Purpose: 3D bioprinting technique has been used to recapitulate the cellular organization of several tissues throughout the body, including the cornea, limbus, and parts of the retina. However, the capacity to recreate these tissues is derived not just from the placement of the printed cells but also in the "bio-ink" material used to print cells and the scaffold substrate on which the cells are printed, both of which can affect the cell survival, gene expression, and cell migration. Here, we will study the effect of different bioink materials on the 3D printing of retinal ganglion cells (RGCs) and astrocytes, studying the survival of the printed cells and the interactions of the two cell types in our model system.

Methods: RGCs and astrocytes were isolated from early postnatal rodents and suspended in bioinks prepared from alginate, RGD peptide conjugated alginate, collagen, matrigel, or mixtures of these gels and printed using an extrusion based bioprinter. Astrocytes and RGCs were printed separately on electrospun radial scaffolds and survival evaluated by live dead analysis and cell morphology / neurite outgrowth. Samples were then printed on the same scaffolds with astrocytes in the scaffold center and RGCs surrounding to test the ability of the astrocytes to secrete factors that polarize RGC growth and to evaluate the ability of the astrocytes to migrate across the scaffold.

Results: RGCs and astrocytes were able to survive the extrusion printing process in all bioinks at a high percentage, however, RGCs were unable to extend neurites and astrocytes were unable to stretch on bioinks that did not include matrigel. On samples where astrocytes and RGCs were printed on the same scaffold, astrocytes secreted factors were only able to polarize RGC growth within 100 μm of the printed astrocytes. On these samples, RGCs were observed entering the matrigel printed at the scaffold center, while astrocytes were able to migrate from the matrigel onto the radial scaffold.

Conclusions: Electrospun scaffolds combined with 3D bioprinting represent a potential device providing an in vitro model for understanding retinal development and the interaction between RGCs and astrocytes.

TITLE: Differences in primary cilia amongst retinal ganglion cell subtypes

SESSION TITLE: Retinal ganglion cells

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Kowal, O. Dhande, K. Ning, B. Wang, Q. Wang, W. Liu, Y. Hu, Y. Sun, Ophthalmology, Stanford University School of Medicine, Stanford, California, UNITED STATES|N. Berbari, Biology, Indiana University Purdue University Indianapolis, Indianapolis, Indiana, UNITED STATES|

Commercial Relationships Disclosure: Tia Kowal: Commercial Relationship: Code N (No Commercial Relationship) | Onkar Dhande: Commercial Relationship: Code N (No Commercial Relationship) | Ke Ning: Commercial Relationship: Code N (No Commercial Relationship) | Biao Wang: Commercial Relationship: Code N (No Commercial Relationship) | Qing Wang: Commercial Relationship: Code N (No Commercial Relationship) | Wendy Liu: Commercial Relationship: Code N (No Commercial Relationship) | Nicolas Berbari: Commercial Relationship: Code N (No Commercial Relationship) | Yang Hu: Commercial Relationship: Code N (No Commercial Relationship) | Yang Sun: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Primary cilia are sensory organelles that project from the surface of most differentiated cells. These microtubule-based structures coordinate several signaling pathways that are involved in cell proliferation, migration, and differentiation. It is known that primary cilia play critical roles in eye development and photoreceptor function; however, less is known about what role the primary cilia might play in mature retinal ganglion cells (RGCs). To begin to understand these organelles, we assessed the presence or absence of a cilia membrane marker Arl13b and a widely distributed neuronal cilia marker AC3 in different subtypes of mouse RGCs.

Methods: Immunofluorescent staining for primary cilia axoneme markers, Arl13b and AC3, and basal body marker centrin 3 was performed on retinas isolated from adult (P25-P35) transgenic mice in which fluorophores were specifically expressed in only one known subtype of RGC. Additional subtype protein markers were analyzed using immunostaining. Subtype marker specificity was confirmed by colocalized with the pan-RGC marker RBPMS, and ARL13b or AC3 signal was only considered a primary cilium if adjacent to centrin 3 signal. Statistical analyses were performed using Student's t-test, and $p<0.05$ was considered statistically significant.

Results: The presence of prototypical cilia markers Arl13b and AC3 in defined subtypes of retinal ganglion cells was analyzed. These markers were not expressed equally amongst the RGCs. Primarily AC3 positive cilia were found on alpha-RGCs identified by protein markers osteopontin (53% AC3 – 17% Arl13b), calretinin (53% AC3 – 44% Arl13b) and SMI32 (47% AC3 - 27% Arl13b). Whereas directionally selective RGCs either CART positive or Trhr positive differentially localize Arl13b or AC3, respectively in their primary cilia. Intrinsically photosensitive RGCs differentially localize Arl13b and AC3 based on melanopsin expression. Cilia in antibody labeled melanopsin cells primarily had Arl13b (30%), whereas transgenic mouse melanopsin (opn4) labeled RGCs primarily have AC3 (54%) positive cilia.

Conclusions: Primary cilia may be differentially organized between the subtypes of retinal ganglion cells. Further analyses are required to better understand what implications this may have on RGC subtype specific function.

ABSTRACT BODY:

Purpose: Pediatric myasthenia gravis (MG) is uncommon, and earlier studies on ocular outcomes were published prior to the widespread adoption of newer treatments such as rituximab. We report outcomes of pediatric MG in patients treated at our institution over the last 10 years.

Methods: We conducted a retrospective chart review of all children (<18 years) seen at our pediatric ophthalmology department from 2011 to 2021 with a diagnosis of MG and at least 1 year of follow-up. We collected data on demographics, treatments, and outcomes in three groups of patients: 1) generalized MG with ocular involvement at presentation 2) ocular myasthenia gravis (OMG) with later generalization and 3) OMG only. Cox proportional hazards regression analysis was conducted to identify factors associated with outcomes.

Results: Of 41 patients, 18 presented with generalized MG with ocular involvement, 6 presented with OMG that later generalized, and 17 had OMG without generalization. The median age at diagnosis was 3 years, and the median duration of follow-up was 6 years. Medical treatments included pyridostigmine (100%), steroids (42%), intravenous immunoglobulin (22%), and steroid sparing agents including rituximab, eculizumab, azathioprine, and mycophenolate mofetil (24.4%). Thymectomies were performed in 67% of patients with generalized MG (groups 1 and 2) and 12% of patients with OMG (group 3, p=0.002). Among patients with ocular presentation who later generalized, the median time to generalization was 0.8 years (range 1 month to 4 years). At last follow-up, 5% of patients had active myasthenia with fluctuating symptoms, 73% were stable on medications, and 22% were resolved off medications. Residual amblyopia was diagnosed in 7%. There were no significant differences in these outcomes among groups. Failure to stabilize symptoms was associated with younger age at presentation (p=0.03). Lack of symptom resolution was associated with use of steroids (p=0.02) and steroid-sparing immunosuppressive agents (p=0.01). There were no factors associated with residual amblyopia or generalization (in patients with ocular presentation).

Conclusions: In our cohort of pediatric MG patients with ocular involvement, rates of stabilization and resolution were similar to earlier studies. The use of steroids and steroid-sparing agents were associated with worse outcomes, likely indicating more difficult to control disease.

ABSTRACT BODY:

Purpose: To evaluate whether the identification of distinct subpopulations among glaucoma patients improves the estimates of future perimetric loss.

Methods: Eyes with ≥5 reliable visual fields were identified in the Duke Glaucoma Registry. Standard automated perimetry (SAP) mean deviation (MD) and visual field index (VFI) values were collected with associated timepoints. The dataset was split at the patient level, with 80% used for model training and 20% for testing. Rates of change were modeled using latent class mixed models (LCMM) and ordinary least square (OLS) regression. LCMM can identify subpopulations clustered around different average rates. Bayesian Information Criteria was used to identify the LCMM with the optimal number of classes. The LCMM was presented with the first 3, 4, 5, & 6 visual fields of eyes from the test set to predict subsequent SAP MD or VFI values. Model performance was compared to OLS with mean square prediction error (MSPE) using Wilcoxon signed-rank test. Analysis was completed in R.

Results: The full dataset contained 52,900 visual fields from 6,558 eyes of 3,981 subjects, with an average of 8.1±3.7 visual fields per eye. The optimal LCMM for SAP MD contained 3 classes with rates of -0.08, -0.17, & -1.33 dB/year (84.0%, 11.4%, & 4.6% of the population respectively). The optimal LCMM for SAP VFI contained 4 classes with rates of -0.21, -0.66, -2.96, & -6.77%/year (82.6%, 10.1%, 5.7%, & 1.5% of the population respectively). For both SAP MD and VFI, MSPE was significantly lower with LCMM compared to OLS regardless of the number of tests used ($p<0.001$ for all comparisons; Figure 1). Notably, MSPE from LCMM was significantly lower than that of OLS when using only the first 3 visual fields of test eyes (4.90 vs. 60.19 for MD respectively, $p<0.001$; Figure 2). MSPE of fast progressors was significantly lower with LCMM versus OLS (27.30 & 79.59 respectively, $p= 0.01$).

Conclusions: LCMM successfully identified different groups of progressors in a large glaucoma population and significantly improved the prediction of future test estimates. LCMM had superior accuracy for future prediction even when using a small number of visual fields, suggesting that it could more easily identify eyes at risk for significant visual field loss.

ABSTRACT BODY:

Purpose: Globally, age-related macular degeneration (AMD) is a leading cause of vision loss for individuals of ages 50 years and older. The different subtypes of AMD are early, intermediate, and advanced including geographic atrophy (GA) and neovascular (NV) AMD. Medications such as nonsteroidal anti-inflammatory drug (NSAIDs), metformin, hormone therapy (HT) and Age-Related Eye Disease Studies (AREDS) supplements have been shown to play a role in AMD. However, there is a paucity of literature on the effect of these medications in the different subtypes of AMD. The purpose of this study was to determine whether there is an association between the use of NSAIDs, metformin, HT, and AREDS in the different subtypes of AMD compared to controls.

Methods: A case-control study was conducted using the University of Colorado AMD registry (July 2014 - December 2021). For this analysis, AMD status was categorized into 3 groups: controls, early/intermediate and advanced (NV and GA AMD) using multimodal imaging. The current use of NSAIDs, metformin and AREDS at enrollment and past and/or current use of HT were reported. The associations between the use of NSAIDs, metformin, HT and AREDS and AMD categories and controls were determined using adjusted odds ratios (ORs) from multinominal logistic regression.

Results: Of all study patients (n=1167) included in the analysis, there were 931 cases and 236 controls. Among the cases, 42.5% had early/intermediate AMD and 57.5% had advanced AMD. Cases were significantly more likely to use AREDS (37.0% advanced AMD and 52.5% early/intermediate AMD when compared to controls (0.9%). The use of AREDS remained significantly higher in cases compared to controls after adjusting for confounders. HT was used significantly more in controls (27.1%) compared to cases (12.7% of advanced AMD patients and 16.3% of early/intermediate AMD patients). After adjusting for age and history of chronic hypertension, the odds of HT was 0.54 (95%CI:0.33-0.90) for patients with early/intermediate AMD and 0.46 (95% CI:0.27-0.77) for advanced AMD as compared to controls. Metformin and NSAIDs use did not significantly differ between the three AMD groups.

Conclusions: We found that AMD cases were much more likely to use AREDS and less likely to use HT compared to controls. The protective effect of HT may provide important insights into systemic mechanisms related to the risk of macular degeneration.

ABSTRACT BODY:

Purpose: To predict the post-operative refractive error in cataract surgery eyes with previous corneal refractive surgery.

Methods: A total of 75 patients with previous myopic and hyperopic LASIK (40 female / 35 male; age: 66 ± 6 y.o.; axial length range: 20.85 - 29.84 mm; RMS HOAs range: 0.11 - 0.81 microns for a 4-mm pupil) were included in the study. Anterior and posterior corneal Zernike coefficients (from Pentacam, Sirius and MS39 corneal topographers), axial distances (corneal thickness, post-operative effective lens position and vitreous chamber depth) and IOL geometry (SN60WF, ALCON Laboratories; Precizon Toric, OPHTEC BV) were exported to ZEMAX (Radiant ZEMAX; Focus software) where the patient-specific eye models were built. Optical quality was described in terms of the metric Visual Strehl (VSOTF). The defocus and astigmatism producing the maximum VSOTF was taken as the optimal target and compared with the post-operative subjective refraction.

Results: The Bland-Altman analyses of the data show the agreement between the predicted refraction of the proposed optimized methodology for IOL power calculation and the post-operative subjective refraction. The bias and limits of agreement (LoA) were -0.02±0.52 [LoA: -1.05, 1.00], -0.03±0.20 [LoA: -0.43, 0.35] and -0.03±0.19 [LoA: -0.39, 0.38] D for M, J_0 and J_{45}, respectively. Average spherical equivalent was -0.36±0.80 D (subjective) and -0.35±0.73 D (predicted), average power vector J_0 was 0.10±0.33 D (subjective) and 0.10±0.37 D (predicted), and average power vector J_{45} was -0.03±0.12 D (subjective) and -0.02±0.15 D (predicted), with ICC of 0.79 for M, 0.71 for J_0 and 0.55 for J_{45}, respectively; showing high reliability between the predicted refraction and the post-operative subjective refraction in all patients. The percentage of eyes within ±0.5D was of 82.6% (M), 84.1% (J_0) and 82.6% (J_{45}), while the agreement within ±1.0D was of 93.3% (M), 98.6% (J_0) and 97.3% (J_{45}).

Conclusions: We develop a patient-specific method for IOL selection based on virtual ray tracing. Strong agreement between the predicted refraction and the post-operative subjective refraction in a large case series of cataract surgery eyes with previous corneal refractive surgery suggest that the proposed optimized methodology provide an accurate tool for IOL selection. The predicted refraction was influenced by the presence of corneal aberrations.

ABSTRACT BODY:

Purpose: Most cases of FECD are caused by a CTG trinucleotide repeat expansion in intron 3 of the TCF4 gene leading to production of toxic RNA foci, global splicing dysregulation, and cellular dysfunction. The mainstay of FECD management is keratoplasty; no disease-modifying therapies are currently approved. GeneTAC™ molecules are small molecule gene targeted chimera compounds designed to target specific genomic sequences through a DNA-binding moiety and modulate transcription. In this study, we evaluated GeneTAC™ molecules designed to selectively target the expanded CTG repeats in TCF4 intron 3 for their effects on RNA foci formation and mis-splicing.

Methods: GeneTAC™ molecules were synthesized and selected for RNA foci-reducing activity in immortalized F35T corneal endothelial cells (CECs). Primary FECD patient-derived CEC lines (n=4) were treated continuously for 2 to 9 days with 7 unique GeneTAC™ molecules at concentrations up to 300 nM. Toxic nuclear RNA foci containing expanded CUG repeats were evaluated using fluorescence in situ hybridization, and disease-related splicing defects in MBNL1, MBNL2 and NUMA1 were evaluated using PCR.

Results: In FECD patient-derived primary CEC lines harboring mono- and biallelic TCF4 repeat expansions, treatment with GeneTAC™ molecules reduced the average number of foci by 40 to 99% in a time- and concentration-dependent manner. Changes in splicing of MBNL1, MBNL2 and NUMA1 mRNA demonstrated that the most active GeneTAC™ molecules corrected splicing to levels observed in unaffected CECs at concentrations > 33 nM.

Conclusions: Treatment with GeneTAC™ molecules corrected key molecular hallmarks in FECD patient-derived CECs. These findings support continuing development of GeneTAC™ molecules as a potential disease-modifying therapy for FECD.

ABSTRACT BODY:

Purpose: Ellipsoid zone (EZ) reflectivity has potential to serve as a biomarker of photoreceptor integrity, but there is variability in the methods used to extract reflectivity values. Here we evaluate normalization methods of EZ reflectivity across four different OCT devices.

Methods: Horizontal 6mm line scans (20 averaged B-scans) were acquired in five control eyes using the Cirrus, Bioptigen, Optovue Avanti, and Spectralis OCT devices. Eight longitudinal reflectivity profiles (LRPs; each 7 pixels wide by 250 pixels in depth) were extracted using ImageJ from each OCT between 0.5–2.0mm (0.5mm intervals) from the fovea. Boundaries of the ganglion cell and inner plexiform layers (GCIPL) and the peak and full width half max (FWHM) of the EZ were identified. Intensity values between the GCIPL boundaries were averaged. Intensity values between the EZ FWHM were averaged, and peak EZ intensity was extracted. Values were averaged across LRPs for each scan. The average intensity of a 300x50 pixel vitreous region was also extracted from each scan. Four intensity normalization methods were evaluated with ICC and Friedman's test: 1) peak EZ, 2) EZ FWHM, 3) GCIPL normalization (EZ FWHM/GCIPL), and 4) vitreous normalization (subtract vitreous from 3 before taking ratio).

Results: The ICC for mean peak EZ (-0.11) and mean EZ FWHM (-0.09) intensity across devices were poor. Friedman test revealed significant differences in peak EZ intensity across devices ($Q(3)=86.2$, $p<0.0001$). Dunn's multiple comparisons test indicated peak EZ differed across all devices except between Optovue vs Spectralis. Mean EZ FWHM across devices also significantly differed ($Q(3)=66.0$, $p<0.0001$), and Dunn's test revealed values from the Bioptigen were significantly different from the other devices ($p<0.0001$). The ICC for GCIPL normalization across devices was poor (-0.21), and Friedman test revealed significant differences across devices ($Q(3)=13.6$, $p=0.0001$), including Spectralis vs Bioptigen ($p=0.009$) and Spectralis vs Optovue ($p=0.018$). The ICC for vitreous normalization across devices was poor (0.042), with significant differences revealed by Friedman test ($Q(3)=11.2$, $p=0.002$), specifically between Bioptigen vs Optovue ($p=0.009$).

Conclusions: Our data demonstrate that the normalization method alters the relationship of EZ reflectivity across devices. Such variability poses challenges to utilization of EZ reflectivity as a biomarker in clinical studies.

ABSTRACT BODY:

Purpose: Vitamin A deficiency (VAD) is a continuing public health problem among children and pregnant women of Nepal. We conducted a comparative cross-sectional study to assess skin carotenoid measurement as a rapid noninvasive screening tool for VAD in children and pregnant women.

Methods: We enrolled 162 pregnant women and 164 children (8 to 12 years old) from three public hospitals in three ecological regions (Mountain, Hill and Terai) of Nepal in this study. Skin carotenoid levels were assessed noninvasively with reflection spectroscopy using the Veggie Meter® (Longevity Link Corporation, Salt Lake City, Utah, USA). The primary outcome was whether skin carotenoid measurement can successfully identify subjects with VAD. Detailed eye evaluations were conducted in subjects with low skin carotenoid scores (<150 RU) and those with symptomatic night blindness. Serum retinol and serum carotenoid levels were measured using high performance liquid chromatography (HPLC). Intra-class correlation coefficients were calculated. P values were considered significant if less than 0.05.

Results: A total of 8.6% of pregnant women and 12.8% of children were VAD (serum retinol <200 ng/ml) even though only four had present or past ocular clinical signs of VAD. There was significant correlation of total skin carotenoids with serum retinol among the pregnant women ($r= 0.255$, $p= 0.001$) and children ($r=0.253$, $p=0.001$). There was significant correlation of skin carotenoids with serum carotenoids among the pregnant women ($r=0.314$, $p <0.001$) and children ($r=0.510$, $p < 0.001$). There was significant correlation of total serum carotenoids with serum retinol among the pregnant women ($r= 0.447$, $p= 0.001$) and children ($r=0.530$, $p<0.001$). When we performed initial statistical analysis using a cutoff of 200 RU, the Veggie Meter® detected VAD with 71.4% sensitivity and 66.0% specificity in pregnant women and with 71.4% sensitivity and 54.6% specificity in children.

Conclusions: Although sensitivity and specificity were moderate for detecting VAD with the Veggie Meter®, skin carotenoid assessment using this rapid noninvasive portable device could still have immense value as a biomarker for high-risk VAD screening in Nepal and similar developing countries with limited access to laboratory measurement of serum vitamin A levels.

TITLE: Assessment of Sex Differences in Clinically Significant Dry Eye and Associated Autoimmune Disease Prevalence

SESSION TITLE: Dry Eye, Clinical

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Li, D. Cui, J. Zeng, P. Mathews, S. VanCourt, E.K. Akpek, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Gavin Li: Commercial Relationship: Code N (No Commercial Relationship) | David Cui: Commercial Relationship: Code N (No Commercial Relationship) | Julia Zeng: Commercial Relationship: Code N (No Commercial Relationship) | Priya Mathews: Commercial Relationship: Code N (No Commercial Relationship) | Shanna VanCourt: Commercial Relationship: Code N (No Commercial Relationship) | Esen Akpek: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate sex differences in dry eye diseases with regards to objective dry eye parameters and autoimmune disease.

Methods: Dry eye patients presenting at a tertiary academic medicine center, evaluated by an ophthalmologist between 3/2015 and 7/2021 were identified using international classification of disease codes (M35.0, H16.222, H04.123, 710.2, 375.15). Patient sex at presentation was obtained using billing records and confirmed with medical record review. A total of 343 (21.0%) male and 1288 (79.0%) female patients were identified. Review of electronic medical records was conducted to evaluate demographics, objective dry eye parameters at baseline visit, autoimmune or inflammatory disease, and ocular comorbidities.

Results: A total of 100 patients, 50 male and 50 female, were included. Mean age was 62.5 years and 81.0% self-identified as White, with no demographic differences based on sex (P>.05). There was no statistically significant difference (all P>.05) for objective dry eye parameters at baseline presentation for mean lissamine green conjunctival staining (2.8 women vs 2.5 men), corneal fluorescein staining (2.0 women vs 1.9 men), Schirmer's test without anesthesia (9.8 women vs 11.2 men), and tear osmolarity (304.7 women vs 304.0 men). Approximately two-thirds (68% men, 66% women; P=.812) had primary dry eye without an autoimmune disease or dry eye-related ocular comorbidity. More women had an established autoimmune disease at baseline visit (14% vs 2%; P=.027), an equal number were diagnosed with an autoimmune disease during follow-up (12% women vs 8% men; P=.505).

Conclusions: No statistically significant difference was observed with regards to demographics and objective dry eye parameters. Prevalence of existing autoimmune disease was greater in women at presentation, however diagnosis incidence during follow-up was similar, indicating autoimmune disease may be underdiagnosed in men on presentation. Additional and larger studies evaluating clinical differences of sex in dry eye patients are warranted.

ABSTRACT BODY:

Purpose: ELOVL2 (Elongation of Very Long Chain Fatty Acids-Like 2) encodes a transmembrane protein that plays critical roles in the biosynthesis of omega-3 docosahexaenoic acid (DHA) (22:6n-3) and very long-chain polyunsaturated fatty acids (VLC-PUFAs), which are highly enriched in photoreceptors and essential for maintaining healthy visual function. Adjacent retinal pigment epithelial (RPE) cells are responsible for daily phagocytosis and subsequent degradation of lipid-rich photoreceptor outer segment tips. The aim of this study was to investigate the functional role of ELOVL2 in RPE cells and to what extent alterations of DHA and VLC-PUFA synthesis contribute to RPE dysfunction.

Methods: We used small interfering RNAs (siRNAs) directed against ELOVL2 in ARPE19 cells and performed immunohistochemistry and fluorescent microscopy studies. To investigate phagocytic function, cells were challenged with FITC-labelled rod outer segments (FITC-ROS) and stained with lysosomal marker LAMP1. The proportion of surface-bound and internalized ROS in control (n=9) and ELOVL2 knockdown (n=9) cells was quantified using ImageJ and normalized to the number of nuclei. Two-tailed Student’s t-test was used for statistical analysis.

Results: ELOVL2 knockdown ARPE19 cells showed ~30% decrease in phagocytosed ROS ($p<0.001$) compared to control. In addition, lysosomal size and distribution differed between the two groups. In normal ARPE19 cells, lysosomes exhibited a perinuclear distribution, while in ELOVL2 knockdown ARPE19 cells, LAMP1 signal was localized to the cell periphery.

Conclusions: Overall, the findings of this study support our hypothesis and suggest that ELOVL2 knockdown and subsequent decline in DHA and VLC-PUFA synthesis result in impaired phagocytic function of RPE cells. This study not only provides insight into the molecular mechanisms of RPE phagocytosis but also opportunities to explore therapeutic treatments for pathologic states such as age-related macular degeneration (AMD) using lipid supplementation.

ABSTRACT BODY:

Purpose: Mutations in RDH12, which encodes a retinol dehydrogenase localizing to photoreceptor inner segments, cause early onset retinal degeneration. We defined changes in retinal structure and function in pediatric patients with Leber congenital amaurosis (LCA) due to RDH12 mutations. We also initiated safety evaluations of AAV8 delivering a photoreceptor-driven human codon optimized (hco) RDH12 cDNA in non-human primates (NHPs).

Methods: Twenty-six patients (ages 2-21 years) with RDH12-LCA underwent a complete ophthalmic exam and imaging with SD-OCT and 20 of these individuals were evaluated longitudinally over 3 years. In animal studies, 4 macaques already enrolled in an AAV vaccine study received bilateral subretinal i(SR) injections of AAV8.RK1.hcoRDH12 in a dose-ranging study (3E10 – 3E11vg). One additional animal was injected with a similar vector that incorporated eGFP. Follow-up was performed with protocols that matched those used in patients. Animals were evaluated for transgene expression and histopathology 4 weeks post-injection.

Results: In the patients, visual acuity ranged from 20/40 to 20/800 and remained stable in most patients. SD-OCT showed early foveal thinning in all patients but detectable outer nuclear layer (ONL) at greater eccentricities from the fovea. ONL extent and thickness declined over the course of the study. FST sensitivities were rod-mediated and reduced on average by ~2.5 log units and declined by about 5 dB over 3 years. In NHPs, retinas developed pigmentary changes outlining the area of subretinal injection similar to that seen in other SR injection studies. SD-OCT imaging revealed injection-related alterations in retinal structure. Histologic analyses revealed minimal inflammation at 3E10 or 1E11 vg and rare monocytic peri-vascular infiltrate at 3E11vg. RDH12 immuno-staining was specific to photoreceptors, as was GFP in retinas treated with AAV.RK1.eGFP

Conclusions: Detectable but dysfunctional photoreceptors in the pericentral and peripapillary retina of patients with RDH12-LCA suggest these regions may be targets for gene augmentation. Subretinal delivery of AAV8.RK1.hcoRDH12 in NHP was safe at 1E11vg with only mild inflammation at 3E11vg. The RK1 promoter limited expression to photoreceptors. The data support plans for a formal GLP preclinical toxicity study prerequisite to a human clinical trial.

ABSTRACT BODY:

Purpose: Glaucoma is the leading cause of irreversible blindness worldwide. The role of mitochondrial dysfunction leading to retinal ganglion cell (RGC) death has been implicated in the pathogenesis of primary open-angle glaucoma. In addition to supporting the high bioenergetic needs of RGCs, mitochondria also play a central role in oxidative stress, calcium dysregulation, and apoptosis pathways. Restoring mitochondrial function by transplantation is a recent development and has been a target of therapeutic intervention.

Methods: Mitochondria were isolated from hSkMCs by magnetically binding to the TOM22 surface protein. Western blot and PCR analysis with gene-specific primers for mitochondrial DNA confirmed the purity of the isolated mitochondria. The integrity of the purified mitochondria was confirmed by transmission electron microscopy. We incubated human induced pluripotent stem cell-derived RGCs (hiPSC-RGCs) with exogenous mitochondria from metabolically active human skeletal muscle cells (hSkMCs). SkMCs were transduced with lentiviral mito-GFP to label donor mitochondria for identification. To test the functional impact of mitochondrial transfer, we treated hiPSC-RGCs with rotenone to induce oxidative stress. The effects of exogenous mitochondria in hiPSC-RGCs were evaluated for oxygen consumption by Oroboros, mitochondrial membrane potential, reactive oxygen species (ROS), and ATP production.

Results: Treatment of hiPSC-RGCs with 730 nM of rotenone induced significant mitochondrial depletion by 12 hours of exposure and thereby decreased ATP production while increasing ROS and superoxide production. hiPSC-RGCs incubated with isolated mitochondria accept them by 1 hour, and the uptake increases with mitochondrial dosage, incubation time, and presence of PEP-1 peptide. ATP production and oxygen consumption by hiPSC-RGCs under oxidative stress improved following mitochondrial transfer. Furthermore, intravitreally injected exogenous mitochondria into C57BL/6 mouse eye were detected in the ganglion cell layer of the murine retina, and its expression co-localized with BRN3, TUJ1, and TOM22 markers.

Conclusions: Through our studies, we hope to demonstrate that mitochondrial transplantation is a viable, novel therapy to rescue RGC function and can be used as a mitigating treatment for glaucoma and other optic neuropathies before the occurrence of permanent vision loss.

ABSTRACT BODY:

Purpose: Cornea guttata (CG) prevalence post keratoplasty varies from 15 to 18%, with 1 to 2% of the cases presenting with significant negative outcomes. The purpose of this research project is to create a program based on artificial intelligence (AI) that helps with the detection of CG in the donor corneas (DC) in the eye bank.

Methods: Preoperative corneal endothelial images (PCEI) of patients who underwent keratoplasty were collected and classified into 2 groups according to the postoperative CG grade. Group 1 included healthy corneas and those having mild postoperative CG, while group 2 included corneas with severe postoperative CG. Using previously tested semi-quantitative morphological criteria along with other characteristics such as donor age and lens status, the PCEI were analyzed and used to create and train an AI-based tool for the detection of CG. The underlying concept of the tool compares previous cases with comparable properties to the DC in test. The postoperative CG grades of previous cases similar to the DC in test determine the prediction for its CG grade. Finally, the features and CG grade of the analyzed DC are stored in the database for future use.

Results: In total, 6221 PCEI belonging to 1078 patients were used to create a transparent and explainable decision support tool for the detection of CG through a hybrid approach combining 2 components. (1) Graphical analytic tools, whereby the PCEI pass multiple OpenCV-based image processing steps including the Watershed transform algorithm. In this step, cell membranes are delineated, and abnormally large cells or cell depleted areas are marked in red. Several other cell representations such as “honeycomb” representation are created for an enhanced visualization of the endothelial layer (EL). (2) Machine learning (ML) classifiers including Case-Based Reasoning were created to detect CG. Initial experiments showed a performance comparable to humans (4-fold evaluation yielded precision: weighted F1 score:0.93).

Conclusions: We presented an AI-based program able to facilitate the detection of CG in the DC in the eye bank by comparing the PCEIs with relevant previous cases, using ML classifiers and offering an enhanced visualization of the EL. The evaluation and optimization of this program will follow as the next stage of our project.

TITLE: Machine Learning for Predicting Early High Postoperative IOP After Trabeculectomy

SESSION TITLE: Data science, machine learning, and AI

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W. Lin, M. Hribar, Medical Informatics & Clinical Epidemiology, Oregon Health & Science University, Portland, Oregon, UNITED STATES|A. Chen, Ophthalmology, Oregon Health & Science University, Portland, Oregon, UNITED STATES|M.F. Chiang, National Eye Institute, Bethesda, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Wei-Chun Lin: Commercial Relationship: Code N (No Commercial Relationship) | Aiyin Chen: Commercial Relationship: Code N (No Commercial Relationship) | Michael Chiang: Commercial Relationship(s);Code C (Consultant/Contractor):Novartis;Code F (Financial Support):Genentech;Code I (Personal Financial Interest):InTeleretina LLC | Michelle Hribar: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Trabeculectomy is the most commonly used surgical method for advanced glaucoma. Many factors may impact the success of a trabeculectomy, such as patient selection, surgical technique, and postoperative management. Studies have shown that IOP control at the early postoperative period is crucial for successful trabeculectomy. Physicians may adjust the frequency of visits, steroid frequency, or other procedures to manage postoperative IOP. Yet, accurately predicting postoperative IOP is difficult due to various factors associated with wound healing. This study aims to develop predictive models to determine which glaucoma patients have higher risk of early high postoperative IOP.

Methods: We identified 1,005 adult glaucoma patients who underwent trabeculectomy from 2010 to 2021 and had at least 5 follow-up visits before surgery at OHSU. Early high postoperative IOP was defined as IOP ≥ 21 mmHg within 1-month postoperatively. Two types of data were extracted and used: static and time-series features. Static features included demographic data, eye exams and medications before surgery, and the highest preoperative IOP and VA. Time-series features included IOP, VA, and medications in the last 5 visits before surgery. We developed several machine learning models with static features to predict whether the patient has a higher risk of early high postoperative IOP, including XGBoost, random forest, and support vector machine. Also, to explore the importance of time-series features, we developed multimodal and long short-term memory (LSTM) models (figure 1). Area under the receiver operating characteristic curve (ROC), precision, recall, and F1 score were used to evaluate the performance.

Results: Figure 2 shows the ROC curves and AUC scores of 5 models. The XGBoost model had the highest AUC score (0.71) and F1 score (0.51). The LSTM and multimodal models showed lower performance, indicating that the fluctuation of eye measures from the visits before surgery is less associated with early postoperative high IOP. The top three important predictors identified in the XGBoost model were age, surgeon, and the highest preoperative IOP.

Conclusions: Machine learning models with secondary use of EHR data can be used to predict early postoperative high IOP patients. The work has implications in improving trabeculectomy postoperative management. In the future, we may incorporate text data into models to improve prediction accuracy.

ABSTRACT BODY:

Purpose: To determine whether tear levels of cytokines and chemokines could be used as a potential reliable biomarker in patients with uveitis and its correlation with plasma levels.

Methods: Twelve cytokines/chemokines were measured in tear and plasma samples of 22 patients diagnosed with active anterior, intermediate, posterior or panuveitis. Patients underwent standard treatment for uveitis were followed longitudinally over 6 months. At that time tear and plasma samples for measurements of the same of cytokines. Levels of these molecules in tears and plasma were compared and associated with degree of activity of the uveitis.

Results: Tear interleukin (IL)-6 percentage of detection was significantly reduced in the inactive phase ($p<0.05$). Tear concentration of epidermal growth factor (EGF), Fractalkine, IL-8, IL-1RA, interferon-inducible protein (IP)-10/CXCL10, vascular endothelial growth factor (VEGF) and IL-6, comparing the active and inactive period were not statistically different. Plasma concentration of EGF, Fractalkine, IL1-β, IL-17A, IL1RA, IL-2, IL-23, IL-8, IP-10, tumour necrosis factor-alpha, VEGF and IL-6, comparing the active and inactive period was not statistically significant. The levels of EGF, fractalkine, IL1-β, IL-17A, IL-1RA, IL-2, IL-23, IL-8, IP-10, TNF- α and IL-6 in patients with uveitis in their active/inactive phase were statistically different ($P<0.05$) to their counterpart levels in plasma. However, the difference between the tear and plasma levels of VEGF was not statistically significant ($P>0.05$).

Conclusions: No isolated cytokine/chemokine in the tear has been found, which concentration could be used as a potential biomarker of treatment response. Furthermore, apart from the VEGF, the cytokine/chemokine concentration in tears was independent of the plasma counterparts.

TITLE: Real-time mimicking of accommodative microfluctuations by a tunable lens and monocular sensing of the sign of defocus

SESSION TITLE: Optics: Accommodation, Lens and Ocular Biometry

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Sharmin, B. Vohnsen, School of Physics, University College Dublin, Dublin, Leinster, IRELAND|

Commercial Relationships Disclosure: Najnin Sharmin: Commercial Relationship: Code N (No Commercial Relationship) | Brian Vohnsen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Accommodative microfluctuations may potentially play a role in the detection of the sign of defocus. The aim of this study was to examine the temporal dynamics of accommodation with and without microfluctuations in the young adult eye. This can provide insight into whether defocus is sensed by the eye and its possible relation to emmetropization.

Methods: Real-time accommodation, with and without microfluctuations (MFs), was analyzed in a monocular vision system with a Hartmann-Shack wavefront sensor (HS-WFS) capturing up to the 4^{th} radial Zernike order at 25 Hz, used along a tunable lens (TL), and a near-IR beacon at 850 nm. Subjects viewed with the right eye a green Maltese cross target (0.86°) on a dark computer screen placed at 1-m distance with a 3 mm pupil. The power of the TL was coded both to trigger an accommodative response and, when desired, to replicate and cancel MFs during the accommodative process using the defocus signal from the HS-WFS. Three subjects (2 emmetropes, 1 myope) were analyzed. In the first set of measurements, it generated constant defocus step changes (from 0 D to the comfortable accommodative range of the subject) at random time intervals (within 5 to 9 s). In the second set of measurements, the TL made the same random-time defocus step changes while mimicking, with opposite sign, detected MFs.

Results: The accommodation followed defocus steps accurately both with and without MFs for all of the subjects. Some accommodation overshooting was noticed when the MFs were mimicked by the TL. The reaction time was found to be in the range of 300 – 750 ms and the response time was found in the range of 250 – 1500 ms. It was noticed that almost in 50% of the cases, the reaction and response time was longer when MFs were compensated by the TL, while for the remaining cases both times were either similar or even faster with MFs compensation.

Conclusions: The findings show that in the absence of MFs accommodation is still in the correct direction. The accommodative response time increased with an increased magnitude of step changes and with the increased measurement time but was only weakly affected by the removal of the MFs cue. Thus, MFs may predominantly aid to maintain an average accommodation level rather than to provide the required direction of accommodation.

ABSTRACT BODY:

Purpose: Retinopathy of Prematurity (ROP) is the worldwide leading cause of preventable childhood blindness. In remote areas of the United States as well as developing countries, in-person screening for ROP by a trained ophthalmologist can be a significant hurdle. In this study, we aim to assess the effectiveness of telemedicine screening for retinopathy of prematurity (ROP) in premature infants in South Dakota.

Methods: A retrospective review of medical records for premature infants were screened for ROP at neonatal intensive care units (NICUs) in Sioux Falls, South Dakota from September 1, 2017 to December 31, 2021. RetCam Shuttle (Natus Medical Inc., Pleasanton, CA) retinal images were posted on a secure server for evaluation by a pediatric ophthalmologist. Patients who were suspected to progress to Stage I ROP or greater were referred to Children's Hospital and Medical Center in Omaha, Nebraska where they received comprehensive examination and, if necessary, anti-vascular endothelial growth factor (VEGF) treatment. The remaining patients received an outpatient comprehensive examination by a pediatric ophthalmologist within two weeks of discharge.

Results: 250 telemedicine examinations were performed on 70 infants during the study period, averaging 3.6 examinations per infant. Of the 70 infants, 6 (8.6%) were transferred for referral-warranted ROP. Remote telemedicine screening for referral-warranted ROP had a sensitivity of 100% and specificity of 97%. We had a positive predictive value of 67% and negative predictive value of 100%. Four of the six infants transferred for referral-warranted ROP required treatment with anti-VEGF, all of whom had good outcomes. No patients progressed beyond stage 3 ROP.

Conclusions: Remote telemedicine screening in at-risk premature infants detected referral-warranted ROP at a high accuracy with no poor outcomes throughout the four-year period. This study demonstrates the efficacy and functionality of telemedicine in screening for ROP and lays out implications for further utility in developing countries.

ABSTRACT BODY:

Purpose: The suprathreshold visual field (SVTF) test using augmented reality (AR) headsets offers a method of portable screening for visual field defects. For patients with refractive error, the current standard of practice utilizes corrective lenses while testing. In this study, we explore whether the omission of corrective lenses impacts the efficacy of the SVTF as a screening tool for visual field loss.

Methods: Twenty-one adult patients with refractive errors were recruited over a two-week period at a tertiary academic eye institute to take the STVF test using the Heru re:Imagine full threshold strategy (Heru, Inc, Miami, FL) implemented on MagicLeap 1 AR headset (MagicLeap, Plantation, FL) with and without lens correction. Of these patients, fifteen underwent full threshold visual field testing. Patients were alternated between taking the STVF with or without correction first. Correction was achieved using classic trial lenses attached to a lens-holder and inserted in the headset. One or both eyes were tested depending on the presence of refractive error. STVF were deemed abnormal if two or more stimuli, other than those in the blind spot, were missed. Measures of sensitivity, specificity, and kappa statistic were calculated.

Results: Our study included 28 eyes, 76% females (n = 16), 57% Hispanic or Latinos (n = 12), with a mean age of 53.6 years. All the patients wore corrective eyeglasses. The mean myopic spherical equivalence was -3.60, and the mean hyperopic spherical equivalence was +2.13. The majority (57%) of the participants had cylinder power in their prescription (n = 12). Relative to the full threshold VF, the sensitivity of the STVF with correction was 57%, while without correction was 29%. The specificity of the STVF test with correction was 92%, while without correction was 58%. The kappa statistic for inter-rater reliability is 0.3, suggesting a fair agreement with a 75 percent observed agreement.

Conclusions: Our data suggest that the use of corrective lenses is of value for the efficacy of the supra-threshold test as a screening tool. Future directions include a larger sample size with a particular focus on patients with high cylinder power, and high-myopes and hypermetropes.

ABSTRACT BODY:

Purpose: The development of ocular structures of the anterior segment is critical for proper aqueous humor production and outflow. Previously, we have demonstrated that deletion of AP-2β from the neural crest and the developing periocular mesenchyme (POM) results in abnormal development of anterior angle structures including the TM, Schlemm's canal and the cornea. In order to determine the specific and the cell-autonomous role of AP-2β in TM development, we have recently developed a new mouse model by deleting AP-2β later during TM development using a tamoxifen-inducible ubiquitin cre recombinase (Ubc-Cre-ERT2) system; a cre recombinase system that allows us to manipulate the time of deletion of AP-2β.

Methods: UbCre$^{ERT2+/-}$; Tfap2b$^{+/-}$ mice were bred with Tfap2b$^{lox/lox}$; tdTomato$^{lox/lox}$ mice to generate pups containing UbCre$^{ERT2+/-}$; Tfap2b$^{-/lox}$; tdTomato$^{lox/+}$ (mutant) and UbCre$^{ERT2+/-}$; Tfap2b$^{+/lox}$; tdTomato$^{lox/+}$ (control). The eyes of all the pups were topically treated with 5μL tamoxifen solution (5mg/mL) three times per day starting post-natal day (P) 4 until P7. The pups were euthanized at P14 and the eyes were enucleated, fixed and processed for paraffin sectioning. H&E and immunohistochemistry (IHC) using antibodies for AP-2β and the TM markers, αSMA and myocilin, were performed on paraffin sections from mutant and control eyes.

Results: The H&E staining of P14 mutant eyes showed adhesion of iris to the cornea near the anterior angle, and fewer TM cells when compared to their control littermates. The morphology of the other anterior structures including the cornea remained unaffected in the mutants (n=6 eyes per genotype). The AP-2β deletion was confirmed by IHC in the anterior ocular structures including the anterior angle and the cornea of the mutant mice. The decrease in the TM cell population in mutants was further confirmed by the reduction in αSMA and myocilin staining (n=6 eyes per genotype).

Conclusions: The absence of TM cells from the anterior angle upon deletion of AP-2β from P4 to P7, after the specification of POM is complete, suggests a cell-autonomous role of AP-2β in TM development. The reduced number of TM cells in the mutants may be primarily responsible for the adhesion of iris to the cornea at the anterior angle. The reduced expression of TM cell markers and TM cell population suggests that AP-2β is critical for proper development and differentiation of TM.

ABSTRACT BODY:

Purpose: To associate morphological characteristics of subretinal hyperreflective material (SHRM) with short-term visual outcomes in patients with neovascular age-related macular degeneration (nAMD) treated with intravitreal antiangiogenic therapy (anti-VEGF).

Methods: An analytical observational study was carried out in eyes with nAMD treated with 3 loading doses of antiVEGF. SHRM optical coherence tomography (Cirrus) characteristics and measures were analyzed including reflectivity, borders, homogeneity, localization, width and the presence of ELM/EZ. Correlations were performed to evaluate the association between OCT characteristics and short-term visual outcomes.

Results: A total of 65 eyes (65 subjects), with a median age of 75,5 years (IQR 16,0) were included. All the subjects had SHRM. Median best-corrected visual acuity (BCVA) pre-treatment was 0,8 (IQR 0,7) LogMAR and post-treatment was 0,7 (IQR 0,6) LogMAR. We found a positive correlation before and after treatment in BCVA (r=0,8) (p=0,001), SHRM extension (r=0.7) (p=0,001), low reflectivity (p=0,017) and non-defined borders (p=0,037) that were statistically significant. The parameters that were associated with an improvement in BCVA after treatment were SHRM characteristics: low reflectivity (p=0.048), non-homogeneity (p=0.048) and width (p=0.043), presence of external limiting membrane (ELM) (p=0.002) and ellipsoid zone (EZ) (p=0.017).

Conclusions: Findings associated with improved short-term visual outcomes were SHRM low reflectivity, non-homogeneity, shorter width and the presence of ELM/EZ. Studies with a larger sample are required to assess the relevance of OCT features with the final visual prognosis.

ABSTRACT BODY:

Purpose: We previously reported that dimethyl sulfoxide (DMSO) acts as a neuroprotectant in light-induced retinal damage (LIRD) and the retinitis pigmentosa Pdeb6$^{rd10/rd10}$ (rd10) mouse models. Because DMSO has side effects, such as halitosis and body odor, we decided to test a metabolite of DMSO, methylsulfonylmethane (MSM), for protection. MSM, the oxidized form of DMSO, has no known side effects and is designated as Generally Recognized as Safe (GRAS) by the FDA. We tested the hypothesis that systemic treatment with MSM would be protective in a LIRD mouse model.

Methods: 90-day-old male BALB/c mice were intraperitoneally (IP) injected the afternoon before and morning of bright light exposure with either 4025 mg/kg MSM, 3.5 ml/kg (3.85mg/kg) DMSO, or saline vehicle. Mice were dark-adapted overnight prior to bright light (2500 lux x 4h) or dim light (50 lux x 4h) exposure. Retinal function was assessed by electroretinogram (ERG) with increasing flash intensities from 0.001 to 10 cd s/m^2 one week later, and outer nuclear layer (ONL) quantification was completed using hematoxylin and eosin (H&E) staining in sagittal retina sections of eyes collected afterward.

Results: When compared to vehicle dim, a-wave and b-wave amplitudes at the highest flash intensity decreased 83% and 76%, respectively, for the vehicle bright group ($p<0.0001$), but only 56% and 42% for the MSM bright group ($p<0.0001$) and 31% and 15% for the DMSO bright group ($p<0001$). The differences between mean amplitudes of the vehicle bright group versus either of the drug bright groups were also statistically significantly different ($p<0.0001$). Compared to vehicle dim mice, vehicle bright mice lost 63% of their ONL nuclei ($p<0.0001$), but MSM bright mice only lost 17.8% ($p<0.02$) and DMSO bright mice only lost 3.21% (n.s.). The differences between the vehicle bright group versus either of the drug bright groups were also statistically significantly different ($p<0.0008$).

Conclusions: MSM is protective against LIRD-induced losses in retinal function and in the number of remaining ONL nuclei. MSM was not as protective as DMSO. We believe this may be due to a difference in molar ratio between the drug concentrations (49.29 mmol/kg for 3.5 ml/kg DMSO compared to 42.76 mmol/kg for 4025 mg/kg MSM). Overall, given the lack of side effects compared to DMSO, the current data suggest that MSM should be further pursued as a retinoprotectant.

ABSTRACT BODY:

Purpose: Pars plana vitrectomy incisions can be self-sealing, sutured, or sealed with ocular adhesives. Complications such as leaks, hypotony, endophthalmitis, inflammation, astigmatism, and suture breakage raise questions regarding what technique and material modifications can improve scleral wound closure. The purpose of this study is to evaluate the effectiveness of combining the patient's own tissues with products that are already FDA approved in a novel technique for scleral wound closure in pars plana vitrectomy.

Methods: Cadaveric Yorkshire porcine eyes (n=3) were manually vitrectomized and a 23-gauge trocar was used to create a scleral wound which leaked saline infusion fluid at baseline. 200µL of platelet rich plasma (PRP) was mixed with 100µl of thrombin for PRP clot formation. In one trial, A 2mm dermatological hole punch was used to mold the clotted plasma. A pair of 23-gauge Grieshaber MAXGrip Forceps delivered the clot through the 23-gauge trocar into the scleral wound. In another trial, the 23-gauge trocar was removed and a 2-20µl pipette delivered the clotted plasma into the wound. The MAXGrip Forceps were used as a plunger to push the clot through the micropipette tip and into the wound. A mixture of whole blood and thrombin were aspirated into 16-,18-, and 20-gauge angiocath tips creating clotted whole blood. The IV angiocath tips were then cut into 6-8mm pieces, creating cylindrical clots. The clots were delivered through the 23-gauge trocar into the scleral wound. This methodology of clot delivery was also used for polymerized ReSure Sealant.

Results: A PRP clot was delivered through a 2-20µl pipette tip using the MAXGrip Forceps, preventing ocular wound leakage up to a pressure of 60 mmHg. A clot of whole blood molded from the 20G IV angiocath tip was successfully delivered through the 23G trocar with no ocular wound leakage at baseline. However, it was dislodged during the Seidel test.

Conclusions: This study provided preliminary evidence that clotted PRP and clotted whole blood could be feasible options for scleral wound closure. Further well controlled, randomized, and live animal studies will be required to determine the efficacy and long-term stability of the outlined materials and methodology of clot formation and delivery, but further studies have the potential to shape the approach to sclerotomy closure.

TITLE: Quantitative assessment of venting techniques to facilitate intraocular perfluorocarbon removal

SESSION TITLE: Vitreoretinal surgery/VR Interface/PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Singh, K. Astafurov, Rutgers Robert Wood Johnson Medical School New Brunswick, New Brunswick, New Jersey, UNITED STATES|

Commercial Relationships Disclosure: Hartej Singh: Commercial Relationship: Code N (No Commercial Relationship) | Konstantin Astafurov: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose:

Perfluoro-n-octane (PFO) is a useful adjuvant for the repair of retinal detachments due to its transparency and high density. However, intraocular PFO retention has been implicated in inflammation, visual field defects, and retinal toxicity. Thus, the total removal of PFO at the end of surgery is critical but, at times, difficult due to corneal edema and intraocular lens fogging. PFO's high vapor pressure in operating room conditions with continuous air venting aids its intraocular elimination. This study seeks to quantitatively characterize optimal conditions for the removal of residual PFO via evaporation during vitreoretinal surgery.

Methods: A standard, 25-gauge (25g) vitrectomy system (Alcon Constellation) and an anatomically-sized model plastic eye (Phillips Studio, UK) were used for the experimental setup. Valved trocars were placed 3.5mm from the corneal limbus, and low, clinically-relevant PFO volumes were instilled into the model eye. The evaporation rates were measured under varying venting conditions with humidified air infused at 40 mmHg by the Alcon Constellation. Four 25g venting methods were examined, a chimney-vent, a needle, and an extrusion cannula with and without a silicone tip. The needle and extrusion cannula trials were conducted at the mid-vitreous position and near the PFO interface.

Results: At the volumes tested, PFO evaporated linearly with all venting methods. The 25g chimney vent offered the fastest evaporation rate (0.019±0.002 cc/min). The 25g extrusion cannula with a silicone tip showed slower evaporation rates both at the mid-vitreous position and close to the PFO interface (0.006±0.0002 cc/min, 0.008±0.001 cc/min, respectively). Removing the extrusion cannula's silicone tip marginally increased the evaporation rate (0.012±0.001 cc/min, near the PFO interface). The 25g needle yielded the slowest evaporation rate (0.005±0.0003 cc/min, near the PFO interface).

Conclusions: Residual PFO can be removed from the eye using air venting due to PFO's high vapor pressure. We show that, with 25g instrumentation, a chimney-vent is the optimal PFO venting method, and, with air infused at 40 mmHg, five minutes are sufficient for eliminating PFO volumes up to 0.1 cc. Our quantitative data would be useful to vitreoretinal surgeons who may encounter challenges with visualization of complete PFO removal not infrequently seen at the end of long surgical procedures.

TITLE: Visual cortex anodal transcranial direct current stimulation (a-tDCS) does not alter GABA concentration

SESSION TITLE: Visual Function: perception, adaptation, spatial, visual acuity and binocular vision

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Abuleil, D.L. McCulloch, B. Thompson, University of Waterloo, Waterloo, Ontario, CANADA|D. Gorbet, J. Steeves, York University, Toronto, Ontario, CANADA|B. Thompson, Center for Eye and Vision Research, HONG KONG|

Commercial Relationships Disclosure: Dania Abuleil: Commercial Relationship: Code N (No Commercial Relationship) | Diana Gorbet: Commercial Relationship: Code N (No Commercial Relationship) | Daphne McCulloch: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Steeves: Commercial Relationship: Code N (No Commercial Relationship) | Benjamin Thompson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Anodal transcranial direct current stimulation (a-tDCS) of the primary visual cortex can alter visual perception in individuals with normal vision and in those with amblyopia. The mechanisms that underpin this effect are unknown. When applied to the primary motor cortex, a-tDCS reduces the concentration of the neurotransmitter GABA within the stimulated region. We investigated whether this effect occurs when a-tDCS is delivered to the primary visual cortex.

Methods: Thirteen adults with normal vision participated in a within-subjects study design consisting of two MRI sessions, one involving active a-tDCS and the other a placebo (sham) a-tDCS to the visual cortex. Each session began with the measurement of binocular rivalry dynamics (oblique gratings, 6.1° size, 0.5 cpd, 60-second viewing time). GABA and glutamate concentrations (magnetic resonance spectroscopy; MRS) and resting state functional connectivity (functional MRI) were then measured before (baseline) and immediately after application of a-tDCS. For MRS, a 2.5 cm^3 voxel-of-interest (VOI) was centered on the calcarine sulcus and positioned so that it covered only brain tissue. For functional MRI, brain volumes were acquired using whole-brain echo-planar imaging with a T2-weighted sequence.

Results: Active a-tDCS stimulation had no effect on visual cortex GABA concentration nor on resting state connectivity. However, there was a trend towards increased glutamate concentration following active stimulation ($p=0.045$). In addition, higher visual cortex glutamate concentrations at baseline were associated with longer piecemeal percepts during binocular rivalry ($r=0.561$, $p=0.046$).

Conclusions: Unlike motor cortex, visual cortex a-tDCS does not appear to be mediated by a reduction in GABA concentration. Unexpectedly, temporal dynamics of binocular rivalry are associated with higher visual cortex glutamate concentration.

ABSTRACT BODY:

Purpose: With the recent emergence and worldwide distribution of COVID-19 vaccines, many side effects may be underreported and possibly unknown. Cases of vaccine-associated uveitis have been linked to almost all vaccines administered in the past, however, there is scarcity of literature providing insight into post COVID-19 vaccine associated uveitis / episcleritis. By documenting patients presenting with uveitis / episcleritis after the administration of mRNA Pfizer and Moderna vaccines, this case series significantly advances our current understanding of potential COVID-19 vaccine ocular complications.

Methods: Patients with ocular symptoms consistent with uveitis / episcleritis within 15 days of the administration of the Pfizer or Moderna COVID-19 vaccine were included in this study. Ocular assessment included a Snellen best-corrected visual acuity (BCVA) converted to logMAR, intraocular pressure (IOP) with Goldmann Applanation Tonometry, pupil check, anterior and dilated posterior segment assessment with slit-lamp, and optical coherence tomography (OCT) imaging. Patients were anonymized and demographics including sex, race, age, and other necessary clinical data were recorded.

Results: A total of 9 patients (6 female and 3 males) with a mean age of 42.9 (range, 19-83) were included. 7 patients received a Pfizer vaccine and 2 received a Moderna vaccine. 5 patients presented with symptoms after their first dose, 2 after their second dose, and 1 after both doses. The mean time of ocular symptoms post vaccine was 6.15 days (range, 1-14) and the mean BCVA was 0.657.

Patients were diagnosed with bilateral anterior granulomatous uveitis (case 1), unilateral nongranulomatous anterior uveitis (case 2, 6-9), bilateral nongranulomatous anterior uveitis (case 3-4), and episcleritis (case 5). Case 1 and 9 have been highlighted and summarized in figure 1 and 2, respectively.

Conclusions: The pathogenesis of vaccine induced uveitis is not properly understood, however, the outcomes of this case series aids in establishing a temporal association between the Pfizer and Moderna COVID-19 vaccines and the onset of uveitis / episcleritis. As the rate of COVID-19 vaccinations increase globally, it is imperative for physicians to be aware of the possible association and presentation of these ocular findings and diagnoses to effectively treat patients.

TITLE: Rho effector Arp2/3 is involved in myofibroblast transdifferentiation of retinal pigment epithelial cells

SESSION TITLE: RPE/choroid pathology: oxidative stress, inflammation and neovascularization

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Tamiya, G. Jagatheesan, Ophthalmology, The Ohio State University, Columbus, Ohio, UNITED STATES|

Commercial Relationships Disclosure: Shigeo Tamiya: Commercial Relationship: Code N (No Commercial Relationship) | Ganapathy Jagatheesan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Myofibroblast transdifferentiation of retinal pigment epithelial (RPE) cells has been implicated as key event in fibrotic complications such as proliferative vitreoretinopathy or fibrosis associated with exudative age-related macular degeneration. We previously demonstrated that Rho GTPase plays a key role in this process. Interestingly, ROCK, one of the main downstream Rho effector, was not involved in this process. The purpose of this study is to examine the role of Arp2/3, another key downstream Rho effector involved in actin polymerization, in myofibroblast transdifferentiation of RPE cells.

Methods: Primary cultured porcine RPE cells were used for experiments. Second passage RPE cells cultured on collagen hydrogels were stimulated with TGF-beta2 to induce myofibroblast transdifferentiation. Expression of myofibroblast markers, alpha-smooth muscle actin and tropomyosin-1, was examined by western blot analyses. Myofibroblast function was assessed by collagen hydrogel contraction. The cell permeable C3 transferase and CK-666 were used to inhibit Rho and Arp2/3, respectively.

Results: As previously reported, TGF-beta2 stimulation of second passage RPE cells induced myofibroblast transdifferentiation, which was demonstrated by significant increase in expression of myofibroblast marker proteins as well as enhanced contraction of collagen hydrogel. Rho inhibitor and Arp2/3 inhibitor significantly reduced myofibroblast marker expression as well as collagen hydrogel contraction.

Conclusions: Rho and its downstream effector Arp2/3 is involved in myofibroblast transdifferentiation of RPE cells. Actin polymerization is a key process in mechanosignaling that affects multiple downstream signaling molecules. Alteration of Rho-Arp2/3 pathway or its downstream targets may lead to therapeutic treatment of fibrotic complications such as proliferative vitreoretinopathy or fibrotic complications of exudative age-related macular degeneration in which RPE cell transdifferentiation to myofibroblasts play a significant role.

ABSTRACT BODY:

Purpose: Sutured intraocular lens (IOL) fixation is used for fixating IOLs in the absence of capsular support. Various IOLs have been employed in the past for this including CZ70BD (Alcon Laboratories, Inc), Akreos AO60 and, most recently, enVista MX60 and MX60E (Bausch & Lomb, Inc). Some of these IOLs have substantial disadvantages, including fracture of IOL eyelets. The purpose of this study was to determine the maximal tensile strength of the eyelet in a newly FDA approved IOL RayOne RAO600C (Rayner, Inc) and compare it to the other commonly used IOLs.

Methods: We tested Rayner RAO600C and CZ70BD lenses. The IOLs were suspended in a testing platform with the optic held by a clamp and a simple pass GoreTex 8-0 suture passed through an eyelet. Gradually increasing downward force was applied to the GoreTex suture/eyelet by adding weight until the fracture of the eyelet was recorded. The resultant force applied to IOL eyelets was calculated. Statistical analysis to compare the mean tensile strength was completed by the two-tailed Mann Whitney U-test.

Results: The mean eyelet fracture force was 0.2609 N ± 0.0305 N for the CZ70BD (n=4) and 1.002 N ± 0.0878 N for the RAO600C IOL (n=4), which was statistically significantly greater (p=0.02857; Mann Whitney U-test). The absolute mean difference was 0.741 N (95% [0.6252, 0.8947]).

Conclusions: The eyelet-haptic complex of Rayner RAO600C lens endured significantly greater (3.8 times) tensile force than that of the CZ70BD. In a prior similar investigation, CZ70BD fractured at a greater force than we observed, which may be related to differences in experimental set-up. Further, in this prior study, CZ70BD had the same tensile strength when compared to Envista MX60E, and 2.3 times lower tensile strength when compared to Akreos AO60 IOL. Extrapolating those results to our data, RAO600C eyelet-haptic complex is potentially significantly stronger than Envista MX60E and may be as strong as Akreos AO60. It also has advantages of being a foldable IOL and could be passed through a small 2.2mm corneal incision. Overall, our findings suggest that the RAO600C may be a sustainable option for transscleral sutured IOL fixation.

ABSTRACT BODY:

Purpose: To use longitudinal OCT and OCT-Angiography (OCTA) measurements to predict visual field (VF) progression in glaucoma suspect and glaucoma patients with a supervised machine learning approach.

Methods: 110 eyes of glaucoma suspect (33.6%) and glaucoma (66.4%) patients with a minimum of five 24-2 VF tests over an average follow-up duration of 4.1 years were included. Participants were required to have at least three pairs of optic nerve head and macula OCTA images during follow-up. VF progression was defined based on a composite measure including either a “likely progression event” on Guided Progression Analysis, a statistically significant negative slope of VF mean deviation, or a positive pointwise linear regression event. Gradient Boosting Classifier was used to predict the probability of VF progression based on different subsets of baseline and longitudinal OCT and OCTA input features at the global and regional levels. Areas-under-ROC curves (AUROC) were used to compare the classification accuracy of different models.

Results: VF progression was detected in 28 eyes (25.5%). The model that used combined baseline and longitudinal OCT and OCTA features at the global and regional level had the best classification accuracy for the prediction of VF progression (AUROC = 0.89 [95% CI: 0.82, 0.95]). Models including combined OCT and OCTA features had higher classification accuracy compared to those with individual subsets of OCT or OCTA features alone. Moreover, including regional measurements significantly improved the classification accuracy of the models compared to using global measurements alone. The addition of longitudinal rates of change of OCT and OCTA measurements as input features (AUROCs = 0.80-0.89) considerably increased the classification accuracy of the models with baseline measurements alone (AUROCs = 0.60 0.63). (Figure 1, all P-values for pairwise comparisons < 0.05)

Conclusions: Artificial intelligence techniques combining longitudinal OCT and OCTA measurements can predict clinically-relevant glaucomatous VF progression. Longitudinal OCTA measurements complement OCT-derived structural metrics for the prediction of functional VF loss in glaucoma patients.

ABSTRACT BODY:

Purpose: Erucamide, a highly hydrophobic fatty acid amide synthesized by photoreceptors, maintains the structure and function of retinas, but its mechanism of action remains unknown. Here we used multiple biochemical techniques to identify erucamide's target cells, binding proteins, and potential mechanism of neurotrophic action.

Methods: Surface functionalized porous silicon nanoparticles (pSiNPs) were used to efficiently deliver erucamide into the retina. BODIPY-erucamide probes were synthesized to facilitate visualization of erucamide in vivo. Photo affinity labeling proteomics were performed to identify the binding proteins of erucamide. Gene profiling experiments were conducted to elucidate molecular pathways in the target cells.

Results: We used silane-modified pSiNPs to overcome the chanllage of delivering hydrophobic erucamide in vivo. Both intravitreal and subretinal injection of erucamide-pSiNPs resulted in wide-spread activation of GS-Lectin positive cells that were subsequently found to be CD11b+ microglia. BODIPY-labelled erucamide was taken up by CD11b+ cells three days after injection, suggesting that microglia may be directly targeted by erucamide. Angiogenic cytokines like VEGF, PDGFa, FGF, IL-6, TNFa were upregulated after erucamide treatment in both microglia sorted from injected mouse retinas or human iPSC derived microglia. Photo sensitive probes of erucamide were designed, synthesized and used for photo affinity labeling proteomics of the human microglial cell line HMC3. Results from these experiments were used to identify potential binding targets of erucamide. Several novel binding protein candidates were subsequently found to be essential for activation of microglia regulated by erucamide.

Conclusions: We hypothesize that, as a known angiogenic factor itself, erucamide may also work in a paracrine fashion to regulate and maintain a neurotrophic microenvironment in the retina. Microglia can be a direct target of erucamide both in vitro and in vivo. This neurotrophic paracrine activity may be mediated by a number of novel microglial-associated erucamide-binding proteins that are responsible for the activation of, and angiogenic cytokine secretion from, microglia. Modulation of these pathways may represent novel targets for drug discovery in the treatment of neurovasculoglial degenerative retinal diseases.

ABSTRACT BODY:

Purpose: Copy number variants in wild-type rhodopsin (RHO) have been reported as a novel cause of autosomal dominant retinitis pigmentosa (adRP) in a 68-year-old male (first reported in ARVO 2019). The current study focuses on (i) modeling the disease phenotype using 3D retinal organoids (RO), and (ii) attenuating the overexpression of wild-type RHO using Photoregulin3 (PR3), a small molecule inhibitor of upstream regulator NR2E3.

Methods: Induced pluripotent stem cells (iPSCs) reprogrammed (n=3 clones/subject) from the patient with adRP associated with four copies of RHO and an unaffected first-degree relative with two copies of RHO (control) were differentiated into RO. RO collected at various time-points of differentiation days (D) - D120 (rod photoreceptor birth), D200 (early maturation), and D300 (late maturation) were assessed for morphology (Bright-field, Transmission electron microscopy; TEM), RHO expression (quantitative real-time PCR; qRT-PCR, bulk RNA-seq), protein localization and quantification (Immunofluorescence; IF and western blotting; WB). Patient RO of D300-350 was treated with varying doses of PR3 (0.5, 0.25, and 0.1 μM) for one week and assessed for RHO levels and localization (qRT-PCR and IF).

Results: Morphological evaluation of patient-specific iPSC-RO displayed delayed maturation or absence of outer segments (Bright-field/TEM), ~6-10-fold increased RHO expression (qRT-PCR, bulk RNA-seq), impaired localization of Rhodopsin (Rho) protein within the cell body as opposed to being present in the outer segments (IF), and ~4-fold elevated Rho (WB) at all the time points compared to control. PR3-treated patient RO showed a substantial decrease in the RHO mRNA levels (10- to 30-fold) in a dose-dependent manner compared to the vehicle-treated RO, along with a partial rescue in the transport of Rho from cell bodies to the inner and outer segments. All data are represented as Mean±SEM (n=3 independent experiments).

Conclusions: Tight regulation of RHO is essential for rod photoreceptor function and maintenance. This study provides a proof-of-principle for personalized medicine by utilizing (a) patient-specific iPSC to model disease and (b) investigated a small molecule approach as a clinically viable strategy to target and modify the disease progression in patients with adRP associated with RHO-overexpression.

ABSTRACT BODY:

Purpose: To determine the effect of hydroquinone (HQ), an oxidative component of cigarette smoke, on inflammatory markers in porcine corneal endothelial cells, and to find an optimum treatment time and concentration for hydroquinone as a model of smoking-induced oxidative stress in corneal cells.

Methods: Four porcine eyes were harvested. The corneoscleral rim was separated from the rest of the eye and treated with 0.5% trypsin for 15 minutes. Corneal endothelial cells were then scraped from Descemet membrane and plated into one well of a 12 well plate. Cells were proliferated to confluency in a low growth factor medium, then passaged three times onto one well of a 6 well plate, two wells of a 6 well plates, then twelve wells of a 12 well plate for treatment. The treatment groups were as follows: HQ for 1, 2, and 4 hours at 200, 250, and 300 μM (9 wells total), and an untreated control group (3 wells). Total RNA was extracted using the RNEasy Mini Kit and then converted to cDNA using the iScript Reverse Transcription Supermix. Expression of inflammatory markers IL-6, TNF-alpha, and p38, and the reference gene GAPDH, were quantified using real-time quantitative PCR (RT-qPCR). The experiment was repeated to obtain 3 biological replicates per treatment group. The delta-delta Ct method was used to calculate relative gene expression, and statistical tests were calculated using delta Ct values.

Results: Single-factor analysis of variance (ANOVA) revealed a statistically significant effect of HQ on TNF-alpha expression ($p<0.005$) and a marginally significant effect on IL-6 expression ($p<0.10$). No significant effect was observed on p38 expression ($p=0.51$). Pairwise t-tests were then conducted on TNF-alpha and IL-6 expression for each treatment group versus the untreated controls, revealing that for both TNF-alpha and IL-6, increase in expression became significant at treatment time of 2 hours at 250 and 300 μM ($p<0.05$), and at treatment time of 4 hours for 200, 250, and 300 μM ($p<0.05$).

Conclusions: HQ treatment beginning at 2 hours and 250 μM significantly increases expression of the inflammatory markers IL-6 and TNF-alpha, but not p38. Higher treatment times and concentrations should be chosen with caution due to increasing HQ cytotoxicity and low RNA yield. HQ may be useful as a novel smoking-induced oxidative stress model in corneal endothelial cells.

ABSTRACT BODY:

Purpose: Anti-VEGF therapy continues to be the gold standard to minimize the risk of vision loss due to neovascular ocular disease, including wet age-related macular degeneration (AMD) and diabetic macular edema (DME). However, current anti-VEGF biologics require frequent intravitreal (ITV) injections, and poor compliance to redosing protocols has been linked to losses in efficacy over the long-term. To solve this problem, Valitor's multivalent protein (MVP) conjugation technology was designed to enable sustained anti-VEGF therapy after ITV injection, thereby substantially reducing the required treatment frequency. The stability of the MVPs after administration is highly dependent on the anti-VEGF biologic, and thus our goal was to engineer an antibody that can maintain the stability of an MVP in the vitreous humor.

Methods: Using phage-display screening and literature searches, we developed a library of single domain anti-VEGF antibodies (anti-VEGF VHH) with variable peptide linkers to facilitate conjugation. We synthesized MVPs comprising multiple copies (i.e. valency) the VHH antibodies conjugated to soluble, long-chain hyaluronic acid. We initially ranked the unconjugated antibodies and MVPs based on their thermal stability. We further tested top MVP performers in stability studies at ~10X the anticipated clinical ITV concentration in a vitreous mimetic buffer at 37C for up to 9 months. Periodically, we assessed stability based on changes in either VEGF binding affinity or hydrodynamic radius.

Results: Using our library, we identified several anti-VEGF VHH constructs that had high thermal stability, were compatible with our MVP conjugation platform, and were able to confer high stability following conjugation. Further, we identified specific VHH sequence characteristics and peptide linkers that enabled anti-VEGF MVPs to maintain their size and remain highly potent and soluble after more than 6 months at in situ conditions.

Conclusions: Based on our findings, we have developed a consensus sequence for in situ stability comprising key VHH and peptide linker characteristics. We then engineered a novel optimized anti-VEGF VHH that has been incorporated into our anti-VEGF product candidate (VLTR-557) that will enable long-acting treatment of wet AMD. We are currenting scaling the manufacturing of VLTR-557, and we plan to initiate IND-enabling preclinical studies in mid-2022.

ABSTRACT BODY:

Purpose: Diagnostic vitrectomy can provide useful information in cases of intraocular inflammation or opacity in which initial work-up has failed to elucidate an underlying etiologic process. Studies have reported a wide range of diagnostic yields, but few have focused on the impact of results on clinical course/management. We hypothesized that patients in whom diagnostic vitrectomy directly impacts subsequent clinical management will have different visual outcomes than patients in whom it does not. Furthermore, we aimed to provide up-to-date information about the rates of positive infectious, inflammatory, and neoplastic diagnostic vitrectomy results.

Methods: A retrospective chart review of the patients who underwent diagnostic pars plana vitrectomy and vitreous biopsy from January 2015 through April 2021 was performed. Baseline characteristics including presumptive diagnosis was collected from the charts and compared with final pathology reports to assess the role of diagnostic vitrectomy. Visual acuities were recorded immediately pre-operatively, at post-operative months 1, 6, and 12, and at the final visit. Changes in visual acuity relative to pre-op were calculated. The microbiologic and pathologic results of each vitrectomy sample were reviewed, the final post-op diagnosis was recorded and categorized by etiologic subtype, and the patients in whom the results led to significant change in diagnosis and/or clinical management were identified.

Results: A total of 117 eyes of 117 patients (57.3% female, mean (±SD) age 63.2 (±18.7); range 4-93 years) were included in this study. Patient characteristics, follow-up, and procedure gauge are summarized in Table 1. The mean (±SD) pre-vitrectomy logMAR visual acuity was 1.20 (±0.95) and mean (±SD) 1 month post-vitrectomy logMAR visual acuity was 0.97 (±0.93; p=0.046), The mean (±SD) 6 month post-vitrectomy logMAR visual acuity was 0.93 (±0.91; p=0.023). Analysis of vitrectomy results and impact on clinical management is presented in Table 2. In 24.8% of cases, vitrectomy result led to change in clinical management.

Conclusions: Diagnostic vitrectomy results lead to a change in clinical management in a minority of cases. Prognosis for visual outcome in these cases may be poorer, possibly due to more severe conditions being more likely to yield positive results. Neoplastic etiologies tend to be underestimated clinically prior to diagnostic vitrectomy.

ABSTRACT BODY:

Purpose: Inflammation-driven scarring is associated with high rates of surgical failure in trabeculectomies and in minimally invasive glaucoma procedures alike. The current gold standard anti-scarring adjuvant mitomycin C (MMC) has variable effectiveness in controlling fibroproliferation and is associated with significant cytotoxic effects. Acetylsalicylic acid (ASA) is unique among non-steroidal anti-inflammatory drugs, exerting its effects through covalent enzyme modifications. When delivered locally, ASA repurposes the typically pro-inflammatory cyclooxygenase (COX-2) enzyme to resolve inflammation, rather than simply suppressing it. By resolving inflammation, it reduces likelihood of inflammation-mediated fibroproliferation and fibrosis.

The aim of this study is to determine whether ASA decreases inflammatory cytokine-induced scarring activity in human Tenon's capsule fibroblasts (HTCFs) and to compare the effects of ASA to MMC in in vitro model of subconjunctival scarring.

Methods: Glaucoma patient-derived HTCFs in 2D and 3D models were co-treated with inflammatory cytokine TGFβ1 with and without ASA (concentrations ranging 100-1600µg/ml), or MMC (0.05-0.2mg/mL), to assess their effects on HTCF activity via Western Blot, immunofluorescence, MTT, LDH and 3D collagen contraction assays. ASA-triggered lipid mediators were measured using liquid chromatography tandem mass spectrometry (LC-MS/MS).

Results: ASA treatment decreased HTCF-mediated collagen contraction, TGFβ1-induced HTCF metabolic activity, and myofibroblast-associated protein expression, in the absence of cell necrosis. In comparison to MMC, ASA was as effective in reducing markers of inflammation and scarring, while being less cytotoxic.

Within cytokine-activated HTCFs, ASA significantly impaired prostaglandin production and significantly increased secretion of the pro-resolving lipid mediators 5-hydroxyeicosatetraenoic acid (HETE), 15-HETE and 18-hydroxyeicosapentaenoic acid (HEPE).

Conclusions: ASA reduces cytokine-induced myofibroblast transdifferentiation in human Tenon's capsule fibroblasts, being non-inferior to MMC in vitro. ASA's unique effects are associated with unique lipid mediator expression profile. ASA-driven resolution of inflammation may be a promising strategy to mitigate cellular events associated with cytokine-mediated scarring.

ABSTRACT BODY:

Purpose: The 10-2 visual field (VF) provides more information in the center of the VF compared to 24-2. An extension of the HFA guided progression analysis (GPA) adding event (i.e. change from baseline) analysis for 10-2 was recently proposed[1]. In this preliminary, retrospective study, we compare the results of the GPA event analyses in 24-2 and 10-2 VFs.

Methods: A retrospective series of VFs were analyzed from 22 eyes of 11 clinically managed glaucoma subjects with at least 5 visits each with 10-2 and 24-2 (or 30-2) SITA Standard VFs using HFA™ II-i or HFA3 (ZEISS, Dublin, CA). 10-2 and 24-2 VFs were typically alternated between visits. 24-2 VFs were extracted if the 30-2 VF was available. VFs were selected to cover the same follow-up period for the shorter of the 10-2 or 24-2 series. A GPA Alert result of “Possible” or “Likely” Progression was considered a progression event. Cohen’s kappa was used to assess agreement between the proposed 10-2 and reference 24-2 GPA event analyses.

Results: Age at first exam ranged from 32.2 to 74.1 years (see Table 1). Mean 24-2 and 10-2 MD at first exam were -1.16 (standard deviation, SD: 3.00, range: -12.47 to 1.43) dB and -0.88 (SD: 2.87, range: -12.33 to 1.08) dB, respectively. Mean follow-up time for the 24-2 series was 5.3 (SD: 2.8, range: 1.2 to 10.0) years, with a mean inter-visit interval of 0.4 (0.1, range: 0.3 to 0.6) years.Mean follow-up time for the 10-2 series was 5.2 (SD: 2.8, range: 1.4 to 9.9) years, with a mean inter-visit interval of 0.6 (0.3, range: 0.3 to 1.2) years. 21/22 cases (95.5%) were observed to agree, resulting in a kappa of 0.83 (95% CI: 0.51 to 1.00).

Conclusions: In this preliminary study, strong agreement was observed overall between the event analysis results for a proposed 10-2 GPA and a reference 24-2 GPA. This may suggest the potential clinical utility of using change from baseline analyses for 10-2 VFs to highlight progression in the central VF that may or may not be detected in the 24-2 VF. Further work may include more extensive comparisons between 10-2 and 24-2 GPA event analyses in cohorts with clinically confirmed diagnoses of progression or non-progression.

ABSTRACT BODY:

Purpose: Macular Telangiectasia Type 2 (MacTel) is a rare, late-onset, degenerative retinal disease with an extremely heterogenous genetic architecture. MacTel has been linked to metabolic defects including reduced circulating levels of serine and glycine, and increased levels of deoxysphingolipids (dSLs). However, there is likely to be serine/glycine/dSL-independent factors contributing to the onset of MacTel as many patients have normal metabolite levels, and multiple MacTel GWAS loci have been identified that are not clearly linked to serine/glycine/dSL metabolism. Here, we differentiated retinal pigment epithelium from induced pluripotent stem cells (iPSC-RPE) derived from a cohort of MacTel case and control patients with diverse genetic backgrounds to screen for functional defects and identify common cell-intrinsic pathological mechanisms that may drive disease.

Methods: We differentiated iPSC-RPE from 9 MacTel patients and 5 unaffected family members. iPSC-RPE differentiation and functional maturity were validated by cell type specific gene expression and measuring polar secretion of VEGF (apical) and PEDF (basal) over 18 weeks. We measured secreted serine and glycine abundance using mass spectrometry. iPSC-RPE phagocytosis ability was measured by the uptake of fluorescently conjugated porcine outer segments (POS). RNAseq and subsequent GSEA pathway analysis were performed as an untargeted screen to identify common defects. Lastly, we measured oxygen consumption rate (OCR) and mitochondrial function using the mitochondrial stress test with a Seahorse Analyzer.

Results: We observed that MacTel iPSC-RPE had elevated expression of enzymes in the serine synthesis pathway, and reduced levels of serine (21%) and glycine (15%) secretion indicating a defect in serine and glycine metabolism. Phagocytosis of POS and secretion of VEGF and PEDF were comparable between MacTel and control iPSC-RPE. GSEA pathway analysis of RNAseq differential expression identified an enrichment of cellular stress pathways (for example hypoxia, NFKB, Complement) and dysregulation of central carbon metabolism in MacTel iPSC-RPE. Lastly, MacTel iPSC-RPE showed a significant reduction in basal OCR (17%) and maximal OCR output (24%).

Conclusions: We provide a comprehensive analysis of MacTel patient-derived RPE to both validate iPSC-RPE as a model for cellular pathologies linked to MacTel, and discover new disease-associated metabolic phenotypes.

ABSTRACT BODY:

Purpose: Schizophrenia is a neurodegenerative disorder that poses a significant burden on society. Optical coherence tomography (OCT) has shown pathology in the retina of patients, mainly retinal nerve fiber layer and ganglion cell layer thinning, but the neurobiological bases of these changes are unknown. One possible source may be vascular abnormalities that have contributed to these changes. The purpose of this study was to use OCT-angiography (OCTA) to analyze macular vessel density (VD), vessel skeleton density (VSD), foveal avascular zone (FAZ) size and acircularity in subjects with Schizophrenia Spectrum Disorder (SSD) and controls to establish whether SSD is associated with macular vascular changes.

Methods: We recruited 50 SSD patients (mean ± SD age: 35.3 ± 11.2 years) and 39 age-matched controls (mean ± SD age: 35.8 ± 13.5 years). We obtained 3x3-mm OCTA images centered on the fovea at three depths: whole retina, superficial capillary plexus (SCP), and deep capillary plexus (DCP). Image analysis was conducted using ImageJ software. To analyze VD and VSD, images were binarized with the local Phansalkar method, then the Early Treatment of Diabetic Retinopathy Study (ETDRS) grid was overlaid to allow regional analysis in superior, nasal, inferior, and temporal quadrants (figure 1). We measured FAZ size and acircularity using whole retina images. IBM SPSS software with a General Estimating Equation was used for statistical analysis.

Results: The mean VD for the whole retina for the SSD group was 50.8 ± 3.0 and for the control group was 51.0 ± 2.5 ($p=0.717$). There was also a non-significant difference in VD between SSD and control groups in SCP ($p=0.523$) and DCP ($p=0.980$) as well as in all quadrants individually. The mean VSD for the whole retina for the SSD group was 9.0 ± 0.6 and for the control group was 9.0 ± 0.5 ($p=0.790$). There was also a non-significant difference in VSD between SSD and control groups in SCP ($p=0.647$) and DCP ($p=0.711$) as well as in all quadrants individually. No significant difference was found between groups in FAZ size ($p=0.381$) or acircularity ($p=0.178$).

Conclusions: Our results suggest that macular vascular structures as measured by VD, VSD, FAZ size and acircularity appeared similar in SSD patients compared with age-matched controls. Other potential causes for the retinal neural tissue changes previously found in SSD should be investigated.

TITLE: Impact of Type 2 Diabetes Mellitus and Insulin Use on Progression to Glaucoma Surgery in Primary Open Angle Glaucoma

SESSION TITLE: Glaucoma epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.T. Sun, S. Pershing, J.L. Goldberg, S. Wang, Spencer Center for Vision Research, Byers Eye Institute, Stanford University, California, UNITED STATES|

Commercial Relationships Disclosure: Michelle Sun: Commercial Relationship: Code N (No Commercial Relationship) | Suzann Pershing: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Goldberg: Commercial Relationship: Code N (No Commercial Relationship) | Sophia Wang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The complex interaction between diabetes, hyperglycemia, insulin treatment and glaucoma remains incompletely understood, and is particularly relevant given insulin has recently emerged as a potential therapeutic target in glaucomatous degeneration. We aimed to investigate outcomes of primary open-angle glaucoma (POAG) patients with and without type 2 diabetes mellitus (T2DM) on either oral hypoglycemic agents or insulin.

Methods: Retrospective observational study using U.S nationwide healthcare insurance claims database. Patients aged ≥40 years old with a diagnosis of POAG were included. A diagnosis of T2DM and use of either oral hypoglycemic agents or insulin therapy were the primary predictors. The main outcome measure was time to first glaucoma surgery. Multivariable Cox proportional hazards regression models evaluated factors associated with POAG progression requiring surgery. Insulin use was analyzed as a time-varying co-variate with the date of first fill considered the start date.

Results: A total of 829,562 POAG patients were included for analysis, of which 212,164 (25.6%) had T2DM. Mean age was 68.7 years (SD 10.7) and 57% were female. There were 211,055 patients taking oral hypoglycemic agents, while 82,413 were on insulin. While T2DM was a significant predictor of progression to glaucoma surgery in univariate analyses (HR 3.50, 95%CI 3.43-3.57, $p<0.001$), this was no longer significant once adjusted for HbA1c, demographic (age, gender, socioeconomic status, race) and glaucoma factors (severity, baseline medications, previous laser trabeculoplasty). When evaluating only POAG patients with T2DM, compared to patients only taking oral hypoglycemic agents, we found that insulin use was associated with a 1.11 higher hazard of requiring glaucoma surgery (95%CI 1.07-1.15, $p<0.001$), and remained an independent predictor in multivariate analyses after adjusting for confounders (HR 1.08, 95%CI 1.04-1.13, $p<0.001$).

Conclusions: Insulin use amongst POAG patients with T2DM may be associated with a higher rate of progression requiring glaucoma surgery. Additional studies are required to better characterize this relationship.

ABSTRACT BODY:

Purpose: In this case series, we aim to report long term follow up data of novel retinopathy associated with pediatric retinal vasculitis.

Methods: Pediatric patients diagnosed with retinal vasculitis at a tertiary uveitis clinic were reviewed between January 2020 and December 2021.Eyes with novel retinopathy were included if follow-up period was more than 12 months.The retinopathy was characterized by three findings: dark retinal areas on Optos wide angle fundus photography (WAFP) with corresponding hypoautofluorescence and ellipsoid zone disruption on optical coherence tomography (Figure).

Retinal vasculitis was graded using fluorescein angiography (FA) per the Angiography Scoring for Uveitis Working Group score.Lesion area was calculated using Image-J.Full field electroretinogram (ffERG) was also performed.Demographic and clinical data including lesion area and FA severity score were collected at 3 time points: baseline, within 2 months from ffERG and at last follow-up visits.

Results: 17 pediatric patients (27 eyes) with retinal vasculitis and novel retinopathy were included. Mean age was 12.7±3.4 years and 35 % were female.Mean follow up duration was 29.4±12.1 months.FA scores decreased from 8±5.04 at baseline to 2.1 ± 2.1 at the last follow up visit (P<0.001). 30% of eyes did not show any disease activity at the last follow-up visit.

The retinopathy persisted in all eyes at the last follow-up visit.However, mean lesion area significantly decreased from 407.6±239.5 mm2 at baseline to 378.4±222.6 mm2 at last follow-up visit (P=0.04).FA scores at baseline were significantly correlated with lesion areas at both baseline (P=0.01) and last follow-up visit (P=0.01).However, FA scores at the last follow-up visit did not correlate with the lesion areas (P=0.9).

ffERG was performed in 19 eyes.Lesion areas, at the time of ffERG, were negatively correlated with amplitudes of scotopic rod b wave (P=0.03), mixed a wave (P=0.05), mixed b wave (P=0.001), cone b wave (P=0.05), and 32 Hz flicker (P=0.006).Delayed 32 Hz flicker timing was also correlated with lesion areas (P=0.009).

Conclusions: Pediatric retinal vasculitis is associated with a novel retinopathy whose area is correlated with decreased retinal function and higher initial disease activity.The retinopathy can persist even after resolution of inflammation.

ABSTRACT BODY:

Purpose: Maternal medical comorbidities and pregnancy complications have been previously studied as risk factors for retinopathy of prematurity (ROP). The relationship between maternal sociodemographic characteristics and ROP risk remains unclear. Therefore, the purpose of this retrospective cohort study was to include maternal sociodemographic data with variables that have been previously found to be significant in assessing an infant's risk for ROP.

Methods: We analyzed data from preterm infants born at a single institution who were referred for ROP screening between 2011 and 2021. Demographic and clinical data for each infant and mother were collected via review of the electronic medical record. Collected maternal data included age at delivery, insurance type, medical comorbidities, pregnancy complications, and smoking status in pregnancy. Self-reported race/ethnicity was recorded and included: Hispanic, black, white, Asian, and other. Collected infant data included gestational age (GA) and comorbidities. The primary outcome measure was the presence of any-stage ROP in either eye. The presence of ROP requiring treatment (type 1 ROP) was examined as a secondary outcome measure. Univariate and multivariate logistic regression models were used to evaluate each predictor for potential association with ROP.

Results: Of 324 preterm infants, 99 (30.6%) developed any-stage ROP and 33 developed treatment-requiring ROP (10.2%). The mean gestational age (GA) for the cohort was 28.8 weeks (range 22-38 weeks). Variables independently associated with increased risk of any-stage ROP included public insurance coverage (OR 7.3; 95% CI 2.6-20.8; $p<0.001$) and maternal smoking during pregnancy (OR 12.3; 95% CI 2.4-62.0; $p=0.002$). Maternal Hispanic ethnicity demonstrated an independent association with treatment-requiring ROP (OR 4.6; 95% CI 1.07-20.0; $p = 0.040$).

Conclusions: We observed a higher risk of treatment-requiring ROP for infants born to Hispanic mothers. In addition, public insurance coverage and maternal smoking during pregnancy were found to be independent modifiable risk factors for developing any-stage ROP. These findings suggest that both maternal comorbidities and sociodemographic factors may independently contribute to ROP risk. Future studies which examine additional socioeconomic determinants should be considered to identify other sources of health inequities and guide intervention efforts.

ABSTRACT BODY:

Purpose: Uncorrected refractive error (URE) is the most common cause of visual impairment in youth. We aimed to identify barriers to wearing eyeglasses among a contemporary sample of U.S. youth.
Methods: A five question, open-ended poll about experiences with eye problems, refractive correction, and reasons youth do not wear eyeglasses if they need them was distributed to the MyVoice Text Message Cohort of U.S. youth aged 14–24 years (www.hearmyvoicenow.org). Respondent demographics were analyzed. Low socioeconomic status (SES) was defined as receiving free or reduced-price lunch. Text message responses were coded using a modified grounded theory approach.
Results: Out of 1204 recipients, 88.3% (n=1063) responded. Mean age was 20.3 ±2.4 years (range 15-24 years); 58.8% (n=625) were male; 74.0% (n=787) were white; and 41.4% (n=440) had low SES. Many (65.8%; n=699) had experienced trouble with their eyesight, including need for eyeglasses or contacts (63.6%; n=676) or medical eye problems (14.9%; n=158). Some youth (2.4%; n=21) reported vision problems consistent with URE that impacted daily life, e.g. "I've been having blurry vision and not seeing clearly for a while now and I'm worried since I'm driving." Some (14.2%; n=96) had discontinued eyeglasses or contacts, often because youth felt they no longer needed refractive correction (51.0%; n=49; e.g. "I stopped because my eyesight got better"), they were a hassle (14.6%; n=14; e.g. "I no longer use them because they need a lot of care and that annoys me"), or they were lost, broken, or expired (14.6%; n=14; e.g. "I don't wear them anymore because I had broken them about 5-6 years ago"). Concerns over appearance (52.0%; n=553; e.g. "they look dorky") and cost (16.1%; n=171; e.g. "the cost of glasses can be expensive especially without insurance") were the most common reasons youth might not wear eyeglasses if they needed them.
Conclusions: Major barriers to correcting refractive error among U.S. youth include cosmesis and cost. Future work should focus on making eyeglasses and contact lenses that are not only appealing, but also affordable for U.S. youth.

TITLE: Regulatable complement inhibition of the alternative pathway mitigates age-related macular degeneration pathology

SESSION TITLE: Pathobiology of AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Parsons, B. Rohrer, Ophthalmology, Medical University of South Carolina, Charleston, South Carolina, UNITED STATES|B. Rohrer, Research Services, VA Medical Center Ralph H Johnson, Charleston, South Carolina, UNITED STATES|

Commercial Relationships Disclosure: Nathaniel Parsons: Commercial Relationship: Code N (No Commercial Relationship) | Baerbel Rohrer: Commercial Relationship(s);Code P (Patent):US 14/043,317

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) occurs after age 65. AMD has two forms, dry (atrophic) and wet (angiogenic). AMD is a multifactorial disease; risk factors include aging, smoking, and complement dysregulation. The amplification loop of the complement alternative pathway (AP) is responsible for the majority of complement activation on cell surfaces and extracellular membranes in animal models of this disease. The AP is inhibited naturally by circulating complement protein factor H (fH). Complement component C3 (C3) protein increases and decreases respective to complement activation. In wet AMD, complement effector molecules increase angiogenesis, activate microglia and recruit immune cells, amplifying the complement-microglia inflammatory feedback loop, leading to tissue damage.

Methods: The C3 promoter (−1005 to +251), pC3, was cloned into a pTR backbone and plasmids (pC3-mCherry/CR2-fH) were synthesized and utilized to generate adeno-associated virus serotype 5 (AAV5) vectors. pC3 activation was determined in transiently transfected ARPE19 cells stimulated with H_2O_2 and normal human serum (+/- TT30 or NAC). Laser-induced choroidal neovascularization (CNV) was analyzed in mice treated with AAV5-pC3-mCherry/CR2-fH, using imaging (optical coherence tomography), functional (electroretinography, ERG), molecular (western blotting, complement activation) and histologic (microglia activation and migration) readouts.

Results: Proof of concept was provided that pC3 is modulated in a complement and oxidative stress-dependent manner in human ARPE19 cells, examining mCherry fluorescence. Safe concentrations of AAV5-pC3-CR2-fH, when injected subretinally, were identified using ERG and OCT (10^{10} - 10^{11} vg/mL). The expression of CR2-fH significantly reduced CNV in a dose dependent manner, with a maximum reduction of lesion size of ~35% when compared to mCherry-treated animals. CR2-fH expression reduced CNV-associated ocular C3 activation as assessed by western-blotting for the C3a breakdown products C3d/C3dg. We expect to document a reduction in microglia migration into the subretinal space.

Conclusions: Here we demonstrated that regulating AP inhibition in a complement-dependent manner can ameliorate pathology, and hypothesize this effect to be due, in part, by reducing microglial activation and the proinflammatory microenvironment.

ABSTRACT BODY:

Purpose: Reducing the treatment burden currently required for optimal management of high-prevalence retinal exudative and vascular diseases is a key focus of next-generation therapeutics development. KSI-301 is an antibody biopolymer conjugate designed to provide potent and long-lasting intraocular vascular endothelial growth factor (VEGF) suppression. Early clinical studies in treatment-naïve patients showed strong efficacy with clinical durability of up to 6-months in patients with wet age-related macular degeneration (wAMD) with an encouraging safety profile. The objective of the pivotal DAZZLE study is to demonstrate that KSI-301 is non-inferior to aflibercept while providing a clinically meaningful reduction in intravitreal injection burden.

Methods: In this prospective, double-masked, multicenter, pivotal clinical trial, treatment-naïve patients with wAMD were randomized 1:1 into two treatment arms: KSI-301 (5 mg) or aflibercept (2 mg). Each subject was scheduled to receive three monthly loading doses of their assigned treatment. Thereafter, subjects in the aflibercept arm continued on every-other-month dosing. The dosing regimen for the KSI-301 treatment arm was every 3 to 5 months based on protocol-specified disease activity assessments. The primary efficacy endpoint was the mean change from baseline in best corrected visual acuity (BCVA) at Year 1 (Figure 1).

Results: 557 subjects across 69 sites in the United States and Europe were randomized and received study treatment. The mean age at randomization was 76.4 years and 62.1% were female. At baseline, mean BCVA was 63.6 ETDRS letters with 44% of patients having a Snellen equivalent of 20/40 or better; mean baseline central subfield thickness (CST) was 354.9 um. The primary efficacy, durability and safety results of this pivotal clinical study will be presented for the first time at the meeting.

Conclusions: Treatment outcomes with currently available anti-VEGF therapies are dependent on a treatment frequency that is challenging to sustain or inaccessible in real-world clinical settings. The DAZZLE study's efficacy, durability and safety results will provide important confirmatory evidence on the potential role for KSI-301 as a more durable anti-VEGF treatment option for patients with wet AMD.

ABSTRACT BODY:

Purpose: Diabetic retinopathy remains a major cause of vision loss worldwide. MR pathway overactivation has been recognized in the pathogenesis of diabetic nephropathy and retinopathy. We previously showed that MR antagonism reduced retinal inflammation and edema in a rat model of type 2 diabetes. We aimed to decipher the role of vascular MR in diabetic retinopathy.

Methods: Diabetes was induced by streptozotocin (STZ) in mice with MR invalidation specifically in vascular endothelial cells (Tie2-MR-KO) or in smooth muscle cells/pericytes (SMA-MR-KO). Electroretinography was performed 2 months after STZ injection. The neuroretina was used for transcriptomic analysis. Human vascular smooth muscle cells (VSMCs) were cultured in high glucose media and treated with aldosterone alone or associated with MR antagonist to validate the MR-regulated genes in diabetic condition.

Results: We observed impairment of scotopic and photopic ERG in diabetic wild-type mice that was improved in SMA-MR-KO mice but not in Tie2-MR-KO mice. Transcriptomic analysis identified a gene encoding stanniocalcin-1 (STC1), a neuroprotective glycoprotein expressed in the smooth muscle cells. Indeed, the expression of Stc1 was significantly downregulated in the retina of diabetic wild-type mice but upregulated in the retina of diabetic SMA-MR-KO mice. In human VSMCs cultured with high glucose, aldosterone downregulated the STC1 and MR antagonist inhibited the aldosterone-induced STC1 decrease.

Conclusions: Vascular smooth muscle/pericyte MR may contribute to the neuropathy in the diabetic retina through regulation of STC1. This hypothesis will be further investigated by the injection of recombinant STC1 in wild-type mice and/or siRNA in SMA-MR-KO mice.

ABSTRACT BODY:

Purpose: Recently, prenatal multivitamins with added lutein (L) and zeaxanthin (Z) have been introduced into the American market with claims of improving maternal and infants' health. Although these claims are physiologically plausible, no evidence exists to support them. Hence, we conducted a prospective controlled trial (NCT03750968; still ongoing) to determine whether prenatal carotenoid supplementation counteracts maternal carotenoid depletion, particularly in the third trimester, and if it can enhance maternal and infants' systemic and ocular carotenoid status.

Methods: In this trial, 47 participants were randomized 1:1 to receive standard-of-care daily prenatal vitamins with or without 10 mg of L and 2 mg of Z for 6 to 8 months. The primary outcome was maternal carotenoid status in the serum, skin, and eye measured at the end of each trimester and postpartum with HPLC, resonance Raman spectroscopy, and dual-wavelength autofluorescence, respectively. The secondary outcome assessed infants' carotenoid levels in the umbilical cord blood, skin, and eyes using similar techniques as above but optimized for infants. Linear regression analysis was used to explore the association between maternal and infants' carotenoid status. A p-value of 0.05 was considered statistically significant.

Results: Participants' mean (±SD) age was 29.7 (±3.7) years. Masked study analysis of all subjects shows a significant increase in maternal serum L+Z, skin carotenoids, and macular pigment optical density and volume at 9^{o} eccentricity (MPOV9^{o}) from the first trimester, a peak at the third trimester, and a decline postpartum. Postpartum maternal serum L+Z levels are significantly associated with umbilical cord blood L+Z levels ($r=0.83$, $p<0.001$) and infants' skin carotenoids ($r=0.66$, $p<0.001$). There was a statistically significant positive correlation between postpartum maternal MPOV9^{o} and cord blood L+Z levels ($r=0.52$, $p=0.003$) and infants' skin carotenoids ($r=0.48$, $p=0.007$).

Conclusions: Unmasked study results will be available in early February 2022, and we will then know whether prenatal carotenoid supplementation prevents maternal carotenoid depletion and enhances infants' foveal development. Our findings may serve as a basis for future large-scale research in normal and high-risk pregnancies and could guide policy decisions about prenatal carotenoid recommendations.

SUBMITTER (NAME ONLY): Irina Saltykova

TITLE: GADD34 does not affect the translational rate in P23H RHO mouse retina

SESSION TITLE: Animal models of human ocular disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: I. Saltykova, A. Zhylkibayev, M.S. Gorbatyuk, University of Alabama at Birmingham, Alabama, UNITED STATES|

Commercial Relationships Disclosure: Irina Saltykova: Commercial Relationship: Code N (No Commercial Relationship) | Assylbek Zhylkibayev: Commercial Relationship: Code N (No Commercial Relationship) | Marina Gorbatyuk: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: P23H Rho mice, mimicking retinitis pigmentosa in humans, manifest chronic unfolded protein response activation during retinal degeneration (RD). GADD34, the UPR mediator and protein phosphatase 1 catalytic subunit, permits protein synthesis through dephosphorylation of eukaryotic initiation factor 2a (eIF2α) in cells. We hypothesized that further upregulation of phosphorylated (p) eIF2α modulates the rate of protein synthesis and affects vision loss in mice with RD.

Methods: C57BL/6, P23H Rho, and P23H Rho GADD34$^{-/-}$ mice were used in this study. Mouse retinas were collected on postnatal (p) day 30 to study protein and RNA expression by western blot and RT-PCR analyses. Retinal function was assessed using electroretinography. The SUnSET method was applied for the in vivo assay of protein synthesis. Apoptotic cells were assessed via TUNEL staining of P22 retinas. Lipopolysaccharide (LPS; 10 mg/kg of body weight) was injected intraperitoneally into mice to induce a pro-inflammatory response at P30.

Results: The P23H Rho mice demonstrated a decrease in protein synthesis associated with sustained phosphorylation of eukaryotic initiation factor 2a (p-eIF2a) compared to the C57BL/6 mice. Knocking out GADD34 resulted in further elevation of p-eIF2α in the degenerating retinas. Surprisingly, this elevation was not associated with a more pronounced decline in the rate of translation or restoration of the p-mTOR axis in P23H Rho GADD34$^{-/-}$ mice. Moreover, sustained upregulation of p-eIF2α was associated with a 30% decline in the a-wave amplitude of the scotopic ERG, while the b-wave was not affected. The ERG recordings were supported by a 50% increase in apoptotic cells in the P23H Rho GADD34$^{-/-}$ retinas compared to the P23H Rho retinas. Because GADD34 controls the expression of inflammatory cytokines in immune cells, we further analyzed IL6 and Tnfa gene expression in the retinas of LPS-treated mice. We found that a 4-fold reduction in Il-6 and a 2.7-fold upregulation in Tnfa expression in P23H Rho GADD34$^{-/-}$retinas.

Conclusions: Our results indicate that GADD34 deficiency does not affect the rate of protein synthesis during chronic ER stress, suggesting that p-eIF2α is not the major point of translational control in progressive RD. GADD34 may control the inflammatory response of P23H Rho retinas, and its deficiency may alter pro- and anti-inflammatory cytokine ratios, thus resulting in compromised photoreceptor homeostasis.

Boye, Department of Ophthalmology, University of Florida College of Medicine, Gainesville, Florida, UNITED STATES|V. Ramamurthy, Department of Ophthalmology and Visual Sciences, West Virginia University, Morgantown, West Virginia, UNITED STATES|

Commercial Relationships Disclosure: Urikhan Sanzhaeva: Commercial Relationship: Code N (No Commercial Relationship) | Shannon Boye: Commercial Relationship: Code N (No Commercial Relationship) | Visvanathan Ramamurthy: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Microtubules, polymers of αβ-tubulin heterodimers, are essential for cell division, intracellular protein trafficking, ciliogenesis, and ciliary function. Recent studies showed a link between autosomal dominant missense mutations in β4B-tubulin isotype (TUBB4B) and Leber congenital amaurosis (LCA) and severe hearing loss. However, the mechanism underlying the diseases caused by TUBB4B mutations and the role of β4B-tubulin in photoreceptor cells remains to be elucidated and is the focus of this study.

Methods: CRISPR-Cas9 generated Tubb4b knockout (KO) and Tubb4b R391H or R391C knockin (KI) murine models were utilized to understand the importance of β4B-tubulin in photoreceptors and the mechanisms behind LCA. Protein and mRNA levels were measured by quantitative immunoblotting and reverse transcription PCR. Electroretinography was performed to measure the response of photoreceptors to light stimuli. Immunofluorescence analysis was used to assess the morphology of the retina. All experiments were performed with wild-type littermates as controls. A two-tailed Student's t-test was used for statistical analysis.

Results: Photoreceptor function and the morphology of the retina were not affected in mice lacking β4B-tubulin, suggesting that other β-tubulin isotypes may compensate for the loss of this particular tubulin isotype in the retina. Indeed, β6-tubulin transcripts and protein levels were upregulated in the Tubb4b$^{-/-}$ retina. Intriguingly, Tubb4b KI mice did not recapitulate patient phenotype as photoreceptor function was normal in these animals. Analysis of published single-cell RNA sequencing of the human and murine retina revealed a species-specific difference in β4B-tubulin expression in photoreceptor cells. Indeed, β4B-tubulin was localized to photoreceptors only in non-human primate retina, while in the mouse retina, it was expressed throughout the retina and localized to photoreceptors and downstream neurons.

Conclusions: This study shows that the β4B-tubulin is not essential for photoreceptor development and maintenance in mice. We found that β6-tubulin transcript and protein levels were upregulated in the absence of β4B-isotype, suggesting functional compensation by β6-tubulin. We demonstrated that the β4B-tubulin is differentially expressed in the mouse and non-human retina. Altogether, our findings indicate that the Tubb4b mice model may not be suitable for investigating mechanisms behind LCA linked to TUBB4B mutations.

TITLE: Intraocular Pressure Response of Selective Laser Trabeculoplasty in Phakic and Pseudophakic patients in an Urban City Academic Glaucoma Practice

SESSION TITLE: IOP and laser therapy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Mishra, J. Dossantos, S. Lesche, A. Ahmed, D. Belyea, The George Washington University School of Medicine and Health Sciences, Washington, District of Columbia, UNITED STATES|

Commercial Relationships Disclosure: Shelly Mishra: Commercial Relationship: Code N (No Commercial Relationship) | Jason Dossantos: Commercial Relationship: Code N (No Commercial Relationship) | Stephen Lesche: Commercial Relationship: Code N (No Commercial Relationship) | Aseef Ahmed: Commercial Relationship: Code N (No Commercial Relationship) | David Belyea: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Selective laser trabeculoplasty (SLT) is a procedure used as a therapy option in glaucoma to lower intraocular pressure (IOP). Currently, there is limited data on statistically significant IOP effects of SLT in pseudophakic eyes vs phakic eyes.1,2,3 This study investigates the postoperative change in IOP in phakic vs pseudophakic eyes with glaucoma.

Methods: This is a retrospective observational study on patients who visited George Washington University Department of Ophthalmology from January 1, 2015 to January 1, 2019 with primary open-angle, pseudoexfoliation, pigmentary, or normal-tension glaucoma and received 360 degrees SLT. Patients were excluded if they had laser or glaucoma surgery either 6 months prior to or 12 months following SLT, other glaucoma types, or used steroids. Demographics were collected and the pre- vs post-SLT IOP were analyzed using Wilcoxon signed rank test.

Results: 160 patients (N=103 African American, 64%, N=37 Caucasian, 23%, N=7 Asian, 4%, N=6 Hispanic or Latino, 4%, N=6 Other, 4%) were included in this study. Mean IOPs for phakic and pseudophakic eyes were collected at baseline, 6-week, 6-month, and 12-month visits (Table 1). P-values comparing interval mean IOP points to the baseline IOP and were found to be significant ($P<0.05$) for phakic and pseudophakic groups. P-values comparing mean IOP between phakic and pseudophakic eyes at baseline, 6-week, 6-month, and 12-month are listed in Table 1.

Conclusions: Our study not only includes a larger study group of 160 patients, but also a novel analysis of a diverse demographic population (64% African American) compared to other studies with an average of 50 participants and exclusively focused on Caucasian populations. Previous history of cataract surgery does not negatively impact decrease in mean IOP 6 weeks, 6 months, and 12 months post-SLT. However, our results are consistent with previous studies in showing no significant IOP reduction between phakic and pseudophakic eyes post-SLT. Further investigation with a diverse population is required to comprehensively understand the correlation between pseudophakia and IOP reduction post-SLT.

ABSTRACT BODY:

Purpose: Reactive optic nerve astrocytes protect retinal ganglion cell (RGC) survival and visual function in glaucoma and traumatic optic neuropathy. To better understand the molecular mechanism of astrocyte-mediated neuroprotection, we conducted gene expression profiling of the optic nerve head and identified Secreted Phosphoprotein 1 (SPP1, also called osteopontin) as one of the leading candidate genes. Here, we directly test the hypothesis that SPP1 acts as a neuroprotective factor that promotes RGC survival, and improves visual function in glaucoma and traumatic optic nerve injury.

Methods: We generated a new transgenic mouse line that combines GFP expression from the endogenous Spp1 locus with the incorporation of loxP sites for conditional deletion of the Spp1 gene and activation of red fluorescent protein after cre recombination. This strain was crossed to B6.GFAP-cre mice to generate an astrocyte-specific Spp1 knock out. Using the microbead model of glaucoma and optic nerve crush, we tested how RGC numbers and visual function (pattern ERG, visual acuity) were affected by astrocyte-specific knock-out of Spp1. Immunohistochemistry, qPCR, and RNA-sequencing were used to identify signaling pathways and molecular mechanisms of neuroprotection. Mitochondrial respiration was measured in cultured astrocytes using a Seahorse metabolic analyzer.

Results: SPP1 expression was increased in optic nerve astrocytes in glaucoma and optic nerve traumatic injury and was driven by the TGF-β1/Runx1/E2f1 signaling pathway. Conditional knock-out of Spp1 in astrocytes led to more pronounced RGC loss and visual impairment in glaucoma and optic nerve traumatic injury. RNA-sequencing showed that in $Spp^{-/-}$ astrocytes genes associated with neuroinflammation were up-regulated, whereas neurotrophic factors, genes associated with phagocytic activity, synaptogenesis, and especially oxidative phosphorylation were down-regulated. Conversely, exogenous SPP1 strongly induced VDAC1 expression and promoted oxidative phosphorylation in astrocytes.

Conclusions: SPP1induces a neuroprotective state in astrocytes, promotes mitochondrial function and VDAC1 expression, and protects RGCs and vision function in glaucoma.

ABSTRACT BODY:

Purpose: In darkness, there is a current that circulates through the rod; Na^{+}along with some Ca^{2+}enters the outer segment through cyclic-nucleotide-gated (CNG) ion channels and K^{+}exits the inner segment through voltage gated ion channels. Photon stimulation hydrolyzes cGMP, closes CNG channels and suppresses the circulating current. By stimulating rod outer segment guanylate cyclase (ROS-GC) to synthesize cGMP at a faster rate in a Ca^{2+}-dependent fashion. bicarbonate has been shown to affect the circulating current in darkness as well as the photon response amplitude and kinetics in amphibian rods. Here, we wanted to see how bicarbonate impacts the physiology of murine rods, which are considerably smaller in size, operate at higher temperature and generate faster photon responses.

Methods: The ex vivo electroretinogram (ERG) was recorded from retinas of mice deficient in cone transducin, in order to isolate the rod response to photic stimulation. Retina were perfused with Ames solution containing either 20μM bicarbonate or equimolar Cl^{-}in place of bicarbonate. 50μM DL-AP4 and 100μM BaCl2 were added to block post-photoreceptoral and glial responses, respectively. Solutions were maintained at 35°C and bubbled with 95% O2/5% CO2. Retinas were stimulated with 20ms flashes at 500nm and with 10s steps at 540nm through various neutral density filters.

Results: Murine rods responded reversibly to bicarbonate with an increased in circulating current by 1.4-fold(n=7). The integration time of dim flash response decreased by 1.3-fold(n=6) indicating faster flash response recovery. Sensitivity to flashes were reduced by 1.7-folds(n=3).

The time in saturation, measured from midflash to 20% recovery of circulating current, were lower for bicarbonate experiments. Flash almost 2-fold brighter was required to hold rods in saturation.

Bicarbonate decreased the step sensitivity of rods by 1.4-fold (for 540nm light), this is attributed to 1.3-fold lower integration time of dim flash response.

Conclusions: In contrast to 20μM bicarbonate used here, previously observed in amphibian rods, bicarbonate at 50mM increased circulating current by 17± 3% with similar dim flash response as in murine rods. Amphibian's sensitivity to flashes was reduced by 52± 10%, while that of murine rods reduced by 7± 0.5% (n=3).

TITLE: Effects of Socioeconomic Deprivation on Visual Acuity in Diabetic Vitreous Hemorrhage

SESSION TITLE: Diabetic retinopathy epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Zeng, Boston University School of Medicine, Boston, Massachusetts, UNITED STATES|N.H. Siegel, M.L. Subramanian, S. Ness, X. Chen, Ophthalmology, Boston Medical Center, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Ke Zeng: Commercial Relationship: Code N (No Commercial Relationship) | Nicole Siegel: Commercial Relationship: Code N (No Commercial Relationship) | Manju Subramanian: Commercial Relationship: Code N (No Commercial Relationship) | Steven Ness: Commercial Relationship: Code N (No Commercial Relationship) | Xuejing Chen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Socioeconomic deprivation is associated with earlier and increased prevalence of diabetic retinopathy. We conducted a retrospective clinical case study to investigate how socioeconomic deprivation affects visual acuity (VA) outcomes in vitreous hemorrhage (VH) secondary to proliferative diabetic retinopathy (PDR).

Methods: This is a retrospective analysis of eyes with PDR presenting with acute VH at a safety-net academic medical center between May 1, 2015 and December 31, 2019. Subject addresses were used to calculate the Massachusetts Area Deprivation Index (ADI), from 1 to 10 with 10 being the most disadvantaged. Two-tailed Welch two-sample t-tests determined differences between low (1-5) and high (6-10) ADI groups. One-way ANOVA was used for measurements involving visual acuity (VA) due to non-normal distributions. The primary outcomes were mean VA, change in VA, and appointment frequency. Subgroup analysis was conducted for different endpoints, including resolution without surgery, progression to surgery, and unresolved cases such as those lost to follow-up. A secondary outcome included time to surgery.

Results: A total of 183 patients were included. The groups of low (n = 86) and high ADI (n = 97) had the same age of presentation (59.2) and similar VA (LogMAR 1.36 v. 1.32). Overall change in VA from presentation to endpoint (resolution without surgery, surgery, or unresolved) was LogMAR -0.53 in the low ADI group versus -0.58 in the high ADI group (△0.05, 95CI -0.20 to 0.30, P=0.68). Low ADI group averaged 5.56 appointments compared to 5.01 in the high ADI group (△0.55, 95CI -0.34 to 1.44, P=0.23). Examining study endpoints, 31.4% achieved resolution without surgery in the low ADI group (vs 21.7% high ADI, P=0.14) and 26.7% in the low ADI group were lost to follow-up or remained unresolved (vs 35.6% high ADI, P=0.23). Among those who progressed to surgery, the low ADI group averaged 7.78 weeks compared to 9.75 weeks in the high ADI group (△-1.98, 95CI -7.36 to 3.40, P=0.47).

Conclusions: There was no statistically significant difference in VA changes and appointment frequency between patients in the low and high ADI groups. The study suggests that there may be a trend for low ADI to be associated with a shorter time to surgery and to achieve resolution without surgery.

ABSTRACT BODY:

Purpose: We assessed the outcomes of eyes with neovascular age-related macular degeneration (nAMD) in routine clinical practice that switched to a reactive (ie. pro re nata) treatment regimen from proactive (treat and extend) after developing macular atrophy (MA) or submacular fibrosis (SMFi).

Methods: We analysed data from the Fight Retinal Blindness! (FRB!) Project database, a prospectively designed registry of “real-world” outcomes from 2006 to 2021. Treatment-naive eyes starting vascular endothelial growth factor (VEGF) inhibitors for nAMD that went on to develop MA or SMFi were included. Patients from Australia, France, Ireland, Netherlands, New Zealand, Singapore, and Switzerland were included.

Results: There were 2125 treatment-naïve eyes with nAMD commencing treatment with anti-VEGF injections who did not have MA/SMFi at baseline from the Registry’s database that were eligible for the present analysis because they subsequently developed one or both complications at the fovea on treatment. Of these, 821 (35%) eyes were diagnosed with MA and 1166 (55%) eyes were diagnosed with SMFi. 7% (MA) and 9% (SMFi) of eyes were switched to reactive treatment regimen likely due to their visual prognosis. Vision was 56 (19.7) & 51 (22.54) letters is those eyes that developed MA and SMFi and continued proactive treatment (SD). Vision of eyes that switched to reactive treatment was 45 letters (28.5) in fluid tolerant MA, 47 letters (22.8) in fluid intolerant MA, 31 letters (23.8) in fluid tolerant SMFi and 38 letters (26.9) in fluid intolerant SMFi lesions (SD). Vision was maintained at a similar rate to proactive regimen to 12 months for eyes with MA and inactive SMFi lesions but not for eyes with active SMFi. Reactively treated eyes had an 8% chance of a large retinal haemorrhage leading to significant vision loss 12 months from switching regimen. The eyes with fluid tolerant SMFi lesions had the highest risk at 15%.

Conclusions: Reactive treatment of nAMD in eyes that develop MA or SMFi carries an 8% risk of a large retinal haemorrhage with significant vision loss. Vision deteriorates at a similar rate as with proactive regimen except for eyes that have active SMFi lesions. Clinicians should be cautious when switching treatment regimens to reactive, particularly in eyes with active SMFi lesions.

ABSTRACT BODY:

Purpose: High alcohol consumption decreases the bioavailability of dietary folate, a possible factor important for exfoliation glaucoma (XFG). We assessed the association between alcohol intake and incidence of XFG in a prospective study.

Methods: We followed 195,408 participants of the Nurses' Health Study (1980–2018), the Health Professionals Follow-up Study (1986–2018), and the Nurses' Health Study II (1991–2019) biennially. Eligible subjects at each 2-year risk period were 40+ years old and free of XFG with available data on diet and ophthalmic examinations. We evaluated cumulatively-averaged total alcohol (primary exposure); information for individual alcoholic beverages including beer, wine, and liquor were obtained from validated dietary food frequency questionnaires repeated every 2-4 years. The main outcome of XFG incidence was confirmed by medical records. We used per-eye Cox proportional hazards models, accounting for inter-eye correlations, to estimate multivariable-adjusted relative risks (MVRRs) and 95% confidence intervals (CIs)

Results: During 6,878,075 eye-years of follow-up, 702 eyes with XFG were documented. Greater total alcohol consumption was significantly associated with XFG risk: the MVRR for cumulatively averaged alcohol consumption ≥15+ g/day vs. non-drinking was 1.54 (95% CI, 1.16–2.05; P_{trend}=.02). Long- and short-term alcohol intake was significantly associated with XFG risk, with the strongest associations with cumulatively-averaged alcohol intake as of 4 years before diagnosis (MVRR ≥15+ g/day vs. non-drinking=1.62 [95% CI, 1.23–2.14; P_{trend}=.003]). Stratifying alcohol consumption by type of beverage revealed a significant trend for liquor. Compared to non-drinkers, consuming 3.6+ drinks per week of beer, total wine or liquor was associated with the following MVRRs for XFG: 1.25 (95% CI, 0.88–1.77; P_{trend}=.43), 1.34 (95% CI, 1.03–1.73; P_{trend}=.10) and 1.41 (95% CI, 1.11–1.79; P_{trend}=.02), respectively. We did not observe interactions by age, latitude, residential tier, intakes of folate or vitamin A ($P_{interaction}$>.40); however, the association between alcohol and XFG was suggestively stronger for those without family history of glaucoma ($P_{interaction}$=.10).

Conclusions: Alcohol consumption was associated with higher risk of XFG, an association that provides more clues regarding the etiology of XFG

ABSTRACT BODY:

Purpose: To describe and evaluate donut-shaped hypertransmission defects on en face sub-RPE optical coherence tomography (OCT) imaging and the associated findings seen on OCT B-scans in eyes with intermediate and advanced age-related macular degeneration (AMD) using a retrospective, observational study.

Methods: This study included 21 eyes with intermediate or advanced AMD imaged at the New England Eye Center. A donut-shaped hypertransmission defect was defined as a hypertransmission defect surrounding a central area of hypotransmission on en face OCT. Donut-shaped hypertransmission defects on custom en face sub-RPE slabs and their associated B-scans were acquired using a 3 μm, 128 kHz A-scan rate ultrahigh resolution spectral-domain OCT (UHR SD-OCT) and/or commercial SD-OCT devices.

Results: A total of 40 donut-shaped hypertransmission defects from 21 patients were identified on en face OCT. The donut-shaped hypertransmission defects were found to be associated with RPE migration, drusen with heterogenous or non-reflective homogenous contents, incomplete retinal pigment epithelium and outer retinal atrophy (iRORA), and/or complete retinal pigment epithelium and outer retinal atrophy (cRORA) on associated commercial and UHR SD-OCT B-scans. In each case, the hypertransmission on en face OCT corresponded to choroidal hypertransmission secondary to RPE disruption on associated B-scans. In 9 lesions, a clump of preserved RPE in the center of iRORA or cRORA lesions was observed with associated relative hypotransmission into the choroid, as seen in Figure 1; this area of preserved RPE corresponded to the central area of hypotransmission on en face OCT.

Conclusions: Donut-shaped hypertransmission defects on en face OCT sub-RPE slabs were evaluated and found to be associated with various findings on SD-OCT B-scans, including RPE migration, drusen with homogenous or heterogenous contents, iRORA, and/or cRORA. Future longitudinal studies may be performed to determine if the presence of donut-shaped lesions is associated with faster progression to advanced AMD.

ABSTRACT BODY:

Purpose: To investigate the non-invasive examination of conjunctival goblet cells (GCs) by moxifloxacin-based fluorescence microscopy (MBFM) in a rabbit model with ocular surface damage (OSD) induced by 0.2% Benzalkonium Chloride (BAC)

Methods: Moxifloxacin-based axially swept wide-field fluorescence microscopy, which can image the conjunctiva with 2.0-μm resolution, 1.2 × 1.2 mm field of view, 2.2-mm depth of field, and 1-fps imaging speed, was used in the study. Four control and eight OSD rabbits were used. For the OSD rabbit model, 0.2% BAC was topically instilled once daily to one eye of each rabbit for 7 days. The same procedure was performed in the control group using Balanced Salt Solution (Alcon, Fort Worth, TX) instead of BAC. MBFM imaging of the superior bulbar conjunctiva was conducted after topical instillation of moxifloxacin 0.5% ophthalmic solution (Vigamox®; Alcon). The imaging was conducted longitudinally every 7 days for 21 days and the changes of GC density were analyzed. Clinical examinations, including fluorescein staining and tear film break-up time (TBUT), were conducted together to measure dry eye severity.

Results: In-vivo GC imaging of rabbits was possible without significant motion artifacts. Longitudinal MBFM imaging of the BAC-induced OSD rabbit model showed significant GC density loss at days 7 (447±246 GCs/mm^2) and 14 (470±260 GCs/mm^2) post administration compared to that at the baseline (877±181 GCs/mm^2) and their recovery at day 21 (833±437 GCs/mm^2). The GC density of control rabbits was unchanged during the longitudinal MBFM imaging for 3 weeks. The corneal staining score and TBUT significantly worsened at days 7 (8.1±2.2, 3.4±1.5 s, respectively) and 14 (6.4±1.6, 4.3±1.3 s, respectively) compared to those at the baseline (1.8±0.5, 6.8±1.6 s, respectively), and had recovered on day 21 (0.8±0.9, 8.4±1.2 s, respectively). They showed strong correlations with GC density.

Conclusions: MBFM visualized conjunctival GCs of rabbit models non-invasively with high-contrast. In the OSD model, the changes of GC density, observed with MBFM, were correlated with clinical severity, demonstrating the potential of MBFM for clinical GC evaluation in ocular surface diseases.

ABSTRACT BODY:

Purpose: Traditional cardiovascular (CVD) risk estimation requires information from blood test. Recently, a deep learning (DL) model based on retinal images to estimate CVD risk has been proposed. However, it is still in black-box how the retinal image-based risk prediction performs. We developed explainable AI-based CVD risk prediction model with explicitly estimating individual traditional CVD risk factors with coupled with image-based risk estimation with a proposal to be speculated in the future potential in CVD screening process not requiring blood test.

Methods: We used a subset data from UK Biobank which contains 52,297 entries. We developed a DL model to predict 5-year cumulative incidence of major cardiovascular events (MACE) using multiple combinations of traditional CVD risk factors and retinal images. A two-stage deep learning neural network is proposed. The first stage is a multi-task learning network which takes the retinal images as input and estimates 10 individual CVD risk factors as outcomes (fig). These estimated risk factors are being used as inputs of the second-stage network to estimate the MACE. We compared variation in the risk prediction models combining CVD risk factors and retinal images.

Results: In terms of MACE prediction, our two-step model xMACE (ROC-AUC 0.738 [95%CI 0.710-0.766]) outperformed the traditional score-based model of SCORE (0.682 [0.640-0.719], and at similar range to the neural network model based on traditional CVD risk factors (0.758 [0.729-0.784]).

Conclusions: MACE risk predicted by the deep learning algorithm from retinal images can perform as good as blood test based risk prediction model, and still providing individualized recommendation for which risk factors to be intervened to reduce the risk of CVD.

ABSTRACT BODY:

Purpose: Immature dendritic cells (imDCs) have recently been reported to migrate at a speed of approximately 1 μm/min in the healthy human cornea, as seen with time-lapsed imaging using in vivo confocal microscopy (IVCM). Mature, immature, and putative sub-epithelial dendritic cell density (DCD) and imDC dynamics were explored in people with and without type 1 diabetes.

Methods: Twenty participants with type 1 diabetes (age 55 ± 11 years, duration of diabetes: 29 ± 14 years) from the LANDMark study (a 7-year, two-site, natural history study of type 1 diabetic participants) and 10 age- and gender-matched participants without diabetes (age 55 ± 17 years) underwent IVCM at the whorl region of the nerve plexus to quantify the density of immature, mature and putative dendritic cell phenotypes. Trajectory (length travelled/time) and displacement (distance from to and end points/time) speeds as well as persistence ratio (displacement/trajectory) were calculated from at least three imDCs per cornea. Blood biochemistry and metabolic measures from plasma (including hemoglobin A1C) and urine samples were retrospectively analysed.

Results: Mature DCD was higher in diabetic participants compared to controls (12 ± 13 vs 4 ± 4 cell/mm2, p=0.02). Other cell dynamics and DCD did not differ between groups. Significant associations were found between imDC density and high-density lipoprotein (HDL) cholesterol (mmol/L) (ρ=0.6; p=0.01) and triglycerides (mmol/L) (ρ=-0.6; p=0.01). Putative DCD correlated with HDL cholesterol (mmol/L) (ρ=-0.5; p=0.02). Average imDC trajectory path (μm/min) correlated with duration of diabetes (ρ=-0.5; p=0.03) and estimated glomerular filtration rate (eGFR) (mL/min) (ρ=0.5; p=0.03). Average imDC displacement associated with duration of diabetes (ρ=-0.5; p=0.03), eGFR (mL/min) (ρ=0.7; p<0.01). Average imDC persistence (ratio) correlated with eGFR (mL/min) (ρ=0.6; p=0.01).

Conclusions: This study suggests that metabolic parameters may be reflected in the cornea as observed by imDC dynamics using IVCM and provides evidence of the link between imDCs dynamics and lipid levels, renal function, and duration of type 1 diabetes.

ABSTRACT BODY:

Purpose: Tonography is the standard method for non-invasive measurement of outflow facility, a critical component of aqueous humor dynamics. With this technique, a pressure decay curve is obtained when a weighted tonometer probe is placed on the eye for several minutes. However, obtaining high quality tracings can be challenging and use of poor-quality tracings can adversely affect the validity of measurements. Also, assessment of tracing quality has typically been subjective, leading to potential bias. The purpose of this study was to develop an objective method for assessing quality of tonography tracings.

Methods: Pneumatonography tracings were obtained from an ongoing multicenter study of aqueous humor dynamics (ClinicalTrials.gov NCT04412096) in participants with glaucoma or ocular hypertension within the Eye Dynamics and Engineering Network (EDEN). IOP was captured digitally at 40 Hz over 2 minutes with a 10 gram weighted probe. A linear best-fit line was obtained for each tracing and root mean square error (RMSE) was calculated as a measure of fit quality. Each tracing was also graded by 7 experienced tonographers using a 1 (worst) to 10 (best, Fig 1) scale for quality (Expert score). A Reference set of 35 tracings was used to determine the relationship between RMSE and Expert score using a logarithmic curve. This relationship was used to calculate a predicted score in a second Test set of 20 tracings. The differences between the predicted scores and the Expert scores were evaluated using Bland-Altman analysis.

Results: The relationship between Expert scores and RMSE was described by the equation: EDEN score= -4.236 ln(RMSE)+7.6569, where the EDEN score is the predicted quality score using a 1-10 scale. For the Test set, there was a very strong correlation between EDEN predicted scores and Expert scores (R=0.94, Fig 2A) using this equation. The mean difference between Expert and EDEN scores was -0.30 ± 0.86 (SD), and the limits of agreement were between -1.99 and +1.39 (Fig 2B).

Conclusions: Objective assessment of pneumatonography tracings can be performed using RMSE of a fitted line and calculation of predicted EDEN quality score on a 1-10 scale. Mean EDEN scores are slightly higher than mean Expert scores, which may result in acceptance of tracing that may be deemed poor quality by expert grading. Further research is needed to determine appropriate cutoff values.

ABSTRACT BODY:

Purpose: The main purpose of the lipid layer in the tear film is to prevent evaporation. The integrity of the lipid layer depends on its rheology, but information regarding individual patients is lacking. We tested the hypothesis that Meibomian gland dysfunction (MGD) patients present lipid with different rheological properties when compared to controls using an experimental model.

Methods: Ten participants over the age of 18 with MGD and 10 healthy controls were included. Exclusion criteria included the use of topical or systemic drugs, ocular disease with the exclusion of MGD, autoimmune disease, contact lens use, history of eye surgery and pregnant or breastfeeding women. Meibum was mechanically expressed from both eyes using cotton swabs and collected in a clean glass slide. It was then immediately dissolved in 1 ml of chloroform and stored at -80 C until analysis. The samples were measured with a quartz crystal microbalance with dissipation. Lipids from single patients at variable concentrations were placed in a clean gold-coated quartz sensor and chloroform was allowed to evaporate. The frequency of oscillations and the dissipation were monitored at 25 C. Samples were then heated to 38 C and the shift in frequency and dissipation recorded. Lastly, samples were allowed to cool down to 25 C. The results of the frequency and dissipation shifts were adjusted to a Kelvin-Voigt viscoelastic model.

Results: The results obtained at 25 C are consistent with the presence of two layers, a thin viscoelastic layer at the interphase (elasticity ≈ 2 MPa and viscosity ≈ 4 cP) and a viscous fluid layer (viscosity ≈ 10 cP). Upon warming the samples to 38 C, the layers lose organization and become a single viscous layer with a viscosity of 8 cP. The two layers reformed and returned to basal values when the samples' temperature decreased to 25 C. The thickness of the viscous layer is greater in controls (≈ 30 nm) when compared to MGD patients (≈ 10 nm) (p value <0.05).

Conclusions: Meibum in MGD patients is less elastic and organized when compared to controls, which may explain its enhanced evaporation. The published information measures viscoelastic characteristics of meibum composed of a pool of samples, not single patients. This method is useful to assess individual patients as it is capable of determining rheological properties in minuscule amounts of sample.

TITLE: Efficacy of a drug-soaked contact lens to achieve target pupillary dilation for UV light treatment of light adjustable IOLs.

SESSION TITLE: Cataract surgery II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Melki, K. Makhoul, F. Kahale, J. Brenner, Boston Vision, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Alexi Melki: Commercial Relationship: Code N (No Commercial Relationship) | Kevin Makhoul: Commercial Relationship: Code N (No Commercial Relationship) | Francesca Kahale: Commercial Relationship: Code N (No Commercial Relationship) | Jason Brenner: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Cataract extraction with light adjustable lens implantation allows post-operative power titration with UV light to attain the desired refractive outcome. The treatment requires exposure of the IOL optic through a pupillary dilation of at least 7 mm at several intervals in the postoperative period. We intend to show that pupillary dilation is reached faster by applying a contact lens soaked in dilating drops compared to a single application or multiple application of eye drops. If shown to be effective, the soaked CL method would significantly improve clinic workflow, reduce patient inconvenience as well as the burden of the postoperative UV light adjustments.

Methods: We recruited 10 patients who had undergone bilateral cataract surgery and received RxSight's Light Adjustable Lens (LAL). We compared three methods of dilation: a one-time set of drops, a 5-minute interval administration, and a CL soaked in dilating drops. One set consisted of one drop each of 1% Tropicamide, 10% Phenylephrine, and 1% Cyclopentolate. The CL was soaked in a solution of the drops for ten minutes. In each patient we placed the soaked contact lens in one eye and simultaneously began either the interval drop regimen or the one-time administration in the other eye. We measured the time needed to achieve a 7mm dilation through each method.

Results: The eyes that received the contact lens soaked method achieved 7 mm pupil dilation faster than one time application of eyedrops and similar at intermittent eye drops application. We noted empirically that dilation with soaked CL lagged behind interval and singular set drops in the early stages before catching up or surpassing over time. Patients reported that the soaked CLs was the most convenient method of dilation. Technicians and physicians had fewer interruptions to their clinical schedule with one-time administration of drops and soaked CLs, which improved workflow efficiency.

Conclusions: Our results show that administration of a soaked CL produced adequate dilation for LAL treatments. It was comparable to administering drops at 5-minute intervals, and outperformed one-time drop administration. This confers a significant benefit to patient comfort in the clinic and minimizes interruptions to the clinic schedule during the dilation period. A study with a larger sample is required to validate these results and to quantify ideal CL soaking time.

ABSTRACT BODY:

Purpose: High repeatability portable autorefractors may enable effective deploy of global-health initiatives to mitigate uncorrected refractive error worldwide. For example, in studies to evaluate the effectiveness of different measures, repeatability has a direct impact on the statistical power and sample size required, while in screening applications, contributes to increased sensitivity and specificity. This work presents a preliminary assessment of the inter- and intrasession repeatability of an affordable autorefractor (QuickSee, PlenOptika Inc) under two separate measurement conditions, with and without fogging lenses.

Methods: 6 volunteers (29,8 ± 8,1 years old) were measured at 2 different sessions spaced 1-week. Each subject was tested 6 times per session with the QuickSee, 3 times in standard mode and 3 using a modified version of the device eyecup to allow over-refraction through fogging lenses (+2.0 D). Intersession measurements were spaced 5 minutes apart and the complete alignment procedure was repeated for each measurement. After converting autorefractor readings into power vectors (M, J0, J45), repeatability was evaluated using the Bland-Altman method to compare differences between all possible combinations from each subject (inter- and intrasession). Repeatability coefficients (RPC), estimated as the 95% limits of agreement, and the mean absolute errors were also evaluated. In all cases, only results for the right eyes were analyzed.

Results: Participants had an average Spherical Equivalent (SE) refraction of -0.75 ± 2.06 D, (Min -5.11 D, Max 0.175 D). A total of 36 samples per dataset were obtained for the intrasession analysis while 54 samples per dataset were used in the intersession comparison. In all cases the mean difference was practically 0 indicating no bias for any of the vector components. SE RPCs for intrasession test were 0.15 D in standard mode and 0.29 D with the fogging lenses. Intersession RPCs were 0.29 D and 0.4 D without and with the fogging lenses, respectively. Detailed results for all vector components are shown in Table 1.

Conclusions: This preliminary analysis shows that the device can provide excellent RPCs in standard mode, which decrease moderately with the use of the fogging lenses. Further work exploring improvements in the eyecup design and measurement averaging techniques may further enhance the RPC values in over-refraction mode.

ABSTRACT BODY:

Purpose: INSPIRE is a prospective, randomized, 3-year study, with aims of characterizing the role of aqueous cytokines with diabetic retinopathy progression. This analysis establishes the cytokine levels in eyes without diabetic retinopathy or other ocular inflammatory conditions. These levels will serve as a normal for comparison with diabetic retinopathy and other inflammatory ocular conditions.

Methods: 104 eyes of 104 non-diabetic patients were enrolled. All eyes underwent unilateral vitrectomy for non diabetic causes such as epiretinal membrane, macular hole, vitreous opacities, vitreous hemorrhage, and retinal detachment. Approximately 0.2 mL of undiluted aqueous sample was obtained with a 30 gauge needle at the time of vitrectomy. These samples were collected and stored at -80 degrees C and later analyzed for 24 pro and anti inflammatory cytokine levels using the Millipore Multiplex Human Cytokine Kit (Millipore Corporation, Burlington, MA) according to the manufacturer's instructions.

Results: Baseline characteristics of the cohort are shown in Table 1. The mean age was 68.4 years +/- SD 7.91. 48 patients were phakic, 55 patients were pseudopakic, and 1 was aphakic. Four patients were on systemic immunosuppressive mediations including methotrexate, fingolimod, azathioprine, and imatinib for systemic autoimmune conditions. Six patients were on topical prostaglandin analogs and one patient was on fluorometholone drops. Six patients had systemic inflammatory diseases including gout, psoriasis, multiple sclerosis, Crohn's disease, and undifferentiated connective tissue disease.

24 cytokines were measured in all 104 eyes. The most clinically relevant cytokines measured included VEGF, TNF-a, IL-8, IP-10, IL-6, IL-1b, IL-17A, IL-10. These cytokine levels are summarized in Table 2. Additional cytokines also detected included FGF-2, Eotaxin, G-CSF, Fit-3L, GRO, MCP-3, MDC, PDGF-AA, PDGF-AB/BB, sCD40L, IL-1RA, IL-2, IL-4, MCP-1, MIP-1b, and RANTES.

Conclusions: To our knowledge, this is the first large scale characterization of normal cytokine levels in eyes without diabetic retinopathy or other ocular inflammatory conditions. This data will be integral to better understand the inflammatory drivers of diabetic retinopathy progression and subsequent therapeutic targets.

ABSTRACT BODY:

Purpose: Visual Impairment (VI) is strongly associated with psychiatric disorders. However, recent research indicates that depression may be less related to quantitated vision loss than it is to the secondary impact of decreased functional status. It remains unclear what functional aspects of vision influence the development of anxiety and depression associated with vision loss. We analyzed the relation between instrumental and non-instrumental activities of daily living (IADL and ADL) and self-reported VI and how the inability to perform tasks may mediate depression and anxiety.

Methods: Cross-sectional responses from the 2016 National Health Interview Survey (n=15,690) were analyzed using a structural equation modeling (SEM) approach to calculate the direct effect of subjective VI on the frequency of anxiety and depression symptoms and the indirect effect mediated by impairment in ADLs and IADLs. Unstandardized regression coefficients were estimated after controlling for baseline demographics, socioeconomic status, and comorbid disease using the Charlson Comorbidity Index. A separate SEM assessed the impact of near and distance vision dysfunction on the severity of anxiety and depression.

Results: IADLS: Both cleaning and communicating difficulty showed a significant mediating effect for anxiety and depression, while shopping difficulty only had a significant relation to depression but not anxiety. Interestingly, transportation difficulty did not mediate either relationship. ADLS: Bathing, dressing, mobility and toileting limitations all demonstrated a significant mediating effect between VI and anxiety frequency (collective $p < 0.0005$), while feeding did not. Only dressing limitations were a significant mediator for depression frequency. Lastly, distance VI was found to be a significant predictor of anxiety and depression frequency ($p = 0.001$, 0.002), but near VI was not ($p = 0.755$, 0.171).

Conclusions: ADL and IADL dysfunction may contribute to depression and anxiety symptoms induced by VI. The indirect effects were minor compared to the direct effects indicating that other factors that could not be studied may play a larger role in the severity of psychiatric illness. These results may help inform which activities should be targeted by low vision and visual rehabilitation providers.

ABSTRACT BODY:

Purpose: This study is aimed to investigate the efficacy of YP-P10 Peptide in several animal models of dry eye disease

Methods: Sprague-Dawley rats were subjected to extraorbital lacrimal gland excision (ELGE) or sham surgery. Seven days after surgery, animals were dosed with Topical ocular YP-P10 Peptide (0.1, 0.3, 1 & 3%) or vehicle BID 14 days. Corneal staining using NEI scale was observed biomicroscopically after instillation of 1% fluorescein. C57BL/6J mice were subjected to desiccating stress (<30% relative humidity) and cholinergic blockage for 1 day (DS). Mice received topical ocular YP-P10 Peptide (0.3, 1 or 3%) or vehicle BID 3 days before starting DS and continued during DS. Additional controls were naïve mice not subjected to DS, and DS mice dosed with ocular dexamethasone sodium phosphate. Tears were collected using capillary tubes and inflammatory mediators were measured using Luminex immunoassay. Cornea and conjunctiva were excised and lysed in RNA lysis buffer and subjected to qPCR for a panel of inflammatory markers that have been implicated in dry eye.

Results: Rats: A statistically significant ($p<0.001$) increase of the fluorescein-stained cornea score based on the NEI scoring scale was observed on the eyes of the ELGE group compared to the SHAM group. Treatment with YP-P10 Peptide reduced corneal damage. Mice: DS increased mRNA levels of G-csf in cornea and Il6, Ccl20, Mmp3, Tnf in conjunctiva. A dose-dependent decrease in several inflammatory mediators associated with dry eye (Il1b, Ccl5 and Cxcl10) was observed in the cornea and conjunctiva, reaching statistical significance compared to vehicle and showing activity similar to dexamethasone in the conjunctiva. This was accompanied by significant decrease in CCL5 and an increase in IL-10 in tear fluid of YP-P10 Peptide treated animals.

Conclusions: Topical ocular YP-P10 Peptide reduced corneal epithelial disease in a rat ELGE dry model and several inflammatory mediators in DS-induced dry eye disease in mice. This anti-inflammatory effect suggests that YP-P10 Peptide might have efficacy in the treatment of dry eye induced ocular surface inflammation.

ABSTRACT BODY:

Purpose: As improvements are made in engineered and recombinant AAV serotypes that are potentially more potent than naturally occurring serotypes, there is an urgent need to explore an effective and direct method for testing the transduction efficiency and tropism of these AAV serotypes in human retinal tissue. Human retinal explants serve as a robust, informative model to evaluate transduction efficiency and tropism in human cells, while the efficacy of non-human primate (NHP) retinal explants needs to be directly compared to human tissue to determine its use as a predictive model. Herein, this study examines the transduction efficiency and tropism of ten different AAV serotypes in the human retinal and non-human primate (NHP) retinal explants ex vivo.

Methods: AAV-3b, AAV-6.2, AAV-6TM, AAV-9rh, AAV-32.33, AAV-PHP.B, AAV-PHP.eB, AAV-rh10, AAV-rh39, AAV-rh43 were tested. AAV2/2 and AAV2/8 served as positive controls. All vectors driving expression of GFP under control of the CB6 promoter packaged by the University of Massachusetts Chan Medical School Vector Core. Three independent experiments were performed, each using a different human donor and NHP eye. Retinal explant cultures were maintained for 7 days post transduction. Immunohistochemistry was performed for GFP and the total number of GFP+ cells was calculated using ImageJ manually. Retinal cell tropism for each AAV serotype was evaluated qualitatively by recording whether cells of the inner nuclear layer (INL) or outer nuclear layer (ONL) that were GFP+ overlapped with markers of different retinal cell types, 7G6, PNA, GS, rhodopsin, and arvalbumin.

Results: AAV-32.33 and AAV-rh10 have the high transducing efficiency for photoreceptor cells and Muller cells, compared with AAV2/2 and AAV2/8 in NHP and human retinal explants. Furthermore, the retinal cell tropism in NHP retinal explants for all serotypes was consistent with retinal cell tropism in human retinal explants.

Conclusions: Our study shows that AAV-32.33 and AAV-rh10 could be useful candidates for intraocular gene delivery to photoreceptor and Muller cells. These results show that human retina explants serve as an effective and direct method for predicting transduction efficiency and tropism of new AAV serotypes in human retina.

ABSTRACT BODY:

Purpose: The aim of this study was to identify genetic variants associated with novel measures of the curvature of the posterior globe derived from macular optical coherence tomography (OCT) scans in a large UK-based cohort.

Methods: A total of 73,032 participants from the UK Biobank study who underwent macular spectral-domain OCT as part of their ophthalmic examination were analysed. A deep learning model was used to segment the scans and polynomial fit was used to calculate the curvature of the macula and fovea. Genome-wide association analyses were performed on individuals of European ancestry using BOLT-LMM with adjustment for age, sex and population structure. Given that foveal curvature is highly dependent on retinal pathology individuals were excluded with diabetes or with ocular diagnoses affecting retinal thickness. Given that macula curvature, synonymous with dome-shaped macula configuration, is associated with myopia further analyses with adjustment for refractive error were performed.

Results: Analyses were performed on 77,324 and 58,348 participants for macula and fovea curvature respectively. Genetic variants associated with macula curvature clustered at 37 unique autosomal genomic regions at genome-wide significance (P<5x10-8) and the most significant locus was LAMA2 ($p=3.40x10^{-49}$). This and several other loci were previously associated with refractive error and myopia. After adjustment for refractive error the most significant locus was DGKD ($p=6.60x10^{-65}$). A larger number genome-wide significant variants were associated with fovea curvature (n=315) which clustered at 128 unique autosomal genomic regions including LINC00461 ($p=5.50x10^{-76}$), ADCY5 ($p=5.90x10^{-73}$) and FLT1 ($p= 9.90x10^{-27}$).

Conclusions: This study has identified a large number of genetic loci influencing the curvature of the macula and fovea. The identified genetic determinants could provide additional insights into axial elongation, macula staphyloma (a risk factor for myopic maculopathy), dome-shape macula configuration and foveal development.

ABSTRACT BODY:

Purpose: To determine agreement on quantitative retinal and choroidal measurements obtained with Duke Reading Center's automatic segmentation software, DRCVisualizer and native Spectralis Heidelberg Eye Explorer (HEYEX) OCT software in eyes with neovascular age related macular degeneration (nvAMD) under treatment in a clinical trial.

Methods: Eighty eyes of eighty participants from a phase 2 nvAMD clinical trial dataset with good quality images were randomly selected. Images were acquired with a 20x20 degree 97-line High Resolution scan protocol. For each scan, the standard nine-field ETDRS grid was centered at the fovea, and the HEYEX software (Version 1.10.4.0) automatically segmented the internal limiting membrane and Bruch's membrane on each B-scan image. Any segmentation errors were manually corrected in HEYEX and all scans were then imported into DRCVisualizer (Version 2.1.1). We compared the following automatically computed parameters generated by both DRCVisualizer and HEYEX: Central Subfield Thickness (CST), Central 1mm Volume, and Total ETDRS Grid Volume. The following parameters were manually annotated on both software by a trained grader: Center point thickness, foveal neurosensory retinal thickness, foveal subretinal hyperreflective material thickness, foveal subretinal fluid thickness, subfoveal choroidal thickness, and Horizontal and Vertical extent of pigment epithelium detachment. Intraclass correlation coefficients (ICC) were used to determine agreement between measurements obtained.

Results: There was excellent agreement between HEYEX and DRCVisualizer for all automatically computed thickness and volume parameters as well as for all manually annotated measurements. ICC were excellent (Table 1) for all parameters (range 0.99-1.00). Measured values were very similar using the two software and percent differences between the measured values for all 10 parameters ranged from 0.048 to 1.513% (Table 2).

Conclusions: Semiautomatic retinal thickness and volume measurements and manually annotated anatomic features generated by the Duke Reading Center's DRCVisualizer software have excellent agreement with and are very similar to the values generated by the Spectralis HEYEX software in eyes with nvAMD in a clinical trial setting.

ABSTRACT BODY:

Purpose: The purpose of this study is to validate the lens thickness (LT) measurement process by anterior segment OCT images, manually and with artificial intelligence.

Methods: A retrospective chart review of patients that underwent uncomplicated FLACS at the Illinois Eye and ear Infirmary was done. 329 anterior segment OCT images of the LenSx Femtosecond platform were reviewed. Lens thickness measurements were done by 4 physicians and interobserver agreement was determined. Using artificial intelligence (AI), the same measurements were made and subsequently compared.

Results: Of the 329 anterior segment images, 36 were excluded because bad quality. Mean LT was 520.3 ± 549.6 µm. Interobserver agreement was high across all 4 physicians. Afterward, LT measurements were compared with AI results. The LT measured by anterior segment OCT showed excellent agreement.

Conclusions: Sensitivity and specificity were high for AI LT measurements. This can improve refractive outcomes when used in biometric formulas.

ABSTRACT BODY:

Purpose: Inherited retinal diseases (IRDs) are classically diagnosed and classified by the electroretinogram (ERG) rod and cone response amplitudes, and the pattern of ERG responses is associated with various clinical diagnoses. Certain gene defects cause primarily cone dysfunction, such as CNGA3, which causes achromatopsia. Other gene defects can cause a cone-rod dystrophy (cone>rod dysfunction), such as ABCA4. Some genes defects cause rod-cone dystrophies (rod>cone dysfunction), known as retinitis pigmentosa (RP), including rhodopsin.

Methods: This study compares residual cone and mixed rod-cone response amplitudes across 5095 ERGs of 1239 subjects with IRDs caused by 84 different genes. The mixed rod and cone response was elicited by 0.5 Hz white flashes at 0.22 cd*s/m2 after dark adaptation. The cone specific response was elicited by 30 Hz flashes after light adaptation. The residual of a curve fit of the cone versus mixed response amplitudes was calculated, which can be considered as a type of cone/rod amplitude ratio.

Results: The lowest cone/rod ratio, indicating primary cone dysfunction, was seen in KCNV2 defects, which causes “cone dystrophy with a supernormal rod electroretinogram”. AIPL1 defects, which also cause an unusual ERG, also had large residual rod signals with low cone signals. These two genes, along with achromatopsia genes such as CNGA3 & CNGB3, have the lowest cone/rod ratios. The highest cone/rod ratios, indicating primarily rod dysfunction, were frequently seen in genes that cause dominant RP, such as rhodopsin, KLHL7, and IMPHD1. (Different relative rankings are obtained with amplitude-independent calculations.) ABCA4, and to a lesser extent RPGR, showed a wide spectrum of ratios, consistent with their ability to cause RP versus cone-rod dystrophy in different subjects. Findings for additional genes are discussed.

Conclusions: This study shows, in an unbiased way, which IRD genes cause more rod versus cone-specific defects, in many human subjects. This pattern likely reflects the underlying biology of the different gene functions and might have implications for therapeutic approaches to gene replacement for IRDs.

TITLE: Phosphatidylserine transport is impaired in the trabecular meshwork of primary open angle glaucoma

SESSION TITLE: Glaucoma: biochemistry, biomechanics and omics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Saleem, K. Jasti, K. Ramlakhan, S.K. Bhattacharya, University of Miami Health System Bascom Palmer Eye Institute, Miami, Florida, UNITED STATES|M. Saleem, Georgetown University School of Medicine, Washington, District of Columbia, UNITED STATES|

Commercial Relationships Disclosure: Meher Saleem: Commercial Relationship: Code N (No Commercial Relationship) | Kavya Jasti: Commercial Relationship: Code N (No Commercial Relationship) | Kaitlyn Ramlakhan: Commercial Relationship: Code N (No Commercial Relationship) | Sanjoy Bhattacharya: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In primary open angle glaucoma (POAG), the trabecular meshwork (TM) has been found to have decreased levels of cytosolic/plasma membrane phosphatidylserine (PS) and the ATPase phospholipid transporting 8B2 (ATP8B2) compared to controls. We hypothesize that PS transport is impaired in the POAG TM, and that the flippase ATP8B2 is specifically responsible for the transport of PS in the TM.

Methods: Primary TM cells were derived from normal cadaveric eyes (n=20) with equal gender distribution. All collections followed the tenets of the Declaration of Helsinki. To evaluate PS transport, TM cells were incubated with nitrobenzoxadiazole (NBD)-PS (excitation=433 nm, emission=540 nm) and imaged with a confocal microscope. This transport method with suitable modifications was also adapted for POAG TM tissues (n=20) and control TM tissues (n=20) with equal gender distribution. POAG and control TM tissue ages were 75±5.5 and 68±4.5 years respectively. Knockout (KO) of the ATP8B2 gene was performed with a CRISPR/Cas9 lentivector in primary TM cells. To complement this experiment, artificial unilamellar vesicles embedded with ATP8B2 and control unilamellar vesicles were incubated with PS. Bligh and Dyer lipid extraction was performed on ATP8B2 KO TM cells, control TM cells, ATP8B2 embedded unilamellar vesicles, and control unilamellar vesicles. The extracted lipids were analyzed with TSQ Quantum Access MAX Triple Quadruple Mass Spectrometer with Equisplash™ internal standard to assay the specificity of ATP8B2. Statistical analysis was performed with a two-way ANOVA test.

Results: The kinetics of NBD-PS transport from the extracellular matrix into primary TM cells occurred over the course of 15 minutes. These kinetics were consistent in control TM tissue, but occurred at a 3-5-fold slower rate in POAG TM tissue. A repertoire of PS lipids (acyl chain length 16-22) exhibited reduced transport in ATP8B2 KO TM cells compared to controls. Unilamellar vesicles embedded with ATP8B2 exhibited increased PS transport compared to controls.

Conclusions: Our results are consistent with the occurrence of impaired PS transport in the POAG TM, and also with the transport of PS by ATP8B2 in the TM. These findings are consistent with the finding of decreased levels of ATP8B2 in the POAG TM, and could indicate that the decreased levels of ATP8B2 could be contributing to impaired PS transport in the POAG TM.

