change direction. The LC of eyes with greater glaucoma damage (thinner RNFL, worse MD, and lower VFI), had a more compliant strain response. These findings may result from progressive LC remodeling with glaucoma damage into a more curved structure or may represent baseline LC biomechanics prone to damage.

TITLE: Underdiagnosis of Risk of Glaucoma in Patients with Retinal Vein Occlusions

SESSION TITLE: Glaucoma epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D.J. Ramsey, D.S. Kelly, T. Ganti, Ophthalmology, Lahey Hospital and Medical Center, Burlington, Massachusetts, UNITED STATES|D.J. Ramsey, D.S. Kelly, T. Ganti, Ophthalmology, Tufts University School of Medicine, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: David Ramsey: Commercial Relationship: Code N (No Commercial Relationship) | Donel Kelly: Commercial Relationship: Code N (No Commercial Relationship) | Tej Ganti: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To compare the rate of glaucoma-related diagnoses in patients with branch retinal vein occlusions (BRVOs) or central retinal vein occlusions (CRVOs) with the rate in patients without retinal vein occlusions (RVOs).

Methods: Patients with RVOs were identified from billing records from 2016 to 2020. These were compared to a reference group of patients with bilateral dry eye syndrome, age- and gender-matched 2:1 to the patients with RVOs. Patients were further classified by subtype of glaucoma. Records of patients without known glaucoma-related diagnoses were evaluated for potential underdiagnosis, utilizing criteria of intraocular pressure (IOP) ≥22mmHg and/or cup-to-disc ratio (CDR) ≥0.6 and/or CDR difference between eyes ≥0.2.

Results: 643 patients were identified with RVOs, including 376 patients with BRVOs and 278 patients with CRVOs. Glaucoma-related diagnoses were significantly more common in patients with RVOs compared with a reference group (9.8% versus 5.4%, $p<0.001$). The rate of diagnosed, open-angle glaucoma was significantly greater in patients with BRVOs (4.0%) and CRVOs (4.7%) compared with a reference group (1.7%, $p<0.001$). By contrast, suspicion for open-angle glaucoma was similar between patients with RVOs compared with the reference group (3.9% versus 2.9%, $p=0.235$). However, patients with BRVOs (28.6%) and CRVOs (33.3%) were more likely to have clinical findings associated with glaucoma risk compared with the reference group (18.2%, $p<0.001$).

Conclusions: Patients with RVOs have higher rates of diagnosed glaucoma when compared with a reference group. By contrast, RVO patients with clinical findings associated with glaucoma risk are often not coded as glaucoma suspects.

Commercial Relationships Disclosure: Luca Rosignoli: Commercial Relationship: Code N (No Commercial Relationship) | Edward Chu: Commercial Relationship: Code N (No Commercial Relationship) | John Carter: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Johnson: Commercial Relationship: Code N (No Commercial Relationship) | Jeong-Hyeon Sohn: Commercial Relationship: Code N (No Commercial Relationship) | Sepehr Bahadorani: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess the difference in visual outcome and incidence of neovascular glaucoma (NVG) among patients with CRAO undergoing hyperbaric oxygen therapy or conservative management.

Methods: We conducted a retrospective chart review of 48 patients presenting with CRAO at University Health System from 2011 to 2020. 15 underwent HBOT based on US Navy Treatment Table 6; 33 patients did not undergo hyperbaric therapy. HBOT parameters and total treatment time were documented. Student's T-test and Chi-square test were used to compare the change in best-corrected visual acuity (BCVA) and incidence of neovascular glaucoma (NVG) in the two groups

Results: In the HBOT group, mean elapsed time between symptom onset and HBOT initiation was 18.27 ± 10.4 hours. In the control group, mean elapsed time between symptom onset and diagnosis was 41.47 ± 55.59 hours. Hyperbaric treatment was stopped for three patients due to anxiety, asymptomatic bradycardia, and one tonic-clonic seizure, respectively. There was no difference in logMAR BCVA improvement among the patients who underwent hyperbaric oxygen therapy and those who did not (0.10 ± 0.14, 0.29 ± 0.30, respectively; p=0.22). Incidence of NVG did not differ significantly between the two groups (HBOT: 20.0%; no-HBOT: 15.2%; p=0.676).

Conclusions: HBOT does not appear to improve final visual outcome or incidence of NVG in cases of CRAO. The efficacy of HBOT in management of CRAO may depend on the implemented treatment algorithm.

ABSTRACT BODY:

Purpose: To compare corneal and ocular biomechanical parameters in phakic, pseudophakic and aphakic subjects with open angle glaucoma.

Methods: The present study includes 83 eyes of 43 phakic patients with primary open angle glaucoma (POAG), 16 eyes of 10 pseudophakic patients with POAG, and 4 eyes of 2 subjects with aphakic glaucoma, all prospectively enrolled. Biomechanical data were acquired using the Corvis ST and Ocular Response Analyzer (ORA). Additionally, central corneal thickness (CCT) was obtained from the Corvis ST and intraocular pressure (IOP) was recorded by dynamic contour tonometry (DCT). Parameters compared include corneal hysteresis (CH), stiffness parameter at first applanation (SP-A1) and highest concavity (SP-HC) and integrated inverse radius. ANCOVA was used to compare ORA data between groups using corneal compensated IOP (IOP_{CC}) as a covariate, and to compare Corvis ST data between groups using DCT as a covariate. The statistical analysis was performed with SAS and significance threshold was set at $P<0.05$. Due to a low n, the aphakic cohort was excluded from statistical analysis.

Results: T-tests revealed no significant between-group differences in IOP_{CC} (17.37 ± 4.41 vs 15.74 ± 2.81; p=0.1607), DCT (18.65 ± 3.78 vs 17.07 ± 2.46; p=0.1114), or CCT (545.74 ± 34.28 vs 538.63 ± 39.32; p=0.4595). CH was significantly greater in the phakic group (9.55 ± 1.9 vs 9.11 ± 1.82; p<0.0001) after controlling for IOP_{CC}. Integrated inverse radius was greater in the pseudophakic group (8.47 ± 0.99 vs 7.79 ± 0.92; p<0.0001) after controlling for DCT. There were no significant differences in corneal (SP-A1) or scleral (SP-HC) stiffness, although the n in the pseudophakic group was too low to be conclusive. Qualitatively, aphakic eyes had a greater unadjusted mean IOP_{CC}, DCT, CCT, SP-A1, SP-HC and CH than both the phakic and pseudophakic cohorts.

Conclusions: Pseudophakic eyes with POAG demonstrated lower stiffness (resistance to deformation) and lower damping (ability to dissipate energy) than phakic eyes. We propose that the contents of the eye affect its response to air-puff-induced deformation, and that the presence of a crystalline lens aids in energy dissipation and limits fluid displacement in the concave corneal phase leading to a stiffer response when compared to pseudophakic eyes. More data are needed to compare the biomechanics of eyes with aphakic glaucoma.

Commercial Relationships Disclosure: Stephen Kaufman: Commercial Relationship: Code N (No Commercial Relationship) | Chase Liaboe: Commercial Relationship: Code N (No Commercial Relationship) | Allesando Meduri: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Intraocular pressure (IOP) measurements, which can be affected by changes in corneal morphology, are used to screen and follow glaucoma. Riboflavin with ultraviolet-A-induced corneal collagen crosslinking (CXL) is used to treat keratoconus and also changes corneal morphology. The purpose of this study is to evaluate the effect of CXL on measured intraocular pressure.

Methods: A retrospective chart review of 60 keratoconic human eyes, which underwent CXL, were included. Indentation (Tono-Pen: Reichert. Depew, NY USA) tonometry was used to evaluate IOP preoperatively and at one, three, and six-month post-CXL follow-up visits.

Results: The average preoperative IOP was 14.1 +/- 2.1. The average IOP at the 1-month, 3-month, and 6-month follow-up were 17.1 +/- 2.7, 15.8 +/- 2.3, and 16.8 +/- 1.8 respectively. Relative to the preoperative IOP, the IOP at the 1-month, 3-month, and 6-month follow-up were statistically significantly higher.

Conclusions: A statistically significant increase was noted in measured IOP by Tono-Pen after CXL for keratoconus, which is likely due to an increase in corneal rigidity after CXL.

SUBMITTER (NAME ONLY): Ankur Nahar

TITLE: Female Authorship Trends in Retina: A 25-Year Analysis

SESSION TITLE: Vision care training and education

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Nahar, M. Rama, Thomas Jefferson University Sidney Kimmel Medical College, Philadelphia, Pennsylvania, UNITED STATES|R. Mahmoudzadeh, R.R. Soares, J.A. Haller, Retina, Wills Eye Hospital, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Ankur Nahar: Commercial Relationship: Code N (No Commercial Relationship) | Raziyeh Mahmoudzadeh: Commercial Relationship: Code N (No Commercial Relationship) | Rebecca Soares: Commercial Relationship: Code N (No Commercial Relationship) | Martina Rama: Commercial Relationship: Code N (No Commercial Relationship) | Julia Haller: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Authorship is a critical component of career advancement in medicine. While there has been a promising trend towards gender equality in academia, men disproportionately outnumber women in first and last author positions even when factoring in comparable publication counts. We performed a cross-sectional study to examine trends in first and last authorship within the field of retina over the last 25 years.

Methods: Original retina articles published between 1995 and 2020 were selected from four journals with the highest h5-index in ophthalmology. Publications by single authors and collaborative study groups as well as those classified as comments, letters, and editorials were excluded. First and last author names were retrieved, and GenderAPI was used to assign sex. Regression analysis was performed to determine whether the changes over time were significant. Chi-square analyses were used to compare distributions of categorical variables in various samples.

Results: A total of 4142 papers were included. The percentage of women in first and last authorship positions significantly increased from 23% to 37.7%, and 14.2% to 24.6% over 25 years, respectively ($P<0.001$, $P<0.001$, respectively; Figure 1A, 1B). When the last authors were women, 32.5% of the first authors were women, and when the last authors were men, only 27.1% of the first authors were women ($P=0.002$). Based on the ASRS 2020 database, only 17% of retina specialists in the United States are female. From our data, 28.2% of first authors and 22.3% of last authors of retina publications from the United States are female authors in 2020 ($P<0.001$, $P<0.001$, respectively).

Conclusions: While a disparity in authorship persists in ophthalmology's subspecialties, our study suggests that retina is a field where the gap is closing. Significantly, a woman as the senior author is associated with a higher likelihood of female first authorship.

ABSTRACT BODY:

Purpose: To describe the characteristics of patients affected by ocular cicatricial pemphigoid, a rare and potentially blinding disorder.

Methods: A retrospective review of the medical records of patients with biopsy-proven ocular cicatricial pemphigoid (OCP) at Manhattan Eye Ear, Throat Hospital was performed. This review includes patients at different stages of OCP seen from January 2017 to July 2021. Age of onset, presenting symptoms and signs, presence or absence of limbal stem cell deficiency, need for immunosuppressive therapy, disease course, and visual outcome were among the data collected.

Results: A total of 29 patient charts were analyzed. 72% of patients were female. Symblepharon and trichiasis were present at the initial visit to the tertiary care center in 82.8% and 82.8% respectively. Significant conjunctival inflammation was a presenting sign in 48.3% of patients, while 44.8% of patients presented with either symblepharon or trichiasis (or both) in an otherwise quiet non-inflamed eye. 20.7% had extraocular involvement, of which oral lesions were the most common. 72.4% of patients required immunomodulatory therapy, and almost one fourth (23.8%) still went completely blind. 82.8% of the cohort had functional vision measured at a single time point, while 48.3% at the same time point had blindness in at least one eye.

Conclusions: Ocular cicatricial pemphigoid is a severe ocular inflammatory condition in which patients have a high predilection of blindness even in the face of aggressive treatment.

ABSTRACT BODY:

Purpose:

The objective of this study is to evaluate the efficacy of a combination of 0.75% phentolamine ophthalmic solution (POS) and 0.4% low-dose pilocarpine (LDP) to improve distance-corrected intermediate visual acuity (DCIVA) in patients with presbyopia.

Methods: The VEGA-1 study is a Phase 2, multi-center, randomized, placebo-controlled, double-masked clinical trial. Subjects with distance-corrected near visual acuity (DCNVA) of 20/50 or worse were randomized to receive either 0.75% POS or placebo vehicle in the evening, followed with and without a morning dose of 0.4% LDP. DCIVA was assessed at multiple time points after a single combination treatment. Logistic regression models comparing POS+LDP to each treatment, with treatment and light/dark irides as factors and baseline DCIVA as a covariate was used to compare the proportion of patients with 5-letter and 10-letter improvements in DCIVA. Mean improvements in DCIVA were also assessed.

Results: Of the 150 participants included in this clinical trial (mean age 53.1 years, 72% female, 89% White), 43 were randomized to placebo alone, 30 to POS alone, 43 to POS+LDP, and 30 to LDP alone. Subjects treated with POS+LDP had a mean (SD) 9.6 (5.7) letter improvement in DCIVA from baseline at 1 hour vs 4.5 (6.7) letters with placebo ($p<0.0001$). This improvement was seen in those with both irides: light 10.4 (5.7) letters; dark 8.4 (5.6) letters. At 6 hours, POS+LDP conferred a 7.1 (6.0) letter improvement from baseline, significantly more than placebo (4.0 [6.3], $p<0.0001$). LDP+POS yielded a greater proportion of patients with a ≥ 10-letter improvement in DCIVA than placebo at 1 hour (49% vs 27%, $p=0.027$). A greater proportion of patients treated with POS+LDP had ≥ 5 letter improvement in DCIVA at 1 hour compared to placebo (86% vs 58%, OR: 5.2, $p=0.004$) and at 6 hours (72% vs 49%, OR: 3.0, $p=0.027$).

Conclusions: In this Phase 2 clinical trial, 0.75% POS and 0.4% LDP significantly improved DCIVA in subjects with presbyopia at 1 hour, with durable results through 6 hours. Phase 3 studies are planned to advance POS+LDP for a potential treatment for presbyopia.

TITLE: APSified Bruch's membrane opening (BMO)-based peripapillary OCT-A in glaucoma

SESSION TITLE: OCT Angiography Clinical Applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Bergua, B. Hohberger, M. Moritz, J. Schottenhamml, C.Y. Mardin, Ophthalmology, Friedrich-Alexander-Universitat Erlangen-Nurnberg, Erlangen, Bayern, GERMANY|

Commercial Relationships Disclosure: Antonio Bergua: Commercial Relationship: Code N (No Commercial Relationship) | Bettina Hohberger: Commercial Relationship: Code N (No Commercial Relationship) | Michael Moritz: Commercial Relationship: Code N (No Commercial Relationship) | Julia Schottenhamml: Commercial Relationship: Code N (No Commercial Relationship) | Christian Mardin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Glaucoma is known as neurodegenerative disease with a vascular component. Retinal microcirculation was observed to be impaired even in early glaucoma stages, visualized and quantified by OCT-angiography (OCT-A). Peripapillary OCT-A scans are challenging for analysis as vessel density (VD) is dependent on demarcation of the optic disc. Thus, it was the aim of the present study to investigate APSified Bruch's membrane opening (BMO)-based peripapillary VD of glaucoma with and without visual field loss compared to controls.

Methods: Peripapillary OCT-A scans of 115 participants were acquired using Heidelberg Spectralis II: ocular hypertension (OHT; n=20), pre-perimetric open-angle glaucoma (pre-OAG; n=9), OAG (n=35), and controls (n=51). Mean vessel density (VD) was computed for each of the four sectors (superior, inferior, nasal, temporal) and for the whole scan using the Erlangen AngioTool, enabling an APSified and BMO-based analysis. For the statistical analysis of mean and sectorial VD, an ANCOVA and a linear mixed model were used respectively. The diagnosis was set as a fixed effect and gender and age as covariates. For sectorial VD the sectors were embedded as repeated measures and a random intercept was added additionally to the model.

Results: Mean VD correlated significantly with diagnosis ($p=0.00018$) and age ($p=0.00013$), but not with gender ($p>0.05$). Moreover, the pairwise comparison showed, that there were significant differences between mean VD of OAG and controls ($p<0.0001$) and OHT and pre-OAG ($p=0.016$), yet not for the other groupings ($p>0.05$). For sectorial VD, diagnosis ($p=0.00018$), age ($p=0.00013$) and sector ($p<E-11$) correlated significantly, while gender did not ($p>0.05$). Looking at the pairwise comparisons of the diagnosis per sector revealed, that in each sector again the difference between sectorial VD of OAG and controls ($p<0.0003$) or pre-OAG and OHT ($p=0.016$) correlated significantly, respectively. No significant differences were observed between primary and secondary OAG ($p>0.05$).

Conclusions: Peripapillary microcirculation was observed to be impaired in perimetric glaucoma eyes and even in early glaucoma stages, yet not in OHT. As previous analysis of macular VD yielded a significantly reduced VD in OHT eyes, we assume that either analysis of peripapillary VD as to be enhanced further on, or the involvement of vascular alterations in glaucoma pathogenesis has a more peripheral origin.

ABSTRACT BODY:

Purpose: Amidst the COVID-19 pandemic, telemedicine has emerged as a safe and cost-effective alternative to traditional, in-person ophthalmology clinic visits. To better understand the implications of this technology on the patient-physician relationship, this study assessed patient perspectives about telemedicine to identify areas for improvement.

Methods: A cross-sectional survey was distributed to patients at University Retina during July 2021. Responses regarding telehealth's ability to ease anxiety of contracting COVID-19, efficiency, patient education, quality of examination, and convenience were collected on a 5-point Likert scale. A positive attitude was defined as ≥ 4 average Likert rating for all questions. Frequencies of positive attitudes were compared across demographic factors by the Pearson chi-square test. Multivariate analysis was used to evaluate factors influencing patient preference for telehealth over traditional visits.

Results: Of 103 respondents, most were female (53.8%), aged 65-74 (34.6%), and high school educated (46.2%). 38% of patients did not know their diagnosis and 62.1% had no prior history of telehealth usage. Overall, patients had a neutral attitude towards telehealth (mean Likert rating (SD) = 3.11/5 ± 0.82). Nearly one-third (31%) preferred telehealth over face-to-face visits. Questions regarding "patient education" had the greatest proportion of positive attitude, whereas "efficiency" had a largely negative attitude (both 63.1%). "Convenience" of telehealth yielded the highest number of responses in strong agreement or disagreement (38.9%). Patients with no history of telehealth usage more frequently reported negative attitudes compared to those with prior experience (87.5% vs. 71.8%, $p = 0.046$). Patients tended to respond more positively as education level increased, but this trend was not statistically significant ($p = 0.18$). On multivariate analysis, patients younger than 75 were more likely to prefer telehealth over in-person visits compared to patients 75 or older (odds ratio [OR] = 2.25, $p = .007$). Patient gender, knowledge of diagnosis, and history of past telehealth usage did not predict preference for telemedicine.

Conclusions: Patients responded with a net neutral outlook on telehealth, indicating room for improvement. Efforts should focus on addressing technological inefficiencies and age-related barriers to patient satisfaction.

ABSTRACT BODY:

Purpose: To evaluate the safety and efficacy of Xen 45 Gel stent (Xen, Allergan, Dublin, Ireland) in eyes that have failed prior surgical intervention, compared to traditional glaucoma drainage device (GDD) or cyclophotocoagulation (CPC). Since this population has low expected success rates with any additional surgery, it is vital to compare to standard of care surgical options.

Methods: This is a retrospective, single-site, case-control study of ab externo transconjunctival Xen in eyes that have previously undergone trabeculectomy and/or GDD surgery. Postoperative data was collected for 18 months. Failure was defined as: 1) no light perception, 2) additional glaucoma surgery required, or 3) intraocular pressure (IOP) of < 6 mmHg after 6 weeks postoperatively.

Results: Eighteen (18) Xen eyes and 36 control eyes matched on both glaucoma type and previous glaucoma surgeries were included. 72% had primary open angle glaucoma, 11% uveitic glaucoma, 6% primary angle closure, 6% pseudoexfoliation and 6% pigmentary glaucoma. 56% of eyes in each group had prior trabeculectomy, 28% of Xen and 31% of control eyes had prior GDD, and 17% of Xen and 14% of control eyes had both. Baseline medicated IOP was lower in the Xen group (21.8 ± 7.2) compared to controls (27.5 ± 9.4, P=0.027). The cumulative failure rate at 1 year was 17% and 20% for Xen and control respectively (P=0.32). All eyes failed by requiring additional surgery, except a control eye which failed due to loss of light perception. The mean survival time was 13.7 (±1.6) months and 11.4 (±0.6) months for Xen and control, respectively. Most Xen failures occurred within the first 6 months. There was no difference in complication rates between groups (P=0.21). When censored for additional glaucoma procedures, there were no differences at post-op month 6 and year 1 in IOP, change of IOP from baseline, number of IOP lowering medications, or number of medications reduced from baseline.

Conclusions: Xen provides a reasonable alternative to traditional surgery in patients that have previously undergone filtering surgery or GDD. But care must be taken to monitor patients closely in the perioperative period as failures occur early. Those devices that were successful beyond 6 months had noninferior IOP reduction compared to GDD and CPC.

ABSTRACT BODY:

Purpose: Hyalocytes are the resident macrophages of the vitreous. They have been implicated in the maintainence of vitreous transparency, response to injury, and involvement in extra-retinal proliferations (PMIDs: 14160361; 32574351; 33168747). Little, however, is known about the behavior of these transparent cells within their native environment, due to the lack of adequate methods of visualization. In this study, we employed a novel imaging system and image processing technique to reliably observe and characterize these cells in living human eyes over time.

Methods: Five healthy subjects were imaged using a non-confocal quadrant-detection adaptive optics scanning light ophthalmoscope (AOSLO) (PMID: 33680539). A 1x1° region of interest (ROI) at the temporal retina was imaged every 5 minutes over 1 hour for a total of 13 time points. To study hyalocyte morphology and movement over time, image registration and cell tracking were performed on all acquired images using ImageJ. Cell velocities were calculated from distances traveled divided by the time elapsed between time points. Hyalocyte morphology and movements over a longer timespan were also evaluated by imaging the same ROI 4 months after the first visit in 2 subjects.

Results: A total of 50 hyalocytes were imaged. Cells demonstrated variability in morphology and movement over time (Fig). Five categories of morphology, described in microglia, were observed, specifically: ramified (74%), hyper-ramified (6%), rod (4%), activated (14%), and amoeboid (2%). Mean±stdev velocities of ramified, hyper-ramified, rod, activated, and amoeboid cells were 0.43±0.22, 0.59±0.30, 1.29±0.40, 1.35±1.21, and 0.26 (one cell only) μm/min, respectively. In the 2 subjects imaged over 4 months, similar numbers of cells were visualized within the same ROI. However, cell tracking between visits could not be confirmed due to substantial variation in cell morphology and location, as well as absence of definitive cell labels.

Conclusions: We have demonstrated the ability to visualize hyalocytes in the living human eye without exogenous labeling using a quadrant-detection adaptive optics scanning light ophthalmoscope. The non-invasive characterization of hyalocyte morphology and movement dynamics may provide better understanding of the roles these cells play in disease progression and response to pharmacologic treatment.

ABSTRACT BODY:

Purpose: Transmissible 'scrapie-type' prion (PrP^{Sc}) deposits have been detected in the retina of patients with sporadic Creutzfeldt-Jakob disease (sCJD); however, the histopathology of retinal PrP^{Sc} deposits is poorly characterized, whereas that in the brain is well established. We performed a retrospective, observational study to characterize the morphometric features of PrP^{Sc} deposits and the histological changes in the retinas of patients with sCJD.

Methods: From July 2015 to July 2017, 14 eyes and 1 brain were collected from 14 neuropathologically-confirmed sCJD autopsy cases (4 males and 10 females; age range: 51-80, mean: 63, SD: 9.0; disease duration: 1.5-27 mo, mean: 10.5, SD: 8.4) and eyes and brains from 6 controls (5 males and 1 female; age range: 51-90, mean: 70.3, SD: 13.8). Immunohistochemistry was performed with Mab12F10 (Cayman Chemical; 1:200) against PrP^{Sc}. The greatest dimension of PrP^{Sc} staining was microscopically measured and statistical significance was evaluated with Mann-Whitney U test, Welch's unpaired t-test, and Brown-Forsythe test.

Results: PrP^{Sc} expression was found in the outer (OPL) and inner plexiform layers (IPL) of the retinas with the strongest deposition as discrete, regularly spaced ovoid deposits in a "beads-on-a-string" pattern along the horizontal axis of the OPL. PrP^{Sc} deposits were not observed in controls nor other ocular structures of the patient group. The average size of retinal PrP^{Sc} deposits in the OPL was 4.94μm, which was significantly smaller than coarse PrP^{Sc} deposits in the brain (32.45μm, $p<0.001$) with a significantly lower SD (0.47μm vs. 23.55μm, $p<0.001$). Retinal lamination and laminar thickness were comparable between sCJD retinas and controls. Spongiotic changes and overt gliosis were not observed in the retinas with PrP^{Sc} deposition.

Conclusions: Our findings show that PrP^{Sc} deposits in the retina have significantly different histologic and morphometric characteristics than those in the brain. Retinal PrP^{Sc} deposits are consistently present in ovoid aggregates in the OPL with a relatively uniform size of 5 μm. In contrast to the spongiform neurodegeneration associated with PrP^{Sc}deposition in the brain, retinal anatomy and organization appear well-preserved despite PrP^{Sc} deposition in OPL. Additional studies are required to determine the cellular location and function of PrP^{Sc} deposits in OPL.

ABSTRACT BODY:

Purpose: Objectively determining the effect of a cataract on visual performance has long been a problem for ophthalmologists. Many candidates for cataract extraction now routinely undergo optical coherence tomography (OCT) prior to surgery. We performed a single center, retrospective, observational study to evaluate the utility of using OCT image quality as an objective measure of the impact of a cataract on visual functioning.

Methods: A database was created of 1645 eyes that underwent cataract extraction and OCT prior to surgery. 1404 eyes met the inclusion criteria of a Best Corrected Visual Acuity (BCVA) of 20/25 or better within 60 days of surgery. This cutoff was chosen to reduce the likelihood of capturing concurrent non-lens pathologies. Pre- and postoperative BCVAs, cataract type and grade, preoperative OCT signal quality, and OCT model were recorded for each eye, and Snellen BCVAs were converted to Logarithm of the Minimal Angle of Resolution (LogMAR) values. The Q value, a standardized measure of signal quality, was created by scaling the proprietary image quality values from all machines to that of the most frequently used model (Zeiss). The data were stratified by postoperative BCVA, OCT model, and cataract type and grade. Simple linear regression was performed for each stratification.

Results: Linear regression of preoperative acuity among all included eyes versus Q returned an R-squared value of 0.1725. The same regression performed with eyes having a postoperative BCVA of 20/20 or better (n=1168) returned an R-squared of 0.2207. Regressing Q on preoperative acuity when stratifying by cataract type returned similar R-squared values for cortical, nuclear sclerotic, and posterior subcapsular cataracts (0.2098, 0.2219, and 0.2520 respectively). Likewise, regressing Q on preoperative acuity when stratifying by machine type returned similar R-squared values for Optovue, Topcon, and Zeiss models (0.2326, 0.2055, and 0.2641 respectively) and a lower value for Heidelberg (0.1502). The R-squared value was low when regressing either Q or preoperative acuity on summed cataract grade (0.0728 and 0.0912 respectively). P-values for all correlations were <0.0001.

Conclusions: These analyses suggest that preoperative acuity correlates better with OCT image quality than clinical cataract grade. Overall, there may be a modest correlation between vision loss caused by cataracts and OCT signal quality.

ABSTRACT BODY:

Purpose: Retinal pigment epithelium lipofuscin and melanolipofuscin (L/ML) gives rise to fundus autofluorescence, which normally increases throughout life and decreases markedly in advanced AMD. Age-related lens opacification reduces light transmission and introduces intrinsic autofluorescence into the light path, thus impacting signal strength. We utilized qAF to investigate L/ML-attributed autofluorescence in eyes with and without early or intermediate AMD, stratified by lens status, in a large cohort of older adults.

Methods: Participants in the ALSTAR2 baseline cohort (NCT04112667) were assessed by the AREDS grading system for color fundus photography. As described (PMID 32855849), qAF images captured using a scanning laser ophthalmoscope and internal fluorescent reference underwent a quality review. Mean qAF intensity values in an 8-segment annulus (inner-outer radii, 9°-11°) centered on the fovea (qAF8) were analyzed with custom FIJI plugins. Pseudophakic eyes were assigned an age of 20 years. Generalized estimating equations were used to evaluate differences in qAF8 by disease status and severity and lens status.

Results: Out of 460 individuals (mean age 72.0 ± 5.9 years, 60% female and 40% male, mean best corrected visual acuity 0.031 LogMAR), 836 eyes were classified as normal (410, 49%), early AMD (eAMD, 250, 29%), and intermediate (iAMD, 176, 21%). Among all eyes, qAF8 differed by lens status (qAF8, median (IQR): phakic 241.0 (198.6-291.1); pseudophakic 208.6 (170.9-257.6); p=0.0009). Additionally, qAF8 differed significantly by AMD presence and severity (mean qAF8: normal 244.1, eAMD 229.8, iAMD 211.4; p=0.0015). When stratified by lens status, this difference remained in phakic eyes (mean qAF8 normal 256.7, eAMD 247.9, iAMD 221.2; p=0.0013) but not in pseudophakic eyes (mean qAF8 normal 228.5, eAMD 211.6, iAMD 205.3; p=0.0974).

Conclusions: In a large cohort, qAF8 was associated with AMD presence and severity in phakic but not pseudophakic eyes, being higher on average in phakic eyes. Unaccounted variation in individual lens density and autofluorescence may explain the association of qAF8 with AMD in phakic eyes. Future studies using qAF in older patients should enroll pseudophakic eyes for best results. Loss of histologic L/ML signal before atrophy in AMD tissues may be undetectable by current qAF.

ABSTRACT BODY:

Purpose: Vascular factors have been shown to be responsible in the pathogenesis of Normal Tension Glaucoma (NTG). This cross-sectional study examined the ability of vessel density (VD) to predict variance across pattern electroretinogram (PERG) parameters, average retinal nerve fiber layer thickness (avRNFLT) and average ganglion cell-inner plexiform layer thickness (avGCL + IPLT) in NTG suspects with Obstructive Sleep Apnea (OSA).

Methods: Four pre-perimetric glaucoma subjects (7 eyes) with normal Humphrey 24-2 visual field tests, normal intraocular pressure (IOP) levels and suspicious optic nerve head were consecutively recruited at Manhattan Eye, Ear and Throat Hospital. Participants underwent Diopsys NOVA PERG and Cirrus Optical Coherence Tomography tests. Patients with documented OSA diagnosis were included. After controlling for Age (Step 1), hierarchical multiple linear regression analysis was used to determine the ability of IOP (Step 2) and VD (Step 3) to predict variance in dependent variables (Magnitude [Mag], MagnitudeD [MagD], MagnitudeD/Magnitude ratio [MagD/Mag ratio], avRNFLT and avGCL+IPLT).

Results: In prediction of Mag and MagD, after controlling for Age, VD explained 70.1% and 72.8% of variance (B= 0.149 [95% CI: 0.037, 0.262], p=0.024) (B= 0.134 [95% CI: 0.031, 0.237], p=0.026), respectively. IOP was not significant. In the prediction of MagD/Mag ratio, Age and IOP explained 62.3% and 29.3% of variance (B= 0.003 [95% CI: 0.000, 0.006], p=0.035) (B= 0.008 [95% CI: 0.002, 0.014], p=0.020), respectively. VD was not significant.
In prediction of avRNFLT, after controlling for Age, IOP and VD explained 76.9% and 11.0% of variance (B= -2.730 [95% CI: -4.316, -1.143], p=0.009) (B= 0.652 [95% CI: 0.079, 1.225], p=0.036), respectively.
In prediction of avGCL+IPLT, after controlling for Age, IOP and VD explained 69.3% and 6.00% of variance (B= -1.466 [95% CI: -2.115, -0.816], p=0.003) (B=-0.274 [95% CI:-0.480, -0.068], p=0.024), respectively.

Conclusions: In NTG suspects with OSA, VD was a significant predictor for Mag and MagD, demonstrating the importance of healthy microvasculature for normal retinal ganglion cell function. We report combined effects of VD and IOP on avRNFLT and avGCL+IPLT, emphasizing the need to further investigate this relationship, IOP diurnal fluctuations and IOP nocturnal elevations in OSA.

ABSTRACT BODY:

Purpose: Endogenous fungal endophthalmitis is a rare entity without a consensus approach to management. The aim of the study is to provide data on the presentation and practice patterns to guide future clinical decision making.

Methods: A retrospective chart review was performed on a cohort with established endogenous fungal endophthalmitis between 2009-2021 at Massachusetts Eye and Ear. Linear regression was performed to analyze the correlation between days to pars plana vitrectomy (PPV) and improvement in visual acuity. Wilcoxon Signed-Rank tests were used to compare VA improvement between initial presentation vs. final visit, early (within 3 days) vs. late (after 3 days) PPV, IV vs. topical antifungals, and intravitreal voriconazole vs. amphotericin.

Results: Fourteen eyes from 13 patients (92.8% male) with a median age of 43.5 years (IQR: 23-79) were included. The initial median VA was 1.676 LogMAR (IQR: 0.301-2.477). Initial slit lamp exam most often revealed vitritis (93.0%), AC flare (86.0%), hypopyon (50.0%), and keratic precipitates (50.0%). It took an average of 1.54 days (Median 0; IQR 0-7) to establish a diagnosis of endogenous fungal endophthalmitis. Cultures were obtained via vitreous (78.6%) or anterior chamber (21.4%) aspirates. Within an average of 7.38 days (IQR: 1-38 days), most cultures (85.7%) grew candida species (albicans, dubliniensis, tropicalis, and glabrata). Most patients received intravitreal (85.7%) and IV (73.3%) antifungals. Two patients (14.3%) received PPV within 1 day of presentation as their initial intervention. 78.5% of the cohort received a PPV within an average of 11.3 days (Median 10, IQR: 1-38). There was a statistically significant improvement in the final median VA, 0.544 LogMAR (IQR: 0-2.477) ($Z=2.8241$, $p<0.005$). No eyes had to be enucleated or eviscerated. There were no statistically significant differences ($p>0.05$) in VA outcomes with early vs. late PPV, IV vs. topical antifungals, or between intravitreal voriconazole vs. amphotericin. There was no statistically significant correlation ($p>0.05$) between the days to PPV and final VA improvement.

Conclusions: The most common causative species to cause endogenous fungal endophthalmitis was Candida. Surgical intervention with PPV was often required to achieve an improvement in visual acuity and outcomes were generally favorable.

ABSTRACT BODY:

Purpose: One of the major challenges in cataract/refractive surgery is to determine the optimal center position for the optical correction. The entrance pupil center (EPC) and the 1st Purkinje image are common centration references. The visual (foveal achromatic) axis along which no transverse chromatic aberration may be another candidate. The purpose of this study was to locate the visual axis with respect to EPC and evaluate the extent of its correlation to the peak of the Stiles-Crawford effect (SCE).

Methods: Six young typical subjects (12 eyes) were enrolled in the study. An optical system was developed to locate the visual axis and measure SCE. A translatable pinhole (diameter: 600 μm) was placed in the pupil conjugate and its location was imaged with a pupil camera. To find the visual axis, two small laser spots at 450 and 680 nm were co-aligned and delivered to the retina. Subjects were asked to move the translatable pinhole until these spots are perceived to be overlapped each other, i.e. zero transverse chromatic aberration. With the same system, the SCE was assessed by a conventional two-channel (reference and test) Maxwellian view system. Three repeated measurements at 19 pupil entrance points distributed within the central 4 mm pupil diameter were conducted. The peak positions were estimated by a two-dimensional Gaussian fitting function and correlated with the visual axis positions.

Results: The visual axis was, on average, located inferonasal to the EPC [x: 0.22 ± 0.40 mm, y: -0.18 ± 0.42 mm]. The SCE peak was also located inferonasal to the EPC [x: 0.26 ± 0.39 mm, y: -0.16 ± 0.38 mm]. The SCE peak positions were highly correlated in both horizontal and vertical meridians to the visual axes (R^2 = 0.97 for x, 0.96 for y coordinates). Five of the six subjects demonstrated mirror-symmetry in the coordinates of the visual axis and the SCE peak of both eyes (R^2 = 0.92 for the visual axis, 0.90 for the SCE peak).

Conclusions: The visual axis and the SCE peak locations were found to be variable between the subjects but highly correlated with each other within each individual. These findings may suggest a potential feedback mechanism between the ocular optics and the cone photoreceptor alignment.

ABSTRACT BODY:

Purpose: Neovascular age-related macular degeneration (AMD) commonly causes vision loss from aberrant angiogenesis, termed choroidal neovascularization (CNV). To unravel the mechanisms underlying CNV, we focused on the p75 neurotrophin receptor ($p75^{NTR}$), a transmembrane protein known to mediate neuronal survival and death, and also vascular changes. $P75^{NTR}$ can couple to different co-receptors to transduce intracellular signals. Our previous results showed that $p75^{NTR}$ increases 7 days post-laser in retinal glia (GS+ or GFAP+) and RPE (retinal pigment epithelium)-choroid infiltrate (F4/80+) cells of mice with CNV. The deletion of the receptor reduced CNV area and prevented photoreceptor dysfunction. It has been reported that $p75^{NTR}$ can potentiate Trk signalling in some scenarios. Thus, we aim to determine if $p75^{NTR}$ modulates Trk activation to modify neovessel formation in a mouse model of laser-induced CNV.

Methods: 2- months old mice were anesthetized and their pupils were dilated; then, 4 injuries were performed in the retina using a photocoagulation laser with a 532nm wavelength slit lamp. 7 days after laser the mice were sacrificed. Samples include RPE-Choroid flatmounts, retina cryosections for immunostaining, and retinal and RPE-Choroid extracts processed separately for Western blot. WT (n=15) and $p75^{NTR}$ KO (n=21) mice were included in the experimental design and animals without CNV (n=10) were used as control.

Results: We estimated Trk activation through the activation of its downstream signaling molecule ERK. We detected decreased expression of phosphor-ERK in retina from CNV mice respect to control (p=0,014) and similar phospho-ERK levels in RPE-choroid 7 days post laser (p=0,227) by Western Blot. Immunostaining did not show localization of pan-Trk nor phospho-ERK in retinal glia. Similarly, no overlapping was detected between pan-Trk and RPE-Choroid infiltrate assessed in RPE-Choroid flatmounts. Consistently, $p75^{NTR}$KO mice showed equal phospho-ERK levels 7 days after laser in retina (p=0,322) and RPE-Choroid (p=0,353).

Conclusions: In sum, our results suggest that the formation of vascular tufts that are produced during the CNV is not mediated by the cooperative signalling between $p75^{NTR}$ and Trk receptors.

ABSTRACT BODY:

Purpose: Graft rejection remains the leading cause of allograft failure in corneal transplantation. Plasmacytoid dendritic cells (pDCs) are implicated in the maintenance of immune tolerance in other models. Herein, we tested the hypothesis that adoptive transfer of pDCs can promote allograft survival via inducing immune tolerance, using an experimental allogenic corneal transplantation model

Methods: Allogenic corneal transplantation was established using BALB/c recipients and C57BL/6 donors. Adoptive transfer of sorted splenic allo-pDCs or saline were performed using fibrin sealant at d1 post-surgery. Anergic T cells, regulatory T cells (Tregs), Th1, and Th17 cells in draining lymph nodes (dLNs), and infiltrating leukocytes and T cells in corneas, were detected via flow cytometry at d14 post-transfer. Grafts was assessed twice weekly for 70 days with slit-lamp to score graft neovascularization (NV, 0-8^{+} scale), opacity (0-5^{+} scale), and rejection (graft opacity≥ score 3). Rejection-free graft survival was evaluated by Kaplan-Meier survival curves followed by log-rank test; unpaired t-test was used for comparisons.

Results: pDCs induced anergic $CD4^{+}$T cells (CTLA-4^{+}: 1.6-fold, PD-1^{+}: 1.8-fold, LAG-3^{+}: 4.6-fold, compared to the saline group; n=3, all $p<0.05$), and expanded the $Foxp3^{+}CD4^{+}$Tregs compartment (2.5-fold; n=3, $p<0.001$), while they had no effect on $IFN\gamma^{+}CD4^{+}$ Th1 and $IL17^{+}CD4^{+}$ Th17 (1.2-fold and 1.1-fold respectively; n=3, both $p>0.05$) in dLNs. In addition, pDCs ameliorated infiltration of $CD45^{+}$ leukocytes and $CD3^{+}$ T cells in corneal beds ($CD45^{+}$: 87.5%, $CD3^{+}$: 79.0% decrease compared to saline group; n=3, both $p<0.05$) and grafts ($CD45^{+}$: 75.8%, $CD3^{+}$: 71.9% decrease; n=3, both $p<0.01$). Moreover, pDCs suppressed corneal NV from d7 until d70 (score 2.8±0.34 SEM to 5.4±0.36, n=12 for pDCs transfer group vs 4.0±0.23 to 6.4±0.22, n=11 for saline control group; $p<0.05$ for all timepoints). Further, pDCs alleviated graft opacity from d14 until d70 (score 0.4±0.15 to 1.5±0.33, n=12 vs 1.1±0.21 to 3.5±0.45, n=11; all $p<0.05$), and improved survival rate of grafts (83.3%, n=12 vs 36.4%, n=11; $p<0.01$) through the end of 70 days.

Conclusions: Adoptive transfer of pDC promote survival of corneal allograft, which is associated with T cell tolerance, suggesting the translational potential of cell-based pDC therapy use in corneal transplantation

TITLE: Comparing Bruch's Membrane Opening, Intraocular pressure, and Pulsatile Ocular Blood Volume when in sitting and supine positions in Glaucomatous and Non-Glaucomatous eyes

SESSION TITLE: OCT Clinical Applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. BUMA, The Ohio State University College of Medicine, Columbus, Ohio, UNITED STATES|N.S. Madhan, Y. Ma, A. Mahmoud, G. Fleming, C.J. Roberts, Ophthalmology and Visual Sciences, The Ohio State University College of Medicine, Columbus, Ohio, UNITED STATES|A. Mahmoud, G. Fleming, C.J. Roberts, Department of Biomedical Engineering, The Ohio State University, Columbus, Ohio, UNITED STATES|

Commercial Relationships Disclosure: Stephen BUMA: Commercial Relationship: Code N (No Commercial Relationship) | Nayasha Madhan: Commercial Relationship: Code N (No Commercial Relationship) | Yanhui Ma: Commercial Relationship: Code N (No Commercial Relationship) | Ashraf Mahmoud: Commercial Relationship: Code N (No Commercial Relationship) | Gloria Fleming: Commercial Relationship: Code N (No Commercial Relationship) | Cynthia Roberts: Commercial Relationship(s);Code C (Consultant/Contractor):Ziemer Ophthalmic Systems AG;Code C (Consultant/Contractor):Oculus Optikgeräte GmbH;Code R (Recipient):Heidelberg Engineering, Inc

ABSTRACT BODY:

Purpose: To investigate Bruch's Membrane Opening-Minimum Rim Width (BMO-MRW), Intraocular pressure (IOP) and Pulsatile Ocular Blood Volume (POBV) between glaucomatous and non-glaucomatous eyes in supine and sitting positions.

Methods: Cross-sectional, prospectively acquired data was used to evaluate 323 eyes of 181 healthy controls (NRL) and 66 eyes of 42 subjects diagnosed with primary open-angle glaucoma (GLA). BMO-MRW was measured using Flex-Arm Spectralis Optical Coherence Tomography (OCT) in both sitting and supine positions, as well as pneumatonometry to measure IOP and ocular pulse amplitude (OPA). A surrogate of POBV was calculated by dividing OPA by diastolic IOP. BMO-MRW in GLA and NRL were compared using ANCOVA with IOP as a co-variate. Univariate regression analyses were performed between BMO-MRW and IOP. Paired t-tests were included between sitting and supine positions. SAS statistical analysis software was used with $p<0.05$ as the significance threshold.

Results: BMO-MRW was significantly smaller in GLA eyes compared to NRL in the supine position (211 ± 60 µm vs 357 ± 61 µm; p<.001). IOP is negatively correlated to BMO-MRW in both sitting (R^2=.08; p<.001) and supine (R^2 =.05; p<.001) positions only in NRL eyes. IOP increases significantly in supine position relative to sitting in both GLA (19±4mmHg vs 23±4mmHg; p<.001) and NRL groups (16±3mmHg vs 21±3mmHg; p<.001). POBV surrogate is significantly lower in the supine position compared to sitting in both GLA (.10±.03 vs .12±.05; p<.001) and NRL (.10±.04 vs .14±.06; p<.001) cohorts.

Conclusions: It is known that BMO-MRW is smaller in glaucoma than normal in the sitting position, and the current study confirms this relationship also exists in the supine position with higher IOP. In addition, this study shows higher IOP is associated with smaller BMO-MRW only in NRL. It is also known that IOP increases with extended time in the supine position during sleep. Although there is no immediate change in BMO-MRW between sitting and supine positions, further studies are warranted to determine if BMO-MRW is affected by extended periods of time in the supine position as IOP increases. Additionally, POBV decreases relative to sitting in both groups indicating less perfusion, which may represent additional risk to the glaucomatous eye during extended periods in the supine position.

ABSTRACT BODY:

Purpose: In our study, we aim to describe changes in the geographic distribution of visual disability over the last decade (2010-2019) in the United States and evaluate these trends in the context of age, gender, and income level.

Methods: Our study used publicly available data from the Census Bureau American Community Survey from 2010-2019. Data gathered from all United States counties (3,220 counties) included age, gender, rate of self-reported vision difficulty (binary responses identifying persons who are “blind or having serious difficulty seeing, even when wearing glasses”), and county-average ratio of income to poverty.

Results: The mean overall prevalence of self-reported visual impairment (VI) from 2010-2019 was 2.31% in the United States, and there was a significant increase in VI over the past decade from 2.25% in 2010-2014 to 2.37% in 2015-2019 ($p<0.001$).VI was significantly higher in rural counties (3.58%), compared to urban (3.10%) or metropolitan counties (2.18%) ($p<0.001$). In terms of geographic region, the South had the highest rate of VI (2.63%), and the Northeast had the lowest rate of VI (2.00%) ($p<0.001$). For age groups >17-years-old in the 2010-2019 data, females had higher rates of VI compared to males. In terms of socioeconomic status, the highest rate of VI occurred in the second lowest income quintile, and the lowest rate of VI occurred in the first, wealthiest quintile. Over the 2010-2019 decade, VI increased by the greatest percentages in the bottom two quintiles.

Conclusions: Prevalence of visual impairment has risen and disproportionately affects certain communities. This includes individuals living in the South, in rural counties, women, and those living in poverty. Patterns of visual impairment over the past decade may inform future trends and guide interventions for populations at highest risk of blindness.

TITLE: Accuracy of automated machine learning in classifying trachoma from field-collected conjunctival images

SESSION TITLE: Machine Learning: Segmentation and Classification

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Milad, F. Antaki, R. Duval, Ophthalmology, Universite de Montreal, Montreal, Quebec, CANADA|

Commercial Relationships Disclosure: Daniel Milad: Commercial Relationship: Code N (No Commercial Relationship) | Fares Antaki: Commercial Relationship(s);Code F (Financial Support):Bayer Healthcare Pharmaceuticals;Code R (Recipient):SNELL Medical Communication Inc | Renaud Duval: Commercial Relationship(s);Code C (Consultant/Contractor):Alcon, Novartis, Bayer, Roche

ABSTRACT BODY:

Purpose: Trachoma is the leading infectious cause of blindness worldwide and is an important public health problem. Determining the community prevalence of trachoma in endemic countries by conjunctival examination is fundamental to guide public health interventions. While machine learning (ML) models have been proposed to automate trachoma detection from conjunctival images, their development is reserved to artificial intelligence (AI) experts. In this study, clinicians with no coding experience developed automated ML (AutoML) models to detect trachoma using a graphical user interface.

Methods: Ophthalmologists with no coding experience carried out AutoML model design using a public data set of field-collected conjunctival images from clinical trial participants in Niger and Ethiopia. The dataset was previously labelled by experts using the WHO Simplified Grading System. Google Cloud AutoML Vision was used for training and testing. We designed two binary models to detect trachomatous inflammation-intense (TI) and trachomatous inflammation-follicular (TF). We then compared them to bespoke TI and TF detection models designed using the same dataset by AI experts (Kim et al., Plos One, 2019). The AutoML model performance is reported using the area under the precision-recall curve (AuPRC), sensitivity, specificity and accuracy.

Results: A total of 1,656 field-collected conjunctival images were included (1,019 normal, 365 TF, 110 TI and 162 TF and TI). The two AutoML models showed high diagnostic properties that were comparable to bespoke deep-learning models. The AutoML TI model had an AuPRC of 0.980, sensitivity of 85%, specificity of 98% and accuracy of 95% (vs. 96%, 74% and 85% for the bespoke models). The AutoML TF model had an AuPRC of 0.907, sensitivity of 81%, specificity of 93% and accuracy of 89% (vs. 86%, 58% and 72% for the bespoke models).

Conclusions: Our study highlights the value of AutoML in the democratization of AI. We demonstrate the feasibility of using AutoML by ophthalmologists with no coding experience to create deep-learning models to detect trachoma from conjunctival images. The model can detect TF and TI with excellent performance results, with metrics similar or better than those designed by AI experts. Our results also demonstrate the potential value of open-access data and big data in improving public health issues worldwide.

ABSTRACT BODY:

Purpose: Retinal remodeling, triggered by photoreceptor death, could either slow down, or exacerbate vision loss. We hypothesize that in typical less aggressive forms of retinitis pigmentosa, where a fraction of rods remains light responsive, the retina initially compensates for reduced receptor input by increasing signal transmission to bipolar cells. This hypothesis was tested, using a mouse model for the most common autosomal-dominant retinitis pigmentosa-associated mutation of rhodopsin, the P23H mutation ($Rho^{P23H/WT}$ = P23H mouse).

Methods: All comparisons were made between P23H mice and their age-matched wildtype control littermates (n=4-8 per group). Both sexes were represented equally in each group. Statistical significance was determined using two-way ANOVA or two-tailed t-test, with correction for multiple comparisons where needed. For behavior and electrophysiology experiments, mice were bred onto the $Gnat2^{-/-}$ background to eliminate cone-mediated light signals. Sensitivity of vision was assessed by optomotor response in ambient light, ranging from scotopic to mesopic levels. Light signal transmission from rods to rod bipolar cells (RBCs) was assessed by ex vivo ERG, isolating the rod component using DL-AP4 and the RBC component by subtracting rod responses from mixed rod/RBC responses. ScRNA-Seq was used to measure differences in gene expression in the rods and RBCs of P23H mouse retinas versus controls. In addition, expression of selected proteins in whole retinas from P23H and control mice were compared, using Western blotting and immunohistochemistry.

Results: Based on scRNA-Seq analysis we found a significant upregulation of several major rod ribbon synapse genes in P23H rod photoreceptors ($p<0.00001$). Ca^{2+} sensor protein synaptotagmin-1 (Syt1) was overexpressed at P30 ($p=0.02$) in whole P23H retinas, as compared to controls. Scotopic contrast threshold changed only at the dimmest background intensity ($5*10^{-4}$ Cd/m^2) in P60 P23H/$Gnat2^{-/-}$ mice, from 60±6% to 76±4% ($p< 0.001$); and the RBC/rod response ratio increased in 1- 6 mo P23H mice ($p<0.005$).

Conclusions: We discovered increased mRNA expression of rod ribbon synapse proteins in P23H mice. These results suggest that presynaptic scaling, potentially via upregulation of Syt1, mediates a compensatory mechanism that promotes night vision during the slow progression of rod photoreceptor degeneration.

ABSTRACT BODY:

Purpose: Proliferative vitreoretinopathy (PVR) is the dreaded cause of failure following retinal detachment repair; however, to this date, no cures or preventative therapies exists. The purpose of this study is to use advanced bioinformatics tools to study drug-gene associations in order to identify drugs/compounds that interact with genes affected in PVR and that could be candidates for further testing as novel management strategies of PVR.

Methods: We queried PubMed Gene to assemble a list of genes associated with PVR to date. Gene enrichment analysis for the compiled PVR gene list was executed via ToppGene against the drug databases. This analysis identifies overepresented compounds and predicts their statistical significance from multiple drug-gene interaction databases to formulate a Pharmacome. Compounds with adjusted p-value <0.05 were chosen. Compounds with no clinical indications (e.g., ozone, ethanol) were filtered out from the resulting drug lists.

Results: Our query identified 34 unique genes associated with PVR. Out of 77,146 candidate drugs/compounds in the drug databases, our analysis revealed multiple drugs/compounds with significant interactions with genes involved in PVR. The drugs predicted amongst the top 100 most significant compounds include anti-proliferatives, corticosteroids, anti-diabetics, antioxidants, statins, and flavonoids. Prednisone ($P=2.08x10^{-7}$), a corticosteroid that affects 4 of the 34 identified PVR genes, and methotrexate ($P=1.70x10^{-4}$), an anti-neoplastic agent that also affects 4 of the 34 genes, have shown promising results in animal studies and ongoing clinical trials for PVR. Other predicted top compounds including metformin ($P=8.30x10^{-12}$), statins ($P=9.76x10^{-19}$), and curcumin ($P=2.03x10^{-17}$), which affect 11, 17, and 18 of the 34 PVR genes, respectively, have well-established safety profiles and could be readily repurposed for PVR.

Conclusions: This bioinformatics approach of studying drug-gene interactions can speculate drugs which may affect genes and pathways implicated in PVR. We use our growing understanding of systems biology to introduce a computational network medicine process for finding novel therapeutic targets for PVR. While further validation from preclinical/clinical studies is required for bioinformatic predictions, this unbiased approach could identify possible candidates out of existing drugs/compounds that may be repurposed for PVR and guide future investigations.

ABSTRACT BODY:

Purpose: Hydroxychloroquine (HCQ) is an antimalarial drug widely used by many specialties for the management of autoimmune diseases. Retinal toxicity with long term HCQ treatment is a major concern and risk factors have been established. Several recent studies detected microvascular changes in patients using HCQ without evident microangiopathy or retinopathy on ophthalmoscopy. In addition, Optical coherence tomography angiography (OCTA) may help to further elucidate the mechanisms of HCQ-induced retinal toxicity. We sought to conduct a systematic review and meta-analysis of the OCTA application to detect HCQ-induced microvascular alterations and further characterize them.

Methods: PubMed, Scopus, Web of Science and Cochrane were systematically searched to November 1st, 2021, along with a manual search. Studies that used OCTA as a primary diagnostic method to evaluate the macular microvasculature of HCQ users were included. Meta-analyses of continuous outcomes were conducted using an inverse variance in the model. Primary outcomes were macular vessel density (VD) and foveal avascular zone (FAZ) at the superficial (SCP) and deep capillary plexus (DCP).

Results: Of 159 screened articles, 8 were found eligible for qualitative and for quantitative analysis. Patients with high risk of HCQ-induced retinopathy due to the longer duration of treatment (> 5 years) presented lower VD in the retinal microvasculature than those with low risk in SCP (SMD -0.53 [-0.93, -0.12], P = 0.01 in fovea; SMD -0.44 [-0.73, -0.16], P = 0.002 in parafovea) and in DCP (SMD -0.53 [-1.01, -0.06], P = 0.03 in fovea) and a trend for wider FAZ in DCP (P = 0.06). When compared with healthy controls, HCQ users had lower VD in SCP (SMD -0.67 [-1.19, -0.15], P = 0.01 in fovea; SMD -0.74 [-1.40, -0.08], P = 0.03 in parafovea) and in DCP (SMD -0.85 [-1.59, -0.10], P = 0.03 in fovea) and presented a wider FAZ only in SCP (SMD 0.61 [0.03, 1.20], P = 0.05).

Conclusions: Microvascular retinal changes were found in patients under HCQ treatment without any kind of retinopathy. These findings seem to precede structural and electrophysiologic changes, placing OCTA as a potential instrument for early detection of reversible retinopathy. In addition, these results support the idea of vasculopathy in the pathogenesis of HCQ-induced retinal toxicity.

ABSTRACT BODY:

Purpose: Optical coherence tomography angiography (OCTA) is highly prone to image artifacts which can hinder the interpretation of OCTA images for clinical and research applications. The aim of this study is to develop a feasible method of characterizing and quantifying OCTA artifacts for objective analysis of image quality.

Methods: This was a retrospective study of 3×3 mm^2 OCTA scans (CIRRUS HD-OCT 5000) from healthy adult subjects without any major eye diseases. The en face angiogram and structural OCT image from each scan at the superficial retinal layer (SRL) was segmented for analysis. Four types of artifact were defined (decentration, motion artifact, defocus, and shadowing) and manually graded on a scale of 0 (not present), 1 (mild), and 2 (severe) as shown in Table 1 and Figure 1. A previously described and validated semiautomated algorithm was used to calculate vessel diameter index (VDI), vessel area density (VAD), vessel skeleton density (VSD), vessel complexity index (VCI), and flux. A linear mixed-effects model was used to analyze the effect of artifact severity on OCTA parameters.

Results: 152 scans from 35 eyes of 19 participants (age 69.4±6.7 yrs, 43.4% male) were included. Severe defocus ($Ps<0.001$), severe shadowing ($Ps<0.001$), and mild defocus ($Ps<0.01$) were negatively correlated with VDI, VAD, VSD, and flux, (range $r=[-3.9\times10^{-3}]$-$[-1.6\times10^{-1}]$). Severe decentration ($Ps<0.05$) was also negatively correlated with VDI, VAD, and VSD, but not flux, with similar magnitudes. Severe motion artifact was positively correlated with VCI ($Ps<0.05$, $r=1.8\times10^{7}$). VCI was not correlated with any other artifacts. Decentration, motion artifact, and shadowing of mild severity were not correlated with any of the vessel parameters.

Conclusions: The presence of severe decentration, defocus, and shadowing on OCTA scans was found to be quantitatively reflected in the vessel parameters of VDI, VAD, VSD, and flux, while motion artifact was uniquely correlated with VCI. Mild artifacts may not significantly impact most OCTA parameters.

ABSTRACT BODY:

Purpose: Exposure keratopathy (EK) is the most common potential ocular complication following general anesthesia (GA), presenting with postoperative pain, tearing, photophobia, and blurred vision. The current study aims to evaluate the incidence of post-anesthesia exposure keratopathy before and after implementation of a bio-occlusive dressing eye protection protocol (Fig. 1).

Methods: We conducted a single-center nonrandomized quality improvement study on 15,585 patients from March 2018 to June 2018 (before protocol) and from August 2018 to February 2019 (after protocol). The primary study outcome was the development of anesthesia-related exposure keratopathy in patients. Odds ratios (ORs) were generated using multivariate logistic regression models. Potential confounders in the model included patient demographics, duration of GA, smoking status, diabetic status, American society of anesthesiologists (ASA) wellness score, anesthesiologist type (i.e., CRNA, resident, faculty) and dependent surgical positioning. Inverse probability of treatment weighting (IPTW) was implemented to create a balanced comparison between periods on the baseline variables. Power analysis found that post-weighted samples sizes were large enough to ensure a power of 98.14% with a type I error of 0.05 to detect a 10% difference (RR=1.1) for outcomes. Two-tailed tests were evaluated with an alpha = 0.05.

Results: There was no significant monthly trend in the number of GA cases during the 11-month period (Fig. 2). Prior to introduction of protection protocol, 25/6506 (0.38%) patients undergoing GA developed EK. After protocol implementation, the number of EK was reduced to 3/9352 (0.03%) ($p<0.001$). After IPTW adjustment, the relative risk reduction was 90.0% (CI: 67.3%, 96.9%) and the number needed to treat was 291.52 (CI: 206.7, 501.5). IPTW binary logistic regression analysis controlling for confounding found that there was a significantly decreased odds of developing EK after protocol implementation when compared to before (OR [95% CI], 0.083 [-0.016–0.182], $P < .001$) (Table 1).

Conclusions: The lack of a standardized eye protection protocol results in higher EK incidence, suggesting that lagophthalmos is the most important factor in the development of anesthesia-related EK. The systematic use of a bio-occlusive dressing represents an effective method for reducing the post-GA keratopathy risk.

ABSTRACT BODY:

Purpose: To investigate whether practicing a full-contrast grating acuity task modifies resolution acuity in adults with astigmatism-related amblyopia.

Methods: We developed a psychophysical test to measure grating acuity. In each trial, a full- contrast sinusoidal grating target (diameter=0.7 deg) was displayed randomly at one of four locations on the monitor screen. The visual task was to indicate the location of the target grating. The spatial frequency of the grating stimuli was controlled using an adaptive staircase technique (3-down 1-up, converged to 79% correct). The mean of the last 12 reversal points was taken as grating acuity. The mean luminance of the grating targets was 70 cd/m2. In the training phase, the participants were required to repeatedly practice the grating acuity task for 10 sessions with the amblyopic eye. The grating orientation was set to the axis of the negative cylindrical correction for myopic astigmatism. Audio feedback was provided for each response. Each participant had given roughly ten thousand responses at the end of the experiment.

Results: Ten adults with astigmatism-related amblyopia participated. Over the course of the grating acuity training, our participants showed rapid recovery from meridional acuity deficits. The meridional anisotropy of grating acuity became significantly normalized from 1.28 to 1.06 after the intervention (paired $t=4.757$, $p=0.001$). All participants showed a significant improvement in grating acuity of the amblyopic eye for the trained grating orientation (mean improvement, 19%; one sample $t=8.228$, $p<0.001$), and the learning effects did not transfer to the untrained orthogonal grating orientation (one sample $t=4.194$, $p=0.683$).

Conclusions: Practicing grating detection near cut-off spatial frequency can improve meridional acuity deficits in astigmatism-related amblyopia. Our findings characterized the learning profile and orientational specificity of grating acuity training. We are currently working towards standardizing this new technique for treatment of meridional amblyopia.

TITLE: Epidemiology of Retinopathy of Prematurity in the United States from 2003 to 2016

SESSION TITLE: Retinopathy of prematurity

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Skrehot, A. Bhatnagar, A. Bhatt, H. Herce, C.Y. Weng, Department of Ophthalmology, Baylor College of Medicine, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure: Henry Skrehot: Commercial Relationship: Code N (No Commercial Relationship) | Anshul Bhatnagar: Commercial Relationship: Code N (No Commercial Relationship) | Amit Bhatt: Commercial Relationship: Code N (No Commercial Relationship) | Honey Herce: Commercial Relationship: Code N (No Commercial Relationship) | Christina Weng: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinopathy of prematurity (ROP) is an eye disorder primarily affecting premature and low birth weight infants that can lead to lifelong vision impairment and blindness. We used a nationwide pediatric inpatient care database to investigate the variability of incidence of ROP across populations, locations, and time in the US.

Methods: The National Healthcare Cost and Utilization Project Kids' Inpatient Databases from 2003 to 2016 were analyzed to find the incidence of ROP across sexes, racial groups, income groups, and geographic regions. Infants with ICD-9 codes (ICD-10 for 2016) for premature birth week or low birth weight (<1500 g) were considered premature. Chi-square tests of independence were used to determine whether incidences changed by year or varied across subpopulations.

Results: The proportion of premature infants diagnosed with ROP has increased from 4.61% in 2003 to 8.54% in 2016. Compared with those born in higher median household income quartiles, premature infants from the lowest quartile had the greatest proportional increase of ROP diagnoses from 5.07% to 9.50% during the same time period ($p < 0.001$). ROP incidence increased between 2003 and 2016 in all considered racial/ethnic groups, but premature Black infants experienced the largest relative increase from 5.98% to 12.12% ($p < 0.01$). The Southern US has seen the greatest growth in the proportion of ROP diagnoses increasing from 3.82% to 9.11% ($p < 0.001$). ROP diagnoses have proportionally increased in urban areas and decreased in rural areas. Premature male and female infants experienced similar relative increases in ROP diagnoses (4.47% to 8.27% vs 4.76% to 8.86%, respectively).

Conclusions: Overall incidence of ROP among premature infants increased from 2003 to 2016. Infants in the poorest areas have the highest proportional incidence of ROP, and this disparity is persistent over time. Black infants appear to be at the highest risk. All regions have experienced a significant increase in ROP incidence, with the most drastic changes occurring in the South and Midwest. Regardless of region, the burden of ROP seems to have partially shifted from rural hospitals to urban ones. These trends indicate ROP is a growing problem in the United States and one that may be disproportionately affecting certain subpopulations.

ABSTRACT BODY:

Purpose: One major effect of the COVID-19 pandemic has been a delay in presentation and interruptions in delivery of care to patients with many different cancer types. The purpose of our study is to compare the clinical and genomic variables of uveal melanoma patients presenting before and after the start of the pandemic to assess the effect of the pandemic on a delay in care.

Methods: This study is a retrospective chart review of uveal melanoma patients presenting during two time periods: May 2019 to February 2020 (Group 1: Before the COVID-19 pandemic declaration by the WHO in March 2020) and May 2020 to March 2021 (Group 2: After the start of the COVID-19 pandemic). Disease stages at presentation were analyzed by clinical and genomic variables including: thickness and largest base diameter of tumor, COMS size class, AJCC stage, GEP class, and Prame status.

Results: A total of 80 patients with uveal melanoma were studied [Group 1: 40 (50%) and Group 2: 40 (50%); mean age: 62.5 years (range 25-84) and 64 years (range 30-91)]. There was no statistically significant difference between the tumor thickness, largest base dimension, and COMS size class between Group 1 (Pre-COVID) and Group 2 (During COVID). The majority of patients were found to be in AJCC class I/IIA in both groups [Group 1: 26 (65%) and Group 2: 27 (67.5%)] with no statistically significant difference in staging between the groups. Analyzed genomic data of GEP class and Prame expression also failed to show a difference between Group 1 and Group 2, with majority of patients found to be GEP Class IA [Group 1: 27 (69.2%) and Group 2: 25 (62.5%)] and Prame negative [Group 1: 28 (71.8%) and Group 2: 28 (70%)] for both groups.

Conclusions: The study showed that the COVID-19 pandemic had no effect on the presentation of uveal melanoma patients at our center across various tumor characteristics that can be used as a surrogate marker for delayed presentation, including size, staging, and genomic data. A large-scale, long-term study is necessary to analyze the long-term consequences of the pandemic on uveal melanoma patients.

TITLE: Biopharmaceuticals: are you into designing your own one? then here's the most decorated build recipe – based on architectures with most wins in 2015-2021 FDA's Novel Drug Approvals

SESSION TITLE: Drug delivery

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.A. Abdulrazik, Innovative Therapeutic Algorithms, East Jerusalem Eye Research Initiative, East Jerusalem, PALESTINE, STATE OF|

Commercial Relationships Disclosure: Muhammad Abdulrazik: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To provide build insights for future tasks of designing new ocular biopharmaceuticals based on optimal balance of affinity vs. avidity and efficacy vs. potency.

Methods: List of approved biopharmaceuticals was obtained from FDA records and structure/function data was mined from regulatory evaluations, publications and patents.

Results: Of 87 approved 67 were monoclonal-antibodies (mAb) – 63/67 full-mAb (145.5±1.5 kDa): 3/63 chimeric, 30/63 humanized, 30/63 human; 8/63 IgG2, 11/63 IgG4, 2/63 hybrid, 42/63 IgG1; 3 bispecific; 6 Fc-modified; 8 mAb-drug conjugates (5 enzyme-, 2 acid- and 1 non-cleavable – drug/mAb ratio of 4.9±1.9). 4/67 non-full: 1 fragment antigen binding (Fab), 1 single-chain variable fragment (scFv), 1 single-domain antibody (sdAb) and 1 Fv-fusion.

Conclusions: Full-mAb hegemony has yet to be truly contested (typically human/-ized IgG1k). Novelties included bispecific-mAb and Fc-altered amino-acid or fucose to boost avidity. Fab, scFv, sdAb and fusions are emerging – no one a racehorse yet. Eye approvals were cenegermin (nerve GF /Neurotrophic Keratitis), teprotumumab for TED (148 kDa human IgG1k) and brolucizumab for wAMD (26 kDa humanized scFv). With prior approvals, aflibercept (115 kDa Fc-fusion receptor) and ranibizumab (48 kDa humanized Fab), the average MW of ocular anti-VEGFs is 63 kDa, well under all-mAb MW mean and contrast to bevacizumab MW (149 kDa humanized IgG1k). As per the standard IVT doses, 1.2 molecules of ranibizumab, 2.1 of aflibercept and 27.2 of brolucizumab, each has an anti-VEGF potency comparable to just 1 bevacizumab molecule. With molecular-radius roughly twice higher, 1 bevacizumab molecule can still cross the retina and perform an anti-VEGF "work" comparable to that of 27.2 molecules of the smaller brolucizumab – practically setting aside the argument of size-related obstacles to mAb penetration across the retina. A no surprise, since bevacizumab has 2 Fab per 1 molecule and Fc region for FcRn assisted passage across retina barriers. Higher mAb concentrations catalyze a growing risk of unleashing a generic tendency to aggregate (en syringe) that could lead to immune-mediated adverse effects. Thus, despite emerging innovative mAb designs, full-mAb based design (e.g. bevacizumab) is still the molecular design to beat in terms of ocular anti-VEGF potency per 1 molecule.

TITLE: Practice Compliance in Documenting and Billing Gonioscopy and Pachymetry in a Resident Ophthalmology Clinic

SESSION TITLE: Clinical studies and trials

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Garcia, K.L. Anderson, Ophthalmology, The University of Texas Health Science Center at San Antonio, San Antonio, Texas, UNITED STATES|

Commercial Relationships Disclosure: Angelica Garcia: Commercial Relationship: Code N (No Commercial Relationship) | Kent Anderson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Gonioscopy and pachymetry are billable procedures for those patients with diagnoses that meet medical necessity as indicated. Residents excel in performing these procedures and documenting them where indicated. However, it was noted that residents may often not bill properly for these procedures and often leave the billing to the attending teaching physician. We retrospectively reviewed our documentation and billing practices for these procedures in a resident ophthalmology clinic.

Methods: All patient encounters performed by ophthalmology residents over a 5-month period (January thru May 2021) were retrospectively reviewed for appropriate documentation and billing of gonioscopy and pachymetry. All patient encounters were supervised by teaching physicians in an outpatient ambulatory ophthalmology clinic at the Texas Diabetic Institute, San Antonio, TX. Each electronic medical record (EMR) was reviewed for appropriate documentation and billing. The data was analyzed using R software.

Results: A total of 1,500 patient encounters were reviewed. Gonioscopy was documented in 37 records, but only 14 (38%) of these records were properly billed for. Gonioscopy was billed for in 3 records where the gonioscopy was not properly documented. Pachymetry was documented in 31 records, but only 20 (65%) were properly billed for. No records showed billing of pachymetry without proper documentation. The exclusion of these billing codes was statistically significant ($P_{gonioscopy} = 0.0$, $P_{pachymetry} = 0.0$). All those records were gonioscopy and pachymetry was documented and/or billed had a diagnosis to support medical necessity for the procedure.

Conclusions: Billing for both gonioscopy and pachymetry were preferentially excluded from recording. This result is likely due to inadequate resident understanding of billing for these procedures. It is ultimately up to the attending physician to review the documentation, attest and cosign the note, and verify the final billing diagnosis and procedure codes. Good practices aim for 100% compliance in both documentation and billing. However, these data emphasize the importance of teaching proper coding and billing practices to residents in training as they prepare to enter independent practice.

TITLE: Spatial Summation of Chromatic Contrast in the Parvocellular Pathway

SESSION TITLE: Fundamental and Applied Psychophysics and Color Vision

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C.S. Wu, N.B. Patel, D.R. Coates, College of Optometry, University of Houston, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure: Christopher Wu: Commercial Relationship: Code N (No Commercial Relationship) | Nimesh Patel: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Coates: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Perimetry is a widely used tool for assessing visual function. Conventional tests measure locational sensitivity to luminance contrast. While the spatial summation characteristics of luminance are well documented, the summation of color is poorly understood. As the visual mechanisms responsible for achromatic and chromatic contrasts are thought to differ, stimuli in chromatic spaces may offer diagnostic benefits. The aim of this study was to determine the spatial summation characteristics of chromatic contrast mechanisms.

Methods: Contrast detection thresholds were measured as a function of size and eccentricity in four color normal subjects. Stimuli were solid circular patches of either luminance or chromatic contrast increments presented for 300 ms on a background averaging 10 cd/m2. Cone contrasts were calculated in DKL color space by modulating along the achromatic magnocellular (L+M) or chromatic parvocellular (L-M) cardinal axes. Stimuli varied between 0.25° to 4.0° in diameter, and were presented in four principal oblique meridians at 5° intervals within the central 40° of visual field. In the chromatic paradigms, luminance noise was added to non-test positions. Thresholds were obtained using interleaved staircases, with subjects responding with the perceived meridian of presentation.

Results: Achromatic thresholds plotted on a log-log scale were fit with a two-line model. The average slope for smaller stimuli sizes was -1.02 (complete summation) which became shallower, averaging -0.32 (partial summation) beyond a critical area (Ricco's Area). This critical area increased with retinal eccentricity and was similar for locations at a given eccentricity. In the chromatic paradigms, a single linear regression model was used, as a bilinear fit poorly represented the data. In the +(L-M) direction, the average slope was -0.67, with an average r^2 of 0.92. In the -(L-M) direction, the average slope was -0.76, with an average r^2 of 0.86.

Conclusions: While achromatic curves followed the expected two-line model, the distinct linearity of chromatic summation suggests different underlying detection mechanisms. Complete spatial summation was absent for tasks that isolated the chromatic parvocellular mechanism for the range of stimulus sizes tested. The linearity of chromatic spatial summation and lack of critical area may provide improved consistency over achromatic tests, as relative sensitivity is unaffected by stimulus area.

TITLE: Endoscopic dacryocystorhinostomy in patients with functional epiphora after canalicular laceration repair

SESSION TITLE: Oculoplastics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Lee, Department of ophthalmology, Chi Mei Medical Center, Tainan, TAIWAN|

Commercial Relationships Disclosure: Po-Yu Lee: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Canalicular laceration usually accompanies eyelid laceration. The orbicularis and medial canthal ligament may be injured at the same time, which leads to defective lacrimal pump function. After canalicular anastomosis and eyelid tightening, most patients can achieve a patent lacrimal system and symptom relief, while few patients may still suffer from functional epiphora. Endoscopic dacryocystorhinostomy (DCR) was considered to reduce the lacrimal drainage resistance and meanwhile preserve lacrimal pump function. We investigate the outcome of endoscopic DCR in patients with functional epiphora after canalicular and eyelid laceration repair.

Methods: Retrospective chart review. All injured patients received primary re-approximation of the canalicus and orbicularis/medial canthal tendon repair. After at least one month, if the patient still complained of tearing, endoscopic DCR with bicanalicular silicone intubation were performed. Patients with re-stenosis of canaliculus or ocular surface disease were excluded. A combination of Munk score and Lac-Q social impact score were used to assess the outcome.

Results: From January 2019 to December 2021, there were 34 patients who received canalicular and eyelid laceration repair. 6 patients received secondary endoscopic DCR due to persistent epiphora after the repair. One had both and the others had lower canalicular laceration. All patients achieved symptom relief immediately after operation. At the last follow-up, all patients were satisfied with the results. Munk score improved from grade 4 to 2 in 2 patients, from grade 4 to 1 in 4 patients). Lac-Q social impact score improved from 5 points to 0 in 3 patients, From 5 to 1 in 1 patient, from 5 to 2 in 2 patients). No recurrence or postoperative complication was found during the follow-up period (Range: 6-17 months, mean: 9.8 months).

Conclusions: Functional epiphora in patients with canalicular laceration can be managed with endoscopic DCR. After successful repair and patent on lacrimal irrigation, there may still be slightly increased outflow resistance. Combining the slightly reduced pump function due to lid laceration, this can lead to postoperative epiphora. Endoscopic DCR decreases lacrimal drainage resistance and affect the lacrimal pump function minimally. There was no significant complication in this study. More case studies are needed to evaluate the outcome.

AUTHORS/INSTITUTIONS: S. Das, C. Kim, B.A. Hughes, M. Juzych, C. Mehregan, F. Ridha Al-Timimi, Kresge Eye Institute, Detroit, Michigan, UNITED STATES|D.V. Tran, Wayne State University School of Medicine, Detroit, Michigan, UNITED STATES|

Commercial Relationships Disclosure: David Tran: Commercial Relationship: Code N (No Commercial Relationship) | Shibandri Das: Commercial Relationship: Code N (No Commercial Relationship) | Chaesik Kim: Commercial Relationship: Code N (No Commercial Relationship) | Bret Hughes: Commercial Relationship: Code N (No Commercial Relationship) | Mark Juzych: Commercial Relationship: Code N (No Commercial Relationship) | Christian Mehregan: Commercial Relationship: Code N (No Commercial Relationship) | Faisal Ridha Al-Timimi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine the efficacy of Kahook Dual Blade (KDB) goniotomy with and without phacoemulsification (PE) in an urban population, we performed a retrospective, observational clinical study and examined longitudinal changes to intraocular pressure (IOP) and number of IOP-lowering medications (ILMs).

Methods: This retrospective study includes 61 eyes of 61 patients with glaucoma, 77% with primary open angle glaucoma (POAG), treated by KDB goniotomy with and without PE. IOP and ILMs were assessed at baseline and follow-up visits for up to 42 months. Patients were categorized into lower (Group A) and higher (Group B) IOP groups. IOP goals for Group A, with baseline IOP ≤ the study population median baseline IOP of 15 mm Hg, were defined as ≤ their baseline IOP. Group B, with baseline IOP >15 mmHg, were designated IOP reduction goals of ≥20% or reaching ≤18 mm Hg if baseline IOP is ≤22 or >22, respectively. Assessing Group A primarily by lowering post-operative ILMs was reasoned to be an appropriate endpoint. Complete-success was defined by the following three principles: (1) reaching post-operative IOP goal, (2) achieving 0 ILMs, and (3) lacking additional IOP-lowering intervention or hypotony during follow-up. We also defined qualified-success with the following criteria: (1) reaching post-operative IOP goal, (2) for Group B, maintaining or improving baseline ILMs, and for Group A, if baseline ILMs is ≤3 or >3, then improving ILMs by at least 1 or 2, respectively, and (3) lacking additional IOP-lowering intervention or hypotony during follow-up. If the patient had two or more consecutive visits failing to meet the success criteria above, the patient would fail at the first of the two visits. Survival analysis was performed using Kaplan-Meier curves.

Results: Reduction in IOP from baseline was statistically significant at day 1, week 1, and months 3, 12, 24, and 30. Reduction in ILM burden from baseline was statistically significant at 1 day through 24 months of follow-up. Survival analysis based on complete- and qualified-success criteria demonstrated approximately 50% survival for both criteria at 3 months and 25% survival by 6 months and 18 months, respectively.

Conclusions: KDB with and without PE is effective at reducing IOP up to 30 months and ILM burden up to 24 months in an urban setting. Limitations of our study include attrition due to the length of follow-up.

ABSTRACT BODY:

Purpose: To investigate the relation between dry eye disease (DED) and high myopia (HM) in Japanese teenagers.

Methods: The Institutional Review Board and Ethics Committee of Tsukuba Central Hospital and Kanagawa Medical Association approved this study. This study was a retrospective, descriptive, consecutive case series. We compared the dry eye condition in 106 HM patients (mean age, 16.4 ± 2.2y), 494 mild myopic (MM) patients (15.0 ± 2.6y), and 82 non-myopic (NM) subjects (13.8 ± 2.6y) aged between 10 and 19 years old at Japanese eye clinics. Myopia, astigmatic error, and anisometropia were assessed. Dry eye-related symptoms questionnaire including; dryness, irritation, pain, fatigue, blurring and photophobia were evaluated. Intraocular pressure, tear film break-up time (BUT) and fluorescein staining were investigated. The need for consent was waived by the Institutional Review Board. Regression analysis of myopic error and other variables was conducted.

Results: Anisometropia and astigmatic error were greatest in the HM group compared with other groups ($P < 0.001$). HM group reported more dryness ($P = 0.034$), less photophobia ($P < 0.001$), and less pain ($P = 0.039$) compared with NM group. Most of the symptoms except for fatigue were apparently associated with myopic error. Regression analysis revealed that astigmatic error ($\beta = -0.231$, $P < 0.001$), anisometropia ($\beta = -0.191$, $P < 0.001$), short BUT ($\beta = -0.086$, $P = 0.028$), and presence of diagnosed DED ($\beta = -0.112$, $P = 0.003$) were correlated with myopic error. Regarding symptoms, dryness ($\beta = -0.127$ $P = 0.004$), photophobia ($\beta = 0.117$, $P = 0.002$), and pain ($\beta = 0.084$, $P = 0.034$) were correlated with myopic error as well.

Conclusions: Our study showed significant clinical findings of DED in HM patients. The present results indicated DED might be associated with HM in teenagers.

ABSTRACT BODY:

Purpose: We evaluated the possible beneficial outcomes of quercetin on human AMD cybrid cell lines.

Introduction

In developed countries, age related macular degeneration (AMD) is the leading cause of progressive central vision loss in aged populations. Previous studies have demonstrated the advantageous impacts of antioxidants such as vitamin E and zinc in lowering the incidence and progression of AMD. Quercetin, a plant flavanol from the flavonoid group of polyphenols, is found in many fruits, vegetables and seeds. Previous in vitro studies have demonstrated the antioxidant and anti-inflammatory properties of quercetin, suggesting it may have therapeutic benefit for human diseases. Its main antioxidant activity is associated with inhibition of the signal transduction pathway and activity of cytosolic glutathione, leading to reduction of reactive oxygen species (ROS) production.

Methods: Cybrids were created by fusion of the mitochondria-deficient (Rho0) ARPE-19 cells with the platelets derived from AMD patients and age-matched non-AMD individuals. The resultant cybrid cell lines have mitochondria originating from different individuals but identical nuclei. Cells were cultured in 96-well plates (10,000 cells/well) and treated with quercetin 20 μM for 24 hours. DMSO was used as vehicle-control. ROS levels and cellular metabolism were measured in control and treated cultures. For ROS assay, after adding 100 μl H2DCFDA solution/well, plates were read via the fluorescent plate reader with the excitation (EX, 492nm) and emission (EM, 520nm) wavelengths. Performing MTT assay, 10 μl of MTT assay reagent was added/well and plates incubated in 37°C for 3 hours. After adding 200 μl/well of DMSO, plates were analyzed (signal at 570 nm and reference at 630 nm) with the absorbance plate reader. Statistical analyses were performed via student t-test.

Results: ROS levels of quercetin treated non-AMD cybrids and AMD cybrids declined to 84.25% (P= 0.0002, n=4) and 86.75% (P= 0.011, n=4), respectively, compared to vehicle-control groups (100%, n=4). Moreover, quercetin increased cellular metabolism of non-AMD cybrids and AMD cybrids to 132.8% (P= 0.002, n=4) and 128.0% (P= 0.001, n=4), in order, versus vehicle-control cells (100%, n=4).

Conclusions: Administration of quercetin 20 μM has positive impacts on treated AMD cybrid cell lines.

ABSTRACT BODY:

Purpose: Microperimetry (MP) is an important technique to evaluate visual performance in patients with age-related macular degeneration (AMD). In this study we examine a large cohort of patients with intermediate AMD (iAMD) with multiple MP retinal sensitivity and fixation stability metrics.

Methods: This is a cross-sectional analysis of baseline data from 247 patient eyes of the longitudinal, prospective, multicenter and non-interventional PINNACLE study. Best Corrected Visual Acuity (BCVA) and Low Luminance Visual Acuity (LLVA) were measured with ETDRS charts. The MAIA (Centervue, Italy) MP metrics of mean sensitivity (MS), Bivariate Contour Ellipse Area (BCEA) fixation indices (63% and 95%) and percentage of fixation points within 1° and 2° of the foveal center (P1 and P2) were recorded. R code by Josan et al., was applied to obtain 3-D hill of vision surface plots and the total volume (V_{TOT}) beneath the plots in dB-deg^2. We report non-normally distributed data with Spearman's R, medians and interquartile ranges (IQRs).

Results: The following baseline medians and IQRs were measured: BVCA LogMAR 0.02 (-0.06-0.1), LLVA LogMAR 0.32 (0.2-0.45), V_{TOT} 1656 dB-deg^2 (1541-1761), MS 24.2 dB (22.8-25.7), P1 93% (82-98), P2 99% (94-100), BCEA63 1 deg^2 (0.4-2.7), BCEA95 2.9 deg^2 (1.2-8.1). There was a significant positive correlation for V_{TOT} and MS ($r = 0.98$; $p < 0.0001$). V_{TOT} exhibited a significant correlation to all MAIA metrics of fixation stability ($p < 0.05$). All metrics of fixation stability were significantly correlated with each other ($p < 0.0001$). All MAIA metrics were significantly correlated to BCVA and LLVA ($p < 0.01$). The performances in most sensitivity and fixation metrics were significantly inversely correlated to age (BCVA: $r = 0.33$, $p < 0.0001$; LLVA: $r = 0.33$, $p < 0.0001$; V_{TOT}: $r = -0.28$, $p < 0.0001$; MS: $r = -0.29$, $p < 0.0001$; P1: $r = -0.16$, $p = 0.01$; BCEA63: $r = 0.19$, $p = 0.003$; BCEA95: $r = 0.19$, $p = 0.03$).

Conclusions: We report reference data for multiple retinal sensitivity and fixation stability metrics in a large cohort of patients with iAMD. Our analysis provides a strong positive correlation between MS, an established metric, and V_{TOT}, a novel volumetric description of retinal sensitivity. The latter might be more precise, since it eliminates the inaccuracy of averaging. Finally, our data provide evidence for the inverse correlation of retinal functional capacities and age in iAMD.

ABSTRACT BODY:

Purpose: Microbubble-enhanced ultrasound has been proposed as a method to achieve targeted ocular drug delivery. We designed an in vitro experiment to identify the optimal concentration of a stable phospholipid mixture that biochemically recapitulates a monodisperse microbubble suspension and is nontoxic to human retinal epithelium cells (ARPE-19). We hypothesize that phospholipid mixture exposure reduces ARPE-19 cell viability in a dose-dependent fashion.

Methods: ARPE-19 cells were plated in 96-well plates and treated with 880 µL of solution containing 0.0125, 0.025, 0.05, 0.1, or 0.5 mg/mL of phospholipid mixture. Phospholipid was dissolved in chloroform at a 80:10:10 molar ratio of DPPC:DPPA:DPPE-PEG5000 (Avanti Polar Lipids) and dried by nitrogen stream and vacuum evaporation before resuspension in PBS. Control wells received media only. MTT (3-[4,5-dimethylthiazol-2-yl]-2,5 diphenyltetrazolium bromide) assay was performed at 24 and 48 hours post-treatment to quantify intracellular metabolism as a proxy for cell viability. All groups were run as 4 technical replicates and two-tailed Mann-Whitney U tests were used for statistical analysis.

Results: At 24 hours post-treatment, ARPE-19 cells treated with phospholipid mixture at concentrations at or above 0.05 mg/mL exhibited statistically significant ($p<0.05$) decreases in viability while cells treated with phospholipid mixture at concentrations below 0.05 mg/mL exhibited non-significant decreases in viability (Figure 1). This trend appeared to be dose-dependent. Only phospholipid mixture concentrations between 0.0125 mg/mL and 0.05 mg/mL were assessed in the 48-hour experiment; there were no statistically significant changes in cell viability between control and treatment groups in the 48-hour experiment (Figure 2).

Conclusions: This study demonstrates that short-term phospholipid exposure in ARPE-19 cells is cytotoxic in a dose-dependent fashion. This observation suggests that microbubble formulations should be fabricated below a certain phospholipid concentration to avoid cytotoxicity in target tissues. Future experiments evaluating phospholipid and microbubble toxicity in different ocular cell types are underway to more clearly characterize their physiological effects and explore the viability of microbubbles as an ocular drug delivery modality.

ABSTRACT BODY:

Purpose: Regarding the functional role of horizontal cells (HCs) in the retina, three mechanisms have been extensively studied at the cone pedicle, including GABA mediated feedback, hemichannel dependent current modulation, and pH effect on calcium current. But, it is yet unclear the functional contribution of HCs in the rod visual pathway. This study tested the hypothesis that HCs may modulate the output signals at the rod synaptic terminal by combining at least two of the three previously mentioned mechanisms.

Methods: Adult, healthy, mouse strain of wild-type C57BL/6J was used for electroretinogram (ERG) and immunohistochemical (IHC) labeling. The physiological study was carried out on dark-adapted (> 12 hours) animals in vivo by recording binocular responses of the rod-mediated ERG signals in response to low intensity full-field light stimuli (≤ 0.01 $cd \cdot s/m^2$) after the right eye of each animal was intravitreally injected with 1 µL of a solution containing GABA (100 mM), Glutamate (100 mM), Bicuculline (10 mM), DNQX (30 mM), APB (25 mM), HEPES (25 mM), TPMPA (5 mM) or the combination of those compounds. Meanwhile, the left eye was injected with 1 µL of PBS solution. We also performed a study about the localization and colocalization of molecular proteins in the retina, including calbindin, GABA, and anion exchanger 3 (AE3).

Results: The rod response was abolished by APB and relevantly diminished by TPMPA. Experimental stimulation of HCs membrane receptors by GABA and glutamate produced a significant increase in the rod response ($p < 0.05$), the injection of its antagonists (Bicuculline and DNQX) produced a significant decrease in the rod response ($p < 0.01$). The rod response showed a statistically significant roll-off decrease since the acid-base condition of the triadic synaptic cleft is justified by intraocular injection of HEPES, whose pH was adjusted to 7.2, 7.4, and 7.6. In the IHC study, it was found that calbindin was localized in the outer plexiform layer, and both GABA and AE3 colocalized with calbindin.

Conclusions: HCs modulate the transmission of light signaling received in the rod visual pathway in the first synapse by strictly sticking to the pH regulation in the synaptic cleft, whose pH condition is determined by the flux of HCO3-, which is controlled by GABAergic HCs′ membrane receptors.

ABSTRACT BODY:

Purpose: Scotopic microperimetry involves fundus-controlled perimetry performed in dark conditions, enabling spatial assessment of scotopic macular sensitivity. Volumetric analyses have been shown to reflect central retinal sensitivity more accurately but are yet to be applied to scotopic microperimetry. We investigate normative volumetric sensitivity values and their repeatability in two-colour scotopic microperimetry in healthy participants.

Methods: Macular sensitivity in 23 healthy participants was assessed using S-MAIA Microperimeter (Centervue SpA, Padua, Italy) displaying a 37-point radial grid, following 20 minutes dark adaptation (light level <1 lux). Both eyes in each participant were assessed with cyan (505nm) stimuli followed by red (627nm) stimuli, with sensitivity measured in decibels. A sub-cohort underwent further testing in the right eye only within 5 weeks to assess repeatability. Comparative non-parametric statistics using SPSS (IBM Version 25.0.0.1) were applied. Hill of Vision volumetric analysis of results was performed using an open-source program.

Results: Mean retinal sensitivity and volumetric sensitivity in the right eye and left eye were obtained (Table 1, 45 eyes, mean age: 34.3 years range: 20-73). Fixation losses >20% as measured by blind spot losses were used to exclude exams from the final analysis. Median volumetric sensitivity in the right eye and the left eye with cyan and red stimuli were significantly correlated (Spearman's Correlation, cyan ρ=0.871, p=0.001, red ρ=0.621, p=0.01, cyan-red ρ=0.468 p=0.068). There was no significant correlation between age and volumetric sensitivity (Spearman's correlation, cyan ρ=-0.414 p=0.099, red ρ=-0.333 p=0.192). Coefficients of repeatability for volumes were calculated (cyan n=10 ±207.1dB-degrees^2, red n=12 ±367.5dB-degrees^2, cyan-red n=8 ±164.9dB-degrees^2).

Conclusions: For the first time, we describe an application of volumetric analysis and correspond repeatability measures in scotopic microperimetry data. The strong inter eye symmetry suggests no significant learning or fatigue effects on test performance. In diseased patients, volumetric measures offer more detailed indication of function than simple mean sensitivity, so here we display a normative dataset from healthy participants.

ABSTRACT BODY:

Purpose: The Vision Loss Expert Group (VLEG) and Global Burden of Disease Study (GBD) collaboratively updated crude and age-standardised prevalence estimates of blindness and vision impairment and investigated inter-regional and age-specific changes over the 1990 to 2020 timeframe. Here we expand the focus to account for global and regional risk factors and address vision loss severities pertaining to all geographical locations.

Methods: (1) Selection of 24 covariates with a potential link to vision-related disease from a database used across GBD modelling. (2) Analysis of the association of risk factors with crude and age-standardised prevalence estimates of blindness and vision impairment in 2020 separately for each severity: blindness, moderate and severe vision impairment, mild vision impairment, near vision impairment due to uncorrected presbyopia. (3) Analysis of the trend contribution of the percentage rates of change in risk factors to the rates of change in prevalence 1990-2020.

Results: For adults (50+ yrs), for crude and age-standardised prevalence estimates for year 2020, we found a significant negative association of smoking prevalence, for all persons and for each sex. Maternal care and immunisation, sanitation proportion, health access & quality index and socio-demographic index were other significant age-standardised negative associations. Ophthalmologists/million population had a weak but significant protective effect, and we found positive associations for pollution (outdoor and indoor), stronger for greater vision impairment severities. Years in education per capita was weakly, negatively associated with vision loss prevalence yet zero education proportion has a stronger but positive association for both sexes. Multiple variable analysis led to generally lower effect sizes and reductions in significance of single variable findings.

Conclusions: This study has confirmed associations at population level globally which appear to be stable over decades. In addition, the study has quantified the contribution of epidemiologically-based risk factors to vision loss at a macroregional level which is novel. This opens useful avenues for targeted intervention by policymakers. For example, reduction in sex inequity in blindness rates over 30 years has been positively associated with reducing overall blindness prevalence.

ABSTRACT BODY:

Purpose: Correlation of in vivo optical coherence tomography angiography (OCTA) of type 3 macular neovascularization (t3 MNV) secondary to AMD with corresponding ex vivo histology.

Exploring the overall value of clinical OCTA for disease observation, diagnosis, and staging by validating OCTA in the analysis of type 3 macular neovascularization secondary to AMD.

Methods: A white woman receiving anti-VEGF (OD, n=37; OS, n=6; last visits 3 and 2 months, respectively, before death at age 97 years) was monitored by optical coherence tomography (OCT) and angiography (OCT and dye-based). Eyes were recovered 4:05 hours after death, processed for macula-wide epoxy-resin histology, and scanned under an oil objective for high-resolution microscopy. Infrared reflectance and eye-tracked spectral-domain OCT(A) clinical imaging were correlated with ex vivo and high-resolution histologic images. Projection artifact removal based on three-dimensional vessel-shape estimation (VSE-PAR) and a Gaussian blur filter for preservation of neovascular flow signal was used.

Results: Clinical OCT(A) imaging showed several neovascular lesions within the central macula of both eyes. Two index lesions of different phenotypes in the right eye displayed a drusenoid pigment epithelium detachment (PED), characteristic of t3 MNV. Projection artifact removal based on VSE-PAR and a Gaussian blur filter demonstrated robust preservation of neovascular flow signal. OCTA decorrelation signal in lesion # 1 corresponded in histology to a vertically oriented collagen-ensheathed vascular complex originating from the intermediate capillary plexus. Lesion # 2 corresponded to a horizontally oriented vascular loop originating from the deep capillary plexus. Both lesions contacted basal laminar deposits that remained after the retinal pigment epithelium (RPE) disappeared due to death in situ or anterior migration. The sub-RPE-basal laminar space (between RPE-basal lamina and inner collagenous layer of Bruch’s membrane) underlying these vascular abnormalities contained calcific nodules and glial processes. No connection between the choriocapillaris and this space was observed for either lesion.

Conclusions: OCTA decorrelation signal of type 3 neovascularization corresponded to two intraretinal neo-vessel phenotypes on histology.
VSE-PAR and Gaussian blur filter demonstrated their value for further use in OCTA decorrelation signal processing.

ABSTRACT BODY:

Purpose: To analyze the topographic distribution of HRF as well as localized retinal layer thicknesses (RLT) in presence or absence of HRF in eyes with large drusen associated with iAMD.

Methods: Sixty-five eyes (59 iAMD patients, (mean age ± SD) 70.9 ± 8.6 years) with large drusen (>125 µm) and 28 control eyes (27 patients; 64.21 ± 9.04 years; unremarkable macula) underwent spectral-domain optical coherence tomography, SD-OCT (volume scan: 30°x25°, 61 B-Scans, spacing 120µm). Within each SD-OCT scan, retinal layers were semi-automatically segmented by a medical reader, HRF manually annotated (at 300% magnification), RLT at each HRF location extracted (using a custom-written ImageJ plugin) and compared to RLT in areas without HRF (HRF area mirrored horizontally at the foveal level) from the same eyes. RLT between positions were compared using the Wilcoxon test, univariate mixed linear models to investigate associations between RLT, HRF presence and HRF size.

Results: In iAMD eyes, 12.8 ± 12.7 HRF per eye were detected with a peak abundance at 0.5 to 1.5 mm eccentricity of the fovea (6.43 ± 8.16 HRF per eye). When HRF are present, outer nuclear layer (ONL) (p=0.0004, average difference -10.06 µm) and retinal pigment epithelium drusen complex (RPEDC) thicknesses (p = 0.0003, average difference +29.54 µm) differed significantly compared to areas with no HRF. In the presence of HRF, ONL thinning was significantly different (p=0.002) even while accounting for RPEDC thickening. Inner and outer photoreceptor segments (IS, OS) and the outer plexiform layer (OPL) thicknesses did not differ significantly. Mixed linear models further revealed a significant association between increasing HRF size and decreasing ONL (association score -0.19, p < 0.0001; 95%CI: -0.24, -0.13) and IS layer thicknesses (-0.09, p = 0.0072: -0.14, -0.04).

Conclusions: In iAMD migrating HRF leave a trail of remodeling that impacts multiple retinal layers. Thickening of the RPEDC with subsequent reduced oxygen and nutrient supply from the underlying choriocapillaris might trigger RPE migration, while the ONL thickness decrease at areas of HRF could result from cell displacement or degradation. Longitudinal studies on the functional impact as well as long-term retinal changes at a cellular and subcellular level are underway to further characterize the importance of HRF as a biomarker for AMD progression.

ABSTRACT BODY:

Purpose: Recent studies approximate that nearly 900,000 individuals suffer from vision-threatening retinopathy in the United States alone. Early detection of retinal disease matters for timely interventions, however, access to vision screening continues to be a limiting factor. Advancements in virtual reality (VR) technologies allow for the digitalization of several tests used in vision screening. In the present clinical study, our group assessed the viability of VR in administering perimetry, color vision, and Amsler grid exams.

Methods: We performed a non-inferiority trial at the Mount Sinai 102nd street Ophthalmology Practice, in which patients received a 24-2 Humphrey Visual Field Analyzer (HVFA) exam, Ishihara Tile test, and an Amsler Grid along with the VR (VIVE Pro and PICO headset) analogues in a randomized fashion. The perimetry analogue is a 24-2 vision field exam with 25 Apostilibs. The Ishihara analogue consisted of a standard 9-plate screen for red-green color deficiencies. The Amsler analogue is a virtual grid to free-draw visually distorted areas. The primary outcome measure (POM) for perimetry was percent agreement of each stimulus point across all patients. The POM for Ishihara Tiles is number of correct tiles. The POM for Amsler grid is the percent agreement area of grid squares. Secondary outcomes are time to complete the test and the patient experience survey.

Results: Form 69 patients recruited, 57 patients underwent color blindness testing for VR and non-VR and demonstrated no significant difference between the two ($p = 0.9692$ in Wilcoxon rank-sum test with VR tests reporting sensitivity = 100% & specificity = 76%. 50 patients took the Amsler grid, demonstrating no significant difference for the right eye ($p = 0.3092$) sensitivity = 100% & sensitivity = 95% and for the left eye ($p = 0.6546$) and sensitivity = 100% & sensitivity = 98%. 24-2 perimetry analog had a 78% overall agreement in the left eye and 76% overall agreement in the right eye with 46 and 42 eyes respectively. The time required to complete the HVFA was significantly longer compared to the VR, $p < 0.0001$.

Conclusions: Our preliminary data suggest that VR can serve as a platform to deliver rapid vision screening exams, particularly perimetry, color blindness, and Amsler tests. The low cost of VR technologies, increased testing speeds with comparable results, user-friendliness for both operators and the patients presents a high-impact solution.

ABSTRACT BODY:

Purpose: To study clinical and genetic aspects of solute carrier (SLC) genes in inherited retinal diseases (IRDs).

Methods: Ethical approval was obtained from the Hadassah Medical Center Institutional Review Board following the tenets of the Declaration of Helsinki. Ocular evaluation included a full ophthalmological examination, Goldmann perimetry, full field electroretinography, color vision testing, and various retinal imaging. Exome sequencing (ES) data were filtered to identify pathogenic variants in SLC genes. Analysis of transcript and protein expression was performed on fibroblast cell- lines and retinal sections.

Results: Comprehensive analysis of 433 SLC genes in ~900 ES IRD samples revealed homozygous pathogenic variants in six SLC genes including two novel ones: Two variants in SLC66A1 causing autosomal recessive retinitis pigmentosa (ARRP) and a variant in SLC39A12 causing AR mild widespread retinal degeneration with marked macular involvement. In addition, a splicing variant in SLC37A3, suggested previously to cause RP, was found in two ARRP patients resulting in enhanced exon skipping and reduced protein expression. Next generation sequenving analysis revealed a complex splicing pattern in which exon 6 is skipped in the vast majority of transcripts leading to no protein expression as verified by Western blotting. The recently reported SLC4A7 - c.2007dup variant was found in two ARRP patients resulting in the absence of protein. Finally, variants in SLC24A1 were found in four individuals with either ARRP or congenital stationary night blindness (CSNB). Immunohistochemical analysis of the human and mouse retinas using antibodoes for four of the studeis SLC proteins revealed expression in the outer nuclear layer.

Conclusions: We report on SLC66A1 and SLC39A12 as novel IRD genes, establish SLC37A3 pathogenicity, and provide further evidence of SLC4A7 as IRD genes. We extend the phenotypic spectrum of SLC24A1 and suggest that its ARRP phenotype may be more common than previously reported.

ABSTRACT BODY:

Purpose: To investigate the three-dimensional eyeball protrusion from the best-fitted ellipsoid and its association with the offset between the Bruch's membrane opening (BMO) and lamina cribrosa (LC).

Methods: Three-dimensional magnetic resonance imaging (MRI) scans were taken from 76 subjects (152 eyes) with a diagnosis of glaucoma or glaucoma suspect. To quantify the three-dimensional shape, an ellipsoid was fitted along the posterior 2/3 contour of every eyeball by customized MATLAB codes, and the outermost protruded part (OPP) was determined from the best-fitted ellipsoid. The eyeball was classified into group A (ellipsoid type) when ellipsoid fitting left no significant protrusion, group B (focal bulging type) when a dominant protrusion could be identified: an adjacent pair of outward protrusion and reciprocal inward depression, and group C (complex type) when a singular dominant protrusion cannot be identified. In case with a dominant protrusion (group B), the angular deviation of the OPP was measured from the nasal side of the foveo-BMO axis and the superior location as a positive value. The LC/BMO offset was evaluated by measuring the central retinal vascular trunk (CRVT) location from the BMO center: 1) the angular deviation in the same manner of OPP deviation measurement, and 2) the offset index as the ratio between the CRVT-BMO center distance and the BMO radius on the same direction.

Results: After excluding 15 eyes due to poor MRI image quality, 45 eyes (33%) were classified as group A, 67 eyes (49%) as group B, and 25 eyes (18%) as group C. The average axial length was in the order of group C (26.15±2.04), group B (25.73±1.62), and group A (24.80±1.99). In group B, the angular deviation of the OPP showed a significant correlation with that of the CRVT/BMO offset ($r=-0.620$, $P<0.001$). A generalized estimating equation analysis revealed that the angular deviation of the CRVT/BMO offset was associated with age ($P=0.045$) and the angular deviation of the OPP ($P<0.001$).

Conclusions: In the eyes having a dominant protrusion, the OPP location was closely associated with the LC/BMO offset direction. This indicates that the focal asymmetry during scleral expansion might be associated with the diverse direction of the LC/BMO offset and accompanied anatomical changes in the optic nerve head canal.

TITLE: Evaluation of Relationship Between Anterior and Posterior Corneal Astigmatism Using a Swept-Source OCT Biometer

SESSION TITLE: Corneal Imaging and Corneal Nerves

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Rosen, E.V. Karakoleva, N. Devireddy, N. Cannon, S. Pantanelli, Penn State College of Medicine, Hershey, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: David Rosen: Commercial Relationship: Code N (No Commercial Relationship) | Ema Karakoleva: Commercial Relationship: Code N (No Commercial Relationship) | Nitya Devireddy: Commercial Relationship: Code N (No Commercial Relationship) | Nathan Cannon: Commercial Relationship: Code N (No Commercial Relationship) | Seth Pantanelli: Commercial Relationship(s);Code F (Financial Support):Alcon, Carl Zeiss Meditec, Ocular Therapeutix, Ziemer;Code R (Recipient):Alcon, Carl Zeiss Meditec;Code C (Consultant/Contractor):Bausch and Lomb, Carl Zeis Meditec

ABSTRACT BODY:

Purpose: Posterior corneal astigmatism (PCA) is an important contributor to total corneal astigmatism. Its magnitude and direction has been previously elucidated using Scheimpflug imaging. However, its relationship to anterior corneal astigmatism (ACA) and other biometric variables like axial length has not been well described. The purpose of this study is to investigate the relationship between ACA and PCA using a swept-source OCT biometer.

Methods: Biometric measurements obtained between February 2020 and May 2021 were exported from a SS-OCT device (IOLMaster 700, Carl Zeiss Meditec AG). Chart review was preformed to associate the exported data with clinical variables and determine any comorbidities at the time of scan. Inclusion criteria were male or female, age 18 or older at the time of measurement. Exclusion criteria included any significant corneal or intraocular media opacity other than cataract, abnormal corneal findings, any anterior segment pathology that could significantly impact astigmatism, history of intraocular or corneal surgery, and failed or poor quality measurements as determined by the device's internal image quality metrics.

Results: Of 385 eyes, 283 eyes from 170 patients met the criteria for inclusion in the analysis. Of all eyes, 106 eyes had with-the-rule (WTR) ACA, 57 had oblique ACA, and 120 had against-the-rule (ATR) ACA. The average ACA magnitude was 1.12±0.86, 0.67±0.50, and 0.94±0.63 D in eyes with WTR, oblique, and ATR ACA, respectively ($p = 0.0002$). The average PCA magnitude was 0.30±0.16, 0.20±0.08, and 0.16±0.08 D in eyes with WTR, oblique, and ATR ACA, respectively ($p < 0.0001$). The proportion of eyes that had the PCA steep axis oriented vertically was 96%%, 91%, and 70% in eyes with WTR, oblique, and ATR astigmatism, respectively. In eyes with WTR and oblique ACA, there was a significant positive linear correlation between the magnitude of ACA and PCA (R^2=0.58 and 0.36 respectively). There was no significant linear relationship between ACA and PCA in eyes with ATR ACA.

Conclusions: The correlation between ACA and PCA magnitude is strongest in eyes with WTR ACA, weaker in those with obliquely oriented ACA, and weakest in those with ATR ACA. Increasing the number of eyes in the analysis will allow us to further elucidate how ACA and PCA relate in vector space, change with age, and correlate with other variables like axial length.

ABSTRACT BODY:

Purpose: Two benign-appearing corneal tumors were characterized by histologic, genetic and functional examinations as corneal myofibromas. Disease-causing mutations and susceptibility to targeted treatment were analyzed.

Methods: Two unrelated males, aged 18 and 13 years, born to non-consanguineous parents presented with white corneal opacifications, photophobia, glare sensitivity and reduced vision. In infancy, both patients had nodular skin lesions consistent with infantile myofibromatosis, which was confirmed by histology in Patient 1. There was no evidence of Kosaki overgrowth or Penttinen syndrome. Slit lamp biomicroscopy, anterior segment OCT and surgical tumor excision by lamellar keratectomy with Mitomycin C (MMC) were performed. Histopathologic evaluation using conventional and immunohistochemical stains followed. Genetic testing was carried out on peripheral blood after written informed consent. In Patient 1, Sanger Sequencing of the platelet-derived growth factor receptor-beta (PDGFRB) exon 12 was performed to test for a variant previously found in an affected cousin. In Patient 2, exome-based sequencing of PDGFRB and the neurogenic locus notch homolog protein 3 (NOTCH3) gene was performed. For functional analyses, the PDGFRB variants were transfected into cells, tested for expression, activation and sensitivity to the tyrosine kinase inhibitor imatinib.

Results: Histology was consistent with corneal manifestations of myofibromatosis. Immunohistochemical stainings demonstrated positivity for alpha-smooth muscle actin and b-catenin, a low proliferation rate in Ki-67 (<5%), marginal positivity in Desmin, negative staining for Caldesmon and CD34. In both patients the corneal myofibroma recurred within 4 months requiring re-lamellar keratectomy with MMC. The genetic analysis detected the novel heterozygous mutations PDGFRB c.1766A>G (p.Y589C) in Patient 1 and c.1949C>G (p.S650W) in Patient 2. When transfected in cultured cells, the PDGFRB variants conferred a constitutive activity to the receptor in the absence of its ligand and were sensitive to the tyrosine kinase inhibitor Imatinib. The variants can be classified as ACMG Class 5 (pathogenic).

Conclusions: We describe two cases of corneal myofibromatosis caused by the novel mutations PDGFRB c.1766A>G (p.Y589C) and c.1949C>G (p.S650W). Imatinib sensitivity under laboratory conditions suggests perspectives for targeted therapy preventing recurrences.

ABSTRACT BODY:

Purpose: Mutations in the PDE6B gene are a rare cause of autosomal recessive Retinitis Pigmentosa (arRP). We report on a non-consanguinous family with pseudodominant inheritance of RP due to PDE6B mutations.

Methods: We conducted a chart review of four members of a Puerto Rican family who underwent a comprehensive ophthalmic evaluation by at least one of the authors. The mutational screening was done using a genotyping microarray provided by Invitae Corporation, using next-generation sequencing (NGS) technology. Genomic DNA obtained from saliva samples was enriched for targeted regions using a hybridization-based protocol and sequenced using Illumina technology. Descriptive analysis was done.

Results: Patient 1 had a normal ophthalmic examination and a heterozygous pathogenic variant in the PDE6B gene c.1540del PLeu514Trpfs*61. Patients 2, 3, 4 had mid-peripheral retinitis pigmentosa, concentric visual field ring scotomas OU, extinguished ERG, and homozygous pathogenic variants in the PDE6B gene c.1540del PLeu514Trpfs*61.

Conclusions: Even though mutations in the PDE6B gene usually lead to arRP, it may be inherited in a pseudodominant pattern in geographically isolated populations. Genotyping studies in patients with RP are warranted to correctly classify inheritance mode.

ABSTRACT BODY:

Purpose: To develop objective measures of retinal function for patient selection in gene therapy of hereditary retinal dystrophies(HRDs).We hypothesize that inner to total mean retinal reflectivity is an independent measure of retinal function

Methods: We have performed a retrospective analysis of a genetically diagnosed RP patient cohort in a tertiary ophthalmological center with a dedicated HRDs service.Data analyzed included visual acuity(VA, ETDRS scale),intraocular pressure(IOP, mmHg),Optical Coherence Tomography imaging(OCT).A custom algorithm was implemented that measured the ratio of the mean reflectance of two areas of an OCT image in MATLAB.We have employed this algorithm to quantify the relative reflectance of the Retinal Nerve Fiber Layer(RNFL) to the retina.Correlation analysis was performed to estimate the interrelations between the different clinical and imaging parameters,Bonferonni corrected for multiple comparisons.All the statistical analyses were performed in MATLAB

Results: We included 115 genetically diagnosed RP patients,with USH2A presenting as the most common genetic defect(23/115,20%).A preliminary analsysis of 60/115 patients is included.Our analysis has revealed a strong positive correlation between the OCT reflectivity ratio and VA in both eyes(OD:r=0.6269,p<0.0001,OS:r=0.5295,p=0.0001.Age was negatively correlated with VA in both eyes (OD:r=-0.3178,p=0.0245,OS:r =-0.4518,p=0.001).There was a weak trend towards negative correlation between age and the OCT reflectivity ratio for both eye(OD:r =-0.2840,OS:r=0.1857).Multiple regression analysis revealed both age and the OCT reflectivity ratio as independent predictors of visual acuity(p=0.0084)

Conclusions: Preliminary results suggest the OCT reflectivity ratio between the RNFL and the retina serves as a predictor of retinal function in genetically diagnosed RP patients.The OCT reflectivity ratio value as computed here can be increased by either or a combination of higher mean reflectance of RNFL and/or lower mean reflectance of the retina.To the best of our knowledge,this is the first work correlating OCT reflectivity and visual function in RP patients.Such approaches can prove to be useful in RP and other HRDs when selecting candidates for gene therapy.Further analysis is needed to elucidate any possible correlation of the OCT reflectivity ratio and the standard analysis of retinal layers thickness by OCT

ABSTRACT BODY:

Purpose: Cystoid macular edema (CME) is a known complication of cataract surgery, which may lead to decreased visual acuity. This cross-sectional study examines the potential association between micro-invasive glaucoma surgery (MIGS) and CME in glaucoma patients undergoing cataract surgery in the California (CA) Medicare population.

Methods: The 2019 CA Master Beneficiary Summary File and 2019 Standard Analytic Files of Part B Carrier Claim data files from the Centers for Medicare and Medicaid Services were used to identify beneficiaries ≥65 years old with open-angle glaucoma (OAG) and cataract surgery. The outcome of interest was CME. Patients with MIGS were defined as those with procedure codes for trabecular microbypass iStent, goniotomy/canaloplasty, XEN subconjunctival gel stent, or cyclophotocoagulation. Chi-squared tests were performed to evaluate univariable associations between MIGS and CME in the study population. Logistic regression was used to assess multivariable associations between MIGS and CME, adjusting for age, sex, race/ethnicity, Charlson comorbidity index, diabetic retinopathy, and retinal vein occlusion.

Results: In 2019, 12,755 CA Medicare beneficiaries with OAG underwent cataract surgery, of whom 6,157 (48.3%) received MIGS. The largest proportion were female (7,118, 55.8%) and White (7,221, 56.6%). Of the 6,157 patients with cataract surgery and MIGS, there were 4,013 (65.2%) with trabecular microbypass iStent, 2,158 (35.0%) with goniotomy/canaloplasty, 94 (1.5%) with XEN subconjunctival gel stent, and 476 (7.7%) with cyclophotocoagulation. CME was not statistically significantly associated with any MIGS in the total study population (odds ratio [OR]=0.92, 95% CI 0.80-1.06) or in diabetic patients (OR=0.89, 95% CI 0.71-1.11). Compared to OAG patients with cataract surgery alone, those with goniotomy/canaloplasty had increased odds of CME in the adjusted analyses (unadjusted OR=1.15, 95% CI 0.96-1.39, adjusted OR=1.25, 95% CI 1.03-1.51), while those with trabecular microbypass iStent had lower odds of CME in unadjusted but not adjusted analyses (unadjusted OR=0.80, 95% CI 0.68-0.95, adjusted OR=0.86, 95% CI 0.72-1.02).

Conclusions: Amongst 2019 CA Medicare beneficiaries with OAG receiving cataract surgery, use of MIGS overall was not associated with increased risk of CME. However, goniotomy/canaloplasty may be associated with increased likelihood of CME, which requires further evaluation.

ABSTRACT BODY:

Purpose: Rates of diabetic retinopathy (DR) and diabetic macular edema (DME) are increasing worldwide, with Black and Hispanic patients displaying worse baseline VA at clinical presentation than White patients (Maholtra, 2021). This study used real-world data to quantify disparities in visual acuity (VA) outcomes at one and two years after initiation of DR/DME treatment in patients based on race/ethnicity (Black, Hispanic, and White) as well as on insurance status (Medicare, Medicaid, or Private).

Methods: We examined the IRIS registry, which includes de-identified data on over 70 million unique patients, including subjects that met strict criteria for presence of a full data-set of information (VA over two years, insurance status, race, treatment provided) and excluding subjects with other comorbidities that might necessitate treatment with anti-VEGF agents. The modified DRSS severity scale was used to classify DR and DME.

Results: With 43,273 eyes, mean VA at baseline were 67.3, 66.3, and 65.2 in White, Black, and Hispanic patients, respectively. After one year, White patients saw a 1.7 letter improvement, relative to a 1.3 and 1.1 letter improvement in Black and Hispanic patients, respectively. Differences persisted after controlling for insurance. A significantly lower proportion of White patients demonstrated 15-letter loss in VA after 1 year than both Hispanic and Black patients and a significantly lower proportion of 15-letter loss in VA after 2 years than Black patients.

Mean modified-DRSS scores at baseline were 56.0, 57.3, 60.7 in White, Black and Hispanic patients. Hispanic patients had a higher proportion of treatment with bevacizumab than White and Black patients across all disease severities, while White patients had a higher proportion of treatment with aflibercept than Black and Hispanic patients across most disease severities.

Conclusions: Race and insurance-based differences in one and two year outcomes following anti-VEGF treatment for DR and differential administration of anti-VEGF therapies by both race and insurance necessitate ongoing examination to ensure earlier and more effective treatment of DR patients nationally.

ABSTRACT BODY:

Purpose: To investigate the effect of online learning and other environmental factors on myopia progression during the COVID-19 pandemic.

Methods: A retrospective, cohort study on children aged from 6 to 14 years with myopia. Data were gathered from 3 visits; pre-COVID 19, at the beginning of the pandemic, and during the pandemic. Patients' demographics (number of hours spent on screens for educational and recreational purposes, type of screen used, and number of hours spent outdoors), best corrected visual acuity (BCVA), uncorrected visual acuity (UCVA), and cycloplegic refraction to quantify spherical equivalent (SE) were measured for all participants. Progression of myopia was calculated based on difference between the three visits.

Results: One hundred and fifty patients met our inclusion criteria. Mean age was 11±2.4 years. There were 70 males (47%). They mainly used mobile phones (62%) and had insufficient outdoor play (88%). Out of 300 eyes, 221 (74%) had progression in myopia. A significant difference was found in SE between pre-COVID-19 (-0.29 ±0.23) and post-COVID-19 (-0.40 ±0.11) with a p-value of 0.023. Additionally, UCVA showed difference between the initial Vs. 1st follow-up visit (0.57±0.37 vs 0.64±0.36, p-value =0.001), and first follow-up visit Vs. 2nd follow-up visit (0.64±0.36 vs 0.70±0.36, p-value =0.001). Survival analysis showed significant hazard ratio on change in SE for high age group (>9 years), (HR [95% CI], 0.71 [0.51 – 0.84]), recreational screen usage (HR [95% CI], 1.26 [1.15 – 1.66]) and insufficient outdoor time (HR [95% CI], 1.45 [1.35 – 1.67]).

Conclusions: Myopia progression was accelerated compared to pre-COVID-19 times in terms of spherical equivalent. Younger age group, prolonged screen users and insufficient outdoor time contributed to the further increase in myopia. However, the type of device had no effect statistically on the progression of myopia.

ABSTRACT BODY:

Purpose: Epigenetic modifications such as DNA methylation are a crucial part of the regulatory repertoire to tailor cell type-specific gene expression. Still, little is known about methylation profiles of induced pluripotent stem cells (iPSCs) and derived cell differentiations. The aim of this project is to assess global methylation in cells of various origin and developmental stages, including primary tissues such as human retina, fibroblasts or peripheral blood mononuclear cells (PBMCs), iPSCs, and iPSC-derived cell lines including retinal pigment epithelium (RPE), endothelial cells (ECs) and 3D retinal organoids (ROs).

Methods: Methylation data were obtained applying the Infinium MethylationEPIC BeadChip (Illumina), which addresses 850k defined methylation sites. After stringent quality control, 127 samples were included in our analysis (retinae N = 12, fibroblast cells N = 4, PBMCs N = 2, iPSCs N = 25 from 22 donors, ECs N = 8, RPE N = 50 from 19 donors, ROs N = 26 from 3 donors). Quantile normalization was performed and clustering of samples was analyzed by principle component analysis. Differences in the methylation status of CpG sites were investigated by a linear regression model adjusting for the donor. Enrichment analysis was performed by gene ontology testing and correction for multiple testing was performed by false discovery rate (FDR < 0.001).

Results: Data showed methylation profiles specific for each cell type/tissue with the highest similarity between ROs and human retinae (24,259 differentially methylated positions, DMPs). Cell type-specific DMPs ranged between 2,762 (ROs) and 47,926 (fibroblast cells). Considering various stages of maturation of iPSC-derived RPE cells and ROs revealed 118,642 and 21,074 DMPs, respectively. Enrichment analysis attributes these changes to developmental processes and structural morphogenesis, as well as cell type-specific pathways for RPEs (cell junction) and ROs (neurogenesis).

Conclusions: Distinct methylation profiles were observed for each primary tissue and cultivated cell line. In the course of maturation of iPSC-derived cell lines general developmental processes are involved besides cell type-specific biological pathways. Of note, iPSC-derived ROs show a strong similarity to human retinae, even more than to their originating iPSC lines, supporting their value as research models for hereditary and complex retinal diseases.

ABSTRACT BODY:

Purpose: Preclinical studies have shown success using cultivated human corneal stromal keratocytes (CSK) and their progenitors (corneal stromal stem cells [CSSC]) to prevent corneal scarring and regenerate transparent corneal stroma. However, there is no study comparing the treatment efficacy of CSK versus CSSC. This work investigated if both cell types have comparable corneal regenerative effects in a mouse corneal injury model.

Methods: Human CSSC and CSK were isolated from same donor corneas (n=3) and cultured following reported protocols. Cell phenotypes were characterized by marker expression, doubling time and collagen deposition. In a mouse model of anterior stromal injury created by Algerbrush burring, CSSC were topically applied in fibrin gel immediately after injury whereas CSK were intrastromally injected after epithelial healing. Corneas were examined weekly with anterior segment optical coherent tomography and harvested at 14 days post-treatment for scar analysis, fibrosis gene expression (Col3a1, aSMA, fibronectin [FN], and tenascin C [TNC])by qPCR and immunostaining.

Results: Cultivated human CSSC were proliferative and expressed stem cell markers (Pax6, ABCG2, nestin and CXCR4), and lumican but negative for keratocan and ALDH3A1. Growth-arrested CSK became quiescence and expressed ALDH3A1, keratocan, and lumican. Using ELISA, CSSC produced significantly less pro-collagen I than quiescent CSK, and both had minimal collagen III expression when compared to stromal fibroblasts. When applied on mouse corneal wounds, both cell types reduced corneal scarring in a dosage-dependent manner and downregulated inflammatory (iNOS, MCP1) and fibrosis markers (Col3a1, aSMA, FN, and TNC), when compared to wound controls. Comparing between CSSC and CSK, fibrosis gene expression was generally lower in CSK group than those treated with CSSC, particularly significant for MCP1, FN and TNC ($P<0.05$, Mann-Whitney U test). The lowest effective dosage for CSSC was $50x10^3$ cells and CSK was $20x10^3$ cells on mouse corneas.

Conclusions: Treatments with CSSC and CSK were effective to reduce corneal fibrosis and scarring. CSK injection showed a greater scar inhibition than topical CSSC. This could be due to a better retention of functional CSK inside stroma whereas CSSC could be partly removed by blinking. In addtion, batch-to-batch variability and differentiation of CSSC could affect the treatment outcomes.

TITLE: Prevalence of Obesity in Adolescents with Amblyopia

SESSION TITLE: Vision Impairment, Visual Function, and Quality of Life

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Drews-Botsch, K. Machicado, A. Weinstein, Global and Community Health, George Mason University, Fairfax, Virginia, UNITED STATES|S.R. Lambert, Ophthalmology, Stanford University School of Medicine, Palo Alto, California, UNITED STATES|

Commercial Relationships Disclosure: Carolyn Drews-Botsch: Commercial Relationship: Code N (No Commercial Relationship) | Kyle Machicado: Commercial Relationship: Code N (No Commercial Relationship) | Scott Lambert: Commercial Relationship: Code N (No Commercial Relationship) | Ali Weinstein: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Children with amblyopia, and the resultant loss of stereopsis, may have fine and gross motor deficits which have been associated with a higher risk of obesity. However, the risk of obesity in individuals with amblyopia is unknown.

Methods: These analyses use data from the 1999–2008 National Health and Nutrition Examination Survey (NHANES). We focus on the 8295 children between the ages of 12 and 18 who participated in the visual examination component of NHANES and had a best corrected visual acuity in the better eye of at least 20/40. Amblyopia was defined as at least a two-line intraocular difference in acuity. Obesity was defined as a body mass index (BMI) or a body fat percentage (BFP) greater or equal to the 95^{th} percentile for age and gender. BFP was measured using a dual-energy X-ray absorptiometry (DEXA). Cardiovascular fitness level (CFL) was assessed using a submaximal exercise test. We calculated Mantel-Haenszel odds ratios to examine the relative prevalence odds of obesity in children with and without amblyopia.

Results: The prevalence of amblyopia was 4.3%. Children with amblyopia had a higher prevalence of high BMI than those without (30.3% versus 21.4%; OR =1.56; 95% CI 1.24-1.98). Children with amblyopia were also somewhat more likely to have a high BFP (15.3% versus 13.2%; OR = 1.15 95% CI 0.77,1.70) and have low CFL (OR = 1.15; 95% CI 0.83,1.57) but these measures were available for only about half of the population.

Conclusions: Our findings suggest that adolescents with amblyopia may be more likely to be obese and sedentary. Given the range of morbidities associated with childhood obesity, targeted interventions promoting physical activity among children with amblyopia could be a viable option for preventing and addressing weight-related health issues.

TITLE: Associations between Statin Use and Glaucoma in the National Health and Nutrition Examination Survey

SESSION TITLE: Glaucoma epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Lee, K. Kitayama, V. Tseng, D. Pan, F. Yu, A.L. Coleman, University of California Los Angeles David Geffen School of Medicine, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Samuel Lee: Commercial Relationship: Code N (No Commercial Relationship) | Ken Kitayama: Commercial Relationship: Code N (No Commercial Relationship) | Victoria Tseng: Commercial Relationship: Code N (No Commercial Relationship) | Deyu Pan: Commercial Relationship: Code N (No Commercial Relationship) | Fei Yu: Commercial Relationship: Code N (No Commercial Relationship) | Anne Coleman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To examine associations between statin use and glaucoma in the National Health and Nutrition Examination Survey (NHANES) population.

Methods: The study population included adult participants of the 2005-2008 NHANES. Statin use was analyzed as a binary variable, with participants classified as either taking or not taking statins at the time of the survey. Glaucoma was defined according to the Wilmer criteria, where a positive glaucoma diagnosis was marked by the “definite” presence of glaucoma in at least one eye according to disc photos graded by ophthalmologists. Covariates included age, sex, ethnicity, level of education, income, body mass index, smoking status, alcohol intake, steroid intake, and history of diabetes mellitus, cataract extraction, macular degeneration, and myocardial infarction. Logistic regression modeling was used to examine the associations between statin use and glaucoma in the study population. Models were unadjusted, partially adjusted for age, sex, and ethnicity, and fully adjusted for all study covariates. Analyses were weighted using NHANES multistage sampling design.

Results: The study population included 5489 participants, representing a weighted US population of 111,882,981, of whom 620,169 (0.6%) had glaucoma. In the unadjusted model, statin use showed a statistically significant association with increased odds of glaucoma (unadjusted odds ratio [OR] = 2.60, 95% confidence interval [CI] = 1.52, 4.45), but this was no longer statistically significant in the partially (partially adjusted OR = 1.23, 95% CI= 0.67, 2.26) and fully adjusted (fully adjusted OR = 1.01, 95% CI = 0.40, 2.53) models.

Conclusions: In the 2005-2008 NHANES population, statin use was associated with an increased odds of glaucoma in unadjusted but not in adjusted models. Further investigation is needed into potential associations between hyperlipidemia, its treatment, and risk of glaucoma in the general population.

TITLE: Phacoemulsification cataract surgery with and without iStent in primary angle closure glaucoma - a retrospective comparative study

SESSION TITLE: Surgery & Wound Healing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Hamze, H. Selvan, A. Saravanan, P. Pandey, I. Masood, V. Sung, Birmingham and Midland Eye Centre, Birmingham, Birmingham, UNITED KINGDOM|

Commercial Relationships Disclosure: Hisham Hamze: Commercial Relationship: Code N (No Commercial Relationship) | Harathy Selvan: Commercial Relationship: Code N (No Commercial Relationship) | Amrita Saravanan: Commercial Relationship: Code N (No Commercial Relationship) | Pravin Pandey: Commercial Relationship: Code N (No Commercial Relationship) | Imran Masood: Commercial Relationship(s);Code C (Consultant/Contractor):Glaukos | Velota Sung: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Phacoemulsification cataract surgery (PCS) is an important surgical treatment for primary angle closure glaucoma (PACG). Since the introduction of iStent, PCS combined with iStent has been advocated in previous studies, however, there is a paucity of comparative data in this area. We conducted a retrospective observational clinical study to evaluate the efficacy, safety and complication rates of PCS only versus combined PCS with iStent in PACG.

Methods: This retrospective study compared the outcomes of 44 patients who underwent combined PCS and iStent with 45 patients who underwent PCS only. Only patients with a diagnoses of PACG were enrolled. The primary success endpoint was defined as intraocular pressure (IOP)<21 mmHg and ≥20% reduction in IOP at 1 year regardless of the number of glaucoma medications (NGM). Secondary endpoints included IOP, NGM, visual acuity (VA) and complications. All patients had at least 1 year of follow-up.

Results: The mean age, pre-operative IOP and NGM in the PCS-iStent and PCS-only groups were 71.2 ± 13 years and 65.3 ± 13.2 years (P>0.05), 21.1 ± 9.3 mmHg and 17.8 ± 7.1 mmHg (P>0.05), and 3.2 ± 1.2 and 2.2 ± 1.7(P<0.01), respectively. In both groups, there was a significant increase in VA and reduction in the IOP and NGM observed post-surgery (P<0.05). At one year, there was no significant difference in IOP and NGM reduction between both groups (P=0.48, P=0.17), 22.3% (5.7 ± 6.4 mmHg) reduction in IOP and 1.7 ± 1.5 reduction in NGM in the PCS-iStent group compared to 20.7% (5 ± 6.9 mmHg) reduction in IOP and 1.3± 1.7 reduction in NGM in the PCS-only group. Four patients (9%) in the PCS-iStent group required further glaucoma surgery to reduce the IOP compared to none in the PCS-only group. At 1 year, 50% in the PCS-iStent group met the success criteria compared to 51.3% in the PCS-only group.

Conclusions: iStent provides no additional IOP reduction when combined with cataract surgery in PACG. There was no increase in complication rate and no significant difference in NGM reduction. Therefore, there is no additional benefits in the use of iStent at the time of PCS for patients with PACG.

ABSTRACT BODY:

Purpose: Mutations in pre-mRNA processing factor 31 (PRPF31) result in autosomal-dominant retinitis pigmentosa (adRP) known as RP11, characterised by global dysregulation of spliceosome in retinal cells and the adjacent RPE cells. This study aims to investigate the disease pathomechanisms in Retinitis Pigmentosa caused by mutations in the PRPF31 gene.

Methods: Human iPSCs from three patients with severe and very severe PRPF31-adRP, unaffected individuals and a CRISPR/Cas9-corrected isogenic control were used to generate RPE monolayers. To fully assess the impacts of PRPF31 mutations, quantitative proteomics analyses of control and RP11-RPE cells and biochemical assays were performed.

Results: Quantitative proteomic analysis of control and patient RPE cells showed RNA splicing, retinoid metabolism and visual perception, and protein folding (UPR) pathways to be affected in RP11-RPE cells. The patient-derived RPE cells were characterised by reduced amounts of tri-snRNPs, spliceosome activity, and the presence of insoluble aggregates containing the mutant PRPF31 and misfolded, ubiquitin conjugated proteins, which accumulated progressively with time. The waste disposal mechanisms via autophagy and proteasome-mediated degradation were impaired, further exacerbating aggregate formation, which was closely linked with activation of cell death. Targeting the waste disposal mechanisms by activating the autophagy pathway using rapamycin resulted in the reduction of these cytoplasmic aggregates in RP11-RPE cells and improved cell survival.

Conclusions: Together these data indicate a vicious circle initiated by mutations in PRPF31, which lead to spliceosome dysregulation and accumulation of misfolded proteins in the form of insoluble cytoplasmic aggregates that affect RPE cell viability. Relieving the RPE cells from accumulation of these insoluble cytoplasmic aggregates presents a novel therapeutic strategy for RP11-patients.

ABSTRACT BODY:

Purpose: To quantify the long-term progression of macular and retina-wide photoreceptor degeneration in Stargardt disease (STGD1) using an array of performance outcome (PerfO) assessments and to assess their responsiveness.

Methods: In a prospective, natural-history study (NCT01736293), patients with a Stargardt disease (STGD1) phenotype and at least one pathogenic ABCA4-mutation underwent extensive visual function testing, including best-corrected visual acuity (BCVA), ISCEV ganzfeld electroretinography (ERG), mesopic microperimetry (MP, OD only, 10-2 grid), and the low-vision Cambridge Color Test (lvCCT) for five years (baseline, month 6, then annually). MP data were summarized in terms of the perilesional sensitivity of responding points (PLS, distance of 2 deg from scotomatous points) and mean responding points sensitivity (RPS). Responsiveness was analyzed using mixed models with the PerfO as the dependent variable, follow-up time as the independent variable, and eyes nested in patients as a random-effects term. To compare responsiveness across different parameters, we computed the effect sizes (i.e., estimates from standardized [std.] data) and the Eta-squared (η^2) defined as the ratio of variability-explained-by-time to overall-variability.

Results: A total of 134 eyes from 67 patients with a median [IQR] follow-up of 4.5 years [3.1, 4.1] were included. There was a statistically significant loss of function across all PerfOs ($P<0.05$) with exception of the light-adapted cone a-wave latency and lvCCT achromatic area.

Among the MP derived PerfOs (available for N=46 patients), the mean PLS was most sensitive to change over time (estimate [95% CI]: -1.24 dB/y [-1.56, -0.91], std. effect of -0.54 [-0.67, -0.4], η2=0.62). Among the full-field ERG parameters (N=67 patients) the scotopic 3.0 cd*s/m^2 b-wave amplitude (-0.02 log10(μV)/y [-0.03, -0.02], std. eff. -0.22 [-0.3, -0.15], η2=0.36) was most responsive. BCVA (0.01 LogMAR/y [0.01, 0.02], std. eff. 0.06 [0.03, 0.09], η2=0.25) showed only minor change over time.

Conclusions: The ability-to-detect-change was best for MP-derived PerfOs. However, MP data could not be acquired for all patients. Full-field ERG did reveal significant changes over time, but the standardized effect sizes indicate that these are suboptimal as a clinical trial endpoint. In STGD1, responsive measures of function enabling inclusive trial designs still constitute an unmet need.

SUBMITTER (NAME ONLY): Daniel Vail

TITLE: Ophthalmic evaluations among patients receiving systemic therapies associated with uveitis

SESSION TITLE: Clinical Uveitis and Scleritis: Therapies and Outcomes

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Vail, Ophthalmology, New York Eye and Ear Infirmary of Mount Sinai, New York, New York, UNITED STATES|A. Al Moujahed, Q.D. Nguyen, Ophthalmology, Stanford Medicine, Stanford, California, UNITED STATES|

Commercial Relationships Disclosure: Daniel Vail: Commercial Relationship: Code N (No Commercial Relationship) | Ahmad Al Moujahed: Commercial Relationship: Code N (No Commercial Relationship) | Quan Nguyen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Recent studies have raised concerns that several classes of systemic medications may increase patients' risk of developing uveitis. Currently, there are no guidelines for ophthalmic screening when initiating therapy. We examine current practice patterns for ophthalmic screening among patients who receive systemic medications associated with increased risk of uveitis.

Methods: We use insurance claims to identify patients with exposure to checkpoint inhibitors, MEK or BRAF inhibitors, TNF- inhibitors, bisphosphonates, cidofovir, and rifabutin. We calculate the percentage of patients who receive baseline visual testing prior to receiving therapy, and the percentage that receive periodic exams after initiating therapy. We calculate the incidence of new diagnoses of uveitis, blurry vision, and exudative retinal detachments in patients after starting therapy. We compare these results to patients receiving hydroxychloroquine, a medication for which ophthalmic screening guidelines have been established for many years.

Results: Of 383,851 patients who met inclusion criteria, 532 developed a new diagnosis of uveitis within 365 days of initiating therapy (0.16%). Approximately 1.4% of patients (N=4,429) developed a new diagnosis of blurry vision within 365 days of initiating therapy. One third of patients (N=108,411, 33%) received an eye exam in the 365 days preceding their first dose; 23,980 (6.2%) had an eye exam within the 30 days preceding the initiation of therapy. One third (N=122,717, 37%) of patients had an eye exam within 365 days after their first dose of medication. One fifth of patients (N=71,909, 21.9%) had both a baseline exam during the 365 days preceding their first dose of medication and a follow-up exam within the 365 days following their first dose.

Conclusions: Patients on medications that may cause uveitis receive irregular and infrequent ophthalmic evaluations. We found no evidence that patients on any of the drugs included in this analysis are routinely being referred for ophthalmic evaluation in the pre-treatment or the immediate post-treatment window. Future recommendations for the ophthalmic management of patients on these medications must account for both the risk that the medications pose to patients' vision as well as the current practice patterns for ophthalmic care that these patients receive.

SUBMITTER (NAME ONLY): Tatyana Appelbaum

TITLE: Detection and characterization of circular RNAs hosted by RPGR exon ORF15.

SESSION TITLE: Biochemistry and Molecular Biology of the Retina/RPE

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Appelbaum, L. Murgiano, G.D. Aguirre, W.A. Beltran, University of Pennsylvania, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Tatyana Appelbaum: Commercial Relationship: Code N (No Commercial Relationship) | Leonardo Murgiano: Commercial Relationship: Code N (No Commercial Relationship) | Gustavo Aguirre: Commercial Relationship: Code N (No Commercial Relationship) | William Beltran: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Mutations in RPGR exon ORF15 cause X-linked retinitis pigmentosa characterized by severe visual impairment early in life. The underlying disease mechanism and variability in the disease severity remains to be fully elucidated. The present study examines structural features of the ORF15 exonic region to provide new insights into the disease pathogenesis.

Methods: RNA samples from canine and human retinas and cultured cells (canine fibroblasts and human cell lines Y79 and ARPE19) were used to examine RPGR transcript heterogeneity, the presence of internal introns (exitrons) in ORF15 exonic region and RPGR circular RNAs (circRNAs). Treatment with RNase R was performed for circRNAs enrichment and validation of circularization. Polysomes from a crude cell homogenate were obtained by ultracentrifugation, using a sucrose cushion.

Results: We found a subset of novel RPGR ORF15-like transcripts in canine and human retina and in cultured cells. Annotation of these transcripts showed that portions of the ORF15 sequence were removed in a variable manner through utilization of noncanonical splicing sites. Notably, the presence of the $RPGR^{orf15}$ transcript was detected only in the retina. Furthermore, using outward-facing primers designed inside exitrons in ORF15 exonic region we discovered a previously unidentified RPGR circRNAs formed via back-splicing events. The RPGR circRNAs were found in all studied cells and tissues and were present in total RNA pool, in cytoplasmic and polysomal RNA fractions.

Conclusions: The obtained data on novel RPGR circRNAs further underline the complexity of RPGR gene organization and provide potential molecular basis of disease phenotypic heterogeneity.

ABSTRACT BODY:

Purpose: Controversy exists regarding the impact of panretinal photocoagulation (PRP) in retinal perfusion in patients with proliferative diabetic retinopathy (PDR). The purpose of this prospective study was to evaluate the changes of foveal avascular zone (FAZ) area and vessel density (VD) in superficial (SCP) and deep capillary plexus (DCP) in association with functional changes in patients with PDR treated with PRP.

Methods: Participants in this study were 21 patients with PDR and no macular edema, who were eligible for PRP. All participants underwent best-corrected visual acuity (BCVA) measurement, optical coherence tomography (OCT) and OCT angiography (OCTA) at baseline (before treatment) and at months 1, 6 and 12 after completion of PRP treatment. Comparison of OCTA parameters and BCVA between baseline and months 1, 6 and 12 after PRP was performed. Correlation of OCTA parameters and BCVA was also done.

Results: 25 eyes of 21 patients with PDR were included in the study. There was a statistically significant decrease in FAZ area at months 6 and 12 of the follow-up period compared to baseline ($p<0.001$ in both comparisons), while no difference was noted at month 1 of the follow-up period ($p>0.05$). Of note, FAZ became significantly more circular 6 months after PRP ($p=0.019$). There was no statistically significant difference in VD in both SCP and DCP at month 1 and 6 of the follow-up period ($p>0.05$ in both comparisons), while VD was significantly higher at month 12 compared to baseline ($p<0.001$). The FAZ area was associated with BCVA during the whole follow-up period ($p<0.001$, $p=0.014$, $p<0.001$ and $p<0.001$ for baseline and months 1, 6 and 12 respectively).

Conclusions: At month 12 after PRP, VD significantly increased compared to baseline, while the FAZ area became significantly circular and decreased significantly, suggesting that re-distribution of blood flow may occur in hypo-perfused foveal capillary plexus after PRP in patients with PDR.

ABSTRACT BODY:

Purpose: Posterior uveitis, both infectious and non-infectious, is a potentially vision-threatening condition caused by systemic inflammatory states. This survey was conducted to 1) better understand the current practice patterns in this patient population and 2) evaluate the interest and likelihood of use of a novel vitreous biopsy device (VBD) for use in an office-based setting. The VBD is designed to safely aspirate 0.25 - 0.4mL of vitreous within 30 seconds in an office-based setting.

Methods: A questionnaire was designed to survey retina and uveitis specialists who treat endophthalmitis and posterior uveitis and gather information on their diagnostic and treatment protocols. The questionnaire consisted of a 12-minute internet survey with 24 questions. The questionnaire focused on practice patterns relating to acquisition of ocular fluid, diagnostic tests used, culture outcomes, and potential interest in using a novel VBD.

Results: We received 77 completed surveys from 34 retinal specialists, 16 uveitis specialists, and 27 retinal and uveitis specialists. On average, each specialist saw 174 patients annually with suspected endophthalmitis or uveitis. Currently, vitreous samples are acquired 32% of the time with a needle and syringe in the office and 15% of the time in the OR. With availability of the VBD, physicians stated they would use the VBD in 30% of endophthalmitis/uveitis cases, they would acquire vitreous more often (5% increase), and for obtaining vitreous samples they would decrease the use of needle and syringe in the office by 39% and frequency of going to the OR by 57%.

Overall, the participants appreciated the ease of use of the VBD, that the device fits within current clinical workflow, the sterile single-use package, and increased efficacy of acquiring vitreous. Concerns raised by the participants included verification of safety, cost, and reimbursement.

Conclusions: Overall, access to a novel vitreous biopsy device (VBD) for use in an office-based setting will improve clinical efficiency and reduce cost by facilitating acquisition of vitreous in an office-based setting. In conclusion, VBD may lead to more rapid and definitive diagnosis as well as improved visual outcomes in patients with uveitis.

TITLE: The expression of NFkB pathway components upregulates in lens epithelial cells post injury

SESSION TITLE: Lens proteins and cataracts

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. O'Neill, A. Faranda, S.G. Novo, Y. Wang, M.K. Duncan, Biological Sciences, University of Delaware College of Arts and Sciences, Newark, Delaware, UNITED STATES|

Commercial Relationships Disclosure: Leah O'Neill: Commercial Relationship: Code N (No Commercial Relationship) | Adam Faranda: Commercial Relationship: Code N (No Commercial Relationship) | Samuel Novo: Commercial Relationship: Code N (No Commercial Relationship) | Yan Wang: Commercial Relationship: Code N (No Commercial Relationship) | Melinda Duncan: Commercial Relationship(s);Code P (Patent):US Patent application 62/944,151

ABSTRACT BODY:

Purpose: While surgical treatment of cataract is highly effective, it also results in ocular inflammation which has the potential to exacerbate other ocular diseases while also contributing to posterior capsular opacification (PCO). Though the pathogenesis of post surgical inflammation is unclear, we discovered that the lens epithelial cells (LECs) remaining behind post cataract surgery (PCS) rapidly upregulate inflammatory cytokine expression. While the mechanisms underlying this upregulation are unknown, NFkB signaling pathways regulate cytokine expression in other systems. Further, Alexander et al. 2003 showed that the lens rapidly elicited NFkB signaling when treated with known inducer, lipopolysaccharide (LPS). The objective of this study is to investigate the dynamics of NFkB pathway activation post lens injury and to elucidate its potential role in inflammation and PCO.

Methods: The Lens Injury Response Time Course (LIRTS), a database of mouse LEC transcriptome profiles generated from multiple time points post lens fiber cell removal, was used to reveal expression dynamics of NFkB signaling components in naive and injured mouse lenses. NFkB signaling was studied by subjecting a dual GFP-luciferase NFkB reporter mouse [FVB.Cg-Tg(HIV-EGFP, luc)8Tsb/J] to lens fiber cell removal surgery.

Results: LIRTS analyses revealed that several components of the NFkB signaling pathway, RelA, RelB, NFkBia, and Map3k8 upregulate their mRNA levels in LECs at 6 hours post injury, trend down at 24 hours and reach baseline by post 5 days. In contrast, the NFkB target gene, Il1b, first upregulates at 24 hours PCS. Little to no NFkB reporter activity was observed in naive adult mouse lenses; however, LECs remaining behind following fiber cell removal exhibited significant reporter gene activity at 6, 24 and 48 hours PCS, with maximal activity at 48 hours PCS which trended down by 72 hours.

Conclusions: The observation that components of the NFkB signaling pathway are expressed at the mRNA level in naive LECs is consistent with prior reports finding that the lens is responsive to LPS induction of the NFkB pathway. The further upregulation of the mRNA levels of NFkB pathway components PCS and the induction of NFkB reporter activity PCS suggests that this pathway may play important roles in post surgical inflammation and PCO pathogenesis. Future work will test the function of the NFkB pathway in the lens injury response.

TITLE: The impact of race on surgical outcomes for rhegmatogenous retinal detachments

SESSION TITLE: Vitreoretinal surgery/VR Interface/PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Xu, S. Davoudi, S. Ness, M.L. Subramanian, Ophthalmology, Boston Medical Center, Boston, Massachusetts, UNITED STATES|J. Yoon, S. Ness, M.L. Subramanian, Boston University School of Medicine, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Jia Xu: Commercial Relationship: Code N (No Commercial Relationship) | Jamie Yoon: Commercial Relationship: Code N (No Commercial Relationship) | Samaneh Davoudi: Commercial Relationship: Code N (No Commercial Relationship) | Steven Ness: Commercial Relationship: Code N (No Commercial Relationship) | Manju Subramanian: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine whether race is an independent risk factor for successful surgical repair of rhegmatogenous retinal detachments (RRDs).

Methods: A retrospective cohort study was conducted for patients who underwent surgical repair of RRDs at Boston Medical Center between October 2013 to September 2021. Surgical repairs included any combination of the following: laser retinopexy, pneumatic retinopexy, cryotherapy, scleral buckle, and pars plana vitrectomy. Patients were excluded if they had previous RRD repair. Main outcome was the single surgery success rate for primary RRD repair, defined as anatomical reattachment without the presence of tamponade agents, between black and non-black patients. Secondary outcomes include whether preoperative anatomical or socioeconomic factors differ between black patients and non-black patients.

Results: A total of 231 patients were identified. Patients were characterized as black (n=85) and non-black (n=146) based on self-reported race. Black race was not associated with worse single surgery success after primary RRD repair (p=0.437) compared to non-black race, and overall had the same final surgery success rate after re-operation (p=0.749). Both groups had similar mean age, distribution amongst sexes, and mean household income. Black patients had no difference in their preoperative visual acuity, intraocular pressure, history of myopia, history of prior cataract surgery, and history of trauma as non-black patients. There was no difference in the location of retinal breaks, number of breaks, number of quadrants detached, the rate of macula-off detachments, nor the presence of proliferative vitreoretinopathy, posterior vitreous detachments, vitreous hemorrhage, choroidal detachments, retinoschisis, or lattice degeneration.

Conclusions: Black race was not associated with primary surgical failure after rhegmatogenous retinal detachment repair. Black patients had similar preoperative baseline characteristics as non-black patients. In contrast to prior studies, our study showed that black race is not an independent risk factor for poor surgical outcomes of RRD repairs if baseline demographic and socioeconomic factors are similar.

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) is an ocular disease that can progress asymptomatically to an advanced vision-threatening stage. DR is particularly pervasive in developing countries, where there exists a severe deficiency of ophthalmologists, and thus alternate diagnosis methods are pressing.

Methods: Exploratory data analysis by way of dimensionality reduction was leveraged to interpret similarities between color fundus images derived from the Asia Pacific Tele-Ophthalmology Society. Subsequently, 16 image enhancement filters were systematically investigated for feature engineering purposes. 24 convolutional neural network architectures, including the previously untested EfficientNet and MobileNet families, were then designed, trained, and compared by their efficacy in the binary classification of DR. Ensemble stacking was leveraged to fuse the top four models through a meta-learner whose weights were optimized by a Dirichlet distribution-based randomized search. Finally, this project developed three small-object detectors (YOLO), serving as the first to localize microaneurysms, hemorrhages, cotton-wool spots, and hard exudates.

Results: Upon evaluation, the ensemble model (286 KB) surpassed all individual models across all metrics considered, attaining an F1-score of 0.978. Coupled with contrast-limited adaptive histogram equalization, the YCbCr color space augmentation was found to be the best feature engineering filter. Further, Shapley value analysis and four novel gradient-based visualizations successfully identified imaging biomarkers characteristic of DR. The YOLOv5x algorithm, with an inference time of 48.4 ms, achieved a mean average precision score of 0.504 at an Intersection over Union threshold of 0.5, a significant improvement over prior lesion localization studies.

Conclusions: Eye-Net is a highly performant machine learning tool for DR diagnosis and lesion localization; it may benefit clinicians or offer an alternate form of DR screening. Additionally, Eye-Net's lightweight frameworks postulate deployment onto mobile applications as promising avenues. Future work will focus on patient risk stratification and prognosis, which could further facilitate the early detection of DR.

ABSTRACT BODY:

Purpose: Fuchs Endothelial Corneal Dystrophy (FECD) is characterized by a progressive loss of corneal endothelial cells (CEnC) from accumulated exposure to oxidative stress. It is one of the leading causes of corneal transplantation worldwide, and no definitive pharmacologic treatment is available. We have previously demonstrated the cytoprotective function of the neuropeptide alpha-Melanocyte-Stimulating Hormone (α-MSH) against oxidative stress in CEnC ex vivo. This study aims to investigate the in vivo protective effect of α-MSH in a mouse model of FECD induced by UV-A irradiation.

Methods: 8-week-old female BALB/c mice (n=6/group) were irradiated with UV-A at 500J/cm^2 for 16 minutes. Mice received an intraperitoneal injection of 0.01mL/g of α-MSH (10^{-4} M) immediately following irradiation and thrice weekly for 8 weeks. The control group received no treatment. CEnC density, hexagonality, and cell size variability (CV) were evaluated by in vivo confocal microscopy pre-irradiation and at 1, 2, and 4 weeks post-irradiation. ZO-1 staining was performed at 8 weeks. Corneal edema was evaluated by measuring central corneal thickness on OCT.

Results: At 4 weeks post-irradiation in the control treatment group, there was a 50.5% decrease in CEnC density (1373±199 cell/mm^2 vs baseline 2773±66, p=0.002), a 29% decrease in hexagonality (41±2.5 vs baseline 57.8±1.7, P=0.032) and a 61% increase in polymegathism (CV: 58±1.22 vs baseline 36±1.3, P=0.001). Compared to controls, the α-MSH treatment group demonstrated significant improvements in these parameters: the decrease in CEnC density was 18.7% (2255±116 vs control 1373±199, P=0.012), the decrease in hexagonality was 6.7% (53.9±2 vs control 41±2.5, P=0.014) and the increase in polymegathism was 8.6% (39±1.8 vs control 58±1.22, P=0.007). Corneal thickness was assessed in N=4 mice at 4 weeks where edema subsided in the α-MSH treatment group but remained elevated in the control group (107.8 ±14.6μm vs 166.3±39.4μm, p<0.05).

Conclusions: Intraperitoneal treatment with α-MSH leads to decreases in UV-A-induced CEnC cell loss, polymegathism and pleomorphism, along with resolution of corneal edema.

ABSTRACT BODY:

Purpose: Greater utilization and insurance coverage for tele-retinal screening during the COVID-19 pandemic in 2020 may enhance awareness and expand remote retinal imaging services. In this study, we performed a retrospective, cross-sectional analysis of utilization and insurance payments of tele-retinal imaging services in the United States in 2020.

Methods: We examined remote retinal imaging utilization and insurance payments from January 1, 2020, to December 31, 2020, using the OptumLabs® Data Warehouse (OLDW), a comprehensive database of de-identified administrative claims for commercial and Medicare Advantage enrollees in the U.S.. We evaluated frequency of claims and insurance payment for services using Current Procedural Terminology codes 92227 and 92228 for remote eye imaging by any provider, and 92250 for fundus photography by non-eye care providers.

Results: Use of remote retinal imaging declined rapidly from 3627 claims in February 2020 to 1414 claims in April 2020, but returned to 3133 claims by December 2020, similar to pre-pandemic levels in 2019 (2841 ± 174.8 claims). Proportion of insurance payments for remote imaging increased temporarily from 47.4% in February to 56.7% in April, then returned to 45.9% in December.

Conclusions: Utilization of tele-retinal imaging declined steeply while insurance coverage increased during the initial COVID-19 lockdown in 2020, but returned to pre-pandemic levels by end-of-year. Changes in utilization and relaxed restrictions on insurance reimbursements for remote retinal imaging during the COVID-19 pandemic were not sustained.

TITLE: Analysis of Reoperation Rates in Strabismus Surgery from Health Databases

SESSION TITLE: Pediatric Ophthalmology Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Ang, A.E. Pogrebniak, Department of Ophthalmology, Prisma Health Midlands, Columbia, South Carolina, UNITED STATES|M. Durkin, Department of Neurology, Prisma Health Midlands, Columbia, South Carolina, UNITED STATES|

Commercial Relationships Disclosure: Su Mae Ang: Commercial Relationship: Code N (No Commercial Relationship) | Alexander Pogrebniak: Commercial Relationship: Code N (No Commercial Relationship) | Martin Durkin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Limited information has been published describing reoperation rates for various strabismus surgeries in relation to age at first surgery. We performed a retrospective, observational clinical study to analyze reoperation rates compared to type of strabismus, age at first surgery, and geographic location within South Carolina and to determine factors associated with repeat strabismus surgery.

Methods: We analyzed 25 years of longitudinal data from the South Carolina Revenue and Fiscal Affairs Office (RFAO). The inclusion criteria for the study were: (1) any admission for procedure with CPT codes 67311, 67312, 67314 or 67316 between January 1, 1996 and December 31, 2016, and (2) patient age <18 years during the time of admission for first surgery. If a second surgery was done, surgery data up to December 31, 2020 was obtained and included in analysis. Patients were categorized into 5 age groups: <2, 2 to <4, 4 to <6, 6 to <10, or 10 to <18 years old. Strabismus types were grouped as pure esotropia, esotropia plus vertical misalignment, pure exotropia, exotropia plus vertical misalignment, vertical misalignment alone, superior oblique palsy, restrictive, paretic, or other. A logistic regression model was constructed using repeat surgery as the outcome and using age and strabismus type as predictors.

Results: A total of 9237 unique patients were identified; 1833 (19.8%) had repeat surgeries captured within the RFAO database, with follow-up time ranging from 4 to 25 years depending on the date of initial surgery. Increasing age was correlated with a decreasing reoperation rate.

For all types of strabismus, reoperation was higher in the <2 years age group compared to ages 2 to <4 years (OR 0.66), ages 4 to <6 years (OR 0.48), 6 to <10 years (OR 0.34), 10 to <18 years (OR 0.24, all P <0.001). The strabismus type with the greatest number of index cases was other (n=3901, 42.2%), followed by pure exotropia (n=2496, 27.0%) and pure esotropia (n=1760, 19.0%).

Conclusions: Across all types of strabismic surgeries, patients operated on at a younger age require a higher rate of reoperation.

TITLE: The lens-corneal separation requires precision control of Hippo-Yap signaling

SESSION TITLE: Lens Biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Q. Wang, H. Wu, X. Zhang, Columbia University Irving Medical Center, New York, New York, UNITED STATES|

Commercial Relationships Disclosure: Qian Wang: Commercial Relationship: Code N (No Commercial Relationship) | Hao Wu: Commercial Relationship: Code N (No Commercial Relationship) | Xin Zhang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The Hippo-Yap signaling pathway is implicated in tissue development and homeostasis. In the lens, Yap is required for the maintenance of the lens progenitor pool, but it is not clear whether this is due to Yap's function as a transcriptional activator or as part of the cell junction complex. In this study, we aim to investigate the role of Hippo-Yap signaling network and its mechanism in regulating murine lens development.

Methods: We generated both conditional knockout and conditional transgenic mouse models using Le-cre, which is specifically expressed in the lens progenitors. Immunofluorescence was performed to characterize the lens phenotype.

Results: Consistent with a previous study, genetic ablation of Yap resulted in substantial loss of the lens epithelium (LE) compartment at embryonic day 13 (E13). This LE defect could be rescued by expression of nuclear Yap (Yap^{5SA}), which is resistant to serine phosphorylation induced by Hippo signaling. In addition, expression of nuclear Yap led to ectopic expression of LE markers in the lens fiber compartment in a cell autonomous manner, suggesting that the nuclear but not the membrane function of Yap is responsible for maintenance of the lens progenitor property. Interestingly, the Yap^{5SA}-expressing lens remained connected to the surface ectoderm (which later develops into the cornea) and formed persistent lens stalk, indicating that Yap signaling is involved in the lens vesicle separation. Moreover, genetic ablation of Hippo signaling kinases mammalian STE20-like kinase (MST) and large tumor suppressor (LATS) recapitulated Yap gain of function (Yap^{5SA}) lens stalk phenotype.

Conclusions: Our study demonstrated that the nuclear function of Yap is both necessary and sufficient to maintain the lens progenitor pool. However, the level of active nuclear Yap must be tightly controlled by Hippo Signaling to ensure separation of the lens vesicle from the surface ectoderm. Suppression of Hippo signaling leads to the lens-corneal separation defect, which mimics Peters Anomaly in humans, suggesting that the Hippo-Yap signaling may underlie congenital lens disease.

TITLE: Evaluation of public interest using internet search queries for uveitis

SESSION TITLE: Clinical Uveitis & Orbital Inflammation: Etiology, Epidemiology & Clinical Assessment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Men, University of California Los Angeles David Geffen School of Medicine, Los Angeles, California, UNITED STATES|E. Tsui, Jules Stein Eye Institute, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Mauranda Men: Commercial Relationship: Code N (No Commercial Relationship) | Edmund Tsui: Commercial Relationship(s);Code C (Consultant/Contractor):Kowa Company Ltd;Code F (Financial Support):Cylite Pty Ltd

ABSTRACT BODY:

Purpose: The rarity of uveitis makes it difficult to gauge overall trends in patient behavior; however, the internet is a popular resource for medical self-education. This study used search engine data to characterize search patterns around uveitis, to better understand what people look for online.

Methods: Google Trends data were analyzed from 2004-21 to find the top related search queries with "uveitis" and "iritis" in the United States (USA), United Kingdom (UK), Canada, Australia, and India. This was further divided into top search terms for three 6-year periods: 2004-09, 2010-15, and 2016-21. Queries were categorized as relating to disease information, disease treatment, other eye conditions, related systemic conditions, or other. The relative search frequency of each term, and the sum of them for each term in a category, measure how many people search for information in those categories after first searching "uveitis" or "iritis."

Results: Within searches for "uveitis," the term "anterior uveitis" was the top or second top related search term in every country in every time period studied. Only the USA had "iritis" or "iritis uveitis" as common terms, with 42 people searching for them out of every 100 people searching for "uveitis." Also in the USA, in 2016-21, 13 of every 100 people searched for "uveitis vs iritis" or "iritis or uveitis" when searching for "iritis." In every country, the majority of related "uveitis" search terms concerned disease information. In the UK, Canada, Australia, and India, the next most common search categories were disease treatment, systemic conditions, followed by other eye conditions. In the USA, the next most common search categories were other eye conditions, disease treatment, then systemic conditions. In each country except India, where it was "psoriasis," the top searched systemic condition was "ankylosing spondylitis," with 10/100 searches in the USA and UK and 22/100 searches in Canada and Australia.

Conclusions: Query categories have been stable over time in several countries, indicating persistent knowledge gaps for the average searcher regarding uveitis causes and presentations. "Anterior uveitis" as a top related search term is logical given the high prevalence of anterior uveitis compared to other subtypes, suggesting demand for more knowledge about it. These data may help caregivers anticipate topics of interest for patients and improve counseling accordingly.

Commercial Relationships Disclosure: Lucia Brunel: Commercial Relationship: Code N (No Commercial Relationship) | Sarah Hull: Commercial Relationship(s);Code P (Patent):US20210244659A1 | Patrik Johansson: Commercial Relationship: Code N (No Commercial Relationship) | David Myung: Commercial Relationship(s);Code P (Patent):US20210244659A1 | Sarah Heilshorn: Commercial Relationship(s);Code P (Patent):US20210244659A1

ABSTRACT BODY:

Purpose: Due to the dearth of graft tissue available globally for patients with corneal blindness, improved corneal regeneration will require bioengineered strategies. Collagen hydrogels have demonstrated potential as matrices for corneal mesenchymal stromal cells (cMSCs) but commonly suffer from opacity and cell-induced contraction, affecting the optical properties of the material. We have developed a transparent, bioorthogonally-crosslinked collagen hydrogel with enhanced stability against cMSC-induced contraction while maintaining cell phenotype for improved regenerative potential.

Methods: Covalently-crosslinked collagen hydrogels were formed by strain-promoted azide-alkyne cycloaddition (SPAAC), a bioorthogonal click chemistry. The hydrogel fibrillar microstructure and corresponding transparency were characterized with second harmonic generation microscopy and UV/Vis spectroscopy, respectively. Human cMSCs were encapsulated within SPAAC-crosslinked or non-chemically crosslinked control collagen hydrogels, and the contraction was monitored over time. In addition, cMSC viability, differentiation markers, and secretome within the hydrogels were analyzed using a Live/Dead assay, immunocytochemistry, and a Luminex immunoassay, respectively.

Results: We demonstrated the improved transparency of the SPAAC-crosslinked collagen across the visible light range compared to non-chemically crosslinked collagen (e.g., 98% vs. 52% transmittance at 500 nm), which resulted from the disruption of collagen fibril formation. The SPAAC-crosslinked collagen resisted deformation from encapsulated human cMSCs over 72 h: the non-chemically crosslinked collagen hydrogels contracted to 20% of their initial diameters, while SPAAC-crosslinked collagen did not detectably contract. In addition, the cMSCs in the SPAAC-crosslinked collagen maintained their characteristic phenotype, with high viability (> 90%), expression of the keratocyte differentiation marker aldehyde dehydrogenase 3A1, and secretion of cytokines similar to cMSCs within the non-chemically crosslinked collagen.

Conclusions: Our results indicate that human cMSCs may be successfully encapsulated within SPAAC-crosslinked collagen to create transparent, bioengineered hydrogels that resist cell-induced contraction while simultaneously preserving the corneal cell phenotype.

ABSTRACT BODY:

Purpose: 1) Explore the feasibility of the Eye911 protocol for the ER and urgent care setting. 2) Assess diagnostic accuracy of protocol and impact of slit lamp (SL) video for diagnosis of ocular pathologies.

Methods: Thirteen patients presenting to the Memphis Veterans Affairs (VA) ER with ocular complaints were recruited. Following informed consent, the Eye911 protocol was carried out. Eye911 protocol includes initial eye workup (history, vision, IOP) and 2D external photos of the eyes. Then, SL video was captured for both eyes (JedMed). A single undilated fundus photo (Canon) was obtained for each eye. The patient was then seen by the on-call ophthalmologist in the traditional face to face (F2F) eye exam. The study data, images, and videos were uploaded into REDCap and sent to four reading ophthalmologists for interpretation. They were blinded to patient identity, F2F exam, and each other's interpretations. The readers first reviewed clinical information and external and fundus photos to make an initial diagnosis (pre-SL). They then accessed the SL video and made a subsequent diagnosis (post-SL). Using percent agreement and Cohen's kappa (κ) statistics, concordance pre and post-SL video between each of the readers and the F2F "gold standard" diagnosis was calculated.

Results: For reader 1, 2, 3, and 4 respectively, the percent agreement pre-SL between reader and F2F diagnosis was 46.2%, 33.3%, 30.8%, and 46.2%. There was no change in percent agreement post-SL (Table 1 and Table 2). In both the pre-SL and post-SL video period, there was no agreement between reader 1 vs 2 ($\kappa = -0.36$) or reader 2 vs 3 ($\kappa = -0.20$). There was slight agreement between reader 2 vs 4 ($\kappa = 0.00$). There was fair agreement between reader 1 vs 3 ($\kappa = 0.37$), reader 1 vs 4 ($\kappa = 0.38$), and reader 3 vs 4 ($\kappa = 0.37$) (Table 1 and Table 2).

Conclusions: Overall, percent agreement between readers and F2F exam ranged from ~30-46%, suggesting that the Eye911 protocol is feasible with moderate diagnostic accuracy. Surprisingly, the SL video did not increase percent agreement. There was also a wide range of agreement between the readers during the pre and post-SL video period ranging from none ($\kappa < 0$) to fair ($\kappa = 0.21$-0.40). These findings suggest that the protocol requires further study. Results may improve as more participants are recruited.

ABSTRACT BODY:

Purpose: Both aqueous humor (AH) and blood-based liquid biopsies can carry tumor-derived cell-free DNA (cfDNA) in retinoblastoma (RB) patients. Detection of somatic copy number alterations (SCNAs) requires approximately 5% tumor fraction, as such have only previously been detected in AH, which is an enriched source of tumor DNA. We analyzed AH and blood cfDNA taken at the time of primary enucleation to compare SCNA profiles and somatic RB1 mutation detection between both biospecimens.

Methods: One patient diagnosed with advanced unilateral RB (Group D/AJCC Stage cT2B) was included. After isolating cfDNA from AH and blood, constructed whole genome libraries were sequenced on an Illumina platform to assess genome-wide SCNAs, which were considered positive at 20% deflection from the baseline. Correlation between SCNA profiles was calculated using Pearson correlation coefficient. The libraries were also used to identify somatic RB1 pathogenic variants using a comprehensive cancer panel that includes all RB1 exons.

Results: In the peripheral blood, a germline RB1 mutation was not detected, however a heterozygous mutation (c.3920T>A) in the APC gene was reported from clinical testing. Genomic analysis of the tumor revealed two somatic RB1 mutations that were not present in germline, c.1589_1590del with a variant allele frequency (VAF) of 84.0% and c.2330dupC with VAF of 40.0%. These mutations were similarly detected in the AH, with VAFs of 78.9% and 45.27% respectively, but were not detected in the blood. Genomic analysis of both tumor and AH demonstrated highly recurrent RB SCNAs such as gains on 1q, 2p, and 6p, in addition to other alterations. The AH SCNA profile was highly concordant with the tumor profile ($r=0.987$; $p<0.0001$). 6p gain was detected in the blood and comparison of the 6p amplitude between AH and blood suggests approximately 12% tumor fraction in the blood.

Conclusions: To our knowledge, this is the first time an SCNA has been detected in the blood of an RB patient, suggesting a high enough tumor fraction. No metastasis has been identified, however monitoring is ongoing. The results illustrate the benefits and limitations of both AH and blood-based liquid biopsies. While AH is composed of more highly enriched eye-specific tumor information, only blood can provide information regarding systemic disease and metastasis.

ABSTRACT BODY:
Purpose: Functional and structural deficits have been reported in the retina of amblyopic eyes compared with fellow eyes. Non-invasive in vivo flavoprotein fluorescence (FPF) imaging provides clinic-based quantitative physiological biomarkers of retinal metabolic function. Based on previous studies in eyes with diabetic retinopathy and glaucoma exhibiting mitochondrial dysfunction, we hypothesized that amblyopic eyes would have higher levels of oxidized mitochondrial flavoproteins (FPF intensity and curve width) than those of fellow non-amblyopic eyes.
Methods: 14 children (aged 5y to 11y) with unilateral anisometropic, strabismic, or combined amblyopia underwent retinal metabolic imaging with the OcuMet Beacon (Ann Arbor, MI). The FPF sampling space was a 13° diameter target centered on the fovea identified with an IR alignment after pupil dilation. Retinal mitochondrial flavoprotein enzymes were activated for 30ms with an excitation wavelength of 467nm; emission filters were tuned to 535nm. Images were reviewed by an investigator masked to the clinical and FPF parameters and excluded if poor quality or decentered. We compared mean FPF intensity values and curve width between amblyopic and fellow eyes using paired t-tests, calculating mean difference with 95% confidence intervals (CI). We hypothesized that if there was a difference between amblyopic and fellow eyes, the mean difference of FPF intensity would be at least 5 units higher in affected eyes (based on studies in diabetic retinopathy).
Results: 9 pairs of images were graded by the masked grader as sufficient quality for analysis. Included children ranged from age 5 to 11 years and amblyopic eye acuity from 20/80 to 20/30. There was no statistically significant difference in FPF intensity between amblyopic and fellow eyes (mean difference -1.6 units, p=0.27) and the 95% CI (-4.59 to 1.47) excluded the hypothesized +5 unit mean difference. There was no difference in FPF curve width between amblyopic and fellow eyes (-1.33 units, 95% CI -2.72 to 0.05, p=0.06).
Conclusions: In contrast to previous reports of functional and structural deficits in the retinas of eyes with amblyopia, we found no evidence of retinal mitochondrial dysfunction by flavoprotein fluorescence (assuming an expected effect size of 5 intensity units greater in amblyopia). Retinal changes in amblyopia do not appear to manifest as abnormalities in retinal mitochondrial function.

ABSTRACT BODY:

Purpose: Optical coherence tomography (OCT) manufacturers add color-coded normative information to circumpapillary RNFLT printouts, to aid in the clinical diagnosis of glaucoma (Fig 1A). In this retrospective study, we investigate whether normative percentiles of RNFLT (pRNFLT) from the Spectralis OCT platform (2009 European-descent norms) enable better prediction of glaucomatous visual field (VF) loss than absolute RNFLT.

Methods: A longitudinal database of Mass Eye & Ear Infirmary patients seen in glaucoma clinic from 2009-2020 was extracted. From a source of 158,484 Humphrey 24-2 VFs and 30,452 OCT scans, reliable OCT-VF pairs acquired within 30 days of each other were selected (Fig 1B). Spectralis normative distributions were extracted from color-coded machine printouts (Fig 1A). Supervised machine learning models predicting mean deviation (MD) and respective glaucoma staging were applied (Fig 1B). Regional structure-function associations were explored with univariate regression, correlating RNFLT or pRNFLT by scan sector with MD. Then, multivariate classification methods were applied to predict VF loss using age, scan radius, and 32-sector RNFLT or pRNFLT. R^2, ROC-AUC, and accuracy scores of models were estimated using cross-validation (CV) techniques.

Results: 3021 OCT-VF pairs from 1427 patients met our reliability criteria. Extracted Spectralis norms were found to be normally distributed across the 768-point scan circle and independent of patient-specific parameters. Regional analysis showed significant decrease in R^2 from pRNFLT input compared to RNFLT in inferotemporal sectors, across all tested regressors (T-tests, p=0.00-0.02). Other regions showed no significant differences (Example in Fig 2A). In multivariate classification, there were also no statistically significant differences in CV accuracy of any model between RNFLT and pRNFLT inputs (T-tests, p>0.05). This is confirmed by the ROC-AUC analysis on the testing set for each model (Fig 2B), with mean score change 0.00±0.02.

Conclusions: Our results challenge the assumption that normative percentiles from OCT machines improve prediction of VF loss. RNFLT alone shows strong prediction of glaucomatous VF loss, with no models showing significant improvement from the manufacturer norms. Greater patient stratification based on demographic factors may produce more predictive norms.

ABSTRACT BODY:

Purpose: Amblyopia is the leading cause of visual loss in children and young adults, affecting up to 5% of people of all ages. Patching and atropine eyedrops successfully treat this condition. However, adherence to treatment is often poor. Current literature has identified factors impacting compliance, but less is known about successful interventions to improve adherence. This study's purpose is to identify parent attitudes towards amblyopia treatment and barriers to treatment compliance in order to inform future provider and multidisciplinary approaches to improve adherence.
Methods: Parents of amblyopic patients ages 0 - 9 years old were recruited from 1 pediatric ophthalmology clinic at the Oregon Health & Science University from May – December 2021. Participants were given surveys to complete in the waiting room before their child's clinic visit. The survey assessed attitudes toward and difficulties with amblyopia treatments, specifically patching and atropine.
Results: A total of 37 participants completed the survey; 34 of these were parents of patients currently patching for amblyopia. Boys accounted for 18 (53%) of children and the average child's age was 5 years old (range 1 - 8). Subjective patching ease and compliance were assessed (Tables 1 and 2). Twenty-four (71%) said that their child had difficulty with how the patch feels. Twenty-six (76%) indicated that their child easily wears the patch. Nineteen (56%) reported that their experience had gotten easier over time.

Write-in responses were collected. The most commonly reported (n = 32) hardest parts of patching were keeping the patch on (9; 28%) and remembering the treatment (7; 22%). Parents (n = 34) indicated that they thought better patch designs and quality (9; 26%) and rewards (6; 18%) could help. Respondents (n = 34) used rewards (21; 62%) and flexibility with patching time (15; 44%) to help encourage their child to wear the patch.
Conclusions: This study suggests that while most parents at our clinic found patching manageable, many had significant difficulties such as logistical issues and discomfort, which is consistent with literature. Suggestions for improvement included improved comfort in patch design and positive reinforcement. Goals for further study include linking difficulties with treatment and its duration, evaluating parent suggestions, and determining whether adjustments based on survey data improve adherence.

ABSTRACT BODY:

Purpose: The Save Sight Dry Eye Registry (SSDER) is the first international web-based multinational, interdisciplinary registry able to collect high-quality outcome data from dry eye patients in clinical settings. We report the characteristics of patients with dry eye disease (DED) at their baseline visit from routine clinical practice from 1 November 2020 to 30 November 2021.

Methods: The SSDER collected data from routine clinical practice in Australia, Spain, Germany, and the United Kingdom. Patient demographics, medical history and index visit characteristics including visual acuity, tear break up time (TBUT), ocular surface staining (none, minimal, mild, moderate, severe) and Oxford ocular surface staining score (OSS, 0-15) were recorded in the prospectively designed electronic database. The Ocular Surface Disease Index (OSDI) symptom questionnaire was also completed. Primary outcomes were the baseline demographic data and dry eye diagnosis, and secondary outcomes, logMAR visual acuity, TBUT, and OSS and OSDI scores.

Results: 31 clinicians from 26 sites were registered to use the registry. Data from 122 patients (222 eyes) were curated. Patient age ranged from 18-85 years (mean 58 ± 15 (SD) years) and 98 (87.5%) were female. Mixed DED and evaporative DED comprised the largest groups 107 (48.2%) eyes versus 99 (44.6%) eyes, respectively. The remainder had aqueous deficient DED 14 (6.3%) eyes or neuropathic corneal pain (NCP) 2 (0.9%) eyes. Four (3.5%) patients (8 eyes) wore a contact lens within the month prior to their visit. Most of the patients (90; 177/222 (88%) eyes) had meibomian gland disease.

The median visual acuity and TBUT were 84 (IQR 76-85) logMAR letters and 4 (IQR 2-8) seconds, respectively. The majority of eyes had minimal or moderate ocular surface staining (none 83(37%); minimal 65(29%); mild 46(21%); moderate 21(9%); severe 7(3%)) that was scored using the OSS as < 3 in 78%(174 eyes), 4-8 in 19%(42), and > 9 in 3%(6). Ninety-six percent of patients completed the OSDI, the median score was 31 (IQR 17-46). The two NCP eyes (one patient) had an OSS of 3 (each eye) and OSDI of 79.

Conclusions: The SSDER allows the efficient capture of dry eye patient data from everyday clinical practice. Meibomian gland disease was present in most patients with dry eye from this real-world setting.

ABSTRACT BODY:

Purpose: To investigate the association between dry eye disease (DED) and myopia by evaluating higher order aberrations (HOAs) and choroidal thickness (CT) among myopic children with DED symptoms. The incidence of dry eye and myopia have increased dramatically in modern society. Is it a coincidence or related to the lifestyle in modern society?

Methods: In this cross-sectional study, we recruited 72 myopic (spherical equivalent of ≤ -0.5 diopter) children with DED symptoms (age, 12.8 ± 2.7 [mean ± standard deviation] years) who presented to Keio University Hospital Myopia Clinic. They were measured for the tear film breakup time (BUT), HOAs, CT, axial length (AL) and refraction. Lifestyle questionnaires were administered, and the correlations between the BUT and HOAs were evaluated. Multiple regression analyses were performed to identify relationships among myopia and BUT/lifestyle factors, myopia and corneal/intraocular/total ocular HOAs (spherical aberration [SA], 3rd-order [S3], 4th-order [S4] and the sum of the 3rd- to 6th-order aberrations [THOA] evaluated with a natural pupillary diameter [average value, φ = 6.1 mm]), CT and BUT/AL.

Results: The BUT, CT, AL, and cycloplegic refraction were 5.7 ± 3.1 seconds, 285.3 ± 38.4 μm, 25.52 ± 1.14 mm, and -4.61 ± 2.38 diopters, respectively. The BUT was correlated significantly with the corneal HOAs (SA, β = -0.323, P = 0.02; S4, β = -0.497, P < 0.001; THOA, β = -0.362, P = 0.009) and intraocular HOAs (S3, β = -0.299, P = 0.04; S4, β = -0.369, P = 0.008; THOA, β = -0.368, P = 0.009) but not with total ocular HOAs. Multiple regression analyses showed that the AL was associated significantly with the BUT (β = -0.067, P = 0.004) and the intraocular S3, intraocular THOA, total ocular S3, and total ocular THOA (β = -21.8, 21.2, -41.7, and 43.6, respectively; P = 0.02, 0.048, 0.045, and 0.049, respectively) but not with the corneal HOAs. The CT was associated significantly with the BUT and AL (β = 9.15 and -7.85, respectively; P < 0.001 and = 0.01, respectively).

Conclusions: We showed that the BUT was associated significantly with the CT that is related to the AL. As the parasympathetic nervous system affects the lacrimal glands and CT, the parasympathetic nervous system might be a common upstream factor in the association between DED and myopia.

ABSTRACT BODY:

Purpose: Deep learning provides a powerful approach to analyze surgical videos and assess surgical skills objectively. We aim to build a model that automatically identifies the locations of cataract surgical tools and eye landmarks, which can be used to grade surgical performance.

Methods: We sampled 1156 frames from 9 core steps of 268 cataract surgical videos, and annotated the regions of 8 different surgical tools, and the pupil border and limbus. We pretrained a real-time object detection and segmentation model called YOLACT on the CaDIS dataset, a public dataset for semantic segmentation of cataract surgical videos. The pretrained model was fine-tuned on our dataset. Object detection was evaluated by average precision score (AP), calculated by averaging the precision of the bounding boxes along the precision-recall curve, and segmentation was evaluated by intersection-over-union (IoU), calculated as the intersection of the predicted mask and the true mask over their union. Tooltip positions were estimated by identifying the edge point of the predicted mask closest to the screen center. Pupil centers were estimated by fitting an ellipse to the outer edges of the pupil mask and localizing the ellipse center. For further validation, the tip position estimation was compared with the ground truth positions of the tips from 46620 frames of 4 phacoemulsification video clips.

Results: The mean AP and IoU across different classes of objects were 0.78 and 0.82, respectively. The segmentation performed the best for the blade, weck sponge, and phaco instruments, whereas performance in the needle or cannula class of instruments was the worst (Table). The average deviation of estimated phaco tip positions from ground-truth positions was 6.13 pixels. Examples are shown in Figure. When considering predictions within 10 pixels from the true position as true positives, the average sensitivities and precisions were 81% and 100%, respectively.

Conclusions: We trained a deep learning model to perform real-time surgical instrument and tooltip detection with good accuracy. The model could be used to develop an automated feedback system that rates surgical performance using cataract surgical videos.

ABSTRACT BODY:

Purpose: Cystoid macular edema (CME) is a known endophenotype of retinitis pigmentosa (RP). Currently, factors associated with CME in RP are unclear. This study aims to identify associations between clinical-genetic findings in RP with CME.

Methods: This was a retrospective cross-sectional study. Patients with RP were identified from a database of inherited retinal disease patients seen at the Shiley Eye Institute, UCSD. Patient clinical, demographic, spectral domain-optical coherence tomography (SD-OCT) and genetic testing data was recorded. PCR amplified genetic tests. A masked retinal fellow assessed SD-OCT images for presence of CME, Epiretinal Membrane (ERM), Posterior Vitreous Detachment (PVD) and Vitreo-macular Traction (VMT).

Two-sample t-tests and $\chi 2$ measured clinical differences between CME patients and Fisher Test was used for multifactorial and two-factor variables which were disproportionate. A generalized linear mixed effect model was created to fit the binomial nature of CME with an array of independent variables. Odds ratio analysis also targeted demographics. Analysis used R statistical software.

Results: The database contained 571 patients. A total of 113 patients (225 eyes) had confirmed RP and were included in the analysis.The mean age of the cohort was 47 years (SD+-19), with 62 (54.91%) females (Table 1). 36% (81 eyes) presented with CME (OD = 38.9%, OS = 32.7%). A correlation was found between ERM (CI= 95%, p = 0.023) and VMT (CI = 95%, <0.001) and CME (Table 2).

An odds ratio of 2.92 (CI = 95%, <.254) was found for CME in males, although gender failed to meet significance during modeling. Black (n= 4, μ = 3.5%) and Asian (n = 11, μ = 9.7%) ethnicities presented with the highest odds of CME presence when compared to Caucasian subjects with CME (n = 33, μ = 40.7%).

Cases with X-linked, AD and AR mutations did not have any significantly increased odds of having CME. Additionally, no significant relationship was found between CME and genetic cause of RP.

Conclusions: CME was commonly seen in RP patients and was associated with vitreoretinal interface changes including ERM and VMT. However, no relationship was found between genetic causes of RP and CME in our cohort despite some genes nearing significance.

Interestingly, males had a higher risk of CME in our cohort. Further study in larger cohorts is warranted to confirm the findings from this study.

ABSTRACT BODY:

Purpose: Color vision in vertebrates requires differential expression of multiple specific cone opsins in different cone populations. One model for the regulation of the human long and medium wavelength sensitive (LWS/MWS) opsin tandem array suggests an upstream regulatory region randomly interacts with replicated opsin genes, resulting in the mutually exclusive expression of a specific opsin. However, our prior investigations into the long wavelength sensitive (lws1/lws2) array in zebrafish (sharing a common ancestral LWS gene with the human array) demonstrates that thyroid hormone (TH) and retinoic acid serve as trans regulators of this gene array in larvae/juveniles (Mitchell et al., 2015, PLOS Genetics; Mackin et al., 2019, PNAS). This project utilizes opsin mRNA expression to explore if cone opsin plasticity to TH treatment is retained in adult zebrafish, where the cone distribution has otherwise been considered stable.

Methods: Adult zebrafish (6-18 months old; both sexes) were treated with NaOH (0.01%, control) or TH (386 nM) for 1 or 5 days. After the treatment period, eyes were harvested and homogenized for mRNA quantification through qRT-PCR. In addition, whole retinas of treated fish underwent hybridization chain reaction (HCR) in situ and then were analyzed by confocal imaging for endogenous expression of lws1 vs lws2 mRNA.

Results: Exogenous TH treatment in adult zebrafish significantly increased lws1 expression in both 1 and 5 day-treated groups ($p<1e-7$, 0.01, respectively) while decreasing lws2 expression ($p<0.001$, 0.001). Other phototransduction-related transcripts (gngt2b, rh2-1) also demonstrated expression changes following TH treatment. Whole retinas showed a substantial expansion of the lws1 domain and restriction of lws2, complementing the qRT-PCR results.

Conclusions: Consistent with our previous studies of larvae and juveniles, exogenous TH induced a drastic shift from lws2 to lws1 in adult zebrafish. The change in gene expression was observed within as little as 1 day of treatment of TH. Visualization through HCR of lws1/lws2 mRNA revealed a switch from lws2 to lws1 in much of the retina. This rapid shift demonstrates a high degree of plasticity retained in adult zebrafish.