TITLE: Remote and In-Lab Eccentric Viewing Training in Patients with Central Vision Loss

SESSION TITLE: Visual Function Assessment and Quality of Life Outcomes

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: B. Bowman, N. Ross, P.J. Bex, New England College of Optometry, Boston, Massachusetts, UNITED STATES|J. Skerswetat, P.J. Bex, Psychology, Northeastern University, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Brittany Bowman: Commercial Relationship: Code N (No Commercial Relationship) | Jan Skerswetat: Commercial Relationship(s);Code C (Consultant/Contractor):PerZeption Inc. | Nicole Ross: Commercial Relationship(s);Code R (Recipient):Eschenbach Optik | Peter Bex: Commercial Relationship(s);Code C (Consultant/Contractor):PerZeption Inc., Adaptive Sensory Technology ;Code P (Patent):Massachusetts Eye and Ear Infirmary

ABSTRACT BODY:

Purpose: Currently, there are no standardized methods to select, quantify or train eye movements in patients with central vision loss (CVL). We developed 2 eccentric viewing (EV) training systems, in-person and remote, to implement and compare alternative feedback methods for CVL rehabilitation.

Methods: CVL patients (n=8 in-lab (median age=71years ± 20 standard deviation); n=8 remote (61 ± 11); n=9 normally-sighted controls (28 ± 5)) were recruited. The remote system, consisting of a laptop and eye tracker (Tobii EyeX or GazePoint GP3), was mailed to participants. Matlab speech and an experimenter on Zoom guided participants through the remote experiment. The in-lab system was led by a researcher and utilized an Eyelink eye tracker. In both systems, a PRL in the inferior visual field was trained with audio, contracting ring, gaze-contingent ring, image of a hand, and tactile feedback in random order and were compared to free viewing. The contrast sensitivity function (CSF) at the PRL was assessed via bandpass-filtered HOTV letters, updated using an adaptive algorithm; fitted after 25 correct responses; maximum 50 trials per condition.
Bivariate-Contour-Ellipse-Areas (BCEAs), Area-Under-the-CSF (AUCs), and CSF Acuities were calculated to measure oculo-motor and perceptual performance, respectively. Analysis-of-variance models and planned multiple comparisons were used to determine statistical effects.

Results: We were able to measure the CSF and BCEAs of all subjects both in-lab and remotely, however, eye tracking data loss was higher in remote-CVL patients, likely due to EV. BCEA was significantly reduced in all feedback conditions in the remote-control group ($p=0.003$), but not for the in-lab control group. In all groups, there were no significant differences in Acuity or AUC across feedback mechanisms.

Conclusions: We developed a novel remote EV training system, which successfully measured contrast-sensitivity in CVL patients and successfully tracked eyes in a subset of participants. Although the present feedback methods did not affect the visual function endpoints tested in this study, this system may be used to evaluate other rehabilitation approaches and functional outcomes.

ABSTRACT BODY:

Purpose: Prospective ophthalmology applicants, particularly racial and ethnic minorities, heavily consider program factors related to program culture and commitment to diversity when researching residency programs. We performed a cross-sectional study to evaluate for the presence of predetermined diversity and inclusion criteria in US ophthalmology program websites. We tested the hypothesis that larger programs and high program rank were more likely to be associated with presence of the diversity and inclusion criteria.

Methods: A complete list of 125 US ophthalmology residency programs was obtained from the Fellowship and Residency Electronic Interactive Database (FREIDA) in May 2021. A total of 121 program website links were found through FREIDA or Google Search and were included in the analysis.

Program characteristics like program size (number of PGY2- PGY4 residents) and whether the program ranked within the top 20 “Best Hospitals for Ophthalmology” per the 2020 U.S. News & World Report were collected. A descriptive analysis was performed. Fisher’s exact tests were used to compare proportions.

Results: Out of 121 program websites reviewed, 29 (24%) met at least 1 of the 6 predetermined diversity and inclusion criteria. Of these 29, 9 (7%) had mention of diversity in mission statement, program director’s statement or department chair’s message, 17 (14%) had a standalone diversity statement, 9 (7%) had information about a rotation or elective for minority students, 11 (9%) had mention of diversity initiatives, 7 (6%) had a diversity page or section, 6 (5%) mentioned appointed diversity leadership. Programs with more than 12 residents (OR 3.58; CI 1.39-9.55; p=0.0039) and programs ranked within the top 20 “Best Hospitals for Ophthalmology” (OR 3.28; CI 1.05-10.1; p=0.023) were more likely to have at least 1 of the diversity and inclusion criteria on their website.

Conclusions: The majority of ophthalmology residency programs do not have mention of, or information regarding, diversity and inclusion on their websites. Larger and higher-ranked programs are more likely to mention or portray their commitment to diversity on their residency website.

TITLE: Diabetic microangiopathy: prevalence of assumed diabetic glomerulopathy in diabetic retinopathy patients in follow-up care in a medical retina clinic

SESSION TITLE: Diabetic Retinopathy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Nassaralla, B.A. Maciel, C. Junqueira de Carvalho, J.L. Orefice, Centro Oftalmológico de Minas Gerais, Belo Horizonte, BRAZIL|A. Sasse, Faculdade de Medicina São Leopoldo Mandic, BRAZIL|

Commercial Relationships Disclosure: Arthur Nassaralla: Commercial Relationship: Code N (No Commercial Relationship) | Amanda Sasse: Commercial Relationship: Code N (No Commercial Relationship) | Bruno Maciel: Commercial Relationship: Code N (No Commercial Relationship) | Claudio Augusto Junqueira de Carvalho: Commercial Relationship: Code N (No Commercial Relationship) | Juliana Orefice: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess the prevalence of diabetic glomerulopathy findings in patients diagnosed with diabetic retinopathy (DR) for over 5 years having follow-up care in Medical Retina (MR) clinic.

Methods: Thirty-three patients were invited randomly and consecutively evaluated in one day in our MR clinic. Along with indirect ophthalmoscopy to evaluate the patients' retinas, various tests and questions to assess the risk factors and presence of kidney damage were performed. Semi-quantitative urine test strips were the main test to detect kidney damage, while questions about patient's lifestyle, past history and knowledge about the disease, medications in use were the main determinant of patients' risk factors. The results were, then, correlated.

Results: Among mild, moderate and severe retinopathy patients, 78,8% (26) had, beyond diabetes, hypertension, other possible etiology for kidney damage. 30,3% (10) had swollen lower limb history and 39,3% (13) reported foamy urine. Using a system to grade the severity (1-4 from mildest to severe), the semi-quantitative urine test strips, were used to analyze proteinuria, hematuria, and glycosuria. 66,6% (22) of the patients presented at least some kind of renal damage. Proteinuria was found in 30,2% (10) of the patients (grade 1- 12,1%; grade 2 - 15,1%; grade 3 - 3%; grade 4 - 0%). Meanwhile 42,2% (14) of the patients manifested glycosuria (grade 1- 6%; grade 2 - 6%; grade 3 – 27,2%; grade 4 - 3%). Lastly, hematuria appeared in 24,2% (8) of the patients (grade 1- 12,1%; grade 2 - 9,1%; grade 3 - 3%; grade 4 - 0%). While 21,2% (7) of the patients had previous knowledge about their proteinuria, only 12,1% (4) of them reported awareness of the renal damage.

Conclusions: Diabetic nephropathy is one of the three most common manifestations of diabetes. In patients diagnosed with diabetic retinopathy for over 5 years undergoing clinical follow-up in a MR clinic the prevalence of renal damage was 66,6%, when compared to only 30% in most studies about diabetes manifestations epidemiology. Therefore, we may infer that, diabetic retinopathy may be a biomarker for diabetic nephropathy in diabetic patients.

TITLE: High myopia and vitreal veils in a patient with Poretti-Boltshauser syndrome due to a novel homozygous LAMA1 mutation

SESSION TITLE: Genetic variants in human ocular disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: I. Balikova, N. Faizi, I. Casteels, Ophthalmology, University Hospital Leuven, Leuven, Please select, BELGIUM|P. Coucke, M. De Bruyne, E. De Baere, Department of Biomolecular Medicine, Center for Medical Genetics, Ghent University Hospital, Ghent, BELGIUM|

Commercial Relationships Disclosure: Irina Balikova: Commercial Relationship: Code N (No Commercial Relationship) | Nawid Faizi: Commercial Relationship: Code N (No Commercial Relationship) | Paul Coucke: Commercial Relationship: Code N (No Commercial Relationship) | Marieke De Bruyne: Commercial Relationship: Code N (No Commercial Relationship) | Elfride De Baere: Commercial Relationship: Code N (No Commercial Relationship) | Ingele Casteels: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We describe a patient from non-consanguineous Caucasian parents who presented at the age of 1 year with nystagmus, reduced visual contact and high myopia. Fundoscopic examination revealed optically empty vitreous and vitreal veils. The electroretinogram (ERG) under general anesthesia showed reduced scotopic and photopic responses, which remained stable during the follow up of 16 years. She had mild axial hypotonia that resolved with age. Her general development was normal. A cerebral MRI was performed at 1 year and 17 years of age and revealed dysplasia of the cerebellum with presence of cysts and atrophy of the superior peduncles with a molar tooth like sign. In the differential diagnosis Stickler and Wagner syndrome were considered. The purpose of this study was to identify the genetic cause of the vitreoretinopathy in this patient.

Methods: Firstly targeted genetic testing using next generation sequencing of COL2A1, COL11A1 and COL11A2 was performed. Secondly, a Next generation sequencing based gene panel analysis was carried outusing a NovaSeq 6000 platform (Illumina). The analysis was performed on a gene panel including RetNet related genes

Results: No pathogenic variants were identified in the COL2A1, COL11A1 and COL11A2 genes. The analysis of the Retnet genpanel showed an interesting homozygous potentially pathogenic variant c.8446C>T, p.(Arg2816Ter) in exon 59 in the LAMA1 gene. This variant creates a premature stop codon in 59/63. Segregation testing of the parents showed that they are both heterozygous carriers of the mutation.

Conclusions: We present a patient with severe early onset myopia and vitreal veils carrying a novel homozygous LAMA1 mutation. Mutations in this gene are shown to underly the Poretti-Bolthauser syndrome (OMIM 615960). The patients have intellectual disability, ataxia and cerebellar abnormalities. Ocular abnormalities described are myopia, oculo - motor apraxia, and retinal dystrophy. Here we show a patient with severe myopia and vitreal veils and no psychomotor retardation except for transient axial hypotonia. These are ocular features typically described in Wagner and Stickler syndromes. We show that Poretti-Bolthauser syndrome should be considered in the differential diagnosis of the vitreoretinopathies together with Stickler, Wagner and Knobloch syndromes.

ABSTRACT BODY:

Purpose: Automated segmentation of in-vivo lamina cribrosa (LC) has been challenging, owing to the complex 3D structure and decreased visibility in the lamina depth. Frangi's vesselness filter, which was originally developed for angiogram segmentation, have been successfully demonstrated in segmenting the ex-vivo LC from micro-CT and second harmonic generation microscopy images. In this project we are proposing a new approach of segmenting the in vivo LC from OCT scans, incorporating the Frangi's vesselness principle to facilitate in vivo LC image analysis in much greater detail compared to our previously described 3D analysis method.

Methods: In-vivo spectral-domain OCT scans (Leica, Chicago, IL) were acquired from healthy non-human primates. Scans of varying degree of image quality were selected for the analysis and underwent automated brightness and local contrast enhancement. 3D Frangi's vesselness filter was applied using a fixed setting for scans of all qualities. Our previously described segmentation algorithm was then used to quantify the LC microstructure. The measurements generated from the Frangi analysis and from our own conventional method were compared with a standard reference (manually segmented LC by an expert). Paired t tests were performed to compare if the differences between standard reference and conventional method are greater than the differences between standard reference and Frangi analysis. The visibility of analyzable lamina and dice coefficient were also compared to the conventional method using the same test.

Results: In vivo scans acquired from 5 rhesus macaques (3 males, 1 female, aged 4.3-10.7 yrs) were used for the analysis. No significant difference was detected for LC microstructure parameters between Frangi's approach and conventional method with respect to the standard reference, except for significantly higher pore count in Frangi's method ($p=0.003$; Table). Furthermore, visibility (Figure) was significantly higher for the Frangi method compared to the conventional approach ($p<0.001$) with no difference detected for the semantic segmentation, as reflected by the dice coefficient.

Conclusions: The use of Frangi analysis substantially increase the analyzable lamina while providing similar quantification of the LC microstructure compared to our previous 3D analysis method. This improves the potential for automated and thorough volumetric analysis of in vivo OCT LC image.

ABSTRACT BODY:

Purpose: The characteristic feature of optic nerve injury and glaucoma is the progressive degeneration of RGCs and their axons. However, the neuronal activities of RGCs and their changes in disease models have not been studied longitudinally in vivo. Here we demonstrate the feasibility of directly visualizing light-evoked RGCs activities by cSLO-mediated high throughput RGC Ca^{2+} imaging. The powerful population and single-cell analytic strategies we developed revealed, for the first time, distinct dynamic RGC activity changes in optic nerve crush(ONC) and glaucoma models.

Methods: Due to the superb optical accessibility of the retina, fluorescence-labeled RGCs can be imaged noninvasively in vivo by cSLO. We specifically delivered Ca^{2+} indicators, jGCaMP7s, to the mouse RGCs by AAV2 and mSncg promoter. Thus, we employed cSLO customized with UV stimulation and jGCaMP7s, to optically record light-evoked activities of about 1200 RGCs/retina simultaneously in naïve living mice, as well as longitudinal recording RGC activities at multiple time points in ONC and glaucoma mice.

Results: In naïve retinas, 47 RGC clusters were recognized by unsupervised algorithms, and then hierarchically re-grouped into 9 groups with distinct ON, OFF, and ON-OFF responses to UV stimulation. Consistent with distinct transcriptomic changes in trauma and glaucoma, population analysis of longitudinal RGC Ca^{2+} imaging reveals initial increase, but later rapid loss of ON-RGC activities in ONC, versus mild decreased but well-preserved ON- and OFF-RGC activities in glaucoma. More strikingly, single-cell Ca^{2+} imaging tracing uncovers unprecedented conversions of RGC activities, majority of ON-to-OFF conversion in trauma and OFF-to-ON conversion in glaucoma. Thus, not static as assumed, individual RGC's light-evoked activity is rather vibrant with unique transformation patterns in different diseases.

Conclusions: Our results demonstrate the potential of in vivo RGC Ca^{2+} imaging as a reliable, sensitive, direct and noninvasive RGC functional measurement at single-cell level, but with high throughput capability. This proof-of-concept study lays out the foundation for in vivo RGC function classification and evaluation with more visual stimuli under normal, disease, and therapeutic conditions, at both population and single-cell levels, which is invaluable in understanding RGC pathophysiology and identifying functional biomarkers for diverse optic neuropathies

ABSTRACT BODY:

Purpose: Current methods of ophthalmic exams can be cumbersome, time consuming, and a burden to administer. This study was performed to evaluate acceptability of a software application on a virtual reality/augmented reality headset. If users and patients accept such tools, they may ultimately lead to increased patient satisfaction and workflow.

Methods: A cross-sectional study was performed at a single center, 5-physician ophthalmology practice in the greater Washington D.C. area. The testing was administered by three technicians to 73 patients all of whom were surveyed. The survey included 18 questions, 13 of which used a Likert scale for answers (strongly disagree to strongly agree). Patient data was deidentified and no patients were excluded.

Results: Of patients who have had experience with other perimeters, 88.5% of patients preferred this device to the gold standard Humphrey Visual Field for visual field testing. 89% of patients would recommend this device to other people compared to 1% [1 individual] who would not [7 patients remained neutral]. 84.9% of patients voted the Heru personality was very helpful in guiding them on how to perform the test compared to 11% [8 patients] who voted somewhat helpful and 4.1% [3 patients] who voted neutral. 93% of appointments had a shorter duration as gauged by technicians due to the implementation of the device.

Conclusions: This device was well received by the patients, technicians, and physicians at this practice. By maximizing effectiveness with time management, ease of use, and consistent patient engagement this device meets many goals of healthcare delivery. Although there are limitations to this study, it is likely that this device will be useful in a variety of clinical settings including larger volume clinics, possibly even at home testing in the future.

ABSTRACT BODY:

Purpose: To examine whether associations between a glaucoma polygenic risk score (GPRS) and various glaucoma traits is modified by age.

Methods: We included UK Biobank participants with demographic information, genetic data, and various glaucoma trait data: intraocular pressure (IOP; n=118,153), macular retinal nerve fiber layer (mRNFL; n=42,132), macular ganglion cell inner plexiform layer (mGCIPL; n=42,042), and prevalent glaucoma status (n=192,283). We generated a GPRS for each individual using 2,673 genetic variants and their estimated effect sizes reported by a recent multi-trait genomic analysis. To assess modification by age of the relation between GPRS and glaucoma traits, we used multivariable linear regression for IOP, mRFNL, and mGCIPL; multivariable logistic regression for prevalent glaucoma risk; and analyzed the associations by age quartiles (Q1: <51, Q2: 51-57, Q3: 58-62, and Q4: ≥63 years), with tests for interactions. All analyses were adjusted for age, age2, sex, ethnicity, social deprivation, body mass index, blood pressure, diabetes, cardiovascular disease, spherical equivalent, and various lifestyle factors. We also sub-stratified interaction effects of GPRS and age for each glaucoma trait by sex.

Results: For IOP and glaucoma, interactions between GPRS and age were significant (P-interactions<2.3e-4). The association between the GPRS and IOP increased with age (mean differences in IOP (mmHg) per standard deviation (SD) of GPRS = 0.95, 1.03, 1.18, and 1.24 for 1st, 2nd, 3rd, and 4th quartile of age; P<2.5e-25). Similar trends were observed with glaucoma risk (odds ratio per SD of GPRS = 2.39, 2.58, 2.80, and 2.75 for 1st, 2nd, 3rd, and 4th quartile; P≤0.001). However, for mRNFL or mGCIPL, we did not observe any interactions between GPRS and age (P-interactions>0.05). We observed that the interactions of GPRS and age were significant (P-interaction<0.02) within each sex stratum, with no differences by sex (P-interaction of PRS, age, and sex = 0.70 for IOP and 0.68 for glaucoma).

Conclusions: A glaucoma genetic predisposition score was more strongly associated with higher IOP and greater glaucoma prevalence in older versus younger adults in the UK Biobank. These data may inform how to prioritize glaucoma screening in genetically predisposed individuals.

ABSTRACT BODY:

Purpose: Our group recently found that metformin protects against the development of age-related macular degeneration (AMD) in a large case-control study. The purpose of this subgroup analysis is to assess the interaction of metformin and other medications in protecting against the development of AMD in diabetic patients.

Methods: This is a case-control study analyzing data from a large health insurance claims database. In our prior study, subjects aged 55 years and over and with a new diagnosis of AMD were included as cases and were matched 1:1 with controls. This study is a subgroup analysis of diabetic cases compared to diabetic controls from the initial matching process. An adjusted regression model was used to identify interactions among diabetics taking metformin and other commonly prescribed medications divided into 5 categories: insulin, sulfonylureas, glitazones, other diabetic medications (exenatide, sitagliptin, or pramlintide), and statins.

Results: 81,262 cases were identified compared to 79,497 control subjects. Analysis revealed an independent protective effect against AMD development with the use of metformin (OR 0.95 [CI 0.93-0.97], $p < 0.001$), insulin (OR 0.92 [0.90-0.95], $p < 0.001$), and sulfonylureas (OR 0.94 [0.92-0.96], $p < 0.001$). When used in combination with metformin versus neither medication, insulin (OR 0.89 [CI 0.83-0.97], $p = 0.004$) and sulfonylureas (OR 0.91 [CI 0.84-0.98], $p = 0.01$) demonstrated a protective effect as well. Subjects taking insulin or sulfonylureas alone had a similar risk of developing AMD as those taking metformin alone (OR 0.96 [CI 0.89-1.01] and OR 0.98 [CI 0.90-1.05), respectively). Those taking other diabetic medications (exenatide, sitagliptin, or pramlintide) were at higher risk of developing AMD (OR 1.08 [CI 1.05-1.11], $p < 0.001$), although when taken with metformin the increased risk was no longer demonstrated (OR 1.04 [CI 0.97-1.13]). Lastly, subjects taking sulfonylureas with metformin demonstrated a further decreased risk of AMD development compared to those taking metformin alone (OR 0.94 [CI 0.91-0.97], $p < 0.001$).

Conclusions: Our results suggest that metformin, insulin, and sulfonylureas are protective against the development of AMD in diabetic patients. Other diabetic medications may place diabetics at a higher risk of developing AMD, but this risk is alleviated when taken in combination with metformin.

TITLE: Nasal Paracentral Corneal Melt Associated with Bacterial Dacryocystitis

SESSION TITLE: Ocular surface health and conjunctiva

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. ONG, A. Serrano, D.T. Tse, E.C. Alfonso, C.L. Karp, University of Miami Health System Bascom Palmer Eye Institute, Miami, Florida, UNITED STATES|S.C. Pflugfelder, Baylor College of Medicine, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure: ERIN ONG: Commercial Relationship: Code N (No Commercial Relationship) | Andres Serrano: Commercial Relationship: Code N (No Commercial Relationship) | David Tse: Commercial Relationship: Code N (No Commercial Relationship) | Eduardo Alfonso: Commercial Relationship: Code N (No Commercial Relationship) | Stephen Pflugfelder: Commercial Relationship: Code N (No Commercial Relationship) | Carol Karp: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To describe six patients presenting with central or nasal paracentral sterile corneal melts in which dacryocystitis was felt to be a risk factor for keratolysis in all cases.

Methods: The medical records of six patients presenting to the Bascom Palmer Eye Institute with non-infiltrated central or nasal paracentral corneal melts and concurrent dacryocystitis.

Results: All patients presented with central or nasal epithelial defects, stromal ulceration, or corneal perforations. All corneal melts were focal and lacked a culture-positive stromal infiltrate. Dacryocystitis was a concurrent diagnosis in all cases. The cultures of the lacrimal sac drainage were positive for Staphylococcus aureus, Streptococcus sp., Pseudomonas aeruginosa, and Propionibacterium acnes. Three patients with corneal perforation required surgical management. The corneal pathology stabilized after treatment of the dacryocystitis.

Conclusions: Nasal or paracentral corneal melts may be associated with an underlying chronic dacryocystitis, suggesting that inflammatory mediators and impaired tear outflow in the setting of bacterial dacryocystitis may create a favorable environment for keratolysis. Prompt management of the lacrimal drainage system infection can lead to stabilization or resolution of the keratolytic process.

TITLE: Retinal ex vivo live imaging indicates microglia interaction with synaptic sites in experimental glaucoma

SESSION TITLE: Neurodegeneration

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: T. Garcia Ruiz, A.K. Yu, J. Hyer, L. Della Santina, Y. Ou, Ophthalmology, University of California San Francisco, San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure: Tonatiuh Garcia Ruiz: Commercial Relationship: Code N (No Commercial Relationship) | Alfred Yu: Commercial Relationship: Code N (No Commercial Relationship) | Jeanette Hyer: Commercial Relationship: Code N (No Commercial Relationship) | Luca Della Santina: Commercial Relationship: Code N (No Commercial Relationship) | Yvonne Ou: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In the CNS, microglia have been shown to be important for synaptic pruning during development but its role during neurodegenerative processes is not well understood. Our previous work demonstrates that after intraocular pressure (IOP) elevation, microglia proliferate, activate, and increase their colocalization with synapses. Here we use live imaging to record microglia movement and their interaction with retinal ganglion cell (RGC) post-synaptic puncta in the inner plexiform layer (IPL).

Methods: Adult Cx3cr1-GFP mice had one eye undergo laser-induced ocular hypertension, a model in which IOP is transiently elevated and returns to baseline by 7 days. Prior to IOP elevation, some animals underwent intravitreal injection with AAV-PSD95-RFP, resulting in RGCs that express fluorescently labelled post-synaptic puncta. Contralateral eye served as control. Animals were euthanized 7 days post-laser. Time-lapse z-stack images of ex vivo retina was acquired with a spinning disk confocal every 30 seconds for a total of ten minutes. Statistics were performed using Student’s t-test.

Results: After IOP elevation, IPL microglia increase in number and exhibit morphological change consistent with activation. Increased movement is seen in the microglia from the lasered eye, where there is active filament displacement, extension, and retraction. In response to IOP elevation, microglia show greater process displacement length (2.14 um in laser (SE=0.45) vs. 0.79 um in control (SE=0.19); P=0.03) and faster process speed in the lasered (0.01 um/s; SE=0.005) in comparison to control (0.002 um/s; SE= 0.0005; P=0.02). Microglia contact with PSD95 is seen in both control and lasered eye. However, microglia in the control eye exhibit less process displacement and motility, and furthermore, microglia contact with PSD95 is more superficial in the control condition. In contrast, after IOP elevation activated microglia appear to have engulfed PSD95.

Conclusions: Activated microglia increase their motility, survey their environment, and possibly engulf synaptic proteins. Whether this activity is neuroprotective or neurodegenerative remains a subject of ongoing study.

TITLE: Progression of Keratoconus in a Pediatric Population

SESSION TITLE: Keratoconus and corneal biomechanics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W.V. Lin, G. Rand, D. Trief, L.H. Suh, Edward S Harkness Eye Institute, New York, New York, UNITED STATES|

Commercial Relationships Disclosure: Weijie Lin: Commercial Relationship: Code N (No Commercial Relationship) | Gabriel Rand: Commercial Relationship: Code N (No Commercial Relationship) | Danielle Trief: Commercial Relationship: Code N (No Commercial Relationship) | Leejee Suh: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine risk factors for progression of keratoconus in a pediatric cohort

Methods: Retrospective consecutive series of keratoconus pediatric patients seen by cornea specialists at the department of ophthalmology at Columbia University Medical Center from February 2015 to September 2020 were included. Mann Whitney U tests and Fisher exact tests were carried out to identify risk factors for progression of keratoconus. Subgroup analysis of older (>14 years of age) pediatric patients was carried out. Advanced keratoconus was defined as a pachymeter measurement of <400um in at least one eye.

Results: Of the 33 included pediatric patients, 7 met the definition of advanced keratoconus. Of the advanced keratoconus patients, age, sex, and reported seasonal allergies were not statistically significant. 4 out of 10 patients of the age <14 cohort presented with advanced keratoconus, compared with 3 out of 20 patients in the age >14 group ($p = 0.161$). The median income of the zip codes of these patients showed a trend (although did not reach statistical significance) of lower incomes in the advanced keratoconus group ($52,200 vs $76,200) ($p = 0.074$). 21 patients showed progression by their second visit. No statistically significant differences were found between the group (in terms of age, sex, and presence of reported allergies) that showed progression and the group that did not. The Kmax value for those that progressed by the second visit was statistically significantly higher (61.8) than the patients who did not progress by the second visit (55.0, $p = 0.042$).

Conclusions: Cross linking treatment for keratoconus is currently approved for age >14 years but not for the very young pediatric population. In our study,here was a non-statistically significant trend for patients of age <14 and for patients from lower income zip codes to present more frequently with advanced keratoconus. The majority of patients progressed by their second visit. Kmax values were shown to be statistically significantly different in the group that showed progression by the second visit Although our retrospective data collection had a limited number of patients, our data suggests that risk factors for presenting with advanced keratoconus may include coming from an area of lower median income, which may be an important factor to note as a social determinant of health.

TITLE: TNFa and other Select Cytokines in Patients with Intermediate Age-Related Macular Degeneration (iAMD)

SESSION TITLE: AMD: Clinical and translational research/AMD therapies (excluding anti-VEGF)

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Ghiassi, B.D. Wagner, A. Palestine, N. Mandava, A.M. Lynch, Ophthalmology, Sue Anschutz-Rodgers Eye Center, University of Colorado Anschutz Medical Campus, Aurora, Colorado, UNITED STATES|

Commercial Relationships Disclosure: Maryam Ghiassi: Commercial Relationship: Code N (No Commercial Relationship) | Brandie Wagner: Commercial Relationship: Code N (No Commercial Relationship) | Alan Palestine: Commercial Relationship: Code N (No Commercial Relationship) | Naresh Mandava: Commercial Relationship: Code N (No Commercial Relationship) | Anne Lynch: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Age related macular degeneration (AMD) is a leading cause of blindness worldwide. The disease affects the local microenvironment of photoreceptors and retinal pigment epithelium causing an irreversible cell loss and subsequent decline in vision. It has been shown by our group that patients with iAMD have significantly altered levels of several inflammatory biomarkers, including complement factors and CCLx chemokines, in cases with iAMD compared to control patients without AMD. Building on this research that supports a role for systemic inflammation in patients with iAMD, we embarked on this study to compare levels of plasma cytokines namely, TNFa, IL-6. IL-8, IL-1ra, IL-4, and VEGF in patients with iAMD compared to controls with no AMD.

Methods: Patients with iAMD who were part of the University of Colorado IRB approved AMD registry were included in this study. Imaging studies and blood plasma samples were obtained from both iAMD and control patients. Cases and controls were defined using the Beckmann classification and multimodal imaging. The cytokine analysis was conducted using current established laboratory protocols. Wilcoxon rank-based tests were used to compare cytokine levels between the two groups.

Results: There were 211 patients with iAMD and 100 controls. The iAMD and control groups were comparable in smoking status, BMI, hypertension, cardiac and vascular disease. We found TNFa levels to be significantly higher in cases with iAMD compared to control patients ($P<0.01$). Levels of IL-6, IL-8, IL-1ra, IL-4 and VEGF levels did not differ between cases and controls (Table-1).

Conclusions: Patients with iAMD had higher levels of TNFa, a key regulator of the inflammatory response, compared with controls. TNFa is produced by macrophages, monocytes and other cells and has been shown to have direct effects on retinal pigment epithelial cells including induction of complement expression and up-regulation of VEGF production. These findings support our hypothesis that systemic inflammatory markers can distinguish patients with and without iAMD. Serum TNFa levels can potentially be used as a biomarker to identify high risk patients with iAMD.

ABSTRACT BODY:

Purpose: Radiation therapy is an effective treatment for a variety of ocular cancers, yet these radiotherapies can damage the retina, resulting in radiation retinopathy (RR) 6 months to 3 years post-radiation. In this post-hoc analysis[ST1] , we monitor and investigate retinal morphological outcomes via spectral-domain optical coherence tomography (SD-OCT), slit lamp, and/or direct ophthalmoscope to identify the most relevant biomarkers related to visual acuity.

Methods: Forty eyes with active RR were randomly assigned to cohorts A, B, and C for intravitreal ranibizumab (RBZ, 0.5 mg) treatment: (A) monthly RBZ injections for 48 weeks (n = 8), (B) monthly RBZ injections for 48 weeks plus targeted retinal photocoagulation to areas of peripheral retinal ischemia one week after the initial RBZ injection (n = 16), or (C) three consecutive monthly ranibizumab injections followed by as needed monthly RBZ injections (n = 16). At week 52, all cohorts entered a standardized treat-and-extend regimen until week 104. Best-corrected visual acuity and qualitative and quantitative SD-OCT parameters were assessed by frequency, univariate, multiple linear regression, and mixed model analyses.

Results: There was a significant difference in the presence of retinal hemorrhages at week 24, 48, 72, and 104 ($P < 0.0001$) and hard exudates at week 48 ($P = 0.016$) from baseline. A significant difference in the percentage of patients with neovascularization was found between cohorts ($P = 0.003$); cohort C had a significantly higher mean percentage of incidences of neovascularization (14.4%) compared to both cohorts A (0%) and B (4.01%). No significant differences were found between cohorts for the other graded parameters. Intraretinal cyst vertical size ($P < 0.001$) and EZ disruption ($P = 0.029$), were found to be most relevant to visual acuity due to their correlation with visual acuity by univariate analysis, with their significance confirmed in the mixed model ($P = 0.001$) and multiple linear regression model ($P = 0.01$), respectively.

Conclusions: This study helps characterize the course of vision in patients with RR by confirming the relevance of intraretinal vertical cyst size and EZ disruption as morphological biomarkers of poor visual acuity from prior studies. Larger, multicenter studies are needed to fully understand and monitor morphological changes affecting visual acuity changes in RR.

SUBMITTER (NAME ONLY): Andrew Shin

TITLE: The Accuracy and Repeatability of Biomechanical Measurements using the Brillouin Optical Scanner System (BOSS^{TM})

SESSION TITLE: Multidisciplinary Ophthalmic Imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Shin, C.S. Barnes, D. Chernyak, Intelon Optics, Lexington, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Andrew Shin: Commercial Relationship(s);Code E (Employment):Intelon Optics | Claire Barnes: Commercial Relationship(s);Code E (Employment):Intelon Optics | Dimitri Chernyak: Commercial Relationship(s);Code E (Employment):Intelon Optics

ABSTRACT BODY:

Purpose: Using Brillouin-scattering theory, the BOSS measures miniscule changes in the wavelength ('frequency shift') of laser light reflected back from an object, such as the cornea or crystalline lens. The measured frequency shift correlates with the material's stiffness, that is, its "longitudinal elastic modulus". In this study, BOSS measurements from water, plastic and porcine eyes were performed to investigate the data accuracy and repeatability.

Methods: A polystyrene cube filled with water was placed on the chinrest. Ten Brillouin frequency-shift measurements were made at each of 5 different positions of the cube, producing 50 Brillouin images for both water and plastic. Five individual old (5 months) and young (8 weeks) porcine eyes were obtained and mounted on a custom setup. In the lens experiment, 3 replicate scans were performed per lens, from the anterior to posterior lens though a single point. Three cornea exams were also performed on each porcine eye, with depth scans at 7 locations around the entire cornea.

Results: In the water and polystyrene experiment, the measured Brillouin frequency shifts were within 0.45% and 0.26%, respectively, of the formulated theoretical values and the coefficient of variation (CV) values were 0.4% and 0.3%, respectively, thus demonstrating exceptional accuracy and repeatability. In the porcine-eye lens experiment, the CV was 1.2% for the old eyes and 1.4% for the young eyes. The Brillouin stiffness of the old lenses (4.007±0.047 GPa) was significantly greater than that of the young lenses (3.699±0.051 GPa, P=0.0002). In the porcine cornea experiments, CV values of 1.0% and 1.4% were obtained for the old and young cornea samples, respectively.

Conclusions: The BOSS measured the biomechanics of various materials, including corneas and lenses, with high precision and repeatability. Consistent with the fact that the crystalline lens becomes harder with aging, this study showed greater Brillouin stiffness in old porcine eyes than in young. Based on the proven measurement accuracy and repeatability, there are many possible applications for biomechanical properties: diagnosis of ophthalmic disorders, such as keratoconus; providing reference parameters for cataract or refractive surgeries; and functioning as a tool to prove the efficacy of newly developed medicines such as lens-softening drugs for presbyopia.

ABSTRACT BODY:

Purpose: To study the superficial and deep macular vessels density in various types of amblyopia in a pediatric cohort and to compare it with fellow and age-matched control eyes.

Methods: In this prospective cross sectional study,20 subjects each anisometropic (AA) and strabismic amblyopia (SA),31subjects of bilateral isometropic amblyopia (BA),in the age group of 3-15years and 21 age-matched controls of were included.Subjects with history of nystagmus, ocular surgery and retinal pathology were excluded.Macular vessel density (VD) in superficial and deep capillary plexus(SCPandDCP) in foveal,parafoveal region and the four quadrants(temporal, superior,nasal,inferior) were measured by optical coherence tomography angiography (OCTA AngioVue version 2018.0.0.18).VD in amblyopia eyes were evaluated and compared with fellow and control eyes.In BA group, right eyes were included for comparison. Foveal avascular zone(FAZ) was evaluated in amblyopia eyes and compared with fellow and control eyes.

Results: The mean SCP VD and DCP VD in foveal region (in the order AA , SA, BA, control) were 22.85±1.3, 22.53±8.3,23.9±7.8,21.97±7.6 and 36.33±7.7,39.25±10.8,37.77±8.4,35.77±8.9 respectively which did not differ between amblyopic eyes and control eyes ($p > 0.05$).

The mean SCP VD and DCP VD in parafoveal region (in the order in AA, SA, BA,control) were 51.03±4.2, 52.26±.9, 52.54±4.2, 53.96±2.5 and 53.55±3.7, 54.48±4.3, 54.34±5.5, 55.91±4.8 respectively.

In AA eye, the SCP and DCP VD in parafoveal region were reduced as compared to control eyes ($p<0.05$) however only the superior and nasal quadrant of SCP in parafoveal region showed reduced VD ($p <0.05$).

In SA eye the SCP VD in parafoveal region was reduced when compared with control eyes ($p<0.05$) in addition only the superior and inferior quadrant showed reduced VD ($p<0.05$). DCP VD in SA eye did not differ from control eyes.($p> 0.05$) Macular VD were similar in BA and control eyes($p>0.05$).

Area of FAZ showed no difference in any type of amblyopia and control eyes. When compared with fellow eye, AA eye showed reduced VD in SCP in parafoveal region and nasal quadrant ($p<0.5$) and SA showed no difference in macular VD in SCP and DCP($p>0.5$).

Conclusions: Of all the amblyopia, the anisometropic amblyopia children showed significant reduction in macular vessel density which can signify structural retinal involvement however needs a prospective study with larger sample size.

ABSTRACT BODY:

Purpose: Nonhuman primates are the only mammals that possess a macula and exhibit soft drusen similar to those in human age-related macular degeneration (AMD). Here, we explored if aged rhesus macaques with soft drusen share similar susceptibility genes as human AMD.

Methods: We performed whole exome sequencing from 15 unrelated rhesus macaques from the California National Primate Research Center (CNPRC) with soft drusen identified on color fundus photography (CFP) and spectral domain-optical coherence tomography (SD-OCT), and compared with sequence data from a reference cohort of more than 1,800 rhesus macaques from various primate research centers. Variants falling within the exons of the orthologues of 34 candidate genes identified from genome wide association studies (GWAS) for human AMD were identified.

Results: Bilateral soft drusen were identified in 15 rhesus macaques with clinical exam, CFP, and SD-OCT. The mean number of macular soft drusen per eye was 25 +/- 31, with no evidence of advanced AMD features such as choroidal neovascularization or geographic atrophy in any study animal. Among genes associated with human AMD, we identified 6 new variants within 4 genes including COL4A3, TGFBR1, ADAMTS9, and CFH that are associated with soft drusen in macaques. All 4 of these genes are expressed in the retinal pigment epithelium (RPE). Although none of these novel variants correspond to human orthologues associated with progression to advanced AMD in humans, such as the well-characterized CFH Y402H variant, one identified variant in CFH appears to correspond to a critical binding position for C3b. Some variants such as those in TGFBR1 and ADAMTS9 also appear to be associated with drusen size and number in this cohort of animals.

Conclusions: Rhesus macaques with soft drusen share some susceptibility genes as those in human AMD including CFH, but not variants associated with progression to advanced AMD, consistent with the absence of advanced AMD features in this nonhuman primate model.

ABSTRACT BODY:

Purpose: The contributory role of the microbiota to the development of autoimmune diseases has emerged in recent years including in mouse models of uveitis. However, less is known regarding the microbiota in uveitis patients. The purpose of this study is to investigate alterations in bacterial diversity and microbiota composition between healthy volunteers and patients with non—infectious uveitis as well as evaluate longitudinal changes in uveitis patients.

Methods: An observational, prospective single center study was conducted at the National Eye Institute, National Institutes of Health, enrolling patients with non-infectious uveitis and healthy volunteers. Stool samples were collected using a standardized stool sampling kit and samples analyzed using 16S ribosomal RNA sequencing. Participants also completed the Diet History Questionnaire (DHQ). Cross-sectional analyses included age, sex, BMI and diet as covariates.

Results: A total of 47 healthy volunteers and 55 patients with non-infectious uveitis were enrolled. Of those 55 uveitis patients, 34 patients were treatment naïve and longitudinal sampling was obtained from 12 patients. There were no significant differences in Alpha diversity, phylogenetic diversity, sample richness or bacterial abundances between uveitis patients and healthy volunteers. Similarly, on subgroup analysis, no significant differences in diversity measures were observed between active and quiet uveitis patients at baseline. However, patients with BCR had higher richness, alpha diversity, and phylogenetic diversity compared to other uveitis etiologies although this was not statistically significant. Differential abundance analyses revealed a significantly lower ($q < 0.001$) abundance of 15 bacterial amplicon sequence variants (ASV) in patients with quiet uveitis compared to active disease. Longitudinal cohort analysis showed that microbiota richness decreased with change in disease activity from active to quiet (coefficient = -56.81, $p = 0.038$).

Conclusions: Our preliminary results suggest that there are differences in the microbiota between active and inactive uveitis as well as longitudinal differences as disease activity changes. Further work is required including with metagenomics to validate these observations.

TITLE: Assessment of crystalline lens shape during accommodation using IOLMaster 700 B-scan images

SESSION TITLE: Optics: Accommodation, Lens and Ocular Biometry

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Pradhan, R. Hughes, E. Pieterse, D.A. Atchison, S. Vincent, S. Read, A. Carkeet, Optometry and Vision Science, Queensland University of Technology, Brisbane, Queensland, AUSTRALIA|A. Pradhan, R. Hughes, E. Pieterse, D.A. Atchison, S. Vincent, S. Read, A. Carkeet, Centre for Vision and Eye Research, Queensland University of Technology, Brisbane, Queensland, AUSTRALIA|

Commercial Relationships Disclosure: Asik Pradhan: Commercial Relationship: Code N (No Commercial Relationship) | Rohan Hughes: Commercial Relationship: Code N (No Commercial Relationship) | Emily Pieterse: Commercial Relationship: Code N (No Commercial Relationship) | David Atchison: Commercial Relationship: Code N (No Commercial Relationship) | Stephen Vincent: Commercial Relationship: Code N (No Commercial Relationship) | Scott Read: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Carkeet: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The Zeiss IOLMaster 700® biometer offers image-based axial measurement of eye structures together with visualisation of the anatomical details in a longitudinal section. We aimed to analyse these B-scan images to determine crystalline lens shape changes induced by accommodation.

Methods: IOLMaster 700 B-scan images were acquired from 10 children (age: mean 11.1, SD 0.4 years) during 0D and 6D accommodation tasks. Scans were analysed using custom MATLAB software to determine the curvature measurements for anterior and posterior cornea and lens surfaces. The process involved segmenting the image to locate the corneal and lens surfaces (Figure 1), correcting for existing distortions in the image to reconstruct ray path distance maps, and using the maps with ray tracing to determine surface positions. Second order polynomials were fit to the surfaces to compute radii of curvature.

Results: The radius of curvature decreased significantly with accommodation for the anterior lens ($t_8 = 5.93$, $p = 0.0003$) (0D accommodation: mean 13.26mm, SD 2.19mm; 6D accommodation: mean 8.87mm, SD 0.94mm) but not for posterior lens ($p > 0.05$) (0D accommodation: mean -5.62mm, SD 0.64mm; 6D accommodation: mean -5.11mm, SD 0.52mm), nor for anterior and posterior cornea. Results for all surfaces are shown in Figure 2 with data for one image (6D accommodation) discarded due to eye movement artefacts.

Conclusions: This is a novel analysis of the data contained in IOLMaster 700 images. The measured changes in both anterior and posterior lens surface curvature were comparable to previous studies that demonstrate its potential of measuring lens shape during accommodation. Because of the wide availability of IOLMaster 700, this may be a useful research tool for studying crystalline lens shape. Further research is required to establish repeatability and accuracy of the technique.

Commercial Relationships Disclosure: Daniel Chavez Velazquez: Commercial Relationship: Code N (No Commercial Relationship) | Karla Arteaga-Rivera: Commercial Relationship: Code N (No Commercial Relationship) | Abril García-Terrazas: Commercial Relationship: Code N (No Commercial Relationship) | Jesus Guerrero: Commercial Relationship: Code N (No Commercial Relationship) | Carlos Muller Morales: Commercial Relationship: Code N (No Commercial Relationship) | Arturo Ramírez-Miranda: Commercial Relationship: Code N (No Commercial Relationship) | Alejandro Navas: Commercial Relationship: Code N (No Commercial Relationship) | Enrique Graue-Hernandez: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Maintaining transparency and avascularity is essential to preserve optimal vision. The administration of mitomycin-C (MMC) has been used intravenously for a hypoxic and embolic effect. This study aims to describe clinical outcomes of intravascular MMC for the treatment of corneal neovascularization.

Methods: A pilot study of 8 eyes with corneal neovascularization injection 0.1ml of MMC. Quantification of neovascularization was measured by an independent observer. ImageJ software (NIH, Bethesda Maryland) was used to trace and quantify vasculature in standardized clinical slitlamp photographs. Briefly all identifiable vessels were drawn upon and the number of pixels quantified. Each image was measured 3 times. Follow-up was done at 1 week, 1 month and 2 months post-injection. Preop and postop values were compared using t-test and statically significant value was set at $p < 0.5$.

Results: A total of 8 subjects were enrolled, of which 37.5% were female with an age range of 17-64 years (average of 37 years). In 62.5% of the cases the left eye was affected. The most frequent etiology responsible for the corneal vascularization was history of herpetic keratitis in 75% of the subject, phlyctenular keratoconjunctivis in 12.5%, and neovascularization secondary to intrastromal rings in 12.5%. One subject 12.5% presented herpes keratitis reactivation 7 days after injection, despite being on oral antiviral suppression therapy. Mean preoperative UDVA was 1.01 (+ 0.42), CDVA was 0.76 (+0.53) LogMAR. Postoperative UDVA was 0.91 (+0.42) and CDVA was 0.63 (+0.42) LogMAR with no statistically significant differences when preop and postop values were compared $p>0.05$. Two patients improved both UDVA and CDVA. Comparing photographs, there was an overall reduction of 60.27% of pixels in corneal vascularization at the las follow-up.

Conclusions: Corneal intrastromal MMC may be a potential therapeutic strategy to treat corneal neovascularization. Here we present short term results demonstrating that neovascularization may be reduced with clinically significant results, thus rendering this patients more suitable for optical surgical procedures. Despite regression of neovascularization visual acuity may not improve particularly if stroma is scarred. Further studies are needed to address its safety and long-term effects.

TITLE: Predicting contrast sensitivity functions with digital twins generated by Hierarchical Bayesian modelling

SESSION TITLE: Machine Learning and Big Data

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: Z. Lu, Division of Arts and Sciences, New York University Shanghai, Shanghai, Shanghai, CHINA|Z. Lu, Y. Zhao, Center for Neuroscience, New York University, New York, New York, UNITED STATES|L.A. Lesmes, M. Dorr, Adaptive Sensory Technology, Inc., San Diego, California, UNITED STATES|

Commercial Relationships Disclosure: Zhong-Lin Lu: Commercial Relationship(s);Code I (Personal Financial Interest):Adaptive Sensory Technology, Inc., Juehua Medical Technology, Ltd;Code P (Patent):Adaptive Sensory Technology, Inc., Juehua Medical Technology, Ltd | Yukai Zhao: Commercial Relationship: Code N (No Commercial Relationship) | Luis Lesmes: Commercial Relationship(s);Code E (Employment):Adaptive Sensory Technology, Inc.;Code I (Personal Financial Interest):Adaptive Sensory Technology, Inc.;Code P (Patent):Adaptive Sensory Technology, Inc. | Michael Dorr: Commercial Relationship(s);Code E (Employment):Adaptive Sensory Technology, Inc.;Code I (Personal Financial Interest):Adaptive Sensory Technology, Inc.;Code P (Patent):Adaptive Sensory Technology, Inc.

ABSTRACT BODY:

Purpose: We developed a hierarchical Bayesian model (HBM) based on repeated measures of contrast sensitivity functions (CSF) obtained across three luminance conditions (Zhao et al., 2021). Here we use the HBM, which extracts covariant features within and between individuals and luminances, to generate digital twins for contrast sensitivity (CS) and predict yet-observed results.

Methods:

The HBM describes CS across a hierarchy of population, individual, and luminance, with hyperparameters at population/individual levels that quantify the covariant relationship between CS parameters (peak gain, peak spatial frequency, and bandwidth) across individuals and luminances. We evenly split 112 subjects in Hou et al. (2016) into Group I (N=56), in which CSF data included three luminances, and Group II (N=56), in which partial data from 0, 1, or 2 luminances were used to train and predict data observed in non-included conditions. Parameter uncertainty was quantified by half-width confidence intervals (HWCI), with smaller HWCI indicating higher model precision.

Results:

Group I data exhibited an average HWCI of 0.061 log10, which was expected to be lower than Group II, for which HWCIs decreased (from 0.101 to 0.089 and 0.084) as the number of training conditions increased (from 0 to 1 and 2). The mean absolute error of Group II predictions likewise decreased from 0.048 to 0.036 and 0.034. HBM predictions accounted for 77% and 83% of the variance of observed AULCSF values, using 1 or 2 luminances. Fig. 1 presents the example of one subject, with observed estimates for peak gain and peak frequency (left; top row), and CSF with confidence intervals (right, top row), in addition to digital twin predications for different training conditions (2^{nd}-4^{th} row). When predictions were used to seed analysis of the observed data, only 30-60% of the data collection was needed to reach the accuracy and precision of original analyses.

Conclusions: The HBM for contrast sensitivity extracted valuable information about covariant features within and between individuals and luminances. The HBM enabled the generation of digital twins for CS that predict yet-observed data, significantly reduces testing burden, and exhibits potential for improving real-world testing of functional vision.

ABSTRACT BODY:

Purpose: Referrals generated from primary care networks have been shown to provide a multiplier effect in contributing value to the larger health system, but there have been few studies on the downstream effects of referrals generated from specialty clinics. We aimed to investigate the impact of an academic ophthalmology clinic on the larger health system by performing a cross-sectional retrospective study to analyze the subsequent utilization of care with other outpatient providers within the system following the initial visit.

Methods: Appointment records of patients aged 18 years and older who had a scheduled new appointment with an attending ophthalmologist at Penn State Health (PSH) Medical Center between January 1, 2019 and December 31, 2019 were analyzed. The patients who showed for this appointment were included for analysis. Patients were considered “Already established with PSH” if they had seen an outpatient healthcare provider within PSH within 3 years prior to the date of the eye appointment, and “Not already established with PSH” if they had not seen an outpatient healthcare provider within PSH within 3 years prior to the date of the eye appointment. Of this latter group, appointment records were analyzed to determine if and which other outpatient healthcare providers within the PSH system the patient received care from within one year after the eye clinic visit. The Institutional Review Board at the Penn State Hershey Medical Center deemed this study to be exempt.

Results: Of the 4628 new patient appointments in 2019, 3869 patients (83.6%) showed for their appointment and were included for analysis. Within this group, 1178 (30.4%) were “Not already established with PSH.” Within this group, 344 (29.2%) went on to see another outpatient healthcare provider within PSH within 1 year after their eye clinic visit. The type of outpatient healthcare provider seen included: another optometrist or ophthalmologist (n=169, 49.1%), another medical specialty (n=154, 44.8%), pre-operative anesthesia (n=65, 18.9%), and primary care (n=14, 4.1%). Some of these patients saw providers in multiple categories.

Conclusions: An academic ophthalmology clinic can serve as a significant gateway for patients to other departments within the larger academic health system.

ABSTRACT BODY:

Purpose: To determine whether the outer retinal layer (ORL) thickness measurement could serve as a clinical biomarker to predict the annual square root enlargement rate (ER) of geographic atrophy (GA).

Methods: Eyes with GA secondary to age-related macular degeneration (AMD) were imaged over a 12-month span with swept-source OCT (PLEX® Elite 9000 (ZEISS, Dublin, CA)) using a 6 x 6 mm scan pattern. GA lesions were manually identified and measured using the en face sub-retinal pigment epithelium (RPE) OCT images, and GA annual square root ERs were calculated. ORL thickness was measured using segmentation boundaries that extended from the upper boundary of outer plexiform layer to the upper boundary of RPE layer using a validated semi-automatic segmentation software. At baseline visit, the ORL thickness were measured in different sub-regions around the GA (Fig.1).

Results: A total of 38 eyes from 27 subjects were included in this study. The same eyes were previously used to compute the correlation between GA growth and the measurements of choriocapillaris (CC) flow deficits (FDs) and RPE-Bruch's membrane (BM) distances[1,2]. A negative correlation was observed between the ORL thickness and the annual GA growth in all the sub-regions (Table 1). The ORL thickness immediately around GA showed the strongest correlation with the GA annual square root ERs ($r=-0.457$, $p=0.004$ for a 0-300 μm rim around the GA). No correlations were found between ORL thickness and the previously published CC FDs in any sub-regions, whereas a significant correlation was found between the ORL thickness and the RPE-BM distances in the region immediately around GA ($r=-0.398$, $p=0.013$).

Conclusions: ORL thickness measurements around the GA showed significant correlations with the annual GA growth, but a significant correlation was also found between the ORL thickness and the RPE-BM distances, suggesting that the ORL thickness and RPE-BM distances do not independently influence the growth of GA. Due to the challenges of segmenting the ORL, RPE-BM distance measurements and CC FDs are sufficient to serve as the clinical biomarkers to predict the annual ERs of GA.

ABSTRACT BODY:

Purpose: To evaluate the associations between dysfunctional CFI rare variant carrier status and progression to advanced age-related macular degeneration (AMD), geographic atrophy (GA) and neovascular disease (NV) in a prospective analysis.

Methods: Analyses were performed using the Seddon Longitudinal Cohort Study (SLCS) of AMD (N=2116 subjects, 3901 eyes, mean follow-up 8.3 years, 22% progression rate to advanced AMD, PMID 30389371) and the Age-Related Eye Disease Study (N=2837 subjects, 5200 eyes, mean follow-up 9.2 years, 18% progression rate to advanced AMD). CFI rare variants with low serum factor I levels and decreased function in a serum based assay (PMID's 24036952 and 32908800), and other common and rare genetic variants related to AMD, demographic and behavioral factors, and baseline and follow-up macular status were evaluated. To estimate the effect of rare dysfunctional CFI variant status on AMD progression, independent of other variants related to progression, odds ratios (OR) were calculated based on Generalized Estimating Equations. Interactions between CFI carrier status and other variants were determined.

Results: Among the 4953 subjects (9101 eyes) in the combined cohort, 1% were rare CFI variant carriers and 44% of the carriers progressed to overall AMD compared with 20% of non-carriers ($P < .0001$). For advanced AMD subtypes, 30% of carriers versus 10% of non-carriers progressed to GA ($P < .0001$), and 18% of carriers and 11% of non-carriers progressed to NV ($P=.049$) over a 12-year follow-up period. CFI carriers were more likely to have a family history of AMD (CFI variant: 36% with 1 family member affected and 14% with 2+ family members affected; no CFI variant: 19% with 1 family member affected and 8% with 2+ family members affected; P for trend =.035). CFI variant carrier status was associated with progression to GA (OR 1.91, 1.03-3.52) but not with NV (OR 0.96, 0.54-1.71), after adjustment for demographic and ocular factors and other genetic variants (Figure). CFI rare variant carrier status was associated with the common CFI (PMID 18685559) and hepatic lipase C (LIPC, PMID 20385826) genetic variants, but no significant interactions between CFI carrier status and other genetic variants were noted for progression to advanced AMD, GA or NV.

Conclusions: These new findings suggest that carriers of dysfunctional CFI rare variants are at higher risk for progression to GA.

ABSTRACT BODY:

Purpose: Adrenomedullin (AM) is a bioactive peptide isolated from human pheochromocytoma. AM is mainly secreted by vascular endothelial cells and has various physiological functions such as anti-inflammatory, anti-apoptotic, and anti-oxidative stress effects. We have reported that AM is also produced in the eye and that exogenous administration of AM ameliorates the pathogenesis of diabetic retinopathy and age-related macular degeneration (Am J Pathol. 2017, 2021). Experimental autoimmune uveitis (EAU) is an experimental model of human autoimmune uveitis and serves to investigate the mechanism of uveitis and evaluate therapeutics for ocular inflammatory diseases. In the present study, we investigated the therapeutic effect of AM-administration on EAU model in mice.

Methods: Female C57BL/6J mice aged 8 weeks were used. To induce EAU, N-terminal peptide fragment of human interphotoreceptor retinoid-binding protein (hIRBP(1-20)) emulsified with complete Freund's adjuvant containing Mycobacterium tuberculosis H37Ra was subcutaneously injected at the base of tails. Subsequently, pertussis toxin was intraperitoneally injected. In the AM group, human recombinant AM was administered subcutaneously using osmotic pump at infusion rate of 29 μg/kg/day for 14 days. PBS was administered to the control group in the same manner. On day 14 after immunization, clinical scores were evaluated. According to the severity of inflammatory findings, clinical scores were classified into 4 categories (0-3) as previously reported, with some modifications. The clinical scores were evaluated by two ophthalmologists in a blinded manner, and the average of both eyes was used as the score for each mouse.

Results: No significant difference was found in the clinical score between AM-treated (2.00±0.42, n=8) and control groups (1.31±0.49, n=8).

Conclusions: In the present study, we could not confirm the therapeutic effect of AM- administration on the clinical score of EAU. Since anterior ocular lesions of EAU have a large variability among individuals, pathological examination including posterior ocular lesions would be necessary for more detailed evaluation. Furthermore, the therapeutic effects of higher concentrations of AM and intraocular AM-injection should be considered in the next study.

TITLE: Effect of tactile meta-guidance on visual perception in people with and without central vision loss

SESSION TITLE: Assistive Devices, Visual Function Assessment, and Vision Restoration Therapies

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Knizak, N. Ross, New England College of Optometry, Boston, Massachusetts, UNITED STATES|P.J. Bex, J. Skerswetat, Northeastern University, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Meghan Knizak: Commercial Relationship: Code N (No Commercial Relationship) | Nicole Ross: Commercial Relationship(s);Code R (Recipient):Eschenbach Optik | Peter Bex: Commercial Relationship(s);Code F (Financial Support):PerZeption Inc.;Code P (Patent):Northeastern University | Jan Skerswetat: Commercial Relationship(s);Code F (Financial Support):PerZeption Inc.; Adaptive Sensory Technology;Code P (Patent):Northeastern University

ABSTRACT BODY:

Purpose: Previous studies have reported visual perception improvements in the space around an observer's hands in normally-sighted participants. We examined whether similar benefits, using tactile meta-guidance, occur in peripheral vision of patients with central vision loss (CVL) across a range of visual functions.

Methods: We tested the effect in three groups of 8 individuals: CVL (median age: 63 years, ±16σ), age-matched controls (63±6σ), and young controls (24±1σ). Inclusion criteria- CVL: acuity of 20/300 or better in the better seeing eye and bilateral central scotomas verified by microperimetry; age-matched and young controls; acuity of 20/20 in the better seeing eye and no comorbidities. FInD (Foraging Interactive D-prime) psychophysics were deployed to measure detection thresholds for contrast, color, motion coherence, pattern coherence, and threshold-versus-contrast. Each of three charts contained a 4*4 grid of 6° cells, a random subset of which contained stimuli of varying signal intensity, ranging from easy to difficult levels, and updated by an adaptive algorithm using the observer's responses on previous charts. Participants completed 2 sessions in random order, either with or without touching with the left hand's index finger each cell before moving on to the next cell. Planned pairwise comparison t-tests were used to test within group differences with and without meta-guidance for each visual function. Analysis-of-variance models were used to compare groups and condition results for each visual function.

Results: A significant effect of visual impairment for all visual functions was found, however tactile meta-guidance did not significantly improve any of the investigated visual functions.

Conclusions: FInD psychophysics successfully detected deficits across a range of visual functions in people with CVL. The investigated visual functions showed deficits in CVL patients compared to control groups that are not improved by tactile meta-guidance. Future directions could explore the relationship of meta-guidance on fixation stability. However, these preliminary results suggest that tactile meta-guidance may not be an effective low vision rehabilitation strategy.

ABSTRACT BODY:

Purpose: To test the hypothesis that longitudinal glaucoma-related ganglion cell complex (GCC) thinning may be separated from aging-related changes within a Bayesian hierarchical linear model.

Methods: 63 eyes (45 patients) with suspected glaucoma (GS) and ≥2 years of follow-up and ≥3 macular OCT scans were recruited. The eyes in this cohort had suspicious optic discs but normal RNFL thickness and visual fields at baseline and final follow-up. The rate of RNFL thinning was required to be below 1 μm/year. GCC thickness at 36 3°×3° superpixels from the central 18° of macular volume scans were exported. Rates of GCC change at the superpixel level were estimated with a Bayesian hierarchical model with subject and superpixel-level random effects and residuals. One-sided Bayesian p-values were defined as the posterior probability that a given parameter was greater or less than zero (cutoff $p < 0.025$). The fixed effect of age was included in the model to assess the magnitude of aging-related GCC thinning. The main outcome measure was the difference in the magnitude of the GCC slopes between the longitudinal slopes and cross-sectional aging-related effects.

Results: Mean (SD) age, follow-up time, and number of OCT images were 61.3 (13.9) years, 3.5 (0.7) years, and 4.2 (1.0). The cross-sectional aging effect was significantly negative in 25 out of 36 superpixels with slopes of -0.56 to –0.22 μm per year in significantly changing superpixels. Longitudinal slopes were significantly negative in 34 out of 36 superpixels with slopes ranging from –1.38 to –0.36 μm per year in significantly changing superpixels. 33 of 36 superpixels had a steeper longitudinal slope compared to cross-sectional slope (Figure) and the differences were statistically significant in 9 of these 36 superpixels.

Conclusions: In this cohort, our proposed model was able to separate longitudinal glaucoma-related GCC thinning from aging-related effects; the longitudinal rates of thinning were significantly faster than the rates of change related to aging. To correctly estimate inner macular changes over time, longitudinal data with proper definition of the mean and variance structures are required.

ABSTRACT BODY:
Purpose: During recruitment for retina trials, screen failure commonly results from discrepancies between inclusion criteria, real-world Snellen VA, and ETDRS VA verified at the study visit. This simulation study evaluated how failure rate is affected by different inclusion criteria and VA tests used for screening: Snellen, ETDRS and quantitative VA (Zhao et al. 2021).
Methods: To screen a population typical for retina (Fig.1 Kaiser 2009), we approximated a general patient (GP) distribution with piecewise uniform distribution of VA thresholds that varied from -0.2 to 1.8 logMAR, and VA range that scaled proportionally: VA range = 0.253 + 0.185 VA threshold (Zhao et al. 2021). We considered four inclusion criteria, bounded by 20/X and 20/320 (X= 25, 32, 40, or 50). To simulate recruitment, patients were randomly sampled from the GP, screened with a VA test (61-letter Snellen, 70-letter ETDRS, and 15-letter qVA), and verified with ETDRS. For each test and criterion, 1000 simulations that each comprised 1000 patient screenings, were used to calculate failure rate as the % of ETDRS scores verified outside of 20/X - 20/320.
Results: Fig. 2 shows that, across criteria, screen failure rates were highest for Snellen (12-15%), and lower for ETDRS (7-9%), and qVA (4-6%). Across tests, most failures were observed when screening for VA (20/50 – 20/320) known to exhibit the highest variability and worst Snellen-ETDRS discrepancy.
Conclusions: In simulations, the well-known deficiencies of Snellen VA lead to the highest screen failure rates (13%), which can be reduced but not eliminated using ETDRS (9%) and qVA (6%). The qVA's intelligent algorithm with 15-letter testing (5 rows of 3 letters) exhibits potential for feasible real-world screening that can improve patient recruitment for retina.

TITLE: Mitochondrial and epigenomic gene transcription analysis in uveal melanoma

SESSION TITLE: Tumor - Diagnosis, prognosis, and molecular mechanism

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P.K. Kopinski, L.A. Dalvin, Ophthalmology, Mayo Clinic Minnesota, Rochester, Minnesota, UNITED STATES|

Commercial Relationships Disclosure: Piotr Kopinski: Commercial Relationship(s);Code I (Personal Financial Interest):Regenxbio;Code I (Personal Financial Interest):Cabaletta Bio;Code I (Personal Financial Interest):Passage Bio;Code I (Personal Financial Interest):Oyster Pharmaceuticals | Lauren Dalvin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Uveal melanoma is a deadly cancer with high metastatic potential. Mitochondrial genetics and epigenetics are known to play a role in tumorigenesis, progression, and metastasis, while mitochondrial metabolites have recently been shown to cause changes in the nuclear epigenome. In this study, we describe the transcriptional state of genes involved in mitochondrial metabolism, chromatin remodelling, and histone modification in uveal melanoma in order to define targetable signaling pathways.

Methods: TCGA database of 80 primary uveal melanoma cases was queried for mRNA transcript levels of key mitochondrial metabolism enzymes and mitochondrial metabolism-dependent chromatin remodeling and histone modifying enzymes. These were selected a priori based on recently described metabolically-induced chromatin changes with known transcriptional outcomes (Kopinski et al. 2019, Picard et al. 2014). Transcription levels were compared against the group mean and samples were grouped based on key enzyme transcriptional profiles.

Results: Of the 80 analyzed samples, a third showed alterations in transcription co-activator PGC1α and citrate synthase (CS), a quarter in ATP-dependent citrate lyase (ACLY), and a fifth in mitochondrial polymerase γ (POLG). A third showed alterations in NAD-dependent deacetylases: Sirtuins 1 and 6 (SIRT1, SIRT6), of which 60% were discordant. Histone 3 lysine 9 (H3K9) demethylases (KDM3A, KDM3B, JMJD1C) were altered in a third of samples with high concordance. A quarter showed highly concordant alterations in DNA methyltransferases DNMT3A and B. Interestingly, Sirt1 expression was highly discordant with that of citrate synthase, while H3K9 methyltransferase showed discordance with H3K9 demethylases.

Conclusions: Primary uveal melanoma samples exhibit distinct transcriptional profiles with differential expression of mitochondrial metabolism and chromatin modifying enzymes, allowing identification of potentially targetable signalling pathways. Patterns of chromatin modifying enzyme expression suggest internally consistent conditions to promote a given chromatin state, with concordant expression of enzymes with similar function and opposing expression of those with opposite function. This suggests a personalized, transcriptonal profile-based metabolic intervention to disrupt these conditions may disable functional chromatin, thus providing a therapeutic target.

ABSTRACT BODY:

Purpose: To evaluate rates of visual field loss in eyes with optic nerve head drusen (ONHD) and to investigate their relationship with intraocular pressure (IOP).

Methods: This was a retrospective cohort study involving patients with ONHD from the Duke Ophthalmic Registry. All records from eyes with at least 12 months of follow-up and at least 2 reliable standard automated perimetry (SAP) tests were included. Linear mixed models were used to estimate rates of SAP mean deviation (MD) loss over time. Rates of progression were classified in slow (slower than -0.5dB/y), moderate (between -0.5dB/y and -1db/y) and fast (faster than -1dB/y). Univariable and multivariable models were used to assess the effect of mean IOP and other clinical variables such as age, race and baseline MD, on rates of change.

Results: The study included 109 eyes of 66 subjects with ONHD followed for an average of 5.6 ± 4.3 years. 27 eyes (24.8%) were treated with IOP lowering drugs during follow-up. Eyes had a mean IOP during follow-up of 14.9 ± 2.5 mmHg. The mean rate of SAP MD change was -0.20 ± 0.18 dB/year, ranging from -1.10 to 0.22 dB/year. 102 (93.6%), 6(5.5%) and 1(0.9%) of eyes had slow, moderate, and fast progression, respectively. There was no statistically significant difference in rates of change between eyes receiving IOP lowering drugs and eyes that did not receive IOP lowering medication (P=0.441). Higher mean IOP during follow-up was not associated with faster rates of MD change in both univariable (P=0.131) and multivariable (P=0.435) models. In a multivariable model including mean IOP, age, gender, race, and baseline SAP MD, only age at baseline was significantly associated with faster rates of SAP MD loss with 0.07 dB/year faster rate of loss for each decade older (P=0.003).

Conclusions: Most eyes with ONHD have a slow progression of MD loss over time. We were not able to find a statistically significant relationship between mean IOP and rates of visual field loss, which suggests that there may not be a clear benefit of IOP lowering treatment in eyes with ONHD. Older age was significantly associated with faster rates of visual field loss.

TITLE: Outcomes after Failed Pneumatic Retinopexy in Macula Off Retinal Detachments

SESSION TITLE: Vitreoretinal surgery/VR Interface/PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Ruff, J. Wallsh, N. Falk, J. Huz, P. Bhatnagar, Ophthalmology, Albany Medical Center, Albany, New York, UNITED STATES|

Commercial Relationships Disclosure: Eric Ruff: Commercial Relationship: Code N (No Commercial Relationship) | Josh Wallsh: Commercial Relationship: Code N (No Commercial Relationship) | Naomi Falk: Commercial Relationship: Code N (No Commercial Relationship) | Jonathan Huz: Commercial Relationship: Code N (No Commercial Relationship) | Pawan Bhatnagar: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Macula off retinal detachments (RDs) represent a potentially visually devastating condition. Pneumatic retinopexy (PR) offers a prompt treatment option, but lower primary anatomic success rates than other surgical options. We aim to evaluate the visual outcomes of eyes with macula off RDs that failed initial PR compared to other primary surgical approaches.

Methods: Retrospective chart review of all patients diagnosed with a macula off RD was undertaken. Those eyes treated with PR were evaluated for anatomic success and final visual acuity (VA), amongst other data points. A comparative cohort was identified consisting of eyes treated with primary scleral buckle (SB) or scleral buckle and pars plana vitrectomy (SB/PPV) with pathology in which PR is an indicated treatment option. These cohorts were compared to the subset of eyes unsuccessfully treated with primary PR, most notably for final VA. Primary SB was also compared to secondary SB following failed PR and primary SB/PPV compared to secondary SB/PPV following failed PR.

Results: In total, 242 eyes were diagnosed with a macula off RD with 90 eyes (37.2%) treated primarily with PR. For all eyes undergoing PR, mean final VA was 0.36±0.05 logMAR (20/45). Pneumatic retinopexy was successful in 44 eyes (48.9%) with a mean final VA of 0.15±0.02 logMAR (20/29) and 90.1% achieving 20/40 or better final VA. Those eyes that failed PR required additional intervention with 33 (71.7%) secondarily treated with SB/PPV, 9 (19.6%) with SB and 4 (8.7%) with PPV. Failed PR undergoing secondary SB/PPV achieved a mean final VA of 0.53±0.11 logMAR (20/67) compared to 28 eyes primarily treated with SB/PPV with mean final VA of 0.59±0.11 logMAR (20/78; p=0.70). Both cohorts had comparable mean VA at initial presentation, 1.89±0.17 logMAR for failed PR versus 2.06±0.14 logMAR for primary SB/PPV (p=0.46). Similarly, failed PR undergoing SB reached mean final VA of 0.45±0.14 logMAR (20/56) compared to 9 eyes treated with primary SB with 0.42±0.18 logMAR (20/53; p=0.83).

Conclusions: When indicated, PR offers eyes with a macula off RD the potential for significant VA improvement and, even if primary PR fails, the VA results are comparable to primary PPV/SB and primary SB.

ABSTRACT BODY:

Purpose: Aging is a major risk factor for cataract due to a combination of factors including age-related protein and lipid oxidation/damage, reduction in the ability of the lens to detoxify reactive oxygen species, and genetic alterations that could disrupt cellular structure. However, most tissues also alter gene expression with age even in the absence of pathology, and we found that the transcriptome of the aging mouse lens does as well, predicting pathways that could be either protective against cataract development or may exacerbate age-related declines in lens transparency. However, lab mice have a much shorter life span than humans thus the relationship between lens aging in mouse and human is unclear. This work seeks to fill this knowledge gap by investigating the transcriptomic changes of the aging human lens.

Methods: Young (20-30 years of age) and aged (70-89 years of age) human lenses were isolated from human cadavers during preservation of corneas for transplant by eye banks and immediately immersed in RNAlater prior to shipment to our laboratory. The lenses were dissected into central epithelium, equatorial epithelium, and cortical fibers, and total RNA prepared. RNA was converted to cDNA then sequencing libraries prepared using SMARTer Stranded Total RNA-Seq Kit-Pico kit and double strand sequenced by DNA Link. Read pairs were mapped to the human genome, data normalized and differential expression assessed using EdgeR. Differential expressed genes were mapped to pathways via iPathway Guide.

Results: Principal component analysis revealed that cell type (central epithelium, equatorial epithelium versus fibers) was the strongest factor driving lens gene expression, while age only accounted for 12% of the variance between samples. Aged lens fibers downregulate the expression of several hundred genes including the BMP regulator Crim1, numerous lens fiber cell markers and several enzymes responsible for glutathione metabolism, while less than 100 genes were upregulated with aging. Central and equatorial epithelial samples exhibit fewer gene expression changes with aging, while GSTM1 is the most downregulated gene in both cell types. Aged equatorial epithelium downregulates the expression of many lens marker genes consistent with the results in the cortical lens fibers.

Conclusions: Human lenses, like those of mice, differentially express numerous genes during aging, including many enzymes involved in glutathione metabolism.

ABSTRACT BODY:

Purpose: Parkinson’s Disease (PD) is associated with a variety of abnormalities in eye movements, and there is ample evidence for specific deficits in convergent eye movements. Often self-report or subjective judgements by clinicians, or objective eye-tracking measures are reported in the literature; but seldom both. Here we used both methods to describe the vergence deficits in PD patients.

Methods: 13 PD and 6 age-matched older adults (OA) were recruited to complete a smooth vergence task. A target mounted on a rod moved steadily closer and farther away (between 48 cm and 0 cm) at 3 different speeds (1, 2 and 4 cm/sec). Subjects fixated at the moving target and pressed a button when they perceived the approaching target as two (i.e. subjective break point). They also pressed the button when the retreating target became one (i.e. subjective recovery point). In addition to subjective reporting, subjects’ eye movements were captured using a binocular eye-tracking headset (Pupil Core 200Hz). The target positions at the time where convergence broke (i.e. objective break point) and at the time when the eyes recovered the binocular tracking (i.e. objective recovery point) were recorded. Each speed was measured twice and each trial comprised 3 cycles.

Results: Based on the objective measure, OA subjects maintained vergence until the target moved significantly closer (OA: 3.31 cm; PD:10.31 cm; $F(1,50) = 18.8$, $p<0.001$) and recovered vergence earlier (OA: 5.24 cm; PD:11.01 cm; $F(1,48) = 9.4$, $p<0.004$). We calculated the differences in target position between these objective points and the corresponding self-reported subjective points. PD subjects delayed in reporting the break point relative to OA (OA: 0.32 cm; PD: 2.22 cm; $F(1,51) = 4.65$, $p = 0.036$), but the groups did not differ in their reporting on the recovery point (OA: 1.70 cm; PD: 3.48 cm; $F(1,48) = 1.14$, $p = 0.29$).

Conclusions: Our PD patients showed expected deficits in objective measures of convergence and recovery. However, we found that PD subjects delayed in reporting a break in vergence but not for recovery. PD patients appear delayed in perceiving a loss of fusion but detect normally its restoration.

ABSTRACT BODY:

Purpose: Purpose: Stargardt retinopathy is an inherited macular degeneration driven by mutations in gene ABCA4 and characterized by the accumulation of the lipid deposits in the retinal pigment epithelium (RPE), leading to its atrophy and photoreceptor death. The presence of ABCA4 in the apical membrane of human RPE cells suggests the involvement of this protein in RPE physiology and Stargardt disease pathogenesis. We developed Stargardt-iPS cells derived in vitro disease model to understand how ABCA4 loss of function promotes disease phenotype in the RPE - a primary injury site in Stargardt and other age-related maculopathies.

Methods: Fully characterized Stargardt- iPSCs (ABCA4 knock out and patient iRPE) were differentiated into RPE using a developmentally guided protocol. Stargardt-iRPE were cultured on semi-permeable membranes for six weeks to obtain a functionally mature and polarized monolayer tissue. Cells were evaluated for RPE-specific functions, including digesting photoreceptors outer segments. In addition, lipid accumulation phenotype was evaluated using a photoreceptor outer segment regimen to determine the human pathogenetic sequence.

Results: ABCA4 loss of function in Stargardt -iRPE triggers a cell-autonomous disease phenotype in RPE cells, including sub and intra-cellular lipid deposits while exposed to photoreceptor outer segment regimen. Stargardt -iRPE exhibited a reduced ability to digest photoreceptor outer segments that this defect was restored by lysosome acidifying drugs.

Conclusions: Our work shows Stargardt-iRPE offers a physiologically relevant in-vitro disease model for Stargardt disease and that ABCA4 loss of function initiates a cell-autonomous disease phenotype in RPE cells contributing to Stargardt disease pathology.

ABSTRACT BODY:

Purpose: Bimatoprost sustained-release (Bimatoprost SR, Durysta, Allergan) is a biodegradable implant that is administered intracamerally to reduce intraocular pressure (IOP) in patients with ocular hypertension or open angle glaucoma (OAG). To date, the efficacy and safety of Bimatoprost SR in patients with prior glaucoma surgery have not been examined. The aim of the present study is to evaluate outcomes of Bimatoprost SR implantation in patients with prior minimally invasive glaucoma surgery (MIGS) or incisional glaucoma surgery.

Methods: A retrospective chart review of 122 eyes that received Bimatoprost SR by six glaucoma specialists at Wills Eye Hospital between March 2020 and September 2021 was performed. Patients were included if they had prior iStent, goniotomy, trabeculectomy, or tube shunt surgery. Statistical analyses, including paired t-tests, were performed.

Results: A total of 41 eyes (39 OAG and 2 chronic angle closure) from 32 patients were included. Median age was 76 years and 24 (75%) patients were women. Of the 41 eyes, 25 (61%) had iStent implantation, 4 (10%) had goniotomy, 5 (12%) had trabeculectomy, 2 (5%) had tube shunt, and 5 (12%) had both trabeculectomy and tube shunt surgery prior to Bimatoprost SR implantation. Mean follow-up time was 26.9 ± 18.9 weeks after implantation. Mean IOP after Bimatoprost SR implantation (16.7 ± 5.0 mmHg) was similar to pre-treatment IOP (17.5 ± 4.5 mmHg, $p=0.37$). Patients required significantly fewer medications to control IOP after Bimatoprost SR implantation (1.2 ± 1.2) compared to baseline (1.9 ± 1.2, $p<0.001$). Two (5%) eyes required additional tube shunt surgery after Bimatoprost SR. No patient had long-term complications following Bimatoprost SR implantation.

Conclusions: Patients who received intracameral Bimatoprost SR with a history of prior glaucoma surgery subsequently required fewer IOP-lowering medications. The present data suggest that Bimatoprost SR may be a valuable alternative treatment option in patients with prior glaucoma surgery.

TITLE: Diagnostic Electrophysiology in a Small Animal Model of Traumatic Optic Neuropathy (TON)

SESSION TITLE: Electroretinography: basic mechanisms and disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Ryan, M.A. Reilly, Biomedical Engineering, The Ohio State University, Columbus, Ohio, UNITED STATES|J. Racine, Nationwide Children's Hospital, Columbus, Ohio, UNITED STATES|

Commercial Relationships Disclosure: Annie Ryan: Commercial Relationship: Code N (No Commercial Relationship) | Julie Racine: Commercial Relationship: Code N (No Commercial Relationship) | Matthew Reilly: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Traumatic optic neuropathy (TON) is a frequent, vision-threatening complication of head injury. No treatments are currently available and translational animal models are limited. The purpose of this study was to develop functional electrophysiologic diagnostic criteria for using a small animal model.

Methods: Male Sprague Dawley rats (~200g) were utilized, and all animal work was performed with IACUC approval. A series of light-adapted ERGs were conducted including flash ERGs (fERGs), flash Visual Evoked Potentials (fVEPs), and Photopic Negative Responses (PhNRs). ERG tests were conducted at least 7 days before injury (baseline), and 24 hours after injury (D1) to assess deterioration of visual function associated with the torsional TON. Rats were anesthetized with an intraperitoneal injection of ketamine/xylazine for each ERG session, and for the injury event (D0). All animals received baseline and D1 ERGs before sacrifice and tissue collection. The right eyes of all animals were injured utilizing a custom torsional injury-inducing device on D0. The left eyes of all animals remained uninjured. ERG signals were compared from baseline to D1 to determine differences in amplitudes and latencies at different time points.

Results: There was a reduction in the right eye amplitudes in fERG b-waves, fVEPs, and PhNRs at D1 as compared to baseline values. The left eye amplitudes at D1 were not significantly different to the left eye baseline amplitudes for fERG b-waves, and PhNRs. However, fVEP amplitudes were significantly different from baseline. Higher b-wave amplitudes in the ERG signal were observed in the left eye at D1 as compared to the right eye amplitude at D1.

Conclusions: A promising diagnostic technique for evaluation of the retina and visual system 24 hours after TON injury in a rat model. Comparing ERG and PhNR amplitudes between the ipsilateral and contralateral eyes may be a diagnostic for TON. Our small animal model detects the presence of visual system damage shortly after injury, which could allow for a promising diagnostic for humans in the future. Utilization of the differential amplitude between eyes may allow for diagnosis in humans where baselines are unavailable. Future work will evaluate changes at shorter time points and utilize these approaches to evaluate the safety and efficacy of candidate therapeutics for TON.

ABSTRACT BODY:

Purpose: Particulate matter (PM) is a well-known trigger for the development of both acute and chronic forms of ocular surface disease. The purpose of this study was to evaluate the prototypic manganese porphyrin, manganese(III) tetrakis(1-methyl-4-pyridyl) porphyrin (Mn-TM-2-PyP), for its ability to protect against PM-induced damage.

Methods: Standardized Reference Material (SRM® 2786) consisting of fine atmospheric particulate of < 4 µm diameter was obtained from NIST. Rabbit corneal epithelial (SIRC) cells were exposed to a dose range of PM (1 - 300 µg/ml) for 24 h. Cell viability and motility assays were performed to evaluate the effect of PM and the protective effect of Mn-TM-2-PyP. The pharmacologic efficacy of Mn-TM-2-PyP (0.05% in saline, BID for 10 d) was tested in PM-induced allergic conjunctivitis in New Zealand White rabbits and assessed by ophthalmic exams and corneal fluorescein staining.

Results: MTT assay revealed dose-dependent loss of cell viability in response to PM exposure with IC_{50} of 13.6 µg/ml PM (n = 3 - 6), while lactate dehydrogenase (LDH) release increase dose-dependently with EC_{50} of 149.1 µg/ml PM (n = 3 - 6). Mn-TM-2-PyP (0.005% and 0.05%; 30 min pre-treatment) protected against PM (100 µg/ml)-induced LDH release (n = 3, $P < 0.05$). Exposure to PM (200 µg/ml) for 24 h significantly reduced motility of SIRC cells in scratch assays. Scratches were 54.4 ± 2.4% of the original width in untreated cells, while the scratch remained at 79.8 ± 2.6% in PM-treated cells ($P < 0.001$). In contrast, Mn-TM-2-PyP improved PM-treated SIRC motility beyond the level in untreated cells with scratch widths at 42.0 ± 1.9% ($P < 0.001$). In vivo, 10 d treatment with Mn-TM-2-PyP completely resolved PM-induced hyperemia (n = 4, $P < 0.001$) and corneal pathology (n = 4, $P < 0.001$) when compared to saline-treated eyes. Mn-TM-2-PyP had no effect on tear volumes.

Conclusions: Mn-TM-2-PyP protected against PM-induced cytotoxicity and impairment in motility in vitro and PM-induced allergic conjunctivitis in vivo. These data corroborate previous studies that have suggested generation of cellular oxidative stress as underlying mechanism of the deleterious effects of PM on epithelial cells. Our data suggest that oxidative stress is an etiological contributor to PM-induced allergic conjunctivitis in rabbits and support future therapeutic development of antioxidants for PM-induced ocular surface disease.

TITLE: Quantitative Characteristics of Sickle Cell Maculopathy in Post Hematopoietic Stem Cell Transplantation Patients Using Optical Coherence Tomography

SESSION TITLE: OCT Clinical Applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Wang, J.I. Lim, Illinois Eye and Ear Infirmary, University of Illinois at Chicago, Chicago, Illinois, UNITED STATES|H. Liu, Icahn School of Medicine at Mount Sinai, New York, New York, UNITED STATES|

Commercial Relationships Disclosure: Daniel Wang: Commercial Relationship: Code N (No Commercial Relationship) | Helen Liu: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Lim: Commercial Relationship(s);Code F (Financial Support):Aldeyra;Code C (Consultant/Contractor):Aura;Code C (Consultant/Contractor):Eyenuk;Code R (Recipient):Iveric Bio;Code F (Financial Support):Regneron;Code R (Recipient):Novartis ;Code F (Financial Support):Chengdu Cognition;Code C (Consultant/Contractor):Santen

ABSTRACT BODY:

Purpose: Hematopoietic stem cell transplantation (HSCT) for sickle cell disease (SCD) has enabled the conversion of hemoglobin SS genotype to either normal hemoglobin AA or to sickle cell trait (Hgb AS) with cessation of systemic crises. While peripheral vasculature abnormalities are the hallmark of sickle cell retinopathy (SCR), prior work by our group and others has shown maculopathy (SCM) characterized as macular thinning and vascular abnormalities on spectral-domain optical coherence tomography (SDOCT) and optical coherence tomography angiography (OCTA). The purpose of this study was to determine whether HSCT resulted in any change in the level of SCR or rate of SCM thinning.

Methods: A retrospective, cross-sectional chart review was performed. Post HSCT SCD patients were identified through a comprehensive chart review of the prospective SCR Study patient database. The SCR Study patients all underwent an annual complete ophthalmic examination, macular SDOCT, and OCTA imaging. A multivariate logistic regression analysis was performed to analyze the relationship between SDOCT thickness and patient transplantation status.

Results: A total of thirteen patients were followed longitudinally over a study interval of ten years and compared to those without HSCT. Best-corrected visual acuity was preserved over the study interval (Pre-HSCT: LogMAR: 0.0821, Post-HSCT: LogMAR: 0.0878, p=0.0023). Average macular thickness prior to HSCT was (312.94 +/- 16.88 μm) and post HSCT was (308.49 +/- 21.911 μm). Despite HSCT, study patients continued to demonstrate a generalized trend for continued macular thinning at rates similar to pre-transplantation (pre-HSCT: -0.276 μm/year; post-HSCT: -0.321 μm/year, p=0.572). No strong associations between SDOCT thickness/rates of thinning and parameters such as Hgb type, smoking status, hydroxyurea use, number of pain crises were identified for the HSCT subgroup.

Conclusions: Progression of SCM appears to occur despite HSCT. Further study using other imaging modalities such as OCTA may provide additional insight into the biological and pathophysiological mechanisms of SCM in HSCT patients.

TITLE: Characterizing Prolonged Undifferentiated Postoperative Pseudophakic Iridocyclitis (PUPPI) at a Tertiary Care Provider Practice

SESSION TITLE: Clinical Uveitis & Orbital Inflammation: Etiology, Epidemiology & Clinical Assessment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Hamati, M. Salabati, R. Mahmoudzadeh, J. Dunn, Wills Eye Hospital, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Jacquelyn Hamati: Commercial Relationship: Code N (No Commercial Relationship) | Mirataollah Salabati: Commercial Relationship: Code N (No Commercial Relationship) | Raziyeh Mahmoudzadeh: Commercial Relationship: Code N (No Commercial Relationship) | James Dunn: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To identify and characterize patients with prolonged undifferentiated postoperative pseudophakic iridocyclitis (PUPPI) after uncomplicated phacoemulsification with posterior intraocular lens implantation (IOL).

Methods: Single-center, consecutive retrospective chart review conducted at Wills Eye Hospital (Philadelphia, PA, USA) to identify all new patients with PUPPI referred to our uveitis specialist between January 2015 and December 2020. Documented demographic features included visual acuity, intraocular pressure, comorbidities such as macular edema, and examination findings for each clinic examination.

Results: A total of 48 eyes of 30 patients were identified with PUPPI out of 1995 new patients (1.50%) during the study timeframe. Mean (SD) age was 68.8 (4) years. African-Americans and women were most commonly affected, making up 86% and 83% of the study population, respectively. Patients were followed for a mean of 10 months (range 0-54 months). The majority of patients remained on topical steroids for the entirety of their follow-up, including 84% of eyes at the 3-month visit, 75% at the 12-month visit, and 88% at the 24-month visit. The uveitis was suppressed in all patients by the 24-month visit when available. Mean visual acuity (MVA) was 20/50 at referral visit among patients with follow-up. There were no statistically distinct changes in MVA at subsequent visits. MVA was 20/36 at the 3-month visit (p=0.12), 20/36 at the 12-month visit (p=0.05), and 20/45 at the 24-month visit (p=0.70). Among patients with follow-up, cystoid macular edema was present in 20-30% of eyes throughout the study period (3-54 months). The MVA in eyes with CME was worse than in eyes without CME (20/66 versus 20/41, respectively) but the difference was not statistically significant (p=0.097).

Conclusions: PUPPI is more common in African-Americans and more chronic in women. Patients may require prolonged courses of topical steroids after surgery with fair visual outcomes. Poorer visual outcomes may be related to presence of CME.

ABSTRACT BODY:

Purpose: Inherited eye diseases leading to degeneration of the retina predominantly result from genomic alterations to retinal proteins. Genome editing is especially attractive to correct mutations in genes associated with phototransduction, the visual cycle and other cellular processes essential for the viability of retinal cells. It is crucial to study and quantify the delivery of genome editors to the eye, to optimize editing efficiency and minimize toxicity in animals before clinical application.

Methods: All animal procedures were approved by Animal Care Committees at the University of California, Irvine and conformed to recommendations of the American Veterinary Medical Association Panel on Euthanasia and ARVO. We used mT/mG Cre reporter mice (Jackson #007676), which constitutively express membrane tdTomato in all cell types, and switch to membrane GFP after Cre-mediated loxP excision.

We assessed the efficiency of Cre delivery via intraocular injection to anesthetized mice, and compared numerous delivery strategies of recombinant Cre protein, including peptidic tags, small molecule labeling, and custom nanoparticle formulations.

Two-photon (2P) microscopy was performed in mouse eyes 6-8 days after intraocular injection of Cre. A 950 nm light was used to simultaneously visualize mT- and mG-labelled cells. Signals were directed into mT and mG channels based on the 2P emission spectra. Fraction of transfected RPE and photoreceptor cells was assessed for different delivery modalities.

Results: After injection of Cre with various delivery tags, we observed distinct color switching from tdTomato to GFP in photoreceptors and retinal pigment epithelium (RPE). The characteristic features of these cells were preserved, including the hexagonal shape and undisturbed mosaic of RPE cells, and outer segments, inner segments, nuclear layer and connecting outer fibers; all of which were clearly visible in photoreceptors. Many delivery tags were effective in the RPE, while some compounds were targeted to photoreceptors.

Conclusions: Clear 2P images were obtained from the entire retina ranging from the RPE to the ganglion cell layer, enabling 3D reconstructions and assessment of color switching. Thus, 2P excitation-based imaging in intact mouse eyes is an effective way to compare the relative efficacy of diverse delivery routes of genome editors by measuring transfection efficiency and impact on retinal structure.

ABSTRACT BODY:

Purpose: Advanced non-neovascular age-related macular degeneration (dry AMD) is a leading cause of vision loss. Recent clinical trials demonstrate the potential of emerging therapeutics for potential first-in-class treatment for geographic atrophy (GA). Identification and characterization of GA will be critical for optimal management with new treatment options. The purpose of this analysis was to assess the feasibility of an OCT-based automated machine-learning platform for detection of GA lesions.

Methods: This was an IRB-approved retrospective image analysis study evaluating eyes with dry AMD. A machine learning enabled multi-layer segmentation system was utilized to segment Bruch's membrane (BM), the ellipsoid zone (EZ), and RPE with manual correction. GA was defined by those areas with the EZ, RPE, and BM all intersection (i.e., total loss of RPE and EZ with only BM remaining. Automated training masks were created based on those areas of intersection of the segmentation lines. A U-Net architecture convolutional model was executed and evaluated on training datasets with varying ratios of annotated OCT images containing (positive) and not containing (negative) GA lesions in dry AMD. Overall, 10,271 B-scans from eyes with dry AMD were utilized including 1,456 B-scans that included GA lesions were utilized for training and tested on a self-generated validation set which including 1027 B-scans.

Results: Following model development, the feasibility of automated GA detection on OCT was demonstrated using a machine learning model (Figure 1). The F-score associated with this model which is tested on validation set was 0.68. Interestingly, the qualitative impression of model performance appeared to be quite good. Scan features that appeared to impact model performance, included low image quality, unusual posterior curvature, and slanted scans.

Conclusions: Automated detection of GA lesions on OCT using a machine learning model is feasible. Future research is needed to optimize performance across a highly diverse scan quality spectrum and evaluate the model for quantification of GA for longitudinal measurements.

ABSTRACT BODY:

Purpose: To compare the effect of early vs late treatment with aqueous suppressants on the surgical outcomes of Ahmed glaucoma valve (AGV) FP-7 implants

Methods: Retrospective comparative cohort study on refractory glaucoma patients who underwent AGV implantation at Wills Eye Hospital from 2016-2021 who received topical aqueous suppressants either in the first 2 weeks (group 1; early) or after 2 weeks (group 2; late) postoperatively. The main outcome measures were incidence of hypertensive phase (HP), defined as an intraocular pressure (IOP) of >21 mmHg within 3 postoperative months, surgical failure at months 6 and 12 (defined as IOP<5 or >21 mmHg), progression to no light perception (NLP) vision, or further glaucoma surgeries.

Results: 199 eyes of 194 patients (group 1=140, group 2=59) were included. Mean age was 68.2±15.8 years old. At baseline, visual acuity (VA) was 1.0±0.9 and 1.2±0.9 (P=0.083), IOP was 36.8±10.7 mmHg and 35.6±11.8 mmHg (P=0.485), and number of glaucoma medications was 2.9±1.4 and 3.0±1.6 (P=0.629), in groups 1 and 2 respectively. 43% of patients had primary open angle glaucoma and 52.7% had severe disease. HP developed in 35.7% of group 1 eyes and 50.8% of group 2 eyes (P=0.011). At month 6 (n=177) the surgical failure rate was similar in both groups (22.8% vs 20.0%, P=0.748). At month 12, (n=137) failure was also similar between groups (25.3% vs 39.5%, P=0.238). Reasons for failure were similar (P=0.055) and included IOP>21 mmHg (45.5%), further glaucoma surgeries (38.6%), and NLP vision (9.1%). Kaplan-Meier survival analysis comparing cumulative probability of failure at 12 months showed no significant difference between groups (P=0.461). Multivariate logistic regression analysis suggests that development of HP was a significant predictor of month 12 failure (P=0.044). Age, sex, race, late use of aqueous suppressants, glaucoma type and severity, baseline VA, IOP, narrow angle, and medication number were not significant predictors of failure.

Conclusions: Our findings suggest that early aqueous suppressant use after FP-7 AGV implantation was associated with decreased occurrence of a HP. Although surgical failure rate was similar between groups, HP was a significant predictor of month 12 failure. Longer-term follow-up with larger sample size studies are warranted on this subject.

ABSTRACT BODY:

Purpose: Selective Laser Trabeculoplasty (SLT) is a useful method to decrease intraocular pressure (IOP) for glaucoma and ocular hypertension(OHT) patients.Upskilling for SLT increase the proficiency of the clinical skills of ophthalmologyst,such as gonioscopy.The purpose of this study is to investigate agreement and correlation of decision-making elements regarding SLT treatment using gonio-photographs (GP)among ophthalmologists inexperienced in SLT.

Methods: A set of 10 GP GS-1 automated gonioscope; Nidek,Japan)with different clinical findings were presented to three ophthalmologists with scarce experience with SLT.They were instructed to follow a 4-step process, which consisted on:(1)selecting aiming beam spot size,(2) a 5-minute review of 10 GP,(3)judgement of the level of difficulty to identify relevant gonioscopic findings helpful to decide about how to perform SLT, and(4)placement of a graphic representation of a SLT spot with a specific energy value(0.1 mJ-1.0 mJ)in the pretended region(s)to treat the same 10 GP.The results of an experienced glaucoma specialist(reference rater or RR)were used to analyze each examiner's results.Inter-rater agreement analysis, rank,concordance and intra-class correlations were used.A p-value of ≤ 0.05 was considered statistically significant.

Results: All participants finished the four-step process.Two raters selected the same spot-size as compared to the reference.Level of discerning clinical findings was poorly correlated.Number of spots had a good inter-rater agreement between the reference observer and one of the inexperienced ones(weighted Kappa=0.55, SE=0.17; 95% IC, 0.23-0.87).Total energy per GP was good and significantly correlated between RR and the same inexperienced observer(rho=0.63; p=0.049).Intraclass correlation was fair regarding totally energy(0.48; 95% IC, 0.16-0.79)and number of spots (0.56; 95% IC, 0.24-0.83).Precision and accuracy had poor correlation among raters (≤0.9). Mean energy used per GP was statistically different in the RR(5.69±1.0mJ)as compared to the others(4.75±1.1mJ, 4.51±0.8mJ, 2.11±0.9mJ).

Conclusions: Unexperienced ophthalmologists' responses in this model based on GP derived from the GS-1 device had poor agreement in most of the studied variables when compared with an experienced ophthalmologist.Further studies using GP are warranted in order to assess the impact of teaching interventions.

ABSTRACT BODY:

Purpose: To assess the impact of COVID-19 on corneal transplant failure.

Methods: A retrospective cohort study was conducted using TriNetx (Cambridge, MA, USA), a national electronic health records research network encompassing multiple large health organizations. Patients who underwent corneal transplantation were identified via Current Procedural Terminology (CPT) codes. They were then divided into those who contracted COVID-19 after corneal transplantation (n=678) and those that did not (n=37,930). Cohorts were matched for age, BMI, gender, primary hypertension, diabetes mellitus, respiratory disease, heart failure, nicotine dependence and alcohol-related disorders. The primary outcome was corneal graft failure over a 120-day post-operative period. Outcomes were compared between both groups.

Results: Prior to propensity matching, there was a significant increase in corneal graft failure in those infected with COVID-19 (RR 1.7, CI 1.11-2.62, p-value 0.014). Underlying medical disease was more prevalent in this group with the greatest difference observed for BMI (57.67% versus 35.49%), hypertension (55.52% versus 28.25%), and diabetes mellitus (33.48% versus 13.73%). After propensity matching, a total of 1354 patients were included in the analysis, with 677 in the negative COVID-19 group and 677 infected with COVID-19. There was no statistically significant difference in corneal graft failure between the two groups (RR 1.31, 95% CI 0.69-2.49, p-value 0.405).

Conclusions: COVID-19 did not have a statistically significant impact on corneal transplant outcomes.

ABSTRACT BODY:

Purpose: To evaluate the Lifestyle-integrated Functional Exercise fall prevention programme for older people with low vision or blindness (v-LiFE).

Methods: A single-blinded randomised controlled trial evaluated the v-LiFE program compared to usual care. Primary outcomes were the activity normalised fall rate over 12 months, measured using prospective falls calendars and function and participation (Late Life Function and Disability Instrument, Function sub-scale LLFI, Rasch scored). Activity was estimated using a wrist worn accelerometer over 1-week periods at baseline, 3 months and 12 months. Multiple imputation was used when accelerometer data were missing, based on self-reported physical activity. The rate ratio (RR) for falls were modelled using a negative binomial regression, mean differences were calculated with 95% Confidence Intervals (CI) for continuous measures, all analyses were on an intention to treat basis with pre-planned sub-groups (high physical activity, peripheral field loss and multiple fallers). The Short Physical Performance Battery (SPPB) was used to investigate if the v-LiFE program led to improvements in strength and balance

Results: 588 participants were randomised and 532 (90%) completed the trial. Mean age was 74 years, 346 (59%) were female, median visual acuity was 1.0 logMAR, (inter-quartile range 0.4-1.9) and 497 (85%) used a mobility aid. The annual falls rate was 2.1±3.5 and similar in the intervention and control groups (RR 0.89, 95% confidence interval, CI 0.69-1.13). The LLFI score was also similar (-0.02 95% CI -0.06-0.03). There was no difference in the rate of falls requiring medical care (RR 1.04 (0.79,1.36). There were no differences in the sub-groups for the primary outcomes. The SPPB total score was similar between groups (0.13 95% CI -0.24-0.51). Cadence in the 4m walk was better in the intervention group (0.20, 95% CI 0.06-0.34 steps/metre), but the timed sit-to-stand, 4m walk time and standing balance scores were not different.

Conclusions: Though strength and balance training has been shown to prevent falls in older people, this trial involving older people with low vision did not demonstrate any benefit. It is possible that a higher dose program and/or a

different approach to implementation will be required to reduce falls and improve function in older people with low vision.

ABSTRACT BODY:

Purpose: Melanin is a major contributor to the intensity and width of the retinal pigment epithelium (RPE) on optical coherence tomography (OCT). It is hypothesized, high melanin concentrations cause scattering making the RPE appear as a thick band and obscures adjacent layers. A split band appearance of the outermost hyperreflective band has been demonstrated in Albinism, meaning the RPE and Bruch's Membrane appear as two separate bands. We performed a cross-sectional observational study to test the hypothesis that a reduction in melanin causes an increased ability to differentiate the hyperreflective bands seen on OCT images of the outer retina.

Methods: Using the UK Biobank dataset, we generated a randomised sample of 300 participants with specific inclusion and exclusion criteria. Inclusion criteria was an age between 40 to 65, visual acuity better than 0.60 logMAR, no ocular pathology, and measurable OCT images of both eyes. We analysed three ethnic groups: White (n=100), Asian (n=100) and Black (n=100). The OCT images of the participants' left eyes were qualitatively analysed for the number of outer retinal hyperreflective bands at the fovea and parafovea. We also analysed the proportion of cases with foveal hypoplasia (FH). FH was graded using the Leicester OCT structural grading system described by Thomas MG et al. 2011.

Results: A significantly less number of outer retinal hyperreflective bands are seen at the fovea (X^2=7.23, p=0.027) and parafovea (X^2=16.24, p=0.0003) in the black ethnicity group compared to the other ethnicity groups. Although there was a higher proportion of cases of grade 1 FH in the white and asian groups compared to the black group this was not statistically significant (p=0.09). No significant (p=0.69) difference in visual acuity is observed between the groups.

Conclusions: We highlight the potential role of melanin in our ability to resolve outer retinal structures using OCT. Higher concentrations of melanin in black populations could be associated with fewer outer retinal hyperreflective bands. As previously described in albinism, the additional outer retinal bands visible are likely due to hypopigmentation. Outer retinal thickness measurements should be interpreted with caution when derived from automated segmentation algorithms.

ABSTRACT BODY:

Purpose: Noninfectious uveitis (NIU) is a major cause of visual impairment with limited treatment options. We performed a randomized, placebo-controlled, double-masked trial of filgotinib, a JAK1 preferential inhibitor, to assess its efficacy and safety in NIU.

Methods: Adults with intermediate-, posterior- or pan-uveitis that was active despite at least 2 weeks of treatment with 10-60 mg prednisone were eligible for this trial. Patients were randomized 1:1 to receive either filgotinib, 200 mg daily, or placebo for up to 52 weeks. On study day 1, all patients began a protocolized prednisone taper beginning at 60 mg to 0 mg by the beginning of Week 15. The primary endpoint was the proportion of patients failing treatment by week 24. Treatment failure was defined as a new chorioretinal and/or retinal vascular lesion, worsening of best corrected visual acuity by ≥15 letters, or an inability to achieve an anterior chamber cell or vitreous haze grade 0.5+ at week 6 or a 2-step increase after week 6. Patients who took study drug and completed at least week 6 of the study were considered evaluable. While in progress, the trial was terminated before full enrollment (planned N = 248) for business reasons. As a result, all hypothesis testing was done without multiplicity adjustment.

Results: Seventy-four (74) patients were randomized. The majority (57%) had idiopathic uveitis. Patients with missing data were imputed as treatment failures. Of the 66 evaluable patients, the proportion failing treatment was 12 of 32 (38%) in the filgotinib arm and 23 of 34 (68%) in the placebo arm ($p = 0.006$). The median time to treatment failure was 22 weeks in the placebo arm and was not estimable in the filgotinib arm as more than half the patients in the filgotinib arm did not have treatment failure (hazard ratio 0.309; 95% CI [0.144 to 0.663]) [Figure]. Adverse events were reported more frequently in patients who received filgotinib than placebo (81% v. 69% adverse events and 14% v. 6% serious adverse events). There were no arterial or venous thromboembolic events, no major adverse

cardiovascular events, no opportunistic infections and no cases of tuberculosis or herpes zoster reported.
Conclusions: In patients with vision threatening NIU, filgotinib 200 mg reduced the risk of uveitis flare compared to placebo and was generally well tolerated.

ABSTRACT BODY:

Purpose: The SITA Fast (SF) visual field (VF) strategy was developed as a faster alternative to the SITA Standard (SS) VF strategy and is routinely used in clinical centers due to its shorter duration. In this study, we correlate visual field measurements of SF on the Humphrey Field Analyzer (HFA) (Carl Zeiss Meditec, Inc, Dublin, CA) with those of the Heru re:Vive VF strategy (Heru Inc, Miami, FL) downloaded onto an augmented reality (AR) headset.

Methods: Thirty-seven eyes from thirty-five subjects underwent visual field testing with SITA Fast and Heru re:Vive strategies. Subjects with a range of neurologic and ophthalmologic pathology were recruited from a tertiary eye institute during their regular clinic visit. Subjects either had a same-day SF VF scheduled or had been tested with SF within three months of study visit, with either the 24-2 (n = 28) or 30-2 (n = 9) field patterns. Eyes with visual acuities of 20/400 or worse or having had intraocular surgery within 6 months of study date were excluded. Heru re:Vive testing was done in a darkened room using the Magic Leap 1, size 2 headset (Magic Leap, Plantation, FL) and lenses were inserted into the headset for refractive correction. For the two tests, HFA and Heru, the correlation coefficient was determined for metrics of mean deviation and mean sensitivity and test duration was compared.

Results: Strong correlations between Heru and HFA tests were found for metrics of both mean sensitivity ($R=0.82$, $p<0.001$) (fig. 1) and mean deviation ($R=0.83$, $p<0.001$) (fig. 2). Sensitivity analysis included all 37 eyes tested and mean deviation analysis included 28 eyes, excluding the 9 eyes tested with the 30-2 VF pattern. Mean test time of both tests were similar (4.27 minutes for Heru versus 4.38 minutes for HFA).

Conclusions: VF measurements of mean sensitivity and mean deviation obtained using the Heru re:Vive strategy installed on a portable headset correlate well to those from the SITA Fast HFA test among neurologic and ophthalmologic patients.

ABSTRACT BODY:

Purpose: Anti-Vascular Endothelial Growth Factor (Anti-VEGF) agents have revolutionized the treatment of many diseases in ophthalmology, and have begun to find increased use in the treatment of Retinopathy of Prematurity (ROP). Although the use of Anti-VEGF agents has demonstrated benefits in severe (i.e., Type 1) ROP, many questions remain about its optimal use and long-term outcomes. Here, we investigate the need for multiple Anti-VEGF injections and factors which may predict a reduced response to treatment requiring repeat therapy for ROP.

Methods: Retrospective chart review study of patients screened for ROP as inpatients in the Neonatal Intensive Care Unit (NICU) between 2011-2021 who also received anti-VEGF treatment. Electronic medical records were used to obtain patient demographics as well as ophthalmic and non-ophthalmic treatments and outcomes. Patients were stratified by whether they received single or multiple anti-VEGF injections.

Results: 32 patients (59 eyes) were identified as receiving at least one injection, and 5 patients (8 eyes) receiving two injections. The mean post-menstrual age of those receiving a single injection was 24.6 weeks [range:22.1-31.7] and for two injections was 23.8 weeks [range:23.3-25.7]. Receiving multiple injections was not correlated with birthweight ($p=0.121$) or gestational age ($p=0.14$), but was associated with decreased age at first injection (OR = 0.31-0.82; $p=0.006$). The mean corrected gestational age at first injection for those receiving a single injection was 36.3 weeks [range:31.5-47.4] and for two injections was 33.1 weeks [range:31-36.6]. Age at first injection was not significantly correlated with gestational age ($R^2 = 0.281$) or birth weight ($R^2=0.062$).

Conclusions: Infants with severe ROP requiring anti-VEGF treatment at earlier ages may be more likely to require repeat therapy at later ages. This data may be helpful when counselling parents during initial treatment discussions, and highlights the importance of close follow-up of these patients to assess the need for additional treatment.

ABSTRACT BODY:

Purpose: Increased intraocular pressure (IOP) is believed to induce oxidative stress and lower antioxidant defenses in the optic nerve, leading to retinal ganglion cell death. A noninvasive retinal metabolic imaging device measures flavoprotein fluorescence (FPF), a potential biomarker for mitochondrial dysfunction and early apoptosis due to oxidants and other stimuli. We evaluated the relationship between FPF and IOP to investigate the functionality of the device and the pathophysiology underpinning glaucoma.

Methods: 52 eyes from 52 patients with glaucoma or suspect glaucoma were imaged. FPF scores were obtained at the optic nerve head (ONH) and macula using OcuMet Beacon (OcuSciences Inc., Ann Arbor, MI). Optical coherence tomography obtained the retinal nerve fiber layer (RNFL) and macular ganglion cell complex (GCC) thicknesses. The association between IOP and FPF, adjusting for age, sex, and RNFL, was evaluated by linear regression.

Results: Glaucoma eyes (n=34) on average had lower IOP (13.4 vs. 16.4mmHg), thinner RNFL (72 vs. 90μm), and thinner macular GCC (66 vs. 79μm) compared to suspects. All glaucoma eyes were treated and most were on IOP-lowering drugs. Among these, higher IOP correlated with a higher FPF score at the ONH but was not statistically significant (p=0.23). For suspect eyes, the opposite relationship was observed between IOP and FPF (p=0.03), but this was not significant when RNFL thickness was taken into account by using the ratio of FPF to RNFL (FPF/RNFL). Two glaucoma eyes were outliers with low IOP (7 and 10mmHg) and high FPF/RNFL. In multivariable analysis, older age, male sex, and greater RNFL thickness were associated with higher FPF scores.

Conclusions: IOP may not be the sole contributor for mitochondrial dysfunction in treated glaucoma patients. Since the majority of glaucoma patients are stable on IOP-lowering drugs, this result may reflect that little RGC stress and apoptosis occur in controlled disease. These drugs are also thought to exert additional antioxidant activity. The two outliers had more advanced glaucoma (RNFL: 49 and 55μm) and may represent greater mitochondrial stress and progressing disease despite adequate IOP control. Longitudinal studies with a wider disease severity spectrum are needed to better establish the relationship between IOP and FPF.

ABSTRACT BODY:

Purpose: A wide range of blinding disorders have been associated with mutations in the rod visual pigment rhodopsin. Point mutations of Glycine 90 to Aspartate (G90D) or to Valine (G90V) have been reported to cause congenital stationary night blindness (CSNB) and retinitis pigmentosa (RP), respectively. In vitro studies have shown that the G90D/G90V mutations cause decreased stability of both chromophore-bound rhodopsin and chromophore-free opsin. This lower stability could produce persistent activation of rod photoreceptors even in darkness and interfere with normal light detection, causing CSNB or RP. However, the molecular mechanism by which these mutations cause abnormal photoreceptor function and degeneration remains controversial.

Methods: Using CRISPR/Cas9 technology, we created homozygous mutant mice with either G90D or G90V rhodopsin and performed their initial characterization. Retinal morphology was analyzed by hematoxylin and eosin staining of retinal cross-sections. Scotopic function was assessed by in vivo electroretinography (ERG). Pigment content and stability of its 11-cis-retinal Schiff base in the dark were measured by spectrophotometry of dodecyl maltoside extracts from whole mouse eyes, in the absence or presence of hydroxylamine (HA), respectively.

Results: The morphology of the retina in both G90D and G90V mutant mice was normal up to 4 months of age, with good preservation of both outer nuclear and photoreceptor layers. However, the rod maximal response (ERG a-wave) in G90V and G90D mice at 2 months was suppressed to ~70% and ~50%, respectively, compared to controls. The rod photosensitivity was also reduced to a greater degree in the G90D than in G90V mice. The amount of rhodopsin in eyes of 2-month-old G90V mice was reduced to 25% of wild type levels. However, its 11-cis-retinal chromophore was not readily accessible to HA in the dark. In contrast, the level of rhodopsin in the eyes of G90D eyes was 35% of that in controls and its chromophore was accessible to HA.

Conclusions: Our preliminary data suggest that both G90D and G90V opsins in mouse rods have reduced chromophore binding. However, unlike in wild type and G90V rhodopsin, the covalent link between chromophore and opsin in G90D rhodopsin appears unstable and susceptible to hydrolysis. We conclude that G90V and G90D mutations in rhodopsin can cause night blindness by two different mechanisms that are being investigated further.

ABSTRACT BODY:

Purpose: An important part of cataract surgery is having excellent postoperative refractive outcomes. Therefore, postoperative refractive surprise is a challenge of significant interest in achieving desired vision. As populations age around the world, the incidence of glaucoma and cataract continue to rise. Further understanding of refractive outcomes in glaucoma patients undergoing cataract surgery is essential. In this study, we investigate post-cataract refractive outcomes of glaucoma versus non-glaucoma patients without any concomitant visually significant co-morbidities.

Methods: Patients who underwent uncomplicated phacoemulsification cataract surgery from 2007 to 2018 were enrolled in this retrospective cohort study. The first eye of each patient that qualified was included. We excluded patients with visually significant ocular or systemic comorbidities, prior non-refractive eye surgeries, combined cataract surgeries, and patients requiring additional procedures post op. Refractive outcome at postoperative 1 month was evaluated between control and glaucoma groups, as well as among glaucoma types.

Results: A total of 503 patients (354 in non-glaucoma and 149 in glaucoma) were included. Among the control group, 67.8% and 95.2% of patients fall within 0.5D and 1.0D of target respectively compared with 65.7% (P=0.659) and 89.9% (P= 0.027) in the glaucoma group. Refractive outcomes were compared between glaucoma types and no significant difference were found in percentage of patients within 0.5D and 1.0D of target (P=0.172 and P=0.9 respectively).

Conclusions: Patients with glaucoma are more likely to have postoperative refractive surprise compared with the general population. This is seen in patients without visually significant comorbidities, which suggest glaucoma plays a role in refractive outcomes not accounted for by current IOL calculations. Of note, the increase in refractive surprise seen in glaucoma patients appears to be irrespective of glaucoma type.

ABSTRACT BODY:

Purpose: To compare racial, ethnic differences in visual acuity (VA) on vision-specific quality of life (VSQOL)

Methods: In the MOCCaS, the impact of VA on VSQOL measured by the National Eye Institute Visual Function Questionnaire (NEI-VFQ-25) was evaluated in a population-based sample of African American (AA), Chinese American (CA), and Latino (LAT) adults. A total of 17,071 adults 40 years of age and older participated in a comprehensive ophthalmologic examination and in-person interviews from 2000 to 2018. Distance VA was measured during a detailed ophthalmologic examination using standard ETDRS protocol at baseline. VSQOL was assessed at the end of the clinical examination using the NEI-VFQ-25. Vision-related daily tasks (VRDT) and well-being composite scores were calculated using item response theory (IRT); classical test theory (CTT) was used to score 11 subscales with values ranging from 0 to 100, with higher scores representing better visual functioning.

Results: 14,570 participants (5,171 AA, 4,151 CA, and 5,248 LAT) with complete data were included in the analysis. Predicted VRDT and well-being composite scores were significantly lower for Latinos across level of presenting VA compared to AA or CA participants. An inverse relationship was found with significantly lower levels of patient reported ability to complete vision-related daily tasks after adjustment for covariates using IRT. A 2-line change in VA was associated with a 4.6 point change in vision-related daily tasks score for LAT participants, 3.9 for CA participants, and 2.9 for AA participants. The difference was greater for those 65 years of age and older. No significant differences in change for well-being were identified by race,ethnicity (3.2 Latino, 3.0 Chinese, 3.0 African American). Classical test theory revealed significant interactions for driving difficulty with VA, age, and race.

Conclusions: Each 2-line loss in VA has a significant impact on patient reported ability to complete vision-related daily tasks. The 2 line difference in VA corresponds to a lower difference in VRDT for African American as compared to Latino adults. Disparities in health are at times attributed to differences in income, education, and barriers to care however differences in VA and VSQOL persisted by race, ethnicity after controlling for measured socioeconomic and clinical variables.

ABSTRACT BODY:

Purpose: Purpose: To describe the long-term safety, intraocular pressure (IOP) lowering effect, and reduced surgical burden of the Kahook Dual Blade® (New World Medical, Rancho Cucamonga, California) as a standalone procedure when used to excise trabecular meshwork in eyes with primary open angle glaucoma (POAG).

Methods: Methods: This is a retrospective chart review of 39 eyes from 2 sites in the United States that included data collection of IOP, IOP-lowering medications, and additional glaucoma procedures at months 12, 24, 36, and 48. Eyes were not washed out of their previous IOP-lowering medications for this analysis. Intra- and postoperative adverse events were tabulated

Results: Results: Analysis from 39 eyes showed a mean IOP reduction from a baseline of 20.4 to 15.0 mmHg at month 48 (26.4% reduction, $p < 0.001$) Medication use at 48 months was similar to baseline ($p=0.123$). 33/39 (85%) eyes required no further surgery to manage IOP. One case of mild iritis related to the procedure was reported.

Conclusions: Conclusion: Excisional goniotomy with KDB effectively decreases IOP over long-term follow up when utilized as a standalone procedure in eyes with POAG. The device also shows a favorable safety profile in line with other minimally invasive glaucoma surgical interventions. Notably, the vast majority of patients (85%) did not require additional surgical intervention to further lower IOP for the duration of the study.

ABSTRACT BODY:

Purpose: To investigate the potential differences in parameters, including axial length (AL), central corneal thickness (CCT), anterior chamber depth (ACD), lens thickness (LT), flat keratometry (Kf), steep keratometry (Ks), mean keratometry (Km), astigmatism, white-to-white (WTW) distance, acquired rate, and intraocular lens (IOL) power, between the two swept-source optical coherence tomography (SS-OCT) biometers, the ANTERION (biometer A) and IOLMaster 700 (biometer B).

Methods: As a prospective observational comparative case series study. We enrolled 198 eyes undergoing cataract surgery. The AL, CCT, ACD, LT, Kf, Ks, Km, astigmatism, WTW, acquired rate, and IOL power were assessed. McNemar tests compared the acquired rate and paired sample t-test compared the quantitative measurement results, between groups.

Results: Nineteen eyes were excluded owing to missing AL data for either biometer. Finally, data from 179 eyes were analyzed. Between the two devices, no significant difference was found in AL, astigmatism magnitude, J0, and J45, while significant differences existed in CCT, ACD, LT, Kf, Ks, Km, WTW, astigmatism axis and IOL power; no statistical significance was found in AL acquired rate (biometer A, 90.9% and biometer B, 93.9%). Approximately 65.4% of eyes demonstrated ≥ 0.5 D difference in IOL power between the two biometers.

Conclusions: The two biometers showed significant differences in all measurements (CCT, ACD, LT, K, WTW, astigmatism axis and IOL power), except for AL.

ABSTRACT BODY:

Purpose: Public safety-net hospital patients have high rates of ocular comorbidities, which can occur in the setting of chronic disease and may affect cataract surgery outcomes. In a retrospective case series, we aimed to characterize the outcomes and complications, as well as identify risk factors for poor outcomes and complications, of resident-performed cataract surgeries at an urban public safety-net hospital.

Methods: The study population included all patients undergoing cataract surgery at LAC+USC with a resident as the primary surgeon from July 2015 to June 2016. Exclusion criteria included cases performed by a fellow; cataract cases combined with retina, glaucoma or corneal surgeries; and cases with inadequate documentation. Pre-operative, surgical, and post-operative characteristics were recorded. Primary outcomes were major intraoperative complication rate, risk factors for major intraoperative complications, rates of visual improvement, and risk factors for poor visual outcome. A multivariable Firth's logistic regression tested risk factors for statistical significance.

Results: 811 eyes were analyzed. 599 (73.9%) cases resulted with post-op best corrected visual acuity (BCVA) 20/40 or better, with 641 (80.9%) cases showing at least two lines of visual improvement. 119 (14.7%) cases had at least one intraoperative complication, most commonly posterior capsule tear (8.6%) and vitreous loss (7.2%). Ocular risk factors significantly associated with lower odds of post-op BCVA of 20/40 or better included history of proliferative diabetic retinopathy (PDR) (OR=0.25; 95% CI=0.14-0.44; p<0.001), intravitreal therapy (IVT) (OR=0.40; 95% CI=0.16-0.99; p=0.047), and vitreous hemorrhage (VH) (OR=0.33; 95% CI=0.15-0.70; p=0.004). Patients with history of VH (OR=0.33; 95% CI=0.15-0.72; p=0.005) were also significantly less likely to improve vision by two lines. History of panretinal photocoagulation (PRP) was associated with significantly increased odds of intraoperative complication (OR=5.22; 95% CI=1.42-19.27; p=0.013).

Conclusions: Several ocular comorbidities and ocular therapies—including PDR, VH, IVT—were significantly associated with poor visual outcomes, while PRP was associated with intraoperative complication, in resident-performed cataract surgery at a public safety-net hospital. These results can better inform both resident education and pre-surgical counseling for this underserved patient population.

TITLE: Pre-operative prognostic risk factors in patients undergoing 27-g Pars Plana Vitrectomy for diabetic tractional retinal detachment

SESSION TITLE: Diabetic Retinopathy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Duong, X. Cai, N. Ambati, Y. Shildkrot MD, University of Virginia School of Medicine, Charlottesville, Virginia, UNITED STATES|

Commercial Relationships Disclosure: Ryan Duong: Commercial Relationship: Code N (No Commercial Relationship) | Xiaoyu Cai: Commercial Relationship: Code N (No Commercial Relationship) | Naveen Ambati: Commercial Relationship: Code N (No Commercial Relationship) | Yevgeniy Shildkrot MD: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: As 27-gauge (27g) pars plana vitrectomy (PPV) for treatment of diabetic tractional retinal detachment (DM-TRD) becomes more widely practiced, there is a growing necessity to determine in which patients the procedure would be the most beneficial. We seek to evaluate pre-operative prognostic indicators for 27g PPV repair of diabetic tractional retinal detachment using a retrospective interventional case series analysis.

Methods: Visual and anatomic outcomes of 110 eyes that underwent 27g PPV for repair of DM-TRD from 2013-2020 were evaluated with respect to various past medical history parameters via linear regression analysis.

Results: The retina was successfully flattened at the end of all cases except one, and overall re-detachment rate was 10.9% (n=12). Pre-operatively, 80.2% (n=88) of patients were legally blind (logMAR > 1) compared to 56.3% (n=40) at postoperative month 6 ($p<.001$). Higher pre-operative logMAR visual acuity was associated with both greater odds of re-detachment (OR 4.95, $p=.002$) and worse visual acuity at month 6 ($p<.001$). Among the patient history parameters assessed, pre-operative use of dialysis ($p=.038$) and neovascularization of the iris (NVI) ($p=.045$) were associated with significantly worse visual acuity at month 6. Longer duration of diabetes in years was also associated less improvement in visual acuity from baseline at 6 months ($p=.037$). No medical history risk factors were identified for re-detachment.

Conclusions: Our results suggest that 27g PPV remains a viable option for repair of DM-TRD with the additional finding that duration of diabetes, dialysis use, and presence of NVI prior to surgery represent negative risk factors of visual outcomes. Comprehensive pre-operative evaluation is required to better estimate prognosis and identify diabetic patients who may most benefit from smaller gauge vitrectomy repair of DM-TRD

Commercial Relationships Disclosure: Eric Gaier: Commercial Relationship(s);Code C (Consultant/Contractor):Luminopia, Inc., Stoke Therapeutics, Inc. ;Code P (Patent):Luminopia, Inc. | Daniel Bowen: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Montgomery: Commercial Relationship: Code N (No Commercial Relationship) | Mark Bear: Commercial Relationship(s);Code C (Consultant/Contractor):Luminopia, Inc.

ABSTRACT BODY:

Purpose: Amblyopia results from abnormal visual experience during development and is a leading cause of visual impairment in children and young adults. Pathologic interocular suppression of the amblyopic eye by the fellow eye serves as a quantifiable property and pathogenic driver of amblyopia. Recently development and implemented “dichoptic”/antisuppression amblyopia therapies have produced mixed results. We aimed to deepen the understanding of pathologic interocular suppression in the context of amblyopia at the level of the visual cortex using a mouse model.
Methods: Juvenile mice underwent chronic electrode implantation prior to visual stimulus presentation at P35. A 3D monitor and polarized lenses were used to selectively present phase-reversing sinusoidal grating stimuli to each eye. Awake visual evoked potentials (VEPs) elicited by a 45-degree grating presented to the contralateral eye were monitored as the concordant or discordant (135-degree) orientation was gradually presented to the ipsilateral eye.
Results: In naïve animals, binocular discordant stimuli significantly reduced VEP magnitudes compared with concordant stimuli primarily through disruption of the late, positive component of the VEP waveform. Reversing the contrast ramp direction showed the same monocular-binocular differences, suggesting these observations were not an artifact of presentation order. VEP responses recorded through the opposite hemisphere showed similar effects of rivalrous binocular stimulation on the VEP waveform. Introducing the discordant orientation in the same, contralateral eye produced a similar suppressive effect but carried a higher contrast threshold, suggesting interocular modulation of cross-orientation suppression. Incrementally adjusting the ipsilateral eye stimulus from concordant to discordant reveals a 15-degree threshold for interocular cross-orientation suppression. Seven days of monocular deprivation disrupted suppression of the early, negative VEP component by binocular discordant stimulus presentation but did not alter effects on the late component.
Conclusions: We have established a useful model of binocular rivalry to study interocular suppression. Disruption of interocular suppression that accompanies monocular deprivation serves to validate this model as tool to study the interplay between interocular suppression and amblyopia development and recovery.

TITLE: Use of iPSC-derived RPE to test the efficacy of elamipretide and SBT-272 in preclinical models of dry AMD

SESSION TITLE: Pathobiology of AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.A. Fields, J. Gong, H. Cai, L. Del Priore, Ophthalmology, Yale School of Medicine, New Haven, Connecticut, UNITED STATES|

Commercial Relationships Disclosure: Mark Fields: Commercial Relationship(s);Code C (Consultant/Contractor):Stealth BioTherapeutics;Code F (Financial Support):Stealth BioTherapeutics | Jie Gong: Commercial Relationship: Code N (No Commercial Relationship) | Huey Cai: Commercial Relationship: Code N (No Commercial Relationship) | Lucian Del Priore: Commercial Relationship(s);Code C (Consultant/Contractor):Stealth BioTherapeutics

ABSTRACT BODY:

Purpose: Identification of compounds that may be of therapeutic benefit in inhibiting progression of AMD is limited by the absence of good animal models as well as a clear understanding of the biology of disease progression. Dysfunction of retinal pigment epithelial (RPE) cells is a key feature of AMD pathogenesis and likely occurs early in the disease. Somatic cells harvested from AMD patients can be reprogrammed to form RPE and model patient-specific disease. We have reported previously that iPSC-derived RPE from AMD patients exhibit a retinal degenerative phenotype and a distinct transcriptome compared to controls. Here, we use an in vitro aged Bruch's membrane model to evaluate the therapeutic efficacy of elamipretide and SBT-272 on RPE derived from AMD patients.

Methods: iPSC-derived RPE were generated from AMD patients (2 atrophic; 1 exudative) and patients with no history of AMD (n = 3). To test the therapeutic efficacy of elamipretide and SBT-272, cell viability was analyzed on nitrite-modified extracellular matrix (ECM), a typical modification of aged Bruch's membrane, for 48 hrs. DNA microarrays were used to elucidate gene expression in AMD-derived RPE cultured on nitrite-modified ECM.

Results: AMD-derived RPE exhibited reduced ability to survive on nitrite-modified ECM. Treatment with both elamipretide and SBT-272 significantly improved cell viability on nitrite-modified ECM. Hierarchical clustering analysis reveals that the AMD-derived RPE segregate into two distinct clusters on nitrite-modified ECM vs. unmodified ECM. Nitration of ECM increases expression of complement component genes, complement C1R (C1R), complement component 3 (C3) and complement C4A (C4A), among others. Both compounds reverse this trend. Both drugs increase expression of complement regulatory genes including complement factor H-related protein 2 (CFHR2). Both drugs also alter the pattern of many mitochondrial-related genes such as glutaminase.

Conclusions: Treatment with elamipretide and SBT-272 significantly improve the ability of AMD-derived RPE to survive on nitrite-modified ECM. Treatment with elamipretide and SBT-272 alter expression of mitochondrial and complement-related genes after nitration of ECM. Disease models using patient-derived iPSC-derived RPE may help pave the way for the development novel therapeutic strategies for AMD.

TITLE: Sensitivity of multicolor imaging in diagnosing age-related macular degeneration and Polypoidal Choroidal Vasculopathy

SESSION TITLE: Imaging of posterior segment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C.S. Tan, Ophthalmology, National Healthcare Group Eye Institute, Singapore, Singapore, SINGAPORE|

Commercial Relationships Disclosure: Colin Tan: Commercial Relationship(s);Code R (Recipient):Roche

ABSTRACT BODY:

Purpose: To evaluate the accuracy of multicolour imaging compared to standard colour fundus photography (CFP) in differentiating AMD from normal eyes, and in detecting features of PCV.

Methods: In a prospective study of 50 consecutive patients presenting with PCV or AMD, standardized multimodal imaging (CFP, multicolour imaging, fluorescein and indoyanine green angiography) was performed. PCV was diagnosed using specific diagnostic criteria, with ICGA as the gold standard. CFP and multicolor images were graded using standardized grading protocols to determine sensitivity, specificity, positive and negative predictive values (PPV and NPV) in differentiating AMD from normal eyes, and in detecting features of PCV.

Results: The mean age of the patients was 70.0 years. Of 100 eyes, 44 had PCV, 11 had neovascular AMD, 21 non-neovascular AMD and 23 were normal. Of 44 eyes, polyps appeared as dark green oval lesions in 39 (88.6%) using the multicolour channel, while the branching vascular network (BVN) appeared as mottled grey lesions in 16 (36.4%) using the infrared channel. Multicolor had superior specificity (73.9% vs. 52.2%) and NPV (94% vs. 85.7%) compared to CFP for detecting all types of AMD. The sensitivity was similar for both multicolor and CFP (97.7% vs. 97.4%). For the detection of PCV, multicolour had higher sensitivity (86.4% vs. 59.1%) and NPV (89.3% vs. 74.3%) compared to CFP. In contrast, the specificity (89.3% vs. 92.9%) and PPV (86.4% vs. 86.7%) were similar between the two. PCV lesions were best visualized on the infrared multicolour images. Using BVN as a parameter, infrared imaging had very high specificity (96.6%) and PPV (88.9%) for detecting PCV.

Conclusions: Multicolour imaging is superior to CFP in differentiating AMD from normal eyes and detecting features of PCV. The presence of BVN on infrared imaging and dark green oval lesions should alert ophthalmologists to the presence of PCV.

TITLE: Optical coherence tomography angiography in inherited retinal disease

SESSION TITLE: OCT Angiography Clinical Applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Lu, J. Sundstrom, Ophthalmology, Penn State Health Milton S Hershey Medical Center, Hershey, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Amy Lu: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Sundstrom: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Diagnosis of inherited retinal diseases (IRD) remains difficult as some diseases do not demonstrate obvious findings on clinical exam. Optical coherence tomography angiography (OCTA) is an emerging, non-invasive imaging modality that may provide new information regarding these diseases. However, studies involving OCTA and IRD generally involve small case series that focus on specific IRDs. Here, we perform a database search to examine global as well as disease-specific changes in OCTA in different IRDs.

Methods: A systematic review and meta-analysis was performed by searching Pubmed. Studies utilizing OCTA in IRD were included. Search results that did not utilize OCTA, did not include eyes diagnosed with IRD, not available in English, not primary research articles or case series, or did not involve human eyes were excluded.

Results: Database search identified 25458 records. After removal of duplicates, 6603 records were subjected to inclusion/exclusion based on manual review of titles and abstract. 153 articles were included for full-text review. The most common reasons for exclusion were no diagnosis of IRD and no use of OCTA. Specifically, 1142 (17%) of non-duplicated search results included eyes that were diagnosed with IRD, of which 153 (13%) these utilized OCTA imaging. 128 (84%) of studies that were included were published between 2018 and 2021. 22 different IRDs were represented after inclusion/exclusion. Most highly represented IRD diagnoses were retinitis pigmentosa, Best disease, Stargardt's disease, choroideremia, adult onset foveomacular vitelliform dystrophy, and X-linked retinoschisis. Preliminary analysis suggests that multiple IRDs demonstrate patterns of enlarged superficial foveal avascular zone (FAZ) and decreased vessel density compared to healthy controls, and compared to earlier forms of the disease. Further, differences in FAZ and vessel density are more prominent to specific deep or superficial layers and capillary beds, and these differ between diseases.

Conclusions: OCTA has been increasingly utilized in characterizing different IRDs as well as different stages of IRD progression. OCTA has also been incorporated in initial reports describing novel IRD entities and novel mutations in known IRDs. OCTA adds new understanding to the pathology of IRD and should be considered in the workup and continued management of IRD patients.

ABSTRACT BODY:

Purpose: Vision loss from age-related macular degeneration (AMD) is currently irreversible as the retinal photoreceptors lack regenerative capacity. Regenerative cell therapies offer a promising treatment in restoring retinal function through transplanted stem cells, but face challenges in tracking the cells in vivo. This study used indocyanine green contrast (ICG) and multimodal imaging to longitudinally monitor the movement and growth of transplanted stem cells in vivo.

Methods: A model of 12 New Zealand White rabbits with localized retinal pigment epithelial (RPE) lesions from photocoagulation represented the RPE cell atrophy causing vision loss in patients experiencing AMD. Optical coherence tomography (OCT) was used to visualize the structural layers of the retina and guide an injection of progenitor human retinal pigment epithelium cells (ARPE-19) labeled with ICG into the lesions. The ICG increased the cell signal sensitivity to allow a noninvasive, multimodal system of photoacoustic microscopy (PAM), OCT, and fluorescence imaging to longitudinally track the distribution of ARPE-19 cells in vivo for 28 days.

Results: PAM and fluorescence imaging optimally visualized ICG labeled ARPE-19 cells at 700 nm. After an injected dose of 30 µL labeled ARPE-19 cells at a concentration of 10^6 cells/mL, PAM and fluorescence imaging tracked cell movement and growth. PAM signals (0.2±0.01 a.u. pre-injection) increased 20-fold (3.93±0.05 a.u.; $P<0.001$) and were detectable for 28 days. Fluorescence signals (0.07 ±0.01 a.u. pre-injection) initially increased by 37-fold (2.41 ±0.01 a.u.; $P<0.001$) and were also detectable for 28 days. Both signals detected stronger concentrations of ARPE-19 cells localized to photocoagulation lesions in the RPE. As a control, injected ICG without ARPE-19 cells did not localize to the lesions and was cleared from the body within 7 days. Histological staining with hematoxylin and eosin (H&E), as well as immunohistochemistry staining with RPE65 antibody confirmed localization and growth of ARPE-19 cells in the photocoagulation lesions as seen in OCT images.

Conclusions: The movement and growth of subretinal transplanted ARPE-19 cells labeled with ICG can be longitudinally tracked in vivo for up to 28 days using a noninvasive multimodal system of PAM, OCT, and fluorescence imaging.

TITLE: Characterising the natural history of retinal degeneration progression associated with a founder mutation in the PDE6B gene.

SESSION TITLE: Inherited Retinal Disease Genetics II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.L. Vincent, E. Edgar - Nemec, S. Hull, Ophthalmology, New Zealand National Eye Centre, The University of Auckland Faculty of Medical and Health Sciences, Auckland, Auckland, NEW ZEALAND| A.L. Vincent, S. Hull, Eye Department, Greenlane Clinical Centre, Auckland, NEW ZEALAND|

Commercial Relationships Disclosure: Andrea Vincent: Commercial Relationship: Code N (No Commercial Relationship) | Elena Edgar - Nemec: Commercial Relationship: Code N (No Commercial Relationship) | Sarah Hull: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To describe the rate of progression of vision and retinal parameters in PDE6B-associated rod cone retinal dystrophy, in a cohort of Māori patients, over a 9 year period, in New Zealand/Aotearoa. All carried at least one copy of the same pathogenic variant, (c.2197G > C, p.(Ala 733Pro)).

Methods: Retrospective review of patients identified from the the New Zealand Database of Inherited Retinal Disease with the PDE6B founder variant. Clinical notes were reviewed to determine best corrected visual acuity at each visit. Sequential Spectralis OCT scans through the fovea and shortwave autofluorescence (SW-AF) were reviewed, with the ellipsoid line identified and measured. The hyperautofluorescent ring was marked and measured in the horizontal and vertical meridian. Progression rates for width of the EZ, AF ring diameters and area, and BCVA were estimated using linear mixed models.

Results: 19 patients were identified (53% female) with an average age at first visit of 47 years (range 21-68 years) and average follow-up of 3.2 years (range 1-9 years), and 16 were homozygous for the p.(Ala 733Pro) allele. Almost all patients in this study had an initial baseline measurement of <3000µm for EZ line width and SW-AF ring diameters, EZ-line widths decreased by 350µm per year, area of SW-AF ring diameters decreased by 2.2mm2 per year and average horizontal and vertical hyper SW-AF ring diameters decreased by 320µm and 430µm per year, respectively. Estimated mean rate of LogMAR visual acuity decline, based on the slope of each patient was 0.0529 increments per year.

Conclusions: This study characterises the rate of progression of a cohort of patients with the same unique PDE6B founder mutation. Consistent with previous studies, disease progression rate was observed to be a function of initial baseline measurement. This study also provides information on the rate of progression for patients with more advanced stages of the disease (<3000µm for EZ line). Documenting the natural history is a prerequisite for preparedness for any gene-directed treatment.

TITLE: Structural and Functional Assessment of Glaucoma Progression in Patients with Boston Keratoprosthesis Type 1

SESSION TITLE: Structure-Function Relationship

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: A. Castillejos, C. Saini, J. Chodosh, L.Q. Shen, Ophthalmology, Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Alexandra Castillejos: Commercial Relationship: Code N (No Commercial Relationship) | Chhavi Saini: Commercial Relationship: Code N (No Commercial Relationship) | James Chodosh: Commercial Relationship: Code N (No Commercial Relationship) | Lucy Shen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To compare the assessment of glaucoma progression in patients with Boston Keratoprosthesis type 1 (KPro) by optical coherence tomography retinal nerve fiber layer (OCT RNFL) and Humphrey Visual Fields 24-2 (HVF), to clinical determination.

Methods: Retrospective analysis of all KPro patients at Massachusetts Eye and Ear between 1990 and 2021. Of 1358 KPro patients, 67 patients had undergone Cirrus OCT RNFL imaging, of which 9 patients had three or more OCT images without significant artifacts and with signal strength ≥6. 101 patients had undergone HVF testing, of which 22 had three or more reliable HVFs (FL<33%, FP<20%, FN<20%). Progression by OCT was defined as >5µm loss of average RNFL thickness or >7µm for superior and inferior quadrants. HVFs were assessed for trend-based and event-based progression using previously published criteria. Clinical determination of progression was based on an increase in cup-to-disc ratio of 0.2 on clinical exam or an escalation of glaucoma therapy.

Results: Sufficient OCT and/or HVF data for progression analysis was available for 24 KPro patients (66.7% male, 83.3% white, mean age 60.9±11.9 years) with follow-up of 5.5±3.3 years. At the time of baseline testing, the average visual acuity was logMAR 0.51±0.47, the RNFL thickness was 88.1±15.1µm, and the mean deviation was -12.5±6.5dB. Glaucoma progression based on OCT and/or HVF was noted in 20.8% (5/24) of patients. 2 out of 9 patients progressed based on OCT, while 3 out of 22 progressed based on HVF. In 6 of the 22 patients (27.3%) with reliable HFVs, progression could not be assessed due to severe loss at baseline. Clinical assessment showed progression in 16.7% (4/24) of patients. Overall, OCT and HVF testing identified an additional 4 progressors (16.7%), who were not identified by clinical assessment (Table 1).

Conclusions: Although the use of structural and functional measurements to detect glaucoma progression is limited in patients with KPro, our data suggest that HVF and OCT can be complementary to conventional clinical assessment of glaucoma in this patient population.

ABSTRACT BODY:

Purpose: To describe in detail the natural history of the central retinal structural and functional changes of a large group of patients with choroideremia (CHM).

Methods: Patients with CHM, ages 6 to 70 years (n= 133), had a comprehensive ophthalmologic evaluation and retinal imaging with spectral domain optical coherence tomography (SD-OCT). OCT cross sections were quantified along the horizontal meridian and related to co-localized visual thresholds measured with automated two-color static perimetry. A subset of patients (n=45) had longitudinal evaluations, which were used to validate predictions from much larger cross-sectional observations.

Results: Most patients (88%) retained visual acuity (VA) better than 0.3 logMAR until the fifth decade of life. VA decline below this level was associated with shortening of the inner segment ellipsoid (EZ) to RPE/BrM band thickness to ~half the normal value, coinciding with approximation of the transitions zones (TZs) of degeneration to the foveal center. No such relationship was identified between VA and outer nuclear layer (ONL) thickness or foveal sensitivity. Earliest abnormalities in regions with normally appearing retinal pigment epithelium (RPE) were the loss of the photoreceptor outer segment (POS) and RPE interdigitation zone associated with rod dysfunction. We confirmed that cone function may remain normal over an extended range when rod sensitivity has fallen well-below normal limits and prior to demonstrable changes in ONL thickness. TZs from relatively preserved retina to severe ONL thinning and inner retinal thickening moved centripetally with age, in either cross-sectional or longitudinal observations. In general, RPE abnormalities paralleled photoreceptor degeneration although there were regions with detectable but abnormally thin ONL co-localizing with severe RPE depigmentation and choroidal thinning.

Conclusions: We found that visual acuity decline in choroideremia relates well to shortening of the POS but not as well with ONL thickness or foveal sensitivity as measured by static perimetry. We confirmed that rod sensitivity loss is the earliest and most sensitive measure of visual function. These results have implications for further gene therapy clinical trials. The relationships established may help outline the eligibility criteria and outcome measures for clinical trials for CHM.

ABSTRACT BODY:

Purpose: This retrospective observational study compares the prevalence and severity of diabetic retinopathy (DR), and the likelihood of receiving anti-vascular endothelial growth factor (anti-VEGF) treatments in limited English proficiency (LEP) patients compared to English proficient (EP) patients.

Methods: We used the Cataract Surgery Outcomes Database to analyze the records of patients who underwent cataract surgery at the University of Colorado between 2014 and 2019. LEP was defined as a need or preference for an interpreter during medical encounters. Demographic and pre-operative characteristics analyzed included gender, race/ethnicity, age, prevalence of diabetes, history of macular edema, and history of DR. Comparisons between groups were made using logistic regression analysis with general estimating equations to account for patients with two eyes included in the study.

Results: A total of 868 LEP and 12,722 EP patients were analyzed. LEP patients had a significantly higher rate of type 2 diabetes (44.9% vs 21.5%, $p<0.0001$), macular edema (9.8% vs 2.9%, $p<0.0001$), and DR (18.1% vs 5.8%, $p<0.0001$). In patients with DR, LEP patients were more likely to receive anti-VEGF injections (34.4% vs 23.5%, $p=0.028$) and have more severe DR (severe non-proliferative DR 8.3% vs 6.5%, proliferative DR 58.6% vs 42.9%, $p=0.023$). LEP patients receiving anti-VEGF injections were less likely to receive >25 injections (2.3% vs 11.3%) and more likely to receive <10 injections as compared to EP patients (73.3% vs 65.5%, $p = 0.111$).

Conclusions: Our data suggests that LEP patients are at increased risk for DR and associated complications. Interestingly, we found that while a greater proportion of LEP patients receive anti-VEGF injections, they are less likely to receive as many injections overall compared to EP patients. This may suggest that LEP patients receive less consistent follow-up care. While this study represents a first step towards examining the relationship between EP status and DR, further studies are needed to better understand how language influences patient outcomes.

ABSTRACT BODY:

Purpose: Topical application of cyclosporin A (CsA) is a widely adopted method for treating ocular inflammatory diseases. However, achieving therapeutic levels of CsA in ocular tissues is challenging due to its significant molecular weight and hydrophobicity and the natural defense system of the eye. The purpose of this study was to investigate the effects of two different types of pH-responsive CsA-eluting contact lenses on the ocular surface of experimental dry eye (EDE) in rabbits.

Methods: CsA-eluting contact lenses were developed using two pH-responsive materials (pH-responsive immine cross-linking hyaluronic acid and pH-responsive cellulose polymer drug-eluting systems). Dry eye was induced using 0.1% benzalkonium chloride in rabbits, subdivided into the normal, EDE, 0.05% CsA, naïve soft contact lens (CL), immine cross-linking hyaluronic acid contact lens (CL type 1), or cellulose polymer contact lens (CL type 2) groups (n=18). CsA release profiles of the CsA-eluting contact lenses were evaluated with high-performance liquid chromatography analysis at pH 7.4 and 37°C, the same environment as the human ocular surface. Tear volume, tear film break-up time (TBUT), and corneal staining scores (CSS) were measured after 7 and 14 days. Periodic acid-Schiff staining for conjunctival goblet cells and TUNEL assay for corneal apoptotic positive cells were performed after 14 days.

Results: CsA was continuously released without an initial rapid release for 24 hours in both types of CsA-eluting contact lenses. All treatment groups showed a significant improvement in tear volume, TBUT, and CSS compared to the EDE group at 7 and 14 days. The CL type 1 and CL type 2 groups exhibited a significant improvement in the clinical parameters than the 0.05% CsA and CL groups after 7 and 14 days. In addition, compared to the EDE group, the CL type 1 and CL type 2 groups had higher goblet cell density and fewer TUNEL positive cells after 14 days ($p < 0.05$).

Conclusions: Two types of CsA-eluting contact lenses manufactured using two pH-responsive substances showed sustained drug release under conditions similar to the ocular surface. Both CsA-eluting contact lens types 1 and 2 could improve clinical signs, increase conjunctival goblet cells, and decrease TUNEL positive cells in a rabbit model of experimental dry eye.

TITLE: Anti-inflammatory effect of prescription eye drops on porcine corneal endothelial cells with induced oxidative stress

SESSION TITLE: Corneal Endothelium

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Abbas, J.J. Bu, K. Agsalud, D.F. Hakim, T. Noguchi, P. Shaw, N.A. Afshari, Shiley Eye Institute, Viterbi Family Department of Ophthalmology, University of California San Diego, La Jolla, California, UNITED STATES|

Commercial Relationships Disclosure: Anser Abbas: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Bu: Commercial Relationship: Code N (No Commercial Relationship) | Khadija Agsalud: Commercial Relationship: Code N (No Commercial Relationship) | Dominic Hakim: Commercial Relationship: Code N (No Commercial Relationship) | Takako Noguchi: Commercial Relationship: Code N (No Commercial Relationship) | Peter Shaw: Commercial Relationship: Code N (No Commercial Relationship) | Natalie Afshari: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess inflammatory markers in a porcine model of smoking-induced oxidative stress in corneal endothelial cells after treatment with three commonly used eye drops: cyclosporine (0.05%), lifitegrast (5%), and tacrolimus (0.1%).

Methods: The corneoscleral rim was separated from eight harvested porcine eyes and treated with 0.5% trypsin for 15 minutes. Corneal endothelial cells were scraped from Descemet membrane, plated into one well of a 12-well plate, proliferated to confluency in a low growth factor medium, and passaged three times until reaching 12 wells of a 12-well plate for treatment. Hydroquinone (HQ) was used to induce oxidative stress. Cells were exposed to medium containing 250 μM HQ and one of the following nine eye drop treatments: 10%, 5%, or 2.5% cyclosporine (Restasis 0.05% eye drops diluted ten-, twenty-, and forty-fold respectively); 10%, 5%, or 2.5% lifitegrast (Xiidra 5% drops diluted respectively); and 5%, 2.5%, and 1.25% tacrolimus (0.1% drops diluted respectively). All treatments were two hours and tested in biological triplicate. Control groups were: each eye drop condition without the addition of HQ (N=3 each), HQ alone (N=5), and untreated (N=7). Total RNA was extracted using the RNEasy Mini Kit and converted to cDNA using the iScript Reverse Transcription Supermix. Expression of inflammatory markers IL-6, TNF-alpha, and the housekeeping gene GAPDH, were quantified using real-time quantitative PCR. The delta-delta Ct method was used to calculate relative gene expression, and statistical tests were calculated using delta Ct values.

Results: Cells with hydroquinone-induced oxidative stress had significantly reduced IL-6 expression when treated with cyclosporine ($p<.05$), lifitegrast ($p<.01$), and tacrolimus ($p<.05$), compared to cells with hydroquinone alone. Single-factor analysis of variance (ANOVA) did not reveal significant differences based on each level of eye drop concentration. In the absence of hydroquinone-induced oxidative stress, eye drop treatment did not significantly impact inflammatory marker expression.

Conclusions: Cyclosporine, lifitegrast and tacrolimus can protect against inflammatory marker expression in corneal endothelial cells in an induced oxidative stress model. More research is needed on these effects at various eye drop concentrations.

ABSTRACT BODY:

Purpose: Aging is the major risk factor for age-related macular degeneration (AMD) but how aging contributes to AMD pathogenesis is unclear. Epigenetic modifications, mainly methylcytosine (mC) and hydroxymethylcytosine (hmC), regulate the genome and gene expression, and are altered with advanced age. DNA methylation analyses of AMD patient blood and retinas suggest differential methylation resulting in gene expression changes during development of AMD. In addition, Müller glial cells (MGC) are activated in AMD patient retinas. The aim of this study is the validation and demonstration of a cre/ERT2-NuTRAP mouse model for the paired interrogation of differential mC/hmC genome-wide and the translatome specifically in MGC with retinal aging.

Methods: Female NuTRAP $^{flox/flox}$ and male Aldh1l1-cre/ERT2$^{+/wt}$ mice were bred to generate Aldh1l1-cre/ERT2$^{+/wt}$; NuTRAP$^{flox/wt}$ (Aldh1l1-cre/ERT2^{+}; NuTRAP^{+}) mice. After systemic tamoxifen treatment mice were euthanized at 6 or 24 months of age and their retinae harvested and processed for: immunohistochemistry of mCherry, EGFP, GS, CD11b, and GFAP expression in retina sagittal sections via confocal microscopy; MGC ribosome bound RNA isolation via TRAP and stranded RNAseq profile; MGC nuclei isolation via INTACT method for bisulfite amplicon sequencing (BSAS) and nuclear RNAseq.

Results: Specific co-localization of EGFP, mCherry, and the MGC marker GS was observed in the Aldh1l1-cre/ERT2^{+}; NuTRAP^{+} retinae. RNA-seq bioinformatic analysis revealed MGC-specific transcriptomic changes associated to inflammation in response to aging, such as purinergic receptor and cytokine-mediated signaling pathways. Nuclear RNAseq data supported the MGC identity of the INTACT-DNA isolates. BSAS showed site-specific decrease of mC in the promoter region of the MGC-specific gene Kcnj10 and hypermethylation in the promoter region of the photoreceptor gene Rho in INTACT-DNA positive fraction relative to input.

Conclusions: Our data show the Aldh1l1-NuTRAP model as a suitable tool for the paired interrogation of DNA methylation and gene expression, specifically in MGC. Differential transcript expression with overrepresentation of pathways and processes related to inflammation was found specifically in MGC in response to aging.

TITLE: Peripheral neuropathy evaluation of diabetes mellitus patients in follow-up care in a medical retina clinic

SESSION TITLE: Diabetic Retinopathy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B.A. Maciel, A. Nassaralla, J.L. Orefice, Centro Oftalmológico de Minas Gerais, Belo Horizonte, Minas Gerais, BRAZIL|

Commercial Relationships Disclosure: Bruno Maciel: Commercial Relationship: Code N (No Commercial Relationship) | Arthur Nassaralla: Commercial Relationship: Code N (No Commercial Relationship) | Juliana Orefice: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess the prevalence of peripheral neuropathy findings in patients diagnosed with diabetic retinopathy (DR) for over 5 years having follow up care in Medical Retina (MR) clinic.

Methods: Thirty-three patients were invited randomly and consecutively evaluated in one day in our MR clinic. Along with indirect ophthalmoscopy to evaluate the patients' retinas, various tests to assess the presence and severity of peripheral neuropathy were performed. Semmes-Weinstein monofilament test, abnormalities in posterior tibial and dorsalis pedis pulse, presence of active or inactive diabetic foot ulcers (DFUs), and questions such as history of DFUs or inadequate outdoor footwear were made throughout the examination. The results were, then, correlated.