Commercial Relationships Disclosure: Kwanchanok Chanthowong: Commercial Relationship: Code N (No Commercial Relationship) | Suthasinee Sinawat: Commercial Relationship: Code N (No Commercial Relationship) | Yosanan Yoipaiboon: Commercial Relationship: Code N (No Commercial Relationship) | Suthasinee Hemanak: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Macular edema (ME) is the most common visual threatening complication of central retinal vein occlusion (CRVO) due to an increased level of vascular endothelial growth factors (VEGF). Considering the high cost of other anti-VEGF, bevacizumab is the most used anti-VEGF for ME in real-world practice. Ziv-aflibercept, an anti-VEGF with similar molecules with aflibercept, is now available for off-label ophthalmic use. This study hypothesized that intravitreal ziv-aflibercept (IVZ) is non-inferior to intravitreal bevacizumab (IVB) as the treatment of ME in CRVO.

Methods: The participants who were diagnosed with ME from CRVO were randomly assigned 1:1 to receive IVZ (1.25 mg/0.05ml) or IVB (1.25 mg/0.05ml) at baseline, 1, and 2 months. Later the participants were followed once every month until 6 months. Additional intravitreal injection of allocated drug was given as a pro-re-nata protocol for recurrent or persistent ME. The primary outcome was the best-corrected visual acuity (BCVA) change from baseline. Mean change in central subfield thickness (CST), the number of injections and adverse events were considered as secondary outcomes.

Results: 22 of 26 participants had completed 6 months follow-up, 11 in each group. The initial mean BCVA was 1.13±0.57 logMAR in IVZ cohort and 1.17±0.59 log MAR in IVB cohort. The initial mean CST was 738.42±264.97 μm and 756.93±262.51 μm in IVZ and IVB, respectively. Baseline characteristics were well balanced between each treatment group. At the endpoint, no statistically significant difference was observed in both visual (mean difference in BCVA change 0.21 log MAR, 95% CI -0.29-0.7, p=0.389) and anatomical outcome (mean difference in CST change 64.53 μm, 95% CI -97.78-171.42, p=0.573) between 2 groups. Although the mean number of injections was less in IVZ group (4.5+1.3) than IVB group (4.8+1.3), there was no statistically significant (p=0.68). No sign of intraocular inflammation, increase lens opacity and IOP elevation and serious systemic adverse events were observed.

Conclusions: Interim results demonstrated that ziv-aflibercept had comparable visual and anatomical outcomes with bevacizumab for treatment of CRVO with ME at 6-months of follow-up. Ziv-aflibercept was safe and efficacious; therefore enrollment to 42 patients should be continued.

ABSTRACT BODY:

Purpose: To evaluate the performance of a novel AI algorithm for precise segmentation of the choroidal thickness in Optical Coherence Tomography (OCT) macular scans in eyes with pathologic myopia.

Methods: 91 pathological myopia eyes were acquired using a commercial swept-source OCT (SS-OCT) system, (PLEX Elite 9000, Carl Zeiss Meditec Inc., Dublin, CA, USA) at a 1050 nm wavelength, scanning speed of 100,000 A-scans/sec and 3 mm × 3 mm scanning protocol, centred at the macula. Manual segmentation of the retina and choroid on OCT images were used as the ground truth. We implemented a novel multi-task deep convolutional neural network architecture, Spatial Aggregated Networks (SA-Net), that reconstructs and segments a target B-scan with the incorporation of spatial context from neighbouring B-scans. Intersection over Union (IoU) of the volumetric segmentation, Dice coefficient and Structural Similarity Index Measure (SSIM) were used to assess performance.

Results: A total of 91 eyes with pathologic myopia were analysed with spherical equivalent of -7.00 ± 3.96 and axial length of 27.54 ± 1.30. Subjects were aged 51.07 ±13.02 with 64 (70.32%) females. 94.51% were Chinese, 4.40% were Malay and the remaining were Others. SA-Net was able to replicate segmentation of the anatomical layers of the retina and choroid on OCT images that was comparable to that of the manually segmented ground truths, with an IoU of 0.87 ± 0.09, Dice coefficient of 0.93 ± 0.05 and SSIM of 0.60 ± 0.18.

Conclusions: Our study demonstrated that the novel SA-Net approach showed a high accuracy in segmentation and delineation of choroid from volumetric OCT cube scans in eyes with pathologic myopia. The results are promising for the automated detection of the choroid and could be beneficial in further studies pertaining to the choroid in eyes with pathologic myopia.

ABSTRACT BODY:

Purpose: To determine the role of topical Caffeine, a Xanthine derivative in slowing myopia either alone or in combination with Atropine.

Methods: In a prospective, randomized, dispensing clinical trial, 96 Vietnamese children with myopia (mean age 10.4 ± 2.0 years, -4.1±1.3D) were randomized to nightly use of either 2% Caffeine, 0.02% Atropine with 2% Caffeine, or 0.02% Atropine (Customcare Compounding Pharmacy, NSW, Australia). Additionally, 86 children with myopia (mean age 10.1 ± 2.1 years, -3.3±1.4D) were enrolled concurrently in a parallel group to wear single vision spectacles only. Cycloplegic autorefraction was conducted six monthly in addition to baseline using a Shin-Nippon NK5001 autorefractor. Axial length was assessed 3-monthly in addition to baseline using a Lenstar LS900. Comparison for change in cycloplegic spherical equivalent and axial length between groups was performed using a linear mixed model. Post-hoc multiple comparisons were conducted using Bonferroni corrections. Level of significance was set at 0.05%.

Results: All groups progressed in myopia. At twelve months, there was a significant difference in progression between the groups. Unadjusted change in spherical equivalent and axial length in the single vision spectacle lens group was -0.76D±0.51D/0.37±0.20mm. In comparison, change in spherical equivalent/axial length with 2% Caffeine, 0.02% Atropine with 2% Caffeine, or 0.02% Atropine was -0.70±0.55D/0.35 ±0.23mm, -0.47±0.38D/0.23 ±0.18mm and -0.46±0.50D/0.24 ±0.19mm, respectively. After adjusting for confounders, change in axial length was found to be significantly less with 0.02% Atropine ($p < 0.001$), and 0.02% Atropine with 2% Caffeine ($p=0.047$) in comparison to single vision spectacles and change in spherical equivalent was significantly less with 0.02% Atropine compared to spectacle lens wearers ($p=0.004$). The 12-month progression was similar between those randomized to 2% Caffeine and single vision spectacle wearers ($p=1.000$). The change in progression between 0.02% Atropine versus 2% Caffeine with 0.02% Atropine was similar ($p=1.000$).

Conclusions: When used in isolation, topical caffeine did not have an impact on progression of myopia. When combined with Atropine, it had no impact on the efficacy of Atropine in slowing myopia.

ABSTRACT BODY:

Purpose: Peripapillary retinal blood vessels (RBVs) are currently segmented within the retinal nerve fiber layer (RNFL) in commercially available OCT segmentation software, contributing to automated calculation of RNFL thickness (std-RNFLT). In this cross-sectional clinical study we developed a fully automated segmentation algorithm capable of subtracting RBVs from RNFLT using OCT Angiography (OCT-A) scans of the optic nerve head (ONH), and we compared vessel-free RNFLT (vf-RNFLT) to std-RNFLT in order to evaluate the impact of RBVs on RNFLT.

Methods: ONH scans of 22 healthy eyes and 4 explicative glaucomatous eyes were analysed. After convolutional neural network-based RNFL and disc margin segmentation, an en face OCT-A image of the RNFL plexus was generated, enhanced and thresholded. Assuming vessels' tubularity, the RBV thickness in the axial direction was extrapolated from vessel pixels distance to the nearest non-vessel pixel. The contribution of RBV thickness was then subtracted from the std-RNFLT map to obtain vf-RNFLT. Std- and vf-RNFLT of healthy eyes were compared with t-test. The influence of covariates was analysed by a linear mixed-effects model (GLMM).

Results: In healthy subjects, average (Avg), superior (S), nasal (N), inferior (I), temporal (T) std-RNFLT and vf-RNFLT (all values in microns, mean±SD) were 111.6±25.1 vs. 104.1±21.7 ($p = .035$), 134.7±14.2 vs. 124.2±13.6 ($p = .016$), 82.9±11.3 vs. 78.2±10.5 ($p = .16$), 130±14.1 vs. 117±12.3 ($p = .002$), 98.7±11.7 vs. 96.9±12 ($p = .633$). The clock hour thickness analysis showed that clock hours 5, 7, 12 were significantly different (all $p < .05$). Peripapillary RBVs accounted for 6.3%, 7.8%, 5.6%, 10%, and 1.8%, of the Avg, S, N, I, T std-RNFLT in healthy eyes, and 9,8%, 15%, 9.4%, 12.7%, and 2.1% in glaucomatous eyes. GLMM showed no association of age, axial length and keratometry values with the difference in clock hour std- and vf-RNFLT.

Conclusions: Peripapillary RBVs account for a significant percentage of the RNFLT, if measured by commercially available OCT segmentation software. Our fully automated deep learning-based segmentation software excluding the RBVs, which are spared by glaucomatous damage, provides more accurate estimates of RNFLT, possibly improving OCT ability to detect early neural damage due to glaucoma.

ABSTRACT BODY:

Purpose: To investigate the demographic data & interventional clinical outcomes of patients presenting to the new Cairo University ocular oncology service with uveal melanomas.

Methods: This was a retrospective analysis of the medical records of patients managed for choroidal & ciliochoroidal melanomas. We reviewed the demographic data & different management modalities, compared the ultrasound measurements of the tumors before and after intervention and analyzed the complications & failure rates.

Results: 41 eyes of 41 patients were included. 30 eyes were managed with episcleral Ruthenium-106 plaque radiotherapy, or brachytherapy, of which four eyes were considered failures. One of the four eyes developed a rhegmatogenous retinal detachment & endophthalmitis necessitating pars plana vitrectomy that ended in exenteration due to extrascleral extension, while the remaining three eyes were enucleated due to progression in the tumor dimensions, demonstrating a failure rate of 13.3%. 10 of the remaining 11 eyes were enucleated based on the large baseline tumor size, while the eleventh eye showed extrasceleral extension necessitating exenteration. The mean age of the brachytherapy group was 56.4 +/- 12.1 years, while the enucleation & exenteration group was 50.2 +/-11.5 years ($p = 0.18$). Mean baseline dimensions for the brachytherapy group was 5.52 +/-2.1 mm height & 9.42 +/-3.2 mm diameter, while the enucleation group was 10.52 +/-3.49 mm height & 13.79 +/- 3.18 mm diameter. ($p < 0.001$ & < 0.01, respectively). For the brachytherapy group, the mean duration of plaque application was 7.02 +/- 4.06 days & the mean delivered radiation dose was 113.34 +/-5.3 Grey. Mean final sonographic follow up periods for the brachytherapy group was 26.4 +/- 16.16 weeks, with the mean height at 4.83 +/- 2.4 mm & base diameter at 8.12 +/- 3.36 mm. ($p = 0.24$ & 0.182, respectively). None of the patients demonstrated metastatic spread on serial Pan or PET/CT.

Conclusions: Timely referral & accurate clinical & investigative assessment of cases with uveal melanomas are invaluable for achieving higher success rates of tumor regression, as well as ocular and/or visual preservation in eyes managed with brachytherapy. Patients with more advanced tumors should be counseled on the importance of more invasive techniques, such as enucleation & exenteration for achieving lower malignancy dissemination & mortality rates.

ABSTRACT BODY:

Purpose: Neuroinflammation is an early and persistent feature of retinal pathophysiology. Understanding the interaction of retinal neurons and resident glia cells (microglia, astrocytes, and Müller glia) is important for identifying disease mechanisms and drug targets. Attributing neuroinflammatory events to resident or infiltrating immune cells is non-trivial since simple tools and models to separate these do not exist. Using a retinal explant model, where axotomy and maintenance of the retina ex vivo drives rapid retinal ganglion cell neurodegeneration, we assessed resident neuroinflammation

Methods: Retina from C57BL/6J mice were dissected and maintained as retinal explants for 0 (control) or 24 hrs. LPS (100 ng / mL) or Valproic acid (1 mM) were dissolved in the culture media. Retinal neuroinflammation was quantified by morphological and protein analysis. Fixed retinas were immunofluorescently labeled for RBPMS (retinal ganglion cells), IBA1 (microglia), and GFAP (astrocytes), imaged on a confocal microscope, and 3D morphology reconstructed using Imaris. Dissociated retinas were assessed for cytokine and chemokine expression by protein array (109 proteins)

Results: Twenty-four hours after axotomy, retinas displayed significantly altered microglia and astrocyte morphologies. The morphology of microglia processes was, on average, more contracted and voluminous, consistent with a shift towards inflammatory phenotypes. Astrocyte networks increased in filament density and connectivity. Key inflammatory cytokines were significantly upregulated (Ccl5, Cxcl10, Ccl2, Il-1α, Cxcl1, Icam-1). This is consistent with in vivo retinal ganglion cell injury. As a putative positive control, LPS (a known inflammatory activator), further retracted microglial morphology and further increased Ccl5, Cxcl10, and Il-12, but did not affect astrocyte morphology. Valproic acid provided neuroprotection, significantly reduced morphological changes of both microglia and astrocytes, and maintained Ccl5, Cxcl10, Ccl22, Il-12, Ccl2, and Cxcl1 at uninjured control levels

Conclusions: We demonstrate that the retinal explant model allows for the isolated study of resident glial neuroinflammation without the influence of the circulatory system. This model allows for rapid testing of compounds which may modify neuroinflammation and identifies Valproic acid as a drug which limits retinal neuroinflammation

ABSTRACT BODY:

Purpose: Despite anti-VEGF, subretinal fibrosis and scar cause vision loss in wet AMD patients. Epithelial-mesenchymal transition (EMT) of retinal pigment epithelial (RPE) cells contributes to subretinal fibrosis. Decorin (DCN) is a proteoglycan with anti-fibrotic and anti-angiogenic properties. The aim of this study was to evaluate the effect of DCN on CNV fibrosis and EMT in a rat model of choroidal neovascularization (CNV)

Methods: Long-Evans rats with to laser-induced CNV were followed by fluorescein angiography (FA) on day 14 and 30. DCN (10µg/eye) or vehicle was injected in the vitreous, either at the time of laser burn, or at day 14, when CNV had developed. At day 30, rats were injected with intravenous FITC-dextran before sacrifice and RPE/ choroid flat-mounts were stained with collagen 1 and phalloidin. CNV volumes were quantified, morphometrics of RPE surrounding laser burns were quantified (size, shape, number of neighbors). In a separate experiment, rats with CNV were injected with DCN at 13 and they were sacrificed at day 16 for RNA seq analysis of RPE-choroid using Illumina HiSeq2000. Differential expression was analyzed using EASYGO threshold-free gene ontology.

Results: On FA, although leakge regressed similarly in both groups at day 30 (71% vs 65% of grade 0 lesions), the CNV volume was significantly reduced in rats treated with DCN at day 14 ($p<0.0001$). In addition to perivascular collagen 1 staining, a dense plug at the center of the impact could be seen. Day 14 DCN treatment significantly reduced perivascular collagen 1 ($p<0.001$) and limited the formation of collagen 1-positive scar at the center of the laser burns (31% of the lesions with central scar vs 62% in controls).

In control rats, at day 30, the RPE that surround the laser burn undergo EMT, with significant increase in RPE mean area and elongation. While no effect of DCN at day 14 was seen on EMT at day 30, normalization of RPE morphometrics was observed with DCN administration at the time of laser. RNA seq analysis showed that DCN significantly regulated pathway involved in angiogenesis, fibrosis, EMT, oxidative stress, inflammation and nerve maturation

Conclusions: DCN reduces the volume of established CNV and its fibrotic scaring. Early DCN treatment prevents EMT.

DCN is a promising candidate for wet AMD patients on top of anti-VEGFs therapies

SUBMITTER (NAME ONLY): Amine Maamri

TITLE: Impact of relative graft size and decentration on the frequency of immune reactions after penetrating keratoplasty in 2160 eyes

SESSION TITLE: Corneal Immunology and Neovascularization

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Maamri, N. Tischer, B. Seitz, E. Zemova, Ophthalmology, Universitatsklinikum des Saarlandes und Medizinische Fakultat der Universitat des Saarlandes, Homburg, Saarland, GERMANY|

Commercial Relationships Disclosure: Amine Maamri: Commercial Relationship: Code N (No Commercial Relationship) | Nicola Tischer: Commercial Relationship: Code N (No Commercial Relationship) | Berthold Seitz: Commercial Relationship: Code N (No Commercial Relationship) | Elena Zemova: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To analyze the impact of ratio of graft size to recipient corneal size and graft decentration on the frequency of endothelial immune reactions (IR) after penetrating keratoplasty (PKP).

Methods: We analyzed eleven years of our longitudinal PKP database at the Department of Ophthalmology in Homburg/Saar (2009-2019). This retrospective study included 2160 patients. Two types of IR were observed: acute diffuse or chronic focal endothelial reaction. The patient age ranged from 1 to 95 years. Microsoft Access and SPSS version 25 were used for statistical analysis and the corneal measurements were performed with ImageJ. With this software we measured the area of the graft and the host cornea as well as the distances between the interface and the limbus at four points (12, 3, 6 and 9 o'clock).

Results: A total of 203 (9.4%) patients presented with an IR (158 (7.1 %) acute diffuse and 50 (2.3 %) chronic focal). The IRs happened on average 14.9 months after PKP for acute diffuse IR and 15.3 months after PKP for chronic focal IR. There were no discernible differences between males and females. There was no significant correlation between donor age and frequency of IR. The smaller the size of the graft, the lower the likelihood of an IR ($p < 0.0001$). A significant correlation between centration from the graft and an IR was found: the smaller the distance between the graft and the limbus (at 12, 3, 6, and 9 o'clock), the higher the likelihood of an immune reaction ($p < 0.01$). Moreover, the strongest correlation appeared at the inferior limbus (6 o'clock) ($p < 0.0001$).

Conclusions: The monitoring in the second postoperative year after PKP should be intensified to detect an IR early. The bigger the size of the graft in relation to the host and the smaller the distance from the limbus, especially at 6 o'clock, the higher the likelihood of an immune reaction. Therefore, the graft size should be adjusted individually to the size of the host cornea. Further advanced methods (possibly intraoperative) for the limbal centration of the graft will be needed, in order to minimize future risk factors of immune response and to improve the postoperative outcome.

TITLE: Inner retinal involvement in retinitis pigmentosa: a quantitative integrated multimodal imaging approach.

SESSION TITLE: Photoreceptors and disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Arrigo, E. Aragona, M. Battaglia Parodi, F. Bandello, IRCCS Ospedale San Raffaele, Milano, Lombardia, ITALY|

Commercial Relationships Disclosure: Alessandro Arrigo: Commercial Relationship: Code N (No Commercial Relationship) | Emanuela Aragona: Commercial Relationship: Code N (No Commercial Relationship) | Maurizio Battaglia Parodi: Commercial Relationship: Code N (No Commercial Relationship) | Francesco Bandello: Commercial Relationship(s);Code C (Consultant/Contractor):Alcon (Fort Worth, Texas, USA), Alimera Sciences (Alpharetta, Georgia, USA), Allergan Inc (Irvine, California, USA), Farmila-Thea (Clermont-Ferrand, France), Bayer Shering-Pharma (Berlin, Germany), Bausch And Lomb (Rochester, New York, USA), Genentech (San Francisco, California, USA), Hoffmann-La-Roche (Basel, Switzerland), NovagaliPharma (Évry, France), Novartis (Basel, Switzerland), Sanofi-Aventis (Paris, France), Thrombogenics (Heverlee, Belgium), Zeiss (Dublin, USA).

ABSTRACT BODY:

Purpose: To investigate the involvement of the inner retina in retinitis pigmentosa (RP) and to assess the influence of each retinal structure on retinal sensitivity status through a quantitative multimodal imaging approach.

Methods: The study was designed as observational, prospective, involving a cohort of RP patients and healthy controls. Multimodal imaging protocol included fundus autofluorescence (FAF), optical coherence tomography (OCT), OCT angiography (OCTA) and microperimetry (MP). The follow-up was 12-months. We performed the overall quantitative analysis of each imaging modality, considering the most used metrics. We also performed a detailed investigation based on the ETDRS-9 sectors grid centered to the fovea. Quantitative parameters included the thickness of each retinal and choroidal layer, vessel density (VD), choriocapillaris porosity (CCP), FAF intensity and MP retinal sensitivity. The main outcome measure was the assessment of those retinal structures ruling the status of retinal sensitivity in RP.

Results: We included 40 eyes (40 patients) affected by RP and 40 healthy eyes (40 controls). Baseline BCVA was 0.14±0.18 LogMAR, resulting 0.18±0.24 LogMAR after 1-year of follow-up ($p>0.05$). RP eyes showed significnatly impaired retinal and choroidal layers on ETDRS-9 sectors grid, together with significant reduction of VD values and significantly higher CCP, with respect to controls (all $p<0.05$). MP retinal sensitivity and FAF intensity resulted significantly decreased in RP than controls. Inner retinal layers were found significantly related with the functional integrity of the posterior pole. In addition, the status of the outer retina, both considering vascular and non-vascular layers, less correlated with MP retinal sensitivity. FAF intensity showed no correlation with MP, whereas it was significantly associated with structural OCT and BCVA alterations. Our ROC analysis provided quantitative cutoffs significantly associated with partial sparing of MP retinal sensitivity.

Conclusions: Inner retina is strongly involved in RP and is more associated with the functional integrity of the posterior pole than the outer retina. Vascular involvement contributes to the morpho-functional deterioration of the macular region in RP. FAF intensity reduction may be interpreted as pigments loss associated with increased phototoxic distress for retinal structures.

TITLE: A novel approach to analyze white noise ERGs in mice

SESSION TITLE: Electroretinography: basic mechanisms and disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Stallwitz, A. Joachimsthaler, J.J. Kremers, Department of Ophthalmology, Section for Retinal Physiology, University Hospital Erlangen, Erlangen, Bayern, GERMANY|N. Stallwitz, A. Joachimsthaler, Biology, Section for Animal Physiology, Friedrich-Alexander-Universitat Erlangen-Nurnberg Naturwissenschaftliche Fakultat, Erlangen, Bayern, GERMANY|

Commercial Relationships Disclosure: Nina Stallwitz: Commercial Relationship: Code N (No Commercial Relationship) | Anneka Joachimsthaler: Commercial Relationship: Code N (No Commercial Relationship) | Jan Kremers: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To analyse the correlation between ERG response to temporal white noise (TWN) stimuli while modulating luminance or single photoreceptor types.

Methods: Mice, with human L-opsin instead of the murine M-opsin were dark adapted overnight, all further handling was done under dim red light. Recordings of the anesthetized animals were performed with the Celeris Ganzfeld stimulator. Measurements were performed at different mean luminances (MLs). The animals adapted to a new mean luminance for 1 min prior to recordings.

ERGs to TWN stimuli (containing all frequencies up to 20 Hz with equal amplitudes and random phases) were recorded. The stimuli were luminance modulation (100% contrast white light) at MLs ranging from −0.7 to 1.1 log cd/m^2. In addition, photoreceptor isolating stimuli using the silent substitution method (52% rod-contrast, 48% L-Cone contrast, 77% S-Cone contrast) were employed with MLs between −0.8 and 1.0 log cd/m^2.

Each recording was performed twice. To study the reproducibility of the recordings, ERG potentials in the two recordings at identical instances during stimulation were plotted against each other. The square of the correlation coefficient (r^2_{repr}) of the linear regression through the data quantified the correlation between the two.

To see how well preserved the distinct peaks of the wnERG were at different MLs, the ERG potentials at all MLs were plotted against those to the highest ML (for the cones) and at the lowest ML (for the rods) at identical instant during recording. The linear regressions and the r^2 (r^2_{ML}) were used to quantify the correlations between them.

Results: For luminance stimuli r^2_{repr} values decreased with increasing ML to −0.1 log cd/m^2 ML above which r_{2repr} increased. For rod isolating stimuli r^2_{repr} values decreased with increasing MLs; for cone isolating stimuli they were similar at all MLs.

R^2_{ML} values for luminance and L- and S-opsin stimuli increased with increasing ML, whereas they decreased for rods.

Conclusions: The differences between the characteristics of the r^2 values between rods and cones point at fundamental differences of the dynamics of the ERG origins. Origins of luminance ERGs are a mixture and depend on ML.

ABSTRACT BODY:

Purpose: To determine if inhibition of Myristoylated Alanine Rich C Kinase Substrate (MARCKS) protein, using novel topical MARCKS inhibitor peptides, will reduce the severity of dry eye.

Methods: Dry eye was induced in the left eye of Sprague-Dawley rats by removal of the extraorbital lacrimal gland. One group of rats had a skin incision, but no lacrimal gland removal (sham group). Topical administration of test compounds was initiated 2 weeks after surgery, given 4 times a day and continued for 24 days. Sham rats (n=6) were untreated. Alacrimal rats (n=6 each) were dosed bilaterally with 10uL of phosphate buffered saline (PBS), or 100 uM of either of two MARCKS inhibitors: BIO-11006 [high molecular weight] or BIO-91201{lower molecular weight]. The efficacy of these MARCKS inhibitor peptides was assessed via clinical examination using biomicroscopy and phenol red test (PRT) tear volume with the observers masked to the treatments. Examinations were at baseline, 2 weeks after surgery, and on days 1, 3, 7, 14, 21, and 24 after initiating dosing. Clinical scores for corneal opacity, vascularization, and corneal fluorescein (FL) retention were recorded at each examination.

Results: Clinical signs of dry eye were observed 2 weeks after surgery in groups with lacrimal gland removal, but not in rats in the sham group. No clinical abnormalities were observed in the right eyes (non-surgical) of the rats throughout the study. Left eyes of rats in the sham group had significantly lower clinical scores and higher PRT values than the PBS-dosed group at each examination day after surgery. Corneal scores were significantly elevated in the PBS and BIO-11006 dosed groups compared to sham ($p<0.002$; pairwise Wilcoxon), but no difference between sham and BIO-91201 was observed. Similarly, BIO-91201 dosed groups had significantly lower FL retention than PBS or BIO-11006 dosed eyes ($p<0.02$) and through day 14, BIO-91201 FL retention scores were not significantly different than sham eyes. PRT was higher in MARCKs inhibitor-dosed groups compared to PBS groups on days 14, 21, and 24 after surgery ($p<0.02$; t test).

Conclusions: Topical MARCKS inhibitor peptides appear well tolerated and may reduce inflammation, corneal opacity, corneal FL retention, and improve tear production in dry eye. Further development of topical MARCKs inhibitors, especially the smaller peptide, BIO-91201, for treatment of dry eye appears warranted.

SUBMITTER (NAME ONLY): Kristina Hess

TITLE: The functional impact of Low dose Vitamin A supplementation in AMD with and without reticular pseudodrusen

SESSION TITLE: AMD: Clinical and translational research/AMD therapies (excluding anti-VEGF)

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Hess, C.A. Cukras, Division of Epidemiology and Clinical Applications, National Eye Institute, Bethesda, Maryland, UNITED STATES|K. Hess, Department of Ophthalmology, Universitatsklinikum Bonn, Bonn, Nordrhein-Westfalen, GERMANY|B. Jeffrey, Ophthalmic Genetics and Visual Function Branch, National Eye Institute, Bethesda, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Kristina Hess: Commercial Relationship(s);Code R (Recipient):Novartis | Brett Jeffrey: Commercial Relationship: Code N (No Commercial Relationship) | Catherine Cukras: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine the functional impact of systemic Vitamin A supplementation in patients with intermediate age-related macular degeneration (iAMD) with and without reticular pseudodrusen (RPD) demonstrating dysfunction in dark adaptation (DA).

Methods: In this prospective non-randomized study, patients with iAMD were separated into a group without RPD (AMD group) and with RPD (RPD group). Assessments included DA, best-corrected visual acuity (BCVA), low luminance visual acuity (LLVA) and the low-luminance quality of life questionnaire (QoL). After a 30% bleach, DA testing was performed on 8 locations (4°,6°,8°, 12° in the sup. and inf. meridian). Rod-intercept time (RIT), steepness of the S2 slope, cone plateau, R-slope and pre-bleach thresholds of red and blue stimuli were analyzed.
After baseline examination, patients were supplemented with 15,000 IU of Vitamin A palmitate for 8 weeks. Follow-up examinations were at 4 and 8 weeks with a final follow-up 12 weeks, 4 weeks after cessation of Vitamin A supplementation.

Results: Five patients were enrolled in the AMD group (age 78.0±4.7 years) and seven in the RPD group (age 74.1±11.2 years). Baseline RIT was significantly lower in the AMD group (17.7 ± 6.5 min) compared to the RPD group (23.4 ± 10.9 min).
In the linear mixed model, RIT improved significantly in the AMD group (mean [IQR] -1.1 min [-1.8; -0.5] after 4 weeks and -2.2 min [-2.9; 1.6] after 8 weeks of Vitamin A supplementation, both $p<0.001$). 4 weeks after cessation, the RIT value was decreasing but a residual treatment effect was measurable (-0.99 min [-1.63; -0.35], $p=0.002$).
For the RPD group, no significant RIT improvement with supplementation was identified.
BCVA, LLVA and QoL were not significantly changed after 4 and 8 weeks of treatment.

Conclusions: Supplementation with 15,000 IU Vitamin A, a lower dose than used in previous studies, appears to improve this function in eyes with AMD but without RPD. This result supports a mechanism where a diseased Bruch's membrane serves as a barrier between the systemic circulation and the photoreceptors. Increases the systemic Vitamin A availability partially overcomes the barrier in less severely affected eyes, as evidenced by changes towards improved the DA.
This study was a pilot study, and it is not yet clear what the long-term effects of supplementation would be and if functional improvement could leads to a preservation of structure.

TITLE: Automated correction of jitter, interleaving and non-uniform image sampling in scanning ophthalmoscopes

SESSION TITLE: Multidisciplinary Ophthalmic Imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Dubra, V. Akondi, A. Hargrave, B. Kowalski, Ophthalmology, Stanford University, Stanford, California, UNITED STATES|

Commercial Relationships Disclosure: Alfredo Dubra: Commercial Relationship: Code N (No Commercial Relationship) | Vyas Akondi: Commercial Relationship: Code N (No Commercial Relationship) | Aubrey Hargrave: Commercial Relationship: Code N (No Commercial Relationship) | Bartlomiej Kowalski: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Sampling jitter and non-uniform scanning angular velocity limit the accuracy and precision of scanning ophthalmoscopes. Here we explore the mitigation of these problems through the recording of the optical scanners' orientation in synchrony with the light detection, followed by resampling of retinal image.

Methods: Distortion grid and photoreceptor mosaic images were captured using a custom scanning light ophthalmoscope modified to record scanner orientation for each image pixel. The horizontal (resonant) scanner orientation samples were fitted to a cosine model for each image line to correct image warping and sampling jitter through image data resampling, as well as to interleave images collected during the clockwise and counterclockwise portions of the scanner rotation. This was followed by image warp correction due to non-uniform angular speed of the vertical scanner through a second image resampling. Jitter correction was evaluated using normalized cross-correlation within each line of images from a Ronchi ruling, and as the norm of standard deviation maps from a stack of co-registered retinal images.

Results: The fitting of the cosine models showed ~0.36 pix jitter (STD) which reduced jitter by more than a factor of 6 after resampling and allowed interleaving image lines captured during the counter-rotating portions of the horizontal scan cycle with sub-pixel precision. The norm of the standard deviation maps, a registration error metric, decreased by ~10-15% with jitter correction and ~16-20% with jitter and vertical warping correction in the distortion grid images. More modest ~1 and ~7% respective reductions were observed in a small set of photoreceptor images affected by eye rotation (not corrected by the registration).

Conclusions: The proposed jitter and warp correction in retinal images from scanning ophthalmoscopes can improve the sensitivity of retinal imaging biomarkers by producing more anatomically truthful images. In adaptive optics scanning ophthalmoscopes, these corrections can also help to reduce the number of images that is captured at each retinal location for subsequent averaging, necessary to increase signal to noise ratio (SNR), and a most important barrier to the translation of this technology to the clinic. This approach could also increase SNR in angiograms from optical coherence tomography.

ABSTRACT BODY:

Purpose: This study compared the clinical outcomes between ab interno trabeculotomy using Tanito microhook (TMH), suture (sLOT), and Trabectome (TOM) and explored the most beneficial trabecular meshwork (TM) incision range.

Methods: A retrospective analysis of pre- and postoperative (up to 60 months) intraocular pressure (IOP), glaucoma medications, and complications was performed for patients with primary open angle glaucoma who underwent cataract extraction combined with ab interno trabeculotomy using TMH, sLOT, or TOM at Kyoto University Hospital between January 2016 and June 2021.

Results: The mean preoperative IOP was 18.8±4.4, 18.8±6.7 and 17.1±6.1 mmHg in TMH (58 eyes), sLOT (69 eyes), and TOM (29 eyes) groups, respectively (P=0.37). The mean IOP value and IOP reduction% were similar at all the study time points. The mean IOP was 13.6±2.3, 14.1±3.5, and 12.9±2.8 mmHg (P=0.19), and IOP reduction% was 24.7±18.6, 18.8±23.8, and 21.0±18.0 % (P=0.31) in TMH, sLOT, and TOM groups at postoperative 3-moth follow-up. IOP spike and hyphema occurred most often in the sLOT group (27.5%, 26.1%), followed by the TOM group (13.8%, 17.2%), and the least in TMH group (6.9%, 6.9%). In all three groups, patients with spike or hyphema did not undergo wider degrees of incision but achieved similar IOP reduction when compared with those without spike or hyphema. The use of anticoagulant and antiplatelet did not increase the risk of hyphema in each group. A correlation between TM incision degrees and IOP reduction was only found in the TMH group (P=0.0014) and not in the sLOT (P=0.31) and TOM (P=0.41) groups. After mixing all the data and reclassifying them by incision degrees into 1- to 4-quadrant groups, we found that the 2-quadrant group had the least incidence of hyphema (P=0.26) and spike (P=0.02), while the 3-quadrant group had the greatest IOP reduction% (P=0.02). Consistently, TM incision degree was a predicator of postoperative IOP reduction% in multiple linear regression analysis of patients within 270 degrees' incision (P=0.0002).

Conclusions: TMH, sLOT, and TOM trabeculotomy provided comparable IOP reduction efficacies, while hyphema and IOP spike were more frequent in the sLOT group. Hyphema and IOP spike did not result from wider TM incision degrees. Incision of 90–180° had the least incidence of complications, while a 180–270° incision conferred the greatest IOP reduction.

ABSTRACT BODY:

Purpose: Sunlight exposure has been found to play an important role in myopia as a lifestyle modification factor. The purpose of this study was to evaluate the performance of an affordable wearable device for measurement of sunlight exposure in children and provide metrics through a dedicated mobile phone algorithm.

Methods: A wearable device LUMINO-SD (India Patent Application no:202141040647) was built that can measure sunlight in terms of light intensity (LI), ultraviolet (UV) and infrared (IR) through an ambient light sensor, and the captured data was synchronised to a mobile phone algorithm. The light data were programmed to be captured once every minute between 7 am to 7 pm and stored. Validation of the measurements was done by placing the device in sunlight alongside a standard luxometer (Lutron LX-101A, USA). Eight protomodel devices were lab tested by placing in the following locations for 1 week each: outdoor sunlight, outdoor shade, indoor near window, indoor with artificial illumination. Hourly readings from 8 devices were averaged, analysed and plotted on a 12 hour graph. Real time data captured over 1 month were incorporated into Python software to define the thresholds of outdoor sunlight exposure duration (60% training, 40% testing). No human beings were used in the study at this point.

Results: Hourly mean LI was found to range between 136 - 5344 lux indoors & 976 – 30,112 lux outdoors. There was statistically significant difference (p=0.046) between outdoor sunlight/outdoor shade and between indoor window/indoor artificial illumination(p=0.001). Hourly mean UV index ranged between 0-15 indoors and 2.5 - 64 in sunlight outdoors. Hourly mean IR was between 0-16 for indoors and 122-3764 for outdoors. The validation between luxometer and device was R^2= 0.786. Machine learning using Python was reliable to define outdoor time based on testing accuracy of 67%.

Conclusions: This prototype – LUMINO-SD provides reliable measurements on sunlight spectrum exposure of the wearer, based on real time data as thresholds. It could be a useful tool to study the correlation between sunlight, UV, IR and outdoor/indoor activities. It would be an effective tool for promoting outdoor time in kids and parental monitoring to manage the myopia epidemic in children worldwide. Because of the low cost manufacturing in India, the device would serve as an affordable one.

SUBMITTER (NAME ONLY): Si Chen

TITLE: Toward blood flow quantification using spectrally extended line field optical coherence tomography angiography

SESSION TITLE: OCT Angiography Clinical Applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Chen, K. Lin, L. Liu, Nanyang Technological University, Singapore, Singapore, SINGAPORE|S. Lou, Tianjin University, Tianjin, Tianjin, CHINA|

Commercial Relationships Disclosure: Si Chen: Commercial Relationship: Code N (No Commercial Relationship) | Shiliang Lou: Commercial Relationship: Code N (No Commercial Relationship) | Kan Lin: Commercial Relationship: Code N (No Commercial Relationship) | Linbo Liu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Blood flow quantification with optical coherence tomography angiography (OCTA) is hindered by the limited dynamic range, which is determined by the B-scan interval time. Multiple interscan time is currently achieved by increasing the number of repeated B-scans at the same sample position. The purpose of this study is to evaluate the feasibility of a novel imaging platform, spectrally extended line field OCTA (SELF-OCTA), in realizing OCTA high dynamic range without increasing the number of B-scan repetitions or sacrificing field of view.

Methods: A 1060-nm spectral domain OCT system with a customized sample arm, SELF-OCTA, is developed for retinal angiographic imaging in vivo. OCTA images were acquired from the macular region in healthy subjects with two B-scan repetitions at each sample position.

Results: SELF-OCTA generated four sets of flow images with the interscan time of 0.54 ms, 1.35 ms, 2.70 ms, and 5.40 ms from one volume scan. These interscan times spanning the range of one order of magnitude enable blood flow quantification over a significantly extended dynamic range: slow flows in small vessels could be visualized with higher contrast, and also, fast flows in large vessels can be differentiated by their different OCTA signals.

Conclusions: SELF-OCTA has the capability to realize flow imaging with high dynamic range but without compromising the imaging speed or field of view, making it a promising tool for blood flow quantification. This technique may help with the understanding and the early detection of retinal disorders associated with blood flow impairment.

TITLE: The Neuroprotection Role of Sirtuin 1 Activator SRT2104 in Retinal Injury Induced by Acute Ocular Hypertention

SESSION TITLE: Pharmacology/cellular mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: X. Bai, D. Ye, Y. Shi, Y. Feng, C. Hu, Y. Xu, J. Huang, Sun Yat-Sen University Zhongshan Ophthalmic Center State Key Laboratory of Ophthalmology, Guangzhou, Guangdong, CHINA|

Commercial Relationships Disclosure: Xue Bai: Commercial Relationship: Code N (No Commercial Relationship) | Dan Ye: Commercial Relationship: Code N (No Commercial Relationship) | Yuxun Shi: Commercial Relationship: Code N (No Commercial Relationship) | Yanlin Feng: Commercial Relationship: Code N (No Commercial Relationship) | Chenyang Hu: Commercial Relationship: Code N (No Commercial Relationship) | Yue Xu: Commercial Relationship: Code N (No Commercial Relationship) | Jingjing Huang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Sirtuin 1 (Sirt1) is a histone deacetylase belonging to the sirtuin family which plays a key role in stress response pathways, apoptosis, and inflammation. It has been reported that Sirt1 expresses in normal ocular structures and plays neuroprotective role in various diseases including retinal degeneration. In this study, we intended to investigate the role of intravitreal administration of Sirt1 activator SRT2104 in retinal injury induced by acute ocular hypertention (AOH) and its underlying mechanisms.

Methods: Intraocular pressure (IOP) was elevated manometrically to 80 mmHg by instilling saline solution into the anterior chamber for 1 h in adult C57BL/6J mice. Intravitreal injection of SRT2104 (200 pmol, 2 μL) was administered immediately after the AOH model was constructed. Immunofluorescence was applied to detect retinal ganglion cells (RGCs) survival and apoptosis, leukocyte infiltration, glial cells activation and inflammation. The protein expression level of related inflammatory factors was observed by western blot. Optical coherence tomography (OCT) and Hematoxylin-eosin (HE) staining were performed to analyse retinal structure. Electroretinogram (ERG) was used to evaluate retinal function.

Results: The expression of SIRT1 significantly increased after SRT2104 treatment. SRT2104 treatment effectively recovered the inner retinal thickness loss indicated by OCT and HE staining ($p < 0.05$). Retinal function partly improved on average amplitude and latency of a-wave, b-wave, and oscillatory potentials in ERG analysis ($p < 0.05$). Furthermore, intravitreal administration of SRT2104 reduced the expression of cleaved-caspase 3, acetyl-p53 and acetyl-NF-κB, declined the levels of inflammatory factors (IL-1β, TNF-α, IL-8, CCL2), and decreased the number of $CD45^+$ leukocyte, activated $Iba1^+/CD68^+$ microglia and $GFAP^+/Vimentin^+$ astrocytes caused by AOH (all $p < 0.05$).

Conclusions: Our data suggested that intravitreal injection of SRT2104 effectively reduced retinal inflammation and protected RGCs from caspase 3 dependent apoptosis via inhibiting deacetylation dependent p53 and NF-κB pathway after AOH injury, and it is expected to be a potential therapeutic method for acute glaucoma.

SUBMITTER (NAME ONLY): Andrew Carkeet

TITLE: Different pictogram vision charts give different slopes for psychometric functions, in preschool children.

SESSION TITLE: Visual Function: perception, adaptation, spatial, visual acuity and binocular vision

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Carkeet, A. Johnson, S. Hopkins, School of Optometry and Vision Science, Queensland University of Technology, Brisbane, Queensland, AUSTRALIA|A. Carkeet, A. Johnson, S. Hopkins, Centre for Vision and Eye Research, Queensland University of Technology, Brisbane, Queensland, AUSTRALIA|

Commercial Relationships Disclosure: Andrew Carkeet: Commercial Relationship: Code N (No Commercial Relationship) | Amy Johnson: Commercial Relationship: Code N (No Commercial Relationship) | Shelley Hopkins: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Knowledge about the shape of the psychometric function for visual acuity charts allows for better modelling of vision testing and more efficient estimation of acuity thresholds. We assessed whether 4 commonly used monitor based chart systems gave different shaped psychometric functions for child participants.

Methods: Data were obtained from 22 children, aged between 38 and 71 months (mean 54), with acuity better than 0.32 logMAR on LEA or EVA testing. For each child acuity measurements were attempted twice on right and left eyes for each of 4 commercially produced pictogram charts, presented on LED monitors: VistaVision Visual Acuity Tester; Thomson Test Chart; Rodenstock Phoromat 2000; and Optos Smart Chart (optotype sets for each, Figure 1). Measurements were analyzed if the maximum correct on one line was 80% or more and the minimum correct on one line was 40% or less. Probit analysis was performed on each measurement's data set (logMAR units), with the upper asymptote set for a 1 % lapse rate and the lower asymptote based on the number of alternatives for each optotype set (Vista 25%, Thomson 12.5%,Rodenstock 16.7%,Optos 11.1%). For each measurement a threshold acuity was obtained and a Probit size (an indication of the flatness of the psychometric function). For each participant the acuity and Probit size were averaged across eyes and sessions (i.e.based on up to four measurements).

Results: Different charts yielded different shaped psychometric functions. Probit sizes differed for different charts, ($F_{3,39}=8.198$, $p<0.001$) averages being (from steepest to flattest): Thomson 0.05logMAR, SD0.024; Optos 0.10logMAR, SD0.04; Vista 0.13logMAR, SD0.05; Rodenstock 0.15logMAR, SD0.11. Acuity values also differed between chart types ($F_{3,39}=51$, $p<0.001$): averages Thomson-0.04 logMAR, SD0.12; Optos 0.08logMAR, SD0.12; Vista 0.13logMAR, SD0.08; Rodenstock 0.24logMAR, SD0.13.

Conclusions: The chart design with the smallest Probit values (Thomson) gives a similar shaped psychometric function to that obtained previously with letter charts in adults. Other charts give much flatter functions, indicating unreliable and inefficient acuity measurements. Optotype selection matters for pediatric acuity measurement.

ABSTRACT BODY:

Purpose: The dynamic course of sulfur mustard (SM) induced ocular insult is characterized by an acute phase, which may be continued to a chronic phase or a quiescent period followed by a late pathology. Visually observing corneal morphological changes in living animals could greatly enhance our understanding of additional aspects of the insult and assist in developing treatments.

Methods: Chemical SM burn was induced in the right eyes of three transgenic mice strains: K15-GFP, VE-Cad-RFP and Thy1-YFP, by vapor exposure. General evaluation, cell infiltration, neovascularization (NV), innervation loss and stem cells (SC) depletion in the cornea were monitored in-vivo by stereomicroscopy up-to 8 weeks. Corneal whole-mount preparations were used to identify 360° structures, infiltrating cells and the decrease in the sub-basal nerve plexus (SNP). Histological evaluation was determined by using H&E, Masson-Trichrome and Periodic acid-Schiff staining.

Results: A 35 seconds exposure induced a mild ocular surface insult with minor mid stromal nerve fiber (MSNF) insult, moderate SNP changes presenting cell infiltration and reversible SC loss, mostly resolving at 4w post exposure. A 120 seconds exposure induced a moderate-severe ocular surface insult involving NV, with extensive MSNF and SNP loss, a wide $CD45^{+}$, $Iba1^{+}$ cell infiltration and irreversible SC depletion. NV, stromal inflammation and edema, epithelial structural changes and conjunctival goblet cells were identified in corneal histological sections, in correlation with the fluorescent stereoscope findings.

Conclusions: The results in this study demonstrate the potential use of transgenic mice as a powerful animal model for studying the SM induced insult and developing new therapies.

TITLE: Extracellular Matrix Protein Periostin Regulates Epithelial Mesenchymal Transition of Lens Epithelial Cells

SESSION TITLE: Lens proteins and cataracts

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. ZHANG, D.W. Li, Zhongshan Ophthalmic Center, Sun Yat-sen University, CHINA|

Commercial Relationships Disclosure: LAN ZHANG: Commercial Relationship: Code N (No Commercial Relationship) | David Li: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Epithelial mesenchymal transition (EMT) of lens epithelial cells (LECs) is one of the most important pathogenic mechanisms in lens fibrotic disorders such as anterior subcapsular cataract (ASC) and posterior capsule opacification (PCO). We recently showed that AKT-EZH2-H3K27me3 axis regulates the activation of mesenchymal genes during lens fibrosis. In the present study, we demonstrated that an important extracellular matrix (ECM) gene POSTN plays an essential role in lens EMT.

Methods: All experiments were based on injury induced ASC mouse model and TGF β-induced EMT of human lens epithelial cells. Quantitative real-time PCR, Digital Droplet PCR, Western Blot, and whole-mount immunofluoresce were used to examine the differential EMT gene expression.

Results: The ECM protein coding gene POSTN was upregulated in TGFβ-induced EMT of human lens epithelial cells, and in the lens capsule of injury-induced ASC mouse model as well as human ASC patients. POSTN gene silencing led to attenuated expression of EMT marker genes in TGFβ-induced EMT of human lens epithelial cells, which can be partially rescued by AKT1 overexpression. Moreover, POSTN knockout using CRIPSR-Cas9 technology in mouse led to suppressed expression of EMT marker genes and ASC plaque formation after injury-induced ASC procedure.

Conclusions: The present study demonstrated that the ECM gene POSTN plays an important role in regulating lens fibrosis. Mechanistically, the TGFβ-AKT–EZH2-H3K27me3 signaling axis activates POSTN expression, and in turn, though the activation of Integrin-AKT signaling, Periostin, encoded by POSTN, controls the activation of mesenchymal genes in lens epithelial cells. Thereby, Periostin participates in a feed-forward EMT signaling cascade, contributing to lens fibrosis. Intervention of important activated ECM genes such as POSTN may present a novel strategy for the prevention of lens fibrosis diseases. Supported by NSFC#81970787, #82000876, #81770910, NSF-Guangdong Province and Guangzhou City Joint Program#20191515120014, ZOC-SKLO#3030901010110.

ABSTRACT BODY:

Purpose: To assess the prevalence of dry eye disease (DED) and Meibomian gland dysfunction (MGD) in a population in Russia.

Methods: The population-based Ural Eye and Medical Study was conducted in an urban and rural region in Bashkortostan/Russia and included 5,899 (80.5%) out of 7328 eligible persons, aged 40+ years. DED and MGD were assessed by Schirmer's test, slit-lamp based examination of the Meibomian glands, and an interview with DED-related questions.

Results: The study included 5153 (87.4%) individuals with DED and MGD assessments (mean age:58.5±10.5 years). Schirmer's test in the worse eye (mean:10.7±6.3mm) was ≤5 mm in 1098 participants (21.3%;95% confidence intervals (CI):20.2,22.4), and the mean subjective dry eye symptoms score was 1.37±1.82. MGD grade 1 (telangiectasia at the lid margin), grade 2 (plugged Meibomian gland orifices with translucent serous secretion when the lid margin was compressed), grade 3 (plugged Meibomian gland orifices with viscous or waxy white secretion when the lid margin was compressed), grade 4 (plugged Meibomian gland orifices and no secretion when the lid margin was compressed), or any grade in the worse eye was diagnosed in 901 (21.1%), 1161 (27.1%), 158 (3.7%), 32 (0.7%), and 2252 (52.6%;95%CI:51.1,54.1) eyes respectively. The prevalence of DED diagnosis #1, #2 and #3 (Schirmer's test ≤5 mm, and dry eye score ≥1, ≥2, and ≥3, respectively), #4 (dry eye score ≥1, Schirmer test ≤5 mm, MGD grade 1+), and #5 (dry eye score ≥1, Schirmer test ≤5 mm, MGD grade 2+) were 598/5142 (11.6%), 426/5153 (8.3%), 273/5142 (5.3%), 335/5142 (6.5%), and 186/5142 (3.6%), respectively. Higher DED prevalence (definition #4) was associated (multivariable analysis) with female sex (odds ratio (OR):1.71;95%CI:1.31,2.22; P<0.001), higher depression score (OR:1.04;95%CI:101,1.07; P=0.009), and higher prevalence of thyroid disease history (OR:1.63; 95%CI: 1.19, 2.24; P=0.006).

Conclusions: DED and MGD were common in this rural and urban population, and their prevalence was associated with female sex, thyroid disease, and depression.

TITLE: CORNEAL GRAFT REJECTIONS DUE TO COVID 19 INFECTION OR VACCINATIONS : A CASE SERIES

SESSION TITLE: Refractive and non-refractive corneal surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Ann John, H. Matalia, N. C, Narayana Nethralaya, Bangalore, Karnataka, INDIA|

Commercial Relationships Disclosure: Ansu Ann John: Commercial Relationship: Code N (No Commercial Relationship) | Himanshu P Matalia: Commercial Relationship: Code N (No Commercial Relationship) | Nandini C: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To report 4 cases of corneal graft rejections which occurred due to COVID19 infection or vaccination.

Methods: Case 1

A 24-year old woman presented with corneal scar in her right eye (due to a resolved microbial keratitis) for which she underwent optical penetrating keratoplasty (PK). The patient presented with hyperacute endothelial rejection 5 weeks later. She had epithelial and endothelial corneal graft rejection (Figure 1) for which she was treated with intravenous methylprednisolone, along with topical steroids prescribed hourly and systemic steroids. 3 days later, she was diagnosed with COVID 19 infection. In spite of adequate treatment, her corneal graft could not be salvaged.

Case 2

A 31-year old male who had history of chemical injury in the right eye in 2017, underwent second PK in 2020, and had graft rejection 4 weeks after 1st dose of COVID vaccine (COVISHIELD). He was successfully treated with hourly topical steroids along with systemic steroids and the corneal graft cleared up.

Case 3

Another 29-year old male diagnosed with Macular corneal dystrophy underwent corneal transplantation in 2016 had graft rejection following 1st dose of COVID vaccine (COVISHIELD) 3 weeks later. The patient was treated with topical and systemic steroids. Though most part of the graft cleared up but inferior graft edema was found to persist (Figure 2).

Case 4

A 17-year old girl, underwent PK for Congenital Hereditary Endothelial Dystrophy and had corneal graft rejection 1 month after the 2nd dose of COVID vaccine (COVISHIELD). With adequate treatment of topical and systemic steroids, the patient’s corneal graft improved and cleared up, and the patient reports an improvement in visual acuity as well.

Results: -

Conclusions: COVID 19 infection and vaccination can induce graft rejection. Hyperacute endothelial rejection is possible with COVID 19 infection. COVID vaccine related corneal graft rejections may be less severe and may be reversed with adequate treatment.

TITLE: A 10-Year Retrospective Analysis of the Specialties and Methods Involved in the Treatment of Eyelid Laceration

SESSION TITLE: Oculoplastics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Uppal, T. Murphy, Rush Medical College, Rush University, Chicago, Illinois, UNITED STATES|K. Williams, Department of Ophthalmology, Rush University Medical Center, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Mohit Uppal: Commercial Relationship: Code N (No Commercial Relationship) | Terrence Murphy: Commercial Relationship: Code N (No Commercial Relationship) | Kenya Williams: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Eyelid lacerations commonly present to academic institution emergency departments as a result of trauma or injury. While eyelid lacerations are often repaired by different medical specialties--despite varying levels of training requirements dictated by the Accreditation Council for Graduate Medical Education (ACGME)--no literature currently exists regarding the incidence of such repairs. We performed a retrospective chart analysis to determine the frequency of eyelid lacerations and respective treatment methods performed by different specialties.

Methods: The electronic health record was queried using International Classification of Disease codes to identify cases of eyelid laceration occurring between 2011 and 2020, determine the specialty involved in treatment, and the respective method of treatment at Rush University Medical Center, a Level II trauma center. The treatment method was classified into two categories: suture or non-suture repair.

Results: Of 468 total cases of eyelid laceration identified, 303 (64.74%) were treated by emergency medicine, 98 (20.94%) by ophthalmology, 27 (5.77%) by plastic surgery, 20 (4.27%) by primary care, 11 (2.35%) by pediatrics, and 9 (1.92%) by otolaryngology. Of these cases, 310 (66.24%) were treated using sutures. Suture-treatment occurred during 181 (59.74%) of emergency medicine's total cases, 86 (87.76%) of ophthalmology's total cases, 26 (96.30%) of plastic surgery's cases, 6 (30%) of primary care's cases, 3 (27.27%) of pediatrics' cases, and 8 (88.89%) of otolaryngology's cases. Year of presentation significantly affected the number of cases that ophthalmology treated, with cases increasing over time ($p=0.032$).

Conclusions: All specialties besides primary care and pediatrics utilized sutures during treatment in most cases. Although ophthalmology-involvement has increased throughout the years, ophthalmology was only involved in a minority of total eyelid laceration cases while emergency medicine was involved in most cases. According to the ACGME, only ophthalmology residents, opposed to residents of other specialties, are required to gain experience treating eyelid lacerations during their training. Despite this uniquely specialized training, ophthalmologist-involvement in eyelid laceration cases is relatively low compared to other specialties, warranting further studies to determine if differences in outcomes exist between specialties.

TITLE: 24 hour IOP diurnal variation analysis with contact lens sensor (triggerfish)-potential benefits, limitations & future challenges.

SESSION TITLE: IOP and laser therapy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Sharma, Ophthalmology, university hospitals derby & burton NHS trust, UNITED KINGDOM|

Commercial Relationships Disclosure: Rohit Sharma: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Diurnal IOP variation is well-known. The exact pattern of circadian IOP fluctuation in glaucomatous patients remains debatable. This prospective observational study is to evaluate the 24-hour pattern of IOP changes in patients with glaucoma measured with a contact lens sensor (CLS) and to compare the variation between CLS and tonometry.

Methods:

The eyes of 24 glaucomatous patients (9 females, 15 males) were examined for diurnal IOP fluctuations for 24 hours with Sensimed Triggerfish® CLS while they carry out their normal activities. The 24-hour period was divided into eight 3-hour time slots (0000-0259, 0300-0559, 0600-0859, 0900-1159, 1200-1459, 1500-1759, 1800-2059, 2100-2359) and the peak and trough values of IOP with their corresponding time slots were recorded. The coefficient variation of mean average of peak and trough value of CLS data and mean average of IOP measured using Goldmann applanation tonometry (GAT) in clinics were compared.

Results:

All patients successfully completed the 24-hour measurement of IOP with CLS safely with no adverse reactions.
The mean patient age was 69.83 (SD: 7.8) years. 15 (62.5%) were left eyes.
13 subjects (54.1%) showed early morning peak.
12 (50%) subjects have their peak IOP at 0600-0859 period, mean peak value was 319.6 mVeq (SD: 174.6). 18 (75%) subjects have their trough IOP at 2100-2359 period, mean trough value was -113.3 mVeq (SD: 123.1). The mean peak and trough average of CLS data was 216.4 mVeq (SD: 77.6) whilst the mean average of IOP value was 16.6 mmHg (SD: 3.02). The coefficient of variation of CLS value was 35.9%. The coefficient of variation of IOP measured by GAT was 18.2%.

.

Conclusions:

The most common circadian IOP pattern was early morning acrophase. Most glaucomatous patients had highest IOP in the morning which coincides with the circadian cortisol peak. These peaks can be missed by the contemporary practice of IOP measurement during daytime clinic hours. The coefficient variation of CLS value was higher than the IOP in daytime IOP clinic measurements. The impact of dimensional corneal curvature change and the standardisation of units of measurement by GAT & CLS needs evaluation. CLS has the potential of supplementing or replacing phasing, better study the therapeutic 24 hour response to medications, laser, surgery & analyse "low" or "normal" pressure glaucoma cases.

SUBMITTER (NAME ONLY): Aarya Ramprasad

TITLE: The Risk of Thermal Dermal Damage in Cataract Phacoemulsification

SESSION TITLE: Cataract surgery 1

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Ramprasad, F. Qureshi, University of Missouri Kansas City School of Medicine, Kansas City, Missouri, UNITED STATES|W. White, Ophthalmology, The University of Kansas Hospital, Prairie Village, Kansas, UNITED STATES|

Commercial Relationships Disclosure: Aarya Ramprasad: Commercial Relationship: Code N (No Commercial Relationship) | Fahad Qureshi: Commercial Relationship: Code N (No Commercial Relationship) | William White: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Modern cataract surgery relies on a phacoemulsification handpiece to disassemble cataracts. The handpiece can generate excessive heat leading to corneal burns which are prevented by using irrigation. The occurrence of burns outside of the eye is not well documented. This study aimed to determine whether the handpiece could cause thermal injury to patients outside the eye and if the device is able to ignite drapes.

Methods: Porcine skin was used due to its physiological similarity to human skin. 3 trials were completed to assess the possibility and speed of char occurring with the handpiece tip being in contact with different materials including the tip directly on a pig foot with no drape, a Henry Schein standard drape, and a 3M plastic Steri-Drape. Trials were performed with the silicone cover on the tip and without. Each trial was repeated 3 times with no statistically significant difference between trials of the same material ($P<0.05$). The Infiniti Vision System by Alcon Labs was used.

Results: With no drape, the tip without sleeve caused char within 3.0 seconds while with sleeve caused char at 10.0 seconds or above(Figure 1). Trials with the standard drape did not cause char but did burn a hole through the drape regardless of the sleeve. The tip with the sleeve burnt through the plastic drape, charring in 2.7 seconds, while no sleeve led to the same result in less than 1.0 seconds(Figure 2). In all trials, charring was quicker without the silicone sleeve. No trials resulted in drape ignition.

Conclusions: Charred skin is considered to be a 3rd-degree full-thickness burn with less severe burns possibly not being visible. One trial showed the body of the handpiece at 53.6°C degrees with immediate destruction of the epidermis known to occur above 44°C. The silicone tip proved to be protective but not effective in preventing burns. The trials were not completed in an oxygen-enriched environment. Increased risk of burn is present in true operating conditions due to the risk of ignition of the oxygen provided beneath the drape or via nasal cannula leading to the possibility of facial, airway, or nasal burns. While beneficial to consider in future studies, it did not prevent us from concluding that focused efforts on using the silicon tip, irrigation, and placing the phacoemulsification handpiece on a surface other than the patient could prevent burns from occurring.

TITLE: IL-6 drives Treg dysfunction in desiccating stress-induced dry eye disease

SESSION TITLE: Corneal Immunology and Neovascularization

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Ortiz, F. Kahale, T. Blanco, A. Naderi, Y. Chen, R. Dana, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Gustavo Ortiz: Commercial Relationship: Code N (No Commercial Relationship) | Francesca Kahale: Commercial Relationship: Code N (No Commercial Relationship) | Tomas Blanco: Commercial Relationship: Code N (No Commercial Relationship) | Amirreza Naderi: Commercial Relationship: Code N (No Commercial Relationship) | Yihe Chen: Commercial Relationship: Code N (No Commercial Relationship) | Reza Dana: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We have demonstrated that T regulatory cells (Tregs) become dysfunctional during dry eye disease (DED) being less able to control pathogenic Th17 cells. Th17-associated cytokines (IL-6, IL-17, IL-23) are implicated in altering Treg function; however, the precise functions of these cytokines on Treg in DED have remained unclear.

Methods: Using a controlled environmental chamber, female C57BL/6 mice were exposed to desiccating stress (relative humidity 10% vs. ~40% normal environment) to induce DED. Western blot of IL-6R, IL-17RA, IL-23R was performed on isolated Tregs (using magnetic activated sorting) from naïve and DED animals. Mean Fluorescent Intensity (MFI) of FoxP3, CD25, CTLA-4 and GITR of naïve and DED Tregs was measured using flow cytometry. Isolated naïve Tregs were in vitro stimulated with 20 ng/ml of IL-6, IL-17A and 30 ng/ml of IL-23 separately for 24 and 72hs. MFIs of IL-6R, IL-17RA, IL-23R, FoxP3, CD25, CTLA-4 and GITR were analysed. The cytokine-stimulated Tregs were then co-cultured with in vitro differentiated Th17 cells for 72hs. Treg suppression assay was calculated as % of inhibition of Th17 cells by flow cytometry. IL-10 and TGFβ1 supernatant levels (in Treg-Th17 co-culture) were quantified by ELISA.

Results: DED Tregs expressed higher levels of cytokine receptors IL-6R ($p=0.004$), IL-17RA ($p<0.001$), IL-23R ($p=0.002$) and lower levels of FoxP3 ($p<0.001$), CD25 ($p=0.013$) and CTLA-4 ($p=0.022$) as compared to naïve Tregs. Culturing Tregs with each of the three Th17-associated cytokines all led to a significant decrease in FoxP3 ($p<0.01$), CD25 ($p<0.05$) and CTLA-4 ($p<0.05$) expression. Conversely, IL-6 and IL-17 enhanced expression of IL-6R ($p<0.001$ for both), IL-17RA ($p<0.05$ for both), IL-23R ($p<0.001$ for IL-6; $p<0.05$ for IL-17). The suppressive function on Th17 by cytokine-stimulated Tregs was reduced with IL-6 being the most potent at rendering Tregs dysfunctional (31.2 ± 4.2% vs. 63.4 ± 2.3% naïve; $p=0.043$). IL-6-stimulated Tregs produced significantly less IL-10 (79.6 ± 6.5 pg/ml) as compared to unstimulated Tregs (198.6 ± 19.4; $p<0.001$).

Conclusions: These results suggest that IL-6 is the most potent cytokine that drives Treg dysfunction in DED, and thus can be a promising therapeutic target for restoring Treg function and reducing disease severity.

ABSTRACT BODY:

Purpose: Activation of sensory nerves innervating the ocular surface (OS) by mechanical and thermal stimuli does not generates tactile and pure thermal sensations but rather evokes sensations referred as dryness, freshness, gritty eyes, discomfort or pain. Central circuits involved in OS sensitivity are still largely unknown. Here we describe the activity of thalamic and somatosensory cortex neurons responding to OS stimulation, analyzing the processing of OS sensory input at higher levels of the CNS.

Methods: In the anesthetized rat, the spontaneous and stimulus-evoked activity of 49 trigeminal ganglion (TG) neurons, 69 somatosensory thalamus (Th) neurons and 101 primary somatosensory cortex (S1) neurons conveying OS information was recorded extracellularly using tungsten electrodes. Stimulation was performed by topical application of saline drops at different temperatures, producing five types of thermal stimulus: intense cooling, mild cooling, neutral, warming, and noxious heating. Neurons were classified into various functional types depending on their response to one or more of the different types of applied stimuli.

Results: Neurons responding to OS stimulation were found in precise locations of Th and S1, spatially grouped depending on their functional type. They encoded the type and intensity of the applied stimulus as the magnitude and temporal components of the firing response. Neurons responding to only one or to two types of stimulus (modality-specific neurons) were found in the TG while Th and S1 neurons responded to multiple types of stimulus (multimodal neurons). Furthermore, in Th and S1 there were more functional types of neurons than in TG. In S1 and Th neurons, noxious and innocuous stimulation evoked responses with different time course, the noxious ones being long lasting.

Conclusions: Thalamic and cortical representation of the OS is functionally reported. While ocular trigeminal neurons are quite selective, being activated most of them by 1-2 types of stimulus, Th and S1 OS neurons process information originated by multiple types of stimulus, suggesting divergence and convergence of ocular sensory information along the somatosensory pathway. This central convergence of information on different types of stimulus does not occur in other territories innervated by the trigeminal nerve, and would explain the diverse and unique sensations evoked at the ocular surface.

ABSTRACT BODY:

Purpose: Social determinants of health (SDOH) are factors defining an individual's social environment that impact eye care and vision outcomes. We used nationally representative data from the National Health Interview Survey (NHIS) to investigate the association of person-level SDOH, including gender, race/ethnicity, level of education, economic stability, employment, and access to healthcare with cataracts in the U.S.

Methods: Sociodemographic and health data for adults aged ≥18 years was extracted from NHIS cycles 2008, 2016, and 2017. Participants were asked if they had ever been diagnosed with cataracts and whether they had undergone cataract surgery. Multivariable logistic regression analysis, adjusted for age, was used to assess the association between SDOH variables and self-reported cataract diagnosis and surgery.

Results: Of the total 81,551 participants, 44,950 (55.12%) were females. 13,453 (16.50%) reported a diagnosis of cataracts, of which 8,012 (59.56%) had undergone cataract surgery. Americans who were unemployed or retired were more likely to report cataracts than working individuals (OR, 1.63; 95% CI, 1.50-1.77). They were also more likely to undergo cataract surgery (OR, 1.39; 95% CI, 1.22-1.58). Individuals who delayed any type of medical care because they could not get an appointment soon enough were more likely to report cataracts than those who had no issues obtaining appointments on time (OR, 1.29; 95% CI, 1.14-1.46). They were also less likely to have undergone cataract surgery (OR, 0.81; CI, 0.68-0.98). Individuals who reported their health status as excellent, very good, or good were less likely to report cataracts than those who reported fair or poor health (OR, 0.76; 95% CI, 0.70-0.82) with no significant difference in odds of undergoing cataract surgery. Compared with Whites, Blacks (OR, 0.68; 95% CI, 0.61-0.77), and Hispanics (OR, 0.63; 95% CI, 0.54-0.72) were less likely to self-report a diagnosis of cataract. Blacks were also less likely to have undergone cataract surgery (OR, 0.76; 95% CI, 0.63-0.91).

Conclusions: Unemployed or retired status, difficulty accessing care, and fair or poor health status were significantly associated with higher odds of reporting cataracts. Future research regarding the impact of SDOH and vision loss from cataracts in terms of its severity, bilaterality, and access to surgery are warranted to address avoidable health disparities.

ABSTRACT BODY:

Purpose: Thorough knowledge of structural changes in inherited retinal dystrophies and their correlation with visual function is crucial for optimal insight into clinical disease course, prognosis, and the selection of suitable candidates as well as endpoints for the therapeutic interventions. This study aims to investigate the evolution of pathological changes on imaging in X-linked retinoschisis (XLRS) patients, and assesses potential correlations with visual acuity and genotype.

Methods: This multicenter, retrospective study collected fundus autofluorescence (FAF) and spectral-domain optical coherence tomography (SD-OCT) images from medical records of XLRS patients. The location of cystoid spaces, foveal volume, foveal thickness was evaluated on SD-OCT. The foveal cystoid space area was measured by adding up the areas of foveal cystoid spaces in the central b-scan on SD-OCT using a novel semi-automated algorithm developed in MeVisLab.

Results: In total, 75 affected males from 43 presumably unrelated families were included. Longitudinal imaging was available in 52 patients, with a mean follow-up time of 4.1±2.2 years, and a mean number of 3.2±1.5 visits. The mean age at last visit was 28.5±9.3 years. The mean foveal cystoid space area, foveal thickness and foveal volume had a significant correlation with age ($R=-0.33$, $R=-0.28$, $R=-0.42$, respectively; all $P<0.001$), but no correlation with visual acuity ($P=0.524$, $P=0.496$ and $P=0.613$, respectively). These parameters also did not differ significantly between patients with truncating and non-truncating variants in the RS1 gene ($P=0.867$, $P=0.672$ and $P=0.785$, respectively). In 65/75 (86.6%) of the patients, the cystoid spaces were located in the inner nuclear layer, in 34/75 (45.3%) in the outer nuclear layer and in 19/75 (25.3%) in the ganglion cell layer. On FAF, 10/75 (13.3%) patients had a normal-appearing macula, 31/75(41.3%) showed spoke wheel pattern, 14/75 (18.6%) showed central hyperautofluorescence, and 20/75 (26.6%) showed central hypo-autofluorescence.

Conclusions: The foveal cystoid space area as well as the foveal volume and foveal thickness, decreased slowly with increasing age in XLRS, but did not correlate with visual acuity or genotype. Phenotypes remained relatively stable during follow-up. The developed method of measuring foveal cystoid space area may be useful in future studies of retinal dystrophies with central cystoid fluid collections.

ABSTRACT BODY:

Purpose: To comunicate the results after 6 months of follow-up of a pilot clinical trial (CT), carried out in five patients, with Non-Arteritic Optic Neuropathy, in its acute phase, who received an intravitreal injection of allogeneic bone-marrow derived mesenchymal stem cells (MSV®-allo) during the first 15 days after acute event.

Methods: Prospective, non-randomized, phase I-IIa CT. (Eudra number 2016-003029-40 and Clinical Trial Registry NCT03173638). After verifying the inclusion criteria (patients ≧ 50 years old, with a vissual acuity less than 0,4 and at least two of the following characteristics: sudden and painless loss of monocular vision; optic nerve head edema; clear relative afferent pupillary defect and without evidence of giant cell arteritis through medical history, erythrocyte sedimentation rate, C-reactive protein)and exclusion criteria, and having signed the informed consent, patients received an intravitreal injection of 0.05 ml containing 150 µl of isotonic medium composed of Ringer-lactate + 0.5% human albumin + 5 mM glucose with a cell concentration of $1.5x10^{6}$ cells / ml with a 25G needle via pars plana after topical anesthesia. Patients were followed at days 1, 7, 30, 90 and 180 after injection. Best corrected visual acuity, anterior and posterior pole examination searching for inflammatory signs. Pattern Reversal Visual Evoked Potential (PRVEP) and Flash Visual Evoked Potential (FVEP) and retinal nerve fiber layer (RNFL) and ganglion cell layer (GCL) thickness was assessed using a Spectral domain optical coherence tomograph (OCT).

Results: One patient developed an epiretinal membrane. Another one showed a retrolental aggregate that was not complicated with cataract progression. No signs of intraocular inflammation were detected in any patient. Most of them showed a clear visual improvement and all patients presented increase in the P2 amplitude on the FVEP. OCT results (RNFL and GCL thickness) showed a significant decrease in agreement with the visible papillary atrophy developed during the follow up.

Conclusions: Despite the appearance of an epiretinal membrane in one patient and a possible cellular deposit in retrolental space, the functional results are encouraging for further studies.

TITLE: Ten-Year Changes in Vision, Refractive Error, and Corneal Thickness after Descemet stripping endothelial keratoplasty for Fuchs Endothelial Corneal Dystrophy.

SESSION TITLE: Refractive and non-refractive corneal surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.V. Patel, Ophthalmology, Mayo Clinic Minnesota, Rochester, Minnesota, UNITED STATES|

Commercial Relationships Disclosure: Sanjay Patel: Commercial Relationship(s);Code C (Consultant/Contractor):GlaxoSmithKline;Code C (Consultant/Contractor):Emmecell;Code C (Consultant/Contractor):AbbVie Inc.;Code C (Consultant/Contractor):Santen Inc.;Code C (Consultant/Contractor):Senju Pharmaceuticals;Code P (Patent):Iris Medicine

ABSTRACT BODY:

Purpose: To determine changes in best-corrected visual acuity (BCVA), refractive error, and central corneal thickness (CCT) during the first decade after Descemet stripping endothelial keratoplasty (DSEK).

Methods: Medical records of all consecutive eyes (including the learning curve) undergoing DSEK for Fuchs endothelial corneal dystrophy (FECD) by one surgeon were reviewed and eyes with comorbidities prior to DSEK, except for cataract, were excluded. DSEK was performed through a 4.5-6 mm temporal scleral tunnel and all eyes were pseudophakic postoperatively. Postoperative changes in BCVA, spherical equivalent refractive error, refractive cylinder (vector analysis), and CCT, were assessed by using generalized estimating equation models (paired analyses). Postoperative data were excluded if new comorbidities affected vision or CCT.

Results: Of 130 eyes (81 subjects) undergoing DSEK for FECD, 34 eyes were excluded because of preoperative comorbidities. BCVA improved between 6 months (0.18 ± 0.12 logMAR; Snellen equivalent, 20/30) and 5 years (0.10 ± 0.10 logMAR; 20/25; n=74, p<0.001) and then remained stable at 10 years (0.09 ± 0.10 logMAR, n=48, p=0.22 vs. 5 years). There was a myopic shift of -0.20 ± 0.51 D between 6 months and 5 years (n=60, p=0.002) that remained stable at 10 years (-0.09 ± 0.44 D; 20/25; n=33, p=0.33 vs. 5 years). Refractive cylinder drifted with-the-rule between 6 months and 5 years (0.76 D axis 075; n=65, p<0.001) and between 5 and 10 years (0.75 D axis 082; n=34, p<0.001). CCT was stable between 6 months (672 ± 57 µm) and 5 years (677 ± 55 µm, n=63, p=0.47), but increased at 10 years (702 ± 60 µm, n=39, p=0.001). The change in BCVA was not correlated with the change in CCT during either interval (p≥0.74).

Conclusions: After DSEK for FECD, BCVA improves through 5 years and remains stable thereafter in functioning grafts. Changes in BCVA are not associated with changes in CCT. Increasing with-the-rule astigmatism after DSEK might be related to late changes in the temporal incision.

ABSTRACT BODY:

Purpose: Currently, the method of intraocular lens (IOL) exchange and choice of lens currently largely rests on surgeon preferences. The purpose of the current study was to analyze the indications, outcomes, and complications of IOL exchanges among a variety of techniques and IOL models at a tertiary ophthalmic referral center.

Methods: Patients at Bascom Palmer Eye Institute that underwent IOL exchange recorded between May 1, 2014 to August 31, 2020 were included. Demographic, clinical, and surgical data were collected, as well as information regarding the IOLs employed.

Results: IOL exchange was identified in 513 eyes of 490 patients. The mean best corrected visual acuity (BCVA) in logarithm of the minimum angle of resolution (logMAR) prior to IOL exchange was 0.695 ± 0.685 (Snellen: 20/99). The most common precipitating reasons for exchange were IOL dislocation (n=285, 46.6%), subluxation (n=52, 8.5%), uveitis-glaucoma-hyphema (UGH) (n=35, 5.7%), broken haptic (n=22, 3.6%), refraction error (n=20, 3.3%), and corneal edema (n=18, 3.0%). The most common lenses used for IOL exchange were Alcon MA60AC (n=116, 22.6%), Alcon MTA3/4/5UO (n=113, 22.0%), Akreos AO60 (n=88, 17.2%), ABBOTT Tecnis PCB00 (n=37, 7.2%), and Alcon MA50BM (n=37, 7.2%). The most frequent complications following IOL exchange were cystoid macular edema (n=38, 11.2%), corneal edema (n=36, 10.1%), elevated intraocular pressure (n=27, 7.9%), and epiretinal membrane (n=22, 6.5%). 14 out of the 21 reoperations following IOL exchange were indicated for a repeat exchange, most commonly due to dislocation (n=9, 64.3%), vitreous hemorrhage (n=3, 21.4%), UGH (n=1, 7.1%), subluxation (n=1, 7.1%), corneal edema (n=1, 7.1%), ruptured globe (n=1, 7.1%), dysphotopsia (n=1, 7.1%), and Weill-Marchesani syndrome (n=1, 7.1%).

Conclusions: In conclusion, lens dislocations were the most common indications for IOL exchange. Certain lens models were also associated with complications, including Akreos AO60 with corneal edema, Alcon MTA3/4/5UO and Akreos AO60 with cystoid macular edema, and ABBOTT Tecnis PCB00 with posterior chamber opacification. While the these complications may also be explained by a patient's ocular history, surgeons may use these findings to guide IOL selection in the setting of IOL exchange.

ABSTRACT BODY:

Purpose: Deep learning (DL) technology in recent studies has shown that automated screening, assisted diagnosis, and grading of retinal diseases using conventional fundus photographs (FPs) of about 50° view angle are efficient in saving workforce and time. Compared to conventional FPs, wide-field (WF) images of true color can provide wider view with sufficient resolution, which might further improve the efficiency of screening and DL models, but have not been investigated. Therefore, we investigated the diagnostic performance of DL models for 8 common retinal conditions using fundus photographs captured using Zeiss Clarus 500, by adapting conventional FP models into WF images.

Methods: We retrospectively analyzed 474 WF images from 197 consecutive volunteers with retinal conditions, including healthy condition, pathologic myopia, macular abnormalities, retinal vein occlusion, retinal detachment, diabetic retinopathy, after laser photocoagulation treatment, and other abnormalities, which were diagnosed by a panel of retinal specialists. An image could be diagnosed with multiple conditions simultaneously. 258 images without any annotations were used to adjust DL models, and the other 216 images with annotations were used to test the models (Table 1).

Considering that WF images show similar appearance in lesions and structures with conventional FPs, we have tried 3 different methods. A model pre-trained on conventional FPs was used to classify whole WF images, and splitted images from WF images, respectively. We also develop a novel method, Global-Local Consistency (GLC), to reach similar diagnostic result between whole and splitted WF images (Figure).

Results: The GLC method was identified as the best diagnostic method for WF images with the highest mean AUC (area under the curve value, 0.8735 vs 0.8541-0.8613). This method was superior to previous models in all conditions except health conditions and retinal vein occlusion (Table 2).

Conclusions: GLC method showed better diagnostic performance for common retinal conditions in this pilot study, even training with a relatively small sample size. Benefit from the similarity between the intrinsic feature of true color of Clarus images and CFPs, model pre-trained on CFPs can be directly used to predict WF images. Our GLC method combining with Clarus facilities might help improve the process of screening retinal diseases.

TITLE: An artificial intelligence platform for the surgical planning of intermittent exotropia

SESSION TITLE: Strabismus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Wang, Q. Meng, Z. Miao, Peking University People's Hospital, Beijing, CHINA|

Commercial Relationships Disclosure: Lejin Wang: Commercial Relationship: Code N (No Commercial Relationship) | Qingyu Meng: Commercial Relationship: Code N (No Commercial Relationship) | Zequn Miao: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Intermittent exotropia (IXT) is the most common type of exotropia, and can lead to abnormal visual function. The success rate of surgical interventions for IXT varies from 42%–63% . The factors involved in the surgical strategy in cases of strabismus are complex, demanding both theoretical knowledge and experience from the surgeon. This study aims to develop a artificial intelligence (AI) strabismus surgery design platform to provide proper surgical advice.

Methods: An AI platform with deep learning (DL) system for operation planning was trained and retrospectively validated using a retrospective development data set. We collected 1076 IXT patients who achieved successful surgical outcomes from September,2015 to November,2020 in Peking University People's Hospital. The following information was recorded including: age; IXT type; Visual Acuity (VA); refraction result; measurement of the deviation in the primary gaze at near and distance; eye dominance; the measurement of versions and ductions. We also collected the surgical parameter including the millimeters of resection of medial rectus and recession of lateral rectus. Wasserstein Generative Adversarial Network with gradient penalty (WGAN-GP) model with was used to enlarge the training dataset, and we conducted Light Gradient Boosting Machine (LightGBM) to test the accuracy rate.

Results: We random selected 80% of the original data as the training set, and 10% of the data are as the test set, and the other 10% as the validation set. Through the step of data enhancement using WAGN-GP model, there were 0.3 million medical records could be automatically generated. DL advice system was trained by these enhancement records. Tested by LightGBM, the accuracy of the AI platform, comparing to the real design, could reach to 84.52%.

Conclusions: Our AI platform can provide reliable references for strabismus surgical planning.

ABSTRACT BODY:

Purpose: Telemedicine-enabled primary eye-care centres (Vision Centre) may be an important component of achieving universal eye care. Thus, we sought to evaluate the use of telemedicine-enabled Vision Centres (VCs) compared with the gold-standard, in-person examinations (IPEs) by an ophthalmologist.

Methods: This prospective, diagnostic accuracy validation study was conducted at a VC belonging to Aravind Eye Hospital (AEH) in south India. We included consecutive new patients, aged ≥16 years, visiting the VC. All participants underwent the tele-ophthalmic examination (TOE), followed by IPE on the same visit. The in-person ophthalmologist was masked to the TOE diagnosis and treatment advice. The primary outcomes were percent agreement, kappa (k), sensitivity, and specificity of TOE versus gold standard, IPE.

Results: The TOE had high percent agreement for all eye conditions ranging from 91.3% (allergic conjunctivitis) to 98.8% (injury, and pterygium). There was substantial agreement between the TOE and IPE for cataracts (k = 0.72; 95% CI: 0.63-0.82) and moderate to substantial agreement for injury (k = 0.55; 95% CI: 0.27 to 0.83), allergic conjunctivitis (k = 0.51; 95% CI: 0.41 to 0.62), infective conjunctivitis (k = 0.61; 95% CI: 0.43 to 0.78), and pterygium (k = 0.55; 95% CI: 0.27 to 0.83) and fair agreement for diabetic retinopathy (k = 0.34; 95% CI: 0.09 to 0.59), and slight agreement for glaucoma (k = 0.16; 95% CI: -0.13 to 0.45). Overall, the sensitivity of TOE ranged from 12.5% (glaucoma) to 91.7% (cataracts) and the specificity ranged from 93.5% (normal eyes) to 99.8% (injury). With respect to treatment advice (cataract surgery, spectacles and medications), there was substantial agreement (k≥0.67) with a sensitivity ranging from 58.1% to 77.2% and specificity ranging from 96.9% to 100%.

Conclusions: The TOE in rural VCs has comparable accuracy to an IPE by an ophthalmologist for correctly identifying and treating major eye ailments. Through providing universal eye care to rural populations, this model may contribute to work toward achieving the U.N. Sustainable Development Goals.

ABSTRACT BODY:

Purpose: The commonly used approach in ophthalmology to determine the breakpoints in brokenstick analysis in either longitudinal or cross-sectional studies is by using the data as if it was acquired cross-sectionally which does not consider repeated measurements per eye. The purpose of this study is to introduce and evaluate alternative approaches of brokenstick analysis in longitudinal studies.

Methods: Four methods for estimating the breakpoints in longitudinal studies were evaluated: 1) segmented mixed model (SEG) using an iterative procedure, 2) backfitting algorithm of the mixed-effect segmented model (MLE), 3) robust backfitting that incorporates the least trimmed squares (LTS) to accommodate outliers, and 4) bootstrap method that uses segmented linear model by resampling longitudinal data cross-sectionally. These methods were compared with the conventional approach where cross-sectional analysis is used by aggregating repeated measurements. A simulation study was conducted to evaluate the performance of each method by comparing bias and mean square error (MSE) in which two breakpoints were simulated. We further apply these methods to a clinical longitudinal study with 216 eyes (145 subjects) of which 164 had open angle glaucoma, 45 glaucoma suspects, and 7 healthy eyes, followed for an average of 3.7±1.3 years, and evaluate the temporal association between visual field mean deviation (MD) and retinal nerve fiber layer (RNFL) thickness.

Results: The simulation study showed all methods performed well in prediction accuracy while the cross-sectional method fail to capture the breakpoints (Table). Among the 4 proposed methods, the average bias and MSE of SEG and MLE are smaller than LTS and bootstrap. In the clinical longitudinal study, the results from SEG indicated that 2 breakpoints at MD = -15.5 and -4.56 dB exist with a significant difference between the rate of change before and after each breakpoint ($p<0.001$) (Figure). Using the cross-sectional approach, a single breakpoint was detected at -6.67 dB.

Conclusions: SEG is recommended in studies with complex dependencies such as repeated measurements and correlations between two eyes because of the accuracy and computational stability. As illustrated, the cross-sectional approach in this setting is not recommended due to the marked differences in the analysis outcome noted in the simulation and clinical data.

ABSTRACT BODY:

Purpose: Variants in genes whose products are expressed at the photoreceptor connecting cilium, including RPGR and USH2A, are common causes of rod-cone degeneration. We compared cone structure and function between RPGR- and USH2A-associated retinal degenerations.

Methods: This single-center, cross-sectional study included 13 eyes (9 subjects) with RPGR-related X-linked retinitis pigmentosa (RPGR), 16 eyes (9 subjects) with USH2A-related autosomal recessive retinitis pigmentosa (ARRP), 15 eyes (10 subjects) with USH2A-related Usher syndrome type 2 (USH2), and 5 healthy eyes (4 subjects). Structural measures included cone density from adaptive optics scanning laser ophthalmoscopy (AOSLO) and photoreceptor inner segment (IS), outer segment (OS) and outer nuclear layer (ONL) thickness from optical coherence tomography (OCT) images. Cone function was assessed by macular integrity assessment (MAIA) microperimetry. OCT angiography (OCTA) images were used to study choriocapillaris flow deficit percent (CCFD%), using the area ratio of flow deficits greater than one mean standard deviation from a normal database. Measures were compared at designated regions (Figure 1) through ANOVA with pairwise comparisons among disease groups, adjusted for disease duration and region eccentricity.

Results: Comparisons to healthy eyes revealed lower cone density in RPGR and USH2 (p=0.02, p=0.04), shorter OS in RPGR and USH2 (p=0.0001, p=0.047), shorter IS in RPGR (p=0.004), thinner ONL in RPGR (p=0.008), and reduced macular sensitivity in RPGR, USH2, and ARRP (p=0.008, p=0.0498, p=0.04). OS were shorter in RPGR than either USH2 (-16.8 μm, p=0.01) or ARRP (-21.2 μm, p=0.001; Figure 2). IS were shorter in RPGR than USH2 (p=0.03). ONL was thinner in RPGR than either USH2 (p=0.03) or ARRP (p=0.03). Mean CCFD% was greater in RPGR than USH2 (p=0.02).

Conclusions: Differences in outer retinal thickness and CCFD% reveal more advanced structural and vascular alteration in RPGR than USH2A-related retinal degenerations. Similarities in macular sensitivity suggest comparable levels of cone dysfunction in these retinal degenerations.

ABSTRACT BODY:

Purpose: Usher Syndrome is an autosomal recessive retinal degeneration associated with deafness. Usher type IIA is caused by mutations in the USH2A gene which encodes the protein usherin, which normally localises to the photoreceptor cilium and cochlear hair cells. CRISPR-mediated base editing is a potential treatment approach for 37.3% of USH2A mutations caused by single base transitions. USH2A c.11864G>A (p.W3955X) accounts for 3-5% of pathogenic alleles worldwide, and is potentially correctable with base editing. We developed an Ush2a knockout mouse model containing a premature termination codon in the homologous location of the murine Ush2a transcript (c.11840G>A; p.W3947X). We investigate the phenotype of this mouse as a model for testing of base editing therapeutics for Usher Syndrome.

Methods: Ush2a-W3947X mice were generated using a homology directed repair knock-in strategy, with a single-stranded DNA template, gRNA and SpCas9 mRNA delivered to zygotes via pro-nuclear injection. Mice were bred on a C57BL/6J background with a repaired Cdh23 age-related hearing loss allele. Homozygous mice were evaluated at 3-, 6-, 9- and 12-months with OCT and ERG. Auditory brainstem response (ABR) threshold testing was performed at 9 weeks. Immunostaining of retinal and cochlear sections and western blot of retinal protein lysates were performed.

Results: Heterozygous Ush2a-W3947X mice were successfully generated with successful insertion of a single copy of the donor confirmed by Sanger sequencing and a ddPCR copy counting assay. Usherin was not detected in immunostaining of retinal or cochlear sections of homozygous W3947X animals, or by western blot of retinal lysates. ABR thresholds were significantly elevated at higher frequencies (8-24kHz). No significant differences were seen in photoreceptor or total retinal thickness on OCT imaging relative to wildtype mice. No differences between dark-adapted, light adapted or flicker responses were seen with ERG testing between mutant and wildtype mice.

Conclusions: The Ush2a-W3947X mouse lacks usherin expression in the retina and cochlea, and displays an early hearing loss phenotype. Ongoing analysis with age will determine if a slow retinal degenerative phenotype is present similar to other Ush2a$^{-/-}$ models. This model is useful for testing of base editing strategies for Usher syndrome.

SUBMITTER (NAME ONLY): Judith Goldstein

TITLE: Developing a care delivery framework for older adults with visual impairment: A mixed methods study on ophthalmologist perspectives

SESSION TITLE: Health Economics and Health Care Delivery

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J.E. Goldstein, F. Naufal, X. Guo, Ophthalmology, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|C. Kerr-Niermann, Ophthalmology, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Judith Goldstein: Commercial Relationship: Code N (No Commercial Relationship) | Catherine Kerr-Niermann: Commercial Relationship: Code N (No Commercial Relationship) | Fahd Naufal: Commercial Relationship: Code N (No Commercial Relationship) | Xinxing Guo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To examine the ophthalmologists' perspective on providing care to older adults with visual impairment (VI), aiming to better understand and improve healthcare delivery to this unique group of patients.

Methods: Ophthalmologists from glaucoma, retina and neuro-ophthalmology subspecialities from Johns Hopkins Wilmer Eye Institute participated in an observational mixed-methods study. Interviews and surveys covered major themes including identification of and methods used to screen for vision-related functional deficits, counselling practices, and low vision rehabilitation (LVR) provision to enhance function.

Results: Participating ophthalmologists (N=20, 65% male) were mostly over the age of 40 (60%) and had 9 years of experience (median) in their respective subspeciality. Most (55%) reported spending 5-10 minutes face-to-face with the patient per encounter and estimated that 36% (5%-67%) of older patients on average have difficulty with visual function. Most (70%) did not systematically screen for visual function difficulty, but when initiated relied on the following parameters: asking the patient directly (90%), visual acuity (70%), visual field (60%), and diagnosis criteria (25%). Time available to screen and counsel patients on visual function and LVR was reported as inadequate (70%), and only one-fifth noted that use of ophthalmic technicians or trainees was a viable option to identify and refer patients to LVR. Use of a reminder within the electronic health record (EHR) to prompt identification and referral to LVR was of interest in over half (55%) surveyed. Most ophthalmologists (70%) referred to LVR when patients expressed difficulty with visual function; over half of ophthalmologists (55%) reported that most patients were interested in pursuing LVR and found LVR beneficial.

Conclusions: Most ophthalmologists recognized the importance of querying about patients' visual function and referring to LVR, however screening approaches were not routine and time constraints often preclude adequate counselling. Relinquishing this responsibility to trainees or technicians was not considered viable given the effect on clinic workflow. An EHR reminder triggered by patient-reported vision concerns and visual acuity offers an initial framework where ophthalmology practices can be standardized to enhance healthcare delivery to older adults with VI.

ABSTRACT BODY:

Purpose: Age-Related Macular Degeneration (AMD) is a leading cause of blindness in the developed world. Despite extensive research, there remains incomplete understanding of disease development and progression. Single nucleotide polymorphisms (SNPs) are one of several mechanisms that have been associated with a predisposition to develop AMD. SNPs have previously been shown to be editable with CRISPR machinery, causing endonuclease mediated double-strand DNA breaks specified by guide RNA (gRNA) targeting. In this instance, CRISPR gene editing can target SNPs in an allele-specific manner. To investigate CRISPR editing of AMD-related SNPs, a retinal pigment epithelium (RPE) cell line, ARPE19, which possesses several AMD-related SNPs, was used. ARPE19 is a spontaneously arising RPE cell line derived from the healthy eye of a 19-year-old male. These cells grow in a stable monolayer, express RPE-specific markers CRALBP and RPE-65 and exhibit a typical RPE morphology including tight junction formation, representing a suitable model to validate CRISPR targeting of AMD-related SNPs.

Methods: SNPs in the ARPE19 cell line were identified via genotyping. U6 promoter driven gRNAs targeting AMD-related SNPs and VEGF were cloned into a gRNA cloning plasmid using BbsI cut sites. gRNAs were transfected into ARPE19 and HEK293T cells in combination with a CMV promoter driven SpCas9 plasmid to achieve a dual transfection system. To assess editing efficiency via tracking of indels by decomposition (TIDE) analysis, target SNPs were PCR amplified using primers designed to flank the target SNP with ~200bp on the 5’ end and ~500bp on the 3’ end.

Results: TIDE analysis of PCR products from ARPE19 cells with dual plasmid transfection of SpCas9 and gRNAs against the following AMD-related SNPs [rs1410996, rs380390, rs2230199, rs147859257, rs641153 CFB SNP, rs4541862] and VEGF targeting gRNA, showed 4-5% targeting efficiency, compared to 30% in HEK293T cells.

Conclusions: The dual plasmid targeting approach using SpCas9 and U6-driven gRNA plasmids efficiently delivers the CRISPR system to HEK293T cells. Low editing efficiency in ARPE19 cells may be due to inadequate time for CRISPR mechanisms to elucidate effect, as ARPE19 cells begin to degrade after 24 hours, or due to the more stable differentiation of these cells which may involve epigenetic changes to targeted genes.

ABSTRACT BODY:
Purpose: While the fovea is best known for its specialized role in spatial acuity mediated by a high density of midget retinal ganglion cells (RGCs), anatomy and transcriptomics indicate that ~15 rarer RGC types are present. However, our understanding of the visual information these RGC types convey to the brain is limited because both the fovea and rarer RGC types are difficult to address with standard physiology approaches. Here, we address these gaps in knowledge by utilizing in vivo calcium imaging to explore the diversity of foveal RGC types in the living primate eye.
Methods: Experiments were conducted in two macaque monkeys expressing GCaMP6s in the foveal ganglion cell layer. We used a fluorescence adaptive optics scanning light ophthalmoscope to measure the calcium responses of a population of GCaMP6s-expressing foveal cells to light stimuli presented directly to the photoreceptors. With this approach, we could simultaneously survey the response properties of 171 and 177 distinct cells in each macaque. Receptive fields were characterized by their responses to achromatic and cone-isolating spatially-uniform stimuli varying in contrast. In addition, we coarsely mapped spatial extent with 4.5 μm wide bars presented in different locations in one macaque.
Results: The vast majority of the 348 cells imaged were consistent with the well-studied L vs. M midget RGCs that dominate in the foveal output, in that they showed either ON or OFF responses, did not respond to S-cone isolating stimuli and had small receptive fields. However, 7% (26/348) had ON-OFF responses and 6% (22/348) had strong S-cone responses. We also mapped the spatial receptive fields in one macaque and found that 13% (23/177) had large receptive fields. Of those 23 cells, 11 had ON-OFF responses and 2 had S-cone responses.
Conclusions: Here we demonstrate an underappreciated functional diversity in the visual information the fovea sends the brain. While the dominance of midget RGCs is consistent with the fovea's specialization for spatial acuity, our results indicate that this is an incomplete picture of visual processing in the fovea. An advantage of our in vivo approach is that we can return to the same cells in subsequent experiments. As a result, the ability to functionally identify the rarest foveal RGCs established here lays the foundation for future experiments directly targeting these elusive RGC types.

ABSTRACT BODY:

Purpose: Although laser photocoagulation and anti-VEGF treatment are effective for advanced diabetic retinopathy (DR), there remains an important need to identify markers and therapeutic targets for DR worsening at earlier stages. Retinol-binding protein 3 (RBP3) is a potential protective factor against DR in the vitreous and retina of individuals with type 1 diabetes for 50 years or longer (Joslin Medalist Study). This study aims to evaluate the association between RBP3 in the aqueous fluid and DR severity in patients with type 1 and type 2 diabetes.

Methods: Aqueous samples were obtained from diabetic patients during cataract surgery at the Joslin Beetham Eye Institute (N=30) and from post-mortem eyes (N=101) of Medalists. RBP3 concentration was measured in all samples using a specific ELISA assay. Individual retinal layer thicknesses in the foveal 1x1mm area were measured by optical coherence tomography (Spectralis) with automated layer segmentation (Heidelberg v6.0c, Germany, N=45).

Results: 131 participants had a mean age of 73 ± 8 years, A1c 7.4 ± 1%, 84% type 1 diabetes, and 72% female. RBP3 levels in aqueous samples decreased with increasing DR severity from mild DR (median 0.7nM ± 0.2) to proliferative DR (PDR, 0.5nM ± 0.2, P=0.001). Aqueous RBP3 concentrations in Beetham Eye Institute and Medalists samples were similar for eyes with PDR (P=0.11). Aqueous RBP3 concentration was inversely associated with the presence of pan-retinal laser photocoagulation scars (β estimate -22.0, 95% CI -31.9;-12.0, P<0.0001), but not with A1c (P=0.60). RBP3 concentrations in aqueous were well correlated between fellow eyes (r=0.65, P<0.0001). RBP3 concentrations in aqueous and vitreous samples were correlated within the same individual (r=0.32, P=0.003, N=89). On average, RBP3 concentration in aqueous was 12-fold lower compared to vitreous samples. Higher aqueous concentrations were associated with increased thickness of the ganglion cell layer (β estimate 0.002, 95% CI 0.0019;0.0023, P<0.0001) and inner nuclear layer (0.0026, 0.0025;0.0028, P<0.0001), and decreased thickness of the retinal pigment epithelium (-0.001, -0.0017;0.0003, P=0.004).

Conclusions: These findings suggest that RBP3 concentrations in aqueous and vitreous fluids are correlated and reduced in people with advanced DR, supporting its potential use as a biomarker and therapeutic agent in people with type 1 and type 2 diabetes.

ABSTRACT BODY:

Purpose: The purpose of this study is to better understand imaging modality utilization for diagnosis of glaucoma over the past decade through analysis of trends among glaucoma specialists. Understanding these trends may contribute to proper planning and development of the healthcare apparatus and newer machine learning models.

Methods: This was a retrospective study of Medicare Provider Utilization and Payment Data from 2012-2019, which is a publicly available aggregate of nationwide information on services and procedures provided to Medicare beneficiaries on a fee-for-service basis. 556 glaucoma providers were identified throughout the Unites States. Procedure count for 92250 (fundus photography with interpretation and report), 92133/92134 (scanning computerized ophthalmic diagnostic imaging with interpretation and report), 92083 (visual field examination with interpretation and report), and 92020 (gonioscopy) were obtained. Trends were analyzed using Mann-Kendall trend test.

Results: Each testing modality increased over the eight year period studied, with the greatest percent increase in optical coherence tomography (OCT) (89.2%). Color fundus photography represented the lowest average year over year increase (Figure 1). A direct ratio of fundus photographs to OCTs showed a downward trend, where in 2012 one fundus photograph was taken for every 3.3 OCTs and in 2019 one fundus photograph was taken for every 4 OCTs (p-value 0.004).

Reimbursements did not decrease significantly for gonioscopy throughout the study period (p-value 0.53619) and decreased for the remaining three modalities. Fundus photography reimbursement decreased by 30% (p-value 0.173), OCT decreased by 20% (p-value 0.009) and visual field testing decreased by 31% (p-value =0.035) (Figure 2).

Conclusions: While visual field testing and color fundus photography did increase in the period analyzed, the change in OCT use increased by almost double. At the current rate, vanishingly few fundus photographs will be captured as part of the management of glaucoma patients. This paradigm shift represents an important change in the field.

ABSTRACT BODY:

Purpose: The potential to control vascular endothelial growth factor (VEGF) induced intracellular signaling by targeting this cytokine offers promising therapeutic potential for vascular diseases and cancer. VEGF-A regulates angiogenesis but modulates the immune microenvironment. Dendritic cells are one of the responsible cell types that orchestrate the immune response in a transplant setting. Modulation of DCs by VEGF-A -trap (Aflibercept) might benefit in reduced inflammation and subsequent transplant survival. In this study, we analyzed the effect of Aflibercept and combinations of VEGF-A bound to Aflibercept on dendritic cells and possible positive effects on the immune system and graft survival.

Methods: Human monocytes were treated with Aflibercept during differentiation, and the expression of surface and activation markers were analyzed. Biological differences of treated cells were determined in a transwell migration assay. To verify the findings in human cell culture, we confirmed them in a murine model of suture-induced neovascularization and subsequent high-risk corneal transplantation. Mice were treated with VEGFR1/R2 trap before transplantation. We analyzed transplant integrity, CD11c+ dendritic cells, and tolerance marker 2 and 8 weeks later.

Results: The treatment of monocytes, with a combination of VEGF-A and Aflibercept during differentiation to DCs leads to an down regulation of MHC II and costimulatory markers on dendritic cells. Furthermore, the frequency of VEGFR1-positive cells increased significantly. As a functional outcome we found that in the presence of VEGF-A and Aflibercept the migration of mature DC was inhibited by aproximatly 50 %. To characterize this results more in details we went into the mouse model and local VEGFR1/R2 trap treatment significantly inhibits the infiltration of CD11c+ dendritic cells into the cornea. Subsequent increased corneal transplantation success was accompanied by a local upregulation of Foxp3 gene expression.

Conclusions: This study demonstrates that the application of Aflibercept modulates the differentiation and migration ability of dendritic cells and contributes to increased transplantation success and less inflammation mediated by DCs in a mouse cornea transplantation model.

ABSTRACT BODY:

Purpose: To determine the efficacy of Rhopressa (Netarsudil, 0.02%) in lowering intraocular pressure (IOP) in patients with secondary forms of glaucoma.

Methods: A total of 68 patients (87 eyes) with either primary open angle glaucoma (POAG) or a secondary form of glaucoma were reviewed retrospectively over the course of one year after starting Rhopressa. The secondary glaucoma group was composed of patients with uveitic, neovascular, traumatic, congenital, and pseudoexfoliative glaucoma. Patient IOP measurements were collected at baseline, 1 month, 3 month, 6 month, and 12 month intervals. Patients that underwent surgical intervention during the study period were not included in the final data analysis. IOP levels and discontinuation rates, due to intolerance or inefficacy, were tracked and monitored at each patient visit. A two sample T-test was used to determine differences in the IOP lowering effect of Rhopressa in the POAG and secondary glaucoma groups.

Results: All patients with either POAG or secondary glaucomas were matched for age (Mean ± SD; 69.7 ± 16.5 vs. 67.3 ± 21.5; $p>0.05$). Both the POAG and secondary glaucoma patients exhibited significant decreases in IOP at each time point (1, 3, 6, and 12 months) when compared to each group's baseline ($p<0.05$). No significant differences were observed in IOP between the POAG and secondary glaucoma groups at most time points, with the exception of the 12 month interval ($p<0.05$). However, both groups showed similar overall decreases in IOP from baseline after 1 year of treatment (5.8 ± 4.5 vs. 5.3 ± 7.3; $p>0.05$). Discontinuation rates of Rhopressa due to intolerance or inefficacy were similar in both groups and less than 10% (Table).

Conclusions: Rhopressa is similarly effective in lowering IOP in patients with secondary glaucomas compared to those with POAG. Discontinuation rates were similar in both groups, supporting Rhopressa's utility in treating secondary forms of glaucoma.

ABSTRACT BODY:

Purpose: Antibiotic-loaded ocular inserts can address challenges in drug delivery and overcome limitations of eye drops use. The aim of this in vitro study was to optimise a sustained ocular drug delivery system for levofloxacin (LFX), a broad-spectrum antibiotic commonly used for external ocular infections.

Methods: Inserts were prepared by a refined quality by design solvent casting procedure, using 0.2%, 0.5% and 1.0% concentrations of LFX solutions with hypromellose, sodium alginate, gelatin and PEG400. Formulations were characterised for physicochemical properties: uniformity of mass and thickness, loss on dryness, moisture absorption, and surface pH. Mechanical properties were assessed and compared against a marketed buccal film, as no ocular formulation was available. Inserts' uniformity of drug content and release profile were assessed by validated analytical method. The effect of LFX fractions released over time on growth dynamics of Staphylococcus Aureus and Pseudomonas Aeruginosa was studied to evaluate extended antimicrobial efficacy.

Results: The optimised formulation including hypromellose (5%), sodium alginate (3%), gelatin (1%), PEG 400 (10%), and prepared with 0.5% LFX solution, resulted in inserts holding good physicochemical properties, in line with eye characteristics. Inserts mass (11.1 ± 0.3 mg), thickness (160 ± 10 µm) and LFX content (232.8 ± 4.4 µg) were found consistent and complying with International Pharmacopoeia guidelines. Inserts withstood unilinar (elongation at max load 25.5 ± 1.9%) and repeated (foldability > 300 times) mechanical stresses, suggesting suitability to manipulation linked to eye administration. The release pattern of 0.5% LFX showed that half of drug content was released within the first 30 minutes, indicating immediate effectiveness of inserts against bacteria, with the remaining LFX released in 24 hours. Kinetic growth assays indicated that the fractions of LFX released within the 24 hours testing period were adequate to prevent Staph. Aureus and P. Aeruginosa growth.

Conclusions: The new LFX-loaded inserts exhibited good physicochemical and mechanical properties, indicating compatibility with ocular anatomophysiology and administration procedure. LFX content and release pattern showed immediate and sustained antimicrobial efficacy of inserts on bacterial growth.

Current research is focusing on formulation cytotoxicity and transepithelial drug permeability.

ABSTRACT BODY:

Purpose: 15% of non-syndromic retinitis pigmentosa (RP) cases belong to a subclass called sector RP. Sector RP is defined by the diseased phenotype being restricted to one or two quadrants of the retina. The most common causes of sector RP are mutations in RHODOPSIN (RHO), where over a dozen mutations have been associated with sector RP including T4K and P23H. Previously, we have shown that altered lighting conditions can modulate retinal degeneration (RD) in transgenic Xenopus laevis models of sector RP. Here, we investigated sector RP-associated RHO mutations for changes in RHO localization in rod cells and RD under different lighting regimes.

Methods: X. laevis expressing human RP-associated RHO mutants under control of the X. laevis rod opsin promoter were generated by restriction enzyme-mediated integration. Transgenes were based on the human RHO cDNA. Tadpoles were raised for 14 days in either constant light, cyclic light, or complete darkness. Eyes were enucleated and used for histology or for protein level analyses through western and dot blots using mammalian rod opsin antibodies.

Results: We found variable degrees of inner segment (IS) RHO retention associated with RP-associated mutations. Most sector RP-associated RHO mutations did not affect RHO trafficking to the outer segment (OS); however, a third of the mutations studied caused significant IS retention of RHO. RD in animals with OS-localizing RHO mutants (including L31Q and T58R) was mitigated when the animals were dark reared. RD in animals with intermediate RHO localization patterns (significantly different than wildtype but with some OS localization, including S22R and D190G) was not prevented by dark rearing.

Conclusions: Localization of mutant RHO in the IS suggests an ER stress-related cell death mechanism while RHO mutants with localization indistinguishable from wildtype is likely indicative of a photoactivation-induced mechanism. The majority of mutations that we examined did not mislocalize to the IS and therefore likely act via a mechanism originating in the OS; however, mutants that localize to both the IS and OS could have multiple cell death mechanisms occurring simultaneously. Classification of RHO mutations using this system may identify mutations that are most likely to benefit from ER stress-alleviating therapies.

ABSTRACT BODY:

Purpose: To evaluate the utility of anterior segment high-resolution optical coherence tomography (HR-OCT) in guiding the diagnosis and management of clinically ambiguous ocular surface lesions.

Methods: Individuals with a clinically ambiguous ocular surface lesion with slit-lamp photographs (SLP), HR-OCT images, and histopathological examination were included in the study. The presumptive clinical diagnosis based on SLP was compared to the diagnosis suggested by HR-OCT findings and ultimately to the definitive diagnosis by histopathology. The main outcome of this study was the frequency in which HR-OCT findings guided the clinician to the correct diagnosis.

Results: Twenty-two individuals were included in this study with a mean age of 53 ± 20 years, of whom, 59% were male, 86% identified as white and 21% as Hispanic. Seven lesions were epithelial, 3 had an epithelial and a subepithelial component, and 12 were subepithelial. HR-OCT was most effective in discerning lesion location (epithelial, subepithelial, or both), successfully identifying the location in 100% of cases. In terms of the final diagnosis, classic HR-OCT findings were detected in 68.18% of cases while suggestive features were detected in 31.8% of cases. Figure 1A-E.

Conclusions: HR-OCT can be a valuable diagnostic tool, assisting in the differentiation of ambiguous ocular surface lesions. It provides morphological patterns of the lesion aiding in the localization and diagnosis of the mass.

ABSTRACT BODY:

Purpose: To compare stress distribution patterns in keratoconus (KCN) and normal (NRL) corneas and the relationships between areas of greatest curvature, thinnest pachymetry and high vs low stress.

Methods: Geometric Corneal Stress Factor (GCSF) was defined according to the hoop stress formula without intraocular pressure (IOP), R/2t, where R is radius of curvature and t is thickness. GCSF was calculated on 66 KCN eyes of 40 subjects and 310 NRL eyes of 155 subjects who were prospectively enrolled and received Pentacam Tomography (Oculus, Wetzlar, Germany). Custom software was developed and used to identify the 2mm diameter zone of greatest curvature ($AvgK_{Max}$), 2mm diameter zone of thinnest pachymetry ($Pach_{Min}$), 2mm zone of greatest GCSF ($Stress_{Max}$), 2mm zone of lowest GCSF($Stress_{Min}$). Average maps were created for KCN and NRL cohorts with central $AvgK_{Max}$ (center located within 3.0 mm diameter central zone), Inferior-Nasal $AvgK_{Max}$ and Inferior-Temporal $AvgK_{Max}$. Paired T-tests were performed between locations of $AvgK_{Max}$ and $Stress_{Max}$ and locations of $AvgK_{Max}$ and $Stress_{Min}$ as well as between locations of $Pach_{Min}$ and $Stress_{Max}$ and $Pach_{Min}$ and $Stress_{Min}$. Univariate linear regressions were performed with significance threshold of $p < 0.05$ for all analyses.

Results: In NRL, greatest stress is significantly associated with both thinnest pachymetry and greatest curvature, while in KCN, lowest stress is significantly associated with greatest curvature. The range of greatest stress in KCN is 6.50 – 15.27 with a mean of 8.82 +/-1.70 and the range of greatest stress in NRL is 5.85 – 8.45 with a mean of 7.07 +/-0.44. The range of lowest stress in KCN is 4.97 – 7.42 with a mean of 6.40 +/-0.54 and the range of lowest stress in NRL is 5.07 – 7.42 with a mean of 6.14+/-0.44. There is a significant difference in greatest stress between KCN and NRL, with KCN being higher than NRL. There is also a significant difference in lowest stress between KCN and NRL, with KCN being higher than NRL.

Conclusions: The hoop stress formula shows greater stress with either lower thickness or flatter curvature (greater R). In NRL, corneal stress distribution is driven by thickness, with greatest stress at lowest pachymetry and greatest curvature. However, in KCN, corneal stress distribution shifts such that it is driven by curvature with lowest stress at greatest curvature.

ABSTRACT BODY:

Purpose: RO-634 is a novel intravitreal bispecific protein (surrobody) with dual inhibition of both Vascular Endothelial Growth Factor-A (VEGF-A) and Angiopoietin-2 (ANG-2). We aim to investigate the half-life of this protein as compared to published data on Aflibercept, Faricimab, Ranibizumab, and Bevacizumab. These findings may have important clinical implications for treatment of retinal disease including diabetic macular edema (DME), proliferative diabetic retinopathy (PDR), and exudative age-related macular degeneration (AMD).

Methods: All experiments were performed in accordance with the ARVO statement for Use of Animals in Ophthalmic and Vision Research. The half -life of RO-634 was determined by measuring vitreous VEGF levels in 6 New Zealand White Cross rabbits with an ocular fluorophotometer (Ocumetrics, Mountain View, CA). These measurements were taken before an injection of fluorescein labeled VEGF (concentration 0.3 ug/mL) and post-injection at hours 1, 12, 24, 48, 72, 96, and 120. Determination of the vitreous fluorescence was made by averaging the values around the vitreous plateau as described by Gray et al.

Results: In vivo intraocular half-life measurements of RO-634 in New Zealand White Cross rabbits were longer than previously published data on aflibercept (3.92 days), ranibizumab (2.88 days), and similar to bevacizumab (6.51 days). Measurements taken from peak averages, demonstrated RO-634 half-life was an average of 6.75 days ± 2.13 days.

Conclusions: Our study demonstrates that RO-634 has a similar half-life when compared to bevacizumab and a longer half-life when compared to aflibercept and ranibizumab. Given RO-634's excellent half-life and novel dual-inhibitory mechanism of action, we propose that this protein is a possible therapeutic candidate for exudative AMD, DME, and PDR. We are hopeful that future studies will continue to shed light on RO-634s safety and efficacy in both animal and human models.

TITLE: Low expression of the vitamin D receptor in patients with dry eye disease

SESSION TITLE: Dry Eye, Clinical

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Zoroquiain, Pathology and Ophthalmology, Pontificia Universidad Catolica de Chile, Santiago, CHILE|J. Meza, Pathology, Pontificia Universidad Catolica de Chile, Santiago, CHILE|A. Vieira, A. Grau, Ophthalmology, Pontificia Universidad Catolica de Chile, Santiago, CHILE|

Commercial Relationships Disclosure: Pablo Zoroquiain: Commercial Relationship: Code N (No Commercial Relationship) | Javiera Meza: Commercial Relationship: Code N (No Commercial Relationship) | Antonia Vieira: Commercial Relationship: Code N (No Commercial Relationship) | Arturo Grau: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Vitamin D (vitD) has been associated not only with bone metabolism but also with inflammatory and degenerative processes. The vitamin D receptor (VDR) is a transcription factor that, linked to vitD, regulates the expression of numerous genes. Dry eye disease (DED) is a frequent multifactorial disease that leads to a serious deterioration in the quality of life. Studies have shown an association of DED with vitD deficiency, however, there are no studies that have analyzed the metabolism of this pathway at the cellular level. It is our objective to study the expression of the VDR in patients with DED.

Methods: Nineteen patients with DED without previous treatment and 10 age matched healthy subjects were studied. The Ocular Surface Disease Index (OSDI) and a cytobrush ocular surface cytology were performed on all patients. Squamous metaplasia was morphologically evaluated by liquid phase cytology with PAP-PAS staining using the Nelson's score (scale 0 to 3, higher score to higher metaplastic change). The immunohistochemical expression of VDR by fully automated immunohistochemistry was also evaluated by multiplying the percentage of cells with nuclear positivity (0-100) by their intensity (0-3) generating a score ranging from 0 to 300 (VDR-SCORE).

Results: Squamous metaplasia was observed in 74% of the individuals with DED in contrast to 0% in the control group. In patients with DED, there was lower expression of VDR compared to the control group (VDR-SCORE: 11.2 ± 13.9 versus 80.9 ± 56; P = 0.0001). Furthermore, an inverse correlation was observed between the Nelson score and VDR-SCORE (P = 0.0001, Sp = -0.71), No correlation was observed between OSDI and VDR-SCORE.

Conclusions: To the best of our knowledge, this is the first study to evaluate VDR in patients with DED. Patients with DED present a lower expression of VDR and this decrease was associated with a greater degree of squamous metaplasia, indicating a greater alteration of the ocular surface. However, the expression of VDR would not be related to the symptoms. The findings described support that VitD could be a therapeutic target in patients with DED.

TITLE: Outcomes of Rhegmatogenous Retinal Detachment Repair in Patients with Nystagmus
SESSION TITLE: Vitreoretinal surgery/VR Interface/PVR
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: A. Shahlaee, M. Salabati, R. Mahmoudzadeh, M. Klufas, Retina, Wills Eye Hospital, Philadelphia, Pennsylvania, UNITED STATES|
Commercial Relationships Disclosure: Abtin Shahlaee: Commercial Relationship: Code N (No Commercial Relationship) | Miratoallah Salabati: Commercial Relationship: Code N (No Commercial Relationship) | Raziyeh Mahmoudzadeh: Commercial Relationship: Code N (No Commercial Relationship) | Michael Klufas: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To report the anatomic and functional outcomes of rhegmatogenous retinal detachment (RRD) repair in patients with congenital or acquired nystagmus.
Methods: A retrospective review was conducted of the clinical and operative records of eyes with nystagmus and RRD underdoing surgical repair from January 1st, 2015 to April 1st, 2021. The primary outcome was the final attachment rate and single surgery anatomic success (SSAS) three months after initial repair. Secondary outcomes included final visual acuity, and mean number of subsequent operations required for complete retinal reattachment.
Results: A total of eight eyes with nystagmus including seven male (87.5%) and one female (12.5%) patient were included in this study. The mean age was 52.1 years (range, 14 to 77 years) and the mean follow-up time was 18.6 months (range, 2.8 to 32.9 months).

Four patients underwent primary pars plana vitrectomy (PPV), three underwent primary scleral buckle (SB), and one underwent PPV-SB. Three eyes required a second PPV which were due to new breaks. Two (25.0%) required a third PPV, one of which was for proliferative vitreoretinopathy (PVR). Mean time to first re-detachment was 29 days. Complete final retinal reattachment was achieved in all patients. SSAS was achieved in five patients (62.5%). This consisted of all three patients undergoing a primary SB and half of those undergoing PPV. The final visual acuity improved or stabilized in seven (87.5%) eyes. Two eyes had silicone eye tamponade, one 1000 centistokes and the other 5000 centistokes, on their final visit and there was no evidence of emulsification 253 and 201 days after surgery respectively.
Conclusions: Repair of RRD in nystagmus is an uncommon but challenging clinical scenario. Single surgery anatomic success in this series was 62.5%. Eyes with nystagmus and long-term silicone oil tamponade did not display silicone oil emulsification with moderate-term follow-up.

TITLE: Schlemm's Canal Outflow Resistance System (SCORS) visualized by Clarification and Immunohistochemistry (IHC)

SESSION TITLE: Aqueous humor dynamics & Trabecular Meshwork

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: E. Martin, Ophthalmology, Indiana University School of Medicine, Indianapolis, Indiana, UNITED STATES|M.A. Johnstone, Ophthalmology, University of Washington, Seattle, Washington, UNITED STATES|

Commercial Relationships Disclosure: Elizabeth Martin: Commercial Relationship: Code N (No Commercial Relationship) | Murray Johnstone: Commercial Relationship(s);Code I (Personal Financial Interest):Healionics;Code I (Personal Financial Interest):Eyeflow;Code I (Personal Financial Interest):Elios

ABSTRACT BODY:

Purpose: Schlemm's canal (SC) inner wall forms funnel-shaped regions that enter SC, narrow to form a tubular conduit with an endothelial-lined lumen and cross SC lumen to attach to the external wall in humans and NH primates. These SC inner wall valve-like (SIV) conduits attach to mobile leaflets forming a second SC outer wall valve-like arrangement (SOV) at collector channels (CC). The TM adheres to SOV-hinged flaps through SIV. Real-time OCT imaging demonstrates that the linkage permits pressure-induced TM motion to modulate CC entrance size. The purpose of our study is 1) To describe a novel combination of techniques permitting IHC to image a distal resistance system. 2) To further characterize the walls, lumen, and connections of the SIV.

Methods: Anterior segments of 16 M. Nemestrina primates underwent IHC labeling; 14 perfused with fluorescent microspheres (MS). Limbal tissues divided into quadrants, viscoelastic introduced into SC, and tissues fixed. Radial segments were cut, tissues clarified, confocal microscopy performed, imageJ 3D projections encompassing the TM, SC, and distal pathways obtained.

Results: 3D relationships between SIV, SOV, and CC were obtained with IHC confocal imaging. Imaging demonstrated CD 31, Collagen Type 1 & 4 in the walls surrounding the SIV lumen and distal pathways. In four eyes, 231 segments were examined, and 293 SIV were identified; 9.2% of the SIV contained microspheres.

Conclusions: Increased imaging depth with clarification and IHC permits the identification of SIV linkage between the TM and SOV. The SIV walls are continuous with SC inner wall endothelium; CD 31 vascular endothelial labeling is identical. Perfused MS demonstrated TM and lumen continuity. The attachments of the SIV to hinged flaps at SC external wall create the SOV. The relationships thus provide a mechanism to control CC entrance dimensions and regulation of distal resistance. The SIV-SOV relationships may provide a SC outflow resistance system.

ABSTRACT BODY:

Purpose: To evaluate macular microvascular changes in patients with Fabry disease (FD) using OCT-A and to correlate with laboratory and ocular findings.

Methods: A total of 76 eyes (38 patients) and 40 eyes of 20 healthy controls were enrolled in this retrospective-prospective study. Macular Vessel Density (MVD) and Foveal Avascular Zone (FAZ) were calculated in 2.9 x 2.9 mm OCT-A images (Heidelberg Spectralis II, Heidelberg, Germany). MVD was measured in three layers: Superficial Vascular Plexus (SVP), Intermediate Capillary Plexus (ICP), and Deep Capillary Plexus (DCP) in circular sectors (c1, c2, and c3). All scans were analyzed using the EA-Tool (Version 1.0), which was coded in MATLAB (The MathWorks Inc, R2017b). FAZ area (mm^2), horizontal and vertical diameters were manually measured in full-thickness scan, SVP, ICP and DCP.

Results: In FD group FAZ was increased in horizontal, vertical SVP and all DCP measurements vs. controls ($p<0.05$). MVD was higher in all sectors except DCP c1 in FD group vs. controls ($p<0.05$). MVD of the SVP, ICP and DCP in c1 and SVP and DCP in c2 showed moderate to strong negative correlation with FAZ. MVD in patients with reduced GLA Enzyme activity was decreased in DCP c1 vs. patients with normal enzyme activity. MVD in patients with elevated lysoGb3 activity was increased in DCP full-thickness, c2 and c3, ICP full-thickness and c3 vs. normal lysoGb3 activity. LysoGb3 activity was increased in patients with cornea verticillata (CV) compared with patients without CV ($p<0.05$). MVD in patients with CV was increased in all ICP and DCP sectors ($p<0.02$). There was no difference in MVD in patients with and without tortuositas vasorum. Extended results are presented in Fig. 1 and Fig. 2.

Conclusions: FAZ and MVD are increased at first examination in FD patients. Enlargement of FAZ could be a result of an underlying microvascular dysfunction in FD. Increased MVD in FD could be a result of vasodilation caused by an increased endothelium-mediated vascular reactivity due to accumulation of the glycosphingolipids in the vascular endothelium. Cornea verticillata and increased lysoGB3 activity seem to be associated with impaired microvasculature in FD.

ABSTRACT BODY:

Purpose: To identify pre-operative characteristics in penetrating keratoplasty (PK) predictive of graft survival in order to develop a standardized web-based outcome risk calculator.

Methods: A retrospective chart review was carried out at the Duke Eye Center using procedure code 65730. Inclusion criteria were adults that underwent full-thickness PK from January 1, 2013, till December 31, 2017, that had at least a 4-year follow-up or failed within. Lack of success was concluded if the patient underwent rejection (acute or chronic) despite anti-inflammatory therapy, graft failure, graft dehiscence, visually significant edema, or complications requiring repeat transplantation. Univariable analysis of pre-operative characteristics was performed followed by a stepwise multivariable logistic regression to obtain a predictive model with a $p<0.05$ cutoff. Discrimination and calibration were assessed using the area under the curve (AUC) and Hosmer-Lemeshow (HL) test, respectively.

Results: 178 transplants were included of which 62 (34.8%) were unsuccessful. History of anterior segment surgery (same eye) ($p<0.001$), diabetes ($p=0.008$), smoking ($p<0.001$), corneal neovascularization ($p<0.001$), conjunctival injection ($p<0.001$), synechiae presence ($p=0.002$), and indication other than keratoconus ($p<0.001$) were associated with non-success in the univariable analysis. Multivariable analysis produced a model consisting of: (1) previous ocular surface surgery in the same eye (OR: 2.09, $p=0.06$), (2) diabetes mellitus (OR: 3.48, $p=0.013$), (3) use of tobacco (OR: 3.77, $p=0.007$), (4) KNV (i.e. corneal neovascularization) (OR: 2.42, $p= 0.042$), and (5) erythematous conjunctiva (i.e. conjunctival injection) (OR: 4.36, $p=0.001$). The predictive model was summarized by the acronym P-DUKE. The AUC achieved was 0.82 and the HL test indicated adequate calibration ($p>0.05$). The calculator was then deployed under the URL: https://pduke.shinyapps.io/PDUKE/

Conclusions: The P-DUKE calculator is a readily accessible tool allowing for a standardized assessment of risk in patients planned for PKs and can supplement clinical judgment regarding follow-up and patient expectations irrespective of physician expertise.

ABSTRACT BODY:

Purpose: Sodium-glucose co-transporter 2 (SGLT2) inhibitors are widely used for the management of diabetes mellitus (DM). SGLT2 is expressed by retinal pericytes, thus SGLT2 inhibition may prevent retinal pericyte loss and have a protective effect in diabetic retinopathy. By decreasing glucose in the retinal microcirculation, SGLT2 inhibitors may reduce glucose-induced endothelial dysfunction. This study aims to evaluate whether SGLT2 inhibitors affect progression of non-proliferative diabetic retinopathy (NPDR) compared to standard of care.

Methods: A retrospective cohort study was conducted to compare subjects enrolled in a commercial and Medicare advantage medical claims database who filled a prescription for a SGLT2 inhibitor between the years 2013 to 2020 to unexposed controls, matched in a 1:3 ratio, who initiated an alternative diabetic anti-hyperglycemic agent. Patients were excluded if they were enrolled for less than two years in the plan, had no prior ophthalmologic exam, had no diagnosis of NPDR on or prior to the index date, had a diagnosis of diabetic macular edema (DME) or proliferative diabetic retinopathy (PDR), had received treatment for vision threatening diabetic retinopathy (VTDR), or were younger than 18 years. To balance covariates of interest between the exposed and unexposed cohorts, an inverse probability treatment weighting (IPTW) propensity score for SGLT2 inhibitor exposure was used. Multivariate Cox proportional hazard regression modeling was employed to assess the hazard ratio (HR) for VTDR, PDR or DME relative to SGLT2 exposure.

Results: A total of 6065 patients initiated a SGLT2 inhibitor were matched to 12890 controls. There were 734 (12%), 657 (10.8%) and 72 (1.18%) cases of VTDR, DME and PDR, respectively in the SGLT2 inhibitor cohort. Conversely, there were 1479 (11.4%), 1331 (10.3%), 128 (0.99%) cases of VTDR, DME and PDR, respectively in the control cohort. After IPTW, Cox regression analysis showed no difference in hazard for VTDR, PDR or DME in the SGLT2 inhibitor-exposed cohort relative to the unexposed group [HR=1.04, 95% CI 0.94 to 1.15 for VTDR; HR=1.03; 95% CI 0.93 to 1.14 for DME; HR=1.22; 95% CI 0.89 to 1.67 for PDR].

Conclusions: Exposure to SGLT2 inhibitor therapy was not associated with progression of NPDR compared to patients receiving other diabetic therapies.

ABSTRACT BODY:

Purpose: Deep learning methods have recently been used for predicting future visual fields (VFs) using baseline or longitudinal VFs. In clinical practice, glaucomatous VF loss progression is a comparatively rare event. It is of particular clinical relevance if these prediction models can accurately identify patients with disease progression to aid clinicians in avoiding vision loss. Here, we evaluate two previously described models for potential biases in over- or underestimating VF changes over time.

Methods: We consider two recent studies, namely Wen et al. (MWen) to predict VF sensitivity and Park et al. (MPark) to predict total deviations (Fig. 1). All reliable (false negatives/positives≤30%, fixation losses≤30%) Humphrey 24-2 VFs from Mass. Eye and Ear glaucoma service from 1999 to 2020 were included. We re-implemented the methods and made them available to other investigators. As in the original studies, pointwise mean absolute error (PMAE) was used to measure model prediction accuracy. A 5-fold cross-validation scheme was utilized, and the models are additionally compared against a no-change model, i.e. the baseline VF for MWen and the last-observed VF for MPark were used as the predicted VF.

Results: The evaluation dataset included 54,373 samples from 7,472 people for MWen and 24,430 samples from 1,809 people for MPark, depending on the method's needs. The PMAEs obtained by each method are shown in Fig. 1, and the results (%95 CI, MWen:2.21-2.24, MPark:2.56-2.61) are close to the original papers. Fig. 2 depicts 4 scatterplots w.r.t. mean of sensitivity for MWen and mean of deviation for MPark where A and B show predicted vs. truth, C and D show the prediction’s errors concerning actual changes. While both approaches produce satisfactory outcomes in Figs 2A and 2B, both methods exhibit a large error in projecting worsening cases, as seen in Figs 2C and 2D (the green dashed line shows a hypothetical unbiased model). It may also be deduced that the MPark that uses longitudinal VFs is superior to MWen that uses only baseline VFs.

Conclusions: Our evaluation of the two VF prediction models confirms the low PMAEs reported in the original studies. However, both models underpredicted worsening of VF loss over time. As detecting the progression of VF loss is a major motivation to obtain clinical VFs, we suggest explicitly considering this aspect in future model evaluations as well as the data characteristics.

TITLE: Comparing functional defects measured by mfERG and standard automated perimetry in patients under (hydroxy-)chloroquine therapy

SESSION TITLE: Macular diseases/Macular edema/Functional testing/evaluation/Laser

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C.R. Huchzermeyer, J.J. Kremers, Ophthalmology, Universitatsklinikum Erlangen, Erlangen, Bayern, GERMANY|

Commercial Relationships Disclosure: Cord Huchzermeyer: Commercial Relationship: Code N (No Commercial Relationship) | Jan Kremers: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We characterized the relationship between multifocal electroretinograms (mfERG) and standard automated perimetry (SAP) in patients receiving therapy with (hydroxy-)chloroquine.

Methods: In this retrospecitve observational study, data from patients who were screened for toxic maculopathy in our outpatient clinic were included. Perimetry was performed with the Octopus 900 perimeter (Haag-Streit, Switzerland) using the M-pattern (81 locations in the central 10°) and a full-threshold algorithm. MfERGs were measured in 61 hexagons in the central 30° of the visual field with the RetiPortSystem (RolandConsult). MfERGs with an amplitude ratio between rings 2 and 5 smaller or equal to 2 were defined as having Bull's-Eye-Maculopathy (BEM).

Results: The right eyes of 49 patients (age at baseline: 52.7 ± 13.4 yrs, 40 female, 35 hydroxychloroquine) were included. Follow-up was between 0.5 and 8.0 years. Clinically, no patient showed clear progression or developed new BEM during follow-up. Therefore, we averaged measurements over several visits for this first analysis. The spatial distribution of functional losses in mfERG and SAP in patients with BEM (n = 9) is shown in Figure 1.

Both mfERGs and visual fields demonstrate that locations/segments that correspond to the second ring were not equally affected - in our patients, regions inferior to the foveola retained better function. Patients with definite BEM in the ERG also had visual field defects. In a first exploratory analysis, a quadratic linear model seemed adequate to describe the relationship between mfERG amplitude and perimetric defect (see inset of Figure 1, $p < 0.001$).

Conclusions: Improved screening for functional consequences of toxic maculapathy might be achieved by techniques that 1) analyze individual loci instead of rings (possibly using artificial intelligence) and 2) combine mfERG and perimetry measurements.

ABSTRACT BODY:

Purpose: Previous studies have used optical coherence tomography angiography (OCTA) to evaluate CRVOs using smaller sized angiograms, namely 3x3 mm and 6x6 mm. We used WF SS-OCTA to quantify macular vascular metrics following CRVO and used these to model the observed visual acuity (VA).

Methods: 109 eyes of 59 patients, (59 eyes with CRVO- 9 ischemic, and 50 fellow eyes) were imaged using WF SS-OCTA (PLEX® Elite 9000, Carl Zeiss Meditec) between March 2019 and October 2021. We analyzed 12x12mm angiograms centered on the fovea using ARI Network (Zeiss Portal) Macular Density Algorithm (v0.7.3) for vessel density (VD), vessel skeleton density (VSD), foveal avascular zone (FAZ) area, circularity, and perimeter. The NPA of each macula was calculated using ImageJ. We performed mixed effects multivariate regression analyses.

Results: Our study population consisted of 33 Male (55.93%) patients with a median age of 63 years (21-86). The median logMAR visual acuity for CRVO eyes was 0.24 (20/35) vs. 0.03 (20/21) in the fellow eye ($p<0.0001$). CRVO eyes had larger NPAs than fellow eyes (median (m) 27.5, 7.16; Interquartile Range (IQR) 23.98, 8.47; $P<0.0001$), and greater irregularity of the FAZ (m 0.53, 0.79; IQR 0.25, 0.15; $P=0.005$). We did not detect a statistical difference in FAZ area (m 0.90, 0.27; IQR 0.29, 0.25, $P=0.66$) or perimeter (m 4.35, 1.23; IQR 1.88, 1.23; $P=0.2$).

Our regression analyses suggest that after controlling for age, ischemic CRVOs (ß= 0.35, $p=0.006$), larger NPAs (ß=0.007, $p<0.0001$), and larger FAZ area (ß= 0.048, $p=0.008$) were associated with worse VA. On receiver operating curve (ROC) analysis, wide-field NPA was the best OCTA metric in predicting VA worse than 20/50, area under the curve (AUC) 0.91.

Conclusions: In patients with CRVO, the WF SS-OCTA allows for quantification of NPAs in a larger region of the macula, while still providing useful information pertaining to the perifoveal vascularity. Our study reinforces prior reports that larger NPAs and larger FAZ area are associated with worse VA. WF SS-OCTA could therefore contribute to the evaluation, management, and counseling of a patient with CRVO, by identifying factors associated with worse visual outcomes following the diagnosis.

ABSTRACT BODY:

Purpose: Cobalt-containing hip implants can in rare cases cause retinopathy in patients. We have examined cobalt's effects in real time on the retinal structure and glia in the mouse eye.

Methods: We examined the effects of cobalt using either an isolated retina or a mouse retinal eyecup preparation. The retina was perfused with an oxygenated Ames Ringer and time lapse imaged using either confocal or optical coherence microscopy on a modified Leica MP microscope. Cobalt (0.2-1mM), cadmium 0.2mM, nickel 0.2mM, and ATP (0.1-1mM) solutions were held in gassed wells and applied by bath application at 35^{O}C. Test agents were applied for 10 minutes followed by a >30min wash out period. To track the microglia, an CX3CR1 GFP (green fluorescent protein) transgenic mouse was used and Z-stack confocal images were taken.

Results: Application of cobalt (1mM) for 10min. caused a rapid increase in the subretinal space (SRS) width in the OCT B-scan which averaged 22±10% at wash out (mean ±s.d., n=6 retinas), and the SRS width continued to swell even after returning to normal Ringer. After cobalt, the width of the outer nuclear layer (photoreceptor cells) also began to slowly increase. A hyperreflective line developed at the border of the inner nuclear and inner plexiform layer. After application of 1mM cobalt, there was a 47±11% increase in the average number of microglia filopodia in the inner retina (n=4 retinas, mean ±s.d. $p < 0.05$), while the outer retinal microglia were less affected. Application of cadmium increased the number of inner microglia filopodia similar to that seen with cobalt, while nickel had little effect. Application of 100uM ATP also increased the number of filopodia of inner microglia, while the outer microglia were less affected (n=5,6 retinas).

Conclusions: Our results indicate cobalt application has rapid and persistent effects on the retina even after prolonged washout. Cobalt was particularly toxic causing photoreceptor swelling. After cobalt application, the number of inner retinal microglia filopodia increased in a manner similar to that seen with ATP. Although cobalt is known for inducing hypoxia dependent transcription mechanisms, our results imply there is a more rapid direct effect of cobalt ions on the photoreceptors and other retinal neurons possibly due to oxidative stress. Which ion channels allow influx of cobalt into the retinal cells is currently unknown.

TITLE: Tolerability and Persistence with Netasurdil Containing Regimens in Patients with Primary and Secondary Glaucomas

SESSION TITLE: Pharmacology/cellular mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Oydanich, E. Roll, Y. Shah, A. Khouri, Institute of Ophthalmology and Visual Science, Rutgers New Jersey Medical School, Newark, New Jersey, UNITED STATES|

Commercial Relationships Disclosure: Marko Oydanich: Commercial Relationship: Code N (No Commercial Relationship) | Elizabeth Roll: Commercial Relationship: Code N (No Commercial Relationship) | Yash Shah: Commercial Relationship: Code N (No Commercial Relationship) | Albert Khouri: Commercial Relationship(s);Code F (Financial Support):Allergan;Code F (Financial Support):Optovue;Code F (Financial Support):NJ Health Foundation

ABSTRACT BODY:

Purpose: Registration clinical trials have reported adverse effects of Netasurdil 0.02% and Netasurdil/Latanoprost 0.02%/0.05% (Rhopressa and Rocklatan, Aerie Pharmaceuticals, NJ, USA) with hyperemia occurring in a significant proportion of glaucoma patients. However, less is known about Netasurdil's tolerability in "real-life" clinical practice and in multi-drug regimens. The purpose of this study was to examine the adverse effects and discontinuation rates in primary and secondary glaucoma patients taking Rhopressa or Rocklatan as part of a multi-drug regimen.

Methods: A total of 105 patients (138 eyes) with either primary open angle glaucoma (POAG) or a secondary form of glaucoma were reviewed retrospectively over the course of one year after starting either Rhopressa or Rocklatan. Discontinuation rates due to intolerance or inefficacy, and patient reported side effects were followed over the course of one year after starting the medication. Chi-squared analysis was used to examine differences in rate of side effects between patient groups.

Results: Reported side effects of Netasurdil regimens included tearing, itching, redness, pain, blurred vision, and headaches. All patients with either POAG or secondary glaucomas were on multi-drug regimens (Mean ± SD; 3.3 ± 1.2 vs. 3.6 ± 1.2; $p = 0.08$). POAG patients reported higher rates of tearing, itching, redness, and headaches compared to secondary glaucoma patients. However, this difference was not statistically significant between groups ($p>0.05$). Patients with secondary glaucoma had a higher discontinuation rate than POAG patients (8.8% vs 4.9%). Further analysis of the discontinuation rate revealed that 4.9% and 5.3% of POAG and secondary glaucoma patients respectively, discontinued their Netasurdil regimens due to intolerance. In 3.5% of secondary glaucoma patients discontinuations were due to inefficacy (none in the POAG group).

Conclusions: Patient reported side effects of Netasurdil regimens ranged from 0-22% in patients on multiple medications. Patient reported hyperemia occurred less frequently than in clinical trials. Discontinuations rates were 4.9-8.8% and were more likely in secondary glaucomas. Many of the side effects overlapped with ocular surface disease signs and symptoms. This information can be useful in guiding physicians using Netasurdil regimens in patients with glaucoma on multiple pharmacotherapies.

ABSTRACT BODY:

Purpose: Current treatments of glaucoma are aimed at lowering intraocular pressure (IOP), which is a key driver of retinal ganglion cell (RGC) death. Another contributing factor to RGC death is exposure to reactive oxygen species (ROS). At present, there is no FDA-approved neuroprotective treatment to prevent glaucomatous optic neuropathy and loss of RGCs. Our novel hybrid molecule, SA-2, contains both a nitric oxide (NO) donating group to lower IOP and a ROS scavenging group to protect RGCs. We hypothesize that SA-2 will inhibit the death of RGCs in an in vitro and an ex vivo neurotrophic factor deprivation model.

Methods: Retinal punches from human explants (n=4 donors/experiments) were isolated and treated with either SA-2 [1 mM] or vehicle and maintained without neurotrophic factors for 7 days ex vivo. In each experiment, 4 baseline retinal explants were collected on day 0. At the end of the experiment, explants were immunostained with RBPMS and Brn-3a (RGC-specific markers) and cell survival was analyzed.

In three biological replicates, primary RGCs were isolated from rat pups and treated with either SA-2 (1 mM, 500 µM, 100 µM) or vehicle with or without neurotrophic factors for 48 h. Active caspase 3 and 7 assay was performed and cell counts were analyzed.

In another set of experiments, rat retinal explants were isolated and incubated with tert-Butyl hydroperoxide (TBHP) along with either SA-2 [1 mM] or vehicle for 2 h (n=2-4 explants/group). Production of superoxide by mitochondria was assessed using MitoSOX reagent.

All cell counts were performed in a masked manner using ImageJ. One-way ANOVA or nonparametric Kruskal-Wallis was used for statistical analysis.

Results: In ex vivo human retinal explants, there was a significant increase in RGC survival by 39% in the SA-2 treated group compared to the vehicle group at day 7 ($p<0.0001$). In rodent primary RGCs, SA-2 mediated a significant decrease in apoptotic cells by 30% ($p<0.01$) and a 67% ($p<0.05$) decrease in dead cell count. In rodent retinal explants, there was a significant decrease (by 59%, $p<0.0001$) in the production of superoxide by mitochondria in the TBHP and SA-2 treated group, compared to the TBHP vehicle group.

Conclusions: SA-2 was shown to be effective at preserving retinal ganglion cell survival in human retinal explants, rat retinal explants and primary rat RGCs by preventing apoptosis and protecting the cells from oxidative stress.

ABSTRACT BODY:

Purpose: We previously reported variable distribution of endothelin-1 effects on choroidal blood flow when injected suprachoroidally (ARVO 2019, #1637). We wanted to determine if this was due differences in IOP at the time of injection. We also wanted to know if a larger volume or splitting the same volume in opposite quadrant injections provided more complete distribution.

Methods: For the SC injections, 34-gauge needles with a stop exposing 700 µm of the needle tip were used. New Zealand White rabbits were injected with 0.0074% indocyanine green (ICG) in balanced salt solution. A single injection of 50 µL was given 5 mm posterior to the corneal limbus in the superotemporal quadrant. The fundus was imaged with a Heidelberg scanning laser ophthalmoscope. The IOP was adjusted to 10 mmHg in one eye and either 35 mmHg or 55 mmHg in the fellow eye manometrically. Six rabbits with a crossover design were used for the 35 mmHg study and three rabbits for the 55 mmHg study. The distribution of ICG in the inferonasal quadrant was measured. In a separate study, two 50 µl injections with ICG and 0.1% fluorescein in opposing quadrants assessed coverage. Single injections of 100 µL were also done. To confirm that the observed fluorescence was not immediately transient, another set of rabbits were injected SC with 50 µL of a virus like particle (VLP) derived from HPV16 conjugated with Alexa Fluor 488 and imaged at 30 minutes and 24 hours post-dose.

Results: IOP did not significantly affect the distribution of ICG given as a single superotemporal SC injection. A single injection of 100 µL had better but still incomplete coverage than 50 µL. Two injections of 50 µL each (one of ICG and one of fluorescein) in opposite quadrants provided nearly complete SC coverage although some overlap and small gaps were present. Labeling with VLP*Alexa Fluor 488 was also incomplete following 50 µL injections and there was no change in the labeling pattern after 24 hours.

Conclusions: Distribution of aqueous solution SC injection is not dependent on IOP but on injection parameters including volume, number, and location of injections. A 100 µL single injection provides improved coverage compared to 50 µL and there is further improvement when two injections are administered in opposite quadrants of 50 µL each.

TITLE: Correlations between Renal Function and Age-Related Macular Degeneration (AMD) Phenotypes

SESSION TITLE: AMD Epidemiology & Systemic Therapies

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: A. Dave, K. Hess, K. Chen, H. Wiley, T.D. Keenan, E. Agron, E.Y. Chew, C.A. Cukras, National Eye Institute, Bethesda, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Amisha Dave: Commercial Relationship: Code N (No Commercial Relationship) | Kristina Hess: Commercial Relationship: Code N (No Commercial Relationship) | Katherine Chen: Commercial Relationship: Code N (No Commercial Relationship) | Henry Wiley: Commercial Relationship: Code N (No Commercial Relationship) | Tiarnan Keenan: Commercial Relationship: Code N (No Commercial Relationship) | Elvira Agron: Commercial Relationship: Code N (No Commercial Relationship) | Emily Chew: Commercial Relationship: Code N (No Commercial Relationship) | Catherine Cukras: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is a leading cause of blindness in the elderly. Chronic kidney disease (CKD) is also commonly associated with age. These two diseases share risk factors such as age, smoking, and hypertension as well as pathophysiologic similarities affecting the glomerular capillaries and the retinal choroid. This study investigates potential correlations between renal function and AMD features as assessed with multimodal retinal imaging.

Methods: Participants were part of a study that investigated dark adaptation (DA) function in those ≥ 50 years of age with varying AMD severities (NCT01352975) who also had eGFR (ml/min/1.73m^2) values obtained from renal function laboratory testing of serum creatinine and cystatin C. Multimodal imaging included color fundus photography and optical coherence tomography volumes from visit dates associated with serum samples and were graded by the Wisconsin Reading Center for the presence of AMD features. Associations of eGFR with AMD features and severity grades, age, smoker status, and DA function represented by rod-intercept time (RIT) were investigated. Simple univariate analyses, age-corrected multivariate analyses, and a feature-selecting LASSO regression were performed for eGFR as a continuous dependent variable.

Results: A total of 110 patients (mean age ± SD 75.1 ± 9.4 years [range 53–95]; mean eGFR ± SD 70.7 ± 18.2 ml/min/1.73m^2 [range 19.3–109.8]) were included. 95 patients had eGFRs < 90 and 36 patients had eGFRs < 60. In univariate analyses age (estimate -1.16 units/year, [CI -1.46 – -0.87], p<0.0001), RIT (estimate -0.54 units/minute, [CI -0.81 – -0.27], p<0.001) and reticular pseudodrusen (RPD) (-11.12 units for RPD presence in either eye, [CI -20.23 – -2.01], p=0.017) were associated with decreased renal function. However, in age-corrected multivariate models, age was the only significant variable associated with renal function, confirmed by LASSO regression.

Conclusions: Age was found to be strongly correlated with decreased renal function in both univariate and age-corrected multivariate analyses. While one of the strengths of this study is the well-phenotyped AMD cohort with serum values estimating renal function, it was a relatively small study. Further studies investigating the relationship between CKD and AMD phenotypes will need larger populations to better understand possible correlations between these diseases.

TITLE: Real World Ophthalmic Ambulatory Surgery Center Endophthalmitis and Toxic Anterior Segment Syndrome Rates

SESSION TITLE: Endophthalmitis/ trauma/Intravitreal/periocular therapies

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Sciulli, A. Miller, D.G. Miller, Ophthalmology, Retina Associates of Cleveland Inc, Beachwood, Ohio, UNITED STATES|H. Sciulli, Ophthalmology, University of Kansas School of Medicine, Kansas City, Kansas, UNITED STATES|A. Miller, Ophthalmology, University of Missouri System, Columbia, Missouri, UNITED STATES|

Commercial Relationships Disclosure: Harrison Sciulli: Commercial Relationship: Code N (No Commercial Relationship) | Alexander Miller: Commercial Relationship: Code N (No Commercial Relationship) | David Miller: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Published rates of endophthalmitis and toxic anterior segment syndrome (TASS) vary in the literature. Due to rarity and hesitation to report, there is a gap in understanding of occurrences of these conditions. We performed a retrospective data analysis of endophthalmitis and TASS rates at a high volume ophthalmic only ambulatory surgery center (ASC).

Methods: We gathered data from the ASC from 2016 to September 2021 for endophthalmitis and from 2009 to September of 2021 for TASS. Surgeries were organized into anterior segment (referring to cataract surgery, glaucoma surgery, and cornea surgery) as well as posterior segment surgery (referring to retina surgery only) relative to case volume. Only intraocular surgeries were counted. Laser surgeries as well as oculoplastic surgeries were excluded. Additionally, we analyzed the responsible organisms by type and gram stain.

Results: The overall rate of endophthalmitis was 0.12% (36 out of 32,051 intraocular surgeries). For anterior segment surgeries, the rate of endophthalmitis was 0.10% (21 out of 21,138). For posterior segment surgeries, the rate of endophthalmitis was 0.14% (16 out of 11,513). The p value using a student's t-test between anterior and posterior segment total cases of endophthalmitis was not statistically significant (P=0.517) nor was the case rate statistically significant (P=0.380). The most common gram positive organism was staphylococcus epidermidis, and the most common gram negative organism was serratia marcescens. The p value using a student's t-test between gram positive and gram negative organisms was significant for both surgery types favoring gram positive (P=0.045 for anterior segment and 0.042 for posterior segment). The rate of TASS from the years recorded per total number of cases was 0.073%.

Conclusions: The rate of endophthalmitis between anterior and posterior segment surgeries was not statistically significant. This information is clinically significant for several reasons. When discussing risks during the pre-operative visit, one can more accurately describe the risk. Additionally, this has led to introspection and changed practices regarding sanitation at the surgery center. The rate of TASS was low without a single case most years.

TITLE: Importance of 23 Selection Criteria Considered When Offering Interview Invitations to Ophthalmology Residency Applicants: A Survey of Program Directors

SESSION TITLE: Vision care training and education

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Cohen, S. Pershing, Stanford University School of Medicine, Stanford, California, UNITED STATES|

Commercial Relationships Disclosure: Samuel Cohen: Commercial Relationship: Code N (No Commercial Relationship) | Suzann Pershing: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Competition for ophthalmology residency positions continues to grow. The purpose of our study was to identify the factors that ophthalmology residency program directors consider most important when determining whether to extend an interview invitation to residency applicants.

Methods: We developed a six-question web-based questionnaire to be distributed to all ophthalmology residency program directors. The first three questions inquired about program demographics while the remaining three questions elicited information regarding the importance (Likert scale 1-5, with one being “not important” and five being “very important”) of 23 different selection criteria used by ophthalmology residency program directors when evaluating applicants for residency interviews. Program directors were also asked to identify the one selection criteria they felt was most important in evaluating residency applicants.

Results: The overall response rate was 56.5% (70/124). The selection criteria with the highest average importance score were core clinical clerkship grades (4.26/5) followed by letters of recommendation (4.06/5), and USMLE Step 1 score (4.03/5) (Table 1). When asked for the single most important selection criteria used when deciding to offer an applicant an interview invitation, the most frequent answer provided was “core clinical clerkship grades” (19/70, 27.1%), with “USMLE Step 1 score” (9/70, 12.9%) and “rotations at your department” (6/70, 8.6%) also common responses (Figure 1).

Conclusions: Our results reveal that core clinical clerkship grades, letters of recommendation, and USMLE step 1 score were the selection criteria deemed most important by ophthalmology residency program directors. With fundamental changes to both USMLE step 1 scoring and the clerkship grading system for many medical schools rapidly approaching, the relative importance of other selection criteria evaluated in this study will likely increase. The results of our study may be useful to medical students navigating the ophthalmology residency application process as well as to residency programs and program directors.

ABSTRACT BODY:

Purpose: Inherited retinal dystrophies (IRDs) affect over two million people worldwide, and commonly have ocular comorbidities requiring surgery. Ocular surgery in IRDs may pose unique risks. There is a lack of information on those risks, partly because the distribution of surgery types in IRDs in poorly understood. The current study aims to describe the associations of IRD phenotype and genotype, age, and sex with surgical prevalence.

Methods: A retrospective chart review was performed on 1472 eyes from 736 individuals seen at the inherited retinal dystrophy clinic at Johns Hopkins. Phenotypes were categorized as belonging to the macular, cone, and cone-rod (MCCRD) spectrum or retinitis pigmentosa (RP) spectrum conditions. Surgeries were grouped into major categories. Descriptive statistics, prevalence odds ratios for surgical categories, age at cataract surgery based on phenotype, sex, and eye were analyzed using R.

Results: Cataract extraction and intraocular lens insertion (CEIOL) made up the majority of surgeries (53.6%). Among all patients, the RP:MCCRD prevalence odds ratio for CEIOL was 2.59 ($p = 0.002$), 0.4 ($p = 0.04$) for refractive surgery, and 0.47 ($p = 0.04$) for retinal surgery. Neither genetic testing status nor sex were significantly associated with surgery prevalence. The age to the first CEIOL surgery in each patient was lower in RP-spectrum compared to MCCRD-spectrum patients (hazard ratio = 2.11, $p < 0.001$), but was not associated with sex, eye, or genetic testing status.

Conclusions: CEIOL was the most common procedure in this cohort of IRD patients, and may generally occur earlier in RP patients than in MCCRD patients. IRD phenotype category may be associated with the prevalence of the different types of ophthalmic surgical procedures in IRD patients. Further studies are needed to further understand the influence of genotypes and phenotypes on ocular surgery prevalence and outcomes in IRD patients.

ABSTRACT BODY:

Purpose: To explore the impact of the extent of reticular pseudodrusen (RPD) on cone-mediated visual sensitivity in individuals with intermediate age-related macular degeneration (AMD).

Methods: 570 eyes from 285 participants with bilateral large drusen underwent microperimetry testing under mesopic conditions to assess the visual sensitivity of the central 3.6-mm region and multimodal imaging to determine the extent of RPD in the central 20^{o}x20^{o} region (at the eye level). Mean visual sensitivity within five sectors in the central 3.6-mm region sampled on microperimetry and the extent of RPD in these sectors, were derived. Linear mixed models were used to examine the association between the extent of RPD on (i) overall mean visual sensitivity, and (ii) sector-based mean sensitivity.

Results: An increasing extent of RPD at the eye level and within sectors were associated with a significant reduction in overall and sector-based mean sensitivity respectively ($P<0.001$ for both). However, when both RPD parameters were considered together in a multivariable model, only an increasing extent of RPD at the eye level ($P<0.001$), and not within each sector ($P=0.178$), was independently associated with reduced sector-based mean sensitivity.

Conclusions: Cone-mediated visual sensitivity is generally reduced in non-late AMD eyes with RPD compared to AMD eyes without RPD, with greater reductions with an increasing extent of RPD. However, reduced sector-based visual sensitivities are explained by the overall extent of RPD present, rather than their extent within the sector itself. These findings suggest that there are generalized pathogenic changes in eyes with RPD accounting for the observed cone-mediated visual dysfunction.

ABSTRACT BODY:

Purpose: There is little to no information available on the impact of phakia versus pseudophakia on the rate of rod-mediated dark adaptation (RMDA) in older adults. RMDA is increasingly used to understand the pathogenesis of AMD and considered as a potential endpoint measure in trials. There is some concern as to whether phakic and pseudophakic participants should be considered separately in studies evaluating rod intercept time (RIT), a measure of the rate of RMDA. Cataract reduces intensity and increases intraocular light scatter reaching the retina. The current analysis compares RIT in a sample of older adults before versus after cataract surgery.
Methods: Sixteen adults, ages ≥ 60 years old with nuclear sclerotic and/or cortical cataract were recruited from three cataract surgeons at UAB. One eye, scheduled for cataract surgery, was studied in each participant. Prior to surgery, RMDA was measured with the AdaptDx, and a slit-lamp photo of the cataractous lens was taken. The Lens Opacity Classification II system (LOCS II) was used by a trained, masked grader to assess the type and severity of the cataract. Approximately 2-3 weeks following surgery, RMDA was again measured. Fundus photography was performed. A trained, masked grader evaluated macular health using the AREDS 9-step classification system.
Results: Eyes had normal macular health (13), early (2) or intermediate AMD (1). Mean visual acuity improved after cataract surgery from 20/25 to 20/20, p=0.02. Mean RIT before cataract surgery was 13.2 minutes (SD 7.3), and mean RIT after cataract surgery was 14.8 minutes (SD 7.3), p=0.03. This difference is within test-retest limits of agreement for RIT. Eyes with more severe cataract (≥ 4 in LOCS II grades in nuclear opacity, nuclear color and/or cortical cataract) had greater increase in RIT post-surgery compared to those with less severe cataract (p=0.0057).
Conclusions: Considering the sample regardless of cataract severity, measuring RIT in pseudophakia provides values similar to RIT measured before cataract surgery, taking test-retest repeatability into account. However, those with more advanced cataract yielded slower RMDA (higher RIT) post-surgery as compared to eyes with mild cataract, perhaps stemming from the bleaching light being more intense after cataract removal. Results can facilitate decisions in AMD clinical trial design where RMDA is used as an outcome measure.

ABSTRACT BODY:

Purpose: Over 200 million people worldwide suffer from moderate-to-severe vision impairment (MSVI) with an estimated global cost of hundreds of billions of US dollars per year in treatment, rehabilitation, and lost income. In absolute terms, most of the cost occurs in high income countries. However, this absolute cost does not fully convey the real-world impact of lost income, for example whether an individual's MSVI implies poverty, as poverty levels differ dramatically across countries. As no suitable measures exist to compare such normalized cost and impact, we propose a new metric by which to estimate and compare the impact of lost income due to MSVI globally.

Methods: Gross national income data per capita (adjusted to purchasing power parity in current international $, GNI-PPP) for 2020 as well as national poverty thresholds (in GNI PPP) were obtained from the World Bank for all available countries (https://data.worldbank.org/indicator/NY.GNP.PCAP.PP.CD). Variance data were not available. MSVI was assumed to carry a 30% average loss of income at the national level (Eckert et al., 2015; Marques et al., 2021). The poverty threshold for the nation was then expressed as a percentage of the adjusted income (Blindness Poverty Risk or BPR).

Results: Among the Global Burden of Disease super regions, high-income countries are home to approximately ten percent of the world's MSVI population but account for thirty percent of the lost income. When evaluating the proportion of income required to exceed the poverty threshold however, lower-income nations bore much of the global burden. The BPR was low in many of the countries with the greatest absolute losses in GNI-PPP due to MSVI (e.g., 19% in the United States), meaning that these countries had a lower proportion of income required to meet the poverty threshold. Central (51%) and East (58%) Sub-Saharan Africa, and Oceania (49%) had the most with Burundi (135%), the Central African Republic (102%), and the Democratic Republic of Congo (94%) requiring the greatest proportion of income to meet the poverty threshold.

Conclusions: Despite higher-income countries having the greatest absolute amount of lost earnings, the risk of poverty due to MSVI is greatest in lower-income countries. These first estimates provide a quantitative measure of the impact of lost income due to MSVI across countries where income and cost of living can vary dramatically.

ABSTRACT BODY:

Purpose: The incidence of macular edema after cataract surgery in patients with diabetes mellitus is higher than in the non-diabetic population, with both diabetic macular edema (DME) and pseudophakic cystoid macular edema (CME) correlating with the severity of pre-operative diabetic retinopathy. Treatment with intravitreal anti-vascular endothelial growth factor (VEGF) has shown improvement in the severity of diabetic retinopathy, as well as reduced the incidence of center-involving DME. The purpose of this study is to explore whether pre-operative anti-VEGF treatment has a positive impact on post-operative development or exacerbation of CME/DME in a large clinical database.

Methods: A retrospective study was performed on the Vestrum Health Database (EMR) looking at the incidence rate of macular edema (ME) seen in DR patients following cataract surgery, stratified by anti-VEGF use prior to surgery. Incidence of ME, VA and FT were tracked at 3 and 6 months post-surgery. Patient specific factors such as age, sex, DR severity were also assessed in modeling.

Results: Of 5,383 eyes matching inclusion/exclusion criteria, 4,565 (84%) were diagnosed with DME prior to cataract surgery. The rate of new onset, post-operative ME was 26% at month 3 (M3) and 33% at month 6 (M6) in eyes with no baseline ME. Of the 548 eyes that reported foveal thickness (FT) at baseline, M3, and M6, the FT remained relatively stable with pre-op anti-VEGF (n=347), with mean changes of +11 and +1 μm at M3 and M6. Eyes without pre-op anti-VEGF (n=201) experienced a lasting increase in FT: +25 and +23 μm at M3 and M6. The largest, independent driver of post-operative FT was baseline FT. However, in multiple linear regression modeling, pre-op anti-VEGF had a stabilizing effect on FT on those < 55 years old ($p = .006$). Multiple linear regression modeling of the 1531 eyes reporting visual acuity (VA) at all time points also demonstrated a beneficial correlation of pre-op anti-VEGF on VA at M3 ($p = .0004$) and M6 ($p = .0008$), independent of patient age.

Conclusions: In a systematic, retrospective review of over 5,000 eyes, anti-VEGF treatment prior to cataract surgery may have positive anatomic and functional effects on eyes with diabetic retinopathy and/or DME. Further study is warranted.

ABSTRACT BODY:

Purpose: To estimate retinal ganglion cell (RGC) count in preperimetric and early glaucoma eyes using optical coherence tomography (OCT) and steady-state pattern electroretinography (ssPERG) parameters.

Methods: In this prospective cross-sectional study, 25 subjects (50 eyes) were recruited at the Manhattan Eye, Ear, and Throat Hospital. Subjects underwent complete eye examinations, OCT, standard automated perimetry (SAP), and ssPERG testing. Eyes were divided into three groups based on clinical data: control (N= 30), preperimetric (N = 14), and early glaucoma (N = 6) eyes. The combined structure-function index (CSFI), which estimates retinal ganglion cell count from SAP and OCT parameters, was calculated in each study subject. Two prediction models were then derived using a step-wise linear regression to predict the CSFI from ssPERG parameters, age, and ARNFLT in 30 eyes selected at random (training sample). The prediction models were then validated using cross-validation with the remaining 20 eyes in our cohort (validation sample).

Results: Average retinal nerve fiber layer thickness (ARNFLT) and all ssPERG parameters were significantly different among groups (ANOVA $p < 0.001$). In each study group, ARNFLT and ssPERG parameters correlated with the CSFI ($r^2 \geq 0.31$, $p < 0.001$). In our training sample (N = 30), two step-wise linear regression models using ssPERG parameters magnitude (Mag) and magnitudeD (MagD), ARNFLT, and age resulted in significant equations ($F(3,26) \geq 63.00$, $R^2 \geq 0.88$, $p < 0.001$). The standard error of the estimate (SE) (SE ≤ 69,771.65) for each model corresponded to a small relative standard error (RSE) ≤ 7.20%. Applying the equations of each model to the validation sample (N = 20) resulted in similar metrics ($R^2 \geq 0.91$, SE ≤ 60,917.46, RSE ≤ 6.29%). ANOVA Games-Howell Post-Hoc analysis demonstrated that study groups exhibited more significant differences in RGC estimates than individual ssPERG and OCT measurements.

Conclusions: ssPERG parameters can be combined with OCT measurements to estimate RGC count in preperimetric and early glaucoma eyes, accounting for > 88% of variance from RGC counts estimated with the CSFI. These new combined structure-function models can distinguish preperimetric eyes from early glaucoma eyes.

Commercial Relationships Disclosure: Megan Quinn: Commercial Relationship: Code N (No Commercial Relationship) | David Yorston: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Historically, macular holes > 400um have been classified as “large”. However, there is growing evidence that closure rates are not reduced until macular hole diameter exceeds 500um. A previous audit of macular hole closure in Glasgow confirmed that holes with a diameter >500um have a worse prognosis. From 1/10/19, we adapted our technique to use an inverted ILM flap in large holes >500um diameter. This study compares large macular hole outcomes in ‘ILM peel’ vs ‘ILM flap’ repair techniques in a tertiary NHS Ophthalmology Unit.

Methods: Electronic participant data was collected from 2015 – 2021, and separated into two groups guided by the macular hole repair technique used. The pre-operative MLD, and the participant’s BCVA, were recorded at first clinic presentation. Post-operative outcomes, including anatomical hole closure and post-operative BCVA were recorded at follow-up. Only macular holes with a MLD >500um were included in this study.

Results: 115 participants were included. After exclusion for insufficient follow-up BCVA data, 110 participants: 13 males and 97 females were studied. In the ILM peel cohort, 78 participants were studied: 8 males and 70 females; 33 left eyes and 45 right eyes. The mean age was 69 years old. In the ILM flap cohort, 32 participants: 5 males and 27 females; 15 left eyes and 17 right eyes were reviewed. The mean age was 71 years old. The average MLD was 606 +/- 78 um vs 612 +/- 131 um, in the ILM peel vs ILM flap groups respectively. Pre-operative BCVA was 1.1 +/- 0.34 logMAR in the ILM peel group vs. 1.3 +/- 0.37 logMAR in the ILM flap group. Failed closure rates were 12/78 (15.4%) in the ILM peel group vs. 1/32 (3.1%) (p=0.11, Fisher’s exact test) in the ILM flap group. In the ILM peel group, BCVA improved by 0.5 logMAR vs. approximately 0.6 logMAR in the ILM flap group.

Conclusions: This audit has shown how the use of clinical data collected contemporaneously in an electronic record can be used to improve patient outcomes. In our practice the ‘ILM flap’ technique leads to higher macular hole closure rates in macular holes >500um compared to ILM peel. The average improvement in BCVA post-operatively was also slightly greater in the ILM flap group. A larger randomised clinical trial is required to confirm that the improved outcomes are the result of the inverted ILM flap technique.

ABSTRACT BODY:
Purpose: Open-source virtual reality (VR) visual field testing offers a substantially more cost-effective and accessible alternative to visual field testing for underserved patients. In this comparative analysis, our aim was to assess the validity of visual field results from a novel open-source VR headset perimeter and test the hypotheses that visual field defect patterns and test-retest repeatability would be similar between the VR headset and Octopus 900 perimeter.
Methods: We tested 19 ocular healthy and 2 subjects with primary open-angle glaucoma five times on the VR headset and twice on the Octopus 900 perimeters using the Open Perimetry Interface perimetry platform with size V stimuli, P-Central 26 grid pattern, and Zippy Estimation by Sequential Testing (ZEST) algorithm. Previous data was also obtained from past studies using the Humphrey Field Analyzer. Additionally, test point locations were divided into three concentric zones for analysis based on distance from center fixation target, and test-retest repeatability for all results was analyzed with the repeatability coefficient (RC). Finally, visual field defect detection was qualitatively assessed through side-by-side comparisons of all fields.
Results: The RC—the expected absolute difference between 2 repeated tests with 95% probability—for the VR headset was 1.03 dB and was 1.16 dB for the Octopus 900. The RC for the HFA, using a different dataset but matched testing parameters was 1.25 dB. Within the central 10° of fixation, the VR headset and Octopus 900 perimeters had an RC of 0.86 dB and 1.31 dB, respectively. Peripherally, between 21.4°-28.2° from center fixation, the VR headset and Octopus 900 perimeter had an RC of 1.71 dB and 1.37 dB, respectively. Visual field defects were qualitatively similar between the VR headset and Octopus 900 perimeter for all glaucoma subjects tested.
Conclusions: It was demonstrated that the open-source VR headset is statistically as repeatable as the Octopus 900 perimeter, and it is capable of accurately mapping glaucomatous visual field defects for both large arcuate defects and smaller peripheral defects. The open-source VR headset is a substantially more cost-effective alternative than traditional perimeters with the potential to improve the accessibility of visual field testing in third-world countries and low-income communities.

ABSTRACT BODY:

Purpose: Humanin is the first identified mitochondrial derived peptide. Humanin-G (HNG) is a variant of Humanin that has significantly higher cytoprotective properties. Here, we describe the stability features of HNG peptide in different conditions and characterize HNG degradation and oxidation patterns. State-of-the-art techniques can be used to develop to identify Humanin-G fragments and dimers for possible use in future therapeutic investigation in age-related disease such as Alzheimer's, cancer and AMD.

Methods: For 1-month stability analyses, HNG solutions were stored in H_2O and phosphate buffer saline (PBS) for 28 days at 37°C. For High-Resolution Mass Spectrometry (HRMS) studies, samples with a concentration of 25 µg/ml HNG in HPLC water or PBS were used to analyze 28-day-old HNG products.

Mass spectrometric analysis was performed using Xevo G2-XS Quadrupole Time-of-Flight mass spectrometer (HRMS) coupled to UPLC. The UPLC method used at 0.3 mL/min from 97% A to 97% B where A is 0.1% Formic Acid in water and B is 100% Acetonitrile. For HRMS analysis, positive electrospray ionization mode was utilized. A capillary transfer temperature of 300°C and a spray voltage of 3.0 kV were used to accomplish ionization. A resolution of 30,000 Full Width at Half Maximum was used for a full scan experiment within a range of m/z 100–2000. Leucine Enkephalin was used as a lock mass for nominal mass correction, and a CsNaI ladder was used for detector calibration.

Results: HNG peptide (molecular mass 2655.46), the main ions were +5, +4, +3 charged states at m/z 532.09, 664.88, and 886.19 (Fig. 1). In Humanin-G, oxidations of cysteine and methionine amino acids were determined using HRMS. Disulfide dimerization in HNG fragments were observed upon incubation of Humanin-G in HPLC water for 28 days at $37^{O}C$ constant. HRMS spectrum of other HNG degradation and their oxidation products are presented in Figures 2, 3 and Table Peptide Sequences.

Conclusions: For the first time, oxidation and degradation patterns of HNG peptide have been analyzed in detail using advanced HRMS technologies. We have identified various HNG fragments that may possess different cellular functionalities and/or receptor activities. Our results may help researchers design better in vitro and in vivo experimental parameters to further understand the critical role of HNG in physiological conditions and human diseases.

ABSTRACT BODY:

Purpose: Tree shrew eyes share many similar features to human eyes, including a structured lamina cribrosa, making them a preferred model for glaucoma than rodents. However, as an emerging animal model, a technique for quantifying and visualizing the retinal ganglion cell (RGC) axon bundle structure for tracking optic neuropathies has yet to be developed. We demonstrate visible-light optical coherence tomography fibergraphy (vis-OCTF) in the tree shrew retina to visualize individual RGC axon bundles and their surrounding vasculature.

Methods: We acquired vis-OCTF images from healthy 5-36-month-old tree shrews. Before imaging, tree shrews were anesthetized using 3% isoflurane with supplemental oxygen and given tropicamide and phenylephrine drops to dilate the pupils. During imaging, tree shrews were kept warm with an infrared heat lamp and given artificial tears to prevent corneal dehydration. We positioned the retina to maximize RGC axon bundle reflectance throughout the field-of-view. We acquired 5 repeated OCTA volumes consisting of 512 A-lines × 512 B-scans with each B-scan repeated twice. With an A-line rate of 75 kHz, each acquisition was completed in ~35 seconds. We registered the repeated volumes in the axial and lateral dimensions and then averaged to reduce speckle noise. Fibergram images were generated by segmenting the retinal nerve fiber layer and taking the mean intensity projection along the axial dimension.

Results: Vis-OCT images are shown in Fig. 1. The mean intensity projection fundus image in Fig. 1a and angiogram in Fig. 1b highlight the tree shrew's unique retinal vasculature. The fibergram in Fig. 1c and resampled B-scan in Fig. 1d depict the densely packed RGC axon bundles around the optic nerve head (ONH). We observed ~16 bundles/mm at 1.2 mm from the ONH with an axial bundle thickness of 59.4±19.8 μm (n=54) and a lateral bundle width of 25.0±8.7 μm (n=96).

Conclusions: Vis-OCTF enables a more wholistic evaluation of RGC axon bundle health and provides new parameters for tracking the progression of optic neuropathies in tree shrews.

ABSTRACT BODY:

Purpose: Diabetic macular edema (DME) is a leading cause of vision loss in patients with diabetes. DME is frequently accompanied by other retinal abnormalities on two-dimensional optical coherence tomography (2D OCT). We trained and tested a CNN to identify various retinal features on 2D OCT images from patients with DME.

Methods: 1,896 2D OCT images through the fovea from 93 patients with DME were randomly sampled from a publicly available dataset of 108,316 2D OCT images. Each image was labeled with the following 5 features: hyperreflective foci, ellipzoid zone disruption, subretinal fluid, vitreoretinal interface abnormalities, and distortion of the foveal contour. An EfficientNet-B3 CNN was trained to identify these features. The training process was repeated 3 times with separate random seeds, resulting in an ensemble of 3 CNNs. Inference was subsequently performed on an independent test set of 250 B-scans from 167 patients with DME by taking the average prediction scores across the 3 CNNs. The area under the receiver operating characteristic curve (AUC) was calculated for each feature. The 95% confidence interval (95% CI) was calculated using the bootstrap method.

Results: The distribution of the 5 features in the training set was: hyperreflective foci (37.1%), ellipsoid zone disruption (23.8%), subretinal fluid (5.2%), vitreoretinal inferface abnormalities (62.3%), and distortion of the foveal contour (50.9%). Among the 5 features, performance (AUC, 95% CI) was highest for subretinal fluid, 0.947 (0.914, 0.974); hyperreflective foci, 0.918 (0.877, 0.954); and distortion of the foveal contour 0.887, (0.802, 0.957). AUCs for ellipzoid zone disruption and vitreoretinal inferface abnormalities were 0.757 (0.693, 0.819) and 0.738 (0.643, 0.824), respectively. Figures 1 and 2 depict class activation maps illustrating which areas of the image contributed most to the predicted features.

Conclusions: CNNs were effective in identifying ancillary DME features in 2D OCT images, particularly hyperreflective foci, subretinal fluid, and distortion of the foveal contour. This can allow for more nuanced assessment of DME severity and prognosis in settings where retina subspecialists are not readily available.

TITLE: Effect of Eye Drop Reminder Software on Medication Counseling Time

SESSION TITLE: Telehealth

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Campagna, V.L. Tseng, K. Shah, Jules Stein Eye Institute, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Giovanni Campagna: Commercial Relationship: Code N (No Commercial Relationship) | Victoria Tseng: Commercial Relationship: Code N (No Commercial Relationship) | Kayur Shah: Commercial Relationship(s);Code O (Owner):EyeDropAlarm

ABSTRACT BODY:

Purpose: To examine the effect of patient use of a medication reminder software application on counseling time in an office setting.

Methods: The study population included patients who were being counseled on their prescribed eye drops for after surgery or active uveitis. All patients were provided information about how to install a software application (EyeDropAlarm). Patients were randomly assigned to either use the application or to not use the application. The length of counseling time was compared between patients who used the software application and those who did not. Counseling was given for the name(s) of the medication(s) and the schedule.

Results: Twenty-five patients were in the study. Thirteeen patients (52%) used the mobile application, and twelve did not. Of the thirteen patients who installed and used the application, eleven patients had underwent cataract surgery, and two had a history of uveitis. Of the twelve patients who did not use the application, ten patients had underwent cataract surgery, and two had a history of uveitis. The mean counseling time for the patients who did not use the application was 2.9 minutes. The mean counseling time for the patients who did use the application was 1.1 minutes. This difference was statistically significant ($P < 0.0001$, Student's t-test).

Conclusions: In this office setting, patient use of a medication reminder application, EyeDropAlarm, was associated with reduced counseling time.

ABSTRACT BODY:

Purpose: As telemedicine in eye care has become increasingly widespread, the clinical accuracy and reliability of these platforms has been well established; but there is limited data regarding patient satisfaction. Since 2015, the national Technology-based Eye Care Services (TECS) program in the Veterans Health Administration has provided ocular telehealth services to veterans with the goal of increasing accessibility to care in underserved and rural communities. After 1 year with a local TECS site, we performed a retrospective review of feedback surveys to evaluate patient satisfaction with the telemedicine experience.

Methods: 145 surveys were distributed to veterans who participated in a visit at the local TECS site from October 1, 2020 to September 30, 2021. Nationally, 3,062 surveys were distributed. The 5-point, Likert-type survey was comprised of 7 statements used to gauge participant experience. Survey response data was analyzed and summarized as proportions of respondents who strongly agreed or agreed, neither agreed or disagreed, and strongly disagreed or disagreed with the statements.

Results: Of 3,062 surveys distributed nationally, 375 were completed and analyzed. Locally, 26 of 145 surveys were completed and analyzed. 84.9% of local respondents felt satisfied overall with care received (75.6% nationally). When asked about increased confidence in this healthcare system as a result of care received, 89.7% strongly agreed/agreed (79.2% nationally). 87.2% strongly agreed/agreed care provided was efficient (85.6% nationally). 100% strongly agreed/agreed they were treated fairly (88.2% nationally). 89.3% strongly agreed/agreed high quality care was provided and their needs were addressed (86.1% nationally). 88.1% strongly agreed/agreed the provider had been helpful (84.7% nationally). Regarding ease in meeting patient needs, 92.5% strongly agreed/agreed (82.5% nationally). 0% to 5.9% of local respondents strongly disagreed/disagreed with the survey statements (3.0% to 8.1% nationally).

Conclusions: The majority of survey respondents demonstrated high levels of satisfaction in all aspects of TECS. This suggests ocular telehealth platforms may represent an alternative means of providing care that is not only high quality but also leaves patients feeling satisfied with their care.

ABSTRACT BODY:

Purpose: Ophthalmology residents are often called upon to repair complex eyelid lacerations, particularly marginal eyelid lacerations, with limited prior experience. Using 3D printing technology we created a novel silicone model of the eyelid to allow residents to easily and affordably practice their surgical skills. We performed a prospective study to determine the efficacy of these models as a training tool for marginal eyelid laceration repair.

Methods: 3D design software was used to create a model of the face and eyelids which served as the scaffold for a silicone eyelid mold. A total of 18 ophthalmology residents participated in a training session on marginal eyelid laceration repair, practicing on these models. Prior to and following the session, residents anonymously responded to a survey assessing their degree of confidence in repairing marginal and non-marginal eyelid lacerations, as well as their overall opinion of the workshop. Questions related to their confidence and ability utilized a 5-point Likert Scale: 1. Poor 2. Fair 3. Good 4. Very Good. 5. Excellent. The responses were compared using the Wilcoxon Signed-Rank test.

Results: Following the training session, residents showed a significant improvement in confidence and knowledge of marginal eyelid laceration repair. Amongst all residents, the average confidence level for repairing marginal eyelid lacerations increased from 2.33 to 3.22 ($p=0.005$) following training with the silicone models. The residents with no prior marginal eyelid repair experience reported a larger increase in the degree of confidence with scores rising from 1.14 pre-session to 2.29 post-session ($p=0.01$). Overall, attitudes regarding the training session were positive. Residents found the simulation to be beneficial with a mean score of 4.47 (SD 0.62). When asked to compare this model to other eyelid simulations for eyelid laceration repair, the silicone model was found to be superior with a mean score of 4.50 (SD 0.53).

Conclusions: 3D printed silicone eyelid models provide an effective and realistic simulation of marginal eyelid laceration repair.

TITLE: Visual field home-monitoring with a tablet perimeter by glaucoma patients.

SESSION TITLE: Clinical studies and trials

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.M. Prea, A.J. Vingrys, Department of Optometry & Vision Sciences, The University of Melbourne, Melbourne, Victoria, AUSTRALIA|S.M. Prea, G.Y. Kong, Royal Victorian Eye and Ear Hospital, East Melbourne, Victoria, AUSTRALIA|G.Y. Kong, A.J. Vingrys, Centre for Eye Research Australia Ltd, East Melbourne, Victoria, AUSTRALIA|

Commercial Relationships Disclosure: Selwyn Prea: Commercial Relationship: Code N (No Commercial Relationship) | George Kong: Commercial Relationship(s);Code P (Patent):Glance Optical Pty. Ltd. | Algis Vingrys: Commercial Relationship(s);Code P (Patent):Glance Optical Pty. Ltd.

ABSTRACT BODY:

Purpose: The primary aim is to determine long-term retention of glaucoma patients to the request for weekly home-monitoring (HM) of visual field. A secondary aim considers test reliability and concordance to in-clinic outcomes.

Methods: Participants with stable glaucoma in one eye performed HM over a 12-month period using the Melbourne Rapid Fields-glaucoma iPad application (MRFg). Loan iPads with broadband connection were provided for a weekly test schedule with text message reminders. Participants attended 6-monthly clinical reviews. Monthly retention (28+1 days), test reliability (false positives and fixation loss <33%), and concordance to Humphrey Field Analyzer (HFA) outcomes were determined. Diagnoses based on linear trends (MRFg mean deviation vs HFA Guided Progression Analysis (GPA)) were compared to the clinical diagnosis of an ophthalmologist (chi-square analysis).

Results: Eighty-five eyes of 47 participants with a mean age±SD of 64±17 years were enrolled. Forty subjects (85%) had successful uptake (≥1 test) with 58% active after 12-months. Retention to HM was 97% after weekly reminders with 77% of results reliable. Progression (≥1.25dB/yr) was identified by HFA-GPA in 3 eyes after 30 months and MRFg linear trend in 4 eyes by 3 months. Two of these eyes from both devices were classified as changed by the ophthalmologist (agreement =96%, χ^2 (3,37)=13.5, p<0.01).

Conclusions: HM over 12-months was sustained in 58% of volunteers with excellent monthly retention (97%). The high volume of tests returned by HM provides good concordance with in-clinic assays identifying 2 cases of progression early. HM should be considered for all high-risk cases of glaucoma.

ABSTRACT BODY:

Purpose: Previous research suggests racial minorities may experience disparities in the emergency room (ER) such as longer wait times compared to White Americans. We performed retrospective data analysis to further explore trends by race in epidemiology and disposition of ocular injuries reported to the ER.

Methods: The National Electronic Injury Surveillance System (NEISS) was queried for eye injuries reported from 2010 to 2020, and weights were assigned in accordance with NEISS guidelines. Analysis was performed with IBM SPSS 24 and stratified by race (White, Black, non-White Hispanic, and Asian). Incidence of ocular injuries reported over time was recorded, alongside codes corresponding to most common diagnoses, consumer products involved, and dispositions. Logistic regression analysis adjusting for variables such as age, gender, and diagnosis was performed for further analysis of racial implications on dispositions.

Results: Cases of 1,113,325 White, 212,176 Black, 21,942 Asian, and 115,548 non-White Hispanics reporting to the ER with ocular injuries from 2010 to 2020 were included. While incidence of Whites, Asians, and Hispanics reporting to the ER with ocular-related complaints decreased over time, little change was observed in Black populations. Contusions/abrasions were the most common coded ocular diagnosis in all groups (>40%), however in Whites and Hispanics foreign bodies were the second leading cause followed by dermatitis/conjunctivitis, while in Blacks and Asians this was reversed. Sources of ocular injury varied by race, for example workshop buffers were responsible for over 10% of ocular injuries in Whites, twice as much for any other race. Finally, while the majority of both racial groups were treated/examined and released (>94%), a significantly increased probability of leaving the ER without being seen was associated with being a racial minority versus White ($p<.001$), with the greatest risk in Hispanics (OR 1.962, 95% CI 1.881 to 2.046, $p<.001$).

Conclusions: These findings suggest racial variation but also shared trends in epidemiology of ocular injuries. These results also suggest a harmful outcome of racial minorities waiting longer in the ER than Whites may be an increased likelihood of patients leaving without being seen.

ABSTRACT BODY:

Purpose: Immune processes in many forms of retinal degeneration, including age-related macular degeneration (AMD), involves migration and ectopic accumulation of macrophages in the subretinal space. Recently, we described a unique subtype of bona fide microglia that are dominant in the subretinal space in mouse models of retinal degeneration. These subretinal microglia are transcriptionally reprogrammed and contribute to protecting the retina pigment epithelium (RPE) from damage caused by degeneration. These findings now prompt new investigations aimed at identifying the molecular players underlying this protective response.

Methods: We utilized single cell RNA-seq and compared subretinal microglia in four distinct disease mouse models that represent key pathobiological aspects of outer retinal degenerative diseases. These individual models included the light damage model, the sodium iodate induced RPE injury model, rhodopsin-P23H knockin mice, and an advanced aging model of 2-year-old mice. Global and microglial-conditional knockout mice were generated to assess the contributions of microglia in mediating this protective response.

Results: We found that the transcriptional signature of subretinal microglia is consistent among all mouse models studied. Confocal microscopy revealed that subretinal Iba1^{+} cells dominantly expressed markers of this signature in all mouse models. Likewise, these markers were also observed in human postmortem retinas with intermediate to advanced AMD, whereas few positive cells were found in either healthy or early AMD subjects. Moreover, we showed that genetic inhibition of this protection exacerbated death of photoreceptors, loss of RPE integrity and impairment of visual function in multiple models. Importantly, the protective activity by microglia was compromised during retinal degeneration, whereas pharmacological bolstering of subretinal microglia protected the retina from degeneration and better-preserved the RPE integrity and vision in mice.

Conclusions: Our findings demonstrate a general signature of subretinal microglia in mice and the possible relevance of this microglial population in forms of human AMD. These results provide a novel focal point for therapeutic strategies in vision preservation with retinal degenerative diseases.

ABSTRACT BODY:

Purpose: To report a possible usefulness of a novel grading for prostaglandin-associated periorbitopathy (PAP) which we referred to the Shimane University PAP Grading System (SU-PAP), distribution of PAP severity among subjects using a topical FP or EP2 receptor agonist was assessed.

Methods: Consecutive 460 Japanese subjects (211 men; mean age ± SD, 69.9±14.5 years) who had used either a FP agonist (latanoprost, tafluprost, travoprost, bimatoprost, or fixed combinations of these) or EP2-agonist (omidenepag) for >3 months in at least one eye were retrospectively included. Age, sex, prostaglandin, intraocular pressure (IOP) measured by Goldmann applanation tonometry (IOP_{GAT}) and iCare rebound tonometry (IOP_{RBT}), difference between IOP_{GAT} and IOP_{RBT} ($IOP_{GAT-RBT}$), and PAP grade were were collected. Clinical parameters were compared among groups stratified by SU-PAP grades; SU-PAP grades were descried and compared among groups stratified by prostaglandins.