Results: Among mild, moderate and severe retinopathy patients: 39,4% presented abnormal Semmes-Weinstein monofilament test; 42,5% and 30,3% showed weak or absent pulse (posterior tibial and dorsalis pedis respectively); While 24,2% reported history of diabetic foot ulcer, only 9,1% demonstrated active DFUs and 3% had amputation history. The inadequate outdoor footwear use was reported by 39,4% of the patients.

Conclusions: Peripheral neuropathy is a common manifestation of diabetes in patients diagnosed with diabetic retinopathy for over 5 years undergoing clinical follow-up in a MR clinic. Therefore, we may infer that, being two of the three most common diabetes manifestations, diabetic retinopathy may be a biomarker for peripheral neuropathy in diabetic patients. Furthermore, patients presenting peripheral neuropathy from diabetic foot that were never submitted to a fundoscopic evaluation have a good chance of presenting undiagnosed diabetic retinopathy.

ABSTRACT BODY:

Purpose: En face optical coherence tomography (OCT) imaging was investigated as a method for the detection and monitoring of calcified drusen in eyes with non-exudative age-related macular degeneration (AMD).

Methods: A retrospective review of a prospective study was performed of same-day color fundus (CF), near infrared (NIR), fundus autofluorescence (FAF), and en face swept-source OCT (SS-OCT) images to identify eyes with non-exudative AMD and calcified drusen. The appearance and subsequent progression of these lesions were compared using the different imaging modalities.

Results: Two hundred twenty eyes from 139 patients with non-exudative AMD were studied with 42.7% of the eyes containing calcified drusen either at baseline or during their follow-up visits. On the en face sub-RPE SS-OCT slabs, calcified drusen appeared as dark focal lesions referred to as choroidal hypo-transmission defects (hypoTDs). The corresponding B-scans showed drusen with heterogenous internal reflectivity and a hyper-reflective cap. In the majority of the calcified drusen, choroidal hyper-transmission defects (hyperTDs) were observed to develop over time around the periphery of the hypoTDs giving them the appearance of a donut lesion on the en face SS-OCT images. These donut lesions were associated with significant attenuation of the overlying retina, and the corresponding FAF images showed hypo-autofluorescence at the location of these lesions. The donut lesions fulfilled the requirement for a persistent hyperTD and is synonymous with complete retinal pigment epithelium and outer retinal atrophy (cRORA). Six eyes displayed regression of their calcified drusen without developing cRORA. B-scans at the location of the regressed calcified drusen showed deposits along the RPE with outer retinal thinning in the regions where the calcified lesions previously existed.

Conclusions: En face rendering of OCT images is a useful method for the detection and monitoring of calcified drusen and future studies will document the evolution of these drusen as they form donut lesions and foci of cRORA.

ABSTRACT BODY:

Purpose: Early pathological changes in the human retina and optic nerve head due to elevated intraocular pressure (IOP) remain elusive due to the unique biomechanical properties of human eye in the context of glaucoma. We generated a new model of acute IOP elevation based on a recently characterized organotypic whole-globe human eye perfusion approach. This system enables us to study the initial response of ex vivo human retina and lamina cribrosa (LC) to pathologically relevant pressure insult.

Methods: Human eyes received from the Eyebank of Canada within 24 hours of enucleation were immersed in Neurobasal-A Medium with supplements. Physiological fluid convection was restored in the eyes by infusion of synthetic aqueous humor into the anterior chamber over 6 hours. For each pair of eye, one was perfused to maintain a physiological IOP of 18-21mmHg, and the contralateral eye was maintained at an elevated IOP of 30-50 mmHg. Following perfusion eyes were fixed in 4% paraformaldehyde and sectioned for confocal microscopy. RBPMS staining and TUNEL assay were quantified to assess retinal ganglion cell (RGC) survival. GFAP and Iba1 staining were quantified to assess astrocyte reactivity and microglial activation in the retina and LC. Two-tailed paired student's t-test was used for statistical analysis.

Results: Whole-globe human eyes maintained a sustained physiological or elevated IOP for 6 hours, for at least three pairs. The retina and LC ctyoarchitecture were well preserved in all samples. There was minimal loss in the number of RBPMS-positive RGC ($p=0.50$) after IOP elevation. TUNEL assay also showed no apoptosis in the ganglion cell layer in both normal or elevated IOP eyes. IOP elevation led to significant activation of retinal microglia ($p=0.015$), indicated by changes in their distribution. IOP elevation showed a trend of increased GFAP intensity in the retina and LC, indicating potential early astrocyte reactivity.

Conclusions: Our model produces sustained, elevated IOP in ex-vivo whole globe human eyes. The pressure insult induces rapid microglial activation that precedes visible neuronal injury. These changes replicate findings in other early-stage glaucoma models, and provide insight into pathological events relevant to early human glaucoma. With further optimization, this model will be used to study IOP-dependent molecular changes in human eyes relevant to glaucoma pathogenesis.

ABSTRACT BODY:

Purpose: To study the outcomes at 1 year after pars plana vitrectomy (PPV) in patients with a history of systemic corticosteroid use prior to PPV.

Methods: A retrospective cohort study was performed using TriNetX (Cambridge, MA, USA), a federated electronic health records research network comprising multiple health organizations in the United States. Patients who underwent PPV were identified using a series of ICD-10 codes and stratified into 2 cohorts - with or without a history of systemic corticosteroid use prior to PPV. Each subject was matched to a control based on age, sex, BMI and the presence or absence of hypertension, diabetes mellitus, chronic lower respiratory diseases, heart failure, nicotine dependence and alcohol related disorders. The primary endpoint of the study was the incidence of vitreous hemorrhage (VH), choroidal hemorrhage, retinal detachment or break, iridocyclitis, retinal edema, cystoid macular degeneration, macula pucker, glaucoma, cataract, corneal edema, central retinal vein occlusion (CRVO) and central retinal artery occlusion (CRAO).

Results: A total of 25,752 patients were included in the analysis with 12,876 patients in each of the cohorts after propensity matching. At 1-year post-PPV, the cohort with a history of systemic corticosteroid use prior to PPV were at greater risk for choroidal hemorrhage (RR 2.16; CI 1.42, 3.28), retinal detachment or break (RR 1.09; CI 1.04, 1.15), iridocyclitis (RR 1.59; CI 1.38, 1.82), retinal edema (RR 1.27; CI 1.15, 1.41), cystoid macular degeneration (RR 1.61; CI 1.45, 1.8), macula pucker (RR 1.42; CI 1.35, 1.5), glaucoma (RR 1.42; CI 1.34, 1.51), cataract (RR 1.28; CI 1.2, 1.36) and corneal edema (RR 2.37; CI 1.55, 3.62).

Conclusions: Patients with a history of systemic corticosteroid use prior to PPV are at greater risks of long-term complications at 1-year post-PPV, possibly from a heightened inflammatory response from an underlying disease process treated by the corticosteroid. These findings can facilitate pre-operative counseling with patients regarding potential surgical risks and post-operative complications.

TITLE: Outcomes of drive-by paintball shootings at a tertiary academic center

SESSION TITLE: Endophthalmitis/ trauma/Intravitreal/periocular therapies

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Amin, A. Farooq, H. Shah, University of Chicago Division of the Biological Sciences, Chicago, Illinois, UNITED STATES|V. Otti, University of Chicago Pritzker School of Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Shivam Amin: Commercial Relationship: Code N (No Commercial Relationship) | Valerie Otti: Commercial Relationship: Code N (No Commercial Relationship) | Asim Farooq: Commercial Relationship(s);Code C (Consultant/Contractor):GlaxoSmithKline, Amgen, Ambrx, Daiichi-Sankyo | Hassan Shah: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To characterize the sequela of ocular paintball injuries from drive-by shootings with a focus on the range and severity of injuries sustained, clinical management, and visual outcomes.

Methods: Retrospective analysis of 20 patients who suffered ocular paintball injuries from drive-by shootings and were evaluated at a tertiary medical center from July 18, 2020, until November 8, 2021.

Results: Mean follow-up interval was 1.7 months from the time of initial evaluation (range: 0 days - 11.4 months). The average age of patient at the time of presentation was 36.6 years (range: 13 - 64 years-old). Fourteen patients (70%) had an initial visual acuity (VA) of hand-motion (HM) or worse. Six patients (30%) suffered ruptured globe injuries requiring urgent surgical repair, of whom three (15%) underwent subsequent evisceration. Nine patients (45%) presented with vitreous hemorrhage, eight (40%) with traumatic hyphema, four (20%) with iridodialysis, three (15%) with traumatic cataract, two (10%) with choroidal rupture, and one (5%) with a retinal tear/detachment. Fourteen patients (70%) suffered two or more ocular injuries. Seventeen ocular surgeries were performed on eleven patients (55%) at our institution with three patients referred to in-network providers for definitive surgical management. A total to fourteen patients (70%) suffered ocular injuries requiring surgical intervention. Final VA was NLP in five patients (25%).

Conclusions: The severity of injury following paintball-induced ocular trauma is higher in this case series than what has previously been reported in the literature. To our knowledge this is the first study to date that specifically characterizes ocular paintball injuries suffered from drive-by shootings where paintball projectiles were used as a means to cause intentional harm. The use of paintballs and paintball guns in unregulated settings bears further scrutiny given their potential to cause devastating ocular injury.

ABSTRACT BODY:

Purpose: Patients with age-related macular degeneration (AMD) and across different severity stages have been shown to have distinct plasma metabolomic profiles compared to controls. Urine is a biofluid obtained non-invasively and, in other fields, urine metabolomics has been proposed as a feasible and more accessible alternative to plasma biomarkers. However, to our knowledge, no studies have evaluated urinary mass spectrometry (MS) metabolomics in AMD. This study aimed to assess urinary metabolomic profiles of patients with different stages of AMD and a control group.

Methods: We conducted a prospectively designed, multicenter, cross-sectional study including patients with AMD and a control group (>50 years old). At our two study sites – Boston, US and Coimbra, Portugal – participants had a complete ophthalmological exam and were imaged with color fundus photographs for AMD classification and staging (AREDS classification scheme). At the same visit, fasting urine samples were collected, which were used for metabolomic profiling (Ultrahigh Performance Liquid chromatography – Mass Spectrometry, Metabolon, Inc). Multivariable logistic and ordinal logistic regression models were used for analysis, accounting for age, gender, body mass index and use of AREDS supplementation.

Results: We included 484 participants, 389 with AMD (89 early, 201 intermediate and 99 late AMD) and 95 controls. Six urinary metabolites differed significantly ($p < 0.01$) across the severity stages of AMD (early, intermediate and late stage) with pathway analysis revealing an enrichment of sphingolipid metabolism. Of note, two of the metabolites (sphingosine and phosphoethanolamine) have been previously shown by our group to also differ in the plasma of patients with AMD compared to controls and all across AMD severity stages.

Conclusions: This is the first investigation of urine metabolomics using Mass Spectrometry in AMD. We identified some differences across stages of disease that support our previous findings using plasma, supporting the potential of these metabolites as biomarkers for this common, blinding disease.

TITLE: Wnt Signalosome Assembly by Small Molecule Wnt-Mimic

SESSION TITLE: Corneal Cell and Molecular Biology | Corneal Development

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Han, C. Bonnet, C. Zhang, J.J. Zheng, S.X. Deng, Jules Stein Eye Institute, University of California Los Angeles, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Christiana Han: Commercial Relationship: Code N (No Commercial Relationship) | Clemence Bonnet: Commercial Relationship: Code N (No Commercial Relationship) | Chi Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Jie Zheng: Commercial Relationship: Code N (No Commercial Relationship) | Sophie Deng: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: One key precursor to Limbal Stem Cell Deficiency is insufficient Wnt-β-catenin signaling pathway; however, therapeutic tools are underdeveloped as manipulation of hydrophobic WNT proteins proves challenging. This study explored the effect of our small molecule WNT-mimic(MFH-ND) on Wnt-β-catenin signaling pathway using an experimental model of 293STF cells treated with MFH-ND and Wnt3a.

Methods: HEK 293 (293STF) cells were treated with vehicle (DMSO), 0-4000 ng/mL recombinant human Wnt3a protein with carrier, 0-800 μM of MFH-ND for 18 hours. Cell viability and firefly luciferase activity was measured using TOP-Flash assays following manufacturer's protocol. Microplate Reader was used to measure cell viability and firefly luciferase activity. The Wnt pathway activity was expressed as the ratio of fluorescence intensity to firefly luciferase. Figure 1 is displayed as Mean ± Standard Error of Mean (SEM). Figure 2 graphs were interpolated from sigmoidal standard curves(Model: Sigmoidal, 4PL, X is concentration) using GraphPad. Hill Coefficient(Model: Specific binding with Hill slope) using Graphpad.

Results: Per. Figure 1

At MFH-ND concentrations starting from 200 uM to 800 uM, across all the Wnt concentrations, there is a drastic increase in WNT Signaling Activation.

Hill Coefficient was calculated to be 1.113.

Conclusions: MFH-ND alteration of the Wnt-β-catenin pathway seemed to be an enhancement of the Wnt3a ability to activate the Wnt pathway. Evidence of cooperative binding(n=1.113 and Figure2) as well as boosted Wnt pathway activation(Figure1) point to evidence of signalosome assembly. Wnt3a alone was sufficient to activate the signalosome complex but had a much lower activation when compared to the high concentrations MFH-ND at the same Wnt3a concentration, suggesting MHF-ND was able to recruit a higher activation through a second mechanism, possibly cooperative binding. Figure 1 shows how Wnt pathway activation can be finely altered, which is important when trying to reach a certain therapeutically ideal target. Prospective animal trials will provide more in-vivo understanding of MFH--ND with in-vivo Wnt-β-catenin signaling to see if MFH-ND could be used as potential therapeutic target to Limbal Stem Cell Deficiency, caused by reduced Wnt-β-catenin pathway activation.

ABSTRACT BODY:

Purpose: Hydroxychloroquine (HCQ), which is used to treat autoimmune diseases, can cause retinal toxicity which manifests photoreceptor loss and damage to the retinal pigment epithelium (RPE), ultimately leading to irrecoverable central vision loss. Structural evidence of retinal toxicity is provided by disruption of the ellipsoid zone (EZ) reflectivity band and change in outer retina thickness (ORT), both of which are detectable on spectral-domain optical coherence tomography (SD-OCT) imaging and display different patterns based on various demographic characteristics. This work investigates spatial differences in retinal susceptibility to these changes to better understand and detect retinal toxicity after HCQ treatment.

Methods: 87 patients (average age, 58.8±12.1 years) on long-term HCQ (14.1±7.3 years) enrolled in a case-control study (NCT01145196) underwent imaging with SD-OCT (Heidelberg Spectralis). Of the 32 patients who demonstrated evidence of toxicity, 20 were White, 6 were Black, 3 were Asian, and 3 were of unknown race. 2D enface maps of EZ loss and ORT were generated with automated algorithms and analyzed within each eye relative to the fovea location and demographic data, including race and ethnicity.

Results: In eyes without foveal involvement, the pattern of EZ loss demonstrated that the location of EZ loss closest to the fovea occurred most commonly in the inferotemporal sector (17/30). Eyes had a range of EZ loss areas and patterns (EZ loss area, Asian=29.88±21.48 mm^2, Black=21.60±16.35 mm^2, Caucasian=9.23±9.43 mm^2, p=0.000254). For eyes without foveal involvement (EZ loss>250 μm from the fovea), areas of EZ loss were greater in Black and Asian eyes. For eyes with large amounts of EZ loss (>20 mm^2), more Asian and Black eyes (6/8) maintained EZ loss further from the fovea (>250 μm). Analyses of ORT in the foveal B scans revealed the differences between affected and unaffected eyes to occur further from the fovea in Black and Asian affected eyes than in Caucasian eyes.

Conclusions: Quantitative analyses of structural changes in HCQ toxicity can reveal differences in retina spatial involvement within an eye and between patients. Causes for differential involvement may be due to gradients within the retina and differences in cellular distributions between patients which may be affected by race. This has implications for screening participants as well as for the development of interventions.

ABSTRACT BODY:

Purpose: Anterior Segment Optical Coherence Tomography (AS-OCT) has shown utility for imaging and quantifying anterior chamber (AC) inflammation after cataract surgery. The objective of this study was to elucidate the effects of iris pigmentation on the degree of AC inflammation after cataract surgery using AS-OCT.

Methods: This was an IRB-approved, observational, prospective case series of patients who underwent cataract surgery by one surgeon (RG) at the Cleveland Clinic Cole Eye Institute. Anterior chamber volume scans were obtained using AS-OCT (Avanti, Optovue Inc, Fremont, CA) at designated time points after cataract surgery including postoperative day 0 or 1 (POD0/1), postoperative week 1 (POW1), and postoperative month 1 (POM1). AS-OCT images were analyzed by an automated, proprietary algorithm, which identified inflammatory cells within the AC as previously described. Iris color was designated by the operating surgeon. Cell fluid density (number of inflammatory cells per mm3 of AC volume) was correlated to iris pigmentation.

Results: 155 eyes of 117 patients were analyzed. 40% of patients were female (n=47), and the average patient age was 69 years (range: 44-91 years). Distribution of iris color was 28% blue (n=43), 51% brown (n=79), 7% green (n=11), and 14% hazel (n=22). On automated analysis, no significant difference (p=0.16) was noted in average cell fluid density between blue (65.2 ± 102.9 cells/mm3) and brown (41.8 ± 48.8 cells/mm3) eyes at POD0/1. Average cell density of brown eyes (4.47 ± 8.87 cells/mm3) was significantly (p=0.04) greater than average cell density of blue eyes (2.11 ± 1.80 cells/mm3) at POW1. Likewise, at POM1, average cell density of brown eyes (2.01 ± 3.50 cells/mm3) was significantly greater (p=0.01) than average cell density of blue eyes (0.75 ± 0.72 cells/mm3).

Conclusions: Eyes with brown irises demonstrated significantly greater inflammatory cell density within the AC compared to eyes with blue irises at the POW1 and POM1 time points after cataract surgery. Brown irises, with greater levels of pigment, may be associated with prolonged inflammation after cataract surgery compared to iris colors with less pigment. Further work into the role of iris pigmentation on the inflammatory response after cataract surgery in larger cohort studies is needed to guide postoperative therapy considerations.

ABSTRACT BODY:

Purpose: To study the choroidal contour map in central serous chorioretinopathy (CSCR) and age related macular degeneration (AMD) and compare with healthy controls.

Methods: Retrospective analysis on 13 healthy eyes, 12 eyes with CSCR and 8 eyes with AMD was performed. Volumetric scans were captured using a widefield swept source optical coherence tomography and CIS and COS in 3D were obtained using previously validated residual U-net (ResUnet) deep learning model for choroidal segmentation. Qualitative analysis of CIS and COS was performed using custom built MATLAB based 3D visualization tool and the choroidal contour shapes were determined in the order of decreasing steepness. Quantitative analysis was based on maximum principal curvature (Pmax) of the surface which was calculated at the center, superior, inferior, nasal and temporal macula.

Results: Qualitative evaluation of CIS demonstrated the shape of a bell, hump, crescent, arc and cupid's bow in 4,3,2,2 and 2 in normal eyes; 2,6,4,0,0 in CSCR eyes and 0,5,2,1,0 in AMD eyes respectively. Qualitative analysis of COS demonstrated the shape of a bell, hump, crescent, arc and cupid's bow in 2,6,2,1,2 in normal eyes; 2,8,1,0,1 in CSCR eyes and 0,6,1,1,0 in AMD eyes. On quantitative analysis of CIS, Pmax at central macula was -0.23, 0.45 and -0.02 in normal eyes, CSCR and AMD respectively (p=0.015). Similarly, Pmax in superior, inferior and temporal macula was significantly different between the 3 groups (p=0.001,0.029,0.019).The difference between CIS and COS was the highest for AMD group (-6.73±2.2) as compared to normal eyes (-2.5±0.4) and CSCR (-2.8±1.7)(p=0.038). On making a comparison within the group, the central Pmax, superior Pmax, inferior Pmax and temporal Pmax between the CIS and COS of normal eyes (p=0.0002,0.00003,0.004,0.003), CSCR (p=0.006,0.001,0.0003,0.033) and AMD (p=0.009,0.005,0.006,0.005) were significantly different from each other.

Conclusions: Choroidal contour was steeper in CSCR and flatter in AMD as compared to normal eyes. More data is continuously being added and will be presented at the meeting.

TITLE: Validation and quantification of optical coherence tomography angiography decorrelation at high and low intraocular pressures in a non-human primate model

SESSION TITLE: Biomechanics and ocular blood flow

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Mohammed, V. Chen, O. Saeedi, Ophthalmology, University of Maryland School of Medicine, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Taariq Mohammed: Commercial Relationship: Code N (No Commercial Relationship) | Victoria Chen: Commercial Relationship: Code N (No Commercial Relationship) | Osamah Saeedi: Commercial Relationship(s);Code F (Financial Support):Heidelberg Engineering;Code F (Financial Support):Aerie Pharmaceuticals;Code F (Financial Support):Vasoptic Medical Inc.

ABSTRACT BODY:

Purpose: Optical coherence tomography angiography (OCTA) is a noninvasive angiographic method that compares the decorrelation signal over time to identify areas of changing signal. Erythrocyte Mediated Angiography (EMA) uses autologous ICG-labelled cells to permit the visualization and absolute quantification of retinal capillary flowrates. We aimed to compare and validate EMA with OCTA and then to compare the OCTA decorrelation and flow values at low and high pressures in a non-human primate model.

Methods: Sequential OCTA and EMA was acquired in two sessions of two non-human primate (NHP) eyes at high and low intraocular pressures (Figure 1). OCTA was acquired using Heidelberg Spectralis (Heidelberg Engineering, Heidelberg, Germany), and EMA was acquired using previously described methods (Tracy 2019). OCTA decorrelation within capillaries of the superficial vascular plexus (SVP) was measured using manual segmentation. We then compared the values of OCTA decorrelation with EMA in the same vessels. We further compared OCTA decorrelation values at high and low IOPs.

Results: In 15 SVP capillaries at low IOP and 11 at high IOP, EMA velocity was 0.61 +- 0.07 mm/s and 0.54 +- 0.21 mm/s respectively and OCTA decorrelation was 0.61 +- 0.06 and 0.56 +- 0.11 respectively (Figure 2). OCTA decorrelation values correlated with absolute EMA velocity ($r = 0.50$, $p < 0.05$). In ten perifoveal SVP capillaries at high and low IOP, the mean OCTA decorrelation at a low IOP (Mean IOP = 14.5 mm Hg, OCTA decorrelation = 0.69 +- 0.11) was significantly higher than at high IOP (Mean IOP = 27.75 mmHg, OCTA decorrelation =0.49 +- 0.08, $p < 0.05$).

Conclusions: In our analysis, a large and statistically significant difference was observed between OCTA decorrelation at low and high IOP, and was correlated with changes in absolute erythrocyte velocity as measured with EMA. This potentially validates the decorrelation values of OCTA.

AUTHORS/INSTITUTIONS: M.A. Salinas-Lugo, M.E. Quiroga-Garza, D. Bastán-Fabián, J.E. Arreola, R.E. Ruiz, M. Sepulveda-Villegas, V. Treviño, J.C. Hernandez-Camarena, J. Valdez-Garcia, Instituto Tecnologico y de Estudios Superiores de Monterrey, Monterrey, Nuevo Leon, MEXICO|

Commercial Relationships Disclosure: Manuel Salinas-Lugo: Commercial Relationship: Code N (No Commercial Relationship) | Manuel Quiroga-Garza: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Bastán-Fabián: Commercial Relationship: Code N (No Commercial Relationship) | Jesus Arreola: Commercial Relationship: Code N (No Commercial Relationship) | Raul Ruiz: Commercial Relationship: Code N (No Commercial Relationship) | Maricruz Sepulveda-Villegas: Commercial Relationship: Code N (No Commercial Relationship) | Victor Treviño: Commercial Relationship: Code N (No Commercial Relationship) | Julio Hernandez-Camarena: Commercial Relationship: Code N (No Commercial Relationship) | Jorge Eugenio Valdez-Garcia: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The aim of this project is the search of related genetic mutations of keratoconus. Previous results were published by our research group, where 37 genes directly related to this ectasia were proposed (Gomez, Lopez, el tal. 2019). This research was continued and the updates are presented here.

Methods: Via a bioinformatic approach using the Pubterm tool, we searched and curated genes and abstracts associated with keratoconus; afterwards, these publications were analyzed in order to classify the genetic alterations into those with evidence of functional variant, and those with other evidence of genetic alterations. Finally, a functional analysis was made according to the signaling pathway implied for each gene.

Results: 405 abstracts were retrieved mentioning 304 relevant genes. After exclusion of non-human genes and those without genetic variants, 74 genes remained. Of these, 25 had evidence of functional variant, including 13 new genes in comparison to the previous publication; such as: VANGL1, miR-184 and FLG. The remaining 49 genes stand for other evidence of genetic alterations including 23 new genes, such as: SOD1 and ADAMTS8. A total of 36 new genes were retrieved. Genes were grouped according to the relevant molecular pathways in which they are involved: Immune regulation, apoptosis, transcription factors, signaling pathways, collagen and cytoskeleton properties. The following genes have the most citations: VSX1, COL4A,TGFB1, miR-184, DOCK9, FLG and ZEB1.

Conclusions: After retrieving these genes and performing a functional analysis, the findings exhibited that different genes from multiple molecular pathways may be involved in keratoconus pathophysiology. These genes could be contemplated for screening purposes as risk factors analysis for Keratoconus; nevertheless, differences across ethnic groups need to be taken into account on a case by case basis.

ABSTRACT BODY:

Purpose: Recent clinical trials demonstrated the feasibility of retinal prostheses for somewhat useful artificial vision. Although the healthy retina is known for transmitting remarkable amount of neural information, the amount of artificial visual information created by prosthetic devices is still unknown. The quality of prosthetic vision is likely to be at least partially dependent on how much information would be transmitted. Here, we investigated neural information as a function of mean firing rate and spiking duration of retinal ganglion cells (RGCs).

Methods: We used neural computational methods to generate correlated spike trains and calculate the amount of information of those simulated RGC spiking activities. First, we created five groups of 1-sec-long spike trains with different mean firing rates using a modified version of ‘Brian 2’, an open-source simulator for spiking neural networks. Second, we created five groups of spike trains that have 60 Hz average firing rate but different spiking duration. Then, we calculated the amount of neural information for each group to examine the effects of varying mean firing rate and spiking duration.

Results: The mean firing rates of the first five groups were 20, 40, 60, 80, and 100 Hz. The amounts of neural information transmitted by 15 cells of each group were 2.95±0.11,4.32±0.15,5.19±0.13, 5.96±0.16, and 6.38±0.13 bits (mean±std), respectively. The spiking duration of the second five groups were 0.2, 0.4, 0.6, 0.8, and 1.0 sec. In each group, 15 cells transmitted neural information 1.54±0.07, 2.82±0.09, 3.76±0.09, 4.37±0.10, and 5.19±0.13 bits, respectively. In both cases, the higher firing rate or the longer spiking duration, the more neural information was transmitted as expected. However, the effects of increments in both parameters were gradually diminished. For example, when the spiking duration was 0.2 sec, the neural information increased by 0.77 bits for the mean firing rate change from 20 Hz to 60 Hz. When the duration was 1.0 sec, the neural information increased by just 2.24 bits for the same change in mean firing rate. Although the duration was 5 times bigger, the information was only ~2.9 times more.

Conclusions: Our results indicate that we can transfer more information as the mean firing rate and spiking duration increase but energy-information efficiency should be considered.

ABSTRACT BODY:

Purpose: Early detection is key in the management and long-term outcomes of numerous ophthalmic disorders, such as glaucoma and diabetic retinopathy, many of which can present insidiously with symptoms unnoticed prior to advanced disease. Teleophthalmologic screening presents a major opportunity to reach populations that traditionally lack access to routine care. The goal of this study is to evaluate the feasibility and reliability of a remote international reading center using ocular imaging.

Methods: 50 patients (mean age 58.5 years, 48/50 female) presented for comprehensive eye exams from an ophthalmologist (Reference Standard, or “Ref”) in Venezuela, and fundus photography and optical coherence tomography (OCT) images were sent to two outside ophthalmologists (Reader 1 and Reader 2, or “R1” and “R2”) blinded to the in-person exam. Features assessed included cup/disc ratio (CDR) on fundus photos and retinal nerve fiber layer thinning on OCT. Fundus findings were compared for reliability and accuracy, with the in-person exam treated as the best available assessment; while OCT findings were compared between R1 and R2 for reliability.

Results: While agreement on exact CDR between the readers and Ref was relatively low (17.6-29.4%), CDR findings were fairly well correlated (r 0.614-0.649, $p<0.01$), with moderate reliability among all evaluators (intraclass correlation 0.665 for right eye, 0.698 for left eye; Table 1). Agreement was higher for CDR estimate on fundus photo (r 0.865-0.848, $p<0.01$). When assessing for CDR > 0.5, accuracy improved (76.5-83.3% agreement) and moderate interrater reliability was observed. On remote OCT assessment, percent agreement between readers were 72% (right eye) and 64% (left eye), with fair reliability (Cohen’s kappa coefficient 0.323 for right eye, 0.236 for left eye; Table 2).

Conclusions: Although CDR agreement rates between in-person fundoscopic exam and remote fundus photography reading were low, findings were well correlated and improved when assessing for the clinically relevant distinction of CDR > 0.5, suggesting that remote screening may be reliable and accurate in assessing for abnormal CDR. Lower reliability of remote OCT assessment was driven by a high disagreement rate between these readers, reflecting the need for consensus, standardization, and further evaluation with a larger pool of readers in a sample better representing the general population.

ABSTRACT BODY:

Purpose: The full scope of ophthalmic manifestations of coronavirus disease 2019 (COVID-19) has yet to be appreciated. We used optical coherence tomography (OCT) to compare subjects with a history of COVID-19 disease and those without evidence of past disease across qualitative and quantitative metrics.

Methods: Subjects diagnosed by reverse-transcriptase polymerase chain reaction with COVID-19 or presence of SARS-CoV-2 antibodies (N=25) and those with no history or antibody evidence of disease (N=25) were prospectively assessed using a Zeiss Cirrus HD OCT Model 5000. Retinal nerve fiber layer (RNFL), macular ganglion cell complex (GCC), and foveal thickness were tabulated. Retinal structural findings were evaluated by a retina specialist. Results were stratified by age, race, ethnicity, gender, and presence of comorbidities (diabetes and hypertension). Student's t-test, linear and logistic regression, univariate analysis with COVID+ subjects, and multivariate analysis with all subjects were performed. Significance was set at $p<0.05$.

Results: COVID+ subjects did not show significant differences compared to COVID– subjects across any parameters. There were significant differences across demographic groups. Univariate analysis showed that COVID+ Asians had thinner RNFL (p=0.014, right; p=0.018, left) and GCC (p=0.041, right; p=0.051, left) than COVID+ Blacks and Whites. COVID+ Hispanics had decreased foveal thickness compared to COVID+ non-Hispanics (p=0.019, right; p=0.004, left). Multivariate analysis confirmed that Blacks (p=0.015, left) and Whites (p=0.010, left) had thicker GCC than Asians and that Hispanics had decreased foveal thickness (p=0.041, left) compared to non-Hispanics. The middle age group had thinner GCC (p=0.022, right; p=0.024, left) than the youngest age group. While COVID+ Blacks were more likely to have retinal structural changes than COVID+ subjects of other races with a trend toward significance (OR=5.00, p=0.084), multivariate analysis did not confirm this disparity.

Conclusions: Analysis of this cohort did not reveal significant differences between COVID+ and COVID– individuals. However, comparison of demographic parameters did show significant differences across age, race, and ethnicity. The reasons for these disparities are obscure. Further studies with a greater number of subjects may reveal differences based on COVID-19 status.

ABSTRACT BODY:

Purpose: Randomized, vehicle-controlled, and double-masked conjunctival allergen challenge (CAC) studies have been successfully used to support marketing applications for treatments of allergic conjunctivitis. These studies have been conducted using standardized challenge methodologies and the endpoints have been evaluated with consistent approach, therefore it may be feasible to use hybrid control arms in future CAC trials. The purpose of hybrid control is to pool the trial control subjects and certain historical control subjects based on adequate statistical matching, such as propensity score (PS). The advantage of using a hybrid control is to expose fewer subjects to allergens for whom there will be no benefit from the vehicle treatment.

Methods: Among three completed Phase II and III CAC studies for the allergic conjunctivitis indication, two are used as historical control and one is selected as a reference. We compare the outcomes between the historical control and the reference trial control, after controlling PS, to evaluate the similarity in vehicle treatment responses. The PS matching incorporates prognostic factors such as age, sex, and baseline post-challenge itchiness and redness. We construct a hybrid control arm for the reference trial using PS matching between the trial treatment group and the historical control. The results of the treatment effect using the hybrid control are compared with the results using the trial control.

Results: The reference study was randomized in a 2:1 ratio to treatment (91 subjects) or control (47 subjects). The combined historical control includes 75 subjects from the two studies. Figure 1 shows the post-challenge mean scores of itchiness and redness for the baseline, 16 hours post treatment time points, and 15-minutes post treatment, displayed by individual study and matched groups using PS matching. The mean differences between the two matched groups are reduced to less than or equal to 0.24. Table 1 shows that the conclusions on treatment effect are unchanged using the hybrid control in the reference trial. The least squares mean differences are less than or equal to 0.17 between the trial and hybrid controls.

Conclusions: Introducing hybrid control arms in CAC studies maintains study integrity and validity. The use of a hybrid control could potentially reduce costs and improve subject safety.

ABSTRACT BODY:

Purpose: To automatically identify, segment, and quantify geographic atrophy (GA) based on optical attenuation coefficients (OACs) and optical coherence tomography (OCT) datasets using deep learning algorithms.

Methods: Normal eyes and eyes with GA secondary to age-related macular degeneration (AMD) were imaged with swept-source OCT using a 6x6 mm scan pattern. Depth-resolved OACs were calculated from OCT scans. For each OCT scan, three images were generated and combined to produce pseudo-color images (Figure 1): (1) the OAC-identified RPE elevation from Bruch's membrane (BM), (2) the sum OAC projection between the inner limiting membrane and BM, and (3) the sub-retinal pigment epithelium slab projection (subRPE) extending from 64 to 400μm below BM. An attention improved U-net model was trained to segment the composite images with a focal loss for a better classification of evolving GA lesions. All GA lesions were manually labeled from the subRPE slabs by senior graders for evaluating the model. User-friendly software with the model was developed to test the algorithm in clinical settings. The performance of the model was evaluated using DICE similarity coefficients (DSCs). The areas of the GA lesions were calculated and compared with manual segmentations using Pearson's correlation and Bland-Altman analyses. Both the model output and the manual outlines excluded GA lesions with greatest linear dimension less than 250μm.

Results: A set of 153 GA eyes, 30 drusen only eyes, and 60 normal eyes were used to develop and test the model. The dataset was split 80:20 for training:validation. Another 30 AMD eyes with GA lesions were prepared for testing. The model reached the dice coefficients of 0.958, 0.941, 0.930 on the training, validation, and testing after 300 epochs of training, respectively. The mean area difference on the testing set was 0.106 mm^2 between manual segmentation and the model, and the Pearson's correlation was 0.957. Figure 2 shows a working example of the software on a case with GA lesions.

Conclusions: The proposed model using composite color images derived from OCT scans effectively and accurately identified, segmented, and quantified GA lesions.

TITLE: Transcorneal fluorescence lifetime spectroscopy
SESSION TITLE: Drug delivery
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: S.P. Srinivas, Optometry, Indiana University Bloomington, Bloomington, Indiana, UNITED STATES|Y. Sun, Y. Povrozin, N. Redes, B. Barbieri, ISS Inc, Champaign, Illinois, UNITED STATES|
Commercial Relationships Disclosure: Sangly Srinivas: Commercial Relationship: Code N (No Commercial Relationship) | Yuansheng Sun: Commercial Relationship: Code N (No Commercial Relationship) | Yevgen Povrozin: Commercial Relationship: Code N (No Commercial Relationship) | Norin Redes: Commercial Relationship: Code N (No Commercial Relationship) | Beniamino Barbieri: Commercial Relationship: Code N (No Commercial Relationship)
ABSTRACT BODY:
Purpose: As an intrinsic property, the fluorescence lifetime of a fluorophore is independent of its concentration but is influenced by electrolyte levels, pH, temperature, membrane potential, and refractive index. Thus, lifetime measurements can probe the dynamics of biophysical/biochemical parameters in transparent tissues. Here our goal is to establish a dedicated ophthalmic time-resolved confocal scanning microfluorometer (OTR-CSMF) for intensity and lifetime measurements across the cornea.
Methods: We established a prototype of OTR-CSMF comprising a fiber-optic-based confocal fluorometer, corneal perfusion system, multiple solid-state pulsed lasers (445, 488, and 532 nm), nanostage, and electronics for rapid lifetime acquisition by digital frequency-domain approach. Next, we developed software for data acquisition, depth scanning, laser control, and data analysis, based on Vinci™, a standard tool for desktop fluorometers. Finally, we have tested and validated OTR-CSMF with references dyes and porcine corneas ex vivo.
Results: By focusing 488 nm laser at the coverglass:water interface using the 40x (0.8 NA; water) objective, depth vs. scatter produced a peak with FWHM of ~1.3 μm. The instrument point spread function (PSF) was assessed by fluorescence correlation spectroscopy (FCS) measurements of fluorescein in water, which led to the axial FWHM and radial beam waist estimates of 1.2 and 0.33 μm, respectively. These confirm the axial resolution and demonstrate the system's single-molecule detection sensitivity. Using rhodamine 110 in water (lifetime = 4 ns) as the standard, we found the lifetime of rhodamine B, fluorescein, and Ruthenium phenanthroline (RuPhen) to be close to values reported previously. Finally, transcorneal measurements with freshly isolated porcine corneas and multiple dyes demonstrated the principal functionality of OTR-CSMF (Figs. 1-2). Since fluorescein and RuPhen are hydrophilic, we secured their accumulation across the cornea by injection into the anterior chamber.
Conclusions: OTR-CSMF transcends the microfluorometer described earlier by Srinivas and Maurice (IEEE Trans Biomed Eng, 39(12): 1283-1291, 1992). It enables transcorneal lifetime measurements (resolution of 50 ps; dynamic range of 100 ps – 1 ms) at a high axial resolution (~1.3 μm) and fluorescence sensitivity (~100 pM of fluorescein).

ABSTRACT BODY:

Purpose: Microincision vitrectomy surgery (MIVS) studies have shown low complication rates. In the setting of the COVID-19 pandemic and rural satellite clinics, we investigated the role of telemedicine as an alternative to postoperative visit (POV) regimens after uncomplicated MIVS.

Methods: This IRB approved, prospective single-site, and single-surgeon study included patients without any history of glaucoma, ocular trauma, or severe systemic or ocular disease who underwent uncomplicated MIVS for any indication between January-August 2021. Prophylactic topical pressure-lowering drops were prescribed if POV intraocular pressure (IOP) was ≥22 mmHg. POVs included the same day after surgery, week(s) 1, 2, 8, and 12. Patients were randomly assigned (1:1) into two arms: telemedicine (TM) or In-person (IP). Weeks 1 and 8 POV utilized protocol-based and questionnaire guided undilated exams performed by an ophthalmology fellow that were conducted either TM or IP, according to arm assignment. Any patients with concerning symptoms identified at these visits were scheduled for dilated exams with the surgeon. All patients underwent dilated exams performed by the surgeon on the same day after surgery, weeks 2 and 12. Primary endpoint was mean best corrected visual acuity (BCVA). Secondary endpoints included changes in intraocular pressure (IOP), retinal nerve fiber layer thickness, and number of additional visits. Statistical analysis included Mann Whitney U and chi-square tests.

Results: Fifty-two eyes from 50 patients (33 female, 17 male; p-value=0.02) with mean ages of 68.4±6.8 years underwent 55 total surgeries with 25 or 27G MIVS platforms. Forty-seven patients have completed all POVs. Mean preop BCVA logMAR was 0.53±0.55 and 0.40±0.45, and at 12 weeks, they were 0.39±0.45 and 0.26±0.33 for the TM and IP groups, respectively. No significant between-group differences were found for primary or secondary outcomes. All cases of abnormal IOP resolved by the following POV with pressure lowering drops. Concerning symptoms were identified in five patients requiring additional visits, revealing two cases of worsening macular edema (1 TM and 1 IP) and one case each of cataract progression (TM), vitreous hemorrhage (IP), and macular hole recurrence (TM). No complications presented at the TM or IP visits.

Conclusions: Telemedicine-assisted POV regimens may be a safe and convenient alternative for patients undergoing uncomplicated MIVS.

ABSTRACT BODY:

Purpose: Juvenile open-angle glaucoma (JOAG) has early childhood disease manifestation and is associated with significant vision loss. Intraocular pressure (IOP) in these patients sometimes ranges over 40 mm Hg. JOAG has a strong genetic component and clinical management of JOAG can be quite challenging with current treatment options only limited to lowering IOP. We have previously shown that the secreted human protein neuritin 1 (NRN1) exhibits neuroprotection, regeneration and preservation of retinal ganglion cell (RGC) function after axonal injury. We propose to model JOAG by culturing human posterior eyecups within our novel ex-vivo Translaminar Autonomous System (TAS). In this system, we will overcome elevated IOP mediated RGC degeneration by over-expressing NRN1 as a therapeutic strategy.

Methods: Human donor eyes were obtained from eye banks. To recapitulate JOAG glaucomatous conditions in an ex-vivo environment, dissected human posterior cups (n=4) were cultured in the TAS model at elevated IOP conditions over 6 days with and without recombinant hNRN1. To induce translaminar pressure changes, the flow rate of the perfusion medium was adjusted and calculated using automated pumps and software. We assessed the survival of retinal ganglion cells with and without NRN1 treatment by TaqMan array analysis of apoptosis/inflammatory markers (retina). Expression of FN and COLIV was examined from the conditioned medium of both groups by Western blot analysis.

Results: We successfully maintained IOP: ICP differentials over 6 days (n=4). The RGCs degenerated faster in non-treated conditions compared to NRN1 treated eyes. In contrast to the controls, the treated group significantly decreased expression of FN and COLIV ($p<0.05$, n=4). We observed downregulated expression of GFAP ($p<0.001$, n=4), BAX and TLR4 expression ($p<0.05$, n=4) after NRN1 treatment.

Conclusions: Our data identified that NRN1 treatment promotes RGC survival under pathological conditions of glaucoma. This study suggests that hNRN1 could be utilized as a potential therapeutic to save RGC and a plausible treatment option for JOAG.

TITLE: Hyperbranched EPC polymer enhanced anti-angiogenic activity and the cellular uptake of aflibercept

SESSION TITLE: AMD and diabetic retinopathy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: X. Zhao, X. Su, Institute of Molecular and Cell Biology, Singapore, SINGAPORE|J.Y. Lim, X. Loh, Institute of Materials Research and Engineering, SINGAPORE|

Commercial Relationships Disclosure: Xinxin Zhao: Commercial Relationship: Code N (No Commercial Relationship) | Jason Lim: Commercial Relationship: Code N (No Commercial Relationship) | Xian Jun Loh: Commercial Relationship: Code N (No Commercial Relationship) | Xinyi Su: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Intravitreal injection anti-vascular endothelial growth factor (anti-VEGF) for the treatment of retinal diseases is invasive and potentially associated with sight-threatening complications. We previously reported the using of nanomicelle form EPC (nEPC) to topically deliver Aflibercept to the retina in a mouse in-vivo model. EPC is a copolymer, made up by covalently linked polyethylene glycol (PEG), polypropyl glycol (PPG) and polycaprolactone (PCL). We hypothesized that hyper-branched poly(PEG/PPG/PCL/Glycerol urethane) (EPCGs), with additional PEG branches on polymer backbone, will improve cellular penetration. The biological effect from the branched structure was then evaluated based on in-vitro biocompatibility, cellular uptake and ex-vivo angiogenic mice choroidal explant.

Methods: - To introduce PEG branches:
Glycerol (0.25 and 0.75%) was added during the synthesis of EPC
- To form nanomicelles with Aflibercept
Polymers were dissolved in the buffer containing required amount of aflibercept.
-To quantify cellular uptaken
aflibercept was covalent linked with rhodamine
- Biological assays:
Biocompatibility of EPCG was evaluated using human umbilical vein endothelial cells (HUVECs) with LDH cytotoxicity assay
Intracellular uptake was assessed by both direct confocal microscopy and flow cytometry.
The anti-angiogenic activity of nanomicelles was evaluated by ex-vivo mice choroidal explant.

Results: The hyperbranched EPCGs are biocompatible with HUVECs. EPCGs were able to inhibit blood vessel sprouting after 48hr exposure to EPCG nanomicelles in a concentration and branching dependent manner. Aflibercept complexed with nanomicelles had increased intracellular uptake into HUVECs and human corneal epithelial cells (hCECs), also in a concentration and branching dependent manner.

Conclusions: Hyperbranched EPCG is biocompatible with HUVEC cells in-vitro. Increased branching induced by glycerol was found to enhance the performance of EPC nanomicelles in two ways: (1) Inhibition of vessel sprouting in mice choroidal explant, (2) Increase intra-cellular uptake of aflibercept, which may potentially translate to increase cornea penetration. This suggests that hyperbranched EPCG might be suitable as a platform for topical drug delivery. Further tests are underway to confirm this.

ABSTRACT BODY:

Purpose: To investigate the cross-sectional associations between components of the visual function system (VFS) and functional health outcomes, in multi-ethnic Asians aged ≥60 years.

Methods: We included individuals from The PopulatION HEalth and Age-Related SEnsory Decline PRofilE (PIONEER), a cross-sectional population-based study of Singaporean Chinese, Malays, and Indians aged ≥60 years. VFS assessments comprised visual acuity (VA, logarithm of the minimum angle of resolution (LogMAR)), contrast sensitivity (CS, Pelli-Robson), and depth-perception (DP, Frisby). Functional health outcomes included instrumental activity of daily living (IADL, using Lawton Scale), mobility (via 4m-walking speed), and self-reported falls in the last 12 months. VFS impairments in the better eye were defined as follows: presenting visual impairment (PVI) as presenting VA worse than 6/12 (logMAR > 0.3); CS impairment (CSI) as CS <1.55 log CS; and DP impairment (DPI) as binocular DP≥150 arc sec. Logistic regression models were used to determine the independent relationship between the VFS and functional health outcomes.

Results: Of the 1,782 participants (mean age [SD]: 72.7 [8.2] years; 54.7% females), 303 (17.0%), 363 (20.4%), and 502 (28.2%) had PVI, CSI and DPI, respectively. Slow gait speed (<0.8m/s), low IADL (IADL score <24 for women and <15 for men) and at least one fall, was present in 662 (37.9%), 264 (17.6%) and 289 (19.2%) individuals, respectively. In multivariable-adjusted analyses including all VFS impairments simultaneously, PVI was associated with higher odds of poor IADL (odds ratio [OR]=1.53, 95% confidence interval [CI]: 1.06-2.21), while CSI was associated with an increased likelihood of poor IADL (OR=1.92, 95% CI: 1.37-2.69) and slow gait speed (OR=2.15, 95% CI: 1.63- 2.85). In turn, DPI significantly increased the odds of having experienced any falls by over 40% (OR=1.43, 95% CI: 1.06- 1.92).

Conclusions: CSI and DPI, independent of VA, are associated with a higher risk of poor functional health outcomes. Strategies such as highlighting steps or uneven surfaces may be warranted to potentially reduce the risk of poor functional health in older adults with low vision.

TITLE: Effect of curcumin through NLRP3-inflammasome pathway inhibition on oxidative stress-injured retinal pigment epithelial cells.

SESSION TITLE: Molecular and Biochemical Mechanisms of Ocular Disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Yu, E. Hong, Y. Shin, M. Seong, H. Cho, Hanyang University, Seongdong-gu, Seoul , KOREA (THE REPUBLIC OF)|

Commercial Relationships Disclosure: Hyo Seon Yu: Commercial Relationship: Code N (No Commercial Relationship) | Eun Hee Hong: Commercial Relationship: Code N (No Commercial Relationship) | YongUn Shin: Commercial Relationship: Code N (No Commercial Relationship) | Mincheol Seong: Commercial Relationship: Code N (No Commercial Relationship) | Heeyoon Cho: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Oxidative stress is the major cause of retinal pigment epithelial (RPE) cell death. Among the inflammatory mechanisms triggered by oxidative stress, the activation of the NLRP3 inflammasome pathway has been known to be associated with the pathogenesis of age-related macular degeneration (AMD). We used oxidative stress-injured RPE cells to investigate the effects of the curcumin, a strong antioxidant, on the NLRP3 inflammasome pathway.

Methods: ARPE-19 cells were treated with several concentrations of curcumin and 300μM hydrogen peroxide (H_2O_2). Cell viability was measured with cell counting kit-8, MTT (3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyltetrazolium bromide) and lactate dehydrogenase assay. To evaluate the effect of curcumin on ARPE-19 proliferation, we performed wound healing assay. The activity of reactive oxygen species (ROS) was also evaluated. Intracellular NLRP3 inflammasome protein levels in various concentration of curcumin treatment were compared using western blotting and Immunocytochemistry.

Results: 300μM H_2O_2 reduced the viability of ARPE-19 cells. However, when treated with 7.5μM curcumin, ARPE-19 cells showed increased viability and decreased cell toxicity. Curcumin also reduced free radical in the H_2O_2-induced damaged cells, promoted the expression of survival-related proteins and attenuated H_2O_2 dependent expression of the NLRP3 inflammasome and its related signaling proteins.

Conclusions: Taken together, these results suggest that curcumin has protective effects on oxidative-stress in RPE cells by attenuating the activation of the NLRP3 inflammasome. Although further researches may be needed, curcumin may have potential therapeutic or protective effect on the pathogenesis of AMD.

ABSTRACT BODY:

Purpose: To characterize the retinal morphology and visual function of sphingosine-1-phosphate receptor 3 knockout (S1PR3KO) mice.

Methods: Spingosine-1-phosphate receptor 3 (S1PR3KO) and C57BL/6J mice of both genders, ages 1-10 months, Rpbms, Iba-1, CRALBP, GFP, RPE65, Neuroligin2, Synaptophysin, PSD95 and other antibodies. Pattern and flash electroretinogram (PERG and FERG), embedding, fixation and confocal microscopy. All results were subjected to statistical analysis. The retina and optic nerve samples were also subjected to biochemical and mass spectrometric analyses following published protocols.

Results: We found significant functional PERG differences in S1PR3KO mice between 7 and 8 months of age. There was significant reduction in PERG amplitude at 8 months (5±2 μV) of age in S1PR3KO compared to that at 7 months (20±5 μV) of age, whereas FERG remained unaltered [results are mean± standard deviation for n=6 (equal male and female mice)]. Control C57BL/6J mice showed no difference during 7-10 months of age for these assessments. At 7 months of age the average individual PERG amplitude for S1PR3KO is a little (2-6 μV) less than that for C57BL/6J of the same age but average for n=6 mice in each group the difference was not statistically significant. We found largely single retinal ganglion cell (RGC) layer in S1PR3KO mice at all ages; C57BL/6J mice showed a 2-3 RGC layer. For S1PR3KO mice, although hematoxylin-eosin staining showed no difference in gross morphology of the retina, the PSD95 and Neuroligin2 showed a disordered pattern at 8 months of age compared to that at 7 months. C57BL/6J mice showed consistent patterns throughout the assessment period of 7-10 months. All data were subjected to Student’s t-test or two-way ANOVA as appropriate. The PERG amplitude differences were found to be statistically significant.

Conclusions: S1PR3KO mice shows both morphological and functional electrophysiological changes at 8 months of age compared to that at 7 months of age suggesting dramatic age-related retinal alteration in these mice.

ABSTRACT BODY:

Purpose: Longitudinal analyses of local structural or functional measures frequently use repeated simple linear regression (SLR) to estimate eye-specific rates of change (RoC). We developed a novel Bayesian hierarchical spatial longitudinal (HSL) model to improve estimation of local macular structural RoC in a prospective cohort of glaucoma patients and compared the results to those of SLR.

Methods: 111 eyes (111 patients) from the Advanced Glaucoma Progression Study with 4 OCT scans and 2 years of follow-up were included. Ganglion cell complex (GCC) thickness within 7x7 arrays of superpixels from Spectralis OCT macular volume scans were exported and analyzed. The current version of our Bayesian HSL model includes superpixel intercept and slope random effects, global patient intercept and slope effects, patient-superpixel interaction intercepts and slopes, and visit effects to improve accuracy of superpixel-patient RoC estimates. Superpixel-patient specific estimates and their posterior variances were calculated from the HSL model and compared with those obtained from Bayesian SLR performed on longitudinal data from each superpixel-patient separately. We considered superpixel-patient specific RoC as worsening or improving (significantly negative or positive) when the upper or lower limit of the 95% credible interval was less than or higher than 0, respectively.

Results: Mean (SD) baseline 10-2 visual field mean deviation was –8.9 (5.9) dB. Mean (SD) follow-up time was 3.6 (0.4) years with 7.3 (1.1) OCT scans per eye. Across 5,419 superpixel-patient curves, the posterior variances from HSL were smaller than SLR for 87% of intercepts and 83% of slopes. The mean (IQR) ratio of posterior variances of SLR over HSL for intercepts and slopes were 4.0 (1.5-4.9) and 3.9 (1.3-4.4), respectively. HSL identified a higher proportion of significant negative slopes (17.6% vs. 15.6%; $p<.001$) and lower proportion of significant positive slopes (1.2% vs. 4.6%; $p<.001$) as compared to SLR.

Conclusions: A novel Bayesian HSL model improves estimation accuracy of local GCC rates of change. The proposed model is 4 times as efficient as SLR for estimating superpixel-patient intercepts or slopes and identifies a higher proportion of deteriorating superpixels when compared to SLR while minimizing false positive detection rates.

TITLE: Salvaging the conventional outflow pathway in neovascular glaucoma (SCOPING) – Pilot results from a multidisciplinary treatment protocol

SESSION TITLE: Surgery & Wound Healing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.A. Kanter, D. Dao, L. Shaw, A. Mackin, R. Komati, P. Amin, D. Skondra, M. Qiu, Ophthalmology and Visual Science, The University of Chicago Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Jacob Kanter: Commercial Relationship: Code N (No Commercial Relationship) | David Dao: Commercial Relationship: Code N (No Commercial Relationship) | Lincoln Shaw: Commercial Relationship: Code N (No Commercial Relationship) | Anna Mackin: Commercial Relationship: Code N (No Commercial Relationship) | Rahul Komati: Commercial Relationship: Code N (No Commercial Relationship) | Pathik Amin: Commercial Relationship: Code N (No Commercial Relationship) | Dimitra Skondra: Commercial Relationship: Code N (No Commercial Relationship) | Mary Qiu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: For NVI/NVG eyes with open angles, we propose a protocol to medically salvage the conventional outflow pathway and reduce the need for subsequent IOP-lowering surgeries. We also propose a novel strategy for utilizing GATT to surgically salvage the conventional outflow pathway in NVG eyes.

Methods: Patients with first-time NVI and/or NVA and at least partially open angles were treated with 6 intravitreal bevacizumab (IVB) injections interspersed with PRP at the discretion of the retina service. IVB injections were encouraged to be spaced by 28 days. Elevated IOP was treated at the discretion of the glaucoma service.

Results: Seven eyes from 6 patients were treated with SCOPING. The etiologies of NVG included PDR (5), CRVO (1), and OIS (1). The median presenting VA was 20/40 (range 20/25 to 20/1250). Median presenting IOP was 38 mmHg (range 15 to 47) on 0 meds at baseline. The median duration between IVBs was 35 days (range 23 to 77), and the median total duration from IVB#1 to IVB#6 was 203 days (range 152 to 224). The median number of PRP sessions during the protocol period was 3 (range 1 to 4). At 1 month after IVB #6, the median IOP was 15 mmHg (range 9 to 19) on median 0 meds (range 0 to 2). All 7 eyes had prompt regression of NVI/NVA and no recurrence throughout the protocol period. Five eyes had 100% open angles upon presentation; each maintained adequate IOP control without surgery. The 2 eyes with 50% PAS upon presentation developed progressive synechial closure; 1 patient elected GATT, and 1 elected Baerveldt 350 in the sulcus. After the protocol was completed, the eye with OIS developed NVA 80 days after IVB#6, and the eye with CRVO developed NVA 119 days after IVB#6. One eye with PDR developed vitreous hemorrhage 152 days after IVB #6 and received 4 subsequent IVB injections. The 5 eyes with PDR did not develop any recurrence of NVA after a median follow-up of 56 days (range 28 to 245) after IVB#6.

Conclusions: Our protocol demonstrates the value of aggressive anti-neovascular treatment for NVI/NVG with completely or partially open angles. In SCOPING, 6 monthly IVBs lead to immediate regression of NV while PRP exerts a long-term effect. If the angle develops partial synechial angle closure, GATT can be attempted to salvage the conventional outflow pathway if the patient and team are committed to close follow-up and ongoing treatment.

ABSTRACT BODY:

Purpose: The mature mammalian retina remains metabolically active to support visual function and life-long photoreceptor outer segment renewal. Recent studies suggest that rodent photoreceptors rely heavily on aerobic glycolysis for both energy supply and cellular anabolic activities. Lactate dehydrogenases are important enzymes that catalyze the bidirectional conversion between pyruvate and lactate. In this experimental study, we assess the impact of disrupting LDHa in both wild-type (WT) and degenerating retinas by performing molecular genetic and biochemical analyses.

Methods: Murine rod photoreceptor-specific LDHa gene deletion was conducted in both WT and Rds/Prph2(P216L) backgrounds using Rho-iCre. Perturbation of LDHa protein was detected using immunocytochemistry. LDH enzymatic activity assay was carried out in WT and Rds mutant retinas. Impact of LDHa rod deletion on the outer nuclear layer (ONL) was examined using rod and cone photoreceptor marker immunolabeling and confocal imaging. Visual function was assayed by electroretinography (ERG) at P51, P84, and P180.

Results: Using an in situ enzymatic assay, the highest LDH activity was detected in the inner segment (IS) of retinal photoreceptors. Rod-specific deletion of LDHa gene resulted in the near abolishment of the LDH protein in the ONL without affecting its inner retina expression. In the WT background, deletion of LDHa in rods did not produce an apparent decrease in ONL thickness or visual function changes as measured by ERG. LDHa rod deletion did not appear to accelerate degeneration in the Rds mutant background. However, ERG detected significant deterioration of photopic b-wave. Furthermore, immunostaining detected abnormal cone cell morphological changes including exuberated opsin mislocalization and lateral dendritic sprouting.

Conclusions: These results show that LDHa is the major LDH enzyme expressed by photoreceptors. The main site for LDH activity in the retina is the photoreceptor IS, suggesting the proximity of LDHa protein localization with mitochondria in the photoreceptor IS. Further, rod-specific LDHa deletion can affect cone cell morphology and function in the Rds background. The apparent lack of disruption of photoreceptor morphology and function in the WT retina likely reflects the metabolic resilience and adaptability of the retinal network.

ABSTRACT BODY:

Purpose: There is no accepted standard of care for the reconstruction of full-thickness lower eyelid defects unable to be repaired by semicircular flaps or primary closure. We present a cross-sectional study of the preferred practice patterns and reconstructive techniques for these defects among U.S. oculoplastic surgeons surveyed 01/2021–03/2021.

Methods: We designed a survey to determine surgeon use and preference for the modified-Hughes procedure, transposition/advancement flap with free tarsal graft, Mustarde flap, bipedicle flap plus free tarsal graft, and free tarsal graft with free skin graft when treating lower eyelid defects. 596 oculoplastic surgeons who completed an oculoplastics fellowship were contacted by email or Doximity messenger. Contact information was obtained via practice and hospital websites, and the corresponding author section of Ophthalmic Plastic and Reconstructive Surgery. Retired physicians and pure cosmetic surgeons were excluded. Pearson chi-square testing compared surgical techniques and respondent demographic data.

Results: 120 surgeons responded (20.1%) with no statistically significant differences in response rate across U.S. regions. Median age range was 41-50 years (29.1%), with most respondents aged 70 or less. The majority of surgeons were in practice for 1–10 years (35.8%), with only 7 surgeons practicing for >40 years. Group practice was the most common practice setting (44.5%). The modified-Hughes procedure was the most common technique (92.5%), followed by the transposition/advancement flap with free tarsal graft (52.5%) and then the Mustarde flap (40.8%). The free tarsal graft with free skin graft was the least commonly used technique (8.3%). Most surgeons performing the Hughes and transposition flap techniques were in their first 20 years in practice (63.1%, 55.6%). The bipedicle flap with free tarsal graft was more common in academics (16 patients) and group practices (8) than solo practices (6). Middle-aged surgeons were more likely to perform free tarsal grafts with free skin grafts (70.0%) than other age groups.

Conclusions: While U.S. oculoplastic surgeons use various techniques for repair of full-thickness lower eyelid defects, the Hughes procedure was the most common in this study. Further quantitative examination is necessary to determine physician justification for technique preference.

TITLE: Sustained increase in human choroidal thickness associated with brief stimulation of the optic disc with short-wavelength blue light

SESSION TITLE: Myopia: Clinical Interventions and Diagnostics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Hoseini-Yazdi, S. Read, M.J. Collins, Queensland University of Technology, Brisbane, Queensland, AUSTRALIA|T. Schilling, H. Bahmani, Dopavision GmbH, GERMANY|

Commercial Relationships Disclosure: Hosein Hoseini-Yazdi: Commercial Relationship(s);Code F (Financial Support):Dopavision GmbH | Scott Read: Commercial Relationship(s);Code F (Financial Support):Dopavision GmbH | Michael Collins: Commercial Relationship(s);Code F (Financial Support):Dopavision GmbH | Tim Schilling: Commercial Relationship(s);Code E (Employment):Dopavision GmbH | Hamed Bahmani: Commercial Relationship(s);Code O (Owner):Dopavision GmbH;Code F (Financial Support):Dopavision GmbH

ABSTRACT BODY:

Purpose: Environmental light regulates ocular growth, through mechanisms that may be mediated by melanopsin retinal ganglion cells (mRGCs). This study aimed to examine the choroidal thickness (ChT) changes following brief stimulation of the melanopsin-expressing axons of the mRGCs at the optic disc with blue light in a group of healthy emmetropic and myopic subjects.

Methods: The sub-foveal ChT of 10 emmetropic and 10 myopic subjects (ages 28 ± 6 years) was measured with enhanced-depth imaging optical coherence tomography before and during a 60-min period after stimulation of the optic disc with a 15 Hz flickering short-wavelength blue light for 1-min. ChT was also assessed following 1-min of no light stimulation on all subjects and following 1-min of optic disc stimulation with a 15 Hz flickering long-wavelength red light on a subset of subjects (3 emmetropes and 3 myopes). These control conditions were assessed on separate days at a similar time of day. Linear mixed model analysis was performed to examine the main effects and interactions of light, time, and refractive group upon changes in ChT.

Results: Averaged across all time points post-stimulation, the ChT increased significantly following the optic disc stimulation with blue light (4 ± 1 μm), compared to the no light (0 ± 1 μm) and red light (0 ± 1 μm) conditions (both $p < 0.001$). Significant choroidal thickening was observed across all measured time points following the stimulation of the optic disc with blue light compared to no light stimulation in emmetropes (change at 60-min post-stimulation, 10 ± 2 μm vs 4 ± 2 μm, $p < 0.001$), but not in myopes (4 ± 2 μm vs 0 ± 2 μm; $p > 0.05$). No significant changes in ChT were observed following the stimulation of the optic disc with red light compared to the no light condition in either refractive group (all $p > 0.05$). The increases in ChT associated with blue light stimulation of the optic disc were significantly greater in emmetropes than myopes after 30 (8 ± 2 μm vs 0 ± 2 μm), and 60 mins (10 ± 2 μm vs 4 ± 2 μm) post-stimulation (both $p < 0.05$; Fig 1).

Conclusions: A refractive error-dependent sustained thickening of the human choroid was observed with brief stimulation of the optic disc with blue light. This choroidal response may relate to a short-wavelength sensitive mRGCs' signaling pathway, given the lack of response of the choroid with red light stimulation.

ABSTRACT BODY:

Purpose: In children receiving corneal reshaping therapy, the myopia progression rate is associated with the change in corneal power, possibly due to its ability in reflecting refractive power changes towards peripheral fields, i.e., peripheral refractive profile – a hypothetical optical cue related to myopia development. As the peripheral refractive profile is typically acquired from refractive powers derived from two meridians (spherical-equivalent error, SE), it is unclear how well conventional topographic powers (axial, tangential, & refractive), which are derived from only a single meridional plane, can represent the peripheral refractive profile. This study compared the abilities of corneal power profile generated by the mean power (derived from the average of the steepest and flattest meridians) vs. conventional topographic powers in representing the peripheral refractive profile for myopic children.

Methods: A hundred fifty low-to-moderate myopic children (Age: 8 to 13 years, SE: –1.00DS to –5.75DS, Cylindrical error ≤1.50DC) with unremarkable ocular health were recruited. Peripheral refractive profile was determined using an open-field autorefractor along the horizontal field up to ±20° eccentricity in a 10° step. Corneal topography was measured by a Placido-disc based corneal topographer. Second-order polynomials ($y=ax^2+bx+c$) were fitted to refractive and corneal power data (y) as a function of eccentricity (x) for each individual. The a-coefficients represent the refractive and corneal power shifts towards the periphery and were used for data analyses.

Results: Pearson's correlations indicated that the peripheral refractive profile obtained from the open-field autorefractor were significantly correlated with the corneal power profiles derived from the mean (r=0.40), tangential (r=0.37), axial (r=0.20), and refractive power (r=0.17, all $P<0.05$). The correlation coefficient for mean power was significantly stronger than for refractive and axial powers (Fisher-Z-transformation, both $P<0.005$), but similar to the tangential power (P=0.31).

Conclusions: Corneal power profile derived from two meridians showed the highest correlation with the peripheral refractive profile, indicating the potential weakness of inferring peripheral refractive profile from the corneal powers derived from just one meridian.

TITLE: RvD1 suppresses microglia activation and improved spatial vision of mice with microbead-induced glaucoma

SESSION TITLE: Neuroprotection and Neuroregeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Cho, L. PAN, A. Rajagopalan, D. Chen, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|L. PAN, School of Optometry, The Hong Kong Polytechnic University, Hong Kong, HONG KONG|

Commercial Relationships Disclosure: Kin-Sang Cho: Commercial Relationship: Code N (No Commercial Relationship) | Li PAN: Commercial Relationship: Code N (No Commercial Relationship) | Aishwarya Rajagopalan: Commercial Relationship: Code N (No Commercial Relationship) | Dongfeng Chen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Suppressing microglia activation has been suggested to be an appealing approach to rescue neuronal degeneration in glaucoma. Recently, specialized pro-resolving mediators such as Lipoxin A4 (LXA4) and Resolvin D1 (RvD1) have been shown to play a key role in resolving inflammation. This study investigated the roles of LXA4 and RvD1 in mediating microglial inflammation and neuroprotection in a microbead (MB)-induced glaucoma mouse model.

Methods: First, we pre-treated mouse microglial cultures with 10-7 M LXA4 or RvD1 for 6 hours followed by incubating with 10-7 M ATP. Naïve microglia and ATP-treated microglia were included as negative and positive controls, respectively. After 24 hours, mRNAs were extracted and RT-PCR detection of proinflammatory markers Cox2 and IL-1b were performed. One-way ANOVA followed by Dunnett's multiple comparable test was used for statistical analysis. Next, we induced unilateral elevation of intraocular pressure (IOP) by anterior chamber injection of MB in adult male and female C57BL/6 mice. The IOP levels were measured at day 3, 7, and then every 7 days post-MB injection until day 28. 2.8x10-5 M LXA4, RvD1 or vehicle was injected into the vitreous at day 3, 10, 17 and 24 post-MB injection. At day 14 and 28, retinal ganglion cell function and spatial vision were measured by recording the positive scotopic threshold response (pSTR) and optomotor response (OMR), respectively. Two-way ANOVA followed by Tukey's multiple comparable test was used for statistical analysis.

Results: ATP induced upregulation of Cox2 and IL-1b ($P<0.01$) in microglia cultures. LXA4 and RvD1 significantly reduced expression of Cox2 ($P<0.01$) and IL-1b. pSTR and OMR showed a gradual decline in vehicle treated glaucoma mice. RvD1 treated mice showed a slight increase in pSTR. RvD1 but not LXA4 treated mice significantly increased of both contrast sensitivity ($P<0.05$) and visual acuity ($P<0.01$) at 4 weeks post-MB injection comparing to the vehicle treated mice.

Conclusions: LXA4 and RvD1 suppressed pro-inflammatory cytokine/marker expressions of ATP-treated microglia. RvD1 but not LXA4 significantly improved the spatial vision of contrast sensitivity and visual acuity in glaucoma mice. Further understanding the mechanism of RvD1 on neuroprotection would unfold its therapeutic potential in glaucoma.

ABSTRACT BODY:

Purpose: Recent evidence (Tang J et al Lancet Glob Health 2019) suggests that glaucoma screening may be cost-effective in developing countries although it is generally not in high income countries. Screening of two major blinding eye diseases (glaucoma and diabetic retinopathy (DR) using the same resources is likely to further improve cost-effectiveness. The aim of this study was to test the efficacy of a one-week online course in training non-ophthalmic DR graders to recognize glaucomatous optic nerves in Vietnam.

Main Research Question: Can non-ophthalmic DR graders be trained inexpensively to accurately screen for glaucoma?

Methods: In this uncontrolled, interventional before-and-after study, 43 non-ophthalmic DR graders participating in an NGO program (primarily nurses and internists) took part in a self-taught, one-week online course on recognizing glaucomatous optic nerves. Their performance (% of images graded correctly as to 'refer/no refer and 'reason for referral' compared to a panel of glaucoma specialists) on a test set of optic nerve photos from the GONE website, population studies and patients taking part in the DR screening program was assessed before and after training, and was compared with 29 local, non-glaucoma-specialist ophthalmologists not taking the course.

Intervention: Self-paced participation in an online course describing various aspects of a glaucomatous optic nerve over one week.

Results: The mean±SD age of the non-ophthalmic graders was 32.3±7.3 years, with a mean±SD working experience of 8.2±7.1 years, compared to 32.6±5.5 and 7.2±5.2 years years for ophthalmologists. Non-ophthalmic graders' test performance improved from a mean of 33.3±14.3% pre-training to 55.8±12.6% post-training ($P<0.0001$). Their post-test performance did not differ from that of ophthalmologists (58.7±15.4%, $p=0.384$). Results (significant improvement with training, no difference between post training graders and ophthalmologists) were consistent regardless of the origin of the optic nerve images (GONE website, population study, local images from the Vietnam program).

Conclusions: Non-ophthalmic graders could significantly improve their accuracy in detecting glaucoma after a brief online course, and had performance comparable to ophthalmologists. This model could contribute to low-cost glaucoma screening in underserved settings.

ABSTRACT BODY:

Purpose: Previous work by our lab has shown that both scotopic and photopic ambient lighting is protective for lens-induced myopia (LIM) in wild-type mice (Landis et al., IOVS 2021). Evidence suggests that both mouse rod and cone photoreceptors can detect photopic lighting (Tikidji-Hamburyan et al., Nat Commun 2017). To investigate the origins of the protective effect of photopic lighting in myopigenesis, we measured the response to LIM in transgenic mice with rod-only retinas exposed to different ambient light levels.

Methods: Rod, cone, and melanopsin photoreceptors were targeted using Gnat1+/+, Gnat2-/-, Opn4-/- mice, respectively, creating mice with rod-only retinas. Mice were used as naïve controls (control, n=20) or received a monocular -10 D lens over the right eye (LIM, n=21). Animals were placed in one of three ambient lighting conditions: 1 lux (scotopic, n=14), 50 lux (mesopic, n=13), or 10,000 lux (photopic, n=14) on a 12:12 light:dark cycle. Refractive errors, corneal curvature and ocular axial parameters were tested at baseline, 1- and 2-weeks post-goggling using an automated photorefractor, keratometer, and SD-OCT. Myopic shifts were calculated as the difference in refractive error between the right and left eyes.

Results: Myopigenesis occurred in all LIM mice over the treatment period, while no myopia developed in control mice (0.02±0.39D). However, the degree of myopigenesis was influenced by light levels ($p<0.001$). LIM mice exposed to ambient 50 lux and 10,000 lux lighting developed comparably severe myopic shifts, (-5.90±0.42 D and -6.68±0.49 D, respectively, p=n.s.). In contrast, LIM mice exposed to ambient 1 lux lighting developed significantly less myopic shift compared to the mice in 50 and 10,000 lux lighting (-3.97±0.35 D, $p<0.01$). Other measured outcomes did not change with LIM or light exposure.

Conclusions: Here, we exploited a transgenic mouse model with intact rod, but disrupted cone and melanopsin, signaling to determine which photoreceptor pathways underlie the protective effect of photopic lighting in LIM. Our results indicate that a rod-only retina provided the needed signaling for the protective effects of scotopic lighting during LIM, while not contributing to the protective effect of photopic lighting for myopic eye growth. Future studies will examine the effects of a cone only retina on LIM under different ambient light levels.

ABSTRACT BODY:

Purpose: Despite the rapid growth of AI in ophthalmology research, translations to clinical settings remain challenging. This study aims at showing AI models trained on standardized publicly available datasets perform well while they are not generalizable to the complex real-world clinical data for predicting glaucoma.

Methods: To compare the relative impact of using public datasets compared to hospital datasets, we used data from three well-studied public fundus datasets (REFUGE, Drishti-GS, and RIM-ONE-DL) as well as data from the Illinois Eye and Ear Infirmary. Given the limited available number of glaucoma images (n=362) in public data, we randomly sampled the same number of non-glaucoma images to create a balanced dataset. Consistently, we sampled 362 images per class from IODA. Using state-of-the-art residual networks, we classified images as glaucoma or non-glaucoma. We created two classification models: (1) a model trained on public data, and (2) another model trained on real-world (RW) data. To investigate the generalizability of these two models, we tested each model on both RW and public test sets. We will refer to each result as a train-test pair (e.g. the model trained on RW data and tested on public data is the RW-public result). We further compared the explainability of each model for predicting glaucoma based on fundus images using Grad-CAM Visualization.

Results: The Public-Public model has significantly higher accuracy (0.88) and AUC (0.95) than the RW-RW model. However, the public dataset model fails to generalize on real-world data as the accuracy and AUC respectively drop by 9% and 18% once tested on RW data. On the other hand, the RW model results in similar accuracy (0.80) and AUC (0.86) regardless of being tested on RW or Public data. Further, based on Grad-CAM visualization, the RW dataset model shows more consistent localization on the Optic Disc (OD) region than the Public dataset model which matches clinical insight for diagnosing glaucoma.

Conclusions: Our results show that standardized publicly available fundus data are not a good representation of RW data resulting in bias models that do not generalize to the RW data. We found the heterogeneous RW data can be used to develop AI models that potentially enable clinical translations.

ABSTRACT BODY:

Purpose: Modern-day staging of a full-thickness macular hole (MH) requires manual caliper measurement of the minimum linear diameter (MLD) on optical coherence tomography (OCT) images. However, these 2-dimensional measurements are technician and OCT segmentation software dependent, with literature demonstrating high inter-user variability in same-eye MLD observations. The aim of this study was to determine if an automated artificial intelligence (AI) model could assess MH volume on swept-source OCT images to improve MH size characterization.

Methods: In this proof-of-concept case series between 2017-2019, patients with an idiopathic full-thickness MH undergoing pars plana vitrectomy surgery with 1-year follow-up were considered for inclusion. Swept-source OCT images were taken at the preoperative, postoperative 1-month and 1-year time-points. MHs were manually graded from preoperative OCT images to delineate MH volume. This information was used to train a 3-dimensional convolutional neural network (CNN) for automatic segmentation. Cross-validation was used to assess performance across all subject eyes. The primary outcome was correlation of manual MH volume to automated volume segmentation.

Results: Twenty-four eyes were included in analysis. The correlation between manual and automated MH volume was R^2=0.94. The average dice coefficient between manual and automated metrics was 0.73 [0.65 - 0.86]. The mean preoperative automated MH volume was 1.3nL ± 1.54 (range 0.04 - 7.18nL); all MHs were closed at the 1-year postoperative follow-up. Automated MH volume metrics demonstrated higher correlation to MLD compared to manual MH measurements (R^2=0.72 and 0.61, respectively). Automated macular hole volume demonstrated significantly higher correlation to change in visual acuity from preoperative to the postoperative 1-year time-point compared to MLD (volume: R^2=0.53, MLD: R^2=0.39).

Conclusions: This deep learning CNN represents the first AI model to analyze MH volume. Fully automated segmentation demonstrated high correlation to manual MH volume measurements. The resulting automated volume assessment creates less inter-user variability and offers improved prognostic considerations for postoperative visual outcomes following MH surgical intervention compared to MLD.

ABSTRACT BODY:

Purpose: To employ an active targeting strategy for intraocular anti-VEGF drug delivery for the management of CNV, we have developed ASL-exosomes composed of Anchor, Spacer, and Arg-Gly-Asp acid (RGD) Ligand modification. Our recent work demonstrated that decorating exosomes with RGD, one of the major integrin binding ligands, allowed selective delivery of exosomes to the area of CNV because integrins are essential in VEGF signaling in CNV. In current study, we aimed to study whether aflibercept (Eylea®) loaded ASL-exosomes enhance the efficacy of anti-VEGF agent in CNV suppression by active targeting of CNV.

Methods: Fluorescent labeled ASL-exosomes were engineered using mouse retina-derived exosomes and loaded with Eylea. Either Eylea loaded ASL-exosomes (4g Eylea/$5x10^7$ exosomes/1l), naive exosomes ($5x10^7$ exosomes/1l), Eylea (40g/1μl) or PBS (1μl) was intravitreally injected in a laser-induced CNV mouse model 3 days after laser treatment (n=6-11 in each group). Retinal sections or choroid/RPE flat mounts at 7 days after exosome treatment were stained with GSA and anti-integrin α_V antibody to assess CNV induction, integrin expression. Total volumes of CNV lesion were quantified and compared between the groups. Retinal sections were also stained with GFAP to assess an immediate reactive retinal gliosis 1 day after intravitreal exosome treatment.

Results: Integrin α_V was highly expressed in CNV lesion. Intravitreally delivered Eylea loaded ASL-exosomes improved CNV suppression by 12 % ($p < 0.05$) compared with Eylea alone treatment despite ASL-exosomes contained 0.1 times of Eylea in Eylea alone treatment group that is relevant to the clinical dose. Intravitreal injection of Eylea-loaded ASL-exosome treatment did not induce immediate reactive retinal gliosis.

Conclusions: ASL-exosomes may be useful for active targeting strategy by targeting CNV, therefore upgrading the functionality of the intraocular drug delivery system. Further study is needed to translate active targeting strategy and exosome based intraocular drug delivery platform for the management of posterior eye diseases.

TITLE:

Prevalence of diabetic retinopathy in Indigenous and non-Indigenous Australians: a systematic review and meta-analysis

SESSION TITLE: Diabetic retinopathy epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Taylor, A. Turner, Lions Eye Institute, Perth, Western Australia, AUSTRALIA|M. Chia, P. Foster, P. Keane, University College London, London, UNITED KINGDOM|

Commercial Relationships Disclosure: Joshua Taylor: Commercial Relationship: Code N (No Commercial Relationship) | Mark Chia: Commercial Relationship: Code N (No Commercial Relationship) | Paul Foster: Commercial Relationship: Code N (No Commercial Relationship) | Pearse Keane: Commercial Relationship: Code N (No Commercial Relationship) | Angus Turner: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) is a leading cause of blindness worldwide and Indigenous Australians suffer disproportionately from diabetic-related blindness. Exploring ethnic variation in disease is useful for service planning and can lead to identification of ethnic-specific modifiable risk factors. Existing studies on DR prevalence in Indigenous diabetic patients have reported variable results. We performed a systematic review to summarise the evidence-base relating to DR prevalence amongst Indigenous and non-Indigenous Australians.

Methods: This study was conducted following Joanna Briggs Institute (JBI) guidance on systematic reviews of prevalence studies (PROSPERO ID:CRD42022259048). We performed database searches of Medline (Ovid), EMBASE, and Web of Science up to October 2021 using a search strategy designed by an information specialist. We included studies reporting DR prevalence amongst diabetic patients (type 2 or mixed) in Indigenous and non-Indigenous Australian populations, with last data collected after January 2000. Two independent reviewers performed risk of bias assessments using a 9-item appraisal tool developed by the JBI. Meta-analysis was performed using double arcsine transformation and a random-effects model comparing Indigenous and non-Indigenous subgroups.

Results: Of 801 records identified through database searches, 14 studies met inclusion criteria and were included in the quantitative synthesis. The Indigenous subgroup scored significantly lower on the appraisal tool compared to the non-Indigenous subgroup (mean score 51% vs 78%, p=0.04). Pooled DR prevalence in the Indigenous subgroup was 29% [95% CI:22-37%] compared to 25% [95% CI:17-33%] in the non-Indigenous subgroup, although there was significant heterogeneity in the pooled results ($p<0.01$, $I^2>94\%$). Of 3 studies reporting within-study comparisons, all 3 found higher DR prevalence amongst Indigenous patients.

Conclusions: Indigenous studies scored lower for methodological quality compared to non-Indigenous studies. Pooled subgroup differences in DR prevalence were inconclusive due to the presence of significant heterogeneity. Further analysis into sources of heterogeneity is needed. Within-study comparisons suggest that DR may be more common amongst Indigenous Australians. Analysis of modifiable risk factors contributing to ethnic variation requires further exploration.

SUBMITTER (NAME ONLY): Sean Kim

TITLE: Evaluation of Ultra-Widefield Fundus Photography as a Screening Tool for New Onset Flashes and Floaters

SESSION TITLE: Imaging of posterior segment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.D. Kim, D. Rosen, R. Wang, E.M. Bowie, Ophthalmology, Penn State Health Milton S Hershey Medical Center, Hershey, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Sean Kim: Commercial Relationship: Code N (No Commercial Relationship) | David Rosen: Commercial Relationship: Code N (No Commercial Relationship) | Rui Wang: Commercial Relationship: Code N (No Commercial Relationship) | Esther Bowie: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: New onset flashes and floaters are common symptoms presenting to ophthalmology clinics. Patients undergo an urgent, thorough dilated ophthalmic exam in order to rule out retinal breaks, holes, or detachments that may require intervention. Utilization of ultra-widefield (UWF) fundus imaging as a screening tool may expedite care received by patients with new symptoms and help guide ophthalmologist examination and intervention. Furthermore, UWF photography may identify breaks not seen on clinical exam to allow earlier detection of retinal breaks, leading to improved outcomes.

Methods: The study protocol was reviewed and approved by the Penn State College of Medicine Institutional Review Board. All adult patients presenting to Penn State Eye Center urgent care with new onset flashes or floaters from 12/1/21 to 1/6/22 were identified as potential subjects. Participating subjects underwent a full standard of care indirect ophthalmoscopy by a resident physician. The findings were confirmed with an attending ophthalmologist. Subjects then underwent a UWF photography with the Optos California icg. The results of resident exam, attending ophthalmologist exam, and UWF photography reviewed by a vitreoretinal surgery attending were compared. Descriptive statistical methods were used to compare the results.

Results: 29 patients met the inclusion criteria. Twenty-four eyes of 12 subjects were included in the study (41%). Posterior vitreous detachment was detected in 20 eyes by attending examination, compared to 20 eyes by residents (100%) and 14 eyes by photography (67%). Retinal breaks were detected in 3 eyes by attendings, compared to 2 eyes (67%) by residents and 2 eyes (67%) by photography. 1 retinal detachment was detected by all modalities. 18 out of 24 eyes (75%) were described to have significant obstruction of peripheral view of retina by the upper and lower lids and lashes on photography.

Conclusions: While limited by lack of depth perception and inability to visualize the entire retina, UWF photography may still serve as a useful tool for documenting various retinal pathologies, particulaly in settings without access to ophthalmologists or in resident education to aid in visualization of retinal pathologies. More data is required to assess the effectiveness of UWF photography as a screening tool for evaluating new onset flashes and floaters.

Birdshot Retinochoroidopathy: Characteristics of Patients Treated at a Tertiary Care Center

SESSION TITLE: Clinical Uveitis & Orbital Inflammation: Etiology, Epidemiology & Clinical Assessment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.M. Samson, G. Fridman, B. Glick, C.M. Samson, Ophthalmology, Manhattan Eye Ear and Throat Institute, New York, New York, UNITED STATES|J.M. Samson, Biology, University of California San Diego, La Jolla, California, UNITED STATES|

Commercial Relationships Disclosure: James Samson: Commercial Relationship: Code N (No Commercial Relationship) | Gabrielle Fridman: Commercial Relationship: Code N (No Commercial Relationship) | Briana Glick: Commercial Relationship: Code N (No Commercial Relationship) | C Samson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To describe characteristics of a cohort of patients diagnosed with Birdshot Retinochoroidopathy (BRC) at a tertiary care center.

Methods:

Retrospective chart review of patients diagnosed with BRC at the Manhattan Eye Ear, Throat Hospital from January 2017 to July 2021. Outcome measures included age of onset, HLA-A29 positivity, laterality, visual acuity and function, presence of cystoid macular edema, need for immunomodulatory therapy (IMT), and disease course.

Results:

Forty-three patients were analyzed. The average age of onset was 50.9 years and 81.4% of patients were female. Forty-two patients (97.7%) were HLA-A29 positive. All patients had bilateral involvement and were visually functional across the time frame of the study. Six patients (14.0%) were blind in one eye. Thirty-five patients (81.4%) experienced cystoid macular edema at some point in their disease. Thirty-five patients (81.4%) required IMT and 30 patients (69.8%) completed at least two years of therapy prior to discontinuing treatment. Of those, 73.3% were free of inflammation for five years, while 20% had recurrence of inflammation. Ten patients (27.9%) of the cohort remained on IMT during the course of the study.

Conclusions:

The characteristics of BRC in our cohort resembled those reported in other studies. Treatment of severe disease with IMT was associated with good visual outcome and disease remission.

ABSTRACT BODY:

Purpose: To assess whether choriocapillaris (CC) loss occurs prior to the development of nascent geographic atrophy (nGA) in intermediate age-related macular degeneration (iAMD) using optical coherence tomography angiography (OCTA) imaging.

Methods: Participants were enrolled as part of a prospective, longitudinal, observational study and underwent swept-source OCTA imaging (Zeiss PlexElite) at 6-month intervals. Only participants with reliable OCTA imaging in ≥2 visits and iAMD without nGA at baseline were included. CC flow deficit percentage (FD%; compensated for shadowing artifacts) and RPE volume/height measurements were determined for the visit prior to nGA development or final visit (n-1). Linear mixed models were utilized to examine the association between CC FD% and future nGA development at a global level and at a local level, defined by 120x120 µm superpixels (Figure 1).

Results: Of 105 eyes from 62 participants, 13 eyes from 10 participants developed nGA during the follow-up period. There was no significant difference in global CC FD% at the n-1 visit between eyes that developed nGA and those that did not ($P = 0.399$). In contrast, CC FD% was significantly higher in superpixels that developed nGA than those that did not ($P < 0.001$). However, the performance of CC FD% for predicting the development of nGA (area under the receiver operating curve [AUC] = 0.83) was not significantly different to the performance using RPE height alone (AUC = 0.83) or when using both CC FD% and RPE height (AUC = 0.84; $P \geq 0.48$) at the superpixel level.

Conclusions: CC flow deficits were significantly greater within local regions (superpixels) that subsequently developed nGA compared to those that did not. This did not hold true at the global level. Although CC FD% did not aid in the prediction of nGA development, these findings provide further insights into the potential patho-etiology of atrophy development.

ABSTRACT BODY:

Purpose: Ocular surface tumors (OSTs) are a rare and vision-threatening condition of the conjunctiva and/or cornea. Potential treatments include observation for small, benign-appearing lesions, topical instillation or subconjunctival injection of medications such as interferon alpha-2b, and surgical excision with or without cryotherapy. We utilized the American Academy of Ophthalmology IRIS® (Intelligent Research in Sight) Registry to characterize the treatment patterns of OSTs in the United States (U.S.).

Methods: A total of 15,086 OST patients were identified in the IRIS Registry between 2013-2019 using ICD codes. Relevant procedures and/or injections of medications were identified using CPT codes. Descriptive statistics and frequencies were calculated for the types of procedures and injections undertaken.

Results: Of the 15,086 OST patients, 2,290 (15.18%) patients underwent a total number of 3,545 procedures and injections of chemotherapy or other agents. The median number of procedures or injections received by patients in the cohort was 2 (range 1 to 34). The majority of these patients underwent at least one surgical procedure (99.30%). Of the surgical procedures, 1982 patients (87.62%) underwent excision only procedures, 64 patients (2.83%) underwent cryotherapy only, and 216 patients (9.55%) underwent both excision and cryotherapy. Only 1.22% of patients underwent at least one injection of chemotherapy or other agent, the majority of which were interferon alpha (76.19%). Of patients who underwent injection of interferon alpha, 5 (21.74%) underwent a single injection while 18 (78.26%) underwent multiple injections. All patients who underwent a single injection of interferon alpha also underwent excisional procedures. Only 3 (16.67%) patients who underwent multiple injections of interferon alpha also underwent excisional procedures.

Conclusions: Our findings highlight frequencies of various treatments of OST patients in the U.S. Only 15.18% of OST patients underwent procedures (surgical or injection); the rest were either observed or treated with topical eyedrops. The majority of OST patients who received procedures underwent excisional procedures, while the majority of OST patients who underwent injection procedures received interferon alpha. Few patients who received multiple injections of interferon alpha also underwent excisional procedures.

ABSTRACT BODY:

Purpose: Gut microbiome alterations have been associated with various autoimmune diseases. There is limited data, however, on relationships between gut dysbiosis and immune-related dry eye (DE). The aim of our prospective, cross-sectional study was to evaluate the gut microbial composition of individuals with early or late markers of Sjögren's Syndrome (SS) compared to controls without DE.

Methods: We compared 20 individuals with positive early markers (anti-SP1, anti-CA6, anti-PSP IgG, IgA, andIgM) or late markers (anti-Ro/SS-A and anti-La/SS-B) of SS with no comorbid autoimmune diagnoses and 20 age- and sex-matched controls. Stool samples were collected and underwent deep RNA sequencing. The main outcomes measured were gut microbial composition and diversity.

Results: A total of 20 individuals with DE (mean age 61±13 years, Dry Eye Questionnaire-5 (DEQ-5) score of 15.2±3.4, Ocular Surface Disease Index (OSDI) score of 55.1±22.8, Schirmer of 7.1±5.2) were compared to 20 controls (mean age 59±12 years, DEQ-5 score of 4.8±3.8, OSDI score of 14.2±12.3, Schirmer of 21.9±9.1). No significant differences were observed in bacterial diversity (Shannon's index, $p=0.97$) or overall community structure (Euclidean PERMANOVA, $p=0.62$). A total of 41 species were differentially abundant between groups ($p<0.01$). Among these, 34 were relatively more abundant in the case group, including 10 species of Lactobacilli and 4 species of Bifidobacteria. A relative depletion of 7 species was found in the case compared to the control group, notably Fusobacterium varium and Prevotella stercorea.

Conclusions: Differences in gut microbiome composition were found in individuals with early or late markers of primary SS compared to an age- and sex-matched control group. Further studies are needed to elucidate the role of gut dysbiosis on immune dysregulation and disease activity in the eye. Gut microbiome modulation as a potential therapy for DE, such as through probiotic use or fecal microbial transplant, is another area of further research.

ABSTRACT BODY:

Purpose: During the COVID-19 pandemic, ophthalmologists were presented with the challenge of providing safe care to patients while limiting the spread of COVID-19. As a result, many institutions implemented universal pre-surgical COVID-19 screening prior to surgery for all patients. The goals of this study are to characterize the rate of COVID-19 positivity during pre-surgical screening at our institution, the surgical outcomes experienced in COVID-19 positive ophthalmic patients, and to report overall cost of universal pre-surgical screening.

Methods: This retrospective study included patients ≥ 18 years who underwent ophthalmic surgical procedures at a tertiary institution between May 11, 2020 and December 31, 2020. Patients without a valid pre-surgical COVID-19 test within the three days prior to their scheduled procedure, incomplete or mislabeled visits, and incomplete or missing data in their file were excluded. COVID-19 screening was completed by the Thermo Fisher TaqPath Polymerase Chain Reaction (PCR) kit.

Results: Of the 3,585 patients who met inclusion criteria, 2,044 patients (57.02%) were female, and the average age was 68.2 ± 12.8 years (mean ± standard deviation). 13 asymptomatic patients (0.36%) tested positive for COVID-19 via PCR screening. Three patients had known positive COVID-19 infection within the 90 days prior to surgery, thus 10 patients (0.28%) were found to have asymptomatic naïve COVID-19 infection via PCR. Testing was associated with a total charge of $788,700. Five of the 13 COVID-19 positive patients (38.46%) experienced a delay in their surgery. The average surgical delay was 17.23 ± 22.97 days (mean ± standard deviation).

Conclusions: Asymptomatic ophthalmic surgical patients experienced a low positivity rate with a limited impact on surgery scheduling at a significant cost. Further studies would be valuable in evaluating a targeted pre-surgical screening population as opposed to universal testing.

ABSTRACT BODY:

Purpose: The epidemiology of retinopathy of prematurity (ROP) changes over time as neonatal care improves across neonatal care units (NCUs). Prior work using an artificial intelligence (AI)-derived vascular severity scale (VSS) demonstrated that NCU-level ROP could be used for epidemiological monitoring and was associated with oxygen management in 13 NCUs in South India. In this study, we evaluated the change in NCU-level ROP severity over time in seven of these NCUs.

Methods: As part of the Aravind ROP tele-screening program, a VSS was derived from retinal fundus images collected during the first eye exam from babies screened at two different time periods: 2015–2017 and 2019–2020. Differences in VSS were evaluated using a one- or two-way analysis of covariance (ANCOVA) to control for gestational age (GA) or GA and NCU, respectively. The proportion of babies diagnosed with ROP was evaluated using a test of equal proportions.

Results: Between the two time periods studied, the proportion of babies diagnosed with ROP decreased across all NCUs from 32% (range: 7.0% – 75.0%) in the earlier time period to 11% (range: 7.1% – 13.1%, $p < 0.001$) in the later period. This was associated with an increase in mean birthweight and gestational age (Table). However, when controlling for GA, there was no clinically meaningful change in the mean ROP severity as assessed by the VSS (2.9 to 3.0), although this varied significantly by NCU and GA. The figure demonstrates the changes in one NCU, with lower VSS in babies born after 31 weeks and higher VSS (and more babies surviving to point of screening) in babies born before 31 weeks.

Conclusions: On average NCUs in South India are screening more babies for ROP now than five years ago, which may in part be due to improved survival especially in the youngest cohort as well as increased awareness of ROP among pediatricians and improvements in NCU care. The NCU-level VSS did not change at the population level but varied at the NCU level due to changes in demographics in each population, with higher VSS in the youngest babies being offset by many low-risk older babies with no disease.

ABSTRACT BODY:

Purpose: Teprotumumab, an IGF-IR inhibitor, was approved for the treatment of thyroid eye disease (TED) in January 2020. Two clinical trials demonstrated efficacy in patients with active moderate-to-severe TED and excluded patients with other types of TED or previous therapy with orbital irradiation, surgery, glucocorticoid use (cumulative dose > 1 gm), or biologic treatments. This study is the first to report the long-term real world outcomes in patients treated with teprotumumab for TED.

Methods: The pooled data of consecutive patients treated with teprotumumab for TED from 3 academic institutions were reviewed. Patient data were collected at baseline, post-treatment, and at long-term follow-up. All patients who completed treatment with ≥4 infusions were included. The percentage of proptosis responders (≥2 mm reduction) and mean changes from baseline in proptosis, Gorman diplopia score (GDS), clinical activity score (CAS), and Graves' ophthalmopathy quality-of-life (GOQoL) score at post-treatment and long-term were calculated. The percentage of patients who had proptosis regression (≥2 mm increase from post-treatment to long-term follow-up) was also calculated.

Results: 48 patients with a mean age of 57.9 (range 30-90) and mean CAS of 4.1 (range 1-7) were included (Fig 1). The mean post-treatment and long-term follow-ups were at 28.9±SD 11.0 and 57.44±11.1 weeks after the first infusion, respectively. Compared to baseline, post-treatment metrics demonstrated a significant decrease in mean proptosis (2.91±2.18, n=47), GDS (0.67±1.22, n=43), and CAS (3.32±1.37, n=44), all $p<0.002$. No significant difference occurred in these values between post-treatment and long-term (n = 40, 39, 34 respectively). The mean GOQoL gain between baseline and post-treatment (19.8±17.6, n=15, $p<0.001$) was maintained long-term (22.7±14.8, n=11). 70.2% were proptosis responders (n=47) post-treatment, but 28.2% (n=39) had proptosis regression. Of the regressors, 81.8% (n=11) continued to have inactive disease (CAS of 0 or 1) (Fig 2).

Conclusions: Our results confirm the efficacy and durability of teprotumumab in consecutive patients with TED using the metrics reported in clinical trials. Although regression of the initially robust proptosis response may occur, most patients do not develop reactivation of active TED. Further investigation on the long-term durability of proptosis response and reason for proptosis regression in a portion of patients is warranted.

ABSTRACT BODY:

Purpose: To analyze and report the 3-dimensional (3-D) structure, qualitative and quantitative parameters in Haller’s layer of the choroid in diseased eyes and compare with age-matched healthy eyes.

Methods: This was a retrospective study and included 3 groups (healthy, age-related macular degeneration (AMD), and central serous chorioretinopathy (CSCR) eyes). Previously validated end-to-end algorithm based on ResUnet, 3D tensor voting and geometrical modeling was used to segment, reconstruct and quantify Haller’s sublayer vasculature in 3D. A heat map showing the relative radius of the blood vessel, vascularity showing the blood flow in the vascular lumen was generated. A histogram showing the distribution pattern of the thickness of Haller's vessel was prepared. Qualitative parameters including symmetricity, arrangement, and branching pattern of vessels, rarefaction of vessel density, hot areas, and focal constriction were analyzed.

Results: A total of 34 eyes (14 healthy, 9 AMD, 11 CSCR eyes) were analyzed. The mean (±SD) Haller vessel radius in healthy, AMD and CSCR eyes was 86.4 ± 4.4 µm (range, 14.96 to 174.1 µm), 88.8 ± 6.4 µm (range, 14.7 to 179.2 µm) and CSCR: 88.3 ± 6.6 µm (range, 14.6 to 171.5 µm) respectively (Figure 1). However, the percentage of eyes with radius > 100 µm was more in AMD (17.7%) and CSCR eyes (16.8%) compared to healthy eyes (14.2%). Two eyes in CSCR and 3 eyes in the AMD group had an asymmetrical pattern of vessel arrangement whereas all the healthy eyes had a symmetrical pattern. Severe vessel rarefaction was seen in 1 healthy eye compared to 3 and 4 in AMD, and CSCR eyes respectively. Either focal or diffuse hot areas i.e., sites of vascular dilatation were seen in all 3 groups (healthy, focal: 8; diffuse: 2; AMD, focal: 6, diffuse: 2; CSCR, focal: 5, diffuse: 3). Focal constriction in Haller's vessels was seen in 2/14 eyes in healthy subjects compared to 7/9 eyes in AMD and 3/11 eyes in the CSCR group.

Conclusions: The diameter of Haller's vessels shows a wide range of variation in healthy as well as diseased (AMD, CSCR) eyes. However, both AMD and CSCR eyes showed a higher percentage of vessels with a radius > 100 microns compared to healthy eyes. Moreover, the qualitative analysis showed a higher percentage with symmetrical distribution, relatively fewer eyes with severe vessel rarefaction, and/ or focal constriction in healthy subjects compared to diseased eyes.

ABSTRACT BODY:

Purpose: Understanding effective limbal epithelial stem cell maintenance is necessary to improve limbal stem cell deficiency (LSCD) treatment using ex vivo cultured limbal stem/progenitor cells (LSCs). We have previously demonstrated that canonical Wnt signaling is crucial for limbal stem cell maintenance and that Wnt2, Wnt6, Wnt11, and Wnt16b are upregulated in the limbus relative to the cornea. The purpose of this study is to investigate the effect and mechanism of supplementing Wnt16b in the LSC cultures on the expansion of the stem/progenitor cell population in vitro.

Methods: Wnt16b was overexpressed in 3T3 cells, which do not express Wnt16b, using a Wnt16b-IRES-GFP lentivirus vector. An IRES-GFP vector served as a control. Transduced 3T3 cells were sorted into low, medium, and high GFP expression groups. LSCs were isolated from five donors and cultured on low, medium, and high Wnt16b-expressing 3T3s compared to their respective GFP controls and an uninfected 3T3 control. After 12-14 days in culture, the cultivated LSCs were evaluated by quantifying cells expressing K12, K14, and high levels of p63α. Canonical and non-canonical Wnt pathway markers expressed in the cultivated LSCs were evaluated by quantitative real-time PCR (qRT-PCR).

Results: LSCs cultured on low Wnt16b-3T3 cells, which most closely corresponded to levels of Wnt16b in the human limbus in vivo, contained significantly higher percentages of p63α-bright cells and the non-canonical Wnt marker phosphorylated cJun than LSCs cultured on low GFP-3T3 cells. LSCs cultured on Wnt16b-3T3s also differentially expressed Wnt6, Wnt7a, and Wnt7b. Proliferation, colony-forming efficiency, and cell size were not significantly affected.

Conclusions: Wnt16b contributes to maintaining a fine balance of canonical and non-canonical pathways to regulate limbal stem cell proliferation, differentiation, and self-renewal in vitro.

TITLE: Comparison of Bruch's Membrane Opening-Based Minimum Rim Width and Retinal Nerve Fiber Layer Rates of Change in Glaucoma Patients

SESSION TITLE: OCT Clinical Applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Shi, M. Mohammadi, V. Mohammadzadeh, E. Su, R.E. Weiss, J. Caprioli, K. Nouri-Mahdavi, Ophthalmology, UCLA Stein Eye Institute, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Lynn Shi: Commercial Relationship: Code N (No Commercial Relationship) | Massood Mohammadi: Commercial Relationship: Code N (No Commercial Relationship) | Vahid Mohammadzadeh: Commercial Relationship: Code N (No Commercial Relationship) | Erica Su: Commercial Relationship: Code N (No Commercial Relationship) | Robert Weiss: Commercial Relationship: Code N (No Commercial Relationship) | Joseph Caprioli: Commercial Relationship: Code N (No Commercial Relationship) | Kouros Nouri-Mahdavi: Commercial Relationship(s);Code F (Financial Support):National Institute of Health R01 grant (R01-EY029792), an unrestricted Departmental Grant from Research to Prevent Blindness, an unrestricted grant from Heidelberg Engineering

ABSTRACT BODY:

Purpose: To compare longitudinal rates of change (RoC) in Bruch's membrane opening-based minimum rim width (BMO-MRW) and peripapillary retinal nerve fiber layer (RNFL) thickness as measured with Spectralis OCT in glaucoma eyes with moderate to severe damage at baseline.

Methods: Spectralis OCT optic disc volume scans from 113 glaucoma eyes (113 patients) with >2 years of follow-up and ≥4 OCT images were exported. BMO-MRW and RNFL raw OCT images were reviewed for centration, artifacts, and segmentation accuracy and incorrect segmentations were rectified. We estimated global and sectoral RoC with linear regression of MRW and RNFL thickness against time. Outcomes of interest were standardized global and sectoral RoC for the 2 outcome measures and proportion of worsening and improving rates (negative vs. positive rates of change with $p<0.05$). Standardized RoC were calculated by dividing absolute RoC by the standard deviation of regression residuals. We also used permutation analyses to control specificity with the 2.5% and 97.5%ile cutoff points used to define true worsening or improvement.

Results: Median (IQR) follow-up and OCT scan sessions were 2.5 (1.0-4.2) years and 5 (4-8), respectively. Baseline average (SD) global RNFL and MRW thickness were 63 (±14) µm and 158 (±50) µm. Baseline mean deviation was -9.2 (±5.8) dB. Based on simple linear regression, a higher proportion of significant negative RNFL rates was observed compared to MRW in the inferotemporal (35% vs. 20%; $p=0.015$) and inferonasal (42% vs. 17%; $p<0.001$) sectors. The proportion of improving sectors was similar except in the inferotemporal sector (2.6% vs. 9.7% for MRW; $p=0.04$). Permutation analyses also demonstrated a higher proportion of worsening RNFL rates than MRW in the inferotemporal ($p=0.026$) and inferonasal ($p<0.001$) sectors with overall lower positive RoC (Figure 1). Standardized RNFL RoC were significantly more negative than MRW globally, inferotemporally, superonasally, and inferonasally (Figure 2; $p\leq0.007$).

Conclusions: RNFL measurements are more likely to demonstrate faster negative rates of change and to detect disease deterioration compared to BMO-MRW in eyes with moderate to severe glaucoma damage. RNFL measurements had a better signal to noise ratio than BMO-MRW globally and in more sectors, suggesting that RNFL is the superior metric for monitoring change in moderate to severe glaucoma.

ABSTRACT BODY:

Purpose: Visual performance can be measured by different tests, such as contrast sensitivity (CS). The Rabin Cone Contrast Sensitivity Test (RCCST [Innova Systems]) is an easy way to evaluate CS. To our knowledge, this has not been validated before in subjects with apparently normal visual acuity (VA). The purpose of our study was to validate the RCCST's CS test in ophthalmologically healthy individuals to determine changes in CS with age and assess test-retest variability.

Methods: This was a retrospective, observational and comparative study performed in the Retina Department of the Asociación Para Evitar la Ceguera en México (APEC). Volunteers agreed to participate in CS testing and signed informed consent. The project was approved by the Institutional Review Board, and adhered to the Declaration of Helsinki.

Patients were aged between 18 and 65, ophthalmologically healthy with a refractive error between -2.00 to +2.00 D, and best corrected VA ≥20/20. Each subject was evaluated for CS 3 times to determine intraobserver repeatability (test-retest reliability). Subjects were grouped by age: 18-29; 30-39; 40-49; 50-60. Comparison between age subgroups was performed. Cronbach’s alpha and Intraclass Correlation Coefficient (ICC) were used to measure correlation between results. Kruskal-Wallis test (KW) was performed to determine differences among subgroups. Spearman's Correlation Coefficient (SCC) was performed to detect correlation between age and CS.

Results: 114 subjects were studied, consisting of 58 women and 46 men, with a mean age of 33.72, standard deviation (SD) 12.32, range 18 - 60. Mean CS was 1.61 CS logarithmic scale (CSLS), 0.10 SD, 95% confidence interval (CI) 1.59 - 1.63 (range: 1.25 - 1.98). Cronbach’s alpha resulted in a correlation of 0.725; ICC for average measures resulted in a correlation of 0.726, 95% CI 0.626 - 0.803 (P< 0.001). Hence, both tests returned “good” reliability of the system.

CS means by subgroups are shown in Table 1. KW resulted in a statistically significant difference between groups: Chi-squared of ranks=14.48, P=0.002. SCC between CS and age resulted in a correlation of -0.355 (P< 0.001) (Graph 1).

Conclusions: Repeatability of CS measurement by RCCST resulted in a “good” correlation. Differences among age groups existed, with a lower CS for older individuals. Therefore, we consider that CS can be accurately measured using the RCCST in a subset of healthy subjects.

ABSTRACT BODY:

Purpose: There is little data on ophthalmic illnesses of the general population in recent years. In this study, we quantified the rates of hospitalization for ophthalmic disease and injury among all individuals in the United States, using the National Inpatient Sample – Healthcare Cost and Utilization Project(NIS-HCUP) database from 2016 to 2018.

Methods: We conducted a retrospective cross-sectional analysis of recent data from the NIS-HCUP database (2016-2018). This database is the largest all-payer inpatient-care database and provides a stratified random sample covering 97% of all discharges from hospitals in the United States. Individuals with primary ophthalmic illnesses were identified by filtering for those with an ICD-10 code related to disease of the eye or adnexa. Data analysis was conducted using R software.

Results: From 2016 to 2018, there were an estimated 23,423 ophthalmic inpatient admissions in the US. Most of these admissions were from non-traumatic disorders (77%). The most common diagnoses among the general population for ophthalmic diseases during this time period are: orbital cellulitis (9.6%), diplopia/visual disturbances (9.2%), orbital floor fracture (9.0%), optic neuritis (7.1%), and zoster ocular disease (5.5%). We compared our results with a previous study that quantified general population ophthalmic hospitalizations from 2001 to 2014.[1] Our results show that the rates of orbital cellulitis have decreased from 14.5% to 9.6% while the rates of optic neuritis have increased from 4.0% to 7.1%.

Conclusions: This is the first published data on ophthalmologic disease and injury hospitalizations in the US during the time period of 2016 to 2018. Our study shows that rates of orbital cellulitis have decreased from previous years while rates of optic neuritis have increased. More research is needed to understand what drives these trends and changes in prevalences in diseases. This will be valuable when applying interventions to reduce the incidence and financial burden of the most common ophthalmic diseases.

TITLE: Epac2 deletion prevents retinal neuronal injury through attenuation of ER stress in a mouse model of retinal ischemia-reperfusion

SESSION TITLE: Retinal ganglion cells

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F. Xia, S. Shi, E. Palacios, W. Zhang, H. Liu, The University of Texas Medical Branch at Galveston, Galveston, Texas, UNITED STATES|

Commercial Relationships Disclosure: Fan Xia: Commercial Relationship: Code N (No Commercial Relationship) | Shuizhen Shi: Commercial Relationship: Code N (No Commercial Relationship) | Erick Palacios: Commercial Relationship: Code N (No Commercial Relationship) | Wenbo Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Hua Liu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal ischemia is one of the most significant pathologies in various ocular diseases, including glaucoma, diabetic retinopathy and retinal vascular occlusion, and results in the death of retinal neurons. Exchange protein activated by cAMP (Epac) is a newly identified mediator of second messenger cAMP. We previously found Epac1 plays a critical role in retinal neurodegeneration. This study aims to investigate whether Epac2, the other isoform of Epac, has a role in retinal neuronal injury in a mouse model of retinal ischemia-reperfusion (IR).

Methods: IR was induced by elevating intraocular pressure to 110 mm Hg for 50 minutes via raising the saline reservoir, to which an infusion needle was connected and inserted into the anterior chamber of the right eyes. Retinal ganglion cells (RGCs) number, apoptosis/necroptosis, and molecules in the endoplasmic reticulum (ER) stress branches were determined by immunohistochemistry and TUNEL assay.

Results: We found that at 12 hours after IR, retinal neuronal apoptosis (TUNEL-positive cells) and necroptosis (p-RIP3-positve cells) were dramatically increased in wild type (WT) IR retinas, which were significantly mitigated by Epac2 genetic deletion. At 7 days after IR, RGCs were significantly preserved in Epac2$^{-/-}$ mice compared with age-matched WT mice. Mechanistically, the expressions of ER stress-related molecules including GRP78, p-PERK and CHOP, and ER stress response mediator ER oxidoreductin 1 (ERO1α) were significantly increased after ischemic injury and Epac2 deletion lowered levels of p-PERK, CHOP and ERO1 whose activation can lead to cell death.

Conclusions: These data indicate that Epac2 deletion is neuroprotective against retinal IR injury through attenuation of ER stress, and Epac2 blockade may be a favorable strategy in the treatment of retinal neurodegenerative diseases.

ABSTRACT BODY:

Purpose: 3-dimensional representations of the visual field and associated calculations of volume “under the hill” have been applied to perimetry data in clinical trials. Changes in volume have been used to monitor subjects and response to treatment. However, existing methods do not enable spatial correlation to volumetric changes. This study aims to develop techniques for calculating and visualizing volumetric changes over time in the Hill of Vision (HOV).

Methods: HOV software was built using MATLAB. HOVs were generated using four different interpolation functions: thin plate spline, natural neighbor, nearest neighbor, and linear interpolation. HOV software was then applied to perimetry data and visualized using plotting libraries. Difference HOVs (dHOVs) were constructed by first comparing a subject’s most recent perimetry data with their baseline, then applying an interpolation function to generate the dHOV. dHOVs were plotted using a green-red color scheme to demonstrate areas of visual improvement or decline respectively.

Results: Our software successfully generated interpolated HOVs and dHOVs. Each interpolation strategy produced distinct HOVs and dHOVS that varied in terms of smoothness. The dHOV was shown to be an effective way of spatially correlating changes in the visual field over time.

Conclusions: dHOV rendering can be easily implemented using several different interpolation strategies. Use of dHOV may prove to be a valuable way to visualize disease progression or visual function improvement.

ABSTRACT BODY:

Purpose: Exosomes are small secreted extracellular vesicles (30-150 nm) to mediate intracellular communication via their content of proteins, lipids, and nucleic acids. We aimed to characterize the exosomes secreted by primary corneal stromal fibroblasts (HCFs) from patients with or without keratoconus (KC).

Methods: Using primary HCFs derived from normal (n=4) and KC (n=4) patients, we collected and isolated exosomes using serial ultracentrifugation. Using nanoparticle tracking analysis (NTA) with ZetaView, we compared the size and concentration of isolated exosomes. Different exosomal markers were identified using a transmission electron microscope (TEM) (CD81) and western blot (CD9 and CD63). Exosomal miRNA profiles were determined by qRT-PCR using Exiqon Human panel I miRNA assays of 368 pre-selected miRNAs. Proteomics profiling was determined using the label-free spectral counting method with mass spectrometry. Differential expression analyses for miRNAs and proteins were done using the student's t-test with a significance cutoff of p-value ≤ 0.05.

Results: We successfully characterized exosomes isolated from HCFs using several complementary techniques. We found no significant differences in the size, quantity, or morphology between exosomes secreted by HCFs with or without KC. Expression of CD81 was confirmed by immuno-EM and expression of CD63 and CD9 with western blot in all exosome samples. We detected the expression of 72-144 miRNAs (threshold cycle Ct < 36) in all exosome samples. In KC-derived exosome samples, miR-328-3p, miR-532-5p, miR-345-5p, and miR-424-5p showed unique expression while let-7c-5p and miR-665 have increased expression. Protein profiling identified 157 proteins present in at least half of the exosome samples with 38 known exosomal proteins. We identified 12 up- and 2 down-regulated proteins in KC-derived exosomes. The proteins are involved in membrane-bounded vesicles, cytoskeletal, calcium binding, nucleotide binding. These genes could be regulated by NRF2, miR-205, and TGFβ1, which are involved in KC pathogenesis.

Conclusions: For the first time, we successfully characterized the KC-derived exosomes and profiled their miRNA and protein content, suggesting their potential role in KC development. Further studies are necessary to determine if and how these exosomes with differential protein/miRNA profiles contribute to the pathogenesis of keratoconus.

Commercial Relationships Disclosure: Anddre Valdivia: Commercial Relationship: Code N (No Commercial Relationship) | Massoud Motamedi: Commercial Relationship: Code N (No Commercial Relationship) | Hossein Nazari: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A growing number of studies have suggested common pathological pathways between Alzheimer's disease (AD) and age-related macular degeneration (AMD) as evidenced by the progressive accumulation of proinflammatory protein, amyloid β (Aβ), in plaques of the AD brain and the drusen of AMD retina. To explore the shared genomic profile between AD and AMD, a bioinformatic pipeline approach was adapted to analyze disease related PheWAS datasets via an interaction predictor database followed by a pathways database.

Methods: Data were collected from the UKBioBank PheWAS datasets (AD: 430 cases and 400600 controls, and AMD: 2180 cases and 395156 controls). Top loci variants were identified as the single genetic variant with a minor allele frequency (MAF) range of 5e-5≤MAF<0.50. Genes corresponding to top loci variants were identified based on the single genetic variant proximity to nearest gene. PheWAS candidate genes were analyzed through the STRING database as 3 different groups, 1) AD only, 2) AMD only, and 3) AD+AMD. Within each group sub-clusters corresponding to a string of protein interactions were identified and further analyzed through the REACTOME pathway database (pathways p-value ≤ 0.05).

Results: STRING analysis revealed minimal protein-protein interaction enrichment (PPI-E) in the AD only group (p-value: 1) and the AMD only group (p-value: 0.072), while the AD+AMD group demonstrated significant PPI-E (p-value: 0.044). REACTOME pathway analysis demonstrated 3 shared pathways unique to the AD+AMD group: 1) glucagon signaling pathway (p-value: 0.024), 2) activation of GABA receptors (p-value: 0.018) and 3) aquaporin mediated transport (p-value: 0.033).

Conclusions: The application of an integrated bioinformatic analysis enabled us to identify three dominant pathways demonstrating the association between AD and AMD. Specifically, glucagon secretion has been shown to be regulated by activation of GABA receptors via an Akt-dependent manner. Glucagon has also been documented to increase the expression of aquaporin. Our findings highlight the convergence of AD and AMD pathologic pathways in the dysregulation of aquaporin with its potential contribution to defective Aβ secretion that may lead to Aβ accumulation in both AD and AMD.

TITLE: Timing of vitrectomy in patients with ocular inflammation and history of lymphoma

SESSION TITLE: Clinical Uveitis and Scleritis: Therapies and Outcomes

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Thura, L. Valdes, Ophthalmology, University of Massachusetts Chan Medical School, Worcester, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Soraiya Thura: Commercial Relationship: Code N (No Commercial Relationship) | Lianna Valdes: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess the clinical course of patients and decision for vitreous biopsy, with history of lymphoma, who present with intraocular inflammation.

Methods: Retrospective chart review of patients who were diagnosed with vitreoretinal lymphoma who also have a history of lymphoma from a non-ocular site. Patients without a prior or concurrent diagnosis of non-ocular lymphoma, but who had eventual diagnosis of vitreoretinal lymphoma, were also assessed for comparison in terms of timeline from symptoms to vitreous biopsy.

Results: A small subset of patients have been identified between 2017 and 2022 at the University of Massachusetts Medical School who presented to Ophthalmology Clinic with uveitis in one or both eyes. All patients underwent vitrectomy with vitreous biopsy samples that came back positive for a diagnosis of intraocular lymphoma. One patient with a history of lymphoplasmacytic lymphoma was found to have a rare presentation of intraocular Richter's transformation, which has only been described a handful of times in the literature since 1928. Another patient with a history of testicular lymphoma was diagnosed initially with retinitis but vitreous biopsy results showed diffuse large B cell lymphoma. In comparison to patients without a prior history of lymphoma, the time to obtain vitreous biopsy from initial clinic presentation was decreased.

Conclusions: The decision to perform vitrectomy for definitive diagnosis in patients presenting with persistent panuveitis, who have a known history of lymphoma from a non-ocular site, can be expedited. In these particular instances, it is prudent to rule out malignancy, as atypical presentations of lymphoma can become evident.

ABSTRACT BODY:

Purpose: Retinitis pigmentosa (RP) is a blinding disease caused by multiple mutations in dozens of genes; therefore, a gene agnostic treatment approach to prevent photoreceptor (PR) degeneration is ideal. We previously demonstrated that pharmacological activation of pyruvate kinase M2 (PKM2) alters central glucose metabolism and is neuroprotective for PRs in a model of acute outer retinal nutrient stress. Additionally, microglia can adopt an inflammatory phenotype, which has been shown to contribute to PR degeneration in RP, and PKM2 has been shown to suppress this inflammatory phenotype in other systems. This study assesses the pharmacologic activation of PKM2 as a novel therapeutic avenue in the rd10 mouse model of RP.

Methods: We employed oral (PO) and intraperitoneal (IP) injections of a known PKM2 activator, ML-265, and a novel PKM2 activator, MCTI-566, in rd10 and wild-type mice from postnatal day 14 (P14) to 49 (P49). At various time-points, the overall retinal PK activity was measured using an enzyme coupled continuous assay that measures the depletion of NADH at 340 nm. In vivo retinal structure and function analyses quantitatively examined the effect of PKM2 activation on retinal degeneration in rd10 mice. Histology and flow cytometry characterized retinal morphology and microglia recruitment and polarization.

Results: PK activity is depressed by over 40% ($p < 0.001$) in rd10 retinas at P14 compared to age-matched wild type animals, prior to any observed PR degeneration. PO administration of ML-265 significantly increased PK activity in rd10 retinas by over 1.5-fold ($p < 0.01$), which was similarly demonstrated with IP MCTI-566. Flow cytometry demonstrated a significant increase in rd10 retinal microglial numbers with a shift toward the pro-inflammatory M1 phenotype.

Conclusions: We previously showed that enhancing retinal PK activity using a small molecule activator of PKM2 is neuroprotective in a model of acute nutrient deprivation. Our new data suggest that decreased PKM2 activity and altered microglial polarization may contribute to PR degeneration in the rd10 mouse model of RP. Therefore, the use of small molecule PKM2 activators as a non-gene-specific therapy may prevent these metabolic and immunologic perturbations in RP.

ABSTRACT BODY:

Purpose: Clinical and research interpretation of WF SS-OCTA requires reference to control data using similar imaging and analysis tools. Literature on WF SS-OCTA with large sample sizes is sparse and often limited to only vessel density (VD). We aimed to analyze a large number of healthy eyes to create the first normative database using the ARI network (Zeiss Portal).

Methods: In this cross-sectional observational study, 383 eyes of 302 subjects were imaged using 3x3mm, 6x6mm, and 12x12mm scans centered on the fovea using 100kHz WF SS-OCTA (PLEX® Elite 9000) between December 2018 and September 2021. Robust exclusion criteria included presence of hypertension, diabetes, glaucoma, >2+ cataract, refractive error >±6D, trauma, and ocular pathology. VD and vessel skeletonized density (VSD) were calculated in the superficial (SCP), deep capillary plexuses (DCP), and whole retina, as well as foveal avascular zone (FAZ) perimeter, area, and circularity (Macular Density Algorithm v0.7.3). Mixed effects linear regression was used.

Results: Subjects had a median age of 54 (11-83) years. 48.3% were male, 72.2% were white, and 8.3% reported Hispanic ethnicity. Median values of OCTA metrics for each scan size are reported (Table). Both VSD and VD decreased significantly with age in most layers and scan types ($p<0.05$). FAZ circularity also declined with age on 3x3mm ($\beta=-0.001$,$p=0.001$) and 6x6mm ($\beta=-0.001$,$p=0.014$) scans. No difference between males and females nor any effect modification with age was observed. No significant differences between white, Black, and Asian patients were observed. Hispanic patients had significantly higher whole retina VSD on 6x6mm ($\beta=0.853$, $p=0.046$) and higher VSD and VD on all 12x12mm layers ($p<0.05$) than non-Hispanic patients. Worse visual acuity was associated with significantly lower VSD and VD ($p<0.05$) and more irregular FAZ in all layers for all scans.

Conclusions: We present the first normative database of OCTA metrics obtained using standardized ARI network algorithms. This represents an uncommonly large sample of control eyes and includes broad vascular metrics as well as scans ranging from 3x3 to 12x12mm. Our results provide a valuable reference for past and future studies using this device.

ABSTRACT BODY:

Purpose: To develop and validate a risk calculator to identify individuals at high-risk for diabetic retinopathy (DR).

Methods: This study includes patients with diabetes from an urban, academic ophthalmology center. Patient demographic characteristics were generated using descriptive statistics. Univariable and multivariable cox proportional hazard model identified risk factors of high-risk diabetic retinopathy. Stepwise akaike's information criteria (AIC) was used to select the best multivariable model. Bootstrap estimate of calibration accuracy for 3-year survival probability showed the existence of model overfitting. The model was then validated using 200 bootstrap resamples to obtain the slope shrinkage factor which could be used to update the model to have better survival prediction. Nomogram and R Shiny app were developed to predict 3-year and 5-year survival probabilities. Statistical analyses were performed using R (The R Foundation, Vienna, Austria) and SAS 9.4 (Cary, NC).

Results: A total of 1363 patients (female, 51.7%) were included in this study. The mean age [SD] was 61.2 [13.5]. The mean hemoglobin A1C [SD] was 8.7 [2.5]. The ethnic and racial breakdowns were 42.9% white, 33.1% Black/African American, 27.5% Hispanic/Latino, and 3.65% Asian. Most patients had a current primary care provider (96.4%), primarily spoke English (80.3%), and had public insurance (63.7%). Patients had a history of the following diabetic and chronic health conditions: nephropathy (10.0%), neuropathy (17.8%), nonhealing ulcer (11.2%), dyslipidemia (31.3%), uncomplicated hypertension (47.5%), and complicated hypertension (2.1%). The validated predictive model included having a primary care provider (HR 2.61; Table 1), insurance provider (private [HR 0.90]; uninsured [HR 2.05]), hemoglobin A1C (HR 1.08), dyslipidemia (HR 0.70), uncomplicated hypertension (HR 1.31), and complicated hypertension (HR 1.66; Table 1). A nomogram was developed to predict 3-year and 5-year probability of developing DR (Figure 1).

Conclusions: Using a predictive model, we show that adult patients with diabetes can be stratified according to their risk of DR. Risk stratification methods may help to improve clinical and surgical decision-making for patients with DR.

TITLE: A wavelength-agnostic, deep learning algorithm segmenting the hyperautofluorescent ring in retinitis pigmentosa

SESSION TITLE: Machine Learning: Segmentation and Classification

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Charng, D.A. Mackey, F.K. Chen, Lions Eye Institute, Nedlands, Western Australia, AUSTRALIA|J. Charng, Optometry, The University of Western Australia, Western Australia, AUSTRALIA|I. Viedma, D. Alonso-Caneiro, Optometry and Vision Science, Queesnland University of Technology, Queensland, AUSTRALIA|

Commercial Relationships Disclosure: Jason Charng: Commercial Relationship: Code N (No Commercial Relationship) | Ignacio Viedma: Commercial Relationship: Code N (No Commercial Relationship) | David Alonso-Caneiro: Commercial Relationship: Code N (No Commercial Relationship) | David Mackey: Commercial Relationship: Code N (No Commercial Relationship) | Fred Chen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Quantification of the hyperautofluorescent ring (HAR) is a key clinical trial outcome measure in retinitis pigmentosa (RP). Segmentation is currently done via traditional programming or manually. We applied a wavelength-agnostic deep learning (DL) algorithm to segment the HAR on fundus AF (FAF) images in RP eyes.

Methods: FAF images in RP patients were acquired using Heidelberg HRA2 in either blue or infrared AF (BAF /IRAF) mode, with a total of 1152 and 1099 images respectively.

For each modality, a fully semantic algorithm (single model) based on a Unet++ architecture with an InceptionV2 encoder was developed and trained with an approximate 50/20/30% data split (training/validation/testing). The same network was then trained using both BAF and IRAF images (dual model) to produce a wavelength-agnostic platform. Model performance was assessed using the Dice similarity coefficient of the AF class, with 1 indicating perfect match to manual delineation. Paired t-test compared the difference in Dice score between the single and dual model.

To test the wavelength-agnostic algorithm, we examined baseline FAF images from one eye (OD, if unavailable then OS) in patients with Usher syndrome. Manual and DL segmentation were performed in all images with HAR, with HAR horizontal extent and area extracted. Bland-Altman evaluated limits of agreement between manual and DL.

Results: For the BAF dataset, comparable mean (standard deviation) Dice coefficient were found in the single 0.952 (0.042) and dual 0.953 (0.048) model (t-test, p=0.14). Single IRAF 0.957 (0.054) and dual 0.959 (0.053) model dice scores were also similar (p=0.24).

In the Usher cohort (n=33), HAR was noted in 21 BAF and 22 IRAF images. In BAF, the mean difference (95% CI) between DL and manual delineation was 0.01 (-0.53 to 0.56) mm and -0.08 (-0.96 to 0.81) mm^2 for horizontal ring extent and area, respectively. In 4 images, poor agreement between DL and manual segmentation was due to low image quality. In IRAF, the mean difference for ring extent was -0.29 (-2.73 to 2.15) mm and -0.89 (-8.59 to 6.81) mm^2 for ring area. Poor agreement was due to low image quality (n=2) or indistinct HAR boundary (n=6).

Conclusions: The wavelength-agnostic DL algorithm was able to segment HAR in AF images, comparable to manual delineation, with manual correction required in a minority of images.

TITLE: Characteristics of symptom reporting on convergence insufficiency symptoms survey (CISS) in adolescent concussion

SESSION TITLE: Strabismus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Raghuram, E.K. Wiecek, B.G. Jastrzembski, A. Shah, Opthalmology, Harvard Medical School, Boston, Massachusetts, UNITED STATES|A. Raghuram, S. Marusic, E.K. Wiecek, B.G. Jastrzembski, A. Shah, Ophthalmology, Boston Children's Hospital, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Aparna Raghuram: Commercial Relationship: Code N (No Commercial Relationship) | Sophia Marusic: Commercial Relationship: Code N (No Commercial Relationship) | Emily Wiecek: Commercial Relationship: Code N (No Commercial Relationship) | Benjamin Jastrzembski: Commercial Relationship: Code N (No Commercial Relationship) | Ankoor Shah: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We aim to understand which CISS items are most frequently reported and if symptom reporting is impacted by age, sex, time since concussion and survey method.

Methods: Retrospective chart review was conducted to identify concussion patients from July 2014 to December 2020 through a multidisciplinary concussion clinic (MDCC) or a direct referral (REF) for evaluation. Patients either self-reported symptoms on the CISS using an iPad (MDCC) or responded verbally to the clinician administered CISS (REF). All individuals met inclusion criteria of < 18 years of age, < 1 year since concussion (sub-acute: 15-120 days, chronic: 121-365 days), 20/30 best-corrected visual acuity, and no ocular disease, strabismus or amblyopia. Age, sex, time since concussion, and CISS scores (15 items: 3 vision-related (CISS-V), 6 somatic (CISS-S), 6 cognitive (CISS-C)) were analyzed. Cronback's analysis was used to assess CISS-subscale inter-item consistency and analysis of covariance (ANCOVA) was used to understand group differences in CISS scores.

Results: Chart review identified 205 eligible patients (mean age 15 years ± 2.1; 141 female, 112 chronic, 105 MDCC). The mean CISS score (n= 205) was 27.80 ± 12.73. The most commonly reported symptoms were headaches (61% of patients reporting often or always), tired eyes (54%), losing concentration (52%), trouble remembering (44%) and uncomfortable eyes (44%). This trend was maintained across sex, time since concussion, and clinic type. Cronback's alpha was 0.70, 0.83, 0.86 for CISS-V, C and S, respectively, indicating excellent inter-item consistency. The highest mean subscale score was for CISS-S (2.05±1.2) followed by CISS-C (1.96±0.98) and CISS-V (1.24±0.98). ANCOVA indicated age was a significant covariate ($p < 0.01$). Higher scores were reported from the MDCC clinic (difference = 7.91; 95% CI: 4.22 – 11.61, $p<0.001$) and from sub-acute than chronic phase of concussion recovery (difference = 4.37; 95% CI: 0.68 – 8.06, $p = 0.02$).

Conclusions: Concussion patients most commonly reported somatic symptoms, such as headaches, tired and uncomfortable eyes. Patients who self-reported symptoms had higher symptoms scores, though symptoms reported were similar to clinician-administered. Clinicians administering the CISS may introduce a positive bias that lowers reported symptom intensity in post-concussion adolescents.

TITLE: Light-induced retinal degeneration in immunodeficient mice.

SESSION TITLE: Novel animal models and neuroprotection in the retina

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C.A. Ku, U. Park, P.A. Sieving, S.S. Park, Ophthalmology, University of California Davis, Davis, California, UNITED STATES|

Commercial Relationships Disclosure: Cristy Ku: Commercial Relationship: Code N (No Commercial Relationship) | Un Chul Park: Commercial Relationship: Code N (No Commercial Relationship) | Paul Sieving: Commercial Relationship: Code N (No Commercial Relationship) | Susanna Park: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A model of retinal degeneration in immunodeficient mice would allow in vivo evaluation of the long-term effects of allogenic or xenogenic stem cell transplantation without concerns about immune rejection of transplanted cells. The ideal immunodeficient mouse for this purpose is the NOD-SCID (non-obese diabetic, severe combined immunodeficiency) mouse which is homozygous for mutations for the severe combined immune deficiency spontaneous mutation $Prkdc^{scid}$ and has an absence of functional T and B cells, lymphopenia, and hypogammaglobulinemia. This study tested the hypothesis that a nonhereditary model of retinal degeneration can be developed in NOD-SCID mice using light damage.

Methods: NOD-SCID mice (6 to 8 week males) were exposed to uniform white fluorescent light (10,000 lux) in a light box over varying durations: 30 minutes (2 mice), 1 hour (3 mice), and 3 hours (10 mice). Following light damage, ERG testing (LKC Technologies) and OCT imaging (Bioptigen) of the retina was conducted to evaluate the effect of light exposure on retinal function and morphology at 1 and 2 weeks after light exposure. OCT scan area included 1.4 mm temporal, nasal, inferior, and superior from the optic nerve head. At the end of the study, the mice were euthanized and the eyes harvested for histology.

Results: Light induced changes in outer retina with corresponding decrease in retinal function on ERG was observed in all mice exposed to light damage. OCT imaging showed loss of outer nuclear layer and IS/OS junction blurring as early as 1 week after light exposure with significant outer retinal atrophy at 2 weeks. The OCT outer retinal structural changes noted 2 weeks after light exposure did not vary with duration of exposure ranging from 30 minute to 3 hrs. ERG testing showed severe attenuation of rod and cone responses in all light exposed mice when compared to mice not exposed to light. The ERG changes correlated with OCT findings. Histologic evaluation is in progress.

Conclusions: Our preliminary data support the hypothesis that a model of light-induced retinal degeneration can be developed in immunodeficient mice that may be used for future studies in allogenic or xenogenic cell-based therapeutics. Work is in progress to evaluate the long term effects of the light induced retinal changes and to determine whether severity of retinal degeneration can be modulated by titrating light exposure.

ABSTRACT BODY:

Purpose: To compare macular vessel density across inner plexiform layer (IPL) depths in glaucoma suspects and patients with glaucoma

Methods: This is a retrospective cross-sectional study from a glaucoma clinic at a single center. 6 by 6 mm^2 en face OCT angiography (OCTA) macular images centered on the fovea were collected. 6 to 7 mm thick sections spanning the internal limiting membrane to the IPL/inner nuclear layer (IPL/INL) border (the outer IPL border) were extracted for each eye. A custom-written MATLAB code was used to distinguish small and large vessels in image stacks. Small and large vessel density (VD) were computed for each stack. A linear mixed effects (LME) model was used for statistical analysis. When comparing macular VD within stacks of a specific thickness in suspect versus glaucoma eyes, the LME model included a random effect for each patient (to account for multiple eyes per patient) and a fixed effect for glaucoma. Multivariable models included the potential confounding factors of age, history of hypertension, and/or history of diabetes.

Results: In the study, there were a total of 87 eyes (56 patients) that met criteria for analysis. Analysis using a LME model revealed glaucoma was associated with decreased small vessel density (SVD) starting 25μm above the IPL/INL border (effect size from -1.31 to -0.39, $p=3.6x10^{-4}$ to 0.045 with a peak negative effect size of -1.20 to -1.31 from 31 to 48μm above the IPL/INL border). To account for the contribution of confounders in the study population, a multivariate analysis that also included age, history of hypertension, and history of diabetes was completed. In this analysis, glaucoma was associated with decreased SVD specifically from 31 to 66μm (-1.17 to -0.54, p= 0.002 to 0.03) and from 79 to 96μm (-0.54 to -0.47, $p=9.2x10^{-4}$ to 0.002) above the IPL/INL border. Of the included confounders, only age demonstrated an effect on VD. Compared to glaucoma, the effect size of age on SVD was smaller in magnitude (-0.08 to -0.04 from 0-12μm and 25-30μm).

Conclusions: We quantified small and large vessel density across IPL depths using OCTA. In this analysis, glaucoma patients exhibited decreased SVD in the inner IPL compared to glaucoma suspects. How variable VD across IPL depths may result from or reflect differences in retinal ganglion cell resiliency and/or susceptibility in glaucoma are important questions for future study.

ABSTRACT BODY:

Purpose: Automated identification of OCT features can improve retina clinic workflow efficiency as they are able to detect pathological findings. The purpose of this study was to validate an OCT-based deep-learning algorithm for the identification of FTIMH features and stages.

Methods: In this retrospective study, subjects solely diagnosed with either FTIMH or Posterior Vitreous Detachment (PVD) were identified excluding secondary causes of macular holes, any concurrent maculopathy, or incomplete records. OCT scans (512x128) from all subjects were acquired with CIRRUS^{TM} HD-OCT 5000 (ZEISS, Dublin, CA) and reviewed for quality. In order to establish a ground truth classification, each OCT B-scan was labeled by two trained graders (Table 1). A retina specialist acted as a tie-breaker whenever there was a labeling disagreement. The FTIMHs were measured using the caliper tool on CIRRUS Review software and classified in stages according to the International Vitreomacular Traction Study. The accuracy of the algorithm to identify disease features in normal and FTIMH OCT B-scans was determined by dividing the number of B-scans in agreement by the total gradable scans labeled by the algorithm. Pearson's correlation was run to determine if the algorithm's probability score was associated with the stages of FTIMH.

Results: Ninety-nine OCT cube scans from 99 subjects (49 with FTIMH and 50 with PVD) were used. Among the FTIMH scans, 63% (n=31) were stage 4, 10% (n=5) were stage 3 and 27% (n=13) were stage 2. A total of 12,354 individual OCT B-scans were labeled gradable by the algorithm and yielded an accuracy of 90.6% in identifying OCT features of FTIMHs. A Pearson's correlation coefficient of 0.31 was achieved between the algorithm's probability score and the stages of the 49 FTIMHs cubes studied.

Conclusions: The OCT-based deep-learning algorithm was able to accurately detect FTIMHs features on individual OCT B-scans. However, there was a low correlation between the algorithm's output and FTIMH stages. The algorithm may serve as a clinical decision support tool that assists with the identification of FTIMHs. Further training is necessary for the algorithm to identify stages of FTIMHs.

TITLE: Laminin-111 Expression in Extraocular Muscles of mdx Mice and the Potential Role of PITX2

SESSION TITLE: Eye movements and nystagmus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L.M. Hitch, D. Fraser, L.K. McLoon, Ophthalmology and Visual Neuroscience, University of Minnesota Twin Cities, Minneapolis, Minnesota, UNITED STATES|

Commercial Relationships Disclosure: Liz Hitch: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Fraser: Commercial Relationship: Code N (No Commercial Relationship) | Linda McLoon: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Extraocular muscles (EOM) are spared in patients with Duchenne muscular dystrophy (DMD), a muscle wasting disease caused by mutations in the dystrophin gene. DMD limb skeletal muscle is highly susceptible to contraction-induced injury, leading to cycles of myofiber degeneration and regeneration. This results in increased extracellular matrix (ECM) deposition and fibrosis, severely impacting myofiber and myogenic precursor cell functions necessary for regeneration. Other labs showed that laminin-111 therapy reduced fibrosis and promoted muscle repair in mouse dystrophic limb muscle. It is expressed during embryological development but absent in adult limb skeletal muscle.

EOM contain a large population of myogenic precursor cells that express either Pax7 or Pitx2. Pitx2 is associated with the maintenance of many EOM-specific characteristics, and in its absence, the EOM begin to resemble limb skeletal muscle. As normal adult EOM express a number of proteins normally down-regulated in adult limb skeletal muscle, we assessed expression levels of laminin-111 in wildtype (WT) EOM and limb muscle and compared its expression to the mdx mouse model of muscular dystrophy and an mdx mouse deficient in Pitx2.

Methods: Immunohistochemistry was used to stain for laminin-111 expression at 3 months and 12 months in EOM and tibialis anterior (TA) muscles taken from WT normal mice, mdx mice, and mdx mice lacking Pitx2 expression.

Results: TA muscles at 3 months showed faint and discontinuous immunostaining for laminin-111. By 12 months in the WT mouse TA, laminin-111 expression was markedly decreased. In the TA from mdx and in mdx/Pitx2 null mice, levels of laminin-111 were extremely low. In the WT EOM, at 3 months there was robust immunostaining, which was maintained at 12 months. In the EOM from the mdx mice at both 3 and 12 months, the expression levels appeared similar to the WT controls. In the mdx/Pitx2 null mice, laminin-111 levels were reduced.

Conclusions: Laminin-111 was differentially expressed in limb muscle compared to EOM, and expression was maintained in the EOM at one year. In the mdx mouse EOM, laminin-111 was retained, but reduced in the EOM from the mdx/Pitx2 null mice. These data suggest that laminin-111 may play a role in EOM sparing in DMD, and that its continued expression at high levels appears to be related to retention of Pitx2 positive cells in the EOM.

ABSTRACT BODY:

Purpose: Exfoliation syndrome (XFS) is a systemic disorder with ocular manifestations that is associated with irregularity in extracellular matrix deposition and remodeling. Given prior data suggesting an association between non-melanoma skin cancer (NMSC), i.e. basal and squamous cell cancers most often located in areas of sun exposure and XFS, a questionnaire was administered to clinic study patients to evaluate this relationship.

Methods: Participants answered a questionnaire designed to assess lifelong UV exposure, including leisure and occupational sun exposure, whether more likely to tan or burn in early life, eye and hair color, smoking behavior, vitamin D deficiency, skin cancer history, alcohol consumption and caffeine intake. The questionnaire was sent to 151 consented XFS study patients and their family members, recruited from the Moran Eye Center clinics. Of these, 53 patients completed the questionnaire and identified as non-Hispanic and white. Twelve respondents were excluded for: age (under 60y); missing birth date and basic demographic information; and unavailable electronic health records (EPIC system) to confirm absence or presence of XFS and medical history.

Results: Among these 41 eligible survey respondents ages 60y and older 31 had XFS (including 23 patients with chart-confirmed exfoliation glaucoma; XFG) and 10 respondents had no XFS diagnosis. These affected XFS and unaffected individuals did not substantively differ by gender, age, eye/hair color, or lifestyle (smoking, alcohol, caffeine consumption). XFS patients with XFG had a slightly higher frequency of NMSC (30%) compared with those unaffected by XFG (22%), and were more likely to reside at higher elevation (>5500 ft). There was an elevated proportion of XFS in those with highest quartile of sun exposure hours during young adult and adulthood (ages 21-64y) and XFS were somewhat younger at age of first sunburn.

Conclusions: Consistent with prior studies, patients with XFS/XFG appeared more likely to reside at higher elevations. Our limited, descriptive findings suggest that greater UV exposure over the adult life course may be associated with a somewhat higher risk of NMSC in XFS patients who have developed XFG. Identifying differences in UV exposure-related and other non-UV demographic and lifestyle risk factors and the development of NMSC between XFS, XFS with XFG, and unaffected individuals should be pursued in larger population-based studies.

TITLE: Exome analysis identifies novel genes associated with intraocular pressure in the UK Biobank cohort

SESSION TITLE: Glaucoma Genetics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: X.R. Gao, M. Chiariglione, A.J. Arch, Ophthalmology and Visual Sciences, Ohio State University, Columbus, Ohio, UNITED STATES|X.R. Gao, Biomedical informatics and human genetics, Ohio State University, Columbus, Ohio, UNITED STATES|

Commercial Relationships Disclosure: Xiaoyi Gao: Commercial Relationship: Code N (No Commercial Relationship) | Marion Chiariglione: Commercial Relationship: Code N (No Commercial Relationship) | Alexander Arch: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Elevated intraocular pressure (IOP) is a major risk factor for glaucoma, the leading cause of irreversible blindness worldwide. IOP is also the only modifiable risk factor for glaucoma. Identifying rare variants that contribute to IOP help uncover the biological mechanisms regulating this trait, provide new therapeutic targets for IOP, and potentially glaucoma.

Methods: We conducted this study using the recent release of 450K whole exomes from the UK Biobank. IOP measurements were obtained using the Optical Response Analyzer (Reichert Corp., Philadelphia, PA). For this study, we used corneal-compensated IOP. The average of the right and left eye IOP measurements was used for downstream analysis. A total of 110,283 study participants who have IOP measurements were included in this analysis. We performed rare-variant analyses to identify the corresponding genes associated with IOP using REGENIE with adjustment for age, sex, and the first 10 principal components of genetic ancestry.

Results: We identified a novel gene, BOD1L1, that was significantly associated with IOP ($P = 5.92 \times 10^{-9}$). BOD1L1 is associated with the use of antiglaucoma preparations and miotics ($P = 3.8 \times 10^{-6}$). Another novel gene associated with IOP was ACAD10 ($P = 1.33 \times 10^{-10}$). ACAD10 is associated with glaucoma ($P = 1.6 \times 10^{-4}$). Further analyses may identify additional rare-variant associations with IOP.

Conclusions: We identified novel genes and rare variants associated with IOP. Our findings provide insights into the genetics of rare variants affecting IOP.

ABSTRACT BODY:

Purpose: This study sought to characterize the need for adjunctive drop therapy with topical steroids or nonsteroidal anti-inflammatory drops (NSAID) in patients who received the Dextenza implant after routine phacoemulsification cataract surgery.

Methods: A retrospective chart review was performed. Patients who received a Dextenza implant after cataract surgery between January 2020 to July 2020 with at least 3 months of follow-up were included. Initiation of steroid or non-steroidal anti-inflammatory drop therapy, reason for therapy, and time of therapy initiation were collected.

Results: A total of 203 eyes were included for analysis with a mean patient age of 71.7 years. 59.1% were female and 87.7% self-identified as Caucasian. Anti-inflammatory drops (steroid, NSAID, or both) were started in 31.2% of eyes (62 eyes, excluding 3 eyes with unknown drop status and 1 eye started on drops after the 3-month follow-up period). Of all included eyes (excluding 9 eyes with unknown drop status), only 21.6% (42 eyes) were started because of persistent corneal edema, inflammation, post-operative pain, or cystoid macular edema. Of the 42 eyes started on drops due to clinical signs or symptoms, the majority of these (64.3%, 27 eyes) were started on topical steroids only. The remaining 35.7% (15 eyes) were started on both topical steroids and NSAIDs. In 72.6% of eyes requiring adjunctive therapy, treatment was started within the first week after surgery. The mean duration of adjunctive drop therapy was 36.6 days.

Conclusions: The majority of eyes that received Dextenza implantation after routine cataract surgery did not require topical anti-inflammatory therapy to control post-operative inflammation. Of those that did, most required the addition of a single drop, usually within the first week after surgery. This demonstrates that the sustained-release intracanalicular dexamethasone implant Dextenza is a viable platform for simplifying post-operative treatment regimens by reducing or eliminating the need for topical therapy after cataract surgery.

ABSTRACT BODY:

Purpose: Teprotumumab is a novel IGF-1R inhibitor used to treat thyroid eye disease (TED). Hearing loss is a known adverse event, with an incidence of 10% in the clinical trials. However, recent reports suggest that the incidence of otologic symptoms, including hearing loss, may be up to 81%. To date, an effective protocol for managing hearing loss in this setting has not been determined. Here we present the first report of the successful treatment of teprotumumab-related hearing loss with prompt oral prednisone.

Methods: Case report with pre- and post-steroid therapy audiometric data.

Results: A 70-year-old woman with a 1-year history of Graves' disease controlled with methimazole presented with a 6-month history of active, moderate-to-severe TED. Initial treatment with oral steroids was ineffective. Five months later, teprotumumab was initiated due to worsening diplopia and a clinical activity score of 4. Ten days after teprotumumab initiation, the patient reported sudden hearing loss and tinnitus in the right ear. Audiogram demonstrated a mild down-sloping to moderately severe mixed conductive and sensorineural hearing loss with a pure tone average (PTA) of 33 dB HL (the conductive component was minimal and ranged from 10-15 dB). Hearing was normal in the left ear (Figure 1). She had no history of prior hearing problems, ototoxic medication use, exposure to loud noise, or infectious symptoms. Two days after hearing loss onset, she was treated with prednisone 60mg for 6 days with a 1-week gradual taper. Three weeks following steroid therapy a repeat audiogram demonstrated PTA improvement of 20 dB HL in her right ear which brought her to a normal level that was symmetric with her left ear (Figure 2). Word recognition scores improved from 92% at 70dB before steroid therapy to 100% at 55dB post-treatment. After improvement in hearing symptoms, the patient completed the 8-infusion treatment with no further hearing symptoms at 52-week follow-up.

Conclusions: Hearing loss is a concerning adverse event of teprotumumab therapy. Effective management of teprotumumab-related hearing loss should include risk factor assessment, patient education, baseline audiometric testing, early identification of hearing symptoms with repeat audiogram testing. If hearing loss is detected, prompt oral prednisone burst therapy should be considered.

ABSTRACT BODY:

Purpose: To study the choroidal contour map in healthy eyes and make a qualitative and quantitative assessment of the inner and outer choroidal surface in a 3-dimensional (3D) view.

Methods:

This was a retrospective study based on wide-field swept-source optical coherence tomography (wide-field SS-OCT) volumes taken from 13 healthy subjects. Images were captured using a wide-field SS-OCT device (Carl Zeiss Plex Elite 9000) with a resolution of 12mm×12mm×3mm. Choroidal inner and outer surface in 3D were obtained using our previously validated residual U-Net (ResUnet) deep learning model for choroid segmentation. Qualitative analysis of inner and outer surfaces was performed using a custom built MATLAB based 3D visualization tool. Quantitative analysis was based on maximum principal curvature (Pmax) of the surface. A 4-quadrant grid with a 1mm circle centered around fovea.

Results:

Mean age of 13 healthy subjects was 30.7 ± 5.2 years. Qualitative evaluation of 13 healthy eyes demonstrated the inner surface of choroid (choroid-retinal interface) to be bell shaped in 4 eyes, hump shaped in 3 eyes, crescent shaped in 2 eyes, arc shaped in 2 eyes and cupid's bow shaped in 2 eyes. Outer surface (chorio-scleral interface) was bell shaped in 2 eyes, hump shaped in 6 eyes, crescent shaped in 2 eyes, arc shaped in 1 eye and cupid's bow shaped in 2 eyes. On quantitative evaluation, the mean central P_max at the inner and outer choroidal boundary was -0.23 ±1.27 and 1.09 ±3.63 respectively and were significantly different from each other (p=0.0002). Mean P_max in the superior, inferior and temporal macula were also significantly different between inner and outer choroidal surface (p=0.00003, 0.0004 and 0.003 respectively), while nasal curvatures were almost similar on both surfaces (p=0.011).

Conclusions:

A 3-dimensional view of inner and outer choroidal surface for the choroidal contour mapping is a unique way of evaluating choroid. The inner and outer choroidal contour curvature values are significantly different at the central macula, superiorly, inferiorly and at the temporal macula. Normative database for different age groups is being established and more data will be presented at the conference.

ABSTRACT BODY:

Purpose: To study the effects of ALK-001 on the progression of Stargardt Disease (STGD1). STGD1 is the most prevalent inherited macular dystrophy and results from defects in the ABCA4 gene that cause accelerated formation of vitamin A dimers in the retina. No treatment exists.

Methods: The TEASE study is a multicenter two-year Phase 2 double-masked, randomized, placebo-controlled clinical trial that randomized 50 patients with STGD1 and a well-delineated area of RPE atrophy. The investigational drug ALK-001 is a selectively deuterated vitamin A used as vitamin A replacement and taken orally once-a-day. Deuterium slows vitamin A dimer formation 4-5 fold without inhibiting the visual cycle. Patients were randomized 2:1 ALK-001:placebo during the first year, with 50% of placebo randomly crossed over to ALK-001 for the second year of treatment. The prespecified primary efficacy outcome measure is the rate of growth of the square root of atrophic lesions, as measured on short wavelength fundus autofluorescence imaging, and evaluated using a linear mixed model. The study was performed at 7 centers in the USA. 50 patients (38 white; 28 female) were randomized. Median age was 46 years (range, 18-60) and disease duration 9 years (0-36). Atrophic lesions were bilateral in 74% of cases with a ~5 mm^2 median area.

Results: The growth rate of the square root of atrophic lesions in the ALK-001 treated group was 21% slower than in the untreated arm ($p<0.001$). When using untransformed areas, the growth rate was 28% slower in the ALK-001 arm than the untreated arm. There were no clinically-significant changes in BCVA in either treated and untreated arms after 2 years as expected in this patient population. On average, ~90% of vitamin A was replaced with deuterated vitamin A, which was maintained over time. ALK-001 was well-tolerated with no unexpected adverse reactions, no report of night blindness or impaired dark adaptation, and no clinically-significant increases in liver enzymes.

Conclusions: These data represent the first time that a therapeutic intervention slows the progression of STGD1 in a clinically and statistically meaningful way. In addition, the data provides clinical evidence that vitamin A dimers contribute to the pathophysiology of STGD1, and that slowing vitamin A dimerization is beneficial even in advanced stages of STGD1.

ABSTRACT BODY:

Purpose: The relationship between endothelial cell loss (ECL) and DMEK injector lumen diameter remains poorly defined. We hypothesized that the LEITR glass injector, which has a narrower distal lumen compared to the Straiko glass injector, would be associated with increased ECL due to the DMEK scroll touching the walls of the narrower lumen. We further hypothesized that loading DMEK tissue into the LEITR injector through its proximal lumen, which is wider in diameter than its distal lumen, would reduce ECL compared to loading DMEK tissue through the proximal lumen.

Methods: A clinically significant difference in ECL was defined as ≥ 10%; for an alpha of 0.05, power of 0.9, and two-tailed tests, we designed the study to have 6 replicates for each comparison (LEITR vs. Straiko; LEITR narrow-lumen-loading vs. LEITR wide-lumen-loading). Surgical-grade mated corneal donor pairs were randomized to each group, prepared for DMEK by a trained technician, loaded into the injectors, expelled and flat-mounted, stained with Calcein-AM, and assessed for ECL using an inverted microscope and Fiji-ImageJ.

Results: We found no significant difference in ECL between the narrower LEITR injector and the Straiko injector (ECL $\Delta = 6.842\% \pm 5.61$, $p>0.05$). We did not observe a significant difference in ECL between DMEK tissues that were loaded through the LEITR injector's narrower distal lumen and tissues that were loaded through its wider proximal lumen (ECL $\Delta = 7.876\% \pm 5.38$, $p>0.05$). No consistent pattern of cell damage was observed between any of the groups, either.

Conclusions: Data from this modest sample of paired corneas suggest that narrower injector lumens may not directly correlate with increased ECL. This observation contradicts prior observations of incision size and ECL in DSAEK, a procedure that mechanically delivers the allograft into the eye rather than injects it with fluid. We hypothesize that DMEK tissue may behave as a deformable solid in a pipe and may thus be relatively insulated from the lumen walls by the no-slip condition described in Poisseuille parabolic flow. Further study is needed to test this hypothesis, which if true, would suggest that flow patterns and velocity may be more related to ECL than lumen diameter.

TITLE: Optical Characterisation of Myopia Control Ophthalmic Lenses

SESSION TITLE: Refractive Error: Myopia, Hyperopia, vision and models

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. ESFANDIARIJAHROMI, A. Ho, Brien Holden Vision Institute, Sydney, New South Wales, AUSTRALIA|A. Ho, School of Optometry and Vision Science, University of New South Wales, Sydney, New South Wales, AUSTRALIA|A. BACK, Vision CRC USA, California, UNITED STATES|

Commercial Relationships Disclosure: HASSAN ESFANDIARIJAHROMI: Commercial Relationship: Code N (No Commercial Relationship) | Arthur Ho: Commercial Relationship: Code N (No Commercial Relationship) | ARTHUR BACK: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Myopic defocus is considered a primary driver controlling myopia progression. Commercially available myopia control (MC) lenses incorporate positive powered lenslets in the treatment area and, through geometrical-based assumptions, are believed to produce a Net Myopic Defocus (NMD) at the retina. Utilising computer-based models and bench measurements we aim to verify the net focusing effect produced by several MC lenses.

Methods: Three MC lenses (Essilor Stellest™ and Hoya MiYOSMART™ spectacles, and Coopervision MiSight™ contact lenses) with comparable proportions of geometrically determined treatment areas were analysed. Designs were optically simulated in Zemax (-1.0 D). Simulations were converted to a power map with an aperture of 30 mm for spectacle lenses and 5 mm for the contact lens. Power map data was analysed using Matlab software to characterise the power across the apertures of lenses but excluding the central optical zones for the spectacle lenses. The average power of a sample of individual treatment regions were measured using the NIMO wavefront power profiler (Lambda-X, Nivelles). Hyperopic powers were subtracted from myopic powers for the calculation of NMD. The MTF was measured on an anatomically correct physical model eye (on-axis for the contact lens and off axis through the treatment region for spectacles) over a range of object vergences (-2.0 D to +5.0 D in 0.1 D steps) using a 5 mm pupil. The results were compared with the corresponding simulation to verify validity.

Results: The MTF confirmed good agreement between simulation and metrology (Figure 1). The MiSight lens showed a high NMD percentage for each analysis method (Table 1). However, both spectacles showed about equal distribution between myopic and hyperopic defocus in the optical analysis which differed substantially from the geometrical analysis of NMD where each treatment element is assumed to introduce only myopic focal points.

Conclusions: The distribution of defocus found with computer modelling and bench measurements were different to conventional geometrical based assumptions in the spectacle lenses studied. The NMD is substantially less than previously understood and the presence of hyperopic defocus was similar to myopic defocus in these spectacle designs. Animal and clinical trials using myopia control lenses incorporating myopic defocus and basing hypotheses on a geometrical rather than optical NMD may need to be re-evaluated.

Paulus: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Stem cell therapy offers a great promise for retinal degenerations which have no current effective treatments, including age-related macular degeneration and retinal pigmentosa. To achieve optimized treatment outcome, it is important to utilize non-invasive imaging technology to track the behaviors of stem cells after transplantation. This study describes a multimodal photoacoustic microscopy (PAM), optical coherence tomography (OCT), and fluorescence imaging for noninvasive and real-time monitoring of stem cells delivered into the subretinal space and follows their biodistribution, survival, migration, and differentiation longitudinally for up to 3 months.

Methods: A precursor human retinal pigment epithelial cell (ARPE-19) were labeled with ultrapure chain-like clusters gold nanoparticle (CGNP) conjugated with indocyanine green and RGD peptide at 100 μg/mL for 24 h. PAM images were acquired at 578 nm and 650 nm were overlaid on the same image plane and on the OCT image. Rabbits were treated with retinal laser photocoagulation to induce RPE injury and received subretinal injection of 30 μL (10^6 cells/ μL) labeled cells into the subretinal space and monitored before and at 1, 3, 7, 14, 21, 28 days, 2 and 3 months after transplantation. All animal studies were approved by the UM IACUC.

Results: PAM images obtained at 578 nm show hemoglobin in retinal vasculature with high contrast. PAM images acquired at 650 show the distribution of ARPE-19 cells in the subretinal space due to strong absorption of the internalized CGNPs inside the cells and minimal absorption of hemoglobin at 650nm. ICG fluorescence imaging correlated well with the 650nm PAM images initially but rapidly lost fluorescent signal after only 1 week. The transplanted cells localized to areas of photocoagulation injury by day 7 post-injection. Subretinal injection of labeled ARPE-19 cells enhanced fluorescent intensity by 39-fold post-injection, PA signal by 30-fold post-injection, and OCT intensity by 180% post-injection. Immunofluorescentanalysis indicated that ARPE-19 cells were effectively localized to areas of damage corresponding to multimodal in vivo imaging.

Conclusions: This study represents an advanced technique for long-term tracking of the transplanted cells using multimodal PAM, OCT, and fluorescence imaging with the assistance of CGNP.

ABSTRACT BODY:

Purpose: To study the influence of ultra-wide field (UWF) fluorescein angiography (FA) on the diagnosis and management of diabetic retinopathy (DR) when presented in addition to UWF color fundus and red free (CF/RF) images.

Methods: This cohort study was an online survey completed by experts who were asked to diagnose and manage DR cases based on different imaging modalities provided. Ten DR experts participated in the online survey. Experts independently reviewed 20 DR cases on a secure website and provided a diagnosis and management plan for each case, first based on UWF CF/RF images alone and again with the UWF CF/RF images and a corresponding UWF FA. Experts were also polled on their diagnostic confidence, their use of FA in clinical practice, and their opinions on the value of UWF FA in the cases presented. Primary outcomes included diagnostic sensitivity and specificity with and without the UWF FA based on the reference standard diagnosis. Secondary outcomes included intergrader agreement, expert confidence, management outcomes, and an analysis of experts' opinions on the clinical utility of UWF FA.

Results: Diagnostic sensitivity (95%CI) increased from 36% (29-43%) to 69% (62-75%, $p<0.05$) with the UWF FA. Intergrader agreement (Fleiss kappa statistic 0.29 [CI 0.21-0.27] vs. 0.44 [CI 0.40-0.47], $p<0.05$) and expert confidence (38% vs. 65%) also improved. Management changed from observation to treatment in 39% of responses. While 40% of experts did not request an FA when presented with UWF CF/RF images alone, 80% found the UWF FA

clinically useful when it was provided.

Conclusions: Diagnosis, treatment, and experts' opinions on the utility of FA all changed when a corresponding UWF FA was available. Incorporating UWF FA into clinical practice may improve DR grading accuracy, intergrader agreement, and expert confidence compared to diagnosis with UWF CF/RF images alone.

TITLE: Static perimetry over 2 years in the RUSH2A study: annual rates of change from mixed effects modeling

SESSION TITLE: Retinal Degenerations, Gene Therapy, Transplantation, and Prostheses

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.L. Duncan, Ophthalmology, University of California San Francisco, San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure: Jacque Duncan: Commercial Relationship(s);Code C (Consultant/Contractor):AGTC, DTx Therapeutics, Editas, Eyevensys, Gyroscope, Helios, Nacuity, Spark Therapeutics, SparingVision, ProQR Therapeutics, PYC Therapeutics, Vedere Bio II;Code F (Financial Support):Acucela, Allergan/Abbvie, Second Sight Medical Products, Biogen/Nightstarx Therapeutics, Neurotech USA;Code I (Personal Financial Interest):RxSight, Inc.

ABSTRACT BODY:

Purpose: Static perimetry (SP) provides quantitative measures of peripheral visual field in patients with inherited retinal degenerations (IRDs). There are few available estimates for rates of change in IRDs. Here we provide estimates of change over 2 years in 4 summary measures of SP from the Rate of Progression in USH2A-related Retinal Degeneration (RUSH2A) study using mixed effects models.

Methods: Participants with visual acuity ≥ 20/80, stable fixation, and kinetic visual field of ≥ 10° at baseline in the study eye had full-field static perimetry at baseline, 1, and 2 years. Summary measures were total hill of vision (V_{TOT}), hill of vision in the central 30° (V_{30}), V_{TOT}-V_{30} (V_{periph}), and mean sensitivity. Mixed effects models were used to estimate the annual rates of change and percentage rates of change using log transformed data with 95% confidence intervals. Models were applied to all eyes (N=102) and to a restricted group of eyes with baseline V_{TOT} > 5 dB-sr (N=88) to mitigate floor effects. A model excluding unreliable test results (false positives ≥ 15%) and a model down-weighting outlier rates of change were also applied to the restricted group.

Results: The average decline in V_{TOT} was 2.05 dB-sr/year (Table 1) or 8.3%/year (Table 2) in the entire cohort, but greater at 2.25 dB-sr/year or 8.8%/year in the restricted cohort. The average decline of V_{30} was 0.48 dB-sr/year or 5.2%/year in the entire cohort versus 0.56 dB-sr/year or 5.9%/year in the restricted cohort. The decline of peripheral visual field (V_{periph}) was 1.53 dB-sr/year or 16.0%/year in the entire cohort, and 1.68 dB-sr/year or 13.6%/year in the restricted cohort. The decline rate for mean sensitivity was 0.55 dB/year or 5.1%/year in the entire cohort and 0.60 dB/year or 5.4%/year in the restricted cohort. Excluding unreliable observations or down-weighting outliers reduced the estimated percentage of decline compared to using all eyes in the restricted cohort.

Conclusions: Estimates of the annual rates of decline of static perimetry measures were greater when the study cohort was restricted to eyes with room for worsening. The annual percentage change was greatest in V_{periph} after 2 years in eyes with USH2A-related retinal degeneration.

ABSTRACT BODY:

Purpose: To quantify patterns of threshold elevation under different light adaptation conditions throughout the macula in patients with retinitis pigmentosa (RP).

Methods: Nine subjects with RP (24 to 59 years old) and 10 visually-normal individuals (18 to 49 years old) participated. Threshold was measured at 7 locations along the horizontal meridian of the visual field (10^{o} nasal to 10^{o} temporal) using Goldmann size III targets. The field locations were grouped into three regions based on eccentricity from fixation: perifoveal (5^{o}-10^{o}), parafoveal (2^{o}) and foveal. Threshold was measured under DA conditions using long-wavelength stimuli and across a broad range of adaptation levels (DA to 50 cd/m^{2}) using short-wavelength stimuli. The relationship between threshold and adaptation level across the field was described using a standard "threshold-vs-illuminance" (TvI) model to derive absolute threshold (T_o), slope (n), and eigengrau (A_o). Repeated measures analysis of variance (ANOVA) was used to compare the three fit parameters between the two subject groups.

Results: Under DA conditions, thresholds for the short- and long-wavelength stimuli were similar throughout the visual field for 8 of 9 subjects, consistent with the cone pathway mediating threshold at all locations. Threshold elevation was greater for the RP subjects under DA and low adaptation conditions, compared to LA conditions. ANOVA indicated significantly elevated T_o and A_o for the RP subjects for each field location. The value of n was approximately independent of field location for the RP subjects and increased with eccentricity for the controls. This pattern resulted in significantly increased n in the fovea and significantly decreased n in the perifovea (both $p < 0.05$), with no significant difference in the parafovea ($p = 0.17$).

Conclusions: The approximately similar elevations in T_o and A_o for the RP subjects suggests that reduced quantal absorption may underlie threshold elevation throughout the macula in this cohort of RP subjects. Alternatively, the results may be attributed to the lack of rod function in these RP subjects, which would elevate DA threshold more than LA threshold.

ABSTRACT BODY:

Purpose: Our research focuses on investigating the utility of PD-OCT for imaging choroidal tumors in human eyes acquired in a clinical setting. Adaptive kernel-based DOPU images of lesions are compared to standard multimodal imaging techniques, including fundus photography, structural OCT, and fundus autofluorescence (FAF).

Methods: We used a custom-built swept-source OCT system for simultaneous detection of two orthogonal polarization signals over a >35° field-of-view (FOV). The melanin structures were segmented by measuring the polarization signal randomness with a novel adaptive kernel. The variability of this melanin specific measurement was assessed both longitudinally and across different demographics for healthy control subjects (N=10) to validate its quantitative measurement ability. In a clinic, two different types of patients, flat choroidal nevi (N=1) and elevated choroidal nevus (N=3) were imaged, and the DOPU contrast results were compared against standard imaging modalities for use in diagnosis and monitoring of pathology. The study received institutional ethics approval for human imaging.

Results: Selective identification of melanin using PD-OCT allowed accurate characterization of tumor dimensions and location within the choroid as shown in Figure 1. Fig. 1(a) shows overall morphological contrast, with the tumor visualized in (b)-(c) with DOPU contrast. Higher melanin concentration (red) signifies lesion presence against choroidal vasculature (blue). Blurring is seen in (b), whereas the adaptive kernel improves uniformity, and boundary and concentration estimates in (c).

Fig. 2(a) shows a healthy volunteer with uniform DOPU and clearly defined choroidal vasculature. Fig. 2(b) shows a flat nevus, highlighted in DOPU contrast by its melanin content in both en face and B-scan images, with a consistent RPE melanin signal. Fig. 2(c) shows a suspicious elevated nevus with associated subretinal fluid. Of note, there is RPE melanin signal loss in the B-scan.

Conclusions: Our proposed adaptive kernel-based DOPU process increases specificity and sensitivity of melanin molecule detection, with potential for improving choroidal tumor characterization, evaluation and follow-up over time.

TITLE: Inhibition of Ryanodine Receptor 1 Reduces Endoplasmic Reticulum (ER) Stress and Promotes ER Protein Degradation in Cyclic Nucleotide-gated Channel Deficiency

SESSION TITLE: Photoreceptor Biology, Protection and Degeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: X. Ding, F. Yang, H. Ma, The University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma, UNITED STATES|R. Garg, A.S. Lewin, University of Florida, Gainesville, Florida, UNITED STATES|

Commercial Relationships Disclosure: Xi-Qin Ding: Commercial Relationship: Code N (No Commercial Relationship) | Fan Yang: Commercial Relationship: Code N (No Commercial Relationship) | Hongwei Ma: Commercial Relationship: Code N (No Commercial Relationship) | Rekha Garg: Commercial Relationship: Code N (No Commercial Relationship) | Alfred Lewin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The cone photoreceptor cyclic nucleotide-gated (CNG) channel plays a pivotal role in cone phototransduction. Mutations in genes encoding the channel subunits CNGA3 and CNGB3 account for about 80% of all cases of achromatopsia and are associated with progressive cone dystrophies. CNG channel deficiency leads to cellular/endoplasmic reticulum (ER) calcium dysregulation and ER stress-associated cone apoptosis. This work investigated the role of the ER calcium channel ryanodine receptor 1 (Ryr1) in ER stress and cone degeneration in CNG channel deficiency.

Methods: The $Nrl^{-/-}$ and $Cnga3^{-/-}/Nrl^{-/-}$ mouse lines were used. The AAV-mediated CRISPR/SaCas9 genome editing was used to knockdown Ryr1 specifically in cones. Mice at postnatal day 5 (P5) received AAV2/5-SaCas9/gRNA-Ryr1 via subretinal injection ($4.4x10^9$ vg, 1.0 µl), and were analyzed for expression levels of Ryr1, cone specific proteins, ER stress markers, and ER retrotranslocation/ER-associated protein degradation (ERAD) proteins at P45-50 days, using western blotting and immunofluorescence labeling.

Results: The expression level of Ryr1 was increased in $Cnga3^{-/-}/Nrl^{-/-}$ retinas, compared with that in $Nrl^{-/-}$ controls. Treatment with AAV2/5-SaCas9/gRNA-Ryr1 nearly completely abolished this elevation. The expression level of cone arrestin (CAR) was reduced in $Cnga3^{-/-}/Nrl^{-/-}$ retinas, and treatment with the viral vector increased expression level of CAR by about 50%, compared with the vehicle-treated controls. The expression levels of the ER stress marker phospho-IRE1α and phospho-eIF2α were significantly elevated in retinas of $Cnga3^{-/-}/Nrl^{-/-}$ mice, and treatment with AAV2/5-SaCas9/gRNA-Ryr1 reversed these elevations. Furthermore, treatment with AAV2/5-SaCas9/gRNA-Ryr1 significantly increased expression levels of the ER retrotranslocation/ERAD protein E3 ubiquitin-protein ligase synoviolin 1 and degradation in ER protein 1 in $Cnga3^{-/-}/Nrl^{-/-}$ retinas, compared with the vehicle-treated controls.

Conclusions: This work demonstrates that Ryr1/ER calcium dysregulation contributes to ER stress/cone degeneration in CNG channel deficiency. The findings support strategies targeting ER calcium regulation to reduce cone degeneration.

TITLE: Influence of pupil and reading distance on aberrations induced by multifocal soft lenses in young myopic adults

SESSION TITLE: Refractive Error: Myopia, Hyperopia, vision and models

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Michaud, R. Marcotte-Collard, M. Malinowska, Optometry, Universite de Montreal, Montreal, Quebec, CANADA|

Commercial Relationships Disclosure: Langis Michaud: Commercial Relationship(s);Code F (Financial Support):Cooper VIsion ;Code C (Consultant/Contractor):VTI TEchnologies | Rémy Marcotte-Collard: Commercial Relationship: Code N (No Commercial Relationship) | Maja Malinowska: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To compare HOAs (total, spherical and coma) induced by 3 different soft multifocal lenses (SMFL) at different distances and to determine for each distance the relationship between the pupil diameter and HOAs vs lenses used.

Methods: Myopic young adults were randomly fitted with 3 types of SMFL (L1- Etafilcon A ; L2- Omafilcon A ; L3- Comfilcon A) . A 30 minutes break is observed between each test. Total HOAs, spherical aberrations (SA) and coma (C) are evaluated (OPD Scan, Nidek) without lenses, and while wearing each lens. Measurements are taken in distance vision, at 50 ,33 and 20 cm . The measurement of the pupil in dynamics was carried out with an open field refractor (Grand Seiko, Wam 5500) in photopic condition.

Statistical anlaysis was done by performing a two-factor within-subjects (3x4) repeated measures Anova. A post-hoc test is performed when significant differences are found. A Pearson correlation is established between aberrations, pupillary diameter, at each distance.

Results: The clinical population consisted of 9 M/18 F, aged 25.1 ± 1.6 years; being -2.75 ± 0.5 D. There is a significant increase in total HOAs with SMFL vs. naked eye . Every lens shows a reduction in HOAs with shorter reading distance.($F(2,54)=15.6$; $p < 0.01$; $\omega^2 = 0.151$) L3 demonstrates lower levels vs L1 and L2, statistically similar . There is a significant difference in total HOAs between all distances, except between 50 and 33 cm ($F(1,5 ;42,3)=30,4$; $p < 0.01$; $\omega^2 = 0,072$.) HOAs correlate strongly with pupil diameter ($r2 = 0.44$, $p <0.001$), for all lenses. SA seems to vary vs lens type. L3 generates less SA than L1 and L2, but this is not statistically significant. ($F(1.5; 41.6)= 3.0$; $p = 0.07$). SA is significantly reduced for all distances except between 50 and 33 cm (AS: $F(1.9; 49.3)=24.6$; $p < 0.01$; $\omega2 = 0.04$.) For C, the lens influences the results ($F(1,6 ;43,8)=8,7$; $p < 0.01$; $\omega2 = 0,13$.) L2 has lower levels than L1 and L3, the latter two being statistically similar.

Conclusions: Lens design and reading distance influence the levels of aberrations induced in the eye. In terms of design, the relationship of the add area vs. the pupil seems to be more important than the add power itself. For distance, it seems that reading at 20 cm reduces aberrations considerably. These results may influence how soft multifocal lenses are designed and used in a young adult myopic population.

ABSTRACT BODY:

Purpose:

To investigate the association between corneal hysteresis (CH) and obstructive sleep apnea (OSA) with regards severity of OSA based on apnea hypoxia index (AHI) and decibels of snoring.

Methods:

This is a cross-sectional observational study. We recruited patients who underwent sleep studies at Cook County Health. Each subject that agreed to participate underwent CH measurements using the Ocular Response Analyzer (ORA), Optical Coherence Tomography of the retinal nerve fiber layer (OCT RNFL), central corneal thickness measurements (CCT) measurements. Results of sleep studies were analyzed for AHI and mean decibels of snoring. ORA measurements were performed on each eye three times and results with a wave-front score <5.5 were excluded. Demographic information including age, gender, and race was collected. Patients were grouped by severity of OSAS as either normal/mild or moderate/severe. Data was analyzed with an ANOVA analysis for all factors recorded.

Results:

A total of 14 eyes have been analyzed, 8 eyes from patients with no or mild OSAS and 6 eyes from patients with moderate or severe OSAS. Patients in the none/mild OSAS group had an average CH of 10.8, patients in the moderate/severe OSAS group had an average CH of 9.1 (p=0.06). Patients were also analyzed to assess for a relationship between CH and decibles of snoring and showed a trend toward a negative correlation between increasing CH and decreasing decibles of snoring (p=0.08). There was no significant difference between groups in regards to average IOP (none/mild OSAS, moderate/severe OSAS: 17.1,17.2, p=0.95) or CCT (547, 522, p=0.14)

Conclusions:

CH had a negative correlation with the severity of OSA, as well as a negative correlation with decibels of snoring. This is potentially attributable to the previously identified upregulation of matrix metalloprotease expression in tissue of patients with OSA and the increased risk of glaucoma in patients with OSA, both of which are associated with lower CH. Another mechanism hypoxia

ABSTRACT BODY:

Purpose: Recognizing a posterior vitreous detachment (PVD) is important for pre-surgical planning and risk-stratification for retinal tears and detachment. Deep learning (DL) methods of optical coherence tomography (OCT) images have been trialed on several retinal diseases to assist diagnosis; however, reliable models capable of detecting PVD have not been established. Our studies aim to develop reliable computer algorithms for automated detection of PVD on OCT images.

Methods: Consecutive OCT volumetric scans of 800 eyes obtained with Heidelberg Spectralis from November 2020 to October 2021 were retrospectively reviewed. Eyes with poor image quality or history of pars plana vitrectomy were excluded. Four trained graders individually labeled the PVD status of each eye by reviewing the entire volume B-scans, in addition to the horizontal and vertical raster scans. A second review was performed by an expert grader if consensus review was needed.

Two computer algorithms were developed. A customized computer vision algorithm based on image filtering and edge detection was designed to localize the posterior hyaloid and identify the presence or absence of a complete PVD in OCT volume scan. A second DL image classification model based on ResNet-50 architecture was trained to detect PVD status on OCT.

Results: Both the customized algorithm and DL model detection results were largely in agreement with the PVD status labeled by trained graders, with the customized algorithm surpassing the DL model in F1-scores for per-volume PVD detection. The accuracy of the customized algorithm and DL model was 85.57%, and 76.90%, respectively. The sensitivity of the customized algorithm and DL model was 78.21% and 86.09%, while the specificity was 93.62% and 70.45%, respectively (Table 1).

Conclusions: Using both traditional computer vision and deep learning approaches, we successfully developed reliable models to recognize PVD status on OCT images, demonstrating the potential for automated image classification to detect vitreoretinal pathologies and assist with pre-surgical planning. Further optimization of the two algorithms are currently in process with plans for validation using a prospective, independent data set.

ABSTRACT BODY:

Purpose: To analyze the longitudinal changes in functional and imaging parameters in eyes with acute or chronic central serous chorioretinopathy (CSCR) over a minimum of 10 years.

Methods: This was a retrospective, multicentric, longitudinal, observational study in patients with a diagnosis of unilateral or bilateral CSCR. Trend in best-corrected visual acuity (BCVA), choroidal thickness (CT), area of double-layer sign (DLS), area of retinal pigment epithelium (RPE) alterations, and area of hyper-autofluorescence were analyzed.

Results: A total of 23 eyes of 16 patients (10 males and 6 females) were included in the study. The mean duration of symptoms prior to presentation was 20.6±50.6 months.

A slow worsening was seen in the chronic CSCR group, while it was relatively stable in the acute CSCR group (baseline 0.11±0.19 logMAR to final 0.08±0.13 logMAR in acute and baseline 0.31±0.47 to final 0.38±0.48 logMAR in chronic CSCR eyes). The trend in CT was more or less stable with a mild decrease in both acute and chronic CSCR groups over time (overall baseline 325±62.5 microns to final 314.8±71.8 microns). There was a slow rise in the area of RPE alteration and in a hyper-autofluorescent area in both acute and chronic CSCR with no overlap. However, there was a late dip in the values of hyper-auto-fluorescent areas. Duration of symptoms was significantly associated with poor final visual acuity in multivariate analysis.

Conclusions: Acute and chronic CSCR had different pattern of change in functional and imaging parameters. This could indicate a non-temporal relationship between acute and chronic CSCR forms.

ABSTRACT BODY:

Purpose: To explore the effects of long-term usage of atropine 0.01% eye drops on spherical and cylindrical refractive errors in myopic Chinese children.

Methods: This study was a single-center randomized clinical trial. Children with myopia less than -6.0 D and refractive astigmatism (RA) less than - 2.0 D were enrolled and randomized to receive atropine 0.01% once nightly with single vision lenses or simply wear single vision lenses, then followed up every three months. Cycloplegic refraction and ocular biometric measurement of axial length and corneal curvature were obtained. The magnitude and direction of RA, corneal astigmatism (CA), and internal astigmatism (IA) were also evaluated during treatment.

Results: A total of 119 eyes (69 eyes in the atropine group and 50 eyes in the control group) were included in the final analyses at the 9-month visit. The atropine-treated eyes showed significantly less progression of myopia than those in the control eye (spherical equivalent: -0.35 ± 0.33 D vs. -0.56 ± 0.49 D, $P = 0.001$ and axial length: 0.20 ± 0.19 vs. 0.33 ± 0.19 mm, $P < 0.001$). Compared with the control eyes, a statistically significant increase of RA was observed in the atropine-treated eyes (-0.14 ± 0.29 D), which was mainly attributed to the increase of CA (-0.17 ± 0.26 D), instead of a minor decrease of IA (0.02 ± 0.32 D).

Conclusions: Atropine 0.01% is effective for preventing the progression of myopia and has potential effects on increasing refractive astigmatism in myopic Chinese children over 9 months of treatment.

ABSTRACT BODY:

Purpose: Plaquenil (hydroxychloroquine, HCQ) is a highly effective drug which can cause maculopathy even after discontinuance. 2016 AAO guidelines (https://www.aao.org/clinical-statement/revised-recommendations-on-screening-chloroquine-h;) dismiss color vision testing as insensitive and non-specific. We question this assertion with new information exemplifying sensitivity of cone color testing for detecting HCQ toxicity.

Methods: Three patients referred by retinal specialists were assessed in our Visual Neurophysiology Service (VNS) for HCQ toxicity. Testing included refraction to best VA, Humphrey (HVF) central fields (10-2 SITA-Standard), spectral domain ocular coherence tomography (SD-OCT), multifocal electroretinograms (mfERGs; ISCEV standard www.iscev.org) which provide cone and cone bipolar cell function from multiple retinal sites, fundus autofluorescence (FAF), and cone specific contrast sensitivity (CS, Innova Systems, Inc.).

Results: An asymptomatic 71-YO HF with Rheumatoid Arthritis was taking 200mg HCQ daily for 20 years (total dose 1,460g). VA: 20/15 OD, OS, FAF: enhanced macular pigment mottling OU, HVF: parafoveal sensitivity loss, SD-OCT: inner retinal thinning OS>OD, mfERGs: reduced foveal & parafoveal >OS, CCT: borderline L cone CS, decreased M cone CS, OS>OD. A 50-YO HF with Systemic Lupus Erythematosus (SLE) took 400mg HCQ per day for 17 years (total dose 2,482g; FAF featured in: https://doi.org/10.3899/jrheum.181375). VA: 20/25 OD, OS, HVF: parafoveal scotomas OS>OD with nasal extension OS, SD-OCT: significant full-thickness macular thinning, foveal sparing OD only, FAF: Bull’s eye pattern of degeneration extending temporally OS consistent with HVF and mfERG results, CCT: significant decrease all cones, >OS. A 73-YO WF with SLE taking 200mg HCQ daily for 20 years (total dose 1,424g) reported decreased color vision for 5 years. VA: 20/30 OD, 20/40 OS, HVF: parafoveal loss OD and central loss OS, SD-OCT: diffuse foveal thinning OU, IS/OS deformities, “flying saucer” OD, FAF: Bull's eye maculopathy OS>OD, mfERGs: decreased centrally OS>OD, increased fovea/ring 2 ratio OU, CCT: severe CS loss all cone types.

Conclusions: Cone CS can be reduced in various stages of HCQ maculopathy, and its decrease can even constitute the only presenting symptom. We advocate its use for adjunctive testing of HCQ patients and plan prospective and retrospective studies to confirm its efficacy.

ABSTRACT BODY:

Purpose: We previously reported that microRNA (miR) 16-5p were increased in tears of patients with Sjogren's syndrome compared to controls. In this study, we intend to investigate the effect of topical miR-16-5p mimic and inhibitor in a mouse model of inflammation-related dry eye syndrome.

Methods: We used 11-week-old NOD.B10.H2b mice, a model for primary Sjögren's syndrome. We measured baseline ocular staining score and tear production. And we topically applied miR-16-5p mimic, miR-16-5p inhibitor or the same volume of phosphate-buffered saline (PBS) four times a day for 1 week to both eyes of the mice. Seven days later, tear production was measured, and the corneal surface was observed for epithelial defects. The number of goblet cells was evaluated in the forniceal conjunctiva. The levels of proinflammatory cytokines were analyzed in the cornea, conjunctiva, and lacrimal glands.

Results: Topical miR-16-5p mimic increased ocular staining score in NOD.B10.H2b mice than PBS. And topical miR-16-5p inhibitor administration improved tear production and reduced corneal epithelial defects. The conjunctival goblet cell density was higher in miR-16-5p inhibitor treated eyes than in miR-16-5p mimic or PBS treated eyes. Mir-16-5p mimic increased the expression of proinflammatory cytokines in the cornea, conjunctiva, and intraorbital gland and miR-16-5p inhibitor suppressed them.

Conclusions: Inhibition of miR-16-5p had the effect of protecting the ocular surface and suppressing inflammation.

ABSTRACT BODY:

Purpose: Uncorrected refractive error (URE) is common among U.S. youth. We aimed to understand how youth perceive eyesight compared to other aspects of their health, as valuing vision highly could facilitate treating URE.
Methods: An open-ended 5 question poll was distributed to the MyVoice Text Message Cohort of U.S. youth aged 14–24 years (www.hearmyvoicenow.org). Question 1 asked, “How important is your eyesight compared to other aspects of your health? Why?” Respondents’ demographic information was analyzed. Low socioeconomic status (SES) was defined as receiving free or reduced-price lunch. Text message responses were coded with modified Grounded Theory.
Results: Of 1204 recipients, 1063 (88.3%) responded. Mean age was 20.3 ±2.4 years (range 15-24 years); 625 (58.8%) were male; 787 (74.0%) were white; and 440 (41.4%) had low SES. Over half (n=609, 57.3%) reported eyesight was very important, 296 (27.8%) reported it was somewhat important and 90 (8.5%) reported that it was not important. Nearly half (n=507, 47.7%) reported eyesight was needed for daily life (e.g. “sight is one of the most important aspects of my health because in our time everything is technology and images”), 152 (14.3%) discussed personal or family experiences with vision problems (e.g. “very important, I've had two blind family members and I am hard of hearing so if my vision goes I'm very screwed”), and 68 (6.4%) expressed fear of developing eye problems (e.g. “very [important], I would be severely depressed if I lost [my eyesight]”).
Conclusions: U.S. youth value vision highly compared to other aspects of their health, yet there are high rates of URE in this population. Future research should focus on identifying barriers to eyeglasses.

ABSTRACT BODY:

Purpose: To measure the photoreceptor response in rodent eyes using phase-sensitive optical coherence tomography (OCT)To measure the photoreceptor response in rodent eyes using phase-sensitive optical coherence tomography (OCT)

Methods: Six Brown-Norway rats (age = 6 weeks) were used for this study. The animals were dark-adapted for 12 hours before being anesthetized using a cocktail of ketamine and xylazine. They were placed on a translational stage with 5 degrees of freedom, and the head was stabilized stereotaxically. A customized spectral-domain OCT system (central wavelength = 840nm, bandwidth = 145 nm) was applied to image the posterior eye, with a field of view of 20 degrees. A single cross-sectional position was traced temporally for 5 seconds, and at t = 1 second, a single 1ms visual stimulus (wavelength = 500 nm) was delivered to create a large and Maxwellian illuminance on the retina. The temporally sequenced cross-sectional OCT scans were registered, and the hyperreflective bands from inner segment and out segment of the photoreceptors were segmented automatically. The phase difference between the two layers was computed and traced over time.

Results: Visual stimulus-evoked nanoscopic photoreceptor response can be detected by phase-sensitive OCT, which is reproducible over different spatial locations on the retina (intra-class coefficient = 0.84). Stimuli with a bleach rate of 0.3% were associated with a transient optical path length change of 48.2 ± 16.4 nm. Signals from underneath retinal blood vessels decorrelated over time, likely due to the influence of the blood flow.

Conclusions: Phase-sensitive OCT provides a novel non-invasive approach to study photoreceptor response in rodents, and the current framework could be applied to investigate different animal disease models with photoreceptor abnormalities.

ABSTRACT BODY:

Purpose: The prevalence of peripheral retinal findings is unclear. We assess the prevalence of peripheral retinal abnormalities in retinal patients in an academic setting to understand how they associate with retinal diagnoses.

Methods: We performed a retrospective, observational clinical study. Ultra-widefield images (Optos P200DTx) were collated from the right eyes of consecutive retina clinic patients with demographic data attending Shiley Eye Institute, UCSD between 1st January and 30th November 2021. Images were included with unobstructed views of >60% of each quadrant and visibility of fourth order arterioles. The images were examined by a masked retinal specialist who recorded abnormal peripheral findings by quadrant (Fig, 1). Statistical analysis was performed using R software with fitted logistic regression models testing each peripheral change. Pearson's Chi-squared test was used for samples lacking logarithmic power.

Results: A total of 556 images were collated. After initial quality control, 312 patient images (mean age 61.9±19.5 years, 55.1% female) were analyzed. 152 (48.7%) patients had peripheral pathology, most commonly in the temporal quadrant. The most common peripheral findings were drusen (n=73, 23.4%) and laser marks (n=28, 9.0%). Diabetic retinopathy (DR) was associated with peripheral blot hemorrhages (P<.001), dot hemorrhages (P<.001), laser marks (P=.002), pigmentation (P=.049) and sclerosis of vessels (P<.001). Age-related macular degeneration (AMD) was associated with peripheral drusen (P=.001). Age was associated with general degeneration including chorioretinal atrophy (P<.001)(Fig. 2).

Conclusions: Peripheral retinal findings were common in our retinal patients, drusen being most prevalent. The findings were validated by associations of DR with common DR peripheral findings. AMD was correlated with drusen, validated by recent literature. New correlations between DR and pigmentation and vessel sclerosis need to be further investigated. This data is useful to retinal specialists using ultra-widefield imaging and can provide a platform for training AI algorithms in detecting peripheral pathology in ultra-widefield imaging.

TITLE: Sebaceous cell carcinoma presenting as an ocular Marjolin ulcer following exposure to a common alkaline cleaning agent

SESSION TITLE: Ocular tumors sans uveal melanoma and retinoblastoma

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B.W. Lee, M. Coroneo, Ophthalmology, University of New South Wales, Sydney, New South Wales, AUSTRALIA|D. Murrell, Dermatology, University of New South Wales, Sydney, New South Wales, AUSTRALIA|S.F. Taylor, Ophthalmology, The University of Sydney School of Medicine, Sydney, New South Wales, AUSTRALIA|A. Gal, Pathology, Histopath Diagnostic Services, Sydney, New South Wales, AUSTRALIA|

Commercial Relationships Disclosure: Brendon Lee: Commercial Relationship: Code N (No Commercial Relationship) | Simon Taylor: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Gal: Commercial Relationship: Code N (No Commercial Relationship) | Dedee Murrell: Commercial Relationship: Code N (No Commercial Relationship) | Minas Coroneo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Marjolin ulcer is a rare and aggressive malignancy that originates from chronically inflamed, ulcerated, or scarred tissue. The potential for malignant transformation of ocular surface chemical injuries to a Marjolin ulcer is not well recognised. In fact, this progression may be accelerated by the immunosuppressive treatments often utilised to control the post-burn cicatrising process.

Methods: A 67-year-old, healthy and non-smoking, Caucasian lady presented with a 2 year history of pain, redness, tearing, and blurred vision in her right eye. She had suffered an alkaline burn of the right eye 4 years ago from a household cleaning agent. Right visual acuity was 6/400. Examination showed marked ocular surface disease and cicatrising conjunctivitis. Initial conjunctival biopsies returned negative for malignancy. Topical and systemic immunosuppression was underwent symblephara excision and amniotic transplantation. She eventually developed microbial keratitis and underwent an evisceration due to corneal perforation. Histopathological analysis showed high grade, poorly differentiated invasive sebaceous cell carcinoma with pagetoid intraepithelial spread and staining for BerEP4 and CK7 (Figure 1). To achieve tumor extirpation, an anterior exenteration was performed. No evidence of recurrence or metastasis was seen for 36 months.

Results: This is the second case of a sebaceous cell carcinoma Marjolin ulcer in the literature. We believe the theory most pertaining to an ocular Marjolin ulcer revolves around a co-carcinogen concept where the initial burn or injury acts to increase tissue susceptibility to other carcinogens such as ultraviolet radiation.

Conclusions: The potential for malignant transformation of ocular and pericoular chemical injuries into Marjolin ulcers needs to be recognised. Sebaceous cell carcinomas should be included in the potential spectrum of histopathology subtypes. We recommend that patients with previous chemical ocular burns, especially those initiated on immunosuppressive therapy, should be carefully evaluated, monitored, and counselled for the potential risk of Marjolin ulcer development.

ABSTRACT BODY:

Purpose: The hallmark of non-arteritic anterior ischemic optic neuropathy (NAION) is vascular compromise to the anterior optic nerve and peripapillary retinal nerve fiber layer (pRNFL) thinning and secondary degeneration of the retinal ganglion cell (RGC) body or macular ganglion cell complex (mGCIPL) thinning. This study investigates OCT and OCTA changes in chronic NAION and identifies imaging biomarkers that best predict disease.

Methods: We performed a retrospective cross-sectional study of 15 chronic NAION patients (20 eyes) and 23 age-matched controls (31 eyes) with swept-source (PLEX® Elite 9000) and spectral-domain OCT imaging, and static perimetry using Humphrey Field Analyzer (all instruments from Carl Zeiss Meditec, Inc, Dublin, CA). OCT pRNFL and mGCIPL were quantified automatically with commercial software, and OCTA were analyzed using custom MATLAB script to measure 12 parameters per eye after large vessel removal: vessel area density (VAD), flux, vessel skeleton density (VSD), vessel complexity index (VCI), vessel perimeter index (VPI), and vessel diameter index (VDI).

Results: Static perimetry mean deviation (MD) was significantly worse in NAION (-13.53 ± 2.36) than controls (-0.47 ± 0.72; $P < .001$), with 64 µm thinner pRNFL and 39.7 µm thinner mGCIPL in NAION eyes than controls ($P<.001$). Spearman correlation analysis show that VAD and flux are highly correlated with visual field MD and OCT measurements. Hierarchical clustering of OCT and OCTA data showed two distinct groups (NAION and control), where standardized measurements for NAION were generally lower than controls. Two-way mixed ANOVAs showed significant interaction between patient status (control and NAION) and structure (optic disc and macula) for annulus VAD and flux values and mean pRNFL and mGCIPL thickness. Post hoc tests showed this effect stems from lower peripapillary values in NAION than controls. Separate logistic regression models with LASSO regularization identified peripapillary VAD, VCI and VDI and macular VAD and flux as the best OCTA parameters to predict NAION.

Conclusions: Ischemic insult to the peripapillary region is more severe likely from primary degeneration while macula is affected by secondary retrograde degeneration and loss of RGC. Other than structural OCT measurements, peripapillary and macular vascular parameters such as VAD, flux, VCI and VDI are good predictors of optic nerve and retinal changes as a result of NAION.

TITLE: Perceived utility of intervention strategies for improving medication adherence in glaucoma

SESSION TITLE: Glaucoma epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Poleon, The University of Alabama at Birmingham School of Optometry, Birmingham, Alabama, UNITED STATES|L. Racette, The University of Alabama at Birmingham Department of Ophthalmology and Visual Sciences, Birmingham, Alabama, UNITED STATES|

Commercial Relationships Disclosure: Shervonne Poleon: Commercial Relationship: Code N (No Commercial Relationship) | Lyne Racette: Commercial Relationship(s);Code C (Consultant/Contractor):Olleyes

ABSTRACT BODY:

Purpose: Interventions for improving medication adherence in glaucoma have had equivocal results due in part to a lack of stakeholder input. Incorporating patient and provider perspectives into intervention design may improve their ability to target key determinants of adherence. We assessed the perceived utility of the most effective interventions identified in the literature by sampling perspectives of glaucoma patients and providers.

Methods: We performed a literature review to identify studies that delivered interventions for improving adherence, and included only studies that used electronic monitoring and had at least three months of follow-up. We categorized the interventions based on the strategies delivered: education, reminders, motivational interviewing (MI), health coaching, instillation skill training, and combination vs polytherapy. We invited patients and providers to assess the utility of each strategy in day-to-day glaucoma management using a 4-point Not Useful to Very Useful Likert scale. We also used the Glaucoma Treatment Compliance Assessment Tool to assess patients' perceived glaucoma severity, susceptibility, treatment benefits, treatment barriers, and glaucoma knowledge. Patients (n = 13) were above age 40, used ocular hypotensive eyedrops, and had glaucoma for at least 2 years. Providers (n = 5) were optometrists or ophthalmologists who had at least 2 years' experience treating glaucoma.

Results: Only four strategies—education, reminders, MI, and health coaching led to a significant increase in adherence. For patients, education (median, IQR = 4.0, 0.25), health coaching (3.0, 1.0), and reminders (3.0, 2.0) had the highest utility, compared to MI (4.0, 0), reminders (3.7, 0.33), and education (3.5, 0.25) among providers. Higher glaucoma knowledge was associated with a preference for education (rho = .603, p = .03), and higher perceived glaucoma severity was associated with a preference for reminders (rho = .626, p = .02), instillation skill training (rho = .754, p = .003), and MI (rho = .754, p = .003).

Conclusions: The most effective strategies based on empirical data—education, reminders, MI, and health coaching—had the highest perceived utility in day-to-day management of glaucoma. Incorporating patient and provider perspectives into intervention design may improve their uptake and effectiveness, ultimately resulting in improved medication adherence in glaucoma.

ABSTRACT BODY:

Purpose: Recent developments in optical coherence tomography (OCT) have demonstrated single acquisition widefield imaging with an optical field of view (FOV) of up to 90°. The purpose of this study is to evaluate the previously developed OCT volume dewarping and normal incidence method, for the measurement of retinal and choroidal thickness maps in human eyes.
Methods: Our previous work (IOVS, Vol. 61, PB00103, 2020) has demonstrated that dewarping and measuring normal to the retinal pigment epithelium layer is a crucial step when analyzing structure and shape of the retina. The mathematical model predicted the results to be dependent on the retinal curvature and to increase as a function of FOV.

In this study we compare retinal and choroidal thickness measurements of 12 healthy right eyes of 12 subjects before and after applying the dewarping and normal incidence method. For each eye we have acquired 12x12 mm OCT volumes with 3 mm scan depth using PLEX® Elite 9000 (ZEISS, Dublin, CA). Axial eye length is needed for the dewarping algorithm and is measured using IOL Master® 500 (ZEISS, Jena, Germany).
Results: The relative difference between thickness measured along an A-scan and thickness measured using the dewarping and normal incidence method ranges between 0% and 4% for 12x12 mm OCT volumes which is consistent with the mathematical prediction. Furthermore, the difference varies in magnitude for every individual eye and increases with FOV. Figure 1 shows the results for all 12 human eyes.
Conclusions: Measurement of human eyes has confirmed that the dewarping and normal incidence method results in thickness maps that are different from the thickness maps calculated along A-scans. The range of differences measured in human eyes matched the previously published mathematical prediction. The results further confirmed that the magnitude of the difference increases with FOV and is different for every individual eye.

TITLE: The role of actin binding protein in the formation of cross-linked actin networks (CLANs) in trabecular meshwork cells

SESSION TITLE: Glaucoma: biochemistry, biomechanics and omics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Dai, N. Rayana, C.K. Sugali, W. Mao, Ophthalmology, Indiana University Department of Ophthalmology, Indianapolis, Indiana, UNITED STATES|W. Mao, Department of Biochemistry & Molecular Biology, IU, Indianapolis, Indiana, UNITED STATES|

Commercial Relationships Disclosure: Jiannong Dai: Commercial Relationship: Code N (No Commercial Relationship) | Naga pradeep Rayana: Commercial Relationship: Code N (No Commercial Relationship) | Chenna Sugali: Commercial Relationship: Code N (No Commercial Relationship) | Weiming Mao: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Cross-linked actin networks (CLANs) are a type of F-actin structure frequently found in glaucomatous trabecular meshwork (TM) cells and tissues. Also, TM cells form more CLANs after being treated with glaucoma-associated agents including TGFβ2 and glucocorticoids. Our recent studies showed that CLANs increase TM cell stiffness, decrease actin dynamics, and inhibit phagocytosis, which are very likely to contribute to elevated intraocular pressure. We previously showed that overexpression of a subset of calcium binding proteins increased CLANs formation. In this study, we determined the effect of gene knockdown of these proteins in primary human TM (pHTM) cells.

Methods: Primary HTM cells were first transfected with different siRNAs against caldesmon, calponin, tropomyosin and/or myosin light chain overnight. Non-targeting (NT) siRNA was used as a control. After siRNA transfection, the cells were treated with 5ng/ml TGFβ2 to induce CLAN formation for 6-7 days. At the end of treatment, the cells were fixed for immunostained with phalloidin-Alexa-568 and DAPI. The CLAN-positive cells (CPCs) over total number of cells per well was calculated and one-way ANOVA was used for analysis.

Results: The percentage of CPCs in the NT-siRNA control group was 13.5% and 21.5% in two different cell strains, respectively (N=4 for each strain). Knocking down of caldesmon, calponin, myosin light chain, or all four proteins (combo) showed a trend of inhibition of CLAN formation but it was not significant (likely due to small Ns). In contrast, the CPCs almost doubled in the tropomyosin knockdown group (24.6% and 45.9%, respectively; $P<0.05$ for both strains).

Conclusions: Our previous gain-of-function study showed that overexpression of tropomyosin did not affect CLANs. In this loss-of-function study, we found that tropomyosin knockdown enhanced CLANs. Therefore, tropomyosin is likely to be necessary, but not sufficient, for CLANs formation.

ABSTRACT BODY:

Purpose: Optical coherence tomography angiography (OCTA) is a relatively novel technology that continues to improve, but variation in image quality remains problematic for reliable image analysis. We developed a deep learning-based system using convolutional neural networks for automated quality assessment of optical coherence tomography (OCTA) images.

Methods: We performed a single center, retrospective study of diabetic patients from August 2017 to April 2019. OCTA imaging with the Cirrus HD-OCT 5000 AngioPlex was performed. Manual grading of image quality was performed on 8x8 mm and 6x6 mm superficial slab images by two independent graders. An image quality score was assigned based on presence of motion and segmentation artifacts, media opacity, and visibility of fine capillaries. Machine-reported signal strength was also recorded. Each image was assigned a final image quality score from 0 to 4 based on a composite assessment from both graders. A ResNet152 neural network classifier pretrained using ImageNet was trained to classify the images. Because requirements for image quality may vary depending on the clinical or research setting, two models were trained – one to identify highquality images and one to identify low-quality images.

Results: 347 scans from 134 patients were included. Our neural network models demonstrated outstanding area under the curve (AUC) metrics for both low quality image identification (AUC=0.98, 95%CI: 0.96-0.99, κ=0.88) and high quality image identification (AUC=0.99, 95%CI: 0.99-1.00, κ=0.92), significantly outperforming machine-reported signal strength (AUC=0.78, 95%CI: 0.73-0.83, κ=0.27 and AUC=0.82, 95%CI: 0.77-0.86, κ=0.52 respectively).

Conclusions: Deep convolutional neural networks featuring skip connections were successfully trained to automatically classify between gradable and ungradable OCTA images, and have been made publicly available as a resource to other physicians and scientists. As OCTA becomes more widely utilized, flexible and robust methods for image quality control will be important.

ABSTRACT BODY:

Purpose: The presence of hyper-reflective foci (HRFs) in the outer retina has been associated with age-related macular degeneration (AMD) and diabetic retinopathy (DR). We have previously employed a deep-learning (DL) model to perform semantic segmentation of HRFs. Here, we conducted a retrospective, observational clinical study to identify a ground truth for the DL model using manual segmentation.

Methods: Optical Coherence Tomography (OCT) images were retrieved of patients who received care at the retina service at the University of Bonn. The dataset included 3644 OCT (3044 AMD & 600 DR) images. Two separate teams of graders reviewed the images; team A consisted of one ophthalmologist, and team B consisted of a medical student and ophthalmologist. ImageJ was used to manually annotate the boundaries of HRFs found in the outer nuclear and/or outer plexiform layers for each OCT image. We measured the variability of manual segmentation of HRFs between two sets of graders and evaluated the accuracy of the DL model compared to manual segmentation by both teams.

Results: Overall, fewer HRFs were marked by the team B compared to team A; in fact, there were images where no HRF was annotated by the team B. Out of 3644 images, 3557 images (97.6%) had annotations which matched across both teams. When excluding images with zero overlap, the average intersection over union (IoU) was 0.285, and the average precision (AP) was 0.343 measured over 2303 images. When the DL model was trained with annotations by team A as the ground-truth, the IoU was 0.33, and the AP was 0.75. When the DL model was trained with the annotations by team B as the ground-truth, the IoU was 0.53, and the AP was 0.78.

Conclusions: There was considerable variability in the manual annotation of HRFs by the two teams of graders. This may be due to a low signal-to-noise ratio in several OCT images and challenges in delineating the outer retina from adjacent structures. A higher IoU was noted in the second set of annotations due to conservative delineation of HRFs and a larger team size. Therefore, a DL approach is essential for accurate and precise segmentation of biomarkers such as HRFs in OCT images.

ABSTRACT BODY:

Purpose: Manual segmentation of early AMD features and associated retinal layers in SD-OCT images is tedious and time-consuming. Using only 5 OCT volumes of the ALSTAR cohort, we trained our existing deep-learning derived, graph-based algorithm to segment the outer-retinal layers in eyes with early AMD. Our goal was to evaluate the accuracy of this algorithm in ALSTAR2 cohort compared with manual segmentation.

Methods: Subjects ≥ 60 years old with healthy eyes or early AMD in at least one eye were enrolled in the Alabama Study on Early Age-Related Macular Degeneration 2 (ALSTAR2). Eye-tracked SD-OCT volumes (8.6x7.2mm, ART > 9, fovea centered) were acquired with Spectralis HRA + OCT2. The outer-retinal layers [inner segment myoid (ISM) (defined to span from the external limiting membrane to ellipsoid zone (EZ) center line), photoreceptor outer segment (EZ center line to outer surface of interdigitation zone), subretinal drusenoid deposits (SDD), retinal pigment epithelium (RPE), drusen, full choroid] were segmented manually by expert graders and fully automatically by our algorithm. Based on these segmentations, mean thickness, total volume, and total area of the 6 layers were computed in 9 ETDRS subfields, and mean measurement difference and correlation coefficients were calculated.

Results: The study cohort included 400 eyes (140 early AMD, 260 normal). The mean difference and correlation coefficients between segmentation methods are shown in Table 1. In general, mean thickness differences for most layers were <1μm (choroid by ~5-7μm) with a significant correlation between the automated and manual measurements for ISM, photoreceptor outer segments, RPE, and choroid layers. Correlations were not as good for drusen and SDD layers.

Conclusions: A deep-learning derived algorithm has promise in segmenting hyporeflective bands of ISM, photoreceptor outer segments, RPE, and choroid in normal and early AMD eyes. Further algorithm training using more OCT volumes with drusen and SDD lesions may be required to improve algorithm performance, and further statistical analysis is planned.

ABSTRACT BODY:

Purpose: A reliable blood supply to the optic nerve neural tissues is essential to prevent damage and vision loss. At the lamina cribrosa (LC) this is achieved by a complex network of capillaries intertwined with collagen beams. Conventional understanding has been that LC blood perfusion originates from the posterior ciliary artery (PCA) at the periphery of the canal and drains into the central retinal vein. To better understand the LC perfusion and potential challenges to perfusion that could lead to ischemia we map the LC 3D vasculature

Methods: The vasculatures of six normal monkey eyes were labelled post-mortem by perfusing lipophilic carbocyanine dyes through the carotid arteries. After enucleation serial coronal cryosections 16μm thick through the LC were imaged using fluorescence and polarized light microscopy to visualize the labeled vessels and label-free collagen, respectively. The collagen structures were registered and used to identify the LC and form an image stack from which the fluorescence was segmented to reconstruct the 3D vascular network. We performed both quantitative and qualitative analyses of the LC vessels

Results: Three of the six eyes exhibited vessel branches directly from the central retinal artery (CRA) to the LC (Fig 1). A watershed analysis revealed distinct perfusion regions for the initial branching levels, after which the vessels interconnected with the rest of the LC vascular network. The LC vessels were heavily interconnected with the adjacent vasculature (Fig 2). For example, in one eye there were 1100 anastomoses between the LC vessels and the exterior. The largest number of anastomoses was with the retro-laminar region (479), followed by the periphery (409), the pre-laminar region (159) and the central vessels (53). A substantial fraction (>20%) of neural tissues were further than 40μm from vessels, and thus at higher risk of ischemia

Conclusions: The LC vascular network is heavily interconnected with the PCA, but also with the CRA and with the pre- and retro-laminar regions. We postulate that multiple potential perfusion sources provide redundancy that can help protect tissues from compromised perfusion and ischemia, at all levels of IOP, particularly for tissues further away from the vasculature. More work is necessary to map more eyes, and develop the technology to measure LC blood flow and perfusion

ABSTRACT BODY:

Purpose: Lifestyle and dietary factors affect health and disease. A traditional Mediterranean diet, rich in unsaturated fats and oils, is often purported as a healthy diet. This study tested the hypothesis that a greater adherence to a Mediterranean diet is associated with a lower risk of dry eye disease (DED).

Methods: 58,993 participants from the Dutch Lifelines population-based cohort were included (aged 20-94 years, 60% female). The Women's Health Study (WHS) dry eye questionnaire was used to assess the primary outcome, WHS-defined DED. Level of adherence to a Mediterranean diet was quantified using a modified Trichopoulou's Mediterranean Diet Score (mMDS). The mMDS ranks participants across nine categories, yielding a sum score from zero to nine, with higher values indicating greater adherence. Logistic regression models were used to assess the relationship between WHS-defined DED and mMDS. Models were corrected for age and sex only (Model 1), age, sex, BMI, smoking status, and income and education level (Model 2), and all variables in Model 2 plus 48 traits and medical comorbidities associated with DED (Model 3). To assess possible reverse causality, participants with a diagnosis of dry eye were excluded, and the relationship between mMDS and symptomatic dry eye was assessed separately.

Results: 9.1% of participants had WHS-defined DED. Greater adherence to a Mediterranean diet was not linked to a decreased risk of dry eye. Contrarily, increasing mMDS values were significantly tied to an increased risk of WHS-defined DED in all models (odds ratio per mMDS unit 1.040, 95% CI 1.020-1.059, P<0.0001, Model 3). Higher mMDS scores were associated with a greater risk of symptomatic dry eye in all models, after excluding those with a diagnosis of dry eye (odds ratio 1.034, 95% CI 1.021-1.048, P<0.0001, Model 3).

Conclusions: Greater adherence to a Mediterranean diet was not tied to a lower risk of dry eye in this large, population-based Dutch cohort. In fact, higher mMDS scores were associated with an increased likelihood of having WHS-defined DED, which was also seen for symptomatic dry eye after excluding those with a clinical dry eye diagnosis. Causes of this observed effect should be explored further.

ABSTRACT BODY:

Purpose: Examination and assessment of disease activity in pediatric non-infectious uveitis can be difficult and subjective. In this pilot study, we assess the feasibility of using quantitative imaging (anterior segment optical coherence tomography [AS-OCT]) and measuring biomarkers in tears to assess ocular inflammation.

Methods: This is an IRB approved study. Children with uveitis were deemed “active” or “inactive” by standard clinical examination graded by SUN criteria. Anterior segment OCT was obtained with Optovue Avanti (Fremont, CA, USA) and cells/mm3 were quantitated using automated software. Tears were collected using Schirmer’s strips. S100A8, A9, and A12 were measured using enzyme-linked immunosorbent assay. IL-18, IL-8, IP-10, MCP- 1, RANTES, and sICAM-1 were measured by Luminex assays.

Results: 10 eyes of 5 patients were included in this pilot study. 2 patients had active uveitis (intermediate uveitis and vasculitis and panuveitis); 3 patients had inactive uveitis (anterior scleritis, posterior scleritis, and intermediate uveitis). AS-OCT mean cells/mm3 in the active cohort was 15 cells/mm3 compared to .22 cells/mm3 in those with inactive disease. IP-10, MCP-1, sICAM-1, s100A12, and s100A8/9 were detected in all patients with sufficient sample. Comparing patients with active vs. inactive uveitis, mean sICAM-1 was 3349.58 pg/ML vs. 1808.07, s100A12 was 436.1 vs. 2219.1, mean IP-10 was 556.42 vs. 396.13, and MCP-1 was 4.77 vs. 9.03 respectively.

Conclusions: In this proof-of-concept study, we demonstrate that imaging-based metrics of inflammation and tear biomarker levels may differentiate active and inactive uveitis in children. AS-OCT quantification of AC inflammation was higher in those with clinically active uveitis. Furthermore, sICAM-1 and IP-10 in tears trended towards higher levels in patients with active uveitis, whereas S100A12 and MCP-10 trended towards lower levels. Imaging and tear-based biomarkers are promising non-invasive methods to monitor uveitis in children.

ABSTRACT BODY:

Purpose: IRBP is the major protein component of the interphotoreceptor matrix (IPM) separating the retina from the RPE. Recently, its presence in vitreous and aqueous has been appreciated. Early expression of IRBP in rats suggests a critical role of the IPM in ocular development (Gonzalez-Fernandez and Healy, J Cell Biol 111:2775-84,1990). Although IRBP promotes the trafficking and protection of visual cycle retinoids in the adult, its function in retinal and ocular development is yet to be understood. Here, we seek to determine the effect of the absence of IRBP on postnatal eye growth and retinal integrity.

Methods: We generated an IRBP CRISPER/Cas9 knockout in a Sprague Dawley background. IRBP(-/-) and wildtype (WT) animals were reared from birth through p103 under dim cyclic light. Body and eye weight were determined together with globe dimensions via laser micrometry. Outer and inner nuclear cell densities were characterized morphometrically by QuPath image analysis of digitized sagittal histological sections oriented through the optic nerve. This data was correlated with scotopic and photopic ERGs, immunohistochemistry, and electron microscopy.

Results: WT animals showed IRBP immunospecific staining in the IPM; IRBP(-/-) did not express IRBP. Beginning at ~1.5 months globe weight was noticeably greater for IRBP(-/-) rats compared to age-matched WT animals. The maximal size difference, which occurred at ~4.5 months, was 18% and 16% for males and females respectively. Beyond that age, the difference in eye size did not increase appreciably further. The differences between age-matched IRBP(-/-) and WT globe size were independent of sex and body mass. Laser micrometry showed a slight increase in the anterior-posterior dimension for IRBP (-/-) which remains to be further studied. The outer nuclear layer began to gradually thin after weaning. The inner nuclear layer was spared relative to the outer nuclear layer. The degeneration was associated with the reduction of ERG A and B waves. Ultrastructural studies showed that the rod outer segments were irregular in contour and often broken.

Conclusions: Knockout of IRBP resulted in a gradual photoreceptor degeneration with concomitant globe enlargement. Transgenic absence of IRBP may provide a useful system not only to study the role of IRBP in the photoreceptor function and survival but also in ocular development and myopia.

ABSTRACT BODY:

Purpose: Painful non-specific orbital inflammation (NSOI) unresponsive to steroids should be re-examined, even in cases of compatible histopathology.

Methods: A retrospective case series of 3 eyes of 3 adult patients initially diagnosed as NSOI, based on clinical and histopathologic findings at University of Texas Health Sciences Center at San Antonio, is presented. These cases were re-evaluated given pain unresponsive to steroids. Follow-up ranged from 1 to 7 years. This study was approved by the Institutional Review Board and is compliant with the Health Insurance Portability and Accountability Act (HIPAA).

Results: Three patients had painful orbital inflammation initially diagnosed as NSOI by biopsy. However, the pain persisted in all despite oral immunosuppression with steroids. Re-evaluation included: repeat biopsy in two patients, expert ophthalmic pathology consultation in two patients, whole-body imaging in three patients, and several laboratory studies. The ultimate diagnoses were: one case of tuberculosis with secondary extraocular muscle amyloidosis, one case of granulomatosis with polyangiitis (GPA), and one case of metastatic lobular breast carcinoma without known primary.

Conclusions: The ophthalmologist must search for a more appropriate diagnosis in cases of biopsy proven painful NSOI unresponsive to steroids.

ABSTRACT BODY:

Purpose: Despite three Texas laws since 2019 aimed at reducing opioid prescriptions, overdoses reached a national record high this year, leaving uncertainty about the efficacy of these measures. This retrospective chart review investigates the effect of these three policies on opioid prescribing practices at the University of Texas Medical Branch Oculoplastic Department.

Methods: This study included charts of approximately 520 participants over the age of 18 who underwent one of ten specified Oculoplastic procedures performed at the University of Texas Medical Branch between January 1, 2018 and July 1, 2021. Demographic data, type of surgery, and prescribed morphine milli-equivalents (MME) were extracted from the charts. T-tests and chi-square tests were utilized to detect significant differences in average MME prescribed per month. This data was analyzed for an overall change in the trend of prescribing patterns as well as individual changes between the timeframes pertaining to each policy.

Results: Out of the 520 subjects screened, 250 received a qualifying post-op opioid medication of any amount. Data shows a 15% decrease in opioid prescribing rates since January 2018 to present. Before any policies were passed, an average of 109.09MME were prescribed per month. This decreased to 98.23MME after the first law and 98.23MME after the second law. After the passage of the third anti-opioid policy, an average of 92.62MME/month were prescribed. Evaluation continues as to the significance ($p<.05$) of this overall decrease, as well as individual changes in average MME/month in timeframes after each law was enacted in September 2019, March 2020, and January 2021 [see Graph 1].

Conclusions: Implementation of the anti-opioid state laws in Texas made a demonstrable impact on the number of opioids prescribed by the Oculoplastic department at UTMB. Such success encourages the support of similar policies in other states. Conclusions will also identify other factors associated with higher MME prescriptions, such as specific patient demographics or type of surgery.

ABSTRACT BODY:

Purpose: Autoimmune uveitis is a sight-threatening disease characterized by intraocular inflammation, which is usually accompanied with Th17 cells-associated systemic autoimmune disorders such as Behcet's disease. Thus, the role of Th17 cells in autoimmune uveitis and the novel treatments targeting Th17 cells are needed. GHRH, synthesized in the hypothalamus, controls the secretion of growth hormone in the pituitary. GHRH receptor (GHRHR) is also expressed in ocular tissues and T cells. We hypothesize that GHRH promotes autoimmune uveitis by regulating Th17 cell differentiation.

Methods: Ghrhr $^{lit/lit}$ mice (n=28) with non-functional GHRHR, were immunized with IRBP to induce autoimmune experimental uveitis (EAU). 21 days after immunization, EAU was assessed based on clinical examinations of cSLO, OCT and ERG. Eyeballs were collected for histology staining. Th17 cells isolated from spleen (SP), eye-draining lymph nodes (LNs) and eyes were evaluated for their activation, apoptosis and gene expression. GHRH agonist and antagonist were applied to wild-type (WT) mice (n=15 per group) immunized with IRBP to verify the role of GHRHR. $CD4^+$ T cells from IRBP-immunized WT and Ghrhr $^{lit/lit}$ mice were differentiated into Th17 cells in vitro following adoptive transfer into naïve recipient mice (n=8 per group) to determine the effect of GHRHR in the differentiation of pathogenic Th17 cells to induce EAU.

Results: Compared with WT mice, Ghrhr $^{lit/lit}$ mice have lower disease score ($p<0.0001$), decreased fold change of retina-choroidal thickness (RCT) ($p<0.0001$), higher amplitudes of b-wave in photopic and scotopic ERG ($p<0.001$). Ghrhr $^{lit/lit}$ mice have fewer $CD4^+$ IL-17a$^+$ T cells in the SP ($p<0.05$), LNs ($p<0.05$) and eye ($p<0.001$). Gene expression of Il17a, Il17f, Il22 and Csf2 is downregulated, while Il10 is upregulated. Compared with WT EAU mice treated with DMSO, mice treated with GHRH agonist have higher disease score ($p<0.05$), increased fold change of RCT ($P<0.05$) and increased Th17 cells ($p<0.05$), while EAU mice treated with GHRH antagonist have lower disease score ($P<0.01$), decreased fold change of RCT ($P<0.001$) and decreased Th17 cells ($P<0.01$).

Conclusions: Our results indicate that GHRH signaling is required in Th17-mediated autoimmune uveitis. GHRH signaling promotes EAU by increasing pathogenic Th17 cells, and Th17-lineage proinflammatory cytokines, but does not alter T cell activation and apoptosis.

SUBMITTER (NAME ONLY): Blake Oberfeld

TITLE: Comparative Outcomes of Phacoemulsification combined with Hydrus or Kahook Dual Blade

SESSION TITLE: Surgery & Wound Healing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Oberfeld, N. Hall, D. Solá-Del Valle, Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|B. Oberfeld, N. Hall, D. Solá-Del Valle, Harvard Medical School, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Blake Oberfeld: Commercial Relationship: Code N (No Commercial Relationship) | Nathan Hall: Commercial Relationship: Code N (No Commercial Relationship) | David Solá-Del Valle: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Understanding the relative efficacy of different microinvasive glaucoma procedures (MIGS) is integral to clinical decision making. For the first time, this study compares outcomes of phacoemulsification combined with Hydrus Microstent (Phaco/Hydrus; Ivantis Inc., CA) or Kahook Dual Blade (Phaco/KDB; New World Medical, CA).

Methods: This retrospective study included patients who underwent Phaco/Hydrus or Phaco/KDB from January 2016 to 2021 at Massachusetts Eye and Ear. Baseline characteristics comprised demographic variables, corrected distance visual acuity, intraocular pressure (IOP), medication burden, glaucoma type, severity, and history of prior laser or surgery. Primary outcomes were IOP and medication burden evaluated by Generalized Estimating Equations (GEE). Two Kaplan-Meier Estimates (KM) assessed survival without additional glaucoma procedure or medication while maintaining: (1) IOP ≤21 mmHg and ≥20% IOP reduction or (2) IOP ≤ preoperatively designated goal.

Results: Mean preoperative IOP was 17.70 mmHg ± 4.91 (SD) on 0.28 ± 0.86 medications in the Phaco/Hydrus group (N=69) and 15.92 ± 4.34 mmHg on 0.19 ± 0.70 medications in the Phaco/KDB group (N=62). The Phaco/Hydrus group was more likely at baseline to have elevated IOP (p=0.02). All other baseline characteristics were statistically similar between surgeries. At 12 months, mean IOP was reduced to 14.98 ± 2.77 mmHg on 0.12 ± 0.60 medications after Phaco/Hydrus and 13.52 ± 4.13 mmHg on 0.04 ± 0.19 medications after Phaco/KDB. GEE models of IOP ($p<0.001$) and medication burden (p=0.04) had significant patterns of reduction across all timepoints, after adjusting for baseline IOP. There was no difference in the pattern of change in IOP (p=0.83) or medication burden (p=0.84) when evaluated over time between procedures, after adjusting for baseline IOP. Phaco/Hydrus and Phaco/KDB were not different in survival by KM1 (p=0.72) or KM2 (p=0.11).

Conclusions: Both Phaco/Hydrus and Phaco/KDB resulted in significantly reduced IOP and medication burden for more than 12 months. Reductions were not significantly different between surgeries. This study compared Phaco/Hydrus and Phaco/KDB for the first time to assert that the surgeries confer similar outcomes in IOP, medication burden, and survival estimates in a population with predominantly mild and moderate glaucoma.

CONTROL ID: 3712800

SUBMITTER (NAME ONLY): Lauren Mehner

TITLE: Effects of high altitude on development of retinopathy of prematurity

SESSION TITLE: Retinopathy of prematurity

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L.C. Mehner, B.D. Wagner, A.M. Lynch, Sue Anschutz-Rodgers Eye Center, University of Colorado Anschutz Medical Campus, Aurora, Colorado, UNITED STATES|

Commercial Relationships Disclosure: Lauren Mehner: Commercial Relationship: Code N (No Commercial Relationship) | Brandie Wagner: Commercial Relationship: Code N (No Commercial Relationship) | Anne Lynch: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Low birth weight and gestational age are two of the most important risk factors for developing retinopathy of prematurity (ROP). Slow postnatal weight gain is also strongly associated with ROP. High altitude remains an important determinant of increased low birth weight rates in places such as Colorado, USA. The purpose of this study was to investigate whether maternal residence at high altitude alters the risk for ROP in premature infants.

Methods: This was a retrospective cohort study comparing elevation associated with the mother's residential zip code and rates of ROP in premature infants in a well characterized ROP registry cohort at a tertiary care facility in Colorado between January 2006 and December 2020. All infants in the study had a gestational age less than 31 weeks, birth weight less than 1500 grams, or an unstable clinical course according to current guidelines, as well as available maternal residential zip code information. Geocoding was performed in SAS by adding a latitude and longitude for the geographic center of each zip code. Coordinates for each zip code were exported and entered into https://apps.nationalmap.gov/elevation to obtain elevation. The resulting file was merged with the ROP registry dataset based on zip code.

Results: 1817 infants were included in the cohort, with 318 unique zip codes with associated elevation data (Figure 1). Elevation ranged from 0 to 10,000 ft, with the majority of births associated with elevations 4,000 - 7,000 ft. Higher elevation was associated with lower birth weight percentiles, higher gestational age and maternal age at delivery. These associations were similar when evaluating data specifically between 4,000 and 8,000 ft. Figure 2 demonstrates the nonsignificant distribution of ROP type by elevation. Severe ROP (type 1 or type 2) developed in 10.2% of infants (186/1817); there was no significant association between ROP and elevation after adjusting for gestational age, birth weight percentile and maternal age (p=0.25).

Conclusions: Despite the known increased rates of low birth weight in babies born to mothers living at high altitude, we found no significant association between altitude and ROP in premature infants in our cohort.

ABSTRACT BODY:

Purpose: Visual impairments associated with Retinitis Pigmentosa (RP) and Leber Congenital Amaurosis (LCA) have significant impacts on patients' vision-dependent activities of daily living (ADL) and broader health-related quality of life (HRQoL). Patient and observer-reported outcome (PRO/ObsRO) instruments can capture the patient or caregiver perspective in clinical trials and provide insights beyond clinical biomarkers. However, it is critical that such instruments have sufficient evidence of content validity (are appropriate for the target population). This study aimed to assess the content validity of the Visual Symptom and Impact Outcomes PRO (ViSIO-PRO) and ObsRO (ViSIO-ObsRO) instruments in RP/LCA.

Methods: Qualitative, semi-structured concept elicitation and cognitive debriefing interviews were conducted with 66 participants (33 adults, 10 adolescents, 8 children and 15 caregivers of children) in the US, France, Germany, and Canada. Patients had a clinical and genetic diagnosis of RP/LCA. Participants completed the ViSIO-PRO or -ObsRO instruments using a 'think aloud' technique to assess understanding, comprehension, and relevance of the items, instructions, response scales and recall period. Interviews were conducted in two rounds, allowing for modifications and subsequent retesting. Framework analysis of interview transcripts was performed.

Results: Participants demonstrated good understanding of the ViSIO-PRO and -ObsRO items (questions) and instructions across both rounds. Concepts assessed in the ViSIO-PRO and -ObsRO items were considered relevant to the majority of participants. The 7-day recall period and response scales were well understood and appropriately endorsed. Participant and expert clinician feedback supported the following modifications between rounds: 5 items were added to the instruments to assess additional concepts and 1 item was removed from the ViSIO-PRO due to

lack of relevance.

Conclusions: Findings support content validity of the ViSIO-PRO and ViSIO-ObsRO instruments as outcome assessments for use across RP/LCA genotypes. Further research to evaluate the psychometric validity of the instruments is underway and will support future use of the instruments as efficacy endpoints in clinical trials to support treatment benefit and in clinical practice to track disease severity.

ABSTRACT BODY:

Purpose: To describe the refractive and visual outcomes at different distances (far and near) in different modalities in the approach of presbyopia in emmetropic patients.

Methods: We evaluated presbyopic patients with axial length (AL) between 22 and 24 mm who had undergone bilateral clear lens exchange. There were two surgical approaches: extended depth of focus (EDOF) only (n=16 eyes) and mix and match (MaM) approach (EDOF IOL in the dominant eye and trifocal IOL in the fellow eye), (n=12 eyes). At the 3-month postoperative visit, visual outcomes with undercorrected distance visual acuity (UDVA), corrected distance visual acuity (CDVA), undercorrected near visual acuity (UNVA), corrected near visual acuity (CNVA) and refractive outcomes (residual spherical equivalent (SE)) were assessed.

Results: Mean age in all patients was 58.14 years and average AL was 23.39 mm. We had 8 male patients (2 in the MaM group and 6 in the EDOF only group) and 6 women (4 in the MaM group and 2 in the EDOF only group).

For the MaM group mean age was 54.4±4.27 years and mean AL was 23.12±6.45mm. CDVA and UDVA was 20/20 postoperatively. UNVA was Jaeger (J) 1 at 33 cm. Residual mean SE was -0.12±0.50 D. For the EDOF IOL mean residual SE was -0.08 D and for the trifocal IOL -0.16 D.

For the EDOF only group mean age was 61±8.05 years and mean AL was 23.58±0.47 mm. UDVA and CDVA was 20/20 postoperatively and UNVA was 20/20 at 33 cm. Residual mean SE was -0.50±0.58 D.

Conclusions: Visual outcomes were similar in both groups, both of which had high levels of visual satisfaction reported by the patient. We observed similar results in visual acuity both at far and near in both groups.

One of our limitations is that we have a small number of patients.

We are currently working in a larger patient data base along with taking into account more variables.

It is important to study more variables in order to determine which ones are relevant when deciding which approach we are taking in our patients giving them a more personalized surgical plan.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is the leading cause of visual impairment in the elderly. Oxidative stress and an aged or diseased Bruch's membrane contribute to the downstream dysfunction seen in retinal pigment epithelial (RPE) cells. The development of robust drug discovery platforms that can identify therapeutics that improve RPE cell function due to these insults would be beneficial. Herein, we demonstrate the use of a phenotypic high-throughput screening (HTS) platform to identify novel small molecules that improve RPE survival in vitro and a blue light damage model of retinal degeneration in vivo.

Methods: A HTS was conducted to identify compounds that protect RPE cells from oxidative damage. Cell viability was tested in models of RPE stress, including tert-butyl hydroperoxide (TBHP) exposure, ultraviolet-B (UV-B)-mediated light damage and nitrosative stress to the basement membrane. PCR and analysis of mitochondrial function were used to elucidate possible mechanisms of drug treatment. Sprague–Dawley CD-1 rats were exposed to blue light to induce dry AMD. Optical coherence tomography (OCT), hematoxylin and eosin, and immunofluorescence were performed to assess retinal structure. Electroretinography (ERG) was used to assess retinal function.

Results: Initial HTS of a library with 65,000 synthetic compounds (ChemDiv library) using TBHP, a chemical oxidizing agentidentified two compounds (M414 and M434) that significantly protect RPE from TBHP-induced cell death. M414 and M434 protected human RPE cells from UV-B light damage and enhanced cell viability on nitrite-modified basement membrane. Both compounds improved mitochondrial function and attenuated expression of mitochondrial apoptotic genes after oxidative damage to RPE cells. The retinal mid-layer thickness was significantly decreased after blue-light exposure in rats. The decreased retinal thickness and photoreceptor survival was improved after treatment with M414 and M434. Like the retinal structure changes, functional loss of ERG amplitude (from blue-light exposure) was restored after administration of both compounds.

Conclusions: Our data demonstrates the capacity of a HTS platform to identify novel small molecules that protect the retina from pathological factors associated with AMD.

ABSTRACT BODY:

Purpose: To analyze the morphometric characteristics of the central corneal endothelium in healthy Hispanic adults 40-years and older from an eye health-care system.
Methods: A cross-sectional, descriptive, and analytical study was designed to assess central corneal specular microscopies of healthy adult Hispanic patients. Photographs of the central corneal endothelium were obtained using a Tomey EM-3000 non-contact specular microscope. We considered endothelial pleomorphism if <50% of cells were hexagonal, and polymegethism if the coefficient of variation was >40%.
Results: 702 eyes from 356 patients were included for study. The mean age was 69.76±10.72 years (range 42-93), with 195 female and 163 male patients included. The mean endothelial cell density (MCD) was 2255.09±488.07 cells/mm2; mean cell area was 458.85±166.62 µm2; and mean central corneal thickness was 522.37±39.97 µm. 75.64% of the patients had pleomorphic endothelium, with a significant difference in cell hexagonality between male and female patients ($p = 0.002$). Moreover, 48.43% of patients had polymegethism and 17.81% cornea guttata (CG); 64% of the CG patients were female.
Conclusions: MCD and cell hexagonality in this Hispanic population was lower than in other reports. A high rate of pleomorphism, polymegethism, and CG was observed. Considering the racial differences in the prevalence of CG established by other authors, our data reveal a high prevalence of this condition in this adult Hispanic population, with a higher preponderance of female patients. More information is needed regarding endothelial morphometric characteristics in Hispanics, as it represents a valuable tool to predict the stress response capability of this essential monolayer to insults. To our knowledge, this is the first study focusing on determining the prevalence of pleomorphism, polymegethism, and guttata in a Hispanic population.

ABSTRACT BODY:

Purpose: Deep learning models in the domain of (medical) computer vision have become increasingly complex and have a high capacity to learn any complex relationship in the data, but this comes at the cost of a high tendency to overfit which negatively impacts the model's ability to generalize and leads to poor performance on future data. Traditional methods of dealing with overfitting often fail due to limited amounts of data in the medical domain. This work presents the stabilized optimization method to train a deep learning model on small medical datasets with reduced variance.

Methods: Traditional methods to reduce overfitting which depend on regularization, drop out, input dimensionality, and batch size often fail on small datasets due to a limited validation set which is more prone to statistical variance and does not generalize well to our data. One naive method to reduce variance is ensembling multiple models and aggregating their predictions but this significantly increases the inference and training times.

Stabilized optimization is a two-step method to find a minimal variance model based on running metric performance. First, we stabilize the training process by finding optimal values for hyperparameters that affect training stability e.g. batch size by minimizing the metric running standard deviation. In doing so, we are actively selecting a model that has a stable performance on the validation set, which will most likely lead to a more generalizable performance outside that validation set. Once the training process is stabilized, we find optimal values for hyperparameters that improve performance e.g. learning rate by maximizing the metric running average to find the best model during the training process.

Results: We conducted experiments on UIC's ptosis dataset. Traditional methods maxed out on validation set for all hyperparameters and resulted in 98% AUCROC and 91% F1 score. An ensemble of 27 models improved performance to 99.5% AUCROC and 95.4% F1 score. The stabilized optimization method achieved 99.9% AUCROC and 96.4% F1 score and had 27 times faster inference time compared to the ensemble model.

Conclusions: Limited data in the medical domain makes it hard to use the traditional methods of handling overfitting. Stabilized optimization provides an effective and efficient method to train a deep learning model that generalizes well to the underlying small dataset and has less variance.

ABSTRACT BODY:

Purpose: To evaluate the efficacy of the new Ahmed ClearPath® glaucoma drainage device in the treatment of refractory primary open angle glaucoma (POAG).

Methods: Intraocular pressure (IOP), number of glaucoma medications, and complications were retrospectively reviewed in POAG patients over 18 years old who underwent Ahmed ClearPath® implantation surgery at our institution with 24 months of follow-up. Patients with previous ocular procedures such as phacoemulsification (n=11), Micropulse transscleral photocoagulation (n=7), and Xen gel stent implantation (n=4) were included.

Results: 12 eyes of 11 patients (mean age 72.3 ± 13.8 years) fit inclusion criteria and were enrolled. Most patients were Caucasian (n=9), female (n=11), and had severe POAG (n=11). Mean baseline IOP was 29.0 ± 7.6 and was reduced to 11.2 ± 3.9, 7.9 ± 4.2, 10.9 ± 5.6, and 11.2 ± 4.6 at 6, 12, 18, and 24 months respectively. Compared to baseline, IOP reductions were 61.4%, 72.8%, 62.4%, and 61.4%. 80% of patients who made the 24-month follow-up reached an IOP of ≤ 14 mmHg. Mean baseline number of medications was 3.0 ± 0.9 and was reduced to 0.67 ± 0.8, 0.57 ± 0.8, 0.7 ± 1.0, and 0.6 ± 0.5 at 6, 12, 18, and 24 months respectively. Compared to baseline, medication reductions were 77.7%, 81%, 76.3%, and 80%. Mild hyphema was noted as a post-operative complication in half of the population (n=6), but resolved during each one month follow-up. No long-term complications were observed.

Conclusions: To our knowledge, this is the first long-term study evaluating the efficacy of the Ahmed ClearPath drainage device in adult patients. The ClearPath device is safe and effective at reducing both IOP and medication burdens in patients with severe POAG. Additionally, minimal short-term complications were noted and no patients within our study experienced long-term adverse effects, increasing comfort for both the surgeon and the patient.

ABSTRACT BODY:

Purpose: Black, Hispanic, and children from less affluent homes are less likely to access eye health services. The aim of this study was to assess vision health disparities among United States (US) adolescents.

Methods: This cross-sectional study utilized the National Health and Nutrition Examination Survey (NHANES) from 2005-2008. Subjects included in the analysis were aged 12 to 18 years with a completed visual function questionnaire and eye examination. Outcomes included self-reported visual function and objective LogMAR visual acuity. Sociodemographic factors investigated included race, ethnicity, family income, and US citizenship status. Multivariable logistic and linear regression analyses were conducted to examine the association between the sociodemographic risk factors and each outcome, adjusting for age, sex, and all other covariates.

Results: The 3,006 participants included represent a survey-weighted 60 million US adolescents of which 15% were Black, 17% were Hispanic, 6% were non-US citizens, and 19% had a family income below the poverty threshold. There was increased odds of self-reported poor vision in subjects who were Black (OR=2.91; 95% CI=2.08-4.08; p<0.001), Hispanic (OR=2.96; 95% CI=1.82-4.81; p<0.001), and low-income (OR=2.39; 95% CI=1.59-3.59; p<0.001). There was a trend towards worse visual acuity in the worse-seeing eye in subjects who were Black (β=0.06; 95% CI=0.03-0.09; p<0.001), Hispanic (β=0.05; 95% CI=0.01-0.09; p=0.023), and non-US citizens (β=0.10; 95% CI=0.01-0.18; p=0.034). Similar relationships were observed in the visual acuity in the better-seeing eye.

Conclusions: Black race, Hispanic ethnicity, and low-income status increased the odds of self-reported poor vision and were associated with worse objective visual acuity in this nationally representative sample of US adolescents. Sociodemographic vision health disparities exist at an early age and interventions targeted towards younger children may be helpful to address future visual impairment.

ABSTRACT BODY:

Purpose: Online optical shops could improve access to eyeglasses, especially for youth, a generally technologically savvy segment of the population. We aimed to understand U.S. youth perceptions about purchasing eyeglasses online. We hypothesized that youth would be open to purchasing eyeglasses online.

Methods: An interactive text-messaging platform, MyVoice (www.hearmyvoicenow.org), sent five questions regarding eye care experiences to U.S. youth aged 14-24 years. Question five asked, “If you needed eyeglasses, how would you feel about getting them online?” The text message responses were coded by two investigators using modified Grounded Theory; disagreements were adjudicated by a third investigator.

Results: Of 1204 recipients, 88.3% (n=1063) responded. The mean age was 20.3 ± 2.4 years (range 15-24 years); 58.8% (n=625) were male; 74.0% (n=787) were white; 99.4% (n=1057) reported having access to technology, including laptops, desktops, smartphones, or tablets. Half (50.7%, n=539) felt positive about purchasing eyeglasses online (e.g. “I think it would be a good idea–more styles and cheaper”), while 35.4% (n=376) felt negative (e.g. “I would feel a little bit out of my depth, I think the optometrist would know best what to provide for eyeglasses”). Even some respondents who felt positive about purchasing eyeglasses online expressed specific concerns. The most prevalent concern among all respondents was a desire to try eyeglasses on prior to purchasing (n=102, e.g. “I would want to try them on first because I have a big head”).

Conclusions: Many U.S. youth are open to purchasing eyeglasses online, which could improve access to eyeglasses for this population. To overcome major concerns, online optical shops could offer the option to try frames before purchasing.

TITLE: Outcomes of Far Posterior Open Globe Injuries: The Case for Zone 4

SESSION TITLE: Anterior Segment and Trauma Epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: I. Bleicher, G.W. Armstrong, E.D. Gaier, Ophthalmology, Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|E.D. Gaier, Ophthalmology, Boston Children's Hospital, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Isaac Bleicher: Commercial Relationship: Code N (No Commercial Relationship) | Grayson Armstrong: Commercial Relationship(s);Code O (Owner):Ocular Technologies Inc.;Code C (Consultant/Contractor):McKinsey & Company;Code C (Consultant/Contractor):Xenon-VR;Code C (Consultant/Contractor):Ophthalytics;Code C (Consultant/Contractor):Kriya Technologies;Code S (non-remunerative):American Medical Association | Eric Gaier: Commercial Relationship(s);Code C (Consultant/Contractor):Luminopia, Inc.;Code P (Patent):Luminopia, Inc.;Code C (Consultant/Contractor):Stoke Therapeutics Inc.

ABSTRACT BODY:

Purpose: Open globe injuries (OGIs) are categorized by zone of injury, with Zone 3 (Z3) defined as ≥5mm posterior to the corneal limbus. Heterogeneity in outcomes of Z3 OGIs precludes precise prognostication and surgical management decisions. We hypothesized that Z3 OGIs with far posterior wounds would have worse visual and anatomic outcomes.

Methods: We performed a retrospective review of Z3 OGIs with at least 30 days of follow-up treated at a tertiary care center over a 10-year period. Far posterior OGIs (pZ3) were defined as those with wounds extending ≥10mm posterior from the corneal limbus. Secondary surgeries, visual outcomes, and anatomic outcomes were compared between pZ3 and anterior Z3 (aZ3) eyes at presentation, the 3 months and the latest available timepoints after injury. Fisher's exact and Mann-Whitney U tests were used to compare pZ3 and aZ3 outcomes.

Results: Of 264 Z3 OGI eyes, 215 met inclusion criteria. Of these, 132/215 (61%) were classified as pZ3. pZ3 and aZ3 eyes underwent means (±SD) of 1.6±1.6 and 1.4±1.5 secondary procedures, respectively ($p>0.4$). At 3 months after injury, pZ3 eyes were less likely to maintain light perception or better vision (pZ3: 53%, aZ3: 77%), count fingers or better vision (pZ3: 28%, aZ3: 49%), or have ≥20/400 Snellen acuity (pZ3: 18%, aZ3: 39%)(p values≤0.01). These relationships were also seen at final follow-up for light perception (pZ3: 53%, aZ3: 71%), count fingers (pZ3: 27%, aZ3: 46%), and ≥20/400 acuities (pZ3: 17%, aZ3: 36%) (p values≤0.01). The effect of zonal group on count fingers and ≥20/400 acuity persisted even when excluding patients presenting without light perception (p values≤0.02). After OGI repair, pZ3 eyes were less likely to have improved visual acuity (pZ3: 34%, aZ3: 49%) and more likely to have reduced visual acuity (pZ3: 20%, aZ3: 7.2%) from presentation ($p<0.01$). A significantly greater proportion of pZ3 eyes became phthisical or were eviscerated/enucleated compared with aZ3 eyes (56% vs 40%, $p=0.02$).

Conclusions: Eyes with OGIs extending ≥10 mm posterior to the corneal limbus have poorer visual and anatomic outcomes compared to those limited to the more anterior Z3. While the potential for recovery in posterior OGIs necessitates careful assessment and emergent repair in all cases, further zonal categorization within zone 3 injuries may help improve prognostic precision and refine surgical approaches.

ABSTRACT BODY:

Purpose: We previously developed a deep-learning system (DLS) to identify diabetic macular ischemia (DMI) on superficial capillary plexus(SCP) and deep capillary plexus(DCP) of optical coherence tomography angiography (OCT-A) images. We aim to further investigate whether the DLS-based DMI classification provides prognostic values on diabetic retinopathy (DR) progression and diabetic macular oedema (DME) development in a cohort of patients with diabetes mellitus (DM).

Methods: This is a retrospective longitudinal study with 293 eyes from 164 patients with DM being followed up for at least 4 years.Image quality assessment and DMI assessment of all OCT-A images were first performed by the previously developed DL system. The presence of DMI was defined as images exhibiting disruption of fovea avascular zone (FAZ) or/and additional areas of capillary non-perfusion in the macula accorded with ETDRS protocols. Cox proportional-hazards model was used to evaluate the relationship of the binary DMI classification (presence or absence of DMI) to DR progression and DME development.

Results: Over a median follow-up of 54.09 ±4.67 months, 89 eyes (33.97%) had DR progression, and 34 eyes (12.98%) developed DME. SCP-DMI classification outcome (hazard ratio [HR], 3.451; 95% confidence interval [CI], 2.062 to 5.776; p <0.001) and DCP-DMI classification outcome (HR, 4.992; 95% CI, 2.884 to 8.645; p <0.001) were significantly associated with DR progression; while only DCP-DMI classification outcome (HR, 1.758; 95% CI 0.753 to 4.122; p <0.001) was associated with DME development after adjusting for age, duration of diabetes, fasting glucose, glycated hemoglobin, mean arterial blood pressure, baseline DR severity, average GCIPL thickness, and smoking status at baseline. Compared with the model based on identified risk factors alone, the addition of DMI classification outcomes improved the predictive discrimination of DR progression (SCP-DMI, C-statistics 0.741 vs. 0.696, p < 0.001; DCP-DMI, C-statistics 0.772 vs. 0.696, p < 0.01) and DME development (DCP-DMI, C-statistics 0.702 vs. 0.663, p = 0.076) in diabetic eyes.

Conclusions: The DL-based DMI outcomes demonstrated prognostic values for DR progression and DME development.

ABSTRACT BODY:

Purpose: To describe the refractive management, visual outcomes and patient satisfaction with refractive cataract surgery in challenging cases.

Methods: Retrospective chart review of selected cases. Throughout decision-making of refractive options after an exhaustive ophthalmological evaluation including IOL selection, aberrometry and surgical options was performed in agreement with all patients.

Results: Five challenging scenarios are reported with their management of refractive error. Case 1 presents a 54 year-old male with a history of LASIK surgery and clear lens, looking for refractive management. Multifocal IOLs were implanted in both eyes achieving UCVA of 20/20 in both eyes and UNVA of J1. Case 2 is a 72 year-old female with a history of LASIK surgery with a central island in the left eye presenting with bilateral cataract. Cataract surgery was performed with multifocal IOL in the right eye and monofocal IOL in the left eye, achieving a 20/20 uncorrected visual acuity (UCVA) and uncorrected near vision acuity (UNVA) of Jaeger (J) 1. Case 3 is a 59 year-old female with a history of RK presenting with bilateral cataract. Cataract surgery was performed with bilateral multifocal IOL implantation, achieving 20/20 UCVA in both eyes and UNVA of J3. Case 4 presents a 65-year-old female with a history of radial keratotomy (RK) with clear lens looking for refractive treatment. Right cornea was highly aberrated so monofocal IOL was implanted and a multifocal toric IOL in the left eye, achieving UCVA 20/20 in the right eye and 20/25 in the left eye, with a UNVA of J1.

Case 5 presents a 53-year-old male with a history of post-LASIK ectasia in the right eye, treated with penetrating keratoplasty (PKP) in which residual astigmatism was treated with LASIK plus enhancement 10 years later. The patient was seeking refractive management so a toric IOL was implanted, achieving a UCVA of 20/50.

Conclusions: Past history of refractive surgery and/or corneal disease makes for complex decision-making during the assessment for cataract surgery. Although challenging, the armamentarium of refractive options allows for excellent visual outcomes with great patient satisfaction.

ABSTRACT BODY:

Purpose: According to data presented before (IOVS 2019 v.60:5969), a strong correlation between the timing of retinal ganglion cell bursts and oscillatory potential (OP) peaks was observed when bright white flashes were presented in rats. Based on that, a hypothesis can be put forward about the existence of a correlation between OPs and the photopic negative response (PhNR) of the full-field electroretinogram (ERG). The purpose of the current study was to compare OP amplitude and PhNR parameters in patients with various retinal pathologies.

Methods: A retrospective chart review and data analysis of patients aged 18 and over undergoing routine ERG testing at USF Eye Institute (Tampa, FL) was conducted. The Photopic 3.0 ERG responses (LA 3.0) were analyzed. Ph3 responses were recorded using DTL electrodes, white xenon flash (2.5 cd.s/m^2) on a white background (30 c/m^2) with a digitization rate of 3750 Hz and bandpass filtering range of 0.3 to 1500 Hz. The ERG signal was filtered using high-pass 4^{th} order Butterworth filter with 58 Hz cut-off frequency. The root means square (RMS) of the filtered signal was calculated for the OP portion of the signal. The OP RMS values were compared (linear regression) to the amplitude of the PhNR response, determined in 3 different ways: measured from the isoelectric baseline (fB), measured from the b-wave peak (fP) and as an area under the curve (AUC).

Results: The records of 11 patients/20 eyes (2M, 9F); mean age 46.7 +/-14.6 yrs. were evaluated. The correlation between OP RMS and PhNR(fB) was moderate at R^2=0.5515 ($p<0.001$), while the correlation with PhNR(fP) was considerably better at R^2=0.8222 ($p<0.001$). Furthermore, several models of a linear regression between OP RMS and AUC extended to different time points after b-wave peak (every 5 ms form 5 ms to 50 ms after b-wave peak), which indicated a good correlation across the range (R^2 0.82 to 0.89) with the best regression model at 15 ms after b-wave peak (R^2 = 0.8875, $p<0.0001$).

Conclusions: A reasonably strong correlation was observed between OP parameters and PhNR amplitude. That supports a relationship between OP amplitude and PhNR under LA 3.0 recoding conditions, which has applicability in clinical practice, especially when determining the amplitude of PhNR with traditional methods is unreliable.

ABSTRACT BODY:

Purpose: Macular holes (MH) can be seen in patients with tractional retinal detachment (TRD) and proliferative diabetic retinopathy (PDR). However, there is a paucity of literature examining the characteristics of these macular holes and the visual outcomes after surgical intervention. This study aimed to characterize the features of TRD MHs in PDR patients, the rate of MH closure following surgical intervention, and the preoperative and intraoperative factors affecting hole closure and visual outcomes.

Methods: A retrospective chart review was conducted for adults diagnosed with a MH secondary to TRD who underwent pars plana vitrectomy (PPV) surgery at Cole Eye Institute between January 2015 and August 2021. Collected variables include patient demographics, procedure performed, rate of MH closure, visual acuity (VA) and OCT biomarkers at time of diagnosis and post-operatively at 3, 6, and 12 months. Fisher's exact test, paired t-test, and p=0.05 were used for statistical analysis.

Results: The final cohort consisted of 11 patients and 11 eyes (8 females, average age of 57.6 years old) who developed a MH secondary to TRD. The mean HbA1c was 8.35%. Five MHs (45.5%) were associated with subretinal fluid, 5 (45.5%) were associated with vitreomacular traction, and 2 (18.2%) were associated with epiretinal membrane. Average MH size was 383.1 μm. During PPV, 12 (85.7%) patients underwent concurrent procedures, including internal limiting membrane (ILM) peeling (2, 18.2%) and/or phacoemulsification and intraocular lens placement (7, 63.6%). Tamponade choice included C3F8 gas for most patients (n=7; 63.6%), air for 1 (9.1%), SF6 gas for 1 (9.1%), and silicone oil for 2 (18.2%). Nine patients (81.8%) achieved MH closure 3 months after surgery. One (9.1%) achieved MH closure after a singular re-operation. There was borderline significance between presence of concurrent procedure and successful MH closure (p=0.0545), and no significance between use of long-acting (C3F8) tamponade and successful MH closure at 3 months (p=0.4909). The mean VA at baseline and 12 months was 1.197 logMAR (20/315) and 0.981 logMAR (20/191), respectively (p=0.185).

Conclusions: This study showed that the majority (81.8%) of repaired MHs secondary to TRD remained closed at the 3-month follow-up without further re-operation. Despite closure, the long-term visual outcomes in patients with TRD macular holes are limited.

ABSTRACT BODY:

Purpose: Patients with active Proliferative Diabetic Retinopathy (PDR) who develop non-clearing vitreous hemorrhage (VH) and macula-involving tractional retinal detachment (TRD) often undergo surgery with pars-plana vitrectomy (PPV). Our understanding of their visual prognoses remains limited. The purpose of this study was to determine visual acuity outcomes after PPV for TRD and VH patients in the IRIS Registry.

Methods: Patients were identified in the IRIS registry who received a new diagnosis of PDR who then developed either VH or TRD and underwent PPV within 90 days. The distribution of visual acuity in logMAR was evaluated at time points three months pre-PPV to one-year post-PPV, and the difference in mean logMAR one-year post-PPV was compared to one-week pre-PPV with an independent t-test. We further stratified by pseudophakic and phakic patients.

Results: Between 2016 and 2018, 1851 PDR eyes who developed VH underwent PPV and 553 with TRD underwent PPV. 18.8 % of VH eyes were pseudophakic preoperatively compared with 19.2% of TRD eyes, compared with 36.4% and 39.4% after one year post PPV. For TRD, preoperative visual acuity was 1.62 (phakic) and 1.59 (pseudophakic) logMAR and one-year postoperative VA was 1.35 and 1.35, and the difference was not significant (p=0.189 and p=0.260). For VH, preoperative visual acuity was 1.65 (phakic) and 1.73 (pseudophakic) logMAR and one-year postoperative VA was 0.84 and 0.83, and the difference was not significant (p=0.001 and p=0.001). On average, phakic eyes gained 0.82 logMAR and pseudophakic eyes gained 0.89 logMAR. Of note, for VH, the vast majority of improvement came within the first postoperative month.

Conclusions: Patients with PDR who developed TRD and underwent PPV on average presented legally blind (1.62 and 1.59 for phakic and pseudophakic) and did not significantly improve one year after PPV (1.35 and 1.35). Patients with PDR who developed VH and underwent PPV on average presented legally blind (1.66 and 1.73 for phakic and pseudophakic eyes) and improved significantly to 0.84 and 0.83 logMAR after one year, with the vast majority of improvement coming in the first month (1.06 and 1.13). For both TRD and VH, 1 week preoperative and 12 month postoperative VA was not significantly different between phakic and pseudophakic patients, and TRD and VH underwent post-PPV cataract surgery at similar rates.

ABSTRACT BODY:

Purpose: To evaluate the performance of IMOvifa®, a new perimeter which performs visual field (VF) testing outside an examination darkroom, and compare with Humphrey Field Analyzer (HFA).

Methods: In this cross-sectional study, 138 eyes (including 25 healthy, 48 glaucoma suspects, and 65 primary open angle glaucoma) of 69 patients were evaluated. Patients were required to be experienced with the visual field testing performed on the HFA. All patients first underwent HFA 24-2 SITA-Fast and then IMOvifa® 24-2 AIZE-Rapid, which is comparable with SITA-Fast, for both eyes on the same day. Mean deviation (MD), pattern standard deviation (PSD), foveal threshold (FT), and visual field index (VFI) were compared between the two perimeters using Wilcoxon signed-rank tests, and Pearson's and Bland-Altmann correlation. Measurement time for performing VF for both eyes was also collected for each device.

Results: Measurement time was significantly faster for IMOvifa® compared to HFA (256sec vs 419sec, P<0.001). Rim artifacts were observed in 18 eyes (13.0%) with IMOvifa® and in 5 eyes (5.1%) with HFA. No differences were seen in mean MD (95% CI) -3.1 (-3.9, -2.4) dB for HFA vs. -3.1 (-3.8, -2.4) for IMOvifa®, and VFI 93.1 (91.1, 95.1) % for HFA vs 92.6 (90.4, 94.9) % for IMOvifa® (both P>0.05). Significant differences were seen in mean PSD 3.2 (2.7, 3.6) dB for HFA vs 4.1 (3.5, 4.6) for IMOvifa® (P<0.001), and FT 33.9 (33.1, 34.6) dB for HFA vs 30.6 (29.3, 31.9) dB for IMOvifa® (P<0.001). Pearson's r was strong for MD (r=0.90, P=<0.001), PSD (r=0.78, P<0.001) and VFI (r=0.94, P<0.001), but not for FT (r=0.21, P=0.023). Bland−Altman scatterplots showed reasonable agreement between the two perimeters (Figure 1).

Conclusions: IMOvifa® reduced measurement time by 38.9%. MD, PSD, and VFI values for IMOvifa® were highly correlated with HFA. This new perimeter appeared to reduce fatigue for both patient and examiner. Additional studies are needed to determine if it be useful for routine visual field testing of glaucoma.

Tornero-Jimenez, Asistencia e Investigación en Glaucoma, Global Glaucoma Institute, Guadalajara, Jalisco, MEXICO|

Commercial Relationships Disclosure: Ana Ponce Horta: Commercial Relationship: Code N (No Commercial Relationship) | Jose Paczka: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Valencia Paredes: Commercial Relationship: Code N (No Commercial Relationship) | Andrea Tornero-Jimenez: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Trabeculectomy is the most practiced surgery in glaucoma, and filtering blebs are usually studied with multiple classifications. The weak correlation of an anterior segment OCT (AS-OCT) classification with IOP in a preliminary cross-sectional study (ARVO 2021) suggested that the classification could have some predictive value. The objective of this study is to analyze the correlation between the Novel Classification System by AS-OCT (NOCTS) and the combination of NOCTS and the Würzburg classification (NOCTS+WC) with the filtering bleb functionality in a longitudinal study.

Methods: Longitudinal study of non-consecutive cases of patients with trabeculectomy. Fifty eyes of thirty-three patients were included. Filtering blebs were examined using the WC (score range, 0-12). A series of AS-OCT images were also evaluated using NOCTS (score range, 0-6) to evaluate 3 tomographic traits of the filtering bleb (wall thickness, cystic spaces and wall inner reflectivity). A weighted score was assigned to each item for every examined case. The blebs were subclassified into 4 types according to their outcome (complete success, qualified success with compression, qualified success with hypotensive drugs, and failure). The correlation between NOCTS, WC and NOCTS+WC with the baseline outcome and after one year of follow-up were analyzed, considering a p-value of ≤ 0.05 as statistically significant.

Results: Patients had a mean age of 60.1±17.7, predominantly female (72.7%), with POAG (51.5%), and pseudophakic (62%). The mean time after trabeculectomy was 49.5±64.1 months. The correlation of NOCTS with the baseline outcome was weak to moderate (r=0.372, p=0.008), and moderate at one year of follow-up (r=0.477 p=0.0001). The correlation of WC with the baseline outcome (r=0.623, p=0.0001) and at one year of follow-up were moderate to strong (r=0.689, p=0.0001). NOCTS+WC score had a strong correlation with the baseline outcome (r=0.788, p=0.0001), as well as at one year of follow-up (r=0.756, p=0.0001).

Conclusions: The combination of clinical and tomographic systems outperformed isolated evaluation with each of these systems, both at baseline, as well as at the one-year post-trabeculectomy outcome. Prospective studies with longer follow-up and larger samples are required to determine this new approach to classify filtering blebs.

TITLE: M2 phenotype microglia polarization is neuroprotective in ischemic/reperfusion model of acute hypertensive glaucoma

SESSION TITLE: Neuroprotection and Neuroregeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Z. Li, W. Su, Y. Zhuo, Sun Yat-Sen University Zhongshan Ophthalmic Center, Guangzhou, Guangdong, CHINA|

Commercial Relationships Disclosure: Zhidong Li: Commercial Relationship: Code N (No Commercial Relationship) | Wenru Su: Commercial Relationship: Code N (No Commercial Relationship) | Yehong Zhuo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Ischemic/reperfusion injury induced neuroinflammation play crucial role in glaucomatous optic neuropathy. While the role of microglia in acute glaucoma and underlying mechanisms remain unclear. Here we investigate the effect and associated mechanism of microglia polarization in an acute hypertensive glaucoma model.

Methods: An acute hypertensive glaucoma model with substantial elevation of intraocular pressure (IOP) was established in adult C57BL/6 mice. Changes of miRNAs at different time point was detected by Real-time PCR. MiRNA-124 was administered intravitreally after model establishment. Retinal ganglion cells survival was evaluated by fluorescence stain and light microscopy. Inflammatory cytokines was detected by qRT-PCR. The number of CD86+ or CD206+ microglia in retina was measured by Flow Cytometry. Two-tailed Student's t-test was used for statistical analysis.

Results: Level of miRNA-155 were elevated in an early stage and remained for long period compared to control group, while miRNA-124 was elevated in a late stage. Treatment with miRNA-124 effectively increased retinal thickness and promoted ganglion cells survival(81.45±5.39%) compare to I/R injury alone(58.94±2.55%, $p<0.05$). Cytokines of IL-1β, iNOS and transcription factor C/EBP-α were suppressed, while TGF-β and Arg-1were promoted. Intravitreal miRNA-124 also decreased the number of CD11b+/CD86+ M1 microglia(36.4±2.35% vs 25.5±4.18%, $p<0.05$), and increased the number of CD11b+/CD206+ M2 microglia(21.3±3.64% vs 36.9±5.81%, $p<0.05$).

Conclusions: Our results indicated that miRNA-124 could alleviate retina injury and promote RGCs survival, by downregulating the expression of inflammatory cytokines. Intravitreal miRNA-124 altered the polarization of retinal microglia and regulate to neuroprotective M2 phenotype. Further experiments will be needed to understand underlying mechanisms.

ABSTRACT BODY:

Purpose: We previously reported that the retinal pigment epithelium (RPE) preferentially metabolizes proline into TCA cycle metabolites and non-essential amino acids (NEAAs), which are exported to be utilized by the neural retina. Proline dehydrogenase (PRODH) is a key enzyme in proline catabolism. In this study, we aim to test the hypothesis that PRODH controls proline utilization and its metabolic support to the neural retina.

Methods: We obtained PRODH deficient (PRO/Re) mice and their parental control strain (C57BL/6J) from the Jackson Laboratory and validated the deficiency of PRODH expression in liver, RPE, and retina by Western blot. We measured the steady-state proline level in the plasma and RPE from PRO/Re mice by Gas Chromatography and Mass Spectrometry (GC MS). To study whether proline utilization was blocked in vivo in PRODH deficient mice, we delivered either ^{13}C or ^{15}N proline through retro-orbital injection to trace proline-derived TCA cycle metabolites and NEAAs using GC MS.

Results: In the wildtype (WT) C57BL/6J mice, PRODH protein was abundant in the liver and RPE, but much lower in the retina. In PRO/Re mice, however, PRODH protein was undetectable in the liver, RPE, and retina. We also found the steady-state proline was substantially accumulated in both the plasma and RPE from PRO/Re mice. These results validate that PRODH is deleted in the PRO/Re mice. Tracing isotope-labeled metabolites in vivo showed proline-derived TCA cycle metabolites and NEAAs were highly enriched in the RPE and retinas from the WT mice. However, in the PRODH deficient mice, both ^{13}C or ^{15}N proline were accumulated in the RPE, and proline-derived metabolites were almost abolished in the retina.

Conclusions: Proline catabolism through PRODH occurs mainly in the RPE but not the neural retina. RPE catabolizes proline into mitochondrial intermeidates and amino acids to provide substrates for retinal metabolism.

ABSTRACT BODY:

Purpose: To compare eyes that developed a retinal detachment (RD) after keratoprosthesis (K-Pro) implantation to those that did not.

Methods: Retrospective review of patients who underwent K-Pro implantation at Duke Eye Center between 2009 and 2018. Demographics, past ocular history, surgical outcomes, and visual outcomes were collected at 3 months, 12 months, 24 months, and 36 months after K-Pro and compared between two cohorts: 1) eyes that developed RD after K-Pro and 2) eyes that did not develop RD after K-Pro.

Results: 87 eyes that underwent K-Pro implantation were identified - 14 of which developed RD after K-Pro and 73 which did not. There was no significant difference in the age, sex, or race of patients who did or did not develop RD after K-Pro. There was no difference in past ocular surgical history or indication for K-Pro between the patients who did and did not develop RD after K-Pro. Among the 14 eyes that developed RD after K-Pro, RD developed between 72 and 229 days postop. Eyes with RD after K-Pro were more likely to have had a pars plana vitrectomy (PPV) prior to, at the same time as, or after K-Pro but before RD (11/14, 78.6%) when compared to eyes which did not develop RD (35/73, 47.9%), $p = 0.035$. Additionally, patients who developed RD after K-Pro were significantly more likely to have had PPV and endophthalmitis (4/14, 29%) compared to eyes which did not develop RD (3/73, 4%), $p = 0.002$. There was no difference in mean visual acuity between groups at 3 months, 12 months, and 24 months after K-Pro. Eyes that developed RD after K-Pro had significantly lower visual acuity at 36 months (20/8000) vs eyes that did not (20/800), $p = 0.036$.

Conclusions: Endophthalmitis and history of PPV either before or after K-Pro are risk factors for the development of RD after K-Pro. Eyes with and without RD after K-Pro had similar visual outcomes at 24 months but not 36 months after K-Pro.

ABSTRACT BODY:

Purpose: To describe the characteristics of patients affected by both arthritis and uveitis.

Methods: Retrospective chart review of pediatric patients, age 18 or less, diagnosed with both uveitis and arthritis at the Manhattan Eye, Ear, and Throat Hospital between 2017 and 2021. Outcome measures included arthritis type, severity, course and relative severity of disease between uveitis and arthritis

Results: Thirty-three patient charts were reviewed. Thirty patients were female (90.9%). Anterior uveitis was the most common type, accounting for 97% of cases. Juvenile idiopathic arthritis (JIA) accounted for 90.9% of uveitis etiologies: oligoarticular (74.2%), polyarticular (22.6%), and psoriatic (3.2%). Thirty-two patients (97%) had bilateral involvement of uveitis. Thirty patients (90.9%) required immunomodulatory therapy. Arthritis severity was classified as follows: mild (60.6%), moderate (35.4%), and severe (3%). Uveitis was relatively more severe compared to arthritis in 72.7% of patients, less severe in 18.2% and equivocal in 9.1%. Of the 6 patients in whom arthritis was the more severe condition, 2 initially had uveitis as the more severe condition. No patients suffered functional disability from their arthritis.

Conclusions: In pediatric uveitis, arthritis often plays a significant role in the disease course and treatment choices. In some patients with severe uveitis, arthritis can later become the predominant clinical condition. Functional disability from arthritis was absent from this cohort.

ABSTRACT BODY:

Purpose: Depth information can be extracted from small retinal disparities (fine stereopsis) and from large disparities that give rise to diplopia (coarse stereopsis). Previously, we showed retrospectively that some children with strabismus have intact coarse stereopsis when fine stereopsis is disrupted, and these children have better ocular alignment after strabismus surgery. Here we describe a prospective study to assess three pre-surgical measures that may predict ocular alignment after strabismus surgery: fine stereopsis, coarse stereopsis, and global motion thresholds, all of which have been shown to be sensitive to disruption of binocular vision.

Methods: Eleven children aged 4-14 years were assessed before and 4-15 months after alignment surgery. Depth-discrimination accuracy (nearer/farther) was measured for cartoon characters relative to a 0-disparity reference frame. 3D stimuli were presented using shutter glasses, with disparities categorized as fine (0.02, 0.17, 0.67 deg) or coarse (2.0, 2.5, 3.0 deg), based on previous work. The stimuli were aligned for each child and presented 20 times per disparity in random order. Global motion direction-discrimination (left/right) coherence thresholds were measured using a staircase procedure. The clinical outcome measure was ocular alignment (prism diopters) after surgery.

Results: Prior to surgery, depth-discrimination accuracy in the fine disparity range was near chance in all children regardless of post-surgical alignment. In the coarse disparity range, the association between pre-surgical depth-discrimination accuracy and post-surgical alignment was large ($r = -0.65$): children with higher accuracy showed smaller misalignment after surgery. For pre-surgical motion direction-discrimination, children with lower thresholds (better performance) showed smaller misalignment after surgery ($r = 0.82$). The association between coarse depth discrimination and motion direction discrimination prior to surgery was moderate ($r = -0.47$).

Conclusions: Our preliminary findings suggest that coarse, but not fine, stereoscopic performance may be useful for predicting ocular alignment outcomes after strabismus surgery. Coarse stereopsis matures before fine and may be important for coordinated binocular eye movements. Future research will determine if pre-surgical global motion perception provides independent information for predicting alignment outcomes.

ABSTRACT BODY:

Purpose: Challenges persist in determining the molecular features of intact retina tissue. IR spectroscopy measures the appearance of vibration and absorption for atomic bonds, and advances in MAIR allow IR to be applied to nontransparent samples. We sought to identify signature peaks in the complex retina spectra and assign them to anatomic and biochemical processes.

Methods: We obtained retina and RPE-choroid from adult albino Sprague Dawley rats for four experiments. Dissections were done in 10 min of bright light or under dim red light only. In two experiments, rod outer segments were isolated by titration and centrifugation at 15,000 xG for 5 min at 4 °C. The supernatant corresponded to the soluble interphotoreceptor matrix (IPM). Retinas, RPE-choroid, 50 ul of rod outer segment suspensions, purified outer segments and IPM supernatant were transferred to separate polyethene (PE) membranes. Sample tissue, extract and fluid were air dried on membranes to avoid a strongly absorbing H_2O IR peak. We used a PE membrane negative control to distinguish its peaks from sample peaks. The samples on membranes were analyzed by MAIR-IR spectroscopy.

Results: Washed and unwashed retina had complex spectra including peaks at 1737, 1652, 1584 and 1540 cm^{-1}. The RPE also showed these peaks, except the peak at 1737 cm^{-1} was distinctly absent. Peaks at 1737 and 1550 cm^{-1} were associated with the pellet (rod outer segments). Peak 1584 cm^{-1} was associated with the supernatant (soluble IPM extract). The fluid loosely associated with the retina did not match to purified hyaluronan and its spectra was interpreted to be protein-rich vitreal or aqueous material. Dissections in light and dark revealed changes in the 3000 – 2,800 cm^{-1} region, which may represent released visual cycle retinoids (all-trans retinol and retinal). The 1737 cm^{-1} peak was not affected by light. This peak matched purified docosahexaenoic acid.

Conclusions: Although the retina generates complex MAIR-IR spectra, assignments can be made. The 1737 and 1150 cm^{-1} peaks represent the rod outer segments. In contrast, the 1600 cm^{-1} peak represents the soluble IPM proteins. Changes in the 3000 – 2,800 cm^{-1} region may represent visual cycle retinoids. MAIR is a powerful approach to characterizing the retina in situ.

ABSTRACT BODY:

Purpose: Augmented reality (AR) has been explored as a tool for lower-cost training in medical, industrial assembly, design, and education. Presentation of AR content requires a balance of its transparency without compromising the visibility of the surrounding physical objects. As a result, AR headsets can cause vergence-accommodation conflict and eye fatigue. It has been found that lower contrast drives weaker vergence and poorer depth perception. However, little is known about the effect of AR transparency on oculomotor eye alignment. Here, we determined the contrast thresholds for horizontal and vertical disparity-driven eye alignments for various levels of transparency.

Methods: Subjects(n=4) performed the task while wearing a pair of Epson Moverio BT300 AR smart glasses. The AR stimuli consist of a one-octave bandwidth filtered noise pattern of 2cpd with a disparity of 5 arcmin overlay on a background with zero disparity. We measured the contrast thresholds for producing a detectable nonius shift for 3 transparency levels (low, middle, and high) and 2 background conditions (grey and a black-and-white natural scene photograph) for horizontal and vertical disparity. Responses from the five staircase runs were combined into a single psychometric function, then fitted with a Weibull that converges to 82% correct performance.

Results: The contrast sensitivity was robust at middle and high transparency. Despite higher opacity at high transparency, there was no significant improvement of sensitivity when compared to the middle level. However, at low transparency, the contrast sensitivity reduced significantly. A cluttered background reduced the sensitivity at all transparency levels by two- to four-fold. There was no significant difference between horizontal vs. vertical results.

Conclusions: Even with a fusible background, the AR overlay with relatively low contrast is enough to drive the eye alignments. Mid transparency with the AR target and its surround in the middle visibility level is sufficient to drive contrast sensitivity of disparity-driven eye alignments. Lower transparency and cluttered background show a weaker drive to vergence, for both horizontal and vertical eye alignments, and may cause strain to the oculomotor systems. Careful manipulation of transparency and its contrasts should be taken into consideration when designing AR visual content.

ABSTRACT BODY:

Purpose: Usher Syndrome type IIA (USH2A) is a genetic disorder characterized by progressive photoreceptor degeneration due to retinitis pigmentosa (RP) and sensorineural deafness. Currently, there exists no therapy to stop or reverse the progressive photoreceptor death in USH2A. In order to understand and treat retinal degeneration in patients, it is essential to create a USH2A animal disease model. Since the Usherin protein is highly conserved in humans and rabbits, rabbits make a great model for USH2A. Furthermore, rabbit eyes have similar anatomical features to human eyes. In this study, we successfully created a USH2A knockout rabbit using CRISPR/Cas9 technology.

Methods: Rabbit embryos were injected with a mixture of 150ng/μL Cas9 mRNA and 50 ng/μL sgRNA at a dose of 2-5 pL. The guide RNA targets the rabbit USH2A gene on exon 12. Each recipient female rabbit received twenty to thirty injected embryos through embryo transfer surgery. Derived founder rabbits were bred to be homozygous for the USH2A knockout. The progression of retinal degeneration is then evaluated for up to 22 months using fundus photography, fundus autofluorescence (FAF), fluorescein angiography (FA), OCT, electroretinography (ERG), and slit lamp examination.

Results: In the three biallelic mutant rabbits, FAF spots were detected in the mid-periphery of the retina, and OCT images showed hyper-reflective disruptions of the photoreceptor layer. ERG signals of both rod and cone function were reduced in the USH2A mutant rabbits at 7 months and worsened at 15-22 months, indicating progressive retinal photoreceptor degeneration.

Conclusions: Due to similar anatomical features and disease progression as noted in humans, our USH2A rabbit model is a useful tool for studying retinal degeneration in Usher syndrome.

ABSTRACT BODY:

Purpose: While drusen and subretinal drusenoid deposits (SDD) are commonly associated with the initial diagnosis of age-related macular degeneration (AMD), early AMD patients are known to have scotopic deficits and presumed photoreceptor alterations. In this study, we sought to better characterize the structural alterations associated with the transition from normal aging to early AMD by quantifying the outer retinal layers on optical coherence tomography (OCT) volumes.

Methods: Subjects ≥ 60 years with either normal macular health (AREDS 1) or early AMD (AREDS 2-4) were enrolled as part of the Alabama Study on Early Age-related Macular Degeneration 2 (ALSTAR2). Eye-tracked SD-OCT macular volumes (1 per participant) were acquired with a Spectralis HRA + OCT2. A novel deep-learning-derived graph-based algorithm was used to segment 6 outer retinal layers (photoreceptor inner segment (inner segment myoid defined as external limiting membrane-ellipsoid zone (EZ) center line), photoreceptor outer segment (EZ center line-interdigitation zone outer surface), SDD, retinal pigment epithelium (RPE), drusen, choroid), and segmentation errors were manually corrected (fig. 1). Retinal layer mean thickness within 9 ETDRS subfields was computed and compared between the groups.

Results: The study cohort included 400 eyes: 140 early AMD and 260 normal. Table 1 shows comparison of mean thickness between normal and early AMD. In early AMD, increased mean thickness of drusen was observed in most subfields. SDD were numerically thicker in all subfields, but statistically significant in only a few. In contrast, the photoreceptor inner and outer segments were numerically thinner in all subfields but not statistically significant. No significant differences were observed in the RPE or choroid layer.

Conclusions: In the transition from normal to early AMD, drusen thickness increases consistently throughout the macula. SDD thickness increases in some subfields. The bacillary layer was thinner in early AMD, but the difference was not statistically significant. The choroid layer showed no difference in thickness in any subfield.

ABSTRACT BODY:

Purpose: Allergic conjunctivitis and various conditions can cause conjunctival vessel dialation, leading to ocular redness (OR). Using an animal model of allergic OR, we evaluated the therapeutic efficacy of topical blockade of substance P (SP), which preferentially binds to neurokinin-1 receptor (NK1R) , in treating red eye.

Methods: Allergic OR was induced in guinea pigs with topical 1.5 mg/mL histamine. NK1R antagonist, L-703,606, was applied 10 minutes before or after OR induction as pre-induction or post-induction treatment, respectively. Animal eyes were imaged by a slit lamp (N= 12/group) every 30 seconds in the first 2 minutes, and at 6, 10, 20, 30, 40, 50, and 60 minutes. The redness was analyzed using the ocular redness index (ORI), a score between 0 to 100. After 60 minutes, tear fluid was collected to quantify SP levels by ELSIA (N= 6/group). Lastly, conjunctiva were harvested and stained with H&E to quantify the size of blood vessels and eosinophil and neutrophil infiltration (N= 6/group).

Results: With histamine induction, the ORI peaked at 10 minutes (maximum ORI: 17.04±0.99). Topical treatment of L-703,606 significantly ($P<0.05$) reduced ORI (pre-induction: 7.38±0.71; post-induction: 10.91±0.59). Compared to naive guinea pigs, histamine increased the conjunctival blood vessel diameter nearly three times (naive: 10.15±1.41; histamine: 30.66±4.12). Both pre- and post-induction treatment decreased blood vessels diameter (pre-induction: 16.84±2.21; post-induction: 23.69±2.36) but only pre-induction had significant ($P<0.05$) change. The tear concentration of SP was 71.64±19.16 pg/mL in the naive group, and 270.60±38.04 pg/mL in histamine-induced group. Pre-induction treatment significantly ($P<0.05$) decreased SP concentrations to 154.10±9.72 pg/mL and post-induction treatment lowered SP levels to 191.10±13.52 pg/mL. The numbers of eosinophils and neutrophils were 8.50±2.69 and 4.67±2.91 respectively in the conjunctiva of the naive group. Histamine increased the eosinophil count to 46.00±2.57 and neutrophils to 31.47±2.33. Post-induction treatment reduced eosinophils to 35.50±1.66 and neutrophils to 21.87±1.97, while pre-induction treatment significantly ($P<0.01$) decreased eosinophils to 26.00±2.92 and neutrophils to 14.53±2.31.

Conclusions: Topical administration of the NK1R antagonist effectively reduces allergy-induced ocular redness by decreasing SP release in the tear fluid and conjunctival leukocyte infiltration.

ABSTRACT BODY:

Purpose: Daylight vision is mediated by cone photoreceptors in vertebrates. The synapse between cone photoreceptors and bipolar cells is functionally and anatomically complex and critical for normal visual function. ON cone bipolar cell dendrites make invaginating synapses and OFF cone bipolar cell dendrites make flat synapses with cone pedicles, however, the mechanism of whole synaptic assembly is not completely understood. Here we report a leucine-rich repeat (LRR) protein, LRFN2 that is expressed selectively at cone pedicles and involved in modulation of cone synaptic function.

Methods: Using an unbiased proteomic approach we identified LRFN2 as a candidate synaptic organizer protein in mouse retina, and generated a $Lrfn2^{-/-}$ mouse line using zinc finger nucleases. Immunohistochemistry was performed in retinal sections to localize protein expression. Biochemical interaction studies were performed in HEK293T cells expressing both LRFN2 and TRPM1. We characterized retinal function of $Lrfn2^{-/-}$ mice using electroretinogram (ERG) recordings.

Results: We show that LRFN2 expression is co-localized with PNA staining at the cone pedicles. We confirmed interaction between LRFN2 and TRPM1 in a heterologous system. In the absence of LRFN2, the synaptic markers: LRIT3, ELFN2, mGluR6, TRPM1 and GPR179 are properly localized. Similarly, LRFN2 expression and localization is not dependent on these synaptic proteins. Functional analysis showed a reduction in the amplitude of the photopic b-wave of the ERG in $Lrfn2^{-/-}$ mice.

Conclusions: Our data show that LRFN2 likely interacts with TRPM1 and is expressed exclusively at the cone pedicles. Further, its absence compromises normal synaptic transmission between cones and ON cone bipolar cells.

ABSTRACT BODY:

Purpose: To evaluate the microstructural optical coherence tomography (OCT) and fundus autofluorescence (FAF) imaging predictors of visual acuity, metamorphopsia and aniseikonia after retinal detachment repair.

Methods: Retrospective analysis of 614 eyes of 614 patients who underwent primary rhegmatogenous retinal detachment (RRD) repair. Best corrected visual acuity, metamorphopsia and aniseikonia were formally tested at 3 months post-operatively. Metamorphopsia and aniseikonia were quantitatively assessed with M-CHARTS and the New Aniseikonia Test. High-resolution spectral-domain OCT and FAF images were captured at 3 months post-operatively. Images were assessed for discontinuity of the outer retinal bands on OCT and retinal displacement detected by retinal vessel printings (RVPs) on FAF by 2 masked graders with disagreements adjudicated by a 3rd senior masked grader. Regression analysis was used to determine the imaging predictors of post-operative visual acuity, metamorphopsia and aniseikonia.

Results: Regression analysis indicated that significant early post-operative (at 3 months) imaging predictors of visual acuity were discontinuity of the external limiting membrane (ELM) (p=0.01) and presence of RVPs on FAF (p=0.033). Discontinuity of interdigitation zone (IZ) was a significant predictor of metamorphopsia [horizontal, MH (p =0.004); vertical, MV (p=0.056); average of MH+MV (p=0.008)] and presence of RVPs was a significant predictor of aniseikonia (p=0.04).

Conclusions: Post-operative discontinuity of the external limiting membrane and retinal displacement were significant predictors of post-operative visual acuity following RRD repair. Discontinuity of the IZ and retinal displacement were significant predictors of post-operative metamorphopsia and aniseikonia, respectively. Modifications of surgical techniques aimed to reduce post-operative discontinuity of the outer retinal bands and retinal displacement may improve functional outcomes after retinal detachment repair.

ABSTRACT BODY:

Purpose: To perform a real-world validation of deep learning (DL) algorithms for automated scleral spur detection and measurement of scleral spur-based biometric parameters in anterior segment optical coherence tomography (AS-OCT) images.

Methods: Participants underwent AS-OCT imaging using the ANTERION OCT system (Heidelberg Engineering, Heidelberg, Germany). Three human graders (Reference, Expert, and Novice) provided labels of scleral spur locations. Scleral spur locations were also predicted using DL algorithms developed by Heidelberg Engineering that prioritize low false positive rate <4% (FPR4) or high true positive rate >95% (TPR95). Performance of human graders and DL algorithms were evaluated relative to the Reference Grader based on similarity of scleral spur locations, biometric measurements, and false negative and positive rates (FNRs and FPRs) of scleral spur detection.

Results: 1,308 AS-OCT images were obtained from 117 participants. Median scleral spur location differences of the FPR4 (52.6 ± 48.6μm) and TPR95 (55.5 ± 50.6μm) algorithms approximated that of the Expert Grader (61.1 ± 65.7μm). Inter-grader reproducibility of biometric measurements was excellent for all three (intraclass correlation coefficient [ICC] range 0.955-0.997). FNR and FPR of the TPR95 algorithm (1.0% and 15.8%) more closely approximated the Expert Grader (2.9% and 17.4%) than the FPR4 algorithm (12.6% and 4.0%). Performance of the Expert Grader and DL algorithms generally exceeded that of the Novice Grader.

Conclusions: DL algorithms on the ANTERION replicate expert-level measurement of scleral spur-based biometric parameters in a diverse real-world patient population. The algorithms could enhance clinical utility of AS-OCT imaging, especially for intraocular lens (IOL) calculations and evaluation of patients with angle closure.

ABSTRACT BODY:

Purpose: Retinal degenerative disease (RDD) is a sight-threatening disease with no effective treatment due to the lack of promising drug delivery for rescue of degenerated retinal neurons. Encapsulated cell therapy (ECT) with cellular release of fresh therapeutics enables local sustained drug delivery to the retina while avoiding repeated intravitreal injections. Glial cell-derived neurotrophic factor (GDNF) has shown its neuroprotective effect on photoreceptor cells. While photoreceptor cell death is common in most RDD, we hypothesized that continuous GDNF delivery by collagen-alginate composite (CAC) ECT device can rescue photoreceptor cells, finally slowing the RDD progression. Here, an injectable CAC ECT device equipped with a Tet-on Caspase 8 system was developed for sustained intraocular delivery of GDNF in rabbit eyes.

Methods: Intravitreal (IV) injection of CAC ECT device was performed on healthy New Zealand White rabbits. Three or six units of CAC ECT device were injected into the rabbit eye and kept for 2 weeks, after which rabbits were sacrificed, and devices were retrieved. CAC ECT device biostability was determined by evaluation of gel morphology, cell viability and internal structure. Its biosafety was examined by assessment of flash electroretinogram (fERG), intraocular pressure (IOP) and retinal histology. Rabbits receiving 3 ECT devices were also given 0.1mg/ml doxycycline in drinking water 7 days post-operation for 1 week to examine gel termination efficacy. Cell viability in retrieved devices was determined by MTS assay and Live-Dead assay.

Results: Our data showed that IV injection of CAC ECT device was safe and imposed no changes on retinal function and morphology. The retrieved CAC ECT device exhibited good mechanical stability, gel integrity with no material degradation, and no host tissue attachment with viable encapsulated cells. Scanning electron microscopy further revealed CAC interpenetrating network and colonies of living cells. A week of oral doxycycline treatment could effectively stop the CAC ECT device.

Conclusions: Our CAC ECT device was safe and terminable after IV injection. It demonstrated good mechanical stability while entrapped cells maintained their viability, suggesting that it is a promising drug delivery platform to treat RDD.

ABSTRACT BODY:

Purpose: Knowledge of the lens dynamics during accommodation can provide insight into age-related changes that contribute to presbyopia. However, in addition to age-dependence, there are also significant inter-individual differences in accommodative responses. The goal of this study is to assess the sources of this variability by quantifying the dynamic changes of the lens, pupil, and ciliary muscle during accommodation from OCT images.

Methods: Following an IRB-approved protocol, OCT images of the left eye of 17 subjects (age: 16 to 70 years; mean: 34 ± 16 years) were captured during accommodation in response to a 2D step stimulus using two synchronized Spectral-Domain OCT systems coupled with an accommodative fixation target (Ruggeri et al, BOE, 2016): transscleral OCT for ciliary muscle imaging (1320nm, 13 fps, 7.5 μm axial resolution, 2.5 mm axial range, Thorlabs Telesto, Newton, NJ) and anterior segment OCT for lens and pupil imaging (840 nm, 13 fps, 8 μm axial resolution, 10.4 mm axial range). Images were recorded for 1.54 s before and 4.61 s after the stimulus for a total of 160 images. The time-dependence of lens thickness (LT), pupil diameter (PD), and ciliary muscle thickness (CMT) at mid-point were quantified. CMT-LT, PD-LT, and CMT-PD response diagrams were generated

Results: 8 out of 15 pre-presbyopic subjects responded to the stimulus. In these subjects, there was synchronous movement of the pupil, lens, and ciliary muscle. Figure 1 shows a typical result illustrating the sequence of pupil constriction followed by lens thinning and additional pupil constriction once the lens reached its asymptotic value. For the 7 eyes that did not respond and 2 presbyopes (>55 years), pupil response was inconsistent across subjects, with an increase in PD.

Conclusions: The combination of all 3 measurements (LT, PD, and CMT) is helpful in assessing the source of variability in accommodative responses and the role of the pupil in accommodation dynamics

ABSTRACT BODY:

Purpose: Swept-source optical coherence tomography angiography (SS-OCTA) images were used to analyze Bruch's membrane (BM) and choriocapillaris (CC) abnormalities in undiagnosed relatives from a family with Sorsby macular dystrophy (SMD).

Methods: In a family with SMD (TIMP3 Tyr191Cys), SS-OCTA imaging was performed using the 6X6mm scan pattern and previously validated algorithms to detect abnormalities in BM and the CC, as well as the presence of reticular pseudodrusen (RPD) and macular neovascularization (MNV). Genetic analyses were performed for TIMP3 mutations.

Results: Of eight family members, two were previously diagnosed with SMD and six were asymptomatic (Figure 1). SS-OCTA imaging of the 33-year-old proband revealed type 1 MNV in the left eye and bilateral RPD, thickening of BM, CC thinning, and increases in CC flow deficits (FDs) (Figure 2). A TIMP3 mutation was confirmed. His niece, despite having no clinical evidence of SMD, showed BM thickening and CC thinning on SS-OCTA. A TIMP3 mutation was confirmed. The proband's younger nephew and niece also carried the TIMP3 mutation without clinical evidence of SMD. Two additional members had normal exams, unremarkable SS-OCTA findings, and no TIMP3 mutation.

Conclusions: SS-OCTA imaging can detect BM and CC abnormalities in vivo in subjects unaware of their TIMP3 status in a family with SMD.

ABSTRACT BODY:

Purpose: Recent studies have demonstrated the ability of OCT to quantify changes in ciliary muscle thickness with age and accommodation, giving insight into the potential role of the ciliary muscle in presbyopia. Prior studies have relied on measurements acquired statically at fixed accommodative demands. The purpose of this study is to quantify the dynamics of the ciliary muscle thickness changes during accommodation.

Methods: Following an approved protocol, transscleral images of the ciliary muscle of the left eye of 23 subjects (range: 16 to 71 y/o) with spherical equivalent refractive errors ranging from -7.5 to +1 D were acquired at 13 Hz during a response to a 2D accommodative step stimulus. A Spectral-Domain OCT system (1320nm, 28,000 A-lines/s, 7.5 μm axial resolution, and 2.5 mm axial range, Thorlabs Telesto, Newton, NJ) coupled with a custom accommodation module (Ruggeri et al, Biomed Opt Exp, 2016: 1351-1364) was used. For each subject, we acquired a series of 160 B-scans containing 897 A-lines. A MATLAB program was developed to measure the ciliary muscle thickness in each frame. Thickness was measured in the vicinity of the middle part of the muscle where the muscle boundaries could be clearly identified. The change in the muscle thickness was calculated as the difference between the average thickness obtained from the first 10 frames (unaccommodated state) and that obtained from the last 10 frames (accommodated state) of the dynamic recording. The relations between the change in thickness of the ciliary muscle and age as well as refractive error were quantified.

Results: Ciliary muscle thickness in the relaxed state was not found to be dependent on age ($p=0.951$) but was dependent on refractive error ($p<0.001$). The average of the ciliary muscle thickness change during accommodation of all other subjects was 0.062+/-0.074mm. There was not a statistically significant dependence on age (p-value > 0.005). The change in ciliary muscle thickness decreased with increasing myopia (p-value < 0.001).

Conclusions: Ciliary muscle thickness changes with accommodation were found to be independent of age but dependent on refractive error.

ABSTRACT BODY:

Purpose: Axons in the optic nerve do not usually regenerate when they are injured, causing permanent loss of vision. However, recent studies indicate that stimulation of PI3K/Akt and RAF/MEK/ERK signaling promotes axon regeneration and neuroprotection. In this study, we examined the effects of constitutively active Ras, K-Ras^{V12}, which powerfully activates these signaling, on retinal ganglion cell (RGC) protection and axon regeneration using an optic nerve crush (ONC) model.

Methods: K-Ras^{V12} was generated by site-directed mutagenesis and incorporated into an adeno-associated viral serotype 2 (AAV2) vector. AAV2-K-Ras^{V12} was injected intravitreally in C57BL/6J mice. One or two weeks after the injection, ONC was performed, and one or eight weeks later, cholera toxin B subunit (CTB647)-labeled regenerating axons were analysed. The number of RGCs was determined by immunolabeling using anti-RBPMS antibody in flatmounted retinas. EdU (50mg/kg) was intraperitoneally injected daily for examination of cell proliferation. Electron microscopy was performed for detailed histological analysis of axons.

Results: AAV2-K-Ras^{V12} treatment demonstrated increased number of RGCs compared with the control after ONC. As Ras is an oncogene, we examined the potential of cell proliferation, but found that RGCs were not proliferated by the AAV2-K-Ras^{V12} treatment. These data showed that the increased RGC number after ONC with AAV2-K-Ras treatment was due to neuroprotection. Furthermore, AAV2-K-Ras^{V12} treatment induced significant amounts of RGC axon regeneration even after 1 week, and some regenerating axons reached the optic chiasm after 8 weeks. These data indicated that AAV2-K-Ras^{V12} treatment induces powerful RGC axon regeneration. In addition, we found that AAV2-K-Ras^{V12} -induced regenerated axons were not myelinated, suggesting that combinatory treatment with promoting myelination may be required for functional recovery.

Conclusions: AAV2-K-Ras^{V12} may be useful for treatment of CNS axon injury in future, and it may be a good tool to study mechanisms for RGC axon regeneration and protection.

ABSTRACT BODY:

Purpose: To evaluate the characteristics of pediatric glaucoma patients with moderate and poor best corrected visual acuity compared to those with good visual acuity.

Methods: A retrospective review of electronic medical records from 2001 to 2019 was conducted for pediatric glaucoma patients or adults with history of pediatric glaucoma diagnosis or treatment. Visual acuity, failed amblyopia treatment, refractive status, axial length, strabismus, nystagmus, failed angle surgery, and media opacity were recorded. Patients without data for the best corrected visual acuity were excluded. Patients were categorized by their most recent WHO visual acuity (VA) status (poor VA <20/200, moderate VA <20/50 to 20/200, and good VA 20/20 to 20/50) and analyzed. One-way ANOVA testing was used to assess axial length differences among the VA groups, while Chi squared testing was used for the remaining variables.

Results: 233 glaucomatous eyes of 142 childhood glaucoma patients were identified. Average follow-up duration was 6.85 ± 4.46 years. 91 patients had bilateral glaucoma. There were 65 eyes with poor VA of which 22 (33.8%) had failed amblyopia therapy, compared to 16 (28.6%) of the 56 moderate VA eyes, and 1 (0.89%) of the 112 eyes with good VA who failed amblyopia therapy ($p<0.00001$). Failed angle surgery was observed in 29.2% of poor VA eyes, 35.7% of moderate VA eyes, and 25% of good VA eyes ($p=0.35$). The mean axial length for eyes with poor VA was 25.27mm, moderate VA 25.70mm, and good VA 23.91mm ($p=0.37$). Thirty of the 65 (46.2%) poor VA eyes had media opacity while 17 of the 56 (30.4%) moderate VA eyes and six of the 112 (5.36%) good VA eyes had media opacity respectively ($p<0.00001$). Strabismus was seen in 7.69% of poor VA eyes, 12.5% of moderate VA eyes, and 1.79% of good VA eyes ($p=0.02$). Similarly, nystagmus was found in 13.8% of poor VA eyes, 16.0% of moderate VA eyes, and 0.89% of good VA eyes ($p=0.0005$). Finally, anisometropia was found in 23.1% of poor VA eyes, 35.7% of moderate VA eyes, and 28.6% of good VA eyes ($p=0.31$).

Conclusions: Eyes with poor and moderate visual acuities tended to have increased rates of media opacity, failed amblyopia therapy, nystagmus, strabismus, and increased axial length though the latter was not statistically significant. Failed amblyopia therapy seems to be by far the most common association with poor vision. Failed angle surgery was not associated with poorer visual acuity.

ABSTRACT BODY:

Purpose: We utilized multimodal imaging with Erythrocyte Mediated Angiography (EMA) and Optical Coherence Tomography Angiography (OCTA) to precisely quantify erythrocyte velocity and acceleration in perifoveal retinal arterioles, capillaries, and venules of humans and nonhuman primates (NHPs) at baseline and high intraocular pressure (IOP).

Methods: 15 eyes of 9 healthy human subjects and 4 eyes of NHPs underwent sequential EMA and OCTA. High intraocular pressure (IOP), defined as 18mmHg or higher, was induced in NHPs using a tight lid speculum. Systolic blood pressure, diastolic blood pressure, and IOP were measured to calculate mean ocular perfusion pressure (MOPP). Erythrocytes in capillaries were tracked using a semiautomated approach. To identify the corresponding vascular plexus, overlays were made using a time-lapse stack of EMA frames and OCTA images of the superficial vascular plexus (SVP), intermediate capillary plexus (ICP), and deep capillary plexus (DCP) (Figure 1). We compared erythrocyte velocity and acceleration in each plexus using generalized estimating equations for statistical analysis.

Results: In human subjects, overall mean capillary velocity was 1.7±1.6mm/s. Differences between capillary velocities were noted between SVP, ICP, and DCP ($p<0.01$ for all comparisons) (Table 1). Overall mean human capillary acceleration was 4.0±2.5x10-3mm/s2, which did not differ significantly between plexuses. In NHPs, overall mean capillary velocity (0.69±0.31mm/s) at baseline IOP was significantly higher than that of high IOP (0.39±0.18mm/s, $p<0.01$). Overall NHP mean capillary acceleration was significantly higher at baseline as compared to high IOP ($p<0.001$). While there were no significant differences between plexus velocities in NHPs at baseline, mean capillary velocities at high IOP varied significantly between DCP and ICP ($p<0.01$) and DCP and SVP ($p<0.01$). Mean capillary accelerations in NHPs at baseline IOP varied significantly between DCP and ICP ($p=0.015$). At high IOP, mean NHP capillary accelerations were significantly lower for SVP and ICP as compared to DCP.

Conclusions: In humans and NHPs, erythrocyte decelerate in arterioles then accelerate in venules as expected. We have shown that blood flow in the SVP, ICP, and DCP can be precisely quantified and can differ between plexuses. Furthermore, elevated IOP results in decreased erythrocyte velocity and acceleration.

ABSTRACT BODY:

Purpose: We performed a retrospective analysis of a large prospectively specified observational database of patients with central retinal vein occlusion (CRVO) treated with vascular endothelial growth factor (VEGF) inhibition from routine practice.

Methods: We identified 527 treatment-naïve patients with CRVO that commenced VEGF inhibitors between January 1, 2010-2018, with a mean (SD) age of 71 years (12), visual acuity (VA) of 41 letters (25). The primary outcome was mean change in VA from baseline to 36 months. Adjusted VA and central subfield thickness (CST) outcomes compared VEGF agents with generalised mixed effects models.

Results: In all eyes, mean VA change (95% CI) was +10 (7, 12) letters, 44% gained and 14% lost ≥15 letters, 37% had final VA ≥70 and 30% ≤35 letters. Mean CST change was -306µm. The adjusted mean VA change was similar with each VEGF inhibitor (+12 letters) despite significant difference in adjusted mean CST change with aflibercept (-310µm), ranibizumab (-258µm) or bevacizumab (-216µm; $P < 0.001$). VEGF switchers (19%) gained +11 letters like non-switchers (69%) but with more injections (20 vs. 10; $P < 0.001$). Eyes that were switched to steroid (12%) had lower mean baseline VA 38 letters, 46% had final VA ≤35 letters and no mean change in VA from baseline. Mean VA change in eyes with trial-eligible baseline VA (19-73 letters, 356/527, 68%) was +7 letters. Eyes outside this range with very-poor baseline VA (<19 letters, 129/527, 24%) gained +22 letters and eyes with very-good baseline VA (>73 letters, 42/527, 8%) lost vision by -7 letters. Completers (257/527, 49%) had a median of 18 injections over 26 visits. Suspension of therapy >180 days occurred in 141/527 (27%) eyes but only 62 (12%) eyes had no macular oedema during that time. Treatment status was known in 356/527 (68%) eyes – 55% were still receiving injections at 3 years while 45% had suspended therapy.

Conclusions: Patients with CRVO that commenced VEGF inhibitors in routine care had VA improvements of around 10 letters at three years - almost matching the outcomes of extension studies that followed RCTs. The choice of

VEGF inhibitor influenced CST but not VA outcomes. Half of all eyes were still being treated at 36-months.

ABSTRACT BODY:

Purpose: Vitrectomies are necessary for treating non-clearing vitreous hemorrhage and tractional retinal detachments. We used the IRIS Registry to better understand vitrectomy rates and demographics that predict which Proliferative Diabetic Retinopathy (PDR) patients would be more likely to undergo a vitrectomy.

Methods: We identified patients with PDR between the years of 2016-2018 in the IRIS Registry and calculated the percentage of eyes with PDR undergoing vitrectomy each year. Multivariate regression was performed to identify how patient sex, age, and race/ethnicity as well as diagnosis influence odds of undergoing vitrectomy. We also compared the number of intravitreal anti-VEGF injections between 2016-2018 for eyes with PDR who underwent and did not undergo vitrectomy in 2018.

Results: Percentage of PDR eyes undergoing vitrectomies between 2016-2018 was 2.27% in 2016, 2.12% in 2017, and 2.40% in 2018 (Table 1). After adjusting for confounders, ages 41-60 (OR 3.0, 95% CI 2.59 - 3.48) and ages 61-40 (OR 2.72, 95% CI 2.42 - 3.05) had the highest odds of undergoing vitrectomy compared to patients aged 21-40. Similarly, compared with White race, Hispanics (OR 1.26, 95% CI 1.19 - 1.34) had the highest adjusted odds of undergoing vitrectomy and Asians (OR 0.72, 95% CI 0.62 - 0.83) and Blacks (OR 0.75, 95% CI 0.71 - 0.80) had the lowest. The mean number of injections for PDR patients who underwent and did not undergo vitrectomy in 2018 was respectively 2.96 and 0.93 ($p < 0.001$).

Conclusions: Within the IRIS Registry, there was no clear trend in the percentage of eyes with PDR undergoing vitrectomy between 2016, 2017, and 2018. Patients ages 41-60 were the most likely to undergo vitrectomy, possibly as a result of surgical candidacy. Interestingly, Hispanic patients had a 26% greater adjusted odds of undergoing vitrectomy than White patients, while Black and Asian patients respectively had a 25% and 28% lower adjusted odds. Eyes undergoing vitrectomy on average had 3 times more intravitreal anti-VEGF injections in the preceding two years than eyes that did not undergo vitrectomy.

ABSTRACT BODY:

Purpose: Uncorrected Refractive Error (URE) among youth is associated with decreased school performance and productivity. We aimed to investigate youth experiences with glasses and contacts, as prior experiences with refractive correction are potential facilitators or barriers to correcting URE.

Methods: A five-question survey including open-ended questions about experiences with refractive correction was sent to the MyVoice Text Message Cohort of U.S. youth aged 14–24 years (www.hearmyvoicenow.org). Responses were coded by two team members independently using a modified grounded theory approach, and disagreements in coding were resolved by consensus.

Results: In total, 1063 participants out of 1204 responded (88.3%). The mean age of participants was 20.3 ± 2.4 years (range 15-24 years); 32.5% (n=346) were female; and 74.0% (n=787) were white. Nearly two thirds (65.8%; n=699) had experienced trouble with their eyesight, and 63.6% (n=676) had worn glasses and/or contacts. Some (31.7%, n=337) discussed a preference for glasses or contacts; of those, 83.7% (n=282) preferred glasses and 16.3% (n=55) preferred contacts. The most common reasons for preferring glasses were problems with contacts (12.8%, n=36, e.g. “I wear glasses because I cannot put contacts in for the life of me”) and convenience (4.3%, n=12, e.g. “I still wear my glasses because I think they're less work than contacts”). The most common reasons for preferring contacts were convenience (16.4%, n=9, e.g. “I wear corrective contacts so I can avoid the hassle of having glasses”), problems with glasses (12.7%, n=7, e.g. “I wear both, mostly contacts day to day because with masks they don't fog up like glasses do”), cosmesis (10.9%, n=6, e.g. “If I’m being active or planning on wearing makeup I’ll wear my contacts”) and preference for wearing contacts for sports (10.9%, n=6, e.g. “I do wear both, mostly contacts so that I can go swimming with ease”).

Conclusions: Glasses may be more popular than contact lenses among U.S. youth. Future work should address youth barriers to glasses to improve access to refractive correction.

ABSTRACT BODY:

Purpose: Boxer dogs are known to be markedly overrepresented with SCCEDs. The clinical presentation of SCCEDs is well known, but the underlying pathophysiology of this condition in Boxers remains unclear. The purpose of this study was to perform multimodal corneal imaging of Boxers with and without SCCEDs to determine if corneal morphologic differences could be identified.

Methods: Eight control (9.5 ± +/- 2.0 yrs, 3 castrated males, 1 intact male, and 4 spayed females) and 15 SCCED-affected (8.5 +/- 1.3 yrs, 8 castrated males and 7 spayed females) Boxers were examined. An ophthalmic examination including Fourier-domain optical coherence tomography (FD-OCT) and in vivo confocal microscopy (IVCM) were performed in the central cornea of both eyes. One-way analysis of variance (ANOVA) was used to compare total corneal thickness (TCT), epithelial thickness, stromal thickness (ST), and density of keratocytes in the anterior stroma between SCCED-affected eyes, unaffected eyes of dogs with SCCEDs, and controls. Corneal endothelial cell density (ECD), cell size and cell side number were calculated using manual frame method (FM) and planimetry (PL) and compared between SCCED-affected and unaffected dogs using a Student's t-test.

Results: The TCT and ST were significantly higher in SCCED-affected eyes versus unaffected eyes of SCCED-affected Boxers with SCCEDs and controls ($P < 0.001$); no significant differences were found in epithelial thickness and anterior stromal keratocyte density between these three groups. Amongst SCCED-affected dogs, 6 had a low ECD with a mean ± SD of 768 ± 376 cells/mm^2 by FM and 892 ± 359 cells/mm^2 by PL. Furthermore, ECD was significantly less ($P < 0.05$) in dogs with SCCEDs (1488 ± 606 cells/mm^2 by FM, 1545 ± 559 cells/mm^2 by PL) versus unaffected dogs (1902 ± 293 cells/mm^2 by FM, 1898 ± 294 cells/mm^2 by PL). Finally, SCCED affected dogs showed significantly greater variability in cell size and side number versus control dogs ($P < 0.01$).