Results: Of the study subjects, 114 (25%) had grade 0 (no PAP), 174 (38%) grade 1 (superficial cosmetic PAP), 141 (31%) grade 2 (deep cosmetic PAP), and 31 (7%) grade 3 (tonometric PAP). The IOP_{GAT} was significantly higher in grade 3 (17.5±5.4 mmHg) than grades 0 (15.0±5.1 mmHg, P=0.0324) and 1 (14.5±4.2 mmHg, P=0.0076), and the $IOP_{GAT-RBT}$ was significantly higher in grade 3 (5.8±3.2 mmHg) than the other three grades (1.3-1.9 mmHg, P<0.0001 for all comparisons); the IOP_{RBT} was equivalent among the four grades. The PAP grade was significantly higher associated with travoprost (2.0±0.8) and bimatoprost (2.0±0.7) than latanoprost (1.0±0.8, P<0.0001 for both comparisons) and tafluprost (1.0±0.7, P<0.0001 for both comparisons), but significantly lower associated with omidenepag (0.0±0.0, P<0.0001 for all comparisons) than the other four prostaglandins. Multivariate analyses showed older age (standard β=0.11), travoprost (0.53, referenced by latanoprost) and bimatoprost (0.65) were associated with higher PAP grades, while tafluprost (-0.18) and omidenepag (-0.73) were associated with lower PAP grades.

Conclusions: The PAP graded using SU-PAP reflects the degree of overestimation of the IOP_{GAT} and different severities of PAP among the different prostaglandins. SU-PAP, the grade system constructed based on the underlining mechanisms of PAP, is a simple grading system for PAP that is feasible for use in a real-world clinical situation.

ABSTRACT BODY:

Purpose: Currently, an estimated 1 in 70 individuals worldwide in need of a corneal transplant will actually undergo corneal transplantation. There is a lack of objective data explaining the underlying reasons for why this discrepancy exists. The purpose of this study was to use a newly developed questionnaire to identify the barriers for successfully performing corneal transplantation in India.

Methods: An online survey was sent to approximately 700 currently-practicing corneal specialists who were members of the Cornea Society of India. Members were invited to complete an online survey between January 1 and July 1, 2021. The survey asked the participants to rate the difficulty or ease of 11 steps of corneal transplantation using a Likert scale. Categories included factors related to donors, organ procurement, tissue harvesting/storage, logistical, physician/staff/facility related, and recipient related.

Results: A total of 148 individuals participated in the online survey (~21% response rate). Of the 11 evaluated steps, the greatest barrier to transplantation was the difficulty in finding donors who fulfilled the screening criteria (55% of respondents reported difficulty). The second greatest barrier was donor willingness to donate (32% of respondents reported difficulty). Lastly, the third most reported barrier was the ability to store tissue after it was prepared by the eye bank (20% of respondents reported difficulty). The two steps with the least reported difficulty were availability of operating room (OR) time and staff, as well as using prepared corneal tissue before the expiration date.

Conclusions: There is a significant shortage of corneal transplants performed around the world, however there has never been a standardized way of identifying forces driving this shortage. Our online survey evaluated each step needed to successfully perform corneal transplantation. In India, it appears that the donor-related factors (both fulfilling donor criteria and patient/family willingness to donate) and ability to store prepared tissue were the greatest barriers in performing corneal transplantation. Therefore, both government and private institutions should focus their resources and efforts on addressing these issues to ultimately reduce the burden of corneal blindness.

TITLE: Ocular, periocular, and facial injuries from cat bites

SESSION TITLE: Anterior Segment and Trauma Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Castillejo Becerra, E. Bradley, Department of Ophthalmology, Mayo Clinic Minnesota, Rochester, Minnesota, UNITED STATES|D.O. Hodge, Department of Health Sciences Research, Mayo Clinic in Florida, Jacksonville, Florida, UNITED STATES|

Commercial Relationships Disclosure: Clara Castillejo Becerra: Commercial Relationship: Code N (No Commercial Relationship) | David Hodge: Commercial Relationship: Code N (No Commercial Relationship) | Elizabeth Bradley: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: There are scarce data regarding the rates of ocular and periocular injuries from animal bites with minimal emphasis on cats as the perpetrators. In this population-based study, we described the incidence and characteristics of ocular, periocular, and facial injuries from cat bites over a 17-year period.

Methods: The Rochester Epidemiology Project (REP), a medical records-linkage system, was used to identify all potential cases of facial injuries from cat bites in Olmsted County, Minnesota from January 1, 1999 and December 31, 2015. The ophthalmic cohort included patients with ocular and periocular injuries with or without facial injuries while the non-ophthalmic cohort included patients with facial injuries not involving the ocular or periocular regions.

Results: There were 19 patients with facial injuries from cat bites in the study period, 6 ophthalmic and 13 non-ophthalmic. Mean age was 8.4 years (0.4-26.1) and 10 (53%) were male. The overall age- and sex-adjusted incidence of facial injuries from animal bites was 0.7 per 100, 000 per year (95% CI: 0.4-1.0) adjusted to the 2010 US white population, 0.2 per 100, 000 per year (95%: 0.0-0.4) ophthalmic and 0.5 per 100, 000 per year (95%: 0.2-0.7) non-ophthalmic. Most cat bites were provoked (n=10, 76.9%) and caused by animals known to the victim (n=14, 88%). All patients with ophthalmic injuries had eyelid lacerations, and none sustained ocular trauma. Patients with ophthalmic injuries had similar rates of cheek laceration (33% vs. 39%), antibiotic prophylaxis (83% vs. 77%), tetanus prophylaxis (17% vs. 39%), and wound closure (33% vs. 15%) as patients with non-ophthalmic injuries. There was a trend toward more cellulitis complicating ophthalmic injuries (17% vs 0%), this difference was not statistically significant.

Conclusions: Periocular and facial injuries from cat bites are rare, with little if any risk of ocular trauma. Children and young adults are at most risk.

SUBMITTER (NAME ONLY): Ema Karakoleva

TITLE: Association of age and HgbA1C with lens thickness and central corneal thickness

SESSION TITLE: Cataract surgery 1

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E.V. Karakoleva, N. Devireddy, D. Rosen, N. Cannon, S. Pantanelli, Ophthalmology, Penn State College of Medicine, Hershey, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Ema Karakoleva: Commercial Relationship: Code N (No Commercial Relationship) | Nitya Devireddy: Commercial Relationship: Code N (No Commercial Relationship) | David Rosen: Commercial Relationship: Code N (No Commercial Relationship) | Nathan Cannon: Commercial Relationship: Code N (No Commercial Relationship) | Seth Pantanelli: Commercial Relationship(s);Code F (Financial Support):Alcon, Carl Zeiss Meditec, Ocular Therapeutix, Ziemer;Code R (Recipient):Alcon, Carl Zeiss Meditec;Code C (Consultant/Contractor):Bausch and Lomb, Carl Zeiss Meditec

ABSTRACT BODY:

Purpose: The aim of this study was to investigate the relationship between age, HgbA1C, lens thickness (LT), and central corneal thickness (CCT) in eyes of patients with diabetes mellitus (DM) using a swept-source optical coherence tomography (SS-OCT) based optical biometer.

Methods: This was a single-center, retrospective consecutive case series including patients with optical biometry (IOLMaster 700, Carl Zeiss Meditec AG) obtained between 02/2020 and 05/2021 in anticipation of cataract surgery. Charts were retrospectively reviewed to associate the biometric data with clinical variables including diabetic status and HbgA1C. Inclusion criteria included male or female, age 18 or older. To be included in the diabetic group, patients must have had a known history of DM (type I or type II) with a documented HbgA1C within 4 months of biometry. Eyes of patients presenting with any clinically significant corneal or intraocular media opacity other than cataract, abnormal corneal findings, any anterior segment pathology, or history of intraocular or corneal surgery (other than panretinal photocoagulation, laser peripheral iridotomy, selective laser trabeculoplasty, or argon laser trabeculoplasty), or failed or poor-quality measurements as determined by the device's quality metrics were excluded.

Results: In total, 256 eyes from 151 patients were identified as eligible for analysis. This included 182 eyes from 107 non-diabetic and 74 eyes from 44 diabetic patients. There was a positive linear correlation between age and LT in both the control and diabetic groups with R-squared values of 0.188 and 0.129, respectively. Despite non-diabetics and diabetics having similar age distributions ($p = 0.57$), diabetics (4.696 ± 0.49 mm) had significantly larger LTs than their non-diabetic (4.47 ± 0.43 mm) counterparts ($p = 0.0007$). Mean CCT values were 0.56 ± 0.03 mm in non-diabetic and 0.55 ± 0.03 mm in diabetic patients ($p = 0.42$). No age-related differences were observed. There was no relationship between HbgA1C and LT in controlled DM (HgbA1C ≤ 7; R-squared = 0.000) but LT decreased with HgbA1C in uncontrolled DM (HgbA1C > 7; R-squared = 0.148).

Conclusions: There is a correlation between age and LT but not CCT in patients without and with DM. Diabetics have increased LT compared with non-diabetics. More sophisticated analysis is needed to evaluate whether HgbA1C is an independent predictor of LT or CCT once the effect of age is removed.

TITLE: A review of concentric macular rings seen on scanning laser ophthalmoscopy ultra-widefield pseudocolour reflectance images

SESSION TITLE: Imaging of posterior segment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: I.G. De Silva, Medical Retina, Moorfields Eye Hospital NHS Foundation Trust, London, London, UNITED KINGDOM|

Commercial Relationships Disclosure: Isuru De Silva: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate the relationship between foveal morphology and the presence of concentric macular rings (CMR) on ultra-widefield scanning laser ophthalmoscopy (SLO) pseudocolour images

Methods: Retrospective analysis of ultra-widefield (SLO) pseudocolour images (Optos California, Optos plc, Dunfermline, UK) performed on patients in a single tertiary care clinic, in the first half of 2021 were reviewed. Patients were included if they had spectral-domain optical coherence tomography (SD-OCT) scans (Spectralis [Heidelberg Engineering GmbH, Heidelberg, Germany) of the macula performed at the same visit. Foveal morphology, visual acuity and diagnosis were recorded.

Results: Fourteen (14) subjects met the inclusion criteria, with a mean age of 8.9 years (standard deviation 3.59, range 3 - 17 years) of whom 8 were female. Of all these patients with concentric macular rings, only 9 demonstrated some degree of foveal hypoplasia on SD-OCT. This included 6 patients with oculocutaneous albinism and one each with a diagnosis of Hermansky-Pudlak syndrome, Microphthalmia and atypical epiretinal membranes. Amongst the 5 subjects demonstrating normal foveal development despite the presence of CMRs, a molecular diagnosis was obtained in 4 which included NR2E3 (2), CHM (1), and RPGP(1). Visual acuity was better in the group with normal foveal development (avg Logmar 0.16) compared to those with foveal hypoplasia (0.47).

Conclusions: Concentric macular rings on SLO ultra-widefield pseudocolour images are infrequently reported findings, previously reported to occur in presence of foveal hypoplasia. Although these findings were more common with foveal hypoplasia, we report that they may be noted in its absence.

ABSTRACT BODY:

Purpose: To examine the prevalence of glaucoma by race/ethnicity in the 2019 California (CA) Medicare population.

Methods: The study population included all 2019 CA Medicare beneficiaries ≥65 years old who had both Part A and Part B coverage. Race/ethnicity was obtained from the Medicare enhanced race/ethnicity code and was categorized into White, Black, Asian, Hispanic, and Other/Unknown. Glaucoma was defined by diagnosis codes and included any glaucoma, primary open angle glaucoma (POAG), secondary open angle glaucoma (SOAG), and angle closure glaucoma (ACG). Covariates included age, sex, Charlson Comorbidity Index, pseudophakia, and macular degeneration. Univariable comparisons of glaucoma prevalence by race/ethnicity was performed using chi-squared tests. Multivariable analyses were performed using logistic regression, while adjusting for all covariates.

Results: The study population included 5,856,492 CA Medicare beneficiaries, of whom 3,340,658 (57.0%) were White, 317,631 (5.4%) were Black, 760,673 (13.0%) were Asian, 1,203,503 (20.6%) were Hispanic, and 234,027 (4.0%) were Other/Unknown. There were 220,662 (3.8%) beneficiaries with any glaucoma, 171,988 (2.9%) with POAG, 8,827 (0.2%) with SOAG, and 12,978 (0.2%) with ACG. Compared to White beneficiaries, Black, Asian, Hispanic, and Other/Unknown beneficiaries had increased adjusted odds of any glaucoma (Black odds ratio [OR]=1.70, 95% confidence interval [CI]=1.67, 1.73; Asian OR=1.60, 95% CI=1.58, 1.62; Hispanic OR=1.05, 95% CI=1.04, 1.07; Other/Unknown OR=1.30, 95% CI=1.27, 1.33), POAG (Black OR=1.79, 95% CI=1.75, 1.83; Asian OR=1.40, 95% CI=1.38, 1.42; Hispanic OR=1.07, 95% CI=1.06, 1.09; Other/Unknown OR=1.26, 95% CI=1.23, 1.30), and ACG (Black OR=2.18, 95% CI=2.02, 2.37; Asian OR=5.09, 95% CI=4.89, 5.30; Hispanic OR=1.69, 95% CI=1.60, 1.78; Other/Unknown OR=2.05, 95% CI=1.88, 2.24) but lower adjusted odds of SOAG for most race/ethnicities (Black OR=0.30, 95% CI=0.25, 0.35; Asian OR=0.47, 95% CI=0.44, 0.51; Hispanic OR=0.47, 95% CI=0.44, 0.51; Other/Unknown OR=1.17, 95% CI=1.06, 1.29).

Conclusions: In the 2019 CA Medicare population, there were racial/ethnic differences in the prevalence of glaucoma with higher odds in Black and Asian relative to Hispanic and White populations, which is different from prior population-based studies. Further investigation is required to determine the etiology of these differences.

TITLE: Demographic variables and systemic comorbidities associated with diagnosis of chalazion and chalazion incision/excision from a US claims database

SESSION TITLE: Pediatric Ophthalmology - Pathophysiology and Imaging Modalities and Oculoplastics

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: D. Kim, B. McGeehan, C.A. Briceno, B.L. VanderBeek, Scheie Eye Institute, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Diana Kim: Commercial Relationship: Code N (No Commercial Relationship) | Brendan McGeehan: Commercial Relationship: Code N (No Commercial Relationship) | Cesar Briceno: Commercial Relationship: Code N (No Commercial Relationship) | Brian VanderBeek: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To identify risk factors associated with chalazion and chalazion surgery.

Methods: Patients with an incident chalazion diagnosis from 2002-2019 were compared 1:5 with matched controls. Multivariate logistic regression identified variables associated with diagnosis and surgical excision, separately.

Results: Chalazion patients (n=134,959) and controls (6,878,160) were analyzed. Risk factors for diagnosis included female sex, non-white race, Northeast location, conditions affecting periocular skin and tear film (blepharitis, meibomian gland dysfunction, rosacea, pterygium), several non-ocular inflammatory conditions (gastritis, inflammatory bowel disease, sarcoidosis, seborrheic dermatitis, Grave's disease) and smoking ($p<0.001$). Diabetes and systemic sclerosis decreased odds of diagnosis ($p<0.001$). Male sex and rosacea increased odds of surgery ($p<0.001$). Anxiety, diabetes, gastritis, seborrheic dermatitis, Sjogren's, and smoking decreased odds of surgery ($p<0.001$).

Conclusions: Female sex, non-white race, conditions affecting periocular skin and the tear film, several non-ocular inflammatory conditions, and smoking were risk factors for chalazion diagnosis. Male sex and rosacea were risk factors for surgical intervention for chalazion. Our results prompt further study of these variables and their relationship to chalazion diagnosis to understand physiology and improve clinical outcomes.

ABSTRACT BODY:

Purpose: Changes in retinal vascular morphology are related to cardiovascular morbidity. Here, we assessed the association between retinal fractal dimension (FD) and incident cardiovascular (CV) events in an ophthalmic hospital-attending population in London, United Kingdom.

Methods: A retrospective cohort study, the AlzEye project, linking retinal imaging of patients aged ≥ 40 years with systemic disease data from hospital admissions between January 1st 2008 and March 31st 2018. Cardiovascular event diagnoses were myocardial infarction and ischaemic stroke, as defined by the International Classification of Diseases, 10^{th} revision codes. Retinal FD was calculated from macular-centered color photographs using the Vascular Assessment and Measurement Platform for Images of the Retina. Odds ratios (OR) from multivariable logistic regression examined the association between incident CV events and retinal FD adjusting for known confounders.

Results: Among a cohort of 62,143 patients, 674 had a CV event at one year, 1731 at three years, and 2330 at five years. Those, who had a CV event, were older (72.2 +/- 11.9 vs 68.8 +/- 12.4, p<0.001) and more likely to be men (53.1% vs 47.9%, p<0.001), diabetic (60.4% vs 46.6%, p<0.001) and hypertensive (90.5% vs 80.5%, p<0.001). Retinal FD was reduced in patients with an incident CV event (1.50 versus 1.51, p<0.001). After adjustment by age, sex, hypertension and diabetes mellitus, retinal FD was inversely associated with incident CV events with similar ORs for one-year, three-year and five-year incidence (one-year, 0.91, 0.85-0.97, three-year 0.91, 0.87-0.95, five-year 0.90, 0.87-0.93 per standard deviation increase). Effect modification by sex was apparent. Stratification by sex showed significant association of retinal FD with female sex only (five-year incident events, Female: 0.86, 0.81-0.92, Male 0.96, 0.90-1.02 per standard deviation increase).

Conclusions: An inverse relationship was found between retinal FD and incident CV events but only among those of female sex. Subsequent research will assess other retinal vascular indices, the contribution of longitudinal oculomic biomarkers and prediction rather than etiological objectives.

ABSTRACT BODY:

Purpose: Retinal ischemia is a major cause of vision loss and a common feature of diabetic retinopathy (DR). This study hypothesized that α-Melanocyte-stimulating hormone (α-MSH) decreased severity of retinal damage after retinal ischemia/reperfusion (I/R) injury by downregulating oxidative stress and excitotoxicity while upregulating anti-inflammatory factor expression under hyperglycemia condition.

Methods: I/R injury was induced in type 1 diabetic C57BL/6J $Ins2^{Akita/+}$ mice by blocking the middle cerebral artery (MCA) for 2 h with reperfusion for either 2 h or 22 h using the intraluminal method. Since ophthalmic artery originates proximal to the origin of the MCA, the filament also occluded blood flow to the retina. Animals were treated intraperitoneally with either vehicle or various doses of α-MSH at 1 h after ischemia and 1 h after reperfusion. Electroretinogram was recorded after dark adaptation. Paraformaldehyde-fixed eye sections were used to count ganglion cells, measure thickness of retinal layers and oxidative stress. Western blot was performed to measure anti-inflammatory factor expression and qPCR was performed to reflect excitotoxicity.

Results: α-MSH significantly increased amplitudes of b-wave and oscillatory potentials (OPs). α-MSH also prevented the I/R-induced histological changes and the development of retinal swelling. Loss of retinal ganglion cells as well as poly-ADP-ribose immunoreactivity were significantly decreased in the α-MSH-treated group. Level of interleukin-10 was significantly increased after α-MSH treatment. In addition, gene expression of glutamate aspartate transporter 1, monocarboxylate transporter (MCT) 1 and MCT-2 were significantly higher in animals treated with α-MSH.

Conclusions: α-MSH was associated with reduced severity of I/R induced retinal damage under hyperglycemic condition. In addition, increased amplitudes of b-wave and OPs were observed in animals treated with α-MSH. These beneficial effects of α-MSH may have important therapeutic implications against retinal I/R injury under hyperglycemic condition.

TITLE:

Geographic distribution of astigmatism in pediatric patients of Latin American descent

SESSION TITLE: Pediatric Ophthalmology Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Peskina, R. Weiss, Ophthalmology, Jamaica Hospital Medical Center, Jamaica, New York, UNITED STATES|

Commercial Relationships Disclosure: Marina Peskina: Commercial Relationship: Code N (No Commercial Relationship) | Rebecca Weiss: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose:

Previous research has shown that there is a higher prevalence of astigmatism in Hispanic children compared to Asians, African Americans and Caucasians, but there is no data available evaluating unique characteristics within the pediatric Hispanic population. We performed a retrospective chart review to determine if there is an association among familial country of origin, astigmatism and refractive amblyopia in pediatric patients of Hispanic heritage.

Methods:

The electronic medical records from 10/1/2020 to 9/30/2021 of pediatric Hispanic patients, aged 2-18 years, with regular astigmatism of 1.5 Diopters or more detected by cycloplegic autorefractometry and/or cycloplegic retinoscopy were reviewed. Cycloplegic refraction was obtained with autorefractometry and retinoscopy at least 30 minutes after instillation of tropicamide 1% and cyclopentolate 1% with or without phenylephrine 2.5%. Only the eye with a higher degree of astigmatism that met inclusion criteria was analyzed in the study. Patients were divided into 13 groups based on familial country of origin. Country of origin, visual acuity, degree of astigmatism and presence of amblyopia were analyzed. One-way ANOVA and Chi-square tests were used for statistical analysis.

Results:

A total of 81 patients meeting inclusion criteria were identified. Three patients were excluded due to comorbidities affecting degree of astigmatism or best corrected visual acuity (such as: ptosis, keratoconus, congenital CMV retinitis), and 1 was excluded due to mixed Hispanic heritage. The study group consisted of 42 females and 35 males. Age distribution was positively skewed with a mean of 7.8 years. Majority of patients were from Ecuador, Guatemala, Mexico, and El Salvador. Descriptive statistical analysis showed a tendency towards higher astigmatism in children with parents from Ecuador and El Salvador, but no statistical significance was reached. Statistical analysis showed higher prevalence of amblyopia in children with families from Ecuador, Guatemala, Honduras and El Salvador ($P>0.05$).

Conclusions:

In our study group, pediatric patients with astigmatism from Ecuador, Guatemala, Honduras and El Salvador had a higher prevalence of refractive amblyopia than patients from other Latin American countries.

ABSTRACT BODY:

Purpose: It is difficult for emergency department (ED) providers to evaluate the posterior segment of the eye with their current standard of care tools. We have previously described the use of robotically aligned OCT (RAOCT) to semi-autonomously acquire high-resolution retinal images. As a next step, we utilize deep learning to triage retinal RAOCT images in a general ED population.

Methods: A deep learning model was developed to classify retinal OCT images as referable vs. non-referable for ophthalmology consultation. Using TensorFlow, the model was trained and internally validated on two publicly available datasets (Kermany DS, et al. Cell 2018; Srinivasan PP, et al. BOEx 2014) and images previously captured with our system. For external testing, adult Duke ED patients presenting with suspected posterior eye conditions were consented and enrolled under an IRB-approved protocol and imaged with the RAOCT. For model evaluation, a reference standard was established using a combination of ophthalmology consult diagnosis and OCT image interpretation by two retina specialists. For interpretability, the integrated gradients method was used to generate heatmaps showing areas contributing most to the model classification.

Results: The training and internal validation datasets included 91739 images, of which 60928 were abnormal. The model had a training accuracy of 96% and a validation accuracy of 98%. For external testing, our ED population (RAOCT volumes for 72 eyes of 38 patients; 51% with referable pathology) included a broad range of posterior eye pathologies such as retinal artery occlusion, papilledema, retinal detachment, macular degeneration, and acute retinal necrosis. In this set, the model had an AUC for the detection of referable posterior eye pathology of 0.88, an accuracy of 82%, a sensitivity of 95%, and a specificity of 69% (Fig 1). Areas contributing most to the model classification matched pathologic regions (Fig 2).

Conclusions: An automated OCT-based approach combining robotic OCT imaging and deep learning triage of the images shows promise to help ED providers evaluate patients with potential posterior eye disease.

ABSTRACT BODY:

Purpose: To assess the long-term clinical outcomes of dry eye patients suspected of Sjögren's syndrome (SS) who received serologic testing for three tissue-specific autoantibodies: anti-carbonic anhydrase 6 (CA6), anti-salivary gland protein 1 (SP1), and anti-parotid secretory protein (PSP).

Methods: Medical records between 2014-2019 were reviewed for 316 dry eye patients who presented at a tertiary academic medical center and received serologic testing for tissue-specific antibodies for suspicion of underlying SS. Patients with a minimum of 3 years follow-up included. Conjunctival lissamine green staining, corneal fluorescein staining, Schirmer's test without anesthesia, and tear osmolarity were recorded for the worst eye at baseline and final clinic visits.

Results: A total of 103 patients with a mean follow-up of 54.7 months were included. Forty-four patients (42.7%) tested positive for tissue-specific antibodies at baseline visit (24 positive for anti-CA6, 10 for anti-SP1, and 17 for anti-PSP) and were included in the antibody-positive group. The remaining 59 were included in the antibody-negative group. At baseline, 3 in the antibody-positive group (1 positive for anti-CA6 and 2 positive for anti-PSP) and 7 in the antibody-negative group were diagnosed with SS based on positive anti-SSA and/or positive minor salivary gland biopsy. Prevalence of SS was not different between the tissue-specific antibody-positive versus negative groups at baseline (%7 vs. %12, P>.05). Two additional patients in the antibody-positive group (1 positive for anti-CA6 and anti-PSP and 1 positive for anti-CA6) and 1 in the antibody-negative group were diagnosed with SS during the follow-up (4% vs. 2%, P>.05). Mean values for objective dry eye parameters at baseline and final visit did not show a statistically significant difference between groups regardless of tissue-specific antibody status.

Conclusions: Tissue-specific autoantibodies did not indicate severe dry eye disease in this longitudinal cohort. However, two patients with tissue-specific antibodies developed SS during the follow-up, albeit the sample size was not large enough. Perhaps the follow-up duration was not long enough to suggest that tissue-specific antibodies are early markers for SS. A larger prospective study with a longer follow-up and repeat serological testing is warranted.

TITLE: Corneal toxicity associated with belantamab mafodotin: a case series

SESSION TITLE: Ocular surface health and conjunctiva

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Denisova, J. Kang, Ophthalmology, Montefiore Health System, Bronx, New York, UNITED STATES|R.A. Sica, Oncology, Montefiore Health System, Bronx, New York, UNITED STATES|

Commercial Relationships Disclosure: Ksenia Denisova: Commercial Relationship: Code N (No Commercial Relationship) | Roberto Sica: Commercial Relationship: Code N (No Commercial Relationship) | Joann Kang: Commercial Relationship(s);Code F (Financial Support):Clinical Care Options

ABSTRACT BODY:

Purpose: Belantamab mafodotin is a new treatment for adults with relapsing or remitting multiple myeloma (RRMM). There are few studies characterizing belantamab-induced corneal toxicity. Our goal is to characterize the ocular adverse effects and toxicities in an underserved minority patient population.

Methods: This is a retrospective case series of 6 patients who were treated with belantamab for RRMM from August 2020 to November 2021. Eye examination findings and visual acuity were graded based on the Keratopathy Visual Acuity (KVA) scale by a single examiner at baseline and every 3 weeks for the duration of treatment.

Results: The average age of patients was 58 years. Three were female, 3 identified as Hispanic, and 3 as African-American. No patients had evidence of preexisting keratopathy on baseline exam. All were started on artificial tear drops prior to belantamab therapy. Three patients reported ocular symptoms after starting belantamab, including blurry vision, photopsias, and ocular irritation. Five patients developed Grade 1 keratopathy at 38.6 days and after 2 doses on average. Of those, 3 progressed to Grade 2 keratopathy after 78 days and 3.7 doses. One patient progressed to Grade 3 keratopathy after 73 days and 3 doses. The most common finding on slit lamp exam after treatment was diffuse superficial punctate epitheliopathy (83%), bilateral in all cases except for one. Three patients developed bilateral peripheral microcystic keratopathy and one patient progressed to central involvement (Figure 1). Mean change from baseline logarithm of the minimum angle of resolution UCVA was -0.05 in those with Grade 1 keratopathy, -0.24 for Grade 2 keratopathy, and -0.32 for Grade 3 keratopathy. Four of the 6 patients required dose interruption due to ocular toxicity, after an average of 3.5 treatments. Response to withholding of treatment was not fully evaluated as patients were lost to follow up due to worsening of their disease.

Conclusions: Ocular toxicity occurred in all but 1 patient after starting belantamab, and 4 patients required dose interruption due to ocular toxicity. Worsening keratopathy correlated with decrease in visual acuity. Corneal changes were not always accompanied by symptoms or changes in visual acuity. Given the high frequency and often asymptomatic nature of keratopathy, close monitoring of the cornea and changes in visual acuity is prudent.

ABSTRACT BODY:

Purpose: Substantial loss of retinal ganglion cells (RGC) has been shown in perimetric glaucoma and empirical estimates of RGC count combining structural and functional test results were found to significantly correlate with the histological reports.in early glaucoma. The purpose was to determine whether estimated RGC count mediated the relationships among steady-state pattern electroretinography (ssPERG) and optical coherence tomography (OCT) thickness measures in glaucoma suspects (GS).

Methods: In this prospective cross-sectional study, 10 GS subjects (20 eyes) were recruited at the Manhattan Eye, Ear, and Throat Hospital, with normal Humphrey visual field tests with 24-2 MD better than -2dB, and suspicious optic nerves. Subjects underwent complete eye examinations, OCT, standard automated perimetry (SAP), and ssPERG testing. Two groups of 10 eyes in each, were created based upon clinical data: healthy subjects and GS. RGC counts were estimated using the combined structure-function index (CSFI). We performed mediation analyses with each ssPERG parameter (Magnitude, MagnitudeD and Mag/MagD ratio) as independent variables (X), estimated RGC count as the mediator (M), and average retinal nerve fiber layer thickness (AvRNFLT), mean deviation (24-2 MD), and average ganglion cell layer and inner plexiform layer thickness (AvGCIPLT) as the dependent variables (Y), for a total of nine analyses. For each analysis, the significance of the indirect and direct effects of X on Y were determined using 5,000 bootstrapped samples with a 95% confidence interval (CI).

Results: Estimated RGC count, AvRNFLT, 24-2 MD, and AvGCIPLT were reduced in GS ($p < 0.015$ for all parameters). Pearson and partial (age-adjusted) correlations revealed that all ssPERG parameters correlated with ARNFLT ($r > 0.51$, $p < 0.027$). MagnitudeD/Magnitude (MagD/Mag) ratio correlated with average GCIPLT ($r = 0.47$, $p = 0.042$). Nine mediation analyses revealed that estimated RGC count mediated the relationships among ssPERG parameters, ARNFLT, and average GCIPLT.

Conclusions: Estimated RGC count mediates the relationships between ssPERG parameters and OCT thickness measures in GS, underlying the importance of addressing the RGC dysfunction as early as possible to prevent future structural damage and RGC apoptosis.

ABSTRACT BODY:

Purpose: Retinitis pigmentosa (RP) is a group of clinically and genetically heterogeneous diseases characterized by progressive photoreceptor degeneration. RP can be inherited as many traits, of which X-linked RP (XLRP) is one of the most severe forms of retinal degeneration and mainly caused by the mutations of the retinitis pigmentosa GTPase regulator (RPGR) gene. We reported RPGR mutations encountered in clinic and investigated the potential role of RPGR and the pathogenesis of mutant RPGR via Rpgr knockout mice and cellular experiments.

Methods: Rpgr knockout mice were efficiently established via CRISPR-Cas9 gene editing technique. The phenotype of Rpgr knockout mice was evaluated by fundus photography, optical coherence tomography (OCT) scans, HE staining, Electron microscope (EM), and electroretinogram (ERG). The potential role of RPGR was investigated by RNA-seq,qRT-PCR, immunofluorescence and western blot.

Results: Rpgr knockout mice were generated successfully. Fundus revealed multiple wide-spread yellowish spots which got larger as the increase of mice age in Rpgr knockout mice. OCT scans of Rpgr knockout mice showed thinner outer retina with uniform hyperreflexia as young as 1 mos of age. The ONL thickness of Rpgr knockout mice reduced from 3 mos onward while the total retina thickness reduced from 5 mos onward. HE staining suggested the abnormal hyperreflexia shown in OCT may well be the disorganized outer segment, which was supported by the findings of EM. Scotopic a wave of Rpgr knockout mice was significantly reduced as young as 3 mos of age. However, photopic b wave was still conserved at even the age of 12 months. Compared with male mice, the retina of Rpgr knockout female mice was impaired both structurally and functionally.

Conclusions: We established the model of Rpgr knockout mice with the characterization of progressive photoreceptor degeneration, including disorganized outer segment, thinned ONL and impaired visual function. We also revealed a series of pathophysiological alterations in Rpgr knockout mice, including chronic inflammatory response, endoplasmic reticulum stress (ERS), changes of vascular regulatory factors, etc. Meanwhile, we revealed abnormalities after Rpgr knockdown: including chronic inflammatory response, ERS, dysregulation of vascular regulatory factors, and even retinal degeneration in XLRP.

ABSTRACT BODY:

Purpose: The potential contribution of multigenic variants in persons with Familial Exudative Vitreo Retinopathy (FEVR) remains as one possible factor contributing to the variable phenotypic severity seen even within a family. Understanding the frequency of combinations of protein-altering variants in different FEVR-related genes is an important first step to establishing if multigenic contributions require attention or can be disregarded. To determine the abundance of multigenic protein-altering variants, we employed a novel custom sequencing panel to analyze seven FEVR-related genes in FEVR patient samples.

Methods: Research genetic sequencing of samples from the Associated Retinal Consultants DNA Eye-Bank was approved by the Oakland University IRB. An Ampliseq panel was designed using the Illumina Design Studio. A three-pool PCR option was designed for a final 180 amplicons, 8 genes, 83 exons with 25 bp adjacent intron sequence. Seven FEVR genes and the Retinoschisis gene were included.: NDP (ChrX), CTNNB1 (Chr3); TSPAN12 (Chr7); KIF11 (Chr10), FZD4 (Chr11), LRP5 (Chr11), ZNF408 (Chr11), RS1(ChrX). A cohort of 76 samples comprised FEVR patients and some unaffected relatives. Ampliseq libraries from up to 50 samples were pooled per sequencing run using the Illumin iSeq-100 platform. Variant impacts and allele frequency data were determined from ClinVar and The Genome Aggregation Databases (gnomAD).

Results: 33 protein-altering variants were found with the following distribution: LRP5 13/33 (40%), FZD4 9/33 (27%), ZNF408 6/33 (18%), (KIF11 3/33 (9%), NDP 1/33 (3%), CTNNB1 1/33 (3%). 37% of persons sequenced had di-genic or tri-genic variants that alter protein sequences. The average number of genes with protein-altering variants was greater in samples from confirmed FEVR (1.46, N=30) compared to unaffected persons (0.95, N=20), (p=0.009).

Conclusions: Multigenic protein-altering variants were present in a substantial fraction of FEVR subjects, 37%. While the contributions to disease are unknown for most of the variants in a multigenic context, their greater multigenic frequency in FEVR subjects suggests that potential multiple endothelial gene contributions to variable phenotypes are a possibility that clinics should consider for patients with FEVR / Norrie Disease.

ABSTRACT BODY:

Purpose: Classify the appearance of retinal atrophy and quantify the growth rate in patients who received voretigene neparvovec-rzyl (VN) for RPE65-mediated retinal dystrophy

Methods: Atrophy was qualitatively classified into different subtypes by expert consensus then manually segmented in ImageJ by two graders. Area of atrophy was calculated and fit to linear models of atrophy and square root of atrophy using Python. Main outcome measures were number of eyes, and slopes and coefficients of determination of linear regression models for each subtype of atrophy. Values are reported as mean ± standard deviation.

Results: 20 eyes from 10 patients across 4 centers developed progressive chorioretinal atrophy after subretinal administration of VN. A mean of 4.9 ± 3.0 images per eye obtained over 1.7 ± 0.7 years were reviewed, and atrophy was categorized into touchdown site (8 eyes), perifoveal (13 eyes), and nummular (11 eyes) subtypes (Fig. 1). 10 eyes demonstrated more than one type of atrophy (mixed). All eyes demonstrated atrophy involving the macula.

The growth rate of all atrophy by area and by square root of area was 18.0 ± 11.0 mm^2/year (R^2 0.9 ± 0.1) and 2.6 ± 1.2 mm/year (R^2 0.8 ± 0.2). Growth rates of the atrophy subtypes were 2.0 ± 1.7 mm^2/year (R^2 0.9 ± 0.2) and 0.8 ± 0.4 mm/year (R^2 0.9 ± 0.2) for touchdown atrophy, 17.2 ± 12.5 mm^2/year (R^2 0.9 ± 0.1) and 2.7 ± 1.4 mm/year (R^2 0.8 ± 0.2) for perifoveal atrophy, and 3.8 ± 2.7 mm^2/year (R^2 0.9 ± 0.0) and 1.5 ± 0.4 mm/year (R^2 0.9 ± 0.1) for nummular atrophy (Fig. 2)

Conclusions: Chorioretinal atrophy following subretinal administration of VN for RPE65-mediated retinal dystrophy developed according to a touchdown site, perifoveal, and/or nummular pattern. Perifoveal atrophy trended toward growing the most rapidly whereas touchdown site atrophy trended toward growing the least rapidly. Atrophy growth was more strongly correlated with atrophy area rather than square root of area, in contrast to other causes of macular atrophy such as dry AMD. These findings suggest distinct mechanisms of atrophy development and demonstrate the need for close observation in studies involving other gene therapies using similar vectors.

TITLE: Developing a care delivery framework for older adults with chronic eye disease and vision impairment: A mixed methods study on patient perspectives

SESSION TITLE: Mental Health Outcomes and Vision Rehabilitation Services

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: F. Naufal, X. Guo, J.E. Goldstein, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|C. Kerr-Niermann, University of Missouri-St Louis, St Louis, Missouri, UNITED STATES|

Commercial Relationships Disclosure: Fahd Naufal: Commercial Relationship: Code N (No Commercial Relationship) | Xinxing Guo: Commercial Relationship: Code N (No Commercial Relationship) | Catherine Kerr-Niermann: Commercial Relationship: Code N (No Commercial Relationship) | Judith Goldstein: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To understand the perspective of older adult patients with visual impairment (VI) and develop a framework that integrates eye and supportive health care services.

Methods: Adults ≥60 years recruited between 11/2019-10/2020 with a diagnosis of glaucoma, retina, and/or neuro-ophthalmologic-related disorders participated in an observational mixed-methods study. Eligible participants were identified through an electronic health record-based query using age and ICD-10 diagnostic code criteria for chronic eye diseases; criteria for participation included self-reported difficulty performing everyday activities due to vision loss (functional deficits). All participants completed a questionnaire and a one-on-one interview. We analyzed perspectives on major themes including changes in vision and condition; loss of functional ability; emotional health and healthcare delivery.

Results: Participants (N=65; mean age 73 years; 70% female) had a median visual acuity (VA) of 20/30 in the better eye. Most participants were diagnosed (41.5%) and experienced functional deficits (53.8%), such as reading, driving, or recognizing faces, within the last 1-5 years. Participants reporting VI in both eyes (60%) were more likely to report a longer duration of functional deficits (p_{trend}=0.03). Worse VA nor VI in both eyes were not associated with emotional health concerns or reliance on others for support. Half (53.8%) reported anxiety or depression related to VI; 70.8% required additional support with function. Despite levels of anxiety and depression, few participants (16%) self-identified a need for additional education, or support groups. Half (50.8%) reported that their eyecare provider adequately inquired about emotional status and one-third (33.8%) tended to normalize chronic eye disease, VI and functional loss as an expected outcome of ageing or family history.

Conclusions: A framework for older adults with chronic eye disease and on average mild VI should include identifying and discussing functional and emotional health concerns to determine individual need. Despite high levels of anxiety, depression, and visual function deficits there was limited interest in pursuing supportive services. However, inquiry regarding emotional health by eyecare providers was important to patients.

ABSTRACT BODY:

Purpose: Recent advances in multiphoton fabrication have made the production of complex structures possible and may allow the production of unique ocular models useful in mechanobiological studies. The purpose of this study is to optimize two photon (2P) subtractive fabrication techniques for patient-specific lamina cribrosas (LC) from segmented images.

Methods: For this study, we used multiphoton images of the human LC from a previous study. The segmented second harmonic signal of these images were used to generate the 2P input binary images. 2P subtractive fabrication was executed on a quarter of the LC image using an Olympus BX51 upright laser-scanning microscope (Insight DS+, Spectra Physics, Santa Clara, CA). The laser was centered at 780 nm and electro-spun polycaprolactone (PCL) sheet was used to laser-cut the LC.

Results: Preliminary results show that the human LC can be produced using 2P subtractive fabrication. An image of the fabricated LC is shown in Figure1. Figure 1A shows the LC segmented input image and Figure 1B shows the fabricated LC.

Conclusions: While we are able to produce a portion of a human LC using 2P subtractive fabrication, there are limitations to this technique. While it may be possible to use this technique to generate LC structural alterations in the Z dimension, our current approach is limited as it is currently only able to produce excellent details of the LC in the X-Y plane. Further work is needed to optimize our technique to improve the fabrication of 3D LC structures.

Research reported in this abstract was supported by the National Eye Institute under award number R01EY020890 to JPVG and grant number R01FD006582 (JV Co-I, PI: Feinberg and Badylak).

ABSTRACT BODY:

Purpose: While sleep apnea has been linked as a potential risk factor for several eye diseases, the relationship between obstructive sleep apnea and diabetic retinopathy has been inconsistent. We performed a cross-sectional study to explore the association between obstructive sleep apnea and diabetic retinopathy in the elderly US California (CA) Medicare population.

Methods: This study was conducted among US CA Medicare beneficiaries using the 2019 part B carriers claims databases attained from the Centers for Medicare and Medicaid Services (CMS). The inclusion criteria were patients who were residing in CA during 2019, were 65 years of age or older, had both Medicare Part A and Part B coverages, and had at least one Part B claim in 2019. The exposure was obstructive sleep apnea (OSA) and the outcome of interest was diabetic retinopathy (DR), both of which were defined by the corresponding ICD-10-CM diagnosis codes in any claims. Potential confounders included age, sex, race/ethnicity, and Charlson Comorbidity Index (CCI) scores. Unadjusted associations were performed using chi-squared tests. Multivariable logistic regression models were utilized to assess the adjusted association by controlling for all aforementioned potential confounders.

Results: Among 2,717,346 CA Medicare beneficiaries who met inclusion criteria, 27.9% (759,062) were 65-69 years of age, 56.8% (1,544,479) were female, 62.8% (1,706,807) were white, 4.3% (117,856) were black, 12.8 (346,723) were Asian, 15.9% (430,597) were Hispanic, and 65.6% had a CCI score of 1 or more. The overall prevalence of OSA was 5.9% (161,350), and the overall prevalence of DR was 3.3% (89,693). Those with OSA had an increased odds of DR (adjusted OR=1.54; 95% CI:1.51, 1.58; $p<0.001$) compared to those without OSA.

Conclusions: Our study identified a statistically significant association between obstructive sleep apnea and diabetic retinopathy in the senior CA Medicare population. This finding indicates the need for further studies to analyze the impacts of OSA on DR, such as the severity and development of DR subtypes.

ABSTRACT BODY:

Purpose: Bimatoprost sustained-release intracameral implant (Bimatoprost SR, Durysta, Allergan) was approved by the U.S. Food and Drug Administration for one-time use in patients with ocular hypertension or open angle glaucoma (OAG) in March 2020. The purpose of the present study is to determine real-world outcomes of Bimatoprost SR on intraocular pressure (IOP) and number of IOP lowering medications in patients with glaucoma. A secondary objective is to determine the efficacy of Bimatoprost SR in patients with a prior history of selective laser trabeculoplasty (SLT).

Methods: 122 eyes that received Bimatoprost SR by six glaucoma specialists at Wills Eye Hospital from March 2020 until September 2021 were examined using a retrospective chart review. A paired sample t-test for IOP and a binomial change test for number of medications was used. Multilevel models were then used to determine if statistical significance remained when controlling for demographic variables and prior history of SLT utilizing the lme4 package in R.

Results: Of the 122 eyes, there were 113 OAG, 4 chronic-angle closure, 3 ocular hypertension, and 2 others. 46 (54%) patients were female, and the median age was 78 years old. Mean follow-up time was 26.9 ± 18.9 weeks. 82 (67%) eyes were on a topical prostaglandin medication prior to intracameral Bimatoprost SR injection. 68 (83%) of these eyes stopped topical prostaglandin medication after injection. Mean post-treatment IOP of 16.6 ± 5.3 mmHg was significantly lower than mean pre-treatment IOP of 18.5 ± 5.8 mmHg ($t=-3.50$, $p<0.01$). The average number of medications following Bimatoprost SR was 1.3 ± 1.3, which was significantly lower than the average number of pre-treatment medications of 2.1 ± 1.4 ($p<0.01$). Analysis of multilevel models demonstrated that there was a statistically significant reduction in IOP and number of medications post-treatment even when demographic variables were controlled for ($p<0.01$ for both). A prior history of SLT ($n=54$) had no impact on treatment outcomes for IOP or number of medications, when controlling for demographics ($p>0.1$ for both).

Conclusions: Intracameral Bimatoprost SR reduced IOP and decreased the number of medications. Prior history of SLT did not impact Bimatoprost SR treatment outcomes.

ABSTRACT BODY:

Purpose: To analyze the incidence rates of endophthalmitis after intravitreal injection of the following medications: bevacizumab (BEVA), brolucizumab (BROL), aflibercept (AFL), ranibizumab (RAN), dexamethasone implant (DEXA), and triamcinolone acetonide (TRIA).

Methods: A retrospective cohort study was performed at a private retinal practice in Ohio. The Institutional Review Board (Sterling) determined this study consisted of non-human subjects. All data was collected through the practice management of Retina Associates of Cleveland, Inc. Data was collected from patients who received injections over a 2 year period of AFL, BEVA, BROL, DEXA, TRIA and RAN from January 2020 through November 2021 and includes: patient number, injection service dates, intravitreal drug injected, procedure codes, and primary diagnoses. The rates of endophthalmitis were then compared amongst the different injections. The total percentage of endophthalmitis cases was tabulated as well.

Results: From January 2020 through November 2021, 109,202 injections were administered. The breakdown of the 109,202 injections was as follows: 66,095 AFL, 28,762 BEVA, 8,650 RAN, 3,010 BRON, 1,958 DEXA and 727 TRIA. Of the 109,202 injections, 39 (0.036%) cases of endophthalmitis occurred. Of the 39 endophthalmitis cases, 22 (0.033% of total AFL injections) after AFL injection, 5 (0.688% of total TRIA injections) after TRIA injection, 5 (0.03% of total BEVA injections) after BEVA injection, 3 (0.153% of total DEXA injections) after DEXA injection, 2 (0.066% of total BROL injections) after BROL injection, and 2 (0.023% of total RAN injections) after RAN injection. Using a student’s t-test, the rate of endophthalmitis for TRIA versus all other medications was statistically significant with a p-value of 0.00152.

Conclusions: The results of the study show a total incidence rate of 0.036% of endophthalmitis after intravitreal injection. This review suggests that TRIA yielded a significantly higher incidence rate of endophthalmitis as compared to the other medications.

TITLE: Corneo-sclera collagen fibers exhibit substantial transverse inclination

SESSION TITLE: Glaucoma: biochemistry, biomechanics and omics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F. Ji, M. Quinn, M. Bansal, Y. Hua, I.A. Sigal, University of Pittsburgh, Pittsburgh, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Fengting Ji: Commercial Relationship: Code N (No Commercial Relationship) | Marissa Quinn: Commercial Relationship: Code N (No Commercial Relationship) | Manik Bansal: Commercial Relationship: Code N (No Commercial Relationship) | Yi Hua: Commercial Relationship: Code N (No Commercial Relationship) | Ian Sigal: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Studies of cornea transverse architecture have shown that collagen fibers that are inclined relative to the cornea surface play a crucial mechanical role, increasing stiffness and controlling shape. However, although the sclera spans most of the globe, the extent that its fibers are also transversely inclined remains unknown. Our goal was to quantify collagen fibers transverse inclination over the whole globe.

Methods: Whole-globe sagittal sections from 7 sheep eyes were imaged using previously described polarized light microscopy (PLM) tools to obtain local collagen fiber orientation and density (1.49 μm/pixel). The measured orientations were post-processed to compensate for local tissue orientation introduced by eye shell curvature. Fiber orientation and inclination angle distributions weighted by fiber density were quantified for 15 regions (Fig 1). Each regional inclination angle distribution was then fitted by a gaussian curve, and the inclination angle range was determined from the full width at half maximum (FWHM) (Fig 2).

Results: Posterior pole (PPS, posterior sclera) had less aligned fibers and a wider range of inclination angles than anterior pole (limbus, peripheral/central cornea) and equator ($p<0.001$). Fiber inclinations were substantial in all regions, whereby even the most aligned regions had inclination angle spread by 15 degrees. Results were consistent across eyes.

Conclusions: Fiber inclinations occur across the globe, not just the cornea. Transverse inclinations may represent interweaving or other features of collagen architecture. It seems likely that they play a role in stiffness, strength and shape in the rest of the globe as they do in the cornea.

ABSTRACT BODY:

Purpose: Behçet's disease (BD) is a recurrent multisystem vasculitis associated with a blinding uveitis. The advent of TNF-α inhibitors have significantly improved treatment, however comparative studies between conventional disease-modifying antirheumatic drugs (DMARDs) and biologic DMARDs in BD are limited. As retention time is a measure of drug effectiveness and tolerability, we compared this in patients with BD uveitis.

Methods: Retrospective case review of patients who met the revised International Criteria for Behçet's Disease (ICBD) treated at the Royal Victorian Eye and Ear Hospital, Australia, between 1985–2021. Demographic, ophthalmic and systemic features, DMARD use and reasons for discontinuation were recorded. Retention time was calculated as total days on drug and number of days per person within each DMARD group.

Results: Forty-eight patients (37 males) with a median age of 28.6 years (IQR 25.4–35.0) were followed-up for a median of 7.8 years (IQR 2.6–13.9). At initial presentation, exactly half had bilateral disease (N=24), and of the 62 eyes with uveitis (16 anterior uveitis, 11 intermediate, 2 posterior and 33 panuveitis) the median logMAR visual acuity was 0.176. During the first visit, 33 patients met ICBD criteria, and the systemic manifestations were oral ulcers (N=33), genital ulcers (N=11), skin (N=7), joint (N=6), and vascular (N=1). Corticosteroid sparing agents used were Cyclosporin (CSA, N=24), Mycophenolate (N=22), Azathioprine (N=21), Methotrexate (N=15), Adalimumab (ADA, N=15), Infliximab (IFX, N=2), and Rituximab (RTX, N=1). Total median drug retention time was 1064, 704, 231, 623, and 917 days, respectively, and 44.3, 32.0, 11.0, 41.5, and 61.1 days per person after adjusting for number of patients per drug (not calculated for IFX and RTX due to low use). DMARDs were discontinued 119 times and the reasons for cessation were adverse reaction (N=34), failure of treatment (N=28), poor adherence (N=25), sustained quiescence (N=15), loss to follow-up (N=14), and unclear documentation (N=3).

Conclusions: Our data suggests that the tolerability and efficacy, as measured with retention time, of ADA is at least comparable to, and possibly better than cDMARDs in young males with BD, who often suffer from vision threatening disease at first presentation. Median drug retention time for CSA was longer than ADA but not after adjusting for patients in each DMARD group.

ABSTRACT BODY:

Purpose: To compare the 2- year outcome of half-time photodynamic therapy (htPDT) in chronic central serous chorioretinopathy (cCSC) with or without choroidal neovascularization (CNV)

Methods: This was a retrospective study of 88 eyes from 88 patients with cCSC who underwent htPDT and were followed up for more than 24 months. Patients were divided into two groups with (21 eyes) or without (67 eyes) CNV before htPDT treatment. Best-corrected visual acuity (BCVA), central retinal thickness (CRT), subfoveal choroidal thickness (SCT), and resolution and recurrence of subretinal fluid (SRF) were evaluated at baseline and 1, 3, 6, 12, and 24 months after PDT.

Results: There was a significant difference in age between the two groups ($P < 0.01$). A significant improvement in the BCVA was found at all time points in eyes without CNV but only at 24 months after htPDT in eyes with CNV. There were significant differences in BCVA between groups at any time points. CRT was significantly reduced in both groups at all time points with no significant intergroup differences. A significant reduction in the SCT was found at all time points in the eyes without CNV, but only at 1 and 24 months after htPDT in the eyes with CNV. There were significant differences between groups in the rate of recurrent and persistent SRF ($P=0.013$ and $P=0.017$, respectively). Multivariate analysis revealed that the presence of CNV was significantly associated with recurrence and persistence of SRF after initial PDT ($P=0.012$ and $P=0.023$, respectively). Logistic regression analysis showed that baseline BCVA, not the presence of CNV, was significantly associated with BCVA at 24 months after initial PDT ($P<0.01$).

Conclusions: A htPDT for cCSC was less effective in eyes with CNV than without CNV regarding the recurrence and the persistence of SRF. Additional treatment might be required in eyes with CNV during 24-months follow-up periods.

ABSTRACT BODY:

Purpose: To evaluate and compare distance and near visual acuity, spectacle independence, and visual disturbances of the trifocal intraocular lens Acrysof Panoptix and the extended-depth-of-focus lenses Acrysof Vivity, Tecnis Eyhance, and Tecnis Symfony.

Methods: One hundred and twenty-seven eyes of 68 patients who underwent bilateral or unilateral cataract surgery with implantation of the non-toric or toric Acrysof Panoptix, Acrysof Vivity, Tecnis Eyhance, and Tecnis Symfony IOL between 2019 and 2021 were included in this retrospective study. Eyes with pre-existing ocular comorbidities were included in this study and 23 eyes undergoing concurrent glaucoma surgery. Pre- and postoperative corrected visual acuities, spectacle independence and visual disturbances were collected and analyzed. Descriptive statistics (mean and standard deviation) were calculated for all visual acuities. Comparison of more than two groups was performed using the Kruskal-Wallis test, non-parametric type of the one-way analysis of variance, and Chi-squared test. P values of 0.05 or less were considered to be statistically significant in all cases.

Results: No statistically significant differences were noted in the best corrected distance visual acuity (BCDVA) after surgery between the cohorts (p-value = 0.3302, Kruskal-Wallis test $p<0.05$). However, there was a significant difference between the best corrected near visual acuity (BCNVA) after surgery between the four cohorts ($p=0.00497$, Kruskal-Wallis test, $p<0.05$). The Symfony lens had the best average BCNVA. There was no statistical difference for spectacle independence at distance between the cohorts ($p = 0.247$; Chi-squared test $p<0.05$). However, the rate of spectacle independence at near between the four cohorts was significantly different (the p-value is < 0.00001, Chi-squared test) and Panoptix has the greatest proportion of spectacle independence. There wasn't a significant difference between the cohorts in regards to visual disturbances (p-value =.06127, Chi-squared test $p<0.05$)

Conclusions: All lenses were similarly effective in visual acuity and spectacle independence with minimal visual disturbances at distance. However, at near, each lens has its own advantages and disadvantages and the preference of each patient should be considered when selecting a trifocal or extended-depth-of-focus lens.

ABSTRACT BODY:

Purpose: The hyper-parallel optical coherence tomography (HP-OCT^{TM}; Cylite, Melbourne, Australia) is a novel platform that uses a light source-splitting micro-lens array to allow for the rapid capture of whole-eye volumetric scans and resulting biometry measurements, with minimal artifact from patient movement. In this pilot study we compared the HP-OCT with the Argos (Santec Corporation, Komaki, Japan) swept-source OCT biometer to compare biometry measurements in patients with mature cataracts.

Methods: Patients with mature cataracts underwent 3 repeat measurements on both the HP-OCT and the Argos biometer. Axial length (AL), anterior chamber depth (ACD), central corneal thickness (CCT), lens thickness (LT), white-to-white distance (WTW), and mean keratometry (K) measurements were compared between the two biometers. Statistical analysis was performed using paired t-tests and Pearson's correlation coefficient.

Results: 21 eyes of 17 patients were measured. Mean AL measured by HP-OCT was 24.61±1.54 mm and by Argos 24.59±1.49 mm ($p=0.34$), with $r= 0.99$ ($p< 0.001$). Mean keratometry values were also similar ($p=0.21$), measuring 43.20±1.94 diopters and 43.31±2.08 diopters for the HP-OCT and Argos, respectively ($r=0.98$, $p<0.001$). ACD was 3.21±0.43 mm (HP-OCT) and 3.33±0.37 mm (Argos), $p < 0.002$, with $r=0.93$ ($p<0.0001$). CCT was 514.22±48.71 µm (HP-OCT), and 511.31±47.80 µm (Argos), $p=0.19$, with $r=0.98$ ($p<0.0001$). LT was 4.65±0.42 mm (HP-OCT) and 4.75±0.40 mm (Argos), $p <0.017$, with $r=0.91$ ($p<0.0001$). WTW was 11.24±0.73 mm (HP-OCT) and 12.43±0.69 mm (Argos), $p<0.0001$, with $r=0.44$ ($p=0.046$).

Conclusions: The HP-OCT and Argos biometers showed excellent correlation and similar measurements for axial length, mean keratometry, and CCT values. Statistically significant differences were seen in ACD, LT, and WTW measurements between the two biometers. Larger studies are necessary to further evaluate the agreement between the HP-OCT and Argos biometers.

ABSTRACT BODY:

Purpose: The EviRed project aims to improve the management of diabetic retinopathy (DR), by taking advantage of new imaging modalities and artificial intelligence. In this study, we investigate the fusion of different modalities acquired simultaneously with a PLEX® Elite 9000 (Carl Zeiss Meditec Inc. Dublin, California, USA), namely 3-D structural optical coherence tomography (OCT), 3-D OCT angiography (OCTA) and 2-D Line Scanning Ophthalmoscope (LSO), for the automatic detection of proliferative DR.

Methods: 151 OCT volumes from 64 diabetic patients were collected for the study. This collection was divided as follows: 88 acquisitions (from 31 patients) for training, 28 acquisitions (from 14 patients) for validation and 35 acquisitions (from 19 patients) for testing. DR severity level, according to the ICDR scale, was graded by a retina specialist using fundus photographs: 30 acquisitions (including 16 in the train set, 5 in the validation set and 9 in the test set) had proliferative DR. Three fusion methods were evaluated: Early Fusion, Intermediate Fusion and Hierarchical Fusion. For each method, the following backbones were investigated: Resnet50, Resnet101, Densenet121, and Densenet169. We used the Area under the ROC Curve (AUC) to assess classification performance. These fusion methods were compared to the classification of a single modality separately.

Results: Using a single modality, the structure data achieved the best performance: AUC reaches 0.859 using Resnet101; this is our baseline. The Flow data reached an AUC of 0.816, using Densenet169. The LSO data reached an AUC of 0.662, using Densenet121. Hierarchical fusion achieves the best results, AUC reaches 0.911 using Densenet121, with an increase in AUC of over 0.052 compared to baseline. While the AUC increase for Early Fusion, on Densenet121, was around 0.006. Intermediate Fusion on Densenet121 performed worse than baseline.

Conclusions: The results show the effectiveness of our multimodal fusion method for proliferative DR detection. Hierarchical fusion method is currently showing good results: in particular, it outperforms the detection in a single modality. However, these experiments will have to be replicated in a larger dataset to achieve clinically useful detection performance.

TITLE: Heterochromatin suppresses oxidative stress-induced cGAS and STING expression in mouse RPE and retina

SESSION TITLE: Biochemistry and Molecular Biology of the Retina/RPE

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W. liu, Z. Ming, R. Qi, Q. Ke, X. zhu, D.W. Li, L. Gong, ZhongShan Ophthalmic Center,Sun Yat-sen University, Sun Yat-Sen University, Guangzhou, Guangdong, CHINA|

Commercial Relationships Disclosure: wei liu: Commercial Relationship(s);Code F (Financial Support):National Natural Science Foundation of China (Grants 82070969, 81970787) ;Code F (Financial Support): Natural Science Foundation of Guangdong Province of China (2021A1515011793) | Zou Ming: Commercial Relationship: Code N (No Commercial Relationship) | Ruili Qi: Commercial Relationship: Code N (No Commercial Relationship) | Qin Ke: Commercial Relationship: Code N (No Commercial Relationship) | xingfei zhu: Commercial Relationship: Code N (No Commercial Relationship) | David Li: Commercial Relationship: Code N (No Commercial Relationship) | Lili Gong: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Heterochromatin is a highly compact, transcription inert chromatin status. cGAS and STING are two key components mediating innate immune response, and are recently shown contributes to geographic atrophy (GA) . After analyzing the published transposase-accessible chromatin sequencing (ATAC-Seq) datasets , we found that STING gene loci exhibited decreased chromatin compaction in RPE of the GA patient. Therefore, we are aimed to investigate whether heterochromatin may regulate cGAS and STING expression upon oxidative stress

Methods: The in vivo oxidative stress was induce by intraperitoneal injection of sodium iodate (SI, 10-70 mg/kg). cGAS and STING expression were determined by qRT-PCR and western blot (WB) analysis in control (PBS-injected) or SI-injected mouse retina and RPE. Retina and RPE structure were asses by immunofluorescence and HE staining. cGAS and STING chromatin accessibility was assessed by the micrococcal nuclease (MNase) digestion assay. The in vivo effects of heterochromatin on cGAS and STING expression were determined in CBX5 knockout mice, in which the heterochromatin structure protein HP1α was depleted.

Results: Both cGAS and STING RNA and protein were upregulated in a dose-dependent manner in mouse retina and RPE. Decreased chromatin compaction were detected in both cGAS and STING gene loci upon SI injury. Increased cGAS, STING and the downstream IL6 and IL1β expression were detected in CBX5 knockout mice retina after SI injection. Depletion of this heterochromatin structure protein led to more severe retina destruction and IBA1-positive immune cell infiltration upon SI injury.

Conclusions: Heterochromatin represses cGAS and STING expression during oxidative injury. Our results suggest a potential role for targeting heterochromatin in the treatment of age-related macular degeneration (AMD).

ABSTRACT BODY:

Purpose: To compare standardized Early Treatment Diabetic Retinopathy Study (ETDRS) best corrected visual acuity (BCVA) and nonstandardized Snellen visual acuity (VA) among subjects enrolled in clinical trials.

Methods: Retrospective multi-center study of subjects enrolled in prospective clinical trials. Best available Snellen VA at the last visit before entering the study and the first visit after exiting the study was compared with the ETDRS BCVA at trial initiation and conclusion. The correlation and discrepancies between Snellen VA and ETDRS methods were evaluated.

Results: A total of 273 eyes were included. Mean Snellen VA was 20/71 (median 20/50, range 20/2000-20/20) at the visit before study entry while mean ETDRS BCVA was 20/49 (med. 20/42, ran. 20/914-20/13) at study entry (mean difference, 8.5 ETDRS letters,$p<0.001$). Mean ETDRS BCVA was 20/39 (med. 20/32, ran. 20/693-20/11) at study exit while mean Snellen VA was 20/62 (med. 20/50, ran. 20/6324-20/15) at the next visit after study exit (mean diff, 10 ETDRS letters,$p<0.001$). The worse the baseline VA, the greater the discrepancy between ETDRS and Snellen ($p<0.001$).

No significant difference in VA change from study entry to exit was found when comparing ETDRS (5 letter gain) and Snellen (3.3 letter gain) methods ($p=0.063$). In 184 (67.4%) eyes, ETDRS and Snellen changed concordantly while in 89 (32.6%) eyes, ETDRS and Snellen changed discordantly. In eyes changing discordantly, 70 (78.7%) improved with ETDRS but worsened with Snellen, while 19 (21.3%) worsened with ETDRS and improved with Snellen. In eyes with concordant vision gain, mean VA change was 12.6 letter gain for ETDRS and 16.8 letter gain for Snellen ($p=0.01$,$n=120$). In eyes with concordant vision loss, mean VA change was 10.4 letter loss with ETDRS and 15.1 letter loss with Snellen ($p=0.04$,$n=64$). In eyes with discordant visual change, mean VA change was 5.8 letter gain for ETDRS and 1.7 letter loss for Snellen ($p<0.001$).

Conclusions: ETDRS BCVA methods produce higher VA scores compared to Snellen VA, especially in patients with worse vision. Snellen may be underestimating VA change when there is a discrepancy in direction of VA change. When Snellen and ETDRS change in the same direction, Snellen may be overestimating VA change. This may have implications for interpreting real world VA outcomes compared to clinical trials.

ABSTRACT BODY:

Purpose: Extracellular vesicles (EVs) are representators of the cellular microenvironment and mediate intercellular communication and pathogenesis. Here, we investigate the protein topology of EVs derived from C57BL/6 murine model of P. aeruginosa endophthalmitis with an aim to understand the pathobiology of the disease.

Methods: Endophthalmitis was induced by intravitreal injection of Pseudomonas aeruginosa in C57BL/6 mice followed by enucleation at 24 hours. EVs were extracted by ultracentrifugation, characterized by DLS and western blotting with tetraspannin markers, CD9 and CD81, and quantified by ExoCet quantification kit. EVs were trypsin digested and subjected to LC-MS/MS. The proteins were analysed for its biological process and protein class by Gene Ontology (GO) and identification of enriched pathways by Kyoto Encyclopedia of Genes and Genomes (KEGG). Statistical analysis was performed by Unpaired t-test and all values represent mean ± SD for 3 biological replicates per time point.

Results: DLS and western blot confirmed the presence of EVs having a mean diameter of 332.2±93nm in infected eyes, while the EVs from the control set was 362±40 nm. Total number of EVs in infected eyes was $1.5X10^{10}$ ($\pm 2.6X10^{9}$), compared to $6.8X10^{9}$ ($\pm 3.6X10^{9}$) in control eyes. Proteome analysis of these EVs identified 2010 proteins (FDR ≤0.01) in infected eyes, of which 131 were differentially expressed (DEPs) (P-value ≤0.05). A total of 101 proteins were upregulated and 36 were downregulated while 55 proteins were found to be unique to the infected set. KEGG and GO analysis revealed presence of Cav1, Cav2, Coronin 1A, Integrin β, Protein kinase C, Tubulin-α, Tubulin-β, Complement C8, G-protein signalling 9 and IL-17 in EV from infected eyes. While Cav1 and Cav2 are reported to regulate inflammatory response of the host, Calnexin, prolactin induced protein and thioredoxin-related transmembrane protein-1 were present significantly in the infection set, suggesting a major role in host immunity and protection against microbial infections.

Conclusions: This study is the first attempt to comprehensively investigate the global proteome of EVs derived from mice model of P. aeruginosa endophthalmitis. The EV proteins Cav1, Cav2, Coronin 1A, Integrin β, type I keratin are known mediators of pathogenesis and are most suitable to study them as potential prognostic markers for endophthalmitis.

ABSTRACT BODY:

Purpose: To determine the age of disease onset and the degree to which viral mediated gene therapy can rescue cone function in a nonhuman primate model of an inherited cone disorder.

Methods: Infant rhesus macaques homozygous for the PDE6C R565Q mutation were generated through a selective breeding program at the California National Primate Research Center (CNPRC). Their genotypes were confirmed by genetic sequencing in the first few months of life. At age 9 months, two of the homozygous animals were treated in the right eye with either a high (1.5×10^{11} vg/eye) or low (1.5×10^{10} vg/eye) dose of adeno-associated virus (AAV5) carrying the rhesus macaque PDE6C gene under the control of the PR1.7 cone-specific promoter. The left eye was used as a control. Animals were tested in each eye by full-field and multifocal electroretinography (ERG) before and after injection. Behavioral testing was performed to assess visual acuity and color perception.

Results: All offspring homozygous for the PDE6C R565Q mutation had an absent cone signal and foveal autofluorescence abnormalities from early infancy. Subretinal injection in infant macaques was successfully accomplished. The virus was given along with systemic corticosteroids and was found to be safe without significant inflammation or toxicity. There were no obvious alterations in retinal lamination or cell loss in treated eyes. The therapeutic virus transduced retinal cells very efficiently and was expressed specifically in cone photoreceptors. Eyes treated with the high dose of the virus exhibited mild inflammation that was controlled with corticosteroids. The high dose restored cone responses on ERG within one month of injection. The responses were sustained and durable for at least 6 months without evidence of decline. Chromatic ERG testing showed restoration of amplitudes in all three cone subtypes. Behavioral testing to assess visual acuity and color perception is in progress.

Conclusions: AAV-mediated gene therapy for PDE6C was safe in the nonhuman primate model. It effectively restored cone function in all cone subtypes. Treated animals had durable restoration of the cone signal on ERG. These results suggest similar approaches in human patients may warrant investigation.

ABSTRACT BODY:

Purpose: To evaluate the effect of topical bromfenac on macular thickness after vitrectomy or phacovitrectomy for epiretinal membrane (ERM).

Methods: Medical records of consecutive patients aged ≥50 who had undergone vitrectomy or phacovitrectomy for ERM removal by a single surgeon from January 2015 to December 2018 were retrospectively reviewed. Phacovitrectomy was performed in all phakic eyes and vitrectomy alone was performed in all pseudophakic eyes. Each group (phacovitrectomy or vitrectomy) was further subdivided into two subgroups according to use topical bromfenac (bromfenac versus none), resulting in a total of four subgroups: Phacovitrectomy-Bromfenac, Phacovitrectomy-None, Vitrectomy-Brofenac, and Vitrectomy-None. Cystoid macular edema (CME) was defined as an increase in macular thickness of 30 μm or greater at the one-month postoperative visit compared to that at baseline. Changes of macular thickness and visual acuity were analyzed for 3 months after the ERM removal.

Results: The four subgroups, Phacovitrectomy-Bromfenac, Phacovitrectomy-None, Vitrectomy-Bromfenac, and Vitrectomy-None included 56, 158, 11, and 42 patients, respectively. CME occurred in 13.6% of the Phacovitrectomy group, which was higher than 1.9% of the Vitrectomy group ($p<0.001$). Comparing among various subgroups, CME occurred in 17.7% of the Phacovitrectomy-None subgroup, which was higher than 1.8% of the Phacovitrectomy-Bromfenac subgroup ($p=0.001$). Macular thickness significantly decreased at 1 month after the ERM removal in all subgroups except the Phacovitrectomy-None subgroup.

Conclusions: CME rarely (1.9%) occurred after the vitrectomy for ERM removal in pseudophakic patients. While not uncommon after phacovitrectomy (13.6%), incidence of CME may be reduced by topical bromfenac. A trigger of Irvine-Gass syndrome may be crystalline lens removal itself rather than inflammation due to intraocular surgery or surgical trauma.

ABSTRACT BODY:

Purpose: To investigate specialized pro-resolving lipid mediator (SPMs) as neuroprotective interventions to ameliorate neuroinflammation, mitigate tissue damage, and preserve visual function after blast exposure. We hypothesized that early administration of the SPMs, NPD1 or MaR1, will preserve visual function in a blast-induced eye injury model by mitigating injurious processes.

Methods: A compressed-air driven shock tube was used to expose anesthetized adult male Long-Evans rats to shock waves simulating an open-field blast exposure. Blast waves of peak overpressure of 133 ± 4 kPa and a positive phase duration of 3.34 ± 0.05 ms were used. The overpressure specific impulse was 163.5 ± 10.4 kPa-ms. Anesthetized rats were exposed to a blast wave. Approximately 30 minutes after blast exposure, rats were treated with either 1.0 µg/kg MaR-1, 0.1 µg/kg NPD1 or vehicle (0.9% saline) delivered via tail vein injection and treated daily thereafter until day 7. Unexposed rats were included as controls. Visual function was assessed using a UTAS BigShot workstation (LKC Technologies) at pre-blast and 8-, 22-, and 32-days post-blast timepoints. This initial analysis is based on the scotopic ERG response, using the Vmax and Km parameters obtained by fitting the Naka-Rushton equation to the scotopic V-LogI curve. Pre- and post-blast statistical analysis was done with ANOVA and Bonferroni multiple comparisons.

Results: The Naka-Rushton function yields an objective measure of Vmax (the maximum response of the ERG rod branch) and the Km (the stimulus intensity at half-maximal response). In rats exposed to the blast wave only, Vmax was reduced up to 25% by day 30 post-blast, compared to the pre-blast average ($p \approx 0.003$). In the blast-exposed and vehicle treated rats, Vmax was depressed up to 50% (p=0-.001) and Km was elevated (p=0.003), indicating reduced visual sensitivity. In the animals exposed to blast and treated with either MaR1 or NPD1, there was no significant change ($p > .0.05$) in the Vmax or Km, indicating maintained visual sensitivity.

Conclusions: Blast wave exposure resulting in retinal damage, manifested by loss of rod sensitivity, was mitigated by either MaR-1 and/or NPD1 intervention. Thus, the treatments of MaR1 or NPD1 suggest an effective strategy to preserve visual function due to retinal and optic nerve injuries following ocular blast trauma.

ABSTRACT BODY:

Purpose: Geographic atrophy (GA) secondary to age-related macular degeneration is a progressive disease with irreversible loss of visual function. Artificial intelligence (AI)-algorithms are able to monitor disease progression on an individual level. The aim of this study was to investigate the predictive power of AI for GA progression in comparison to retinal expert judgement.

Methods: The set-up of the study consisted of three rounds with two weeks of breaks to prevent memorization, each round entailing two tasks: 1) Experts had to sort GA progression into three subgroups based on anticipated growth rates: slow, intermediate and fast, with a square root growth of <0.2mm, 0.2-0.4mm and >0.4mm, respectively. 2) Experts selected the faster growing case out of two cases. The first round comprises baseline fundus autofluorescence (FAF), the second infrared (IR) and optical coherence tomography (OCT) and the third FAF, IR and OCT images. To compare AI prediction with human experts, FAF annotations of GA performed by a centralized reading center were employed as the reference. For the first task, accuracy and Kappa index between predictions and ground truth were evaluated. For the second task, the concordance index was calculated.

Results: A total of 134 eyes from 134 patients from a phase II clinical trial (FILLY, Apellis) were included, among those 53 were from sham arm and 81 from fellow eyes. Four retinal experts evaluated 120 eyes and 120 eye pairs for respective tasks in each round, resulting in 2880 human gradings. The experts on average reached accuracy of 0.37, 0.43, 0.41 and a Kappa index of 0.05, 0.14, 0.12 on FAF, IR+OCT and FAF+IR+OCT, respectively. On the second task experts achieved a concordance index of 0.62, 0.59 and 0.60. The AI was able to reach an accuracy of 0.48 and Kappa index of 0.21 on the first task, and concordance index of 0.69 on the second task solely utilizing OCT imaging.

Conclusions: Prediction of lesion growth will become an important task for future patient counselling, most importantly after treatments become available. Human gradings improved when the estimation was based on OCT features. However, AI performs this task in a superior manner compared to human experts. AI-supported decisions will guide future management and improve patient care in one of the leading causes for irreversible loss of vision.

ABSTRACT BODY:

Purpose: According to the Colorblind awareness organization, color vision deficiency (CVD) affects 1 in 12 men (8.3%) and 1 in 200 women (0.5%) globally. In India (Kundu et al., 2020), the overall prevalence of CVD is 3.89% in males, followed by 0.18% in females. However, most cases are undiagnosed and only detected in screening programmes or during work empowerment. Besides this, CVD patients experience multiple difficulties in day-to-day life. The current study aimed to investigate the quality of life in a sample of CVD patients in India and how color vision impairment affects them psychologically, economically, and work-productivity wise.

Methods: This descriptive and cross-sectional questionnaire study was conducted on N=44 diagnosed CVD patients (male=36 and female=8) who visited two eye hospitals in the Hyderabad region between 2020 to 2021. The comparison group included a age matched control group of normal color vision (normal CV) participants (N=12). In the current study, we validated and used a Telugu version of a questionnaire (CVD-QOL) which was developed and validated by Barry et al. in 2017 for CVD patients. In this study, Color vision was assessed by Ishihara color vision test. The questionnaire consists of twenty-three questions on Likert scale with variables (Lifestyle, Emotions and Work). Six-point Likert scale was used, with lower scores indicating worse quality of life (1=severe problem to 6=no problem).

Results: Data analysis included 66 participants (CVD= 44 and normal CV= 12). Shapiro Wilk normality test resulted in normal data distribution. The mean age of participants did not show ($p=0.064$) a significant difference between the groups. There was a significant difference between CVD and normal CV participants for Color vision score ($p<0.001$). There was also a significant difference between the groups for the CVD-QoL variables, Lifestyle ($p<0.001$), Emotions ($p<0.001$) and Work ($p=0.027$) The results are shown in Table-1. The group differences among gender revealed that men tend to be more psychologically weaker in facing CVD than women.

Conclusions: This study results revealed that color vision deficiency has a significant impact on the quality of life in this sample of Indian population. The mean scores on the questionnaire for Lifestyle, Emotions and Work was much lower than the UK sample (Barry et al. 2017) indicating that there was a higher impact of CVD on these domains in this population.

SUBMITTER (NAME ONLY): Suh-Hang Juo

TITLE: The clinical applications of anti-microRNA-328 therapy in myopia control and dry eye disease

SESSION TITLE: Vision Impairment, Visual Function, and Quality of Life

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.H. Juo, China Medical University, Taichung, TAIWAN|C. Liang, Bright Eyes Clinic, TAIWAN|J. Chen, W. lai, Kaohsiung Veterans General Hospital Department of Ophthalmology, Kaohsiung, TAIWAN|

Commercial Relationships Disclosure: Suh-Hang Juo: Commercial Relationship(s);Code O (Owner):Dreamhawk Vision Biotech, Inc.; Sunhawk Vision Biotech, Inc. | Chun-Ling Liang: Commercial Relationship(s);Code O (Owner):Dreamhawk Vision Biotech, Inc.; Sunhawk Vision Biotech, Inc. | Jiunn-Liang Chen: Commercial Relationship: Code N (No Commercial Relationship) | Wei-Yu lai: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We previously reported that over-expression of miR-328 in the retina and sclera as a novel risk factor for myopia. Our recent study showed that corneal miR-328 also leads to dry eye disease. The present report is to show the first-in-human clinical trial of anti-miR-328 oligonucleotide in healthy subjects.

Methods: Several anti-miR-328 oligonucleotides were synthesized and tested in both in vitro and in vivo models. The candidate oligonucleotide, called SHJ002, was selected based on its anti-sense effect and safety data. SHJ002 was formulated as an ophthalmic solution for topical instillation. SHJ002 was used for good-laboratory-practice (GLP) toxicity studies via ocular instillation and systemic IV injection. With sufficient pre-clinical results and satisfactory safety data, we filed the investigational new drug (IND) application to both US and Taiwan FDA for a first-in-human clinical trial. The clinical trial recruited pediatric subjects with mild to moderate myopia. For each study subject, one eye was randomly selected to receive one eye drop, and the fellow eye was not treated. The initial 3 subjects were assigned to the dose-escalating study, where 3 different doses were sequentially tested for tolerability. The highest tolerable dose was used for 28 days in another 9 subjects to test the safety of SHJ002 ophthalmic solution.

Results: The SHJ002 ophthalmic solution was produced by a good manufacture practice (GMP) manufacturer, and it has very good stability under 4^{o}C and 25 ^{o}C. The toxicity studies did not observe any adverse effects via systemic or ocular topical administration. Both US and Taiwan FDA approved the IND application for a phase-I trial in pediatric subjects. In the clinical trial, all 3 different doses were well tolerated, and accordingly the highest dose was selected for a 28-day treatment. The results show that SHJ002 was well tolerated and no adverse effect was reported in the treated eyes. Although punctate keratitis was reported in one non-treated eye during the study period, this event was judged not-drug related and it was transient and spontaneously resolved before the end of this study.

Conclusions: This is a first-in-class ophthalmic drug for myopia control and dry eye disease. The phase-I data demonstrate its safety and high tolerance. The phase-II trials will be conducted to test its efficacy in controlling pediatric myopia and treating dry eye disease in adults.

Commercial Relationships Disclosure: Noriko Kubota: Commercial Relationship: Code N (No Commercial Relationship) | Joanna Kempska: Commercial Relationship: Code N (No Commercial Relationship) | Kensuke Shima: Commercial Relationship: Code N (No Commercial Relationship) | Paula Enzian: Commercial Relationship: Code N (No Commercial Relationship) | Svenja Sonntag: Commercial Relationship: Code N (No Commercial Relationship) | Jan Rupp: Commercial Relationship: Code N (No Commercial Relationship) | Salvatore Grisanti: Commercial Relationship: Code N (No Commercial Relationship) | Ralf Brinkmann: Commercial Relationship: Code N (No Commercial Relationship) | Yoko Miura: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Mitochondrial uncoupling is one of the intrinsic cellular functions that directly modifies the energy metabolism of the cell. It induces hyperactivation of mitochondrial respiration by interfering with the proton gradient. Recent studies have shown that mitochondrial uncoupling is also closely associated with the maintenance of various cellular functions, such as antioxidative stress. In this study, the influence of mitochondrial uncoupling on fluorescence lifetime (FLT), the possible indicator of metabolic change, of ex-vivo retinal pigment epithelial (RPE) cells was investigated.

Methods: RPE/choroid-explants from freshly enucleated porcine eyes were maintained in static culture conditions and incubated with or without mitochondrial uncoupler, carbonyl cyanide 4-(trifluoromethoxy) phenylhydrazone (FCCP), for; (1) 24 hours under 5% CO_2 at 37°C, and then FLT was measured once, or (2) 70 minutes in a custom-made chamber for FLT measurement at room temperature, during which FLT measurements were repeated several times. The sublethal FCCP concentration was determined in advance by calcein-AM assay, and the experiments were conducted with 0.6 µM FCCP. The respiratory function of ex-vivo RPE exposed to FCCP was confirmed with Seahorse metabolic analyzer. FLT was measured with Fluorescence Lifetime Imaging Ophthalmoscopy (FLIO, excitation at 473 nm, Emission: short spectral channel (SSC) for 498-560 nm, long spectral channel (LSC) for 560-720 nm).

Results: Calcein-AM assay showed that FCCP less than 10 µM did not significantly increase the death of RPE cells after 24h of incubation. FLIO results indicated that the RPE explants incubated with FCCP for 24 hours had significantly shorter mean FLT (τ_m) than those of explants without FCCP in SSC (252.7 ± 5.5 ps vs. 279.6 ± 6.7 ps, $p<0.05$). In the time course measurement of the FLT, larger decrease in τ_m was observed in FCCP-treated RPE than non-treated ones. Mitochondrial assay indicated the rapid increase of oxygen consumption rate of ex-vivo RPE by treatment of 0.6 µM FCCP.

Conclusions: Results suggest that the enhanced mitochondrial uncoupling may shorten FLT of the RPE and this could be detected by FLIO. We assume that this is due to the increased activity of fluorescent co-factors associated with the respiratory function. For treatments that may activate endogenous uncoupler, FLIO might be a useful tool to evaluate their efficacy.

ABSTRACT BODY:

Purpose: We are developing a gene therapy approach, in which autologous pigment epithelial cells will be genetically modified to overexpress the anti-angiogenic Pigment Epithelium-Derived Factor (PEDF) using the Sleeping Beauty (SB100X) transposon system to treat neovascular Age-Related Macular Degeneration (nvAMD). We compared the long term hPEDF expression and secretion from primary RPE cells transfected directly after isolation (“freshly isolated”) or after ≥3 weeks of culture (“pre-cultured”) from different species and their usability in preclinical efficiency studies.

Methods: Human (h), porcine (p) and rabbit (r) RPE cells were transfected using the Neon Transfection System with 0.03 and 0.47µg of the SB100X transposase and the pFAR4-ITRs CMV PEDF BGH miniplasmid, seeded (n=5) with 10k (pre-cultured) or 50k (freshly isolated, pre-cultured) cells; and cultured in DMEM/Ham’s 12 with 10% (pre-cultured) or 20% FBS (freshly isolated) until confluence (reduction to 1% FBS). PEDF expression and secretion were monitored with RT-PCR and ELISA. Cultures were maintained and analyses performed every 3 weeks until cells detached.

Results: pRPE and hRPE cells grew normal for up to 252d, while rRPE start to detach around 90d. We saw significant differences in PEDF gene expression at 82d with low expression in pre-cultured rRPE cells (10k=5.9k; 50k=12.0k fold change) compared to freshly isolated rRPE (50k=467.2k fold change) and pre-cultured pRPE (10k=67.7k; 50k=431.3k fold change); hRPE RT-PCR is ongoing. PEDF secretion differed significantly between species (p=0.037) with following amounts of PEDF for 10k pre-cultured cells: rRPE=1.2±2.5; pRPE=4.6±6.5; hRPE=32.5±93.5ng/h/10^4cells; 50k pre-cultured cells: rRPE=3.9±3.7; pRPE=4.9±5.0; hRPE=8.7±15.2 and 1.2±1.6ng/h/10^4cells for freshly isolated hRPE cells. Gene expression did not differ significantly between species and did not correlate well to protein expression and though hRPE were the most fragile cells, their PEDF secretion was highest.

Conclusions: Summarized, pRPE cells can be transfected similarly efficient as hRPE and are a suitable long-term efficiency model, differentially to rRPE that are not viable in long-term culture. Differences between 10 and 50k cells seeded are not significant and a high gene expression does not necessarily mean high protein secretion.

SUBMITTER (NAME ONLY): Maya Eiger-Moscovich

TITLE: BAP1 immunohistochemistry in post-brachytherapy uveal melanoma

SESSION TITLE: Not all who wanders is lost - Prognostication, diagnosis, and treatments of ocular tumors

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: M. Eiger-Moscovich, Ophthalmology, Hadassah Medical Center, Jerusalem, Jerusalem, ISRAEL|C.L. Shields, Ocular Oncology Service, Wills Eye Hospital, Philadelphia, Pennsylvania, UNITED STATES|R.C. Eagle Jr., T. Milman, Pathology, Wills Eye Hospital, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Maya Eiger-Moscovich: Commercial Relationship: Code N (No Commercial Relationship) | Carol Shields: Commercial Relationship: Code N (No Commercial Relationship) | Ralph Eagle Jr.: Commercial Relationship: Code N (No Commercial Relationship) | Tatyana Milman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: BAP1 immunohistochemical (IHC) stain has emerged as a powerful and inexpensive prognostic tool in uveal melanoma (UM), correlating with UM molecular genetics and patient outcome. We aim to assess BAP1 IHC in irradiated UM eyes that ultimately underwent enucleation and to compare performance of BAP1 IHC with non-irradiated UM.

Methods: The medical records of all UM patients who underwent enucleation at the Oncology Service of Wills Eye Hospital from December 1st, 2007 to December 31st, 2014 with available paraffin-embedded tissue and either chromosome 3 (ch3) status or sufficient follow-up (>5 years or development of metastasis) were reviewed. Nuclear BAP1 (nBAP1) IHC was interpreted as intact (positive in >90% of nuclei), lost (positive in <5% of nuclei), or heterogeneous (positive in 5-90% of nuclei). Retina, intratumoral inflammatory cells, and blood vessels served as internal positive controls. Eyes without sufficient internal positive controls or with <5% viable tumor were labeled “non-interpretable”.

Results: There were 34 irradiated UM enucleated eyes compared to 47 non-irradiated UM eyes (controls). BAP1 IHC was non-interpretable in 7/81 (9%) eyes (4 irradiated and 3 non-irradiated). There was no significant difference between irradiated and non-irradiated UM with respect to nBAP1 IHC (lost in 41% vs 51%, p=0.19), ch3 status (monosomy 3 in 59% vs 60%, p=0.48), and outcome (metastatic disease in 44% vs 47%, p=0.8). Correlation of BAP1 IHC with disomy 3 (ch3D), monosomy 3 (ch3M), and outcome [intact BAP1:ch3D and/or no metastasis AND lost BAP1:ch3M and/or metastasis] in irradiated tumors was significantly lower when compared with non-irradiated tumors [21/30 (70%) vs 41/44 (93%), p=0.004*, Bonferroni correction 0.04*]. On re-evaluation of discordant cases, decreased or absent retinal staining overlying the tumor and weak intratumoral control were seen in six irradiated UM, pointing to a false-negative nBAP1 stain. With those cases excluded, the correlation of nBAP1 IHC with ch3 status and outcome was not significantly different in irradiated and non-irradiated UM [18/24 (75%) vs 41/44 (93%), p=0.017*, Bonferroni correction 0.15].

Conclusions: There are pitfalls in the interpretation of BAP1 immunostain in irradiated UM. This test should be used judiciously in tumors with prior plaque brachytherapy.

ABSTRACT BODY:

Purpose: The sight threatening sulfur mustard (SM) induced ocular injury presents specific symptoms for each clinical stage. The acute injury develops in all of the exposed eyes and may heal or deteriorate into chronic pathology. Early detection of eyes at risk to develop the chronic pathology may assist in providing unique monitoring and treatments only to relevant cases. In this study, we used machine-learning model for predicting the development of chronic pathology in rabbits.

Methods: Clinical data from 166 rabbit eyes that were exposed to SM vapor was collected retrospectively. The data included a comprehensive clinical evaluation of the cornea, eyelids and conjunctiva using a semi-quantitative clinical score. A machine-learning model, based on random forest classifier, was trained to predict the development of corneal neovascularization at 4 weeks using clinical data collected three weeks earlier.

Results: The overall accuracy in predicting the clinical outcome of SM-induced ocular injury was 73%. The accuracy in identifying eyes at risk to develop corneal neovascularization and future healed eyes was 75% and 59%, respectively. The most important parameters for accurate prediction were conjunctival secretion and corneal opacity at 1week and corneal erosions at 72 h post exposure.

Conclusions: Predicting clinical outcome of SM-induced ocular injury based on the acute injury parameters using machine-learning model is demonstrated for the first time. Although the prediction accuracy was limited, probably due to small dataset, it pointed out towards various parameters during the acute injury that are important for the prediction of SM-induced chronic pathology.

TITLE: intra-Corneal channels as drainage aqueducts in Axenfeld Rieger subjects with glaucoma

SESSION TITLE: Aqueous humor dynamics and Trabecular Meshwork

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Gupta, V. Gupta, V. Nathiya, K. Mahalingam, RPC, All India Institute of Medical Sciences, New Delhi, Delhi, INDIA|

Commercial Relationships Disclosure: Shikha Gupta: Commercial Relationship: Code N (No Commercial Relationship) | Viney Gupta: Commercial Relationship: Code N (No Commercial Relationship) | Venkatesh Nathiya: Commercial Relationship: Code N (No Commercial Relationship) | Karthikeyan Mahalingam: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Glaucoma associated with Axenfeld Rieger Syndrome (ARS) is often refractory, presents in advanced stage and requires surgical intervention. An in-vivo study of the angle using high definition ASOCT showed some prominent alternate routes of aqueous drainage in these children. Hence this study was conducted to look at routes of aqueous drainage in children with ARS.

Methods: A cross-sectional single center observational study comparing ARS children with Primary congenital glaucoma (PCG) was conducted. Study population for clinical arm consisted of 32 treated patients of ARS and 28 children with PCG old enough (≥8 years) to cooperate for ASOCT (Spectralis, Heidelberg Inc.). Children (20) formed the control arm. High resolution in vivo ASOCT of ARS subjects was used to assess the angle and the cornea and compared with the PCG arm and the control arm. For histopathology, ARS corneal tissues (5) harvested for keratoplasty were compared with those of PCG (5) and bullous keratopathy corneae (5).

Results: On ASOCT, ARS eyes displayed severe angle dysgenesis in form of iris adhesions over the TM visible as PAS, membrane over TM (46%) and absent Schlemm's canal (83%) as causes of angle dysgenesis (90%); this was comparable to PCG eyes. Besides this, they showed well-defined intra-corneal dilated cisterns forming discrete communications either with supraciliary aqueous drainage pathway (5/32, 15.6%; figure 1a) or conventional pathway of aqueous drainage (4/32, 12.5%;figure 1b) or both (figure 1c). No such finding was perceived in eyes with PCG or healthy controls. ($p<0.001$; chi square test) Histo-pathologically, presence of large intracorneal cisterns lined by basement membrane were confirmed in ARS eyes (Figure 2a), which was significantly greater in dimensions compared to those seen in PCG (Figure 2b), PBK (Figure 2c) or controls ($p<0.01$; Wilcoxon rank sum test).

Conclusions: Despite the presence of severely distorted angle drainage in ARS, these intracorneal communications with both conventional and unconventional pathways of aqueous drainage could be considered the alternative aqueous drainage pathways in the affected eyes. This could explain why many ARS patients present with glaucoma later in life.

ABSTRACT BODY:

Purpose: Despite the benefits of low vision services (LVS), a discrepancy in the need and the uptake of these services has been reported internationally. Only a few studies examined the professional's perspective regarding barriers and facilitators in accessing LVS. This study aims to explore these parameters from both the perspective of visually impaired people and professionals from different eye care providers in the Netherlands.

Methods: A sample of older adults with macular degeneration, diabetic retinopathy and glaucoma (n=14) and a sample of healthcare professionals including ophthalmologists, low vision optometrists and LVS professionals (n=17) participated in this study. Semi structured interviews with patients and professionals were conducted and were analyzed with framework analysis using Atlas.ti software.