Conclusions: SCCED-affected Boxers had corneal morphologic features that differed from unaffected dogs including a low ECD in some. Additional Boxers are required to evaluate the prevalence of endothelial disease in this breed and its potential impact on the occurrence of SCCEDs.

Commercial Relationships Disclosure: Eric Jung: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Lee: Commercial Relationship: Code N (No Commercial Relationship) | Aaron Nagiel: Commercial Relationship(s);Code C (Consultant/Contractor):Allergan Retina, Regenxbio, Novartis, Biogen

ABSTRACT BODY:

Purpose: There is ongoing research on the safety and efficacy of recently introduced anti-vascular endothelial growth factor (VEGF) biosimilars for the treatment of retinal disease, especially in the pediatric population. We report our initial experience with intravitreal bevacizumab-bvzr, a bevacizumab biosimilar FDA-approved in 2019 and recently introduced by our institution for off-label ophthalmologic use.

Methods: This was an IRB-approved single-institution retrospective case series of pediatric patients 21 years or younger who received at least one intravitreal injection of biosimilar bevacizumab-bvzr.

Results: 12 eyes of 9 patients were identified as having received intravitreal bevacizumab-bvzr, with a total of 13 injections performed. The mean number of injections performed per eye was 1.1 (range: 1 – 2 injections). The median follow-up time from first injection was 16 weeks (range: 4 – 33 weeks). The dose used was 0.125 or 0.625 mg in 0.025 ml for 7 retinopathy of prematurity (ROP) injections, and 1.25 mg in 0.05 ml for the remaining injections. Indications for injection included ROP (7/13), macular neovascularization (3/13), retinal vein occlusion (2/13), and Coats disease (1/13). All four patients with ROP experienced regression of Stage 3 disease, and all four patients with intraretinal or subretinal fluid on optical coherence tomography exhibited reduction or resolution of fluid following injection of bevacizumab-bvzr. No occurrences of post-injection inflammation, intraocular pressure anomalies, or endophthalmitis were observed.

Conclusions: This case series supports the continued use of intravitreal bevacizumab-bvzr as an anti-VEGF therapy option, including in the pediatric population. In light of its favorable cost profile compared to bevacizumab and other anti-VEGF agents, these results should encourage larger studies and its use in resource-poor settings.

TITLE: Diet-induced inflammation and immune sexual dimorphism as driving factors for geographical and gender disparities in diabetic retinopathy prevalence

SESSION TITLE: Diabetic retinopathy epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Narendran, K. Ramasamy, Aravind Eye Care System, Madurai, Tamil Nadu, INDIA|

Commercial Relationships Disclosure: Siddharth Narendran: Commercial Relationship(s);Code P (Patent):University of Virginia | Kim Ramasamy: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Previous epidemiological studies have reported significant geographical and gender disparities in the prevalence of Diabetic Retinopathy (DR) and vision-threatening diabetic retinopathy (VTDR). However, the drivers responsible for this heterogeneity are yet to conclusively determined. The two contiguous South Indian states, Tamil Nadu (TN) and Kerala (KL) possess similar geographical, genetic, and ethnolinguistic landscapes. Despite these similarities, the prevalence of several non-communicable diseases, including DR, has been reported to be significantly higher in KL compared to TN.

Methods: Data were evaluated by accessing the electronic health records of individuals presenting to five tertiary eye care facilities across South India from 2015-2019. The primary outcome was the diagnosis of DR or VTDR. Plasma Interleukin-6 (IL-6) concentration was measured using a commercial immunoassay. The secondary data from the National Sample Survey Organization was analyzed to study the per capita consumption patterns. Multivariate regression, Propensity score matching, Inverse probability treatment weighting, and doubly robust estimation, were employed to study the factors influencing the prevalence of DR and VTDR.

Results: A total of 922,158 patients were included in the analyses, among which there were 263,592 patients with Type II DM. After adjustment for individual confounders, Type II DM patients from KL were 2.05 times (adjusted hazard ratio, 2.056; 95% CI, 2.009 to 2.114; $P < 0.01$) and 2.27 times (adjusted hazard ratio, 2.272; 95% CI, 2.138 to 2.413; $P < 0.01$) more likely to be diagnosed with DR and VTDR respectively. Men were 1.6 (adjusted hazard ratio, 1.633; 95% CI, 1.508 to1.687; $P < 0.01$) and 1.84 (adjusted hazard ratio, 1.835; 95% CI, 1.752 to 1.922; $P < 0.01$) times more likely to be diagnosed with DR and VTDR respectively. Plasma IL-6 was significantly higher in patients with DR (2.44 vs 1.39 pg/ml), in men (2.27 vs 1.41 pg/ml), in patients from KL (2.23 vs 1.65 pg/ml), and in patients consuming a coconut oil-rich diet (4.05 vs 2.29 pg/ml).

Conclusions: The results of this study ascertain the existence of gender and geographical disparities in the prevalence of DR and suggest that elevated circulating levels of IL-6 could be a potential driving factor for both the gender and spatial heterogeneity in the prevalence of DR.

TITLE: Spatial summation of increments and decrements in the human fovea.

SESSION TITLE: Fundamental and Applied Psychophysics and Color Vision

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W.S. Tuten, Herbert Wertheim School of Optometry and Vision Science, University of California Berkeley, Berkeley, California, UNITED STATES|J.I. Morgan, Scheie Eye Institute, University of Pennsylvania, Philadelphia, Pennsylvania, UNITED STATES|J.I. Morgan, Center for Advanced Retinal and Ocular Therapeutics, University of Pennsylvania, Philadelphia, Pennsylvania, UNITED STATES|D.H. Brainard, Department of Psychology, University of Pennsylvania, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: William Tuten: Commercial Relationship(s);Code P (Patent):University of California, Berkeley;Code P (Patent):University of Pennsylvania | Jessica Morgan: Commercial Relationship(s);Code P (Patent):8226236;Code P (Patent):16/389,942;Code F (Financial Support):AGTC | David Brainard: Commercial Relationship(s);Code P (Patent):16/389,942

ABSTRACT BODY:

Purpose: Measured with adaptive optics, the area of complete spatial summation (i.e., Ricco's area) for light increments delivered to the fovea has a diameter of ~2.5 arcmin. How the visual system integrates adjacent increments and decrements delivered within Ricco's area may yield insights into the mechanisms of spatial summation. To that end, we measured detection performance for various combinations of increments and decrements using an adaptive optics scanning light ophthalmoscope (AOSLO).

Methods: An AOSLO was used to image the retina and deliver stimuli to the central fovea in three subjects. Rectangular stimuli (1.0 x 1.3 arcmin; λ = 550 nm; duration = 187.5 ms; no compensation for fixational eye movements) were presented in pairs against a background of the same wavelength (~2900 cd/m^2). The component rectangles of the paired stimulus were positioned directly adjacent to one another. Stimuli were presented along various meridians in a two-dimensional stimulus space whose principal axes corresponded to the Weber contrasts (range: -100 to +233%) of the component rectangles. Stimulus directions included increment-only, decrement-only, increment-increment, decrement-decrement, and increment-decrement conditions. Detection was measured using a yes/no paradigm and psychometric function fits were used to derive isodetection contours. In one subject, detection for homotypic (incr-incr, decr-decr) and heterotypic (incr-decr) stimuli was assessed at five component rectangle separations ranging from 0 to 2.5 arcmin. Behavioral results were compared to computational observer (CO) simulations generated in ISETBio.

Results: In all subjects, homotypic stimuli exhibited linear summation, and heterotypic stimuli were less detectable than contrast-matched same-sign pairs, suggesting some cancellation of increments and decrements. In two subjects, the magnitude of this cancellation exceeded the amount plausibly accounted for by optical factors, as determined in the CO simulations. The change in detectability of homotypic stimuli as separation increased agreed with CO predictions, whereas heterotypic stimuli were less detectable than CO predictions for separations under 1 arcmin.

Conclusions: Our results suggest the partial cancellation of increments and decrements confined to Ricco's area reflects a combination of optical and neural factors, and may have implications for the underlying ON- and OFF- visual pathways.

ABSTRACT BODY:

Purpose: Trabeculectomy is still the method of choice for surgical treatment of glaucoma, especially for advanced cases. Follow-up and after-treatment manuevers are of outstanding importance for the postoperative clinical course and long-term outcomes. Ocular digital massage (ODM) is a commonly post-operative manuever that promotes aqueous flow through the surgical site, enlarging the bleb, reducing IOP and inhibiting scar formation. There is scarce information regarding the impact of ODM on trabeculectomy outcomes after at least one year of follow-up. The objective of this study is to evaluate the effect of ODM in a cohort of cases with at least one year of post-operative course.

Methods: A retrospective analysis of an electronic database of cases which underwent trabeculectomy in a glaucoma center (November 2017 - December 2020) was carried out. Cases with complete clinical information and a follow-up of at least one year after trabeculectomy were included in the study. The analyzed variables were best-corrected visual acuity, visual field stability, glaucoma stage of severity, number of antiglaucoma medications, time of trabeculectomy follow-up, site of ODM, effect of ODM on IOP and bleb formation. ANOVA analysis was performed for continuous variables. A p-value of ≤ 0.05 was considered as statistically significant.

Results: From 668 cases identified with trabeculectomy, 501 eyes of 416 patients (mean age, 64.2±13.9 years; 61% female; 68% POAG) were included in the study. One hundred and thirty one cases (25.9%) required ODM, and they were significantly younger (mean age, 59.5±.9.8 years, p=0.0012; 69% female; 52% POAG) and with higher pre-operative mean IOP, as compared with the eyes not requiring ODM (20.4±9.2 mm Hg vs 18.3±8.4 mm Hg, p=0.017). Eyes requiring ODM had an early (prior to 8 days) IOP of 16.6±.6.8 mm Hg, decreasing after the maneuver to 11.7±3.4 mm Hg (p<0.0001). After one year, mean IOP (15.3±6.0 mm Hg) of eyes not requiring ODM (n=478) was significantly greater (p=0.04) than IOP (14.0±5.1 mm Hg) of eyes requiring ODM (n=104). No persistent or serious complication was related to ODM.

Conclusions: Findings from the current report suggests that ODM after trabeculectomy is a post-operative maneuver that can induce a sustained benefit to reduce IOP and has to be investigated in well-designed trials in order to recognize its real applicability and limitations, in the long-term.

ABSTRACT BODY:

Purpose: Dendritic cells (DC) density is increased in vernal keratoconjunctivitis (VKC) and allergic conjunctivitis (AC), and we have also shown altered morphology of DC in AC. This study compared the distribution of corneal and conjunctival epithelial DC in VKC, AC, and healthy controls to examine if allergy type causes differences in immune cell activation.

Methods: In vivo confocal microscopy (HRT III) was performed on the right eye of 60 participants (mean age 22.4±8.1 years, 70% male) based in Shiraz, Iran: 20 with limbal VKC, 20 with AC, and 20 healthy controls. Locations scanned included: corneal centre, corneal periphery (1mm inside limbus), corneal limbus, and bulbar conjunctiva (2-3 mm temporal to limbus). DC were counted manually, and corneal morphology was graded for cell body size, presence of dendrites, and dendrite appearance. Differences between groups and between locations were examined using linear mixed model analysis (density), Chi-Square test, Kruskal-Wallis test (morphology).

Results: DC density was higher in VKC, and AC compared to controls, at all locations ($p \leq 0.001$). DC density was significantly higher at the limbus of VKC participants compared to AC ($p < 0.001$), but there was no difference at other locations ($p \geq 0.08$). In all groups, DC density was highest at the limbus than at other locations ($p \leq 0.001$), with the fewest DC observed at the conjunctiva ($p < 0.01$). DC cell bodies were larger in VKC than AC at the corneal centre only ($p = 0.01$). DC cell bodies were larger in VKC, and AC compared to controls, at all corneal locations ($p \leq 0.001$). Dendrites were present on more DC in VKC, and AC compared to the controls, at the corneal centre and periphery ($p \leq 0.001$). VKC and AC groups had more long dendrites compared to the controls at the corneal periphery and limbus ($p \leq 0.001$). The VKC group had more long dendrites compared to controls at the corneal centre ($p = 0.04$) and more thick dendrites at the limbus ($p = 0.048$).

Conclusions: Increased DC density and altered morphology at the ocular surface were evident in both VKC and AC, a marker of the upregulated immune response. Greater DC density in both forms of ocular surface allergy, but higher density at the limbus may be a marker of the more severe VKC. Larger DC cell bodies and more with long dendrites could help to differentiate allergy from non-allergy and more severe forms of allergy from milder forms.

ABSTRACT BODY:

Purpose: Maturing human cone precursors serve as the retinoblastoma cell of origin, yet the cone maturation-associated gene expression changes that contribute to retinoblastomagenesis are not defined. This study aimed to elucidate developmental trajectories and gene expression changes in early photoreceptor precursors and across cone maturation, define the role of cone-specific features in retinoblastoma genesis, and evaluate whether relevant cone maturation features are represented in human retinal organoids.

Methods: 794 single CD133+/CD44,CD49b- cells comprising cone and rod precursors and retinal progenitors were FACS- and microfluidics-isolated from 18 dissociated human fetal retinae (GW15-21). 867 single cells were FACS isolated from retinal organoids (55-225 DIC). After full-length scRNA sequencing, transcriptomes were clustered, and RNA velocity, differential expression, and SCENIC were used to define trajectories and identify cluster-specific gene expression and transcription factor regulons. Expression patterns were validated using RNA-FISH and immunofluorescence staining.

Results: Two post-mitotic photoreceptor precursor clusters were identified: common cone/rod precursors that co-expressed cone (THRB) and rod (NRL) regulons, formed bifurcating cone- and rod-directed trajectories, were marked by CHRNA1, and were detected by CHRNA1 FISH and NRL/RXRg staining; and rod-only precursors that solely expressed rod markers and regulons. Early cone precursor maturation was characterized by sequential expression of lncRNAs (CTC-378H22.2, HOTAIRM1, CTD-2034I21.2, and RP13-143G15.4), as validated by FISH, which marked distinct cone precursor domains. All maturing cone precursor states had high MYCN regulon activity and SYK expression, and inhibition of SYK impaired cell cycle entry in response to pRB knockdown. Retinal organoids did not show a common cone-rod precursor population or sequential cone lncRNA expression but had cone-specific SYK expression.

Conclusions: Full-length scRNA-seq of developing human retina revealed two potential routes to rods, features of common cone-rod precursors, lncRNAs that discriminate early cone maturation stages, and a role for intrinsically expressed SYK in the cone proliferative response. Retinal organoid cones failed to replicate several aspects of human cone development, which may influence the accuracy of retinal organoid development and disease models.

ABSTRACT BODY:

Purpose: This work aims to quantify the growth and the characteristics of atrophy in age-related macular degeneration (AMD) using spectral domain optical coherence tomography (SD-OCT).

Methods: A 5-year prospective study of patients enrolled in a longitudinal study of dark adaptation (NCT01352975) with a range of AMD severities included annual imaging with SD-OCT (Spectralis, Heidelberg, Germany). Atrophy on SD-OCT was defined according to the Classification of Atrophy Meetings (CAM) guidelines as complete retinal pigment epithelium (RPE) and outer retinal atrophy (cRORA). SD-OCT volumes (30^{o}x25^{o}, 60 µm spacing) were first manually graded for presence/absence of cRORA and then a custom semi-automated algorithm contoured the cRORA regions in each OCT B-Scan. Enface 2D projection of the contoured cRORA regions was used to calculate the area atrophy (mm^2). The growth rate of atrophy was calculated for each eye by finding the slope of the best linear fit of the square root area measurements over available timepoints.

Results: Of the 31 patients with cRORA in either eye, 18 (58.1%) had unilateral cRORA whereas 13 (41.9%) had bilateral cRORA (i.e., total of 44 eyes with cRORA). Of these 44 eyes, 24 (54.0%) had cRORA already present at baseline (Group 1, median visual acuity 20/40), and 20 (45.5%) developed cRORA at follow-up visits (Group 2, median visual acuity 20/25). The mean (±SD) area of cRORA at the baseline visit for Group 1 was 2.88 ± 4.10 mm^2 and at the first visit with cRORA in Group 2 was 0.66 ± 0.70 mm^2. The median growth rate of atrophy in Group 1 (mean followup time 2.9 years) was 0.21 mm/year (range 0.024 - 0.64 mm/yr) and in Group 2 (mean followup time 1.3 years) was 0.17 mm/year (range -0.06 - 0.89 mm/yr). For eyes in Group 1, most visits (62.5%) had AMD severity scores 9 (non-central GA) or 10 (centrally involved GA) on color grading (range 5-10), while eyes in Group 2 had fewer visits (30%) with AMD severity scores of 9 or 10 (range 7-10).

Conclusions: Assessment of cRORA/atrophy in OCT can augment the current understanding of atrophy and its growth using color or autofluorescence imaging modalities. The detection and quantification of small, incident areas of atrophy could be used as a more sensitive outcome of advanced disease. The accurate quantification of the growth of these lesions is important in understanding disease progression and for the design of clinical trials.

ABSTRACT BODY:

Purpose: Although it is widely accepted that corneal endothelial cell (CEC) damage occurs during phacoemulsification surgery, it remains unclear if the elevated intraocular pressure (IOP) used during phacoemulsification contributes significantly to this damage. Using a novel experimental method enabling quantification of CEC damage in intact porcine eyes, we tested the hypothesis that elevated IOP under conditions relevant to phacoemulsification surgery leads to increased CEC damage.

Methods: Corneal endothelia of fresh, intact explanted porcine eyes were stained with two nucleic acid viability dyes and imaged through a fluorescence microscope without removing the cornea from the globe. The anterior chambers of the eyes were perfused with BSS to a pressure of 73.6mmHg (bottle height=100cm) for 10min (n=4) prior to restaining and reimaging. Baseline images were analyzed using custom algorithms to determine initial total cell counts (TC_1) and damaged/dead cell counts (DC_1). Images acquired after pressurization were analyzed to obtain final cell counts (TC_2, DC_2). CEC damage was quantified as the change in percent of cell damage/death, PCD ($PCD=100*DC_2/TC_2 - 100*DC_1/TC_1$). As a negative control, additional eyes were pressurized to a physiological IOP of 18.4mmHg for 10min (n=4). The experimental and negative control groups were compared using a two-tailed Student's t-test. As a positive control, one eye was perfused with deionized water at a pressure of 18.4mmHg for 10min.

Results: There was no significant difference in mean PCD values between the experimental (0.22%) and negative control (0.30%) groups (p=0.78). The positive control sample yielded a PCD of 84.5%, indicating that the method is able to detect CEC damage.

Conclusions: Our results suggest that the elevated IOP used over the duration of phacoemulsification surgery does not lead to a significant increase in CEC damage. However, further studies are needed to expand the sample size and ensure statistical power. Notably, the mean PCD measured in the experimental group was less than the yearly decrease in the central CEC density of healthy individuals (0.59%), strongly suggesting that surgical IOP alone does not result in clinically-significant CEC damage.

ABSTRACT BODY:

Purpose: To evaluate microvascular changes in the macula and extra-macular region on WF SS-OCTA and assess their association with visual acuity (VA) following RRD repair.

Methods: We conducted a retrospective, cross-sectional, observational study of 241 patients imaged with WF SS-OCTA (PLEX® Elite 9000) between Dec. 2018 and June 2021. The Advanced Retinal Imaging Network (Zeiss Portal) was used to obtain vessel density (VD) and vessel skeletonized density (VSD) of the superficial capillary plexus (SCP), deep capillary plexus (DCP), and whole retina as well as foveal avascular zone (FAZ) parameters from 3×3 mm, 6×6 mm, and 12×12 mm fovea-centered scans. Mixed-effects multiple regression models adjusting for age, presence of diabetes mellitus or hypertension, lens status, extent and duration of detachment, and interval from surgery to imaging were used for statistical analysis.

Results: We included 97 eyes of 92 patients who underwent successful repair of macula-off (n=54) or macula-on (n=43) RRD, 67 unaffected fellow eyes, and 185 control eyes of 149 healthy patients. Median interval from surgery to imaging was 13 (3-78) months. Compared to controls, RRD eyes showed reduced SCP VSD (β=-0.18, p=0.02), VD (β=-0.02, p=0.01), and FAZ circularity (β=-0.06, p=0.004) in 3x3 mm scans and lower VSD/VD in the SCP (β=-0.87, p=0.04; β=-0.03, p=0.03), DCP (β=-1.17, p=0.03; β=-0.03, p=0.03), and whole retina (β=-0.90, p=0.05; β=-0.03, p=0.04) in 12x12 mm scans. RRD eyes also had lower SCP VSD (β=-0.55, p=0.03), VD (β=-0.01, p=0.01), and FAZ circularity (β=-0.06, p<0.001) in 3x3 mm scans than fellow eyes. Postoperative VA at the time of imaging was associated with SCP VD (β=-1.07, p=0.04) in 3x3 mm scans. Macula-off eyes had lower FAZ circularity (β=-0.05, p=0.02) than macula-on RRD eyes, while eyes treated with cryopneumatic retinopexy showed increased FAZ perimeter (β=0.71, p=0.009) and reduced circularity (β=-0.13, p=0.01) compared to vitrectomized eyes.

Conclusions: Vessel densities in the SCP and DCP were reduced on 3×3 mm and 12×12 mm scans of postoperative RRD eyes compared to controls and fellow eyes. SCP VD was significantly associated with postoperative VA.

ABSTRACT BODY:

Purpose: Proliferative vitreoretinopathy (PVR) is the most common cause of failure of retinal reattachment surgery. The development of PVR occurs following a retinal tear and rhegmatogenous retinal detachment resulting in epiretinal and/or subretinal membrane formation that can redetach the retina and lead to blindness. Determining the specific cell types present in the membranes will allow us to have a better understanding of the disease process and may lead to the development of novel target therapies for the prevention of PVR. In this study, we sought to characterize the cell types and identify genes that are critical to the development of PVR.

Methods: Four idiopathic epiretinal membranes, 1 subretinal membrane and 1 ciliary body membrane were obtained from patients during surgery and were immediately processed for single cell isolation according to our previously published protocol. Single cell suspension of PVR membranes was prepared according to the protocol as specified by the 10x Genomics sample preparation guide (CG00053) and single cell RNA-seq (scRNA-seq) was performed using 10x Genomics Chromium Single Cell 3' Reagent Kits version 2. The single cell sequencing data were then analyzed using the open-source Seurat kit. The counts matrix was filtered to only include the top 5,000 variable features before clustering.

Results: The full dataset contains 33,694 features and 4,627 cells. Using the associated marker genes, five cell types were identified as retinal pigment epithelium (RPE), microglia, T cells, B cells and fibroblasts. Remarkably, about 56% of the total cells were categorized as immune cells. Heatmap analysis identified several genes that are involved in PVR development including genes involved in inflammation and epithelial-mesenchymal transition (EMT). Enrichment analysis based on gene ontology pathway analysis suggested that the common differential expressed genes were significantly enriched in oxidative phosphorylation and EMT.

Conclusions: This study illustrates how scRNA-seq may be used to understand the pathophysiology of PVR. Identification of specific cell types and genes that are critical to PVR development will provide the basis for discovery and development of novel treatments and PVR prevention. Our findings also highlight the role of immune cells in PVR pathobiology.

ABSTRACT BODY:

Purpose: Phosphatidylinositol-3-phosphate 5-kinase (PIKfyve) is a phosphoinositide 5-kinase that phosphorylates PI(3)P to generate $PI(3,5)P_2$. PI(3)P is generated from PI by the action of class III PI3K, Vps34. Vps34 loss in rods resulted in rod degeneration. The 5'-phosphatase (called FIG4) dephosphorylates $PI(3,5)P_2$ to PI(3)P. FIG4 loss also resulted in retinal degeneration. The role of PIKfyve in photoreceptor functions is unknown. This study examined the role of PIKfyve in the retina.

Methods: PIKfyve KO mice were generated under the control of retina-specific Chx10 (abbreviated as $^{ret}Pikfyve^{-/-}$) promoter. $PI(3,5)P_2$ levels were measured and immunoblot analysis with anti-PIKfyve, anti-rhodopsin, cone-arrestin, and sodium-potassium ATPase-alpha (NKAα) antibodies was performed in PIKfyve floxed and $^{ret}Pikfyve^{-/-}$ mouse retinas. Structure and function were assessed at 8 months of age. PIKfyve floxed and $^{ret}Pikfyve^{-/-}$ mice were subjected to light stress (LS) at 10,000 lux for 7 days. $PI(3,5)P_2$ is needed for late endosome and lysosome maturation. We examined the expression of NKAα, removed through the lysosomal degradation pathway. One week after LS, mice were subjected to ERG, followed by histological examination.

Results: $^{ret}Pikfyve^{-/-}$ retina had 70% less PIKfyve protein and more than 80% less $PI(3,5)P_2$ when compared to PIKfyve floxed retina. However, there was no significant difference in retinal function and structure between PIKfyve floxed and $^{ret}Pikfyve^{-/-}$ mice at 8 months of age. Light-stressed PIKfyve floxed mice exhibited photoreceptor degeneration; the structure was well preserved in light-stressed $^{ret}Pikfyve^{-/-}$ mice. Immunoblots showed no significant difference in the levels of rhodopsin, NKAα, and cone arrestin between PIKfyve floxed and $^{ret}Pikfyve^{-/-}$ mice without LS. Light-stressed PIKfyve floxed mice had significantly reduced levels of rhodopsin, cone arrestin, and NKAα compared with light-stressed $^{ret}Pikfyve^{-/-}$ mice. Light-stressed $^{ret}Pikfyve^{-/-}$ mice had a normal retinal function and well-preserved retinal structure, whereas light-stressed PIKfyve floxed mice had significantly reduced function and exhibited retinal degeneration.

Conclusions: The data suggest that PIKfyve-generated $PI(3,5)P_2$ regulates late endosome and lysosome maturation, and loss of PIKfyve promotes photoreceptor neuroprotection. Modulating the PIKfyve activity under retinal degenerative conditions may have therapeutic benefits.

ABSTRACT BODY:

Purpose: The purpose of this study is to evaluate the use of various rho-kinase inhibitors (ROCKi) for the propagation of primary human corneal endothelial cells (HCEnCs).

Methods: Pairs of donor corneas unsuitable for transplantation were procured, isolated and expanded using a dual media approach. Several ophthalmic ROCKi (Netarsudil and its derivative (AR-13324, AR-13503), Verosudil (AR-12286), Ripasudil (K-115)), along with various classes of ROCKi compounds (Indazole, Aminofurazan, Amide, Benzodiazapiene) were comparatively evaluated for their effect on HCEnCs over a range of concentrations, and their capacity to improve cellular adherence. Control group was donor-matched HCEnCs treated with Y-27632. Initial experiments were performed using xCELLigence cell analyzer (n=3). Impedance readings from experiments were recorded and used as a quantitative measure to evaluate the effect of each ROCKi on HCEnCs. From the initial results, the two most efficacious ROCKi (AR-13324 and AR-13503) were further assessed for their capacity to improve HCEnCs proliferation using an EdU incorporation Click-iT assay.

Results: The classes of Indazole and Amide ROCKi compound, and K-115 were comparable to Y-27632 in terms of their working concentrations (100nM to 30mM). Both classes of Aminofurazan and Benzodiazapiene ROCKi had a negative impact on HCEnCs at 30mM, whereas the Y-39983 molecule were detrimental to the HCEnCs from 10mM. Of the AR-compounds, AR-12286 was comparable to Y-27632 at all 3 concentrations evaluated, whereas AR-13324 and AR-13503 negatively affected HCEnCs from 10mM. In fact, AR-13324 was cellular toxic from 10mM. Interestingly, at 100nM, both AR-13324 and AR-13503 significantly improved the attachment of HCEnCs over Y-27632. Proliferatively, both AR-13324 (100nM) and AR-13503 (1mM) were comparable to that of Y-27632 (10mM) even though lower concentrations were used.

Conclusions: We were able to demonstrate that various ROCKi evaluated including Ripasudil (K-115) and Netarsudil (AR-13324 and AR-13503) were comparable in their capacity to improve cellular attachment of HCEnCs at various concentrations. Subsequent evaluation revealed the Netarsudil molecules to aid proliferation of HCEnCs even when used at lower concentrations to Y-27632. Further functional assessment of Netarsudil within a cell injection rabbit model of bullous keratopathy is currently on going.

ABSTRACT BODY:

Purpose: Patient-reported outcomes (PROs) provide patients' perspective of the disease. Positive psychological factors, such as happiness, have been credited with improving human functioning, and helping people live more successful lives. Happiness (a higher order concept, reflecting a more a stable state of being well) is not frequently used as a PRO in eye research. However, since an important goal of glaucoma management is the preservation of patients' visual function and quality of life (QoL), happiness could be a useful descriptor to interpret the wellbeing of patients with glaucoma. This pilot study attempts to measure the correlation between happiness and QoL, with the functional impact of the disease.

Methods: Telephone contact was carried out with patients identified in a database of a glaucoma center. Once their identity was confirmed and they provided verbal consent, they were invited to answer a set of questionnaires (OSDI, Subjective Happiness Scale or HSH, and NEI-VFQ-25). The local research board granted permission to perform this study. The analyzed variables were best-corrected visual acuity, glaucoma stage of severity (Hodapp et al classification), perimetry parameters (MD, PSD, VFI), average RNFL thickness (OCT), and number of antiglaucoma medications. The correlations between the variables were analyzed. A p-value of ≤ 0.05 was considered as statistically significant.

Results: Eighteen out of 23 contacted patients accepted to participate in the study. All patients had complete clinical information regarding glaucoma and underwent the entire set of questionnaires. The mean age of patients was 68.8±10.2 years (10 female, 8 male). All of them had POAG (7 mild, 6 moderate, 5 severe). General and specific information comparing three groups of glaucoma severity is presented in table 1. Scores of happiness had either a good or very good correlation (and statistical significance) with average RNFL thickness (OD, r=0.49, p=0.038; OS, r=0.65, p=0.003), OSDI (r=-0.51, p=0.03), severity of glaucoma (r=-0.50, p=0.033), and mean NEI-VFQ 25 score (r=0.79, p=0.0001).

Conclusions: Up to our knowledge, this preliminary study approaches happiness as a PRO for the first time in a glaucoma study. Our results suggest that this outcome can be a useful PRO to be added to other questionnaires, which can broaden the clinician perspective about the impact of glaucoma on patients' lives.

Commercial Relationships Disclosure: Luis Vasquez: Commercial Relationship: Code N (No Commercial Relationship) | Zachary Harbin: Commercial Relationship: Code N (No Commercial Relationship) | Zachary Brooke: Commercial Relationship: Code N (No Commercial Relationship) | Jihad Isteitiya: Commercial Relationship: Code N (No Commercial Relationship) | Celina Villanueva: Commercial Relationship: Code N (No Commercial Relationship) | Ahmad Kheirkhah: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Ocular pain is an important symptom of dry eye disease (DED) which can substantially affect patients' quality of life. The purpose of this study is to evaluate severity and frequency of ocular pain in patients with DED and investigate their associations with other clinical parameters.

Methods: This cross-sectional study included 62 patients with DED. Using a questionnaire, they were asked to quantify the frequency and severity of their ocular pain using a 10-point scale with 10 indicating the most severe or most frequent pain, respectively. Patients also underwent a comprehensive ocular surface evaluation, including Ocular Surface Disease Index (OSDI) questionnaire, tear break up time (TBUT), corneal fluorescein staining, conjunctival lissamine green staining, and Schirmer test with anesthesia. The associations between severity and frequency of ocular pain with other clinical parameters were also investigated by regression analysis.

Results: There were 44 women and 18 men, with a mean age of 60.8 ±13.8 years (range, 27-87 years). The mean OSDI score was 53.4 ± 19.7. The mean values were 2.6 ± 2.7 for pain severity and 2.8 ± 3.3 for pain frequency. Regarding severity, mild pain (scores 1-4) was reported in 24 patients (38.7%), moderate pain (scores 5-7) in 8 (12.9%), and severe pain (scores 8-10) in 6 (9.7%). 24 (38.7%) did not report any ocular pain. Pain frequency was reported as infrequent (scores 1-4) in 21 (33.9%), moderately frequent (scores 5-7) in 8 (12.9%), and very frequent (scores 8-10) in 9 (14.5%). Severity and frequency of ocular pain demonstrated significant, but weak, correlations with the OSDI score ($P = 0.04$, $rs=0.26$, for both). Regression analysis showed a significant association between pain severity and Schirmer score ($P=0.001$, $\beta=0.28$). There were no significant associations between severity or frequency of ocular pain and age, sex, ethnicity, history of depression or anxiety, or clinical signs of DED.

Conclusions: Most patients with DED report experiencing ocular pain, which was mild and infrequent in majority. Ocular pain had only a weak correlation with OSDI and no significant association with other clinical parameters including signs of DED. In addition to routine questionnaires and clinical tests, a detailed evaluation of ocular pain symptoms is important in patients with DED.

ABSTRACT BODY:

Purpose: In the VEGA-1 Phase 2b presbyopia clinical trial, 0.75% phentolamine ophthalmic solution (POS) in combination with low dose pilocarpine (LDP) had a tolerable safety profile and met its primary efficacy endpoint by improving near vision by 3 lines. This abstract describes a pre-specified secondary analysis evaluating the efficacy of POS alone for improving distance-corrected near visual acuity (DCNVA) by 3 lines in presbyopia patients.

Methods: In the VEGA-1 trial, a Phase 2b, multi-center, randomized, placebo-controlled, double-masked clinical trial, a pre-specified secondary analysis evaluated the efficacy of POS alone for the treatment of presbyopia. Subjects with DCNVA of 20/50 or worse were randomized to receive POS vs placebo for 3-4 nights. The following morning at study visit 2, the percent of patients with ≥15 letters (3 lines) binocular photopic DCNVA improvement relative to baseline on an ETDRS chart in the POS and placebo arms were compared using logistic regression. We also assessed ≥ 10 letter (2 line) DCNVA improvement outcomes. Mean change in number of ETDRS letters read between treatment arms was compared using analysis of covariance. Percentage of subjects achieving DCNVA of 20/40 or better was also assessed.

Results: After randomization, 73 and 75 subjects received POS and placebo, respectively. Twelve or more hours after treatment, 30% of subjects in the POS arm and 14% in the placebo arm had a ≥ 15 letter binocular DCNVA improvement (p=0.027). POS compared to placebo resulted in more subjects achieving DCNVA improvements of ≥ 10 letters (53% vs 28%; p=0.005) and ≥ 5 letters (75% vs 55%; p=0.01). Compared to baseline, POS conferred a mean 10.2 letter improvement in DCNVA, significantly more than the 5.8 letter improvement with placebo (p=0.0008). Forty-one (56%) patients treated with POS and 27 (36%) treated with placebo had DCNVA of 20/40 or better (p=0.014). POS demonstrated similar improvements in monocular DCNVA. POS showed a favorable safety profile with only few mild adverse events and no headaches.

Conclusions: In this Phase 2b clinical trial, POS showed clinical efficacy to achieve a ≥15 letters improvement in DCNVA in presbyopia subjects. Given these results, advancement to Phase 3 trials is planned to evaluate the efficacy of POS alone and in combination with LDP for presbyopia.

ABSTRACT BODY:

Purpose: During retinal development, the cell cycle progression of retinal progenitor cells (RPCs) needs to be tightly controlled to ensure proper cell differentiation. CDKs (cyclin-dependent kinases), cyclins, CDK inhibitors, and several transcription factors are known to play key roles in regulating the cell cycle progression of RPCs. We looked for mechanisms that can bridge the regulation at the protein/kinase and transcriptional levels, and propose to elucidate the roles of post-transcriptional m6A (N^6-Methyladenosine) modification of mRNAs in regulating RPCs cell cycle.

Methods: We conditionally knocked out m^6A writer methyltransferase-like 14 (METTL14) from the beginning of retinal development. The histology of the METTL14 conditional knock-out (CKO) retinas was evaluated and compared to wild-type retinas at different development stages. The proliferation of RPCs was assessed by EdU cell proliferation assay. Cell cycle analysis was conducted by Fluorescence-activated cell sorting flow cytometry (FACs). RPCs lineage tracing was performed using retroviruses. The m^6A high-throughput sequencing (m^6A-seq) and single-cell sequencing technology were used to map out the differential gene expression profiles and the downstream signaling pathways.

Results: We found that the genes involved in directing m6A modification are expressed in the mouse retina. Mettl14 CKO retinas showed abnormal RPCs cell cycle arrest at neonatal stages. The majority of these arrested RPCs underwent apoptosis. A small fraction of them can bypass the apoptosis pathway and differentiate mainly into Müller cells. We further identified the m6A modified genes in the retina via m6A-seq and single-cell RNA-seq and uncovered their potential roles in regulating the RPCs cell cycle.

Conclusions: Our work demonstrates that epitranscriptomic m6A modification is essential for regulating the RPCs cell cycle during development. Manipulation of the m^6A modification pathways may provide promising control of abnormal cell proliferation observed in some retinal diseases.

ABSTRACT BODY:

Purpose: Astrocytes in the lamina cribrosa (LC) play important roles in cell signaling and extracellular matrix remodeling, impacting the physiology of neural tissues necessary for vision. Although LC astrocyte morphology is known to undergo substantial changes throughout the pathogenesis of glaucoma, techniques to evaluate LC astrocyte morphology are limited. We hypothesized that multicolor DiOlistic labeling allows visualization of LC astrocytes and evaluation of key morphological features.

Methods: Gold microparticles were coated with all combinations of three fluorescent lipophilic dyes (DiI, DiD, and DiO) to create 7 different groups of microcarriers. Coronal vibratome sections were obtained through the LC of pig, sheep, and goat eyes (N = 2 sections each) at 200μm thickness. Dye-coated microcarriers were ballistically delivered into sections with a Helios gene gun. Cells were imaged via confocal microscopy and collagen was imaged via second harmonic generation (SHG). 25 total dyed astrocytes were segmented and morphological features quantified in Imaris.

Results: Microcarriers embedded within cells delivered dye that distributed across their respective cell membranes. Somas and fine ramified processes of astrocytes labeled with all 7 different combinations of dyes were visualized. Label density allowed visualization of individual astrocytes within LC pores. Distinct dye combinations allowed discerning individual astrocytes with processes in close proximity to one another, sharing spatial domains. SHG imaging allowed for visualization of astrocytes within the context of surrounding collagen beams. Average astrocyte branch number, length, depth, and straightness were 147.4 ± 106.7, 11.5 ± 10.2μm, 9.1 ± 5.3, and 0.9 ± 0.1.

Conclusions: Multicolor DiOlistic labeling in vibratome sections of collagenous LC is a suitable technique for visualization and morphological analysis of astrocytes. LC astrocytes demonstrated diverse morphologies and physical interactions with surrounding structures. Healthy LC astrocyte morphologies and interactions can later be compared with those in glaucomatous LCs to better understand the role of astrocytes in pathogenesis.

ABSTRACT BODY:

Purpose: Evidence suggests that inflammasome activity contributes to the pathogenesis of diabetic retinopathy (DR), but there remains uncertainty in the role of the NLRP3 inflammasome in DR. We sought to elucidate the timing of inflammasome activation and evaluate the involvement of NLRP3 inflammasome constituents including NLRP3, the adaptor ASC, and the protease Caspase-1 using a streptozotocin (STZ) induced DR mouse model.

Methods: The STZ model was used to induce diabetes (DM) in C57BL/6J wild type (WT) mice (male (m) N=60; female (f) N=20) as well as Caspase-1 knock out (KO) (m N=7; f N=5), ASC KO (m N=9; f N=9), and NLRP3 KO (m N=9; f N=8) mice. Vehicle control was used for control (CTL) mice of each genotype and sex. After one, three, and eight months of hyperglycemia, bilateral eyes were harvested with one eye being embedded for cryo-sectioning and the other being dissected for whole retina collection. Collected neuroretina were evaluated for inflammasome activity with immunoblotting. Gliosis and neuroinflammation were visualized through immunofluorescence staining of cryosectioned eyes for NLRP3 inflammasome constituents. Retinal neurodegeneration was also evaluated using scotopic electroretinography (ERG).

Results: At one and three months after STZ induction, immunoblotting of whole retinal lysates showed minimal increase of inflammasome activation in WT DM mice compared to WT CTL mice. On ERG evaluation at three months, there was a 23.1% decrease in a-wave and a 32.3% decrease in b-wave between DM and CTL WT mice. For Caspase-1 KO mice, there was a lesser decrease of 10.8% and 21.8% in a- and b-waves respectively, and in ASC KO mice there was also a lessened decrease of 5% in a-wave and 18.3% in b-wave between DM and CTL mice.

Conclusions: Our results suggest that while inflammasome activation may not be evident on protein analysis, on ERG evaluation there is a decrease in readings that may be indicative of a reduction in neuroretinal function by three months of DR. Additionally, the reduced loss of electrical function in both Caspase-1 KO and ASC KO mice may represent a partial rescue of neuroretinal function when components of the NLRP3 inflammasome are absent. This finding helps to establish a direct connection between inflammasome constituents to the pathological processes of DR. Further investigation is needed to elucidate the precise role of NLRP3 inflammasome activation in the pathogenesis of DR.

TITLE: Evaluation of Long-Term Intravitreal Anti-Vascular Endothelial Growth Factor (VEGF) Injections on Renal Function

SESSION TITLE: Anti-VEGF in AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Choi, B. McGeehan, B.L. VanderBeek, Scheie Eye Institute, University of Pennsylvania, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Daniel Choi: Commercial Relationship: Code N (No Commercial Relationship) | Brendan McGeehan: Commercial Relationship: Code N (No Commercial Relationship) | Brian VanderBeek: Commercial Relationship(s);Code C (Consultant/Contractor):EyePoint Pharmaceuticals

ABSTRACT BODY:

Purpose: Studies have shown that intravitreal anti-VEGF can reduce plasma free-VEGF. However, the literature is sparse on the safety of long-term intravitreal anti-VEGF injections on the body, especially the kidney. We assessed the risk of developing chronic kidney disease or end-stage renal disease in patients receiving multiple anti-VEGF injections.

Methods: A commercial and Medicare Advantage medical claims database was used to identify all patients who were given an intravitreal anti-VEGF agent. The number of injections was then totaled for the proceeding 4 years following the initial injection. Exclusion occurred if patients at the time of the first injection were <18 years old, had <2 years of data in the plan or had any history of kidney disease (defined by either ICD code or estimated glomerular filtration rate). Patients were then divided into quartiles based on number of injections to compare the highest and lowest quartiles. Subanalysis was also done on those with individual disease states: neovascular AMD, macular edema due to RVO (MERVO), or diabetic retinopathy (DR). A weighted multivariable logistic regression analysis compared the odds of being diagnosed with chronic or end-stage kidney disease. A second time updating analysis, which did not require a specific time in the plan, used Cox proportional regression to assess an every 5-injection increase in the hazard of developing kidney disease.

Results: 13,895 patients in the lowest quartile (representing 1-3 injections) were compared to13881 in the highest quartile (≥21 injections). The nAMD had 6228 (1-4 injections) and 6172 (≥24); MERVO had 573 (1-2) and 580 (≥12); and DR had 523 (1-2) and 517(≥13) in the lowest and highest quartiles, respectively. Weighted analysis showed no association overall (OR=1.00, 95% CI:0.98-1.01, p=0.58) or in nAMD (OR=0.99, 95% CI:0.97-1.02, p=0.48), decreased odds in MERVO (OR=0.93, 95% CI:0.86-0.99, p=0.04) and increased odds in DR (OR=1.12, 95% CI:1.03-1.22, p=0.01) for the highest quartile. Time updating Cox analysis showed no association overall or for any subgroup (HR=0.97-1.01, p>0.27 for all comparisons).

Conclusions: While logistic regression showed some association of increased number of injections with kidney disease, time updating cox analysis was unable to confirm these findings, suggesting time was a confounder in the logistic regression analysis.

TITLE: Alternative oxidase expression slows photoreceptor degeneration due to RPE mitochondrial dysfunction

SESSION TITLE: Modeling inherited retinal degeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Chen, D. Vollrath, Department of Genetics, Stanford University School of Medicine, Stanford, California, UNITED STATES|Y. Wang, J. Du, Department of Ophthalmology and Visual Sciences, West Virginia University, Morgantown, West Virginia, UNITED STATES|

Commercial Relationships Disclosure: Ming Chen: Commercial Relationship: Code N (No Commercial Relationship) | Yekai Wang: Commercial Relationship: Code N (No Commercial Relationship) | Jianhai Du: Commercial Relationship: Code N (No Commercial Relationship) | Douglas Vollrath: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Compromised RPE mitochondrial function has been implicated in the pathogenesis of AMD. We previously reported that ablation of Tfam in the mouse RPE (RPEΔTfam) results in OXPHOS deficiency, unexpected effects on RPE cell phenotype, and photoreceptor degeneration. We hypothesize that expression of alternative oxidases from C. intestinalis (AOX) and yeast (NDI1) in the RPE of RPEΔTfam mice will bypass loss of function of complexes III and IV (AOX) and complex I (NDI1), and restore respiration without ATP generation to the OXPHOS-deficient RPE in vivo. We sought to test this hypothesis and determine the effects of alternative oxidase expression on the RPEΔTfam retinal phenotype.

Methods: We used φC31 integrase-mediated site-specific transgenesis to generate C57BL/6J mice with Cre-conditional expression of epitope-tagged AOX and NDI1. BEST1-Cre;Tfam$^{fl/fl}$;tg:AOX-NDI1 mice were generated and assessed by immunoblot of RPE cell lysates and immunofluorescence imaging of RPE/choroid flatmounts. Cre expression, RPE morphology, and mean RPE cell area were assessed by flatmount staining. Oxygen consumption of eyecups in the presence of OXPHOS poisons was assessed with the Seahorse platform. Retinal structure and function were evaluated by OCT and ERG. Statistical analyses were done by two-tailed Student's t-tests.

Results: AOX and NDI1 proteins are specifically expressed in the RPE of BEST1-Cre;Tfam$^{fl/fl}$;tg:AOX-NDI1 mice and co-localize with Hsp60, a mitochondrial marker. Eyecups from AOX/NDI1 expressing mice maintain oxygen consumption in the presence of cyanide, consistent with AOX function. 18 week-old BEST1-Cre;Tfam$^{fl/fl}$;tg:AOX-NDI1 mice have a smaller mean RPE cell area (432 ± 28 μm^2) compared to RPEΔTfam mice (667 ± 101 μm^2; p=0.034, n=3 each). AOX/NDI1 expression slows retinal thinning at 22-24 weeks (242 ± 7 vs 208 ± 10 μm for RPEΔTfam; p=0.006, n=4 each), and AOX/NDI1 expression improves scotopic a-wave (p=0.044), scotopic b-wave (p=0.015), and photopic b-wave (p=0.013) amplitudes at 40-41 weeks (n=4 each).

Conclusions: AOX/NDI1 expression in the OXPHOS-deficient RPE of RPEΔTfam mice has significant beneficial effects on RPE cell phenotype, and photoreceptor viability and function in vivo. We are actively investigating which metabolic changes correlate with these profound phenotypic changes.

ABSTRACT BODY:

Purpose: To study the incidence and clinical presentation of acute idiopathic posterior vitreous detachment (PVD) at a tertiary care eye center.

Methods: Patients with less than 2 months of symptoms with any significant ocular history in the presenting eye were included in the study. Patients with symptoms of floaters/flashes longer than 2 months; significant ocular history including eventful cataract surgery, inflammation, trauma, YAG capsulotomy, ocular migraine were excluded. Between September 2019 and May 2021, a total of 101 consecutive patients with complaints of floaters and/or flashes in at least one eye underwent dilated fundus examination by a single retinal specialist to detect the presence of PVD. All patients were followed up by the same retina specialist at week 1, week 4, week 8, and then on an as-needed basis.

Results: This study included 101 patients presenting with 94.05% patients presenting with unilateral symptoms and 5.9% bilateral complaints. PVD was diagnosed in 129/202 eyes (63.9%) with 73 eyes (36.1%) having unilateral PVD and 56 eyes (27.7%) with bilateral PVD. A retinal break was identified in 15.5% of eyes with PVD. Prevalence of pre-existing PVD in fellow eyes was 20.7%, however, a further 13.7% unaffected eyes developed fresh PVD during follow-up. None of the study eyes developed additional new breaks during follow-up.

Conclusions: Patients presenting with symptoms suggestive of acute PVD unilaterally need to be screened for PVD in both eyes, as almost $1/5^{th}$ population may have fellow-eye involvement. Future screenings should be decided based on individual risk and PVD status at presentation.

TITLE: Corneal nerve changes on confocal microscopy after cenegermin treatment for neurotrophic keratitis

SESSION TITLE: Corneal Imaging and Corneal Nerves

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Kwan, C. Kim, Y. Shi, S. Garg, O.L. Lee, Ophthalmology, University of California Irvine, Irvine, California, UNITED STATES|

Commercial Relationships Disclosure: Changyow Kwan: Commercial Relationship: Code N (No Commercial Relationship) | Cinthia Kim: Commercial Relationship: Code N (No Commercial Relationship) | Yue Shi: Commercial Relationship: Code N (No Commercial Relationship) | Sumit Garg: Commercial Relationship(s);Code C (Consultant/Contractor):Dompe | Olivia Lee: Commercial Relationship(s);Code C (Consultant/Contractor):Cloudbreak Therapeutics

ABSTRACT BODY:

Purpose: Cenegermin, a recombinant human nerve growth factor (rhNGF) eye drop formulation, was recently approved by the U.S. Food and Drug Administration for the treatment neurotrophic keratopathy (NK), a degenerative condition of the cornea characterized by decreased corneal sensation and poor corneal healing. This study aims to better understand the effects of cenegermin on patients with NK by analyzing corneal sensation, epithelial healing and corneal nerve structure through in vivo confocal microscopy (IVCM) before and after treatment.

Methods: This study included five eyes from five patients with NK stage 1 or 2 who completed a 6-week course of cenergemin treatment. Patients underwent clinical examination with assessment of corneal fluorescein staining, corneal sensation using a cotton wisp and examination of IVCM images of the corneal nerves in the basal epithelium neural plexus at baseline and after completing a 6-week course of treatment. The percentage area of corneal epithelial defect on fluorescein images was measured with ImageJ. IVCM images were analyzed for neuron density using NeuronJ (NIH, Bethesda, MD).

Results: Zero out of five eyes had visible corneal nerves on ICVM imaging prior to cenergemin treatment. After treatment, three out of five eyes had visible nerves on ICVM imaging (average density 2284.75 um/mm^2). The two patients who did not have visible nerves after treatment had comorbidities including corneal transplant and acanthamoeba infection. Epithelial fluorescein staining improved in all patients. The two eyes with stage 2 NK had epithelial defects at baseline examination, and both had complete resolution after treatment. Corneal sensation was stable in two out of five eyes and improved in three out of five eyes after treatment.

Conclusions: Treatment with cenegermin is effective in promoting corneal epithelial healing and nerve regrowth in patients with NK. Patients had improved epithelial appearance, corneal sensation and nerve density on IVCM after treatment with cenegermin. IVCM is a safe and minimally invasive imaging method that can be used to track structural response to cenegermin treatment.

ABSTRACT BODY:

Purpose: While theoretical models envision the possibility that accommodative microfluctuations aid in deciphering the sign of defocus, empirical evidence for the same remains ambiguous. This study investigated this issue by determining the initial direction and dynamics of blur-driven accommodation through real-time manipulation of these microfluctuations.

Methods: A PlusOptix PowerRef3™ photorefractor recorded the ocular refraction of 10 young adults (23.8±3.8yrs) at 50Hz while they fixated on a Maltese cross stimulus that stepped between 1D and 3D demands with randomized onset time. The difference between two consecutive refraction data points was considered as an accommodative microfluctuation and its sign-reversed values were synchronously fed into an Optotune™ electrically tunable lens (ETL) to neutralise the microfluctuations in real-time. The initial direction, magnitude, latency and peak velocity of the step response was determined while manipulating the ETL accommodative microfluctuation feedback relative to baseline viewing.

Results: ETL manipulation of accommodative microfluctuations did not alter the proportion of step responses with correct initial direction (median(IQR) accommodation: 73.2 (56.1 – 81.8) %; disaccommodation: 75.0 (47.8 – 80.0)% or their response magnitudes (accommodation: 1.97±0.40D; disaccommodation: 1.95±0.40D), relative to baseline (correct response proportion 83.3 (73.0 – 92.3) %; response magnitude: 1.83±0.37D) ($p \geq 0.09$, for all). Response latency increased (accommodation: 275.8±38.1ms; disaccommodation: 322.3±82.6ms) and peak velocity decreased (accommodation: 5.37±1.6D/s; disaccommodation: 5.94±1.9D/s) with ETL manipulation, relative to baseline (latency: 276.8±59ms; peak velocity: 6.96±2.0D/s), but none were statistically significant ($p \geq 0.05$, for all).

Conclusions: The accommodative system responds in the desired direction despite neutralization of accommodative microfluctuations. While the response dynamics may have slowed-down in the absence of these microfluctuations, reflecting a conservative strategy, the change appears marginal and inconsequential for accommodation control. Overall, the results do not support the idea that accommodative microfluctuations aid in deciphering the direction of accommodation. Their role may be limited to maintaining the steady-state response.

TITLE: Impact of Delayed Corneal Cross-Linking in Keratoconus Patients

SESSION TITLE: Keratoconus and corneal biomechanics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Lang, A. Nguyen, M. Heur, G. Chiu, University of Southern California Keck School of Medicine, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Paul Lang: Commercial Relationship: Code N (No Commercial Relationship) | Annie Nguyen: Commercial Relationship: Code N (No Commercial Relationship) | Martin Heur: Commercial Relationship: Code N (No Commercial Relationship) | Gloria Chiu: Commercial Relationship(s);Code C (Consultant/Contractor):Glaukos;Code C (Consultant/Contractor):Acculens;Code C (Consultant/Contractor):BostonSight

ABSTRACT BODY:

Purpose: To highlight the impact of delayed corneal cross-linking (CXL) in patients diagnosed with progressive keratoconus.

Methods: Patients with progressive keratoconus were identified through retrospective chart review and eyes with a time interval of greater than 6 months between decision to perform cross-linking and treatment were included in analysis. Variables included in analysis were time to treatment, best corrected visual acuity (BCVA), manifest refraction, and tomographic data such as maximum keratometry (KMax) and pachymetry at the apex. A Wilcoxon rank test was used to compare measurements for statistical significance.

Results: 5 eyes of 3 patients were included in analysis. Mean time from decision to undergo crosslinking to treatment was 36±14.63 months. Reasons for delayed crosslinking included lack of insurance coverage, delayed insurance authorization, and lack of access to eye care during the pandemic. In this time interval, the mean change in manifest refraction was -6.051±5.64D (p=0.058), mean change in KMax was 3.94±6.08D (p=0.31), and mean change in pachymetry at the apex was -37.6±28.92µm (p=0.063). BCVA for 2 eyes worsened by 1 or more lines and all patients required the use of either scleral or rigid gas permeable contact lenses to achieve functional vision.

Conclusions: Keratoconus is characterized by progressive corneal thinning and steepening, and often associated with irregular astigmatism, corneal striae and central scars. Corneal cross-linking (CXL) aims to slow progressive keratoconus, and an FDA approved CXL protocol became available in the United States in 2016. Many barriers to prompt care still exist, however, that negatively impact visual function and quality of life for patients.

TITLE: Transient Receptor Potential Nociceptors are Required for Contact Lens-Associated Corneal Parainflammation

SESSION TITLE: Contact lens

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: A. DATTA, J. Lee, H. Horneman, D.J. Evans, S.M. Fleiszig, Optometry and Vision Science, University of California Berkeley, Berkeley, California, UNITED STATES|H. Horneman, Department of Pediatrics Hematology/Oncology, University of California, San Francisco, San Francisco, California, UNITED STATES|D.J. Evans, COP, Biological & Pharmaceutical Sciences, Touro University California, Vallejo, California, UNITED STATES|

Commercial Relationships Disclosure: ANANYA DATTA: Commercial Relationship: Code N (No Commercial Relationship) | Justin Lee: Commercial Relationship: Code N (No Commercial Relationship) | Hart Horneman: Commercial Relationship: Code N (No Commercial Relationship) | David Evans: Commercial Relationship: Code N (No Commercial Relationship) | Suzanne Fleiszig: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Previously, we used a contact lens wearing murine model to show that lens wear was associated with corneal para-inflammation involving CD11c+ cells (24 h) and Ly6G+ cells (5-6 days). Recently, we showed transient receptor potential (TRP) ion-channels associated with corneal nerves were involved in corneal CD45+ and CD11c+ cell responses that correlated with protection against bacterial colonization. Here, we explored the role of TRP nociceptors in contact lens-mediated parainflammation.

Methods: Contact lenses were fitted onto one eye of C57BL/6 wild-type (WT) or double or single gene-knockout mice in TRPA1V1(-/-), TRPA1(-/-) or TRPV1(-/-). Contralateral eyes were used as controls. After 24 h or 6 days of lens wear, lenses were removed, and mice euthanized. Freshly enucleated eyes were fixed in ice-cold methanol or 2 % paraformaldehyde and corneal expression of MHC Class II+ cells or Ly6G+ cells detected using antibody labeling and imaging. Student's t-test and One-way ANOVA were used for statistical analysis and $P < 0.05$ considered significant.

Results: Lens-wearing corneas of WT mice showed a significant increase in MHC Class-II+ cells after 24 h, and in Ly6G+ cells after 6 days, vs. non-lens wearing controls ($P < 0.0001$, Student's t-test). Corneas remained free of visible pathology. Lens-wearing corneas of all TRP gene-knockout mice showed a significant increase in MHC Class-II+ cells at 24 h vs. respective baseline controls ($P < 0.0001$, Student's t-test). Non-lens wearing corneas of each TRP gene-knockout mouse showed significant reduction in MHC Class-II+ cells vs. WT at 24 h ($P < 0.0001$, One-way ANOVA). Corneas of lens-wearing TRP gene-knockout mice each showed a significant reduction in Ly6G+ cell infiltration vs. lens-wearing WT after 6 days ($P < 0.0001$, One-way ANOVA). Little or no corneal Ly6G+ cells were observed in 6 day non-lens wearing controls.

Conclusions: TRP nociceptors are required for contact lens-associated corneal para-inflammatory responses involving Ly6G+ cell (neutrophil) infiltrative after 6 days of lens wear, but not the MHC Class-II+ (CD11c+) responses after 24 h of lens wear. TRP nociceptors are involved in modulating baseline levels of corneal MHC-II+ cells. Specific role(s) for TRPA1 or TRPV1 in mediating these corneal phenotypes remains to be determined.

SUBMITTER (NAME ONLY): Susmit Mhatre

TITLE: DEVELOPING A NOVEL LIPID-BASED SYSTEM OF DIALLYL TRISULFIDE (DATS) FOR SUSTAINED DELIVERY OF HYDROGEN SULFIDE FOR THE TREATMENT OF GLAUCOMA

SESSION TITLE: Clinical studies and trials

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Mhatre, C. Opere, S. Singh, Pharmacy and Health Professions, Creighton University School of Pharmacy and Health Professions, Omaha, Nebraska, UNITED STATES|

Commercial Relationships Disclosure: Susmit Mhatre: Commercial Relationship: Code N (No Commercial Relationship) | Catherine Opere: Commercial Relationship: Code N (No Commercial Relationship) | Somnath Singh: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Glaucoma, an ocular neuropathy, is characterized by progressive degeneration of retinal neurons. Current glaucoma therapies provide only symptomatic management by reducing IOP. Since glaucoma is reported even in normotensive patients, the ideal glaucoma medication should simultaneously lower IOP and confer neuroprotection to retinal neurons. Hydrogen sulfide (H_2S) has been reported to reduce IOP and elicit retinal neuroprotection in mammalian ocular tissues. Due to gaseous nature of H_2S and narrow therapeutic index, its delivery in ocular tissues involves unique challenges. Diallyl Trisulfide (DATS) is a lipophilic, potent, and fast H_2S donor reported to degrade rapidly under normal aqueous conditions. The objective of this study is to develop a novel lipid-based delivery system of DATS to provide sustain release of H_2S up to 8-9 hours upon topical application on cornea.

Methods: DATS content was determined by HPLC method in the concentration range of 3.12 – 100 µg/ml. The method was validated for specificity, linearity, accuracy and precision. The solid lipid nanoparticles (SLNs) loaded with DATS were prepared by using hot emulsification process and solvent evaporation method. DATS-SLNs characterized for particle size, zeta potential, drug loading and encapsulation efficiency. The in vitro release studies for both DATS and H_2S were performed by incorporating DATS-SLNs in PEG ointment base.

Results: A well resolved peak of DATS was detected at 2.8 mins run time. The method showed good linearity (R2 > 0.999) over the concentration range of 3.12-100 ug/ml. Particle size was higly dependant on the concetration of polymer, lipid and surfactant. In presence of surfactant (poloxamer 1%, soy lecithin 0.2%), the particle size was 238.6 ± 8 nm and 85 ± 4.5 nm for glyceryl behenate and glyceryl monostearate, respectively showing a corresponding decrease of 28 ± 0.56% and 66 ± 1.8%. PEG ointment base incorporated with DATS-SLNs showed a sustained release of DATS up to 9 hours releasing 67.89 ± 2.04% of the initial loaded amount with corresponding hydrogen sulfide concentration of 112 ± 2.16 µM.

Conclusions: A precise and accurate method for quantification of DATS was developed and validated in compliance of USP guidelines. A biocompatible system capable of sustaining H_2S release from DATS was obtained with a particle size less than 200 nm up to 9 hrs.

TITLE: Artificial Intelligence-assisted Projection-resolved Optical Coherence Tomographic Angiography (aiPR-OCTA)

SESSION TITLE: OCT Angiography Clinical Applications

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. WANG, T. Hormel, Y. Jia, Oregon Health & Science University, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure: JIE WANG: Commercial Relationship(s);Code P (Patent):Optovue Inc. | Tristan Hormel: Commercial Relationship: Code N (No Commercial Relationship) | Yali Jia: Commercial Relationship(s);Code F (Financial Support):OptoVue Inc;Code P (Patent):OptoVue Inc;Code P (Patent):Optos

ABSTRACT BODY:

Purpose: To improve the voxel-wise projection-resolved optical coherence tomographic angiography (PR-OCTA) using artificial intelligence.

Methods: In this study, a total of 4600 OCTA scans from 708 eyes, including 3224 AMD scans and 1376 DR scans, were acquired in the 3×3-mm central macular area. The projection-resolved ground truth was generated by allowing graders to adjust parameters within the rules-based PR-OCTA algorithm in order to independently optimize the appearance of flow signal in inner/outer retina, choroid and the area below the large vessels, separately. This enabled graders to ensure that residual artifacts were cleaned while real flow signal from posterior vessels, including pathological choroidal neovascularization, were preserved. The model in this study consists of a combined convolutional neural network and sequence-to-sequence network that produce the PR OCTA volume from volumetric structural OCT and uncorrected OCTA inputs. The performance of the proposed aiPR-OCTA algorithm was evaluated on 126 normal eyes by quantifying the vessel density (VD), flow signal-to-noise ratio (fSNR), vessel connectivity (VC), structural similarity between the vascular patterns in an en face angiogram and another formed by projection over all anterior layers, and the remaining artifacts in outer retina.

Results: Compared to the previous reflectance-based PR (rbPR-OCTA) algorithm, the aiPR-OCTA algorithm was able to remove more projection artifacts and preserve more flow signal. The aiPR-OCTA algorithm was able to remove large residual vessel patterns in the rbPR-OCTA (Fig.1 case1&2 B2) while preserving true anatomic detail at the capillary scale (Fig.1 case1&2 B3). The large vessel shadows caused by overprocessing in rbPR-OCTA (Fig.1 case1&2 C2) were also filled with capillary flow in aiPR-OCTA (Fig.1 case1&2 C3). Quantitative assessment also indicates that the aiPR-OCTA also increased both VD and VC (Table 1), which is consistent with aiPR-OCTA preserving more flow signal then rbPR-OCTA. Finally, aiPR-OCTA suppressed more background artifacts as the fSNR was improved and remaining artifacts in outer retina was reduced (Table 1).

Conclusions: The proposed aiPR-OCTA algorithm can remove more projection artifacts and preserve more flow signals than previous approaches. This voxel-wise aiPR-OCTA algorithm could enable reliable vascular quantification in deeper anatomic slabs.

ABSTRACT BODY:

Purpose: To determine the burden of uncorrected refractive error (UCRE) and the risk factors associated with UCRE in a population-based sample of African American adults.

Methods: A population-based sample of self-identified African Americans 40 years of age and older (n = 6347) from thirty contiguous census tracts in Inglewood, California, underwent a complete ophthalmic examination and an in-home-administered questionnaire to assess sociodemographic (e.g. marital status, employment status, education level, annual income level), lifestyle (e.g. smoking history), and biological and medical (e.g. weight and height, health and vision insurance, healthcare and eye care utilization) risk factors associated with UCRE. UCRE was defined as a ≥ 2-line improvement with refraction in the better seeing eye. Sex- and age-specific burden of UCRE were calculated and multiple regression analyses were used to identify independent risk factors.

Results: Of the 7957 eligible participants in AFEDS, 6347 (80%) completed both the in-home interview and the clinical examination. The overall prevalence of UCRE was 14.6% (n = 925). The prevalence of UCRE was higher for men than for women (15.9% and 13.8%, respectively, P = 0.02). There was no significant age-related trend in the burden of UCRE (P > 0.05). Annual household income of less than $20,000 and lack of vision care insurance were significant independent risk indicators for UCRE.

Conclusions: Our data confirm the high burden of UCRE in African Americans making it the leading cause of visual impairment in this population. Providing universal coverage for vision care and prescription lenses or glasses is an affordable and achievable health care intervention that would reduce the burden of visual impairment in African American adults and help improve vision health in this vulnerable minority population.

TITLE: Efficacy of intravitreal methotrexate and rituximab for intraocular diffuse large B-cell lymphoma

SESSION TITLE: Endophthalmitis/ trauma/Intravitreal/periocular therapies

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W.S. Gange, S.C. Oliver, Sue Anschutz-Rodgers Eye Center, University of Colorado Anschutz Medical Campus, Aurora, Colorado, UNITED STATES|

Commercial Relationships Disclosure: William Gange: Commercial Relationship: Code N (No Commercial Relationship) | Scott Oliver: Commercial Relationship(s);Code F (Financial Support):Roche/Genentech, Regeneron, Aura Bioscience;Code C (Consultant/Contractor):Castle Bioscience

ABSTRACT BODY:

Purpose: To determine the relative efficacy of intravitreal methotrexate and rituximab for treatment of intraocular lymphoma.

Methods: Single-center retrospective chart review of patients with intraocular diffuse large B-cell lymphoma (either primary vitreoretinal lymphoma or secondary from a non-central nervous system primary) who received either intravitreal methotrexate or rituximab as part of their treatment course. Patients were excluded if they were diagnosed with central nervous system lymphoma prior to onset of eye involvement. Time to ocular remission (<1+ vitreous cells or vitreous tap with no evidence of disease), progression free survival (PFS), and overall survival (OS) were compared for patients receiving intravitreal methotrexate and rituximab. PFS was calculated as time from onset of treatment to recurrence of ocular disease (≥1+ vitreous cells or positive vitreous tap) and OS was calculated as time from onset of treatment to death.

Results: 18 eyes of 11 patients were included. 4/11 (36.3%) patients were female, and median age at diagnosis was 59 (range 42-83). 8/11 (72.7%) patients had primary vitreoretinal lymphoma and 3/11 (27.3%) patients had secondary intraocular lymphoma from a systemic non-central nervous system primary. 7 patients (10 eyes) received intravitreal methotrexate and 4 patients (8 eyes) received intravitreal rituximab as initial intravitreal therapy. All 18 eyes receiving intravitreal injections achieved ocular remission at some point during their course. Ocular remission occurred after a median of 3 injections (range 2-9) in the methotrexate group and 3 (range 2-7) injections in the rituximab group. Mean number of total injections in the entire sample was 10.4 (SD 4.2) per eye. Mean PFS was 54.6 ± 5.2 months (44.5 to 63.7 95% CI) for patients receiving methotrexate compared with 15.4 ± 3.4 months (8.7 to 22.1 95% CI) for patients receiving rituximab. Mean OS was 53.2 ± 5.8 months (41.8 to 64.6 95% CI) for patients receiving methotrexate and 48.5 ± 12.2 months (24.7 to 72.4 95% CI) for patients receiving rituximab.

Conclusions: Both rituximab and methotrexate are effective treatments for intraocular lymphoma, resulting in ocular remission after a median of 3 injections. Patients receiving methotrexate had a longer ocular progression free survival than those receiving rituximab, though mean overall survival was similar in both groups.

TITLE: RUNX3 expression in the retina and its effect on retinal neovascularization

SESSION TITLE: Retinal vascular diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: X. Lu, Y. Xu, X. Liang, Sun Yat-Sen University Zhongshan Ophthalmic Center State Key Laboratory of Ophthalmology, Guangzhou, Guangdong, CHINA|

Commercial Relationships Disclosure: Xi Lu: Commercial Relationship: Code N (No Commercial Relationship) | Yue Xu: Commercial Relationship: Code N (No Commercial Relationship) | Xiaoling Liang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate the expression of Runx3 in murine retina, and the effects of RUNX3 overexpression on retinal neovascularization (RNV) in oxygen-induced retinopathy (OIR) mice, as well as to explore its effect on HIF1α-VEGF signaling pathway.

Methods: Neonatal C57BL/6J mice were randomly divided into four groups: control (CON) group, OIR group, RUNX3-overexpression-OIR (RUNX3-AAV-OIR) group and vector-OIR (GFP-OIR) group. RUNX3-AAV-OIR group and GFP-OIR group were intravitreal injected with RUNX3-overexpressing adeno-associated virus (AAV) vectors and scramble vectors on P3, respectively. Neonatal mice of OIR group, RUNX3-AAV-OIR group and GFP-OIR group were exposed to 75% O_2 for 5 days from P7 to P12, and then abruptly returned to room air. The size of neovascular area, avascular area, the number and morphology of tip cells were assessed and quantified by immunostaining in the flat-mounted retinas. The protein levels of HIF1α and VEGF in the retina were detected by Western blot.

Results: RUNX3 mainly expressed in retinal vascular endothelium, and also in ganglial cell layer and inner nuclear layer of neonatal C57BL/6J mice on P17. Compared to OIR group, the size of retinal neovascular aera and avascular area, and the number of tip cells of RUNX3-AAV-OIR group decreased significantly, and the number and length of filopodia increased significantly, the elevated level of HIF1α and VEGF in the retina of OIR were significantly reduced by overexpressing the RUNX3 gene; while there were few changes of GFP-OIR group compared to OIR group.

Conclusions: Overexpression of RUNX3 inhibited RNV as well as improved retinal vascular repair and remodeling of OIR, meanwhile decreased the expression levels of HIF1α and VEGF in OIR retina.

ABSTRACT BODY:

Purpose: Though current treatment guidelines predominantly call for observation of non-proliferative diabetic retinopathy (NPDR), recent studies indicate that intravitreal anti-VEGF can reduce disease progression. In this study, we evaluated trends of intravitreal anti-VEGF and PRP administration to NPDR patients from 2016-2018.

Methods: We identified patients with an NPDR diagnosis from 2016-2018 in the IRIS registry and excluded patients once they developed proliferative diabetic retinopathy, vitreous hemorrhage, or macular edema. We calculated the percentage of NPDR patients receiving intravitreal anti-VEGF or PRP each year and performed a multivariate regression with patient characteristics of age, sex, and race/ethnicity to determine how these factors influence odds of treatment.

Results: In 2016, 2017, and 2018 there were 257,446, 400,301, and 504,001 eyes with NPDR, respectively. The yearly increase in number of eyes is in part due to an expanding number of clinicians participating in the IRIS Registry. In 2016, 2017, and 2018, 0.10%, 0.15%, and 0.15% of eyes received PRP, respectively; while 0.87%, 0.88%, and 0.94% of eyes received intravitreal anti-VEGF, respectively. Yearly increases in rates of PRP and anti-VEGF were significant ($\beta = 1.13$ and 1.04, respectively). Compared with white patients, Hispanic and Black patients were more likely to receive PRP (OR = 1.53 and 1.26, respectively) and less likely to receive anti-VEGF (OR = 0.85 and 0.73, respectively). Asian patients were less likely to receive anti-VEGF (OR = 0.68). Compared with patients aged 41-60, those aged 0-20, 61-80, and 81-100 were less likely to receive PRP (OR = 0.27, 0.66, 0.36, respectively); while those aged 0-20, 61-80, and 81-100 were more likely to receive anti-VEGF (OR = 2.69, 1.35, 1.83, respectively) and ages 21-40 were less likely (OR = 0.6).

Conclusions: Among NPDR patients, we found that 1) rates of PRP and anti-VEGF treatment increased slightly year-over-year; 2) Hispanic and Black patients were more likely to receive PRP and less likely to receive anti-VEGF than white patients, while Asian patients had comparable rates of PRP but were less likely to receive anti-VEGF; 3) patients aged 41-60 were more likely than other age groups to receive PRP except for those 21-40 (whose rates are comparable), and less likely than other age groups to receive anti-VEGF except for those 21-40 (whose rates are lower).

ABSTRACT BODY:

Purpose: Optical coherence tomography (OCT) and OCT angiography visualize in vivo human retina and its vasculature three-dimensionally with high-spatial resolutions. Involuntary eye movements make the trade-off between a field of view (FOV) and high-density sampling tight. We have developed a Lissajous scan OCT method that extends FOV with high-densely spatial sampling. The imaging capability of this method for diseased eyes is investigated.

Methods: A clinical prototype OCT device with a scan speed of 100,000 A-line/s is used. The OCT probe beam scans along with a modified Lissajous pattern. The continuous shifting of the Lissajous trajectory extends the FOV. Motion-free three-dimensional volumes and en-face OCT and OCTA images were generated by motion estimation and correction algorithms.

Twelve eyes of 12 subjects with branch retinal vein occlusion (BRVO) were scanned. The scanning range exceeded around 22-degree in diameter. After motion correction, data are remapped in 812 x 812 grid points. Eyes were also scanned with a raster scan of 320 x 320 pixels, and 20-degree (6-mm) scanning size by a commercial OCTA device (DRI-OCT, Topcon).

Results: Figure 1 shows en-face OCTA images of a representative case (79y, male). The en-face OCTA images of the superficial retinal slab with the Lissajous scan and the raster scan of the commercial device visualize the retinal vasculature. However, the enlarged images (the green box) show that the fine structure of retinal capillaries is visualized by the Lissajous scan method owing to high-spatial density. In 8 of 12 eyes, the capillaries around non-perfusion areas were better visualized.

The en-face slice and cross-sectional images of another patient’s eye (76y, male) are shown in Figure 2. The distribution of cysts and abnormal blood flow patterns can be visualized in en-face and arbitrary cross-sectional images.

Conclusions: We have shown that the Lissajous scan OCT enables high-dense en-face and three-dimensional posterior eye imaging more than >20-degree FOV. This technique will enable the assessment of biomarkers in more detail with a large FOV.

ABSTRACT BODY:

Purpose: Leber's hereditary optic neuropathy (LHON) is a rare genetic disease caused by mitochondrial gene mutations, such as MT-ND1, MT-ND4, and MT-ND6. MT-ND4 (G11778A) is the most common mutation causing LHON eye diseases worldwide. It causes sudden progressive vision loss in the affected patients, and there is no approved treatment currently available for LHON. This study aims to develop a gene replacement therapy product, NFS-01 (rAAV2-ND4), for the treatment of LHON associated with MT-ND4 mutation.

Methods: A recombinant AAV2-based therapeutic vector (NFS-01) was constructed to express a codon optimized human ND4 protein with a mitochondrial targeting sequence. After NFS-01 transduction, ND4 expression and cellular localization in 293T cells were examined by mitochondria/cytosol fractionation following by western blot. The NFS-01 function was investigated by comparing the productions of oxidative phosphorylated ATP and oxygen consumption rate in LHON patient-derived BLT2 hybrid cells with or without rAAV2-ND4 transduction. Furthermore, NFS-01 expression, tissue distribution, and biosafety were studied in rabbits and macaques after intravitreal (IVT) injection.

Results: ND4 protein expressed from rAAV2-ND4 vector was localized to mitochondria. ATP produced through oxidative phosphorylation in the mutant BLT2 cells was increased significantly after NFS-01 infection, indicating that NFS-01 at least partially restored ATP production in the mutant BLT2 cells. Consistently, rAAV2-ND4 significantly increased spare respiratory capacity of BLT2 cells as showed by Seahorse assay in the galactose medium condition. Furthermore, dose-response expression for ND4 gene was demonstrated in the rabbit retina after IVT injection. And the GLP toxicity studies showed no adverse effect or toxicity following IVT injection of NFS-01 in macaque. As part of the GLP studies, biodistribution of the vector was also performed and showed minimal spread of vector genome to spleen and lymph nodes. Neutralizing antibodies against AAV2 were either undetectable or no increase at 1- and 3-months post-injection.

Conclusions: Our gene therapy product NFS-01 allotropically expresses human ND4 protein in mitochondria and compensates for the loss function of ND4 in LHON derived cells. NFS-01 demonstrates effective retina delivery, expression, and safety post IVT injection in rabbits and macaques.

ABSTRACT BODY:

Purpose: Thyroid-associated ophthalmopathy (TAO) is most often seen in middle-aged patients with autoimmune thyroid disease, and immunosuppression is optimal therapy for active TAO. In elderly patients, TAO is less frequent but more severe. In this study, we aimed to determine the clinical characteristics and therapeutic schedule in elderly patients with TAO.

Methods: This retrospective study comprised 106 elderly patients with TAO (65.24±4.90 years). Data were obtained from a follow-up survey. The patients with active TAO received intravenous injection of methylprednisolone (MP) (39 cases) , or periocular injection of triamcinolone acetonide (TA) (16 cases) , or TA+oral cyclosporine A (TA+CsA) (35 cases). The NOSPECS classification, the clinical activity score (CAS) and $^{99m}T_c$-octreotide scintigraphy were used to evaluation of severity and activity of TAO before and after treatment.

Results: 106 elderly patients with TAO were identified (61 male, 45 female). At the time of initial diagnosis, 74.53% of the patients were hyperthyroid. 95.28% of the patients had bilateral TAO. Main symptoms were eyelid swelling (79.25%), exophthalmos (79.25%), eye movement limitation (81.13%) and double vision (75.47%). 12.26% of the patients had optic neurophathy. Orbital CT showed 86.79% of the patients had enlarged extraocular muscles. The exophthalmos, CAS score and NOSPECS grades of the patients with thyroid dysfunction were significantly higher than those with normal thyroid function ($P<0.05$). $^{99m}T_c$-octreotide scintigraphy was positive in active TAO patients (95%) with elevated uptake ratio (UR) ($P<0.05$). Smoking showed a significant correlation with CAS score ($P<0.05$), and age correlated with NOSPECS grade ($P<0.05$). Both UR and CAS scores of 90 patients with moderate to severe active TAO decreased significantly after treatment ($P<0.05$). The response rates of MP group and TA+CsA group were significantly higher than TA group ($P<0.05$), and with no significant difference ($P>0.05$).

Conclusions: The clinical manifestations of elderly patients with TAO were usually severe. Exophthalmos and eye movement limitation were the most common features and bilateral involvement. Thyroid dysfunction, smoking and age may increase the activity and severity of TAO. Intravenous corticosteroid pulse therapy and periocular injection of triamcinolone acetonide combined with cyclosporine A are effective for moderate to severe active TAO in elderly patients.

ABSTRACT BODY:

Purpose: Diabetic retinopathy is one of the main causes of blindness among the working age Australian population. This study investigates the relationship between demographic factors and diabetic ocular complications requiring vitreoretinal surgery at the only tertiary eye hospital in Victoria, Australia.

Methods: Single-centre retrospective study using data extracted from the Australian and New Zealand Society of Retinal Specialists Registry (2015-2019). Demographic information for all patients who underwent surgery for complications of proliferative diabetic retinopathy (PDR) at the Royal Victorian Eye and Ear Hospital (RVEEH) were included. Population proportions were compared to 2016 Census of Population and Housing data for Victoria, and Primary Health Networks (PHN).

Results: A total of 594 vitreoretinal surgeries for vitreous haemorrhage and tractional retinal detachment (47%) in 424 patients (60% male) were identified. Working age patients (25-65 years) made up 75% of the study population. The great majority of patients (75%) included in the study were insulin dependent despite only 18% of patients having type 1 diabetes mellitus.

Of the study population, 18% were born outside of Australia (as compared to Census 26%), with 14% identifying English not as their first language. 1.4% of patients identified as Aboriginal and/or Torres Strait Islander (Census 0.8%).

Geographically, in Victoria the PHN with the highest number of included patients was the North Western metropolitan region making up 34% of patients (Census 29%). Of the total, 19% of patients were from regional and rural Victoria (Census 24%).

Conclusions: This study identifies working age men, who are insulin dependent as most at risk of PDR complications requiring surgery. There is also an association with geographical location, which may well be a proxy marker for socio-economic status. Aboriginal and / or Torres Strait Islander people appear to also be at higher risk. Interestingly, being born outside Australia, or from a regional / rural location do not seem to be risk factors in our population.

This work shows the importance of ocular screening in this population. Future work will involve characterization of ophthalmic screening access in the most at risk locations.

ABSTRACT BODY:
Purpose: To assess whether a polygenic risk score for primary open angle glaucoma predicts treatment commencement amongst treatment naive glaucoma suspects.
Methods: A prospective, longitudinal genetic association study combining a discovery cohort of glaucoma suspects who were treatment naive at enrollment into the Predicting Risk of Glaucoma: RElevant SNPs with Significant Association (PROGRESSA) study, and a replication cohort comprising of treated early manifest and suspect glaucoma cases.

In the discovery phase, a per-allele weighted polygenic risk score was calculated for 301 glaucoma suspects who were treatment naive at enrollment into the PROGRESSA study. Multivariable cox proportional regression analysis assessed the correlation between polygenic risk score and time to initiation of Intraocular pressure (IOP) lowering therapy. A replication analysis assessed the correlation between polygenic risk score and time to escalation of IOP lowering therapy amongst 539 suspect and manifest glaucoma cases who were on IOP lowering therapy at study enrolment.
Results: A higher glaucoma PRS was correlated with earlier initiation of IOP-lowering therapy after adjustments for age, gender, IOP, and family history of glaucoma (adjusted HR: 1.43/SD 95% CI: [1.04, 1.95] P=0.024). Participants in the highest normative population quintile demonstrated a 3.4-fold likelihood of requiring IOP-lowering therapy within 5 years than participants in the lowest quintile (HR: 3.38/SD 95% CI [1.12, 10.20] P=0.017).

A replication analysis then evaluated the correlation between polygenic risk score and escalation of therapy amongst participants on therapy at enrolment. A higher polygenic risk score for glaucoma was correlated with a greater risk of requiring treatment escalation (HR: 1.24 95% CI: [1.05, 1.24] P=0.009), and was correlated with maximum number of required IOP-lowering agents during monitoring (beta: 0.17/SD 95% CI: [0.07, 0.26] P<0.001).
Conclusions: This study demonstrates novel associations between polygenic risk of primary open angle glaucoma and time to initiation of IOP lowering therapy. It builds upon previous work highlighting the therapeutic utility of genetic

risk stratification in glaucoma.

ABSTRACT BODY:

Purpose: We evaluated the impact of the systemic metabolic and cardiovascular risk factors (e.g., HbA1c level, hypertension renal parameters or dyslipidemia) on the response to anti-VEGF treatment in patients with diabetic macular edema (DME).

Methods: In prospective, monocentric interventional study (LIPSIA Trial) in total 148 eyes of 90 patients with DME received clinical examinations as 24-hour blood pressure measurement and laboratory examination of metabolic, renal and cardiovascular parameters. These investigations were conducted prior to the montly aflibercept treatment and after 6 months. We investigated the correlation with demographic parameters, baseline best corrected visual acuity (BCVA) and the blood pressure levels as well as laboratory blood parameters.

Results: The mean age was 61.1±14.9 years. The mean body mass index (BMI) was 32.1±5.9 kg/m2. HbA1c values were >7.0% in 63% of all patients. The blood pressure (BP) of 77% patients was above the target values of systolic <140 mmHg and diastolic <80 mmHg. LDL cholesterol was above the target value of 1.4 mmol/l in 92% of patients. Worse baseline BCVA and lower age were associated with a more pronounced gain in BCVA 6 months after initiation of intravitreal therapy. Furthermore, patients with normal glomerular filtration rate (GFR≥ 90 ml/min/1.73m2) had a significant better functional outcome at 6 months compared to patient with reduced GFR (10.0 ± 11.7 letters vs. 2.9 ± 8.1 letters, EM mean [adjusted for baseline BCVA and age]: 7.7 ± 1.3 letters vs. 3.9 ± 1.1 letters, p=0.019). The better the baseline BCVA, the less likely a patient gained ≥ 5 letters at month 6 (OR: 0.913, 95% CI: 0.86 – 0.97, p=0.003). Patients with a GFR ≥ 60 ml /min /1.73m2 were more likely to gain ≥ 5 letters compared to patients with GFR <60 ml /min /1.73m2 (OR: 3.73, 95% CI: 1.28 – 10.92, p=0.016). HbA1c levels, fasting glucose or blood lipid levels did not show an association with visual outcome.

Conclusions: The DME patients in the LIPSIA study presented several systemic comorbidities that were mainly poorly controlled. The response to aflibercept intravitreal treatment correlated with the age, baseline BCVA, and the renal parameters, but not with the HbA1c level.

ABSTRACT BODY:

Purpose: Extracting oriented structure in natural scenes is a fundamental and highly conserved computation in the visual system. Orientation selective (OS) ganglion cells (osRGCs) have been identified in the retina, but many features of their responses remain unclear. Thus, we sought to understand the receptive field (RF) structure of osRGCs, how the retina produces OS, and whether OS is maintained across rod and cone vision.

Methods: We measured RGC responses to visual stimuli from ex vivo rat retinas using a large-scale multi-electrode array. We used drifting and contrast reversing gratings to identify osRGCs and determine their spatial frequency tuning. We used checkerboard noise to estimate RF structure. A linear-nonlinear model based on the estimated RF was used to determine the extent to which osRGCs perform linear spatial integration.

Results: Consistent with previous work, we found osRGCs with peak tuning along either the horizontal or vertical meridians. However, among osRGCs, we identified two distinct types of RFs. Some osRGCs exhibited RFs reminiscent of cortical simple cells: their responses had narrow spatial frequency tuning and were highly phase-dependent. Importantly, they had an OFF-center RF flanked by ON-responsive zones, producing an even-symmetric RF that accurately predicted visual responses, indicating a relatively linear RF. Other osRGCs exhibited RFs similar to cortical complex cells: their responses had broad spatial frequency tuning that weakly depended on phase. Furthermore, like cortical complex cells, their linear RF had a speckled organization with small ON and OFF subzones that poorly predicted their visual responses, indicating a nonlinear RF. Both kinds of osRGCs maintained tuning down to rod-mediated light levels, and tuning was largely eliminated by blocking GABAa receptors.

Conclusions: We demonstrate two distinct RF structures among osRGCs that parallel the division of simple and complex cells in primary visual cortex. These results suggest that the emergence of simple and complex OS tuning emerges first in the retina, at least in rodents. Both forms of tuning span rod to cone vision. Finally, both forms of tuning depend on GABAa receptors, suggesting that they are mediated by feedforward inhibition onto RGCs. Intracellular measurements will be needed to understand how these simple- and complex-like responses are achieved by retinal circuits.

ABSTRACT BODY:

Purpose: Analysis of sex hormones in tear fluid will aid understanding of their role in regulation of tear production and in dry eye disease. Levels of sex hormones in tears are unknown due to low tear volumes available and a lack of sufficiently sensitive quantification methods. This pilot study applied an ultrasensitive LC-MS method to estimate androgens and oestrogens in tears of pre- and post-menopausal women.

Methods: An ultrasensitive LC-MS method previously developed for serum sex hormones was applied. The accuracy of this method for tears was assessed by absolute recovery from pooled basal tears of pre-menopausal women spiked with three levels of known amounts of sex steroids. Flush tears (where 60 µL saline was applied to the ocular surface, collected using a microcapillary tube and samples pooled from both eyes/participant) from pre- and post-menopausal women (n=2/category) were subsequently analysed for testosterone (T), estradiol (E2) and progesterone (P4) concentration on an API-5000 triple-quadruple mass spectrometer equipped with an atmospheric pressure photoionization source. Recovery tests were run in six replicates and other analyses were run in duplicate.

Results: Excellent absolute recoveries were observed for all steroids analysed at the concentrations tested, with accuracy ranging from 93.7% (P4) to 99.3% (T) for basal tears. Concentrations of E2 were 2.90±1.01 pg/mL in flush tears of post-menopausal women and 8.40±1.70 pg/mL in pre-menopausal women. P4 was 0.30±0.07 ng/mL in flush tears of pre-menopausal women but was not quantifiable in all tear samples from post-menopausal women. T was not detectable in any of the flush tear samples.

Conclusions: The ultrasensitive LC-MS method showed high accuracy for analysis of sex hormones in basal tears. The method effectively quantified E2 and P4 in flush tears of pre- and post-menopausal women. Further work will explore this method for analysis of sex hormones in flush and saline-diluted basal tears to tackle the limitations of tear sample volume

Commercial Relationships Disclosure: Manisha Malani: Commercial Relationship: Code N (No Commercial Relationship) | Surbhi Sharma: Commercial Relationship: Code N (No Commercial Relationship) | Manisha Jhunjhunwala: Commercial Relationship: Code N (No Commercial Relationship) | Manthan Hiremath: Commercial Relationship: Code N (No Commercial Relationship) | Shovan Gayen: Commercial Relationship: Code N (No Commercial Relationship) | Chittaranjan Hota: Commercial Relationship: Code N (No Commercial Relationship) | Jayabalan Nirmal: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Despite the ocular barriers, systemic drugs enter eye and causes toxicity. We hypothesize membrane transporters expressed in lacrimal gland (LG) to transport endogenous molecules from blood to tear, could falsely recognize the systemic drugs thereby gives access to eye. Hence, to understand the role of transporters (Organic Cation Transporter-1(OCT1)) in ocular toxicity, Artificial Intelligence (AI) methods and molecular docking studies were used to screen the drugs. Expression of OCT1 in LG and invivo tear kinetics study of predicted substrate (Cyclophosphamide(Cyc)) for OCT1 was performed to delineate the functional role of OCT1 in LG.

Methods: AI models were developed using a dataset of 193 drugs (substrate/non-substrates for OCT1) to predict drug-OCT1 interaction. Molecular Mechanics/Generalized Born Surface Area (MMGBSA) was used to calculate binding energy of protein (homology model of OCT1) and ligand (substrate/non-substrate/toxic drugs). Around 513 toxic drugs were screened through AI models and their binding energies were calculated using MMGBSA to classify them as substrate or non-substrate for OCT1. Expression of OCT1 in rabbit's LG was confirmed by real time polymerase chain reaction. Invivo tear kinetics was performed to validate AI predictions and the functional role of OCT1 in LG. Cyc was injected intravenously to rabbits (n=4) with or without topical OCT1 inhibitor (Atropine). Tear was collected using Schirmer strips at various time points and analyzed using HPLC. Data was presented as mean ± SD and analyzed using t-test. $P<0.05$ was considered to be significant.

Results: Developed AI models showed an accuracy of 81% to 83%. Binding energy of substrate molecules was found to be below -14613.30 kcal/mol. Many novel interactions were unrevealed between drugs and OCT1 (Table1). RNA expression confirms the OCT1 presence in LG. Tear secretion of Cyc was decreased with inhibitor, with a significant difference at 1h (870 ± 60 ng/ml without inhibitor, 570 ± 60 ng/ml with inhibitor), $p<0.01$.

Conclusions: Out of 513 systemic drugs causing ocular toxicity, 44% of them were predicted as OCT1 substrate. OCT1 expression in LG, molecular docking and tear kinetics studies confirms the functional role of OCT1 in the entry of systemic drugs (OCT1 substrates) into eye. Further studies will be carried in detail to delineate the role of OCT1 in LG.

TITLE: Endoscopic pars plana vitrectomy outcome after open globe injury with corneal opacity

SESSION TITLE: Endophthalmitis/ trauma/Intravitreal/periocular therapies

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Abouodah, K. Hamada, M. Pfannenstiel, R. Ajlan, Department of Ophthalmology, University of Kansas School of Medicine, Kansas City, Kansas, UNITED STATES|

Commercial Relationships Disclosure: Hythem Abouodah: Commercial Relationship: Code N (No Commercial Relationship) | Karam Hamada: Commercial Relationship: Code N (No Commercial Relationship) | Matthew Pfannenstiel: Commercial Relationship: Code N (No Commercial Relationship) | Radwan Ajlan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The primary objective is to determine the surgical outcome of endoscopic pars plana vitrectomy (PPV) during or shortly after open globe repair. The secondary objective is to detect the number of patients who later required corneal transplantation.

Methods: This is a retrospective cohort study of patients who received endoscopic PPV during open globe repair or within one month later. Inclusion criteria involved adult patients with a history of open globe injury, corneal opacity, and endoscopic PPV. Data was collected for the period between 12/2018 and 8/2021. Patients with corneal pathology not obliterating the fundus view were excluded from the study. The University of Kansas institutional review board approved this study.

Results: Ten patients met the study inclusion criteria (3 females, 7 males) with an average age of 61± 22.6 years old. Indications for endoscopic PPV included: retinal detachment in five patients, vitreous hemorrhage in three patients (one with retinal tear, and one with choroidal hemorrhage), and intraocular foreign bodies in two patients. Final visual acuity ranged from 20/70 to no-light-perception (NLP). All patients had their retina successfully attached. Two patients developed phthisis bulbi after one year. Corneal opacity was treated with scleral contact lens in one patient, penetrating keratoplasty in two patients, and the remaining seven patients were deemed unsuitable to receive a corneal transplant due to poor visual potential.

Conclusions: Endoscopic PPV may be a useful tool to repair posterior segment pathology in patients with recent open globe injury and corneal opacity. It can help address posterior segment disease and postpone corneal transplant surgery until visual potential can be fully determined. A larger prospective study is needed to better elucidate the role of endoscopic PPV in similar patient cohorts.

ABSTRACT BODY:

Purpose: Multi-planar clear corneal incisions (CCI) are the standard in cataract surgery for better wound closure and hence decreased risk of endophthalmitis. However, in previous limited experience examining cataract surgery incisions with OCT, we have not observed distinct incision multi-planarity. We sought to test the hypothesis that the manual multi-planar CCI may not actually be multi-planar.

Methods: Under controlled wetlab conditions, 4 ophthalmic surgeons with prior cataract experience (2 attendings, 2 residents) were re-familiarized with the multi-planar CCI and instructed to make 3 CCIs with a standard 2.4 mm keratome in porcine eyes. Each eye's anterior chamber was filled with viscodispersive prior to the 3 incisions. A research swept source MIOCT (1050 nm, 400 kHz) captured volumes at the CCIs (15 x 15 x 7.2 mm consisting of 750 B-scans x 750 A-scans x 950 depth pixels). For analysis, the anterior surface of each CCI was semi-automatically segmented. Each incision's center B-scan was refraction corrected and used to calculate the following metrics: incision length, length:width ratio, and internal angles. The internal angles were the angles between the incision's entry, center, and exit vectors calculated from the first 5%, mid 30%, and last 5% of incision length respectively (Fig. 1E). A Wilcoxon Signed-Rank test was performed to compare both sets of angles to the theoretical 90° of an ideal multi-planar incision and to 135° for a less acute multi-planar incision.

Results: Table 1 shows the metrics for each surgeon's CCIs. The null-hypotheses (entry and exit angles are part of distribution around 90°) were rejected in the t-tests ($p = 4.9 \times 10^{-4}$ and 4.9×10^{-4}). The result was the same with the t-test against 135° ($p = 4.9 \times 10^{-4}$ and 4.9×10^{-4}). All incisions had mean length:width ratios >=0.82.

Conclusions: CCIs created with a standard keratome do not appear to have multi-planarity in model porcine corneas. Despite this, length:width ratios show nearly square incisions, and the increased surface area from attempted multi-planar CCIs likely contributes to clinical incision closure.

ABSTRACT BODY:

Purpose: There is limited data regarding the role and efficacy of minimally invasive glaucoma surgery in the management of uveitic glaucoma (UG). We examined surgical outcomes in patients with UG after cataract extraction with lens implantation (CEIOL) plus endocyclophotocoagulation (ECP) or CEIOL plus OMNI™ ab-interno canaloplasty +/- trabeculotomy (Sight Sciences) (OMNI).

Methods: All patients aged >18 years with UG who underwent CEIOL + ECP or CEIOL + OMNI between August 2019 and September 2021 at a single academic center with a single surgeon were retrospectively reviewed. Surgical success was defined as intraocular pressure (IOP) ≤21 mmHg or reduction from baseline by 20% for two consecutive visits, without hypotony (IOP ≤5 mmHg), additional glaucoma surgery, or loss of light perception. Uveitic control was defined as less than a two-step increase in anterior chamber (AC) cell or lack of increase in steroid drop frequency. Outcomes were measured at three months post-operatively.

Results: Nine patients (14 eyes) were identified (eight ECP, six OMNI). Baseline pre-operative characteristics including IOP, AC cell grade, visual acuity (VA), age, sex, race, and affected eye(s) were not significantly different between groups. All cases were successful and had improved VA. In CEIOL + ECP and CEIOL + OMNI cases, IOP was reduced an average of 7.0 mmHg (p=0.06) and 8.9 (p=0.03) respectively. The number of glaucoma medications reduced by 0.3 (p=0.18) and 1.0 (p=0.04) respectively. Outcome differences between groups did not meet statistical significance. No cases had a two-step increase in AC cell, however there was an increase in steroid drop frequency for 50% of patients in each group. Post-surgical complications included cystoid macular edema (1/8 of ECP and 3/6 of OMNI cases), hyphema (2/6 of OMNI cases), and IOP spike (1/6 of OMNI cases).

Conclusions: Both ECP and OMNI with CEIOL improved VA, IOP, and glaucoma medication use, without a two-step increase in AC cell in UG at three months. An increase in steroid drop frequency may be the cost of a prolonged post-surgical inflammatory course related to the underlying uveitis. Further investigation with a larger population, longer follow-up, and prospective design are necessary.

TITLE: Risk Factors Predicting Loss to Follow-Up, Hospital Admission, and Medication Noncompliance Among Patients with Infectious Keratitis at a Public County Hospital

SESSION TITLE: Ocular surface health and conjunctiva

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J.B. Lopez, L. Chan, M. Saifee, M. Yung, M.F. Chan, Department of Ophthalmology, University of California San Francisco, San Francisco, California, UNITED STATES|M.F. Chan, Francis I. Proctor Foundation, University of California San Francisco, San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure: Jacqueline Lopez: Commercial Relationship: Code N (No Commercial Relationship) | Lawrence Chan: Commercial Relationship: Code N (No Commercial Relationship) | Murtaza Saifee: Commercial Relationship: Code N (No Commercial Relationship) | Madeline Yung: Commercial Relationship: Code N (No Commercial Relationship) | Matilda Chan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Infectious keratitis is a vision-threatening condition requiring close follow-up and disciplined eye drop administration to achieve resolution. Although patients presenting to county hospitals often have a more severe presentation, there is a paucity of risk and outcomes data in this setting. This study investigates social risk factors predicting loss to follow-up, medication noncompliance, hospital admission, and poor outcomes for infectious keratitis in the county setting.

Methods: We performed a retrospective case-control study at Zuckerberg San Francisco General Hospital and Trauma Center. Inclusion criteria were all patients who had corneal cultures for suspected infectious bacterial or fungal keratitis obtained between 2010-2021. Exclusion criteria were patients with viral keratitis only. Multivariable logistic regression was used to analyze the relationship of social and medical risk factors with loss to follow-up, medication noncompliance, hospital admission, worsened visual acuity, and delayed time to resolution.

Results: Of 174 patients with infectious keratitis, 69 (40%) were lost to follow-up. Unemployment was associated with increased risk of loss to follow-up (OR 2.58, p=0.049). There was a trend toward an association with homelessness and noncompliance (OR 3.48, p=0.095). 47 patients (27%) were hospitalized for treatment of corneal ulcers. Hospitalization correlated with unemployment (p=0.033), homelessness (p=0.033), and drug use (p=0.006). Unemployment was significantly associated with worse final visual acuity (p=0.001). Increasing age correlated with longer healing time of the ulcer, with each one-year increase in age associated with delayed resolution by 0.549 days (p=0.042).

Conclusions: Patients experiencing homelessness, unemployment, drug use, or increased age demonstrate higher risk for treatment barriers including loss to follow-up and medication noncompliance, resulting in worse visual acuity, risk for hospital admission, and delayed time to resolution. These risk factors should be considered when determining the need for hospitalization or more deliberate follow-up measures in patients with infectious keratitis.

ABSTRACT BODY:

Purpose: In this study we use short term repeatability data to investigate the specificity of mixing 24-2C SITA visual field (VF) exams using the HFA GPA limits to detect change.

Methods: 24-2C SITA Standard (SS) and 24-2C SITA Faster (SFR), as well as 10-2 SS, and 10-2 SITA Fast VFs were acquired on an HFA3 Model 860 perimeter (ZEISS, Dublin, CA) at two repeat visits on one eye each for healthy and glaucomatous subjects. 24-2 VFs were extracted from 24-2C. 10-2 VFs were not used. All four visit series permutations having two baselines were comprised of the same SITA strategies (SS or SFR) were created (baseline order does not matter).

We also substituted 24-2C MD for the 24-2 MD in GPA to select change limits. Differences between Pattern Deviations (PD) of both follow-ups to the averaged baselines for each test point were compared to change limits used for analogous regions of the commercial 24-2 GPA.

Any change observed in this data was defined as a false positive because the repeated visits occurred over a short time period. False positive rates (FPR) with 95% confidence intervals (CI) were pooled from all 224 series and all 24-2C test points for both follow-ups. Specificity was defined as 1 – FPR. GPA excluded test locations where the MD or PD are too poor (marked as "out of range" or "X" on reports or analyses). FPR was calculated two ways: a) pooling all points and b) pooling only points not marked “X”.

Results: Mean age was 57.3 (standard deviation, SD: 7.6; range: 44.3 to 74.7) years for 28 healthy eyes and 71.3 (SD: 9.0; range 54.0 to 97.9) years for 28 glaucoma eyes (creating a total of 224 series permutations). Mean 24-2 SS MD was 0.38 (SD: 1.17; range: -1.89 to 2.62) dB and -7.92 (SD: 7.72; range: -23.42 to 1.63) dB in healthy and glaucoma eyes, respectively.

24-2C and 24-2 MDs showed strong agreement with an R^2 of 0.99 (slope: 1.04 and offset: 0.00). FPR was 0.060 (CI: 0.057 to 0.063) using all 27,776 pooled points and 0.066 (CI: 0.063 to 0.069) for the 25,300 pooled valid points, consistent with specificity of ~94%.

Conclusions: Short term specificity was ~94% for detecting change from baseline events in pooled test locations in 24-2C VF series consisting of mixed SITA exams using limits previously established for 24-2 GPA. This suggests that even without the temporal and spatial confirmation used in the standard commercial GPA, a mixed SITA 24-2C GPA may have reasonable specificity for determining progression.

ABSTRACT BODY:

Purpose: To compare VF hemifield vs. global mean deviation (MD) rates of progression.

Methods: Eyes with ≥10 VF tests (Swedish Interactive Thresholding Algorithm 24-2) and ≥3 years of follow-up were included from patients at Columbia University Irving Medical Center. Rates of progression (dB/yr) in global, superior, and inferior hemifield mean deviation were calculated. The presence of rapid (worse than -0.5 dB/year), very rapid (worse than -1.0 dB/year), and catastrophic (worse than -2.0 dB/year) progression were determined.

Results: VFs from 4,217 eyes (average number of tests, 15.0; mean follow up, 9.3 years) of 2,435 patients were included. The rate of change in global, superior hemifield, and inferior hemifield MD were statistically different among all three groups (-0.30dB/year vs. -0.31 dB/year vs. -0.28 dB/year, respectively, $p < 0.01$) (Table 1). In the superior hemifield, a larger percentage of patients demonstrated rapid progression (26.9% vs. 25.4%), very rapid progression (11.0% vs. 8.7%), and catastrophic progression (2.0% vs. 1.2%) compared to global mean deviation. A similar result was seen in the inferior hemifield but only in those that demonstrated catastrophic progression (1.7% vs. 1.2%). Comparing symmetry of progression between the superior and inferior hemifield (Figure 1), although a plurality of eyes (82.1%) had minimal difference between hemifield change (superior minus inferior hemifield slopes between 0.0 and -0.5 dB/year), a substantial percentage of patients had asymmetry between the hemifields, with 17.9% of eyes having a difference greater than -0.5 dB/year and 5.5% greater than -1.0 dB/year.

Conclusions: Superior, inferior, and global VF MD rates of progression often differ, but a large difference may serve as an indicator for rapidly progressing glaucoma and necessitate a treatment change or earlier surgical intervention. Identification of these areas of regional, rapid progression can be used to individualize management and treatment decisions.

ABSTRACT BODY:

Purpose: In this cross-sectional study, we aim to evaluate optical coherence tomography angiography (OCTA) and microperimetric findings in non-paraneoplastic autoimmune retinopathy (AIR).

Methods: Ten eyes (6 patients) with a diagnosis of AIR, using the criteria proposed by Sen et al., 2014 , were included along with ten healthy control eyes of five healthy age-matched subjects. Each eye underwent microperimetric evaluation using the CenterVue MAIA device (Padova, Italy) and OCTA examination using RTVue Avanti OCTA (Optovue Inc, Fremont, California, USA). Clinical and demographic data, including OCTA and microperimetry, were analyzed and compared between the 2 groups.

Results: Mean (SD) age for the AIR and control groups was 44.2 ± 25.2 and 37.2 ± 22.9 years, respectively (p=0.30). Mean LogMAR BCVA for the AIR and control groups was 0.29 ± 0.33 and 0, respectively (p=0.002).

Total and parafoveal superficial capillary plexus densities were significantly lower in the AIR group (45.6 ± 3.7% and 46.9 ± 4.8%, respectively) compared with the control group (52.2 ± 2.4% and 54.1 ± 1.8%, respectively), (p =0.001 and 0.003, respectively). Total and parafoveal deep capillary plexus densities were not significantly different between AIR and control groups (p=0.24 and 0.08, respectively). Foveal avascular zone (FAZ) area was not statistically different between AIR group (0.25 ± 0.06 mm) and control group (0.24 ± 0.04 mm), (p=1).

As for microperimetric findings, average threshold values were significantly lower in the AIR group (20.6 ± 5.4 dB) compared with the control group (26.6 ±1.7 dB), (p=0.006). Percentage reduced thresholds were higher in the AIR group (70.5 ± 36.8%) compared with the control group (20.3 ± 22.1%), (p=0.009). Fixation stability measurements (P1 and P2) were not statistically different between the 2 groups (p=0.8).

Conclusions: OCTA and microperimetry may show abnormal results in AIR patients. Both ancillary tests may be helpful in evaluation and management of this rare disease. Further studies are required to elucidate these findings.

ABSTRACT BODY:

Purpose: Teprotumumab was approved as a treatment for thyroid eye disease (TED) in 2020, but some clinicians question whether its high cost is worth its benefits. Cost-effectiveness analyses (CEAs) can help answer this question, but the health utility scores required are rare in TED. In this study we compare costs of teprotumumab with other treatments and use the validated Graves' orbitopathy quality-of-life (GO-QoL) score to measure change (Δ) in QoL. Our aim is to help clinicians think critically about treatment costs for TED as health care shifts to focus on cost-effective solutions.

Methods: Analysis was limited to first and second-line therapies for moderate-to-severe active TED (as per the 2021 European Group on Graves Orbitopathy guidelines) with pre- and post-intervention GO-QoL scores available in the literature. The costs of these treatments were obtained from the Turquoise Health database using Medicare billing codes. Prices were then generated from 1,903 hospitals in 50 states. Full treatment costs, including costs of medication and infusion, were calculated using recommended dosing guidelines and standardized to a 70kg patient (Table 1).

Results: Costs of teprotumumab, rituximab, orbital radiotherapy (ORT), and IV methylprednisolone (IVMP) were analyzed. Among these, teprotumumab had the highest mean treatment-related cost at $386,424 (SD $65,217) followed by rituximab at $18,549 (SD $2,556), ORT at $4,316 (SD $1,183), and IVMP at $4,025 (SD $1,647). Teprotumumab yielded a ΔGO-QoL of 19.4 (SD 18.8), rituximab 17.9 (single study), IVMP 13.5 (SD 25.2), and ORT 6.6 (SD 27.8). Treatment cost/ΔGO-QoL for teprotumumab was greatest at $19,888, followed by rituximab at $1,036, ORT at $651, and IVMP at $298 (Table 2).

Conclusions: Treatment cost/ΔGO-QoL of teprotumumab is nearly 20 times that of rituximab and around 50 times that of IVMP. Long-term data regarding the effect of teprotumumab on reducing the rates of orbital and strabismus surgery and improving ocular sequelae, as well as studies evaluating the impact of treatment on QoL using quality-adjusted life years, are needed to be able to determine the cost-effectiveness of the various treatment options for TED.

ABSTRACT BODY:

Purpose: Iron is essential for retinal metabolism, but excess iron can cause oxidative stress. In glaucoma eyes, progressive retinal ganglion cell (RGC) death has been associated with dysregulation of iron homeostasis. Transferrin (TF) is an endogenous iron transporter that controls iron ocular levels. Local administration of TF is neuroprotective in various models of retinal degeneration, controlling iron-induced oxidative stress without undesirable side-effects. Herein, we evaluated the protective effects of TF on RGCs in retinal explants exposed to various stresses and in a rat model of ocular hypertension (OHT).

Methods: Rat retinal explants (n = 6-10/stress condition) were subjected for 24 hours to 1mM $FeSO_4$, 100µM NMDA, or 100µM $CoCl_2$, and maintained in culture until 96 hours. TF (50 mg/mL) was added during the whole stress incubation period. Survival of Brn3a-immunolabeled RGCs was quantified at 96 hours. In vivo, OHT was induced by injection of magnetic microbeads into the anterior chamber of adult Brown Norway rats (n = 5/group). Animals then received four weekly intravitreal injections of TF or vehicle (BSS). Naïve rats served as normotensive internal controls. RBPMS-immunolabeling of flat-mounted retinas and PPD-stained optic nerve sections were used for, respectively, RGC and axon quantification at 4 weeks.

Results: All three stresses induced about 50% RGC cell loss in retinal explants. Incubation with TF significantly preserved RGCs against $FeSO_4$-induced toxicity (+49.5 %, p = 0.0354). Similarly, TF partly protected RGCs against NMDA-induced excitotoxicity (+42.2 %, p = 0.0027) or $CoCl_2$-induced RGC hypoxia (+54.4 %, p = 0.0053). In IOP rats, RGC density at 4 weeks was significantly decreased in BSS-treated animals in comparison to naïve animals (-49.7%) whereas RGC number was not statistically different from naïve animals in TF-treated rats (p = 0.2475). TF preserved RGCs by about 70% compared to BSS-treated animals with OHT (p = 0.0008). Similarly, the axon density at 4 weeks was not different from the naïve group in TF-treated rats (p = 0.2480), while preserving about 47% of the axons when compared to vehicle group (p = 0.0027).

Conclusions: These results indicate that TF can interfere with different cell death mechanisms involved in glaucoma pathogenesis and demonstrate the ability of TF to protect RGCs exposed to elevated IOP. Altogether these results suggest that TF could benefit glaucoma patients.

ABSTRACT BODY:

Purpose: Myopic foveoschisis involves splitting of retinal layers at the fovea in highly myopic eyes which can resemble changes in X-linked retinoschisis (XLRS). Here, we characterize a novel nonhuman primate model of myopic foveoschisis by clinical exam, imaging, genetic, immunohistochemical, and single-nuclei transcriptomic analyses, focusing on retinoschisin 1 (RS1) – the extracellular retinal protein involved in maintaining retinal architecture and defective in XLRS.

Methods: We identified a 27-year-old rhesus macaque with visual behavior of myopia and performed ophthalmic examination with streak retinoscopy and biometry. Multimodal imaging including fundus photography (FP), fluorescein angiography (FA), and optical coherence tomography (OCT) was performed to monitor progression over 16 months prior to necropsy. Sanger sequencing was performed using human primers for RS1. Antibodies against rhodopsin, M/L opsin, GFAP, and Iba-1 were used to evaluate photoreceptors, macroglia, and microglia in the right eye. Single-nuclei RNA-sequencing (snRNA-seq) was performed on macular tissue for clustering, differentially expressed genes (DEGs), and pathway analyses.

Results: Ocular examination showed a prominent choroidal pattern and peripapillary atrophy suggestive of myopia, with mean refractive error of -13.5D and axial length of 21.5mm in the two eyes. FA showed no active choroidal neovascularization, but OCT revealed foveal schisis in outer plexiform layer (OPL) of the macula that worsened over time. Sanger sequencing showed no coding defects in the RS1 gene. Immunohistochemistry showed increased GFAP expression within Müller glia in the OPL, and loss of ramified Iba-1+ microglia, but no definite disruption of photoreceptors. SnRNA-seq of the macula showed transcriptionally-distinct cell types including rod, cone, bipolar, horizontal, amacrine, Müller, and ganglion cells that were similar in proportion to controls. Most retinal cell types showed predominantly upregulated DEGs, especially in cones. SnRNA-seq showed RS1 expression primarily in cones and rods that did not differ significantly from control eyes.

Conclusions: This spontaneous nonhuman primate model of myopic foveoschisis demonstrates a structural phenotype resembling XLRS with activated glial cells, but does not exhibit photoreceptor degeneration, RS1 mutation or changes in RS1 expression pattern, suggesting different molecular mechanisms between the two conditions.

ABSTRACT BODY:

Purpose: Visual acuity exams are the primary subjective exam to detect or track progression of ophthalmic disease. However, the ability to distinguish certain features to correctly identify objects is labeled “recognition” acuity and may interfere with accurate visual acuity measurements. Therefore, we sought to characterize the recognition of optotypes seen on common visual acuity exams.

Methods: Optotypes were displayed on a high-definition digital monitor and images were captured using cell phone placed behind a phoropter with various spherical, cylindrical and axis lenses. Using a custom in-house application, images with differing amounts of distortion were displayed to human subjects with normal best-corrected visual acuity in a “forced-choice” style multiple-choice exam. Subjects were forced to determine what optotype character was displayed. Test results were presented as heatmaps to optotype recognition accuracy for a range of optical distortions.

Results: 36 healthy human subjects completed the exam. Heatmaps of each optotype show accuracy of the 4 subjects evaluated for their recognition of each optotype. No optical distortion (0 sphere/cylinder with no axis of rotation) is displayed in top left corner. Allen and Wright (pediatric) optotypes had the highest recognition accuracy, whereas letter-based optotypes scored the lowest.

Conclusions: Optotypes have differing levels of recognition and could potentially result in a variation in performance on visual acuity exams. These results support findings that ETDRS and Snellen optotypes are not interchangeable, and this non-interchangeability applies to all optotypes. Additionally, visual acuity results may not be interchangeable unless the optotype used is fixed.

ABSTRACT BODY:

Purpose: Current approaches to close sclerotomy wounds following pars plana vitrectomy (PPV), including (1) no-closure, (2) suturing, and (3) application of fibrin glue sealants (FG) are at risk for hypotony and endophthalmitis, potentially time-consuming to perform and uncomfortable for patients, and hard to prepare and apply, respectively. In this study, the efficacy and stability of a novel visible-light curable natural hydrogel (LC-COMatrix) was evaluated for closure of sclerotomy wounds following PPV in ex-vivo models.

Methods: The human corneoscleral tissues with exposed sclera (removed conjunctiva) were mounted on an artificial anterior chamber connected to a pressure pump and a pressure sensor. A sclerotomy wound was created 4-mm from the limbus using a 23g trocar. The created wounds were left unclosed (N=10), closed with FG (N=10), or closed with LC-COMatrix (N=10). Afterwards, the pressure was increased (0.2 ml/s) and the burst pressure was recorded. In addition, fresh adult porcine eyeballs underwent a 2-port 23g PPV with vitreous removal and replacement with saline. One of the created slcerotomy wounds on each eyeball was closed with LC-COMatrix (N=10) or left unclosed (N=10). The infusion pressure was increased (5 mmHg/s) and closure/failure pressure was recorded. Furthermore, 23g sclerotomy wounds on human scleras (N=12) were closed with LC-COMatrix and the tissues were subjected to rotational shake while incubated in corneal preservation solution. The scleral adhesivity of LC-COMatrix was followed up using anterior segment optical coherence tomography (AS-OCT) and slit lamp biomicroscopy for 30 days.

Results: The average burst pressure for human scleras closed with LC-COMatrix was 220.48 mmHg (range 75.1-400.0), which was significantly higher than those of FG (133.7 mmHg, range 5.0-430.0, $p=0.049$, and no-closure (20.5 mmHg, range 6.1-75.3, $p<0.001$). The average burst pressure of porcine eyeballs' sclerotomy wounds closed with LC-COMatrix was 234.9 mmHg (range 35.2-543.2), while the burst pressure in the control group was 25.4 mmHg (range 6.4-60.0) ($p<0.001$). Regular examination with slit-lamp and AS-OCT showed that LC-COMatrix was consistently attached to the human scleras during the 30 days of follow-up.

Conclusions: LC-Comatrix is a novel visible-light curable natural and easy-to apply hydrogel with potential application for closure of sclerotomy wounds following pediatric and adult PPVs.

TITLE: Automated Henle's fiber layer segmentation from non-directional optical coherence tomography images with deep learning

SESSION TITLE: Machine Learning: Segmentation and Classification

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Kesim, M. Hasanreisoglu, Ophthalmology, Koç University School of Medicine, Istanbul, TURKEY|S. Cansiz, Computer Engineering, Bilkent Universitesi, Ankara, Ankara, TURKEY|Z. Kulali, S. Bektas, Koç University School of Medicine, TURKEY|M. Hasanreisoglu, Koç University Research Center for Translational Medicine, TURKEY|C. Gunduz-Demir, Computer Engineering, Koc Universitesi, Istanbul, Istanbul, TURKEY|C. Gunduz-Demir, KUIS AI Center, Koc Universitesi, Istanbul, Istanbul, TURKEY|

ABSTRACT BODY:

Purpose: To develop a deep learning algorithm that performs Henle’s fiber layer (HFL) segmentation from non-directional optical coherence tomography (OCT) images of retina.

Methods: Directional OCT (D-OCT) images from the macular 20°×20° area of healthy subjects were acquired to manually segment HFL. A deep neural network was designed and trained to estimate these manual segmentations only from their corresponding standard non-directional OCT images. This deep learning algorithm was then validated by another set of standard non-directional OCT images of healthy subjects.

Results: Standard OCT images from 20 and 10 eyes were used for training and validation, respectively. The trained deep neural network segmented HFL on validation OCT images with 81.74 percent recall, 86.31 percent precision, and 83.70 percent f-score rates on the average. On the validation OCT images, the total HFL volume and the mean HFL thickness values calculated by deep neural network were 0.65 ± 0.07 mm^3 and 23.20 ± 2.51 μm respectively.

Conclusions: The current study shows that Henle’s fiber layer, which had been previously visualized and segmented with the help of D-OCT, could be segmented from standard, non-directional OCT scans by a deep learning algorithm, which proves to be a beneficial tool to improve HFL segmentation by reducing the need to perform D-OCT imaging.

TITLE: Comparison of a Photogrammetry for Anatomical CarE (PHACE) system with other affordable technologies for 3D imaging of the orbit and adnexa

SESSION TITLE: New improvements in imaging and development of biomarkers

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.K. To, A.N. Vu, A. Browne, L.S. Ediriwickrema, Ophthalmology, Gavin Herbert Eye Institute, Irvine, California, UNITED STATES|A. Browne, Department of Biomedical Engineering, Institute of Clinical and Translational Science, Irvine, California, UNITED STATES|

Commercial Relationships Disclosure: Josiah To: Commercial Relationship: Code N (No Commercial Relationship) | Anderson Vu: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Browne: Commercial Relationship: Code N (No Commercial Relationship) | Lilangi Ediriwickrema: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A need exists for cost-effective standardized tools to objectively characterize morphology and volume of orbital and adnexal anatomy. We compared a custom Photogrammetry for Anatomical CarE (PHACE) system with other low and mid-cost 3D imaging technologies for quantitative facial modeling.

Methods: We compared two low-cost and two mid-cost 3D scanning technologies. The PHACE system and the iPhone Scandy Pro application (Scandy, USA) are low-cost systems (<$500), whereas the Einscan Pro 2X (Shining 3D Technologies, China) and ARC7 facial scanner (Bellus 3D, USA) are two mid-priced structured light sensing scanners (~$5000). Imaging was performed on human subject faces with Fitzpatrick skin types 2, 4 and 6, with and without 3D printed phantom lesions affixed above the brow line. The PHACE system used two Google Pixel 3 smartphones on two rotating turntables to acquire 90 photographs, which were then rendered into 3D models using Metashape (Agisoft, Russia) - a photogrammetry software. The rendered hemisphere volumes using PHACE, Einscan, Scandy, and ARC7 devices were calculated with CloudCompare (open-source point cloud software). The performance of each facial scanning technology was evaluated by quantitatively comparing digitally measured volumes to the calculated volumes of the 3D printed phantom lesions.

Results: The Einscan qualitatively (Fig. 1A) and quantitatively rendered 3D printed phantom lesions with greatest resolution and accuracy (mean difference of 2.2 ± 2.8% for 33.5 µL). The mean differences between the calculated volume of the small phantom lesion (124 µL) and the rendered volumes for the PHACE, Scandy, and ARC7 systems were 4.7 ± 3.7%, 9.1 ± 0.9%, and 22.0 ± 17.9%, respectively.

Conclusions: The PHACE system outperforms the Scandy and more expensive ARC7 system to accurately render volumes as little as 124 µL. The Einscan can accurately render volumes down to 33.5 µL but it is 10x the cost. We demonstrated an optimized system to generate 3D models of the human orbit and adnexa while balancing cost and performance.

TITLE: rAAV2-ND1 gene therapy for Leber's hereditary optic neuropathy(LHON) with mitochondrial ND1 mutation

SESSION TITLE: Gene Therapy and Gene Editing for Ocular Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Li, C. He, Y. Tao, C. Cheng, X. Zhang, A. Luk, Q. Li, Neurophth Therapeutics, CHINA|

Commercial Relationships Disclosure: Bin Li: Commercial Relationship(s);Code E (Employment):Neurophth Therapeutics | Congwu He: Commercial Relationship(s);Code E (Employment):Neurophth Therapeutics | Yu Tao: Commercial Relationship(s);Code E (Employment):Neurophth Therapeutics | Chao Cheng: Commercial Relationship(s);Code E (Employment):Neurophth Therapeutics | Xin Zhang: Commercial Relationship(s);Code E (Employment):Neurophth Therapeutics | Alvin Luk: Commercial Relationship(s);Code E (Employment):Neurophth Therapeutics | Qiutang Li: Commercial Relationship(s);Code E (Employment):Neurophth Therapeutics

ABSTRACT BODY:

Purpose: LHON is an inherited mitochondrial disorder characterized by bilateral vision loss due to the degeneration of retinal ganglion cells (RGC). Approximately 13%-25% of LHON cases are caused by G3460A point mutation in ND1 mitochondrial gene. There is currently no effective treatment for LHON. Drugs such as Coenzyme Q and various antioxidant exhibit limited beneficial effects. This study is to design and characterize the recombinant AAV2-based gene replacement therapy (rAAV2-ND1, NFS-02) for the treatment of LHON with ND1 mutation

Methods: The ND1 sequence was optimized by adjusting codon usage preference, sequence repeats, mRNA secondary structure stability, and GC composition. The codon optimized human ND1 protein was tagged with COX10 mitochondrial targeting sequence and inserted into rAAV2 viral vector. After transducing into 293T cells, ND1 expression and mitochondrial localization were examined by Western blotting and co-immunofluorescent microscopy, respectively. The NFS-02 rescue of ND1 deficiency on the LHON patient derived cells was evaluated by oxygen consumption rate measured with Seahorse assay in the galactose medium condition. The in vivo expression, tissue distribution, and biosafety were also studied in rabbit and macaque after intravitreal (IVT) injection

Results: NFS-02 was constructed with the codon optimized ND1 coding sequences showing higher translation efficiency in vitro. The exogenous ND1 protein from rAAV2-ND1 vector was co-localized with mitochondrial marker ATP5A1, suggesting its mitochondrial localization. Consistent with its role in mitochondrial complex I, rAAV2-ND1 transduction significantly increased spare respiratory capacity of LHON patient-derived ND1 mutant cells, suggesting its therapeutic efficacy in vitro. Dose-dependent ND1 expression in RGC was observed in rabbit retinas after IVT injection. No neutralizing antibodies against AAV2 were detected in rabbit eyes after 6-months of NFS-02 injection at 5E9 vg/eye dose, and the GLP toxicity studies on macaque showed no adverse effect or toxicity following NFS-02 injection

Conclusions: Our gene therapy product, NFS-02, can allotropically express human ND1 protein in mitochondria, which compensates for the loss function of ND1 in LHON mutant cells. IVT administration of NFS-02 can efficiently achieve RGC delivery and expression, without noticeable biosafety concern in rabbit and macaque eyes

TITLE: Effects of biomechanical cues on filopodia, tunneling nanotubes, and myosin-X in trabecular meshwork cells

SESSION TITLE: Aqueous humor dynamics and Trabecular Meshwork

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K.E. Keller, Y. Sun, Y. Yang, Oregon Health & Science University Casey Eye Institute, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure: Kate Keller: Commercial Relationship: Code N (No Commercial Relationship) | Ying YIng Sun: Commercial Relationship: Code N (No Commercial Relationship) | Yong-Feng Yang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Tunneling nanotubes (TNTs) are modified filopodia, which emanate from the trabecular meshwork (TM) cell surface and are important for cellular communication. As a filopodia grows, their tips transiently engage the underlying extracellular matrix (ECM) via integrins before a second round of growth occurs. This suggests changes to the biomechanical environment could affect filopodia and TNT formation. Here, we describe the effects of substrate stiffness, or mechanical stretch, on filopodia and cellular communication via TNTs. In addition, we investigate Myo10-integrin interactions, which could aid stabilization of the growing filopodia.

Methods: Primary human TM cells were grown on: (1) surfaces mimicking the stiffness of normal TM (4 kPa) or glaucoma (50 kPa); or (2) collagen-coated FlexCell plates, which were subject to 24 hour static mechanical stretch. A fluorescent vesicle transfer assay was performed to measure cellular communication via TNTs. Western immunoblots measured Myo10 protein levels. TM cell lysates were immunoprecipitated using a Myo10 antibody and pull-downs were separated by SDS-PAGE. Western immunoblots were probed with antibodies against integrins α5, β1, αvβ5 and αvβ3.

Results: As substrate stiffness increased, there was a significant increase in fluorescent vesicles transferred between cells (34% (4kPa) vs 49% (50 kPa); n=39; p=0.001). However, filopodia length and the number of filopodia per cell were unaffected by substrate stiffness. Mechanical stretch produced a 7% increase in the number of fluorescent vesicles transferred between TM cells (n=74; p=0.015). Concomitantly, Western immunoblots and densitometry showed a small (5%), but significant increase in Myo10 protein levels (n=15; p=0.023). Co-immunoprecipitation assays showed interaction of Myo10 with integrins α5, αvβ5 and αvβ3, but not with β1-integrin.

Conclusions: Investigating the effects of substrate stiffness and mechanical stretch on filopodia and cellular communication via TNTs gives us further insight into how cellular communication could be affected in glaucomatous TM in situ, or in response to elevated intraocular pressure. Our results expand the repertoire of integrins to which Myo10 binds to. Further studies are required to investigate if Myo10-integrin interactions are necessary for filopodia growth, or the transition of filopodia to TNTs.

ABSTRACT BODY:

Purpose: Examine differences in baseline characteristics and treatment of chronic ocular graft versus host disease (oGVHD) patients in two geographically distinct locations.

Methods: Patients diagnosed with definite chronic oGVHD as defined by the International Chronic Ocular GVHD Consensus Group between 09/2014 and 09/2021 at two locations were identified. Clinic 1 (C1) is located in Arizona and Clinic 2 (C2) is located in Minnesota. IRB approved retrospective chart review was conducted and the following data was collected for initial and follow-up visits: demographic information, ocular surface disease index (OSDI), corneal fluorescein staining (CFS), and treatment (hot compresses, moisture chambers, punctal plugs, punctal cautery, autologous serum tears (AST), and scleral contact lenses). Differences by site were tested using Chi-Square tests or linear model ANOVA.

Results: C1 (n=79) and C2 (n=50) baseline mean age was 58.4 years and 57.5 years, respectively. Mean length of follow-up was 108.2 weeks for C1 and 115.9 weeks for C2. By last follow-up, mean OSDI change was -17.6 at C1 (95% CI -24.2, -11.1) and +5.3 (95% CI -1.4, 12.1) at C2. The difference in changes was statistically significant ($p<0.001$). At baseline, C1 mean CFS was significantly worse for both eyes than C2 mean CFS (OD $p=0.012$, OS $p<0.001$). By last follow-up, mean CFS OD change was -0.5 at C1 (95% CI -0.7, -0.2) and -0.1 (95% CI -0.4, 0.2) at C2. The mean CFS OS change was -0.5 (95% CI -0.7, -0.2) at C1 and +0.1 (95% CI -0.2, 0.4) at C2. The difference in changes was statistically significant for CFS OS ($p=0.006$) but not for CFS OD ($p=0.130$). Moisture chambers and scleral lenses were used in similar frequencies at C1 and C2 (14% vs 18%, 16% vs 18%, respectively). However, punctal plugs, punctal cautery, and AST were used more frequently at C1 than C2 (85% vs 60%, 67% vs 26%, 52% vs 8%, respectively).

Conclusions: oGVHD patients at C1 were associated with significant improvement in OSDI and corneal fluorescein staining in the left eye and were also associated with more frequent use of punctal plugs, cautery, and AST. The significance of these associations is limited by the retrospective nature of this review. Greater severity of baseline CFS at C1 supports previous studies showing that desert climate is associated with more severe signs of dry eye. Future prospective studies are needed to confirm the validity of these findings.

TITLE: Relationship between Severity and Laterality of Age-Related Sensory Decline and Frailty In Multi-ethnic Elderly Asians

SESSION TITLE: Vision Function, Aging Outcomes, and Quality of Life

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: E.L. Lamoureux, R. Man, A.T. Gan, E.K. Fenwick, P. Gupta, Singapore Eye Research Institute, Singapore, SINGAPORE|E.L. Lamoureux, R. Man, E.K. Fenwick, P. Gupta, Duke-NUS Medical School, Singapore, SINGAPORE|

Commercial Relationships Disclosure: Ecosse Lamoureux: Commercial Relationship: Code N (No Commercial Relationship) | Ryan EK Man: Commercial Relationship: Code N (No Commercial Relationship) | Alfred Gan: Commercial Relationship: Code N (No Commercial Relationship) | Eva Fenwick: Commercial Relationship: Code N (No Commercial Relationship) | Preeti Gupta: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate the relationship of the severity and laterality (i.e., unilateral or bilateral) of vision, hearing, and dual sensory impairments (VI, HI and DSI, respectively) with frailty in older Asians.

Methods: We included individuals from The PopulatION HEalth and Age-Related SEnsory Decline PRofilE (PIONEER), a population-based study of Singaporean Chinese, Malays, and Indians aged ≥60 years. Participants underwent visual acuity (VA) assessment using a LogMAR chart, and a hearing test using a portable audiometer at four frequencies (500, 1000, 2000, 4000 hertz). The Fried frailty phenotype was used to assess physical frailty, defined as meeting at least three out of five criteria comprising unintentional shrinking (BMI<18.5 kg/m^2); slowness (≤0.8m/s on 4m-gait speed); weakness (handgrip strength <30 kg (men) and <20 kg (women)); exhaustion (measured using the vitality domain of the 12-item Short-form survey); and low self-reported physical activity. Any, mild and ≥ moderate VI was defined as presenting distance VA >0.3 logMAR; 0.3< VA ≤0.48 logMAR; and VA >0.48 logMAR, respectively; and any, mild and ≥ moderate HI as an average threshold of ≥40 dB, 40≤ hearing loss <60 dB; and hearing loss ≥60 dB, respectively.

Results: Of the 1,510 PIONEER adults (mean±SD age 72.1 ±7.9yr), 44.0%, 43.7% and 23.1% had any VI, HI and DSI, respectively. Of these, 34.0% had bilateral VI only; 64.7% had bilateral HI only, and 18.3% had DSI+ comprising (a) bilateral VI/HI and unilateral HI/VI; or (b) bilateral VI and bilateral HI). Notably, 33.9% of participants were frail. In multivariable-adjusted analyses, the presence of bilateral VI or HI (any severity) was independently associated with almost twice the odds of having frailty (odds ratio [OR]: 1.82, 95% confidence interval [CI]: 1.25, 2.44; for VI; OR: 1.84, 95% CI: 1.32, 2.57; for HI) compared to those with no sensory impairment. Critically, those with DSI+ had even higher odds of being frail (ORs between 2.15-3.35). Unilateral VI, HI and DSI (i.e., unilateral VI and HI) of any severity were not associated with frailty.

Conclusions: Elderly Singaporeans with bilateral VI or HI of any severity; and DSI comprising any bilateral impairment are at high risk of frailty. Strategies to prevent and delay progression to bilateral sensory losses are warranted to reduce frailty in our ageing society.

TITLE: Macular OCT findings in patients with congenital nystagmus syndrome.

SESSION TITLE: Pediatric ophthalmology and imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W. Wahbi, Tel Aviv Sourasky Medical Center, Tel Aviv, ISRAEL|O. Nasser, Orasis World Class Eyecare Medical Center, ISRAEL|

Commercial Relationships Disclosure: Wahbi Wahbi: Commercial Relationship: Code N (No Commercial Relationship) | Orwa Nasser: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To describe the macular optical coherence tomography findings in eyes of patients with congenital nystagmus syndrome compared to healthy subjects.

Methods: In this comparative cross-sectional observational study, a spectral-domain optical coherence tomography was conducted on eyes of congenital nystagmus syndrome patients and compared with those of healthy individuals (control group). ETDRS macular map was used in the analysis and average thickness of central 6mm (C6T), average thickness of central 1mm (C1T) and thinnest central thickness (CRT) were obtained and compared between the groups. Prevalence and grading of foveal hypoplasia and albinism were assessed in the patients group.

Results: 46 eyes of 23 congenital nystagmus syndrome patients and 46 eyes of 23 healthy individuals were included in the study. 80% of the eyes in nystagmus group had foveal hypoplasia. The mean grade of foveal hypoplasia is 3.45 ±0.9323 in the above group. 40% of patients with nystagmus had either ocular albinism or oculocutaneous albinism. CRT was 258.2 ± 48.31 µm in the nystagmus group compared to 189.3 ± 24.25 µm in the control group with a mean difference of 68.85 ± 7.97 µm ($P<0.001$). C1T was 267.2 ± 36.01 µm in the nystagmus group compared to 231.0 ± 26.0 µm in the control group with a mean difference of 36.20 ± 6.548 ($P<0.001$). C6T was 256.2 ± 26.15 µm in the nystagmus group compared to 279.1 ± 9.532 µm in the control group with a mean difference of -22.90 ± 4.104 µm ($P<0.001$).

Conclusions: The results of this study show that the majority of congenital nystagmus syndrome patients have foveal hypoplasia. Macular optical coherence tomography can be used to assess the foveal thickness and grading of foveal hypoplasia patients with nystagmus.

TITLE: Punctal stenosis associated with topical netarsudil use

SESSION TITLE: Clinical studies and trials

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P.P. Chen, T. Meirick, R.C. Mudumbai, M. Zhang, Ophthalmology, University of Washington School of Medicine, Seattle, Washington, UNITED STATES|

Commercial Relationships Disclosure: Philip Chen: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Meirick: Commercial Relationship: Code N (No Commercial Relationship) | Raghu Mudumbai: Commercial Relationship: Code N (No Commercial Relationship) | Matthew Zhang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To report a series of patients who developed punctal stenosis secondary to the use of topical netarsudil for treatment of glaucoma.

Methods: Patients using topical netarsudil for management of glaucoma and noted to have punctal stenosis ipsilateral to the eye(s) being treated with netarsudil were included. Each chart was reviewed to identify other potential causes of punctal stenosis and result of cessation of netarsudil.

Results: Sixteen patients had punctal stenosis; 13 developed unilateral punctal stenosis while using netarsudil unilaterally, and 3 patients developed bilateral punctal stenosis with bilateral use. Time from initiation of netarsudil to recognition of symptoms or documrntation of punctal stenosis ranged 2 to 35 months (mean 14.0 ± 8.7 months). Thirteen patients endorsed tearing, but two had no symptoms. Ectropion was seen in one eye. Corneal verticillata was noted in 14 (87.5%) patients. In 8 eyes, netarsudil was discontinued and the punctal stenosis was reversed, with resolution of associated symptoms.

Conclusions: Netarsudil use can lead to the development of reversible punctal stenosis, which may cause tearing and associated symptoms and which may be sufficiently severe as to require discontinuation of treatment. Patients reporting these symptoms while using netarsudil should not be assumed to have dry eye disease, ocular surface toxicity from topical medications, or other forms of acquired punctal stenosis.

Commercial Relationships Disclosure: Idara Akpandak: Commercial Relationship: Code N (No Commercial Relationship) | D. Claire Miller: Commercial Relationship: Code N (No Commercial Relationship) | Yuwei Sun: Commercial Relationship: Code N (No Commercial Relationship) | Benjamin Arnold: Commercial Relationship: Code N (No Commercial Relationship) | Nisha Acharya: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine whether there is an increased risk of herpes zoster ophthalmicus (HZO) following COVID-19 vaccination.

Methods: Retrospective observational study utilizing OptumLabs® Data Warehouse, a longitudinal, real-world data asset with de- identified administrative claims and electronic health record data. A cohort study design and a self-controlled design were both utilized to investigate HZO following vaccination, defined by an ICD-10 diagnosis code within 30 days after vaccine administration (or up to the second dose if a second dose was administered), plus a new prescription or dose escalation of antivirals within 5 days of HZO diagnosis. Using a cohort design, COVID-19 vaccinated individuals from 12/11/2020- 6/30/2021 were compared to two influenza-vaccinated cohorts: a pre-pandemic group (1/1/2018-12/13/2019) and an early pandemic group (3/1/2020-11/1/2020). Cox proportional hazard models were used to identify unadjusted and adjusted hazard ratios for HZO. Using a self-controlled design, the incidence rate ratio comparing the risk of HZO in the risk intervals following COVID-19 vaccination to a control interval 60 to 90 days prior to the first dose was estimated using conditional Poisson regression.

Results: Among 3,567,715 patients in the COVID-19 vaccinated cohort, there were 60 post-vaccine HZO cases. Patients vaccinated against COVID-19 were not at increased risk of HZO compared to pre-pandemic influenza vaccinated patients (N= 5,101,709; HR= 0.84; 95% CI: 0.61 – 1.16; p= 0.29) and early pandemic influenza vaccinated patients (N= 4,060,412; HR= 0.93; 95% CI: 0.64 – 1.34; p= 0.69) after adjustment for demographics, comorbidities, zoster vaccine, and medication use. Additionally, HZO cases post-COVID-19 vaccination were less likely to be prescribed ophthalmic steroids compared to cases following pre-pandemic and early pandemic influenza vaccination (18.3% vs 29.6% vs 41.4%, respectively). In the self-controlled design, patients were not at increased risk of HZO after COVID-19 vaccination compared to their control interval (IRR= 0.74; 95% CI: 0.49 – 1.12; p= 0.15).

Conclusions: There is not an increased risk of HZO following COVID-19 vaccination. These results provide reassurance for the safety of the COVID-19 vaccine from an ophthalmic standpoint.

ABSTRACT BODY:

Purpose: COVID-19 pandemic has become a major global public health challenge. The ophthalmology office setting involves close encounters between the patient and the health care workers increasing risk of viral transmission. Use of PPE decreases risk of person-to-person viral transmission. The purpose of the study was to evaluate breath-induced air currents in subjects without a facemask, with a procedure mask, with an improvised face, and in the setting of slit-lamp examination.

Methods: Breath-induced air currents were studied in healthy volunteers utilizing a vape pod system and videography during gentle and heavy breathing simulation. Video frames at 2 seconds after the initiation of expiration were captured and analyzed.

Results: A total of 210 recordings were made for 7 settings. Without a face mask, the aerosol moved forwards and spread vertically and horizontally reaching a mean distance of 23.1 inches for gentle, and 36.1 inches for heavy breathing at 2 seconds ($P < 0.001$). Using PPE the airflow patterns included: a) procedure mask- forward 0 cases, upward 19 (63%) cases, side 28 (93%) cases, downward 22 (73%) cases, and backward 22 (73%) cases. Adding a tape at the upper border of the mask eliminated upward flow in all cases. b) Improvised face mask- forward 0 cases, upward 0 cases, side 30 (100%) cases, downward 30 (100%) cases, and backward 17 (57%) cases. In 14 (47%) cases trace of aerosol was detected adjacent to the front surface of the mask. Adding a second layer eliminated the trace of aerosol in all cases. In the setting of simulated slit-lamp examination without the breath shield, the aerosol reached the chin rest in 9 (60%) cases during gentle breathing and in all cases during heavy breathing. The breath shield was effective in blocking forward airflow in all cases.

Conclusions: Use of a procedure mask by patients, while effective in blocking forward breath-induced airflow, redirects the flow upwards, potentially increasing the risk of contamination during an office procedure. An improvised facemask alters breath-induced air currents favorably and partially absorbs respiratory droplets.

TITLE: Optic nerve crush elicits proteomic alterations in the rat retina

SESSION TITLE: Animal models of human ocular disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: X. Xin, Ophthalmology, Sichuan Provincial People's Hospital, University of Electronic Science and Technology of China, Chengdu, Sichuan, CHINA|

Commercial Relationships Disclosure: Xiaorong Xin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Optic nerve (ON) injury and neurodegenerative disorders trigger a cascade of retinal ganglion cells loss, which leads to the failure of the ON to regenerate. Our current study was to explore the involvement of the alterations of proteome and key candidate proteins in the pathological event of ON degeneration in response to optic nerve crush (ONC).

Methods: In our current study, we established rat ON injury model through ONC. A quantitative comparison of the proteome in the rat retina was analyzed through TMT labeling, HPLC fractionation, LC-MS/MS and PRM proteomics analysis. Western blot was performed to validate the protein level of the candidate proteins following ON-crushed injury.

Results: ONC induced a total of 58 proteins downregulated and 13 proteins upregulated in the retina. Subcellular prediction was performed to characterize the subcellular localization of these differentially expressed proteins. ONC downregulated proteins that were mainly accumulated in the nucleus, extracellular domain, cytoplasm, and mitochondria. Most of the upregulated proteins were localized in the nucleus, cytoplasm, endosplasmic reticulum, mitochondria, extracellular region in response to ONC. For the biological process enrichment, the dysregulated proteins are important for maintenance of biological process including cellular metabolic process, phagocytosis, neurological system development, sensory perception, and visual perception. ONC elicited quantitative changes in proteins that associated with extracellular matrix, intermediate filament and cytoskeleton. The identified proteins predominantly participate in structural molecule activity, binding, transport, catalytic activity, and regulating molecular function. We found that longevity regulating pathway was significantly enriched through KEEG enrichment. Notably, of these differentially expressed proteins in the pathway, we noticed that AKT3, one of the isoform of AKT, was the most dysregulated after ONC. We further validated AKT3 protein level and our results showed a markedly decrease in its expression level responding to the ON injury.

Conclusions: Our proteomic analysis suggests that ON injury imposes a pathological impact on retina through altering proteomic profile. The identification of down-regulation of ATK3 provides a valuable clue that ATK3 is involved in the pathological cascade of ON degeneration and may be an important therapeutic target for ON regeneration.

ABSTRACT BODY:

Purpose: Older adults report difficulties performing daily activities, such as walking and stepping, under low light levels, particularly those with age-related macular degeneration (AMD). This study explored the effect of low light levels and target contrast on precision stepping accuracy in older adults with and without AMD.

Methods: Twenty-four older adults (12 AMD and 12 controls, aged over 65 years) walked along a 14-m level walkway containing stepping and distractor targets (10 each, 15x15cm). Participants stepped as closely as possible to the middle of stepping targets and avoided distractor targets. Stepping tasks were performed under three light levels (photopic, 440lx; 2 levels of mesopic, 10 and 3lx) and two stepping target contrasts (high 89% and low 54%). Foot placement during stepping was recorded using leg mounted cameras. Custom software determined anteroposterior (AP) and mediolateral (ML) stepping errors for each step (ball of foot to target centre), as well as absolute error (Euclidean distance).

Results: For absolute stepping errors, there were significant effects of group ($p=0.004$), light ($p<0.001$) and a significant group*light interaction ($p=0.015$), but no effect of contrast ($p=0.14$) (Figure). Controls showed similar errors under all light levels ($p=0.99$) but the AMD group had greater errors overall, and more errors under mesopic conditions compared to photopic ($p<0.001$). For both ML and AP stepping errors, there were significant effects of light ($p\leq0.008$) but no group effect ($p\geq0.13$); all participants stepped more laterally and posteriorly under low mesopic compared to photopic conditions. Target contrast had a significant effect on ML ($p=0.007$) but not AP stepping errors ($p=0.48$); all participants stepped more laterally for low compared to high contrast targets. There was a significant light*contrast interaction for AP ($p=0.019$) stepping errors; all participants stepped posteriorly for low compared to high contrast targets under photopic conditions.

Conclusions: Reduced light levels and lower contrast stepping targets negatively impacted stepping accuracy. Findings have implications for enhancing environmental design, including lighting and contrast, to promote safe mobility and minimise falls risk, particularly in older adults with AMD.

TITLE: Clock-hour Topography and Extent of the Photoreceptor and Retinal Pigment Epithelium Damages in Hydroxychloroquine Retinopathy: Functional Correlation and Implications for Classifications

SESSION TITLE: New drugs, mechanisms of action and ocular toxicology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Ahn, Hanyang University, Seongdong-gu, Seoul, KOREA (THE REPUBLIC OF)|K. Kim, Ophthalmology, Asan Medical Center, Songpa-gu, Seoul, KOREA (THE REPUBLIC OF)|

Commercial Relationships Disclosure: Seong Joon Ahn: Commercial Relationship: Code N (No Commercial Relationship) | Ko Eun Kim: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the clock-hour topographic characteristics on the photoreceptor and retinal pigment epithelium (RPE) damages and correlate them with functional defects in eyes with hydroxychloroquine retinopathy

Methods: Among 152 eyes diagnosed with hydroxychloroquine retinopathy, those with coexistent retinal or macular diseases or those with poor image quality of optical coherence tomography (OCT) and fundus autofluorescence (FAF) images were excluded. In total, 149 eyes of 75 patients were included for the analyses and classified into parafoveal, pericentral, and mixed retinopathy according to disease pattern and also into early, moderate, and severe ones. Clock-hour topographic characteristics (from the fovea) and extents of the photoreceptor and RPE defects were evaluated by reviewing the OCT images obtained by 12 radial scans and wide-field FAF. The extent (numbers of involved clock-hour areas) of photoreceptor and RPE damages was correlated with perimetric parameters such as mean deviation (MD), pattern standard deviation (PSD), and visual field indices (VFI).

Results: Whereas the photoreceptor damages were most commonly noted at the 6 o'clock area in both parafoveal and pericentral retinopathy, the RPE damages were most commonly noted at the nasal area, peripapillary ones, in pericentral eyes. The extent of RPE damages was almost identical between OCT and FAF imaging, whereas that of photoreceptor defects was significantly greater in OCT, indicating superior sensitivity of OCT for the detection of the photoreceptor damages. The extent of photoreceptor damages significantly correlated with MD and VFI (both $P < 0.05$) and this seemed to better reflect the functional defects in eyes with the retinopathy, as the disparity in the visual function between moderate and severe eyes and the variability of the perimetric parameters in the same severity (moderate or severe) could be explained by the disparity or differences in the extent.

Conclusions: This study showed clock-hour topographic characteristics and extents of the photoreceptor and RPE damages in eyes with hydroxychloroquine retinopathy. From the significant correlation between the extent of photoreceptor damages and perimetric parameters, the information may be utilized for functional correlation and classification of hydroxychloroquine retinopathy.

ABSTRACT BODY:

Purpose: Ocular and systemic variables previously reported to be associated with the presence of disc haemorrhages (DH) are compared in visits with and without DH.

Methods: Thirty patients with open-angle glaucoma and a new DH were recruited from Moorfields Eye Hospital for 5 visits (0, 1, 3, 6, and 12 months). The following examinations acquired in all visits were compared between DH+ and DH- visits: optic disc photography, nailbed capillaroscopy (4^{th} and 5^{th} fingers of the non-dominant hand), autorefraction, ocular response analyzer, heart rate and blood pressure, questionnaires to assess the number of days during the previous month with headache, aura, cold hands, hearing loss, insomnia, and reduced thirst, and the European Quality of Life-5 Dimensions (EQ-5D) questionnaire. A DH+ visit was defined as the presence of a DH in one or both eyes based on fundus photography. All visits started with the questionnaires and nailbed capillaroscopy; the patient and examiner were unaware of that visit DH status.

In all included participants and for all variables, the difference between the mean of DH+ visits was compared with a paired t-test with the mean value of DH- visits.

Results: Four patients were excluded from this analysis because all of their visits were classified as DH+. The 26 included participants attended 127 scheduled visits, 64 were DH+ and 63 DH-. Nailbed haemorrhages were identified in 24 (38%) of DH+ visits compared to 31 (49%) of the DH- visits (p= 0.183). In 44% of the visits, the same haemorrhage status was identified in the disc and the nailbed. Continuous variables are presented in Table 1. A higher corneal resistance factor (CRF) was identified in each eye during DH+ visits. Although it was not statistically significant, there was a trend toward more headaches during DH+ visits. IOP values were very similar between DH+ and DH-visits.

Conclusions: There was a tendency toward more headaches during DH+ visits. The CRF was higher in both eyes during DH+ visits, although it is unlikely to change between visits. The difference in CRF may be related to IOP or multiple testing. There was a high rebleeding rate in the disc and nailbed. The trends observed over only 5 visits in this small exploratory study warrant further investigations comparing systemic and ocular variables between DH+ and DH- visits.

ABSTRACT BODY:

Purpose: To generate childhood refractive centile curves for Asian and Western populations in order to facilitate evidence-based myopia control.

Methods: 35,645 refraction measurements from 8 large population-based studies were included (12,965 European/North American eyes, and 22,680 Asian eyes). An individual meta-analysis of right eye SER was performed by region, age and gender. Quantiles were generated by age group and gender. Combined curves for each calculated centile were generated by weighted cubic spline interpolation according to the number of participants in each age group/study.

Results: Western and Asian population centiles differed at all ages (Figure 1). At age 6, median refraction was 1.33D and 1.34D in Western boys and girls, respectively and 0.25D and 0.24D in Asian boys and girls. Western children at the 97th centile were hyperopic at age 6 (0.11D boys; 0.18D girls). In Asia, 6-year-olds at the 97th centile were significantly more myopic (-1.71D boys; -1.77D girls). In the West, the median refraction did not reach the threshold for myopia (≤-0.50D) by age 18. In Asia, median refraction met the myopia threshold by age 10 in boys and age 9.5 in girls. Gender differences were most marked in hyperopes in the West, with boys 0.60D more hyperopic at age 7.5 at the 3rd centile. At age 10.5, girls were 0.22 D more myopic at the 97th centile, but by 18 the gender difference was <0.05D at all centiles. Median refraction varied less than 0.02D between sexes at all ages in the West. In Asia, gender differences were minimal (<0.20D) below age 11 but increased with age and were greatest in myopes. The gender difference in median refraction increased from age 6 to 15, with girls 0.55D more myopic by age 15, reducing to 0.40D by age 18.

Conclusions: Population-based centile analysis offers the prospect of monitoring the treatment efficacy of myopia control interventions outside a clinical trial, but must be gender- and region-specific. Historic data derived from the period before myopia treatments were introduced represent a valuable natural history resource on myopia progression. Pooling data from the large number of existing surveys provides a mechanism to standardize reference centile charts relevant to the management of myopia.

ABSTRACT BODY:

Purpose: Scleral contact lenses (ScCL) are large diameter gas permeable contact lenses that enhance vision for a variety of ocular conditions. Several case reports have suggested ScCL can improve upper eyelid ptosis, but there have been no previous studies of the change in non-ptotic eyelid position with ScCL. In this observational clinical study, we hypothesize that ScCL wear increases interpalpebral fissure height (IPF) and margin to reflex distance (MRD).