Results: Both patients and professionals consider having self-advocacy, motivation, social support, acceptance of the impairment, high participation needs and experienced negative impact of the impairment to facilitate access to LVS. Having good communication skills, paying attention to patient's LVS needs and informing them about LVS as a provider, as well as having a long patient-provider relationship were also identified as facilitators. In addition, professionals perceived communication between providers regarding LVS, the presence of low vision consultation hours in the ophthalmic practice and national service provision of LVS to facilitate referral to LVS. Barriers in accessing LVS that have been identified in both samples are being less assertive, and having low motivation, low acceptance of the impairment and lack of awareness about LVS as a patient. Besides that, lack of time and absence of communication about LVS by eye care providers to patients were mentioned as barriers. According to professionals, low participation needs of patients, short disease duration, short patient-provider relationship and unavailable care coordination hinder referral to LVS as well.

Conclusions: Findings imply that provider's lack of information provision about LVS, especially to patients who are less assertive, hamper referral to LVS. Providers should have attention for patient's LVS needs and actively inform them and their social network about LVS to facilitate access to LVS. Educating and training providers about how and when to address LVS may help to reduce barriers in the referral pathway to LVS.

TITLE: An Improved Strabismus Screening Method with Combination of Meta-Learning and Image Processing under Data Scarcity

SESSION TITLE: Strabismus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. KIM, S. Lee, Ophthalmology, Kosin University Gospel Hospital, Busan, Busan, KOREA (THE REPUBLIC OF)|S. Choi, Pukyong National University, Busan, Busan, KOREA (THE REPUBLIC OF)|

Commercial Relationships Disclosure: CHANGZOO KIM: Commercial Relationship: Code N (No Commercial Relationship) | Sangjoon Lee: Commercial Relationship: Code N (No Commercial Relationship) | Seonhan Choi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Meta-learning provides a promising pathway to train convolutional neural networks (CNNs) under data scarcity, yet its accuracy is restricted in screening strabismus due to the inability to make full use of eye information of data. To alleviate this issue, this study proposed a method by combining a meta-learning approach with image processing methods to fully extract the information that helps determine strabismus, thereby improving the classification accuracy for screening strabismus

Methods: The meta-learning approach was initially pretrained on a public dataset to obtain a well-generalized embedding network for extracting relevant pixel features while image processing methods were used to extract the position features of eye regions (e.g., iris position, corneal light reflex) as supplementary features. The dimensionality of pixel features was reduced to integrate with the low-dimensional supplementary features via principal component analysis, and the integrated features were used to train a support vector machine classifier for performing strabismus screening. A total of 60 images (30 normal and 30 strabismus) were used to verify the effectiveness of the proposed method, and its classification performance was assessed by computing the accuracy, specificity, and sensitivity through 5000 experiments.

Results: The classification accuracy using only the meta-learning approach achieved 0.709 with a sensitivity (i.e., correctly classify strabismus) of 0.740 and a specificity (i.e., correctly classify normal) of 0.678 while the proposed method achieved 0.805 classification accuracy with a sensitivity of 0.768 and a specificity of 0.842 in strabismus screening.

Conclusions: The proposed strabismus screening method achieved promising classification accuracy and improved the classification performance by about 10% than using the meta-learning approach alone under data scarcity. We expect that this combination approach can be an effective solution in medical fields where data scarcity is common.

ABSTRACT BODY:

Purpose: OCT angiography (OCTA) is a promising imaging modality for improving the management of diabetic retinopathy (DR). The EviRed project aims to develop artificial intelligence tools to automate DR diagnosis and prognosis evaluation using this imaging among others. Given the large amount of data to process, we investigate the potential redundancy of the two 3-D channels in OCTA scans, namely structure and flow. In particular, can any of these two channels be predicted by the other?

Methods: High-definition OCTA scans (6x6mm) from 112 eyes of 61 diabetic patients (one scan per eye) were acquired with a PLEX® Elite 9000 (Carl Zeiss Meditec Inc., Dublin, CA, USA). DR severity level in each eye was graded by a retina specialist using fundus photographs. Scans were randomly distributed between three subsets with equal distributions of DR severity: 84 scans (45 patients) to train, 12 scans (6 patients) to validate and 16 scans (10 patients) to test. Next, various 3-D U-Nets were trained to predict the flow channel from the structure channel. A similar set of 3-D U-Nets was trained to predict the structure channel from the flow channel.

Results: Using the ICDR scale, 29 eyes had no DR, 28 had mild NPDR, 26 had moderate NPDR and 29 had more advanced DR; the test set contained 4 scans from each severity category. Based on the validation set, the best neural architecture was 3-D U-Net with a ResNet-152 backbone. In the test set, the mean absolute error (MAE), in 3-D, between the true and predicted flow was 4.19% and the MAE between the true and predicted structure was 4.11%. The Pearson correlation coefficient (PCC) between the true and predicted flow was 0.684 and the PCC between the true and predicted structure was 0.961. No significant Spearman correlation was found between the PCC and DR severity (p-value = 0.721 for both transfer tasks).

Conclusions: Flow and structure channels in 6x6mm PLEX® Elite OCTA scans can be predicted from one another, which indicates potential redundancy between these channels. Prediction performance does not depend on DR severity. Visually, we observe that pathological features (e.g., exudates in the structure channel, avascular zones in the flow channel) can be also predicted. Further investigations are needed to quantify the prediction accuracy, at voxel level, and evaluate the possibility of using one single OCTA 3D channel for DR management in the future.

ABSTRACT BODY:

Purpose: Real-time imaging in vitreoretinal surgery directly impacts the handling of surgical instrumentation and the decision-making process of the surgeon. This experimental study tested the hypothesis that deep learning neural networks can concurrently track and segment instruments and target tissue landmarks within the retina when attached to a surgical microscope.

Methods: A hundred and one (101) vitreoretinal procedures consisting of core vitrectomy, membranectomy, and endolaser application were employed to train and validate an instance segmentation convolutional neural network. Three vitreoretinal surgeons manually annotated the following features from six-hundred and six (606) fundus frames: vitrector, forceps and endolaser tooltips, optic disc, fovea, retinal tear and detachment, fibrovascular proliferation, endolaser spot, the area where endolaser was applied, and macular hole. Five-fold cross-validation was employed to assess the performance of the model.

Results: The model detected and classified the vitrector tooltip with a mean area under the precision-recall curve (AUPR) of 0.972±0.009. Segmentation of target tissues such as optic disc, fovea, and macular hole reached mean AUPR values of 0.928±0.013, 0.844±0.039, and 0.916±0.021 respectively (Table 1 and Figure 1). The post-processed image was rendered at a resolution of 1920x1080 pixels at 38.77±1.52 frames per second when attached to an intraoperative visualization system.

Conclusions: Deep learning neural networks can detect, classify, and segment tissues and instruments during different phases of vitrectomy surgery in real time. We propose a model that creates a framework to develop surgical guidance tools that may guide surgical decision-making in real time. Potential applications include (1) warning of unintended instrument-tissue interactions and potential intraoperative complications, (2) data extraction for the control of equipment parameters such as the vitrector cutting rate, and (3) retroactive data acquisition of instrument maneuvers for surgeon’s skills analysis.

ABSTRACT BODY:

Purpose: When applied to primary visual cortex, anodal transcranial direct current stimulation (a-tDCS) has been reported to reduce crowding in peripheral vision indicating a potential therapeutic use for patients with central vision loss. To further assess the potential of a-tDCS as a vision rehabilitation tool, we tested the hypothesis that visual cortex a-tDCS, but not sham a-tDCS, would improve reading of Chinese characters presented to left lateral peripheral vision in normally sighted adults.

Methods: Sentences of Chinese characters were presented one character at a time 10^{o} to the left of fixation at various speeds and print sizes. Participants (n = 10, 60 to 73 yrs. of age) read the sentences out loud and character recognition accuracy was recorded. Accuracy data were fitted with a continuous linear piecewise function that rises and then flattens to estimate all combinations of print sizes and speeds that elicit 55% accuracy. The point where both linear functions meet denotes the critical print size (CPS), defined as the smallest print size eliciting the participant's fastest reading speed. Using a double-blind, within-subject design, participants were then tested with sentences of print size and reading speed corresponding to 0.2 logMAR below the CPS on 2 stimulation days on which 20 mins of active or sham a-tDCS was applied to the visual cortex. Each test consisted of 15 sentences, and one test was administered before, during, 5 mins post, and 30 mins post stimulation. Reading accuracies were compared across time-points.

Results: A within subjects ANOVA revealed no significant interaction between Stimulation Type (anodal vs. sham) and Time (pre, during, 5 min post and 30 min post stimulation) ($F(3,27)=0.59$, $p=0.63$).

Conclusions: A-tDCS did not improve reading of Chinese characters in left lateral peripheral vision in normally sighted individuals. The effect of a-tDCS on reading of Chinese characters or other writing systems presented to other regions of the visual field, including inferior peripheral vision, is yet to be determined.

ABSTRACT BODY:

Purpose: Among the treatment options available for DME, intravitreal injections of anti-VEGFs have been the most practiced option. However, response to the anti-VEGF injection varies from patient to patient. In order to assist clinicians in optimizing treatment, we developed an automatic algorithm that predicts the potential change in CST for a given DME patient before administrating the anti-VEGF injection.

Methods: For the development and verification of the machine learning (ML) models, we collected data from a total of 906 DME patients who received anti-VEGF treatment. Each patient's multiple visit data points were collected where both pre- and post-injection OCT scans were acquired using CIRRUS™ HD-OCT 4000/5000 (ZEISS, Dublin, CA) with signal strength ≥ 0.4. The patients' data were divided into train and test sets containing 775 and 131 patients' data respectively.

Four benchmark models including Linear Regression, Support Vector Regression (SVR) with Radial Basis Function (RBF) kernel, SVR with linear kernel and Random Forest (RF) were trained using clinical parameters such as patient's age, gender, near BCVA value, distance vision (DV) BCVA value, pre-injection CST value, the other eight ETDRS grid values, number of previous anti-VEGF injections, and number of days after injection. Fig 1 shows the schematic diagram of the ML model development.

Using the test set, the performance of the CST change prediction algorithms was evaluated in terms of correlation coefficient (CC). The performance of all 4 models was further evaluated for four different scenarios - number of injections administered: ≥ 1, ≥ 2, ≥ 3 and > 3.

Results: SVR with linear kernel model achieved best performance in terms of CC with 0.65, 0.73, 0.75 and 0.85 for four scenarios respectively. Fig 2 shows the performance of all four ML models for the four scenarios. Linear regression, RF and SVR with RBF kernel model perform in the descending order of correlation coefficient.

Conclusions: In this study, we demonstrated how various ML regression models perform, with best CC of 0.85 with linear SVR for > 3 injections, in predicting the change in CST value for DME patients undergoing anti-VEGF treatment. This may help specialists to better plan the treatment of DME patients.

ABSTRACT BODY:

Purpose: Meibomian gland dysfunction (MGD) is a common condition of the eyelids leading to tear film instability and resulting in dry eye disease or ocular surface disease (OSD). Oral doxycycline has been used for a long time for the treatment of MGD but is associated with systemic side effects. Topical azithromycin has therefore been proposed as a valuable alternative to systemic antibiotic treatment. The present study set out to compare the effect of topical azithromycin with oral doxycycline on tear film thickness (TFT) in patients with MGD.

Methods: Twenty patients with MGD were included in this observer-masked, parallel-group study and were randomized to either receive topical azithromycin for 4 weeks or oral doxycycline for 6 weeks. Main outcome of the study was the change in TFT as measured with ultra-high resolution optical coherence tomography before and 6 weeks after treatment start.

Results: Six weeks after treatment initiation, TFT increased from 5.0 ± 1.0 to 5.5 ± 1.1 µm (11.5 ± 30%) in the azithromycin group and from 4.7 ± 0.9 to 5.6 ± 1.1 µm (21.0 ± 28.6%) in the doxycycline group ($p = 0.028$ over time) with no difference between the two groups ($p = 0.267$). Systemic Adverse Events (AEs) occurred more frequently in the doxycycline group, while eye-related AEs were more common in the azithromycin group.

Conclusions: The present study found that topical azithromycin as well as systemic doxycycline improves TFT in patients with MGD with no difference between the two treatments. Due to the higher occurrence of systemic side effects when taking doxycycline, azithromycin eye drops seem to be an alternative with comparable efficacy.

ABSTRACT BODY:

Purpose: The Danish Registry of Diabetic Retinopathy (DiaBase) includes screening information from approximately 200,000 patients attending diabetic retinopathy (DR) screening in Denmark between 2013-2018. We performed a national, clinical validation study of the DR-gradings in the database to explore the inter grader agreement between the primary, screening ophthalmologist and a secondary certified grader.

Methods: Invitations to participate in the study were sent to all screening hospital departments as well as every practicing ophthalmologist nationwide. Fundus images and information on DR level, region of screening, image style and screening facility was uploaded by the primary grader to a secure database. These data were all blinded to the secondary grader during the grading process.

All grading of DR in a clinical setting in Denmark is standardized and performed using the International Clinical Diabetic Retinopathy (ICDR) scale, which was also the system applied in this study.

Fundus photographs from 230 patients (457 eyes) were included in the analysis.

Results: Images were received from all five Danish regions, from both practices (52.6%) and hospital based (47.4%) screening facilities.

Overall the reported levels of DR was 67.4%, 12.4%, 13.5%, 1.3% and 6.2% for no, mild, moderate, severe and proliferative DR. A significant difference ($P<0.001$) in the reported levels of DR between the screening facilities was observed; images from practicing ophthalmologists showed a distribution of 92%, 5%, 2%, 0% and 1% whereas images from hospital based ophthalmologists showed a distribution of 41%, 21%, 26%, 3%, and 11% for no, mild, moderate, severe and proliferative DR.

A weighted prevalence-adjusted, bias-adjusted kappa (PABAK) analysis was performed. The overall agreement between the primary and secondary graders was 93% ($\kappa = 0.83$). When sub-analyzed for screening facility the results were 96% ($\kappa = 0.89$) for practices and 90% ($\kappa = 0.76$) for hospitals.

Exact agreement between graders was observed in 78% of images.

Conclusions: In this nationwide study, we observed a high inter grader agreement of the gradings of DR performed by primary screening ophthalmologist and secondary certified grader in this nationwide study. From these results, it is reasonable to assume that the DR grades available in DiaBase, used for several large register-based studies, are primarily correct and eligible for continued use.

ABSTRACT BODY:

Purpose: The need for an effective therapeutic intervention in patients with vision loss due to retinal degeneration still remains high. We performed a multicentre, prospective, randomised, double-blind, placebo-controlled study to investigate the effects of omega-3 fatty acids in patients with dry age-related macular degeneration (AMD) or Stargardt disease (SD).

Methods: The main inclusion criterion was the best-corrected visual acuity (BCVA) to be between 21 and 55 (ETDRS letters) at screening visit. The final number of patients was 21; of those, 9 females and 12 males, with mean age 60.0 ± 2.3 years. Treatment consisted of daily oral administration of either placebo (sunflower oil; 7 patients) or active product (Eyetas®, 3.7g of eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA); EPA:DHA=5:1; 14 patients), for 24 weeks. The number of letters gained from BCVA measurements and the ratio of arachidonic acid (AA)/EPA (using gas chromatography) was determined at screening, 12 weeks and 24 weeks. The total score of a questionnaire on perceived vision and subjective mood was obtained at 12 weeks and 24 weeks. The SPSS software (version 25.0) was used for the statistical analyses.

Results: Within the active group, the mean BCVA increased from 40.93 ± 9.18 at screening to 46.93 ± 9.18 at 24 weeks (p=0.003; Wilcoxon signed-rank test), whereas within the placebo group there was no significant increase. A comparison of the mean letters gained at 24 weeks showed a significant difference between the active and placebo groups (p=0.002; independent samples t-test). Similar findings were obtained for the letters gained at 12 weeks. For the active group, the mean level of AA/EPA had a significant decrease from screening (5.84 ± 1.05) to 12 weeks (1.50 ± 0.23, p=0.002, Wilcoxon signed ranks tests) and 24 weeks (1.47 ± 0.16, p=0.002), whereas for the placebo group, the AA/EPA had no significant differences. Finally, the mean score of the questionnaire was similar in the two groups at 12 weeks (9.23 ± 3.14 in active, 9.33 ± 2.42 in placebo), but it was higher for the active group compared to the placebo group at 24 weeks (9.38 ± 3.35 vs. 7.28 ± 2.36).

Conclusions: Oral supplementation of omega-3 fatty acids (3.7g; EPA:DHA=5:1) can improve objective and subjective vision in patients with dry AMD and SD.

ABSTRACT BODY:

Purpose: In branch retinal vein occlusion (BRVO), central retinal laser has to some extend been replaced by angiostatic agents as first line treatment. While these efficiently reduce macular edema and increase visual acuity, the treatment is often inconvenient and expensive. In order to investigate a novel treatment strategy, we aimed to evaluate if combined treatment of aflibercept and navigated central retinal laser could lower injection burden in patients with BRVO and macular edema.

Methods: Forty treatment-naïve patients with BRVO and macular edema were included and randomized 1:1 to three monthly intravitreal injections of 2.0 mg aflibercept with (Group A) or without (Group B) navigated central retinal laser at month three. Patients were followed monthly from month four through 12, and re-treated with aflibercept according to re-treatment criteria: increase in central retinal thickness (CRT) ≥ 20% compared with lowest measurement, or decrease in best corrected visual acuity (BCVA) > 5 Early Treatment Diabetic Retinopathy Study (ETDRS) letters as compared to baseline.

Results: Median age was 69.6 years, 45% were male, median BCVA was 66.6 letters, and median CRT was 541.4 µm, with no difference between groups. Seventy-five percent of patients needed retreatment after month three, and median number of retreatments was one with no difference between groups A and B (71.4% vs 79.0%, p=0.72, and one vs. two, p=0.38). Between baseline and month 12, median BCVA increased 13.0 ETDRS letters and median CRT was reduced by 192 µm with no difference between groups (+12.0 vs. +14.0 ETDRS letters, p=0.30, and -195µm vs. -185µm, p=0.96). Change in central retinal sensitivity, measured by microperimetry, did not differ according to treatment regimen (+2.87dB vs. +3.93 dB, p=0.40).

Conclusions: In a randomized trial of patients with treatment-naïve BRVO and macular edema, we found no difference in efficacy, side effects or treatment-burden when comparing combinational treatment of aflibercept and navigated central laser with aflibercept monotherapy. This may to some extend be explained by a lower than expected need for re-treatment of the intravitreal monotherapy group.

ABSTRACT BODY:

Purpose: With this research project we wanted to approach the question of whether SARS-CoV 2 can infect the eye. In order to infect ocular tissues, virus-specific receptors; coreceptors or proteases must be present in the eye tissue. SARS-CoV 2 uses the human angiotensin converting enzyme 2 (ACE2) receptor to enter cells. In addition, the mammalian serine protease TMPRSS2, the protease furin and the glycoprotein neuropilin are identified as relevant proteases for the interaction of the virus with ACE2. Last year, we were able to show that ACE2 is significantly more expressed in ocular tissue of covid patients. Here the expression level of the co-receptor and glia markers, as well as the present of virus was confirmed in this study.

Methods: Seven eyes from donors without covid disease (COVID-) as well as ten fixed eyes from COVID-19 patients (COVID+) were analysed for their expression profile of ACE2, TMPRSS2, neuropilin and furin in the retina and cornea. The ocular tissues were examined for protein expression by immunohistochemical staining or for RNA expression by quantitative real-time PCR. In addition, viral spike protein was detected histologically in eyes, and expression profiles of GFAP and Iba-1 were assessed.

Results: Similar to ACE2 and TMPRSS2, the two proteases neuropilin and furin were detected in the retina and cornea. Interestingly, the expression profile differed in terms of strength and localization, especially in the retina. The presence of the virus in both cornea and retina was also demonstrated by the detection of viral spike protein. In all COVID+ retinas, strong GFAP staining was observed as well as some Iba-1 positive cells, suggesting activation of macro- and microglia.

Conclusions: Expression of ACE2, TMPRSS2, furin and neuropilin was demonstrated in COVID+ ocular tissues. In addition to the virus detection in retina and cornea, a glial reaction could also be observed. One can therefore assume an infection of the eye in these cases. However, in summary it can be said that an infection of the eye tissue is possible since all demanded receptors are present.

ABSTRACT BODY:

Purpose: Microperimetry (MP) process requires an uncomfortable amount of time to assess elderly age-related macular degeneration (AMD) patients. This study aims to develop a machine learning model that predicts terminal AMD end-stage lesions (ESLs) of the retina using information provided by multi-modal imaging, shortening the MP process by only analysing the ameliorable early-stage retinal lesions.

Methods: Optical coherence tomography (OCT), infra-red (IR) and colour fundus images were taken from 130 AMD-afflicted eyes. OCT B-scans were graded for AMD lesions by 2 markers where discrepancies were resolved by a senior retina specialist. The OCT markings were translated onto the IR fundus to form lesion boundaries that acts as ground truth. A data framework (Fig. 1) was established using template matching of retinal vasculature in each imaging type, resulting in the superimposition of the different imaging modalities. The dataset used to train a XGBoost classification model was generated by running circular beams throughout and across the framework where each beam will encapsulate information of all framework layers. Physical properties of each layer were condensed into the mean and standard deviation of the pixels captured within the beam.

Results: The dataset was split into testing, training, and validation sets (10/85/5%). The models were evaluated by lesion prediction rate (LPR) and overall prediction rate (OPR). LPR and OPR is defined by the proportion of the lesion and overall beams being classified correctly respectively. The modelling process was performed twice with 2 different validation datasets where each set was taken from only early or late AMD eyes. LPR and OPR of both types of beams in the test set is 98-99%. Beams in the validation set have an LPR of 69-72% while the OPR of early AMD eyes is at 90% and late AMD eyes at 77%. A visualisation of the model's prediction on an eye in the validation dataset is in Fig. 2.

Conclusions: There is strong evidence that the classification model can pick up information provided by multiple imaging modalities to identify areas affected by ESLs. Model output visualisation shows that the central areas of ESLs were well established, though model performance deteriorated at the boundaries. Inclusion of more imaging modalities into the framework may improve future models.

TITLE: Phenotype heterogeneity and the association between visual acuity and outer retinal structure in a cohort of Chinese X-linked juvenile retinoschisis patients

SESSION TITLE: Retinal Degenerations, Gene Therapy, Transplantation, and Prostheses

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Q. Guo, Henan Eye Institute, Henan Provincial People's Hospital, Zhengzhou, Henan, CHINA|

Commercial Relationships Disclosure: Qingge Guo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: X-linked juvenile retinoschisis (XLRS), caused by mutations in the RS1 gene, is an X-linked recessive inherited disease that typically involves both eyes in the first two decades of life. Recently, phenotype heterogeneity of this condition has drawn increasing attention. We reported various phenotypes caused by RS1 gene mutations in eleven patients from ten Chinese families.

Methods: Data on the medical history of the patients from ten Han families of central China were collected. Ophthalmic examinations including the BCVA, fundus photography, ultra-wide angel sweep source optical coherence tomography, electroretinography were performed. Adaptive optics (AO) images were acquired to evaluate the cone photoreceptor mosaic when applicable. Venous blood of the probands and their family members was collected, and DNA was subjected to sequencing based on next-generation sequencing with a custom designed targeted gene panel PS400 for inherited retinal diseases. Validation was performed by Sanger sequencing and cosegregation. Pathogenicity was determined in accordance with the American College of Medical Genetics and Genomics (ACMG) guidelines.

Results: Ten RS1 mutations including 8 missense mutations and 2 terminator mutations were identified in 10 XLRS families. These patients showed a variety of clinical phenotypes including fovea schisis, bullous retinoschisis, macular or peripheral atrophy. Fifteen eyes of eight patients exhibited macular retinoschisis, and twelve eyes of seven patients exhibited peripheral retinoschisis. In addition, three patients showed asymmetrical fundus manifestations.Of importance, three patients without macular retinoschisis were misdiagnosed until genetic testing results were obtained. AO showed decrease of cone density and loss of regularity in the cystic schisis macular of XLRS. Furthermore, the BCVA was associated with the photoreceptor inner segment and outer segment (IS/OS) thickness.

Conclusions: With complicated clinical manifestations, a considerable portion of XLRS patients may present various phenotypes. It should be noticed that asymmetry fundus appearance in both eyes could lead to misdiagnosis easily. Thus, genetic testing is crucial for making a final diagnosis in those patients. In addition, residual cone photoreceptor structure was critical for the maintenance of useful vision.

TITLE: Complete traumatic optic nerve head avulsion after blunt ocular trauma: two case reports and literature review.

SESSION TITLE: Endophthalmitis/ trauma/Intravitreal/periocular therapies

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Kaeowichian, Ophthalmology, Srinagarind Hospital, Khon Kaen, THAILAND|

Commercial Relationships Disclosure: Arisara Kaeowichian: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Optic nerve head (ONH) avulsion is the traumatic separation of the optic nerve fibers at the lamina cribosa with intact the nerve sheath and adjacent sclera. It is a rare and usually visually devastating form of anterior traumatic optic neuropathy. We report cases of complete ONH avulsion following blunt ocular trauma.

Methods: Medical charts, ocular imagings and radiological investigations were reviewed.

Results: Two patients had sudden visual loss after motorcycle accident and slingshot rebounding attack. Their initial and final visual acuity (VA) was no light perception (LP). Microscopic hyphema, mild mydriasis and relative afferent pupillary defect were found in the first teenager. Fundus examination showed dense preretinal hemorrhage overlying the ONH area with surrounding retinal edema and vitreous hemorrhage. Although there were multiple displaced orbital fractures, normal eye globe and optic nerve contour were demonstrated on the computerized tomography. The intravenous methylprednisolone was prescribed. The second boy presented with partial corneal laceration and total hyphema. Ocular ultrasound showed normal globe contour, dense vitreous opacity and posterior lens dislocation. Due to questionable no light perception, pars plana vitrectomy was performed. Total ONH excavation and central retinal artery occlusion were found intraoperatively. The total retinal detachment and epimacular membrane developed one week later, however, the ONH was clearly seen and the optical coherence tomography revealed bottomless cup. A probable small gap of nerve at the entry point of globe was detected after reviewing the magnetic resonance imaging.

Conclusions: Complete ONH avulsion is a rare manifestation of blunt ocular trauma. Radiological imaging usually could not detect the ONH avulsion which was support and obscured by the orbital tissue and optic nerve sheath. In case of media opacity, we suggest the visual evoked potential test for evaluation optic nerve function.

ABSTRACT BODY:

Purpose: Microscopic optical coherence tomography (mOCT) has an imaging resolution of 1 μm in all voxel dimensions but individual epithelial cells are difficult to resolve due to lack of scattering contrast. Adding dynamic contrast processing to mOCT (dmOCT) scans enables visualization of individual cells and quantification of subcellular motion to evaluate cell function. We propose this technique as a novel method of evaluating the ocular surface after exposure to a toxic chemical, benzalkonium chloride (BAK).

Methods: Ex-vivo cross-section images were acquired with a custom-built frequency domain mOCT system. A dynamic contrast (dmOCT) scan consists of 150 B-scans with 512 A-scans. Five sets of dmOCT scans were consecutively taken at each imaging time point per eye. Eyes were explanted from healthy adult (21 weeks) C57BL/6 mice (n = 6; 6 control group, 6 BAK group), glued to cell culture dishes, and immersed in cell culture media. After baseline images were acquired in all eyes, BAK group media was replaced with 0.005% BAK media. Eyes were imaged every 30 min and were incubated at 37C between imaging sessions. Total epithelium and stroma thickness were measured from a single mOCT B-Scan while measures of cell motility and hue were acquired from dmOCT scans. Cellular motility was calculated by the normalized intensity standard deviation over time. Hue was created from the frequency spectra of the dmOCT signal with the blue channel for slow (0-0.5 Hz), green for medium (0.5-5 Hz), and red fast motion (5-25 Hz).

Results: After 30min exposure to 0.005% BAK, epithelium thickness increased and cell motility decreased compared to controls (Fig 1). Basal cell motility decreased after 60min exposure and the hue shifted red after 90min. Stroma thickness did not significantly swell until 120min exposure to BAK.

Conclusions: dmOCT allows us to view the behavior of the cornea epithelium under toxic stress due to BAK, showing changes to subcellular motion and swelling of the extracellular matrix.

ABSTRACT BODY:

Purpose: Drusen-like deposits are hallmarks of age-related macular degeneration (AMD) that can be found between the retinal pigment epithelium and Bruch’s membrane. On OCT they can present different sizes, shapes, and localizations. We evaluate the performance of models based on EfficientNet B0 architectures to automatically detect B-scans with drusen-like deposits (DLD).

Methods: OCT(A) data acquired in the scope of a DR screening program that is running in Coimbra, Portugal were used for training the models. The imaging data were acquired by the ZEISS AngioPlex OCT Angiography (ZEISS, Dublin. CA) using the Angio 6x6 mm protocol. The dataset includes 960 B-scans collected from 67 healthy eyes (71±4.8 years) and 842 Bscans collected from eyes having drusen-like deposits (DLD) from 123 eyes (68±3.5 years). The DLD were identified by an ophthalmologist that classified the pathological scans into two categories: with the presence of DLD with a size equal or superior to 63 µm (28%), and with the presence of DLD of size less 63 µm (72%). Deep learning models based on EfficientNets B0 architectures were trained and evaluated using a 5-fold cross-validation approach to detect B-scans having DLS. The specificity and the sensitivity metrics were used to evaluate the performance of the models.

Results: An overall sensibility equals to 84.4±10.5 % and a specificity equals to 80±11.9 % were measured on the testing folders. When were only considered DLD equals or largers than 63 µm the value of the sensibility was equal to 92±7% and the and specificity to 80.0±11.6%.

Conclusions: Our results show that EfficientNet B0 architectures can detect DLD even when trained with a small dataset. Is expected that the addition of more data will improve the performance of the models. Automatic detection of DLD is especially important in the scope of screening programs.

TITLE: A novel mutation located in the intermembrane space domain of AFG3L2 causes dominant optic atrophy through decreasing the stability of the encoded protein by ubiquitin-proteasome pathway

SESSION TITLE: Retinal ganglion cells

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Yang, B. Lei, Zhengzhou University, Zhengzhou, Henan, CHINA|L. Yang, J. xiuxiu, B. Lei, Henan Provincial People's Hospital, Zhengzhou, Henan, CHINA|

Commercial Relationships Disclosure: Lin Yang: Commercial Relationship: Code N (No Commercial Relationship) | jin xiuxiu: Commercial Relationship: Code N (No Commercial Relationship) | Bo Lei: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To verify the mutation of AFG3L2 intermembrane spaces can cause mitochondria disfunction dominant optic atrophy (DOA) and investigate the potential pathologic mechanisms.

Methods: The AFG3L2 gene variant was detected by whole-exome sequencing (WES), and then Sanger sequencing and co-segregation were conducted in the family members. We established fibroblast cell lines from this DOA family harboring AFG3L2 mutation and normal controls. Pathogenicity and molecular mechanisms of the identified variant was studied in patient-derived fibroblasts and HEK293T cell lines.

Results: We showed a large DOA family with 11 patients. WES revealed a novel pathogenic mutation (c.524T>C, p.F175S) in the AFG3L2 gene intermembrane space domain (IMSD), rather than in the ATPase domain which is the hot mutation region associated with most of the DOA reported previously. Functional studies in the skin fibroblasts generated from the patient donors and HEK293T cells showed that the mutation impaired mitochondrial function and decreased the ability of AFG3L2 protein entering the mitochondrial inner membrane. In addition, the novel mutation leaded to protein degradation and reduced the stability of AFG3L2 protein, which appeared associated with the proteasome-ubiquitin pathway.

Conclusions: A AFG3L2 mutation (c.524T>C, p.F175S) located between two transmembrane domainsIn caused isolated DOA. This may be related to the decreased stability of mutated protein mediated by the ubiquitin-proteasome pathway.

ABSTRACT BODY:

Purpose: Uveal melanoma (UM) is the most common intraocular primary malignancy. Patients with UM are predominantly treated by irradiation. This eye-sparing treatment results in absence of tumor tissue for mutation-analyses. Mutations in BAP1-mutated tumors metastasize regularly within 5 years, SF3B1-mutated tumors pose an intermediate risk and metastasize in 5-15 years and EIF1AX mutations rarely metastasize. Without tumor tissue, the gene mutation related prognosis is unobtainable.

We aimed to elucidate prognostic information non-invasively by deriving serum metabolic expression patterns from patients harboring either a BAP1, SF3B1 or EIF1AX mutated tumor.

Methods: We have performed untargeted liquid chromatography tandem mass spectrometry (LC-MS/MS) using an Orbitrap system on plasma isolated from peripheral blood from 58 UM-patients in our discovery cohort. Additionally, plasma samples from a replication cohort and non-UM controls were used. Blood was drawn prior to treatment between 1998 and 2021 and gene-mutation was used for group stratification. Afterwards, the obtained metabolite expression was analyzed using MetaboAnalyst 5.0 and supervised clustering for metabolic patterns was performed using R.

Results: We have obtained patterns in differentially expressed metabolites between patients harboring an EIF1AX (low metastatic risk) and BAP1 (high metastatic risk) mutated tumors (Figure 1). In the metabolite expression we have identified two clusters, each with two subclusters. These subclusters are correlated with a gradual worsening of survival from patients harboring an EIF1AX to SF3B1 and BAP1-mutated tumor ($p < 0.0001$) (Figure 2).

Conclusions: Our preliminary data show that metabolomics performed on plasma of peripheral blood can distinguish between low and high risk of metastasizing and these promising results can be combined with other modalities for an integrative noninvasive prognosticator.

ABSTRACT BODY:

Purpose: Cell therapeutics for AMD were often implanted regardless of RPE status in the target zone. This may result in RPE multilayering. Here we study a novel laser to remove RPE without collateral damage prior to RPE implantation to encourage better subretinal integration.

Methods: Pigment rabbits (n=24) were immunosuppressed with Sirolimus, Doxycyclin and Minocyclin. Using a SLO/ OCT (Heidelberg Engineering) extended with a prototype laser (Meridian Medical; wavelength: 532 nm; pulse duration, 8 µs), a large area of RPE was selectively removed in 19 rabbits. Animals without laser lesions served as controls (n=5). A 25 gauge vitrectomy (Geuder) with removal of posterior hyaloid membrane was performed thereafter. Human iPS-RPE (1000 cells/ µl) were manually injected using a 100 µl syringe (Hamilton) connected to a 38G cannula (MedOne) into the RPE laser lesion, or over healthy RPE in controls, monitored by intraoperative OCT imaging (RESCAN 700, Zeiss). In vivo follow up/ retinal imaging was up to 12 weeks including fluorescein and indocyanine angiography, as well as SD-OCT (Spectralis ®, Heidelberg Engineering).

Results: Representative RPE laser wounds exhibited mild late phase FA& ICGA leakage, without abnormal outer retinal or choroidal hyperreflectivity on OCT. By contrast, lesions with earlier leakage on FA/ ICGA showed beam-sized outer retinal hyperreflectivity on OCT, suggesting coagulation. The size of the RPE wounds was typically 10-12mm^2.

iOCT demonstrated in an immediate and directed spread of the bleb retinal detachment (bRD) within the lasered zone. By contrast, bRDs performed over non-lasered RPE raised slower with a circular spread. Subretinal injection ranged from 5-70µl, with lesser volumes/ larger bRDs areas over lasered regions.

At 6 and 12 weeks, none of implanted regions showed FA/ICGA leakage, some lesions had blockage due to hyperpigmentation; on OCT, representative areas showed preserved ellipsoid bands, with some RPE undulations. Lasered/implanted areas with a peripheral hyperpigmentation showed central outer retinal atrophy along with irregular RPE. Control implantation sites showed retinal atrophy and a variably thickened RPE band.

Conclusions: Large-area RPE removal with laser disruption is feasible in healthy rabbits and appears to facilitate superior integration of RPE suspension grafts, compared to subretinal injection alone. Future work aims to correlate histology with in vivo imaging.

ABSTRACT BODY:

Purpose: Glaucoma is a neurodegenerative disease in which various triggers induce cascades of secondary events, which ultimately lead to retinal ganglion cell (RGC) death. Once started, the cell death program is generally considered to be irreversible. However, recent studies reveal that recovery of dying cells is possible, even after reaching critical events in the cell death program. This phenomenon is termed anastasis. Harnessing mechanisms of anastasis may represent a previously unrecognized therapeutic strategy to rescue dying differentiated cells that are difficult to replace. We study neuronal cell death with the aim of rescuing dying RGCs in glaucoma.

Methods: Primary rat RGCs and differentiated PC12 cells were treated with ethanol to induce cell death. Live cell imaging with fluorescent probes (Mito-Tracker, TMRM, DCFDA, Fluo-8AM) were used to visualize the progression of the cell death program in individual RGCs and differentiated PC12 cells with high-resolution live-cell spinning disk confocal microscopy. Electron microscopy (EM) was used to observe the ultrastructure of mitochondria. Immunostaining was used to detect cytochrome c translocation.

Results: Exposure to 5% ethanol for 24 h induced 80.7% ($p<0.001$) and 69.1% ($p<0.001$) cell death in RGCs and PC12 cells, respectively. In both cell lines, live cell imaging showed significant mitochondrial fragmentation and membrane potential loss after ethanol treatment for 3 h. The average length of mitochondria decreased from 7.2 ± 6.2 μm to 1.3 ± 0.3 μm in RGCs ($p<0.0001$), and 6.1 ± 4.5 μm to 1.1 ± 0.12 μm in PC12 cells ($p<0.0001$). Moreover, removal of ethanol and further culturing in fresh cell culture medium for 20 h restored normal mitochondrial structure (RGC, 6.1 ± 4.5 μm; PC12, 4.7 ± 3.7 μm) and membrane potential. EM results confirmed the ethanol induced mitochondrial fragmentation and its reversibility. In addition, during the mitochondrial fragmentation cells showed higher levels of reactive oxygen species ($p<0.001$) and intracellular Ca^{2+} ($p<0.001$), which levels returned to normal after removal of ethanol stimulus. However, immunostaining showed that no cytochrome c release from mitochondria had occurred at this stage of reversible mitochondrial injury.

Conclusions: The results indicated that targeting and harnessing mitochondria may hold promise as therapeutic strategy to rescue dying RGCs in glaucoma and reduce its vision loss.

ABSTRACT BODY:

Purpose: To report preliminary data on the automated detection of focal morphologic changes - Focal Events - on spectral domain-optical coherence tomography (SD-OCT) in the ongoing PINNACLE trial, a prospective observational study in intermediate age-related macular degeneration (NCT04269304).

Methods: Four automated algorithms, segmenting drusen, photoreceptors, hypertransmission, as well as intra- and subretinal fluid are applied. Pre-specified post-processing criteria define four types of Focal Events, as shown in Figure 1, for which eyes are screened at every 4-monthly visit in the prospective PINNACLE trial. We herein report interim descriptive data on the frequency and sequence of Focal Event occurrence.

Results: Volume OCT data of 855 follow-up visits of 334 eyes of 259 patients have so far been screened for the occurrence of Focal Events. Drusen regression (DR) was detected in 3%, photoreceptor loss + hypertransmission (PLH) in 11%, subretinal fluid in 1% and intraretinal fluid in less than 1% of visits. In 44 eyes Focal Events occurred at more than one follow-up visit. The majority (52%) of such sequential events consisted of sole recurrence of PLH, followed by 11% of cases in which PLH was followed by a combination of PLH and DR. A representative example case is shown in Figure 2.

Conclusions: The established processing pipeline has shown reliable detection of predefined morphologic changes. The occurrence of sequential non-fluid related Focal Events, showing aggravation of outer retinal atrophy, as well as atrophic signs preceding drusen regression and vice versa, demonstrate these subtle changes to present meaningful events along progressive outer retinal degeneration. Once prospective data collection is completed, evaluation of the predictive value of Focal Events for the progression toward late non-neovascular as well as neovascular AMD will be performed.

ABSTRACT BODY:

Purpose: Many activities of daily living rely on reading, thus is not surprising that complaints from presbyopes originate in reading difficulties rather in visual acuity. Here the effectiveness of presbyopia correction with multifocal contact lenses (CLs) is evaluated using a new method of sustained reading performance, based on eye fixation analysis.

Methods: Visual performance of thirty presbyopic volunteers (age: 50±5 yrs) was assessed monocularly and binocularly using monthly disposable CLs (Air Optix Plus Hydraglyde, Alcon Laboratories) with: (a) single vision (SV) lenses – uncorrected for near (b) aspheric multifocal (MF) CLs. LogMAR acuity was measured with ETDRS charts. Reading performance was evaluated using standard IReST paragraphs displayed on a screen (0.4 logMAR print size at 40cm distance). Eye movements were monitored with an infrared eyetracker (Eye-Link II, SR Research Ltd). Data analysis included computation of reading speed, fixation duration, fixations per word and percentage of regressions. Frequency distributions of fixations durations were analysed with an ex-Gaussian fitting, a convolution of a normal (with μ as the mean) and exponential (with τ as the mean) distribution, that can characterize its location and shape.

Results: Average reading speed was 250±68 and 235±70 wpm, binocularly and monocularly, with SV CLs, improving statistically significantly to 280±67 and 260±59 wpm, respectively, with MF CLs ($p<0.001$ in both conditions).Moreover, fixation duration, fixations per word and ex-Gaussian parameter of fixation duration, μ, showed a statistically significant improvement when reading with MF CLs, with fixation duration exhibiting the stronger correlation ($r=0.79$) with improvement in reading speed. The correlation between improvement in VA and reading speed was low ($r=-0.36$), as was also the case between VA and any eye fixation parameter.

Conclusions: Reading speed in a presbyopic population was found improved with MF compared to SV CL correction and was faster with binocular compared to monocular viewing: this was mainly due to the faster average fixation duration. The enhancement in reading performance could not be predicted by the observed improvement in VA. Evaluating reading performance using eye fixation analysis could offer a reliable outcome of functional vision in presbyopia correction.

ABSTRACT BODY:

Purpose: Earlier studies have indicated that the associations between depression and diabetic microvascular complications may be bidirectional, but evidence from population-based studies is still scarce. We aim to test whether the associations between diabetic retinopathy (DR) and major depression are bidirectional in a 5-year prospective cohort study.

Methods: In Denmark, DR screening has been nationally implemented and results have mandatorily been registered in the Danish Registry of Diabetic Retinopathy (DiaBase) database since 2013. We performed a register-based national cohort study including persons with type 2 diabetes who had attended DR screening with data collected between January 2, 2013 and December 28, 2018. Major depression was defined according International Classification of Disease 10 codes: F32 (unipolar depression), F33 (recurrent depression) or F34.1 (dysthymia) from the Danish National Patient Register. Multivariable adjusted Cox proportional hazard models were used to evaluate the risk of incident major depression among persons with DR along the reverse association.

Results: In 164,452 patients with type 2 diabetes followed for 508,133 persons-years, 1.2% developed at least one episode of major depression. In a model adjusted for age and gender, hazard ratio (HR) of incident major depression was 1.39 (95% CI 1.24-1.56) for patients with DR at baseline compared to those without. However, this was no longer statistically significant after adjusting for insulin use (HR 1.07 95% CI 0.95-1.21). Conversely, major depression did not predict 5-year incident of DR (adjusted HR 0.97 95% CI 0.88-1.06).

Conclusions: Although DR and major depression were not longitudinally linked, the use of insulin was a strong predictor of incident major depression in a nationwide cohort of persons with type 2 diabetes. Insulin use may be a proxy of dysregulated blood glucose or more advanced disease, which may cause the increased risk. Psychological problems due to insulin injections should also be suspected.

ABSTRACT BODY:

Purpose: To determine the associations between rare genetic variants in the complement factor H(CFH) and the phenotypic characteristics of age-related macular degeneration(AMD) patients from the Coimbra Eye Study(CES).

Methods: AMD patients from the Incidence Study(NCT02748824) underwent multimodal imaging: color fundus photography(CFP), spectral-domain optical coherence tomography(SD-OCT), fundus autofluorescence(FAF), near-infrared imaging(NIR). Phenotypic characterization of both eyes was performed in a centralized reading center. The coding and splice-site regions of the CFH gene were sequenced in collaboration with the EYERISK consortium. Variants with MAF<0.05 resulting in splice-site or protein change(nonsynonymous) were selected. Differences in phenotypic features between carriers and noncarriers were analyzed using generalized estimated equations logistic regression models, considering inter-eye correlations and controlling for age, sex and AMD stage.

Results: We included 39 eyes of 23 carriers and 284 eyes of 188 noncarriers. Carrying rare CFH variants was associated with larger drusen areas in the inner ETDRS circle (OR,3.29[95%CI,1.16–8.98];p=0.025); and having a total area occupied by drusen of 10-50% in: inner ETDRS circle (OR,5.53[95%CI,1.63–18.82;p=0.006), outer ETDRS circle (OR,4.39[95%CI,1.10–17.49];p=0.036), and full ETDRS grid (OR,4.89[95%CI,1.17–20.37];p=0.024). In SD-OCT a lower total macular volume (OR,0.456[95%CI,0.254–0.946];p=0.034) and of the inner retinal layers (OR,0.490[95%CI,1.25–22.59];p=0.024) was more common in carriers. Despite not reaching statistical significance, hard drusen were more common in non-carriers, and intermediate/large drusen were more common in carriers. Plus, carriers had thinner choroids (208.7±83.8µm vs 228.3±87.7µm), larger pseudodrusen areas (7.89±16.8mm^2 vs 4.64±10.10mm^2), and a trend of more pigment epithelial detachments (12.82% vs 3.17%, p=0.062) and hyperreflective foci (28.21% vs 15.85%, p=0.073).

Conclusions: We identified phenotypic differences between carriers and non-carriers of CFH variants in AMD patients. Carriers seem to present with more severe disease, including superior drusen burden and thinner retinas, independently of AMD stage. These patients are probably at increased risk for progression, and identification of such features could direct towards further genetic investigation if complement targeted therapies are to be pursued.

ABSTRACT BODY:

Purpose: Fusional vergence ranges are typically measured subjectively using Risley prisms or a prism bar. In this study, new methods to measure fusional vergence ranges at near objectively were validated against the two conventional tests used in clinics.

Methods: A total of 46 typical adults (23.3±3.0 years) participated in the study. Participants' BO (base out) and BI (base in) near fusional vergence ranges were measured objectively in an haploscopic set-up and recording eye movements with an Eyelink 1000 Plus (SR Research) at 500Hz. Firstly, stimulus disparity changed smoothly at 1PD/s up to 45PD for both divergence (BI) and convergence (BO), mimicking a Risley prism. Secondly, disparity was changed in steps of 2PD every 2 seconds mimicking a prism bar. Break and recovery points were determined offline using a custom Matlab code for the analysis of eye movements. Fusional vergence ranges were also measured with the conventional tests using a Risley prism and a prism bar, and the results were compared.

Results: When stimulus disparity changed smoothly, narrower BI ranges were obtained with the objective method (mean±SD break of 13.7±4.7PD and 10.6±5.1PD recovery) than with the Risley prism (break of 17.5±3.8PD and 12.8±4.2PD recovery) with a mean±SD difference between methods of -3.8±3.5PD (break) and -2.2±4.7PD (recovery). BO ranges were wider with the objective method (35.4±10.9PD break and 24.4±10.7PD recovery) than with the Risley prism (25.8±7.5PD break and 14.6±5.8PD recovery) with a mean difference of 9.2±10.7PD for the break, and 9.6±10.1PD for the recovery. When disparity changed in steps, fusional ranges measured with the objective method (15.7±5.1PD BI break, 12.8±4.7PD BI recovery, 36.3±11.4PD BO break, 23.9±10.6PD BO recovery) were not significantly different than with the prism bar (14.5±3.8PD BI break, 10.7±3.4PD BI recovery, 34.0±7.8PD BO break, 23.0 ±5.7PD BO recovery). Mean differences between these two methods were 1.2±5.2PD (BI break), 2.1±4.7PD (BI recovery), 2.3±13.0PD (BO break), and 0.9±11.3PD (BO recovery).

Conclusions: This study showed the possibility to measure fusional vergence ranges objectively. The agreement between the objective method with smooth-changed disparity and the conventional test using the Risley prism was considerably poorer than between the two methods where disparity changed in steps. However, a wide variability across subjects was still found, especially for the BO fusional ranges.

ABSTRACT BODY:

Purpose: Detection of luminance-modulated flicker under monocular and binocular viewing conditions worsen with a reduction in retinal illuminance.The impact of interocular difference in retinal illuminance on these thresholds however remain unknown.This study investigated the impact of purposely-induced variations in retinal illuminance of one or both eyes on monocular and binocular flicker modulation thresholds (FMTs) and on the binocular summation ratios (BSRs) of flicker.

Methods: Monocular and binocular FMTs were measured using the Flicker-Plus test for 30' target at fovea and four parafoveal (5^{O}) locations in 10 healthy adults at a baseline retinal illuminance of 930Td (7mm pupil diameter) and with 10 to 80% (827 to 186Td) induced interocular difference in retinal illuminance using neutral density filters over one eye,all in random order. The measurements were repeated in 5 subjects with bilateral change in retinal illuminance from 388 to 1553Td. BSRs were calculated by dividing the monocular threshold of the non-attenuated eye (for interocular difference condition) or the better eye (for bilateral condition) to the binocular threshold.

Results: The mean (±1SE) non-attenuated monocular foveal and parafoveal FMT was 2.98±0.28% and 5.3±0.63% respectively. These FMTs increased with reduction in monocular retinal illuminance (3.71±0.73% to 6.2±0.9%) and with increasing interocular difference in retinal illuminance(1.99±0.35% to 3.19±0.76%)($p<0.05$, for both).The resultant BSRs were thus larger for interocular differences <50% (1.56±0.12) than for those ≥60% (1.27±0.13) ($p\leq0.01$).This trend remained the same in the parafoveal region. Monocular(3.83±0.1% to 3.0±0.12%) and binocular(1.84±0.1% to 1.82±0.09%) FMTs and BSRs (1.68±0.1) remained largely stable with bilateral reduction in retinal illuminance.

Conclusions: The worsening of binocular flicker detection capability is proportional to its monocular value up to 50% of interocular difference in retinal illuminance. Beyond this range, the binocular loss is proportionally greater than the monocular loss, leading to a reduction in binocular summation of flicker. These results are in agreement with the negative impact of naturally-occurring interocular differences in monocular FMTs on binocular summation of flicker, observed in our earlier study.

ABSTRACT BODY:

Purpose: The adoption of antiseptic prophylactic strategies is important for patients receiving IVTs to prevent endophthalmitis onset, by avoiding the administration of antibiotics and their associated risk of antimicrobial resistance. The aim of this study was to evaluate the antimicrobial activity of a novel ocular spray containing Biosecur citrus extract (Oftasecur®, Off Health, Florence, Italy).

Methods: This study had a prospective and cross-sectional design. Patients undergoing IVTs were included and trained to administer Oftasecur spray into the treatment eye 4 times a day starting 4 days before the IVT procedure. The sound eye not undergoing IVT procedure was adopted as control. At baseline, a conjunctival swab for microbiological analysis was done in both eyes before the 4-day Oftasecur treatment regimen and at the time of IVT. All the patients were administered a Brief Ocular Discomfort Inventory (BODI) questionnaire, based on a 11-point scale (0 for no discomfort and 10 for maximum discomfort).

Results: In this study 30 patients were enrolled, including 15 males and 15 females (average age 64.7 ± 11.6 [standard deviation, SD] years). At baseline, 53.3% of the total eyes resulted positive after the microbiological analysis of the conjunctival swabs. After the completation of the treatment cycle, only 20% of the eyes were positive at the time of the IVT, referring a significant decrease in the microbial load ($p < 0.01$). In the treatment group, there was a significant reduction in the positive swabs' percentages between baseline and the completation of the Oftasecur ocular spray treatment cycle (decreasing from 70.4% to 29.6%; $p = 0.003$, McNemar's test). Overall, Oftasecur ocular spray resulted safe and well tolerated, showing a mean BODI score of 1.2 (± 0.70 SD).

Conclusions: Prophylactic treatment with Oftasecur ocular spray is associated with a significant reduction in the microbial load in those patients undergoing IVTs. Thus, Oftasecur ocular spray may display a role in the reduction of the risk of IVTs-related endophthalmitis without the need of using antibiotics.

ABSTRACT BODY:

Purpose: Several studies have indicated that inflammatory process is involved in the pathogenesis of diabetes, however little is known for an effect of immune responses impaired in diabetic condition on development of autoimmune diseases. Experimental autoimmune uveitis (EAU) is widely accepted as a model of endogenous uveitis of suspected autoimmune etiology in humans. In this study, we investigated effects of hyperglycemia on development of EAU using type 1 diabetic mice.

Methods: In this study, we used $Ins2^{Akita}$ (Akita) mice, which spontaneously develop Type 1 Diabetes Mellitus by a mutation in the insulin 2 gene. C57BL/6 (B6) mice and Akita mice were subcutaneously immunized with 200 μL total CFA supplemented with M. tuberculosis strain H37RA to 2.5 mg/mL emulsion containing 2 mg/mL human IRBP 1-20 (1:1 wt/vol) and administration of 0.5 μg pertussis toxin (i.p.). Clinical scores of EAU were performed by funduscopic examinations on day 0, 7, 14, 21 after immunization and histological scoring was evaluated on day 21. Splenocytes were also obtained on day 21 and were stimulated with 0, 5, 10 μg/mL human IRBP 1-20 for 72 hr. Supernatants were collected and contained cytokines (IL-2, IL-4, IL-6, IL-17A, and IFN-γ) were measured by Bio-Plex Multiplex Immunoassay System. In addition, cell-surface expression of CD4 and Foxp3, and production of cytokines were analyzed by flow cytometory.

Results: Clinical scores of EAU in Akita mice (0.23±0.53) were significantly lower than those in B6 mice (1.75±0.91). There was also statistically difference in histological scores between Akita mice (0.11±0.52) and B6 mice (1.1±0.22). IFN-γ production by splenocytes was apparently reduced in Akita mice compared with B6 mice (935±514 pg/ml vs. 2031±1237 pg/ml), although IL-17A production was higher in Akita mice (1084±35 pg/ml) than in B6 mice (739±140 pg/ml). There were no differences in IL-2, IL-4, and IL6 production between Akita mice (323±75, 62±25, and 126±18 pg/ml) and B6 mice (396±8.4, 107±4.0, and 212±0.8 pg/ml). Similar results were obtained by flow cytometory for splenic $CD4^+$ cells. On the other hand, population of $CD4^+$ $Foxp3^+$ T cells in the spleen was significantly augmented in Akita mice (9.03±0.91%) compared with B6 mice (4.80±1.04%).

Conclusions: It is indicated that EAU in Akita mice was downregulated by impaired Th1 cell activation rather than Th17 cells via augmentation of Treg cells.

ABSTRACT BODY:

Purpose: Fuchs endothelial corneal dystrophy (FECD) is a leading cause of endothelial keratoplasty worldwide. To elucidate the pathophysiology of FECD, we conducted multi-omic analyses of FECD in Japan.

Methods: A total of 104 eyes of 104 Japanese participants were included in our analyses, comprising a mix of cases (FECD: 13 eyes, bullous keratopathy [BK]: 46 eyes, healthy control: 45 eyes). Transcriptomic analysis of corneal endothelial cells (CEnC) was conducted in 27 eyes (FECD: 7 eyes, BK 12 eyes, healthy controls: 8 eyes). Metabolomic analysis of aqueous humor (AqH) was conducted in 77 eyes (FECD: 6 eyes, BK: 34 eyes, healthy controls: 37 eyes).

Results: Among the 57,955 genes in the transcriptomic analysis of CEnCs, 1241 up-regulated and 242 down-regulated genes were identified in FECD, while 730 up-regulated and 1270 down-regulated genes were identified in BK. Compared to healthy controls, these findings were statistically significant with non-FDR P values < 0.05. Functional gene ontology enrichment showed several cellular components: genes with significantly higher expression in FECD exhibited T cell receptor signaling, reactive oxygen production, and cytokine signaling, while genes with lower expression in FECD exhibited RNA synthesis, regulation of cell death and ER stress. However, no statistically differences were observed between FECD and BK in transcriptomic analysis. Metabolomic analysis of AqH identified 82 out of 147 metabolites, measured by mass spectrometry. Among the 82 metabolites in AqH, only lactate was significantly lower in FECD compared to healthy controls ($P<0.05$ after Bonferroni correction). Furthermore, in BK, 10 up-regulated and 9 down-regulated metabolites were identified, compared to healthy controls ($P<0.05$). No differences were detected in metabolite levels between FECD and BK.

Conclusions: The multi-omic analyses of CEnCs and AqH suggested that the mRNA and metabolites in the Japanese population affected by FECD may be similar to those with BK, although specific alterations were detected both in both.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is a complex multifactorial disease in which inflammation is considered a key factor, but the exact molecular mechanisms are unclear. The pro-inflammatory S100A9 proteins were amply found in drusen. These calcium-binding proteins have diverse signaling roles and can contribute to chronic inflammation, but their pathological and possibly physiological role in the retina is unknown. S100A9 were shown to be intrinsically amyloidogenic, possessing the capacity to self-assemble into amyloid structures in vitro and in vivo. Here, we hypothesized that the retinal effects exerted by S100A9 are related to their amyloid conformation.

Methods: ARPE-19 cells were treated with monomeric or fibrillary S100A9 (0.1 nM- 0.1 μM) for 12 h. Cell viability was determined by the XTT assay.

Wild type rats were treated with intravitreal injection (10μl) of monomeric or fibrillary S100A9 (0.1 μM) to right eye and vehicle in the left eye. Retinal function was assessed at baseline and through 28 days post injection. At each time point, electroretinography (ERG) measures were compared between eyes.

Results: Cell viability assays and ERG in rats delineated distinct retinal effects of S100A9. The number of living ARPE-19 cells was increased by exposure to 0.1- 1nM fibrillar S100A9 but was decreased by treatment with 0.01- 0.1 μM of the S100A9 fibrils. Monomeric S100A9 had no significant impact on the cellular counts.

Similarly, while retinal function remained normal in the eyes treated with monomeric S100A9, amplified ERG responses constituting increased amplitudes mostly of the b-wave were noted in the experimental eyes compared with their fellow (control) eyes through 14 days following injection of fibrillar S100A9 in rats. Thereafter, the retinal function became impaired, showing decreased ERG amplitudes in the treated eyes compared with controls.

Conclusions: Fibrillar S100A9 exerted pronounced effects on the retina, which included cell proliferation in vitro and increased amplitudes of the ERG responses in rats. In contrast, exposure to higher doses of S100A9 fibrils induced cell death in vitro and prolonged exposure to these assemblies resulted in decreased retinal function in vivo. This complex behavior supports the importance of the amyloid conformation of S100A9 to its retinal implications, and suggests a clue both to the pathological and possibly physiological role of S100A9 in the human retina.

ABSTRACT BODY:

Purpose: The purpose of this study was to assess the quantified parameters by Tear Film Imager (TFI), a new technology that enables quantification of the lipid and muco-aqueous layer thicknesses of the tear film on the cornea with a nanometer resolution developed by AdOM (Israel) and compare the clinical parameters from conventional ophthalmic examinations and other commercially available interferometry devices.

Methods: Patients with dry eye (DE), meibomian gland dysfunction (MGD), and non-DE/MGD were enrolled at Itoh Clinic (Saitama, Japan) from February 2020 to January 2021. Quantified outputs from TIF were as follows: Lipid Layer Thickness (LLT), Muco-Aqueous Layer Thickness (MALT), MALT Rate of change (MALTR), and Lipid Break Up Time (LBUT). Two other interferometry devices, LipiView2 (Johnson & Johnson Vision, CA, USA) and DR-1α (Kowa, Nagoya, Japan), were used for comparison. Correlation analysis was conducted with these TFI values and the following clinical signs: lid margin abnormalities, fluorescein staining score, meiboscore, fluorescein tear breakup time (BUT), Schirmer's test, the Standard Patient Evaluation of Eye Dryness (SPEED) questionnaire score, Dry Eye related Quality of life Score (DEQS), LLT measured by LipiView2, and interferometric patterns and noninvasive BUT measured by DR-1α. Each patient had one or several study visits. Baseline and changes from baseline values were analyzed.

Results: Twenty-eight patients (8 DE, 13 MGD, and 7 non-DE/MGD) participated in this study. The baseline values of TFI, LipiView2, and DR-1α were correlated with different clinical parameters. The LLT of TFI and LipiView2 showed correlation with lid margin abnormalities: Plugging and Vascularity scores (R=-0.42, -0.43). LBUT and MALTR correlated with Schirmer (R=0.47, -0.46). In correlation with changes, many TFI values showed higher correlation than those of LipiView2 and DR-1α, especially with the questionnaire scores. The correlation coefficients of MALTR and LBUT with SPEED score were 0.59 and -0.50.

Conclusions: TFI can measure the time variation of the thickness of the lipid and aqueous layers separately, and shows good correlation with key DE and MGD parameters. These results suggest that TFI might be useful for objective quantification of the signs and symptoms of DE or MGD, and for treatment monitoring.

TITLE: Bilateral persistent placoid maculopathy following COVID-19 Vaccines: real or co-incidence?

SESSION TITLE: Macular diseases/Macular edema/Functional testing/evaluation/Laser

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Chean, E. Ali, P. Kulkarni, B. Kapoor, P. Kumar, Ophthalmology, Leicester Royal Infirmary, Leicester, Leicester, UNITED KINGDOM|

Commercial Relationships Disclosure: Chung Shen Chean: Commercial Relationship: Code N (No Commercial Relationship) | Esraa Ali: Commercial Relationship: Code N (No Commercial Relationship) | Priti Kulkarni: Commercial Relationship: Code N (No Commercial Relationship) | Bharat Kapoor: Commercial Relationship: Code N (No Commercial Relationship) | Periyasamy Kumar: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: COVID-19 vaccination has been accompanied by reports of inflammatory events. We aim to report the first case of bilateral persistent placoid maculopathy (PPM) following COVID-19 vaccination.

Methods: Case report

Results: A 58-year-old man presented with bilateral sudden painless decrease in vision approximately two weeks after the second dose of AstraZenaca® COVID-19 vaccine. Visual acuity (VA) at presentation was 1.00 LogMAR in the right eye (RE) and hand movement in the left eye (LE). He had no known medical or ophthalmic history, up until after his first AstraZenaca® COVID-19 vaccine dose, he was diagnosed with palmoplantar pustular psoriasis and was started on 60mg of oral Prednisolone. Fundus examination revealed bilateral well-delineated whitish plaque-like macular lesions involving the fovea, sparing the peripapillary region in the RE (Figure 1a & e). Multimodal imaging including fluorescein angiography, indocyanine-green angiography, fundus autofluorescence and optical coherence tomography were consistent with PPM (Figure 1 & 2). Infective and auto-immune screen were all negative apart from a positive MPO-ANCA, prompting a rheumatology review which subsequently excluded any systemic vasculitis. Patient was monitored closely and his VA improved and stabilised with tapering regime of oral Prednisolone. To prevent relapse of PPM, patient was commenced on Mycophenolate Mofetil as a long-term steroid sparing immunosuppression.

Conclusions: Our case demonstrated a likely inflammatory or autoimmune response affecting choriocapillaris driven by the COVID-19 vaccine and there may be a correlation between the two. The patient in our case portrayed features classical of PPM, which is a selective autoimmune vasculitis causing microinfarcts on choriocapillaris, resulting in focal choroidal hypoperfusion after the COVID-19 vaccine.

ABSTRACT BODY:

Purpose: To characterize the two-year occurrence of macular edema of different diabetic retinopathy phenotypes in type 2 diabetes (T2D) focusing in changes in central retinal thickness (CRT).

Methods: A prospective longitudinal cohort study (CORDIS, NCT03696810) was conducted with 3 visits (baseline, 6-months and two-year). Demographic and systemic data included age, sex, diabetes duration, lipidic profile and hemoglobin A1c (HbA1c). Ophthalmological examinations included visual acuity, color fundus photography (CFP) and optical coherence tomography (OCT and OCTA), identified the presence of nonproliferative diabetic retinopathy. Phenotype classification was performed, at 6-month visit, based on microaneurysm turnover (MAT, on CFP) and CRT (on OCT). Only risk phenotypes B (MAT<6 and increased CRT) and Phenotype C (MAT≥6 with or without increased CRT) were included. ETDRS grading was performed at the baseline and last visits based on 7-fields CFP. OCT data was analyzed with OCT-Leakage, a novel technique for noninvasive assessment of abnormal accumulation of fluids in the retina through low optical reflectivity ratios (LOR).

Results: Of the 133 T2D individuals included in the study, 81 eyes (60%) were classified as phenotype B and 52 (40%) eyes as phenotype C. Of these 127 completed the two-year follow-up, with 24 (19%) developing central-involved macular edema (CIME) and 2 (1.6%) clinically significant macular edema.

Patients that developed CIME showed an increase in CRT with time when compared to patients that did not (ß=10.318, p<0.001). This difference remains statistically significant when controlling for age, sex, diabetes duration and HbA1c.

Changes in time for CRT, over the two-year period of follow-up, are positively associated with longitudinal changes in LOR ratios (ß=53.113, p<0.001) and with longitudinal changes in vessel density (increase) in the deep capillary plexus (ß=0.811, p<0.001) and superficial capillary plexus (ß=1.516, p<0.002). Patients with different ETDRS levels have similar alterations across visits for CRT, as well as for both phenotypes, B and C.

Conclusions: In the two-year period of follow-up CRT changes followed similar response patterns for both phenotypes and different ETDRS levels. CRT changes showed a clear association with the development of CIME.

ABSTRACT BODY:

Purpose: To investigate the recent trends of uveitis in Kyushu University Hospital, the regional center for uveitis care in southwestern Japan.

Methods: We retrospectively investigated the medical records of patients with uveitis who first visited Kyushu University Hospital between April 2015 and March 2020. Clinical data obtained included age, gender, diagnosis, anatomical location of ocular inflammation (anterior, intermediate, posterior, pan). We compared them with the previous studies of our facility and the national survey (Jpn J Ophthalmol. 2021).

Results: The total number of new patients with uveitis who visited Kyushu University Hospital was 790 (327 males, 463 females) accounting for 4.8% of all the new cases in our eye clinic. Mean age was 52.9 ± 19.8 years (men 52.0 years, women 53.5 years). The frequency of anterior uveitis, intermediate uveitis, posterior uveitis, and panuveitis were 23.0%, 3.0%, 9.9%, and 64.1%, respectively. Definite diagnoses were made in 506 cases (64.1%). In contrast to the national survey, Vogt-Koyanagi-Harada disease was the most frequent (11.4%), followed by sarcoidosis (9.4%), scleritis (5.8%), acute anterior uveitis (5.1%), herpetic iridocyclitis (4.9%), Behçet's disease (4.7%), malignant diseases (3.2%), acute retinal necrosis (3.2%), cytomegalovirus (CMV) retinitis (2.2%), and human T lymphotropic virus type 1 (HTLV-1)-associated uveitis (1.8%). Four of the top 10 most frequent uveitis were infectious in our study, whereas only 2 in the national survey. When compared with our previous reports, the present study showed increasing trends in Vogt-Koyanagi-Harada disease, scleritis, herpetic iridocyclitis, acute retinal necrosis, CMV retinitis, and malignant diseases. Among the herpetic iridocyclitis, CMV was found to be the most frequent agent. Behçet's disease and HTLV-1-associated uveitis were decreasing. Among the patients over 70 years old, intraocular lymphoma was the second most frequent disorder after sarcoidosis.

Conclusions: Although southwestern Japan has been an endemic area of HTLV-1, frequency of HTLV-1-associated uveitis is decreasing, reflecting on improvements in public health. Increases of CMV-associated diseases and malignant diseases, commonly observed in this study and the national survey, seem to be associated with the development of the diagnostics.

TITLE: Acute Dietary Supplementation with Omega-3 Fatty Acid Confers Novel Mechanistic Changes in Retinal Proteome in Mice with Targeted Gene Deletion of Cytochrome P450

SESSION TITLE: Glaucoma: biochemistry, biomechanics and omics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Manicam, A. Herfurth, F. Grus, N. Pfeiffer, N. Perumal, Department of Ophthalmology, Universitatsmedizin der Johannes Gutenberg-Universitat Mainz, Mainz, Rheinland-Pfalz, GERMANY|

Commercial Relationships Disclosure: Caroline Manicam: Commercial Relationship: Code N (No Commercial Relationship) | Anna Herfurth: Commercial Relationship: Code N (No Commercial Relationship) | Franz Grus: Commercial Relationship: Code N (No Commercial Relationship) | Norbert Pfeiffer: Commercial Relationship: Code N (No Commercial Relationship) | Natarajan Perumal: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Cytochrome P450 (CYP) gene mutations are a common predisposition associated with glaucoma. Although the molecular mechanisms are largely unknown, omega-3 polyunsaturated fatty acids (ω3) and their CYP-derived bioactive mediators play significant roles in proper maintenance of neurovascular functions and homeostasis in the retina. We tested the hypothesis that acute dietary supplementation with ω3 confers neuro-vasculoprotective effects attributed to inherent lack of the main murine CYP gene (Cyp2c44) in the retina in vivo.

Methods: Male mice with targeted deletion of the Cyp2c44 gene (KO) and their wild type floxed littermates (WT) were subjected to daily oral gavaging for 7 days with 0.01 ml/g ω3 composed of menhaden fish oil. Another group in respective strains served as vehicle-treated controls. Retina was isolated at day 8 post-treatment (n=9/group) and subjected to mass spectrometry (MS)-based proteomics and in-silico bioinformatics analyses.

Results: Proteomics analysis identified a total of 1402 retinal proteins (FDR<1%) and ω3 administration elicited significant ($p < 0.05$) differential expressions of 56 and 61 proteins in KO and WT mice, respectively. Noteworthy, ω-3 had a profound influence on the regulation of proteins involved in neuronal and mitochondrial activities in WT mice, while significantly improving the retinal metabolic status in the KO mice. The key molecular mechanistic changes conferred by ω3 in the WT retina were implicated in neurotransmission (p=4.22E-3), mitochondrial organization (p=1.62E-2), inhibition of neuronal cell death (p=2.33E-2) and activation of nitric oxide signalling (p=1.39E-2). Remarkably, ω3 supplementation in KO mice resulted in significant changes in the proteins involved in vision functions (p=3.69E-2), heightened metabolic activity via glycolysis (p=2.11E-2) and AMPK signalling pathway (p=2.33E-2), and inhibited apoptosis (p=7.78E-3).

Conclusions: Our findings provide the first in-depth experimental data that support our hypothesis that short-term dietary supplementation with ω3 can provide physiologically relevant beneficial effects in the retina via specific neuro-vasculoprotective signalling mechanisms, particularly by ameliorating retinal bioenergetics in the absence of Cyp2c44. The potential adjunct use of ω3 for glaucoma therapy needs further investigation.

TITLE: Demographic and clinical characteristics of patients with retinoblastoma in Seoul National University Children's Hospital in recent 30 years

SESSION TITLE: Intraocular tumors - Uveal melanoma and retinoblastoma

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Jo, Department of Anatomy and Cell Biology, Seoul National University College of Medicine, Seoul, KOREA (THE REPUBLIC OF)|J. Kim, Department of Ophthalmology, Seoul National University College of Medicine, Seoul, KOREA (THE REPUBLIC OF)|

Commercial Relationships Disclosure: Dong Hyun Jo: Commercial Relationship: Code N (No Commercial Relationship) | Jeong Hun Kim: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: This study aims to demonstrate the demographic and clinical characteristics of patients with retinoblastoma who visited Seoul National University Children's Hospital, Seoul, the Republic of Korea from 1991 to 2020.

Methods: Medical records of patients with retinoblastoma who visited Seoul National University Children's Hospital from 1991 to 2020 were reviewed. Age at diagnosis, sex, laterality, and tumor grading were recorded. During the study period, gross national incomes per capita were obtained from Statics Korea.

Results: In total, there were 464 patients with retinoblastoma during the study period. Among them, 209 (45%) were female. The mean age of diagnosis was 21 months. In recent ten years, it was 19 months, which showed a significant decrease. During the study period, gross national incomes per capita were increased from 7,634 USD (the year 1991) to 31,634 USD (the year 2020).

Conclusions: Seoul National University Children's Hospital is a representative tertiary center in the Republic of Korea. From 1991 to 2020, 464 patients with retinoblastoma visited the center. There was a dramatic increase in gross national incomes per capita during the study period, which reflected economic progress. This case series might be an excellent example for studying the effects of economic status and technical development on treatment patterns and outcomes in patients with retinoblastoma.

ABSTRACT BODY:

Purpose: To measure monocular and dichoptic color vision thresholds in amblyopic patients, controls, and congenital color deficient subjects.

Methods: Ten patients with amblyopia (mean age = 31.4 ± 9.2 years; 6 males) and without congenital color vision deficiency were included in the study. The control group (mean age = 27.8 ± 6.3 years) comprised 17 color normal (10 males) and 10 color deficient (8 males) subjects. Visual stimulation was based on pseudoisochromatic tests: the target was a mosaic made of small chromatic dots on a borderless background with random varying luminance (mean luminance = 11.9 ± 0.2 cd/m^2) presented dynamically (10Hz). Color vision thresholds were measured from the reference stimulus (background mean chromaticity: u'=0.1894, v'=0.4415, CIE1976) towards u'=0.3187, v'=0.4583, approximating protan and towards u'=0.1821, v'=0.2354, approximating tritan confusion lines with a 3D calibrated (LG) display using interleaved polarization via 3D goggles. Measurements were performed monocularly and dichoptically (non-tested eye viewing background noise). Color deficient subjects also performed the Cambridge Colour Test (CCT) to characterize their color deficiency and to validate the new test.

Results: There was high correlation between our monocular condition and CCT thresholds, especially for the protan vector (Spearman $rho_{(N=9)}$=0.82, p=0.007, $rho_{(N=9)}$=0.70, p=0.036 for protan and tritan, respectively). In the monocular condition, interocular differences were comparable for both protan and tritan thresholds (group main effect: $F_{(2,34)}$=2.04, p =0.14, group*vector $F_{(2,34)}$=0.70, p =0.50) among the groups, both eyes having similar thresholds (single mean t-test against zero mean: all t≤1.92, p≥0.09). On the other hand, protan and tritan interocular thresholds were significantly elevated in amblyopic subjects under dichoptic condition compared to both color normal and color deficient subjects (main effect of group: $F_{(2,34)}$=7.70, p=0.0017, group*vector $F_{(2,34)}$=0.40, p=0.67). Most likely, this increase is the result of unbalanced binocular interactions preventing the background noise presented to the amblyopic eye to influence color perception of the dominant eye in amblyopic subjects.

Conclusions: The results emphasize potential use of dichoptic stimulation to measure color thresholds when evaluating amblyopic status as well as to test the effects of amblyopic treatment for visual improvement.

SUBMITTER (NAME ONLY): Ellen Ingolfsland

TITLE: Iron Status and Retinopathy of Prematurity Outcomes among Infants in the Preterm Erythropoietin Neuroprotection Trial (PENUT Trial)

SESSION TITLE: Retinopathy of prematurity

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E.C. Ingolfsland, R.B. Rao, Pediatrics, University of Minnesota Academic Health Center, Minneapolis, Minnesota, UNITED STATES|N. Rubin, Clinical & Translational Science Institute, University of Minnesota Academic Health Center, Minneapolis, Minnesota, UNITED STATES|

Commercial Relationships Disclosure: Ellen Ingolfsland: Commercial Relationship: Code N (No Commercial Relationship) | Nathan Rubin: Commercial Relationship: Code N (No Commercial Relationship) | Raghavendra Rao: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine the impact of iron status on short- and long-term ROP outcomes among extremely preterm infants (<28 wk gestation) enrolled in the randomized trial of erythropoietin (EPO) or placebo (PENUT Trial). We hypothesized that infants with evidence of low or high iron status would have more severe ROP compared with those with normal iron status.

Methods: A post-hoc analysis of archived NINDS data from the PENUT trial was conducted. Baseline characteristics, iron status (defined as low when serum ferritin (SF, ng/mL) was ≤ 75 or zinc protoporphyrin to heme ratio (ZnPP/H) > 184, normal when SF 75-400 or ZnPP/H 30-183, or high when SF > 400) at 14, 28 and 42 days and 36 wk corrected gestational age (CGA), ROP outcomes (any ROP, ROP stage ≥ 2, ROP requiring treatment, retinal detachment, glasses and strabismus), growth rates, infection rates, hematocrit (hct) and inflammatory biomarker data were reviewed. Association with ROP was analyzed with Chi-squared tests (iron status) and analysis of variance (continuous variables) (significance set at $p < 0.05$).

Results: 940 infants (mean gestation 25.9 wk; mean birth weight 799 g) were included in the analysis. 51% received EPO. Any stage ROP occurred in in 398 infants (59%), ROP stage ≥ 2 in 229 (34%), and ROP requiring treatment occurred in 47 (7.1%). In unadjusted analysis, there was an association between higher iron status at 14, 28 and 42 days, but not at 36 wk CGA, with any ROP, ROP stage ≥ 2, and ROP requiring treatment. Table 1 summarizes associations between iron status and ROP requiring treatment. Higher IL-6, IL-8, IL-10 and EPO levels on day 14 were associated with ROP requiring treatment. Iron status at 14, 28, and 42 days was associated with EPO administration, delayed cord clamping, rate of weight gain, number of infections from day 0-14 and 14-42 and mean hct wk 1 and wk 2.

Conclusions: Severe ROP may be impacted by systemic iron status. Association with higher iron status on univariate analysis may be explained by pending analyses of timing and dosing of iron supplementation, RBC transfusions and hematocrits. As management of iron status through these means is highly controlled by the clinician, determining this association may have important clinical implications to reduce severe ROP.

ABSTRACT BODY:

Purpose: Excessive eyeball elongation leads to various changes in retinal structures and visual functions, as characterized by the chorioretinal thinning, enlarged photoreceptors spacing, and declined contrast sensitivity. This study compared the cone morphometrics and contrast sensitivity at central and mid-peripheral retina between highly myopic and emmetropic eyes, and investigated the relationships between structural and functional changes.

Methods: Thirty-six healthy adults aged 19 to 41 years were recruited, including 17 high myopes (HM, ≤ -8.00D) and 19 emmetropes (EM, -0.50 to +0.50D). Monocular contrast detection thresholds of vertical sinusoidal gratings (spatial frequency at 0°: 1, 2, 4, 8, and 16 c/deg; 10°: 0.5, 1, 2, 4 and 8 c/deg) were measured at central and 10° temporal retina, by 3-down-1-up staircases using 2-interval-forced-choice paradigms. After log transformation, the contrast sensitivity (i.e., a reciprocal of contrast detection threshold) was fitted with symmetric parabolic function to calculate the area under the curve (AUC). Cone morphometrics (i.e., density, cell spacing, regularity, dispersion) at fovea (1.5° to 2°) and 10° temporal retina were determined from the retinal images captured by the adaptive optics retinal camera using customized Matlab software with ocular magnification corrected.

Results: The contrast sensitivity at central vision was comparable in HM and EM, as suggested by comparable AUC in two groups (2.16 vs. 2.27 log unit, p=0.248). In contrast, HM exhibited a general reduction of contrast sensitivity at 10° peripheral vision, with smaller AUC than EM (1.72 vs. 1.89 log unit, p=0.037). For the cone morphometrics, HM had lower cone density (2011.80 vs. 2396.09 cells/deg^2, p=0.002) and regularity (91.10% vs. 93.15%, p=0.019), but increased cell spacing (1.50 vs. 1.38 arcmin, p=0.019) and dispersion (13.97% vs. 11.83%, p<0.001) than EM at fovea. However, the cone density (1311.08 vs. 1163.83 cells/deg^2, p=0.008) was increased while the cell spacing was decreased (1.84 vs. 1.94 arcmin, p=0.017) at the temporal retina of HM. There were no significant correlations between contrast sensitivity and cone morphometrics at 10° temporal retina.

Conclusions: Eyeball elongation affected the cone morphometrics at both foveal and mid-peripheral retina diversely. However, retinal function in terms of contrast sensitivity was preserved at central vision but was less resistant to high myopia at mid-periphery.

Verbraak: Commercial Relationship: Code N (No Commercial Relationship) | Ger M.H.B. Rens: Commercial Relationship: Code N (No Commercial Relationship) | Ruth van Nispen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In previous research the EyeQ item bank which measures vision-related quality of life (Vr-QoL) was developed and calibrated for future use as a computer adaptive test (CAT). In theory, the CAT-algorithm uses only a few items for a reliable Vr-QoL estimation ('ability'), reducing patient burden. But before using a CAT in clinical practice it is essential to conduct preliminary analyses to evaluate the appropriateness of patient ability estimations (θ) against full test length and actual test length reduction. The aim of the current study was to optimize performance of the CAT-EyeQ by customizing stopping rules.

Methods: Post-hoc CAT simulations were performed using real responses. Patients (N=704, mean age 76.2), having macular edema due to several exudative retinal diseases completed the EyeQ (46 items). θ's were estimated after fitting Samejima's graded response model. Subsequently, plausible responses were imputed and again θ`s based on complete data were obtained. Pearson`s correlation was calculated between EyeQ θ_{incom} (incomplete data) and EyeQ θ_{imput} (plausible imputed data). Four CAT simulations were performed which varied in combinations of stopping rules: for $CAT_{DefaultPROMIS}$, a minimum and maximum length of 4 and 12 items, and an accuracy level of 0.32 (4|12|0.32) was set; for CAT_{Alt1} 2|15|0.32 and for CAT_{Alt2} 4|12|0.25. $CAT_{Besthealth}$ was defined as CAT $_{DefaultPROMIS}$ plus abort if the first four responses were rated as 'best possible health'. Mean test length, percentage unreliably estimated CAT θ`s and mean standard error was evaluated. The conditional standard error across different levels of ability was examined graphically.

Results: Pearson`s correlation between EyeQ θ_{incom} and EyeQ θ_{imput} was 0.99. $CAT_{DefaultPROMIS}$ showed the lowest mean number of items needed to administer (6.9), where CAT_{Alt1} showed the lowest amount of unreliably estimated CAT scores (11.5%). CAT_{Alt2} performed worst; mean number of items needed (9.7) and 37% unreliable estimations. Outcomes of $CAT_{BestHealth}$ were similar to $CAT_{DefaultPROMIS,}$ but further reduced the mean test length to 6 items. In all applied conditions, the conditional standard error was found to be highest at lower levels of ability.

Conclusions: This study shows that measuring Vr-QoL in clinical practice using the CAT-EyeQ with optimized stopping rules is useful as it leads to a higher measurement efficiency where reliable test outcomes can still be achieved.

ABSTRACT BODY:

Purpose: One in three adults with vision impairment (VI) experience symptoms of depression. However, healthcare providers often experience difficulties in recognizing and discussing depression in this population. Detection of depression, and subsequently providing mental health support, can be improved by determining predictors to detect depression in adults with VI from the perspective of healthcare providers.

Methods: Cross-sectional data on demographics, work, confidence, experienced barriers, intention to identify depression and taking initiative to discuss depression was analyzed in Welsh (n=122), Australian (n=94) and Dutch (n=100) healthcare providers. Multivariable logistic regression analysis was performed in the Welsh sample. The derived model was internally validated by using a bootstrap method, followed by external validation of the recalibrated model in the Australian and Dutch samples.

Results: Work experience (β -0.05; 95% confidence interval (CI) 0.92 to 0.99) and experienced barriers (β -0.05; 95% CI 0.92 to 0.98), such as lack of time, knowledge and standard procedures, were found to predict healthcare providers' initiative to discuss depression. Internal validation of the model provided an area under the curve (AUC) of 0.73, reflecting good discrimination. The recalibrated model showed a good fit in the Australian sample (AUC = 0.77) and a poor fit in the Dutch sample (AUC = 0.63).

Conclusions: Predictors for discussing depression by healthcare providers lacked generalizability. Dutch healthcare providers experienced less barriers in depression management than their Welsh and Australian colleagues, which could be a result of the increased attention for mental health in their education and work, and the difference in healthcare systems. Furthermore, a previous study showed intention to discuss depression, self-efficacy and social support predict healthcare providers' initiative to discuss depression. To improve the detection of depression in adults with VI, the found predictors for each country should be addressed, for instance by means of tailored training programs and effective referral pathways.

TITLE: Fluorescent protein tdTomato is deleterious to the retina

SESSION TITLE: Novel animal models and neuroprotection in the retina

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Zhang, H. Mou, Z. Jin, Beijing Institute of Ophthalmology, Beijing Tongren Eye Center, Beijing Tongren Hospital, Beijing, Beijing, CHINA|

Commercial Relationships Disclosure: Chang-Jun Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Hao Mou: Commercial Relationship: Code N (No Commercial Relationship) | Zi-Bing Jin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Fluorescent proteins (FPs) are widely used in imaging techniques to investigate cellular molecular interactions and trace biological events. However, some FPs have been demonstrated to cause undesirable cellular damage. So far, the effects of red fluorescent protein (RFP) tandem dimer Tomato (tdTomato) on retina remains unknown. Here we study the effects of tdTomato expression on mice retina.

Methods: Electroretinography (ERG) was carried out to investigate the changes of retinal function comparing tdTomato mice with C57BL/6J wild-type control mice. Optokinetic Response (OKR) was measured to detect visual contrast sensitivity. Color fundus camera and high-resolution spectral-domain optical coherence tomo-graphy (SD-OCT) were taken to compare the retinal structural alteration. Immunofluorescence staining was used to label proteins in retina. Transmission Electron Microscope (TEM) was used to observe the retinal ultrastructure. Expression levels of mitochondrial specific genes were quantified via quantitative real-time PCR (qPCR).

Results: The tdTomato mice showed progressively attenuated electroretinogram (ERG) responses in scotopic a-wave and photopic b-wave, and reduction of visual contrast sensitivity was detected via OKR. Mitochondrial vacuolation and broken mitochondrial crest were found by TEM. And down-regulated mitochondrial DNA (mtDNA) expression were found in tdTomato mice. The apparent changes in retina of color fundus camera, SD-OCT and immunofluorescence staining measurements were not found.

Conclusions: tdTomato expression cause functional and ultrastructural defects in the retinas of tdTomato mice, indicates potential toxicity of tdTomato to mouse retina. Mitochondria should be a potential target of the fluorescent protein tdTomato that hazard to the mouse retina. Our findings provide valuable insights into using the tdTomato mice more efficiently and reasonably.

ABSTRACT BODY:

Purpose: To assess the rate of epiretinal membrane (ERM) recurrence after the surgical removal and to describe the morphological features of recurrent ERM as well as their clinical course over time. Finally, clinical and optical coherence tomography (OCT) findings were correlated to identify associated risk factors.

Methods: 640 patients who underwent pars plana vitrectomy (PPV) for an ERM at University Eye hospital, Tübingen, Germany between 02/2007 and 05/2017 were included into a retrospective observational study. ERM recurrence was identified by OCT imaging at a first visit within 3 months after surgery and at the last follow-up examination available. ERM extension was classified as “dot-like” (small dot or deposit-like circumscribed ERM), “focal-ERM” (measuring 50 µm or less) and “large ERM” (measuring more than 50 µm). Morphology analysis included if an ERM remnant edge was within the 1.5mm radius of the foveal center, if the membrane was extrafoveal or involved the fovea and if intraretinal cysts were visible at any postoperative visit. OCT endpoints were correlated with patient related clinical parameters and surgery related factors.

Results: Out of 506 eyes 38% showed OCT signs of an epiretinal membrane at the last available follow up visit (mean follow up period 28.3 months). Large foveal ERM however was only visible in 10% and only 4% of all eyes were reoperated a second time for an epiretinal membrane. An ERM remnant edge, hyperreflective epiretinal dots, small focal ERM and intraretinal cystic spaces were found to be possible risk factors for large foveal ERM recurrence at later timepoints with an odds ratio of 5.66 (95% confidence interval: 2.0-15.99; p=0.003), 3.63 (95% confidence interval: 1.34-9.84; p=0.02), 2.89 (95% confidence interval: 1.21-6.89; p=0.02) and 1.95 (95% confidence interval: 1.06-3.58; p=0.03).

Conclusions: The recurrence rate depends significantly upon the definition of ERM recurrence. Foveal ERM recurrence is much less frequent than ERM recurrence outside of the fovea. Insufficient peeling with neighboring remnant membrane is an important predisposing factor for clinically relevant foveal ERM recurrence.

ABSTRACT BODY:

Purpose: To validate the feasibility and performance of the Notal Vision Home OCT (NVHO) system for daily self-imaging at home, and to characterize retinal fluid dynamics in neovascular AMD (nAMD).

Methods: In this prospective observational study, 15 participants who have at least one eye with nAMD undergoing anti- VEGF treatments performed daily self-imaging at home with NVHO for 3 months. Scans were uploaded to the cloud, analyzed by the Notal OCT Analyzer (NOA), evaluated by human experts for fluid presence and compared with in-office OCT scans. Weekly self-scan rate, image quality, scan duration were obtained; agreement between NOA and human expert grading for fluid presence and agreement between NVHO and in-office OCT scans for fluid presence, central subfield retinal thickness (CST) and retinal fluid volume, characteristics of fluid dynamic during the study and in response to treatments were analyzed.

Results: The mean weekly scan frequency was 5.7±0.9 scans per week, and 93% of scans were eligible for NOA analyses. Mean scan time was 42 seconds. NOA and human experts agreed on the fluid status in 83% of scans and discrepancies were limited to trace amounts of fluid. NVHO scans analyzed by NOA and in-office OCT scans graded by human experts agreed on the fluid status in 96% of cases. CST and retinal fluid volume measurements from home OCT and in-office OCT scans demonstrated Pearson correlation coefficients of $r = 0.90$ and $r = 0.92$, respectively. Novel parameters such as retinal fluid volume, area under the retinal fluid volume curve (AUC) demonstrated wide variations in fluid exudation and fluid load over time among patients. Parameters, such as the rate of reduction in fluid volume in the first week after treatments and AUC between treatments captured the speed and duration of response to anti-VEGF agents.

Conclusions: Daily home OCT imaging is feasible among patients with nAMD. It demonstrated good agreement with human expert grading for retinal fluid identification, and excellent agreement with in-clinic OCT scans. Home OCT allows for detailed graphical and mathematical analyses of retinal fluid volume trajectories, including novel parameters to inform clinical decision making.

ABSTRACT BODY:

Purpose: In the Netherlands, c.768G>T (p.Leu257Valfs*17), a severe mutation in ABCA4, is one of the most frequently found variants underlying Stargardt disease (STGD1). In light of potential upcoming mutation-specific intervention trials, we performed a retrospective study on the disease progression in a large cohort of STGD1 patients homozygous or compound heterozygous for the c.768G>T mutation.

Methods: We included patients with genetically confirmed STGD1 and that were homozygous or compound heterozygous for the c.768G>T mutation in ABCA4, from the STGD1 database of Radboud university Medical center, Nijmegen, The Netherlands. Clinical data were extracted from medical files, including age of onset and best-corrected visual acuity (BCVA). Atrophy was quantitatively assessed with area of definitely decreased autofluorescence (DDAF) and questionably decreased autofluorescence (QDAF) on fundus autofluorescence (FAF). Total decreased autofluorescence (DAF) was calculated as the sum of DDAF and QDAF. External limiting membrane (ELM) and ellipsoid zone (EZ) loss was measured at the foveal OCT-scan. Mean progression rates per year were calculated and data was compared between ages of onset and genotype.

Results: We included 72 patients. Median age of onset was 16.5 years (IQR 9.0-31.5). A larger part consisted of early onset patients (age of onset ≤10 years) compared to our general STGD1 population (32.4% vs. 23.4%). Median DDAF and QDAF progression per year was 0.30 mm^2 (IQR 0,00-1.26) and 0,00 mm^2 (IQR 0.00-0.16). ELM and EZ decreased by 160 µm per year (ELM IQR 68.7-324.7; EZ IQR 68.7-310.8) . BCVA detoriated by 0.10/year (Snellen decimals (IQR -0.06-0.00)). Rate of ELM and EZ loss was significantly higher in late onset (≥45 years) compared to intermediate onset (11-44 years) (p=0,04 and p=0.02). DAF progression rate was also significantly higher in patients with another severe mutation next to c.768G>T, compared to patients with a second mild/moderate mutation (DAF 2.33mm^2 (IQR 1.56-2.99) in severe vs 0.33mm^2 (IQR 0.00-1.42) in mild/moderate, p=0.02).

Conclusions: The c.768G>T variant is one of the most occurring mutation in STGD1 and is of high interest due to possible mutation-specific intervention. The disease progression rate of STGD1 patients with c.768G>T seems to be dependent on age of onset and severity of the second mutation and can be monitored using DDAF/QDAF and ELM/EZ loss measurements.

ABSTRACT BODY:

Purpose: We aimed to develop a deep-learning model for detecting and localizing retinal breaks in ultra-wide-field fundus (UWF) images

Methods: We retrospectively enrolled treatment-naive patients diagnosed with retinal break or rhegmatogenous retinal detachment and who had UWF images. The YOLO v3 architecture backbone was used to develop the model, using transfer learning. The performance of the model was evaluated using per-image classification and per-object detection.