Methods: IPF and MRD were measured on 115 eyes of 64 established ScCL patients from photographs incorporating a millimeter ruler at three time points: before insertion of the ScCL (control), 5 minutes after insertion of the ScCL, and after 2 or more hours of ScCL wear. ScCL diameter and sagittal depth (sag) on eye, longevity of ScCL wear, patient sex and age, and reason for ScCL wear were documented for each subject and controlled for during statistical analysis. Sag of the ScCL on eye at the 2 hour time point was measured with Oculus Pentacam. The caliper tool available with the Scheimpflug images was used to measure the distance from the apex of the ScCL to a line bisecting the pupil. A linear mixed effects model was utilized for analysis of mean difference in IPF and MRD between time points.

Results: Mean IPF of control conditions was 8.6±1.6mm. IPF measurement was greater after 5 min of ScCL wear than before ScCL placement (mean difference: 0.8mm, 95% CI 0.54, 1.06, $p<0.001$) and after 2 hours of ScCL wear than before ScCL placement (mean difference: 0.69mm, 95% CI 0.43, 0.95, $p<0.001$). There was no difference in IPF between 5 min and 2 hours of ScCL wear (mean difference: 0.11mm, 95% CI -0.15, 0.37, $p=0.595$). Mean MRD of control conditions was 3.4±1.4mm. MRD measurement was significantly greater after 5 min of ScCL wear than pre-ScCL insertion (mean difference: 0.35mm, 95% CI 0.14, 0.55; $p<0.001$) and after 2 hours of ScCL wear pre-ScCL insertion (mean difference: 0.28mm, 95% CI 0.08, 0.48, $p<0.001$). There was no significant difference in MRD between 5 min and 2 hours of ScCL wear (mean difference: 0.07mm, 95% CI -0.14, 0.27, $p=0.732$).

Conclusions: Study findings support the hypothesis that ScCL wear increases IPF and MRD in eyes without ptosis.

ABSTRACT BODY:

Purpose: PAX6 variants can be associated with pan-ocular phenotypes such as aniridia, keratopathy, anterior segment dysgenesis, cataracts, colobomas, foveal hypoplasia and optic nerve hypoplasia. Previous genotype-phenotype correlation studies have shown strong correlation between the severity of aniridia associated phenotypes and the type of PAX6 variants. In this multi-centre study, we aimed to specifically characterise the foveal phenotypes associated with PAX6 variants.

Methods: We established the foveal development investigators group (FDIG) aimed at exploring foveal phenotypes in developmental retinal disorders across different centres (n=10) in 8 countries. We included all patients with pathogenic PAX6 variants and high-resolution optical coherence tomography (OCT) scans of the fovea from FDIG and the literature. Variants were classified into truncating and non-truncating based on predicted effect. Foveal OCTs were graded by at least two expert graders and classified into grades of foveal hypoplasia according to the classification by Thomas MG et al. 2011. The groups were further classified into with cone photoreceptor specialisation (PRS+) and without (PRS-).

Results: We identified a total of 106 patients that met the inclusion criteria. There were more cases with truncating mutations (n=71) compared to non-truncating mutations (n=35). Grade 4 foveal hypoplasia was the most common (40.6% of cases). There was a significantly higher proportion of PRS- cases associated with truncating variants ($X2 = 12.6$, $p=0.0004$) compared to non-truncating variants. The visual acuity was significantly worse for truncating variants compared to non-truncating variants (median difference=0.35 logMAR, $p<0.0001$).

Conclusions: We show that truncating PAX6 variants are associated with severe arrested retinal development with loss of cone photoreceptor specialisation. These loss-of-function variants are predicted to generate no protein and hence result in relatively severe foveal phenotypes compared to missense variants. This also translates to poorer visual acuity in patients with truncating PAX6 variants.

ABSTRACT BODY:

Purpose: Uveal melanoma (UM) is the most common intraocular malignancy in adults.
Currently, there is any effective therapeutic option for patients with metastatic disease since the UM is resistant to conventional chemotherapy and immune checkpoint blockade, showing poor response rates and limited overall survival.
Recent advances in the identification of early driver mutations and aberrant signaling pathways that contribute to the progression of UM, open new therapeutic strategies against specific targets.
To develop a mice xenograft model that mimics the metastatic process and that could to be used in pre-clinical studies to analyze the efficacy of new drugs or inhibitors that might interfere the growth of liver metastases.

Methods: We developed a xenograft model of human uveal melanoma in NSG (NOD-scidIL2Rgnull) strain mice that have severe immunodeficiency. UM cells have been orthotopically implanted in the suprachoroidal space by surgery of previously anesthetized mice. We had incorporated the luc2 gene into the cells and the bioluminescence signal in vivo was detected with the IVIS-LUMINA XR imaging system to follow the development of metastasis. Immunohistochemical studies were performed to verify the melanocytic origin.
Tissue samples were collected, paraffined, and immunohistochemical studies were performed to verify the melanocytic origin and cellular and molecular characteristics of the primary tumor and metastatic lesions developed in the mice.

Results: Our results show that 100% of mice injected with either $2x10^5$ OMM2.5 cells (n = 23) or MP # 41 cells (n = 24) have developed a primary tumor, which was detected at 10 ± 2 days after implantation. Enucleation of primary tumors was performed in all cases 16 ± 2 days after implantation. The bioluminiscence signal was detected at 23 ± 2 days and in liver at 31 ± 9 days after implantation of UM cells. Lung metastases were confirmed in 100% of the animals at necropsy (sacrifice per day 45 ± 11). Liver metastases were found in 87% of the animals that received OMM 2.5 cells and in 100% of those implanted with MP # 41. We also observed the presence of kidney metastases in 19% of mice on both lines. In contrast, only MP# 41 cells generated lymph node metastases.

Conclusions: We have successfully developed an in vivo mice metastatic model that allows to follow up the whole process of metastasis formation where new therapeutic strategies can be studied.

ABSTRACT BODY:

Purpose: Retinal pigment epithelium (RPE) dysfunction plays a central role in the progression of age-related macular degeneration (AMD). Our previous studies have shown that macular RPE cells of AMD patients have a notably increased accumulation of cytosolic damaged nuclear DNA (nDNA) fragments. This accumulation not only induced RPE cellular senescence and pro-inflammation via STING pathway, but also promoted the secretion of a variety of factors that are detrimental to the microenvironment of neighboring tissues. In the present study, we examined the role of paracrine effects exerted by dysfunctional RPE cells on neighboring cells in the pathogenesis of AMD, identified a novel culprit of this paracrine effect, and investigated the underlying mechanisms of these effects.

Methods: Since DNASE2A is essential for the degradation of cytosolic damaged nDNA fragments, CRISPR/Cas9 was used to generate DNASE2A$^{-/-}$ RPE cells that accumulate cytosolic nDNA, mimicking the AMD patients RPE cells. The levels of 2’3’ cGAMP and STING expression in macular RPE cells from AMD patients and DNASE2A$^{-/-}$ RPE cells were analyzed. Long-term treatment with 2’3’ cGAMP and/or a Volume-Regulated Anion Channel (VRAC) inhibitor was administered to wild-type and STING$^{-/-}$ ARPE-19 cells. Components of the STING pathway, pro-inflammatory factors and cellular senescence markers were tested. C57BL/6J mice were subretinally injected with 2’3’ cGAMP and examined by fundus photography and Optical Coherence Tomography (OCT). Activation of microglial cells, pro-inflammatory factors and complement system components were measured.

Results: We have identified 2’3’ cGAMP, the agonist in the STING-dependent cytosolic DNA sensing pathway, as a culprit for these paracrine effects. STING expression was increased in AMD donor RPE cells in a distribution pattern similar to that of RPE lesion formation. The level of secreted 2’3’ cGAMP was higher in macular RPE cells from AMD donors compared to age-matched controls. Chronic exposure to 2’3’ cGAMP can induce RPE degeneration in vitro, as well as outer retinal degeneration, microglial and complement activation in vivo. The deleterious effects caused by exposure to mediums containing 2’3’ cGAMP were ameliorated by STING knock-down and VRAC inhibition.

Conclusions: These findings suggest a potential role for 2’3’ cGAMP and STING in the progression of AMD, as well as new targets for the development of novel therapeutics.

ABSTRACT BODY:

Purpose: To investigate the break starting strength (BSS) of human cornea inline with ISO: 7198 – 2016 to evaluate the suture tolerating strength of the cornea without losing its functionality.

Methods: 10 corneas with a suture bite distance of 2 mm from limbus were tested for a suture pullout test at a pulling rate of 3 mm/min. A lower pulling rate was used in the tests considering the physiology of the human eye. A steel wire of 0.4 mm is used for testing to negate the elastic effects of the sutures as per ISO 7198 – 2016. Tests were carried in a universal tensile testing machine with a 10 N load cell. Specimens were imaged while testing with the help of a microscopic imaging system with 16X magnification.

Results: BSS of the cornea is 4.072±0.859 N found at a 3 mm/min pull rate. The 10 N load cell is sensitive enough to capture the BSS, and the imaging system helps in situations where BSS is not visible in the load vs. time curve. The present system is efficient enough to evaluate BSS.

Conclusions: BSS of the cornea is evaluated with the help of a robust experimental setup.

ABSTRACT BODY:

Purpose: Diabetic Retinopathy (DR) is a common complication of diabetes mellitus demonstrating neovascularization and remains a leading cause of loss of vision. Treatment of DR focuses on targeting vascular endothelial growth factor (VEGF) to reduce neovascularization with repeated intravitreal injections. The complications with repeated intravitreal injections are retinal detachment, trauma, etc. To reduce the frequency of intravitreal injections, we loaded ant-VEGF drug into small extracellular vesicles (sEVs) as recent reports suggested the ability of EVs in sustained drug delivery. The ability of the anti-VEGF loaded sEVs were tested for their sustained antiangiogenic potential in STZ induced rat model of DR.

Methods: Small EVs were isolated from bone marrow-derived mesenchymal stromal cells (BM-MSC) and characterized. Avastin was loaded into sEVs by freeze-thaw, co-incubation 0.2% saponin, and sonication methods. Avastin loaded in EVs was checked for its antiangiogenic properties by chorioallantoic Membrane (CAM) assay in the egg chick embryo. To tract the avastin loaded EVs in the retina, FITC conjugated avastin was loaded into PKH26 labeled sEVs. Further, DR was induced in Wistar Albino rats through administration of streptozotocin. Blood sugar levels were monitored multiple times over months after the STZ injection, and the presence of exudates in the retina was confirmed by FITC-dextran perfusion. The effect of anti-VEGF-loaded EVs on neovascularization was evaluated at different time intervals using VEGF immunostaining.

Results: Characterization of EVs using NanoSight tracking demonstrated a mean size of 167nm, and TEM analysis revealed cup-shaped morphology, and western blot analysis revealed positive for TSG101 and CD 63 while negative for GM130. Significant amounts of avastin was loaded by all the tested methods. The avastin loaded EVs significantly inhibited the angiogenesis in the CAM assay. We have tracked avastin-loaded EVs in different retina layers in naive rats. In DR, avastin loaded EVs decreased the number of exudates in the retina, and the VEGF expression was low in the avastin loaded EV group compared to avastin alone group over a period of time.

Conclusions: Due to sustained drug delivery ability, avastin loaded EVs may be ideal for the controlled release of avastin for a longer duration to inhibit neovascularization in DR.

ABSTRACT BODY:

Purpose: Chorodial neovascularization (CNV) is a defining characteristic feature of neovascular age-related macular degeneration (nAMD) that frequently results in irrversible vision loss. The current strategies for the treatment of nAMD are mainly based on neutralizing vascular endothelial growth factor (VEGF). However, anti-VEGF therapies are often associated with subretinal fibrosis that eventually leads to damages in macula. It was the aim of this study to investigate wheter an anti-fibrotic and anti-angiogenic protein CCN5 can a potential novel stratey for the treatment of nAMD with a capability to inhibit CNV and fiborsis stimultaneously.

Methods: To induce CNV in mouse eyes, laser photocoagulation was utilized. At 5 days after laser-induced CNV, recombinant adeno-associated virus serotype 2 encoding CCN5 (rAAV2-CCN5), rAAV2-virus-like-particle (VLP), and bevacizumab were administered via intravitreal injection. One week after injection, fundus fluorescent angiography (FFA), immunostaining, and cell counting were performed to determine rAAV2-CCN5 inhibits CNV leakage, retinal gliosis, change of retinal pigmented epithelium (RPE) cell morphology, and epithelial-mesenchymal transition (EMT) on RPE.

Results: Our data demonstrated that rAAV2-CCN5, but not a control viral vector, rAAV2-VLP, prominently attenuated both CNV lesions and angiogenesis. Bevacizumab, which was utilized as a positive control, exhibites similar effects on CNV lesion and angiogenesis. Upon laser photocoagualtion, RPE cells underwent significant morphological changes including cellular enlargement and loss of hexagonality. rAAV2-CCN5 significantly normalized these morphological defects, while bevacizuumab did marginally. Laser photocoagulation also led to fibrotic deformation in RPE cells through inducing EMT, which was completely blocked by rAAV2-CCN5. In a striking contrast, Bevacizumab as well ase rAAV2-VLP failed to exhibit any effects on EMT.

Conclusions: Our data demonstrate that rAAV2-CCN5 can inhibit CNV and EMT in RPE cells that are induced by laser photocoagulation in mice. Therefore, we suggest that rAAV2-CCN5 can be a safer yet efficient therapeutic modality for nAMD.

ABSTRACT BODY:

Purpose: Optical coherence tomography (OCT) has been proposed as a retinal biomarker for Alzheimer's disease (AD), however, current diagnostic performance is limited but may be improved by reducing the inter-individual variability of circumpapillary retinal nerve fiber layer (cpRNFL) measurements. We developed a multiple-regression framework including compensation for anatomical confounders, and combination of the cpRNFL and macular layers to increase discrimination between cognitively normal participants, mild cognitive impairment (MCI) and AD.

Methods: This cross-sectional study included 62 AD (n=92 eyes), 108 MCI (n=158 eyes), and 55 cognitively normal control (n=86 eyes) participants. Using an Early Treatment Diabetic Retinopathy Study circle at the macular level, thicknesses of the macular RNFL (mRNFL), macular ganglion cell layer (mGCL), macular inner plexiform layer (mIPL) were determined. Circumpapillary (cpRNFL) measurements were compensated for potential confounders including demographics (ethnicity and age), refractive error, optic disc (ratio, orientation, and area), fovea (distance and angle), retinal vessel density and signal strength. Thickness measurements of each layer and their corresponding areas under the receiver operating characteristic curves (AUCs) were compared between the groups.

Results: Age and gender did not differ among groups. In the multivariate analysis, MCI/AD participants showed significantly thinner measured and compensated cpRNFL, mRNFL, mGCL, mIPL, and altered retinal vessel density ($p<0.05$). Compensated RNFL outperformed measured RNFL for discrimination of MCI (AUC=0.74 vs 0.68; $p=0.02$) and AD (AUC=0.79 vs 0.71; $p=0.025$) from controls. Combining macular and compensated cpRNFL parameters further improved the detection of MCI (AUC = 0.79 vs 0.68; $p<0.001$) and AD (AUC=0.87 vs 0.71; $p<0.001$).

Conclusions: This study suggests that accounting for interindividual variations of ocular anatomical features in cpRNFL thickness measurements and incorporating information from macular layers may allow for a improve the identification of high-risk individuals with early cognitive impairment and dementia.

TITLE: CCT5 Protects against MerTK-Associated Retinitis Pigmentosa in Retinal Pigment Epithelial Cells by Interacting with F-Actin and Activating the LIMK1/Cofilin Pathway

SESSION TITLE: Molecular and Biochemical Mechanisms of Ocular Disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Feng, Y. Zhuo, Sun Yat-Sen University Zhongshan Ophthalmic Center, Guangzhou, Guangdong, CHINA|S. Zhang, Shenzhen Eye Hospital, Shenzhen, Guangdong, CHINA|

Commercial Relationships Disclosure: Lujia Feng: Commercial Relationship: Code N (No Commercial Relationship) | Shaochong Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Yehong Zhuo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinitis pigmentosa (RP), characterized by the gradual loss of rod and cone photoreceptors that eventually leads to blindness, is the most common inherited retinal disorder, affecting more than 2.5 million people worldwide. However, the underlying pathogenesis of RP remains unclear and there is no effective cure for RP. Mutations in the Mer receptor tyrosine kinase (MerTK) gene induce the phagocytic dysfunction of retinal pigment epithelium (RPE) cells, leading to RP. Studies have indicated that filamentous actin (F-actin)—which is regulated by chaperonin-containing TCP1 subunit 5 (CCT5)—plays a vital role in phagocytosis in RPE cells. However, whether CCT5/F-actin signaling is involved in MerTK-associated RP remains largely unknown. Therefore, the present study explored the relationship between CCT5, F-actin, and RP, and the potential molecular mechanism underlying this disease.

Methods: In the present study, we specifically knocked down MerTK and CCT5 through siRNA transfection and upregulating CCT5 using CCT5-specific lentiviral vectors (CCT5-Le), then examined the expression of CCT5, F-actin, cofilin, LIMK1, and SSH1, the arrangement of F-actin, the cell proliferation, migration, and phagocytic function of human primary RPE (HsRPE) cells.

Results: We found that MerTK downregulation inhibited cell proliferation, migration, and phagocytic function; significantly decreased the expression of F-actin; and disrupted the regular arrangement of F-actin. Importantly, our findings firstly indicate that CCT5 interacts with F-actin and is inhibited by MerTK siRNA in HsRPE cells. Upregulating CCT5 using CCT5-Le rescued the cell proliferation, migration, and phagocytic function of HsRPE cells under MerTK-associated RP by increasing the expression of F-actin and restoring its regular arrangement via the LIMK1/cofilin, but not the SSH1/cofilin, pathway.

Conclusions: In conclusion, CCT5 protects against MerTK-associated RP in RPE cells by interacting with F-actin and activating the LIMK1/cofilin pathway. This finding provide a new perspective for research into the mechanisms underlying MerTK-associated RP and provide a new direction for future studies of the molecular mechanisms of RP pathogenesis.

ABSTRACT BODY:

Purpose: To identify the specific expression patterns of systemic factors and vitreous fluid (VF) cytokines in patients with proliferative diabetic retinopathy (PDR).

Methods: The study group (males / females: 18 / 7, mean age ± standard deviation [SD]: 58.6 ± 13.5 years old) was composed of 26 PDR eyes in 25 patients with type 2 diabetes mellitus, who underwent pars plana vitrectomy (PPV) for vitreous hemorrhage and/or tractional retinal detachment. The control group (males / females: 13 / 18, mean age ± SD: 71.2 ± 8.34 years old) consisted of 14 eyes patients with idiopathic macular hole and 17 eyes patients with idiopathic epiretinal membrane. As systemic factors, age, body mass index (BMI), systolic blood pressure (SBP), diastolic blood pressure (DBP), pulse pressure difference between SBP and DBP (PPD), heart rate (HR), international normalized ratio of prothrombin time (PT-INR), activated partial thromboplastin time (APTT), fasting blood glucose (FBG), hemoglobin A1c (HbA1c), and estimated glomerular filtration rate (eGFR) were measured. Undiluted VF was obtained at the beginning of PPV. IL-1ra, IL-6, IL-7, IL-8, IL-13, eotaxin, IFN-γ, IP-10, MCP-1, MIP-1β, TNFα and VEGF-A were measured by a multiplex bead array. Hierarchical cluster analysis was used to examine a comprehensive functional evaluation of systemic factors and VF cytokines as biomarkers in the pathology of PDR.

Results: In control group, the explanatory variables were broadly classified into one cytokine and two principal clusters: 1; IP-10, 2; a cluster composed of age, SBP, DBP, PPD, HR, FBG, eGFR and MCP-1, and 3; another cluster consisting of BMI, PT-INR, APTT, HbA1c and the remaining cytokines including VEGF-A. Age, SBP, DBP, PPD, HR, FBG, eGFR were grouped into a subcluster, and MCP-1 was proximately located to the subcluster. In PDR group, the explanatory variables were roughly divided into one cytokine and two principal clusters: 1; IP-10, 2; a cluster composed of MCP-1 and VEGF-A, and 3; another cluster consisting of all systemic factors and the remaining cytokines. VEGF-A was proximately located to MCP-1, not resembling to the arrangement in control group.

Conclusions: In PDR, the association between systemic factors and intraocular factors of inflammation and angiogenesis would be vulnerable, suggesting that the intraocular factors independently affect the pathology of PDR.

TITLE: A new nonhuman primate model of desiccating stress-induced dry eye disease

SESSION TITLE: Dry eye regulators: lacrimal gland, Meibomian gland, basic mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W. Zeng, L. Gong, B. Li, L. Pan, Sichuan Primed Shines, Ya'an, CHINA|S. Chauhan, W. Cho, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Wen Zeng: Commercial Relationship: Code N (No Commercial Relationship) | Sunil Chauhan: Commercial Relationship(s);Code C (Consultant/Contractor):Sichuan Primed Shines | Li Gong: Commercial Relationship: Code N (No Commercial Relationship) | Baowen Li: Commercial Relationship: Code N (No Commercial Relationship) | Lingzhen Pan: Commercial Relationship: Code N (No Commercial Relationship) | WonKyung Cho: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To develop a desiccating stress-induced dry eye disease model using nonhuman primates (NHP).

Methods: Four to 5-year-old Rhesus macaque monkeys were housed in a controlled-environment room where relative humidity (RH), temperature (T) and airflow (AF) are regulated (RH = 6.4% ± 1.4%, T = 22.5°C - 25.3°C, AF = 12 L/min). Monkeys were placed in the controlled-environment room for 21 to 36 days to induce dry eye disease (DED). Post 21 days of DED induction, corneas were topically treated with 1 % Pred Forte or normal saline (placebo) thrice daily for 14 days. Corneal fluorescein staining (CFS), tear film break-up time (TFBUT), and proinflammatory cytokines in tears were measured to assess DED severity.

Results: A significant increase in corneal fluorescein staining (9.7 ± 1.8, $P < 0.001$) and proinflammatory cytokines levels (IL-17, $P < 0.01$; IL-2, $P < 0.05$) were observed on day 21 of controlled-environment room exposure. Moreover, TFBUT significantly decreased following DED induction (7.3 ± 2.4 vs. 4.4 ± 0.8, $P < 0.001$). Corticosteroid treatment significantly reduced CFS scoring (6.0 ± 1.2 vs. 9.3 ± 1.8, $P < 0.001$), restored TFBUT (6.1 ± 2.0 vs. 3.9 ± 0.6, $P = 0.001$), and prevented upregulation of tear proinflammatory cytokines, compared to the placebo treatment.

Conclusions: Desiccating stress induces dry eye disease in nonhuman primates, closely resembling the clinical symptoms and treatment response observed in human DED patients.

ABSTRACT BODY:

Purpose: Robotically Aligned OCT (RAOCT) systems can image patients without a fixation target or stabilization (chin/forehead rest). Additionally, through robotic angular positioning control, RAOCT enables automatic acquisition of retinal images at different regions of interest (ROI), which can subsequently be montaged to synthetically increase the field-of-view (FOV) of the system.

Methods: Utilizing custom software, pupil tracking cameras estimated ocular pupil location and gaze of the eye, enabling autonomous alignment of a robotic arm mounted 20° FOV SSOCT retinal scanner (1050nm; Fig. 1A). The tracked gaze was utilized to control the orientation of the scanner relative to the optic axis of the eye, allowing control over the OCT beam's angle of incidence into the eye. Control of the angle of incidence allowed imaging multiple ROI by pivoting the scanner about the pupil (Fig. 1B). For each imaging session, the robot automatically aimed at and imaged 25 different ROIs over a 20° range. We subsequently montaged acquired volumes onto a single large FOV volume utilizing the gaze tracking information for localization and further optimized using b-spline based registration. We imaged consented freestanding subjects under an IRB approved protocol.

Results: Imaging performance on a healthy 26-year-old is demonstrated in Figure 2. Retinal montaging allowed us to synthetically double the FOV of the system from 20° to 40° with automatic alignment and aiming of the OCT scanner with minimal discontinuities along the retinal vasculature. The mean residual error corrected with registration was 0.21° across the entire field of view.

Conclusions: We demonstrated automatic retinal volumetric acquisition over multiple ROIs over a 20° range in freestanding subjects. With montaging, we demonstrated increased image FOV comparable to fundus photography.

ABSTRACT BODY:

Purpose: To investigate the accuracy of strip meniscometry tube (SMTube) in dry eye screening and diagnosis in the context of a Chinese community.

Methods: This cross-sectional random population-based study initiated on 27 September 2021 and continuing until now. Chinese subjects aged 50 and above were recruited through randomized mail invitation in the Southern district in Hong Kong. Overall, the response rate was 96%, and cooperation rate was 49%. In total, 298 consecutive subjects underwent comprehensive dry eye assessment in order from least invasive to most invasive, including dry eye questionnaire (OSDI score), Non-invasive keratographic tear breakup time, tear meniscus height, tear breakup pattern, SMTube, NEI cornea staining score. The definition of dry eye was adopted from Asia Dry eye Society. Incremental (1 mm) strip meniscometry readings were tested for accuracy of dry eye diagnosis. The right eye of each subject was used for analysis.

Results: Among the 298 recruited individuals, mean age was 62.6 (± 7.20) years. Overall, 19.5% had dry eye disease (OSDI >/=13 and TBUT <10s). Among dry eye patients, random break was the most common tear breakup pattern, accounting for 62% of cases. Subjects with dry eye disease had significantly lower SMTube readings compared to those who did not have dry eye disease on Student’s t test. A low SMTube result had high specificity and high negative predictive value for dry eye disease, OSDI score >/=13 and presence of significant cornea staining. A cut off value of 3 mm was shown to be achieve optimum specificity and negative predictive value for dry eye disease (90.8% and 80.4%), cornea staining (94.1% and 64.8%) and OSDI score >/=13 (91.7% and 78.1%)

Conclusions: In a community setting, where dry eye prevalence is relatively low, an abnormal SMTube reading had high specificity and negative predictive value, suggesting excellent diagnostic value for an abnormal test result. A cut off value of 3 mm was proven to have the highest diagnostic accuracy for dry eye disease.

ABSTRACT BODY:

Purpose: This study sought to investigate the association between the apolipoprotein E (APOE) E4 allele and longitudinal retinal thinning in the 'Progression Risk Of Glaucoma: RElevant SNPs with Significant Association' (PROGRESSA) cohort, a prospective study of suspect and early manifest glaucoma.

Methods: Apolipoprotein E alleles and genotypes were determined in PROGRESSA, and an age- and ancestrally-matched normative cohort, the Blue Mountains Eye Study (BMES). Structural parameters of neuroretinal atrophy measured using spectral-domain optical coherence tomography (SD-OCT) including the macular ganglion cell complex (mGCIPL) and peripapillary retinal nerve fibre layer (pRNFL) were compared within the PROGRESSA cohort on the basis of genotype and presence of APOE E4 allele.

Results: Prospective rates of mGCIPL thinning were faster in participants harbouring at least one copy of the APOE E4 allele (beta coefficient=-0.13μm/year; $p=3.6x10^{-4}$). These participants also had a thinner average mGCIPL (70.9μm vs. 71.9μm; p=0.011) and pRNFL (77.6μm vs. 79.2μm; p=0.045) after a minimum of three years of longitudinal follow-up.

Conclusions: The APOE E4 allele was associated with faster rates of average mCGIPL thinning and a thinner average pRNFL, suggesting that the APOE E4 allele is a risk factor for retinal ganglion cell degeneration.

Yam: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Despite advancements in globe-preserving treatments, improvements in retinoblastoma (RB) outcomes are inconsistent across income levels and geographical locations. Both socio-economic factors and healthcare structure (SEH) were associated to the outcome. There are also regions with scarce literature coverage which hinder comprehension of the global landscape. We aim to use machine learning to categorize countries for care capacity with consideration to both socio-economic backgrounds and clinical services and identify differences in research focus.

Methods: We used hierarchical clustering to assess strata using 26 SEH variables from the World Bank and 10 clinical factors (e.g. treatment modalities) covering 129 countries. We collected literature published after Jan 1, 2001 from PubMed, Embase, ScienceDirect, Web of Science, and Global Index Medicus with search term ‘retinoblastoma’. A BERT model was trained to filter literature by relevance. Topic modelling was done with hierarchical Dirichlet Process (HDP). Abstracts and publication info were geotagged for relevant locations.

Results: 4 major country clusters with 10 subgroups were identified and interpreted with reference to SEHs and clinical delivery. BERT model attained 91.47% accuracy (sensitivity: 93.07%, specificity: 87.91%). 28,347 abstracts were identified as relevant. HDP identified 52 sub-topics over genetics of RB, genetics of associated diseases, clinical presentation and work-up, and treatment options. While coverage on clinical presentation and work-up were fairly sufficient across the world, genetics of both RB and associated diseases were rarely discussed in part of sub-Saharan Africa and the Middle-east and was predominantly dominated by localities of European descent. Stratification by our computed strata identified slim coverage of genetics presentation in Tier 1 and 2 countries and even distribution in Tier 4.

Conclusions: Capacity strata could serve as more comprehensive reference than income levels for targeted intervention, with implications on cross-border referral which should be considered when regional hubs are established. Our study proved machine learning can feasibly map existing knowledge on a disease. The scant evidence of RB genetics in ethnicity apart from the European descent should be tackled, which would implicate accuracy of genetics testing, identification of subtypes and general understanding of RB.

ABSTRACT BODY:

Purpose: Accurately predicting a patient's risk of progressing to late age-related macular degeneration (AMD) is difficult but crucial for personalized medicine. While current risk prediction models are useful, none utilizes a longitudinal series of images in patients' history to estimate the risk of late AMD in a given time interval. In this work, we seek to evaluate how deep neural networks capture the sequential patterns of longitudinal fundus images and improve the prediction of 2-year and 5-year risks of progression to late AMD.

Methods: We developed a hybrid architecture that consists of a Convolutional Neural Network and a Recurrent Neural Network, popularly known as CNN-RNN (Fig 1). Specifically, we used a ResNet to extract features from the images and applied an LSTM layer on top for the prediction. Two training strategies were used: (1) we used the ResNet trained on a late AMD detection task as a fixed feature extractor, and (2) we fine-tuned the weights of ResNet together with the LSTM in an end-to-end manner. We also compared our model with a ResNet which predicts AMD progression using a single image.

Results: We trained and evaluated the models using longitudinal fundus images from the Age-Related Eye Disease Study (AREDS). The AREDS dataset includes 4,315 participants, a large majority of whom had annual visits over 10 years. The dataset was split into train/validation sets with a 0.7:0.3 ratio. We evaluated models using the area under the receiver operating characteristic curve (AUC). Table 1 shows that the CNN-RNN model outperforms the baseline on 2-year (0.926 vs. 0.892) and 5-year (0.904 vs. 0.829) predictions. In the meantime, our model's performance increases with up to 5 visits, but drops with more visits in patient history. This might be due to the data imbalance and sparsity issues. We also observed that the end-to-end training did not show significant improvement.

Conclusions: We presented a CNN-RNN model for predicting late AMD progression for each patient in this study. Our experiments show that our model can capture dynamic sequential patterns and outperforms baselines. This study sheds light on the potential of deep learning to facilitate and support clinical decision-making on an individual basis.

ABSTRACT BODY:

Purpose: Efforts at automatic identification of the optic disc and its neural rim have been reported, but have not been used to grade glaucoma severity with an accepted metric. In this retrospective observational study, we propose a DDLSNet pipeline consisting of a rim segmentation (RimNet) branch and a disc size classification (DiscNet) branch to automate glaucoma grading with the disc damage likelihood scale (DDLS).

Methods: To develop RimNet, funduscopic images from the UCLA Stein Glaucoma Division were randomly split into training, validation, and test datasets (80/10/10). Optic rims of the training set were drawn by glaucoma specialists. RimNet uses contrast enhancement, an InceptionV3/LinkNet rim segmentation model, and computer vision to identify the thinnest rim location and calculate the rim-to-disc ratio (RDR). To develop DiscNet, paired funduscopic images and OCT data from UCLA Stein Glaucoma Division were randomly split into training, validation, test datasets (80/10/10). DiscNet uses a VGG19 network to label disc size as small, medium, or large. The DDLS grade is calculated from RDR and disc size. Three glaucoma specialists graded the RimNet test set with DDLS (scale 1-10). The main outcome measure was a weighted kappa agreement with agreement defined as +/- 1 DDLS grade between graders and DDLSnet.

Results: RimNet was developed on 857 images (mean age=60.3 (±14.2) years, male:female ratio=0.42), and achieved an RDR mean absolute error of 0.06 (±0.04) on test set between RimNet and physician. DiscNet was developed on 8366 images (mean age=67.6 (±14.5) years, male:female ratio=0.57), and achieved 77% classification accuracy on test set. DDLSNet was evaluated on 87 images from the RimNet test set; Table 1 lists the agreements between DDLSNet and graders and between individual graders.

Conclusions: DDLSNet achieved acceptable performance as shown by fair weighted kappa agreement with grader 2 and 3. This illustrates the feasibility of developing an automated process such as DDLSNet for glaucomatous grading of optic disc images. Further improvements are required, and will be achieved by further training of graders, increasing sample size, and algorithm enhancement.

ABSTRACT BODY:

Purpose: To develop and test a closed-loop system for modulating iris activity and assessing the role of dynamic iris behavior in primary angle closure disease (PACD).

Methods: Participants aged 18 years or older were recruited from the University of Southern California Roski Eye Institute. Three consecutive videos of one eye per participant were recorded using the ANTERION OCT system (Heidelberg Engineering, Heidelberg, Germany). During recording, custom software was used to control a light-emitting diode (LED) and modulate ambient lighting to hold the iris in a dilated, constricted, or mid-dilated position. Dynamic iris behavior in the form of peak constriction velocity (PCV) and mid-dilated iris activity (MDIA) were measured in real-time. Linear regression analysis was performed to assess the relationship between participant age and PCV and MDIA.

Results: A total of 58 participants were recruited, with 40 (69.0%) being eligible for analysis based on patterns of iris behavior. Mean participant age was 50.0 (SD = 18.7) years. The system maintained a mid-dilated position for 69.0% of the participants with a mean difference of 0.071 (SD = 0.13) mm between the calculated and observed mean mid-dilated pupillary diameters. There was a negative linear correlation between PCV and age (slope= -0.02; $p < 0.01$) and MDIA and age (slope= -0.003 ; $p < 0.01$).

Conclusions: A novel closed-loop iris control system can modulate dynamic iris behavior and hold the pupil in a stable mid-dilated state. Dynamic iris behavior during pupillary constriction and in the mid-dilated state decrease with age. This system may be applied in the future to study dynamic disease processes involving the iris, including acute primary angle closure (APAC).

ABSTRACT BODY:

Purpose: In retinal laser treatment, the tissue effect only partially correlates to laser energy due to differences in light absorption, light scattering and retinal pigmentation. Especially in subvisible laser treatment, the therapeutic accuracy is low. Thus, treatment reliability and reproducibility are limited.

We have previously reported on real-time temperature-guided retinal laser therapy to improve reproducibility. In this study, we report on the correlation of retinal temperature and laser-tissue effect.

Methods: A conventional 532nm continuous wave laser (Zeiss VisuLas 532) is used with a custom-build modulation module (Medical Laser Center Lübeck), which can measure the temperature rise in real-time with a rate of 3 kHz. Based on this, it controls the laser power in real-time such that a desired target temperature is quickly obtained and held for the rest of the irradiation.

Irradiations with target temperatures from 45 to 69 °C were performed in rabbits with a diameter of 200 µm and an exposure time of 100ms. With a laboratory PC-controlled module, we performed irradiations in 5 eyes of 3 rabbits. For an upcoming clinical study, it was converted to a microcontroller-based system, with which so far 1 eye of 1 rabbit was treated. Funduscopy, optical coherence tomography (OCT) and fluorescence angiography (FAG) were used for evaluation.

Results: With the PC system, the following ED-50 values were determined: Funduscopic visibility 60.2 °C, FAG visibility 60.2 °C, OCT visibility 59.4 °C. In OCT, the greatest linear diameter (GLD) of the lesions correlated better to temperature (R^2 = 0.62) than to laser power (R^2 = 0.47). The aim temperature was reached with an average error of 3.5%.

With the microcontroller system, comparable results could be reproduced. The average error in aim temperature was 2.3% (97% of lesions within a maximum error of 5%). ED-50 values were comparable in FAG (61.9 °C) and slightly higher in funduscopy (68.2 °C; pilot data with small sample size).

Conclusions: It could be shown that temperature-guided laser irradiations can improve accuracy in retinal laser therapy. Lesion strength is better correlated to temperature than to bare laser power. We are planning to begin a clinical study for temperature-guided non-damaging laser treatment in patients with central serous chorioretinopathy in early 2022.

ABSTRACT BODY:

Purpose: The aims of this study were to identify individuals from the UK Biobank (UKBB) cohort with detectable retinopathy on retinal imaging and to describe their sociodemographic and clinical characteristics.

Methods: Colour fundus photographs and macular optical coherence tomography (OCT) scans were acquired using a Topcon 3D OCT-1000 Mark II system (Topcon, Japan). Grading was performed by trained and certified graders and clinicians of the Network of Ophthalmic Reading Centres UK (NetwORC UK-Belfast, Liverpool, and Moorfields Ophthalmic Image Reading Centres). Retinopathy was defined as the presence of one or more microaneurysms in either eye, with or without other retinal microvascular abnormalities on either imaging modality. Diagnosed diabetes (DM), diabetic retinopathy (DR) and hypertension (HTN) were ascertained from self-reported (verbal interview), linked hospital episode statistics and primary care records at the time of imaging. Self-reported medication history was obtained from touchscreen questionnaire responses. HbA1c >48mmol/mol was considered diagnostic of DM. Systolic or diastolic blood pressure (BP) measurements ≥140mmHg and ≥80mmHg respectively were considered diagnostic of HTN.

Results: Among 68,517 UKBB participants who underwent fundus imaging, 265 (0.4%) individuals were identified to have retinopathy from retinal imaging. The median age at assessment for this group was 59 years (interquartile range 52-64), 70.9% were men and 79.6% were of white ethnic background. When retinopathy grading data were compared against medical records, 69.8% and 49.8% had a diagnosis of DM and DR respectively. The majority (55.5%) had a HbA1c level in the diagnostic range for DM (mean 54.5 mmol/mol) and 47.2% self-reported using insulin. A diagnosis of HTN was recorded for 59.2%, while 55.1% self-reported taking anti-hypertensive medication and 73.6% had BP measurements in the hypertensive range. Overall, 95.1% had either DM or HTN (diagnosed or undiagnosed), while 63.0% had both. Of the 13 (4.9%) individuals without DM or HTN, 7 had only a single microaneurysm in one eye.
Conclusions: This is one of the largest prospective cohort studies containing validated grading data for retinopathy, showing a high prevalence of both DM and or HTN. These results demonstrate the quality of the retinal image grading and highlight the potential for detecting systemic pathology.

ABSTRACT BODY:

Purpose: The visual acuity (VA) outcomes, intra- and postoperative complications of cataract surgeries complicated by posterior capsule rupture (PCR) or dropped nucleus fragments (DNF) have not been reported. Here, we report the results of a retrospective, multicenter study comparing uncomplicated cataract surgeries to those complicated by PCR or DNF.

Methods: After inclusion and exclusion criteria were met, we analyzed 178,859 eyes according to the VA at baseline and within three-month follow-up. Successful visual outcome was defined as VA≤0.3logMAR, and uncomplicated surgeries considered as reference group. Incidence of cystoid macular edema (CME), rhegmatogenous retinal detachment (RRD), and epiretinal membrane (ERM) were also analyzed. Statistical analysis between the pre- and postoperative VA and gains in Snellen lines was generated using ANOVA and chi-square tests with Bonferroni correction. Statistical significance was set at P<0.003. Multivariate logistic regression modeling to calculate the odds ratio between VA≤0.3logMAR and surgical complications at different time intervalswas also performed.

Results: DNF and PCR group eyes developed inferior visual outcomes compared to reference group (0.67±0.65 vs.0.43±0.55 vs.0.20±0.33, respectively, p<0.003) with mean change in VA of -0.32±0.86 vs. 0.34±0.72 vs.-0.42±0.5, respectively, (p<0.003). DNF and PCR group eyes gained ≥0.3logMAR (~3Snellen lines) in 46.8% and 50.9% of eyes, respectively, compared to the 62% in the reference group (p<0.003). Among those eyes in DNF group, 204 eyes (41.23%) were managed surgically with pars plana vitrectomy (PPV) (44.79±28.5 days between procedure and PPV) and 315 eyes (58.77%) were conservatively managed. Mean change in VA among those eyes with DNF managed by PPV was higher than eyes managed conservatively (-0.17±0.90 vs.-0.48±0.79, p<0.003). The odds ratio of having CME, ERM, and RRD among eyes with DNF or PCR was significantly higher than reference group (1.603, 2.133, 3.646 in DNF group, vs. 2.18, 1.28, 1.76 in PCR group, respectively, p<0.003).

Conclusions: We found that eyes are at risk of inferior VA when cataract surgery is complicated by DNF compared to eyes with PCR. In addition, eyes with PCR or DNF had worse VA and higher risk of CME, ERM, and RD compared to uncomplicated cases. Eye complicated with DNF that managed with PPV, had better VA compared to conservatively managed eyes.

ABSTRACT BODY:

Purpose: Myopia progression is characterized by axial elongation which is commonly considered as irreversible. In this study, we observed differences in the frequency and magnitude of axial shortening among myopic children following repeated low-level red-light (RLRL) therapy.

Methods: This prospective analysis was performed on a real-world study (RWS) and a subset sample of a randomized control trial (RCT). In the RWS, myopic children (cycloplegic spherical equivalent refraction [SER] of at least -0.50 diopter [D]) who completed RLRL treatment for at least 12 months were included in the analysis. In the 12-month RCT, children aged 8 to 13 years with myopia of cycloplegic SER of -1.00 to -5.00D, astigmatism ≤2.50D, and anisometropia ≤1.50D were recruited and randomly assigned to RLRL treatment (intervention group) or a single vision spectacle (control group). Children in the intervention group were included in the present analysis. Axial length (AL) was measured prior to cycloplegia. A subset of the RCT underwent swept-source optical coherence tomography where choroidal thickness (ChT) was obtained.

Results: Among the 434 myopic children in the RWS, 115 (26.50%), 76 (17.51%) and 20 (4.61%) of them had AL shortening according to cutoffs of 0.05 mm/year, 0.10 mm/year, and 0.20 mm/year, respectively. In the multivariable model, older baseline age, female gender and longer baseline AL were significantly associated with the presence of AL shortening. For AL shortened eyes, mean AL shortening (standard deviation, SD) was -0.142 (0.094) mm. Among the 111 children in the intervention group of the RCT, 26 (23.42%), 18 (16.22%) and 7 (6.31%) had AL shortening of 0.05 mm, 0.10mm, and 0.20 mm or more per year respectively, with mean of AL shortening (SD) of -0.156 (0.086) mm. In multivariate analysis, older baseline age was significantly associated with the presence of AL shortening, whereas among those with AL shortening, longer baseline AL was significantly associated with greater magnitude of AL shortening.

Conclusions: More than a quarter of the children had >0.05 mm AL shortening following RLRL therapy with a mean of -0.142 and -0.156 mm. This axial shortening cannot be explained by measurement error and/or choroidal thickening. Further studies are needed to explore mechanisms underlying axial shortening.

ABSTRACT BODY:

Purpose: Restoring vision in patients blinded by advanced optic neuropathies requires therapies that promote retinal ganglion cell (RGC) survival and direct RGC axon regeneration. Previously, we showed that electric fields (EFs) direct RGC axon growth towards the cathode (negative electrode), in vitro. Here, we hypothesized that exogenous application of EFs can be exploited to direct optic nerve regeneration in vivo using the optic nerve crush model.

Methods: Adult male Long-Evans rats underwent optic nerve crush injury with intra-orbital and intracranial electrode implantation. Five days later, rats were stimulated with various electrical waveforms for 5 hours daily for 10 or 30 days. Treatment efficacy was assessed via 1) histologic tests, such as RBPMS staining for surviving RGCs and CTB anterograde labeling of regenerated axons, 2) behavioral tests, such as optokinetic reflex and visual cliff tests, and 3) electrophysiologic studies, including visual evoked potential (VEP) and pattern electroretinogram (PERG) recordings. Analysis performed with ANOVA and Sidak's multiple comparisons test.

Results: 10 days of EF treatment directed 2-fold more RGC survival and 5-fold more axon regeneration at 250μm from crush site over untreated rats (n=5, $p<0.05$). Full length optic nerve regeneration was observed with 30 days of EF treatment. This was associated with 10-fold more RGC survival and 7-fold more axon regeneration at 250μm from crush site over the untreated rats (n=4, $p<0.05$). VEP recordings demonstrated partial recovery of visual function in 62% of superior colliculus sites in the 30-day treated rats (n=3, $p<0.05$) compared to 2% of the untreated (n=4). The PERG N95 amplitude (crushed nerve normalized to contralateral uncrushed nerve) was 0.66 in the 30-day treated rats (n=6, $p<0.05$) compared to 0.28 in the untreated (n=4). On visual cliff testing, 67% of 30-day treated rats (n=3) dismounted correctly (mean latency 184 sec) compared to no correct dismounts in the untreated (n=3).

Conclusions: Our results demonstrate that EF application can promote RGC survival and direct axon regeneration with partial recovery of visual function and suggests that EF application may be a viable therapeutic to help restore visual function in patients blinded by advanced optic nerve disease.

ABSTRACT BODY:

Purpose: A growing body of research indicates that abnormal retinal microvascular features may serve as a novel biomarker reflecting the severity of underlying cardiovascular, neurodegenerative, and microvascular disease. Since blood flow to the retina is predominantly supplied by the internal carotid artery, we hypothesized that retinal microvasculature may change after carotid endarterectomy reflecting the disease status or therapeutic effects in patients with severe carotid stenosis.

Methods: Nine patients with carotid artery stenosis >70% underwent complete ophthalmic examinations and Optical Coherence Tomography Angiography (OCTA, Spectralis, Heidelberg) before carotid endarterectomy and 48 hours (h) and 3 months post-surgery. Image J software (National Institutes of Health, Bethesda, MD) was used to analyze OCTA images. Non-local means denoising filter, Phansalkar as adptative local thresholding methods and binarization algorisms were used to process the images. Eyes on the operated side constituted the ipsilateral eye group, and the other eye constituted the fellow eye group.

Results: : 8 male and 7 female were included, with a mean age of 73 years old.

In the ipsilateral eye group, FAZ area reduced significantly after endarterectomy (before vs 48h after surgery, p=0,012; before vs 3 months after surgery, p=0,012). FAZ area also decreases from 48h post-surgery to 3 months after surgery; however, this difference is not statistically significant (p=0,41). No differences in FAZ area were found in the fellow eye during follow-up (p=0,095).

Regarding vessel densities (VD), no statistical differences were found in the ipsilateral eye in macular or papillary scans both in superficial (SCP) and deep capillary plexus (DCP) ($p<0.05$), although a tendency for an increase in VD is evident in SCP of macula centered scans.

Similarly, no differences in vessel density were found during the follow-up in the fellow eye.

Conclusions: Endarterectomy for severe carotid stenosis reduce FAZ area in the immediate and midterm post-surgery.

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) is a vision-threatening microvascular complication that affects one-third of all diabetics. Fundus examination and imaging, commonly spectral domain optical coherence tomography (SD-OCT), are used to screen for, diagnose and monitor complications of DR. Disorganization of retinal inner layers (DRIL) is an understudied SD-OCT parameter. To investigate the clinical utility of DRIL in DR, we evaluate its relationship with several DR risk and progression factors.

Methods: A retrospective cohort study was conducted at a large academic center following Institutional Review Board approval. The cohort comprised 1,175 randomly selected, non-consecutive patients with ICD-9/10 codes for type 2 diabetes with and without retinopathy between September 2009 and January 2019 (n=2,083 eyes). Demographics, anti-hyperglycemic history, hemoglobin A1c (HbA1c), and VA were obtained by electronic medical record review. SD-OCT scans were evaluated for DRIL by two trained, double-blinded graders. Disagreement was arbitrated by a third blinded grader. Interrater reliability was tested with a kappa statistic. Generalized estimating equation logistic regression models were used to evaluate relationships between variables.

Results: Of 2,083 eyes, 28.08% (n=585) demonstrate presence of DRIL with high interrater reliability (K=0.88, 95% confidence interval (CI) [0.86-0.90]). Insulin users have more severe DR (p<.0001). DRIL is associated with worse VA (p<.001) and DR severity (p<.0001). Unadjusted, insulin usage appears to be associated with DRIL (OR 1.91, 95% CI [1.49-2.45]), however after accounting for DR severity, we find that DRIL is not associated with insulin usage (p=0.25).

The remaining DR-related factors (other anti-hyperglycemic usage, HbA1c, sex, race and age) are not associated with DRIL.

Conclusions: DRIL is a promising clinical parameter in patients with DR. SD-OCT marker DRIL is strongly associated with severity of DR and worse VA, supporting its utility as an unfavorable prognostic predictor. Initially, DRIL appeared strongly associated with insulin use, however after adjusting for DR severity, DRIL is not associated with insulin use. Thus, DR severity confounds the relationship between DRIL and insulin use.

ABSTRACT BODY:

Purpose: To evaluate the effect of pre-analytical sample handling on tear fluid protein levels.
We empirically tested variations of common tear collection and handling procedures.

Methods: We created sample sets that address the effect of tear collection, storage and extraction on protein recovery. Tear fluid was collected using Schirmer's strips from healthy subjects. Proteins were extracted by elution and centrifugation. The total protein content was measured with the BCA assay.

Results: Protein recovery was the highest after direct ('fresh') extraction. Minimal protein loss was found after intermediate storage at -80°C and -20°C (-3.1% and -4.5%, respectively). Protein concentration in the 'wet' storage condition of strips was 8.5 ± 6.0% higher compared to 'dry' storage. Protein recovery increased with increasing extraction volumes but also results in higher dilution of the sample. Sonication did not improve protein extraction efficiency. Protein concentration within the Schirmer's strip was the highest in the 0-5 (+head) mm region (1034.7 ± 72.7 µg/mL). Consecutive tear fluid collection did not greatly affect protein concentration. Protein recovery decreased with protein concentration but was independent of molecular weight.

Conclusions: There is a need to construct standardized operation procedures for pre-analytical handing of tear fluid in order to facilitate to build tear fluid biobanks and the use of tear fluid-based biomarkers in the clinical setting.

ABSTRACT BODY:

Purpose: Amyloid-beta (Aβ) has been implicated in the pathophysiology of age-related macular degeneration. We have shown that Aβ species possess differential retinal neurotoxicity, where oligomeric and fibrillar assemblies of Aβ42 mediated the primary retinotoxic effects. The mechanism of internalization of extracellular Aβ42 species in the retina is not well defined. In the brain, Aβ binding to the 67kDa laminin receptor (67LR) mediated the internalization of oligomeric Aβ42 and related neuronal cell death. We have found that PEDF335, a pigment epithelium-derived factor derived peptide, can bind to 67LR. Here, we hypothesized that 67LR mediates Aβ42 uptake in the retina, and PEDF335 may limit extracellular Aβ internalization, thereby inhibit Aβ42 retinal toxicity.

Methods: ARPE-19 cells were cultured with PEDF335 for 6h before treatment with oligomeric or fibrillar Aβ42 for 24 h. Cell viability was determined by XTT assay. The uptake of Aβ42 was assessed using immunostaining. Wild type rats were treated with intravitreal injection (10µl) of PEDF335 (3mM) in each eye two days prior to administration of oligomeric or fibrillar Aβ42 to the right eye. Retinal function was assessed at baseline and thereafter through 6 weeks after the injection. At each time point, electroretinography (ERG) measures were compared between eyes. The presence of 67LR in ex-vivo retina was determined using immunostaining.

Results: PEDF335 treatment blocked amyloid internalization into ARPE-19 cells and maintained their viability in the presence of oligomeric and fibrillar Aβ42. ERG responses in rat eyes treated with oligomeric or fibrillar Aβ42 assemblies were near-normal in eyes previously treated with PEDF335, whereas those measured in eyes treated with Aβ42 alone showed pathologic attenuation through 14 days. No adverse effects were noted in response to PEDF335. Retinal immunostaining demonstrated the expression of 67LR in rats' retina.

Conclusions: Our results show that PEDF335 protects against oligomeric and fibrillar Aβ42 retinal toxicity, at least in part, via binding to 67LR and inhibition of Aβ42 internalization. These observations provide evidence on the importance of extracellular versus intracellular Aβ42 in the retina and suggest that the mechanism of toxicity of fibrils possibly involves secondary release of oligomers. Such insights may promote the mechanistic understanding of the retinal pathogenicity of Aβ.

ABSTRACT BODY:

Purpose: Assessing image quality of optical coherence tomography (OCT) beforehand is very essential for subsequent retinal disease identification. We developed, validated, and tested deep-learning algorithms to assess the quality of macular scans obtained from two OCT devices.

Methods: This study was a retrospective analysis of OCT images obtained from the Chinese University of Hong Kong Eye Centre and Hong Kong Eye Hospital. The OCT images of different scanning protocols and devices (macular cube 512×128 B-scans from Cirrus OCT; and macular volume 512×31 B-scans, 1024×25 B-scans, and 1024×19 B-scans from Spectralis OCT) were included. The gradability of B-scan images and volume scans were labeled as gradable or ungradable. Gradable B-scan/volume scan was defined as absence of any artifact or; OCT artifacts affect less than 25% peripheral area or; fovea off centration presents in the central 50% area. Ungradable B-scan/volume scan was defined as OCT artifacts affect the central 50% area or fovea off centration is outside the central 50% area or fovea motion artifact. The ground truth was independently labeled by two masked well-trained graders. The discrepancy during the grading was resolved by adjudication by a senior grader. A total of 2,277 Cirrus scans and 33,633 Spectralis B-scans of 1,557 volume scans were divided into training (70%), validation (20%), test (10%), respectively. We developed, validated, and tested a 3D residual network (ResNet)-18 for Cirrus 3D cube scans, a dense convolutional network (DenseNet)-121 for Spectralis 2D B-scans, and a multiple-instance learning model for Spectralis 3D volume scans (Figure 1).

Results: In the primary validation of Cirrus cube scans, Spectralis B-scans, and Spectralis volume scans, the algorithms achieved the area under receiver operating characteristic curves (AUCs) of 0.930, 0.972, and 0.906 (Figure 2); sensitivities of 94.6%, 90.1%, and 86.5%; specificities of 83.3%, 94.2%, and 95.7%; and accuracies of 93.3%, 91.1%, and 87.2%, respectively.

Conclusions: The proposed deep learning algorithms achieved good performance, to distinguish gradable and ungradable OCT macular images. Incorporating with an artificial intelligence-based model, a volume-level quality indicator allows only gradable scans to be referred, which can smooth clinical operational flow for enhancing disease screening and diagnosis.

ABSTRACT BODY:

Purpose: To investigate the impact of the ratio between photoreceptor (PR) loss and retinal epithelium (RPE) loss in geographic atrophy (GA) on lesion growth as well as on the effect of pegcetacoplan treatment.

Methods: Spectral domain-optical coherence tomography (SD-OCT) volumes of patients included in the prospective, multicenter, randomized phase II FILLY trial, investigating the safety and efficacy of intravitreal C3 complement inhibition by pegcetacoplan in GA, were analyzed. All eyes were imaged with Spectralis OCT (Heidelberg Engineering, Heidelberg, Germany) were included. PR thickness as well as RPE loss were segmented automatically based on two separate deep learning algorithms. We investigated the difference in progression of RPE loss at year 1 between baseline quartiles of PR loss / RPE loss ratio as well as the effect of treatment within these quartiles. To this end, a multivariable regression model was calculated considering quartiles of PR loss / RPE loss at baseline and their interaction with treatment.

Results: GA growth in sham-treated eyes increased with higher baseline PR loss / RPE loss ratio quartiles (Figure 1). Lesions in the highest quartile showed statistically significantly increased growth of RPE loss of 284µm (95% CI: 84, 485; p=0.006) compared to lesions in the lowest quartile. Accordingly, the effect of monthly treatment also increased with higher PR loss / RPE loss ratio quartiles, reaching a statistically significant effect of -207µm, equaling a 57% growth reduction compared to SM treated eyes (95% CI: -408, -6,5; p=0.043) in the fourth quartile.

Conclusions: High baseline PR loss / RPE loss presents as a risk factor of increased GA growth. Furthermore, the treatment effect was observed to be dependent on baseline PR loss / RPE loss ratio, showing a significant RPE loss growth reduction for AM- compared to SM-treated eyes in the highest ratio quartile. These results highlight the importance of baseline characteristics for investigating treatment effects in GA. We expect such baseline characteristics identified by AI tools to be of relevance for defining robust criteria for patient selection as well as treatment guidelines for forthcoming clinical trials as well as clinical routine.

ABSTRACT BODY:

Purpose: Reduced blood flow and neurovascular deficits are recognized features of glaucoma, but the mechanisms underlying these alterations are poorly understood. Pericytes, the contractile cells that wrap around capillaries, regulate blood supply by modulating capillary diameter. Here, we developed a novel live imaging and femto-scale delivery system to study the role of single-pericyte hemodynamics in glaucoma.

Methods: Ocular hypertension (OHT) was induced by intracameral injection of magnetic microbeads in NG2-DsRed mice, which allow visualization of retinal pericytes. Two-photon laser scanning microscopy (TPLSM) was combined with a femtomolar delivery system (FemtoJet Microinjector) to visualize and modulate single-pericyte longitudinal responses in living mice. A micromanipulator was used to place the microneedle adjacent to a pericyte-capillary pair, and vasomodulators (e.g. ET-1:endothelin-1, NO donors) were delivered at a femtomolar scale. Capillary diameter was measured by placing a linear probe perpendicular to the plane of the vessel, and blood flow was quantified by counting the number of red blood cells crossing a pre-fixed vessel location.

Results: TPLSM adapted with a femto-microinjector provided high spatial-temporal resolution of single-pericyte-capillary responses without affecting neighboring vessels. Our data show decreased capillary diameter and blood flow at pericyte locations in glaucoma (sham: n=13 capillaries, OHT-2 wks: n=18 capillaries, N=5-7 mice/group, $p<0.01$). Femtomolar delivery of ET-1 in glaucomatous mice exacerbated the magnitude and duration of capillary constriction at pericyte locations and decreased blood flow relative to controls (vehicle: n=11 capillaries, ET-1: n=16 capillaries, N=3-5 mice/group, $p<0.001$). In contrast, NO donor administration rescued the ability of capillaries to dilate at pericyte locations enhancing blood flow despite OHT (vehicle: n=16 capillaries, NO donor: n=7 capillaries, N=3-5 mice/group, $p<0.01$), suggesting that microvascular defects in glaucoma are reversible.

Conclusions: We demonstrate the utility of combining TPLSM live longitudinal imaging and femtomolar delivery of vasoactive substances to study neurovascular defects caused by OHT. Our study identifies pericytes as critical regulators of capillary hemodynamics and unveils their potential as therapeutic targets to restore neurovascular function in glaucoma.

ABSTRACT BODY:

Purpose: Lowering intraocular pressure (IOP) is currently the only treatment strategy to slow the progression of glaucoma. The increased IOP is attributed to abnormally elevated trabecular aqueous outflow resistance that can be caused by fibrosis of the trabecular meshwork (TM). We recently found that the specific sigma-1 receptor (S1R) agonist fluvoxamine (FLU) effectively reduces profibrotic factor-induced cytoskeletal rearrangement and cell proliferation of TM cells in vitro, therefore we propose that FLU may prevent TM fibrosis in vivo and thus can reduce IOP.

Methods: To induce IOP C57BL/6J wild type (WT) and S1R knock-out (KO) mice were weekly injected (n=8-12/group) with vehicle or Dexamethasone Acetate (Dex) through periocular conjunctival fornix to both eyes. FLU eye drops (30mM) were given bilaterally twice daily after 1 week of Dex. IOP was measured with Icare Tonolab weekly. After 4 weeks, the eyes were enucleated and bisected just posterior to the limbus. The retina, choroid, vitreous, and lens were removed carefully and the remaining anterior segments were frozen for further investigations. For S1R labeling fluorescent beads were injected intracamerally and TM regions with engulfed beads were imaged with confocal microscope.

Results: Dex increased the IOP in 7 month old WT mice after three weeks from baseline 17.26±1.46 to 18.61±1.05 mmHg (+7.82%; $p<0.05$) and two weeks of FLU eye drop treatment lowered IOP to 16.90±1.19 mmHg (-9.18%; $p<0.05$) compared to Dex group. In younger (2 to 5 month) WT mice IOP was elevated from baseline 17.66±1.01 mmHg to 19.65±2.00 mmHg (+11.27%; $p<0.05$) which is more pronounced than in aged mice. In KO mice the IOP increased from 16.81±1.41 to 18.72±1.04 mmHg (+11.36%; $p<0.05$). Of note the increase of IOP started earlier in KO mice (1 week) than in WT (2 weeks). As novelty, confocal images showed that S1R is present in the mouse TM region and preliminary PCR results revealed that the expression of key fibrosis elements (fibronectin and α-smooth muscle actin) were upregulated by Dex.

Conclusions: Fluvoxamine treatment effectively reduced the steroid-induced fibrosis and cytoskeletal rearrangement of trabecular meshwork tissue and prevented the increase in intraocular pressure in vivo. Thus Sigma-1 receptor agonists could be potential candidates for the development of a novel IOP-lowering drug.

ABSTRACT BODY:

Purpose: Immune-mediated graft rejections remain the most common cause for graft failure after organ and tissue transplantation. There is a great unmet medical need for pharmacologic strategies to promote graft survival without unduly compromising the health of the recipient. Recently, our group showed that pre-treatment of the corneal donor tissue with sCD83 improves graft survival. Here, we further elucidate the mode of action of pre-treatment of corneal donor tissue and determine the effect of sCD83 on direct allosensitization after corneal transplantation.

Methods: A murine model of high-risk corneal transplantation with C57BL/6N mice as donor and BALB/c mice as recipients was used. Corneal grafts were pre-incubated with sCD83 for 48 h. Excessive sCD83 was removed prior to transplantation by alternating incubation in hydrating and dehydrating medium (removal strategy). Corneal sCD83 content was assessed by immunoblotting and immunohistochemistry. Long-term allograft survival was determined by grading the graft opacity weekly for eight weeks. Moreover, the inflammatory phenotype of dendritic cells (DCs) and macrophages (Mφ) in the draining lymph nodes (dLNs) of the recipient was analyzed by flow cytometry eight weeks post transplantation.

Results: Applying the removal strategy to pre-incubated donor corneas resulted in a strong decrease of sCD83 in the stroma whereas sCD83 was still co-localized with immune cells of the donor cornea. Subsequent transplantation of those grafts into high-risk recipient beds improved long-term graft survival. Moreover, the frequencies of both regulatory DCs ($CD11c^+MHCII^+CD200R^+$) as well as Mφ ($F4/80^+CD200R^+$) were significantly increased in dLNs of mice that received sCD83-modulated grafts.

Conclusions: This study demonstrates that sCD83-induced corneal graft tolerance can be mediated directly by immune cells of the donor tissue and thereby modulates direct allosensitization in corneal transplantation. Thus, targeting the initial alloimmune response can already improve the long-term outcome. This new pharmacologic strategy of "direct allotolerance" could be a seeding point for novel therapeutic approaches in which pre-treatment of grafts with sCD83 could induce tolerance to the donor tissue and avoid lifelong immunosuppressive treatment of the patient.

ABSTRACT BODY:

Purpose: Differentiation of lens epithelial cells (LECs) to lens fiber cells (LFCs) is a lifelong process involved in physiological lens development. Circular RNA, a class of covalently close-loop non-coding RNAs, plays important roles in lens development regulation. To unearth its potential specialized functions during human LECs differentiation, circRNA expression profiling in LECs and LFCs was analyzed.

Methods: Clear human lenses of five organ donors were obtained from Guangdong Eyebank and dissected into LECs and LFCs for RNA extraction. Matching RNA samples from two cell types were assessed by Agilent microarray to identify differentially expressed circRNAs (DEcircRNAs). Gene ontology (GO) enrichment and Kyoto Encyclopedia of Genes and Genomes (KEGG) analyses of the DEcircRNAs were performed to determine the related biological modules and pathways.

Results: There was a significant difference of circRNAs expression profiling between human LECs and LFCs, indicating that molecular regulation via circRNAs differs greatly in the process of LECs differentiation. A total of 218 DEcircRNAs were identified, among which 114 were up-regulated and 104 were down-regulated in LECs compared with LFCs. GO enrichment analyses revealed the DEcircRNAs were most signifcantly targeted to ephrin receptor signaling pathway (biological process), protein binding (molecular function) and cytosol (cellular compoment). Apoptosis, autophagy and Wnt signaling pathway were the most enriched pathway in KEGG analysis.

Conclusions: Our findings uncover the circRNA profiling in human LECs and LFCs, and analyzed the most related biological modules and signaling pathways of DEcircRNAs, which paves the way for futher characterization of potential regulatory mechanism of circRNA in LECs differentiation.

ABSTRACT BODY:

Purpose: To evaluate 7-year clinical outcomes in patient with central serous chorioretinopathy (CSC) according to age at presentation.

Methods: This retrospective study reviewed clinical and multimodal imaging data (color fundus photography, optical coherence tomography, fundus autofluorescence, fluorescein angiography, indocyanine green angiography) of 75 eyes of 71 patients with CSC. All subjects were followed up at least 7 years. The eyes were divided into 3 groups according to age at presentation, as <50 years old (Group 1, 28 eyes), 50 to 59 years old (Group 2, 28 eyes), and ≥60 years old (Group 3, 19 eyes). Best corrected visual acuity (BCVA), subfoveal choroidal thickness (SFCT), central subfield retinal thickness (CST), multimodal imaging were analyzed.

Results: At baseline, mean BCVA and mean CST among three groups were statistically different (BCVA; $p = 0.047$, CST; $p = 0.034$). Seven-year mean change of SFCT were -7.0 ± 56.7 μm in Group 1, -12.3 ± 51.0 μm in Group 2, and -66.4 ± 57.6 μm in Group 3. Mean SFCT in Group 3 significantly decreased compared to that of other groups ($p = 0.004$; compared to Group 1, $p=0.016$; compared to Group 2). Seven-year prevalence of shallow RPE elevation was 10.7% in Group 1, 25.0% in Group 2, 42.1% in Group 3. Seven-year prevalence of choroidal neovascularization (CNV) was 7.1% in Group 1, 14.3% in Group 2, 36.8% in Group 3. In older age group (over 50), advanced fundus autofluorescence patterns appeared and progressed during 7-year follow-up.

Conclusions: During 7-year follow up of CSC, mean subfoveal choroidal thickness decreased by 7.0 μm in age 30-49, by 12.3 μm in age 50-59, and by 66.4 μm in age over 60 which was significantly different. Age at presentation were associated with decreases of choroidal thickness. In CSC, long-term and planned researches are needed.

ABSTRACT BODY:

Purpose: Trabecular meshwork (TM) is the main pathway for aqueous humor drainage from the eye. The fibrotic-like remodeling of the actin cytoskeleton in TM cells results in altered stiffness and impaired outflow which are the primary cause of increased intraocular pressure (IOP) leading to glaucoma. Thus, cytoskeletal-disrupting drugs could be a novel therapeutic approach to lower IOP. Recently, we proved that fluvoxamine (FLU), a specific Sigma-1 receptor agonist is antifibrotic in the kidney. Therefore, here we investigated whether FLU is effective in the prevention of cytoskeletal rearrangement and in vitro TM fibrosis in primary mouse- (MsTM) and non-glaucomatous human TM cells (HTM5).

Methods: Immunocytochemistry and Western blot were used to detect S1R on HTM5 and on MsTM cells. Primary MsTM cells from wild type (WT) and S1R knock-out (KO) mice and HTM5 cells were treated for 24h with 20 ng/mL platelet-derived growth factor (PDGF) combined with 10 μM of FLU. Cell proliferation was determined by thiazolyl blue tetrazolium bromide assay, cell toxicity by LDH assay, cell migration was measured by scratch assay, and F-actin was visualized by phalloidin staining and detected with fluorescent microscope. The fibrotic protein levels (fibronectin and αSMA) were measured by Western blot.

Results: S1R is present both in primary MsTM and HTM5 cells and is localized in the endoplasmic reticulum. Cell proliferation, migration, levels of fibrotic proteins (fibronectin, αSMA) and cytoskeletal rearrangement were induced by PDGF. FLU treatment was not toxic to the cells and ameliorated or even prevented the PDGF induced changes in all assays. Furthermore,upon PDGF treatment the integrated density of phalloidin staining increased with 19.73% in primary KO MsTM cells compared to WT and the formation of F-actin bundles and actin clumps was more pronounced in the absence of S1R suggesting its protective role in TM fibrosis.

Conclusions: FLU is non-toxic and effectively reduces profibrotic factor-induced cytoskeletal rearrangement and cell proliferation of TM cells. Therefore one can speculate that it might lead to lower outflow resistance also in animals and it could be an IOP-lowering drug candidate for glaucoma.

ABSTRACT BODY:

Purpose: To compare the clinical evaluation of intra- and subretinal fluid (IRF, SRF) presence and volume change between eye care professionals and a deep learning-based algorithm in real-world OCT images of patients with neovascular age-related macular degeneration (nAMD).

Methods: Patients were diagnosed with nAMD and treated at our retina department between 2007 and 2018 and are included in the Vienna Imaging Biomarker Eye Study (VIBES) registry. Five retinologists (RET), three ophthalmology residents (RES), three ophthalmologists working in private practice (PRIVO), three orthoptists (ORTH) and three certified readers from the Vienna Reading Center (VRC) subjectively graded the presence of IRF/SRF at two consecutive visits and the level of change (increase/no-change/decrease). There were 28 to 120 days between two visits and anti-VEGF injections were given at any timepoint between the two visits. For the presence of IRF/SRF, the majority vote of RET was used as ground truth and compared to the majority vote of each of the other four professional groups as well as to an algorithm for automated fluid quantification (fluid presence ≥5nl). For the comparison of fluid change (change ≥ ±5nl), the same algorithm served as the objective ground truth and was compared to all five professional groups.

Results: Spectralis OCT volumes of 248 visits (=124 visit pairs) were included in our analysis. Compared to RET, the agreement on IRF presence was 93% (RES), 93% (PRIVO), 92% (ORTH), 88% (VRC), 89% (algorithm); agreement on SRF presence was 92% (RES), 89% (PRIVO), 89% (ORTH), 94% (VRC), 90% (algorithm). Compared to the algorithm, agreement on IRF change was 84% (RET), 87% (RES), 85% (PRIVO), 80% (ORTH), 87% (VRC); agreement on SRF change was 87% (RET), 87% (RES), 85% (PRIVO), 83% (ORTH), 88% (VRC).

Conclusions: The consensus of human experts from different professional background appears to be consistent in respect to overall fluid evaluation. However, in quantitative terms, artificial intelligence allows a precise assessment of fluid change over time and thus a management of macular edema that is better or comparable to different human eye-care professionals.

ABSTRACT BODY:

Purpose: The study aims to evaluate the retinal and choriocapillary vascular density (VD) in a group of patients affected by Systemic Sclerosis (SSc) compared to healthy controls (HC) and to highlight a possible correlation between the (VD) at this level and the characteristics of the disease, the results of capillaroscopy and the organ involvement.

Methods: VD was assessed by Optical Coherence Tomography Angiography (Ultra-fast Spectral Domain OCTA, 6.4 mmmx 6.4 mm macular scan) at the level of the superficial (SCP), deep retinal capillary plexus (DCP), and the choriocapillary (CC) of 30 SSc patients compared to 30 subjects of the same sex and age without any retinal disease.

Results: 30 % of SSc patients (age 57.3 ± 10.0, female 86.7%) had a diffuse cutaneous variant ,a mean duration of disease of 10.4 ± 7.2 years, and patients with antibody positive-centromer and anti-Scl70 account respectively for 40.0% and 30.0%. Compared to HC, SSc patients showed altered VD at the level of the SCP (47.7 ± 3.6 vs 59.1 ± 3.5%, p = 0.009), of the DCP (50.0 ± 6.7 vs 54.3 ± 6.4%, p = 0.015), and CC (67.1 ± 2.2 vs 68.6 ± 1.7, p = 0.005). Furthermore, in the SSc group, the presence of digital ulcers (46.7%), telangiectasias (43.3%) and interstitial lung disease (46.7%) was related to reduced VD (46.8 ± 4 , 1 vs 50.3 ± 4.3%, p =. 033), of the CC (66.1 ± 1.4 vs 67.9 ± 2.4%, p = 0.004) and of the DCP (47.2 ± 8.8 vs 51.9 ± 4.3, p = 0.004). Finally, the mean capillary density at capillaroscopy showed a positive correlation with the VD at the level of the SCP (r = .474, p = .008), of the DCP (r = .414, p = .023) and of the foveal CC (r .482, p .007) and there was also a correlation between the density at CC and both DLco (r = .467, p = .009) and FVC / DLco (r = -. 436, p = .004) .

Conclusions: SSc patients in our cohort showed lower vascular density than healthy controls. Furthermore, the compromised VD at different levels of the eye is related to organ involvement and the degree of digital and pulmonary microvascular impairment. According to these data, OCTA could be proposed as a biomarker to study microvascular anomalies in SSc.

ABSTRACT BODY:

Purpose: To evaluate the short- (30 days) and mid- (90 days) term efficacy of 0.1% cyclosporine A cationic emulsion (CsA-CE) in dry eye (DE) patients exposed to normal (NCE: 23^{O}C, 50% relative humidity) and adverse controlled environment (ACE: 23^{O}C, 10% relative humidity, localized airflow).

Methods: This clinical trial (www.clinicaltrials.gov NCT04492878) included DE patients with moderate-severe keratitis. There were 3 visits: baseline, and 1 and 3 months after one daily instillation of CsA-CE in both eyes. Patients were evaluated 2 times in each visit, under NCE (pre-ACE) and 2 hr post-ACE. Symptoms were evaluated with the DE questionnaire (DEQ)-5, symptom assessment in DE (SANDE) II, and change in DE-symptoms questionnaire (CDES-Q). Clinical signs evaluated were: conjunctival hyperemia (Efron scale), meibomian gland secretion quality and expressibility, tear breakup time (TBUT), corneal fluorescein staining (Oxford scale), conjunctival staining (Oxford scale), and Schirmer test. To assess the effect of time and environment, linear mixed effects models or cumulative link mixed models were adjusted for quantitative (expressed as mean±standard deviation) or ordinal (expressed as median [interquartile range]) variables, respectively.

Results: Twenty patients were included. After 1 month of CsA-CE therapy there were significant improvements compared to baseline (in NCE) in: DEQ-5 (14.0±3.1 vs 9.7±4.3; $p<0.0001$), conjunctival hyperemia (2.5 [1] vs 2.0 [0]; $p<0.0001$), and corneal fluorescein staining (3.0 [1] vs 2.0 [1]; $p<0.0001$). These improvements were still significant ($p\leq0.001$) after 3 months. In contrast, TBUT, meibomian gland parameters, and Schirmer test did not change after treatment.

Comparing pre- and post-ACE evaluations, DE signs and symptoms worsened. However, corneal fluorescein staining post-ACE at 1 month (2.0 [2]) and 3 months (2.0 [2]) was significantly ($p<0.01$) better than baseline post-ACE values (3.0 [1.25]).

Conclusions: A short-term efficacy of 0.1% CsA-CE was observed, as keratitis and symptoms already improved after the first month, and were maintained after 3 months. In general, parameters worsened after ACE, although keratitis always remained lower than before treatment, meaning that patients treated with CsA-CE could be more protected when living under adverse environments.

ABSTRACT BODY:

Purpose: Efficacy and safety of gene therapies for retinal diseases (RDs) have been proven with preclinical success translated into clinical effectiveness. However, this approach is rarely chosen for dominant forms. Based on our previous published work, we focused on dominant-negative mutations in the transcription factor CRX. We developed a mutation-independent AAV vector that could circumvent the clinical and genetic heterogeneity of CRX mutations. We also tested the neuroprotective potential of our gene therapy product for CRX-independent retinopathies.

Methods: AAV-CRX is an AAV2/5 allowing the expression of human CRX specifically in photoreceptors, using Rhodopsin Kinase 1 promoter. The efficacy of AAV-CRX for different CRX-associated diseases was assess tested by injecting at P30 either $Crx^{Rip/+}$ mice, a model of Leber Congenital Amaurosis, or Tg(CRX^{R41W}) mice, carrying the human CRX^{R41W} mutation causing cone dystrophy. The effects on CRX-independent RD was also tested in rd10 mice by injecting at P14. The efficacy was assessed by immunohistochemistry, electroretinogram (ERG) and using a Dark/Light box test.

Results: AAV-CRX injection led to specific expression of CRX in photoreceptors with no toxicity. Three months after subretinal injection in $Crx^{Rip/+}$ mice, we observed: i) a rescue of rod and cone opsin expression, ii) a rescue of outer segment formation, iii) some degree of ERG response whereas it remained flat in controls iv) a fully restored behavioral response to light stress. Tg(CRX^{R41W}) characterization revealed a dose-dependent deleterious effect of CRX^{R41W} expression. Indeed, heterozygous Tg(CRX^{R41W}) carrying a single insertion displayed a functional retina while homozygous Tg(CRX^{R41W}) exhibited reduced retinal function after 3 months. These results support the relevance of increasing the amount of CRX^{WT} to counteract the dominant-negative effect of mutant CRX. The beneficial effects of AAV-CRX were observed in Tg(CRX^{R41W}) mutant mice with a cone only retina ($Nrl^{-/-}$ background). Finally, we showed that AAV-CRX has also a beneficial effect on CRX-independent RD by preserving rod photoreceptors in rd10 mice.

Conclusions: Overall, our gene therapy approach shows promising results for treating CRX-associated RDs, as well as CRX-independent retinopathies. It also highlights the potential interest of gene therapy to treat patients with RD carrying dominant-negative mutations.

ABSTRACT BODY:

Purpose: Google AutoML, an online machine learning platform, has demonstrated comparable performance to hard-coded deep learning (DL) algorithms for the identification of pathology in fundus photos. Here we explore whether a small labeled training set can be leveraged to train AutoML to detect disc hemorrhages (DHs) in a large unlabeled test set using an iterative approach to prepare data with reduced time burden.

Methods: A retrospective analysis of fundus photographs of different resolutions and sources centered on the optic disc obtained from the Ocular Hypertension Treatment Study, New York Eye and Ear Infirmary of Mount Sinai, Massachusetts Eye and Ear, Thessaloniki Eye Study, and GONE datasets were included. Ground truth was established by the consensus of grades from two masked glaucoma specialists. We trained AutoML to distinguish DH positive and DH negative images. Predictions for a held-out validation set were obtained in batches. Positive predictions over a confidence threshold of 0.9 confirmed by a glaucoma specialist were added to the positive dataset to retrain the model. This process was repeated for the entire held out dataset. Area under the receiver operator curve (AuROC) for the AutoML model and a custom model based on the Inception v3 architecture were calculated.

Results: Baseline DH identification model was trained using 391 case and 990 control images. A held-out validation set of 80,000 images was partitioned into 8 batches. Classifications by the baseline model of the 1st batch yielded 2521 positives (out of 13530) with 51 true positives on review (Positive Predictive Value (PPV) = 0.020). AutoML Model v2 included these 51 positive images, testing with a 2^{nd} batch produced 1182 positive classifications (of 10912) with 27 positives on manual review (PPV = 0.023). Repeating this process for 8 iterations identified 275 DH positive images. The PPV of the final AutoML Model was 0.400 (Fig 1). The AutoML and Inception models achieved AuROCs of 0.79 and 0.64, respectively, in the final imageset. False positive examples depict challenges in learning the DH phenotype (Fig 2).

Conclusions: DHs are rare events in glaucoma patients and somewhat resistant to machine learning. Iterating on a baseline model using a large held out dataset led to a 20-fold increase in PPV.

ABSTRACT BODY:

Purpose: Current myopia quality-of-life (QoL) questionnaires are burdensome to administer, have complicated scoring systems, and primarily assess vision functioning deficits. To address these issues, we are developing a myopia-specific QoL item bank (IB) that will be operationalized using a computerized adaptive testing (CAT) system to optimize administration and scoring. We report on the content generation and item refinement phases of this myopia specific IB; and compare its content with published literature.

Methods: Myopia-specific QoL domains and items were generated from: (1) existing visual and refractive-error specific questionnaires; (2) published articles; and (3) semi-structured interviews with patients with myopia (n=39); and healthcare practitioners (clinicians, optometrists, psychologists, and researchers; n=9) recruited from the Singapore National Eye Centre between 2020 and 2021. Following thematic analysis, items were systematically refined and subsequently tested using cognitive interviews with 24 additional patients across the myopia severity spectrum.

Results: Of the 39 participants with myopia (mean ± standard deviation age: 41.4±16.3 years; 76.9% female), 16 (41.0%) were spectacle wearers, 10 (25.6%) wore contact lenses regularly, 18 (46.1%) had undergone myopic refractive surgery, and 1 (2.5%) was on atropine drops. Ten (25.6%) patients had clinically-diagnosed pathologic myopia (PM). Whilst some myopia-specific QoL issues identified have been reported previously, e.g., activity limitation and mobility, others like work anxiety, refractive surgery and PM-related issues were novel. Initially, 912 items within seven independent QoL domains were identified: Activity limitation, Concerns, Emotional, Mobility, Management Comfort, Management Convenience, Management Concern, and Work. Following refinement, 249 items were retained, of which 69 (27.7%) were novel. During cognitive interviews, 14 items underwent amendment to improve clarity.

Conclusions: Our myopia specific IB comprises 7 QoL domains and 249 items, of which over a quarter are new. It will likely provide a comprehensive assessment of the broad impact of myopia and associated long-term complications, and the patient-centred effectiveness of myopia treatment. The IB will now undergo rigorous psychometric testing to generate item calibrations for the validation of a novel myopia CAT.

ABSTRACT BODY:

Purpose: Atropine, a non-selective muscarinic receptor antagonist, is often used as a treatment for common childhood myopia, but it is unclear whether it is useful for the treatment of syndromic myopia. Here, we evaluate the effect of atropine on the regulation of eye growth in mice with a Foxg1-conditional knockout of low-density lipoprotein receptor-related protein 2 (Lrp2), which causes Donnai-Barrow syndrome characterized by extremely high myopia in humans.

Methods: Male (M) and female (F) C57BL/6 mice homozygous for both $FoxG1^{cre}$ and $Lrp2^{fl}$ (M n=9; F n=7) and littermates negative for $FoxG1^{cre}$ (M n=7; F n=4) were housed under full-spectrum 200 lux illumination (18h day/6h night). From postnatal day (P) 30 to 56, left eyes received one droplet 1% atropine sulfate daily, while right eyes received saline. Ocular biometry including axial length was measured using SD-OCT in anesthetized mice at P28, P30, P42 and P56.

Results: At P28, KO mice had significantly larger axial length (AL), compared to littermate controls (means±SEM KO M: 3269±38, Ctr M: 3166±19; KO F: 3262±50, Ctr F: 3102±30 µm; both M and F, $p<0.05$, unpaired t-tests). Atropine reduced AL growth significantly in both KO and Ctr mice (dAL, atropine minus saline treatment: KO M: -26±9; Ctr M: -42±7; KO F: -55±8; Ctr F: -62±4 µm, $p<0.01$ for treatment, MANOVA), which was mainly caused by a reduction of anterior chamber depth growth (KO M: -54±6; Ctr M: -42±6; KO F: -51±3; Ctr F: -47±3, $p<<0.0001$ for treatment, MANOVA). Lens thickness and vitreous chamber depth were not significantly affected by atropine.

Conclusions: Atropine reduced axial elongation in a mouse model lacking Lrp2, a protein which is directly implicated in controlling growth cues of the eye. This suggests that the mechanism of action of atropine is robust and that this treatment could be beneficial in humans with a syndromic cause of myopia.

ABSTRACT BODY:

Purpose: Infectious keratitis is an important cause of visual impairment worldwide, particularly in low-income communities. This study examines the social risk factors associated with polymicrobial infection and multidrug resistance, the spectrum of pathogens, and the impact on outcomes in a county hospital setting.

Methods: We performed a retrospective case-control study of patients at the Zuckerberg San Francisco General Hospital treated from 2010 to 2021 for infectious keratitis in inpatient and outpatient settings. Data on social, medical, and psychiatric risk factors were collected. Outcomes included final visual acuity, ulcer size, and time to resolution. Microbiological culture data and antibiotic sensitivities were documented. Multivariable logistic and linear regression analyses were performed.

Results: Of a total of 174 patients with infectious keratitis, 16.6% (n=29) of patients had polymicrobial infections confirmed by culture. The most common organisms in polymicrobial infections included coagulase-negative staphylococci (55%), coryneform bacteria (45%), Moraxella spp. (41%), Streptococcus viridans (21%), and Staphylococcus aureus (14%). 6.9% of all patients (12 of 174) were started on antibiotic eye drops prior to presentation to ophthalmology; of these patients, none had polymicrobial infections on culture, and there was no increased risk of multidrug-resistant organisms. Unhoused patients were 2.86 times more likely to present with a polymicrobial infection (P=0.047). HIV positivity, contact lens use, recreational drug use, smoking, and multiple corneal cultures were not associated with an increased risk of polymicrobial infection. The presence of a polymicrobial infection did not significantly impact ulcer size, final visual acuity, time to resolution, and need for tectonic keratoplasty/gluing.

Conclusions: Homelessness correlates with increased risk of polymicrobial infection, which supports initiating broad antibiotic coverage in this population. Initiation of antibiotic eye drops by a non-ophthalmology provider did not increase risk of polymicrobial infections. Polymicrobial infection did not significantly worsen clinical outcomes.

TITLE: REV-ERBα regulates retinal function and protects against retinal degeneration in experimental retinitis pigmentosa

SESSION TITLE: Neuron rescue and regeneration in the retina

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: F. Yemanyi, C. Liu, S. Huang, K. Bora, M. Maurya, A.K. Blomfield, Z. Fu, J. Akula, J. Chen, Ophthalmology, Boston Children's Hospital, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Felix Yemanyi: Commercial Relationship: Code N (No Commercial Relationship) | Chi-Hsiu Liu: Commercial Relationship: Code N (No Commercial Relationship) | Shuo Huang: Commercial Relationship: Code N (No Commercial Relationship) | Kiran Bora: Commercial Relationship: Code N (No Commercial Relationship) | Meenakshi Maurya: Commercial Relationship: Code N (No Commercial Relationship) | Alexandra Blomfield: Commercial Relationship: Code N (No Commercial Relationship) | Zhongjie Fu: Commercial Relationship: Code N (No Commercial Relationship) | James Akula: Commercial Relationship: Code N (No Commercial Relationship) | Jing Chen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: About 50% of retinitis pigmentosa (RP), an inherited retinal degenerative disease, results from mutations in >60 genes, yet gene therapy exists for only 1% of RP patients. Broad-spectrum therapies regardless of the RP-causing gene or other unknown factors are needed. REV-ERBα is a cytoprotective nuclear receptor that regulates development, metabolism, inflammation, and oxidative stress. We sought to determine whether REV-ERBα regulates retinal physiology in Rev-erbα-deficient (Rev-erbα$^{-/-}$) mice, and whether REV-ERBα activation could ameliorate photoreceptor loss in the rd10 mouse model of RP.

Methods: Localization and relative abundance of Rev-erbα were determined in C57BL/6J mice retinas via immunohistochemistry and laser capture microdissection. The role of Rev-erbα in retinal function and metabolism was analyzed in wild-type (WT) vs. Rev-erbα$^{-/-}$ mice retinas via electroretinography (ERG), Seahorse assay, microarray analysis, and RT-qPCR. The role of Rev-erbα in 661W cell (photoreceptor) metabolism following its knockdown was determined in vitro. Rd10 mice were injected intraperitoneally with REV-ERB agonist (SR9009) or vehicle from postnatal day (P) 7 to P30; retinal structure, apoptosis, and visual function were evaluated via histology, TUNEL staining, Western blotting, and scotopic ERG. Effect of SR9009 on photoreceptor cell survival and metabolism was determined in vitro.

Results: Rev-erbα localizes throughout the mouse retina and its transcripts are more enriched in the photoreceptor layer than the inner retina. Rev-erbα$^{-/-}$ mice showed markedly dampened visual function in ERG relative to WT, associated with reduced mitochondrial respiration, and without retinal thinning. Microarray expression from the Rev-erbα$^{-/-}$ vs. WT retinas also demonstrated altered expression of genes involved in metabolism, signal transduction and molecular transport. Rev-erbα knockdown in 661W cells supported its role in photoreceptor metabolism, signal transduction and molecular transport. Activation of REV-ERBα in rd10 mice significantly protected against photoreceptor thinning, apoptosis, and loss of visual function. Modulation of REV-ERBα in 661W cells corroborated its role in improving photoreceptor cell survival and metabolism.

Conclusions: These data suggest REV-ERBα regulates retinal function and metabolism, and may be activated to slow RP progression by promoting photoreceptor survival.

ABSTRACT BODY:

Purpose: To compare retinal and choroidal indices among patients with stable Vogt Koyanagi Harada (VKH) disease without macular edema and post-resolution of the macular edema.

Methods: Patients with a confirmed diagnosis of stable VKH between 2009-2017 were divided into two groups based on the absence of macular edema (Group 1) and history of resolved macular edema (Group 2). SD-OCT (Heidelberg Spectralis®) was utilized to capture 5-line High Definition (HD) raster scan with Enhanced Depth Imaging. Semi-automated segmentation tool of Heyex Software Version 6.2 was utilized to segment the retinal layers into 1) Full Retina (FR); 2) Retinal Nerve Fiber Layer (RNFL); 3) Ganglion Cell Layer (GCL); 4) Inner Plexiform Layer (IPL); 5) Inner Nuclear Layer (INL); 6) Outer Plexiform Layer (OPL); 7) Outer Nuclear Layer (ONL); 8) Photoreceptor Layer (PRL); 9) Retinal Pigment Epithelium (RPE). A manual segmentation of choroid was also performed. Similar segmentation was also performed on 22 normal eyes (11 Patients).

Results: Forty-two eyes (22 patients) with VKH disease were enrolled. 32 eyes were in Group1 and 10 eyes in Group 2. Mean of average thickness and volume for the segmented layers were compared between the two groups and between the groups and controls (Table 1 and 2). The RNFL and INL layers were significantly thicker and voluminous and ONL and PRL were thinner with lower volume in Group 2 compared to other groups. Both Study groups showed thickening and an increase in volume of OPL compared to normal eyes. The RPE layer was thickened with volumetric expansion in Group 1 but thinned out with a decrease in volume in Group 2. The mean central (1mm) choroidal thickness, average choroidal thickness, and choroidal volume were all significantly higher in group 1 compared to group 2 and controls. The choroidal indices were lower in group 2 compared to controls but failed to reach statistical significance.

Conclusions: VKH disease has a significant effect on different retinal layers despite having minimal impact on the FRT. Furthermore, it has a pronounced effect on both choroidal thickness and volume. Macular edema is a very rare complication of VKH and the significant changes in choroid of patients with macular edema underscores the role of choroidal vasculature abnormalities as underlying pathogenesis.

ABSTRACT BODY:

Purpose: The aim of this study is to clarify the developmental characteristics and transcriptome profile of Müller glial cells (MGCs) in an human induced pluripotent stem cells (hiPSCs)-derived retinal organoids (ROs), and establish protocols to enrich these cells, thus to facilitate the basic and translational study of MGC-related retinal diseases.

Methods: hiPSCs were maintained with mTeSR1, and differentiated into ROs according to our published protocol. ROs were sequentially collected to evaluate the temporal and spatial development of MGCs in ROs . Neural retina (NR) of ROs were collected and dissociated into single cells to amplify MGCs under adherent culture. Optical microscope was used to observe the morphology of the passaged MGCs, RNA-Seq and immunofluorescence staining to detect the expression of specific MGCs markers, and electronic microscopy to observe the ultrastructure of MGCs. The functional features of MGCs were also evaluated by the whole cell membrane clamp.

Results: In ROs, retinal progenitor cells (RPCs) progressively differentiated into SOX9+ Ki67- MGC precursors during differentiation day (D) 60 to D90, while mature MGCs markers CRALBP and GS did not appear until D120. Specific transcriptome profiles of MGCs were revealed by RNA-seq with ROs. Cells isolated from ROs aged older than D120 was an optimal source for the enrichment of iMGCs with high purity and expansion ability. They had typical features of human MGCs in morphological, molecular and functional aspects, and could be passaged serially at least 10 times, yielding large number of cells in a short period. The transcriptome pattern of the expanded MGCs was also revealed. MGC-related genes such as VIM, CRYAB, CD44, DBI and CCL2 were enriched in the passaged MGCs, while other retinal cell markers were down-regulated. SEM and TEM showed that MGCs had many microvillus projections, large nucleus with obvious nucleoli. The whole cell membrane clamp showed MGCs could depolarize in response to L-glutamate puff.

Conclusions: This study firstly clarified the timecourse of human MGC development in the RO model, where the MGCs could be enriched and expanded. The transcriptome pattern of MGCs was also revealed. These findings will pave the way for downstream investigation and application of MGC related retinal disorders.

ABSTRACT BODY:

Purpose: Endophthalmitis is a severe inflammatory disease following ocular surgery, or penetrating ocular trauma, associated with irreversible vision loss. Despite acknowledging the impact of biological variables along with the antibiotic susceptibility profile of the infecting agent on various diseases, its effect in human endophthalmitis is not fully elucidated. We therefore studied the impact of age and sex on cytokine production in patients with culture proven bacterial endophthalmitis

Methods: In this cross-sectional study, a total of 93 patients were stratified into three groups according to their age: A (0-30 years), B (31-54 years) and C (>55 years) and 20 patients with non-infectious retinal disorders as controls were included. Expression of IL-6, IL-10, IL-1β, IL-8, IL-17, TNF-α and LCN-2 were analysed in the vitreous fluids of these patients by magnetic bead based multiplex immunoassay (MILLIPLEX, Merck) and correlated with the demographics and its antibiotic susceptibility data.

Results: Patients in Group B, aged between 31-54 years exhibited higher IL-6, TNF-α, IL-17. On the contrary, group A showed higher level of IL-1β ($p < 0.05$), IL-10 ($p = 0.04$) and IL-8. LCN-2 was found be higher ($p = 0.01$) in the older age group (group C) only. Although IL-1β, IL-6 and IL-10 levels were comparatively higher in female patients, only IL-8 was found to be statistically significant ($p = 0.009$). Notably, patients infected with antibiotic resistant pathogens exhibited higher IL-1β, IL-8 and TNF-α ($p < 0.05$) compared to antibiotic-susceptible group indicating higher inflammatory response irrespective of age and sex.

Conclusions: Our study suggests that immunosenescence and drug resistant have a pivotal role in the incidence of bacterial endophthalmitis. Further work would focus on correlating these variables with systemic status and clinical outcome. The results of this study would help form strategies to differentially engage signalling pathways in the design of immunotherapeutic approaches for better prognosis in aging and drug-resistant endophthalmitis.

ABSTRACT BODY:

Purpose: To assess the performance of a machine learning-based algorithm in estimating axial length (AL) based on refraction and demographic data.

Methods: A machine learning-based algorithm (AL estimator) was trained using age, sex, spherical refractive error, astigmatism and corneal radius of curvature data derived from 4403 participants (aged 6-22 years) of Irish and Korean epidemiological studies. AL estimator performance was tested using right eye AL data from participants involved in myopia treatment trials (three Irish, one Australian). Bland-Altman statistics and linear regression were used to compare estimated and actual AL. Receiver operator characteristic analysis was used to assess the ability of the AL estimator to identify children with a high AL (≥26mm) and fast progressors (≥0.3mm axial elongation in 12 months), compared to spherical equivalent (SE).

Results: The AL estimator was tested on 507 participants (n=354, 69.8% Irish), of whom 437 (86%) had 12-month follow-up data [mean age: 11.3 years, range: 6-17; female: 304 (60%); mean AL: 24.8mm, range: 22.1-28.9]. Using baseline visit data, the mean difference in AL (actual – estimated) was -0.07mm (95% limits of agreement [LOA]: -0.97, 0.83; absolute mean error=0.36; R^2=0.80). When assessing 12-month AL progression, the mean difference between actual and estimated AL change was -0.001mm (LOA: -0.31, 0.31; absolute mean error=0.12; R^2=0.57). The AL estimator performed worse for Australian compared to Irish participants (respective mean errors: AL estimate=-0.16 vs -0.03mm, p=0.003; AL change=-0.04 vs 0.02, p=0.001). Compared to SE alone, the AL estimator was better at identifying eyes with an AL ≥26mm (area under the curve [AUC]: 0.97 vs 0.83) and eyes that progressed ≥0.3mm over 12 months (AUC: 0.90 vs 0.85; Figure 1).

Conclusions: In this cohort of myopic children, the machine learning model was able to provide a reasonably accurate estimation of actual AL. Importantly, the AL estimator demonstrated high diagnostic performance in identifying individuals with long AL and those who exhibited excessive axial elongation. Where biometry is unavailable, the AL estimator may represent a useful clinical tool for identifying children at risk of axial growth-related complications of myopia.

ABSTRACT BODY:

Purpose: The purpose of these experiments was to test and optimize uptake of mesenchymal stem cells (MSC) exosomes by human retinal pigment epithelium (ARPE-19) cell line utilizing the natural uptake mechanisms of exosomes by ARPE-19 cells.

Methods: We used human mesenchymal stem cells (MSC) exosomes labeled using ExoGlow (red-fluorescent dye) or human embryonic kidney 293 cells (HEK-293) exosomes X-Pack GFP-loaded (green-fluorescent protein). The concentrations of exosomes and the incubation period of transfected ARPE-19 were varied to determine which conditions allow for the highest transfection rate. ARPE-19 were labeled using an Oregon Green Phalloidin or CellTrace calcein red/orange AM and were imaged using an Olympus FV3000 confocal and ImageXpress Micro XL high-content microscopes. Assays were done in 96-well plates with four replicates, and plates were scanned on the ImageXpress Micro XL high-content screening system (Molecular Devices) at UC Davis IDDRC Biological Analysis Core. Additional images were obtained using a confocal microscope Olympus FV3000.

Results: Results indicate that ARPE-19 cells were able to uptake exosomes from two different heterologous sources, human mesenchymal stem cells (MSC) and human embryonic kidney 293 (HEK-293) cells. The highest transfection rate was achieved with 0.20 ug of exosomes added to 1x10^4 ARPE-19 cells/well, after a 5-hour incubation period. Imaging was best within the first 30 hours after exosomes were added to ARPE-19 cells. Signal diminished significantly after 30 hours. A higher quantity of exosomes did not equate to a higher transfection rate.

Conclusions: Exosomes are mediators of long-distance communication among different tissue and cells in the body. Exosomes carry cargo (proteins, mRNA, and microRNAs) to communicate messages to target tissues or cells. Our lab has previously identified a set of microRNAs (miRNAs) dysregulated in DR patients' ocular fluids, that may play a role in diabetic retinopathy (DR) pathogenesis. Our results strongly suggest that exosomes were quickly taken up by naïve recipient ARPE-19 cells by natural mechanisms. Our long-term goal is to develop miRNA-based therapies for DR using exosomes as natural carriers of miRNAs.

ABSTRACT BODY:

Purpose: We are exploring pathways for autofluorescent granule (AFG) resolution by retinal pigment epithelium (RPE) cells to identify new therapeutic targets.

Methods: We are using an experimental model of RPE monolayers in culture where there is accumulation of AFGs similar to lipofuscin in vivo, after a single pulse of photoreceptor outer segments (POS). We previously observed that lysosomal dysfunction results in incomplete POS degradation and AFG accumulation. Here we are exploring gene therapy using adeno-associated viruses (AAV) and/or pharmacological approaches to target pathways that promote lysosomal function and biogenesis leading to AFGs reduced formation or its resolution, accessed by a variety of light and electron microscopical techniques, flow cytometry and western blot.

Results: We show that AAV-mediated over-expression of transcription factor EB (TFEB) reduces the load of AFG accumulation in RPE monolayers. Use of pharmacological inhibitors of mTOR leading to activation of TFEB, such as rapamycin, as well as other mTORC1 inhibitors, also led to a decrease in POS-dependent AFG accumulation in RPE.

Conclusions: These results suggest that viral or pharmacological approaches acting on the mTOR/TFEB axis may be beneficial in early/intermediate cases of AMD to delay progression of the disease.

ABSTRACT BODY:

Purpose: We investigated the consistency of the subjective ocular refraction between Binocular Simultaneous Looking-in Type (Chronos, Topcon) and real space.

Methods: Twenty-eight healthy volunteers (21.2 ± 1.4 years old) participated in this study. The objective ocular refraction in all subjects was achieved by a conventional autorefractometer that measures eyes one by one (KR-800, Topcon Corp.) and Chronos. The subjects were undergone four times of visual acuity tests in four conditions randomly: performing the subjective refraction test with the Chronos value using the Chronos (Condition i); performing the test with the Chronos value using the real space (TCU-600, Fuji Kogaku Co., Ltd.) (Condition ii); performing the test with the KR-800 value using the Chronos (Condition iii); and performing the test with the KR-800 value using the real space (Condition iv). In both the real space and Chronos, the subjective refraction test distance was set at 5.0 m. The best-corrected subjective ocular refraction was defined as 0.18 logMAR. The subjective ocular refraction was converted to spherical equivalent (SE). Furthermore, astigmatism was transformed into a power vector. Then, the SE and astigmatism were compared between Chronos (merged Conditions i and ii) and real space (merged Conditions iii and iv).

Results: The SE was significantly and negatively greater in Chronos (−3.68 ± 2.83 D) than in the real space (−3.37 ± 2.85 D) ($P < 0.001$). No significant difference in J0 and J45 was observed between Chronos (J0, 0.28 ± 0.42 D; J45, −0.01 ± 0.18 D) and real space (J0, 0.29 ± 0.42 D; J45, −0.04 ± 0.16 D).

Conclusions: Chronos measured with an error of less than 0.50 D compared with the real space. We considered that Chronos is valuable for screening refractive errors and visual acuity in eye checkups.

SUBMITTER (NAME ONLY): Ester Reina-Torres

TITLE: The relationship between pressure-dependent changes in outflow facility and dimensional changes in the anterior segment during perfusion of enucleated mouse eyes

SESSION TITLE: Aqueous humor dynamics and Trabecular Meshwork

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Reina-Torres, J. van Batenburg-Sherwood, D.R. Overby, Bioengineering, Imperial College London, London, London, UNITED KINGDOM|

Commercial Relationships Disclosure: Ester Reina-Torres: Commercial Relationship: Code N (No Commercial Relationship) | Joseph van Batenburg-Sherwood: Commercial Relationship: Code N (No Commercial Relationship) | Darryl Overby: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Outflow facility (C) is typically determined by perfusing eyes over multiple pressure steps while measuring the flow rate (Q) into the eye and intraocular pressure (P), with C given by C=Q/P . In enucleated mouse eyes perfused via the anterior chamber (AC), C tends to increase with P. Yet in other species, C reportedly declines with P. In mice, the P-dependent rise in C may be related to the phenomenon of AC deepening that occurs when AC pressure exceeds that in the posterior chamber, causing retrodisplacement of the iris and lens that applies traction on the outflow pathway. The aim of this project was to assess whether dimensional changes associated with AC deepening are correlated with P-dependent changes in C in enucleated mouse eyes.

Methods: To visualise dimensional changes in the AC, enucleated eyes were imaged under a stereomicroscope with the anterior-posterior axis within the focal plane (15x, 1fpm). We examined two mouse strains: C57BL/6J (n=7) and FVB/N (n=5). We measured Q into the AC as P was increased stepwise from 4.5 to 21mmHg using iPerfusion. The last image from each step was used to estimate AC depth (ACD) and pupillary diameter (PD). We examined correlations between C, P, ACD and PD by linear regression (Bonferroni correction).

Results: P-dependent changes in C were more pronounced in C57BL/6J mice relative to FVB/N (400 vs 61% relative increase in C from first to last step). ACD was tightly correlated with P in both strains (R^2=0.8, R^2=0.7; p<0.001), while the relationship between PD and P was negligible (R^2=0.05, R^2=0.1). In C57BL/6J, changes in C were correlated with both ACD and PD (R^2=0.7, R^2=0.3; p<0.001). However, in FVB/N mice, changes in C were correlated with only ACD (R^2=0.5; p<0.001) and not PD (R^2=0.01; p=0.4).

Conclusions: These results reveal that in response to increasing AC pressure, there is significant deformation of the anterior segment in enucleated mouse eyes, including retrodisplacement of the lens and, to a lesser extent, expansion of the iris and widening of the pupil. These results suggest that the iris and lens both may apply traction to the outflow pathway to increase C, but the lens displacement appears to have a stronger effect on facility. Mouse strain differences, which exhibit different P-dependent changes on C despite similar dimensional changes, is worth further investigation.

Commercial Relationships Disclosure: Pirro Hysi: Commercial Relationship: Code N (No Commercial Relationship) | Mark Simcoe: Commercial Relationship: Code N (No Commercial Relationship) | Anthony Khawaja: Commercial Relationship(s);Code C (Consultant/Contractor):Abbvie, Aerie, Google Health, Novartis, Reichert, Santen, Thea | Christopher Hammond: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Aggregation of single-marker information into polygenic risk scores (PRS) is a popular glaucoma risk-prediction approach, but its implementation and utility is impeded by the variability of disease genetic architectures in ethnically diverse populations. The purpose of this study was to evaluate the factors that affect the performance of PRS built on genome-wide association study (GWAS) results from cohorts of predominantly European ancestry in populations of African and admixed genetic heritage.

Methods: Variable selection using Elastic Net models were conducted on markers previously reported as associated with glaucoma in a large GWAS among subjects participating in the UK Biobank cohort. The predictive models built on the selected markers in ethnically homogeneous groups were tested both in UK Biobank subjects (through a 80:20 holdout cross-validation) and in a fully independent cohort of European, African-Caribbean and “other” glaucoma cases and controls (576:287, 298:194 and 124:79, respectively) genotyped on a Human Omni Express Exome 8v1-2 BeadChip (Illumina) and imputed on 1000 Genomes haplotypes.

Results: Our optimized Elastic Net models effectively built sufficiently sparse pan-ancestral models that performed reasonably well, even in populations of non-European descent, including UK participants of African-Caribbean (Area Under the ROC Curve, AUC=0.65-0.71). These models performed better in the UK Biobank than in the smaller case-control cohorts (AUC difference of 0.05-0.10 in subjects of African and European ancestry), suggesting that the predictive performance of the PRS is in part affected by genotyping coverage and quality. Other factors likely affecting performance include similarity between training and testing datasets, levels of genetic admixture, and models shrinkage and scaling of parameters.

Conclusions: It may be possible to adapt the current European-driven information for effective PRS-based prediction in multiethnic populations. Future predictive PRS-based models will benefit from more ethnicity-specific GWAS information, but also from finer mapping of risk-associated genetic loci.

ABSTRACT BODY:

Purpose: To study changes in the birefringent properties of human cornea across healthy, thin corneas (< 500 µm), asymmetric and clinical KC.

Methods: In this study, the birefringent properties of 40 eyes from 20 subjects divided across 4 groups (healthy, thin, asymmetric KC and clinical KC corneas) were measured using our custom-built ultrahigh-resolution PS-OCT. Groups-1, 2 and 4 consisted of 10 eyes from 5 subjects each. Group-3 consisted of 5 eyes that showed normal topographical features, while their fellow eye showed classical KC features were put in Group-4 along with eyes having bilateral clinical KC. To achieve a near limbal-to-limbal scan field with uniform signal strength throughout the cornea a conical scan setup was incorporated in the PS-OCT design. Phase retardation (PR) enface maps from the posterior surface of the cornea were generated to obtain a succinct representation of the corneal fibril distribution.

Results: Figure-1 shows the PR enface maps of representative cases from each group and their corresponding axial curvatures (AC) maps. Columns 1 and 2 represent maps from a healthy cornea and a thin cornea. Columns 3 and 4 are from the same subject, with OD being the KC eye and OS being the contralateral eye having normal topography. While column 5 constitute the clinical KC eye. PR enface maps of healthy corneas showed the preferential arrangement of collagen fibrils with least retardation in apex and anchoring fibrils in the periphery. Thin corneas mimicked healthy eyes in collagen fibrillar arrangement. Asymmetric KC eyes followed common definitions of sub-clinical and forme fruste KC, but PR maps from PS-OCT confirmed a near-healthy collagen fibrillar distribution in these eyes. Clinical KC corneas showed large disruptions in collagen fibrillar arrangement at all annular zones ($p<0.05$) with complete loss of peripheral anchoring fibrils.

Conclusions: Distinctive changes in the structural arrangement of collagen fibrillar distribution were observed in KC, thin corneas, and healthy eyes. Spatial variations (zonal analyses) in polarization-sensitive information can assist in effectively minimizing the susceptive, erroneous classifications between healthy and diseased corneas in a clinical setting.

ABSTRACT BODY:

Purpose: Möbius syndrome (MBS) is a rare disease with congenital limitation of ocular abduction and facial weakness, and frequently accompanied by multiple congenital malformations, including orofacial malformations, limb defects and musculoskeletal etc. The study aimed to investigate the clinical and genetic characteristics of Chinese MBS cohort.

Methods: Inclusion criteria were congenital, nonprogressive facial weakness and abduction deficit with full vertical motility and/or hypoplasia of CN6 and CN7 (MRI). All participants underwent standardized ophthalmologic examination, general physical examination, MRI of cranial nerves and WES.

Results: The study enrolled 17 unrelated patients (8 males, 9 females). Nobody had a family history, even if three patients were one of the twins. MRI revealed all patients had the hypoplasia of CN6 and CN7. 65% of patients (n=11, 11/17) showed bilateral facial weakness and the bilateral hypoplasia of CN7. 35% of patients (n=6，6/17) showed unilateral facial weakness (all were left), corresponding MRI revealed 3 of the patients were hypoplasia of left CN7，while the other three cases showed the hypoplasia of bilateral CN7. 82% of patients（n=14，14/17）showed bilateral abduction deficit and the bilateral hypoplasia of CN6. 12% of patients（n=2，2/17）showed unilateral abduction deficit (both were left), corresponding MRI revealed the hypoplasia of CN6, one was left and the other was bilateral. One patient (6%, 1/17) showed left facial weakness and full ocular motility, however, MRI revealed the hypoplasia of left CN7 and right CN6. In our cohort, 15 patients (88%, 15/17) also accompanied by other multiple congenital malformations, including tongue disfunction and abnormal development (n=13), dysarthria (n=7), high arched palate (n=6), limb defects (n=4) and poor listening (n=2). No causative mutations were found in REV3L, PLXND1 and other known pathogenic genes of CCDDs.

Conclusions: The genetic contributors to our Chinese MBS cohort were elusive. In our MBS cohort, facial weakness and abduction defects, as well as the hypoplasia of CN6 and CN7, were often bilateral involvement, and in cases with unilateral involvement, the left seemed to be more easily involved. Some atypical MBS patients showed facial weakness and full ocular motility, however, MRI revealed the hypoplasia of both CN6 and CN7, so we propose using MRI as an effective examination to obtain accurate clinical diagnosis.

ABSTRACT BODY:

Purpose: To explore parents' experiences and preferences with dichoptic action video gaming or patching as amblyopia treatment. In addition, information needs from parents to support patient participation in clinical decision making was investigated.To explore parents' experiences and preferences with dichoptic action video gaming or patching as amblyopia treatment. In addition, information needs from parents to support patient participation in clinical decision making was investigated.

Methods: In a prospective Randomized Clinical Trial (NCT 03767985) newly diagnosed children with amblyopia were recruited. Visual Acuity (VA) was measured using the crowded tumbling E-chart. After informed consent they were randomized to patching therapy: 2 hrs/day; compliance was monitored electronically using the Occlusion Dose Monitor; or dichoptic video game therapy using VR goggles: 1 hr/wk under direct supervision. Following completion, a qualitative study using semi-structured interviews was carried out. The parents of children who fulfilled their 6 weeks follow-up measurement were eligible for participation. The interviews were audio-recorded and transcribed verbatim. The data were analyzed thematically using Braun and Clarke's approach.

Results: So far, parents of 10 children have been interviewed. Three themes have emerged from the data in both the patching and gaming group: 1) misunderstanding the diagnosis of amblyopia and its treatment, 2) the need to establish a routine and 3) the influence of the child's age in explaining the need for treatment and child's participation with treatment. In the gaming group, parents reported the feeling of not being responsible for carrying out treatment themselves as a positive element. In the patching group parents experienced the treatment as flexible and easy to understand.

Conclusions: Despite the differences, parents described the efficiency and the effect of treatment as the most important aspects in choosing the sort of amblyopia treatment. However, they preferred to leave the choice of treatment to the professional.

ABSTRACT BODY:

Purpose: Ocular coloboma arises from genetic or environmental perturbations which inhibit optic fissure fusion in early eye development. Despite high genetic heterogeneity, 70-85% of patients remain molecularly undiagnosed. We report BMPR1B as a novel causative gene using cross-species comparative meta-analysis.

Methods: Evolutionary conserved differentially expressed genes were identified through in silico analysis of mouse and zebrafish datasets over time points covering optic fissure closure. In situ hybridization, morpholino bmpr1b gene knockdown and human mRNA rescue experiments were performed in zebrafish to confirm spatiotemporal gene expression and phenotype. We interrogated the UK 100,000 Genomes Project for putative pathogenic variants within a cohort of genetically undiagnosed MAC (microphthalmia/anophthalmia/coloboma) probands.

Results: Nine conserved DEGs between zebrafish and mouse were identified. Expression was shown in the optic fissure, periocular mesenchyme cells or ciliary marginal zone. Knockdown of bmpr1b revealed a coloboma and microphthalmia phenotype. Novel pathogenic variants in BMPR1B were identified in 4 unrelated MAC families. We show BMPR1B rescued the knockdown phenotype, however mRNA carrying the patient-specific variants failed. confirming the loss of function impact of the variants on BMPR1B.

Conclusions: We demonstrate the utility of cross-species meta-analysis to identify novel coloboma disease-causing genes, including BMPR1B. There is potential to increase the diagnostic yield for new and unsolved patients, whilst adding to our understanding of the genetic basis of optic fissure morphogenesis.

TITLE: Comparison of four commercially available antiglaucoma drugs on the corneal healing process in the ex vivo eye irritation test (EVEIT) model

SESSION TITLE: New drugs, mechanisms of action and ocular toxicology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Chauchat, H. Rebika, C. Guerin, Horus Pharma, FRANCE|C. Panfil, N. Schrage, Aachen Centre Of Technology Transfer In Ophthalmology (ACTO), GERMANY|H. Rebika, Centre Hospitalier Universitaire de Clermont-Ferrand, Clermont-Ferrand, FRANCE|

Commercial Relationships Disclosure: Laure Chauchat: Commercial Relationship(s);Code E (Employment):Horus Pharma | Claudia Panfil: Commercial Relationship(s);Code F (Financial Support):Horus Pharma | Hayette Rebika: Commercial Relationship(s);Code E (Employment):Horus Pharma | Norbert Schrage: Commercial Relationship(s);Code F (Financial Support):Horus Pharma | Camille Guerin: Commercial Relationship(s);Code E (Employment):Horus Pharma

ABSTRACT BODY:

Purpose: Corneal epithelial toxicity and effect on healing process have been already attributed to preservatives or some excipients. The goal of this study was to evaluate the corneal toxicity in high-frequency-application of 4 different latanoprost eyedrops formulated with or without preservatives, and containing more or less excipients with known effects as Macrogolglycerol hydroxystearate 40 (MGHS 40).

Methods: 4 different Latanoprost 0.005% formulations were tested: A. preservative free (PF); B. preserved with benzalkonium chloride (BAC) 0.02%; C. PF with MGHS 40 at 2.5% and D. PF with MGHS 40 at 5%. As references, negative control (-) PF Hyaluronic acid 0.18% eyedrops and positive control (+) BAC 0.02% were used. Eyedrops were applied over three days, six times daily on rabbit corneas cultured on an artificial anterior chamber the Ex Vivo Eye Irritation Test (EVEIT) system. Initially, four corneal abrasions (2.1–3.8 mm2) were induced. All defects were monitored by fluorescein stains and photographs. Corneal integrity (fluorescein permeability) and vitality (lactate and glucose quantification) were controlled during experiments.

Results: Total epithelial healing was observed for test products A, C and (-) at day 3. For test product D, a delayed healing of the initial lesions, not completed on day 3, was noted. As expected, B and (+) show increased and equally pronounced epithelial damage over the observation period. Additionally, the corneal barrier function was significantly affected for B and (+); Also, a higher permeability value of fluorescein was reported for D compared to A, C and (-). Daily quantification of the metabolic activity of each cornea showed an increase in lactate metabolism for B, D and (+). Glucose levels remained in physiological range for all tested items.

Conclusions: Delayed healing process and metabolic stress symptoms were highlighted for test products B and D containing notably BAC 0.02% and MGHS 40 at 5% respectively. BAC is already well known as toxic for ocular surface, and these results confirm EVEIT as an accurate and reproductible ex vivo model. Besides, MGHS 40, excipient with known effects, seems also to induce a concentration dependent corneal toxicity. Therefore, the use of this preservative and this excipient at high concentration in patients with epithelial defects should be a concern for corneal surface.

ABSTRACT BODY:

Purpose: Giant cell arteritis (GCA) is a potentially sight threatening disease. Although it is associated with polymyalgia rheumatica (PMR), visual loss is not common in PMR. We performed an observational, cross-sectional study to investigate if retinal oxygen saturation and retinal vessel calibers in GCA- and PMR differed similarly from controls.

Methods: Retinal oximetry was performed with Oxymap T1 (Oxymap, Reykjavik, Iceland) on 20 GCA-patients (n=38 eyes), 18 PMR-patients (n=33 eyes) and 12 controls (n=20 eyes) at Odense University Hospital, Odense, Denmark. Age < 50 years, poor image quality (<6.0) and eyes with neurodegenerative-, severe retinal-, or optic nerve disease were excluded. Images were analyzed with Oxymap Analyzer software 2.5.0 (Oxymap, Reykjavik, Iceland). Cluster Robust Standard Error was used in a linear mixed model regression analysis adjusted for age and sex, to determine the principal outcomes consisting of retinal arteriolar- and venular oxygen saturation, retinal arterio-venular difference and retinal vessel diameters.

Results: Median age (interquartile range) for GCA, PMR and controls were 69.0 years (66.5-76.5), 69.0 years (67.0-72.0) and 75.5 years (71.5-81.0), respectively. According to the age- and sex-adjusted linear mixed model regression, the retinal arteriolar diameters were wider for GCA as compared to controls and PMR as compared to controls (13.4 pixels vs. 12.4 pixels, p=0.02 and 13.5 pixels vs. 12.4 pixels, p=0.04, respectively). There were no differences with respect to retinal venular diameters (17.4 pixels vs. 16.7 pixels, p=0.1 and 17.3 pixels vs. 16.7 pixels, p=0.2, respectively), retinal arteriolar oxygen saturation (92.9% vs. 91.4%, p=0.2, and 93.4% vs. 91.4%, p=0.1, respectively), retinal venular oxygen saturation (53.8% vs. 55.0%, p=0.7, and 52.8% vs. 55.0%, p=0.5, respectively) or retinal arterio-venular difference (39.1% vs. 36.3%, p=0.3, and 40.6% vs. 36.3%, p=0.1, respectively).

Conclusions: Compared to controls, patients with GCA and PMR both had wider retinal arterioles but unaffected retinal venular diameter and retinal metabolism. While this indicates a similar effect on the retinal vascular structure, prospective studies are needed to determine, if these parameters can be used to predict the clinical outcome.

ABSTRACT BODY:

Purpose: Studies have shown that diurnal rhythms of axial length (AL) are altered by imposed defocus, suggesting that small short-term changes in AL may be used to predict the efficacy of myopia control treatments. The goal of this study is to evaluate the influence of different types of myopia control spectacle lenses (MCL) on the diurnal AL changes of young adults.

Methods: AL measurements were obtained for 6 young adults (emmetropic or contact lens users) that were asked to wear spectacles with an MCL in the dominant eye having a plano central region and imposed peripheral defocus, and a plano control lens in the non-dominant eye. The peripheral defocus was induced with three different types of MCL: Type A (Miyosmart®, Hoya®, Malaysia), Type B (Stellest®, Essilor®, Malaysia) and Type C (a noncommercial prototype, IOT®, Spain). AL measurements were taken over 4 consecutive days. Baseline data without test glasses were collected in day 1. Each following day a new spectacle with an MCL was fitted and tested, in a randomize order. A Lenstar Myopia biometer (Haag Streit AG) was used to register 5 AL measurements within 2 hour intervals each day. Differences between control and treatment eyes for each MCL type and differences between the baseline and each treatment day for the dominant eye (eye with the treatment) were analyzed.

Results: Statistically significant differences were found between the control and treatment eye for MCLs B and C after 2 hours of use of the lenses, showing a significant increase of AL in the treatment eye. Non statistical differences between eyes were found for MCL A at any time while using the lens. When comparing AL change of the treatment eye between the baseline day and the treatment day, statistically significant differences were found for the 3 tested MCL types, showing that all the MCL treatments produce an increase of AL (figure 1). Minimal daily changes in AL were found during the baseline (control) day, showing variations lower than 0.01mm across all time intervals.

Conclusions: Myopia control spectacle lenses influence diurnal rhythms of AL in young adult human, producing a short-term small increase of AL that varies in intensity and time interval for each of the MCS. Additional studies with higher sample size and longer follow-up periods are necessary to confirm that short-term variations of diurnal rhythms can be used as predictor of myopia control efficacy.

De Baere, Department of Biomolecular Medicine & Center for Medical Genetics, Ghent University & Ghent University Hospital, Ghent, BELGIUM|

Commercial Relationships Disclosure: Víctor López-Soriano: Commercial Relationship: Code N (No Commercial Relationship) | Alfredo Dueñas Rey: Commercial Relationship: Code N (No Commercial Relationship) | Stijn Van de Sompele: Commercial Relationship: Code N (No Commercial Relationship) | Frauke Coppieters: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Webster: Commercial Relationship: Code N (No Commercial Relationship) | Miriam Bauwens: Commercial Relationship: Code N (No Commercial Relationship) | Elfride De Baere: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Whole genome sequencing revealed an increasing number of pathogenic non-coding variants in inherited retinal diseases (IRD), with a majority of deep-intronic variants and only a few regulatory variants. Here we focus on the role of ultraconserved non-coding elements (UCNEs), defined as genomic regions >200 bp characterized by at least 95% human-chicken conservation. Regions under strong selective pressure are more likely to be involved in the cis-regulation of neighboring genes, mainly during development. However, most of these regions have not yet been functionally annotated, and their association with disease remains largely unknown. Therefore, we set out to assess a potential cis-regulatory role for active UCNEs in human retina using an integrated multi-omics analysis.

Methods: To predict active UCNEs, we integrated publicly available and published transcriptomic (bulk and scRNA-seq) and epigenomic (chromatin accessibility using ATAC-seq and DNase and histone modifications for active enhancers markers such as H3K27ac) datasets derived from developing and adult human retina. In order to characterize the genes within putative UCNE-associated genomic regulatory blocks we made a selection of genes with retinal expression. Whole genome sequencing (WGS) data from ~3,331 probands of the eye cohort of the UK 100,000 Genome Project Genomics England was mined.

Results: Interrogation of multi-omics human retina-derived data revealed a total of 1,349 retina-active UCNEs. Interestingly, 40 genes under putative UCNE control are linked to an eye disease phenotype. To assess their mutational load and their possible contribution to missing heritability in IRD, WGS data from the UK 100k Genome Project eye cohort was queried for sequence variants (SNVs) and structural variants (SVs) within UCNEs. A total of 79 SNVs and 10 SVs related to genes implicated in IRD or other eye phenotypes were identified. None of these are found in public genomic databases.

Conclusions: We identified 1,349 retina-active UCNEs potentially acting as CREs and representing an understudied target of non-coding variants that may explain missing heritability in IRD. Deciphering retinal UCNEs and their cis-regulatory landscapes contribute to functional genome annotations in the retina and to the non-coding morbid genome of IRD. Ultimately, they may represent novel targets for treatment.

TITLE: Automatic Visual Acuity Measurement by Using a Calibration-free Eye Tracking System
SESSION TITLE: Visual Function: perception, adaptation, spatial, visual acuity and binocular vision
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: N. Murata, H. Toda, H. Ubukata, T. Sonobe, A. Hasegawa, Department of Orthoptics and Visual Sciences, Niigata University of Health and Welfare, Niigata, Niigata, JAPAN|
Commercial Relationships Disclosure: Noriaki Murata: Commercial Relationship: Code N (No Commercial Relationship) | Haruo Toda: Commercial Relationship: Code N (No Commercial Relationship) | Hokuto Ubukata: Commercial Relationship: Code N (No Commercial Relationship) | Takuma Sonobe: Commercial Relationship: Code N (No Commercial Relationship) | Aino Hasegawa: Commercial Relationship: Code N (No Commercial Relationship)
ABSTRACT BODY:
Purpose: The calibration-free eye tracker is equipped with a face recognition function that allows the examinee to start eye tracking when they sit on the device. We attempted to measure visual acuity automatically by combining this device with vertical stripe targets and investigated visual axis retention time at each spatial frequency of a visual stimulus.
Methods: A total of 44 eyes from 22 healthy participants (mean age: 20.2 years ± 0.7 years) were included in this study. The mean spherical equivalent of the right and left eyes were −4.6 D ± 2.2 D (range: −10.25 D to −1.5 D) and −4.5 D ± 2.2 D (range: −10.1 D to -1.5 D), respectively. Participants with visual field defects detected by a Humphrey field analyzer (24-2 Swedish Interactive Threshold Algorithm Fast Strategy) or with abnormal eye positions were excluded. Participants were seated in front of a calibration-free eye tracker (EMR ACTUS, Nac Image Technology, Tokyo, Japan) with an integrated monitor and freely observed a vertical stripe stimulus. Three types of stimuli (8.4, 12.9, and 25.8 cycles/degree [c/d]) were presented three times each. Areas of Interest (AOI) were set on the stripes, and the percentage of visual axis retention time in the AOI during the presentation of the stimuli was measured. A one-way repeated analysis of variance was used to compare the percentage of visual retention time for each stimulus. P values of less than 0.05 were considered significant.
Results: Among the 44 eyes, one (2.2%) was excluded from the analysis because of measurement error. The mean retention time per stimuli of the right eye were 79.9% ± 22.2%, 72.3% ± 27.9%, and 58.2% ± 30.7% at 8.4 c/d, 12.9 c/d, and 25.8 c/d, respectively, which were all statistically significantly different ($F = 12.9$, $p < 0.01$). In the left eye, the mean retention time per stimuli were 79.5 ± 22.7%, 77.4% ± 24.8%, and 61.0% ± 28.5% at 8.4 c/d, 12.9 c/d, and 25.8 c/d, respectively, which were all statistically significantly different ($F = 9.1$, $p < 0.01$). In both eyes, the percentage of visual axis retention time decreased with increasing spatial frequency.
Conclusions: The correct responses declined with the increasing spatial frequency even with the stripes displayed on the eye tracker. Further studies with a greater number of cases are needed to examine the correlation between LogMAR visual acuity and refractive error.

ABSTRACT BODY:

Purpose: To investigate the long-term changes in macular microvasculature and explore a reliable retinal biomarker of Fabry Disease (FD).

Methods: Retrospective-prospective study of 26 eyes with FD (13 patients, 9 treated, 4 untreated) followed up to 48 months (mean 24, range 8-48). OCT Angiography (OCT-A) images (2.9x2.9 mm) were obtained using Heidelberg Spectralis II (Heidelberg, Germany). All OCT-A scans were analyzed using EA-Tool (Version 1.0), which was coded in MATLAB (The MathWorks, Inc., R2017b). Macular Vessel Density (MVD) was measured in three layers: Superficial Vascular Plexus (SVP), Intermediate Capillary Plexus (ICP), and Deep Capillary Plexus (DCP) in circular sectors (c1, c2, and c3). The Foveal Avascular Zone (FAZ) area (mm^2), horizontal and vertical diameters were manually measured in full-thickness scan, SVP, ICP and DCP.

Results: MVD decreased over time in SVP and ICP in c2 and c3 and in all sectors in DCP in FD patients ($p<0.04$). MVD reduction was predominantly seen in treated FD patients. FAZ full-thickness scan area and horizontal diameters increased at follow up in FD patients compared to baseline ($p<0.03$). FAZ at follow-up was larger in full-thickness scans and ICP in untreated vs. treated FD patients ($p<0.03$). Correlation analysis showed a moderate negative correlation between MVD in the inner most circle of SVP and DCP and FAZ in treated FD patients ($|r|>-0.6$). Extended results of MVD and FAZ follow up in all and treated vs. untreated patients are presented in Fig. 1 und Fig. 2.

Conclusions: This is the first long term follow-up OCT-A study in FD patients. MVD decreased in peripheral circle and deeper layers in follow-up in FD patients. Meanwhile FAZ increased at follow-up in the FD group. These changes over time are most likely linked to the vascular remodeling during the course of the disease. The reduction of MVD was predominantly seen in treated FD patients. This could be a result of enzymatic replacement therapy and could be potentially used as a reliable biomarker for monitoring the treatment of the disease. A baseline examination of MVD und FAZ before treatment initiation is meaningful. Larger studies are needed to establish the use of MVD und FAZ as biomarkers for treatment monitoring.

TITLE: The hierarchical response of human corneal collagen to controlled inflation

SESSION TITLE: Keratoconus and corneal biomechanics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Bell, S.R. Morgan, E. Koudouna, S. Hayes, K.M. Meek, Cardiff University, Cardiff, Cardiff, UNITED KINGDOM|

Commercial Relationships Disclosure: James Bell: Commercial Relationship: Code N (No Commercial Relationship) | Siân Morgan: Commercial Relationship: Code N (No Commercial Relationship) | Elena Koudouna: Commercial Relationship: Code N (No Commercial Relationship) | Sally Hayes: Commercial Relationship: Code N (No Commercial Relationship) | Keith Meek: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To elucidate the hierarchical deformation mechanisms of human corneal collagen under controlled inflation of physiological and pathological magnitudes.

Methods: 6 human donor corneas with scleral rim were mounted onto a bespoke sealed cell, which was connected via two pressure regulators and an expansion vessel to a source of compressed nitrogen. The cell included a window transparent to X-rays and was connected to translation and rotation stages inside beamline I22 at the Diamond Light Source synchrotron, UK. Images were acquired naso-temporally across the cornea from limbus to limbus at intraocular pressures of 5.5 mmHg, 17.5 mmHg and 40 mmHg. These increments were chosen for comparison with previous static results in the literature and to mimic the normal physiological state and ocular hypertension.

Results: The inflation apparatus was able to maintain pressure to an accuracy better than 0.1 mmHg. Features corresponding to collagen fibril diameter, spacing, D-period and orientation as well as tropocollagen spacing and orientation were measured simultaneously. Preliminary analysis revealed a radial distribution of strain (manifested as a change in D-period) across the cornea, which was accentuated in the outer periphery and limbus. In general, the interfibrillar spacing in the periphery and limbus (where collagen fibrils are arranged circumferentially) was found to increase with pressure.

Conclusions: The trends in D-period strain are indicative of bulging under increased pressure, which is pronounced at the limbus and the outer periphery. This agrees with the general consensus that the outer periphery and limbus act as a buffer zone, which takes up most of the strain under changes in intraocular pressure, and thus minimises changes in focussing power of the cornea. Further in-depth analysis of this data will allow us to calculate the supramolecular twist (which gives rise to a spring-like stretch in collagen fibrils) and examine in more detail the hierarchical response of corneal collagen to changes in intraocular pressures.

ABSTRACT BODY:

Purpose: To determine auto fluorescent multispectral imaging (AFMI) signatures in a human retinal pigment epithelium (RPE) cell culture system under normal conditions and under glycolytic stress.

Methods: Human RPE cells (h1RPE7 cell line) were treated with a glycolytic inhibitor, iodoacetic acid (IAA) at 1 μM, 5 μM, and 10 μM concentrations for 24 hours. Cell viability was assessed using a fluorescent live/dead assay and dihydroethidium (DHE) was used to quantify cellular reactive oxygen species (ROS). Imaging was initially performed with routine confocal microscopy. ROS detection was then performed in the absence of exogenous fluorescent probes using a novel autofluorescence multispectral imaging (AFMI) microscopy method. A total of 33 spectral channels spanning specific excitation (345-505 nm) and emission (414-675 nm) wavelength ranges were used.

Results: A dose-dependent cell death occurred after 24 hours of exposure to IAA, peaking at 80% cell death at the 10 μM concentration. ROS production was significantly increased in cells under glycolytic stress ($p < 0.001$). There were highly significant changes in the patterns of spectral signals between treated and control groups using the AFMI microscopy ($p < 0.001$).

Conclusions: These results show that ROS can be detected using non-invasive multispectral imaging in retinal cells. This imaging technique may be adapted to in vivo use and has potential for the detection and monitoring of clinically relevant retinal disease states such as macular degeneration and glaucoma.

ABSTRACT BODY:

Purpose: Photoreceptor cell degeneration, inflammation, and oxidative stress are commonly associated with retinitis pigmentosa (RP), a retinal degenerative disease. Glucagon-like peptide-1 (GLP-1) is an endogenous neuropeptide synthesized by the retina that has exhibited neuroprotective effects in diabetic retinopathy. Therefore, this work aimed to evaluate a possible neuroprotective effect of a novel GLP-1 eye drop formulation (FNP120) in a mouse model of RP.

Methods: Rd10 mice were used as a model of RP. Topical ocular treatment with GLP-1 or vehicle was administered to rd10 mice from postnatal day 16 to P25 twice a day as eye drops in both eyes (5µL/eye). Three GLP-1 concentrations were tested (1, 2, and 4 mg/mL). Optomotor test and scotopic electroretinography (ERG) were used to evaluate mice retinal function after the treatment. Secondly, retinal cryostat cross-sections were performed to quantify the number of photoreceptor rows throughout the retina. Retinal morphology was analyzed using immunohistochemistry.

Results: Retinal function improved after 10-days of GLP-1 topical ocular administration. Rd10 mice treated with GLP-1 eye drops at a concentration of 2 mg/mL displayed significantly higher scotopic a- and b-wave amplitudes compared to vehicle-treated mice. Optomotor test also showed higher visual acuity found in 2 mg/mL treated rd10 mice. These functional findings correlated with a higher number of photoreceptor rows found in GLP-1 treated rd10 mice retinas. Also, these photoreceptors showed slightly better-preserved morphology and longer outer segments. GLP-1 administered at a concentration of 1 or 4 mg/mL did not achieve significant protective effects.

Conclusions: Topical administration of GLP-1 at 2 mg/mL was able to preserve retinal function loss and photoreceptor cells surviving in the retina of rd10 mice. These data support the view that GLP-1 may emerge as a new therapeutic strategy against retinal neurodegenerative diseases.

TITLE: Imaging of corneas after deep anterior lamellar keratoplasty using polarization sensitive optical coherence tomography

SESSION TITLE: Refractive and non-refractive corneal surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Sinha Roy, R.P. Patil, R. Narasimhan, Y. Patel, A. Pisharody, P. Khamar, R. Shetty, Narayana Nethralaya Foundation, Bangalore, INDIA|

Commercial Relationships Disclosure: Abhijit Sinha Roy: Commercial Relationship: Code N (No Commercial Relationship) | Rahul Patil: Commercial Relationship: Code N (No Commercial Relationship) | Raghav Narasimhan: Commercial Relationship: Code N (No Commercial Relationship) | Yash Patel: Commercial Relationship: Code N (No Commercial Relationship) | Anchana Pisharody: Commercial Relationship: Code N (No Commercial Relationship) | Pooja Khamar: Commercial Relationship: Code N (No Commercial Relationship) | Rohit Shetty: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate the polarizing properties of corneas following deep anterior lamellar keratoplasty.

Methods: In this study, 20 patients were imaged using our custom-built ultrahigh resolution polarization sensitive optical coherence tomography (PS-OCT). A near limbal-to-limbal imaging field with uniform signal strength throughout the cornea was achieved using a conical scan setup. Cross sections (B-Scans) and enface maps of the cornea at various locations and depths were derived from the polarization sensitive information to observe localized changes in phase retardation (PR) and depolarization.

Results: PS-OCT provided an improved image contrast (Figure 1b) that can potentially assist in better diagnosis compared to the conventional intensity image (Figure 1a). Since tissue birefringence originated from alignment of collagen fibrils in the stroma, PR information showed strong birefringence at the graft-host interface (see Figure), indicating the microstructural alteration of collagen in those regions. Further, scar morphology and rupturing can also be precisely studied with using PR as a surrogate for wound healing.

Conclusions: PS-OCT can enable visualization of the alteration of tissue properties following corneal transplant and may reveal unique structural changes prior to graft failure.

Commercial Relationships Disclosure: Fanny HENRIOUX: Commercial Relationship: Code N (No Commercial Relationship) | Valentin NAVEL: Commercial Relationship: Code N (No Commercial Relationship) | Corinne Belville: Commercial Relationship: Code N (No Commercial Relationship) | Frédéric CHIAMBARETTA: Commercial Relationship: Code N (No Commercial Relationship) | Loic Blanchon: Commercial Relationship: Code N (No Commercial Relationship) | Vincent SAPIN: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In dry eye syndrome, hyperosmolarity is one of the main factors inducing ocular surface inflammation. The objective of this work is to decipher the cellular and molecular cascades in cornea and conjunctiva, which are involved in triggering inflammation, by focusing particularly on the nuclear factor of activated T-cells 5 (NFAT5) and its implication.

Methods: HCE (Human Corneal Epithelial) and WKD (Wong-Kilbourne derivative of Chang conjunctival cell) were cultured in normal medium or hyperosmolar medium (addition of 70 mM or 90 mM NaCl). Quantitative reverse transcription (RT-qPCR) and Western-Blotting assays were performed to analyze NFAT5 expression in corneal and conjunctival cells regarding medium (normal or hyperosmolar) and exposure times (6h, 12h and 24h). The activation of NFAT5 signaling pathway by hyperosmolarity cells was tested using Luciferase NFAT5 reporter assay system. Furthermore, cytokines expression analysis were performed by RT-qPCR and Multiplex assay, respectively at 24h and 48h, in both cells. Finally, the implication of NFAT5 in inflammation (cytokines production and release) was confirmed using the transfection of siRNA NFAT5.

Results: Our result demonstrate the NFAT5 induction and activation in both HCE and WKD in hyperosmolar context. Furthermore, among the inflammatory messages induced in hyperosmolar stress conditions, MCP1 levels were significantly reduced after inhibition of NFAT5 in WKD cells, and reduction of IL1 beta, TNF alpha and MCP1 levels in HCE cells.

Conclusions: These in vitro results highlight the major role of NFAT5 in the hyperosmolarity pro-inflammatory consequences but looks to be cell type specific between conjunctival and corneal epithelial cells.

ABSTRACT BODY:

Purpose: To assess the longitudinal change in macular thickness and visual function in highly myopic eyes with and without myopic traction maculopathy (MTM).

Methods: 109 eyes of 65 highly myopic patients were enrolled from the Myopic and Pathologic Eyes in Singapore (MyoPES) cohort and followed for at least 12 months. Axial length (AL) and logMAR best-corrected visual acuity (BCVA) were measured. Swept-source optical coherence tomography (SS-OCT) was performed, and images were evaluated for MTM and central subfield retinal thickness (CRT). Macular sensitivity (MS) was measured with MP-3 microperimetry.

Results: At baseline, mean age was 57.5±13.5 years and mean AL was 29.3±2.7mm and 20 eyes (18.4%) had MTM. On average, compared to eyes without MTM, eyes with MTM had significantly longer AL (30.8±1.7mm vs. 29.1±2.8mm, p=0.01), greater CRT (319±74um vs. 242±42um, p<0.001) and lower MS (19.8±4.1dB vs. 22.6±5.3dB, p=0.03). BCVA did not differ (0.33±0.39 vs. 0.24±0.29, p=0.22). At 1 year, MTM progressed in 5 eyes (25%) and resolved in 1 eye (5%). In eyes with progression, CRT increased from 302±57um to 359±83um (p=0.14). MS at 1 year in eyes with (20.2±4.1dB) and without MTM (21.8±5.5dB) did not significantly differ from baseline values (p=0.60 and 0.16, respectively).

Conclusions: Although visual acuity did not differ, visual function as measured by microperimetry was significantly worse in highly myopic eyes with MTM than those without at baseline. Over the span of 1 year, no significant change in macular sensitivity was observed in eyes despite MTM progression.

ABSTRACT BODY:

Purpose: Fluid dynamics in neovascular age-related macular degeneration (nAMD) might negatively affect visual acuity (VA) during anti-VEGF treatment. The aim of this study was to investigate the differential effects of fluid fluctuations, fluid persistence and fluid volumes on VA using artificial intelligence algorithms (AI) (Vienna Fluid Monitor, RetInSight, Vienna, Austria) over a time period of three years in a real-world cohort.

Methods: Real-world data (OCT and electronic medical records) from patients with treatment-naive nAMD of the Fight for Retinal Blindness (FRB) Zürich database were extracted. Patients were included if ≥24 months follow up was available and if treated with Aflibercept, Bevacizumab or Ranibizumab. OCT scans were analyzed using AI to quantify intraretinal fluid (IRF), subretinal fluid (SRF) and pigment epithelial detachment (PED) in the central 1mm, adjacent 1-3mm and 3-6mm rings. Each persistent fluid parameter was defined as presence of either SRF, IRF or PED on ≥60% of the available OCT scans of each time window, respectively. The standard deviations of SRF, IRF and PED fluctuations were computed and sorted into quartiles. The effect of fluid parameters on change of VA after a loading dose was calculated using univariate mixed effect models.

Results: A total of 172 consecutive eyes from 135 treatment-naïve nAMD patients were included in the statistical analysis. Eyes with more frequent anti-VEGF treatments showed an increased change of VA from baseline to year 1 (p=0.040, estimate: -0.01 logMAR/injection). By year 2 and 3, eyes with the greatest IRF fluctuations (Q4) showed a worse VA in comparison to eyes with the least IRF fluctuations (Q1) (p=0.019, 0.11 logMAR, and p=0.012, 0.16 logMAR). Eyes with higher IRF volumes in the central area had a worse VA after 3 years of follow up. (p=0.031, estimate: 0.01 logMAR/nL). A correlation of the number of treatments and SRF dynamics in comparison to IRF dynamics could be identified (Figure 1).

Conclusions: Greater IRF fluctuations and greater IRF volumes are associated with worse VA after three years of follow up, while an increased number of injections improved VA gain in the first year. Fluid dynamics can be quantified using AI for real-time measurements and result in improved patient management in clinical practice.

TITLE: Inhibition of cGAS-STING by JQ1 alleviates oxidative stress-induced retina inflammation and degeneration

SESSION TITLE: Cell biology of retinal diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Gong, M. Zou, Q. ke, R. Qi, X. zhu, W. liu, D.W. Li, Zhongshan Ophthalmic Center, Sun Yat-Sen University, Guangzhou, Guangdong, CHINA|

Commercial Relationships Disclosure: Lili Gong: Commercial Relationship: Code N (No Commercial Relationship) | Ming Zou: Commercial Relationship: Code N (No Commercial Relationship) | qin ke: Commercial Relationship: Code N (No Commercial Relationship) | Ruili Qi: Commercial Relationship: Code N (No Commercial Relationship) | xingfei zhu: Commercial Relationship: Code N (No Commercial Relationship) | wei liu: Commercial Relationship: Code N (No Commercial Relationship) | David Li: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: cGAS-STING pathway is a key cytosolic DNA sensor signaling in innate immunity. Activation of cGAS-STING has been previously detected in retinal pigment epithelium (RPE) of Geographic atrophy (GA) patients, potentially contributes to pathogenesis of AMD [(1)]. We have recently shown that cGAS and STING are dose-dependently upregulated in RPE and retina of an experimental GA-like mouse model [(2)]. In the current study, we are aimed to identify drugs that can inhibits cGAS-STING signaling and prevents oxidative stress-induced RPE and retina injury.

Methods: X-ray irradiation (8 GY) was used to induce cytosolic DNA leakage in ARPE-19 cells. Immunofluorescence-based high-content analysis was used to screen an epigenetic library which contains 288 FDA-approved small molecules. Western blot and RT-PCR analysis confirmed the inhibitory effects of the identified molecules on cGAS and STING expression in ARPE and photoreceptor cell line 661W. Fundus photography, RPE flat mount and immunohistochemistry analysis determined the effects of the identified molecule on sodium iodate (SI) (35mg/kg)-induced RPE and retina degeneration.

Results: X-ray irradiation lead to obvious DNA damage and accumulation of cytosolic DNA. Drug screening identified BET inhibitor JQ1 exerts significant suppressive effect on cytosolic DNA release ($P < 0.05$). The RNA and proteins level of cGAS and STING were upregulated after irradiation or H_2O_2 treatment, whereas JQ1 treatment significantly represses such upregulation as well as the expression of downstream NFκB signaling ($P < 0.01$). Application of JQ1 (50mg/kg) after SI injection alleviates oxidative stress-induced RPE and retina inflammation and degeneration.

Conclusions: Together, we identified that JQ1 suppresses cGAS and STING expression in cells and in mouse retina and RPE upon oxidative stress. This study may provide new treatment strategy for GA.

ABSTRACT BODY:

Purpose: The perceived brightness of different visible light sources can be compared with photometric units based on the standardized luminosity curves (300-780nm range). As reported previously (PNAS 111(50), pp. E5445-E5454 (2014)), near-infrared (NIR) radiation can cause isomerization of visual pigments by one- or two-photon absorption. The perceived color of the stimulus is red in the case of one-photon vision (1PV) or corresponds to half of the short-pulsed laser wavelength for the two-photon vision (2PV) mechanism. Since no luminosity curves for NIR range, comparison of such sources with photometric units is impossible. This study aims to provide an initial data for the 2PV spectral sensitivity curve (SSC).

Methods: We measured the scotopic visibility thresholds at fovea for 4 healthy dark-adapted subjects (2 males, 2 females; 27-43 y/o) between 750-1075nm. Up to 930nm, the total visibility threshold corresponds only to 1PV mechanism. For the 810-930nm, subjects distinguished 2 thresholds: the loss of half of the wavelength hue (2PV threshold) and total visibility (1PV) threshold. Starting from 950nm, only 2PV mechanism caused the visual sensation. The stimulus was a 0.5 deg diameter flickering circle projected in the retina by scanners. Two tunable pulsed light sources: OPO (750-990nm, F_{rep}=76MHz, τ_p=204fs) and fiber laser (872-1075nm, F_{rep}=51.5MHz, τ_p=205±9fs) were employed for psychophysical tests. The study complied with the Declaration of Helsinki and was approved by the Ethics Committee of the Collegium Medicum, NCU.

Results: The 1PV thresholds agreed with the previous works (JOSA 37(7), pp. 546-554 (1947)). Within the 810-930nm range, a relatively high standard deviation of the 2PV thresholds was observed, as finding the disappearance of half of the wavelength hue is a relatively difficult task. 2PV thresholds slightly differ for OPO and fiber laser, which is explainable by differences in pulse durations and repetition rates. For ~1040nm, the 2PV threshold values agreed to the previous authors' results.

Conclusions: The 2PV sensitivity increased with wavelength of about 1 order of magnitude (810-1075nm range). Starting from 1010 nm, the shape of the obtained 2PV SSC differs from the wavelength-doubled scotopic luminosity curve for 1PV, corrected by the eye media transmittance. The maximum of 2PV SSC was not found. The results allowed us to obtain the first approximation of the 2PV SCC shape up to 1075nm.

ABSTRACT BODY:

Purpose: ABCA4-retinopathy is the most common monogenic inherited retinal disease but current prognostic capability is limited by genetic heterogeneity with more than 1000 possible variants, for which combinations due to recessive inheritance result in a number of genotypes of at least n(n+1) / 2. Full-field electroretinography (ERG) is used clinically in the diagnosis and prognosis of ABCA4-retinopathy by measuring the activity of retinal cell populations in response to light stimuli. This study investigates whether regression analysis of genetic variants with ERG data can be used to derive coefficients relating to severity from a uniquely large single-centre patient cohort.

Methods: In this retrospective cohort study, multiple ISCEV-standard ERG parameters were labelled (DA 10, LA 3, and LA 30Hz ERGs) from 495 patients with confirmed ABCA4-retinopathy and compound heterozygous or homozygous pathogenic ABCA4 variants. ERG trace labelling was automated through custom peak-finding algorithms on additionally bandpass-filtered traces and labelled values normalised for ElasticNet regression analysis against the ABCA4 variant background of the cohort. ElasticNet is an extended regression method to deal with a large number of potentially correlated features.

Results: The analysis generated beta coefficients associated with individual variants. Within the 50 most frequent variants in the cohort, higher coefficient values were observed to be associated with previously identified milder variants including c.5882G>A p.(G1961E), c.5603A>T p.(N1868I) and c.4253+43G>A and lower coefficients with nonsense mutations and the severe intronic variant c.5461-10T>C. Many variants had intermediate coefficients consistent with partial function of the resultant protein. The resultant models had an average r^2 value of 0.726, and results were consistent for the derived coefficients across the measured ERG features DA 10 a-wave and b-wave, LA 3 a-wave and b-wave and LA 30Hz peak amplitude (avg. r=0825. (range 0.724-0.931)).

Conclusions: This analysis provides a novel quantification of the impact of specific ABCA4 variants on retinal function in a data-driven regression analysis based on clinical ERG recordings; the findings were consistent with previously described genotype-phenotype correlations.

ABSTRACT BODY:

Purpose: Humans can perceive pulsed near-infrared light as a visible about halved wavelength by two-photon absorption in photoreceptors (PNAS 111(50) (2014) pp. E5445-E5454). The contrast sensitivity function (CSF) of two-photon vision is not yet known. This study aimed to provide the first data to compare CSF for one- and two-photon vision.

Methods: A custom-built optical system employing 1040 nm and 520 nm pulsed laser beams (200 fs, 76 MHz) was used to measure two-photon and one-photon CSF, respectively, of 3 healthy volunteers (2 women, 1 man, age 24-43). The stimuli were tumbling E of 5 spatial frequencies (3, 6, 8, 15, 18 cyc/deg) formed by scanning laser beam. The background was obtained by Maxwellian view illumination of the retina with white LED. A contrast threshold was determined in a four-alternative forced-choice procedure: by finding the minimum stimulus brightness for which the subject was able to state the letter orientation in 4 of 5 trials correctly. The study was approved by the Ethics Committee of the Collegium Medicum, NCU.

Results: The CSFs were calculated as the reciprocal of Weber contrast. Since the background was one-photon in both cases and there is a lack of luminosity function for two-photon vision, the two-photon CSF was normalized to equalize sensitivities for the maximum value of one-photon CSF. Both curves show a decline from 3 cyc/deg to 18 cyc/deg. However, the two-photon CSF has a slightly broader range than the one-photon CSF – the differences between these ranges were 21, 7, 5 for the individual subjects.

Conclusions: CSF for two-photon vision was shown the first time. The obtained result may suggest that the two-photon CSF has a broader range than CSF of normal vision.

ABSTRACT BODY:

Purpose: Corneal defects measured by slit lamp/OCT incorporate several qualitative diagnostic readouts that include fluorescence which helps visualize the extent of epithelial debridement and raster scan which captures corneal inflammation. However, these multi-readout instrumentations have limited quantification capabilities. Herein, we have designed methodology to quantitatively assess the extent of corneal defect in a mouse model of alkali-induced stromal injury

Methods: Mice with deep alkali-induced stromal injury (penetrating lamellar keratoplasty, 2 mm wide and 50 µm depth, followed by 0.75 N sodium hydroxide for 30 s) were imaged using a slit lamp (AIA12 5 S /5 S L, Appasamy associates, India) and OCT (Avanti Widefield OCT, Optovue, Inc., USA) to obtain fluorescence images (blue filter) and corneal raster scans, respectively. A custom Matlab script (R2020b, The MathWorks Inc., USA) was generated for each readout and employed to extract quantitative measurements from the regions of interest by thresholding the raw images.

Results: The region of epithelial defect captured via the blue filter through slit lamp examination was quantified to have an area of 2.6mm^2 for mice at day 0 post alkali burn. The extent of inflammation from OCT data was quantified through hyper-reflectivity regions of the raster scan. The %reflectivity for healthy cornea was found to be <15% & mean pixel intensity <13. Thus, the progress of re-epithelization of the corneal wound along with the degree of inflammation was quantified over a study period of 4 weeks. Consequently, as the scar regenerated, the area of the wound and the hyper-reflectivity gradually reduced to 0 & <15% respectively, indicative of corneal wound healing.

Conclusions: Our results demonstrate a reliable quantitative methodology to visualize progression of corneal wound healing through standard slit lamp/OCT instrumentations for any animal model.

TITLE: Deep learning based segmentation of retinal fluids using optical coherence tomography (OCT) data

SESSION TITLE: Machine Learning: Segmentation and Classification

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Schmid, Digital Pathology, Carl Zeiss Meditec AG Oberkochen, Oberkochen, Baden-Württemberg, GERMANY|K. Patel, Center of Application and Research in India, Carl Zeiss India Pvt Ltd, Bangalore, Karnataka, INDIA|

Commercial Relationships Disclosure: Alexander Schmid: Commercial Relationship(s);Code E (Employment):Carl Zeiss Meditec, Inc. | Krunalkumar Ramanbhai Patel: Commercial Relationship(s);Code E (Employment):Carl Zeiss Meditec, Inc.

ABSTRACT BODY:

Purpose: OCT, a non-invasive imaging modality, plays a central role in ophthalmology. Efficient and precise segmentation of various abnormalities seen in OCT imaging can help detect and monitor disease progression, thus advising and supporting effective treatment decisions. For this purpose, we propose a new deep learning-based segmentation pipeline for retinal fluids in OCT.

Methods: The underlaying data is formed by an OCT B-scan dataset containing 1540 images and masks, split in 1291 training and 249 validation cases, annotated for three different retinal fluids: intraretinal fluid (IRF), subretinal fluid (SRF) and pigmented epithelial detachment (PED), captured by a CIRRUS™ HD-OCT 4000 (ZEISS, Dublin, CA). The performance of the model is also evaluated using the RETOUCH dataset, containing 70 SD-OCT volumes from three different OCT vendors. The segmentation model is based on a squeeze-and-excitation architecture including transfer learning strategies with partial freezing variants utilizing trained weights from ImageNet. The whole implementation is done using Tensorflow-Keras and the model is optimized using Tversky loss. The quantitative evaluation of the model prediction is performed using the Dice coefficient and the MeanIoU.

Results: According to the efficient interplay of transfer learning techniques across ImageNet and the OCT data, an overall validation Dice coefficient of 66.3 and MeanIoU of 69.6 percentage points could be achieved by training all fluid categories simultaneously. Figure 1 a) reveals the reached metric values for each individual label. In addition, the RETOUCH examinations resulted in the mentioned numbers in Figure 1 b).

Conclusions: This work constitutes that an individual adaptation of the network and the integration of domain-specific knowledge of other modalities through special transfer learning techniques enables semantic features to be learned even with minimal, complex data sets. Overall, adaptions and transfer learning scenarios of this network could increase the segmentation performance by 15.3 % measured by the Dice coefficient, compared to a standard segmentation implementation (nnUnet).

ABSTRACT BODY:

Purpose: Our environment is continuously enriched in pollutants that contribute to increase the prevalence of diseases or even the emergence of new pathologies. The effects of endocrine disruptors (EDs) on the eye remain unclear. Bisphenol A (BPA) is an ED widely used in the production of polycarbonate plastics leading to organ dysfunction and/or cancers. Fluoride, used to prevent tooth decay by its addition to municipal water supplies and dental products is now considered as ED. The aim of this study is to assess the effect of BPA and Fluoride on RPE cells.

Methods: ARPE-19 and hiPSC-derived RPE (iRPE) cells were exposed to different concentrations of BPA or Sodium Fluoride (NaF) during 1 or 7 days. Mitochondrial activity (MA) and transepithelial resistance (TER) were evaluated at 1 and 7 days on both cell lines. Cell viability and death were evaluated by flow cytometry on ARPE cells following 1 day of exposure. Immunofluorescence staining were used to evaluated iRPE cells phenotype following 1 day of exposure.

Results: Exposure during 24 hours of BPA at 0.5mM and NaF at 1.5mM significantly reduced MA by 90% and 55% respectively on ARPE cells. While BPA induced the loss of viability and the cell death, NaF had no effect on ARPE cells viability/death, as observed by cytometry. In iRPE cells exposed during 1 day, BPA at 0.5mM and 1mM decreased by 50% and 100% the MA and induced 100% of decrease of TER. At 0.1mM, BPA significantly slight increased MA without changes for TER. Following 7 days of exposure, 0.1mM of BPA slightly decreased MA and significantly decreased TER (50%). NaF exposure during 1 day had no effect on MA of iRPE cells even at 2 mM, but led to a dose-dependent increase of TER. After 7 days, 2mM NaF still not had effect on MA but decreased TER (20%). Immunostaining of iRPE cells shown a decrease of RPE65 intensity and an increase of vimentin intensity following 1 day of BPA exposure. NaF did not change the iRPE cells phenotype even at high dose.

Conclusions: Our results show that BPA induces a decrease of viability, cells death and loss of RPE phenotype, whom are increased with longer exposure. NaF induces a reduction of cell viability and cell death only at high dose. In conclusion, chronic exposure with ED may contribute to reduce function of RPE and promote the prevalence of neurodegenerative diseases.

ABSTRACT BODY:

Purpose: Childhood cataract significantly impact the quality of life of children. Evidence from epidemiological studies are required in planning yet, there remains a dearth in data from sub-Saharan African countries including Ghana. The present study investigates the prevalence of childhood cataract and its associated factors among a pediatric population at a tertiary health facility in Ghana.

Methods: We conducted a retrospective chart review on 263 pediatric cataract cases examined (from January 2019 to December 2020) at the pediatric ophthalmology department of the Komfo Anokye Teaching Hospital, Kumasi, Ghana. Patient clinical data including sociodemographic, signs and symptoms, primary diagnosis and associated ocular complications were gathered and analyzed using Statistical Package and Service Solution (SPSS). Chi-square and regression statistics were used to summarize data at a significance of $p<0.05$.

Results: The prevalence of childhood cataract was 4.25% (263/6,188). The proportionate distribution of cataracts was congenital (39.5%), traumatic (33.1%) and developmental (26.6%). Over half (51.7%) of the subjects had unilateral cataract. The major complications of childhood cataracts were strabismus (5.70%), nystagmus (3.0%) and retinal detachment (1.90%). Older age (2-12 years, OR = 0.27, $p<0.001$;> 12 years, OR = 0.12, $p<0.001$) was significantly associated with reduced odds of congenital cataract. Similarly, increasing age (2-12 years, OR = 12.59, $p<0.001$; >12 years, OR = 7.57, $p = 0.004$) and female sex (OR = 0.58, $p = 0.038$) was significantly associated with decreased odds of traumatic cataracts. Conversely, older age (2-12 years, OR = 11.02, $p<0.001$; >12 years, OR = 26.57, $p<0.001$) and female sex (OR = 2.27, $p = 0.008$) were significantly associated with increased odds of developmental cataracts.

Conclusions: Over four in every hundred children had childhood cataract. This high prevalence is a major challenge, which warrants the institution and implementation of vision screening and eye health education programs to improve early detection and safety among the pediatric population.

ABSTRACT BODY:

Purpose: To evaluate the management of neovascular age-related macular degeneration (nAMD), factors that predict receiving treatment, and the relationship between treatment frequency and visual outcomes in routine clinical practice.

Methods: This retrospective analysis assessed electronic medical records from the Vestrum Health Retina Database for treatment-naïve eyes newly diagnosed with nAMD from January 1, 2014 that had ≥1 year of follow-up. Cumulative incidence of eyes receiving treatment was evaluated using the Kaplan–Meier (KM) method, and factors that predicted receiving treatment through one year were evaluated by logistic regression.

Results: Of 90,681 eyes included in the analysis, the percentage of eyes not receiving treatment was 23%, 16%, 15% and 13% at diagnosis and years 1, 2 and 3, respectively. The mean baseline visual acuity (VA) of eyes not treated and treated were 39 and 52 letters, respectively. Higher odds ratio (OR≥1.50, [95% CI]) of receiving treatment was found for eyes with baseline VA 20/40-20/100 vs ≥20/40 (1.52 [1.44, 1.61]); and for eyes with macular edema (3.26 [3.11, 3.42]), subretinal fluid (4.97 [4.75, 5.20]), or sub-retinal pigment epithelium fluid (1.64 [1.56, 1.72]). Lower OR (OR£0.50) for receiving treatment was found for patients with simultaneous bilateral diagnosis (vs. unilateral diagnosis, 0.32 [0.31, 0.34]);and for eyes with baseline VA<20/400 vs. ≥20/40 (0.29 [0.27, 0.30]). When treated within 1 month from diagnosis, eyes gained a mean (SD) of 5 (3) letters from baseline at 6 months, which was maintained at year 1. If treatment initiation was delayed 6 months from diagnosis, eyes gained a mean (SD) of 1 (0) letter at year 1. Mean BCVA change from baseline at year 1 was −1.21, 0.58, 4.31 and 5.6 letters in eyes treated with 1-3, 4-6, 7-9 and >9 injections, respectively. Within the subgroup of eyes that received 7-9 and >9 injections, those with baseline VA<20/400, gained 20.3 and 27.2 letters, respectively.

Conclusions: Almost one quarter of eyes with nAMD did not receive treatment at diagnosis. Simultaneous bilateral nAMD diagnosis and poor baseline VA (<20/400) were primary factors associated with not receiving anti-VEGF treatment. Greater VA gains were observed with prompt treatment and increasing number of injections, with eyes with poor baseline vision (<20/400) gaining a mean of ≥4 lines with ≥7 injections from baseline at year 1.

ABSTRACT BODY:

Purpose: Drug delivery to the eye still is a challenge. One way currently investigated is administration of drug-loaded nanoparticles (NP) that are able to penetrate ocular barriers. The purpose of this study is to check to what extent NPs made from pseudo-proteins loaded with the fluorescent dye Nile are able to penetrate ocular tissues and are taken up by cultured cells.

Methods: Biodegradable NPs of various types were prepared by nanoprecipitation of a pseudo-protein composed of L-leucine, 1,6-hexanediol and sebacic acid (8L6). Arginine-based cationic polyester amides 8R6 and comb-like polyester amides containing lateral PEG-2000 chains along with 8L6 anchoring fragments in the backbones were used to construct positively charged and PEGylated NPs. The NPs were loaded with fluorescein Nile red (NR) as a fluorescent probe. Suspensions of the NPs were given to cultivated pig microglial cells and retinal pigment epithelial (RPE) cells as well as topically or retrobulbary on eyes of C57BL/6 mice. Penetration of NPs into the eyes was checked by fluorescence analysis.

Results: Two different kinds of NP (TK-1 and TK-4) were prepared, loaded with Nile Red, and their physicochemical properties were characterised. Size of TK-1 was 128-131 nm, and of TK-4 164-190 nm. NP were stable over weeks and did not release the lipophilic dye. After topical administration, NP penetrated into the cornea, and we also found them in the sclera, as demonstrated by fluorescence and electron microscopy. Fluorescence was found in the cornea and the sclera 1 day and 3 days after both topical and retrobulbar administration. We also detected fluorescence in the isolated retina and lens, indicating that NP did reach the inner parts of the eyes. Fluorescence did vanish after 3-4 days, most probably due to wash-out. In cell culture, NP were taken up only by a small portion of RPE cells and apparently not at all by microglial cells. When BSA was omitted in the growth medium, microglial cells clearly took up NP.

Conclusions: The results show that the NPs made of pseudoproteins penetrate ocular tissues after topical or retrobulbar administration. This raises hope that the NPs may be useful carriers of therapeutic agents for ocular delivery. Future research should be directed at a longer presence of the NP inside the eye. For substances that should act inside the cells, NP should be modified in a way that they are taken up specifically by the target cells.

TITLE: ATP's Potential Role as a Hydrotrope Thereby Preventing Intralenticular Protein Aggregation

SESSION TITLE: Lens proteins: normal and pathogenic biochemistry

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J.V. Greiner, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|T. Glonek, Clinical Eye Research of Boston, Winchester, Massachusetts, UNITED STATES|J.V. Greiner, Ophthalmology, Harvard Medical School, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Jack Greiner: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Glonek: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: This study provides evidence for the role of intralenticular adenosine triphosphate (ATP) as an endogenous hydrotrope for prevention of Protein Aggregation (PA) known to be an etiology of age-related cataractogenesis.

Methods: Calculation of ATP concentration and spectral line widths (indicators of atomic mobility) were determined in both H_2O and 98% D_2O buffers in intact (ex vivo) lens (N=12) among multiple species using a 200 MHz NMR spectrometer for phosphorus-31 detection. The line widths of each resonance multiplet of the three phosphorus atoms of ATP were determined during a time-course [baseline (0 hr) to 3 hr].

Results: Intralenticular concentration of ATP [2.4 ±0.15 millimolar (mM)] far exceeds the micromolar (μM) amounts required for intracellular metabolism. The field strength of the spectrometer permitted resolution of the spectral line width in the α-group phosphate (11.6 ±0.5 Hz) relative to the γ-group phosphate (18.8 ±0.5 Hz) of ATP ($P < 0.01$). When incubated in D_2O buffer, the line widths of the phosphates progressively narrow with time such that after 3 hr the line width of the α-group phosphate was 9.7 ±0.5 Hz and the γ-group phosphate was 8.9 ±0.5 Hz which indicates the direct interaction of the hydrogen atoms of water with the phosphate groups. With time, the γ-group phosphate line width narrows significantly more than the α-group phosphate line width ($P < 0.01$) indicating that the γ-group phosphate is interacting with the interstitial water, whereas the α-group is closer to the protein surface and less free to interact.

.

Conclusions: 1. The large mM concentration of ATP in the metabolically quiescent lens is 3 orders of magnitude greater than what is believed to be required for all the known functions of ATP (metabolic or otherwise) combined. 2. Incubating in control H_2O buffer, the different signal widths of the α-and γ-phosphate signals indicate that the ATP is acting as a hydrotrope with the adenine moiety bound to and shielding the protein surfaces and the γ-phosphate extending into the interstitial water between neighboring α-crystallin protein molecules. 3. With incubation in D_2O buffer, the γ-group phosphate line width narrows significantly more than observed in the α-group phosphate. This data supports the hypothesis that ATP functions as a hydrotrope preventing cataractogensis secondary to PA. Prevention of PA is essential for maintaining lens transparency.

ABSTRACT BODY:

Purpose: Febuxostat (FBX), which is a therapeutic agent for hyperuricemia, has an inhibitory effect on xanthine oxidase. Some previous studies reported that the inhibition of uric acid production by FBX may prevent diabetic nephropathy due to reduced oxidase stress and an anti-inflammatory effect. However, it remains unclear whether FBX has a beneficial effect on diabetic retinopathy. We investigated the effect of the long-term administration of FBX on impaired retinal blood flow regulation in response to flicker stimulation, which is an index of retinal neurovascular coupling, in type 2 diabetic mice.

Methods: Six-week-old db/db mice were randomly divided into an untreated group that received placebo (n=6) and a treated group, which received FBX (n=6). The longitudinal changes in retinal blood flow responses to systemic hyperoxia and flicker stimulation were evaluated every 2 weeks in diabetic db/db mice from 8 to 14 weeks of age. Retinal blood flow was assessed using laser speckle flowgraphy.

Results: Resting retinal blood flow was steady and comparable between the two groups throughout the study. In db/db mice treated with FBX, the blood flow responses to systemic hyperoxia and flicker stimulation were significantly restored from 10 weeks of age in comparison to diabetic mice in the untreated group ($P<0.05$, $P<0.001$), and these beneficial effects were observed until 14 weeks of age.

Conclusions: Our results suggest that the long-term administration of FBX can improve the impaired regulation of retinal blood flow in response to systemic hyperoxia and flicker stimulation in type 2 diabetic mice.

ABSTRACT BODY:

Purpose: To develop a reliable in vitro protocol for generating 3D retinal organoids (ROs) from cynomolgus macaque iPSCs using a highly scalable multi-well plate (wp) format. This aims to inform knowledge of mammalian retinal differentiation and reduce the pre-clinical use of animal models.

Methods: Two iPSC lines from cynomolgus macaque (Macaca fascicularis) were exposed to several known and novel human retinal differentiation protocols, using early BMP4 addition, an IGF1 based media, or RPE conditioned media (-CM), in a 96-wp format. The differentiation protocols were applied using a timeline adjusted for the shorter macaque gestation, relative to human.

iPSC-derived ROs were characterised morphologically and molecularly throughout differentiation, for protein and gene expression of known neural-retinal and mature cell markers. Immunohistochemistry was performed using validated antibodies. RT-qPCR was performed on RNA from multiple organoids, using validated primers. Two-way ANOVA analysis of gene expression data was performed on two independent replicates.

Results: By adapting the timeline of human RO differentiation protocols to the shorter gestation of the macaque, macaque iPSC derived ROs were generated and maintained phase-bright retina and mature cell marker expression at day 120. Macaque ROs show the sequential expression of neural-epithelia (RAX, PAX6, SOX2), photoreceptor precursor (CRX), interneuron (AP2α, PRKCα), photoreceptor (ARR3, OPN1SW, OPN1LW/MW, RHO), and Müller glia (RLBP1) markers indicating some retinal development and maturation throughout differentiation. Method efficiency to generate ROs as determined by morphology was ~40% at day 120.

Macaque iPSC lines showed variable responses, with the IGF1-based protocol improving RO structure and photoreceptor gene expression (RCVRN, ARR3, CRX) significantly ($p<0.0001$) in both cell lines, and additionally significantly increasing Müller glia (RLBP1) and rod (RHO) expression ($p<0.0001$) in 1 cell line. RPE-CM addition from day 15 significantly increased Müller glia (RLBP1) and cone (ARR3) expression ($p<0.0001$) at late stages (day 90-120) in both cell lines.

Conclusions: The use of an adapted differentiation timeline and retinal stimulating factors, IGF1 and RPE-CM, resulted in high method efficiencies for differentiation of cynomolgus macaque iPSCs to ROs and confirms the amenability of production in a multi-well format.

ABSTRACT BODY:

Purpose: To evaluate the prevalence of non-intraocular pressure (IOP)-related characteristics in a cohort of individuals with ocular hypertension (OHT) and primary open-angle glaucoma patients (POAG) at risk of optic nerve degeneration (OND).

Methods: A multicenter, analytical, observational, cross-sectional study was performed using a representative sample of 412 volunteers of both sexes recruited from 8 hospitals (Spain and Portugal). Participants were classified as OHT subjects (n=198) and POAG patients at initial stage (n=214). Data from the clinical history, anamnesis, and ophthalmological examination (intraocular pressure -IOP-, central corneal thickness -CCT-, optical coherence tomography -OCT- and visual field -VF-) were recorded to define the study groups. Also, sociodemographics, anthropometric, endocrinologic, nutritional, toxic habits, psychotropic drugs, cardiovascular and respiratory variables were studied. Statistics were carried out by the SPSS 25.0 program.

Results: Mean age of the study population was 62 years. Gender distribution was 53% men and 47% women in the POAG group, and 39% men and 61% women in the OHT group. In the POAG group, IOP was 16 mmHg in the right eye and 18 mmHg, meanwhile in the OHT group was 20 mmHg in the RE and LE. Among the 14 potential risk factors for OND (age, gender, thyroid dysfunction, body mass index, coffee or tea consumption, smoking or drinking habits, psychotropic drugs, cold hands/feet síndrome, migraine, asthma, chronic obstructive pulmonary disease - COPD, and sleep apnea/hypopnea syndrome - SAHS) stood out in both groups for its prevalence the coffee habit (2/3 of the population, 64% POAG, 65% OHT), overweight (1/2 of the study volunteers, 34% POAG, 44% OHT) and psychotropic drug intake (1/3 of the participants, 36% POAG, 37% OHT), whereas the less frequent comorbidities were asthma (12% POAG, 9% OHT), COPD (5% POAG, 16% OHT) and SAHS (11% POAG, 13% OHT).

Conclusions: In this Spanish-Portuguese cohort, new non-IOP-related factors have been identified to help assess the risk of POAG and to prevent or delay OND and glaucoma blindness.

SUBMITTER (NAME ONLY): Evan Berger

TITLE: Comparative Analysis of Face-Down Support Systems

SESSION TITLE: Vitreoretinal surgery/VR Interface/PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Berger, A. Wagner, K.G. Kapoor, Ophthalmology, Eastern Virginia Medical School, Norfolk, Virginia, UNITED STATES|

Commercial Relationships Disclosure: Evan Berger: Commercial Relationship: Code N (No Commercial Relationship) | Alan Wagner: Commercial Relationship: Code N (No Commercial Relationship) | Kapil Kapoor: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: E-commerce and expedited shipping have changed the landscape of patient options for access to face-down support systems (FDSS) for vitrectomy. The purpose is to compare the latest types of FDSS, their cost, and their expedited availability. A comparative analysis will help optimize patient preoperative counseling, help understand options to ensure positioning compliance post-operatively, and reduce cost surprises.

Methods: A Google search for “face down positioning equipment” and an Amazon search for “face down support” was conducted. On Amazon a search filter was used for products with a ≥ 4-star rating. A comprehensive list of FDSS was compiled. The device cost, shipping costs, option to rent vs. buy, and availability of next-day delivery were reviewed. The 1-week and 2-week costs for each FDSS was calculated.

Results: Three categories of FDSS were identified: face supports, seated supports, and sleep supports. Three online medical device companies were identified that offer FDSS (Table 1). Next-day shipping was available from two companies. On Amazon there were two popular FDSS available with free shipping through Amazon Prime. Table 2 provides a comparison of 1-week and 2-week costs. Regardless of shipping method, the most cost-effective FDSS type is a face support. Among ground shipped devices, the least expensive face/seated/sleep support package is The Standard Comfort Package 2. The most affordable option with next-day delivery is the face support from Vitrectomy.com. At 2 weeks it becomes less expensive to purchase this device. The Vitrectomy.com Ultimate Vitrectomy Package is the only face/seated/sleep support available with next-day shipping.

Conclusions: Patients that can wait for ground shipment have a number of FDSS options. Patients in need of next-day delivery have fewer options and will encounter significant delivery costs. These may be prohibitory for some patients as health insurance does not routinely cover FDSS. The optimal FDSS for a given patient will ultimately depend on their individual needs. This analysis helps vitreoretinal surgeons and their patients understand what FDSS options are available. The data can streamline preoperative counseling and increase the transparency of FDSS costs. In turn, this could lead to increased FDSS adoption, better positioning compliance, and possibly improved surgical outcomes.

ABSTRACT BODY:

Purpose: Macular pigments possess antioxidants, anti-inflammatory and light filtering properties implicated in visual function, and protection against retinal diseases, yet their average levels have not been previously determined in the general Ghanaian population. This study was designed to evaluate macular pigment optical density (MPOD) and its associated factors in a Ghanaian sample.

Methods: One hundred and fifty-four (aged 12 -72 years) subjects MPOD were determined in the best corrected visual acuity (BCVA) eye using customized heterochromatic flicker photometry. BCVA and Contrast sensitivity (CS) were assessed using LogMAR Early Diabetic Retinopathy Treatment Study (EDRTS) and Peli Robson charts respectively. Anthropometric assessment was performed following standard procedures and dietary carotenoid intake evaluated using a 3-day 24-hour dietary recall. Demographic and health status characteristics were gathered with a structured questionnaire. Data were summarized using frequencies, percentages, means, and standard error of means and associations between variables investigated with linear regression analyses at a significance level of $p<0.05$.

Results: The average MPOD at 0.5° and 1.0° retinal eccentricity were 0.22 ± 0.02 and 0.23 ± 0.01 density units whereas critical flicker frequency at the fovea and meso estimated at 17.31 ± 0.51 and 18.12 ± 0.36 Hertz respectively. MPOD was not influenced ($p > 0.05$) by age, sex, smoking, light exposure, body mass index, body fat, visceral fat and family history of eye diseases. Similarly, macular pigment was unrelated ($p > 0.05$) with BCVA, and CS.

Conclusions: Our results suggest lower average macular pigment levels than those obtained from previous investigations in Caucasians, Chinese, Europeans, and African descendants. Given the unsatisfactory mean MPOD levels, we recommend dietary interventional programs to help improve macular pigment levels in this sample.

ABSTRACT BODY:

Purpose: To evaluate the performance of a deep learning model for diabetic retinopathy (DR) and diabetic macular edema screening when using ultra-widefield (UWF) imaging.

Methods: For model development, 67,200 UWF images were collected from DR programs and ophthalmology clinics worldwide. 30,836 images were double graded and adjudicated at 8 grading centres by 125 certified graders using ETDRS extension of the Modified Airlie House Classification of Diabetic Retinopathy following the JVN Clinical Trial Ultrawide Field Grading Manual v1.0. The grading system used traditional ETDRS 7-SF field definition as well as extended fields 3-7 to evaluate the retinal periphery. A further 36,364 UWF images were graded using a grading protocol based on the ICDR classification. The dataset was split into training, tuning and testing. The final DR model is an ensemble of 10 EfficientNet-b0 neural networks, independently trained with standard image augmentation techniques. For model validation, two independent sets of images were collected. Model performance was evaluated by comparing its predictions to the adjudicated ground truth for both sets of images.

Results: Prior to clinical validation, the model performance was internally evaluated on an independent set of 1967 images, of which 1050 were graded via adjudication as negative for more than mild diabetic retinopathy (mtmDR negative), and 917 as having referable diabetic retinopathy (mtmDR positive). The overall performance (Table 1) was weighted by target DR distribution. Clinical validation evaluated an independent data set of 420 images selected to achieve a target distribution that enabled appropriate confidence intervals for mtmDR sensitivity and specificity A panel of three graders adjudicated these 420 images and assessed 241 as mtmDR negative, 179 as mtmDR positive and 135 as vtDR positive. Model’s performance on the clinical validation set is shown in Table 2.

Conclusions: The deep learning model was developed with high quality graded UWF images and performed at a level that highly suggests usefulness in a clinical screening setting. A large, prospective multi-center clinical trial is currently evaluating the performance of a similar model in a real-world clinical setting.

ABSTRACT BODY:

Purpose: Deletions in Inherited Retinal Disease (IRD) genes are a common cause of IRDs, but they can be time consuming to characterise. Short-read next generation sequencing (NGS) can struggle to characterise deletions accurately, particularly in exome or targeted sequence, where it may detect a deletion but fail to capture the breakpoints. Genome sequencing allows more effective characterisation of deletions, but many deletions occur due to the presence of repetitive elements, which inhibit accurate alignment of short-read sequences. The ability to characterise deletions efficiently is essential for confirming and defining breakpoints detected by NGS. The goal of this study was to develop a cost-effective long-range sequencing method to characterise deletions.

Methods: Four cases with large deletions in IRD genes, detected in exome sequence but not further characterised, were selected. These were amplified with Long Range PCR primers encompassing the deletion, using the Sequel Prep Long-Range PCR kit, to give 9.5kb, 4.4kb, 5.8kb and 4.2kb products. Samples were purified with an AxyPrep Mag PCR Clean Up Kit. Sequencing was performed on a MinIon using separate Flongle Oxford Nanopore adaptors. The resulting fast5 files were basecalled using Guppy, trimmed using Porechop and aligned using Minimap2. Filtering was performed using NanoFilt. Nanopore sequencing results were verified by Sanger Sequencing

Results: This method allowed fast, cost-effective characterization of deletion breakpoints in EYS, PRPF31, CNGA1 (see figure) and CNGB1. A high output was achieved for each case, with maximum 1.5Gb. A high proportion of reads were on target, up to 99.78% of generated bases were in the target loci. For three of the cases, Nanopore sequencing captured the breakpoint at a nucleotide level. The presence of repetitive Alu elements at the breakpoints of the PRPF31 deletion prevented nucleotide level characterization. For all cases, Sanger sequencing was then performed to confirm the sequence of the breakpoint.

Conclusions: This study has designed and tested a long-range, low-cost, labour efficient strategy to characterise breakpoints in deletions. This will allow for rapid characterisation of deletions detected by NGS.

ABSTRACT BODY:

Purpose: Mutations in the RPGR gene represent a major contribution to retinitis pigmentosa. The photoreceptor-specific isoform, RPGR^{ORF15}, contributes to the intracellular cargo movement between inner and outer segments of rods and cones. Glutamylation of RPGR^{ORF15} by the enzyme TTLL5 is essential for its normal function and mutations in the glutamic acid-glycine rich region have been shown to impair this post-translational modification. The aim of this study was to evaluate the effect of disease-causing mutations in the C-terminal basic domain of RPGR^{ORF15} on its interaction with TTLL5 enzyme as a way of predicting the level of glutamylation in gene therapy vectors used in clinical trials.

Methods: RPGR^{ORF15} mutant constructs were generated by site-directed mutagenesis using a wild type (WT) construct as a template. RPGR WT and mutant constructs were transfected into HEK293 cells. The level of RPGR^{ORF15} glutamylation was assessed by western blot analysis using the GT335 antibody and a human RPGR antibody raised against the N-terminus. To analyse the interaction between the WT and mutant RPGR constructs with TTLL5, a proximity ligation assay was performed using the Duolink® detection technology from Sigma-Aldrich. The level of fluorescence was quantified in both assays to determine the level of glutamylation and the interaction between both proteins.

Results: GT335 western blot showed that the full-length RPGR^{ORF15} expressed with the wild type construct is strongly glutamylated. However, quantification of glutamylation levels by densitometry showed that all the mutations producing a truncated basic domain in RPGR^{ORF15} cause a decrease in the level of glutamylation, between 50 and 90%, compared to the full-length protein. However, the binding between truncated forms of RPGR and TTLL5 appeared not to be affected, suggesting that there are other mediators involved in the glutamylation of RPGR^{ORF15}.

Conclusions: Mutations in the C-terminal of RPGR^{ORF15} significantly reduce the level of glutamylation, despite apparently not impairing the binding to TTLL5. These results suggest that there are other proteins required for the glutamylation of RPGR^{ORF15}. Since glutamylation of RPGR^{ORF15} influences its stabilization and folding, and its interaction with other proteins in the connecting cilia, it is critical to ensure that gene therapy vectors provide the fully glutamylated protein to the retina in order to be biologically active.

ABSTRACT BODY:

Purpose: Stargardt disease is an inherited retinal disease caused by mutations in the photoreceptor-specific gene ATP-binding cassette transporter type A (ABCA4). Interestingly ABCA4 has a high occurrence of splicing-affecting mutations. Here, we screened 9 antisense oligonucleotides (AONs) designed to correct pseudoexon (PE) inclusion due to a recurrent deep-intronic variant (c.769-784C>T) in ABCA4.

Methods: AON efficacy to induce PE exclusion in the ABCA4 transcript was assessed in three cell models carrying the c.769-784C>T variant. First, AONs were tested at a final concentration of 0.5 μM in HEK293T cells transfected with an ABCA4 midigene (splice reporter vector) carrying the deep-intronic change. Next, AONs were tested in patient-derived fibroblasts at the same final concentration. Based on the splicing-correction efficacy of each individual AON, the three most efficacious AONs were selected for a final assessment in photoreceptor-progenitor cells (PPC). Selected AONs were delivered at a final concentration of 0.5 μM and 1 μM. One-way ANOVA test with subsequent Bonferroni correction was used for statistical analysis.

Results: The AON screening using the HEK293T-midigene model indicated high efficacy of all AONs. Given these results, the same pool of AONs was evaluated in the patient-derived fibroblasts. Based on PE correction AON2, AON7 and AON5 were selected for further assessment in the patient-derived PPC model. AON2-mediated splicing correction was the most efficacious at the lower concentration (0.5 μM, $p<0.001$), followed by AON7 ($p<0.001$). AON5 was least efficacious reaching statistical significance at final concentration 1 μM only ($p=0.03$).

Conclusions: PE exclusion is a thoroughly researched therapeutic approach that has been shown to rescue protein function. It can be achieved using AONs, however it is crucial to select the most efficacious therapeutic molecule for further testing by employing different models. Taking this into account, AON2 and AON7 showed a high degree of PE skipping in PPCs, which provide a retina-like cellular context. Further research of AON2 and AON7 includes protein rescue studies and safety profile assessment in advanced retina models to mimic the cellular environment in patients.

ABSTRACT BODY:

Purpose: The aim of this study is Evaluation role of umbilical cord patch transplantation for corneal perforations and descemetoceles by assessment of healing of corneal perforation and increased corneal thickness in case with descemetoceles by using slit lamp bio microscopy and anterior segment optical coherence tomography.

Methods: After topical anesthesia for cases with corneal thinning patients and general anesthesia in corneal perforation cases. the base and surrounding of the ulcers were cleaned of necrotic tissue. The Umbilical cord patching with epithelium side facing up was trimmed to fit the shape and depth of the ulcer, and interrupted sutures were placed to anchor the UCP to the cornea. A large piece of the amniotic membrane with epithelium side up was applied over the entire cornea. Finally, bandage contact lens was applied. All patients were followed up daily throughout the first week, weekly for 1 month, then monthly for the first 6 months.

Results: There were 20 eyes with Corneal perforation or thinning. The diameter of corneal thinning ulcers of 3.5±2. 5mm.The anterior chamber in all 20 eyes formed at first postoperative day with improvement of preoperative photophobia foreign body sensation. The corneal thickness was increased in cases with corneal thinning from mean 86.00 ± 24µm to 194± 25µm postoperatively. Healing of corneal defect of cases with corneal perforation at average of 4 weeks. Best Correction Visual acuity in cases with thinning improvement from (-1.82 ± 3.455) by Log MAR to (-0.66 ± 1.942). While, cases with perforation there was an improvement from (-0.53 ± 0.548) to (0.79 ± 0.677)

Conclusions: The current study demonstrated the promising effects of combining UCP with amniotic membrane transplantation is a promising alternative for corneal insult, providing satisfactory reconstruction. Because of its stem cell therapy plus easy availability and efficacy .

ABSTRACT BODY:

Purpose: Age-related Macular Degeneration (AMD) is a multifactorial disease involving oxidative stress, inflammation, complement activation and ferroptosis. Elevated retinal iron levels in AMD patients have been well documented and could contribute to all these pathophysiological hallmarks suggesting that iron chelation could benefit AMD. We previously demonstrated that local administration of Transferrin (TF), an endogenous iron chelator, is effective for reducing iron retinal content and oxidative stress and slowing down photoreceptor loss in various animal models of retinal degeneration. Here, we further explored the protective mechanism of action of TF in oxidative stress conditions at the retinal pigment epithelium (RPE) level.

Methods: Differentiated ARPE-19 (dARPE-19) and hiPSC-derived RPE (iRPE) cells were exposed for 24 hours to $FeCl_3$NTA or 4HNE in presence of TF. Viability of RPE cells was assessed by quantification of mitochondrial activity (CellTiter) and LDH release. Changes in the expression pattern of genes involved in iron homeostasis (TFR1, H-FT, L-FT, LCN2), oxidative stress (HMOX, SOD1), complement activation (C3), lipid metabolism (ABCA1), and ferroptosis (GPX4) was defined by RT-qPCR.

Results: Both $FeCl_3$NTA and 4HNE induced a dose-dependent decrease in dARPE-19 and iRPE cell viability. Incubation with TF significantly protected dARPE-19 and iRPE against $FeCl_3$NTA-induced toxicity (+101.1% and +91.2% viability, respectively), and against 4HNE-induced oxidative stress (+57.3% and +71.3% viability, respectively). 24h exposure of iRPE cells to $FeCl_3$NTA drastically decreased the expression of TFR1 (0.41-fold change) and increased the expression of H-FT and L-FT (2.47- and 3.39-fold change, respectively) and LCN2 (1.982-fold change). Moreover, a significant increase in C3, ABCA1, SOD1 and GPX4 genes was highlighted. Co-treatment with TF restored almost control levels of all genes impacted by $FeCl_3$NTA. Exposure to 4HNE drastically increased the expression of HMOX1 (11.77-fold change) which was significantly prevented by TF (2.39-fold change, $p < 0.0001$).

Conclusions: By controlling iron homeostasis, TF has the potential to counteract oxidative stress, complement activation and other pathways involved in AMD pathogenesis. The protective effect of TF in iron-independent stress condition suggests TF has activities beyond iron chelation.

ABSTRACT BODY:

Purpose: Standard biconvex intraocular lenses (IOLs) are designed to optimize focus at the eye's central retina but degrade optical quality in the peripheral retina with respect to the natural crystalline lens. In order to prevent this drawback of current IOLs, a new lens with an inverted meniscus shape (ArtIOL, Voptica SL, Murcia, Spain) was developed to provide better image quality in the peripheral retina. Moreover, IOL implantation can be associated with image distortion. The aim of this study is to compare the inverted meniscus lenses with the standard biconvex with respect to the induced image distortion.

Methods: Pre- and post- cataract surgery fundus images were taken with an ultra-widefield retinal camera (CLARUS 500, Zeiss, Germany) in 55 eyes of patients implanted with a standard biconvex IOL (control group) and 43 eyes of patients implanted with the inverted meniscus ArtIOL lens. For each eye, retinal landmarks (such as vessel bifurcations) were identified and their relative radial position was identified using a purposely written MATLAB (MathWorks, Inc. Natick, MA, USA) script. Retinal distortion at these locations was obtained for both groups.

Results: Although there was a large variability among subjects, we have found distortion to be significantly lower in the ArtIOL group than in the control group. Furthermore, distortion was found to linearly increase with eccentricity roughly twice faster in the control group than in the ArtIOL group (see figure), therefore predicting even larger differences for higher eccentricities than the 40 deg range studied.

Conclusions: Its inverted meniscus design bestow ArtIOL lenses with a better performance on the peripheral field, significantly reducing distortion of the retinal image in pseudophakic eyes with respect to traditional biconvex IOLs. This may have an impact in the quality of vision affecting patients' tasks relaying in peripheral performance.

ABSTRACT BODY:

Purpose: To assess the effect of iCare HOME tonometry on clinical management of glaucoma patients who were progressing with low in-office intraocular pressures (IOP).

Methods: 72 eyes of 36 patients with primary open-angle glaucoma (n=36 eyes), low-tension glaucoma (n=20), pigmentary glaucoma (n=6), pseudoexfoliation glaucoma (n=2), chronic angle-closure glaucoma (n=2), open-angle glaucoma
suspects (n=2), and steroid response (n=2) were enrolled during office visits. Patients were asked to record IOP four times daily (around 8 am, 12 pm, 4 pm, and 8 pm) for 1 week using iCare HOME. Upon review of home tonometry readings, a decision was made whether to advance therapy. Home tonometry IOP mean, maximum, minimum, range, standard deviation, and coefficient of variation, as well as Goldman applanation tonometry (GAT) immediately prior to the home trial were compared retrospectively between patients who underwent changes in glaucoma therapy versus those whose management did not change.

Results: 42 eyes (58.3%) of 21 patients had changes in glaucoma management after review of iCare HOME readings. Of these, 30 (71.4%) changed medical therapy, 6 (14.3%) received selective laser trabeculoplasty, and 6 (14.3%) underwent surgery (Table 1). Patients for whom treatment was advanced demonstrated significantly greater maximum IOP (26.6 ± 10.5 mmHg vs 21.2 ± 7.3 mmHg, p = 0.01 and IOP range (17.6 ± 10.5 vs 12 ± 6.8, p = 0.01) than patients whose management was unchanged (Table 2). Mean IOP (15.3 ± 6.3 mmHg vs 14.1 ± 4.3 mmHg, p = 0.4) and GAT prior to the home trial (13.3 ± 4.2 mmHg vs 14 ± 3.3 mmHg, p = 0.4) were similar between the two groups.

Conclusions: The iCare HOME is a valuable tool for glaucoma specialists in determining whether to advance therapy among glaucoma patients who may be progressing despite meeting in-office IOP targets. Alternative iCare HOME testing may have value in assessing whether patients require additional treatment.

ABSTRACT BODY:

Purpose: To develop and validate a survival analysis and machine learning algorithm to predict the individual future risk of NPDR worsening to PDR using RW EHR data.

Methods: In this retrospective study of 4408 patients with diabetes, NPDR, and ≥ 365 days of follow-up at Cleveland Clinic Cole Eye Institute from January 2012 to February 2020 (Babiuch A et al. Invest Ophthalmol Vis Sci. 2021;62(8):1120), EHR data from the NPDR index visit (diabetes type, age, race, gender, smoking status, BMI, Charlson Comorbidity Index [CCI] score, diabetic macular edema [DME] status, HbA1c, creatinine, systolic blood pressure, eGFR, BUN, insulin use, anti-VEGF treatment, logMAR letters) was used to build prognostic models of PDR progression. Data was randomly split into 80% development data and 20% test data. Both survival analysis and linear regression models were evaluated. To assess association of baseline characteristics with PDR progression, time-dependent Cox proportional hazards modeled PDR progression as time-to-event data. Median imputation addressed missing data in covariates. Linear regression models were trained for predicting probability of progression to PDR for 6 months (month [M] 6, M12, M18, M24) with respect to index visits. Performance of the Cox model was assessed using time-dependent dynamic area under the curve (AUC) and the linear regression model was evaluated using AUC and 95% CI.

Results: The Cox model performed well, with a dynamic AUC of 0.81 on average over the study period (Figure 1). The linear regression models predicted progression to PDR at M6 with an AUC (95% CI) of 89% (75%, 96%), at M12 with 89% (81%, 95%), at M18 with 86% (78%, 91%), and at M24 with 87% (79%, 92%; Figure 2). The Cox model revealed DME, Black race, and higher baseline CCI and HbA1c as significant positive associations with PDR progression, whereas anti-VEGF treatment and older age had significant negative associations. Linear models showed DME, higher CCI, and lower age as the most important predictors.

Conclusions: Results from 2 prototype models demonstrated feasibility in predicting PDR from individual NPDR patients using RW EHR data, which may inform clinical management of patients with DR; identified risk factors may also help clinical research of DR development in the RW.

ABSTRACT BODY:

Purpose: Klotho is a transmembrane proteins implicated in aging-related phenotypes (in brain, kidney, cardiovascular system, organism longevity) in humans and experimental animals. Klotho has been shown to be protective during aging and overexpression of it has been demonstrated to be neuroprotective in the brain. The klotho family of genes includes α-klotho, β-klotho and γ-klotho. α-klotho is expressed in the lens and the brain. However it is not known how α-klotho affects aging of the lens. Here we investigated the effect of α-klotho overexpression in the lens across the mouse lifespan.

Methods: α-klotho overexpressing transgenic and littermate non-trangenic mice were bred, maintained and genotyped at Boston University. Male and female mice were sacrificed at selected ages across the lifespan. Lenses were isolated and imaged under with a custom-adapted Zeiss stereophotomicroscope and digital Nikon camera.

Results: Aged mice displayed age-related cortical opacities. There was no overt different phenotype between the normal α-klotho expressing non-transgenic mice and the transgenic α-klotho overexpressing mice. In contrast to previously reported studies in the brain, overexpression of α-klotho did not appear to have any gross effect on aging lens phenotype.

Conclusions: Aged mice displayed age-related cortical opacities. There was no overt different phenotype between the normal α-klotho expressing non-transgenic mice and the transgenic α-klotho overexpressing mice. Further studies using α-klotho knock-out mice may provide further insight into the role of α-klotho in lens aging as has been reported for other tissues.

Marin-Sanchez: Commercial Relationship: Code N (No Commercial Relationship) | Pablo Artal: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Cataracts increase the amount of intraocular light scattering in the crystalline lens causing vision impairment by blurring and reducing the contrast in retinal images. Wavefront shaping techniques in combination with the Optical Memory Effect (OME) have been suggested for the optical (non-surgical) correction of scattering in cataractous lenses. In this context, we aim to characterize the scattering properties of excised human lenses by measuring their OME.

Methods: The Optical Memory Effect is an intrinsic correlation of scattering media that provides the isoplanatic patch of a cataract's correction imaging technique, determining how the transmitted speckle pattern changes with a tilt/shift of the incident beam. We measured it using a 594nm laser incident on cataractous lenses by recording the transmitted pattern. With the lens mounted on a shift/tilt holder, the similarity between the speckle patterns for different values of shift and tilt of the lens was examined via cross-correlation. We characterized the OME for different cataract stages. For each case, we also included other scattering metrics, as the straylight parameter, measured with the Optical Integration Method, the transport mean free path and contrast image quality, studying the variation of the OME with the measured scattering parameters. We measured a total of 22 lenses of donors aged between 29 and 67, leaving the cataract develop with time to increase the scattering range.

Results: We found that OME is non-negligible for cataracts, being strongly dependent on the scattering strength. For severe cataracts (straylight parameter Log10[s]=2.45 and image contrast below 16%), the OME was mainly limited by a tilt of 6 deg, whereas for weak cataracts (Log10[s]=1.32 and image contrast 90%) this range was extended up to 10 deg. We also found a linear relationship between the straylight parameter, image contrast and OME decorrelation, providing us with a new tool for the prediction of the OME range when only quantitative scattering measurements are taken.

Conclusions: The OME of cataractous excised human lenses has been measured for the first time. Together with quantitative scattering parameters measured simultaneously, it provides with a useful tool for the optical correction of cataracts using wavefront shaping techniques. This work paves the way to new potential approaches for the non-invasive and real-time correction of cataracts with wearable devices.

ABSTRACT BODY:

Purpose: The COVID-19 pandemic has accelerated the introduction and dissemination of telemedicine into ophthalmic secondary care. Yet this pivot to telemedicine-dominated care could exacerbate the differential in health outcomes for certain groups. This study seeks to quantify and characterise factors associated with non-attendance within a population of patients attending synchronous tele-ophthalmic hospital outpatient appointments.

Methods: A retrospective cohort study at a tertiary-level ophthalmic institution comprising a principal central site, four district hubs and five satellite clinics in London, UK between January 1st 2019 and October 31st 2021. Multivariable logistic regression modeled attendance status against sociodemographic, clinical and operational exposure variables for all new patient registrations.

Results: Between January 1st 2019 and October 31st 2021, a total of 6843 eligible patients (mean age of 45 +/- 32, 58.0% female) were newly registered to attend synchronous teleophthalmology clinics. Self-reported ethnicity identified 3.4% as South Asian, 1.4% Black, 25.3% Other Ethnic Group and 7.6% White. 62.3% did not report their ethnicity. Most appointments were in general ophthalmology (59.9%, n=4096), followed by cataract (20.2%, n=1379), adnexal (19.1%, n=1310), medica retina (0.1%,n=55) and glaucoma (0.0%,n=3).

Increased rates of non-attendance were associated with male sex (adjusted OR 0.74, CI 0.62-0.88), greater levels of deprivation (adjusted OR 0.88, CI 0.84-0.92), incompletion of self-reported ethnicity (adjusted odds ratio 0.3, CI 0.17 - 0.54) and a previously cancelled appointment (adjusted OR 0.65, CI 0.5-0.83) (all $p<0.001$). Individuals identifying as Asian or Black ethnicity had worse attendance in synchronous clinics with adjusted odds ratios of 0.42 (CI 0.20-0.90, $p = 0.02$) and 0.28 (CI 0.12-0.65, $p=0.0025$) respectively. Patients with diabetes were more likely to attend with an adjusted odds ratio of 1.03 (CI 0.3 - 3.55, $p = 0.9$).

Conclusions: With regards to synchronous teleophthalmology clinics, poorer attendance is associated with male sex, greater socioeconomic deprivation and self-reported Asian and Black ethnicities. Further study is warranted to evaluate whether enhanced surveillance of these cohorts could improve their non-attendance rates.

ABSTRACT BODY:

Purpose: Report preclinical pharmacology and safety data of GT005, an investigational AAV2 expressing recombinant human Complement Factor I (hCFI), after subretinal delivery in non-human primates (NHP).

Methods: GT005 was assessed in a 6-month NHP GLP toxicology study after subretinal injection at low dose (LD) $7x10^{10}$ and high dose (HD) $3.5x10^{11}$ vg/eye (3 animals/sex/dose). Optical coherence tomography, intraocular pressure, electroretinography, vector shedding, ELISPOT, antibodies to capsid and hCFI, and hCFI levels in vitreous humor (VH) were measured throughout the study. Histopathology, vector biodistribution and hCFI expression in tissue were evaluated at termination.

Results: There were no systemic effects of GT005 and no treatment-related findings outside the eye. There were histopathology findings in the injection area for both doses, with variable severity. Mononuclear cell infiltrates were found in ocular tissues, optic nerve, optic disk, VH and iris/ciliary body. Loss of RPE and photoreceptors was detected from week (wk) 13. These changes correlated with a significant anti-hCFI antibody response in serum and VH of most treated NHPs at wk 13 and 26 ($P<0.01$). Serum levels of antibodies to AAV2 at wk 4 were weaker and remained constant at wk 13 and 26. No T cell responses to hCFI or AAV2 were found in NHPs, except for one animal in the HD group which developed a significant response against AAV2. Vector biodistribution was similar for both doses with levels highest at the dose site in ocular tissues and falling to below the limit of detection in most organs. Vector shedding was confined to tear samples up to wk 4. hCFI mRNA and protein expression was observed in the outer retina and hCFI protein was detected in VH from 2 wks up to 26 wks. Maximal levels of hCFI were found in the VH at wk 4 in the HD (1437±551 ng/mL) and at wk 13 in the LD (805±249 ng/mL). Reduced hCFI levels at later timepoints correlated with antibody titres to hCFI ($R=0.83$; $P<0.001$).

Conclusions: GT005 was well tolerated with no safety findings outside the eye. GT005 led to local hCFI expression. Ocular dose-dependent inflammation-induced changes were observed, and correlated strongly with anti-hCFI antibody generation. These were deemed to be species-specific and therefore unlikely to translate to the clinic. These data supported the clinical development of GT005.

ABSTRACT BODY:

Purpose: Rose Bengal photodynamic antimicrobial therapy (RB-PDAT) has been shown to be an effective adjunct therapy for treating infectious keratitis. However, the average penetration depth of Rose Bengal (RB) as previously reported is insufficient to treat deeper infections such as those of acanthamoeba and fungus. The purpose of this study was to determine the effect of solvent and RB formulation (disodium versus lactone) on penetration depth within the cornea.

Methods: Eight pairs of human donor corneas were obtained from the Florida Lions Eye Bank. These corneas were initially received from donors to use as grafts in corneal transplant surgery but later were deemed unsuitable for transplant due to the donor's history or disqualifying medical indications. Prior to experiments, the corneal tissue was placed in Optisol medium and kept viable in sealed plastic containers at 4○C. The post mortem time was less than 15 days for all corneas. To test the effect of solvent, 5 pairs of corneas were soaked epithelial side down in a 0.01% solution of disodium RB in H_2O (OS) or in NaCl (OD) for 25 minutes. To test the effect of type of RB, an additional 3 pairs of corneas were soaked in a 0.01% solution of disodium RB in NaCl (OS) or a 0.01% solution of lactone RB in NaCl (OD). DAPI stain was applied to the endothelial layer of all corneas, and they were imaged via confocal microscopy. Penetration depth and corneal thickness was assessed from the Z-stack. Two tailed t-tests were used to evaluate statistical significance.

Results: Utilizing H_2O versus NaCl as the solvent for disodium RB had no effect on the mean corneal thickness after soaking (833±28μm in H_2O and 824±17μm in NaCl; p=0.55). The solvent also had no effect on the penetration depth of RB in the cornea (120±23μm in H_2O and 113±21μm in NaCl; p=0.62). The type of RB had no effect on the mean corneal thickness after soaking (938±16μm for disodium and 907±61μm for lactone; p=0.48). However, there was a significant difference between the penetration depth in the cornea of disodium compared to lactone RB (153±17μm for disodium and 202±13μm for lactone; p=0.016).

Conclusions: Our results suggest that the solvent used has no effect on penetration depth and that more hydrophobic RB groups will increase penetration depth. However, the swelling that occurred during soaking was higher than expected and requires more investigation before translation of this research into clinical treatment.

ABSTRACT BODY:

Purpose: To assess the safety and tolerability of BI 836880, a dual vascular endothelial growth factor (VEGF)/angiopoietin-2 inhibitor, in a two-part single rising dose (SRD) and multiple rising dose (MRD) study in patients with wet age-related macular degeneration (wAMD).

Methods: This Phase I/IIa open-label, non-randomized study (NCT03861234) includes patients with wAMD who, in the SRD part and the first cohort of the MRD part (1.00 mg), have progressed despite ≥3 prior anti-VEGF injections. The second cohort of the MRD part (2.00 mg) will enroll treatment-naïve patients with wAMD. In the SRD part, patients received one single intravitreous injection of BI 836880 (either 0.06, 0.18, 0.50, 1.00, or 2.00 mg) and were followed for up to 43 days. Based on the highest tolerated doses identified in the SRD part, patients in the MRD part will receive three consecutive 1.00 or 2.00 mg doses of BI 836880 over a 3-month period. The primary endpoint is the number of patients with dose-limiting ocular events in the SRD part and the number of patients with drug-related adverse events (AEs) in the MRD part. Secondary endpoints in the MRD part include change from baseline in best-corrected visual acuity (BCVA) and central subfield foveal thickness.

Results: In the completed SRD part, 15 patients received BI 836880 (n=3 per dose group); all were white with a mean age of 76 years. In total, 40% of patients had an AE; all were ocular. No AEs were dose-limiting or drug-related; one patient had a serious AE of wAMD in the fellow eye. Overall, 26.7% of patients had procedure-related AEs (vitreous floaters, conjunctival hemorrhage, dry eye). The mean change in BCVA from baseline to end of study in the SRD part was +5.3, +7.3, +0.3, +6.0, and +7.0 letters (doses of 0.06, 0.18, 0.50, 1.00, and 2.00 mg, respectively). In the ongoing MRD part, four patients have been enrolled and received 1.00 mg BI 836880 to date; all are white with a mean age of 76.5 years. Two patients have had a reported AE, one of which was ocular. Neither was serious, dose-limiting, or drug-related.

Conclusions: BI 836880 was well tolerated by patients in the SRD part and has been well tolerated by patients in the MRD part to date, with no dose-limiting or drug-related AEs reported. BCVA data from the SRD part demonstrate preliminary signs of efficacy, which are being further investigated in the ongoing MRD part.

ABSTRACT BODY:

Purpose: Oral Prednisolone (oPSL) at doses of ≥20 mg for ≥4 weeks is a well-documented moderate to high-risk factor for reactivation of chronic HBV (cHBV), especially in combination with immunosuppressants. Risk of iatrogenic cHBV reactivation in ophthalmology has not been reported. This retrospective case series describes cases of Uveitis with cHBV on oPSL and concurrent immunosuppressives to highlight the role for pre-treatment risk stratification for ophthalmologists.

Methods: Our large tertiary centre database was screened for uveitic patients receiving csDMARDs and had previous cHBV for inclusion. Patient records were retrospectively analysed and baseline patient characteristics, therapeutic, and serological data collected.

Results: 13 uveitic patients (8 female and 5 male) were included. Median age was 42 (±16.75). Sarcoidosis n=3 (23.1%) and VKH n=3 (23.1%) were the most represented uveitides. 11 patients (84.62%) received Prednisolone ≥20 mg for ≥4 weeks. Median duration in weeks oPSL >20mg was 10 (±37). Average maximum oPSL dose at each prescription was 60mg (±5). 6 patients (46.15%) were on Adalimumab. All patients were on csDMARD therapy. Of the 13 patients, 1 (7.69%) patient had reactivated HBV (rHBV) with a positive HbsAg during treatment. For the 1 patient with rHBV, the ALT level increased by 2857.69% from initial ALT measurement. 2 Patients (15.4%) required anti-HBV therapy.

Conclusions: This study demonstrated that Prednisolone can cause reactivation of cHBV in ophthalmology; our 7.69% reactivation rate is in keeping with the literature (<10%). Further higher-powered studies are warranted to identify causality and other independent predictors of reactivation in an ophthalmic patient population.

TITLE: LRG1-driven phenotypic switch in pericytes is an early event in diabetic retinopathy

SESSION TITLE: Molecular events in diabetic retinopathy

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: G. De Rossi, M.E. Da Vitoria Lobo, J. Greenwood, S.E. Moss, Institute of Ophthalmology, University College London, London, London, UNITED KINGDOM|

Commercial Relationships Disclosure: Giulia De Rossi: Commercial Relationship: Code N (No Commercial Relationship) | Marlene Da Vitoria Lobo: Commercial Relationship: Code N (No Commercial Relationship) | John Greenwood: Commercial Relationship(s);Code O (Owner):PanAngium Therapeutics;Code P (Patent):PanAngium Therapeutics | Stephen Moss: Commercial Relationship(s);Code O (Owner):PanAngium Therapeutics;Code P (Patent):PanAngium Therapeutics

ABSTRACT BODY:

Purpose: Pericytes have a fundamental role in maintaining vascular homeostasis and their malfunction is thought to be an early event in diabetic retinopathy (DR). Cross-sectional studies have reported increased levels of leucine-rich α-2 glycoprotein 1 (LRG1) in the plasma and vitreous humor of diabetic patients but failed to establish whether LRG1 plays an active role in disease pathogenesis. Our study aimed to elucidate the role of LRG1 in the early microvascular events taking place in the diabetic retina using experimental models of DR.

Methods: We took advantage of two murine models of type I diabetes (STZ and Akita) to correlate Lrg1 expression to the retinal vascular changes happening over 6 months of hyperglycaemia. We also compared global Lrg1-deficient mice to wild-type littermates to identify the contribution of LRG1 to the vascular abnormalities in diabetic retinas (N=10/group, males, C57Bl/6). We then designed in vitro culture models incorporating human primary retinal pericytes (HRP) to assess the effects of LRG1 on the morphology, signalling and function of pericytes (N=3).

Results: We found increased LRG1 expression in diabetic retinas early after hyperglycaemia onset (4-8 wks). In both models, diabetic retinas were characterised by an increased number of semi-detached pericytes (or ‘pericyte bridges’), stretching their processes between adjacent capillaries of the deep plexus (50% increase at 16 wks). This increase did not occur in the diabetic retinas of Lrg1-deficient mice. Morphometric analyses revealed that these hyper-activated pericytes, and their processes, were almost-exclusively associated with bent capillaries (Fig.), suggesting that these structures can exert tractional forces on endothelial cells (ECs). Based on these observations, we subjected cultured HRPs to increasing doses of recombinant LRG1 and revealed a phenotypic switch towards a more star-shaped morphology coupled to an enhanced ability to contract collagen type I. This contractile phenotype was associated with increased expression of typical myofibroblast proteins (αSMA, vimentin, fibronectin).

Conclusions: We have shown that LRG1 is up-regulated early on after hyperglycaemia onset in the retina and triggers a myofibroblastic-like phenotype in pericytes. We believe that targeting LRG1 could prevent or revert EC-pericyte decoupling and normalise the vasculature, paving the way to more timely and effective treatments in DR.

ABSTRACT BODY:

Purpose: A navigation task was developed to study the impact of illumination and disease stage on navigation performance in people with AMD.

Methods: 64 subjects with AMD and 10 similarly aged healthy controls recruited to the MACUSTAR study at 2 sites; Quinze-Vingts CHNO (n=35, mean age: 72, AMD stage: 3 controls/27 early or intermediate[e/i]/5 late) and Moorfields Eye Hospital (n=39, mean age: 74, AMD state: 7/26/6) undertook a navigation task at Streetlab (S) and Pedestrian Accessibility Movement Environment Laboratory (P) respectively. 4 obstacle seeded mazes were developed at each site. Due to different platform sizes (S:9x5m, P:11x7m) and availability of obstacles maze configurations varied. Subjects navigated 1 of 4 randomly selected mazes under 1 transition (256 reducing to 1lux) and 3 static (256, 4, 1 lux) light conditions. Preferred walking speed (PWS) for an unobstructed path was measured under 256lux and %PWS calculated for each trial. A linear mixed model was constructed using %PWS as the outcome measure, adjusted for age and site. Disease stage, light condition and their interaction term were also included.

Results: A site effect was present with %PWS being 9 percentage points higher ($p < 0.001$) at S compared to P. Subsequent findings are adjusted for this effect. There were no direct effects of AMD stage or light level on %PWS, however their interaction term indicates %PWS is differentially affected by luminance depending on AMD stage. Specifically, e/i AMD had a significant interaction with the transition condition ($b = -5.87$, $p = 0.047$), whereas late AMD had significant interactions with 4 lux ($b = -7.68$, $p=0.04$) and transition condition ($b = -11.37$, $p = 0.003$).

Conclusions: Results indicate that whilst those with late AMD have poorer navigation performance under low and transient light conditions, people with e/i AMD do not experience a deleterious effect of static low light, but are negatively impacted by a sudden reduction in luminance. This may be a real-world manifestation of delayed dark adaptation and impaired vision in low luminance. These findings support the exploration of the utility of navigation-based endpoints for future novel treatment trials in both e/i and late AMD.

TITLE: Incidence of Ocular Herpetic pathologies in a hospital setting, United Kingdom

SESSION TITLE: Public Health II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Verma, R. Sharma, University Hospitals of Derby and Burton NHS Foundation Trust, Derby, UNITED KINGDOM|

Commercial Relationships Disclosure: Devika Verma: Commercial Relationship: Code N (No Commercial Relationship) | Rohit Sharma: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The incidence of ocular herpetic pathologies, in particular Herpes Zoster Ophthalmicus (HZO), has seemingly been on a rise over the past years, especially among the elderly and immunocompromised. The nature of this rise is likely multifactorial ranging from access to Shingles vaccination programmes, potential increase in immunocompromised individuals, social factors and most recently, Covid-19 infection. The relationship between Covid-19 and ocular herpetic pathologies has anecdotal basis. Certain studies have hypothesized T-cell dysfunction as a mechanism of Varicella Zoster virus reactivation in patients affected by Covid-19. This retrospective, observational study analyses the pattern of incidence of ocular herpetic pathologies in a secondary care centre, United Kingdom (UK).

Methods: This study was set in an eye casualty clinic in Queens Hospital, Burton-on-Trent (University Hospitals Derby & Burton NHS, UK). Diagnoses of each patient was recorded in the Eye Casualty Patient Register. Data was extracted from three time periods – i. Pre-covid pandemic (July -December 2019), ii. Pandemic (July - December 2021) and iii. Post coronavirus vaccine introduction, UK (April and May 2021). Extracted data was pooled into the following groups – Herpes Simplex Keratits (HSK)/ HZO/ Shingles/Herpetic Kertatouveitis/ Herpes Zoster/Herpes Simplex/Herpes simplex endothelitis.

Results: The data between pre-pandemic and post-pandemic periods highlighted an increasing incidence of certain ocular herpetic conditions. Highest number of diagnoses were recorded as HSK and HZO. HSK accounted for the highest incidence across all time periods - 41% (pandemic), 34% (pre-pandemic) and 37.5% (after vaccine introduction). On the other hand, similar incidence is noted with HZO diagnoses - 32.9% (pandemic), 32.7% (pre-pandemic) and 37.5% (after vaccine introduction).

Conclusions: Overall, a gradual increase in incidence of ocular herpetic pathologies was observed from 2019 - 2021 at this centre. Multiple factors could be responsible for this rise, with Covid-19 infection as a potential factor. However, there is insufficient data to draw up a definitive association between the increasing incidence of such conditions and Covid-19, especially as the immune response to the infection and vaccinations are poorly understood. Larger, multi-centre studies would be required to assess the burden of incidence in the UK.

TITLE: Corneal crosslinking ameliorates degree of corneal edema in subsequent acute keratoconus

SESSION TITLE: Keratoconus and corneal biomechanics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Cursiefen, W. Zhang, Y. hou, S. deng, A. Howaldt, F. Bock, Dept. of Ophthalmology, Universitat zu Koln, Koln, Nordrhein-Westfalen, GERMANY|

Commercial Relationships Disclosure: Claus Cursiefen: Commercial Relationship(s);Code C (Consultant/Contractor):Roche;Code C (Consultant/Contractor):Medupdate;Code R (Recipient):Ziemer | Wei Zhang: Commercial Relationship: Code N (No Commercial Relationship) | yanhong hou: Commercial Relationship: Code N (No Commercial Relationship) | shuja deng: Commercial Relationship: Code N (No Commercial Relationship) | Antonia Howaldt: Commercial Relationship: Code N (No Commercial Relationship) | Felix Bock: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Corneal edema in acute keratoconus is caused by a sudden break of Descemet membrane. This study aims to assess whether pre-treatment with corneal crosslinking (CXL) can ameliorate corneal edema in a subsequent hydrops.

Methods: Normal or keratoconic human tissue (obtained during penetrating keratoplasty; n=6 each) was incubated with Corneal Culture Medium (CCM) I for hydration for 1 day and then dehydrated with CCM II for 24 hours. Then either CXL with 30-minutes topical application of 0.1% riboflavin followed by a 30-minutes UVA irradiation (3mW/cm2) or riboflavin only (in controls) followed. Afterwards, tissues were incubated with CCM I and central corneal thickness was measured using OCT (before treatment: hydration, dehydration; after treatment: overnight, 1 day, 2 days, 4 days). In the vivo experiment, C57BL/6 mice received CXL or only riboflavin (controls). Fourteen days later, a linear perforating incision was performed as murine model of acute keratoconus. Corneal thickness was measured by OCT after incision at 15 and 30 minutes, 1 and 4 hours, 1, 7 and 14 days (thickness from 5 naïve mice as the baseline).

Results: In the ex vivo experiments, crosslinked normal and keratoconic tissue had a significantly reduced swelling after rehydration: For normal corneas (normalized to “Dehydration”), the percentage of increase in thickness between Dehydration and 24 hours was 15.87% in the CXL group and 89.3% in controls (P=0.0019). For keratoconus corneas, results were 6.53% in CXL-treated and 38.2% in controls (P=0.0323). In the in vivo experiment, the average corneal thickness was significantly reduced in the treatment group at 15 minutes, 4 hours and 1 day post treatment compared to the controls (P<0.05).

Conclusions: CXL seems to ameliorate acute swelling of normal and keratoconic human corneas. Also, it can ameliorate the degree of early corneal edema in subsequent acute keratoconus in the murine model.

TITLE: Anatomical characterization of the choroidal nervous system
SESSION TITLE: Mechanisms of Refractive Error and Eye Development
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: B. Leclercq, M. Zhao, F. Behar-Cohen, UMRS1138, INSERM, Paris, Île-de-France, FRANCE|
Commercial Relationships Disclosure: Bastien Leclercq: Commercial Relationship: Code N (No Commercial Relationship) | Min Zhao: Commercial Relationship: Code N (No Commercial Relationship) | Francine Behar-Cohen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The choroid vasculature, constituted by a network of arteries and capillaries, is essential to answer the metabolic needs of the outer retina. To avoid hypo or hyper-perfusion, which can lead either to ischemia or oedema, the choroidal blood flow is finely regulated by a very dense nervous system. This choroidal nervous system is known to be constituted by extrinsic components (autonomous and sensory) and by an intrinsic component (intrinsic choroidal neurons). While the choroidal vasculature has been thoroughly studied, the anatomy and the role of the choroidal nervous system and its implication in the etiology of pathologies is still poorly understood.

Methods: To better characterize the choroidal nervous system, choroids of mouse and rat, as well as human choroids, have been fixed and studied by histological approaches on transverse sections and/or flat-mounted tissue. Anatomical and neurochemical properties have been revealed by immunohistochemistry (IHC) using different markers of the autonomous and sensory nervous system such as TUBB3, myelin basic protein (MBP), neuropeptide Y (NPY) and calcitonin gene related peptide (CGRP). Furthermore, Electron microscopy (EM) has been used to analyze the ultrastructure of the nerve fibers and the myelination.

Results: The NPY-positive sympathetic fibers seem to be located close to the blood vessels, the labelling is almost exclusively concentrated around the vessels, probably at the synaptic level. There are very few CGRP-positive sensory fibers, the labelling is visible all along the fibers and these fibers are not preferably organized around the vessels, covering different zone of the choroid. EM analysis and IHC labelling on transverse sections showed both myelinated and unmyelinated nerves. Finally, IHC showed that a consequent quantity of fibers is located in the choriocapillaris, very close to the Bruch’s membrane.

Conclusions: The choroidal nervous system is a very dense and heterologous network. The sympathetic innervation seems to target preferably blood vessels, consistently with its role in the blood flow regulation. On the other hand, sensory nervous system displays a very different organization suggesting a different role in the choroid physiology. Moreover, the nervous fibers proximity with the Bruch’s membrane/retinal pigment epithelium complex could suggest a role of the choroidal nervous system in the regulation of the molecule efflux between the choroid and the retina.

ABSTRACT BODY:

Purpose: Protein folding chaperones have critical roles in proteostasis. In the human ageing brain and neurodegenerative disease, there is a significant decrease in the expression of these proteins. This study aimed to investigate their expression in relation to ageing in the retinal pigment epithelium (RPE).

Methods: The publicly available microarray transcriptome dataset GSE29801 of RPE/choroid was re-analysed to assess the ageing effect on gene expression in RPE/choroid. A linear model using limma was applied to find the differential expressed genes with age, and the respective significant genes were further subjected to gene set enrichment analysis. Fifteen RNA samples of human RPE/choroid (47-83 years old) were used to validate the significance of ageing for DNAJB1 (HSP40) gene. DNAJB1 expression was also assessed in ARPE-19 cells cultured on extracellular matrix exposed to glycolaldehyde to induce glycation end products (AGE) or exposed to lipid peroxidation (LPE) by qPCR and Western blot. Two-way ANOVA was performed for statistical analysis.

Results: The transcriptome data of 96 human RPE/choroid (9-93 years old) was analysed by limma. The analysis showed 620 genes differentially expressed with ageing (277 upregulated and 343 downregulated). Among the differentially expressed genes, gene-set enrichment analysis showed co-chaperone activity as a significant gene set (FDR<0.05), including down-regulation of DNAJB1, DNAJB4 and DNAJA1. The negative correlation of DNAJB1 transcription with ageing was validated in an independent set of 15 RPE/choroid samples by qPCR ($p<0.05$). There was an increase in mRNA expression but lower protein expression of DNAJB1 in ARPE-19 cells cultured in the presence of AGE and LPE ($p<0.05$).

Conclusions: Differential expression of the chaperone DNAJB1 in RPE/choroid of increased ageing was characterised using a publicly available human transcriptome RPE/choroid dataset, in-house human RNA samples extracted from human RPE/choroid and AGE-/LPE-exposed ARPE-19 cells. The results indicate the downregulation of DNAJB1 in ageing RPE. In the presence of AGE and LPE, DNAJB1 protein level is reduced in ARPE-19 cells, possibly due to increased turnover, but the cells might subsequently compensate by increasing mRNA expression of DNAJB1. Our results suggested that DNAJB1 could be a critical regulator of proteostasis in ageing RPE/AMD similar to the ageing brain and other neurodegenerative diseases.

ABSTRACT BODY:

Purpose: In this study, we explored the therapeutic efficacy of Mesenchymal stromal cells -derived extracellular vesicles (MSC-EVs) in a mouse model of dry eye disease (DED) and assessed its ability to modulate immune responses and promote tissue repair in dry eye disease.

Methods: DED was induced in female C57BL/6 mice by exposure to controlled environment chamber and subcutaneous injection of 0.5mg/0.2mL scopolamine hydrobromide four times per day for 14 days. Mice were grouped and treated with either MSC-EVs or PBS eye drops for comparison purposes. Samples of cornea, conjunctiva and draining lymph nodes were collected after treatment. Dendritic cells (DCs) were detected by immunofluorescence and flow cytometric analysis to assess its number and the expression of MHC-II and CD86. Th17 cells were detected by flow cytometric analysis to evaluate the antigen-presenting function of DCs. RT-PCR was performed to determine the mRNA expression of inflammatory cytokines in cornea and conjunctiva. In vitro, human corneal epithelial cells (HCEC) were cultured in hyperosmotic media and treated with MSC-EVs. Then cell viability was assessed by CCK8, and expression of inflammatory cytokines was detected by RT-PCR.

Results: MSC-EVs-treated mice presented more tear production ($P<0.05$) and lower corneal fluorescein staining scores ($P<0.05$). DED upregulated the number of DCs and their maturation level, and treatment with MSC-EVs effectively reduced the number of DCs ($P<0.05$) and suppressed the expression of MHC-II ($P<0.01$) and CD86 ($P<0.05$). Reduction of Th17 cells was also observed in cornea and draining lymph nodes. Compared with untreated control group, expression of inflammatory cytokines was downregulated in cornea and conjunctiva of MSC-EVs-treated mice. In vitro, MSC-EVs protected HCECs against loss of cell viability induced by hyperosmotic stress. MSC-EVs also reduced the expression of inflammatory cytokines, including TNF-α, IL-1β, IFN-γ and IL-6.

Conclusions: The results of our study revealed the role of MSC-EVs in regulating DC functions and promoting tissue regeneration in DED mice. MSC-EVs hold a great promise as a novel treatment method for DED and other ocular surface diseases.

ABSTRACT BODY:

Purpose: Infectious keratitis is one of the leading causes of blindness worldwide, frequently associated with the use of contact lenses. It is primarily due to the invasion of the corneal tissue caused by a great variety of microorganisms, mainly bacteria. Exosomes are nanovesicles of 30 to 150 nm in diameter involved in both physiological and pathological intercellular communication processes. Regarding eye diseases, the knowledge of their role is still very limited. Based on this, the hypothesis that arises is that microorganisms in contact with exosomes produced by human corneal epithelium cells (HCE), an experimental model, would produce changes in the expression of bacterial virulence factors.

Methods: Exosomes were isolated and purified from HCE and then added to Gram-positive (Staphylococcus epidermidis) and Gram-negative (Pseudomonas aeruginosa) bacterial cultures. Afterwards, the variation in the expression levels of genes encoding virulence factors were analysed by means of RT-qPCR over time compared to bacteria without any contact with exosomes.

Results: The expression levels of 7 virulence factors were studied at different times, from 30 minutes to 16 hours. When Staphylococcus epidermidis data was analysed, two clear tendencies were observed: while one group increased their expression up to 4-8 hours and then they remained stable, the other group, after a slight increase in the first 30 minutes, decreased over time. In the case of Pseudomonas aeruginosa, the genes analysed present a common trend, decreasing strongly in the first hours and recovering their expression levels over time.

Conclusions: Staphylococcus epidermidis, considered a commensal microorganism but also one of the main agents responsible for bacterial keratitis, increases the expression of genes encoding toxins and biofilm, while those related to quorum sensing are reduced over time. In the case of the pathogen Pseudomonas aeruginosa, the virulence factors related to biofilm establishment also modify their levels. Taking into consideration these results, it is deduced that bacteria have the ability to respond and change the expression of virulence factors in the presence of exosomes, with no need for direct tissue contact.

ABSTRACT BODY:

Purpose: The retinal pigment epithelium (RPE) has a high natural requirement for lysosomal degradation due to the daily phagocytosis and clearance of photoreceptor outer segments. Lysosomes are known to be heterogeneous in terms of morphology and content of classical lysosomal markers, but the functional significance of this is unclear. We aimed to characterise lysosomal heterogeneity in the RPE in order to determine the extent to which different lysosomal subpopulations represent stages in the lysosomal life cycle, which maintains the degradative capacity of the cell.

Methods: Morphology and content of lysosomal markers in primary porcine RPE and other cell models was determined by conventional and immuno-electron microscopy. To determine accessibility of lysosomes to the endocytic pathway cells were loaded with either fluorescent dextrans or colloidal gold particles and examined by live cell confocal microscopy and electron microscopy. Electron tomography was used to assess the 3-dimensional structure of RPE lysosomes.

Results: Vacuoles positive for lysosomal membrane proteins could be subdivided into those composed exclusively of lamellae, those with lamellar regions and those completely lacking lamellae. Endocytosed BSA gold particles were found exclusively in non-lamellar regions whilst the lamellar regions contained much of the lysosomal acid hydrolase, cathepsin D. Pulse chase experiments employing BSA gold showed that after degradation of the BSA that stabilises the gold particles, undigested aggregated gold particles were segregated into non-lamellar lysosomes. Parallel experiments employing sequential pulses of dextrans labelled with different fluorophores, separating the two pulses by up to 7 days, showed that a proportion of dextran-containing lysosomes lose accessibility to the endocytic pathway, suggesting that they have dropped out of the lysosome cycle. Electron tomography indicated multiple connections between lamellar lysosomes whilst at least some non-lamellar lysosomes have lost connection with this lysosomal network.

Conclusions: Morphologically heterogeneous lamellar and non-lamellar lysosomes within the RPE represent different stages in the lysosome cycle. Undigestible material is segregated into non-lamellar lysosomes that appear to lose the ability to interact with endosomes and lysosomes and drop out of the lysosome cycle.

ABSTRACT BODY:

Purpose: One of the most frequent ocular pathologies worldwide is keratitis, which may be associated with infectious processes. Fungal keratitis is caused by a broad spectrum of microorganisms, which differs depending on the geographical area involved. The identification of the epithelial receptors which enable adherence and colonization is key with respect to fungal keratitis. Previous studies have shown that, in bacterial keratitis, pathogens specifically bind to certain regions of the glycosaminoglycans (GAGs) chains, which are usually highly sulphated. This study tested the hypothesis that GAGs can act as receptors of yeasts in corneal infection and possible changes in the gene expression of the modifying enzymes of the GAGs chains.

Methods: The adherence inhibition assays were performed on immortalized corneal epithelial cells (HCE-2) monolayers. Firstly, FITC-labeled yeast (Candida albicans, Candida glabrata or Candida parapsilosis) were co-incubated with heparan sulfate (HS), chondroitin sulfate A (CSA), chondroitin sulfate B (CSB), chondroitin sulfate C (CSC), or a mixture of the four, and then all incubated with HCE-2. Variations in the transcription levels of the GAGs chains modifying enzymes were analysed by RT-PCR. The data were analysed with statistical analysis. The mean values of two samples were compared using the Mann-Whitney U test with $p<0.05$ being considered as significant.

Results: The inhibition of adherence showed a decrease in the adherence of the 3 yeasts to the corneal cells although there are differences between fungal species and the interfering molecule used. HS and CSB showed the greatest inhibition in C. albicans, contrary to what occurs in C. parapsilosis, which were CSA and CSC. In C. glabrata, HS and CSC were those with the highest inhibitory capacity. The adherence of the fungus induced significant alterations in the expression levels of both HS and CS chains modifying enzymes. Among modifying enzymes of CS, 6 out of 9 enzymes showed sub-expressions induced by C. glabrata. In the case of modifying enzymes of HS, 10 out of 14 enzymes showed sub-expressions, although depending on the gene and yeast used.

Conclusions: Corneal surface GAGs are involved in the adherence of C. albicans, C. glabrata and C. parapsilosis. The interaction of the microorganism with cells induces alterations in the transcription levels of the GAGs chains modifying enzymes that are dependent at the yeast species.

ABSTRACT BODY:

Purpose: Corneal collagen cross-linking (CXL) using riboflavin and ultraviolet-A light (UVA) is a minimally invasive treatment used to prevent progression of keratoconus. Recently, some have advocated rinsing the cornea with balanced salt solution (BSS) prior to UVA exposure to remove the superficial riboflavin film and prevent UVA shielding. This study assesses the impact of rinsing on CXL effectiveness by examining the enzymatic resistance of the tissue following treatment.

Methods: 40 porcine eyes (with corneal epithelium removed) were assigned to 4 groups. Group 1 remained untreated. Groups 2, 3 and 4 received a 10-min application of 0.1% riboflavin/HPMC eyedrops. Group 3 was immediately exposed to 9 mW/cm^2 UVA for 10-mins and Group 4 received the same UVA exposure after a corneal surface rinse (0.25 ml BSS). Central corneal thickness (CCT) was recorded at each stage of treatment. Trephined 8.0 mm central corneal buttons (n = 5 per group) were subjected to 0.3% collagenase digestion at 37°C. The samples were monitored at 1-hr intervals for the first 30-hrs, and 2-10hr intervals thereafter, to determine the time required for complete digestion.

Results: A 10-min application of riboflavin/HPMC solution to the de-epithelialised cornea led to an increase in CCT (54 µm ± 26; $p<0.01$) (Fig. 1). During UVA exposure, the CCT of the unrinsed CXL corneas (Group 3) returned to pre-treatment levels but the CCT of the BSS-rinsed CXL corneas (Group 4) continued to rise above the pre-treatment value (75 µm ± 15; $p<0.01$). All CXL-treated corneas displayed a 3-to-4-fold greater resistance to collagenase digestion than non-irradiated corneas. Complete digestion occurred at 12 ± 0.9 and 12 ± 0.8 hours in the untreated (Group 1) and riboflavin only treated (Group 2) corneas respectively and at 36-49 hours in the CXL treated corneas (Groups 3 and 4). There were no notable differences in enzymatic resistance between the two CXL groups.

Conclusions: Both CXL protocols were equally effective at enhancing the resistance of the cornea to collagenase digestion, although BSS-rinse CXL may be advantageous for the treatment of thin corneas which require tissue swelling. Further studies are needed to assess the impact of different volumes of BSS rinse on CXL effectiveness.

ABSTRACT BODY:

Purpose: Optical coherence tomography angiography (OCTA) can capture the microvascular structure of macular neovascularization (MNV) in eyes with age-related macular degeneration (AMD).In this study, we evaluated several deep learning algorithms designed to detect activity of MNV using en face OCTA images.

Methods: En face OCTA 6x6 mm images from 97 subjects with neovascular AMD imaged on RTvue-XR Avanti SD-OCTA (Optovue. Inc, Fremont, CA) device were included in this study and retrospectively analyzed. En face OCTA images of the MNV lesion were generated using a customized 10 microns thick slab,with the boundaries adjusted to display the maximum extent of the MNV lesion. Multiple machine learning models were trained to classify the presence of MNV activity on the OCTA images, using the presence of fluid on the structural OCT as the ground truth. Specifically, a five-fold cross-validation was applied to assess the different models' performance:four-fifths of the patients were used for training and a fifth for validation. This process was computed 20 times to generate a total of 100 different receiver operating characteristics (ROCs).The different performances were evaluated by using the ROC,its area under the curve (AUC). To further assess the ability of the algorithms to detect activity of MNV using en face OCTA images only, a leaky cross-validation approach was used.

Results: For 97 patients participated 637 en face OCTA scans were exported as .png images. Macular neovascularization (MNV) evident on en face OCTA images was a poor predictor of disease activity as defined by the presence of fluid on structural OCT. The algorithms used did not have a good performance and using the leaky cross-validation approach we conclude that even if a larger number of cases were used a substantial improvement in performance is not expected: Resnet (0.59 [0.47,0.71]), simple CNN (0.60[0.49,071]), LR+PCA (0.53[0.41,0.64]), Resnet-Scratch (0.62[0.54,0.70]). The leaky cross-validation applied to the top performing model, Resnet-Scratch, resulted in an AUROC of 0.67[0.60, 0.74].

Conclusions: In this study, we observed that en face OCTA images alone of MNV lesions are poor predictors of MNV lesion activity.This suggests that strong biomarkers of disease activity at a point time may not be encoded within the en face OCTA image.

TITLE: Age correlated reduction of photoreceptor connecting cilium length in XLRP mouse model and C57BL/6J mice

SESSION TITLE: Retinal Degenerations, Gene Therapy, Transplantation, and Prostheses

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Müller, A. Penner, K. Stieger, Ophthalmology, Faculty of Medicine, Justus-Liebig-University Giessen, Giessen, GERMANY|

Commercial Relationships Disclosure: Brigitte Müller: Commercial Relationship: Code N (No Commercial Relationship) | Annette Penner: Commercial Relationship: Code N (No Commercial Relationship) | Knut Stieger: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The C57BL/6-RPGR^{tm1Sti} mouse model for X-linked retinitis pigmentosa (XLRP model) carries a point mutation in the mutational hotspot exon ORF15 of the rpgr gene. To assess the reduction of photoreceptor connecting cilium (cc) length in the XLRP mouse model, immunohistochmically labeled cc were evaluated and compared to cc length in wildtype mice. Our central question was whether there is an age related reduction of cc length in photoreceptors (PRs) of the XLRP mouse model vs healthy wild type cc.

Methods: Hemizygous male or homozygous female mice (age: 3, 9 or 15 months) of the XLRP model and C57BL/6J wild type mice with respective age were sacrificed, enucleated and the eyes immediately frozen in embedding medium to cut frozen sections. Connecting cilium region was analyzed after immunohistochemical labeling with antibodies against Centrin, AcTub and RPGR using confocal laser scanning microscopy.

Results: Only Centrin and AcTub antibodies labeled the cc region of PRs in both mouse lines completely, in contrast to the RPGR antibody. Within each mouse line, the cc length got shorter with age. In XLRP mice, cc length is significantly shorter at 3 and 9 months compared to wild type retina. At 15 months, cc length in PRs of both mouse lines show no significant difference.

Conclusions: During the course of life cc length of PRs is decreasing significantly in both mouse lines investigated. In 3-months old XLRP mice, the cc length corresponds to 9-months old wild type mice. Therefore, age correlated reduction of photoreceptor cc length starts earlier in XLRP mouse model compared to wild type mice.

TITLE: Corneal higher-order aberration in corneal endothelial decompensation secondary to obstetrical forceps injury

SESSION TITLE: Corneal Imaging and Corneal Nerves

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. kasamatsu, Y. Yagi-Yaguchi, T. Yamaguchi, J. Shimazaki, ophthalmology, Tokyo Shika Daigaku Ichikawa Sogo Byoin, Ichikawa, Chiba, JAPAN|

Commercial Relationships Disclosure: hirotsugu kasamatsu: Commercial Relationship: Code N (No Commercial Relationship) | Yukari Yagi-Yaguchi: Commercial Relationship: Code N (No Commercial Relationship) | Takefumi Yamaguchi: Commercial Relationship: Code N (No Commercial Relationship) | Jun Shimazaki: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Corneal endothelial decompensation with Descemet's membrane (DM) breaks secondary to obstetrical forceps trauma is a rare condition, for which endothelial keratoplasty may be technically challenging due to abnormal contour of the corneal endothelial side. This study aimed to characterize the corneal high-order aberration (HOA) and corneal topographic changes in corneal endothelial decompensation with DM breaks.

Methods: This retrospective study included 18 healthy controls and 23 eyes of 21 patients diagnosed with corneal decompensation with DM breaks (nine men and 12 women; mean age of 54.0 ± 9.1 years) at Tokyo Dental College Ichikawa General Hospital. We classified the corneal topographic patterns obtained by anterior segment optical coherence tomography (AS-OCT, CASIA II, Tomey, Aichi, Japan) into five categories. We quantified HOA of the anterior and posterior surfaces and the total cornea using AS-OCT. We classified corneal topographic patterns (asymmetric, protruding, flat, posterior irregular pattern, and regular astigmatism) based on corneal topography maps. We evaluated the correlations between visual acuity and either corneal HOA, corneal opacity grading, or severity of corneal edema.

Results: The logarithm minimum angle of resolution of visual acuity was 1.45 ± 0.84 in eyes with corneal decompensation with DM breaks. The most common topography patterns were protruding and regular astigmatism (six eyes, each 26.1 %), followed by asymmetric pattern (five eyes, 21.7 %).HOA and coma within the diameters of 4 and 6 mm in corneal decompensation with DM breaks were significantly larger than those in healthy controls ($P<0.0001$). We found positive correlations between visual acuity and coma of the total cornea of 6-mm diameter, opacity grade, and corneal edema severity.
($r=0.482$, $P=0.023$, $r=0.695$, $P=0.0003$, $r=0.675$, $P=0.0006$, respectively)

Conclusions: Corneal HOA of total cornea and anterior and posterior surfaces were larger in patients with DM breaks secondary to obstetrical forceps injury than in normal individuals. Furthermore, coma significantly correlated with visual acuity, indicating that coma may be a useful parameter for assessing visual function in eyes with DM breaks.

TITLE: The absorption of diethyl phthalate conventional hydrogel contact lens

SESSION TITLE: Contact lens

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Won, J. Ahn, M. Choi, Optometry, Seoul National University of Science and Technology, Nowon-gu, Seoul , KOREA (THE REPUBLIC OF)|M. Choi, Convergence Institute of Biomedical Engineering and Biomaterials, Seoul National University of Science and Technology, Nowon-gu, Seoul , KOREA (THE REPUBLIC OF)|

Commercial Relationships Disclosure: Sungjin Won: Commercial Relationship: Code N (No Commercial Relationship) | Jihye Ahn: Commercial Relationship: Code N (No Commercial Relationship) | Moonsung Choi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Diethyl phthalate (DEP) is commonly used in cosmetics, perfumes and is contained in contact lens cleaning solutions. Contact lenses float on the surface of the ocular and are used to correct vision. In addition to proteins and lipids, which are tear components, harmful substances in the atmosphere are adsorbed to the contact lens and their properties can be changed. The purpose of this study is to evaluate the binding strength between DEP and contact lens and the physical properties of contact lenses.

Methods: Daily disposable contact lenses, etafilcon A material 1-Day ACUVUE MOIST (Johnson& Johnson Inc.) and hilafilcon B material SofLens Daily (Bausch&Lomb Inc.), were used. All the contact lenses were washed to minimize the effect of multi-purpose solution by soaking the contact lenses in 3rd distilled water for 1 hour. Contact lenses were incubated with different concentrations of DEP solution; 2mL of 25μM, 50μM, 75μM, 100μM. The amount of absorbed DEP was measured using a UV-vis spectrometer at a wavelength of 228nm. Various parameters such as water content, and refractive power were measured.

Results: Both etafilcon A and hilafilcon B materials completed the binding reaction in 5 minutes. As the DEP concentration increased, the amount of absorbed DEP and the rate constants (k_{obs}) were increased. Among the two materials, etafilcon A showed the greater amount of absorbed DEP and the rate constants (k_{obs}). The water content of contact lenses tended to decrease as the amount of absorbed DEP increased. However, in terms of refractive power, there were only slight changes.

Conclusions: This study showed that DEP has a high binding effect on the contact lenses and reduces water content among several physical properties. Hilafilcon B has a nonionic-surface and etafilcon A has an ionic-surface. It is predicted that the difference in the amount of absorbed DEP and the rate constants (k_{obs}) were derived from this difference between the two materials. Contact lenses are in long-term contact with the ocular surface and the atmosphere, so adsorption of DEP can negatively affect ocular disease or wearability.

ABSTRACT BODY:

Purpose: Polarization-sensitive OCT (PS-OCT) is expected to be the next generation OCT for clinical applications. The degree of polarization uniformity (DOPU) obtained by PS-OCT visualizes melanin distribution in retinal pigment epithelial cells (RPE) and depicts RPE abnormalities. However, the requirement of additional hardware for PS-OCT instrumentation has hindered the spread of PS-OCT. Here, we generated a pseudo-DOPU from ordinary OCT intensity using a convolutional neural network (CNN) and investigated its performance to detect abnormalities.

Methods: Fifteen eyes of 12 normal cases and 157 eyes of 123 abnormal cases were imaged by PS-OCT to obtain DOPU and OCT images. A CNN was trained to generate DOPU from OCT images using 10 eyes from 7 normal cases and 137 eyes from 103 cases of diseases.

Twenty eyes from 20 cases of disease and 5 eyes from 5 normal cases were used for evaluation. Ophthalmologist 1 extracted abnormal suprachoroidal regions from the OCT images, and ophthalmologist 2 identified RPE defects, thickening, prominences, and hyperintense retinal foci (HRF) in the DOPU and pseudo-DOPU faults at five locations within the regions. In normal eyes, the presence of abnormalities was assessed at five locations in each case.

Results: Representative pseudo-DOPU images of normal and abnormal cases which are not used in training are shown in Fig. 1. In these cases, pseudo-DOPU images well resemble DOPU images. In the disease case, RPE elevations (black arrows) and an RPE defect (white arrows) are in good agreement.

The recall and precision of pseudo-DOPU with respect to DOPU were as follows: for RPE deficiency (0.86, 0.37), for thickening (0.93, 0.65), for prominence (0.98, 0.98), and for HRF (0.74, 0.39). Of the 25 pseudo-DOPU cross-sectional images of normal eyes, 3 showed RPE defects, 1 showed RPE migration, and 1 showed abnormally low DOPU values, which were not confirmed by DOPU.

Conclusions: For the RPE abnormalities shown in DOPU, the pseudo DOPU did not show high precision but showed high sensitivity. For normal eyes, pseudo-DOPU seems to be similarly informative to PS-OCT, but we need to care about false abnormal findings.

ABSTRACT BODY:

Purpose: In patients with intermediate age-related macular degeneration (iAMD), the risk of progression to advanced stages is highly heterogeneous and the prognostic imaging biomarkers remain unclear. Building optical coherence tomography (OCT)-based deep learning prognostic models is challenging due to large dimensionality of OCT scans and limited size of longitudinal datasets. We train a deep survival model, to estimate from OCT an individual risk of conversion to macular atrophy.

Methods: The deep learning model was trained on a development dataset consisting of 267 eyes (1459 OCTs) with iAMD imaged every 6 months with Spectralis OCT (512x49x496 voxels). The model learns a probability of a conversion to macular atrophy, with a prognosis for every 6 months up to 36 months in the future. The model is trained on raw OCTs with Logistic Hazard (LH) loss, combining the advantages of survival models and deep learning. We compared our model with a standard deep learning classification approach trained with a Binary Cross Entropy (BCE), as well as with a traditional survival model with Cox Proportional Hazards (CPH) trained on a set of clinically relevant quantitative OCT biomarkers. The models were evaluated with a five-fold cross-validation. In addition, an independent longitudinal OCT dataset with 240 eyes (240 OCTs) was used as an external test set. The model performance was measured with Concordance Index (CCI).

Results: The prognostic deep survival models achieved a CCI of 0.79+/- 0.03 on the cross-validation, and 0.74 on the external test set. The resulting population risk estimates in the form of Kaplan-Meier curves for the converter and censored eyes (conversion beyond 36 months) on the development set are shown in Fig. 1. The BCE model achieved CCI of 0.78 +/- 0.06 on the cross-validation, and 0.73 on the external test set. Finally, the CoxPh model obtained CCI of 0.75 +/- 0.1 on the cross-validation, and 0.73 on the external test set.

Conclusions: Deep survival models allow building risk estimators for progression from iAMD to macular atrophy. They successfully combine the advantages of deep learning that can learn from raw OCT images with survival modelling paradigm that accounts for censoring and predictions for multiple time intervals.

Fischer, Center for Medical Statistics, Informatics and Intelligent Systems, Medical University of Vienna, Vienna, AUSTRIA|

Commercial Relationships Disclosure: Clemens Vass: Commercial Relationship: Code N (No Commercial Relationship) | Florian Schwarzhans: Commercial Relationship: Code N (No Commercial Relationship) | Stefan Steiner: Commercial Relationship: Code N (No Commercial Relationship) | Sylvia Desissaire: Commercial Relationship: Code N (No Commercial Relationship) | Hemma Resch: Commercial Relationship: Code N (No Commercial Relationship) | Georg Fischer: Commercial Relationship: Code N (No Commercial Relationship) | Michael Pircher: Commercial Relationship: Code N (No Commercial Relationship) | Christoph Hitzenberger: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To trace the retinal nerve fiber bundles (RNFBs) and to study the (mostly) decay of parameters describing the retinal nerve fiber layer (RNFL) along the RNFBs in healthy and early glaucoma eyes using polarization-sensitive optical coherence tomography (PS-OCT).

Methods: In this prospective cross-sectional study we used a prototype PS-OCT instrument to acquire wide-field scans composed of 7 times 3 volume scans in 21 early glaucoma (age 64.5 ±9.5 years) vs. 45 healthy eyes (age 50.7 ±13.7 years). The RNFL was segmented and the RNFBs were traced, starting at a 3 mm radius circle centered on the optic disc (OD) with 2 deg. spacing both towards the OD and the periphery. We focus on a sample of 5 RNFB traces at 40° (above the disc to fovea line), 20°, 0°, 340°. and 320°. The mean values and slopes along the bundles of RNFL-thickness (RNFL-T), RNFL-retardation (RNFL-R), RNFL-T times inter-trace distance (RNFL-TD), i.e. the bundle cross-sectional area, and RNFL-R times distance (RNFL-RD) were determined and compared between groups with t-tests for sections of 0.5 mm length.

Results: Glaucoma eyes showed statistically significantly reduced RNFL-T and RNFL-R over 2 to 6 mm depending on trace label. The largest difference between groups was observed temporal inferior (320°), where the significant differences extended over 5 to 6 mm for all parameters. For the 320° trace at 3 mm from the OD the difference between groups regarding the slopes of RNFL-T, and RNFL-TD was 6.0 µm/mm and 53.2 μm^2/mm ($p < 0.0005$ and $p < 0.005$) with the healthy eyes showing more negative slopes. The courses along the bundles are shown in fig. 1 and fig.2 for the mean parameter values and the mean slope values.

Conclusions: Early glaucoma shows significantly reduced RNFL-T and RNFL-R along large parts of the RNFBs. We find more negative slopes along the bundles for the healthy as compared to the glaucoma cases. The local slope of the parameters tested may contain information about the local number of remaining ganglion cells, which is to be confirmed in a future study.

TITLE: Extensive autophagy and unique nuclear excisosome formation from mitochondria characterize organelle degradation in lenses from Galago (bush baby) monkeys

SESSION TITLE: Lens epithelial cell stress and function

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: K. Schey, Biochemistry, Vanderbilt University, Nashville, Tennessee, UNITED STATES| M.J. Costello, K.O. Gilliland, Cell Biology and Physiology, University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, North Carolina, UNITED STATES|

Commercial Relationships Disclosure: M Costello: Commercial Relationship: Code N (No Commercial Relationship) | Kurt Gilliland: Commercial Relationship: Code N (No Commercial Relationship) | Kevin Schey: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Our previous paper described the formation of the nuclear excisosome (NE) in Galago lenses from modified mitochondria that initiated the process in the presence of numerous autophagic vesicles within equatorial epithelium. Further examination revealed how elaborate autophagy processes near the fulcrum produced large degradative bodies in the young fiber cells as extended mitochondria and NE cores elongated into rod-like “beads on a string” structures that degraded nuclei at the organelle-free zone (OFZ).

Methods: Lenses from Galago (bush baby) monkeys (n=4, age 2-5) were fixed in formalin followed by paraformaldehyde, then Vibratome sectioned. Sections were fixed and processed for thin-section transmission electron microscopy or stained with fluorescent dyes for Airyscan confocal microscopy. Nuclei were stained with DAPI, actin with Alexa-phalloidin, lectins with WGA and membranes with DiI.

Results: Galago monkey lenses formed unique four-membrane organelles in the equatorial epithelium from modified mitochondria with collapsed cristae that condensed and surrounded core proteins with a single membrane. Enlarged beads appeared to assist in fusing smaller rods into longer ones as the complexes migrated into fiber nascent fiber cells and attacked nuclear envelopes near the OFZ. The high cellular activity in transition region was supported by extensive autophagy of the classical type and a new variation of expanded extracellular space (ECS) between epithelial cells where material to be degraded and degradative enzymes entered by exocytosis. These ECS autophagic vesicles became so prominent that they started a new complex interdigitation to isolate them as bounded degradative bodies in young fiber cells. Smaller autophagic vesicles were seen throughout the formation and degradation of organelles in the OFZ.

Conclusions: Autophagy plays a prominent role throughout the degradative process including formation of new large ECS based autophagic vesicles with single plasma membrane borders.

TITLE: Contact Lens Induced Full- and Peripheral-Field Myopic Defocus on Choroidal Thickness with Time of Day

SESSION TITLE: Myopia: Clinical Interventions and Diagnostics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Ravikumar, L.A. Ostrin, Optometry, University of Houston System, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure: Ayeswarya Ravikumar: Commercial Relationship: Code N (No Commercial Relationship) | Lisa Ostrin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Short-term modulation of choroidal thickness may be an indicator of long-term myopia control. A previous study showed that the choroid thickens to full field spectacle lens myopic defocus, and more so in the evening than morning. Multifocal soft contact lens that provide peripheral myopic defocus have been shown to be effective in myopia control. The goals of this study were to assess short-term effects of full field or peripheral myopic defocus on choroidal thickness and to investigate time-of-day effects in young adults.

Methods: Healthy young adults (n=10) ages 28.2 ± 3.19 years participated in four sessions, separated by 1 to 4 days, two in the morning (9am) and two in the evening (5pm). For each session, participants first watched a movie for 10 min in a large screen at 2 m with single vision distance corrected contact lenses (+0.5 D for the working distance), and choroidal thickness was measured using optical coherence tomography(OCT) in both eyes. Then, the experimental lens, which provided an additional +2.5D full field or peripheral field defocus was placed on the left eye, and the participant continued to watch for 60 minutes. OCT was repeated. The distance-correction was replaced and recovery was measured after 20 minutes. Choroidal thickness change was determined for control and experimental eyes, and the difference between eyes was calculated. Repeated measures ANOVA with post-hoc Bonferroni correction was used to assess changes in choroidal thickness.

Results: Baseline choroidal thickness was similar in the morning (320.3±25.7 μm) and evening (335.6±26.6 μm, P=.4) and was similar between right and left eyes (P=.2). Following 60 min exposure to full field myopic defocus, the choroid of the experimental significantly thickened relative to the control eye in the morning (7.9±2.4 μm, P=.03), but not in the evening (6.0±2.7 μm, P=.15). Following 60 minutes exposure to peripheral field myopic defocus, the choroid did not significant change in the morning or evening (P=1 for both).

Conclusions: Findings show that short-term exposure to full field contact lens induced myopic defocus leads to significant thickening in the morning, but not in the evening. Peripheral field contact lens induced myopic defocus did not induce choroidal thickness changes. Future analysis including a larger sample size may be able to better distinguish small changes in choroidal thickness using OCT imaging.

TITLE: Serum c-reactive protein (CRP) relationship with macular pigment and response to carotenoid supplementation in open-angle glaucoma

SESSION TITLE: Glaucoma: biochemistry, biomechanics and omics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Biba, E. Loskutova, G. Lingham, J.S. Butler, C.J. O'Brien, J. Loughman, Centre for Eye Research Ireland (CERI), Technological University Dublin, Dublin, Dublin, IRELAND|C.J. O'Brien, Mater Misericordiae University Hospital, Dublin, IRELAND|

Commercial Relationships Disclosure: Matilda Biba: Commercial Relationship: Code N (No Commercial Relationship) | Ekaterina Loskutova: Commercial Relationship: Code N (No Commercial Relationship) | Gareth Lingham: Commercial Relationship: Code N (No Commercial Relationship) | John Butler: Commercial Relationship: Code N (No Commercial Relationship) | Colm O'Brien: Commercial Relationship: Code N (No Commercial Relationship) | James Loughman: Commercial Relationship(s);Code F (Financial Support):Alliance Pharmaceutical

ABSTRACT BODY:

Purpose: To evaluate CRP response to carotenoid supplementation and analyse its relationship to macular pigment optical density (MPOD) in glaucoma.

Methods: A randomised, double-blind, placebo-controlled clinical trial was conducted on 62 open-angle glaucoma subjects, with no known underlying systemic or ocular pathology. Subjects were randomly assigned (2:1 ratio) to treatment or placebo control groups and were required to ingest a daily dietary supplement for 18 months. The treatment group received the active capsule comprised of 10mg lutein, 2mg zeaxanthin and 10mg meso-zeaxanthin. Serum CRP levels, MPOD (Spectralis) and microperimetry (MAIA II) were measured at baseline and following 18 months supplementation.

Results: No significant differences in CRP and MPOD were found between treatment groups at baseline. MP volume was statistically significantly higher in the treatment group relative to placebo at 18 months ($p<0.01$; Table 1), but no significant difference in CRP was observed between groups. A statistically significant, inverse correlation was found between CRP and MP volume in the central 6^0 macular area (Fig. 1) and MPOD at 0.23, 0.51, 0.74 and 1.02 retinal eccentricities ($p<0.01$ for all). No significant correlation existed between CRP and glaucoma severity ($p=0.4$). To assess the direct effect of supplementation on CRP levels, a linear mixed model analysis was conducted with log(CRP) as the dependent variable and added fixed effects of time*treatment interaction. Baseline and 18 month data were used and participant ID was included as a random intercept to account for within-person correlation. No significant effect of supplementation on log(CRP) levels was found (estimate±SE: -2.5±1.64; t-test:-1.52; $p=0.13$).

Conclusions: The relationship between CRP and MPOD agrees with previous observations. The substantial increase in MP in response to supplementation, however, did not lead to a meaningful change in serum CRP (albeit that the treatment group mean CRP reduced and placebo group mean CRP more than doubled). Although further analysis is required with a larger study population, it appears that macular carotenoid supplementation has limited impact on this inflammatory marker among individuals with open angle glaucoma.

ABSTRACT BODY:

Purpose: To determine the association between the density of Demodex colonization, meibomian gland dysfunction (MGD) severity, and ocular symptoms in an Afro-Caribbean population.

Methods: The research study is a prospective, single-center, cross-sectional observational study. All enrolled participants will be analyzed in the following sequence: ocular surface disease index (OSDI) questionnaire, slit-lamp biomicroscopic examination, fluorescein tear film break-up time (F-BUT), and Demodex folliculorum count. Grading of the severity of MGD will be performed by a board-certified cornea specialist who will be blinded to the counting of Demodex specimens and OSDI score. Exclusion criteria include patients less than 18 years of age, active keratitis, intraocular surgery within three months, history of a pterygium, Sjogren syndrome, and uncontrolled autoimmune diseases. Demographics, ocular conditions, and comorbid medical conditions were collected and compared to patients without Demodex. Association with OSDI raw score and mite count will be calculated with Spearman correlation with the construction of 95% confidence interval.

Results: Twenty-eight patients ranging from 65 +/- 12 (mean +/- standard deviation) years of age met the criteria for inclusion. A total of 35.7% of patients were positive for Demodex colonization. The average count of Demodex was 1.37 +/- 1.00. No association with gender, age, OSDI score, or MGD severity was seen with Demodex colonization. Comorbid medical conditions such as DM and HTN were similar between patients with and without Demodex. Collarettes and scurf findings on clinical exam were associated with higher rates of Demodex, $p<.05$.

Conclusions: Demodex is relatively common in the Afro-Caribbean Population with higher rates among patients with collarettes and scurf. However, no association with worsening MGD or OSDI was linked to Demodex colonization.

TITLE: The effect of pH on the surface charge of contact lens and lysozyme deposition

SESSION TITLE: Contact lens

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. shin, S. Won, M. Choi, Optometry, Seoul National University of Science and Technology, Nowon-gu, Seoul, KOREA (THE REPUBLIC OF)|M. Choi, Convergence Institute of Biomedical Engineering and Biomaterials, Seoul National University of Science and Technology, Nowon-gu, Seoul, KOREA (THE REPUBLIC OF)|

Commercial Relationships Disclosure: jihun shin: Commercial Relationship: Code N (No Commercial Relationship) | Sungjin Won: Commercial Relationship: Code N (No Commercial Relationship) | Moonsung Choi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Ocular pH has been measured for decades and reported to range from 6.5 to 7.7 and from 5.9 to 7.6 in normal; by a variety of factors, the ocular pH could be changed such as age, time, diseases, wearing contact lens, air pollution. The pH of the ocular surface could affect the ionization state of contact lens; protonation and deprotonation. In this study, we investigated the change of surface charge and protein deposition on contact lenses depending on the pH condition.

Methods: The etafilcon A material contact lens (1-Day ACUVUE MOIST, Johnson& Johnson Inc.) and 10mM phosphate buffer solutions were used throughout the study. The contact lenses were incubated in each buffer solution pH range from 6.0 to 8.0 for 48 hours to remove residual blister solution and reach equilibrium state. The surface charge of contact lens was evaluated via point of zero charge (POZC). The quantity of deposited lysozyme per unit area(mm^2) was calculated by dividing the total quantity of deposited lysozyme in each pH solution by its surface area(mm^2).

Results: The POZC of contact lenses were lower than each pH condition though they were increased under pH 7.2 and showed relatively constant values above pH 7.2. The surface area of contact lens was increased under pH 7.2 and showed relatively constant values above pH 7.2. The quantity of deposited lysozyme per unit area(mm^2) was increased under pH 7.2 and showed relatively constant values around and above pH 7.2.

Conclusions: The lower POZC than the given pH condition implies that the surface of contact lens has negative charge which attracts lysozyme that has positive charge. The POZC, surface area, and quantity of deposited lysozyme per unit area(mm^2) showed constant values above pH 7.2 which implies that the contact lens had fully ionized, and maximum amount of lysozyme had been deposited. It was found that the surface charge of contact lens is affected by the pH around them, and a maximum amount of lysozyme is deposited on contact lenses in physiological condition.

TITLE: Filters can negatively affect clinical stereopsis measures with the impact being greater in induced near exophorias.

SESSION TITLE: Visual Function: perception, adaptation, spatial, visual acuity and binocular vision

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F.A. Ennis, S. Cox, Optometry and Vision Sciences, Cardiff University College of Biomedical and Life Sciences, Cardiff, Cardiff, UNITED KINGDOM|

Commercial Relationships Disclosure: Fergal Ennis: Commercial Relationship: Code N (No Commercial Relationship) | Scott Cox: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Clinical stereopsis tests are known to give different thresholds but the underlying mechanism is not fully understood. Specifically why does the TNO threshold differ from other tests (e.g. Titmus)? The global versus local stereo theory has been disproved. The effect of illumination levels and filter impact has been partially explored but is inconclusive. Also, differences between compensated and decompensating individuals have not been fully explored. This preliminary study investigates to what extent clinically used anaglyphic (red/green) and vectographic cross-polarised filters impact on clinical stereo results in the presence and absence of an induced decompensating near exophoria.

Methods: Stereoacuities (SA) were measured using TNO and Titmus in 41 binocularly normal (i.e. fully compensated) participants (ages 19–32, mean age: 21.1 ± 2.5) both conventionally with their appropriate red/green or cross-polarised filters, and then with both filter options in place. This procedure was repeated in the presence of a base-out-prism-induced near exophoria (NXOP). The individual prism values required were calculated by manipulation of Sheard's criterion to give a base-out prism value that theoretically leaves the subject still fusing but with a consistently compromised state of compensation.

Results:

Combining filters only: There was no significant reduction in the TNO SA ($p = 0.246$) but there was a significant reduction in the Titmus ($p = 0.001$)

Inducing decompensation (NXOP) with single filters: There was a significant reduction in SA for both tests, more so for the Titmus (TNO $p = 0.044$, Titmus $p < 0.001$)

Combining filters and inducing decompensation (NXOP): There was a reduction in SA in both tests (TNO $p = 0.001$, Titmus $p < 0.001$). This reduction was greater than in either of the above single-manipulation scenarios.

Conclusions: The results of this pilot study suggest that the filters used to measure stereopsis may have a detrimental impact on stereopsis performance, especially in the presence of decompensating heterophoria: specifically the significant impact of red/green anaglyph filters on Titmus results suggest they may be more "invasive" than polarised filters and hence have a greater impact on the recorded threshold. Further research is needed to quantify this phenomenon and its relation to clinical data gathering and decision making.

TITLE: Prevalence and Risk Factors of Macular Retinoschisis in highly myopic eyes: the Beijing Eye Study 2011

SESSION TITLE: Myopia epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Z. Pan, Y. Wang, Beijing Tongren Eye Center, Beijing, CHINA|C. Zhang, Peking University Eye Center, Beijing, CHINA|

Commercial Relationships Disclosure: Zhe Pan: Commercial Relationship: Code N (No Commercial Relationship) | Ya Xing Wang: Commercial Relationship: Code N (No Commercial Relationship) | Chun Zhang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate the prevalence and risk factors of macular retinoschisis (MRS) in highly myopic eyes and their morphological features observed by optical coherence tomography (OCT) in Chinese population.

Methods: The population-based Beijing Eye Study 2011enrolled 3468 participants (1963 women, 56.6%) with a mean age of 64.6 ± 9.8 years (50 - 93). Spectral-domain OCT was applied in every participant, including the macula cube scan of 30× 25°centered in the fovea. High myopia was defined as a refractive error ≤ -6 diopters or an axial length ≥ 26.0 mm. MRS were detected by OCT images.

Results: A total of 213 highly myopic eyes of 129 participants were analyzed, with a mean refractive error of -8.5 ± 3.2 diopter, or a mean axial length 26.8 ± 1.4 mm. MRS was found in 36 subjects (48 eyes) with a prevalence of 27.9% (95% confidence interval (CI): 20.5%, 35.7%) per subject or 22.5% (95%CI: 16.9%, 28.6%) per eye. MRS was observed most frequently in the extrafoveal region (15 eyes, 65.2%), as compared with other locations, including 3 eyes in the foveal only region (13.0%), 2 eyes in the fovea plus part of parafoveal region (8.7%) and 3 eyes in the entire macular region (13.0%). The presence of MRS was more often seen in participants of a higher body weight (P=0.014), with more myopic refraction (P<0.001; OR, 0.75; 95%CI, 0.64, 0.88) (Figure 1), with a higher intraocular pressure (P=0.013), and with a wider parapapillary gamma zone (P=0.004), after multivariate analysis.

Conclusions: The prevalence of MRS was 27.9% in highly myopic participants in an older Chinese population. Body weight, intraocular pressure and gamma zone width may play a role in the development of MRS, besides the effect of myopic refraction.

ABSTRACT BODY:

Purpose: Amniotic membrane (AM) transplantation has been used successfully in treatment refractory macular holes. We have previously shown that amniotic membrane has regenerative capacities in the retina. In this comparative study we investigate retinal hole closure with and without AM in a porcine model of retinal hole. Our hypothesis is that AM transplantation can close large retinal holes either by scar tissue formation or regeneration of retinal cells. The aim of this study is to evaluate the anatomical, functional, and histopathological outcomes after AM transplantation in a porcine model for retinal hole.

Methods: Danish landrace pigs were vitrectomized in full anesthesia and a subretinal bleb was created before cutting a retinal hole using a 23G vitrector. Pigs underwent either transplantation of humane freeze-dried amniotic membrane into the subretinal space or were left untreated. No tamponade was used, but sclerotomies were sutured with 7-0 Vicryl^{TM}. Prior to surgery and two and four weeks after surgery, the eyes were examined by Optical Coherence Tomography (OCT), multifocal electroretinogram (mfERG) and fundus photographs. At the end of follow-up, the eyes were enucleated for histology.

Results: Retinal hole closure seemed to be time dependent showing that some time passes before spontaneous closure. Furthermore, it was possible to calculate a hole closure rate. We found no spontaneous hole closure in retinal holes larger than 1350 um at 4 weeks. In the AM group all holes closed regardless of size.

Conclusions: We present a porcine model for retinal hole. Spontaneous hole closure is not a static event but happens over time. AM transplantation acts as a “band aid” or stimulator for retinal hole closure by glial scarring.

ABSTRACT BODY:

Purpose: The objective of this study was to determine whether canine adipose derived mesenchymal stromal cells (adMSC) express keratocyte-specific phenotypic markers when cultured under conditions inducing differentiation of corneal stromal stem cells to keratocytes in 2D.

Methods: AdMSC were differentiated in keratocyte differentiation media (KDM) containing basic fibroblastic growth factor (bFGF) and ascorbic acid in the absence of serum for 3 weeks and compared to cells pre-cultured in corneal stromal stem cell media (CSSCM) containing ascorbic acid, platelet derived growth factor (PDGF), epidermal growth factor (EGF) and low serum for 7 days followed by 3 weeks KDM. This was performed in a biological triplicate and cells were characterized using quantitative RT–PCR and immunostaining. Statistical analysis included Shapiro-Wilk normality test, ANOVA, followed by the Tukey's post hoc test.

Results: AdMSC differentiated into KDC showed keratocyte-like morphology, expressed keratocyte associated proteins Keratocan, Lumican and ALDH1A3 and but not the stem cell marker Pax6 when cultured in KDM. Pre-culturing adMSC in CSSCM before differentiating in KDM increased the level of Keratocan and Lumican gene expression significantly but not ALDH1A3. AdMSC cultured in CSSC media showed a trend of upregulated Pax6 and N-cadherin, which was downregulated after keratocyte differentiation. Expression of differentiation markers was quantitatively lower than following the keratocyte differentiation of primary canine CSSC.
BFGF increased the cell expansion of adMSC-KDCs but retained a fibroblastic cell morphology. AdMSCs express α-smooth muscle actin (α-SMA) at the protein and mRNA level in the undifferentiated state and at all stages of differentiation.

Conclusions: Keratocyte-like cells derived from canine adMSCs may serve as a source of keratocytes but expressed myofibroblastic features when cultured in 2D.

Lopez: Commercial Relationship(s);Code E (Employment):AbbVie Inc

ABSTRACT BODY:

Purpose: Microperimetry is a useful assessment to evaluate visual function across the macula in detail. In geographic atrophy (GA), test points that fall within scotomas provide limited information. This study evaluates the feasibility and test-retest reliability of scotopic and mesopic microperimetry in patients with GA, using an optimized patient-customized grid.

Methods: This is a prospective pilot study conducted at 2 sites in the United States. At each of the 4 study visits (Baseline, Day 7, Months 3 and 6), scotopic then mesopic microperimetry were performed using an S-MAIA (CenterVue, Padova, Italy). Customized grids were generated by a reading center. Nine points were placed on the subject's preferred retinal locus and ~50 equidistantly spaced points were distributed in two concentric rings 200 and 450 µm from the lesion border. Test-retest reliability of average threshold sensitivities was assessed by evaluating data from the Baseline (test) and Day 7 (re-test) visits. Spearman correlations and Bland-Altman plots were used to evaluate association and equivalency between measurements, respectively. The coefficient of repeatability (CR) was also computed with 95% confidence intervals (CI) to quantify the smallest real difference between test and re-test. Values presented are means ± standard error of the mean unless otherwise stated. Statistical analysis was conducted using R Software (v4.1.2) under RStudio.

Results: Eleven subjects were enrolled (82% female). Median age was 80 years (range 63-91). GA lesion area was 19.8±1.5 mm^2, and mean best-corrected visual acuity was 56.5±5.3 letters. The average threshold sensitivity for each visit was: 7.3±2.2, 6.9±2.4, 5.4±2.5, and 5.2±1.9 dB for scotopic; 11.6±1.7, 12.1±1.7, 11.0±2.1, and 10.3±1.9 dB for mesopic conditions. In general, scotopic microperimetry was less reliable than mesopic (lower Spearman correlation and wider Bland-Altman limits of agreement). Similarly, average threshold sensitivity CRs were 13.6 dB for scotopic and 2.9 dB for mesopic, 95% CI [0, 17.2] and [0.1, 3.1].

Conclusions: This study demonstrates that patient-customized grids in GA offer a feasible and reliable way to conduct microperimetry in large scale clinical trials, particularly with mesopic microperimetry. Analysis of individual point sensitivity "by zone" and its reliability is currently ongoing.

TITLE: Deep Learning for Automated Detection of Neovascular Leakage and Vascular Nonperfusion in Diabetic Retinopathy Using Ultra-widefield Fluorescein Angiography

SESSION TITLE: Machine Learning and Image Processing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P.Y. Zhao, N. Bommakanti, G. Yu, M.T. Aaberg, T. Patel, Y.M. Paulus, W K Kellogg Eye Center, Ann Arbor, Michigan, UNITED STATES|

Commercial Relationships Disclosure: Peter Zhao: Commercial Relationship: Code N (No Commercial Relationship) | Nikhil Bommakanti: Commercial Relationship: Code N (No Commercial Relationship) | Gina Yu: Commercial Relationship: Code N (No Commercial Relationship) | Michael Aaberg: Commercial Relationship: Code N (No Commercial Relationship) | Tapan Patel: Commercial Relationship: Code N (No Commercial Relationship) | Yannis Paulus: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Neovascular leakage and vascular non-perfusion are angiographic features of diabetic retinopathy. The goal of this study was to determine whether these features could be accurately classified by a deep learning algorithm.

Methods: We used retrospective fluorescein angiogram images captured on the Optos ultra-widefield platform between January 2009 and May 2018. Images were randomly split into training (60%), validation (20%), and test (20%) sets. A ResNet-101 convolutional neural network that was pre-trained on ImageNet was trained on fluorescein angiogram images. The neural network was configured to output predictions on the presence of neovascular leakage and vascular non-perfusion. Predictions were compared to the ground truth labeled by masked, trained graders.

Results: 1452 images from 342 subjects were included. 60% of images were from female subjects, and 79% of images were from patients with type 2 diabetes mellitus. Mean hemoglobin A1c was 8.1% (SD=2.1%). Mean visual acuity was logMAR 0.35 (SD=0.30). Neovascular leakage was present in 21% of images, and non-perfusion greater than a pre-determined threshold (77.5 mm^2) predictive of development of proliferative diabetic retinopathy was present in 42% of images. The mean total non-perfusion area was 80.8 mm^2 (SD=63.3). The algorithm achieved an area under the curve (AUC) of 0.976 for neovascular leakage, and an AUC of 0.949 for detecting vascular non-perfusion. At operating points selected for high sensitivity, the algorithm achieved 97% sensitivity and 89% specificity for neovascular leakage, and 94% sensitivity and 79% specificity for non-perfusion. At operating points selected for high specificity, the algorithm achieved 75% sensitivity and 94% specificity for neovascular leakage, and 86% sensitivity and 86% specificity for non-perfusion.

Conclusions: A convolutional neural network was trained to recognize the presence of neovascular leakage and non-perfusion in ultra-widefield fluorescein angiography. Further research may help improve algorithm performance and better characterize the relationship between non-perfusion, neovascularization, and vision-threatening complications of diabetic retinopathy.

TITLE: Associations between clinical measures and quality of life in refractive error

SESSION TITLE: Vision Impairment, Visual Function, and Quality of Life

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Prem Senthil, Optometry, Flinders University, Adelaide, South Australia, AUSTRALIA|R. Chakraborty, Optometry, Flinders University, Adelaide, South Australia, AUSTRALIA|

Commercial Relationships Disclosure: Mallika Prem Senthil: Commercial Relationship: Code N (No Commercial Relationship) | Ranjay Chakraborty: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Refractive errors are associated with structural and functional changes in the eye. While previous studies have assessed the impact of refractive error on quality of life, the association between the objective structural and functional measures of refractive error and quality of life has not been studied. This study aims to determine the association between clinical measures and quality of life in refractive error.

Methods: Fifty participants with corrected refractive error (spectacles, contact lens or refractive surgery) between the ages of 18 and 35 were recruited for this cross-sectional pilot study. Best corrected visual acuity, contrast sensitivity, and spherical equivalent refractive error (SER) were measured for all participants. Measurements of, axial length, corneal curvature and anterior chamber depth were obtained using the IOL Master, and macular thickness was measured using the optical coherence tomography. Vision related quality of life was assessed using the Quality of Life Impact of Refractive Correction questionnaire (QIRC).

Results: The mean age of the participants was 24.37±3.41 years (68% females). The mean spherical equivalent was -2.74± 1.87 D and the mean QIRC score was 44.07±6.61 logits. The QIRC based quality of life was significantly associated with axial length (r^2=0.16, p=0.004) and SER (r^2=0.12, p=0.013). A 1 mm increase in axial length reduced the QIRC scores by 2.41 logits and a one dioptre increase in SER caused a 1.03 logits reduction in QIRC scores. None of the other measured parameters were significantly correlated with the QIRC scores.

Conclusions: Quality of life positively correlated with spherical equivalent and negatively with axial length. Clinicians and researchers can use clinical measures to predict the quality of life in refractive error. Future studies should confirm these results in larger populations.

ABSTRACT BODY:

Purpose: Baicalein is a natural flavonoid derived from the dried roots of Scutellaria baicalensis Georgi. We have previously demonstrated that baicalein lowers intraocular pressure (IOP) by increasing trabecular meshwork (TM) outflow facility. In this study, we investigated the mechanistic effects underlying the baicalein-mediated increase in outflow facility.

Methods: Five independent strains of primary human TM (hTM) cells were used. The effects of baicalein on hTM cell volume regulation, cell contractility and cell migration were determined by electronic cell sorting, collagen gel assay and scratch assay, respectively. Measurements of phosphorylated myosin light chain (pMLC) were conducted by Western blot analysis. Differential protein expression profile after baicalein treatment for 3 hours was assessed using isobaric tag for relative and absolute quantitation (iTRAQ) based quantitative proteomics.

Results: Our results showed that baicalein (1-100 μM) had no effect on cell volume under iso-osmotic condition, but caused a concentration-dependent inhibition of regulatory volume decrease (RVD) by up to 70% under hypotonic condition. Similarly, baicalein exhibited a concentration-dependent hTM cell relaxation and retarded cell migration when compared to the vehicle control. At 100 μM, baicalein reduced MLC phosphorylation by 18±9% ($n=4$, $p<0.05$). After a 3-hour baicalein treatment, 47 proteins were significantly regulated in hTM cells ($n=3$, $p<0.05$). Consistent with in vitro findings, baicalein significantly altered the expression of pre-B-cell leukemia transcription factor-interacting protein 1 (PBXIP1, ↓60%), matrix metalloproteinase-14 (MMP-14, ↑14%) and cathepsin B (CTSB, ↑51%).

Conclusions: These findings suggest that baicalein triggers cell relaxation via MLC phosphorylation along with inhibiting RVD and migratory behavior in hTM cells. The baicalein-mediated changes in protein expression support the notion of altered extracellular matrix homeostasis, potentially contributing to a reduction of outflow resistance and thereby IOP.

TITLE: Osteopontin might mediate photoreceptor neuroprotection following GSK3 inhibition

SESSION TITLE: Neuroprotection, blood flow and ischemia

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Hottin, S. Lourdel, M. Perron, J.E. Roger, Institut des Neurosciences Paris-Saclay, Saclay, Île-de-France, FRANCE|

Commercial Relationships Disclosure: Catherine Hottin: Commercial Relationship: Code N (No Commercial Relationship) | Sophie Lourdel: Commercial Relationship: Code N (No Commercial Relationship) | Muriel Perron: Commercial Relationship: Code N (No Commercial Relationship) | Jerome Roger: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Glycogen Synthase Kinase 3 alpha (GSK3α) and beta (GSK3β) kinases are key regulators of cell survival and death pathways. GSK3 inhibition has been a therapeutic approach for neurodegenerative disorders such as Alzheimer's and Parkinson's disease. In the retina, drug inhibition of GSK3 showed promising beneficial effects under pathological conditions. In our study, we aimed at deciphering the neuroprotective mechanism of GSK3 inhibition using mouse genetic models and identifying other therapeutic factors for new treatment.

Methods: Conditional mouse lines were generated using αPax6-Cre with retinal specific deletion of either isozyme of Gsk3 (Gsk3α/Gsk3β). Photoreceptor degeneration was induced in vivo using MNU, and ex vivo on retinal explant culture. RNA-Seq analysis was performed on control and MNU-injected mice carrying only one allele of Gsk3α (Gsk3α^{f+}β^{ff} α-Cre) expressed in the retina. Recombinant protein Osteopontin (OPN) was injected intra-vitreally or added to explant culture medium. Cell death was assessed with TUNEL assay.

Results: GSK3 is significantly inactivated during photoreceptor degeneration. Such inhibition was mimicked using mouse models with partial deletion of either Gsk3. In these models, induced-photoreceptor cell death ex vivo and in vivo following MNU injection was significantly decreased compared to controls. RNA-Seq analysis showed that most downregulated genes belonged to the phototransduction cascade. Upregulated genes identified were mostly related to inflammatory response and cell chemotaxis including secreted factors such as Spp1 and Fgf2. Increased transcriptomic and proteomic expression of both was confirmed between Gsk3α^{f+}β^{ff} α-Cre and Gsk3α^{f+}β^{ff} mice under degenerative and physiological condition. Immunostaining showed that OPN (Spp1) expression is limited to ganglion cells in WT and induced in Müller cells under different degenerative conditions. OPN treatment results in increased photoreceptor survival in ex vivo and in vivo degeneration model in WT mice. Interestingly, FGF2 expression was increased following OPN treatment.

Conclusions: Our work strongly suggests that the neuroprotective effects of GSK3 inhibition might be mediated by increased expression of OPN in Muller cells, triggering upregulation of FGF2 in photoreceptors. Such a feedback loop could be critical to modulate inflammatory response following retinal injury and sustain photoreceptor survival.

ABSTRACT BODY:

Purpose: The aim of the study was to assess the safety of the measurements taken with a new non-contact esthesiometer -Brill Engines esthesiometer (BEE) and to compare the sensitivity obtained with the Cochet-Bonnet esthesiometer (CBE).

Methods: Sixty eight eyes of thirty six healthy volunteers were included in the study. Corneal central sensitivity was measured with the new BEE and with the CBE, with a 0,08 mm of diameter nylon monofilament. Measurement was performed according with the manufacturer instructions. BEE was mounted in the slit lamp and CBE measurement was used manually. A sub-umbral esthesiometry strategy was performed. To assess whether the data followed a normal distribution, the Kolmogorov-Smirnov test was used. Likewise, the data obtained with the BEE were compared with those obtained with the CBE. A 95% confidence level was considered statistically significant. Measurements obtained with the CBE esthesiometer were converted to millibar for their comparison with the obtained with the BEE .

Results: Sixty eight eyes of thirty six consecutive healthy volunteers, 30,6% males and 69,4% females, underwent and complete the participation in the study. No adverse effected, ocular surface or corneal damage were detected and both test were well tolerated by volunteers. Correlation between both esthesiometers ICC was -0.123. (Table. 1). Bland Altman plots showed the great majority of data were inside the boundaries (2 SD). (Figure. 1).

Conclusions: A new non-contact air jet corneal esthesiometer was tested in healthy volunteers with good tolerance, no adverse effects. Values show that the lower force applied by CBE is more than 10 times higher than the BEE. This indicates, on the one hand, that it is not essential to exert so much force on the ocular surface to determine the sensitivity of a healthy cornea and, on the other, that BEE is more sensitive compared with CBE.

To confirm the pressure margins of BEE at each level and know the intervals in subjects with eye conditions, more studies will be conducted in the future with a more diverse population.

Brill Engines esthesiometer could be used as easy use, non-invasive and portable alternative of the Cochet Bonnet esthesiometer.

ABSTRACT BODY:

Purpose: The polysaccharide capsule of Streptococcus pneumoniae is an important factor in the pathogenesis of pneumococcal diseases such as pneumonia; however, the capsule is not required for bacterial conjunctivitis and its role in keratitis is poorly understood. The aim of this study was to investigate the importance of capsule using an in vitro corneal cell binding assay and a topical infection model of pneumococcal keratitis.

Methods: Adhesion to human corneal epithelial cells (HCECs) was determined for a keratitis strain of S. pneumoniae, K1544, and its isogenic capsule-deficient mutant, K1544Δcps. Each strain was inoculated onto the scratched corneas of 6-week-old A/J mice for acute experiments evaluating bacterial recovery (4 time points) and cytokine quantitation (2 time points) and long-term experiments evaluating clinical severity (1, 2, 3, 6, 8, and 10 days) and cytokine quantitation (10 days). Forty cytokines were quantified using antibody array densitometry.

Results: K1544Δcps binding to HCECs was significantly higher than that of K1544 ($p = 0.004$). Mouse corneas infected with K1544Δcps had significantly higher mean clinical scores than those infected with K1544 ($p = 0.033$; $n \geq 22$ per group) 24 hours post-infection. Beyond 24 hours and ending on day 10, there were no significant differences in clinical scores. All eyes were sterile by day 10 regardless of strain. Four and 8 hours post-infection, the mutant maintained significantly higher loads than the parent strain ($p = 0.014$ and 0.024, respectively). Bacterial loads were not significantly different at 12 or 24 hours. Protein levels of ocular IL-9, IL-10, IL-12-p70, MIG, and MIP-1-alpha were significantly higher for mice infected with K1544Δcps 24 hours post-infection compared to scratch controls or those infected with K1544 ($p \leq 0.043$; $n = 3$ per group). Cytokine levels were not significantly different 8 hours or 10 days post-infection.

Conclusions: Enhanced binding to corneal epithelial cells, retention of bacterial loads early in infection, and slightly higher clinical scores combined with an increase in cytokines one day after infection, suggest that non-encapsulated S. pneumoniae may have enhanced virulence in the cornea in the early stages of keratitis.

ABSTRACT BODY:

Purpose: To study the effects and the underlying mechanism of latanoprost on induced myopia in chicken

Methods: Myopia was induced in the right eyes of chicks using diffuser lenses (FDM) or -10D single vision lenses (LIM) for 12 days, while the left eyes were untreated control. One drop of topical latanoprost 0.005% or saline was administered daily in the treated and control groups, respectively. Refractive errors, tonometry and high-frequency A-scan ultrasonography were measured on days 0, 4, 8 and 12. Eyeballs were enucleated and processed for hematoxylin & eosin staining and western blot respectively. A total of 40 chicks were randomly divided into four groups (n=10). Data are presented as mean interocular differences ± standard deviation (SD).

Results: After 12 days of treatment, latanoprost inhibited both FDM and LIM. FDM control: -16.02±2.80D vs FDM latanoprost: -10.86±2.54D, $p<0.0001$. LIM control: -10.90±1.37D vs LIM latanoprost: -6.62±1.39D, $p<0.0001$) respectively. Intraocular pressure (IOP) was increased in FDM and LIM groups applied with saline, but decreased in those applied with latanoprost. Histology showed that latanoprost inhibited the thinning of sclera in the FDM and LIM groups. Latanoprost also upregulated retinal Early Growth Response 1 (Egr1) protein expression at the 12-day time point.

Conclusions: Topical latanoprost inhibit FDM and LIM in the chicken model and its effect was associated with a reduced IOP and upregulated Egr1 protein expression.

ABSTRACT BODY:

Purpose: To measure the innervation of the corneal subbasal nerve plexus of Covid-19 patients and compare the results with values of healthy patients.

Methods: A prospective, observational study was conducted analyzing 39 eyes of patients who had overcome Covid -19 and 46 eyes of healthy volunteers included as a control group (verified by antibody analysis and negative qPCR result) which underwent in vivo confocal microscopy with Rodstock Cornea Module© attached to Heildelberg HRT3©. Ocular surgery procedures, previous ocular infections or systemic diseases that could cause alteration in corneal innervation were exclusion criteria. At least 5 non overlapping images of each eye were selected and only one eye of each patient was included in the study. Following sub basal nervous plexus parameters were measured with ACC Metrics© software: Corneal Nerve Fiber Density (CNFD), Corneal Nerve Branch Density (CNBD), Corneal Nerve Fiber Length (CNFL), Corneal Total Branch Density (CTBD), Corneal Nerve Fiber Area (CNFA), Corneal Nerve Fractal Dimension (CNFrD). Data analysis was performed with SPSS® software for Windows 22.0 (SPSS® Inc, Chicago, IL.). The differences of age and sex between groups were checked with T-test and chi-square tests. The normality of the sample was checked with the Shapiro-Wilk test and the results were compared with the T test or the Man-Whitney U test based on the distribution of the data. The differences were considered statistically significant for $p<0.05$.

Results: There was no difference in the sex distribution between the groups ($p= 0.248$). The average age (± standard error) was 46.61±17.55 years for Covid-19 patients and 43.11±16.95 years for healthy control group ($p=0.353$) The mean of the analyzed variables (± standard error) from Covid-19 patients versus control group were CNFD: 16.09±6.92 and 23.03±8.31 fibers/mm^2 ($p=0,00008$), CNBD: 21.93±15.37 and 28.93±17.84 branches/mm^2 ($p=0.064$), CNFL: 11.61±3.61 and 14.05±3.71 mm/mm^2 ($p=0.002$), CTBD: 38.48±20.02 and 43.29 ± 23.94 ($p=0.41$), CNFA: 0.0057±0.0017 and 0.006±0.0023 mm^2/mm^2 ($p=0.853$), CNFrD: 1.46±0.041 and 1.47±0.037 ($p=0.007$).

Conclusions: According to the data obtained, corneal subbasal nerve plexus is decreased in Covid-19 patients compared to the healthy control group, statistically significant for density, length, and fractal dimension. The results show the presence of possible small fiber neuropathy induced by Covid–19 disease.

TITLE: Age-related changes in optical density and geometry of human crystalline lens measured with SS-OCT.

SESSION TITLE: Multidisciplinary Ophthalmic Imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Gupta, E. Safarian Baloujeh, D. Ruminski, A. Jimenez-Villar, G. Gondek, I. Grulkowski, Faculty of Physics, Astronomy and Informatics, Uniwersytet Mikolaja Kopernika w Toruniu, Torun, Kujawsko-Pomorskie, POLAND|R.D. Toledo, P. Artal, Laboratorio de Óptica, Universidad de Murcia, Murcia, Murcia, SPAIN|

ABSTRACT BODY:

Purpose: To demonstrate in vivo three-dimensional imaging of crystalline lens in healthy eyes with SS-OCT. To objectively determine age-related effects on the crystalline lens by studying lens geometry and optical densities of back-scattered signals from sub-layers of the lens.

Methods: This study includes 50 eyes of 50 healthy volunteers (age range: 9-78 years old). Volumetric images of the crystalline lens were acquired for each eye using the SS-OCT system and the optical scatter index was measured using a double-pass system. The radius of curvature (ROC) and thickness of sub-layers of the lens was measured after refraction correction of the segmented layers. The enhanced intensity image is used to measure densitogram with the optical axis as the center of the image and to average the intensity values in the 54 μm region of interest (ROI). The Oxford nomenclature was used as a reference for the segmentation of distinct CL zones and the nucleus (figure 1). The enhanced intensity image is also used to determine the mean scattering index intensity of each layer of the crystalline lens.

Results: The thickness of the whole lens and measured thickness of the cortex increases with age. The mean ROC of the anterior cornea is 7.34 ± 0.24 mm, the posterior cornea is 6.39 ± 0.20 mm, the anterior lens is 10.1 ± 1.7 mm, the anterior nucleus is 4.06 ± 0.37 mm, the posterior nucleus is 3.67 ± 0.33 mm, the posterior lens is 5.90 ± 0.40 mm. ROC of anterior lens interface, anterior nucleus, and posterior nucleus decreases with age. However, there was no statistical correlation of age with ROC measured for the posterior lens ($R = 0.15$, $P = 0.298$). Thickness and mean intensity signal of each layer of the crystalline lens and their relationship with the aging of the eyes are presented in figure 2.

Conclusions: The SS-OCT imaging analysis of the lens indicated age-dependent development of sub-layers in the crystalline lens. SS-OCT for lens imaging is a useful tool for performing in vivo fundamental studies on the development and aging of the human lens.

ABSTRACT BODY:

Purpose: We demonstrate the evolution of bedside, swept source, handheld optical coherence tomography (HH-OCT) and OCT angiography (OCTA) imaging with increasing scanning speeds for patients at risk for retinal ischemic events in infant and adult intensive care units (ICU).

Methods: We developed an investigational swept source OCT system at 100 kHz and increased scanning speed to 200 and 400 kHz to shorten the time of structural OCT capture and acquire OCTA. The handheld probe was lightweight and optimized for supine imaging. The increase in OCT speed required a heavier probe and was redesigned to fit comfortably and optimize balance in the operator's hand (Fig 1). We tested an ergonomic chair for stabilization body and forearm during imaging.

Results: At 100 kHz, we acquired OCT volumes without pharmacological pupil dilation in infants in the ICU. At 200 kHz, we readily obtained non-dilated OCT volumes in infants with congenital cardiac diseases and in adults before, during and after cardiac surgery. The 200 kHz OCTA capture was poor without pupil dilation, and was limited by pupil size and cardiac surgical motion. At 400 kHz, stabilization of the imager by an ergonomic chair decreased imager fatigue and imager-related motion artifacts. The decrease in OCTA scan acquisition time from 6 sec (at 200 kHz) to 3.6 sec (at 400 kHz) decreased motion artifacts and allowed for a stronger OCTA signal despite lack of pupil dilation.

Conclusions: The evolution of the handpiece, capture speed and ergonomic support, allowed capture of high quality structural OCT as well as OCTA with minimal artifacts. We are applying these advances to improve our understanding of the pathophysiology of retinal vascular events in cardiac patients.

ABSTRACT BODY:

Purpose: To create and validate automated deep learning models for DR that are trained on handheld retinal images for community-based DR screening program (DRSP) in the Philippines.

Methods: AutoML Vision (Google Cloud) models were generated based on previously acquired 2-field retinal images (macula and disc centered, 1,600 images) from the Philippine DRSP. Image labeling was based on the International DR and DME classification obtained from primary grades and secondary adjudications by a reading center (RC). Images for the initial model were split 8-1-1 for training, validation and testing to detect referable DR [(refDR), defined as moderate nonproliferative DR or worse or any level of diabetic macular edema (DME). External testing of the autoML model was performed using a published image set (N=225 eyes) using the same devices in the same population, evaluated by the same RC. Sensitivity and specificity (SN/SP) for refDR were calculated.

Results: Training set distribution of DR severity by RC: no DR 66.0%, mild NPDR 10.7%, moderate NPDR 7.9%, severe NPDR 3.3%, PDR 5.6%, ungradable 6.5%. DME severity was: no DME 83.6%, DME 6.3%,center involved DME 7.4%, ungradable 2.7%. RefDR was present in 18.5% of images. Area under the precision-recall curve (AUPRC) was 0.947 (figure 1). The model’s overall accuracy for RefDR was 89.4%. External testing set DR/DME distribution: no DR 54.2%, mild NPDR 17.8%, moderate NPDR 9.8%, severe NPDR 3.3%, PDR 5.8%, ungradable 1.8%. DME severity was: no DME 62.7%, DME 6.2%, center involved DME 19.1%, ungradable 12.0%. RefDR was present in 39.1% of images. SN/SP for refDR on the external test set was 0.94/0.81. Table 1 shows a comparison with reported metrics from FDA approved algorithms.

Conclusions: This study demonstrates the accuracy and feasibility of autoML models for the identification of refDR developed for a DRSP using handheld retinal imaging in a low-resource setting community program. The performance approaches published diagnostic accuracy metrics of commercial models used for DRSP. Potentially, the use of autoML may increase access to machine learning models that may be adapted for specific programs that are guided by clinicians to rapidly address disparities in patient care.

ABSTRACT BODY:

Purpose: To determine if there were differences in long term outcomes in patients requiring pars plana vitrectomy (PPV) for diabetic retinopathy (DR) with preoperative bevacizumab intravitreal injection versus without.

Methods: This retrospective cohort study utilized data from TriNetX (Cambridge, MA, USA), a federated electronic health records research network comprising 56 large health organizations in the United States. Patients who underwent PPV for DR were identified by CPT code and stratified by preoperative bevacizumab injection and no preoperative bevacizumab injection. Patients were matched for age, gender, and medical comorbidities (essential hypertension, diabetes mellitus, cerebrovascular disease, heart failure, nicotine dependence, alcohol related disorders, and body mass index). Primary outcomes measured over a year after the procedure included: vitreous hemorrhage (VH), choroidal hemorrhage, cystoid macular degeneration (CME), puckering of macula, glaucoma, cataract, dry eye syndrome (DES), central retinal vein occlusion, central retinal artery occlusion, vitreous opacities, ptosis, dislocation of lens, endophthalmitis, and retinal vascular occlusions. These long-term outcomes were compared between the cohorts after propensity score matching using logistic regression.

Results: A total of 6,810 patients were analyzed with 3,405 in each cohort after propensity matching. The preoperative bevacizumab cohort showed a significantly greater risk of developing VH (RR, 1.72; 95% CI, 1.36-2.17), Cataract (RR, 1.32; 95% CI, 1.14-1.53) and DES (1.66; 95% CI,1.29-2.14). The cohort without preoperative bevacizumab injection had a slightly greater risk of developing CME (RR, 1.36; p=0.034, 1.02-1.81) and increased risk of dislocation of lens (RR, 2.22; p=0.002 ,1.33-3.70). No other significant differences were found between the cohorts.

Conclusions: Preoperative treatment with bevacizumab before PPV for DR is a technique utilized in an attempt to lower intraocular VEGF levels and counter proliferation for the procedure. In this study, preoperative treatment of bevacizumab significantly increased risk of vitreous hemorrhage and cataract. However, lack of preoperative bevacizumab injection was associated with a more frequent occurrence of CME. This study illustrates that using bevacizumab preoperatively may have outcomes over a year after the operation.

ABSTRACT BODY:

Purpose: To evaluate the duration of effect in photopic distance-corrected intermediate visual acuity (DCIVA) in presbyopia study participants treated with AGN-190584 on Days 1 and 30.

Methods: The durations of attainment of ≥3-line, ≥2-line, and ≥1-line improvement in photopic DCIVA were calculated in participants who received AGN-190584 bilaterally, once daily for 30 days (n=375). Intermediate visual acuity was assessed at a distance of 66 cm (26 in).

Results: On Day 30, the median final time point of sustained gains in photopic DCIVA was Hour 7 for a ≥3-line gain, Hour 8 for a ≥2-line gain, and beyond the 10-hour study visit duration for a ≥1-line gain in participants who achieved ≥3-line, ≥2-line, and ≥1-line gains, respectively (Figure). 96 study participants in the active treatment group achieved at least a 3-line gain, 205 at least a 2-line gain, and 312 at least a 1-line gain. On Day 1, the median final time point of sustained gains in photopic DCIVA was Hour 5 for a ≥3-line gain, Hour 7 for a ≥2-line gain, and beyond the 10-hour study visit duration for a ≥1-line gain in participants who achieved ≥3-line, ≥2-line, and ≥1-line gains respectively. 60 study participants in the active treatment group achieved at least a 3-line gain, 158 at least a 2-line gain, and 300 at least a 1-line gain.

Conclusions: In photopic illumination conditions, participants treated with AGN-190584 obtained ≥3-, ≥2-, and ≥1-line gains in DCIVA over the course of the 10-hour study visit on Days 1 and 30.

ABSTRACT BODY:

Purpose: Dry age-related macular degeneration (AMD) is a leading contributor to visual impairment across the globe. No current treatment exists to improve visual function or reduce disease progression outside of vitamin supplementation and lifestyle changes. LIGHTSITE III is evaluating multiwavelength photobiomodulation (PBM) therapy using the LumiThera Valeda® Light Delivery System in dry AMD

Methods: LIGHTSITE III (NCT04065490) is a prospective, double-masked, randomized, sham-controlled, parallel group, multi-center study to assess the safety and efficacy of PBM in dry AMD. Target enrollment was approximately 96 subjects (144 eyes). Subjects are treated with six series of PBM/Sham treatments (3x per week for 3 weeks) delivered over a 24-month period with a 13-month efficacy analysis of data. PBM therapy consists of low-level light exposure to selected tissues resulting in positive effects on mitochondrial output and improvement in cellular activity. Valeda is used to deliver multiwavelength PBM treatment using 590, 660 and 850 nm of light. Subjects are assessed for clinical and safety outcomes (i.e., best-corrected visual acuity (BCVA), low-luminance BCVA, contrast sensitivity, reading speed, color vision, VFQ-25 and perimetry). Independent OCT, FAF and color fundus imaging outcomes at selected timepoints are analyzed by a masked imaging reading center

Results: A total of 148 eyes from 100 subjects with dry AMD have been enrolled and randomized in a 2:1 design (PBM:Sham). The majority of subjects are female (68%) and Caucasian (99%). The average age at enrollment was 75 years and mean time since dry AMD diagnosis is 4.9 years. COVID-19 interference has been minimal and not significantly impacted subject enrollment or retention. Clinical and anatomical outcome data from the interim analysis conducted at Month 13 is presented. Results from the 21-month time point are expected at end of 2022

Conclusions: LIGHTSITE III provides the largest, randomized controlled trial evaluating the effects of PBM in dry AMD subjects. PBM therapy may offer a new treatment strategy with a unique mechanism and modality for patients with dry AMD

ABSTRACT BODY:

Purpose:

Retinal organoids can be differentiated from human pluripotent stem cells (hPSCs) that effectively recapitulate the major stages of human retinogenesis. These organoids are becoming valuable tools for studying human retinogenesis and retinal diseases, yet shortcomings in the efficiency and reproducibility of current retinal organoid differentiation protocols have hindered their abilty to serve as effective models for the earliest stages of human retinal lineage specification.

Methods: In the current study, we refined an existing retinal organoid differentiation protocol using more standardized, quick reaggregation methods to generate highly reproducible 3D retinal organoids from human pluripotent stem cells (hPSCs). BMP signaling contributing to retinal specification was analyzed by treatment with either BMP4 or the BMP inhibitor LDN-193189, and differentiation efficiency was assessed at various time points based on morphological analyses and the expression of retinal markers. Additionally, to identify transcriptional changes that underly retinal fate dermination events, mRNA-seq analyses were conducted at the earliest stages of retinal specification.

Results:

Retinal organoids generated using quick reaggregation methods were highly reproducible in both their size and shape compared to more traditional methods. Following treatment of early aggregates with either BMP4 or LDN-193189, pure populations of either retinal or forebrain organoids were derived, respectively. Subsequently, RNA-seq methods analyzed the transcriptional profile of the earlies stages of retinal vs forebrain specification, long before these lineages have been reliably identified previously. These refined methods also yielded retinal organoids with greatly expedited differentiation timelines, with differentiated retinal neurons arising at earlier stages than traditional differentiation methods, also exhibiting higher levels of self-organization.

Conclusions: Taken together, this study provides a novel and highly reproducible method for generating retinal organoids suitable for analyzing the earliest stages of human retinal fate specification in an organoid model. These results elucidate some of the earliest transcriptional changes occurring at the most immediate stages of human retinal development, and provide a more optimized and rapid method for generating retinal organoids for translational applications.

ABSTRACT BODY:

Purpose: Loss of endothelial cell integrity is a critical factor of ischaemic retinopathies. The pathogenesis is highly complex and multifaceted but the AT2 pathway has been implicated in vascular pathology in both the retina and brain. For example, in a murine model of cerebral malaria, deletion of AT2 augmented blood barrier breakdown and localized hemorrhage. This study tested the hypothesis that deletion of AT2 could lead to damaging effects in the retinal vasculature during ischaemic conditions.

Methods: AT2 knockout (KO) and C57BL/6J wildtype (WT) mice were subjected to the OIR protocol. At postnatal days 13 and 17 (P13; P17) eyes were enucleated, flat-mounted and the vasculature stained using lectin and TER119 (red blood cell marker). Using ImageJ, levels of retinal vasobliteration, neovascularization and hemorrhage were assessed. In a parallel in vitro experiment, vasopermeability was induced in Human Retinal Microvascular Endothelial Cells (HRMECs) monolayers with VEGF (50ng/ml) and/or treated with an endogenous agonist for AT2 (EA)(10^{-10} μM) with barrier function being assessed via xCELLigence.

Results: At P13 OIR, AT2KO mice (N=11) displayed an increase in retinal vasobliteration as compared to WT (N=12)($P<0.01$). $IBA1^{+}$ microglia, displayed regular and diffuse staining patterns within the WT retina coupled with highly ramified morphology, whereas the AT2KO mice, showed dense clustering of microglia along the avascular interface with the vasculature while displaying an amoeboid-like phenotype. At P17 OIR, AT2KO mice (N=13) had increased retinal neovascularization when compared to WT (N=12)($P<0.05$). Retinal hemorrhage was macroscopically visible in AT2KO mice, but not in WT. This was further supported via TER119 staining in murine retinas, where AT2KO (N=4) had a greater $TER119^{+}$ area than WT (N=5)($P<0.05$). HRMECs exposed to VEGF showed a reduction in endothelial integrity ($P<0.05$), which was attenuated upon pre-treatment with EA ($P<0.05$).

Conclusions: Genetic deletion of AT2 induced greater vasobliteration and neovascularization in OIR. AT2 is a key regulator of retinal vascularisation and barrier integrity with a lack of AT2 being detrimental and activation being protective. Taken together, our data suggest that activation of AT2, may provide a therapeutic option in strengthening tight junctions in diseases where endothelial integrity is compromised.

ABSTRACT BODY:

Purpose: Paracentral acute middle maculopathy (PAMM), a retinal disease characterized by sudden-onset ischaemia of the deep vascular complex, could be the only presenting sign of incomplete central retinal artery or central retinal vein occlusion. Furthermore, isolated PAMM can be the presenting feature of carotid disease. PAMM has the potential to develop more severe ischemic disease which known as the ischemic cascade and may be the result of progressive vascular obstruction.

There has been equivocal evidence that PAMM may be associated with cardiovascular events. In this study, we explored the incidence of myocardial infarction and ischaemic stroke following a new diagnosis of PAMM at a large tertiary ophthalmic institution.

Methods: A total of 47 patients were newly diagnosed with PAMM by an ophthalmologist specializing in medical retina between January 1st 2008 and December 31st 2017 and had linked secondary care Hospital Episodes Statistics Admissions data. Myocardial infarction (MI) and ischaemic stroke were identified through previously validated International Classification of Diseases 10th Edition codes I21/I22 and I61-I64.