Results: A total of 4,505 UWF images from 940 patients were used in the current study. In the per-image classification, the model showed an area under the receiver operating characteristic curve (AUROC) of 0.957 within the test set. With the best threshold from the validation set, the accuracy, sensitivity, and specificity were 0.9118, 0.9474, and 0.8535, respectively. With respect to per-object detection , the average precision for the object detection model considering every retinal break was 0.840. (Figure)

Conclusions: The UWF image-based deep-learning model evaluated in the current study performed well in diagnosing and locating retinal breaks. Owing to its fast detection speed, we conclude that this model can be generalized for the real-time detection of retinal breaks.

ABSTRACT BODY:

Purpose: The increasing demand for diabetic retinopathy (DR) screening represents a significant burden for eye care services. Deep learning systems (DLS) for DR detection have shown promise in bridging the gap between demand and availability of health resources. However, an important limitation is a tendency for poor generalisability. External validation within populations intended for use is therefore critical. Indigenous Australians are an understudied ethnic group who suffer disproportionately from diabetic-related blindness. This study evaluates the performance of a DLS for DR detection in an Indigenous Australian population.

Methods: We performed a retrospective external validation study comparing the performance of a DLS against a retinal specialist for the detection of more-than-mild (mtmDR) and vision-threatening diabetic retinopathy (vtDR). The validation set consisted of 1682 consecutive, single-field, macula-centered retinal photographs from diabetic patients at an urban Indigenous primary health service in Perth, Australia. Adjudication by a panel of three retinal specialists and trained graders served as the reference standard.

Results: The validation set comprised 1682 eyes of 866 patients (mean age 54.9 years, 52.4% female). For mtmDR detection, sensitivity of the DLS was superior to the retinal specialist (98.0% [95% CI:96.2-99.1%] vs 88.0% [95% CI:84.5-91.2]) with a small reduction in specificity (95.0% [95%CI:93.5-96.5%] vs 97.9% [97.0-98.8%]; both significant by two-sided permutation test, $p < 0.001$). For vtDR, the DLS's sensitivity was again superior to the human grader (96.2% [95% CI:93.9-96.3%] vs 84.5% [95% CI:79.3-89.7%], $p<0.001$) with a slight drop in specificity (95.5% [95%CI:94.3-96.7%] vs 98.3% [95%CI:97.6-99.0%], $p<0.001$). These results are comparable to reported performance in other populations, including Indian and Thai diabetic screening populations.

Conclusions: In this retrospective sample, the DLS showed improved sensitivity and similar specificity compared to a retinal specialist for the detection of mtmDR and vtDR. This demonstrates the potential of the system to support DR screening amongst Indigenous Australians, an underserved population with a high burden of diabetic eye disease. Further prospective validation in real-world clinical settings is required.

ABSTRACT BODY:

Purpose: Biomarkers of activity of macula neovascularisation (MNV) in those deemed stable with conventional structural optical coherence tomography (OCT) could help to determine the requirement for further treatment and their associated monitoring interval for further visits. The aim of this study was to describe features of disease activity of treated stable MNV due to neovascular age related macular degeneration (nAMD) using optical coherence tomography angiography (OCTA).

Methods: 32 eyes of 32 patients with nAMD were included in this prospective, observational study. These patients were undergoing treatment with aflibercept on a treat-and-extend regimen. They were identified as attending a 16-week interval treatment visit and had been assessed as clinically stable based on clinical evaluation (visual acuity assessment, clinical examination and structural OCT assessment). All patients then underwent macular OCT imaging and OCT angiography on the same day (Spectralis, Heidelberg Engineering, Heidelberg, Germany). These images were analysed by the Moorfields Eye Hospital Reading Centre, London, United Kingdom.

Results: Evaluation of structural OCT confirmed no evidence of subretinal or intraretinal edema, but presence of subretinal hyperreflective material (13, 40.6%), pigment epithelial detachment (31, 96.9%), outer retinal tubulation (10, 31.3%) and macula atrophy (19, 59.4%). 31/32 OCTA images were gradeable (1 had significant signal attenuation); 28/32 (87.5%) OCTA images were noted to have signal artefacts. The mean MNV size was 3.6 ± 4.6mm and 29 (93.5%) and 27 (87.1%) had detectable MNV blood flow. 29 (93.5.%) subjects had MNV maturity including 10 non-specific, 10 tangle, 3 deadtree and no medusa or seafan phenotypes. MNV halo and MNV central feeder vessel were noted in 18 (58.1%) and 19 (61.3%) of subjects respectively; only 1 (3.2%) subject was noted to have a MNV capillary fringe.

Conclusions: CNV blood flow is still detectable using OCTA in the majority of subjects in this study. The majority of MNV were of mature phenotype. OCTA features associated with this clinically stable MNV activity included MNV maturity, feeder vessel, halo and absence of capillary fringe. These features could be helpful as possible OCTA biomarkers of disease activity and help inform treatment decisions with anti-vascular endothelial growth factor agents.

ABSTRACT BODY:

Purpose: Ocular blood flow is important for eye health and for understanding the pathogenesis of ocular diseases, such as diabetic retinopathy and glaucoma. The purpose of this study was to a test a simple, noninvasive method to assess pulsatile ocular blood volume (POBV) in healthy subjects and to determine effects of posture changes and glaucoma medications.

Methods: A subset of data was evaluated from a prospective, randomized crossover-design of glaucoma medications (ClinicalTrials.gov NCT04412096) in healthy subjects. Aqueous humor dynamic measurements were made at baseline, after 1 week of timolol 0.5% dosed twice daily, and after 1 week of latanoprost 0.005% dosed nightly. The treatments were separated by a 6-week washout period. Study criteria for this subset analysis included high quality recordings of intraocular pressure (IOP) by pneumatonometry with two or more pulses measured at each visit in sitting and then supine positions. Thirty-two eyes from 16 subjects, ages 44 to 72 years, met study criteria. Ocular pulse amplitude (OPA) was defined as the IOP difference between diastolic (IOPdia) and systolic (IOPsys) values. POBV was calculated as OPA/IOPdia, as previously described. Student t-test with Bonferroni correction for multiple comparisons was used with significance threshold at $p<0.017$ to compare the effects of posture and under medication treatment conditions.

Results: At baseline, there was a significant increase in supine versus sitting position in IOPsys (16.7 ± 2.3 mmHg to 21.4 ± 2.4 mmHg, $p<0.0001$), IOPdia (14.4 ± 2.2 mmHg to 19.5 ± 2.2 mmHg, $p<0.0001$), and mean IOP (15.5 ± 2.2 mmHg to 20.5 ± 2.2 mmHg, $p<0.0001$). Calculated POBV was significantly decreased in supine versus sitting positions (0.17 ± 0.06 vs. 0.10 ± 0.04, $p<0.001$). These effects were similar at baseline and after treatments with timolol or latanoprost. The position-related POBV change was not affected by treatment or order of treatment.

Conclusions: In the supine position of healthy adults, IOP increased and POBV calculated by OPA/IOPdia decreased relative to the sitting position. Our future studies will compare POBV in patients with glaucoma where the autoregulation of retinal blood flow may be affected, to investigate whether changes in pulsatile blood volume in the supine position may play a role in glaucoma pathogenesis. Changes from glaucoma treatments also will be investigated.

ABSTRACT BODY:

Purpose: To ensure adequate oxygenation of the retina, one of the most metabolically demanding tissues in the body, photoreceptors are mainly supplied by the choroid and inner retinal neurons by the retinal vasculature. Vascular damage in retinal degenerative diseases, e.g. diabetic retinopathy, or attenuated retinal blood vessel development in retinopathy of prematurity (ROP) result in retinal hypoxia. We tested whether hypoxia underlies compromised phototransduction and light signal transmission, and whether changes are reversible, by measuring photoreceptor (PR) and ON-bipolar cell (ON-BC) light responses in mouse models of these conditions.

Methods: Diabetic (db/db) and non-diabetic (db/+) mice were used as a diabetes model. For oxygen-induced retinopathy (OIR, a model of ROP), we exposed C57BL/6J pups to high (75%) O_2 from postnatal day (P)7 to P12, before returning them to room air. We recorded scotopic in vivo electroretinograms (ERGs) or ex vivo ERGs in isolated retinas. To modulate O_2 concentrations we provided hypoxic gas (8% O_2) through a nose cone in vivo or perfused with hypoxic superfusate (containing 2.5% O_2) ex vivo.

Results: ON-BCs lose function within 8 minutes of ex vivo hypoxia, whereas PRs retain >50% response amplitudes after 30 min (n=2-3). In vivo PR and ON-BC amplitudes in diabetic mice progressively decrease at 4.5 and 6, but not at 3 months. Diabetes reduces the b/a-wave ratio at 6 months (2.20±0.23 in db/db compared to 2.65±0.27 in db/+, p= P<0.001, n=9-10), indicating that ON-BCs or light signal transmission are more susceptible to diabetes than phototransduction. During ex vivo ERG (with 95% O_2) PR and ON-BC responses were not different between 6 month old db/db and db/+ mice (n=11). Ex vivo PR and ON-BC function were reduced in OIR mice on P12 (n=7-10, P<0.001) and on P24 (n=8-10, P<0.001).

Conclusions: Although retinal neurons critically depend on sufficient O_2 supply, PRs maintain better function during hypoxia compared to ON-BCs, possibly by adapting to low O_2 conditions they are exposed to daily during the normal light-dark cycle. Deficits in retinal function in diabetic mice in vivo are reversed ex vivo with high O_2. Irreversible PR damage in OIR likely occurs during the hyperoxic phase, before hypoxic damage. Investigating these discrepancies will allow us to better understand importance and therapeutic potential of adequate O_2 supply in different retinal diseases.

ABSTRACT BODY:

Purpose: Focal laser retinal injury models are a robust platform for in vivo testing of retinal regeneration strategies. However, quantitative assessment of the retinal structural changes resulting from laser photodamage is prohibitively labor-intensive, requiring manual segmentation of longitudinal volumetric datasets. Here, we present a deep-learning based approach for automated qualitative assessment of lesion volumes using OCT images to enable real-time assessment of injury severity and longitudinal tracking of tissue response to photodamage.

Methods: In vivo OCT retinal imaging was performed longitudinally to track retinal injury response and analyze the reproducibility of retinal photodamage in murine models. Lesions with different severity were induced by varying the laser pulse duration, pulse power, and number of pulses. OCT images were denoised using self-fusion and fed into a convolutional neural network to segment lesion cross-sections. The network was trained to quantify photodamage between the outer plexiform layer (OPL) and retinal pigmented epithelium (RPE) accurately without the need for extensive image pre- and post-processing. The consensus of manually labeled OCT cross-sections from two independent image annotators were used as ground-truth.

Results: The automated method was compared against the manual segmentation using the Dice coefficient achieving a score of 0.91 for training and 0.87 for testing. Figure 1 shows high degree of spatial co-registration between the manual (B) and automated lesion segmentation (C). Likewise, projections of lesion height of manually (E) and automatically (F) segmented lesions overlaid on the OCT en face projections demonstrate that both methods are well-correlated.

Conclusions: Automated volumetric OCT segmentation enables efficient and robust quantification of lesion severity after laser delivery and during longitudinal follow-up. The proposed approach will allow for large-scale quantitative injury studies by eliminating the need of burdensome manual lesion segmentation. While promising, this initial proof-of-concept study will need to be validated on larger comparative studies with multi-grader segmentations that evaluate benefits in segmentation sensitivity and specificity.

ABSTRACT BODY:

Purpose: Peripheral prism glasses expand the field of view for patients with homonymous hemianopia (HH), but perimetry fails to evaluate effectiveness for real world mobility. We report pilot testing of a new pedestrian collision detection test, including the challenge of developing a method to keep gaze and attention toward the forward path, as would be the case in everyday walking.

Methods: The test, presented on a large screen (104°H × 63°V), simulated walking through a busy shopping mall with multiple pedestrians moving in various directions. For each trial, there were three possibilities: pedestrian on a collision course (constant eccentricity with looming) from the left, from the right, or neither side. Iterative rounds of development and pilot testing were conducted with HH subjects. We report results from 3 phases: free gaze; following a lead child through the mall; and addition of a secondary task (ST). Collison detection rates and response times (RT) were recorded for pedestrians at eccentricities of 20° or 25°. Misses were assigned the maximum response time, 5 s (maximum time to collision).

Results: With free gaze, HH subjects quickly learned to “beat the test” by keeping their gaze well over to the blind side in a manner impossible when walking in the real world. A lead child and walking path were added, but even with instructions to “not lose sight of the child”, blind side detection rates were still very high. A ST was then added to keep gaze and attention mostly toward the forward path, but still allow scanning. Subjects called out numbers appearing within a string of letters moving randomly (±1.25°H × ±2.5°V) behind the lead child’s head. In ST-1, each character subtended 1.5° and was presented for 1 s. Blind-side median detection (N = 6) was 50% without prisms. In ST-2, the characters were smaller (1°) and presented for a random variable duration (0.5 to 1.5 s, mean 1 s). Blind-side median detection was 0% without prisms (N = 7), suggesting ST-2 better kept gaze in the walking direction. With ST-2 and 57Δ oblique peripheral prisms, blind-side detection improved significantly to 90% ($p = 0.03$) and median response times improved significantly from 5.0 s without to 3.4 s with prisms ($p = 0.03$).

Conclusions: Our test measures the impact of field loss and the effectiveness of field expansion aids in a task relevant to real-world walking.

TITLE: Infectious Scleritis: A 30 years Retrospective Study
SESSION TITLE: Antimicrobial Resistance, Epidemiology and New Antimicrobials
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: G.A. Requejo, A. Santiago, Universidad de Puerto Rico Recinto de Ciencias Medicas, San Juan, PUERTO RICO|E. Vázquez Valencia, E. Báez Rivera, L. Rivera Román, A. Oliver, C. Santos, Ophthalmology, Universidad de Puerto Rico Recinto de Ciencias Medicas, San Juan, PUERTO RICO|

ABSTRACT BODY:

Purpose: Infectious scleritis is a rare disease with few large series reports in the literature and an etiology that varies based on geographic region and different climates. In addition, knowledge of disease epidemiology and predisposing factors is scarce. Since there is no previous study describing this ocular infection in Puerto Rico, we decided to determine the etiology of infectious scleritis, predisposing factors, complications, treatment strategies, and final disease outcomes in a cohort of patients living in Puerto Rico.

Methods: A retrospective chart review of infectious scleritis cases, dating from 1988 to 2018, of three cornea specialist practices in Puerto Rico. Both culture-proven, as well as cultures-negative cases, were included in the study. Demographic characteristics were recorded. In addition, the following information was gathered from each patient chart: inciting event, time from predisposing event to disease development, time of infection onset to cornea specialist evaluation, cultures results, involved organism (for positive culture cases), presenting signs and symptoms, visual acuity upon presentation, final visual acuity outcome, photographic documentation, treatment strategy, complications, and final disease outcome.

Results: Forty-five patients who met the research criteria for a diagnosis of infectious scleritis were identified and included in the analysis. The most common ocular sign was hyperemia (87%) and the most frequent symptom was pain (87%). Visual acuity at presentation was worse than 20/200 in 36% of eyes. The median duration of therapy was 112 days. Surgical intervention was performed on 17% of eyes which consisted of debridement (4%), tenoplasty and amniotic membrane graft (4%), corneal/scleral patch graft (2%), removal of a hardware device (6.7%, 3 scleral buckles), and pars plana vitrectomy (2%). Final visual acuity was 20/200 or better in 69% of eyes. 100% of the patients were able to save their eye from infection and 69% maintained useful vision.

Conclusions: Our findings are consistent with previous reports. Pterygium surgery was the most common surgical intervention associated with the subsequent development of infectious scleritis, followed by glaucoma surgery. Pseudomonas aeruginosa is the most common bacteria involved in the widespread use of adjunctive therapies, like mitomycin C, in these two ophthalmic procedures, which may explain the high incidence of infectious scleritis after these surgeries.

ABSTRACT BODY:

Purpose: Diabetic Retinopathy (DR) is a significant complication of diabetes that causes blindness in adults. DR is also associated with the disintegration of the blood-retina barrier (BRB). The altered inner BRB formed by endothelial cells in the plexiform layers has been investigated broadly in DR pathogenesis; however, in DR the malfunction of the outer BRB consisting of retinal pigment epithelium (RPE) and choroid has rarely been studied. This study investigates the potential role of Akt2 in the diabetes-induced breakdown of the outer BRB in RPE cells.

Methods: Best1-Cre generated RPE-specific Akt2 conditional knockout (cKO) mice were used. Rodent body weights and blood glucose levels were monitored while diabetes was induced in $Akt2^{fl/fl}$ and Akt2 cKO mice by intraperitoneal injection of Streptozotocin for 5 consecutive days. The mice were sacrificed after an 8 month duration of diabetes (10 months of age), and HbA1c, tight junction proteins, and epithelial-mesenchymal transition (EMT) markers were examined.

Results: Blood glucose and HbA1c were elevated in diabetic $Akt2^{fl/fl}$ and Akt2 cKO mice. $Akt2^{fl/fl}$ and Akt2 cKO diabetic mice exhibited significantly lower body weights than appropriate non-diabetic controls. After 8 months of diabetes, the $Akt2^{fl/fl}$ mice showed a diabetes-induced reduction of the RPE tight junction protein ZO-1 and adherence junction proteins occludin and E-cadherin; Both RNA and protein levels of the EMT markers SNAIL/SLUG and TWIST were elevated in the RPE cells of $Akt2^{fl/fl}$ diabetic mice compared to $Akt2^{fl/fl}$ non-diabetic mice, while such alterations were inhibited in Akt2 cKO diabetic mice. Vimentin was elevated in the RPE of $Akt2^{fl/fl}$ diabetic mice and was decreased in Akt2 cKO diabetic mice. The junction proteins and EMT markers in the non-diabetic control groups showed no significant changes.

Conclusions: Deletion of Akt2 in the RPE prevents diabetes-induced alterations in outer BRB and inhibits diabetes-induced elevation of EMT markers.

ABSTRACT BODY:

Purpose: To examine the relationship between intraocular pressure (IOP) and retinal oxygen saturation in open angle glaucoma (OAG) patients of African (AD) and European descent (ED).

Methods: 31 patients with OAG (13 AD, 18 ED) were assessed in a cross-sectional analysis for IOP via Goldmann applanation tonometry and retinal oxygenation via retinal photographic oximetry (Oxymap Retinal Oximeter; Oxymap ehf, Reykjavik, Iceland). Age-adjusted two-sample t-tests and Spearman correlations were used to test for differences and associations between measurements, with $p<0.05$ considered statistically significant.

Results: OAG patients of AD and ED demonstrated significantly different relationships between IOP and retinal venous oxygen biomarkers, despite statistically similar IOP ($p=0.418$) and visual field outcomes (mean deviation, pattern standard deviation, and visual field index, all $p>0.05$). Strong negative correlations were found between IOP and oxygenation biomarkers in OAG patients of ED, while these correlations were weaker and/or positive in AD patients ($p=0.008$-0.038; e.g., IOP vs. oxygen saturation ($SatO_2$) in the inferior nasal vein ED $r=-0.99$, AD $r=-0.19$, $p=0.008$). IOP was also strongly and positively correlated with the infero-nasal arterio-venous difference in OAG patients of ED, while the correlation was weak and negative in AD patients (ED $r=0.97$, AD $r=-0.13$, $p=0.021$). Although OAG patients of AD had higher ocular perfusion pressures (OPP), compared to those of ED ($p=0.021$); OPP was not found to be significantly different in its relationships with ONH oxygen biomarkers ($p<0.05$) between groups.

Conclusions: In this cohort of patients, the relationship between IOP and retinal oxygen saturation were significantly different between OAG patients of AD and ED. Our results suggest that despite statistically similar IOP, the impact of IOP on retinal metabolism may be different in persons of AD, especially within the venous circulation.

ABSTRACT BODY:

Purpose: To assess the antimicrobial activity of a novel ultraviolet-C device against microorganisms implicated in contact lens related adverse events.

Methods: The Ultraviolet-C device with 265nm emitting LED was used. Delfilicon-A (Dailies Total-1), Senofilicon-A (Acuvue OASYS), Comfilicon-A (Biofinity), Balafilicon-A (Purevison 2), Samfilicon- A(Ultra) silicone hydrogels, Omafilicon-A (Proclear) hydrogel contact lens materials and Lens cases (B&L) were exposed to Staphylococcus aureus 38, Pseudomonas aeruginosa 6294, Candida albicans ATCC 76615 and Fusarium Solani 10696 with overnight incubation at 37°C followed by 30 seconds exposure to UVC from 8 mm distance. After this, lenses were gently washed with phosphate buffer saline and were plated on nutrient agar plates for determination of viable count. Viable bacteria were enumerated as CFU/lens and CFU/lens case.

Results: Exposure to ultraviolet rays by a novel UVC device statistically significantly ($P<0.05$) reduced mirobial contamination of contact lens and lens cases. Exposure to UVC device induced 2.15±1.52, 3.15±0.92, 3.27±0.19, 2.80±0.64, 3.54±0.82, 3.15±0.28 and 4.69±0.04 log reduction against S. aureus 38, 0.90±1.28, 3.01±0.85, 1.72±0.43, 2.56±0.56, 3.54±0.35, 2.28±1.06 and 4.79±0.54 log reduction against P. aeruginosa 6294 ,1.55±1.07, 2.09±0.30, 0.72±0.25, 1.66±1.47, 1.66±0.13, 1.32±0.16, and 3.76±0.13 log reduction against C.albicans ATCC 76615, 4.18±0.07, 2.16±0.32, 4.03±0.50, 3.34±0.77, 2.16±0.32, 2.16±0.32 and 3.60±0.35 log reduction against F.Solani 10696 on Delfilicon-A, Senofilcon-A, Comfilicon-A, Omafilicon- A, Balafilicon-A, Samfilicon-A lenses and lens cases respectively.

Conclusions: Ultraviolet-C has high antimicrobial efficacy against most of the predominant microorganisms implicated in contact lens related keratitis and it could be readily used as a broad-spectrum antimicrobial treatment.

ABSTRACT BODY:

Purpose: Purpose: Toll-like receptor 3 (TLR3) and interferon-beta promoter stimulator-1 (IPS-1) are associated with antiviral responses to double-stranded (ds) RNA viruses, and contribute to innate immunity. We previously reported that TLR3 is expressed on the surface of corneal epithelial cells (CECs), and confirmed that MDA5 and RIG-I, dsRNA receptors that bind to IPS-1, are also expressed in CECs (Ueta M, et al. Prog Retin Eye Res. 2012). We also reported that TLR3 and IPS-1 signaling regulates the distribution and migration of $CD11c^{+}$ cells in murine corneas (Ueta M, et al. Immunol Lett. 2019). However, the functions of TLR3 and IPS-1 in CECs and the differences in their respective roles for their common ligands remain unclear. The purpose of this present study was to elucidate the function of TLR3 and IPS-1 in CECs via comprehensive analysis of gene expression in response to polyinosinic:polycytidylic [poly(I:C)] stimulation using cultured primary murine CECs (PMCECs) derived from TLR3 and IPS-1 knock-out (KO) mice.

Methods: Methods: PMCECs were obtained from the corneas of 4- to 6-week-old BALB/c background wild-type (WT), TLR3KO, and IPS-1KO mice, and then stimulated with or without poly(I:C) (10 μg/ml) for 6 hours. Total RNA was then extracted from the PMCECs, and comprehensive gene expression analysis was performed using the GeneChip™ (Thermo Fisher Scientific) microarray scanner system. Gene expression was further evaluated via quantitative polymerase chain reaction analysis.

Results: Results: The expression of 121 genes was upregulated more than 2-fold in the WT PMCECs after poly(I:C) stimulation compared with those without stimulation. Gene ontology analysis showed that the upregulated genes included those associated with viral responses. Compared to the WT PMCECs, genes downregulated in the TLR3KO or IPS-1KO PMCECs also included those associated with viral responses. The genes Neurl3, Irg1, and Lipg were specifically downregulated in the TLR3KO PMCECs, while the genes Oas2, Slfn4, Trim30a, and Gbp9 were downregulated in the IPS-1KO PMCECs.

Conclusions: Conclusions: Our findings show that murine CECs contribute to the antiviral response through TLR3 and IPS-1 signaling, thus suggesting that both immune cells and CECs play an important role in innate immunity, and that TLR3 and IPS-1 may possibly regulate genes involved in different viral response pathways.

ABSTRACT BODY:

Purpose: Overcoming the burden of intravitreal injections represents an unmet need in retinal pharmacotherapy. NaMESys is a novel drug delivery systems composed of monophasic, optically isotropic, thermodynamically stable, clear and self-assembling dispersions formulated by oil, water, surfactants and cosurfactant. Aiming to delivery sorafenib to the posterior segment of the eye, NaMESys formulations were developed and characterized by stability and ocular biodistribution studies after single dose administration.

Methods: NaMESys containing sorafenib were prepared by self-assembling method (phase titration method). The performance of preparations by means of stability and pharmacokinetic profile was evaluated. Long term (36 month 25±2°C/60±5%RH) and accelerated condition (6 month 40±2°C/75±5%RH) stability studies were conducted, chemical-physical parameters were evaluated at different time points. Bioavailability study in NZW rabbits (n=6 per time point) after single dose administration (50µL topical administration in the right eye) was conducted and sorafenib ocular distribution at t= 5, 15, 30, 60, 90, 120 min was quantified by LC-MS.

Results: Long-term and accelerated stability data showed a stable profile of all chemical-physical parameters under study. The droplet size of the dispersed phase is equal or less than 30 nm with a very low polydispersity and the recovery percentage of sorafenib is within specification limits (95-105%) for all formulations. Biodistribution study showed that sorafenib was detected in cornea, vitreous, conjunctivae and sclera but not in the aqueous humor of the treated eye neither in tissues of the contralateral eye. In retina of treated eyes, sorafenib maximum content (170 ±80 ng/g) was observed 5 min after treatment and decreased rapidly 2h post dose and was not quantified in left untreated eye. Sorafenib was not detected in plasma between 5 min to 30 min post dose, maximum content was observed 2h after treatment.

Conclusions: NaMESys was shown to allow topical delivery of poorly water-soluble drugs, such as sorafenib, increasing their penetration and bioavailability to the ocular posterior segment otherwise possible only by intravitreal injection. Data highlight a strong stability profile endowed with a low droplet size distribution guaranteeing a 36-month shelf life. NaMESys promises to be a tool to improve delivery strategies in retinal pharmacotherapy.

ABSTRACT BODY:

Purpose: Ghana has the highest rate of glaucoma in the world, often resulting in blindness. We aimed to investigate therapy compliance and identify associated risk factors in Ghanaian glaucoma patients to define targets for functional improvement.

Methods: A total of 468 patients visiting the eye clinic of the Komfo Anokye Teaching Hospital who were treated with at least one type of glaucoma medication were included in this study. Therapy compliance was determined using the Simplified Medication Adherence Questionnaire (SMAQ); potential risk factors for compliance such as socio-economic and treatment-related characteristics were assessed with structured questionnaires and analyzed using multivariate logistic regression.

Results: 195 (41.7%) patients were labeled as non-compliant to their glaucoma treatment regimen. Compliance was significantly associated with higher age (OR, 1.03; 95% CI, 1.01-1.04; $P<0.01$) and monthly prescription costs (OR/USD increase, 1.02; 95% CI, 1.00-1.03; $P<0.05$). Patients were less compliant when they were treated for more than 2 years (OR, 0.54; 95% CI, 0.33-0.91; $P<0.05$) or when they had difficulty with applying eye drops (OR, 0.45; 95% CI, 0.23-0.87; $P<0.05$). Awareness of glaucoma was poor in this population; 211 (45.1%) patients were not convinced that ceasing medication could lead to blindness.

Conclusions: Therapy compliance in this African population of glaucoma patients was poor. Here, the most important risk factors for non-compliance were young age, low prescription costs, long duration of treatment, and difficulty with application of eye-drops.

ABSTRACT BODY:

Purpose: Neural reorganization following lesions of the central visual system and the mechanisms enabling recovery of visual function are still poorly understood. We here combined transcranial magnetic stimulation (TMS) and electroencephalography (EEG) to directly assess visual cortex function in stroke patients in order to non-invasively capture lesion-induced alterations in neural signal processing as well as their associations to visual field deficits.

Methods: We employed neuronavigated TMS-EEG over primary visual cortex (V1) of the lesioned and the intact hemisphere (120 single TMS pulses per hemisphere at 80% maximal stimulator output) in 10 patients with hemi- or quadrantanopia due to ischemic stroke in occipital cortex. TMS-evoked EEG potentials were recorded using a TMS-compatible 64-channel EEG system. Preprocessing and data analyses, i.e., global mean field power, time-frequency analysis, and phase locking value, were performed using in-house MATLAB scripts based on functions of the open-source toolbox EEGLAB.

Visual field deficits were quantified using an Octopus 900 perimeter and PeriData. Mean defects (MD) were computed for each visual hemifield averaged across both eyes to quantify the homonymic deficit, and subsequently correlated with TMS-EEG parameters.

Results: TMS-EEG revealed signal alterations in the time and time-frequency-domain of ipsilesional as well as contralesional V1 in the acute phase after stroke. This indicates not only changes of neuronal processing in the ischemic area but also in contralateral brain regions that are functionally connected, yet structurally intact. Interestingly, when analyzing the local spreading of induced activity, we found a shorter time course of significant coupling in the contralesional hemisphere ($p=0.029$), which was directly linked to visual field deficit ($r=-0.771$ $p=0.036$). Moreover, stronger alterations of the TMS-evoked oscillatory activity in both hemispheres were associated with more pronounced visual field deficits (ipsilesional: $r=0.78$, $p=0.033$; contralesional: $r=0.829$ $p=0.021$).

Conclusions: Brain responsivity parameters as assessed by TMS-EEG are linked to visual field deficits in stroke patients. Hence, TMS-EEG does not only present a novel tool to assess central visual system integrity, but may also help to uncover brain mechanisms driving functional compensation following lesions to the visual system.

ABSTRACT BODY:

Purpose: To evaluate the prevalence and factors associated with optic disc Gray Crescent (GC) in African Americans with primary open-angle glaucoma.

Methods: Two experienced readers independently graded quantitative features of the optic disc in stereo color images, including GC (Figure 1), cup shape and depth, tilt, sloping of the retina to the outer rim border, beta peri-papillary atrophy, baring of lamina cribrosa and circumlinear vessels, bayoneting, , Cilio-retinal vessels, notching, and pallor of the disc rim. Differences were adjudicated by an ophthalmologist. Univariable and multivariable logistic regression modelling through backward variable selection were performed to identify risk factors of GC. Generalized estimating equation was used to account for the inter-eye correlation.

Results: The multivariable results are shown in the Table. Among 1437 glaucoma subjects, 272 (18.9%) had GC, including 11.7% % unilateral and 7.2% bilateral. Among 2759 eyes, 376 (14%) had GC. Adjusted Odds Ratio (aOR) with 95% CI was 0.77 (0.68, 0.87) for every age decade ($p<0.001$) and 1.62 (1.23,2.12) for subjects with diabetes. Among 2759 glaucoma eyes, 376 (14%) had GC. The aOR with 95% CI was 1.86 (1.41, 2.47) for stereoscopically identified disc tilt ($p<0.001$), 1.81 (1.41, 2.32) for sloping of the retina towards the disc outer rim ($p<0.001$), and 1.30 (1.01, 1.68) for vessel bayoneting ($p=0.04$) (Table).

Conclusions: Unilateral gray crescent is not uncommon in African Americans with open-angle glaucoma. Diabetes and several ocular features are associated with GC.

TITLE: Application of Rasch analysis to the TeachCVI survey tool in a spectrum of CVI patients
SESSION TITLE: Visual Function Assessment and Quality of Life Outcomes
SESSION TYPE: Paper Session
AUTHORS/INSTITUTIONS: J. Martin, S. Yee, N. Ross, New England College of Optometry, Boston, Massachusetts, UNITED STATES|C. Bradley, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|
Commercial Relationships Disclosure: Jem Martin: Commercial Relationship: Code N (No Commercial Relationship) | Chris Bradley: Commercial Relationship(s);Code P (Patent):IrisVision | Shannin Yee: Commercial Relationship: Code N (No Commercial Relationship) | Nicole Ross: Commercial Relationship(s);Code R (Recipient):Eschenbach Optik
ABSTRACT BODY:
Purpose: Cerebral visual impairment (CVI) is the leading cause of visual impairment in children. Given the diversity of clinical presentations of CVI, we are interested in whether questionnaires appropriately target the spectrum CVI cases, specifically the TeachCVI Screening Tool. Rasch analysis is a common psychometric technique for assessing the targeting of questionnaire items, however to date, this analysis technique has not yet been applied to this questionnaire.
Methods: We performed a retrospective review of clinical CVI cases from the NECO Center for Eye Care and Perkins School for the Blind from January 1, 2016 to December 31, 2021. Electronic medical records were reviewed to identify patients with an ICD-9 or ICD-10 code of CVI or other neurological visual impairment. Age, gender, diagnoses, visual acuity, contrast sensitivity, visual fields, ocular alignment, and TeachCVI survey responses were collected.
We applied the method of successive dichotomizations, a polytomous Rasch model, to estimate item measures and person measures from the three levels of the TeachCVI survey. Targeting of questionnaire items to the sample population was explored by comparing estimated item measures to person measures. Multiple linear regression was used to determine which factors influence patient functional ability (i.e., person measure).
Results: 102 patients fit our inclusion criteria; 51% were female. The mean (SD) age was 9.49 (5.7) years, with a range of 0 to 33. 8.8% of patients had no impairment, 5.9% only had CVI, 38% had CVI and an ocular impairment, 8.8% had CVI and a physical disability, and 38% were multiply impaired (CVI, ocular, and physical). Mean (SD) visual acuity was 0.40 (0.40) logMAR, mean (SD) contrast sensitivity was 1.58 (0.47) logCS, and 33% had a visual field deficit.
Estimated item measures were well-targeted to the persons: the mean item measure was 0 by convention with an SD = 0.92 logits, and the mean (SD) person measure was 0.27 (1.19) logits. The only statistically significant factor in influencing patient functional ability was the level of impairment, i.e., the presence of multiple comorbidities. Visual acuity, age, gender, contrast sensitivity and visual field loss were not statistically significant.
Conclusions: This study shows that TeachCVI surveys are well targeted and are appropriate screening tools for CVI.

ABSTRACT BODY:

Purpose: Stereo vision is a vital aspect of ophthalmic exams and diagnosis of ocular disease. Limited options exist to extend stereo viewing for use in real-time ophthalmic education and remote consultation. We aimed to develop a novel stereoscopic device prototype using virtual reality (VR) headsets to allow for 3D live streaming of ophthalmic exams, with intention for low-cost, adaptable use in education, outreach, and consultation

Methods: Color cameras (See3CAM-CU135 by e-consystems),13.0 MP, 60 fps, were mounted to slit-lamp oculars in an ophthalmic exam room, using custom mounting hardware. The slit-lamp operator and an in-room observer each wore customized VR headsets of varying resolution (Operator: 4k, observer: Smartphone),. while a slit lamp exam of the anterior segment and external anatomy was performed in multiple test iterations. Live video of the slit lamp exam was fed via USB-C cables to a laptop. Using Open Broadcasting Software, the side-by-side 3D live video feed from each slit-lamp camera was optimized and securely streamed to the VR headsets worn by the slit lamp operator (streamed via HDMI) and the in-room observer (streamed via the VR's smartphone WiFi).

Results: A stereoscopic Prototype A Teleophthalmology Device was developed and provided high-quality, real-time, dynamic, and replicable 3D visualization of the anterior segment and external anatomy to the slit-lamp operator and in-room observer. Advantages of the device included ease of set-up, reliable stereopsis, low cost of development, and wide availability of device components. Limitations of the prototype included wired connections to computer and operator VR headset, intermittent feed latency, exposure variability, and intermittent user disorientation before adaptation.

Conclusions: The Prototype A Teleophthalmology Device is a visual communication system developed to capture and distribute 3D exam imaging among providers and trainees to enable diagnosis, consultation, and educational goals. Widespread availability of device components allow for low-cost, adaptable use, including for teaching and consultation in low-resource environments. Additional optimization and study of the prototype in the clinical environment is needed to further establish its utility and to assess performance parameters.

ABSTRACT BODY:

Purpose: Tear levels of CX3CL1/fractalkine, a chemokine implicated in inflammation, were found increased in dry eye patients. Benzalkonium chloride (BAC) is a well-known preservative used at low doses in eyedrops for which toxic effects on ocular surface were described, mainly based on oxidative stress, apoptosis and chronic inflammation mechanisms. BAC not only alters the ocular surface epithelia but also corneal innervation, emerging from the trigeminal ganglion (TG).

Our aim is to investigate the role of CX3CL1/CX3CR1 axis in an in vitro BAC Toxicity-Induced Dry Eye (TIDE) model on a TG cell culture, in relation with the cell death mechanisms induced, apoptosis, ferroptosis, and pyroptosis.

Methods: We established a reproducible method for primary cultures of TG from wild type (WT) or CX3CR1-KO mice. We investigated the modulation of oxidative stress (CellRox assay, HO1), apoptosis (CASP3), ferroptosis (GPX4) and pyroptosis (NLRP3, GSDM) after exposure to a low concentration (5.10^{-4}%) of BAC. A RT-PCR gene expression kinetic study (1h, 2h, 4h, 6h, 8h and 24h of BAC exposure) and western blot analysis were conducted.

Results: We found that BAC-induced oxidative stress was reduced at 4h, correlated to a major increase (from 2h to 24h) of HO-1 gene expression in CX3CR1-KO compared to WT. Moreover, GPX4 protein, known to protect against ferroptosis, was depleted at 2h, its gene expression being only upregulated at 1h and 2h in presence of CX3CR1. The increase of CASP3 gene expression was delayed in CX3CR1-KO mice (6h instead of 2h in WT). As for inflammatory cell death processes, NLRP3 inflammasome and GSDM pyroptosis modulator regulations occurred at later time points and were more important in presence of CX3CR1. Indeed, NLRP3 gene expression was upregulated at 24h only in WT whereas GSDM gene expression and protein level were increased at 6h only in WT. Nevertheless, GSDM gene expression at 24h was increased in both WT and CX3CR1-KO mice.

Conclusions: We confirm that BAC induces not only apoptosis but also other emerging cell death mechanisms with key events occurring in a kinetic manner as follows: 1. oxidative stress, 2. apoptosis, 3. inflammasome activation and pyroptosis. In absence of CX3CR1, oxidative stress is reduced and this effect impacts the subsequent cell death mechanisms. Further studies are needed to deepen the exact role of CX3CR1 axis on cell death mechanisms involved in TIDE.

ABSTRACT BODY:

Purpose: Dominant Optic Atrophy (DOA) is characterized by degeneration of the retinal ganglion cells (RGC) that can lead to vision loss for which there is no treatment. The optic atrophy (OA) can be isolated or syndromic: OA associated with sensorineural deafness, myopathy, etc. DOA is caused by mutations in genes with a mitochondrial function. The underlying pathophysiology remains to be understood.

The single strand DNA-binding protein 1, SSBP1 gene was recently identified for causing DOA. SSBP1 tetramers bind mitochondrial DNA (mtDNA) and is essential for mtDNA replication. Our purpose is to shed light on the pathophysiological consequences of ssbp1 alteration in a zebrafish model.

Methods: A knockdown (KD) of ssbp1 in zebrafish was generated by microinjection of translation blocking morpholino (MO-ssbp1) in Zebrafish embryo. Fish injected with Standard-MO designed to have no impact in zebrafish and non-injected zebrafish were used as controls. KD was validated by Western Blot analysis of Ssbp1.

The transgenic zebrafish line tg(Brn3c:mGFP) labeling RGC and ON was used throughout this study. Confocal microscopy and the IMARIS software were used to generate 3D reconstruction of the optic nerve GFP labeling. Sensorimotor responses were investigated using either Visual Motor Response assay (VMR) to measure the locomotor response to a visual stimulus (traveled distance measurement) or Auditory Startle Response (ASR) to measure motility after acoustic and vibration stimuli.

Results: ON morphology analysis revealed an atrophy of the ON in 2dpf ssbp1 KD zebrafish, with a significant reduction of its volume.

A significant decrease of the traveled distanced by 5dpf MO-ssbp1 fish was found in both light and dark stimuli conditions using VMR assay. However, the ability to perceive differences in bright light stimulation did not seem impaired in MO-ssbp1.

A diminution of motility of 5dpf MO-ssbp1 was also found using the ASR assay and preliminary result show a decrease of startle response induced by sound and vibration stimuli.

Conclusions: ssbp1 KD in zebrafish revealed an optic nerve atrophy at 2 dpf which could indicate that ssbp1 is important for ON development. This result did not translate to bright light perception defect in 5dpf ssbp1 KD fish. Moreover, the KD caused an overall diminution of the traveled distance that could reflect locomotion defect as well as a likely alteration of sound and vibration perception.

ABSTRACT BODY:
Purpose: Optical coherence tomography (OCT) scans are often degraded by noise, which complicates further analysis. We demonstrate an unsupervised denoising method that uses OCT angiography (OCTA) information to keep the informative speckle used for OCTA computation and removes flow-unrelated speckle noise. Qualitative and user-study analyses demonstrate noise removal and improved sharpness compared to other unsupervised denoising methods.
Methods: In a first step, a U-Net is trained via unsupervised Noise2Void (N2V) to denoise OCTA B-scans. In a second step, a second U-Net is trained via N2V on OCT B-scans. A constraint in the loss function ensures that the OCTA image computed from two denoised OCT B-scans is similar to the denoised OCTA B-scans from the first step. The workflow of this algorithm is depicted in Figure 1. The training/test set consisted of 90/18 measurements (with 500 B-scans per volume and 2 volumes per patient) from 30/9 patients. Field sizes included 3x3 mm and 6x6 mm areas around the fovea and included various pathologies (choroidal neovascularization, diabetes mellitus without diabetic retinopathy (DR), non-proliferative DR, proliferative DR, early age-related macular degeneration, geographic atrophy, non-arteritic anterior ischemic optic neuropathy and healthy controls). We compared our method (speckle split N2V (SSN2V)) to other unsupervised denoising algorithms (N2V (without the constraint), BM3D, TV, WNNM). A user study was performed on the test set. One expert ophthalmologist graded 35 randomly selected B-scans and the results of the denoising algorithms from 0 (does not like the image) to 5 (likes the image).
Results: The user study shows that the clinical expert preferred the results produced by our proposed algorithm (input: 1.11±0.622; BM3D: 2.2±0.92; TV: 2.74±0.73; WNMM: 3.37±0.93; N2V: 1.51±0.77; SSN2V: 4.09±0.87). Qualitative results of the results of the different denoising algorithms are shown in Figure 2.
Conclusions: Using the additional constraint for the unsupervised OCT denoising improves the denoising capability and performs superior to the compared methods in an expert user study.

TITLE: Adherence to the Mediterranean Diet and Geographic Atrophy Enlargement Rate in the Age-Related Eye Disease Study 2

SESSION TITLE: Public Health

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: T.D. Keenan, E. Agron, E.Y. Chew, Division of Epidemiology and Clinical Applications, National Eye Institute, Bethesda, Maryland, UNITED STATES|J.A. Mares, Department of Ophthalmology and Visual Sciences, University of Wisconsin-Madison, Madison, Wisconsin, UNITED STATES|

Commercial Relationships Disclosure: Tiarnan Keenan: Commercial Relationship: Code N (No Commercial Relationship) | Elvira Agron: Commercial Relationship: Code N (No Commercial Relationship) | Julie Mares: Commercial Relationship: Code N (No Commercial Relationship) | Emily Chew: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: No approved treatments exist to slow geographic atrophy (GA) enlargement. The aim was to determine whether closer adherence to a Mediterranean diet (and its individual components) was associated with altered speed of GA enlargement.

Methods: The design was a cohort study within the AREDS2 clinical trial. The study population comprised 1155 eyes (of 850 participants, mean age 74.9 years) with GA at two or more consecutive visits. GA area was measured by planimetry from color fundus photographs collected at annual study visits. A modified Alternative Mediterranean Diet Index (aMedi) score was calculated for each participant by food frequency questionnaire at baseline. Mixed-model regression analyses of square root GA area were performed according to aMedi. The outcome measure was change in square root of GA area over time.

Results: Over mean follow-up of 3.1 years from first appearance of GA, the mean GA enlargement rate was 0.282 mm/year (95% confidence interval 0.270-0.293). GA enlargement was significantly slower in those with higher aMedi, at 0.256 mm/year (0.236-0.276), 0.290 (0.268-0.311), and 0.298 (0.280-0.317; P=0.008), for aMedi tertiles 3, 2, and 1, respectively. Of the nine aMedi components considered separately, significant differences in GA enlargement rate were observed for four: whole fruit (P = 0.0004), red meat (P = 0.0002), alcohol (P = 0.006), and monounsaturated: saturated fatty acid (MUFA: SFA; P = 0.040). GA enlargement was slower in those with higher whole fruit, lower red meat, moderate alcohol, and higher MUFA: SFA intake (Table).

Conclusions: A Mediterranean-type diet was associated with slower GA enlargement. Such diet patterns may therefore lead to clinically meaningful delays in vision loss, particularly for individuals without foveal involvement. Several components contributed most to this protective association, in a pattern that differed from those most associated with decreased progression to GA. Hence, the Mediterranean diet is associated with protection against both faster progression to GA and faster enlargement of GA, but for partially distinct reasons. Understanding the mechanisms responsible may provide insights into the underlying biology and lead to the development of dietary recommendations and nutritional supplements.

TITLE: Understanding RGC differentiation and development in retinal organoids by scRNA-seq

SESSION TITLE: Retinal Degenerations, Gene Therapy, Transplantation, and Prostheses

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Z. Luo, K. Chang, B. Tanasa, J.L. Goldberg, Spencer Center for Vision Research, Stanford University, Stanford, California, UNITED STATES|

Commercial Relationships Disclosure: Ziming Luo: Commercial Relationship: Code N (No Commercial Relationship) | Kun-Che Chang: Commercial Relationship: Code N (No Commercial Relationship) | Bogdan Tanasa: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Goldberg: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal ganglion cell (RGC) replacement therapy could provide an approach to vision restoration in glaucoma and other optic neuropathies. RGCs generated from retinal organoids are promising donor cells. The present research aims to understand how organoid RGCs (oRGCs) differ from human fetal RGCs.

Methods: We generated retinal organoids from Brn3b-tdTomato-H9 hESC line. Then, we utilized single cell-RNA sequencing (scRNA-seq) to delineate the oRGC differentiation and compare their transcriptomic profiles to human fetal RGCs. EdU incorporation assays were used to visualize the newly born oRGCs in retinal organoids of different developmental stages. All experiments were conducted at least three times independently. Data were analyzed by ANOVA and post-hoc t-test with Tukey correction, with a P-value of <0.05 considered statistically significant.

Results: At early developmental stages, oRGCs had similar expression patterns to fetal RGCs in corresponding timepoints. By UMAP plotting and pseudotime analyses, we found oRGCs overlapped with fetal RGCs at earlier time points. However, with ongoing development, RGC numbers decreased rapidly in retinal organoids, and their transcriptomes diverged from fetal developmental patterns. Transcripts from neurofilament genes were relatively low and did not increase along developmental time in oRGCs, but were highly expressed in adult RGCs. Moreover, POU4F2 (Brn3b) expression in oRGCs was maintained at a high expression level for a longer time, while in fetal RGCs, Brn3b was significantly downregulated with maturation. Interestingly, RBPMS, an RGC-specific marker, was barely expressed in organoid RGCs. EdU incorporation assays revealed that oRGC generation slowed down around the 10^{th} week of differentiation, coming nearly to a complete halt by the 15^{th} week in retinal organoids.

Conclusions: In the present study, we describe the transcriptomic differences between oRGCs and fetal RGCs, providing substantial insight into towards stem cell-derived RGC development, towards enhancing our understanding of stem cell differentiation and in the future, stem cell-based therapeutic interventions towards restoring vision in human disease.

ABSTRACT BODY:

Purpose: To evaluate the efficacy of sulfasalazine (SSZ) for recurrent acute anterior uveitis (AAU) in a cohort of Spanish patients.

Methods: Retrospective chart review of patients diagnosed with recurrent AAU treated with SSZ from January 2008 to December 2021. The grading of uveitis activity was defined as per SUN working group. The major outcome was the reduction in the number of uveitis flare-ups over a one-year and three year-period, compared to pretreatment year. The response criteria of SSZ were defined as normal ophthalmologic examination. Mann-Whitney Paired samples Wilconxon test U testand Kaplan-Meier survival curve were calculated using SPSS statistical software ($p < 0,05$).

Results: Thirty-three patients were included, (males =17; 51,5%). The mean age at the beginning of SSZ was 42 years old (range 22-73, SD= 11.3) and at uveitis onset was 37 years old (range 18-54, SD= 10.1). Mean time of follow up was 48.3 months (range 2-270, SD= 58.75). In 60.6 % of cases (n=20) uveitis was bilateral. Two patients (6.1%) presented with associated macular edema. One patient developed hypertransaminasemia (3%) and two patients showed leukopenia (6.1%). Three patients (9%) had to interrupt SSZ due to clinical inefficacy. Ankylosing spondylitis was the most frequent association (n=18, 54.5%), followed by idiopathic juvenile arthritis (n=2, 6.1%). 8 patients (24.2%) were not related to immune-mediated disease. HLA-B27 was positive in 66.7% (n=22). Indication for SSZ was based on ocular activity in 36.4 % (n=12), joint activity in 36.4% (n=12) or both in 24.2 % (n=8). At the time of SSZ onset, 97% of patients (n=32/33) were on systemic steroids and 48% (n=16/33) on topical steroids; and 3% (n= 1/30) and 20% (n= 6/29), respectively at one year. Four patients (12%) had started SSZ associated with other immunomodulators. The mean number of flare-ups in the pretreatment year was 1.9 (SD 1.4), at one year 0.7 (SD=0.95) with statistical significance (p=0.02), and at third year 1.0 (SD 1.0) with no significance (p=0.10). The mean time to flare-up of AAU after SSZ was 53.5 moths (IC 95%, Range: 23.3-83.8).

Conclusions: We suggest sulfasalazine as an effective treatment to reduce flare-ups in patients with recurrent non-infectious AAU of different etiologies. Its low cost and high safety profile make it an interesting therapeutic alternative, especially in women of childbearing age

ABSTRACT BODY:

Purpose: The current rate of female ophthalmologists in the United States is 26.7%. Gaps in female representation still exist in ophthalmology with regards to appointment of senior faculty positions and chairpersons. Invited lectures are an important factor in career advancement. This report examines the gender differences in faculty invited to give visiting lectures at top ophthalmology programs in the United States.

Methods: This retrospective observational study analyzed the invited lectures at 20 ophthalmology programs from January 2019 - June 2022. The top 20 institutions on the Doximity Residency Navigator reputation ranking were selected for inclusion in this study. Institution websites were queried for ophthalmology lecture events. Examples include grand rounds lectures, eponymous visiting professor lectures, and featured presentations at institutional conferences. The names, years since completion of training, and genders of visiting faculty were recorded. Chi-square test and student t-test were used for data analysis. Primary analysis focused on the proportion of female invited lectures.

Results: Of the 20 institutions selected, 13 had publicly-available information on their websites about their lectures, which yielded a sample size of 200 invited lectures. Of those 200 lectures, 29.5% were given by female faculty members, which was similar to the ratio of female ophthalmologists ($p=0.8750$). When examining only the eponymous lectureships, there was a trend toward fewer women, with only 2 of the 20 listed given by women, although the comparison with overall rates of women in ophthalmology was not statistically significantly different ($p=0.4075$). Female lecturers were found to have completed their training more recently than non-female lecturers on average, 2002 compared to 1995 ($p < 0.001$).

Conclusions: Overall, female representation in the invited lectures of our sample matches overall female representation in ophthalmology. The more prestigious eponymous lectureships did show a trend toward fewer women, although it was not statistically significant. It is possible that a larger sample size would show a statistically significant difference in this type of lecture. Future research should focus on both identifying gender ratios and in determining best practices for rectifying any discrepancies.

ABSTRACT BODY:

Purpose: The purpose of this study was to evaluate the meibomian gland (MG) morphology (atrophy and tortuosity) in children aged 4 to <18 years. In addition, risk factors were identified for MG atrophy and tortuosity.

Methods: A total of 160 children (4 to 18 years) presenting at the Illinois Eye Institute from Sep 2020 to July 2021 were recruited into the study. All children had a comprehensive eye exam as well as height/weight was measured for BMI. Tear film parameters was collected with the Keratograph 5M (Oculus), including non-invasive tear film break-up time and tear meniscus. The upper and lower eyelids were everted and the meibomian glands imaged with the Keratograph 5M (Oculus). MG dropout scores were assessed by two masked graders using a validated 4-point JENVIS scoring system. Tortuosity of MG were evaluated by two masked graders using a 5-point HALLERAN scoring system. Both children and their parents were surveyed on electronic screen time, diet, and outdoor activities. To determine relationships between MG morphology and potential risk factors (including age, gender, race/ethnicity, refractive error, screen time, diet, outdoor activities, and BMI), linear multiple regression analyses were performed.

Results: Among 160 children recruited into the study, 76 were males and 84 were females (mean age = 10.9 years, ranged from 5.7 to 17.8). Mean tear meniscus were 0.23mm and 0.36mm, OD and OS respectively. Mean NI-TBUT were 15.60 sec and 15.96 sec, OD and OS, respectively. Severe MG atrophy (MG score of 2 or greater) presented in children: 6.8% of upper eyelid OD, 19.7% of lower eyelid OD, 5.6% of upper eyelid OS, and 19.7% of lower eyelid OS. Severe MG tortuosity (Score of 2 or higher) presented in children: 72.7% of upper eyelid OD, 3% of lower eyelid OD, 65.6% of upper eyelid OS, and 4.4% of lower eyelid OS. Significant risk factors for MG atrophy and/or tortuosity were identified including BMI (OD MG atrophy: $\beta=0.36$, $p < 0.001$, OS MG atrophy $\beta=0.25$, $p=0.007$), diet (lower eyelid tortuosity: $\beta=0.23$, $p = 0.011$), and outdoor activity (OD MG atrophy: $\beta= -0.21$, $p = 0.022$). No association was found between MG morphology and screen time.

Conclusions: High BMI, decreased outdoor activities, and unhealthy diet are the significant risk factors for the MG morphology change in children aged 4 to 18 years. Eye care practitioners should consider evaluating MG morphology routinely in children during eye exam.

ABSTRACT BODY:

Purpose: To elucidate the relationship between CSF and WF SS-OCTA metrics in patients with DME.

Methods: This cross-sectional prospectively recruited observational study included 53 eyes of 37 patients with DME imaged with WF SS-OCTA (PLEX® Elite 9000, Carl Zeiss Meditec) and tested for CSF with the Active Learning Quantitative CSF (qCSF) Manifold Contrast Vision Meter (Adaptive Sensory Technology) from November 2018 to March 2021. Functional outcomes included Early Treatment Diabetic Retinopathy Study (ETDRS) visual acuity (VA), and the following qCSF metrics: Area under the Log CSF (AULCSF), contrast acuity (CA), and contrast sensitivity thresholds at 1 to 18 cycles per degree (cpd). The ARI Network (Zeiss Portal v5.4) was used to quantify vessel density (VD) and vessel skeleton density (VSD) in the superficial (SCP) and deep (DCP) capillary plexus and whole retina, as well as foveal avascular zone (FAZ) area, circularity, and perimeter on 3x3 mm, 6x6 mm, and 12x12 mm OCTA images. Mixed effects multivariate regression analyses were performed.

Results: In our DME cohort, VA and contrast sensitivity (CS) outcomes were strongest associated with vascular metrics measured on 3x3 mm OCTA images compared to 6x6 mm and 12x12 mm images. While controlling for age and lens status, regression analyses revealed worse LogMAR VA was significantly associated with decreased SCP VD ($\beta = -0.049$, $p = 0.026$) and VSD ($\beta = -2.562$, $p = 0.026$) on 3x3 mm images. Among the CS outcomes, decreased AULCSF, CA, and CS thresholds at 1.5, 3, and 6 cpd were significantly associated with decreased SCP VSD ($\beta = 3.533$, $p = 0.020$; $\beta = 2.826$, $p = 0.029$; $\beta = 2.629$, $p = 0.035$; $\beta = 3.590$, $p = 0.033$; $\beta = 4.672$, $p = 0.023$, respectively). Decreased CS thresholds at 6 cpd was also significantly associated with SCP VD ($\beta = 0.080$, $p = 0.043$). While VA was not significantly associated with FAZ circularity, decreased CS thresholds at 1 and 1.5 cpd were significantly associated with decreased FAZ circularity ($\beta = 0.567$, $p = 0.028$; $\beta = 0.669$, $p = 0.026$, respectively).

Conclusions: We demonstrate novel structure-function associations in patients with DME leveraging a novel CSF device and WF SS-OCTA. Our results suggest that decreases in VD and VSD in the SCP of DME patients may be associated with larger changes in contrast sensitivity than in VA.

ABSTRACT BODY:

Purpose: The Vascular Endothelial Growth Factor (VEGF) challenge model first developed by Edelman et. al.[1], is routinely used in the rabbit to evaluate the potential of therapies for ocular diseases such as neovascular age-related macular degeneration (nAMD), diabetic macular edema (DME), and retinal vein occlusion (RVO). Compared to the rabbit, the minipig is a useful species for evaluating intravitreal ocular therapies due to the size, fluid dynamics, and vasculature of the minipig eye. We have developed an experimental VEGF challenge model for use in the Yucatan minipig to evaluate the effect of anti neovascularization therapies on the retina/choroid.

Methods: Yucatan minipigs were injected IVT with a dose range of $VEGF_{165}$. Fluorescein angiography (FA) was used to image the retinal vasculature, and a clinical scoring system was developed to quantify retinal vasculopathy at several timepoints post VEGF challenge. Placebo polymer implants and an Avastin positive control were utilized to assess viability of the model.

Results: An optimal amount of $VEGF_{165}$ was determined that induces significant leakage in the miniature swine, with the ability to induce leakage for up to 5 days post VEGF challenge. The positive control Avastin was able to inhibit the $VEGF_{165}$ induced leakage, while the negative control placebo polymeric implants did not protect against retinal vasculature leakage.

Conclusions: The VEGF challenge model commonly utilized in rabbits can be adapted for use in the Yucatan minipig, a species with more relevant ocular anatomy to humans.

ABSTRACT BODY:

Purpose: The prevalence of myopia is accelerating worldwide possibly because of the decrease in outdoor activity including COVID-19 home confinement. We have reported the effective treatments of suppressing myopia progression, including oral administration of crocetin (Mori K et al. Sci Rep. 2019) and violet light exposure (Jiang X et al. Proc Natl Acad Sci USA. 2021). In this study, we examined the therapeutic effects of bunazosin, known as one of the α1-adrenergic receptor antagonists, in a lens-induced myopia mouse model.

Methods: C57BL/6J mice were induced myopia at 3-week-old by a method established in our research group (Jiang X et al. Sci Rep. 2018). For 3 weeks, mice were equipped with lenses in both eyes, a left for 0 D lens as internal control and a right for -30 D lens as myopia induction. During this period, we administered 0.01% bunazosin hydrochloride solution by intraperitoneal injection (IP group) and eye drop (E group) once a day, and PBS as control. Ocular components including refraction error, axial length, and choroidal thickness before and after myopia induction were measured by an infrared photorefractor and an SD-OCT. The choroidal blood flow was evaluated by an SS-OCT angiography.

Results: In the eye with -30D lens of control group, significant changes in a myopic shift of refraction ($p < 0.01$), axial elongation ($p < 0.05$), and choroidal thinning ($p < 0.01$) compared to 0D lens were observed. In contrast, IP or E groups showed no significant difference between both eyes, suggesting myopia progression was suppressed by bunazosin treatment. The choroidal blood flow of the eye with -30D in E group (58.9±8.9%) was higher than that of the control group -30D (44.0±6.4%)($p < 0.05$).

Conclusions: Bunazosin has a preventive effect on myopia progression by suppressing axial elongation and choroidal thinning together with an increase of choroidal blood flow.

ABSTRACT BODY:

Purpose: 15q13.3 microdeletion syndrome is characterized by a broad spectrum of psychiatric disorders. Seven genes are located in the target region of chromosome 15 (MTMR10, FAN1, TRPM1, MIR211, KLF13, OTUD7A, and CHRNA7). While the contributions of several of the genes to the disorder have been studied using mutant mouse models, no single mouse model has been able to recapitulate the whole behavioral spectrum of human 15q13.3 microdeletion syndrome. Trpm1, one of the genes located in the target region of 15q13.3 microdeletion syndrome, has been implicated as a retinal ON bipolar cell visual signal transduction channel. Trpm1 has not been investigated concerning this syndrome because the visual impairment in $Trpm1^{-/-}$ mice may confound the results of behavioral tests involving vision. Emphasizing non-visual behaviors, we performed a comprehensive behavioral test battery using Trpm1 null mutant mice to examine the relationship between TRPM1 and 15q13.3 microdeletion syndrome.

Methods: $Trpm1^{-/-}$ mice were generated as described previously [Koike, et al, PNAS 2009]. Mice used for behavioral test battery were housed as pairs of $Trpm1^{-/-}$ and WT mice. Brain weight measurement and monoamine quantification in brain tissues were performed with 129 Sv/Ev males at 4 months or 1 month. Gene expression analysis was performed with 129 Sv/Ev male mice at 1 month. Mice used for monoamine quantification were housed in pairs of $Trpm1^{-/-}$ mice and WT mice, and tissue dissection was performed at the same time-point.

Results: $Trpm1^{-/-}$ mice exhibit abnormal behaviors that may explain some phenotypes of 15q13.3 microdeletion syndrome: including reduced anxiety-like behavior, abnormal social interaction, attenuated fear memory, and, most prominently, hyper locomotor activity. While the ON visual transduction pathway is impaired in $Trpm1^{-/-}$ mice, we did not detect compensatory higher sensitivities for other sensory modalities. The pathway for visual impairment is the same between $Trpm1^{-/-}$ mice and $mGluR6^{-/-}$ mice, but hyper locomotor activity has not been reported in $mGluR6^{-/-}$ mice. Unexpectedly, the data suggest that the phenotype of $Trpm1^{-/-}$ mice extends beyond that predicted from visual impairment alone.

Conclusions: We present the first evidence associating TRPM1 with impairment of cognitive function similar to that observed in phenotypes of 15q13.3 microdeletion syndrome.

ABSTRACT BODY:

Purpose: Imposing defocus on the retina triggers short-term changes in choroidal thickness that are assumed to predict future refractive changes, both in humans and animal models. Artificial visual stimuli, on the other hand, can uncouple choroidal thickness changes from changes in axial eye growth. It is therefore necessary to verify under which conditions thicker choroids can predict less myopia development.

Methods: Seven day old chicks were kept in large plastic boxes (60x60x30 cm) with walls covered with 27” screens. Dynamic stimuli were presented on the screens and were also projected on the floor from above by two video projectors as described by Wang et al. (doi: 10.1167/iovs.18-26471). Checkerboard patterns with squares with repeated sawtooth-shaped temporal luminance profiles, either with a rapid ON or rapid OFF, were presented. Stimuli were applied at 3 different square sizes (68x39, 40x22, 28x16 squares/monitor) in combination with different cycle frequencies (0 Hz, 0.8 Hz, 1.2 Hz, 2 Hz, 3 Hz, 5 Hz, 8 Hz). SD-OCT (HRA+OCT Spectralis) was used to measure choroidal thickness in alert animals at baseline and 3 hours after treatment. A multi-factor ANOVA was used to determine the influence of size, frequency and character (ON/OFF) on choroidal thickness (ChT) changes.

Results: The size of the stimuli had a significant main effect (delta ChT: smallest size: -26.4±1.6 µm, medium size: -6.9±2.14 µm, largest size: -15.1±2.3 µm). Changes in ChT were also significantly influenced by the stimulus frequency with the strongest effect at 3 Hz (-30.2±4.6 µm) and smallest at 2 Hz (-12.1±3.3 µm). The interaction between frequency and size was also significant. Comparing all treatment groups, only one of the stimuli (1.2 Hz ON, medium size) caused an increase in choroidal thickness (+4.75±6.5 µm) while OFF stimuli at this field size and frequency caused the thinnest choroids (-41.6±6.2 µm).

Conclusions: Dynamic artificial stimuli of different frequency, size and ON/OFF characteristic influence choroidal thickness in a complex way. Except for one stimulus (1.2 Hz ON medium size), all others caused choroidal thinning which was partially explained by diurnal choroidal thickness changes during the examination period. Further experiments, using longer stimulation periods, are needed to fully describe the predictive power of choroidal thickness changes on axial eye growth.

TITLE: Long-term Outcomes of Alpha Cor Keratoprosthesis For Management Of High-Risk Keratoplasty Patients: Device Retention, Complications, and Snellen Vision

SESSION TITLE: Refractive and non-refractive corneal surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Haghnegahdar, J.E. Sutphin, K. Goins, Ophthalmology, The University of Kansas Medical Center, Kansas City, Kansas, UNITED STATES|

Commercial Relationships Disclosure: Megan Haghnegahdar: Commercial Relationship: Code N (No Commercial Relationship) | John Sutphin: Commercial Relationship: Code N (No Commercial Relationship) | Kenneth Goins: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To report the long-term clinical outcomes of AlphaCor keratoprosthesis implantation through analysis of complications, device retention, and visual outcomes in eight patients.

Methods: This is retrospective chart review of eight patients who received AlphaCor keratoprosthesis between 2004 and 2008. Primary data points collected included presence of ocular surface disease (OSD), post-operative complications, time from device implantation to removal, and best corrected visual acuity (BCVA). OSD was defined as aniridia, chemical or thermal injury, herpetic or microbial keratitis, ocular rosacea, stem cell deficiency, and cicatricial conjunctival disorders. Comparisons between both groups were made using the 2-tailed student's t-Test. P value less than 0.05 was considered statistically significant.

Results: Device retention rate at 1, 5, and 10 years was 87.5%, 50%, and 12.5% respectively. Device retention was decreased in OSD eyes at 67.8 months compared to 92 months in those without OSD ($p = 0.20$). Eyes that were able to achieve surface protection with bandage contact lens wear had a longer mean retention time of 128.5 months compared to those that could not at 55.67 months ($p = 0.16$). Complications included retroprosthetic membrane formation (50%), corneal melt (62.5%), infection (25%), and optic deposits (62.5%). Of the five patients that developed corneal melt around the device, four had OSD. Patients with OSD demonstrated stromal loss sooner postoperatively (51.4 months) compared to the patient without OSD (85 months). Five of the eight patients had the device removed (62.5%). Reasons for removal were stromal melt without associated infection in three patients, melt associated with infection in one patient, and discoloration with poor visual acuity in one patient. Preoperative BCVA ranged from hand motion to 20/100. Four eyes had little change in postoperative BCVA, however Snellen BCVA in the four remaining eyes improved an average of 8.5 lines, with a BCVA range of 20/70 to 20/20 using various contact lenses.

Conclusions: Patients with OSD who have undergone AlphaCor keratoprosthesis implantation are more likely to develop negative outcomes. Modern treatment options, such as serum tears, recombinant human nerve growth factor, and scleral contact lenses may offer a contemporary solution for these patients.

ABSTRACT BODY:

Purpose: To quantify changes of individual early atrophic features over time that are part of the recently introduced definitions of incomplete and complete retinal pigment epithelium and outer retinal atrophy (iRORA and cRORA) in age-related macular degeneration (AMD)

Methods: Optical coherence tomography (OCT) data from fellow eyes with intermediate AMD at baseline, that were obtained from a prospective natural history study of disease progression in patients with unilateral geographic atrophy (GA, NCT02399072), were assessed for presence of iRORA and cRORA lesions at the final study visit. Two independent readers, followed by mixed arbitration review involving up to two senior readers, assessed qualitative AMD characteristics and annotated – on the most representative B-scan – seven individual features of each iRORA and cRORA lesion at the final and each preceding study visit. Kappa statistics and Bland-Altman agreements between readers were determined and linear regression analysis applied to estimate changes over time.

Results: In 24 out of 32 fellow eyes with iRORA and cRORA but no conversion to exudative AMD or GA (minimum lesion size 0.15 mm^2) during the study, a total of 49 individual lesions (193 time points) were included. Moderate agreement was found for presence of choroidal hypertransmission (kappa 0.54), followed by subsidence of outer plexiform (0.46) and inner nuclear layers (0.43). For quantification of lateral dimensions of features, choroidal hypertransmission (mean difference 7.1 µm [-302.2;316.4]) was again the feature with the highest agreement, while lowest was found for RPE attenuation/disruption (-238.1 µm [-1101.2;624.9]). The mean dimensions of choroidal hypertransmission and external limiting membrane disruptions at first manifestation were 319.7 µm (95% confidence interval [231.3;408.1]) and 609.1 µm [382.6;835.6], showing an enlargement of 141.2 µm/year [75.58;206.8] and 108.6 µm/year [63.2;154.0], respectively.

Conclusions: Early progression of iRORA and cRORA lesions can be reliably quantified, which may be helpful to assess new therapeutic interventions aiming to slow down the early growth of atrophy. Further, these results suggest

that the enlargement rate of these early atrophic lesions is slower compared to previously published data on the lateral spread of larger GA lesions.

ABSTRACT BODY:

Purpose: The long-term use of an efficacious and safe topical anti-inflammatory compound with a rapid onset of action for dry eye and other chronic ophthalmic inflammation mediated diseases presents an unmet medical need in ophthalmology. In this study, a murine allergic eye disease (AED) model of dry eye disease (DED) was used to evaluate mitigating effects of a class of anti-inflammatory compounds on DED progression. We hypothesize that compounds that engage and down-regulate disease-relevant pro-inflammatory pathways in our AED model have potential to treat ocular signs and symptoms of DED in human patients.

Methods: Female C57Bl/6 mice immunized against ovalbumin (OVA) were challenged with a topical OVA solution to induce inflammation and DED progression prior to treatment. A representative compound (compound A) from a novel class of Aerie anti-inflammatory compounds was evaluated in the AED model of DED. An ophthalmic solution of compound A, vehicle control, and a dexamethasone phosphate (positive control) solution was applied topically TID. Subjective masked and randomized clinical scoring of observable ocular inflammation was taken over the course of 4 days. Post-mortem tissue measurements of inflammation include flow cytometry of immune infiltrate, qPCR analysis of inflammatory biomarkers within Meibomian Gland (MG), and ELISA assays for inflammatory biomarkers.

Results: Topical administration of Compound A and the positive control dexamethasone phosphate significantly reduced clinical signs of inflammation including lid edema, conjunctival hyperemia, and MG plugging compared to vehicle. Quantitative analysis by qPCR demonstrates that both Compound A and dexamethasone reduced IL-17a, INFg, IL-6, IL-1b, and MPO infiltrates relative to vehicle in the mouse eyelid, the target site for MGD associated DED.

Conclusions: By targeting and engaging inflammatory pathways in a murine AED model of DED we show a significant reduction in inflammation and clinical signs of disease. Compound A represents a novel class of Aerie anti-inflammatory compounds that have the potential to be fast-acting, safe and efficacious treatment for ocular inflammatory diseases.

TITLE: Effect of Glare on Contrast Sensitivity for Myopia Control Spectacles

SESSION TITLE: Refractive Error: Myopia, Hyperopia, vision and models

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Jagadeesh, A. Ho, Brien Holden Vision Institute, Sydney, New South Wales, AUSTRALIA|A. Ho, University of New South Wales, Sydney, New South Wales, AUSTRALIA|

Commercial Relationships Disclosure: Divya Jagadeesh: Commercial Relationship: Code N (No Commercial Relationship) | Arthur Ho: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Lenslet-type optics utilized in myopia-control spectacle lenses (MCSL) has been shown to cause minimal impact on visual performance under conventional clinical light conditions (Li et al, 2021). Whether lenslet features introduce visual artefacts under more severe conditions such as glare has not been tested. This study explored the feasibility of a glare tester (GT) to detect and discriminate between MC lenses.

Methods: A GT based on that of Buhren et al (2006) was constructed to measure Glare Effect (GE) on contrast sensitivity (CS), consisting of a ring of 8 equally-spaced 6400 mcd LEDs, positioned on a dark base board. A square aperture at the centre of the LED ring enabled viewing of test charts displayed on an electronic vision chart (EVC) monitor (Sony LMD-DM20) 6 metres from the participant. The ring of LEDs subtended an angle of 6.4° at the participant's eye. The participant viewed Pelli Robson CS letters displayed on the EVC. Letter sizes tested were 6/38, 6/24, 6/15 and 6/9.5. CS for each letter size was measured monocularly under mesopic (<8 lux) and photopic (380–400 lux) conditions with and without LED-induced glare for two commercially-available MCSL (Hoya MiYOSMART and Essilor Stellest) and habitual correction for 4 participants and were instructed to view through the lenslet region of the lenses. A glare effect quotient (GE, Figure 1 equation) was calculated as a measure of device-induced glare relative to habitual correction. General linear model was used to account for the effect of lens type, light and letter size on GE. 95% CI was used to determine the difference from habitual correction.

Results: Participants age range was 25 to 39 years. The 95% CI showed that MiYOSMART lens had a similar or better contrast sensitivity when compared to habitual correction for all letter sizes under both illumination conditions (Table 1). Although not statistically significant, reduction in CS by 0.02 $\log_{10}$ units was observed at 6/38 for the Stellest lens under both light conditions and in photopic condition a minimal reduction in CS was noted at 6/9.5. At 6/15, the MC devices had similar CS increase of around 0.05 $\log_{10}$ units.

Conclusions: This small-sample exploratory study suggests that a GT can identify differences in participant performance of MCSL under glare conditions. With further refinements, a GT may be useful in determining the vision acceptability of MCSL.

ABSTRACT BODY:

Purpose: Individuals with macular-foveal capillaries (i.e., a fragmented foveal avascular zone, FAZ) have been proposed to have an anomalous distribution of macular photoreceptors, based on an absence of the typical foveal scotoma on scotopic microperimetry.[1] Here we sought to replicate these findings in individuals objectively classified as having a fragmented FAZ.

Methods: 14 individuals participated, 7 with fragmented FAZs and 7 with normal FAZ morphometry. Each subject had testing performed on their right eye. Five 3 × 3-mm (nominal area) angiograms were acquired with the AngioVue OCT-A system (Optovue, Inc., Fremont, CA). Two scans (1 horizontal, 1 vertical) each consisting of 304 B-scans with 304 A-scans/B-scan were acquired and co-registered to create an angiogram for analysis (AngioVue software version:2018.1.0.43). From each volume, a custom slab from inner limiting membrane to 9mm above the outer plexiform layer was extracted. Slabs from five volumes were registered and averaged using bUnwarpJ in FIJI. The presence of a fragmented FAZ was objectively determined using a previously described method.[2] Scotopic microperimetry testing was performed using a MP-1S microperimeter (Nidek Technologies, Gamagori, Japan). A customized microperimetry pattern of 45 points within the central 8 degrees centered near the fovea was used, and interpolated maps of foveal sensitivity were generated from scotopic microperimetry responses. Where possible, scotoma area in deg^2 was estimated using a 1db threshold.

Results: For all participants (10 female, 4 male; aged 12-55 years) there was a central area of reduced sensitivity, though the scotoma area could only be estimated in 12 participants. The mean scotoma area in those with fragmented FAZs was 1.86 deg^2 (range: 0.310-4.15 deg^2), while the mean scotoma area in the normal FAZ group was 1.53 deg^2 (range: 0.293-3.62 deg^2). These values are consistent with histological estimates of the rod-free zone. There was no significant difference in scotoma area between individuals with normal and fragmented FAZs (p=0.42, unpaired t-test).

Conclusions: In contrast to previous reports, we do not observe an absence of a foveal scotoma using scotopic microperimetry in individuals with a fragmented FAZ.

ABSTRACT BODY:

Purpose: Patients deficient in peroxisomal β-oxidation, which is essential for the synthesis of DHA (C22:6n-3) and the breakdown of VLC-PUFAs, present with retinopathy and reduced plasma DHA. A mouse model lacking peroxisomal multifunctional protein 2 ($Mfp2^{-/-}$ mice) also develops an early onset retinal decay, accompanied by reduced plasma and retinal DHA. We hypothesized that a reduced supply of DHA causes the $Mfp2^{-/-}$ retinal phenotype.

Methods: To define the contribution of local versus systemic supply of DHA for the neural retina, we investigated the retina of photoreceptor-specific $Mfp2^{-/-}$ ($Crx\text{-}Mfp2^{-/-}$) and of liver specific $Pex5^{-/-}$ mice, which lack all peroxisomal functions in hepatocytes. Next, a 0.1% DHA or control diet was fed to $Mfp2^{+/-}$ pregnant female mice and their offspring until sacrifice at 4w, 8w or 16w. $Mfp2^{-/-}$ mice and controls were analyzed for retinal function via full-field ERG, for lipid composition of NR and plasma with LC-MS/MS and GC, and histologically using retinal sections and RPE flatmounts.

Results: $Alb\text{-}Pex5^{-/-}$ mice displayed reduced plasma and retinal DHA levels, impaired ERG responses and shortened POS at 8w. In contrast, DHA levels and retinal morphology were normal in $Crx\text{-}Mfp2^{-/-}$ mice. DHA supplementation to $Mfp2^{-/-}$ mice increased plasma DHA even above levels in WT mice on control diet. Lipidome analysis showed normalization of DHA-containing phospholipids in the NR, such as LPC(22:6) and PC(44:12). Phospholipid species containing ultra-long-chain-PUFAs (>C36) still accumulated. Remarkably, until the age of 8w, the retinal morphology considerably improved with regard to: POS length, photoreceptor cell death and maintenance of the RPE honeycomb pattern, and inflammation was dampened. However, visual function improved only at the age of 4 weeks and deteriorated subsequently. Despite the initial rescue of retinal integrity, DHA supplementation could not prevent a complete retinal degeneration at 16w.

Conclusions: Our data prove that systemic supply of DHA is essential for the DHA pool in the NR. DHA supplementation rescues the retinal morphology of $Mfp2^{-/-}$ mice at an early age, but cannot prevent the retinal demise at later age. We hypothesize that the supplied DHA is converted into the protective lipid mediator Neuroprotectin D1 but that accumulating ultra-long-chain-PUFAs are toxic.

ABSTRACT BODY:

Purpose: Adaptive optics enhanced indocyanine green (AO-ICG) imaging can be used to image the photoreceptor (PR) - retinal pigment epithelium (RPE) - choriocapillaris (CC) complex in the living human eye (PMID 30456310). In this study, we applied this technique to evaluate the PR-RPE-CC complex in choroideremia, an X-linked retinal degeneration.

Methods: AO-ICG imaging was performed at the fovea in 6 female carriers and 3 affected male patients (n=16 eyes) with confirmed mutations in the CHM gene. A subset of patients (3 carriers, 1 affected male, n=7 eyes) were imaged a second time, approximately 1-2 years after the initial visit. The transit phase immediately after ICG dye injection was used to obtain an image of the CC, and the late phase (at least 30 minutes afterward) was used to image the RPE. Images of the cone PRs were simultaneously obtained. Images were co-registered and quantified for cell-to-cell spacing (PR, RPE) or average flow void diameter (CC) were quantified using custom software.

Results: The PR-RPE-CC complex was intact in all patients imaged. Quantitative analysis of the initial visit of each eye revealed that the RPE was the most disrupted layer (average cone spacing increase compared to the expected normal value, 7%; RPE spacing increase, 156%; CC flow void diameter increase, 14%). Longitudinal follow-up imaging further corroborated this result, with the largest visit-to-visit changes occurring in the RPE when compared to the cone PR and CC layers (average increase from visit 1 to visit 2: cone PR, 1%; RPE, 24%; CC, 4%). Together, these results suggest that the PR, RPE and CC degenerate at different rates, with the largest changes occurring in the RPE.

Conclusions: We demonstrate, for the first time, longitudinal assessment of the PR-RPE-CC complex using AO-ICG. In choroideremia, the RPE appears to be affected to a greater degree than the surrounding cone PR and CC layers and shows the largest change over time.

ABSTRACT BODY:

Purpose: The ICD-10 glaucoma severity classification is based on 24-2 visual field (VF) test.[1] Given that 24-2 can miss central or early damage,[2] we hypothesized that using the same principles, the optical coherence tomography (OCT) would provide a better estimation of severity.

Methods: Severity was determined for 55 eyes with glaucoma, according to the ICD-10 guidelines, which include assessing the presence of regional abnormalities in each hemifield, as well as the central 5 degrees of fixation (Fig. 1a). Grading was performed for each eye using either 24-2 VF or OCT macular and RNFL images by two independent groups of masked graders. Agreement between the two grading methods was evaluated. In addition, the accuracy of each method was determined by comparing the results to a reference standard (RS) based upon an automated structure-function topographic agreement method for the evaluation of regional abnormalities.[3]

Results: Based on the VF, glaucomatous eyes were classified as mild, moderate and advanced in 13, 17 and 25 cases respectively. Based on the OCT alone, glaucomatous eyes were classified as mild, moderate and advanced in 7, 4 and 44 cases respectively. The OCT classification was more severe than the VF in 22 (40%) of the 55 cases. In 26 (47%) cases, central involvement was detected by OCT, but not by the 24-2. In only 5 (9%) of the 55 cases, the OCT classification was less severe than the VF. The Kappa value showed weak agreement between VF and OCT (0.16±0.08, P=0.041). According to the RS, eyes were classified as mild, moderate and advanced in 3, 14 and 38 cases, respectively. The 24-2 gradings showed fair agreement with the RS (Kappa value 0.30±0.1, P=0.001), while the OCT gradings had good agreement with the RS (Kappa value 0.40±0.1, P<0.001). Compared to 24-2, the OCT also had better agreement with the RS in all 3 regions (Fig. 1b). A combination of using 24-2 to determine hemifield involvement and OCT for central involvement did not improve agreement compared to OCT alone (Kappa 0.36±0.1, P=0.001).

Conclusions: The current ICD-10 system relies on a functional (24-2 VF) test alone, which can underestimate the severity of glaucoma in a significant portion of eyes. OCT revealed advantages over 24-2 for accurate classification. Adding 24-2 to OCT data did not improve classification accuracy. 1. ICD-10 Glaucoma Reference Guide, 2019, aao.org; 2. Commercial Relationships Disclosure: Monichan Phay: Commercial Relationship: Code N (No Commercial Relationship) | Sophia Bauer: Commercial Relationship: Code N (No Commercial Relationship) | Petr Baranov: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A key challenge in retinal ganglion cell (RGC) replacement therapy is low donor cell survival. Phosphatidylserine (PS) is a ubiquitous “eat me” signal that is externalized and permanently displayed on the surface of apoptotic cells to facilitate their engulfment and clearance by tissue macrophages. Under stress, viable neurons also expose PS to the outer membrane in a reversible fashion. Since donor RGCs experience a significant stress during the isolation and transplantation process, we hypothesize that PS-mediated neurophagy by the host microglia/macrophages is a major contributor to donor cell death.

Methods: Donor human RGCs were derived from Brn3b-Tdtomato-Thy1.2 embryonic stem cells through retinal organoid approach with gentle dissociation and sorting for Thy1.2. To mask the externalized PS from macrophage/microglia recognition, donor cells were pretreated with annexin V (5mg/mL) for at least 20 minutes. We transplanted 20,000 viable donor RGCs subretinally into wild-type mice and processed whole mount retinas at day 1 and day 4 for immunostaining and confocal imaging to carry out subsequent analysis.

Results: Annexin V pretreatment led to the increase in transplant success: 92% (11 out of 12 recipients) had >1% (200) donor cells at day 4, compared to only 55% (6 out of 11) in the control group. We also observed ~2.5 fold-change in number of donor RGCs per eye: 1,280 cells in pretreated vs. 520 cells in control. In both groups, grafted donor RGCs displayed extensive neurite outgrowth (>150mm) and axon projections (>1000mm). Furthermore, donor cells axon fasciculation and entry into the optic nerve head were observed in the successful grafts: 33% vs. 9% in the Annexin V group vs. control. The recruitment of $Iba1^+$ and $CD45^+$ cells to the delivery site and their co-localization with donor RGCs was lower in the annexin V pretreated group at day 1 (19% vs. 40%) and was not different between groups at day 4.

Conclusions: Blocking externalized PS “eat me” signal with annexin V resulted in a drastic improvement in donor RGC survival and transplant success. However, persistent recruitment of $Iba1^+$ and $CD45^+$ to the delivery site and their co-localization with donor RGCs indicates that annexin V pretreatment only offers temporary protection. Our findings suggest that neurophagy by host microglia plays a significant role in eliminating viable donor RGCs.

Symptom Based Triage Tool in Ophthalmology
SESSION TITLE: Eyecare delivery and economics
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: E. Meer, M.S. Ramakrishnan, G. Whitehead, B.L. VanderBeek, Ophthalmology, University of Pennsylvania, Philadelphia, Pennsylvania, UNITED STATES|
Commercial Relationships Disclosure: Elana Meer: Commercial Relationship: Code N (No Commercial Relationship) | Meera Ramakrishnan: Commercial Relationship: Code N (No Commercial Relationship) | Gideon Whitehead: Commercial Relationship: Code N (No Commercial Relationship) | Brian VanderBeek: Commercial Relationship: Code N (No Commercial Relationship)
ABSTRACT BODY:
Purpose: Acute care ophthalmic clinics can suffer from call overload and inefficient triage, leading to suboptimal patient access. An automated symptom checker and triage tool may offload the call volume while creating a more efficient and effective system for matching patients with their appropriate level of care. Here we describe the development and preliminary results from a novel automated ophthalmology triage tool.
Methods:
A symptom based triage algorithm was developed using the Wills Eye Manual and literature searches of acute ophthalmic diagnoses.[1] This patient facing automated algorithm (Figure 1) used a series of questions and answers to triage patients into 3 different acuity levels based on duration and characterization of symptoms (i.e. eye pain, blurry vision, flashes/floaters, eyelid lesions, etc): 1. Urgent: Same day appointment 2. Semi-Urgent: Appointment in less than 4 weeks 3. Non-Urgent: Appointment in 4 - 9 weeks.

The automated triage tool was built into an academic eye institution's website, available to both patients and non-clinical personnel for triaging eye-related symptoms. Upon completion of the tool, results were sent via an automatically generated email along with the patient information for review by an ophthalmic technician who would schedule the patient based on triage output.

Basic descriptive statistics were used to present demographic data, tool usage data, and time from symptom presentation to care access across the call center and patient-facing website.
Results:
Via the call center and the clinical website, the automated triage tool was used 1370 and 95 times, respectively. 66.7% of patients utilizing the tool were female, 50.7% identified as African-American, 28.7% Caucasian, 4.4% Asian, and 9.8% Hispanic/Latino. Among call center triage tool users, 33.5% were triaged to non-urgent, 60.4% were triaged to semi-urgent, and 6.1% were triaged to urgent same-day appointments. Among patient-facing website triage tool users, 15.5% were triaged to non-urgent, 39.7% were triaged to semi-urgent, and 44.8% were triaged to urgent same-day appointments.
Conclusions:
Automated Triage algorithms may be beneficial by offloading non-acute phone calls and clinical volume. Similarly, it can be used by non-clinically oriented staff members to guide clinical judgements. Additional work should focus on validation and electronic implementation into EHR systems.

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) is one of the leading causes of blindness in the modern world. Recent studies show an association between cell senescence and DR, but the underlying mechanism is not clear. The cyclic GMP–AMP synthase(cGAS)/stimulator of interferon genes (STING) pathway has been implicated in type I interferon (IFN)-induced cell senescence, inflammation, and oxidative stress, which are known contribute to the development of DR, indicating that this pathway might be a novel target for DR. This study investigates the potential role of STING in the pathogenesis of DR.

Methods: Immuno-blot and immunohistochemistry were used to characterize the activated state of retinal cGAS/STING in proliferative DR (PDR) patients and diabetic mice. β-galactosidase-based cell senescence assays and flow cytometry were used to determine whether IFN-β and STING activator 2′,3′-cyclic GMP-AMP (cGAMP), induced cell senescence in human retinal microvascular endothelial cells (hRMEC) and mouse retinal microvascular endothelial cells (mRMEC) in vitro. To evaluate the role of STING in diabetes-induced retinal alterations, diabetes was induced by IP injection of streptozotocin in STING mutant ($STING^{GT}$), $STING^{-/-}$ and wild type mice. Retinal blood vessels, expression of inflammatory proteins, production of superoxide, acellular capillary formation, and pericyte loss were measured.

Results: The retinal protein level of cGAS and STING increased in PDR patients and diabetic mice compared to non-diabetic controls. PDR patients show positive STING staining in retinal blood vessels. cGAMP-mediated STING activation increased IFN-β secretion in mRMEC. The percentage of senescent hRMEC and mRMEC increased when cells were treated with IFN-β relative to untreated cells. Diabetes-induced increase in retinal vascular senescence, leukostasis, inflammatory proteins ICAM-1 and iNOS, and production of superoxide were inhibited in $STING^{-/-}$ and $STING^{GT}$ mice after 2 months of diabetes in mice. $STING^{-/-}$ and $STING^{GT}$ also inhibited acellular capillary formation and pericyte loss in diabetic mice at 8 months.

Conclusions: Retinal cGAS/STING is activated in PDR patients and diabetic mice. Activation of STING increases IFN-β secretion in hRMEC and mRMEC in vitro, thereby leading to cell senescence. Loss of STING function inhibits retinal vascular senescence, inflammation, oxidative stress, capillary degeneration and pericyte loss caused by diabetes.

ABSTRACT BODY:

Purpose: To assess retinal sensitivity (RS) in extensive macular atrophy with pseudodrusen-like appearance (EMAP) using microperimetry (MP)

Methods: Cross-sectional, observational study. 22 EMAP patients without pathogenic mutations for dystrophies and without macular neovascularization (44 eyes) and 12 healthy controls (24 eyes) underwent best-corrected visual acuity (BCVA), MP, fundus photography, optical coherence tomography (OCT) and blue autofluorescence (BAF).
A customized 20-stimuli grid was used to test mesopic (mRS) and dark-adapted scotopic (sRS) sensitivity in macular and paramacular areas. Fibrosis was evaluated on fundus photographs, while BAF images were analyzed for background autofluorescence of the posterior pole (iso- or hyper-autofluorescent) and to measure the size of macular atrophy. Foveal atrophy, vitreo-macular interface abnormalities, outer retinal tubulations, central sub-field thickness (CST) and sub-foveal choroidal thickness (SCT) were also investigated on OCT.

Results: Mean age was similar for patients and controls (57.6±3.2 vs 57.3±2.1 years, p=0.77). BCVA was significantly lower in the EMAP group (60.1±21.0) compared with controls (85.0±0.0) (p<0.001).
RS turned out to be significantly reduced in EMAP patients both in macular and paramacular regions (all p<0.001). Lower mRS was significantly associated with foveal atrophy, fibrosis, hyper-autofluorescent background, larger atrophic areas and with lower BCVA, CST and SCT. Reduced sRS was instead associated with hyper-autofluorescent background, lower BCVA and with smaller CST and SCT.
On multivariate analysis, only fibrosis (p=0.04) and more extensive macular atrophy (p=0.02) were associated with reduced RS under mesopic conditions while no independent factor meaningfully affected scotopic RS in EMAP patients.

Conclusions: Impaired dark adaptation and night blindness are frequent, burdensome symptoms arising in the early stages of EMAP.
Our study is the first functional assessment in EMAP using MP and provides evidence on the reduced macular function particularly under dark conditions. Our findings indicate that macular sensitivity significantly drops when signs of end-stage disease (e.g., fibrosis and extensive macular atrophy) appear. The absence of independent factors associated with sRS might be related to the presence of diffuse pseudodrusen-like deposits. This explains the significant visual impairment referred by this group of patients.

ABSTRACT BODY:

Purpose: Due to the important role that myoepithelial cells (MEC) play in lacrimal gland contraction helping to expel lacrimal fluid, the purpose of the current study was to investigate if the proinflammatory cytokines, interleukin-1β (IL-1β), tumor necrosis factor alpha (TNFα) and interferon gamma (IFNγ), are implicated in the reported impaired MEC contraction in chronically inflamed lacrimal glands.

Methods: MEC were isolated from lacrimal gland explants of α-Smooth Muscle Actin (SMA) - GFP mice (C57BL6) / $SMA^{CreErt2}$ strain strain. Cultured lacrimal gland MEC were treated with IL-1β alone (10 ng/ml) or a combination of IL-1β, TNFα and IFNγ (10 ng/ml) for a total of 7 days. Cells were maintained in complete RPMI-1640 medium (Roswell Park Memorial Institute) supplemented with 5% fetal bovine serum, and media was changed every other day with fresh addition of cytokines. At day 2, 4 and 7, GFP intensity, cell area, amounts of contractile proteins SMA and calponin, and MEC contraction were assessed. Analyzing GFP intensity is an indicator of SMA protein levels since GFP expression is under the control of the SMA promoter.

Results: At day 0, control and treated cells showed no differences in GFP intensity and cell size. GFP intensity started to decrease in treated MEC at day 2 (20% ± 0.32; $p=0.02$), continuing at day 4 (25% ± 0.51; $p=0.007$) and day 7 (30% ± 0.48; $p=0.0001$). Mean cell area was also reduced at day 2 (34% ± 0.0001; $p=0.0005$), day 4 (51% ± 0.0003; $p<0.0001$) and day 7 (30% ± 0.001; $p=0.0015$). The contraction assay at day 2 showed a 70% ± 0.032 decrease of contraction in treated MEC compared with control ($p<0.0001$), 73% ± 0.008 ($p<0.0001$) at day 4 and a significant drop of 82% ± 0.006 ($p=0.0015$) at day 7. Also, at the last time point, levels of contractile proteins were measured by western blotting showing a decrease in the amount of SMA and calponin protein in treated MEC compared with the control group (30% ± 0.001; $p=0.0016$ and $p=0.0206$; respectively). Similar results were observed when tumor necrosis factor alpha (TNFα) or interferon gamma (IFNγ) were added along with IL-1β.

Conclusions: Our results demonstrated that MEC contractile ability is impaired in the presence of pro-inflammatory cytokines IL-1β, TNFα, IFNγ making them potential therapeutic targets to restore MEC contractile ability and tear secretion in Sjogren syndrome dry eye disease.

TITLE: Functional Vision Assessment in People with Ultra-Low Vision using Virtual Reality: A Reduced Version

SESSION TITLE: Assistive Devices, Visual Function Assessment, and Vision Restoration Therapies

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Sargur, Whiting School of Engineering, Johns Hopkins University, Baltimore, Maryland, UNITED STATES|A. Kartha, R. Sadeghi, C. Bradley, G. Dagnelie, Wilmer Eye Institute, Johns Hopkins University, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Krishna Sargur: Commercial Relationship: Code N (No Commercial Relationship) | Arathy Kartha: Commercial Relationship: Code N (No Commercial Relationship) | Roksana Sadeghi: Commercial Relationship: Code N (No Commercial Relationship) | Chris Bradley: Commercial Relationship: Code N (No Commercial Relationship) | Gislin Dagnelie: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Ultra-Low Vision (ULV) is a profound visual impairment limiting individuals to only detecting lights, silhouettes, and high contrast objects. Previous studies (Adeyemo et al 2017, Dagnelie et al 2017) have shown that visual information gathering under variable lighting conditions is one of the most common functional domains affected by ULV. In this study, we tested a reduced version of the functional assessment (Kartha et al. 2018) that can be useful for clinical evaluations.

Methods: Participants were tasked with completing a series of spatial localization and detection activities in a virtual reality environment. They were scored on the number of correct responses (m-alternative forced choice; m-AFC), for each of the 22 scenes presented. Data was processed into d prime (d') values that assessed participant performance compared to average (Person Measure), and scene difficulty based on chance performance (Item Measure; 0 for chance performance, more negative for easier tasks). Data collected from two centres (n=59 for C1; n=45 for C2) were compared using item and person measures.

Results: The results from C1 and C2 lie within the expected range, and all scenes except one have a better than chance performance. An expected trend is that scenes with lower contrast had less negative d' values as they were more difficult tasks.

There was significant correlation between the item measures from both centres ($r_{(21)} = 0.70$, $p<0.05$). Item measures from C2 were consistently higher than those from C1 for all items. On examining person measures, it became evident that person measures from C2 were significantly higher than those from C1 ($p<0.001$) which shows a higher functional ability and therefore, less item difficulty for C2 than C1.

Conclusions: Our data suggests that item measures and person measures can be compared across centres but may be shifted, depending on the functional ability of participants in each centre. They also suggest that this reduced set is an effective functional measure of ULV. The use of a VR headset enables this test to be performed easily both at homes and hospitals, making this a novel tool with a potential for widespread impact due to its portability, and ease of administration.

ABSTRACT BODY:

Purpose: Herpes family viruses represent a well-established etiology for infectious uveitis, specifically anterior uveitis. Information regarding such patients' demographic and presentation characteristics in Hispanic populations is scarce. We aim to describe the demographic and clinical characteristics in a cohort of Hispanic patients with Herpes Simplex Virus (HSV) associated uveitis who live in Puerto Rico.

Methods: We performed a retrospective medical chart review of patients with a clinical diagnosis of Herpetic Uveitis at two private uveitis practices in Puerto Rico. All patients underwent an appropriate medical workup; those whose uveitis diagnosis could be explained by any etiology other than HSV were excluded from the study. The demographic characteristics and ocular findings were recorded and moved to an external database, and a descriptive statistical analysis was performed.

Results: The analysis included 145 patients who met the criteria for HSV-associated uveitis. The median age at presentation was 65 years (range 24 – 93 years); 62.86% of the patients were female, and 100% were Hispanic. Prior diagnosis of glaucoma was present in 61.43% of patients. From those patients whose serological data were available, 93.67% of patients were positive for HSV1 IgG (N=79), 26.92% were positive for HSV1 IgM (N=52), 44.16% were positive for HSV2 IgG (N=77), and 28.57% were positive for HSV2 IgM (N=49). Seventy-three percent of patients presented with unilateral uveitis. Visual acuity was equal or better than 20/50 in 78.93% of the involved eyes. Active anterior uveitis was present in 91.43% of eyes, while 41.41% were pseudophakic, 32.86% had keratic precipitates, 16.43% had cells in the anterior vitreous, and 12.86% had iris atrophy with transillumination defects.

Conclusions: As was expected, our study suggests that HSV-associated uveitis most commonly affects females and occurs unilaterally. Interestingly, over half of the patients with HSV-associated uveitis had a past ocular history of glaucoma, suggesting a possible association between both conditions. In general, we found the clinical and demographic characteristics of patients with HSV-associated uveitis to be similar to those of Caucasian cohorts.

ABSTRACT BODY:

Purpose: It has been reported that RPE cells isolated from age-related macular degeneration (AMD) patients present decreased chromatin accessibility and reduced expression of RPE signature genes, likely due to the upregulation of histone deacetylase 11 (HDAC11), an enzyme that deacetylates the histones and results in a more closed chromatin structure. In this study, we aim to dissect the role of HDAC11 in regulating RPE genes and RPE function.

Methods: Best1-Hdac11 constitutive knock-in (KI) mice were generated for this study. Hematoxylin-eosin (HE) and periodic acid-Schiff (PAS) staining were performed on retina sections from 12-month-old WT and Hdac11 KI mice. Electroretinography (ERG) was performed on Hdac11 KI and age-matched WT mice to measure retina function. RPE flatmount cultures and Hdac11 adenoviral constructs were used for Hdac11 gain of function studies in vitro. Quantitative PCR analyses were performed to evaluate mRNA levels of genes involved in multiple biological processes in RPE cells from WT and Hdac11 KI mice or RPE flatmounts.

Results: Histological results revealed decreased pigmentation of RPE cells, increased thickness of Bruch's membrane (BM), BM breaks, and abnormal photoreceptor outer segments in 12-month-old Hdac11 KI mice. ERGs showed decreased a, b and c wave amplitudes in 12-month-old Hdac11 KI mice indicating impaired retina function compared to WT mice. Immunofluorescence experiments showed reduced opsin and PNAL (peanut agglutinin lectin) staining in 12-month-old Hdac11 KI mice. Decreased expression of visual cycle genes such as Rpe65 and Lrat were found in Hdac 11 KI mice relative to WT mice at both 5 and 12 months of age. RPE flatmounts overexpressing Hdac11 also showed significantly decreased expression of visual cycle genes (Rpe65, Lrat, Rdh5, Rbp1, Rgr), but not lysosomal genes (Atp6v0, Lamp1), or genes involved in other processes such as Il1b, Bcl-2, and Sox9. No significant changes in the expression of Hdac1, Hdac2, Hdac6, Hdac7, Hdac8 were found in RPE flatmounts overexpressing Hdac11.

Conclusions: Our results suggest that HDAC11 may control the chromatin accessibility for RPE-specific genes, such as visual cycle genes, and thereby normalize physiological functions of the RPE/retina. The current study provides mechanistic insight as to the upregulation of HDAC11 reported in patients with dry AMD and thereby provides a novel therapeutic avenue for delaying the progression of the disease.

TITLE: A framework for automating psychosocial distress screening in ophthalmology clinics using an EHR-derived AI algorithm

SESSION TITLE: Public Health I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Berchuck, A.A. Jammal, K. Weinfurt, D. Page, T. Somers, F.A. Medeiros, Duke University, Durham, North Carolina, UNITED STATES|

Commercial Relationships Disclosure: Samuel Berchuck: Commercial Relationship: Code N (No Commercial Relationship) | Alessandro Jammal: Commercial Relationship: Code N (No Commercial Relationship) | Kevin Weinfurt: Commercial Relationship: Code N (No Commercial Relationship) | David Page: Commercial Relationship: Code N (No Commercial Relationship) | Tamara Somers: Commercial Relationship: Code N (No Commercial Relationship) | Felipe Medeiros: Commercial Relationship(s);Code C (Consultant/Contractor):Aerie Pharmaceuticals, Allergan, Annexon, Biogen, Carl Zeiss Meditec, Galimedix, IDx, Stealth Biotherapeutics, Reichert;Code F (Financial Support):Allergan, Carl Zeiss Meditec, Google Inc., Heidelberg Engineering, Novartis, Reichert;Code P (Patent):nGoggle Inc.

ABSTRACT BODY:

Purpose: In patients with ophthalmic disorders, psychosocial risk factors play an important role in morbidity, mortality, and overall disease outcomes. Proper and early screening of psychosocial distress (i.e., anxiety and depression) can result in prompt intervention, and mitigate many of the factors listed above. Since screening is resource intensive, we developed a framework for automating distress screening using an electronic health record (EHR) derived artificial intelligence (AI) algorithm.

Methods: We performed a retrospective longitudinal study using the Duke Ophthalmic Registry (DOR). DOR consists of EHR data of over 100,000 patients seen at the Duke Eye Center (DEC) from 2009 to 2018. Our cohort included encounters for patients with at least two DEC encounters and a year of follow-up. At each encounter, distress was defined using a validated computable phenotype that relied on diagnostic and procedure codes, and medical history. Risk factors included available EHR history, including diagnostic and procedure codes, medical and encounter history, demographics (age, race, sex, ethnicity, marital status, income, education, and alcohol, smoking and illicit drug use), and problem list items. At each encounter, risk factors were used to discriminate patient distress status using the elastic-net classifier. Performance of the model was evaluated using the area under the receiver operating characteristic curve (AUC). Odds ratios (OR) for the top-25 predictors are presented, along with all non-zero demographic variables.

Results: Our cohort consisted of 358,135 encounters from 40,326 patients with an average of 9 encounters per patient over 4 years. The AUC was 0.91, with sensitivity of 0.97, and 0.90 at specificity levels of 0.75, and 0.9, respectively. Top predictors are listed in Figure and contained mostly predictors associated with psychiatric conditions. Also, present are conditions associated with high levels of distress, including suffocation, esophageal disorders, and headaches.

Conclusions: Using EHR data, we automatically identified psychosocial distress in ophthalmology patients upon encounter to a tertiary eye clinic. Our screening framework will be most effective on improving ophthalmic outcomes when paired with an effective referral and treatment program.

ABSTRACT BODY:

Purpose: Test-retest variability (TRV) is an important characteristic of perimetric algorithms. We evaluated the TRV of Zippy Adaptive Threshold Algorithm (ZATA) Standard and ZATA Fast and compared it with the Swedish Interactive Thresholding Algorithm (SITA) Standard and SITA Fast, in a prospective cross-sectional study.

Methods: We recruited 22 healthy participants and 53 patients with glaucoma, mean (±SD) age 54.7 (±11.0) and 64.0 (± 9.4) years, respectively, from the ophthalmology clinics at Kasturba Hospital, Manipal, India. Participants had no additional ocular condition other than cataract or uncomplicated operated cataract. Those who could complete a session of approximately 1.5 hours, with four visual field tests, were included. Glaucoma patients with uncontrolled intraocular pressure (IOP) or known to be inconsistent with medication or follow-up visits were not included. Participants performed ZATA tests on a Henson 9000 perimeter (Topcon Healthcare, UK) and SITA tests on Humphrey Field Analyser (720i, Carl Zeiss Meditec, USA). Tests were repeated within one to ninety days.

Results: The Mean Deviation (MD) values of the ZATA strategies were closely related to those estimated with the SITA strategies (Figure 1). Differences between test and retest appeared similar between the four strategies (Bland Altman plots in Figure 2). ZATA Standard was approximately 30% faster than SITA Standard and ZATA Fast was approximately 6% faster than SITA-Fast.

Conclusions: In terms of MD, the ZATA strategies agreed closely with SITA. Compared with SITA, the retest variability of the ZATA strategies appeared similar or lower, but with a shorter test duration.

ABSTRACT BODY:

Purpose: A mouse model with a knockout of multifunctional protein 2 (MFP2), the central peroxisomal β-oxidation enzyme, shows retinal degeneration mimicking the pathology in MFP2 deficient patients. To understand the origins and mechanisms of this degeneration, specifically in the RPE, we used global and RPE-specific Mfp2 knockout mice.

Methods: Eyes were collected either in the morning (2-3h post light onset) or in the afternoon (7h post light onset) at ages between 3 weeks and 12 months. They were used for immunostaining, immunoblotting, LC-MS lipidomic analysis and TEM imaging.

Results: The first pathological signs in $Mfp2^{-/-}$ RPE were lipid accumulations at 3w visualized by Perilipin-2 staining, which were not present at 2w, suggesting that peroxisomal β-oxidation is important for digestion of lipids coming from ingested POS, rich in VLC-PUFAs. The accumulation of neutral lipids and lipid species containing VLC-PUFAs was confirmed using lipidomics. TEM analysis at 3w showed accumulation of POS phagosomes, suggesting lysosomal dysfunction, confirmed with rhodopsin staining on RPE flat mounts. In addition, mitochondria were increased in number and were more circular in appearance. Immunostaining on flat mounts showed loss of the honeycomb structure and mislocalization of mitochondrial and peroxisomal markers. $Mfp2^{-/-}$ RPE progressively dedifferentiated with mislocalization of ezrin, a reduction in visual cycle genes and increases in dedifferentiation markers PCNA and SMA. mTOR, previously shown to induce RPE dedifferentiation, was already activated at 3w. The distribution and expression of the principle lactate transporters MCT1 and 3 was altered, suggesting impairment of lactate transport in the retina of these mice. The RPE-specific MFP2 knockouts show similar RPE degeneration. Interestingly, this caused pathology in the neural retina, as evidenced by increased inflammation, loss of photoreceptor nuclei and visual function towards 10-12 months of age.

Conclusions: Our results strongly indicate a crucial role for peroxisomal β-oxidation in the digestion of POS, with defects leading to lysosomal and mitochondrial abnormalities in RPE cells and their dedifferentiation. The RPE-specific MFP2 knockouts showed that the RPE degeneration was cell autonomous, but had negative consequences for the underlying neural retina.

ABSTRACT BODY:

Purpose: Usher 1F is caused by mutations in the PCDH15 gene, which encodes the tip-link protein PCDH15 in the inner ear. In the eye it has been shown to localize to the calyceal processes of the photoreceptor. Usher 1F is characterized by profound congenital deafness, and by progressive blindness beginning in the second decade. Gene addition therapy could be an attractive treatment, however, the PCDH15 coding sequence of ~5.8 kb is too large to fit into a single AAV capsid. We used a dual-AAV strategy to circumvent the size limitation.
Methods: We engineered two vectors that each encode part of the full-length protein. In cells, AAV genomes can recombine to creat a full-length coding sequence. To evaluate function in cochlea in vivo, Pcdh15 cKO mice were treated with dual AAVs. Hearing tests and histological analyses were performed at P30. To assess the potential of dual-AAV gene expression in human retina in vitro, we transduced retinal organoids from human iPSCs with dual AAVs and five weeks later evaluated HA-tagged PCDH15 expression and localization with immunofluorescence and immunogold SEM imaging.
Results: In HEK cells, full length PCDH15 was successfully produced using dual-AAV delivery. Proper recombination and splicing were confirmed with RT-PCR and Sanger sequencing. We found that Pcdh15 cKO mice, injected into inner ear with dual AAVs, displayed tip links four weeks after injection. They also showed robust rescue of hair bundle morphology, and rescue of mechanotransduction. While uninjected Pcdh15 cKO mice were deaf and had degenerated hair bundles, mice treated with dual AAVs encoding PCDH15 demonstrated good hearing rescue.

We also characterized the ultrastructure of photoreceptors in retinal organoids. SEM showed that a majority of photoreceptors developed inner segments, while some formed outer segments and connecting cilia. We observed nascent calycal processes at the apical ends of inner segments. Retinal organoids from human iPSCs transduced with dual AAVs encoding HA-tagged PCDH15 showed antibody labeling of HA-tag in photoreceptors, which was localized on the surface of the inner segments and at the inner/outer-segment junction where calyceal processes develop.
Conclusions: Dual-AAV delivery of PCDH15 mostly restores hearing in a mouse model of Usher 1F, and mediates expression and normal localization of PCDH15 in human photoreceptors in vitro. It holds promise for treatment of Usher 1F.

ABSTRACT BODY:

Purpose: The impact of glaucoma on the retinal capillary plexi (RCP) and its relationship to retinal ganglion cell (RGC) injury is not well understood. In this project, we studied microvascular injury in mice exposed to elevated IOP with the microbead model.

Methods: We used microbead injection in one eye of seven 12-week-old wild-type mice to induce IOP elevation. IOP was measured prior to injection and then 3 times per week. After 2 weeks, we immunostained retinas with CD31 (endothelium), Collagen IV (vascular basement membrane), and RBPMS (RGCs) and performed z-stack confocal microscopy. We performed Sholl analysis to quantify the number of intersections in the retinal capillary network. Using ImageJ we quantified RGC density and processed the confocal images to separate the three RCP into distinct images. We then established a novel, optimized image workflow to semi-automatically quantify the vascular anatomy using Angiotool (NIH, open-source). This provided topographical vascular features as well as spatial dimensions for the vascular network.

Results: IOP elevation of 1-4 mmHg above baseline was achieved throughout the study. IOP elevation to this level and duration did not cause RGC loss. Sholl analysis showed a 15% ± 3.50% reduction ($p \leq 0.01$) in the total number of capillary intersections at a distance of 1500µm from the optic nerve head. We also identified a plexus-selective phenotype. There was a significant reduction in the number of capillary junctions/mm^2 for both CD31 (26% ± 5.91%, $p \leq 0.01$) and Collagen IV (26% ± 5.77%, $p \leq 0.01$) in the intermediate retinal capillary plexus (IRCP). Furthermore, the total capillary vessel length/mm^2 was reduced for both CD31 (12% ± 2.04%, $p \leq 0.01$) and Collagen IV (12% ± 2.55%, $p \leq 0.001$) in the IRCP. There was also a decrease in the IRCP vessel area for CD31 (19% ± 2.09%, $p \leq 0.01$). No differences between control and bead injected eyes were detected for the superficial or deep RCP.

Conclusions: We have discovered a novel vascular phenotype in which the IRCP is rapidly sensitive to the effects of IOP elevation. This vascular phenotype is not detected in other retinal plexi and precedes RGC loss. This study advances our knowledge of microvascular deficits during glaucomatous pathology.

ABSTRACT BODY:

Purpose: The treatment of endophthalmitis consists of intravitreal antibiotics injections and, in selected circumstances, pars plana vitrectomy. However, severe or refractory cases may require an enucleation or evisceration (ENEV) to control the infectious process. Our study seeks to identify risk factors leading to enucleation or evisceration in patients with infectious endophthalmitis.

Methods: Medical records covering from August 2015 to August 2020 in a tertiary referral hospital in Puerto Rico were reviewed. Charts of patients with a clinical diagnosis of infectious endophthalmitis were selected for analysis. Affected eyes were stratified into two groups; those undergoing ENEV and those in which the globe was preserved (EP). Accordingly, the frequencies of clinical characteristics in each of the two groups were compared and statistically analyzed using Pearson's Chi-square test, Fisher's exact test, and Welch Two Sample t-test.

Results: A total of 69 patients diagnosed with endophthalmitis were identified and included in our study, of which 32 underwent ENEV. The median age was 70, and 40.6% were female. There was a higher frequency of exogenous endophthalmitis in the ENEV group versus the EP group (56.2% and 13.5%, p=0.0002). However, there was a lower post-surgical endophthalmitis frequency in the ENEV versus the EP groups (21.9% vs. 51.4%, p=0.014). A visual acuity of no light perception was most common in the ENEV vs. the EP group (46.9% vs. 5.4%, p= 0.00003). While a visual acuity of finger counting or better was less common in the ENEV group vs. the EP group (9.4% vs. 32.4%, p= 0.04). Orbital involvement (panophthalmitis) was more frequent in the ENEV versus the EP group (37.5% vs. 5.4%, p= 0.002).

Conclusions: Our study suggests that eyes with endophthalmitis that present with a visual acuity of no light perception, panophthalmitis, or exogenous etiology have a higher risk of ENEV. Conversely, patients with a post-surgical etiology or a visual acuity of finger counting or better may be at a lower risk of ENEV.

TITLE: Evaluation of factors affecting visit adherence in patients receiving intravitreal injections for neovascular age-related macular degeneration during the COVID-19 Pandemic

SESSION TITLE: AMD: Clinical and translational research/AMD therapies (excluding anti-VEGF)

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Dong, A. Bains, S. Davoudi, A.H. Nguyen, X. Chen, Boston University School of Medicine, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Kaylin Dong: Commercial Relationship: Code N (No Commercial Relationship) | Ashank Bains: Commercial Relationship: Code N (No Commercial Relationship) | Samaneh Davoudi: Commercial Relationship: Code N (No Commercial Relationship) | Anh Nguyen: Commercial Relationship: Code N (No Commercial Relationship) | Xuejing Chen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The COVID-19 Pandemic has disrupted the care of patients receiving intravitreal injections for neovascular age-related macular degeneration (nAMD). This study looks at the factors that affected visit adherence for this population of patients during the height of the first pandemic surge.

Methods: In this retrospective, observational, case-control study, we included nAMD patients receiving anti-VEGF injections with an appointment scheduled during the target periods of March 11, 2020 – May 26, 2020 at either an urban hospital-based or suburban eye clinic. Patients who did not present for their appointment (cases) were compared to patients who did present to their appointment (controls). Medical records were reviewed to collect age, sex, race, presence of appointment attendance, language, marital status, distance from clinic, and area of deprivation index (ADI), which is a measure of socioeconomic health. Multivariate regression models were created with Stata (College Station, Texas) to determine the differences of these factors between no-show and show groups.

Results: 115 no-show patients (21% male, mean age 81 years) and 129 controls (26 % male, mean age 80.9 years) were enrolled. The odds of no-show were higher in non-White patients compared to White [(odds ratio (OR) = 2.7, 95% Confidence Interval (CI) = 1.22-6.17, P = 0.01)], the urban site compared to suburban site (OR = 3.1, 95% CI = 1.70-5.76, P = 0.0001) and single patients compared to married (OR = 2.3, 95% CI = 1.09-4.89, P = 0.02) in univariate analysis. The associations remained significant in multivariate analysis for non-White patients (OR = 3.1, 95% CI = 1.30-6.88, P = 0.01) and urban site (OR = 4.3, 95% CI = 1.78-10.3, P = 0.001) after adjusting for age, gender, language, distance from clinic and ADI. Age, distance from clinic, gender, ADI, and language were not statistically different between the two groups.

Conclusions: Visit adherence was lower for non-White patients during the first surge of the COVID-19 pandemic underlying the disparities which can be seen during the pandemic. Patients treated at an urban hospital were less likely to present for their anti-VEGF treatments than those receiving care in a suburban clinic. Further research is needed to determine whether differences in visit adherence effected long-term vision outcomes.

ABSTRACT BODY:

Purpose: Peroxisomal biogenesis disorders (PBDs) represent a group of rare diseases that can cause retinal degeneration, sensorineural hearing loss, and other systemic abnormalities, due to defects in peroxisome structure and function. Over two-thirds of all PBDs are caused by biallelic pathogenic variants in PEX1 or PEX6. Despite retinal degeneration manifesting in many PBDs, precisely how peroxisomal dysfunction causes retinal pathology is not well understood. To this effect, we differentiated PEX1 and PEX6 wild-type and knock-out induced pluripotent stem cells (iPSCs) into retinal pigment epithelial (RPE) cells to evaluate the effect of peroxisome dysfunction on this disease-relevant cell type.

Methods: CRISPR/Cas9-mediated genome-editing was used to generate PEX1 and PEX6 gene knockouts in the Gibco Human Episomal iPSC Line (Thermo Fisher Scientific, Inc.). We differentiated RPE from knock-out iPSC lines, normal parental lines, and a positive control line (3D1.8). We characterized and validated the iPSCs with flow cytometry using the pluripotency markers SOX2, NANOG and TRA-1-60 antibodies. At day 40 of RPE differentiation, we purified the cells by cell sorting and characterized the iPSC-derived RPE by morphology, pigmentation, and analysis of proteins associated with differentiated RPE using immunostaining followed by flow cytometry. Lastly, we evaluated peroxisome function by assessing very long-chain fatty acid and phytanic acid content in our iPSC-derived RPE cells.

Results: We successfully characterized and validated PEX1 and PEX6 knock-out iPSCs, parental control iPSCs, and a positive control iPSC line. The iPSCs expressed the appropriate stem cell markers as determined by flow cytometry. In addition, we successfully differentiated each iPSC line into RPE cells. The differentiated RPE cells expressed the appropriate markers indicating maturation. Detailed biochemical and peroxisomal function studies are underway.

Conclusions: We have demonstrated the successful differentiation, characterization, and validation of human-derived iPSC into RPE cells to model the effect of PBDs on a retinal cell type. Future studies will evaluate the requirements of PEX1 or PEX6 in RPE maturation and how abnormalities in peroxisome structure and metabolism influence RPE function.

ABSTRACT BODY:

Purpose: Corneal Endothelial Cells (CEnC) maintain normal corneal hydration. Damage to the corneal endothelium can lead to persistent corneal edema due to limited CEnC proliferative capacity. Studies have shown a concomitant decrease in density and/or function of both corneal nerves and CEnC following ocular injuries, suggesting nerves exert trophic effects on CEnC. Here we investigate the efficacy of neuropeptide α-MSH on CEnC proliferation and function following injury.

Methods: Wound healing was evaluated using CEnC derived from a healthy 21-year-old male donor cultured in Chen's medium supplemented with/without α-MSH (10-5M, 10-7M, or 10-9M) for 48hrs. Corneal injury was induced by transcorneal freezing in BALB/c mice (n=8/group) by placing a -72^{O}C 2 mm-diameter steel rod on the center of the cornea. Mice received 10μL subconjunctival injections of α-MSH (10-4M) or PBS (control) twice weekly for two weeks. Mice were injected with 5-ethynyl-2'-deoxyuridine (EdU) every 6 hours for 48hrs, and CEnC proliferation was evaluated by frequency of EdU+ cells. CEnC functional differentiation was assessed by comparing mRNA and protein expression of Na+/K+-ATPase by RT-PCR and Western blot, and by measuring central corneal thickness (CCT) via optical coherence tomography (OCT).

Results: Supplementing culture media with 10-5M α-MSH resulted in the fastest wound healing compared to the culture medium alone (P=0.03). In vivo, α-MSH treatment following injury increased the frequency of EdU+-CEnC within the wound area (61.6%±8.3% vs. control: 33.7%±5.0%; P=0.02) after 48hrs. CEnC Na+/K+-ATPase expression decreased 0.35-fold (P=0.01) at the mRNA level and dropped 0.63-fold (P=0.002) at the protein level in the control group 2 wks after the injury relative to values before injury; there was also a significant edema at 28 days post-injury (CCT:78.1±28.5mm; P=0.04). α-MSH administration restored CEnC Na+/K+-ATPase expression to baseline control values by causing a 2.3-fold increase in mRNA (P=0.04) and a 1.85-fold increase in protein expression (P<0.001) vs. control. α-MSH treatment led to a 54.9±15.0mm decrease in CCT (P=0.03) compared to the control group by 42d post-injury.

Conclusions: Our results demonstrate that following corneal endothelial injury, treatment with α-MSH prevents corneal edema by promoting proliferation of CEnC and maintaining function of mobilized/newly-generated CEnC.

ABSTRACT BODY:

Purpose: Retinitis pigmentosa (RP) patients commonly experience negative psychological states due to their progressive and unpredictable loss of vision and visual variations related to stress. The aim of this study was to examine hair cortisol concentrations (HCCs), which is usually associated with chronic stress, pretending to unveil possible associations between underlying psychological factors and disease severity in RP patients.

Methods: Seventy-eight RP patients and 148 healthy controls were included in this A complete ophthalmological exam was performed in all patients to grade into severity disease groups. Perceived stress and trait-anxiety were measured by the State-Trait Anxiety Inventory (STAI) questionnaire.

Results: Fifty-two (67%) patients had severe RP and 26 (33%) mild-moderate RP. Fifty-eight (58,9%) patients reported severely levels of stress and 18 (23.,1%) highly levels assessed by STAI questionnaire. RP patients exhibited higher HCCs (500.04±120.99 pg/mg) than in controls (136.17±60.51 pg/mg; $p<0.001$). Severe RP patients had significant higher HCCs than mild-moderate patients differing in 274.27pg/mg ($p<0.001$). There were no differences between RP severity grade and perceived anxiety levels in the questionaries. Group differences were not affected by relevant covariates (age, grade of severity, stress status, and gender).

Conclusions: HCC seems an effective biomarker associated with chronic stress in RP patients. This study shows that HCC in patients with RP are elevated compared to population-based controls, and association between HCC and RP severity was found. Future research is needed to characterize the effect of untreated negative psychological states on increased variability of vision and progression of the disease if any.

ABSTRACT BODY:

Purpose: Many activities that define independence and productivity in our society rely on good vision. As a result, one of the most devastating consequences of advancing visual impairment in any type of uveitis is loss of independence which would then affect the patient's quality of life. In this study, we will examine Quality of Life (QOL) data between patients with non-ocular vs ocular sarcoidosis and determine if the treatments (ex. systemic vs ocular implant) they receive have a significant impact on visual QOL or general QOL outcomes.

Methods: This is a prospective cross-sectional study of patients recruited from Loyola University Medical Center. Each participant was asked to complete a scientifically validated vision-related quality of life questionnaire, the National Eye Institute Visual Function Questionnaire (NEI-VFQ), and a scientifically validated HRQOL questionnaire, the Sarcoidosis Health Questionnaire (SHQ). Clinical data collected included a complete ophthalmic examination and systemic evaluations as indicated.

Results: In our sample, there was not a correlation between Best corrected visual acuity (BCVA) and NEI VFQ or SHQ scores. Patients on systemic therapy had lower NEI VFQ and SHQ scores regardless of their diagnosis. No correlation was found between the NEI VFQ and the SHQ.

Conclusions: As treatments in sarcoidosis and uveitis advance, it is important to see how patients' quality of life is affected to determine where further advancements should be focused and what types of accommodations or services may be most beneficial to them. Currently, there is little data in the literature studying QOL in patients with uveitis and systemic diseases. We would like to add to this area of research because increasing clinicians' understanding of which patients have low QOL and why will allow them to be better able to holistically care for their patients. Ophthalmologists get a unique view into how patients are able to go about their daily lives, and because of the necessity of good vision to function independently in our society, the front line for directing patients to social and mental health resources.

ABSTRACT BODY:

Purpose: Aging is a risk factor in the development of glaucoma, an optic neuropathy characterized by progressive degeneration of retinal ganglion cells (RGCs). Astrocytes interact closely with RGCs and have been demonstrated to be maladaptive to injury in aged humans; however, the mechanisms related to aging or to astrocyte reactivity in optic neuropathies are poorly understood. In this study, we utilized an optic nerve crush (ONC) injury model to test the hypothesis that aging increases susceptibility to nerve injury by altering glial responses.

Methods: Young adult (3-months old) and aged (16-months old) C57/Bl6 wild-type mice underwent ONC in the left eye by implementation of self-closing forceps 1mm posterior to the globe for 1 second. Injured and fellow uninjured eyes were collected on post-injury day (PID)-3 and PID-7. Retinal whole mounts were prepared and stained for RGC-specific marker Rbpms and glial-specific markers S100β and GFAP. To further investigate candidate pathways and mechanisms for differentiated injury response in aged animals, whole retina transcriptomics was performed on PID-3.

Results: Cell counts revealed a significant decrease in RGC density at PID-3 among aged (-18.7±0.94%, n=6, p=0.01) but not young mice. By PID-7, young and aged animals demonstrated 64.1% and 51.2% loss of Rbpms cells, without significant difference between age groups. Aged animals demonstrated a significant decrease in S100β cell density (265.7 vs 224.5 cells/mm^2, n=6, p=0.002) and GFAP reactivity (1.5×10^6 vs 1.1×10^6 integrated density per field, n=6, p=0.0003) compared to young animals at uninjured baseline. Significant increases were seen in S100β cell density on PID-7 in both young and aged animals, but GFAP reactivity was significantly increased on PID-7 in aged animals alone. Whole retina transcriptomics on PID-3 is underway, and may reveal early differential molecular changes that occur in aged animals in response to injury.

Conclusions: Age-related acceleration of neurodegenerative RGC loss after optic nerve injury is associated with increased reactive gliosis. Elucidating RGC and glial cell responses after optic nerve injury in young and aged animals could clarify mechanisms of progressive vision loss in age-related optic neuropathies (e.g., glaucoma) and assist development of novel neuroprotective strategies.

ABSTRACT BODY:

Purpose: Ophthalmic manifestations of West Nile virus (WNV) infection include optic neuritis, retinal vasculitis, and chorioretinitis. In general, most reports of ophthalmic WNV involve patients with a history of symptomatic systemic disease. However, the vast majority of human WNV infections occur without systemic symptoms. Our study aims to describe a cohort of patients with serologic evidence of WNV infection, no history of systemic symptoms, yet with characteristic features of ophthalmic WNV involvement.

Methods: We performed a retrospective medical records review of all patients with a history of optic neuritis, retinal vasculitis, and chorioretinitis with positive WNV serology. Patients with a history suggestive of symptomatic WNV infection, or any other systemic condition that may have explained the ocular findings, were excluded from the study. The University of Puerto Rico, Medical Sciences Campus Internal Review Board reviewed and approved this protocol.

Results: Six patients met the study criteria and were included in the analysis. The median age at presentation was 61 years; all the patients were female and Hispanic. All patients were positive for WNV IgG antibodies. Eighty-three percent of patients had bilateral disease—eleven eyes were affected. Eighty-one percent of eyes had a visual acuity of 20/30 or better upon presentation, 67% had chorioretinal lesions, and 50% had vitritis. Optic neuritis and retinal vasculitis were present in 33% of eyes each.

Conclusions: Our study suggests that patients with asymptomatic WNV infection may develop ocular manifestations, which are similar to those with symptomatic disease. Physicians should beware of the possibility of ophthalmic WNV without systemic manifestations and consider adding WNV to the work-up of patients with the characteristic choroidal lesions or optic neuritis.

ABSTRACT BODY:

Purpose: To examine the relationship between leakage patterns, quantitative ultra-wide field fluorescein angiography (qUWFA) parameters, diabetic retinopathy severity score (DRSS) and measures of treatment response using baseline images in the PRIME study.

Methods: The PRIME study is a prospective randomized trial. Baseline angiograms were analyzed using an automated machine learning platform to acquire qUWFA parameters including perivascular leakage index (PLI), general leakage index (GLI), microaneurysm (MA) count, and ischemic index for both panretinal and macular regions. Perivascular leakage was identified as leakage within 5 pixels of the segmented blood vessel wall. General leakage was classified exclusively as leakage which exceeded the 5 pixel distance from the segmented blood vessel wall. PLI and GLI were correlated with other qUWFA metrics and measures of treatment response including the time required for 2-step DRSS improvement. The baseline DRSS score was used to sort eyes into severe non-proliferative (NPDR) and proliferative (PDR) DR groups. Time until 2-step improvement was used to sort eyes into ≤16 weeks and >16 weeks groups. Mean LIs were compared between NPDR, PDR, ≤16 weeks and >16 weeks groups using Student's t-test.

Results: Thirty-eight eyes were included for this analysis. Panretinal PLI correlated positively with total MA count (r=0.32, p=0.04) and panretinal ischemic index (r=0.39, p=.01). Panretinal GLI positively correlated with macular MA count (r=0.40, p=0.009) and panretinal ischemic index (r=0.39, 0.01). Severe NPDR eyes had a greater macular PLI compared to PDR eyes (4.5% vs 2.8%, p=0.035), however there was no significant difference between groups for other leakage parameters. Eyes requiring >16 weeks of monthly therapy for achieving 2 step DRSS improvement had a greater baseline panretinal GLI than eyes in ≤16 weeks group (2.8% vs 1.9%, p=0.026).

Conclusions: Perivascular and general leakage patterns appeared to be uniquely linked to different angiographic and DR-related variables. The ability to quantify and discriminate between these leakage types may provide important information regarding additional DR features and should be further explored for prognostic significance.

ABSTRACT BODY:

Purpose: Convergence insufficiency is associated with a variety of symptoms, but the relationship between symptoms and quality of life has not been studied. We explored associations among clinical measures, symptoms, and quality of life before and after treatment in adults with symptomatic convergence insufficiency.

Methods: In a prospective observational study we evaluated 57 adults with symptomatic convergence insufficiency (near exodeviation ≥4Δ and at least 4Δ larger than distance, reduced near point of convergence, reduced near positive fusional vergence, and Convergence Insufficiency Symptom Survey [CISS] score ≥ 21 points). 35 participants were treated with vision therapy/exercises and 22 with base-in prism. Spearman correlation coefficients (R) and 95% confidence intervals (CI) were used to assess associations among near clinical measures (exodeviation magnitude, near point of convergence, positive fusional vergence) and patient-reported outcome measures (CISS, Diplopia Questionnaire, and the Adult Strabismus (AS)-20 quality-of-life (QOL) questionnaire [general function, reading function, interactions, and self-perception domains]) prior to treatment (baseline), and 10 weeks and 1 year after treatment initiation. To account for multiplicity, associations were interpreted as present only when the lower limit of the 95% CI indicated a moderate to strong association [R ≥ 0.4].

Results: At baseline, the only moderate to strong correlation was between the CISS and AS-20 reading function scores (R = 0.62; 95% CI: 0.43 − 0.76). For change from baseline, the only moderate to strong correlations were between change in CISS score and change in AS-20 reading function score at 1 year in the vision therapy group (R = 0.78; 95% CI: 0.57 − 0.89), and at 10 weeks (R = 0.78; 95% CI, 0.52 − 0.91) and 1 year (R = 0.85; 95% CI, 0.65 − 0.94) in the prism group.

Conclusions: In adults with symptomatic convergence insufficiency, baseline symptoms correlated with reading function QOL, and improvements in symptoms following treatment with vision therapy/exercises or prism correlated

with improvements in reading function QOL. There were no correlations between clinical measures and symptoms or QOL. Patient-reported outcome measures appear useful in the assessment and management of convergence insufficiency in adults.

ABSTRACT BODY:

Purpose: Adiponectin receptor 1 (ADIPOR1) is a regulator of lipid and glucose metabolism that possesses ceramidase activity. ADIPOR1 mutations are associated with retinitis pigmentosa. Ablation of ADIPOR1 in mice leads to photoreceptor death; however, the underlying mechanisms remain unclear. We hypothesize that (1) lack of ADIPOR1 ceramidase activity in AdipoR1$^{-/-}$ mice leads to ceramide accumulation in the retina; (2) pharmacological inhibition of ceramide generation can prevent photoreceptor death and improve retinal function.

Methods: We analyzed ceramide levels in the retina and retinal pigmented epithelium (RPE) by liquid chromatography-mass spectrometry (LC-MS). To reduce ceramide levels, two groups of AdipoR1$^{-/-}$ mice (n=6) were i.p.-injected with desipramine and L-cycloserine (DC) or saline; and examined with optical coherence tomography (OCT), electroretinography (ERG), measurements of visually evoked potential (VEP), and V1 cortex neuron responses. Then, the eyes were used for histology, TUNEL assay, and ceramide quantification by LC-MS.

Results: We found an accumulation of ceramides in the retina (up to 7.4-fold increase; p=0.011) and RPE (up to 3.1-fold increase; p=0.0008) of 4-week-old AdipoR1$^{-/-}$ mice, and confirmed its localization with ceramide antibody staining.

DC-treatment for ~4 months resulted in:

(1) Increased number of photoreceptors in the DC- vs. saline-treated AdipoR1$^{-/-}$ mice, as shown by OCT (33.8±3.9%, p<0.0001) and histology (37.3±4.8%, p<0.0001); (2) 16-28% decrease in ceramide levels (p<0.028); (3) fewer apoptotic photoreceptors (56.8±11.8%, p=0.023); (4) improved ERGs (p=0.013); (5) enhanced electrical responses of the primary visual cortex to visual stimuli (p=0.003); (6) improved V1 cortex neuron responses to drifting-grating stimuli (p<0.001).

Conclusions: Our results support the hypotheses that (1) mice with ablated ADIPOR1 have pathologic build-up of ceramides in the retina and RPE; (2) DC-treatment lowers ceramide levels, resulting in increased photoreceptor survival.

We found that DC-treatment of AdipoR1$^{-/-}$ mice improved photopic ERGs and the electrical responses of the primary visual cortex to visual stimuli, approaching near-normal levels for some parameters. These studies suggest that a similar approach with retinitis pigmentosa patients could effectively attenuate the photoreceptor degeneration resulting from elevated ceramide levels.

ABSTRACT BODY:

Purpose: To develop and test an automated method for detecting progression based upon topographical agreement of changes in the optical coherence tomography (OCT) maps and 24-2 and 10-2 visual fields (VF) in eyes with early glaucoma.

Methods: Widefield OCT (12x9mm) scans and 24-2 and 10-2 VFs were acquired from 55 eyes with early or suspected glaucoma (baseline 24-2 mean deviation >-6dB) and 25 healthy controls (HC) as part of a longitudinal, prospective study. Baseline (V1) OCT maps and VFs were compared to those from the last follow-up visit (V2), which was obtained at least 1 year later. Continuous probability change (pc-) maps were determined for both the retinal nerve fiber layer (RNFL) and retinal ganglion cell plus inner plexiform layer (GCL+) (Fig. 1) by comparing the difference of the thickness between V1 and V2 to an estimation of short-term variability for scans within 4 months. Red (p<1%) and yellow (p<5%) in Figs. 1 & 2 indicate significant change. The same approach was applied for the VFs. A custom R program [1] superimposed VF locations on RNFL and GCL+ pc-maps and determined the number of locations with both progressive structural (pS, p<10%) and functional (pF, p<5%) change (diamonds in Figs. 1&2). The criterion number of pS-pF locations for a 95% specificity was estimated based upon sampling the HC group with replacement. A reference standard based upon experts' evaluation of V1 and V2 OCT data (b-scans, and RNFL and GCL thickness and change maps) and VF tests identified 12 progressing (P) eyes.

Results: For the HC eyes, a threshold of 10 total pS-pF locations on the RNFL and GCL+ pc-maps achieved a specificity of 95% (1 HC false positive). The same threshold identified 8 eyes as 'progressors', 7 of which were true positives (sensitivity from 12 P eyes: 58%). A post-hoc analysis of the other 5 P eyes revealed that 4 of the 5 showed a very narrow progressive region on the OCT with pS-pF agreement within the same arcuate region, but no overlap (Fig. 2). The commercial GPA correctly identified only 4 of the 12 P eyes (sensitivity: 33%).

Conclusions: An automated method for detecting progression based upon topographical OCT and VF agreement showed good specificity and identified more P eyes than the commercial GPA. Eyes with narrow arcuate progression can still be missed, mainly due to the spatial resolution of the 24-2 and the limited extend of the OCT scan size. 1. Tsamis et al, TVST, 2020.

ABSTRACT BODY:

Purpose: The intraflagellar transport (IFT) complexes have a well-established role in the assembly and maintenance of primary cilia, including photoreceptor outer segments. The focus of our study was IFT20, a non-conventional subunit of the IFT-B particle that associates with the rest of IFT-B reversibly and is thought to play a role in recruiting IFT cargo from the Golgi to the cilium. We sought to explore the role of IFT20 in photoreceptor cells by analyzing the phenotype of the conditional IFT20 knockout.

Methods: A rod-specific knockout of IFT20 in mice was generated by crossing a floxed IFT20 line with the iCre75 line that expresses Cre under control of the rhodopsin promoter. While Cre expression in this line begins as early as postnatal day 7, the depletion of IFT20 protein does not complete until after photoreceptor outer segments are fully developed. This allowed us to study the function of IFT20 in outer segment maintenance independent of its role in the outer segment development.

Results: We found that the depletion of IFT20 protein from rods was followed by a complete degeneration of these cells within a period of several weeks. During this period of time, outer segment structure rapidly disintegrates followed by cell death. Yet, our analysis of outer segment resident proteins during the short window when outer segments are still present revealed only a minor mislocalization of rhodopsin and no mislocalization of peripherin-2. Interestingly, mislocalized rhodopsin was not found in the inner segment biosynthetic membranes but rather in extracellular vesicles accumulating around photoreceptor cell bodies.

Conclusions: Taken together, this data suggest that the primary function of IFT20 in photoreceptors is in ciliary maintenance rather than in post-Golgi protein transport.

ABSTRACT BODY:

Purpose: The aim of the present study is to evaluate the different clinical complications associated with vitreous substitutes, especially silicone oil (SO).

Methods: This is a retrospective, observational and single-center study of consecutive patients operated by pars plana vitrectomy (PPV) between 2015 and 2020 at the Clinical University Hospital of Valladolid due to different vitreoretinal pathologies, such as retinal detachment (RD), epiretinal membrane (ERM), macular hole (MH) or vitreous hemorrhage (VH). The characteristics of the patients and their complications were recorded in an Microsoft Excel database. The statistical analysis was performed with the SPSS program (version 21.0).

The mean (± standard deviation) or median was used to describe all continuous variables, and frequencies to explain nominal or categorical variables. Normality was analyzed using the Kolmogorov-Smirnov statistic for data greater than 50 and the Shapiro-Wilk statistic when less. The analysis of the study data was performed with the Chi-square test, establishing significance $p<0.05$.

Results: We included 669 surgeries performed on 472 eyes of 424 patients. Their mean age was 60 years (range 8-87) and their follow-up was 25.24±1.02 months. The main cause of primary surgery was retinal detachment or re-detachment in 406 cases (60.8%), followed by epiretinal membrane (14.5%), hemovitreous (12.8%) and macular hole (10.3%).

In 140 surgeries, SO was used as a tamponading agent and in the rest; air, balanced saline or gas. The median time of AS permanence was 7 months (range 1-107). Long-term complications in both groups included acute ocular hypertension in 254 eyes (28.6% vs 20%) and chronic ocular hypertension in 105 interventions (15.7%). Other undesirable events were ERM formation (29.04%), vitreoretinal proliferation (21.41%), retinal re-detachment (10.8%), cystic macular edema (25.4%), corneal decompensation (8.98%), cystic macular edema (25.4%) and posterior synechiae (SPs), all occurring with a higher frequency and statistical significance in the AS group ($p<0.01$).

Conclusions: Vitreous substitutes agents used in PPV generate complications that should be recognized early. Among them, SO is the one that causes the most severe complications and adverse events. Hence, future directions in the development of vitreous substitutes are needed.

ABSTRACT BODY:

Purpose: Mutations in CNGA1 result in autosomal recessive retinitis pigmentosa (arRP), a rare progressive degenerative disease, leading to blindness.
A detailed clinical observation of the phenotype correlated with the genotype is necessary for the future development of potential treatments.

Methods: Six patients with arRP and mutations in CNGA1 were examined at the University Eye Hospital in Tübingen. This included BCVA, visual field, photopic and scotopic pupil campimetry (CPC), dark adapted chromatic perimetry (DAC), full-field stimulus threshold test (FST) as well as imaging with funduscopy, optical coherence tomography (OCT) and fundus autofluorescence (FA). All six patients were examined at baseline and five patients at follow-up one year later.

Results: The median age of the patients was 46 years (range 38-67 years). The BCVA varied between 20/80 and 20/20 with stable findings at follow up. The kinetic perimetry showed concentric restriction of the visual field in all patients. Scotopic and photopic CPC showed loss of rod function in all patients with good cone function in the morphologically preserved central retinal area. The FST measurements showed increased thresholds for blue and red color, indicating loss of rod function, whereas dark-adapted cone thresholds were unaffected. DAC with blue and red stimuli showed a small central island with preserved rod function in three patients. OCT and widefield FA underlined peripheral degeneration and preserved central retina. OCT findings showed perifoveal loss of outer retinal cells. One patient had macular edema.

Conclusions: CNGA1-linked arRP presents with late-onset, slowly progressive rod-cone degeneration with pronounced loss of rods but well-preserved cone-function into late adulthood. Clinical examination showed stable results within an expected range of variation during a one-year follow up period. Carefully chosen multimodal diagnostics can detect residual rod function in small, morphologically preserved retinal areas of CNGA1-RP patients.

ABSTRACT BODY:

Purpose: Early vascular changes in response to tissue inflammation includes the selective rolling and crawling of circulating immune cells along the venular endothelium. Recently, we have imaged single immune cells in vivo using label-free adaptive optics scanning light ophthalmoscopy (AOSLO) with phase contrast. Here, we image and measure the rolling/crawling speeds of immune cells that precede cell transmigration into the retina.

Methods: A custom AOSLO with phase contrast capabilities (796 nm, 200-500 μW, 800 μm pinhole, 30 airy disc diameter offset) was used. Image locations were within 10° of the optic disc, focusing on arterioles and venules adjacent to the ganglion cell layer. C57BL/6J male mice were anesthetized using ketamine (100 mg/kg)-xylazine (10 mg/kg) and isoflurane (1% v/v). Baseline videos were captured before mice were injected intravitreally with 0.5 ng of lipopolysaccharide in 1 μL PBS. The same mice were reimaged within five epochs: 0.5, 4, 6, 24 and 72 hours post injection. Rolling cell speed was quantified at 6 hours (n=4 venules in 3 mice, 53 cells tracked) by manually tracking cell position over time using ImageJ Manual Tracking plugin (Fig 1).

Results: By morphology, we observed two types of adherent cells; those with a circular appearance rolling along the endothelium and a more adherent class of cells showing tank-treading behaviors (Fig 2). Rolling and crawling immune cells were found in venules; arterioles showed few endothelial interactions. Rolling and crawling was predominantly observed at the 4-6 hour time epoch; few rolling cells were observed in 24 and 72 hours epochs. Average rolling speed was 10.9±9.9 μm/s. Speeds were variable across the same cells (0-103.9 μm/s) indicating patches of greater adhesion. Two cells were nearly stationary (0.2±0.9μm/s), indicating firmly adherent cells that may later extravasate. We observed one cell actively moving against the direction of blood flow in a venule shown as negative velocity -0.3±0.5 μm/s (Fig.2).

Conclusions: Here we reveal some of the earliest features of inflammation at the single cell level in vivo. Phase contrast AOSLO enables label-free noninvasive measurements, allowing an unperturbed assessment of retinal inflammatory response. This work provides a foundation for detailed study of immune cell adhesion in vivo, a key target for new drugs that seek to modulate such behavior.

ABSTRACT BODY:

Purpose: While intravitreal injection of viral vectors is the mainstay for gene delivery to retinal ganglion cells (RGCs), the delivery technique results in non-specific targeting of other retinal cells including amacrine cells. Here, we developed a novel strategy to more specifically target RGCs for gene delivery using optic nerve injection of viral vector in rodents.

Methods: Five 8-9 month old Brown Norway rats underwent unilateral delivery of 2.5mL of AAV-PhP-eb expressing GFP (1×10^{13} vg/mL), either intravitreally (n=3) or directly into the optic nerve via a retro-orbital approach (n=2). Animals were euthanized 21 days post-injection. Retinal whole mounts were fixed and underwent immunofluorescent labeling with anti-GFP antibodies, Lycopersicon esculentum to label vasculature and glia, and DAPI, followed by confocal microscopy. Contralateral eyes served as negative controls. Random sampling of the retinas by a blinded observer were analyzed and quantified for total DAPI-labeled and GFP-labeled nuclei in the ganglion cell layer (GCL) and the inner nuclear layer (INL). Student's t-test was used for statistical analysis.

Results: Direct optic nerve injection of viral vector resulted in GFP expression specifically in the retina, without expression in other cells within the optic nerve (including astrocytes and blood vessels) or the contralateral eye. GFP expression rate within the retina was highest in the GCL after optic nerve injection of viral vector (26.0 ± 21.9%) and was statistically comparable to post-intravitreal injection GFP expression rates within the GCL (45.3 ± 5.6%; p=0.28). However, GFP expression in the INL appeared much less after optic nerve injection of viral vector (0.012 ± 0.008%) compared to intravitreal injection GFP expression rates within the INL (0.11 ± 0.042%; p = 0.07). Among all GFP-expressing cells within the retina, optic nerve injection of viral vector appeared to more specifically target GCL neurons relative to intravitreal injection (86.9 ± 5.6% vs. 72.7 ± 6.0%; p = 0.09). Neurons within the INL following optic nerve injection appeared to be displaced RGCs. Further studies are underway with larger animal groups.

Conclusions: Optic nerve injection of viral vector AAV-PhP-eb for gene delivery to the retina specifically targets the retina, with comparable expression efficiency to intravitreal injection and a potential advantage of higher specificity for RGCs.

ABSTRACT BODY:

Purpose: To assess the single surgery anatomic success (SSAS) rate after scleral buckling (SB) procedure for primary rhegmatogenous retinal detachment (RRD), and to identify clinical factors associated with increased risk of surgical failure. Surgical failure was defined as any additional intervention required for retinal re-attachment. Interventions included pneumatic retinopexy, SB revision, or pars plana vitrectomy (PPV) at any time after SB placement.

Methods: Single-center, retrospective cohort study. Demographic, clinical, and surgical characteristics were extracted from patient charts and compared between eyes with SSAS and eyes experiencing surgical failure. A multivariable logistic regression model was completed to assess the effect of demographic, clinical, or surgical characteristics on SSAS.

Results: A total of 499 patients with primary RRD who underwent primary SB were included, with a SSAS of 86% (n=430/499). On multivariate analysis, eyes with surgical failure after primary SB placement were more likely to be male (adjusted odds ratio [aOR]: 2.98, 95% CI: 1.58-5.62, p = 0.0007), have a macula-off status on preoperative examination (adjusted OR: 2.15, 95% CI: 1.10-4.20, p = 0.03), and have presence of preoperative PVR (adjusted OR: 4.26, 95% CI: 1.10, 16.5, p = 0.04).

Conclusions: SSAS after primary SB for primary RRD was 86%. Male sex, macula-off status at presentation, and presence of PVR were factors with increased odds of surgical failure.

ABSTRACT BODY:

Purpose: Williams-Beuren Syndrome (WBS) is a complex genetic disorder caused by a microdeletion on chromosome 7q11.23. This work aims to provide a detailed description of foveal features in WBS through quantitative metrics and qualitative classification.

Methods: Individuals with WBS who were examined at the National Institutes of Health as part of the Impact of Elastin Mediated Vascular Stiffness on End Organs study and had Optical Coherence Tomography (OCT) were included in this analysis. The inner limiting membrane and retinal pigment epithelium were manually segmented on foveal OCT scans and processed for pit diameter (PD), foveal slope (FS) and central foveal thickness (CFT). Scans were qualitatively classified as broad if they had a widened area of extrusion of the inner retinal layers or widened PD. Mann-Whitney, Fisher's Exact test and Spearman correlations were used for analyses.

Results: Forty-four WBS patients were included in this study; 21 males and 23 females, 77.3% identifying as non-Hispanic White, with a median age of 22 years (range 5-60 years). Mean best-corrected visual acuity (BCVA) was 20/30 (range 20/20-20/100) OU. Imaging of the right eye of one patient and the left eye of two patients was excluded for poor quality. Mean PD was 1832 μm (range 1195-2345 μm) OD and 1836 μm (range 1278-2304 μm) OS, strongly correlated between eyes ($R=0.84$, $p<0.001$). CFT had a moderate inter-eye correlation ($R=0.56$, $p<0.001$), mean 186 μm (range 157-250 μm) OD and 187 μm (range 166-234 μm) OS, which is thinner than reported healthy population means. FS was also correlated between eyes (Nasal $R=0.78$, $p<0.001$; Temporal $R=0.62$, $p<0.001$). Subgroup analyses were performed on those qualitatively classified as broad fovea (N=36, 81.8%) and normal; there was no significant difference in BCVA, refractive error, age, or sex between groups. PD was significantly wider ($p\leq0.003$) and CFT was thinner ($p=0.002$) in the broad fovea group, while FS did not differ between groups. Thinner CFT was not correlated with BCVA.

Conclusions: This study provides foveal metrics in a cohort of WBS patients, showing a thinned CFT and quantitatively widened PD in eyes with a qualitatively broad fovea, despite a largely White racial identity and balanced sex representation in the cohort. We postulate this foveal morphology is associated with the WBS microdeletion region, supporting the need for future studies of WBS to help understand the molecular basis of foveal development.

TITLE: Preliminary Antibiotic Resistance Data Among Ocular Bacterial Pathogens in the ARMOR 2021 Study

SESSION TITLE: Anti inflammatory agents, antibiotics and antivirals

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P.A. Asbell, Ophthalmology, The University of Tennessee Health Science Center, Memphis, Tennessee, UNITED STATES|C.M. Sanfilippo, H. DeCory, Medical Affairs, Bausch and Lomb Rochester, Rochester, New York, UNITED STATES|

Commercial Relationships Disclosure: Christine Sanfilippo: Commercial Relationship(s);Code E (Employment):Bausch Health US, LLC | Heleen DeCory: Commercial Relationship(s);Code E (Employment):Bausch Health US, LLC | Penny Asbell: Commercial Relationship(s);Code C (Consultant/Contractor):Glia, Senju, Blephex;Code F (Financial Support):Regeneron, Mitotech, Sylentis, Tear Science, MC2, RPB, NIH/NEI

ABSTRACT BODY:

Purpose: Antibiotic resistance among pathogenic bacteria can hinder treatment of infections. Data from antibiotic resistance surveillance studies can provide clinicians with information to guide empiric therapy. The annual Antibiotic Resistance Monitoring in Ocular micRoorganisms (ARMOR) study is the only ongoing nationwide surveillance initiative focused exclusively on antibiotic resistance among common ocular pathogens. Here, we report on interim findings for bacterial isolates collected in 2021.

Methods: As in prior years of the ARMOR study, participating clinical sites across the US submitted isolates of Staphylococcus aureus, coagulase-negative staphylococci (CoNS), Streptococcus pneumoniae, Pseudomonas aeruginosa, and Haemophilus influenzae cultured from ocular infections to a central laboratory for species confirmation and in vitro antibiotic susceptibility testing. Minimum inhibitory concentrations (MICs) for up to 16 antibiotics (10 drug classes) were determined using broth microdilution methodology and interpreted as per Clinical and Laboratory Standards Institute (CSLI) guidelines and breakpoints.

Results: A total of 446 isolates were included in this interim analysis. Among staphylococci (167 S. aureus/178 CoNS), in vitro resistance was 53%/60% to azithromycin, 37%/37% to oxacillin/methicillin, and 31%/20% to ciprofloxacin; as well, 29% of CoNS exhibited trimethoprim resistance. Multidrug resistance (MDR; ≥3 antibiotic classes) was found among 32% of S. aureus (32%) and 40% of CoNS isolates (40%), with the rate of MDR more than doubled among methicillin-resistant (MR) isolates (81% and 84% among MR S. aureus [MRSA] and MRCoNS, respectively). All 84 P. aeruginosa isolates were resistant to polymyxin B, with <10% resistance to other drug classes. Among the 7 S. pneumoniae isolates, resistance to azithromycin and oral penicillin (both 43%) as well as tetracycline (29%) was detected. The 10 H. influenzae isolates exhibited no resistance to tested drugs.

Conclusions: High rates of in vitro antibiotic resistance were observed among ocular staphylococci collected in 2021, with MR isolates demonstrating considerable MDR. Overall, these resistance profiles should be considered in combination with known ocular pharmacokinetic attributes of antibiotics. These preliminary findings appear consistent with 2020 ARMOR data.

ABSTRACT BODY:

Purpose: To study the types of uveitis examined in a hospital serving indigent populations in need of low-cost care and to assess prescribing patterns required to limit treatment cost.

Methods: A retrospective chart review examined the electronic medical records of all patients with uveitis-related ICD-9 codes from September 1, 2011 through September 30, 2014 at Drexel Eye Physicians. Data collected included sex, race, anatomic location of the uveitis, systemic disease associations, treatment modalities and insurance carrier. Statistical analysis was performed using χ^2 or Fischer exact tests.

Results: 270 patients (366 eyes) were included for analysis, 67% of patients identified as African American. Most eyes (95.3%, N=349) were treated with topical corticosteroid drops, and only 6 (1.6%) received an intravitreal dexamethasone implant. Nearly 80% depended to some extent on Medicare or Medicaid Assistance for treatment coverage and patients had a median copay of $4 (range $0-80) per eye drop bottle.

Conclusions: Oral prednisone and intravitreal triamcinolone injections were more financially feasible treatments as bridge therapy until the start of antimetabolites as first line agents. Biologic agents may have a higher up-front cost and patients were only switched to that class if it was required for treatment of an associated systemic disease or if the patient was intolerant of antimetabolite side effects.

ABSTRACT BODY:

Purpose: An estimated 55 million people live with dementia worldwide mainly due to Alzheimer's disease and vascular dementias (e.g. cerebral small vessel disease). There is increasing interest in identifying novel tools for early detection of cognitive impairment. We investigated optical coherence tomography angiography (OCTA) based metrics of retinal capillary density and perfusion as a biomarker of cognitive function in asymptomatic, community-dwelling African Americans, who are at high risk of vascular dementia.

Methods: African American participants over the age of 40 without any history of cognitive impairment were recruited. In-clinic neurocognitive assessment was conducted using NIH Toolbox Cognitive Function Battery tests, including Fluid Cognition Composite (episodic memory, executive function, and information processing abilities), Oral Symbol Digit (simple processing speed), and Crystallized Cognition Composite (past learning) tests. 3x3 mm swept source OCTA images centered on the fovea were captured from both eyes. Quantitative measures of retinal vascular density (Vessel Area Density (VAD)) and perfusion (Vessel Area Flux (VAF)), were computed for both eyes and averaged. The relationship between the OCTA measures and cognitive function tests was evaluated using multiple linear regression analysis controlling for age, gender, and level of education.

Results: Ninety six participants were recruited (mean age, 66.4 ± 9.6 years; 31 male, 32.3%, Table 1). VAD and VAF were positively correlated with Fluid Cognition Composite ($p = 0.02$ and 0.005, respectively) and Oral Symbol Digit test scores ($p = 0.0007$ and 0.005, respectively; Fig 1) in the multivariable analyses. OCTA measures were not significantly correlated with Crystallized Cognition Composite score. Results were similar if analyses were limited to data from one eye per person.

Conclusions: OCTA-derived measures of retinal perfusion were correlated with cognitive measures of new learning, information processing, and executive function, but not with measures of past learning. Our results suggest that OCTA might be a useful additional tool for screening and early diagnosis of cognitive impairment.

ABSTRACT BODY:

Purpose: Traumatic brain injury (TBI) research is undergoing an overhaul via the creation of “common data elements” with the goal of improving comparability of work between laboratories. There is also a growing push to understand differences in outcomes between injury models. For example, what are benefits to precise, focal injury models like controlled cortical impact vs diffuse models like weight-drop? While a blunt head injury results in bilateral damage to the optic nerve, is visual system injury also present after diffuse blast injury to the left cranium? Characterization of visual/optic system disruption after a diffuse blast injury of this type has not been characterized in comparison to other TBI models, and little is known about visual system injury outside the optic tract after blast TBI. Our labs hypothesized that there would be differences in functional and histologic outcomes after blast vs blunt head trauma-induced optic nerve injury.

Methods: Male C57BL6/J mice underwent a mild closed-head weight drop (blunt) TBI, one or two mild closed-head blast injuries, or sham injury. Within 7 days, mice underwent behavioral testing for the optokinetic response (OKR). Seven days after injury, eyes were enucleated and flash frozen for western blotting against retinal ganglion cell (RBPMS) and apoptosis (Caspase 3) markers. Mice were then perfused with 4% paraformaldehyde and brains taken for immunohistochemical analysis for neurodegeneration (FluoroJade-B) with planned regions of interest including: optic tract, lateral geniculate nucleus, superior colliculi, and accessory optic system nuclei.

Results: Blunt injury reproducibly resulted in bilateral injury with a significantly blunted OKR, reduced RBPMS, and increased degeneration and gliosis in all regions. Although blast injury also resulted in OKR deficits, we found no reduction in RBPMS. More interestingly, degeneration was limited to the contralateral optic tract and superior colliculi with no degeneration in other visual regions.

Conclusions: Injury modality influences behavioral and histological outcomes to the visual system with a blunt injury producing more severe damage in retina, optic tract, and optic nerve projection targets. Additionally, we appear to be the first to note unilateral injury after blast TBI.

ABSTRACT BODY:

Purpose: To compare the rate of progression (RoP) of visual field (VF) damage between the two arms of the HORIZON prospective randomized multicentre trial

Methods: A total of 556 participants (one eye per participant) were randomised 1:2 to receive cataract surgery alone (CS, n = 187) or in combination with a Hydrus Microstent (Ivantis, Inc. Irvine, CA; CS-HMS, n = 369). Patients followed for 5 years had planned VF tests at baseline and 6, 12, 24, 36, 48 and 60 months after surgery using a Humphrey Field Analyzer (HFA, Zeiss Meditec, Dublin, CA, USA), 24-2 pattern, SITA-Standard strategy. Additional tests were performed if a worsening in mean deviation of 2.5 dB or more was observed. A total of 3701 VF from 554 (99.6%) patients were available for analysis. Of these, 121 VFs were excluded due to poor reliability (false positive rate > 15%). To eliminate any effects of cataract on VF, pre-surgery baseline tests were excluded from the analysis (561 reliable VFs). We analysed eyes with at least 3 VFs available over at least one year (165 CS and 352 CS-HMS, 2966 VFs). A secondary more inclusive analysis was conducted on all eyes with at least 2 VFs (177 CS and 361 CS-HMS, 3008 VFs). The difference in RoP between the two groups was estimated using a hierarchical mixed effect Bayesian model, modelling point-wise sensitivity values grouped by location, Garway-Heath clusters, eye (all random effects) and arm of the trial (fixed effect). A statistically significant difference in RoP was tested via an interaction term between the effect of the arm assignment and the time from surgery. Significance was reported using a Bayesian p-value. Estimates of the effect are reported, along with 95% Bayesian Credible Intervals.

Results: There was no significant difference in the estimated baseline (intercept of the model) between the two arms, either with the main or secondary analysis. The RoP was -0.26 [-0.36, -0.16] dB/year (47%) slower in the CS-HMS arm (p = 0.0138) in the main analysis and -0.23 [-0.40, -0.05] dB/year (43%, p = 0.0284) in the secondary analysis. Numerical results are reported in Table 1 and Figure 1.

Conclusions: CS-HMS significantly reduced the speed of VF loss compared to CS alone in glaucoma patients by a clinically significant amount.

ABSTRACT BODY:

Purpose: To examine the presence of micrometastases (MM) in the liver and other organs in patients diagnosed with primary uveal melanoma who underwent autopsy without previously known metastatic disease. The study was a retrospective, observational study.

Methods: Data from a total of 4282 patients who had been diagnosed with primary uveal melanoma at St. Erik Eye Hospital between 1960 and 2020 was cross-referenced against autopsy and pathology registers. Formalin-fixed paraffin-embedded (FFPE) tissue was collected from patients who had undergone autopsy without known macrometastases. MM was defined as clusters of tumor cells that had not been detected in radiological examinations and had a diameter of ≤ 5 mm. The density of MM per mm^2 was calculated for each organ with digital image analysis (DIA). FFPE tissue was then stained with BAP1, MIB1, CD3, CD20 and CD56.

Results: Eleven patients who had no metastases during routine radiological screening were identified and included. Out of these, three (27 %) had been diagnosed with metastatic disease while hospitalized shortly before death, whereas no macrometastases had been detected in radiological screening of the remaining eight (73 %). In eight of 11 patients (73 %), MM were detected. In turn, four of eight patients with MM (50 %) did not have macrometastases (>5 mm). MM were most common in the liver and lung and their highest density was in the liver. There were no differences in the presence of MM (Fisher's exact p=0.24) or in the density of MM in organs from patients with and without macrometastases (p>0.16). MM showed a low proliferative activity with MIB1, ranging from 0 to 3 % positivity, indicating possible dormancy. There was a 100 % proclivity for CD3 infiltration in all MM, whilst 79 % of MM in the lung and liver was positive for CD20 and 70 % were positive for CD56.

Conclusions: MM could be identified in most patients with primary uveal melanoma, regardless of concurrent macrometastases. This seems to confirm that uveal melanoma can seed MM early.

ABSTRACT BODY:

Purpose: To compare the accuracy of deep learning (DL) in detecting glaucoma using optic nerve head (ONH) fundus photos versus optical coherence tomography (OCT) across different patient populations, disease severity, and axial lengths.

Methods: Longitudinal imaging and 24-2 visual field (VF) testing was collected on a Diagnostic Innovations in Glaucoma Study (DIGS) and African Descent and Glaucoma Study (ADAGES) cohort of 546 glaucoma (935 eyes) and 346 healthy (626 eyes) patients. The dataset included 20,828 ONH fundus photos and 25,751 unsegmented Spectralis circle scans. Eyes in the glaucoma group had repeatable glaucomatous VF damage or glaucomatous ONH damage based on clinical ONH examination or expert review of photos. Healthy eyes were required to have normal appearing ONHs and VF results. Participants were randomly divided into independent training (85%), validation (5%), and test (10%) sets. Accuracy was evaluated using area under the receiver operating characteristic curve (AUC) and evaluated as a function of participant ancestry (African vs. European), glaucoma severity (24-2 MD > -4.0 dB vs. 24-2 MD <= -4.0 dB), and axial length (AL <= 25 mm vs. AL > 25 mm).

Results: Fundus DL models achieved an AUC of 0.91 (95% CI: 0.89 – 0.92), significantly higher ($p=1.3x10^{-5}$) than OCT DL models, AUC = 0.86 (95% CI: 0.84 – 0.87). Fundus DL accuracy was significantly higher ($p<1x10^{-6}$) in

African (AUC = 0.97) vs. European (AUC = 0.85) descent participants, significantly higher (p $p<1x10^{-6}$) in eyes with 24-2 MD <= -4.0 dB (AUC = 0.99) vs. 24-2 MD > -4.0 dB (AUC = 0.88), and significantly higher (p=0.03) in eyes with AL > 25 mm (AUC = 0.94) vs. AL <= 25 mm (AUC = 0.90). ONH OCT DL accuracy was significantly higher (p=0.001) in European (AUC = 0.87) vs. African (AUC = 0.81) descent participants, significantly higher ($p<1x10^{-6}$) in eyes with 24-2 MD <= -4.0 dB (AUC = 0.95) vs. 24-2 MD > -4.0 dB (AUC = 0.81), and comparable (p=0.82) in eyes with AL > 25 mm (AUC = 0.84) vs. AL <= 25 mm (AUC = 0.85).

Conclusions: Photo-based DL glaucoma detection significantly outperformed OCT-based detection. In both cases, ancestry and disease severity had a significant impact on DL model accuracy. These findings underscore the importance of understanding how patient characteristics, disease severity, and reference standard definitions influence the performance of DL models in glaucoma.

ABSTRACT BODY:

Purpose: When a cornea is injured, the release of ATP from damaged cells activates the ionotrophic purinergic receptor P2X7, which localizes to the wound edge within two hours of injury. This correlates with the presence of prominent calcium signaling events that have a high probability of communication between clusters of adjacent cells. Our goal is to determine if calcium signaling differs between the corneal epithelium and the corneal-limbal interface, and analyze whether calcium signaling correlates with cellular motility after injury.

Methods: A 3-D printed holder was used to stabilize the intact globe for imaging cell-cell communication and motility after injury. Globes were incubated in Fluo-4AM and CellMask DeepRed, and imaging performed over time using the Zeiss 880 Confocal Microscope. Images were collected after injury on the corneal epithelium and corneal-limbal regions of male C57Bl6 mice. Image J and MATLAB were used for analysis of clustering between cells, the probability of communication between adjacent cells, and to identify the presence and abundance of conductor cells

Results: Calcium signaling was detected at both the central corneal epithelium and at the corneal-limbal interface. Mobilization was detected between layers of basal and wing cells in the central cornea and was absent in apical cells. In the corneal-limbal region, we again did not detect communication in the apical cells and detected a strong correlation between sensory nerves and basal cells. Only the basal cells migrated into the wound bed to close the wound. Using a unique machine learning approach we identified a subpopulation of cells that signal at a significantly greater frequency and duration than others. We hypothesize that the presence of this functionally distinct cellular population is decreased with age.

Conclusions: Injury induces P2X7-driven calcium signaling events in both the corneal and the corneal-limbal regions. The calcium signaling events propagate between different layers of epithelial cells in both central and peripheral corneal regions, and between epithelial cells and nerves in peripheral regions. High-signaling conductor cells were found throughout the cornea after injury, with the greatest number of conductor cells found adjacent to the wound. These results demonstrate that cell-cell communication driven by a functional subpopulation of conductor cells occurs throughout the corneal region.

ABSTRACT BODY:

Purpose: Cataract surgery in people with dementia (PWD) has been evaluated in the context of claims-based retrospective studies. However, due to limitations of these studies, detailed clinical and surgical information is lacking for this population. This retrospective cohort study characterizes pre-, intra-, and post-operative information from PWD in a cataract surgery outcomes database.

Methods: Demographics, medical and ocular history, surgical characteristics, and postoperative measures were analyzed for differences between PWD and non-PWD cohorts. Patient-level data were analyzed with Fisher's Exact Test, and eye-level data were analyzed with logistic regression using generalized estimating equations to account for correlation of eyes from the same individual.

Results: 507 eyes from 296 PWD were identified using appropriate ICD codes and cross referenced to a cataract surgery outcomes database containing 12,949 eyes from 7,853 patients who underwent cataract phacoemulsification at a single center between January 2014 and October 2019. PWD were older by almost 5 years (73.4 (SD=11.5) vs. 68.5 (SD=11.1), $p<0.001$) and all subsequent analyses were adjusted for age. PWD had shorter duration cataract surgeries (18.2 (SD=11.0) min. vs. 20.4 (SD=14.8) min., $p=0.010$), were more likely to have mature cataract (3.9% vs. 2.4%, $p=0.013$), and were more likely to have complex surgeries (capsular staining, mechanical pupillary expansion, CTR) (19.9% vs. 15.6%, $p=0.028$). The rate of general anesthesia was higher in PWD (1.6% vs. 0.7%, $p=0.003$). There were no differences in complication rates between PWD and non-PWD cohorts. Both preoperative best corrected LogMAR visual acuity (BCVA) (0.454 (SD=0.586) vs. 0.378 (SD=0.519), $p<0.001$) and postoperative BCVA (0.153 (SD=0.387) vs. 0.096 (SD=0.305) $p<0.001$) were worse in PWD. BCVA significantly improved in both groups ($p<0.001$), however, the average magnitude of improvement in BCVA was better in PWD (-0.308 (SD=0.439), vs. -0.286 (SD=0.423), $p=0.030$).

Conclusions: In this single center analysis, PWD present for cataract surgery at a later age, and were more likely to have mature cataracts, complex surgery, and general anesthesia, but did not have higher rates of complication, and showed significant improvement in BCVA following surgery. These findings should be encouraging to PWD undergoing counseling for cataract surgery, and for the potential for improved function in PWD.

ABSTRACT BODY:

Purpose: To explore associations between sensory impairment (vision and/or hearing) and Coronavirus disease 2019 (COVID-19) in the adult 2020 California Health Interview Survey (CHIS) population.

Methods: A cross-sectional study was conducted using the 2020 CHIS, the nation's largest state health survey with a sample representative of the population of California. The exposure of interest was having sensory impairment, defined as answering "Yes" to the question, "Are you blind or deaf, or do you have a severe vision or hearing problem?" The outcome of interest was whether a health professional suspected the respondent had COVID-19, assessed among those adults who had or thought they had COVID-19 and contacted a health professional. Logistic regression models were constructed to determine the odds of suspected COVID-19 by sensory impairment status, controlling for the following covariates: age, sex, race/ethnicity, self-reported general health status, current smoking habits, overweight/obese body mass index, and current health insurance status. All analyses were weighted according to the CHIS sampling design.

Results: A total of 21,949 sampled participants were included, representing a weighted estimate of 29,684,882 individuals. The weighted prevalence of sensory impairment was 5.9% (95% confidence interval [CI] 5.4-6.4%). Approximately 10.9% (95% CI: 10.3-11.6%) of all participants had or thought they had COVID-19, 4.9% (95% CI: 4.5-5.3%) contacted a health professional about COVID-19 concerns, and 1.7% (95% CI: 1.4-2.0%) were suspected of having COVID-19 by a health professional. Regression analyses were performed in a subgroup of 988 participants representing 1,431,690 individuals who had or thought they had COVID-19 and contacted a health professional. Those with sensory impairment had 2.12 times the unadjusted odds of suspected COVID-19 compared to those without sensory impairment (odds ratio [OR]: 2.12, 95% CI: 0.98-4.63). Those with sensory impairment had 2.51 times the adjusted odds of suspected COVID-19 compared to those without sensory impairment (adjusted OR: 2.51, 95% CI: 1.03-6.10).

Conclusions: In the 2020 CHIS adult population, individuals with vision and/or hearing impairment had greater odds of having COVID-19 suspected by a health professional. Additional studies are necessary to triangulate these findings and further explore this possible increased risk for COVID-19 in this vulnerable population.

ABSTRACT BODY:

Purpose: To identify income levels and demographics among patients admitted to the hospital with a primary diagnosis of an eye disease and severe illness during hospitalization.

Methods: Inpatients with a principal diagnosis of an eye disease were identified from the National Inpatient Sample (NIS), a nationally representative de-identified database of US hospitalizations for years 2014, 2016, and 2018. The healthcare cost and utilization project (HCUP) uses MDCs (Major Diagnostic Categories) to provide insight into what conditions are being treated in hospitals. Only patients with a principal diagnosis (MDC) of Diseases and Disorders of the Eye during admission were included. Cases with the highest severity of illness were identified based discharges with a score of 3 or 4 on the all patient refined diagnostic related group (APR-DRG) severity of illness scale (4 indicating extreme severity of illness). Age, insurance type and status (Medicare, Medicaid, private insurance, or uninsured), median income of patient zip-code, sex, and geography of patient residence were recorded. Descriptive statistics were analyzed among these patients.

Results: 24,829 inpatients with a principal diagnosis of eye disorder or disease and highest severity of illness were identified during the three-year period. 51.8% were male and most patients resided in large central metropolitan areas. Medicare insurance (50.1%) was the most prominent payer, and the average age of adult patients was 60.7. Most patients resided in large central metropolitan areas. Patients from low-income codes comprised a minority of patients with highest severity of illness (30%) and represented a decreasing percentage of these patients over time.

Conclusions: Between 2014-2018, an increasing number of patients were hospitalized with a primary diagnosis of an eye condition and categorized with highest severity of illness during their hospital stay. Patients from low-income zip codes comprised a minority of these patients with decreasing prevalence over time. This study shows that low-income status may not be associated with increased severity of illness during hospitalization for eye diseases. Further studies involving specific eye conditions and complications are necessary to explore this conclusion.

ABSTRACT BODY:

Purpose: Caveolin (CAV) 1 and 2 are integral membrane proteins that constitute the major components of small membrane pouches termed caveolae. Despite the recognized pleiotropic functions in diverse tissues, their roles in the ocular surface compartments are not fully understood. In the cornea, CAV1 expression was previously found to increase with aging and was negatively associated with wound healing. However, the exact molecular roles of CAV1 and CAV2 in corneal epithelium remain to be elucidated. In the current study, we investigated the contribution of CAV1 and CAV2 to the maintenance of the corneal epithelial phenotype.

Methods: Human donor corneas were obtained from the Saving Sight eye bank, Kansas City, MO and CorneaGen, Seattle, WA. Immunostaining was performed to determine the distribution of CAV1 and CAV2 expression in the cornea. Limbal epithelial cell cultures were transfected with CAV1- and CAV2-targeting siRNAs designated as CAV1 KD #1, CAV1 KD #2, CAV2 KD #1 and CAV2 KD #2. Western blotting, colony-forming assays and RNA-seq were performed using CAV1 and CAV2 knockdown cells and their controls.

Results: Immunohistochemical analyses revealed high CAV1 and CAV2 expression by the transit-amplifying cells (TACs) located in the basal epithelial layer of the limbus and to a lesser degree of the central cornea. siRNA-induced CAV1 and CAV2 KD in cultured limbal TACs resulted in significant reduction of their self-renewal potential as evidenced by attenuated

colony-forming efficiency (66.6 +/- 16.8% decrease by CAV1 KD #1 and 36.8 +/- 21.4% decrease by CAV1 KD #2; 72.4 +/- 13.2% decrease by CAV2 KD #1 and 34.8 +/-14.7% decrease by CAV2 KD #2; all compared to controls, Ps = 0.0002, 0.0118, <0.0001 and 0.0024, respectively). RNA-seq analyses showed that loss of CAV1 and CAV2 led to significant downregulation of genes involved in corneal epithelial formation (e.g., IVL, MUC21, and KRT78) and induction of genes involved in stromal development (e.g., FBN1 and SMPD1).

Conclusions: Our study reveals novel functional roles of CAV1 and CAV2 expressed by TACs in the human cornea. Specifically, CAV1 and CAV2 are essential for TAC self-renewal and the maintenance of the corneal epithelial phenotype.

ABSTRACT BODY:

Purpose: Tear exchange beneath rigid contact lenses helps to supply the cornea with the oxygen required for normal corneal metabolism. Studies of short-term wear of scleral lenses (SLs) in healthy volunteers have suggested that minimal tear exchange occurs during SL wear. The purpose of the present study was to document tear exchange in established SL wearers.

Methods: Established SL wearers (≥ 6 months of wear) were recruited for this study during routine follow-up evaluations. All participants had worn their SLs for at least 2 hours prior to their study visits. Demographic data and landing zone (LZ) design for each lens was recorded. Sodium fluorescein (NaFl) was instilled over the lens in each eye. Presence or absence of NaFl in the post-lens fluid reservoir (FR) was recorded 10 seconds, 1 minute, 2.5 minutes, and 5 minutes after instillation. Differences between NaFl uptake into the FR between different lens designs and diameters were compared using Chi-squared tests.

Results: 30 established SL patients (53 eyes) with a were recruited (mean age of 46 ± 14.6 years (range 24-76)). Mean duration of lens wear prior to study visit was 4.8 ± 2.1 hours (range: 2.1-10 hours). Twenty-seven lenses (50%) had quadrant-specific LZ, 18 (34%) had toric LZ, and 8 had spherical LZ. Overall, NaFl was observed in the FR in 9 eyes (17%) at 10 seconds, 14 eyes (26.4%) at 1 minute, 25 eyes (47.2%) at 2.5 minutes, and 33 eyes (62.3%) at 5 minutes. With quadrant-specific LZ (n=25), NaFl was observed in the FR in 4 eyes (14.8%) at 10 seconds, 5 eyes (18.5%) at 1 minute, 11 eyes (40.7%) at 2.5 minutes, and 14 eyes (51.9%) at 5 minutes. With toric LZ (n=18), NaFl was observed in the FR in 3 eyes (16.7%) at 10 seconds, 7 eyes (38.9%) at 1 minute, 12 eyes (66.7%) at 2.5 minutes, and 15 eyes (83.3%) at 5 minutes. With spherical LZ (n=8), NaFl was observed in the FR in 2 eyes (25%) at 10 seconds, 1 minute, and 2.5 minutes and in 4 eyes (50%) at 5 minutes. No significant differences were noted between any LZ design at any time point (p=0.8, 10 seconds; p=0.3, 1 minute; p=0.08, 2.5 minutes; p= 0.09, 5 minutes).

Conclusions: Tear exchange occurs beneath SLs in a majority of established wearers. Neither lens diameter nor LZ design were associated with an increased likelihood of tear exchange in this sample.

ABSTRACT BODY:

Purpose: Alpha-hemolytic streptococci, especially viridans group streptococci (VGS), have been increasingly associated with endophthalmitis. The prevalence and diversity of toxins secreted by alpha-hemolytic streptococci are largely uncharacterized. The purpose of this study was to identify and characterize the toxicological profiles of recent alpha-hemolytic streptococci recovered from endophthalmitis.

Methods: Twenty ocular streptococcal isolates recovered from endophthalmitis between January 10, 2019 and October 29, 2021 were included in this study. PCR and DNA sequencing were conducted to confirm genotype identification and screen for 3 toxins: autolysin, hyaluronidase, and pneumolysin. Isolates' genotypes were compared to phenotypes generated using Vitek2 and/or API kits. E tests were used to confirm antibiotic susceptibility profiles for cefuroxime, vancomycin, levofloxacin, benzylpenicillin, and moxifloxacin.

Results: Nineteen (95%) isolates were identified as members of the alpha-hemolytic group. Thirteen (68.4%) isolates of this group included members of the VGS group. S. mitis/oralis (n=8, 57.1%) was the most common isolate among VGS species. Other members included S. sanguinis (n=3), and 1 each of S. mutans, S. pseudopneumoniae, and S. thermophilus. S. pneumoniae (n=5) was the most common isolate among non-VGS group isolates. Streptococcus dysgalactiae was the sole non-alpha-hemolytic strain. Phenotype-genotype identification agreement was present among 15 (75%) of the 20 isolates.

At least one toxin was found among 9 (45%) isolates, with 5 (55.5%) identified as members of VGS. Hyaluronidase was identified in 5 (25%) samples, pneumolysin in 4 (20%) samples, and autolysin in 2 (10%) samples. Dual toxins (hyaluronidase, pneumolysin) were identified in a S. pneumoniae and S. mitis/oralis strain. No isolate was positive for all three toxins. In vitro susceptibility profiles included: vancomycin (100%, MIC90-1 mcg/mL), moxifloxacin (90%, MIC90-0.642 mcg/mL), levofloxacin (90%, MIC90-5 mcg/mL), cefuroxime (80%, MIC90-3.3 mcg/mL), and benzylpenicillin (75%, MIC90-0.492 mcg/mL).

Conclusions: Definitive laboratory identification of alpha-hemolytic streptococci may be challenging. The high level of toxin production among endophthalmitis VGS isolates could contribute to their aggressive clinical course and poor patient outcomes.

ABSTRACT BODY:

Purpose: The pathophysiologic processes in FECD, ABMD, and AMD all involve basement membrane dysfunction. We tested the hypothesis that FECD is independently associated with presence of ABMD and AMD.

Methods: This is a single-center cross-sectional study, approved by the University at Buffalo IRB. A single ophthalmologist for this study systematically examined consecutive patients for FECD, ABMD and AMD. We enrolled individuals >18 years old with documented exam findings for all three ocular diseases, and excluded those with bilateral corneal scarring (preventing full exam) and penetrating keratoplasty. FECD was graded (modified Krachmer scale) based on findings of central corneal guttae (0=absent to 6=confluent with corneal edema). Patients that had undergone endothelial keratoplasty were assigned FECD grade 7. Patients with characteristic map-dot fingerprint changes of the epithelium were considered ABMD positive. Patients with macular drusen, pigmentary changes, or atrophy of the retinal pigment epithelium were considered AMD positive. Those with sparse small drusen or absence of pigment abnormalities were considered AMD negative. Poisson regression with robust estimation was used to estimate crude and age-adjusted prevalence ratios and 95% confidence intervals of ABMD, AMD or both among participants with different severity levels of FECD compared to individuals with absent FECD (grade 0 used as reference group). Significance was set at $p<0.05$.

Results: Among 435 participants (ages 18-96, mean 61 years; 262 female, Table 1), the prevalence of having ABMD, AMD, or both, was greater in those with FECD grades of 3-5, 7, and ≥ 1 vs. 0 (Table 2). After age adjustment, we continued to find a statistically significant increased prevalence of ABMD, AMD or both among those with FECD grade 7 vs. 0 (Table 2).

Conclusions: Advanced FECD may be significantly associated with ABMD and AMD. However, these findings seem to be driven by associations in those who have undergone corneal transplantation, suggesting a role for corneal transplantation in the progression of ABMD and AMD.

ABSTRACT BODY:

Purpose: Brg-1 is a catalytic subunit of the SWI/SNF chromatin-remodeling complex, which contains a bromodomain and helicase/ATPase activity. Although mutated in some cancers, Brg-1 is not mutated in uveal melanoma. Targeting Brg-1 in uveal melanoma (UM) could promote chromatin instability and sensitize it to alkylating agents. Herein, we examined the effects of the small molecule inhibitor PFI-3 which binds the bromodomain of Brg-1 in non-metastatic MEL270 and metastatic OMM2.5 UM cell lines. We previously showed that the STAT3 transcription factor was highly activated in metastatic UM cells versus non-metastatic UM cells. We also examined BRG1 and STAT3 expression in UM tissue in situ.

Methods: Brg-1 protein expression was verified using immunoblot analysis. UM cells were plated into 96 well plates and exposed to varying concentrations and combinations of PF-I3 and temozolomide (10-100 mM), and cell death assays were performed by ELISA. RNA in-situ hybridization was performed on 5-µm FFPE sections of archived enucleated eyes.

Results: Immunoblot analysis shows the Brg-1 protein is present in both UM cell lines. PFI3 alone had minimal effect on either UM cell line at 72 hours but increased sensitivity to TMZ-induced apoptosis. RNA-ISH showed co-localization of Brg-1 and STAT3 in vivo.

Conclusions: Our study shows Brg-1 is present in UM cell lines. PFI3 sensitizes UM cell lines to temozolomide leading to increased cell death. Targeting the bromodomain in Brg-1 presents a possible novel therapeutic treatment for metastatic UM. Furthermore, BRG1 and STAT3 RNA is co-expressed in specific niches in UM tissue in situ.

TITLE: Suppression of electromagnetic interference in electroretinography from a patient with an implanted left ventricular assist device (LVAD)

SESSION TITLE: Electroretinography: basic mechanisms and disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Schur, A. Yuan, Ophthalmic Research, Cleveland Clinic, Cleveland, Ohio, UNITED STATES|B. Eck, Imaging Institute, Cleveland Clinic, Cleveland, Ohio, UNITED STATES|

Commercial Relationships Disclosure: Rebecca Schur: Commercial Relationship: Code N (No Commercial Relationship) | Brendan Eck: Commercial Relationship: Code N (No Commercial Relationship) | Alex Yuan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A left ventricular assist device (LVAD) is an implantable cardiac pump that uses a magnetically-levitating rotor to pump blood into circulation in patients with congestive heart failure. In a patient with an implanted LVAD, the high-frequency pump rotation introduces significant interference in electroretinography (ERG) recordings. We evaluate filtering methods to improve ERG quality in the presence of LVAD interference.

Methods: A patient with an implanted LVAD was referred for ERG testing on suspicion of a retinal dystrophy. Full-field ERG (ffERG) and pattern ERG (pERG) were performed according to ISCEV standards. Recordings were acquired in full-bandwidth mode and again in low-bandwidth mode. Digital low-pass and band-stop filtering were performed to mitigate ERG interference. Post-processing was also evaluated in a control subject with no implanted device.

Results: High-frequency interference corresponding to the speed of the pump was present in all recordings (Fig. 1). When applied in post-processing, both low-pass and band-stop filters suppressed the interference and presented readable ERGs without affecting peak times or amplitudes (Fig. 2). By contrast, when recording in low-BW mode, the filter drop-off was not steep enough to remove the interference and peak delays were introduced that could not be readily corrected.

Conclusions: LVAD interference in ERGs can be successfully removed using simple digital filters. If post-hoc data processing capabilities are unavailable, a large amount of interference can be suppressed with a lower acquisition bandwidth and additional recordings of each stimulus response.

ABSTRACT BODY:

Purpose: Reliable choroidal layer analysis has become an important diagnostic tool for retinal diseases. We propose a choroidal-scleral junction (CSJ) segmentation method for swept-source optical coherence tomography (SS-OCT) volumes. Our method is independent of scan field of view (FOV) and designed based on a novel deep learning (DL) algorithm.