Results: Among the cohort, 28 were male and the average age was 59.0 (12.3) years at diagnosis. Three had myocardial infarctions, one prior and two of which followed an episode of PAMM; there were no cases of ischaemic stroke. Average age at time of MI was 75.3 (9.9) years. The two cases occurred 29 days and 1516 days following the diagnosis of PAMM

Conclusions: In this regional cohort of PAMM, there were no cases of ischaemic stroke and few cases of MI following an episode of PAMM. While underpowered to detect a difference with age-standardised rates of MI, our results did not identify a strong association between PAMM and elevated incidence of cardiovascular events.

ABSTRACT BODY:

Purpose: Although Inherited Retinal Disease (IRD) are well characterized in terms of anatomical and functional progression, their impact on patients' daily lives is often poorly understood and lacks standardized measures as performance-based outcomes (PerfO) evaluating the performance in daily-life tasks, such as orientation and mobility. We developed a new mobility test in real (IRL) and virtual (VR) conditions and performed a prospective, interventional non-invasive, longitudinal study (test-retest) to compare the performance of IRD patients and healthy participants in both conditions (IRL v.s. VR).

Methods: Fifteen retinitis pigmentosa patients and 15 age-matched healthy participants had to walk through a maze either physically presented (IRL) or displayed in a virtual reality headset (HTC Vive Pro Eye). In multiple light level conditions (between 1 Lux and 400 Lux in IRL), participants were instructed to step over two steps, pass under two flags, avoid a cone and two high obstacles, avoid a dead-end, and finally reach an end goal. Trial duration and errors were automatically recorded in VR condition. In IRL condition, errors were live coded by an experimenter and recorded by a different experimenter after the session. We computed a performance score taking in account duration and errors.

Results: Preliminary results indicate a good construct validity (discrimination between groups, ROC area>.9), a very good agreement of the performance score between sessions (ICC>.95) and between VR and IRL conditions (ICC>.9), and a good content validity (correlation with a visual score .41 and .65). Moreover, test duration was acceptable for 95% of participants (both conditions) and the VR experience was rated as enjoyable for 73% of participants. 78% of RP participants felt that the VR test was representative of their difficulties in daily life.

Conclusions: We have designed a locomotion test, both in real (IRL) and virtual (VR) conditions, that has excellent reproducibility and high agreement between both conditions. Additional data are awaited to confirm these results, and measure sensitivity to change which will determine its interest in monitoring the progression of a retinal disease and assessing the efficacy of new treatments.

ABSTRACT BODY:

Purpose: COVID changed follow-up logistics starting 3/2020 in South Texas (STX). The incidence of proliferative retinovascular (RV) events in the emergent setting increased after shut down in STX. We investigate patterns of follow-up behavior in patients with and without proliferative complications of RV diseases.

Methods: We used CPT and ICD-10 codes in date range 1/2018 to 4/2021 to include patients diagnosed with diabetic retinopathy (DR) and retinal vein/artery occlusions (RVO/RAO) and analyzed them as two groups: anti-VEGF ± panretinal photocoagulation (PRP) (nonvitrectomy group) vs vitrectomies. We compared before and after COVID-era: appointment intervals and lapses, rate of progression in EDTRS staging for patients with DR.

Results: At initial encounter, 2/133/125 patients of 1503 had mild/moderate/severe DR. 40/5 patients had RVO/RAO. There were 429/1074 patients in the vitrectomy/nonvitrectomy group. Vitrectomy group had 123 non-clearing vitreous hemorrhages, 72 tractional retinal detachments, and 189 unclassified proliferative retinovascular complications. Prior to COVID, visit interval was 28.4 ± 43.2 vs 30.8 ± 47.8 days in the vitrectomy vs nonvitrectomy group ($p=0.61$). After COVID, the interval duration for the vitrectomy group increased to 39.8 ± 76.5 days with no increase in the nonvitrectomy group ($p<0.001$). Time to diagnosis of EDTRS-staged progression after COVID increased by an average of 21.5 days in the vitrectomy group and by 26.7 days in the nonvitrectomy group.

After COVID restrictions, missed appointments in the vitrectomy vs nonvitrectomy group changed from 24.5% to 30.8% vs 28.1% to 33.4%. Across all encounters, the vitrectomy versus nonvitrectomy group had 19.1% vs 21.9% cancellation rate (6.08 vs 5.85 appointments/patient) and 7.81% vs 8.39% no show rate (3.09 vs 2.97 appointments/patient). Overall, patients with DR who experienced EDTRS-staged progression missed 21.2% of appointments (6.8 per patient for those with missed appointments).

Conclusions: Patients who required vitrectomy versus those able to be managed in clinic missed appointments in the same proportion and quantity before COVID and increased appointment lapses similarly after COVID restrictions, but interval duration and variability was significantly higher in patients that eventually suffer a complication severe enough to necessitate vitrectomy.

ABSTRACT BODY:

Purpose: The optimization of customized spectacle lenses often considers individual user parameters such as morphological data, frame parameters, and working distances to compensate oblique aberrations. Recently, it has been proposed a new optimization method that considers the accommodative ability of the user to optimize the lens in a more realistic object space and to modulate the oblique aberrations of the user in a more efficient way. The goal of this study is to compare the performance of single vision lenses (SV) optimized with this method against standard spherotorical lenses.

Methods: Double-blind study in which 66 non-presbyopic users were evaluated when wearing a spherotorical SV lens (control) and a customized SV lens optimized with a new method considering user accommodative ability (DRP2). Accommodative lag (LAG) was measured on-axis and 20 degrees off-axis using near retinoscopy at 40cm with a near fixation card attached to the retinoscope. Static visual acuity (VA) was measured on-axis and 20 degrees off-axis at 5.25m. Dynamic visual acuity (DVA) was measured using the software COI-Sport with a speed of 100cm/s at 5.25m. User experience (UX) was evaluated with a satisfaction survey after subjects used both pairs of lenses for 7 days each. Satisfaction rates in scale 1-5 and preferred lens choice were analyzed. Statgraphics Centurion XVI.II software was used to determine differences between lens designs.

Results: Significant higher dynamic VA and UX were found, showing better values for the lens DRP2. Non-significant differences were found in the LAG and static VA between both lenses at any of the viewing positions (Table 1). When the participants were asked to select their preferred lens, 51% preferred the DRP2 lens, 27% selected the control lens and 22% of the participants did not perceive differences between them.

Conclusions: Single-vision lenses optimized with a new optimization method that considers user accommodative ability provide better dynamic visual acuity and user experience than spherotorical lenses. Nevertheless, the accommodation lag of the user remains stable on and off-axis.

ABSTRACT BODY:

Purpose: Allergic conjunctivitis (AC) is a common ocular disease with a growing incidence rate. Novel topical therapies add to a physician's armamentarium. The efficacy of a new once-daily Bilastine 0.6% multi-dose preservative-free ophthalmic solution (BOS) for the treatment of the signs and symptoms of AC was evaluated. Non-inferiority testing was conducted between BOS and a marketed multi-dose formulation of ketotifen 0.025% (KOS).

Methods: This was a multi-center, double-masked, randomized, vehicle and active controlled, phase 3 study conducted to assess the efficacy for treatment of the signs and symptoms of AC, safety, and tolerability of BOS. The Ora-CAC® Allergen Challenge Model was used to assess acute ocular and nasal allergic responses. Subjects must have had a history of ocular allergies and a positive skin test reaction to a seasonal or perennial allergen. On Day 1, 228 adult subjects with AC were randomized to receive BOS N=91, KOS N=90, or vehicle N=47. A duration-of-action (16 hours post drop on Day 1) and an onset-of-action (15 minutes post drop on Day 15) visit was conducted. The primary efficacy endpoint was ocular itching. Statistical testing included superiority comparisons of BOS vs. vehicle at onset and duration of action and non-inferiority of BOS to KOS at onset.

Results: BOS showed efficacy reducing ocular itching at 15 minutes and 16 hours post treatment ($P<0.001$) while KOS showed efficacy at 15 minutes ($P<0.001$). BOS was non-inferior to KOS at onset. BOS demonstrated improvement over vehicle ($P<0.05$) for conjunctival/ciliary/episcleral redness, chemosis, eyelid swelling, tearing, rhinorrhea, ear/palate pruritus and nasal congestion at onset. BOS was safe and well tolerated. BOS was significantly more comfortable ($P<0.05$) than KOS immediately upon instillation and similar to vehicle.

Conclusions: Bilastine 0.6% preservative free eye drops developed by Faes Farma is effective at reducing ocular itching up to 16 hours post-treatment. Bilastine was safe and well tolerated. This multi-dose preservative-free formulation can be used as a once-daily treatment for the signs and symptoms of AC.

ABSTRACT BODY:

Purpose: Corneal endothelial dysfunctions are the main cause of corneal blindness in developed countries and to date, the shortage of endothelial tissue for its treatment represents an emerging problem. Therefore, finding substitutes to corneal endothelium in other tissues should be a priority in order to treat more patients. In this study we compare the gene expression from primary xeno-free cultures of human lens capsule epithelium and human corneal endothelium in order to evaluate the potential use of lens capsule epithelial cells as a surrogate of corneal endothelium.

Methods: Four corneal endothelia deemed inappropriate for surgery and four lenses were obtained from Asturias tissue bank. Corneal endothelium was dissected following the Schwalbe line and anterior lens capsule was dissected from the stroma. Both tissues were digested with TrypLE for 90 min at 37 °C and seeded on a culture plate and cultured until confluence. Subsequently, we performed bulk RNASeq in both cell types and analyzed their gene expression profiles. RNA was isolated using the Arcturus^{TM} PicoPure^{TM} kit followed by NEBNext Ultra II RNA library preparation. Samples were sequenced with Illumina NextSeq550. Additionally, cultured cells were fixed using ice-cold methanol for 10 min and immunocytochemistry of major corneal endothelial markers (Na^+/K^+ ATPase, ZO-1) were performed.

Results: We identified 19.677 similarly expressed genes out of 22.641 lens capsule epithelium and corneal endothelium genes. Essential genes for the correct function of the corneal endothelium such as, those responsible for the barrier function and ion pump (Na^+/K^+ ATPase, ZO-1) present a similar level of expression. Moreover, protein expression of major functional markers was confirmed by immunocytochemistry. The 2964 differentially expressed genes (DEGs) were mainly clustered in the gene ontology of epithelial cell proliferation, extracellular matrix organization and eye development.

Conclusions: Corneal endothelium and lens epithelium share substantial similarities in functional gene and protein expression, supporting the proposal to use lens capsule epithelial cells as a possible surrogate for corneal endothelium

ABSTRACT BODY:

Purpose: Uveitis is a significant cause of severe visual handicap. Evidence links induction of experimental autoimmune uveitis to T cell mediated pathogenesis which is believed to be regulated, at least in part, by natural killer (NK) cells. Here we present the unsupervised multimodal omics of the circulating NK cell compartment in a large cohort of 160 non-infectious uveitis patients (48% with systemic treatement and 52% with no systemic treatement at baseline) and 51 healthy controls.

Methods: Cases and controls were recruited and clinically phenotyped under a prospective clinical study (NCT02656381). We conducted 38-parameter flow cytometry [BD LSR-Fortessa] on freshly collected blood samples, bulk RNA sequencing and single cell RNAseq (scRNAseq) analysis of purified periperhal blood mononuclear cells (PBMCs) [Illumina NovaSeq 6000, 10x Genomics Chromium], and serum targeted proteomics using the Somascan array (SOMAlogic].

Results: Bulk RNA sequencing analysis revealed a clear distinction of PBMCs transcriptome between healthy donors and uveitis patients which was driven by a significant upregulation of NK biology gene (NCAM1, $P = 0.012$). At the single cell level, scRNAseq analysis could attribute these changes to the enrichment of a distinct subset of NK cells ($P < 0.05$) characterized by high FCGR3A gene expression in uveitis cases. Flow cytometric analysis confirmed a significant increase of CD16+ NK cells ($P = 0.003$), and a concomitant decrease of $CD56^{bright}$ NK subsets ($P = 0.002$) in the PBMCs of uveitis patients. SOMAlogic analysis revealed a significant decrease ($P = 0.028$) of NK-inhibitory soluble protein Thrombospondin-1 in the serum of uveitis patients.

Conclusions: The current data are in line with a role for NK cells as an active modulator of autoimmune responses in uveitis patients. A previous study involving blockade of IL2Ra (daclizumab) in uveitis patients showed expansion of $CD56^{bright}$ NK cells. Our current observation indicates expansion of activated NK cells and decrease in regulatory NK cells in uveitis patients. Further studies are needed to examine the role of NK cells in the development, progression and treatment of uveitis.

ABSTRACT BODY:

Purpose: To quantify accommodative movements of the lens and choroidal movements in the human eye and the anterior hyaloid movements in the monkey eye, to determine if they are related to accommodative amplitude and presbyopia.

Methods: In eyes of 4 rhesus monkeys (aged 8-19 yrs), accommodative responses were induced by central electrical stimulation of the midbrain in a dose-dependent manner, from minimal to maximal accommodative responses. Accommodation was induced in the human eye by 4% topical pilocarpine. Accommodative amplitude was measured by Hartinger coincidence refractometry. OCT and ultrasound biomicroscopy (UBM; 50, 20 MHz) images were collected in the region of the lens, ciliary body and over the entire extent of the globe in monkey and human subjects in resting and accommodated states.

Results: Monkey: In this preliminary study, accommodative anterior hyaloid posterior movement was significantly related to accommodative amplitude in all 4 animals thus far measured (the more the anterior hyaloid moved posteriorly during accommodation, the higher the accommodative amplitude) but the relationship changed with age. In the young eye the average slope of the regression equation was 44.2 ± 5.5 diopters/mm (p= 0.001, n=2), but in the older eye it was 16.02 ± 3.23 diopters/mm (p= 0.007, n=2). Human: Lens accommodative thickening was significantly related to accommodative amplitude (26.02 ± 3.28 diopters/mm, n=22) but the relationship changed with age; young = 12.5 ± 6.6 diopters/mm (p=0.08, n=14); older = 3.72 ± 3.65 diopters/mm (p=0.35, n=8). In the older eye accommodative centrifugal choroidal movement around the optic nerve was negatively correlated with accommodative amplitude; the more centrifugal choroid movement the less accommodative amplitude (-0.63 ± 0.11 mm/diopter, p=0.028, r=0.97, n=4). Choroidal thinning was positively correlated with accommodative amplitude; the more the choroid thinned the higher the accommodative amplitude (43.5 ± 9.2 µm/diopter, p=0.042, r=0.96, n=4).

Conclusions: There are statistically significant accommodative movements of the choroid and various intravitreal structures. The posterior anterior hyaloid and choroidal movements may provide insights to the mechanism of accommodation, presbyopia, accommodating IOL function and perhaps glaucoma.

ABSTRACT BODY:

Purpose: Diabetes affects 9.3% of the adult population globally and is a leading cause of preventable blindness. The burden of diabetic complications will increase rapidly in the coming decades. Effective detection of diabetic retinopathy offers the best strategy for timely intervention. As has been shown for glaucoma, systematic search strategies may enable more efficient grading, however there are no formalised strategies for grading diabetic retinopathy in clinical practice. Better understanding of the localisation of features of diabetic retinopathy may inform the development of a search strategy to aid the training of eye health care providers.

Methods: Three publicly available datasets of annotated retinal photographs were obtained, with a combined total of 757 images with diabetic retinopathy and 70 images of normal retinal vasculature. Annotations for venous beading, intraretinal microvascular abnormalities (IRMA) and neovascularisation were added to the existing annotations. Images were standardised to correct for centration, rotation and field of view. Vessel and lesion locations were extracted and collated into a frequency matrix. Heatmaps were generated showing frequency distributions of the location of arterioles, venules, microaneurysms, haemorrhages, exudates, cotton wool spots (CWS), IRMA, venous beading and neovascular changes.

Results: Retinal arterioles typically conform to two distinct temporal arcades, whereas the distribution of the temporal venular arcades is more heterogeneous (Figure 1). Microaneurysms and haemorrhages are diffusely distributed in the posterior pole. Exudates appear to cluster in the temporal macular region. CWS and IRMA occur most frequently in the peripapillary area. Neovascular changes are diffusely distributed in the posterior pole. Venous beading is clustered around the venular arcades in the peripapillary area (Figure 2).

Conclusions: Our study finds that diabetic retinopathy lesions are unevenly distributed in the posterior pole. The cause of exudate clustering at the temporal macular is not well understood and requires further study. These lesion distribution patterns will be used to derive a clinical algorithm to facilitate accurate diabetic retinopathy grading by trainee eye health care providers.

ABSTRACT BODY:

Purpose: To compare the longitudinal dynamics of quantitative ellipsoid zone (EZ) integrity on OCT in eyes with diabetic macular edema (DME) when treated with laser photocoagulation or intravitreal aflibercept injection (IAI) in the Phase 3 VISTA study.

Methods: VISTA was a randomized phase 3 study in DME patients. This post-hoc analysis included 361 eyes treated with laser photocoagulation, 2mg IAI every 4 weeks (2q4), or every 8 weeks following 5 initial monthly doses (2q8). OCT images were evaluated using machine learning-assisted retinal layer mapping software. EZ integrity parameters were EZ-RPE central subfield thickness (CST, μm), EZ-RPE panmacular volume (mm3), and percentage of partial and total EZ attenuation (proportion of macular area with 20μm or less and 0μm EZ-RPE thickness, respectively).

Results: There were no baseline differences in EZ metrics between the laser group and IAI groups. At week 4, laser eyes showed worsening integrity parameters with IAI eyes already improving. At week 100, the EZ-RPE CST and Volume were significantly higher in the IAI group ($p<0.0001$), while partial and total EZ attenuation were significantly lower ($p<0.0001$) compared to the laser group.

Specifically, the pooled IAI group demonstrated significantly improved EZ integrity parameters compared to baseline, while the laser group demonstrated significant worsening at week 100 (Table 1) despite ~41% of laser patients receiving IAI between weeks 24 and 100. At week 100, 2q4 demonstrated significant improvement in total EZ attenuation whereas the improvement in 2q8 did not reach statistical significance (-32.5%, $p<0.026$; -24.3%, $p=0.16$ respectively), although all other EZ metrics significantly improved in both groups. There were significant correlations between EZ metrics and BCVA at week 100 (Table 2).

Conclusions: IAI therapy for DME was associated with sustained improvement of outer retinal integrity parameters through week 100, whereas laser demonstrated significant worsening in EZ integrity despite a large proportion of patients receiving IAI treatment in addition to laser. This may explain some of the differences in functional outcomes between treatment approaches and provide a potential biomarker for outer retinal integrity in response to therapeutic interventions.

ABSTRACT BODY:

Purpose: Being able to precisely track bloodflow dynamic inv vivo is important in understanding a number of disease of the eye, CNS and systemically. Direct imaging of medium to large vessels is complicated due to relatively slow frame rates and aliasing artifacts, hence the development of XT (X direction by Time) imaging, whereby the slow scanner is paused for a period of the scan creating a normal rate structural image and a fast scan rate over the vessel of interest. The aim of this study is to design an algorithm to extract such measurements automatically from these images.

Methods: In the temporal portion of XT, blood cells move past the fast scanner resulting in a streak. Depending on the speed of the bood cell, the angle and length of the streak will vary. Streak orientation was selected by sliding a diagonal convolution kernel (consisting of a line of a certain slope) along the XT Scan, the fit of such kernel was evaluated at each pixel location. The speed of erythrocytes was automatically estimated by testing kernels with several slopes and selecting the best fit.

Results: The angles of lines belonging to the best fitting kernels were plotted against angles estimated by human graders. We evaluated our algorithm on 100 consecutive XT Scan frames from a BMC Apaeros AOSLO, revealing the known fluctuation of blood velocity and flow during the cardiac cycle. Plotting the graders' estimates against those produced by our algorithm resulted in a Pearson correlation coefficient = 0.70 (P=2E-35).

Conclusions: Here we present a pipeline to automatically detect time portions of XT images and extract streak angle, thus determining blood flow. Our method compared favorably with human graders, while taking a fraction of the time to compute. This pipeline can be used automatically within further analysis pipleines to determine new insights into diabetes and other vascular diseases.

ABSTRACT BODY:

Purpose: The main purpose of this work is to computationally simulate the effect of thermal stimuli on fluid transport to enhance intravitreal drug delivery. The goal is to take into consideration the partial liquefaction of the vitreous due to syneresis.

Methods: In an earlier experimental investigation (Huang and M. Gharib), a thermal stimulus applied to an eye model showed an enhancement of fluid flow in the vitreous due to the density stratification resulting from thermal expansion. While this was done for a wholly liquid vitreous, in the current computational investigation the vitreous is considered to be partially liquefied due to syneresis. The vitreous is modeled as a Darcy fluid for the fibrous gel part and a Newtonian fluid for the liquefied part. A thermal stimulus consisting of a Peltier heater is applied over a 0.25-cm^2 circular area to provide a steady temperature of approximately 10C above the normal body temperature of 37C. The choroidal tissues and those surrounding the eye have been modeled with the Pennes bioheat equation for transport between the vitreous and the vasculature. The density changes in the ocular fluids due to heating create a gravitational body force and induces fluid motion over and above the normal physiological flow. The simulations were conducted for various eye orientations with respect to the direction of gravity. The liquefied region was kept as a simple spherical segment in the posterior region. The computational simulation was carried out using Star CCM+.

Results: The simulations show that after 5-10 minutes of heating at 10C above the body temperature at the cornea leads to fluid motion in the aqueous and the vitreous humors. As expected, the liquefied region within the vitreous experiences significant motion owing to the free mobility of the fluid therein. Fluid velocities up to 0.07 cm/s are predicted.

Conclusions: Thermal stimulation of the eye for approximately 10 minutes at the cornea by 10C elevation of the temperature provides substantial increase of the fluid velocity, particularly in the syneretic regions. This technique has the potential to significantly enhance intravitreal drug delivery to the retina. Detailed studies to further explore and quantify the degree of enhancement are needed along with clinical recommendations for ophthalmologists as well as patients.

ABSTRACT BODY:

Purpose: While age is the major risk factor for developing AMD, age-matched comparisons found that women have a higher risk of developing wet AMD indicating an additional life-span-independent, sex-dependent risk factor. The primary cellular target of AMD is retinal pigment epithelial cells (RPE), which are post-mitotic and, as they age, undergo a slow degeneration leading to a loss of function. We hypothesize the increased susceptibility of women to AMD is caused, in part, by an age-related RPE degeneration that is more prominent and progresses faster in females than in males.

Methods: Functional and morphological analyses were performed on young (2-4 months) and aged (16-36 months) female (f) and male (m) C57BL/6 mice. Visual function was assessed by ERG a, b, and c- waves and optomotor reflex (OMR), which measured visual acuity and contrast sensitivity. Morphological analyses were performed by immunohistochemical staining of f-actin on RPE/choroid flat mounts. RPE cell density, cell area, and the number and size of RPE lesions (area with amorphic and enlarged cells) were quantified. P2ry12 immunostaining was used to monitor microglia recruitment to the subretinal space.

Results:

As expected, visual function was significantly reduced in aged mice as compared to young mice. However, aging female mice (18 months) displayed a significant decrease in contrast sensitivity vs age-matched males (mean % contrast 25.4 (f) vs 18.2 (m) at 0.267 cycl/deg, p=0.0001). This loss in vision coincided with a functional decline in RPE as shown by a significant reduction in the ERG c-wave (mean amplitudes [μV] 192 (f) vs 229.3 (m) at 24.1 cd.s/m^2, p=0.0001), while the a- and b-waves were not different. Highly geriatric mice (24-36 months) showed gross PRE morphological anomalies characterized by areas with amorphic and enlarged cells, which were significantly more frequent in females, 77% of RPE/choroid flat mounts (n=10 of 13) with at least 1 or more areas of aberrant RPE, as compared to males with < 10% (n=1 of 15). Interestingly, the loss of RPE morphology and function in female mice coincided with an increased recruitment of microglia to the subretinal space.

Conclusions: We conclude the age-dependent decline in visual function in mice is sex dysmorphic with females showing an accelerated loss of function that coincides with a decline of RPE. Implying RPE dysfunction may account for the AMD sex-dependent risk factor in women.

ABSTRACT BODY:

Purpose: The optic nerve, like other pathways in the mature CNS, cannot regenerate after traumatic injury or degenerative diseases, leading to permanent vision loss. Altering the intrinsic growth ability of retinal ganglion cells (RGCs) by manipulating transcription factors or by activating growth factor-induced signaling pathways has resulted in appreciable levels of axon growth, but we are still far from achieving substantial visual recovery, underlining the need for therapies with higher efficacy. Oncomodulin (Ocm), an 11 kDa protein expressed by neutrophils and macrophages, is a critical mediator of optic nerve regeneration induced by intraocular inflammation. Intraocular inflammation combined with a cAMP analog and deletion of Phosphatase and tensin homolog (Pten) is one of the few treatments reported to promote optic nerve regeneration back to central brain target areas. This study's purpose is to obviate the need for intraocular inflammation and to apply treatments in a clinically relevant manner.

Methods: We incorporated the Ocm gene into the glial-specific shH10 virus, and injected this virus intraocularly together with AAV2 viruses expressing constitutively-activated adenylyl cyclase (AAV2-c/a-AC to elevate cAMP, a co-factor of Ocm) and shPten (AAV2-shPten) after optic nerve injury. Regenerating axons were labeled by an antereograde tracer cholera toxin subunit B (CTB) and quatified at different distances distal to the nerve injury site.

Results: After survival periods of up to 8 weeks, this combined treatment stimulated axon growth through the full length of the optic nerve, with 500-800 axons at the end of optic nerve and many axons crossing the optic chiasm and entering the brain.

Conclusions: Gene therapy directed at manipulating defined molecules and delivered after injury has occurred can promote substantial optic nerve regeneration and provides a model for future studies of brain target reinnervation.

TITLE: Corneal stromal stem cell-derived extracellular vesicles transport TGF β3 to mediate anti-fibrosis effect on corneal scarring

SESSION TITLE: Corneal stromal biology, wound healing modulators and regeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Santra, L. Weng, M. Louise Geary, T. yang, V. Jhanji, G. Yam, Ophthalmology, University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Mithun Santra: Commercial Relationship: Code N (No Commercial Relationship) | Lin Weng: Commercial Relationship: Code N (No Commercial Relationship) | Moira Louise Geary: Commercial Relationship: Code N (No Commercial Relationship) | tiangbing yang: Commercial Relationship: Code N (No Commercial Relationship) | Vishal Jhanji: Commercial Relationship: Code N (No Commercial Relationship) | Gary Yam: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Transparent cornea is paramount for vision. Corneal scarring is a top leading cause of global blindness. The conventional corneal transplantation has been challenging due to the scarcity of donor tissue. Alternative corneal stromal stem cell (CSSC) therapy was reported to successfully prevent the scarring development. The paracrine action of CSSC, mediated by extracellular vesicles (EVs), was shown to block corneal fibrosis and stimulate native tissue regeneration. This study investigated the role of anti-fibrotic transforming growth factor (TGF) β3 transported in CSSC-EVs in the scarless regeneration of mouse corneas after injury

Methods: Primary human CSSCs isolated from donor limbus were co-cultured with lipopolysaccharide-treated pro-inflammatory M1 mouse macrophages (RAW264.7) or conditioned media concentrates. The time course cellular and EV expression of hTGFβ1, 2 and 3 were examined by immunofluorescence and qPCR, respectively. Naïve CSSC or hTGFβ3 knockdown CSSCs were applied to mouse corneas after wounding by Algerbrush burring Corneal clarity (scar development), corneal thickness and the expression of inflammatory and fibrosis genes on mouse corneas were examined.

Results: hTGFβ3 was upregulated in CSSCs after stimulation with M1 RAW cells, in both co-culture and paracrine conditions. More importantly, EVs derived from the stimulated CSSCs contained increasing levels of hTGFβ3 mRNA transcripts. After CSSC application to injured mouse corneas, hTGFβ3 was significantly upregulated, in conjunction with the inhibition of mouse fibrotic genes. At day 14 post-injury, the treated corneas remained clear and the expression of fibronectin, hyaluronan synthase 2, SPARC, tenascin C, collagen 3a1, and α-smooth muscle actin were significantly reduced. CSSCs with TGFβ3 knockdown by specific siRNAs lost these therapeutic effects.

Conclusions: Our study revealed the paracrine action of human CSSCs on corneal scar prevention through EV-mediated delivery of TGFβ3 mRNA transcripts. The elevated TGFb3 expression in injured corneas could redirect the wound healing process to a reduced scarring or scar-free tissue regeneration, resulting in clear corneas.

ABSTRACT BODY:

Purpose: In glaucoma, astrocytes within the optic nerve head (ONH) rearrange their actin cytoskeleton, while becoming reactive and upregulating intermediate filament glial fibrillary acidic protein (GFAP). Increased transforming growth factor beta 2 (TGFβ2) levels have been implicated in glaucomatous ONH dysfunction. A key limitation of using conventional 2D culture to study ONH astrocyte behavior is the inability to faithfully replicate the in vivo ONH microenvironment. Here, we engineer a 3D ONH astrocyte hydrogel to better mimic in vivo mouse ONH astrocyte (MONHA) morphology, and test induction of MONHA reactivity using TGFβ2.

Methods: Primary MONHAs (N = 6 independent preparations) were isolated from C57BL/6J mice and cell purity confirmed. To engineer 3D cell-laden hydrogels MONHAs (2.5 x 10^6 vs. 5.0 x 10^6 cells/ml) were mixed with photoactive extracellular matrix components (collagen type I, hyaluronic acid) and crosslinked for 5 minutes using a photoinitiator (0.025% riboflavin) and UV light (405-500 nm, 10.3 mW/cm2). Sholl analysis was used to assess MONHA process complexity over time (1-3 weeks) in hydrogels. MONHA-encapsulated hydrogels were cultured for 3 weeks, and then treated with TGFβ2 (2.5, 5.0 or 10 ng/ml) for 7 days. Treated hydrogels were evaluated for F-actin staining intensity, GFAP upregulation, and fibronectin/collagen IV deposition.

Results: MONHAs were ~95% positive for astrocyte marker GFAP, and <5% for oligodendrocyte marker OSP-1 and microglia/macrophage marker F4/80. Following encapsulation, MONHA retained high cell viability (~89%) in hydrogels and continued to proliferate over 4 weeks as determined by live/dead staining and MTS assays. Sholl analysis demonstrated that MONHAs within hydrogels developed increasing process complexity ($p<0.05$) with increasing process length over time ($p<0.0001$). Cell processes connected with neighboring cells, coinciding with Connexin43 expression within astrocytic processes. Treatment with TGFβ2 induced reactivity in MONHA-encapsulated hydrogels as determined by altered F-actin cytoskeletal morphology ($p<0.0001$), ~7.4-fold increase in GFAP expression ($p<0.0001$), and ~2.5-fold elevation in fibronectin ($p<0.05$) and collagen IV ($p<0.0001$) deposition.

Conclusions: Our data supports use of this 3D biomimetic ONHA-encapsulated hydrogel to further investigate ONHA behavior in response to glaucomatous insult.

ABSTRACT BODY:

Purpose: The degree of variability in intraretinal fluid (IRF) and configuration in patients with macular holes (MHs) has prompted studies to evaluate its prognostic value. This study investigates the association between preoperative intraretinal fluid (IRF) area and preoperative and postoperative in surgically repaired idiopathic MH. This study further evaluates other prognostic indices related to MH repair which may assist clinicians' understanding of MH operative management.

Methods: A retrospective cohort study of 251 patients who were diagnosed with idiopathic MH and IRF in the edges of the hole and underwent successful surgical repair were selected for the study. OCT scans were segmented by expert readers to obtain IRF area. Preoperative and postoperative best visual acuity (BVA) at 1,3, and 6 months were collected along with associated MH characteristics such as size, staging, postoperative closure status, type of closure (type I vs type II) and preoperative and postoperative central subfield thickness (CST). Associations between IRF area and these variables were evaluated using Spearman's correlation analysis.

Results: At preoperative baseline, the mean(SD) BVA was 46.4(19.03) and mean(SD) CST was 366.11(77.75). Preoperative IRF area was moderately correlated with preoperative BVA ($r = -0.32$, $p < 0.001$), negligibly correlated with postoperative BVA at 1, 3, 6 months ($r = -0.14$, $p = 0.026$; ($r = -0.21$, $p < 0.001$; $r = -0.19$, $p < 0.001$, respectively). Preoperative IRF area was strongly correlated with MH minimum linear diameter ($r = 0.56$, $p < 0.001$) and MH base diameter ($r = 0.65$, $p < 0.001$), moderately correlated with baseline CST ($r = 0.36$, $p < 0.001$) and negligibly with 6-month CST ($r = -0.2$, $p = 0.01$). Relationships between IRF and MH closure status ($r = 0.048$, $p = 0.45$) and closure type ($r = 0.047$, $p = 0.47$) were not statistically significant.

Conclusions: Preoperative IRF area in patients with idiopathic MH demonstrated a moderate correlation with preoperative BVA and a negligible/weak correlation with postoperative BVA up to 6 months, suggesting that vision may not have a clinically significant relationship with IRF in the setting of MH. Further, this study reinforced previous findings that preoperative IRF was strongly correlated with MH size.

ABSTRACT BODY:

Purpose: Photoreceptor transplantation is envisioned as a possible treatment for degenerative retinal diseases. In homeostasis, photoreceptor cell maturation and survival are partly regulated by extrinsic cues. However, in the transplantation context, the effect of extrinsic cues on the maturation and survival of donor cells following placement in the recipient niche is incompletely understood. Here, we aimed to investigate the maturation of transplanted human stem cell-derived photoreceptor cells in a mouse model of degenerative retinal disease.

Methods: Retinal organoids derived from Crx.tdTomato^{+} H9 human embryonic stem cells and cultured for 134 days were microdissected and subretinally transplanted into adult immunodeficient Rd1 mice. Age-matched organoids served as in vitro controls. After three months, we assayed photoreceptor maturation using single-cell RNA sequencing, immunohistochemistry, and patch-clamp electrophysiology.

Results: Genes expressed in mature cone and rod photoreceptor cells were upregulated in transplanted photoreceptor cells compared to the controls. By pseudotime analysis of gene expression changes, we found that the transcriptome of the transplanted photoreceptor cells was more closely aligned with that of normal adult human photoreceptor cells than the transcriptome of the control cells. Photoreceptors that expressed L/M opsin, S opsin, and rhodopsin were more abundant in the transplanted than the cultured organoids. In addition, we detected more abundant photoreceptor inner/outer segment-like structures, and presynaptic terminals, in the transplanted than in the cultured condition. Functionally, patch-clamp electrophysiological responses in the transplanted condition were consistent with cone outer segment maturation.

Conclusions: Human stem cell-derived photoreceptor cells that were transplanted in a mouse model of degenerative retinal disease showed maturation characteristics that exceeded those of in vitro controls. Pseudotime analysis of single-cell RNA sequencing data provides a facile method to assay the maturation of transplanted retinal cells by integrating the expression levels of thousands of genes in multiple cell populations.

ABSTRACT BODY:

Purpose: We have identified complex structural variants (SVs) at the RP17 locus as a major cause of autosomal dominant RP (adRP). The genomic structure of each SV at the RP17 locus implicates altered topologically associated domain (TAD) structure and ectopic retinal enhancer-gene contact as a potential gain-of-function mechanism, with increased retinal expression of GDPD1. We explored this hypothesis by generating RP17 patient-derived 3D retinal organoids (ROs) and investigated the cellular and retina localisation of GDPD1.

Methods: Cells from RP17 patients were reprogrammed into induced pluripotent stem cells (iPSCs) using episomal vectors or lentiviral transduction, then differentiated into 3D ROs, alongside ROs differentiated from control iPSC. ROs were harvested at D200 and subjected to transcriptomic and lipidomic analyses (Lipotype GmbH), given the reported role of GDPD1 as a lysophospholipase. The GDPD1 gene was cloned into an expression vector for transient transfection in HEK-293 cells, and site-directed mutagenesis was used to create double and single mutants that are predicted to be catalytically inactive. GDPD1 was localized in HEK-293 cells and mouse retina using a commercial antibody to GDPD1 (Proteintech).

Results: iPSCs were developed from two individuals with the NL-SV1 and two individuals with the UK-SV2 SVs. All RP17 iPSC lines differentiated into ROs. The transcriptome of D200 RP17-SV ROs was compared to control ROs using RNAseq, and differentially expressed genes identified. Preliminary lipidomic analysis of RP17-SV vs. control retinal organoids revealed altered phospholipid ratios. The expression of wild-type and mutant GDPD1 was investigated in HEK-293 by immunocytochemistry and Western blotting. Immunohistochemistry demonstrated weak anti-GDPD1 immunoreactivity in photoreceptor inner segments in control ROs and mouse retina.

Conclusions: Our current data support the hypothesis that altered TAD structure leads to ectopic retina- specific enhancer-gene accessibility and interaction with GDPD1, resulting in increased retinal GDPD1 expression. Studies are underway to further test this hypothesis through transcriptomic, epigenetic, lipidomic and morphological analyses.

ABSTRACT BODY:

Purpose: To characterize the birefringence behavior of rabbit cornea using digital photoelasticity technique.

Methods: Eight rabbit corneas were subjected to intraocular pressure using an in-house designed anterior chamber. Then, the central 11 mm of the cornea was imaged using a polariscope in the transmission mode under white light. The images were captured at 20 mm of Hg pressure. The ten-step phase-shifting technique was employed, and the obtained phase maps were then unwrapped to obtain the full-field corneal birefringence data.

Results: The rabbit corneas exhibited a saddle-back distribution of isochromatic (contours of constant retardation). These isochromatics form their skeleton around the points of zero retardation, also known as isotropic points in photoelastic literature. The corneal isoclinics (contours of constant angle) were found to be distributed around the isotropic points as they pass through them. Further, the distance between isotropic points was found to vary amongst the tested corneas.

Conclusions: The birefringence of the cornea shows inter-individual variability yet maintains the saddle-back distribution. Since the isochromatics form their skeleton around isotropic points, it is proposed that the isotropic points are an implication of stable microstructure and curvature under pressure loading. Therefore, it is suggested that tracking the movements of these points during various interventions would be beneficial to clinical practice. However, detailed studies are required to test this hypothesis. Further, the analysis based on digital photoelasticity could be translated into clinical usage due to its simplicity and ability to capture full-field birefringence data.

ABSTRACT BODY:

Purpose: Enlarged foveal avascular zone (FAZ) has been associated with lower visual acuity in diabetic patients. Accurate and automatic FAZ measurements could be a valuable tool in the management of diabetic macular edema. Here, we compare manual (MS) and automated segmentation (AS) FAZ tracings from 3 x 3mm optical coherence tomography angiography (OCTA) scans in healthy and diabetic macular edema (DME) patients.

Methods: This IRB approved study prospectively collected OCTA images in patients evaluated in a tertiary care center where 43 eyes from 43 healthy individuals and 36 eyes from 36 DME patients were included. The FAZ superficial vascular plexus was traced by three masked, trained graders using ImageJ. The raw images were analyzed with the Advanced Retinal Imaging (ARI) network algorithm. All images were analyzed for perimeter, circularity, and area. Paired t-tests were used to compare the manual and automated methods.

Results: For the healthy subjects, the FAZ area was 0.267 ± 0.149 mm^2, and 0.244 ± 0.189 mm^2 by MS and AS respectively (P=0.25). In DME patients, the FAZ area was 0.428 ± 0.222 mm^2 and 0.347 ± 0.217 mm^2 by MS and AS respectively (P=0.024). There was a statistically significant difference between the two methods for both perimeter and circularity in both cohorts of patients with AS underestimating perimeter (P=<0.001) and overestimating circularity (P=<0.001).

Conclusions: Our study shows that while automatic FAZ segmentation is reliable in healthy subjects, the reliability is reduced when estimating FAZ area in patients with DME.

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) is a common and specific neurovascular complication of diabetes. Dysregulation of amino acid metabolism has been showed to be involved in the pathogenesis of DR. Glutamine is the most abundant and versatile amino acid in human and many other mammals and extensively involved in various metabolic pathways. The present study was designed to investigate whether reprogramming amino acids metabolism by supplement of Ala-Gln, serving as a substitute for glutamine, plays protective roles on the diabetic retinopathy in streptozotocin (STZ)-induced rat model.

Methods: Visual function of the rats was measured by electroretinogram (ERG). The expression of neurovascular markers and inflammation markers, such as glial fibrillary acidic protein (GFAP) and vascular endothelial growth factor (VEGF) were evaluated by western blot and immunofluorescence. The function of mitochondria was measured by immunostaining of TOM20. Regular body weight and blood glucose levels of rats were also monitored.

Results: Amino acid sequencing indicated the ratio of glutamate/glutamine was upregulated in the retinas of STZ-induced rat compared to normal control. The activity of ERG was declined in STZ-induced diabetic rats, while the supplement of Ala-Gln increased ERG activities in the diabetic rats. In addition, pro-inflammatory factors VEGF and VCAM-1 were decreased in diabetic rats treated with Ala-Gln compared to those treated with vehicle. Further, the protein expressions of glutamine synthase, GFAP were decreased in Ala-Gln treated diabetic rats. Immunostaining of GFAP indicated less of Muller cells were activated in the retina of Ala-Gln treated diabetic rats. The glycolysis indicated by levels of PKM2, LDHA and LDHB were significant increased after Ala-Gln treatment. The mitochondrial TOM20 was upregulated in the retina of Ala-Gln treated diabetic rats.

Conclusions: Our study has demonstrated that Ala-Gln has beneficial effects in diabetic retinopathy by improving the retinal neuronal function, reducing retinal glial activation and enhancing the glycolysis and the function of mitochondria in diabetic retinas. Therefore, reprograming metabolism by Ala-Gln may be a novel therapeutic avenue for retinal degeneration in DR.

TITLE: Changes in fluorescence lifetime of the fundus after intravitreal ranibizumab injection in patients with exudative age-related macular degeneration

SESSION TITLE: AMD: Clinical and translational research/AMD therapies (excluding anti-VEGF)

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.R. Sonntag, S. Schlunk, J. Kempska, S. Grisanti, Y. Miura, Department of Ophthalmology, University of Lübeck, GERMANY|Y. Miura, Institute of Biomedical Optics, University of Lübeck, GERMANY|

Commercial Relationships Disclosure: Svenja Sonntag: Commercial Relationship: Code N (No Commercial Relationship) | Stella Schlunk: Commercial Relationship: Code N (No Commercial Relationship) | Joanna Kempska: Commercial Relationship: Code N (No Commercial Relationship) | Salvatore Grisanti: Commercial Relationship: Code N (No Commercial Relationship) | Yoko Miura: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The purpose of this study is to compare the fluorescence lifetime (FLT) of the fundus before and after the intravitreal ranibizumab injection for exudative age-related macular degeneration (AMD).

Methods: Seventeen consecutive patients with exudative AMD were examined with fluorescence lifetime imaging ophthalmoscopy (FLIO: Heidelberg Engineering GmbH) before and 4 weeks after a scheduled intravitreal injection of ranibizumab. Number of past injection and the condition of the pre-treatment retina were not specified. The FLT was calculated for the separated macular areas defined by the Early Treatment Diabetic Retinopathy Study (ETDRS) grid. The relationship between the change in visual acuity and the change in FLT ($\triangle\tau_m$) or central retinal thickness ($\triangle$CRT) was assessed with an univariate regression analysis.

Results: The $\triangle$CRT after a single injection of ranibizumab ranged from -80 µm to 47 µm, with the median of 0 µm. The range of $\triangle\tau_m$ at the center was -166 ps to 293 ps, with the median of 8 ps for the short spectral channel (SSC: 498-560 nm), and -116 ps to 60 ps, with the median of 0 ps for the long spectral channel (LSC: 560-720 nm). In the inner ring $\triangle\tau_m$ ranged from -163 ps to 175 ps in SSC and from -68 to 28 ps in LSC, and in the outer ring from -126 ps to 9 ps in SSC and -49 ps to 26 ps in LSC. The results of the regression analysis showed that a decrease in FLT (negative $\triangle\tau_m$) is significantly associated with an increase in visual acuity ($p<0.01$) in all three analyzed areas in both channels. In contrast, there was no significant association between the change in visual acuity and the $\triangle$CRT.

Conclusions: The change in FLT induced by ranibizumab injection was shown to vary widely among individuals. However, it was shown that the shortening of FLT in the macula is associated with the improved visual acuity more strongly than the change in the morphology of the central retina. This presumably reflects activation of the metabolic state of the retinal cells. Therefore, using FLIO to evaluate the changes in FLT before and after anti-VEGF injection may be useful in evaluating the response of the metabolic state and function of the retina to anti-VEGF treatment.

ABSTRACT BODY:

Purpose: To assess long-term visual and anatomical outcomes following surgical repair of idiopathic full thickness macular holes (FTMH) with pars plana vitrectomy (PPV) and internal limiting membrane (ILM) peel in patients with 5 to 9 years of post-operative follow up

Methods: A retrospective study evaluated patients diagnosed with idiopathic full thickness macular hole who received surgical repair at a single academic tertiary center with at least 5 years of post-operative follow up. Data collection included demographic and pre-operative characteristics including best visual acuity (BVA), lens status, prior ocular history, and macular hole structural integrity as determined by spectral domain optical coherence tomography (OCT). Surgical techniques along with functional and structural improvement were assessed by collection of BVA and findings of ellipsoid zone (EZ) integrity and intraretinal fluid (IRF) on OCT at determined time points of 3 months, 6 months and each year until 9 years of follow up.

Results: The study comprised 90 eyes of 80 patients with a mean age of 67.2 +/- 6.8 years with an average post-operative follow up of 80.8 +/- 17.5 months (range 54-130 months). 61 eyes out of 70 phakic eyes (87%) received cataract surgery at the time of FTMH repair, with the remaining eyes receiving cataract surgery at an average of 9.5 +/- 4.6 months (range 5-18 months) post-surgery. Macular hole reoperation occurred in 4 eyes (4%) at a mean duration of 6.1 +/- 6.0 months (range 1-13 months). Over the study duration, EZ integrity was restored in 78% of eyes, with an absence of IRF in 96% on OCT. The pre-operative mean ETDRS BVA of 51 (Snellen equivalent 20/80-20/100) improved to a mean BVA of 76 (Snellen equivalent 20/25-20/30) at 5 years post operation, with an average gain of 25 letters at 1 year that remained stable over 5 years ($P<0.05$). >80% of eyes achieved a BVA > 65 (Snellen equivalent 20/50) 8 years after surgical repair.

Conclusions: Vitreoretinal surgery for idiopathic FTMH resulted in successful hole closure and sustained visual acuity improvement over long-term follow up.

ABSTRACT BODY:

Purpose: To measure longterm safety and efficacy of a novel less scarring Ahmed valve implantation technique.

Methods: Study design: retrospective comparative case series Methods: the clinical records of consecutive patients operated with an Ahmed valve implanted by adopting a novel technique (between 2012 - 2019) or with a more traditional approach (time frame between 2005 - 2011) were reviewed. Data analyzed: anti glaucoma medications,IOP, visual acuity,post-op complications. Surgical technique: "Group A" Ahmed valvei traditionally implanted and left open. "Group B": the tube was ligated and closed by a 7.0 polygalactin and the 9.0 nylon limbal mattress suture was placed by passing the needle "through" the tube, thereby allowing the aqueous to spill out through the tube's wall. In the expectations of the investigators, this approach was expected to lead to an anterior filtering bleb which scarred during a time-frame compatible with the dissoluiton of the peritubular 7.0 polygalacting suture. A flow of a less "inflamed" and "irritating" aqueous through the imiplant to the plate was then expected to occur, allowing the formation of the proper retroequatorial bleb with less chance of intense scarring. Statistical analysis: the data were analyzed by (a) parametric statistics (IOP) , (b) non paramteric statistics (medications, visual acuity, complications) . Kaplan-Meier survival curves were further created according to different cut-off levels of IOP (with or without medications).

Results: 235 patients, with at least 5-year follow up , (Group B) compared with n = 127 (Group A).
Group A: Pre-op IOP (mean, SD): 26.1 (9.1) , 5-yr IOP 15.7 (4.2), Pre-op medications: 2.8 (1.2), 5-yr medications: 1.5 (1.1). Group B: Pre-op IOP (mean, SD): 26.7 (9.3) , 5-yr IOP 13.6 (3.8), Pre-op medications: 3.5 (1.7), 5-yr medications: 1.2 (0.9). Both IOP values ($p < 0.001$ Student t test) and number of medications ($p < 0.01$, Chi Square test) were significantly different between the two groups 5 years after surgery. Post operative hypotony (11/235 and 15/168) and serous choroidal detachments (11/235 and 8/168) were comparable between the groups (Fisher exact tests, $p > 0.4$ for both variables). 4 hemorragic choroidal detachments occurred in group B and 2 in Group A. .

Conclusions: The described novel implantation technique for the Ahmed valve allows a better 5-yr IOP outcome compared with the traditional approach.

TITLE: Cyclic strain-induced scleral myofibroblast escape from topographic confinement is ERK dependent

SESSION TITLE: Pharmacology/cellular mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: I.F. Pitha, A. Mozzer, Ophthalmology, Johns Hopkins University, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Ian Pitha: Commercial Relationship: Code N (No Commercial Relationship) | Annie Mozzer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Myofibroblasts are associated with pathologic scleral remodeling in myopia and glaucoma development.[1,2] We showed reduced myofibroblast alignment with collagen topography in human sclera can be modeled by cyclic strain exposure in vitro.[3] Here, we characterize the scleral myofibroblast response to cyclic mechanical strain.

Methods: Primary human peripapillary scleral (PPS) fibroblasts were cultured on topographically aligned grooves to promote cell alignment, exposed to TGFb (2 ng/ml) in the presence of vehicle or kinase inhibitors, and exposed to uniaxial strain (1 Hz, 5%, 12-24 hours). Alignment with grooves was determined at baseline, immediately following strain, and 24 hours after strain cessation with 0° being completely aligned and 90° being perpendicular to grooves. A wound healing assay was developed to investigate fibroblast migration across topographic cues in the absence of strain. Transcriptional profiling of myofibroblasts with or without strain was performed by RT-PCR and pERK, pSMAD2, and pSMAD3 levels were measured by immunoblot.

Results: Pre-strain alignment (6.2±1.5°) was significantly reduced after strain (21.7±5.3, $p<0.0001$) and restored 24 hours after cessation (9.5±2.6°). ERK and TGFbR1 inhibition preserved alignment after strain; however, loss of alignment occurred after ROCK, YAP, or SMAD3 inhibition. TGFb-induced myofibroblast markers were reduced by strain. While TGFb-induced phosphorylation of ERK and SMAD2 was unaffected by strain, SMAD3 phosphorylation was reduced significantly ($p=0.0004$). Wound healing across grooves was enhanced by ROCK and SMAD3 inhibition but not ERK or TGFbR1 inhibition.

Conclusions: Strain-induced myofibroblast migration across topographic confinement is ERK dependent and associated with pSMAD3 inhibition. These results inform potential mechanisms of pathologic scleral remodeling.

ABSTRACT BODY:

Purpose: The permeability of the cornea to topically applied formulations is a major factor determining their clinical efficacy. Various agents could influence the corneal permeation including Benzalkonium chloride (BAC) or surfactants which help lipophilic agents solubilization. The purpose of the study was to evaluate the permeation of different Latanoprost formulations through an in vitro reconstructed human 3D corneal tissue model (EpiCorneal^{TM}).

Methods: EpiCorneal tissues are comprised of normal human corneal epithelial cells and attain morphology, barrier properties, and gene expression similar to the human cornea. 3 different formulations of 0.005% Latanoprost were tested: A. preservative-free (PF) and surfactant-free (SF) formulation; B. same SF formulation but containing BAC 0.02%; and C. different PF formulation but containing Macrogolglycerol hydroxystearate 40 (MGHS 40) at 5%. 100 µL of 1:5 diluted formulations were applied onto the EpiCorneal tissue surface and incubated at standard cell culture conditions (37°C, 5% CO2, 95% RH). Samples were collected after 0, 0.5, 1, 2, 3, 4, 5, 6, 8, 10, and 12 hr permeation and analyzed with a validated HPLC method for Latanoprost acid (LAT) detection (active form). Barrier integrity (TEER, Transepithelial Electrical Resistance) was determined before and after the permeation. For each formulation, plots of the cumulative amount of LAT that permeated through the tissue versus time were constructed. From the steady state flux region of the plot (<4 h), the permeation coefficient (Papp) was calculated.

Results: The transport profile of LAT formulations was linear from 2 to 12 hours for C and from 1 to 4 hours for A and B and then curved to reach a plateau. A and B had a similar permeation pattern, comparable at each timepoint. Papp was fastest and comparable for A and B (~8.5 cm.s^{-1}); C had the lowest Papp (3.14 cm.s^{-1}). Tissue integrity was maintained in all experiments.

Conclusions: The absence or presence of BAC within the formulations A and B did not influence the permeation profile as similar LAT cumulative amount and Papp were obtained. However, formulation C resulted in a lower and slower permeation pattern when compared to formulations A and B which may be due to the presence of MGHS 40. Thus, the EpiCorneal tissue model allowed us to anticipate the pharmacokinetics of LAT and the excipients' role. The results were confirmed in an in vivo rabbit model study.

TITLE: Pilot Data on Safety and Efficacy of Combined Corneal Crosslinking and Fine Needle Diathermy for Regression of Pathological Corneal Neovascularization and Corneal Stabilization Prior to High-Risk Keratoplasty

SESSION TITLE: Corneal Immunology and Neovascularization

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Mestanoglu, H. Heinen, F. Schaub, F. Bock, D. Hos, C. Cursiefen, Department of Ophthalmology, Universitat zu Koln, Cologne, Nordrhein-Westfalen, GERMANY|D. Hos, C. Cursiefen, University of Cologne Center for Molecular Medicine Cologne, Cologne, Nordrhein-Westfalen, GERMANY|

Commercial Relationships Disclosure: Mert Mestanoglu: Commercial Relationship: Code N (No Commercial Relationship) | Heide Heinen: Commercial Relationship: Code N (No Commercial Relationship) | Friederike Schaub: Commercial Relationship: Code N (No Commercial Relationship) | Felix Bock: Commercial Relationship: Code N (No Commercial Relationship) | Deniz Hos: Commercial Relationship: Code N (No Commercial Relationship) | Claus Cursiefen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Corneal neovascularization (CNV) causes decreased vision and is an important risk factor for graft rejection after (high-risk) keratoplasty (KP). Corneal crosslinking (CXL) and fine needle diathermy (FND) have previously been demonstrated to regress pathological CNV in both experimental and clinical studies. However, the impact of a combination of both treatment modalities on CNV has not been studied before. This pilot evaluation aimed to investigate whether combined CXL and FND are safe and efficient for regression of pathological CNV and corneal stabilization prior to high-risk KP.

Methods: This retrospective case series included ten patients (7 male, 3 female, mean age 58.1 years) with CNV and the need for high-risk penetrating KP. Patients were treated with CXL and FND followed directly by penetrating KP. Corneal vessel-covered areas were measured on pre- and postoperative slit-lamp images via a semi-automatic morphometric method. Patients were followed up for adverse events and graft rejection.

Results: Mean follow-up was 21.2 ± 7.8 weeks (range 4–31 weeks). No intraoperative complications were observed. In 4 eyes, wound leakage was observed during the early postoperative period. One of these patients required repeat-KP due to fungal keratitis, while two patients received amniotic membrane transplantation during the follow-up. One of these two patients developed endophthalmitis. Recovery of graft transparency was delayed in two eyes, and neurotrophic ulceration was observed in one graft. Combination treatment with CXL and FND resulted in a significant reduction of vascularized areas (mean reduction of 66.2%, ± 22.0%). Revascularization was not observed. All transplanted corneas remained clear and without immune reactions (except the one with fungal keratitis needing re-KP).

Conclusions: Combined CXL and FND prior to high-risk KP seems to be an efficient method to regress pathological CNV in this pilot evaluation. Leakage from corneal incision sites may be an early postoperative risk, possibly due to delayed corneal healing. Longer follow-up of the patients and future prospective studies are required to assess the impact of CXL and FND on long-term graft survival after high-risk KP and the potential of combined CXL and FND as a novel angioregressive method.

ABSTRACT BODY:
Purpose: Age-related Macular Degeneration (AMD) has a wide spectrum of both phenotypic and functional presentations. Yet, the contributing factors for this phenotypic variability remain not fully understood. Metabolomics reflects the downstream products of all the genetic transcription processes, making it appropriate to study multifactorial diseases like AMD. We hypothesize that there are distinct AMD endotypes (i.e. subtypes defined by functional or pathobiological mechanisms) that confer clinically meaningful differences. In this study, we aim to derive AMD endotypes based on metabolomics and correlate these endotypes with current AMD stage and retinal function.
Methods: Prospective, cross-sectional study including patients with any stage of AMD (n=196). All included participants had a complete ophthalmological exam and were imaged with color fundus photographs for AMD staging. Dark adaptation testing was performed with a 20 minutes protocol, and both rod intercept time (RIT) and area under the curve (AUDAC) were registered. Metabolomic profiling on fasting plasma samples was performed using ultra-performance liquid chromatography–mass spectrometry (LC-MS). Similarity Network Fusion (SNF) and spectral clustering were performed on the metabolomics and used to identify metabo-endotypes of AMD. Clinical differences across the metabo-endotypes were explored using one-way analysis of variance (ANOVA) for continuous variables and chi-squared test for categorical variables. Multivariable logistic regression models adjusted for covariates were then used to identify metabolomics drivers of each endotype.
Results: We identified 4 AMD endotypes using SNF and spectral clustering with metabolomics data. AMD stage (pval=0.002), RIT (pval=0.003), and AUDAC (pval=0.01) significantly differed across the endotypes. As shown in Figure 1, endotype membership tracked closely to RIT but appeared to be independent of the AMD stages. The most important drivers of the endotypes were amino acids (isoleucine, leucine, and valine metabolites), lipid metabolites (polyunsaturated and long-chain fatty acids), and nucleotides (purine metabolism).
Conclusions: Metabo-endotypes of AMD can be derived using metabolomics data and correlated with clinical and functional features. By interrogating the drivers of these metabo-endotypes, there is potential to better understand the pathophysiology behind AMD.

TITLE: Electroretinography as a biomarker to monitor Stargardt disease

SESSION TITLE: Electroretinography and disease

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J. Sajovic, A. Meglič, M. Šuštar Habjan, M. Hawlina, A. Fakin, Department of Ophthalmology, Univerzitetni klinicny Center Ljubljana, Ljubljana, SLOVENIA|

Commercial Relationships Disclosure: Jana Sajovic: Commercial Relationship: Code N (No Commercial Relationship) | Andrej Meglič: Commercial Relationship: Code N (No Commercial Relationship) | Maja Šuštar Habjan: Commercial Relationship: Code N (No Commercial Relationship) | Marko Hawlina: Commercial Relationship: Code N (No Commercial Relationship) | Ana Fakin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To determine which electroretinographic (ERG) responses best correspond with disease progression in Stargardt disease (STGD1).

Methods: 42 patients with STGD1 (ABCA4 retinopathy) were included. Group 1 harboured two null mutations (8 patients, 3 male), while group 2 had other genotypes (34 patients, 10 male). Age at the time of exam, age at onset and decimal Snellen visual acuity were collected from the medical records. Full-field ERG and pattern ERG (24°X30° checkerboard) were recorded according to ISCEV standards. S-cone ERG was also recorded, according to the ISCEV approved extended protocol. The amplitudes of the following responses were analysed cross-sectionally with age: PERG P50, dark-adapted (DA) 0.01 ERG b wave, 3.0 ERG a wave and oscillatory potentials; light-adapted (LA) 30 Hz flicker ERG and 3.0 ERG b wave; and S-cone ERG. The right patients' eyes were taken for the analysis. Correlation between ERG responses and age at the exam was compared using simple linear regression. Mann-Whitney U Test was used for comparing age at the exam, age at onset, visual acuity and ERG amplitudes between the two groups.

Results: The median age of onset was significantly earlier in group 1 (8 vs 18 years; $p<0.01$); however, disease duration was similar between the two groups (12.5 and 12.0 yrs; $p>0.05$). Group 1 had also significantly worse visual acuity (0.02 vs 0.16; $p<0.01$) and significantly lower all ERG responses ($p<0.01$). Group 1 had no detectable macular function measured with PERG P50, whereas it was detectable in 79% of patients in group 2. Simple linear regression analysis revealed that in group 1, age had a significant effect on DA 0.01 ERG b wave ($\beta=-0.8$, $R^2=0.6$, $p<0.01$) and DA 3.0 ERG a wave ($\beta=-0.9$, $R^2=0.7$, $p<0.01$). In contrast, other ERG parameters did not show age dependency. In group 2, age was significantly associated with S-cone ERG amplitude ($\beta=-0.7$, $R^2=0.5$, $p<0.01$).

Conclusions: For double null patients, the best ERG biomarkers for follow-up were DA 0.01 and 3.0 ERG responses, representing retina rod system response. For other genotypes expected to confer residual ABCA4 function, the best ERG biomarker for follow-up was S-cone ERG. Different ERG responses may be best suited to monitor disease progression in different Stargardt genotypes. However, additional studies on larger datasets with precisely grouped genotypes would be needed.

TITLE: Novel finding of morphologic characteristics of neovascular age-related macular degeneration (nAMD) with tolerable subretinal fluid (SRF)

SESSION TITLE: AMD: Clinical and translational research/AMD therapies (excluding anti-VEGF)

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Kim, B. Lee, H. Park, H. Jeong, Dept of ophthalmology, Hanyang University, Seongdong-gu, Seoul, KOREA (THE REPUBLIC OF)|B. Lee, J. Heo, Ophthalmology, Theoneseoul eye clinic, Seoul, KOREA (THE REPUBLIC OF)|

Commercial Relationships Disclosure: Jihong Kim: Commercial Relationship: Code N (No Commercial Relationship) | Byung Ro Lee: Commercial Relationship: Code N (No Commercial Relationship) | Jangwon Heo: Commercial Relationship: Code N (No Commercial Relationship) | Hae Min Park: Commercial Relationship: Code N (No Commercial Relationship) | Hyochan Jeong: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: There has been a lot of debate about fluids in nAMD. Several studies have recently reported tolerating SRF in nAMD. However, none of the studies revealed the morphologic characteristics of nAMD with tolerable SRF. This study is aimed to present the morphologic characteristics of nAMD with tolerable SRF.

Methods: This is a longitudinal observational case series study. Tolerable SRF was defined as nAMD patient even with resistant SRF who maintained good visual acuity (VA) with no deterioration. Those patients with tolerable SRF at least 6 months were enrolled. They underwent additional anti-VEGF and observed for six-more months. Patients who showed deterioration of VA or appearance of hemorrhage and intraretinal fluid (IRF) during the study period were excluded. Structural OCT was performed to evaluate detailed PED and SRF morphology. OCT angiography was also performed to confirm CNV activity by evaluating morphology, size, and vascular density of CNV from en face images, and relative flow area from cross-sectional images. These parameters and visual acuity were assessed at 4 time points; SRF recurrence, study enrollment, last injection and last follow-up.

Results: A total of 25 eyes from 25 patients with nAMD with tolerable SRF were included in the study. The naïve diseases causing tolerable SRF were typical nAMD in 8 eyes (32%), PCV in 12 eyes (48%), and pachychoroid neovasculopathy (PNV) in 5 eyes (20%). During the study period, there were no statistically significant changes in VA, SRF height and CNV activity; size, vascular density and relative flow area, respectively (all $P>0.05$). Remarkably, during tolerable SRF span, all patients showed common morphological characteristics, which were vascularized shallow irregular PED with low activity, serous SRF, and absence of IRF.

Conclusions: Although initial CNV morphologic characteristics were different from each other, nAMD with tolerable SRF showed common morphological characteristics in OCT and OCT angiography. Hypothetically, remodeling of CNV following multiple treatments may eventually lead to this common morphology, Therefore, if a patient has eyes with nAMD with tolerable SRF could be managed with very relaxed Tx protocol

ABSTRACT BODY:

Purpose: Subvisible retinal thermal laser treatments are becoming more popular, but lack an objective dosing control. This is very demanded since the laser-induced temperature rise differs largely due to inter- and intraocular variations of light scattering and pigmentation at the fundus. Therefore we developed an optoacoustic (OA) method to determine and control the average temperature rise during laser irradiation. In order to calibrate and analyse the OA-method, the time-resolved 2D-temperature distribution was investigated in this study by means of the thermosensitive fluorescent dye, ERthermAC, being taken up into the endoplasmic reticulum of the cells.

Methods: Porcine retinal pigment epithelium (RPE)/choroid-sclera explants were incubated with the dye for 30 min and then placed in a cuvette filled with phosphate buffer saline (PBS) for laser exposure. The samples were repetitively irradiated with a slitlamp-coupled Q-switched Nd:YLF-laser (527 nm wavelength, 250 ns pulse duration) on a spot diameter of 200 µm. ERthermAC absorbs between 480 and 590 nm and fluoresces from 560 to 700 nm. The fluorescence light was decoupled from the laser path with a dichroic mirror in front of the slitlamp. The laser spot was imaged enlarged on a sensitive camera. The OA transients were measured with an ultrasonic transducer embedded in a contact lens. Calibration curves were recorded by frequently exciting the probe with 9 µJ/pulse while heating the PBS with a rate of 2 °C/min from 20 to 60 °C. For laser-induced heating a repetition rate of 1 kHz with a pulse energy of 30 µJ was applied for 200 ms.

Results: The dye was well accumulated in RPE cells. An almost linear fluorescence intensity decay of 1.87 % per 1 °C was noticed for calibration. The fluorescence emission was stable and did not bleach over the irradiation time. Laser-induced heating revealed the expected temperature-correlated pressure rise by OA and the corresponding fluorescence decrease over time, strongest at the center of the spot. Both methods are in good accordance with an average difference in temperature rise of about 9.8 % after 200 ms.

Conclusions: The thermosensitive dye ERthermAC shows high affinity to ex-vivo RPE cells and enables time-resolved 2D-temperature monitoring during laser exposure. It shows a good accordance with the OA-method and is generally a useful tool to investigate temperature-related cellular effects.

ABSTRACT BODY:

Purpose: Non-viral gene therapy could provide a safer alternative approach to conventional viral therapy for the delivery of large cDNAs in patients affected by inherited retinal diseases. We assessed the use of non-viral S/MAR vectors to produce functional protein in patient cellular and zebrafish models of choroideremia, an X-linked chorioretinal dystrophy caused by mutations in the CHM gene encoding Rab escort protein 1 (REP1), a protein involved in prenylation and intracellular trafficking.

Methods: S/MAR vectors were generated with human CHM coding sequence, the GFP reporter gene and ubiquitous promoters (CMV or CAG). The nanovector versions with minimal bacterial backbones were produced by Nature Technology.

Results: GFP expression was assessed in transfected patient fibroblasts and chm^{ru848} zebrafish micro-injected with the vector at the one-cell stage. CHM-S/MAR vectors restored REP-1 expression with a partial rescue of prenylation function in CHM patient fibroblasts. Human REP-1 expression was detected in micro-injected zebrafish at 6 days post-fertilisation. A mild but significant improvement in survival of 7.1 ±0.7 days (n=21) was observed in injected chm^{ru848} zebrafish compared to 5.9 ±1.2 days (n=43) in un-injected ($p<0.0001$). GFP expression was detected in the retinal photoreceptors.

Conclusions: S/MAR vectors have shown promise as a novel non-viral retinal gene therapy, warranting further development.

ABSTRACT BODY:

Purpose: The impact of cataract surgery on low luminance visual acuity deficit (LLVAD) measurements was investigated by comparing LLVAD measurements before and after cataract surgery.

Methods: Both normal luminance best-corrected visual acuity (NL-BCVA) and low luminance BCVA (LL-BCVA) were obtained using the Early Treatment Diabetic Retinopathy Study (ETDRS) charts. LL-BCVA was measured by using a 2.0-log unit neutral density filter in front of the examined eye (Wratten filter; Kodak, Rochester, NY). LLVAD scores were calculated by subtracting the LL-BCVA letter score from the NL-BCVA letter score. To estimate the test-retest variability of these visual acuity measurements, we used data from a previously published study entitled Complement Inhibition with Eculizumab for the Treatment of Nonexudative Age-Related Macular Degeneration (COMPLETE) Study, where the NL-BCVA, LL-BCVA, and LLVAD measurements were obtained at an interval of three months. In the current study, the impact of cataract surgery on LLVAD measurements was analyzed by comparing the NL-BCVA, LL-BCVA, and LLVAD measurements before and after cataract surgery.

Results: In the COMPLETE study, a total of 37 eyes were included at baseline and at the month-3 follow-up visit. There were no clinically significant differences in the NL-BCVA, LL-BCVA, and LLVAD measurements between baseline and the month-3 follow-up visits with mean differences in ETDRS letter scores of -1.1 (P=0.02), -1.3 (P=0.11), and 0.1 (P=0.88). In the current study, a total of 25 eyes were assessed before and after cataract surgery. Not surprisingly, there were significant increases in the NL-BCVA (+7.3) and LL-BCVA (+10.2) letter score measurements after cataract surgery (both $P < 0.001$); however, a statistically significant decrease in the average LLVAD measurement (-3.0) was observed after cataract surgery ($P = 0.002$). This change was due to the greater impact of cataracts on LL-BCVA measurements compared to the NL-BCVA measurements.

Conclusions: A greater effect of cataracts on LL-BCVA than NL-BCVA measurements caused a significant change in LLVAD values after cataract surgery. Caution should be exercised when using LLVAD measurements as a predictor of disease progression in phakic eyes with age-related macular degeneration.

ABSTRACT BODY:

Purpose: Photocoagulation of the retina is currently performed with different continuous wave (cw) and pulsed laser modalities. It is well known that the extent of laser induced tissue damage differs by inter and intraocular variations of scattering and fundus pigmentation. However, the influence of different laser modalities on the tissue denaturation has not been investigated in detail so far. Therefore, this work investigates the induced damage range on retinal pigment epithelium (RPE) explants between cw and pulsed irradiation in correlation to the temperature rise measured by optoacoustics (OA).

Methods: RPE/choroid/sclera explants from porcine eyes were irradiated via laser slitlamp on a 200 µm spot diameter with a cw laser at 532 nm wavelength, and with a Q-switched frequency doubled Nd:YLF laser at 523 nm with a pulse duration of 160 ns at a repetition rate of 10 kHz. The pulsed heating excites thermoelastic pressure waves, which contain the present RPE temperature. The pressure waves were detected with an ultrasonic transducer embedded in a contact lens and processed for real-time temperature evaluation. In an open-loop setup, the power of the cw laser and the pulsed laser were kept constant until the end of the irradiation period, where the final temperature was noticed. For a closed-loop feedback control, the pulse energy was actively modulated with respect to quickly achieve a desired aim temperature and by then keep this temperature constant for the rest of the irradiation time. The laser-induced RPE-cell damage was evaluated with Calcein-AM assay.

Results: Temperatures up to 70°C could be achieved in both modalities as well as with open- and closed-loop temperature-controlled irradiations. An average power of 60 mW in an open-loop setup for example revealed the same temperature of 44 °C in the cw mode as well as in the pulsed mode at the end of an 800 ms irradiation period at the same site of a low absorbing sample. The slopes of the temperature rise were almost identical.

Conclusions: It is shown that cw as well as pulsed irradiation with high repetition rate can be used to heat the tissue in a similar way. When using the same average laser power, the same temperature rise is achieved. The pulsed heating provides the unique feature that it additionally excites optoacoustic pressure waves, which can be used for real-time temperature monitoring and control.

ABSTRACT BODY:

Purpose: Ophthalmic questionnaires (e.g. NEI-VFQ-25) are validated to assess quality of life (QoL) in retinal diseases including neovascular age related macular degeneration (nAMD), diabetic macular edema (DME) or branch-/central retinal vein occlusion (B/CRVO). They do not thoroughly assess the patients' social and psychological status. We present the new BPZ-9, a novel, exploratory questionnaire which intends to capture a more comprehensive view on the patients' situation.

Methods: The BPZ-9 instrument consists of 9 questions which assess patient dependency and wellbeing in terms of requirement for domestic care, walking difficulties, accompanying person necessary, anxiety about visual impairment or their disease or treatment, satisfaction with treatment, information provided and eye examinations, evaluated at baseline.

Results: The BPZ-9 questionnaire was completed at 102 sites. No patient had previously received anti-VEGF injections. Data was collected from 1444 nAMD (mean 78 years), 445 DME (67 y), 233 BRVO (70 y) and 144 CRVO (71 y) patients. 27% of patients had walking difficulties, ranging from 18% (BRVO) to 29% in nAMD (DME 24%, CRVO 22%). 12-23% of patients needed an accompanying person (23% nAMD, 21% DME, 12% BRVO, 19% CRVO). Most patients reported anxiety concerning visual impairment: 77% of nAMD patients, 73% DME, 73% CRVO and 60% of BRVO patients. Concern about their disease or treatment was mixed: while 32% and 44% of nAMD patients were very/moderately distressed, distress about treatment and disease control was lower (11% very, 34% moderately distressed). Within the DME, BRVO and CRVO groups a lower proportion of patients was very distressed by the disease (26%,24%, 23%), the majority was “moderately distressed” (42%,47%, 42%). Concern about treatment and controls was at the same level compared to nAMD patients. Overall, most patients were very satisfied with their treatment (73%) and felt very well informed (81%).

Conclusions: When patients with retinal disease initially require anti-VEGF therapy, they might face impaired mobility, dependency on others, distress and anxiety about their retinal condition and therapy. These factors may lead to social and psychological concerns influencing their behavior and attitude towards their disease. More research on patient psychology, attitude and impairments in treatment outcome is needed.

ABSTRACT BODY:

Purpose: There is a need in studies of patients with retinal disease for testing paradigms that can quickly, accurately, and reproducibly define the level of visual function as well as the patient's functional vision. We designed a virtual reality orientation and mobility (VR-O&M) protocol for such a purpose. The goal of this study was to initiate steps to validate this protocol in normal-sighted individuals as well as those with a diverse set of inherited retinal dystrophies (IRDs).

Methods: Using commercially available hardware and custom-generated software, we developed a task whereby individuals are tasked to follow a set of dimly lit red arrows to a 'course exit' while identifying obstacles that are adjacent to or directly in their path. Subjects with normal vision (n = 21, ages 10-66 y) as well as patients with IRDs (n= 16, ages 7-63 y) representing a spectrum of disease severity were invited to participate. All individuals first underwent a training and practice session and then were dark-adapted for 30 minutes. Subjects were asked to follow the VR-O&M courses presented at a range of increasing luminance levels using a set of 35 randomly selected configurations of similar difficulty. Performance was graded automatically by the software.

Results: Normal-sighted individuals were able to accurately navigate the course over a range of luminances and were able to identify over 90% of the objects at about 0.02 $cd.m^{-2}$. With the exception of one subject with light perception level of vision, all subjects with IRDs were able to complete the test. However, in the IRD group, light intensities allowing detection of the obstacles were significantly higher than in normal-sighted subjects. At the lowest level of luminance where normal subjects consistently detected nearly all objects, IRD patients could detect 10 to 80% of the presented objects which related to their disease severity.

Conclusions: This novel VR-O&M test promises to be a useful outcome measure for quantifying the impact of disease and treatments thereof on functional vision in inherited retinal degenerations.

ABSTRACT BODY:

Purpose: The responsible gene for the association at the Age-Related Maculopathy Susceptibility 2-High-temperature requirement protein A1 (ARMS2-HTRA1) locus with age-related macular degeneration (AMD) is still a matter of debate. A previous study demonstrated increased systemic HtrA1 protein concentrations in AMD, which were suggested to lead to subsequent degradation of Bruch's membrane and eventual choroidal neovascularization in AMD (Pan et al 2021, J Biol Chem 296:100456). We aimed to verify these results and therefore performed an enzyme-linked immunoassay (ELISA) targeting this protein in plasma samples of a case-control study.

Methods: A total of 200 advanced AMD patients and 200 controls without AMD were selected from the European Genetic Database (EUGENDA). An ELISA was performed for plasma HtrA1 concentrations. Multiple linear regression analysis with backward elimination based on adjusted-R^2 was used to assess the association between the HtrA1 plasma concentrations and AMD.

Results: We excluded 9 AMD and 3 control samples due to an absorption below the standard curve. Median plasma level of Htra1 was slightly higher in AMD patients (514 pg/ml) than in controls (500 pg/ml). However, the association between HtrA1 plasma level and AMD adjusted for age and age x AMD status was not significant (R^2 = 0.011; p = 0.10).

Conclusions: This study was unable to replicate the association between HtrA1 plasma concentrations and AMD. Further study is required to elucidate the causal gene dysfunction at the ARMS2-HTRA1 locus in AMD.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is a leading cause of irreversible blindness with limited treatment and management options. Metformin has been shown to have immunomodulatory roles which could influence the pathogenesis of AMD. This study investigates whether metformin confers a protective effect in delayed onset and slower progression of AMD.

Methods: This is a single-center retrospective cohort study, which included 18,431 patients aged 50-80 years, visiting ophthalmology clinics from September 2006 to August 2019. Among these, 132 patients with concurrent diagnoses of AMD and diabetes were further analyzed, stratified by metformin use. Data included demographics, presence and type of AMD, examination findings including visual acuity (VA), ocular coherence tomography (OCT) features and anti-VEGF injection frequency. These were compared between patients prescribed or not prescribed metformin.

Results: Among the 18,431 study patients, the average age was 63.7 ± 8.2 years in the metformin group and 63.0 ± 8.5 years in the non-metformin group (P = 0.0002). 74.6% of the metformin group had diabetes, compared to 9.3% of the non-metformin group (P < 0.0001). Incidence of AMD during the study period (4.2% compared to 5.1%, P = 0.049) and prevalence of AMD at the final visit (6.9% compared to 8.4%, P = 0.015) were found to be significantly lower in the metformin group compared to the non-metformin group. Several analyses were performed in a subset of 132 patients with concurrent diagnoses of AMD and diabetes. The metformin group exhibited less decline in VA (0.009 ± 0.041 logMAR/year), compared to the non-metformin group (0.013 ± 0.041 logMAR/year, P = 0.29) and less expansion of the area of geographic atrophy measured on OCT over time (1.10 ± 1.08 mm^2/yr), compared with the non-metformin group (1.66 ± 1.94 mm^2/yr, P = 0.33); however, these did not reach the level of statistical significance. A similar number of intravitreal anti-VEGF injections was required in the metformin group (2.2 ± 3.2 injections/year), compared with the non-metformin group (1.6 ± 2.1 injections/year) (P = 0.39).

Conclusions: Our data suggest that metformin may confer a protective effect against the onset and progression of dry AMD, though this protective effect may not apply to wet AMD.

ABSTRACT BODY:

Purpose: To evaluate compartmental SD-OCT imaging biomarkers using machine learning-enhanced outer retinal segmentation and textural radiomics that are associated with the development of geographic atrophy (GA).

Methods: This was a retrospective image analysis study that included 114 subjects with dry age-related macular degeneration (AMD) without GA at baseline with 5 years of clinical and SD-OCT follow-up. All SD-OCT scans were analyzed using a machine learning-enhanced multi-layer retinal segmentation platform that enabled quantitative ellipsoid zone (EZ) integrity assessment and EZ-RPE compartmental extraction. Eyes were categorized as either GA developers or non-GA developers based on development of GA on SD-OCT by year 5 of follow-up. Baseline quantitative features between the GA developers and non-developers were compared using traditional statistics and a radiomic classification model combined with a Random Forest algorithm. Radiomic features were identified using a Minimum Redundancy Maximum Relevance feature selection method, and the 10 topmost features were used to train a Random Forest classifier.

Results: At baseline, eyes that developed macular GA (n = 33) significantly decreased EZ integrity as measured by mean EZ-RPE central subfield thickness (28.5 vs 36.2μm $p<0.001$) and EZ-RPE volume (1.23 vs 1.30 mm^3 $p=0.002$) compared to eyes that did not develop GA (n = 81). In addition, eyes that developed GA increased partial (5.4% vs 0.9%, $p<0.001$) and total EZ attenuation (2.6 vs 0.3%, $p<0.001$) compared to eyes that did not develop GA. Random Forest modeling utilizing identified radiomic features yielded a classifier performance of AUC=0.88±0.02 for GA development. Increased heterogeneity in the EZ-RPE compartment was associated with the development of GA.

Conclusions: The development of GA was significantly associated with reduced EZ integrity at baseline as well as radiomics-based EZ-RPE compartment textural features. These potential biomarkers could be key tools for risk-stratification of eyes for future development of GA and clinical trial enrichment.

ABSTRACT BODY:

Purpose: Currently, mydriatic slit-lamp examination is the gold standard for cataract evaluation. Discomfort following mydriasis, small pupil, and inability to dilate pupil may limit mydriatic examinations. Optomap is a widely used modality that captures ultra-wide fields without mydriasis. In clinical practice, peripheral cataract shadows are often visualized with a single, non-mydriatic ultra-widefield retinal imaging. In this study, we intended to evaluate whether non-mydriatic UWFRI can effectively screen cataracts.

Methods: Patients who underwent non-mydriatic ultra-widefield retinal imaging with Optomap were included in this study. Two ophthalmologists assessed cataract grading via 2 diagnostic modalities: (1) non-mydriatic ultra-widefield retinal imaging (UWFRI) and (2) mydriatic slit-lamp examination. Lens opacity classification system (LOCS II) was used as a reference grading scheme. Concordance of cataract gradings between the 2 modalities was evaluated. Red and green separation images, that can be generated via embedded software, were also evaluated and their utility in cataract grading was qualitatively assessed.

Results: A total of 170 eyes from 85 patients with cataract were included in this study. The mean age was 72.5 ± 10.4 years. Concordance between non-mydriatic UWFRI and mydriatic slit-lamp was 90.58%. With respect to cataract types, cortical opacity (CO) and posterior capsular cataract (PSC) had better concordance rate than nuclear sclerosis (NS). Qualitatively, grading of NS was most difficult when it was associated with vitreous disorders. 23 cases had cataract with vitreous opacity and red separation view was useful at differentiating cataract from vitreous opacity. On the other hand, green separation view was more useful at visualization of cataract itself.

Conclusions: Non-mydriatic ultra-widefield retinal image can be considered as a less inconvenient and effective tool for cataract screening. Various image modes provided by Optomap may aid clinicians to differentiate cataract from non-retinal posterior disorders.

ABSTRACT BODY:

Purpose: Contact lens (CL) disinfection is critical for the prevention of microbial keratitis (MK) associated with contact lens wear. An investigational multi-purpose solution was designed as a low concentration, triple disinfectant system containing polyaminopropyl biguanide (PAPB), polyquaternium-1 (PQ-1), and alexidine. An evaluation of the investigational MPS was performed to determine the efficacy against the five ISO/FDA organisms, with and without the incorporation of organic soil. The organic soil was added with the organism preparation to further challenge the antimicrobial activity of the triple disinfectant system.

Methods: Testing was performed using Staphylococcus aureus (Sa), Pseudomonas aeruginosa (Pa), Serratia marcescens (Sm), Candida albicans (Ca), and Fusarium solani (Fs), prepared with and without organic soil, to achieve a final concentration from $1.0x10^5$ to $1.0x10^6$ colony forming units (cfu)/ml.

The test solution (10 ml) was dispensed into conical tubes and inoculated with each challenge organism (with or without organic soil). After 4 hours of disinfection, each test solution was neutralized with Dey-Engley Broth (DEB), plated in triplicate, and incubated. Additionally, an inoculum control (IC) was prepared in a suitable diluent to determine the initial concentration of each challenge organism.

Plates were enumerated for the recovery of organisms and log reduction values (LRV) were calculated, based on the mean log recovery of the IC. Three lots of the investigational MPS were tested and the mean LRV determined.

Results: The mean LRV for the bacterial organisms (Sa, Pa, and Sm) without organic soil were 4.7, 4.6, and 4.8, and with the incorporation of organic soil were 4.7, 4.6, and 4.7, respectively. The fungal organisms (Ca and Fs) without organic soil showed mean log reduction values of 3.4 and 4.5 and with the incorporation of organic soil were 4.6 and 4.4, respectively.

Conclusions: The investigational MPS containing the disinfectants PAPB, PQ-1, and alexidine, was efficacious and exceeded the ISO 14729 primary acceptance criteria for each challenge organism. Additionally, there was no decrease to the biocidal activity with the addition of organic soil.

The investigational MPS demonstrated a robust disinfectant system, formulated to reduce the potential risk for MK associated with contact lens wear.

ABSTRACT BODY:

Purpose: Congenital cataracts develop through multiple mechanisms, but often lead to common endpoints, including protein aggregation, impaired fiber cell differentiation, and absence of fiber cell denucleation. It is now apparent that other metabolic abnormalities associate with cataractogenesis, including reductions in levels of amino acids, glutathione, and taurine. Here, we analyze the proteome and metabolome of mice expressing a mutant ubiquitin protein (K6W-Ub) to determine the molecular mechanisms underlying formation of its congenital cataract.

Methods: C57BL/6J wild-type or cataractous K6W-Ub transgenic mouse lenses were dissected at E15.5, P1, or P30 and proteins were analyzed via MS-based tandem-mass-tag (TMT) quantitative proteomics. Small molecules were spatially quantified using computational molecular phenotyping (CMP), a tool that enables acquisition of free amino acid fingerprints for every cell in the lens. Validation of proteomics findings was also performed using Western blot analysis and immunohistochemistry.

Results: Proteomic analyses revealed pathways that were altered during lens differentiation, by expression of K6W-Ub, or both. Prominent pathways included glutathione metabolism; glycolysis/gluconeogenesis; and glycine, serine, and threonine metabolism. Within the glutathione metabolism pathway, GSTP1 and GGCT were most strongly downregulated by K6W-Ub. Other consistently downregulated proteins were PGAM2, GAMT, and HMOX1. Proteins that were upregulated by K6W-Ub expression belonged to pathways related to lysosome, autophagy, Alzheimer's disease, and glycolysis/gluconeogenesis. Analysis of the metabolome via CMP revealed statistically significant decreases in taurine and glutathione and smaller decreases in glutamate, glutamine, aspartate, and valine in all ages of K6W-Ub lenses. Lens metabolites were spatially altered in the cataractous K6W-Ub lens.

Conclusions: K6W-Ub expressing lenses replicate many congenital cataract phenotypes and are useful disease models. The large reductions in levels of taurine and glutathione may be general signatures of cataract development, as human cataracts also have reduced glutathione and taurine. Key roles for amino acid metabolism and glycolysis/gluconeogenesis in cataractogenesis are emerging. Together our data point toward potential common metabolic/proteomic signatures of cataracts.

ABSTRACT BODY:

Purpose: Genetic testing for RPE65 retinopathies is critical to providing access to potentially sight preserving gene therapy to qualifying patients. Limiting the number of variants of uncertain significance (VUS) and increasing the number of accurately curated variants in public databases is vitally important to ensure that all patients who could potentially benefit from this clinical therapy are appropriately identified.

Methods: In 2015, the American College of Medical Genetics and Association for Molecular Pathology (ACMG/AMP) developed a framework to assess variant pathogenicity; however, the guidelines were written broadly. The Clinical Genome Resource (ClinGen), funded by the National Human Genome Research Institute, convened the Leber Congenital Amaurosis (LCA)/Early-onset Retinal Dystrophy Variant Curation Expert Panel (LCA VCEP) in July 2020 to develop rule specifications for curating variants in the REP65 gene through their Federatal Drug Administration approved process.

The LCA VCEP members meet monthly to specify ACMG-AMP rules, initially for the RPE65 gene, and to discuss resulting variant assertions. There are plans to expand this work to additional genes starting with GUCY2D, AIPL1 and CEP290 once rule specifications for the RPE65 gene are completed. Each rule was assessed for its appropriateness for the RPE65 gene and whether there would be any benefit to adding detailed criteria for its use and/or modifying its strength based on availability of evidence.

Results: Variant curation specifications were applied to 19 ACMG-AMP rule criteria and 9 rules were deemed not applicable to the RPE65 gene. Criteria modifications included setting allele frequencies in normal controls, defining phenotype criteria and conditions for adjusting rule strength. Fifty RPE65 variants were chosen for a pilot study to test the rule specifications, comprising of 20 pathogenic/likely pathogenic, 15 VUS and 15 benign/likely benign variants.

Conclusions: Results of this effort will aid clinical variant interpretation of the RPE65 gene and help standardize variant curations across laboratories. Expert level variant curation from this VCEP will be deposited in the ClinVar database for public access.

ABSTRACT BODY:

Purpose: Conjunctival keratoacanthomas are rare, low-grade, hyperkeratotic crateriform tumors. The purpose of this study was to investigate the clinical, histopathological, immunohistochemical, and diagnostic imaging results that define conjunctival keratoacanthomas.

Methods: Retrospective chart reviews of 8 patients with pathologically confirmed conjunctival keratoacanthomas were performed. The demographics, clinical history, diagnostic testing (slit-lamp photography, high-resolution anterior segment optical coherence tomography, and high-resolution ultrasound biomicroscopy images), treatment modalities, histopathology, immunohistochemical testing, visual outcomes, and recurrences were extracted after identifying the patients in a database search of the Florida Lions Ocular Pathology Laboratory records.

Results: The mean age of the 8 identified patients was 54.5 years + 22.4 years. 75% (6/8) of patients were male and 62.5% (5/8) were of Hispanic ethnicity. All lesions were rapidly growing, white nodular lesions located on the bulbar conjunctiva located in the interpalpebral exposure zone. All lesions were surgically excised, and two underwent partial spontaneous resolution prior to surgery. No cases recurred at up to one year of follow-up. A prominent keratin-filled cup-shaped lesion with faulty maturational sequencing that extended full thickness with variably pale cytoplasm and foci of dyskeratosis and hyperkeratosis was present on histopathology in all cases. Hyper-reflective, thickened epithelium often overlying disorganized subepithelial tissue was seen on high-resolution anterior segment optical coherence tomography.

Conclusions: Conjunctival keratoacanthomas are rare lesions of the ocular surface with distinct clinical, histopathologic, and diagnostic features. Further research is required to better understand the clinical course and optimal treatment approach of this rare condition.

ABSTRACT BODY:

Purpose: Using multimodal imaging, literature proposed the following risk factors for choroidal nevus growth into melanoma: increased tumor thickness, subretinal fluid, decreased visual acuity, presence of orange pigment, ultrasound acoustic hollowness, and increased tumor diameter. This study investigated the presence of mentioned risk factors in choroidal nevi, choroidal melanomas, and indeterminate choroidal melanocytic lesions.

Methods: This retrospective, single-center chart review assessed choroidal melanocytic tumors with multimodal imaging. We defined our primary outcome as the cumulative presence of mentioned risk factors. Further, we evaluated various optical coherence tomography (OCT), ultrasound, and autofluorescence findings. Finally, we examined the electronic charts for any tumor-targeted therapeutic actions and tumor-related complications such as secondary choroidal neovascularization, accompanying retinal detachment, toxic tumor syndrome, or any form of metastases.

Results: We analyzed 51 tumors from 49 patients during the period from April 2008 to June 2021. Reviewing the diagnoses made in our archived consultation reports, we found 58.8% (30 of 51) choroidal nevi, 23.5% (12 of 51) choroidal melanomas, and 17.6% (9 of 51) indeterminate choroidal melanocytic lesions. During the entire observation period, no choroidal nevus and no indeterminate choroidal melanocytic lesion transformed into a choroidal melanoma. The median (IQR) age was 64.0 (56.0 to 70.5) years, with 23 of 49 (46.9%) patients being female. The follow-up time for all tumors was median (IQR) 25.0 (12.0 to 39.0) months. The choroidal nevi had a median (range) risk score of 0.0 (0.0 to 3.0), and the choroidal melanoma of 5.0 (3.0 to 6.0), with statistically significant different ratings ($p < 0.001$). Figure 1 shows an example tumor of an indeterminate choroidal melanocytic lesion with two risk factors present.

Conclusions: Multimodal imaging with fundus photography, OCT, autofluorescence, and ultrasonography, along with visual acuity assessment, creates a score that may help to distinguish choroidal nevi from melanomas objectively. Future studies should re-evaluate the above risk score using a larger study population.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is the leading cause of blindness in the elderly worldwide and it is estimated that nearly 300 million people will have advanced AMD with vision loss by 2040. No effective treatment exists for halting dry AMD progression, the form which affects 90% of all AMD patients. Early AMD is characterized by the presence of drusen, a protein-and lipid-rich deposits formed under Retinal Pigmented Epithelium (RPE) cell monolayer, or sub-RPE deposits. Efforts to understand how sub-RPE deposits, complement dysregulation and immune-cell recruitment contribute to AMD have been limited by the lack of relevant (age-dependent / cell-type-specific) models that faithfully recapitulate these pathogenic aspects of the disease.

Methods: Here, we describe a an in vitro AMD model based on isogenic RPE cell lines harboring a Fibulin-3 gene mutation that causes inherited macular degeneration with phenotypic similarities to AMD.

Results: Mutant RPEs secreted dense sub-RPE deposits after four-weeks of culture. Proteomic analysis of sub-RPE deposits showed striking similarity with protein composition of human drusen from AMD patients. Treating the cells with complement C3 inhibitor reversed of the phenotype.

Conclusions: These observations demonstrate that the model has pathophysiological relevance for AMD, allowing in vitro validation of drug targets and elucidation of molecular mechanisms underlying AMD pathogenesis.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is a neurodegenerative disease that is among the leading causes of blindness worldwide. The molecular pathways that lead to chronic inflammation and vision loss in AMD are not well understood. Our hypothesis is that functional changes in glia influence neurodegeneration in AMD, and these changes may be targeted to halt disease progression and preserve vision.

Methods: To identify cell populations that drive AMD progression, we isolated frozen retinal nuclei from the macula of lesion and non-lesion control samples and performed single-nucleus RNA-sequencing on 11 AMD tissue samples and 6 control tissue samples, creating the first single-cell dataset of AMD pathology. We used a suite of computational tools based on topological data analysis and data diffusion geometry to identify salient levels of the hierarchy, automatically characterize clusters, identify pathogenic populations, and rapidly compute differentially expressed genes between clusters of interest.

Results: We identified two populations of activated glia enriched in the nonexudative form of AMD, one microglial subset and one astrocyte subset. Applying our single cell dataset to other degenerative diseases revealed the same activated glial states in Alzheimer's disease and multiple sclerosis, indicating a common glial signature during neurodegeneration. In neovascular AMD, we identified a microglia-to-astrocyte signaling axis driving VEGFA expression and angiogenesis characteristic of disease pathogenesis. We validated this mechanism using in vitro and in vivo assays, identifying a possible new therapeutic target for AMD.

Conclusions: We apply our computational framework to a new dataset: the first single-cell transcriptomic atlas of AMD across disease stages. The algorithm identified and characterized specific subpopulations of microglia and astrocytes enriched in nonexudative AMD displaying activation signatures related to phagocytosis, lipid metabolism, and lysosomal function. This set of analyses has clear implications for potential therapeutics for AMD. Currently, anti-VEGF therapy is the primary intervention approved to treat AMD and is only effective in the most advanced stage of disease. Our unbiased topological analysis not only identified the cell-type specificity of VEGFA expression but also identified pathogenic signaling interactions that promote AMD disease progression.

ABSTRACT BODY:

Purpose: A high incidence of sinu-orbital Mucormycosis as a fulminant and opportunistic fungal infection happened following the COVID-19 pandemic. Traditionally, patients with apical or extensive orbital involvement are candidates for exenteration. We designed and applied CT scan guided orbital amphotericin C delivery. In this study we aimed to report this novel technique and results of this method in control of orbital mucormycosis with apical involvement.

Methods: A high incidence of sinu-orbital Mucormycosis as a fulminant and opportunistic fungal infection happened following the COVID-19 pandemic. Thus named as CAM. Traditionally, patients with orbital mucormycosis with apical or extensive involvement are considered hopeless for saving the eye. We designed and applied CT scan guided orbital amphotericin C delivery.

Results: A total of thirty patients with mean age of 52±11.86 were enrolled in this study. Twenty-three (76.7%) patients were male; group A: 11 (73.3%) and B: 12 (80%). The majority of the patients in both group were diabetics (A: 10 (66.7%), B: 10 (76.9%)). Most patients in both groups had received corticosteroids and antiviral therapy for their recent COVID-19, 23 (82.1%) and 25 (89.3%), respectively. No patient in group A underwent exenteration. Eleven (78.6%) patients in group B underwent orbital exenteration. Of the 6 expired patients, 5 (83.3%) were in group B ($P<0.0001$). Peri-orbital ecchymosis and intracranial air extension were observed in 2 (13.3%) and 1 (6.7%) in group A patients, respectively.

Conclusions: Intra-orbital amphotericin injection under CT-guidance can be considered as a highly effective method in patients with orbital mucormycosis. This method may decrease exenteration without increasing mortality of patients.

Commercial Relationships Disclosure: Alicia Donahue: Commercial Relationship: Code N (No Commercial Relationship) | Ava Bittner: Commercial Relationship: Code N (No Commercial Relationship) | Alexis Malkin: Commercial Relationship: Code N (No Commercial Relationship) | Meghan Knizak: Commercial Relationship: Code N (No Commercial Relationship) | Bridget Peterson: Commercial Relationship: Code N (No Commercial Relationship) | Melissa Chun: Commercial Relationship: Code N (No Commercial Relationship) | Max Estabrook: Commercial Relationship: Code N (No Commercial Relationship) | Cecilia Idman-Rait: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Ho: Commercial Relationship: Code N (No Commercial Relationship) | Nicole Ross: Commercial Relationship(s);Code R (Recipient):Eschenbach Optik

ABSTRACT BODY:

Purpose: Testing for contrast sensitivity (CS) loss is valuable given its impact on visually-mediated tasks and to monitor ocular disease progression. The Pelli-Robson (PR)(a gold standard CS test) requires an in-person visit and that patients know the English alphabet. The SpotChecks (SC) CS test does not require this and may be feasible to complete remotely. SC has not been widely evaluated in people with visual impairment (VI). We evaluated the agreement between CS measurements on the PR and SC charts across a range of VI levels.

Methods: Better-eye distance visual acuity (VA) and binocular logCS measurements with the PR and SC tests were obtained using standard protocols in 25 subjects with VI due to various ocular diseases (mean age 70 years; range 55-89) enrolled in the Community Access Through Remote Eyesight (CARE) study. 95% limits of agreement (LoA; +/-1.96xSD) between the PR and SC tests were assessed according to subgroups for VA and age.

Results: As expected, the SC test overestimated logCS across all subjects when compared to the PR test since SC does not require optotype discrimination. Mean differences in logCS between tests were -0.16 (95% LoA:-0.64,+0.35; p=0.01) for VA <0.55 logMAR (n=13) and -0.12 (95% LoA:-0.43,+0.24; p=0.004) for VA 0.55-1.00 logMAR (n=7), these between-test differences were significant. For 5 subjects with VA >1.0 logMAR, the mean difference of -0.45 and LoA were larger (95% LoA:-1.31,+0.41; p=0.03). Mean differences between CS tests also increased significantly with age. The mean difference was -0.12 logCS (95% LoA:-0.40,+0.15; p=0.01) for ages 55-65 years (n=9), -0.20 (95% LoA:-0.80,+0.38; p=0.04) for ages 66-75 (n=8), and -0.25 (95% LoA:-1.10,+0.59; p=0.05) for ages 77+ (n=8). Age and VA were not significantly related (p=0.78).

Conclusions: The LoA between the PR and SC tests were largest in those with severe VI or the oldest subjects with VI. The 95% LoA between the PR and SC tests in all VI groups were larger than those of normally-sighted young adults in prior literature, reported as −0.24 to 0.09 right eye and −0.23 to 0.14 left eye. SC could be valuable in remote assessment and in patients with language barriers, illiteracy and aphasia, but SC results are not comparable to the PR. Future directions include evaluation in a larger sample (enrollment ongoing), assessment of test-retest repeatability and examining differences by ocular diagnosis.

ABSTRACT BODY:

Purpose: Benzalkonium chloride (BAC), the most common preservative used in anti-glaucoma eyedrops, has been described in the literature as increasing prostaglandin corneal penetration but to date, this fact seems to be controversial. In addition, surfactants may play a role in lipophilic agent solubilization and could, therefore, influence active substance (AS) penetration. The purpose of the study was to evaluate the role of formulation on the AS bioavailability by assessing the pharmacokinetics (PK) profile of different latanoprost eyedrops solutions on a rabbit model.

Methods: 3 different formulations of 0.005% Latanoprost were tested: A. preservative-free (PF) and surfactant-free (SF) formulation; B. same SF formulation but containing BAC 0.02%; and C. different PF formulation but containing Macrogolglycerol hydroxystearate 40 (MGHS 40) at 5%. The ocular concentration of Latanoprost free acid (LAT) was monitored according to GLP standards in 3 parallel groups of Dutch Belted rabbit following a single ocular administration of each tested items in the right eye (n=6). Aqueous humor (AH) and iris-ciliary body (ICB) samples were collected at the following timepoints: 0.5h, 1h, 2h, 3h, 4h, 8h, 24h post-dose. LAT concentrations were measured by RRLC-MS/MS validated method; statistical analysis (Fisher LSD) was performed. PK parameters (AUC, C_{max}, T_{max}, $t_{1/2}$) were calculated.

Results: In both AH and ICB, the concentration of LAT was statistically not different for A and B at each timepoint, except for t1h in ICB ($p=0.005$). However, LAT behavior in C was statistically inferior to A and B in AH and ICB from t30min to t3h ($p<0.05$). In terms of AUC, A (521 ng/mL.h; 300 ng/g.h) and B (470 ng/mL.h; 269 ng/g.h) were at least 2 times higher than C (210 ng/mL.h; 97 ng/g.h) in both AH and ICB respectively. C_{max} follow the same ratio for A and B vs C. T_{max} was 2h in AH and between 0.5 to 1h in ICB.

Conclusions: The absence or presence of BAC within the formulations A and B did not influence the PK profile as a similar behavior in LAT concentrations is described all over the study duration. Therefore, BAC for penetration purposes is no longer justified. However, these in vivo PK results highlighted the importance of formulation as a significantly lower absorption in AH and ICB is measured for the C formulation. This may be due to the presence of MGHS 40 which could be a matter of questioning.

TITLE: Stimulation of Trigeminal Ganglion Neurons by Capsaicin Affects Corneal Leukocyte Migration Via Alterations in Neuropeptide Expression

SESSION TITLE: Corneal cell and molecular biology | Corneal Development

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S. Puri, B. Kenyon, V.G. Sendra, D.L. Harris, P. Hamrah, Ophthalmology, Tufts Medical Center, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Sudan Puri: Commercial Relationship: Code N (No Commercial Relationship) | Brendan Kenyon: Commercial Relationship: Code N (No Commercial Relationship) | Victor Sendra: Commercial Relationship: Code N (No Commercial Relationship) | Deshea Harris: Commercial Relationship: Code N (No Commercial Relationship) | Pedram Hamrah: Commercial Relationship(s);Code S (non-remunerative):Novartis, Oyster point, Dompe;Code C (Consultant/Contractor):Kala, Novartis, Dompe, Clementia, Novaliq, Santen

ABSTRACT BODY:

Purpose: Corneal nerves and resident leukocytes are closely associated, and we have previously demonstrated that trigeminal ganglion (TG) neurons express various chemotactic neuropeptides/chemokines. The purpose of this study was to characterize alterations in neuropeptide expression in the TG and their subsequent effect on migration of leukocytes following capsaicin stimulation.

Methods: We investigated if stimulation of TG neurons with capsaicin altered the expression of chemotactic molecules and affect the migration of leukocytes. To study the effect of capsaicin (30nM or 1mM) added to the culture media of TG neurons, mRNA and protein levels of neuropeptides were assessed in cultured TG neurons and media via RT-qPCR and ELISA. For the leukocyte migration assay, TG neurons with or without capsaicin treatment were co-cultured with splenic plasmacytoid dendritic cells (pDCs) isolated from pDC-GFP mice in a modified Boyden chamber, using transwell inserts with 5mm pore size.

Results: Capsaicin treatment of the TG neurons reduced the mRNA expression of neuropeptides Substance P (2.07-fold decrease), CGRP (3.09-fold decrease), and Somatostatin (1.60-fold decrease) compared to vehicle controls ($p<0.05$) and no change in Urocortin expression ($p>0.05$). The respective protein level was also significantly lower in the culture media of TG neurons treated with capsaicin compared to untreated TG neuron controls (Substance P ELISA, $p<0.05$). TG neurons treated with capsaicin and co-cultured in the modified Boyden chamber with pDCs in the transwell had less pDCs migrating through the transwell membrane after 24 hours incubation period, compared to untreated TG neurons co-culture (3.78-fold decrease; $p<0.05$).

Conclusions: Corneal nerves and resident corneal leukocytes share expression of neuropeptides and their respective receptors, suggesting a potential crosstalk. TG neurons exert chemotactic effects on leukocytes via neuropeptides and changes in expression levels of neuropeptides in the TG neurons following capsaicin stimulation affects the migration of leukocytes.

ABSTRACT BODY:

Purpose: This study aimed to provide a genetic diagnosis for patients presenting with a mild peroxisome biogenesis disorder (PBD). Peroxisomes play a vital role in a variety of metabolic processes including β-oxidation of fatty acids and glyoxylate detoxification. Pathogenic variants in 13 PEX genes have been associated with PBDs. Clinical features vary but can include failure to thrive, developmental delay, retinal degeneration and liver disease. PEX5 encodes a peroxisomal import receptor protein and two isoforms exist in humans: PEX5S and PEX5L, the latter contains an additional exon.

Methods: Two affected siblings were recruited to the Target 5000 inherited retinal disease (IRD) study following a clinical diagnosis of PBD with retinitis pigmentosa. An unaffected sibling was also recruited. Targeted sequencing of the exons of 254 IRD genes was carried out on one affected sibling. Subsequently whole genome sequencing (WGS) was employed on the same individual as a more comprehensive sequencing measure.

Results: At last examination the patients were in their 8^{th} and 9^{th} decades of life. Following targeted sequencing no candidate variants were detected. WGS revealed a homozygous nonsense variant in PEX5, c.709C>T, p.(Arg237Ter), situated in the exon specific to PEX5L, leaving PEX5S unperturbed at the DNA level. This variant was present homozygously in both affected siblings while the unaffected sibling was homozygous for the wild-type base at this position. Pathogenic variants in PEX5 are typically associated with phenotypically severe PBDs. These patients did not display classical symptoms associated with a PEX5 defect including reduced life expectancy, epilepsy, growth delay or intellectual disability.

Conclusions: To the best of our knowledge, this is the first report of a significantly milder form of PBD than typically associated with PEX5 defects suggesting that the severity of the phenotype depends on the location of the given variant. Awareness of this unusual clinical presentation will allow for a more targeted diagnostic approach. This study highlights the value of WGS over targeted sequencing, where only the former was informative in terms of disease pathogenesis. The findings also underscore the importance of interrogating genes typically associated with more severe forms of disease even when the clinical presentation is relatively mild by comparison.

TITLE: Implementation of Quality Improvement Measures For Inpatient Consults Improves Follow-up In Eye Clinic

SESSION TITLE: Public Health II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Sambhav, D. Zhang, R. Michael, J. Hunt, M. Epps, S. Wetzstein, D. WuDunn, S. Grover, Ophthalmology, University of Florida Health Science Center Jacksonville, Jacksonville, Florida, UNITED STATES|

Commercial Relationships Disclosure: Kumar Sambhav: Commercial Relationship: Code N (No Commercial Relationship) | Dalia Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Raman Michael: Commercial Relationship: Code N (No Commercial Relationship) | John Hunt: Commercial Relationship: Code N (No Commercial Relationship) | Michael Epps: Commercial Relationship: Code N (No Commercial Relationship) | Sara Wetzstein: Commercial Relationship: Code N (No Commercial Relationship) | Darrell WuDunn: Commercial Relationship: Code N (No Commercial Relationship) | Sandeep Grover: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Patients seen as inpatient consults are generally followed up in the eye clinics at some point in the future. This study was conducted to identify causes that reduce the follow-up rate of inpatient consults and analyze data before and after implementation of intervention to determine the quality improvement.

Methods: In this Department of Ophthalmology, starting July 1st 2021, certain interventions were implemented in order to improve the follow-up rate in the clinic. This included more robust communication with the in-patient and providing them with a clinic appointment at bedside along with a clinic contact number, more objective communication with the staff via e-mail regarding the date and time of appointment which would then be entered into the electronic medical records (EMR). This study analyzed the effect on quality improvement before and after the implementation of these measures. This IRB-approved study adhered to the tenets of the Declaration of Helsinki. Retrospectively, the pre-intervention data were collected and analyzed for a 3-month period between April – June 2020. The post-intervention data were analyzed for a one-year period between July 2020 – June 2021.

Results: In the pre-intervention period of 3 months, 46 inpatient consults were seen. Of these patients, 26 (56.5%) were seen for follow-up, 13 (28.3%) did not show for their initial follow-up and 7 (15.2%) patients did not have follow-up appointments in the EMR system.

After implementation of corrective measures, 348 inpatient consults were seen in a one-year period. Of these, 7 patients (2%) were referred to an outside facility. Of the remaining 341 patients tracked, only 30 patients (8.8%) did not have a follow-up in the EMR system. Thirty five patients had an appointment in the system after the cut-off date for analysis. Of the remaining 306 patients, 180 (58.8%) were seen as follow-up in the clinic and 96 patients (31.4%) did not show up.

Conclusions: There was a definite improvement in the number of patients seen as follow-up, the no-show rate remained similar to the University average no-show rate but there was a significant improvement in the number of patients who did not have a follow-up appointment. Implementation of these measures improved the quality of care and continuity of care provided to these patients.

ABSTRACT BODY:

Purpose: The optimization of deep learning models for fluid feature extraction to enable reader-independent assessment of fluid presence and characteristics in retinal disease is an important milestone for automated image processing. This analysis aims to compare a next generation fully automated deep learning model for fluid segmentation against human generated output in diabetic macular edema (DME).

Methods: This was a retrospective assessment of eyes with DME undergoing treatment with anti-VEGF therapy. All eyes had concurrent SD-OCT scans. All scans were initially analyzed with an earlier generation intraretinal fluid (IRF) segmentation system with subsequent expert reader manual correction, as needed. A next generation fluid segmentation model with enhanced sensitivity and specificity was evaluated with automated volumetric outputs and compared to reader-edited findings. An automated SD-OCT quality assessment system was used to stratify scan quality as “good”, “moderate”, and “poor” for image quality-based assessment of performance.

Results: A total of 1572 OCT scans were included in this analysis.The model correctly identified the presence or absence of IRF in 96% of the scans. Scans identified as “good” quality demonstrated significantly closer volumetric agreement to expert readers than “moderate” and “poor” quality scans ($p<0.001$).

Conclusions: This fully automated fluid model demonstrated overall strong agreement with human edited fluid segmentation. Image quality appears to have an important impact on agreement between automated and manually-edited results. Future assessments will include using the next generation system as foundational starting-point for expert reader corrections for future comparisons and assessing minimum quality standards for automated image analysis platforms.

ABSTRACT BODY:

Purpose: The presence of microneuromas within the subbasal nerve plexus as identified via corneal in vivo confocal microscopy (IVCM) has been associated with corneal neuropathy, including with neuropathic corneal pain. However, the association of microneuromas with other nerve and immune cell parameters has not been established.

Methods: This is a secondary analysis of a retrospective study that involved the collection of IVCM images from ocular surface disease patients. All IVCM images were viewed by the grader, and presence or absence of microneuromas was determined for each patient based on all images. In addition, three representative images from the subbasal nerve plexus were selected for each patient. ImageJ with NeuronJ plug in was used to quantify each selected image for the total, main, and branch nerve densities and count. The results from these three images were averaged. In addition the number of immune cells were counted for each image and averaged. Patients with microneuromas were compared to those without using t-test or Mann-Whitney U test as appropriate.

Results: The patients showed an average of age of 58.3 ± 1.6 years and 76.2% were female. Compared to the non-microneuroma group (NMG), the microneuroma group (MG) had a lower average total density [11,995.28 μm/mm^2 (range: 3,580.00-14,173.55) vs 13,806.47 (range: 0.00-26,158.00); p=0.012], average total nerve number [6.7/frame (range: 1.7-10.3) vs 8.7 (range: 0.0-23.3); p=0.014], average branch nerve density [3,082.49 μm/mm^2 (range: 0.00-7,205.11) vs 4,553.88 (range: 0.00-14,601.73), p = 0.044] and average branch number [3.3/frame (range: 0.0-8.0) vs 5.0 (range: 0.0-19.3), p=0.024]. There was no significant difference in main nerve density (7,054.33 ± 541.44 μm/mm^2 for MG; 8,373.31 ± 271.68 for NG; p=0.070), main nerve number (2.9 ± 0.3/frame for MG; 3.5 ± 0.1 for NG; p=0.094), or immune cell density [14.6/mm^2 (range:0.0-175.0) for MG; 35.4 (range: 0.0-285.4) for NG; p=0.144].

Conclusions: Patients with microneuromas likely also have reduced nerve density, which is more apparent in branch nerves compared to main nerves, suggesting that patients with increased nerve loss have a higher likelihood of presenting with microneuromas.

ABSTRACT BODY:

Purpose: Epithelial corneal wound healing is a multifaceted process that encompasses cell proliferation, migration, and communication from the corneal stroma. Upon corneal injury, bi-directional crosstalk between the epithelium and stroma via extracellular vesicles (EVs) has been reported. We previously demonstrated that human corneal epithelial cell (HCEC) EVs can promote corneal fibroblast (FB) to myofibroblast (MFB) differentiation; however, the mechanisms by which, corneal stromal EVs exert their effects on the corneal epithelium remains unclear. Here, we investigated the roles of corneal stromal (keratocyte (KER), FB, and MFB) EVs in epithelial corneal wound healing.

Methods: EVs were isolated from corneal KER, FB, and MFB conditioned media by using differential ultracentrifugation and characterized by western blotting (WB), transmission electron microscopy (TEM), Zetaview™ nanoparticle tracking analysis (NTA) and Zeta (ζ) potential. The HCEC's migratory ability and cell velocity following PKH26-labelled KER-/FB-/MFB-EV treatment was assessed in a scratch assay and determined by brightfield/immunofluorescent microscopy. HCEC's viability, proliferative and apoptotic activity following EV treatment was also assessed by a WST-8 and a Caspase-Glo® 3/7 assay. KER-/FB-/MFB-EV protein cargo was determined by mass spectrometry and ingenuity pathway analysis.

Results: WB revealed that FB-/MFB-EVs were enriched for CD63, CD81, INTGNAV and THBS1 compared to KER-EV, whilst all EVs were negative for GM130 as a negative control. All EVs showed minimal differences in biophysical properties (NTA, TEM and ζ-potential). MFB-EVs significantly increased HCEC migration and cell velocity in our scratch assay compared to KER-/FB-EVs and untreated controls. MFB-EV treatment elevated HCEC proliferation and lowered apoptosis levels compared to KER-/FB-EVs. At the proteomic level, we observed the MFB-EV protein cargo showed a >2-fold change in CXCL12, MMP1, COL6A1/-2/-3, TGFBI and EFEMP1 compared to KER-/FB-EVs; with other proteins unique to KER-/FB-EVs.

Conclusions: These findings highlight that MFB-EVs contains a unique protein cargo that promotes HCEC-migration, cell velocity, and proliferation compared to KER-/FB-EVs. Understanding these elements may offer novel modalities to accelerate epithelial corneal wound healing and future studies in promoting scarless-wound healing.

ABSTRACT BODY:

Purpose: Antibiotics as the conventional treatment option for bacterial keratitis has raised the problems such as antimicrobial resistance and allergy, and these problems promoted innovation of alternatives for antibiotics. We designed an antibiotics-free biocidal corneal bandage with photo-sensitive nanocomposites embedded in enzyme-modified hydrogel. Nanocomposites and enzyme produce reactive oxygen species (ROS) to disinfect bacteria. The nanocomposites release ROS under near-infrared light (NIR) irradiation, and the enzyme in hydrogel produces ROS by catalyzing glucose in eye tear.

Methods: The generation of ROS was characterized using colorimetric analysis, and dyes that can react with ROS were used as the indicators. The antibacterial property of the bandage against Staphylococcus aureus (S. aureus) and Pseudomonas aeruginosa (P. Aeruginosa) suspended in medium was compared with the blank control group through spread plate method (N=3), Live/dead staining (N=3). The morphology of bacteria was examined by scanning electron microscopy (SEM). The ROS level in bacteria after treated by the bandage under NIR irradiation was also evaluated with DCFH-DA.

Results: Dyes were oxidized after treated with bandage under NIR irradiation, and the enzymes on the bandage could also oxidize dye in darkness in the presence of glucose. The living colonies decreased significantly to (52+/-2)% (S. aureus) and (27+/-2)% (P. aeruginosa) after treated by the bandage and NIR irradiation. The antibacterial rates from Live/dead staining were ((54+/-1)% to S. aureus and (83+/-2)% to P. aeruginosa). Severe damage on bacteria membrane and ROS signals were found only in bacteria that were treated by the bandage and NIR irradiation.

Conclusions: The catalysis of the dyes indicated that the biocidal corneal bandage produces adequate ROS in the presence of glucose with NIR irradiation. The decreasing of living colonies after treated by the bandage, indicated that our bandage has excellent antibacterial property. The in-vitro results suggested that our bandage has the potential to be a treatment alternative for bacterial keratitis, but further evaluations on ex-vivo and in-vivo models are required to justify its translational potential.

ABSTRACT BODY:

Purpose: To describe the demographic and clinical and characteristics and risk factors of neonates with retinopathy of prematurity (ROP) detected in the ROP screening programs in Colombia

Methods: Cross-sectional analytical retrospective observational study. Records of neonates from Neonatal Intensive Care Units (NICU) were screened for ROP between 2015 and 2020. The screening criteria were: 32 or less gestational age (GA) in weeks or 1,500 grams or less of birth weight (BW). Indirect ophthalmoscopy was performed by retina specialists or pediatric ophthalmologists. The first examination was performed between the fourth and sixth weeks of life, with repeat examinations until retinal vascularization was complete. Eyes were graded for ROP severity based on the Classification International ROP (ICROP). A database was created in which demographic variables were recorded, maternal and neonatal risk factors, ROP classification and treatment.

Results: The records of 1,691 infants were reviewed and included 727 (43%) males and 94 (57%) females. Mean gestational age was 32.44 ± 2.6 weeks (range 24-39) and mean birth weight was 1,536 ± 404 grams (range 650-3,700). Mean postmenstrual age at the time of examination was 36.72 weeks (range 26-60). The mean gestational age of preterm infants with ROP was 28.66 ± 2.87 weeks (range 24-38); the mean birth weight was 1,230 ± 538 grams (range 650-2,100).

The proportion of ROP in less than 1,000 grams was 42.1%, and of them, 42.6% presented affection in zones I and II. The most frequent risk factors were sepsis and suplemmentary oxygen and 8.6% of neonates with ROP required surgical treatment.

Conclusions: The global prevalence of ROP was 17.5%, with a mean gestational age of 28.66 weeks and mean mean birth weigh of 1,230 grams.

ABSTRACT BODY:

Purpose: PAX6 mutations are associated with an underdeveloped macula, lower cone density and decreased cone-related visual function. How rod-related visual function and the retina are affected outside the macula is not known. We performed a cross-sectional study to measure dark adapted rod and cone sensitivity and association with retinal structure in congenital aniridia.

Methods: Dark-adaptation curves were measured after 5 minutes exposure to bright light in 25 participants with aniridia (8 males; 11–66 years) and 36 healthy controls of similar age with red (635 nm) and green (530 nm) 2° circular light stimuli presented at ~20 degrees temporal retinal eccentricity. A double-exponential model was fitted to each participant's responses to determine cone and rod thresholds over time. Thicknesses of the inner and outer retinal layers were measured from semi-automatically segmented spectral domain optical coherence tomography images of the macula in 20 of the aniridia patients and all the healthy controls. Examination of the anterior segment was performed to evaluate aniridia associated keratopathy (AAK, grade 0–3).

Results: Participants with aniridia had elevated thresholds for both the cone and the rod part of the dark-adaptation function compared with healthy age-matched controls [cone: −0.90±0.60 and −1.62±0.33 log cd/m^2, t(34.2)= -5.5, p<0.0001; rod: −3.62±0.65 and −4.26±0.29 log cd/m^2, t(30.7)= -4.6, p<0.0001, for aniridia and healthy controls, respectively]. The time to rod-cone break was similar between the aniridia and the control group (11.4±2.2 vs. 11.0±2.1 minutes, t(51)= -0.72, p=0.47). In aniridia, there was a significant correlation between foveal outer retinal layer thickness and final cone (r = -0.49, p=0.03) and rod (r = -0.45, p=0.03) threshold. The thresholds tended to be higher with more severe grades of AAK, but not significantly [H(2)=5.58, p=0.06 and H(2)=4.49, p=0.11 for cone and rod thresholds, respectively]. A multiple regression model indicated that foveal outer retinal layer thickness and age were the most important explanatory variables to predict both final cone threshold (r^2=0.38, p=0.016) and rod threshold (r^2=0.45, p=0.006) in aniridia when the AAK grade was 2 or less.

Conclusions: The results show that both rod and cone related function are affected and suggest that retinal changes in PAX6-associated aniridia are not confined to the central macula.

ABSTRACT BODY:

Purpose: Periocular mesenchyme (POM) is a subgroup of neural crest cells, responsible for forming anterior structures, including the anterior segment (AS) of the eye. Despite the importance for the development of a healthy eye, molecular knowledge about this cell group is limited. The purpose of this study is to characterize genes involved in regulation of POM cells as they form the zebrafish AS. We employed scRNA analyses over the course of AS development to identify potential candidates and used CRISPR/Cas9 knockouts to analyze resulting phenotypes.

Methods: Larval eyes of transgenic zebrafish Tg(Foxc1b:GFP) and Tg(Lmx1b:GFP) were collected every 24 hours between 48hpf and 144hpf. GFP+ cells were isolated via FACS cell sorting and processed with the 10x genomics chromium single cell transcriptome kit. The subsequently resulting Illumina sequencing single cell transcriptomes were processed with the Cell Ranger pipeline. Analysis was done with the Cell Loupe Browser 5.0 and Monocle3. Gene expression was confirmed via in situ hybridization and gene function via Alt-R-CRISPR induced knockouts.

Results: Over 40,000 Foxc1b+ and Lmx1b+ cells from eyes only were collected. Transcriptome analyses showed that these cells were organized in re-occurring clusters during zebrafish anterior segment development. We identified and tracked clusters representing the iridocorneal angle (ICA) and the cornea. Our analysis revealed several genes associated within these clusters, including hgd, si:ch211-251b21.1, nusap1 and apoda1 with the cornea and ano9a, mdka, clu and zgc158463 with the ICA. Initial gene knockouts and drug treatments showed a crucial role in eye development for hgd and si:ch211-251b21.1. Specifically, the drug Nitisionone induced hgd inhibition, resulting in cloudy lenses and an overall maldeveloped eye morphology.

Conclusions: Our results provide the first single cell transcriptome atlas for AS development in zebrafish. Our efforts have identified several new genes previously not associated with AS development. Particularly, we have discovered that hgd and si:ch211-251b21.1 play roles in AS development. Ultimately, this type of approach is likely to advance potential for genetic screening of anterior segment related diseases and/or treatment of ocular diseases such as glaucoma.

TITLE: Incidence and risk factors for extremes in intraocular pressure after rhegmatogenous retinal detachment repair with pars plana vitrectomy.

SESSION TITLE: Vitreoretinal surgery/VR Interface/PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Nigussie, N. Ambati, O. Elghawy, J. Patrie MS, J. Bogaard MD, Y. Shildkrot MD, University of Virginia, Charlottesville, Virginia, UNITED STATES|

Commercial Relationships Disclosure: Amen Nigussie: Commercial Relationship: Code N (No Commercial Relationship) | Naveen Ambati: Commercial Relationship: Code N (No Commercial Relationship) | Omar Elghawy: Commercial Relationship: Code N (No Commercial Relationship) | James Patrie MS: Commercial Relationship: Code N (No Commercial Relationship) | Joseph Bogaard MD: Commercial Relationship: Code N (No Commercial Relationship) | Yevgeniy Shildkrot MD: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Acute drops and elevations in intraocular pressure are common post-surgical complications following rhegmatogenous retinal detachment (RRD) repairs. Predictors of acute intraocular hypertension (≥ 35mmHg) as well as hypotension (≤6mmHg) after RRD repair with pars plana vitrectomy (PPV) were evaluated. We tested the hypothesis that history of glaucoma, use of C3F8 and higher concentrations of expandable gases were responsible for extremes in IOP during postoperative day 1 (POD1) and postoperative week 1 (POW1). We designed a retrospective cohort study to assess these potential risk factors.

Methods: A chart review of 754 patients undergoing RRD repair at the University of Virginia between July 1, 2012 and July 1, 2020 was conducted. All cases of PPV with completed postoperative day POD1 and POW1 visits were included. 178 eyes of 178 patients met the inclusion criteria for this study. Demographics, past medical history, ocular history, surgical and postoperative notes were reviewed. Additionally, data was gathered to compare different tamponades (C3F8 vs SF6 vs silicon oil) utilized during surgery.

Results: 16 (9%) cases had IOP elevation on POD1 and 14 cases (7.9%) on POW1. Out of those 14 patients, 12 (85.7%) did not present with elevated IOP during their POD1 visit. We did not find a significant relationship between acute elevation in postoperative IOP and type of tamponade. There was an association with history of glaucoma and increased IOP only during POW1, but it was not statistically significant (P=0.076). 8 patients (4.5%) experienced hypotony during POD1 and 13 cases (7.3%) on POW1. Silicon oil and SF6 tamponade were positively associated with postoperative hypotony on both POD1 (P=0.037) and POW1 (P<0.001). However, we did not find correlations between fill concentrations and acute drops in IOP.

Conclusions: Our results revealed silicon oil and SF6 to have statistically significant correlations with acute drops in postoperative pressure (≤6mmHg). To our knowledge, there are no studies clearly stating these associations. Larger studies are needed to better understand the roles that silicon oil and SF6 tamponade play in postoperative hypotony. Finally, although we did not find significant risk factors for hypertony, we discovered that 12 cases (6.7%) had delayed spikes in IOP. This data highlights the utility of 1-week post-op appointments.

Gore & Associates Inc.;Code F (Financial Support):Ocular Therapeutix

ABSTRACT BODY:

Purpose: Diagnosing Sjögren's syndrome (SS) underlying ocular surface inflammation is critical due to systemic co-morbidities and complications, however, currently not feasible using available tests. We tested the hypothesis that reduced tear levels of immunoregulatory Thrombospondin (TSP)-1, which also inhibits Matrix Metalloproteinase (MMP)-9, would reflect SS pathology. We performed a prospective observational case-control study to learn about changes in tear TSP-1 and MMP-9 levels in patients with ocular surface inflammation associated with SS vs. Non-SS causes.

Methods: Total 61 participants (healthy or with clinically significant ocular surface inflammation with or without a definitive diagnosis of SS) were included. In addition to tear sampling, clinical evaluations included non-invasive tear break-up time (BUT), tear osmolarity, Schirmer's test without anesthesia, and ocular surface staining (lissamine green for conjunctiva and fluorescein for cornea). Tear TSP-1 and MMP-9 levels were determined using custom magnetic bead-based multi-plex assay (MilliporeSigma, Burlington, MA, USA) in a masked fashion. Statistical analysis procedures included regression analysis and Fisher's Exact test.

Results: Average tear TSP-1 and MMP-9 levels in healthy participants (control group) were 322 and 12.2 ng/ml respectively. Significantly higher proportion of participants with SS-associated ocular surface inflammation than non-SS causes had tear TSP-1 levels below the control group average (55% vs. 29%, OR=3, 95%CI=1.64 to 5.35, $p<0.05$) and tear MMP-9 levels above the control group average (65% vs. 24%, OR=5.8, 95%CI=4.46 to 19.81, $p<0.05$). Tear TSP-1/MMP-9 ratio was significantly reduced when ocular surface inflammation was associated with SS as against non-SS causes (B= -2.36, 95% CI= -3.94 to -.0.79, $p<0.05$), regardless of tear MMP-9 levels. Patients with higher ratio were 72% less likely to have SS (OR=0.28, 95% CI= 0.1 to 0.75, $p<0.05$) and this ratio showed significant correlations with conjunctival and corneal staining scores (R= -0.3 and R= -0.29, respectively $p<0.05$).

Conclusions: Our results are consistent with our hypothesis and indicate that reduced tear TSP-1 level is associated with SS pathology underlying ocular surface inflammation. Thus tear TSP-1/MMP-9 ratio can be a useful test that aids in diagnosis of SS-associated ocular surface inflammation.

ABSTRACT BODY:

Purpose: To determine the effect of non-coding putative promoter/regulatory region variants in BBS10 and GUCY2D identified by whole genome sequencing (WGS) in trans with a protein altering variant in patients with atypical presentation of BBS10 and GUCY2D disease.

Methods: Patients underwent WGS as part of the UK's 100,000 genomes project followed by clinical variant interrogation identifying a single candidate coding region variant in BBS10 (patient #1) and GUCY2D (patients #2 & #3). Non-coding variant analysis of the suspected gene was performed including promoter region interrogation (Eukaryotic Promoter Database; https://epd.epfl.ch). Promoters were amplified, cloned into pGL3 vector, and suspected variants were introduced by site-directed mutagenesis. Luciferase reporter assays in HEK293 cells were used to determine the effect of promoter variants.

Results: Patient #1 harboured variants in BBS10: c.2119_2120delGT (p.Val707Ter), and c.-80dupC within a predicted promoter region. Patients #2 and #3 harboured GUCY2D c.-148T>C in the TAAT core (5'-TAAT-3' > 5'-TAGT-3') of a predicted CRX binding element in trans to c.2837C>A [p.(Ala946Glu)], and c.3043+5G>A (proven pathogenic impact via minigene assay), respectively. Luciferase assays showed that BBS10 c.-80dupC caused a ~70% decrease in activity compared to the wild-type promoter. For GUCY2D, the c.-148T>C variant only altered the luciferase activity when co-transfected with a CRX expression plasmid. In this instance, the mutant GUCY2D promoter exhibited ~75% ($p<0.02$) activity of the wild-type promoter.

Conclusions: Heterologous expression of luciferase under the control of BBS10 and GUCY2D promoters indicated that the candidate variants are likely to affect intrinsic expression of these genes in the retina. Patient #1 has no extra-ocular features of Bardet-Biedl syndrome at the age of 71 years, and patient 2 presented atypically for GUCY2D-Leber congenital amaurosis with a stationary retinal dystrophy affecting both rods and cones but retaining some visual function (BCVA 1/60 OD, 2/60 OS) at age 46 years. Patient #3 presented with LCA (no further details available at the time of writing). These findings suggest that in patients #1 and #2, the genotypes may be hypomorphic, evidenced by the clinical presentation at the mild end of the disease spectrum and retained promotor function (predicting about 30% for BBS10 and 75% for GUCY2D).

ABSTRACT BODY:

Purpose: Satralizumab reduced the risk of protocol-defined relapse (PDR) vs placebo in the double-blind periods (DBP) of two trials in NMOSD: SAkuraSky (NCT02028884; satralizumab + baseline immunosuppressants [IST]) and SAkuraStar (NCT02073279; satralizumab monotherapy). We present long-term efficacy and safety data from the DBP and open-label extension (OLE) of these studies.

Methods: Satralizumab or placebo was administered in the DBP; patients could then enter the OLE (satralizumab 120 mg Q4W). PDRs in the DBP were adjudicated by a Clinical Endpoint Committee; PDRs in the OLE were determined by the investigator (iPDRs). Current analyses included all aquaporin 4-immunoglobulin G seropositive (AQP4-IgG+) adults who received ≥1 dose of satralizumab in the DBP and/or OLE (overall satralizumab treatment [OST] period,

data cutoff: Feb 22, 2021). Efficacy analyses assessed the annualised iPDR rate (ARR), time to first iPDR, severe iPDR (≥2 point increase in the Expanded Disability Status Scale [EDSS] score), and sustained EDSS worsening (EDSS increase of ≥2, ≥1, or ≥0.5 points for patients with baseline scores of 0, 1–5, or ≥5.5, respectively, confirmed ≥24 weeks post-initial-worsening). Safety assessments compared rates of adverse events (AEs) per 100 patient-years (PY) in the OST period vs the DBPs.

Results: 106 AQP4-IgG+ adults were included (SAkuraSky: 44; SAkuraStar: 62). Median (range) duration of satralizumab exposure was 5.4 (0.1–7.0) years in SAkuraSky and 4.0 (0.1–6.0) years in SAkuraStar. The overall ARR (95% CI) in the OST was 0.11 (0.07–0.17) in SAkuraSky and 0.08 (0.05–0.13) in SAkuraStar; the ARR remained stable throughout the studies. At Week 192 (3.7 years) in SAkuraSky and SakuraStar, 74% and 73% of patients had no iPDR, 94% and 90% had no severe iPDR, and 89% and 86% had no sustained worsening of EDSS, respectively. Rates of serious AEs (95% CI) in the OST period were comparable with the DBP (serious AEs: SAkuraSky 13.7 [8.9–20.1]/100 PY; SAkuraStar 10.6 [6.9–15.6]/100 PY). Rates of infections and serious infections in the OST period were comparable with the DBP and did not increase over time. No deaths or anaphylactic reactions to satralizumab were reported in either study.

Conclusions: Satralizumab efficacy and its favorable safety profile are sustained with long-term treatment.

ABSTRACT BODY:

Purpose: To better understand the natural history of cone and rod degeneration in patients with Retinitis Pigmentosa (RP) carrying mutations in the RHO, PDE6A, and PDE6B genes.

Methods: PHENOROD1 was a longitudinal retrospective study carried out at the national reference center for rare diseases (REFERET) at the Centre Hospitalier National d'Ophtalmologie des Quinze-Vingts (Paris, France). A total of 110 patients with RP due to mutations in RHO, PDE6A, or PDE6B were enrolled, and the following parameters were collected from their medical records: best-corrected visual acuity (BCVA), binocular kinetic visual field (VF) (III4e), retinal sensitivity, color vision, full-field electroretinogram, optical coherence tomography, and fundus autofluorescence imaging. Differences between genotypic groups were analyzed using ANOVA, and the progression rates were estimated using a mixed error-component model.

Results: A total of 75 (68%) patients carried a mutation in RHO, 14 (13%) in PDE6A, and 21 (19%) in PDE6B. Mean age at onset was 23.4, 13.9, and 16.2 years in RHO, PDE6A and PDE6B patients, respectively ($p>0.1$).

There were no significant differences between genotypes with regard to the presentation of initial symptoms (night blindness and VF restriction), BCVA progression rates (on average +0.01 LogMAR per year in both eyes), and preservation of the ellipsoid zone.

In contrast, the evolution of VF and area of preserved autofluorescence between the ages of 20 and 60 was statistically different between genotypes, with a slower decline observed in the PDE6B group.

Interestingly, BVCA remained stable until ~40 years of age before starting to decline, while the inflection point for VF occurred earlier, in the patient's third decade.

Conclusions: The analysis of functional and structural visual parameters allowed to better define the natural history of rod-cone dystrophy according to underlying genotypes. This is of particular interest for the selection of patients in the development of photoreceptor rescue treatments such as SPVN06, a novel dual gene therapy based on the expression of neurotrophic factor RdCVF and thioredoxin RdCVFL, both encoded by the nucleoredoxin-like 1 gene.

ABSTRACT BODY:

Purpose: To use spatial amplitude modulation method for vision improvement by deblurring the retina images in cataractous eyes.

Methods: The image formation on retina is the result of light propagation and focusing through crystalline lens, therefore the interaction of light with the opacities (cataractous lens) results in scattering and forming blur retinal images. We used spatial amplitude modulation method of masking the pupil plane, in such a way that light can only pass through the remained transparent parts of lens. The method depends on the imaging of pupil plane of cataract eye to estimate the spatial location of opacities to make an opacity map. This is used to design a complementary mask, which can be conjugated at the pupil plane by a spatial light modulator. The proposed method has been verified via simulation, where cataractous lens with opacities has been generated. The point spread function (PSF) was calculated by taking the FFT of the cataractous lens. Retinal image was calculated by convolving the PSF with ground truth image (I_g). The phase map of cataractous lens was used to generate a complementary binary mask to mask the pupil plane and retinal image was again generated by convolution of PSF of masked pupil with I_g. The quality of the retinal images was quantified by structural similarity (SSIM) index without and after applying the method.

Results: Cataractous lenses were simulated as phase elements with circular function acting as pupil with diameter 2.7 mm. Three levels of straylight described by $Log_{10}(s)$ = 1.75, 2 and 2.37 (at an angle of 6 degrees), corresponded to nuclear cataracts of rank 3 or higher in the Lens Opacity Classification System III (LOCS III) has been simulated. Images of sine-wave grating of 6, 12 and 20 CPD, were used as ground truth images. Measured SSIM has shown improvement for higher CPD for all grading's of cataract. For 20 CPD, the SSIM for $Log_{10}(s)$ = 1.75 has been improved from 0.33 to 0.38, for $Log_{10}(s)$ = 2, from 0.1 to 0.22 and for $Log_{10}(s)$ = 2.37, from 0.008 to 0.11.

Conclusions: Spatial amplitude modulation has been evaluated by numerical simulations of retinal images, corresponding to different grades of cataracts and by SSIM which has shown significant improvements after applying the method.

TITLE: An executive function task in mixed reality affects dynamic accommodation

SESSION TITLE: Machine Learning and Augmented Virtual reality

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W.K. Yego, R.C. Baraas, J. Stuart, E. Svarverud, National Centre for Optics, Vision and Eye Care, Faculty of Health and Social Sciences, University of South-Eastern Norway, Kongsberg, NORWAY|

Commercial Relationships Disclosure: Walter Yego: Commercial Relationship: Code N (No Commercial Relationship) | Rigmor Baraas: Commercial Relationship: Code N (No Commercial Relationship) | J.Gilson Stuart: Commercial Relationship: Code N (No Commercial Relationship) | Ellen Svarverud: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The use of mixed reality (MR) displays in education and training have become increasingly commonplace. However, the inherent conflict between vergence and accommodation (VAC) causes concern that these technologies may have an effect on vision. We investigated dynamic accommodation in young adults before and after performing an executive function task in MR.

Methods: Dynamic accommodation (DA) in diopters (D) was measured (PowerRef 3) in 20 participants (11 males) age 20–24 yrs with habitual correction before and after performing an executive function task (Tower of London) in a head-mounted 3D display (HoloLens 2) for 30 min. The task involved arranging virtual objects at 50 cm distance to match a pattern presented on a physical 2D screen at 4 m. DA was measured over a 1 min period where participants binocularly viewed two accommodative targets, at 40 cm and 4 m, alternately at 3 sec intervals while instructed to keep the targets focused and fused. Data were analyzed using Wilcoxon and Kruskal-Wallis tests and Bonferroni corrections.

Results: The difference in accommodative change (ΔAC) between near and distance — before and after the MR task — was calculated. Accommodation behavior fell into two groups, those with no difference (<0.012 D, classified as stable) and those with a difference in ΔAC (unstable). Stable and unstable ΔAC median (interquartile range) were +0.10 (0.07) D and +0.26 (0.13) D, respectively, and significantly different from each other ($p<0.001$). Further analysis showed that those with unstable ΔAC either had contracted ΔAC (smaller ΔAC after the MR task, n=5) or expanded ΔAC (larger ΔAC, n=7). There was a statistically significant difference in ΔAC between the three groups (stable, contracted and expanded) ($p=0.002$, $H=0.70$) with pairwise comparisons showing significant differences between all groups ($p<0.001$). The mean (±SD) ΔAC of the groups were -0.44 (0.26) D, +0.27(0.12) D and 0.27 (0.12) D for the contracted, stable, and expanded groups respectively.

Conclusions: For some individuals, there was a large difference in accommodation behavior before and after performing the MR task. We hypothesize that the unstable ΔAC could be an effect of the VAC and that using MR over longer time periods could be disadvantageous for individuals with contracted ΔAC. An expanded ΔAC could imply a potential of increased flexibility in the vergence-accommodation system that may be beneficial for these individuals.

ABSTRACT BODY:

Purpose: Retinal damage in sickle cell disease (SCD) begins with vascular occlusion by sickled red blood cells. Inner retinal thinning due to tissue volume loss is the most common finding in OCT retinal images of SCD patients. Inner retinal thinning from neuronal migration is one of the characteristics of normal fovea. This project aims to develop and validate a deep learning system to detect retinal thickness changes due to sickle cell retinopathy (SCR) using retinal OCT from children with SCD.

Methods: We use a grid-based object detection algorithm, You Only Look Once (YOLO), to detect retinal thinning caused by SCR. Our dataset contains 3906 B-scans from 63 OCT studies of 33 SCD patients (14 male, 21 SS, 9 SC, 2 Sβ+ and 1 Sβ0, age 12.99±4.56, 5.35 to 20.26 years). Instances of SCR and fovea were annotated by an ophthalmologist using bounding boxes on each image. We divided the dataset into 5 sets, each containing approximately equal numbers of B-scans, to perform a 5-fold cross validation. The algorithm was trained 5 time, and each time on different 4 sets and tested on the remaining set using a Tesla V100 Graphical Processing Unit. We measured the training loss using Binary Cross-Entropy and Focal loss. Mean Average Precision (mAP) based on Intersection over Union between annotated and predicted bounding boxes was used as a performance metric.

Results: Our trained model achieved an average mAP of 96% and 72% on fovea and SCR detection, respectively. Figure 1 presents the corresponding confusion matrix. Low mAP on SCR detection can be attributed to the ambiguity and inconsistency in annotating SCR instances, as depicted by the Background column in Figure 1. Figure 2 compares SCR and fovea detection made by the trained model verses annotated images.

Conclusions: In this examination of retinal OCT images from children with SCD, a deep learning system has shown good precision in identifying SCR and differentiating disease injuries from similarly structured profiles of the normal fovea. Our future research combines the current approach with computer vision-based analysis of retinal layer thickness, extending our work towards predicting SCR progression by analyzing multiple OCT scans of re-visiting patients.

ABSTRACT BODY:

Purpose: Sedentary behavior (SB) is a modifiable risk factor for several adverse health outcomes, such as cardiovascular disease and all-cause mortality, but its association with dry eye disease (DED) remains unclear. SB may increase low-grade systemic inflammation, which can contribute to DED, making it important to understand DED's relationship with this potentially modifiable risk factor. This large population-based, cross-sectional study aimed to test the hypothesis that SB is tied to an increased risk of DED.

Methods: We included participants from the population-based Lifelines cohort (n=48,418, 58% female, mean age = 51.4 years). DED was assessed using the Women's Health Study (WHS) dry eye questionnaire, and SB with the Marshall Sitting Questionnaire. We analyzed the relationship between DED and SB using logistic regressions, corrected for age, sex, BMI, smoking status, demographics, and 48 comorbidities. Additionally, we corrected for time of moderate to vigorous physical activity (MVPA) and stratified by WHO's recommendations of MVPA (<150 vs. ≥150 min/week) in analyses above. Finally, to investigate the impact of SB independent of computer screen exposure, the analyses were repeated for sitting time excluding time spent sitting behind a computer at home or at the office.

Results: In total, 9.1% of the population had WHS-defined DED. Greater SB was associated with an increased risk of dry eye (odds ratio (OR) 1.015 per hour/day, 95%CI 1.005-1.024, P=0.004). This result did not change after MVPA adjustment. Interestingly, the association between SB and WHS-defined DED was only significant for those with <150 min of MVPA/week (OR 1.022, 95%CI 1.002-1.042, P=0.027, n=11,783), and not in those with ≥150 min/week (OR 1.011, 95%CI 0.999-1.023, P=0.076, n=32,353). Lastly, when excluding time spent sitting during computer use, the relationship between SB and DED was substantially attenuated, and no longer significant (OR 1.009, 95%CI 0.996-1.023, P=0.19).

Conclusions: Supporting the hypothesis, we found that greater SB was tied to an increased risk of DED. However, sufficient physical activity appeared to mitigate the risk. Finally, as there was no association when only analyzing the subsample with <2 hours of daily computer use, future studies should investigate the impact of sitting time with and without computer use separately.

TITLE: Differences in keratorefractive surgery outcomes between patients with and without glucocorticoid use in the 12 months preceding surgery: A TriNetX analysis

SESSION TITLE: Refractive and non-refractive corneal surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Tamm, H. Pakhchanian, G. Martin, D. Belyea, Ophthalmology, The George Washington University Milken Institute of Public Health, Washington, District of Columbia, UNITED STATES|R. Raiker, West Virginia University School of Medicine, Morgantown, West Virginia, UNITED STATES|

Commercial Relationships Disclosure: Brendan Tamm: Commercial Relationship: Code N (No Commercial Relationship) | Haig Pakhchanian: Commercial Relationship: Code N (No Commercial Relationship) | Rahul Raiker: Commercial Relationship: Code N (No Commercial Relationship) | Gwen Martin: Commercial Relationship: Code N (No Commercial Relationship) | David Belyea: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To compare differences in outcomes following keratorefractive surgery in patients who used glucocorticoids for the 12 months preceding surgery, and those who did not.

Methods: A retrospective cohort study was conducted using TriNetX (Cambridge, MA, USA), a federated electronic health record research network comprising multiple large health organizations in the US. Patients who underwent keratorefractive surgery were identified by CPT code and stratified cohorts based on glucocorticoid use. Cohorts were matched for age, gender, and comorbidities (essential hypertension, diabetes mellitus, cerebrovascular disease, heart failure, nicotine dependence, alcohol related disorders, and body mass index). Primary outcomes were Dry Eye Syndrome, Recurrent Corneal Erosion, Corneal Edema, Corneal Scar or Opacity, Corneal Ectasia, Acute Conjunctivitis, Diffuse Lamellar Keratitis, Corneal Neovascularization, Vitreous Degeneration (VD), Vitreous Hemorrhage (VH), Retinal Detachment or Break(RD/B), Retinal Edema, and Cystoid Macular Degeneration (CMD). Outcomes were compared between cohorts after propensity score matching using logistic regression and greedy nearest-neighbor matching algorithm.

Results: A total of 13,704 patients were included in analysis with 6,852 in each cohort after propensity matching. The glucocorticoid use cohort had a significantly greater risk of developing dry eye syndrome (RR, 1.61; 95% CI, 2.79-4.59), corneal neovascularization (RR,2.1; 95% CI, 0.99-4.46), vitreous degeneration (RR, 1.43; 95% CI, 1.17-1.75), vitreous hemorrhage (RR,1.82; 95% CI, 1.08-3.06), retinal detachment or break (RR,2.15; 95% CI, 1.61-2.87), retinal edema (RR, 2.17; 95% CI, 1.24-3.78), and cystoid macular degeneration (RR,1.98; 95% CI, 1.38-2.83). No significant difference was seen in development of recurrent corneal erosions, corneal edema, corneal scar, corneal ectasia, acute conjunctivitis, diffuse lamellar keratitis, or ischemic optic neuropathy.

Conclusions: Glucocorticoid use is an important consideration when evaluating for postoperative complications following keratorefractive surgery. Glucocorticoid users were more likely to develop dry eye, corneal neovascularization, VD, VH, RD/B, retinal edema, and CMD. These differences should be considered when evaluating patients and discussing outcomes with patients both pre and post-operatively.

ABSTRACT BODY:

Purpose: To improve the quantification of vitreous haze (VH), a key clinical feature of uveitis, we modified the Passaglia quantitative vitreous algorithm (PQVHA). The PQVHA was developed to improve upon the Miami Scale, which utilizes color fundus photographs (CFP) graded by an expert reader rating the VH as an integer from 0 (no haze) to 8 (extreme haze). The PQVHA addresses important limitations of the Miami Scale: dependence on an expert reader, subjective grading and a categorical scoring system. Our modifications to the PQVHA aim to reduce its sensitivity to variability of image acquisition and quality.

Methods: The data was from a phase 2 randomized, double-masked and placebo-controlled study to evaluate the efficacy and safety of Sarilumab in 58 patients with Non-infectious, Intermediate, Posterior or Pan-Uveitis. Each of the 5 PQVHA steps were modified. 1) The green channel of the CFP had the most contrast so was used for analysis, rather than a grayscale conversion. The images were then histogram normalized and gamma corrected. 2) A Gaussian kernel was used as a high-pass filter instead of a rect function, as the latter provides non-monotonic sinc-weighting to spatial frequencies. 3) Local entropy was not used because it can provide extreme weighting to small artifacts. 4) The magnitude spectrum was used instead of the power spectrum, as the latter's square function provides excessive weighting to a small number of high spatial frequencies. 5) The magnitude spectrum was integrated, and log transformed for a final value. Given the lack of ground truth to assess haze scores, the robustness of PQVHA and our algorithm were assessed by comparing the correlation of the scores with two expert readings in N=3245 images.

Results: The R^2 between our algorithm values and raters 1 and 2 was 0.33 and 0.50, respectively. For comparison, the R^2 between the values from the PQVHA and raters 1 and 2 were 0.10 and 0.08, respectively, and the R^2 between rater 1 and rater 2 was 0.34.

Conclusions: Our method builds upon the PQVHA to increase robustness against the particular experimental conditions between subjects and time points common to clinical trials.

ABSTRACT BODY:

Purpose: To evaluate the retinal starbust amacrine cells (SBACs) by morphological and morphometrical approaches, in a rat model of chronic ocular hypertension (OHT).

Methods: Weekly intracameral injections of sodium hyaluronate (HYA) were used to induce chronic OHT in the left eye (LE), whilst salt solution was injected in the sham operated right eyes (RE) of seven male Wistar rats, during nine consecutive weeks. Intraocular pressure (IOP) measurements were done weekly, by means of a rebound tonometer. Retinal cryosections were obtained for immunohistochemical techniques (specifically ChAT antibody to SBACs), and morphometric approaches. Statistics were performed by the 28.0 SPSS program.

Results: The OHT was significantly higher and sustained during the follow-up in LE respect to RE at most timepoints. Considering that in the retinal ganglion cell (RGC) layer, the displaced amacrine cells (DACs) constituted up to 50% of all cells, and the SBACs account for 20% of the DACs population, mild-to-moderate OHT induced noticeable morphologic changes and a significant reduction in ON/OFF SBACs in the HYA-treated eyes (17.7 ± 2.9 cells/mm) with respect to the controls (24.8 ± 3.1 cells/mm), ($p<0.01$), contributing to the RGC layer global reduction.

Conclusions: The HYA intracameral injections in the rat eye induced a mild-to-moderate sustained IOP elevation and RGC loss, mimicking most human open-angle glaucoma milestones. The decreased density of SBACs and its deteriorated ON/OFF plexus in our chronic OHT model, probably started the fall off in the signal transduction and visual performance, that for the first time, may be related to specific anomalies in motion perception described in glaucoma patients.

ABSTRACT BODY:

Purpose: The impact of central choriocapillaris (CC) flow deficits (FDs) on low luminance visual acuity (LLVA) measurements was investigated in pseudophakic normal eyes and in eyes with nonexudative age-related macular degeneration (neAMD) to determine if LLVA measurements correlated with the stage of AMD and its progression.

Methods: Both normal luminance best-corrected visual acuity (NL-BCVA) and low luminance BCVA (LL-BCVA) were obtained using the Early Treatment Diabetic Retinopathy Study (ETDRS) chart. LL-BCVA was measured by using a 2.0-log unit neutral density filter in front of the examined eye (Wratten filter; Kodak, Rochester, NY). LLVA deficit (LLVAD) scores were calculated by subtracting the LL-BCVA from the NL-BCVA letter scores. The percentage of central CC FDs (%FDs) was determined in a 1mm diameter circle centered on the fovea from 6x6 mm scans using swept-source OCT angiography (SS-OCTA) imaging (PLEX® Elite 9000, Carl Zeiss Meditec, Dublin, CA) along with a previously validated algorithm. Pseudophakic eyes were chosen since an ongoing study determined that cataracts have an unpredictable effect on LLVA measurements. Eyes with neAMD were categorized as drusen-only eyes and eyes with non-foveal geographic atrophy (nfGA). In eyes with nfGA, the posterior margin of atrophy could not be within 150 µm of the foveal center, and the area of nfGA could not comprise more than 10% of the central 1mm circle.

Results: In 30 normal eyes ranging in ages from 56 to 79, there were no statistically significant correlations between the central CC FD% and the NL-BCVA, LL-BCVA, and LLVAD measurements (all $|r|$ values ≤ 0.04, all p-values ≥ 0.85). However, in 27 drusen-only eyes ranging in ages from 67 to 90, significant correlations were found between the central CC FD% and the NL-BCVA ($r=-0.49$; $p=0.010$), LL-BCVA ($r=-0.65$; $p<0.001$), and LLVAD ($r=0.54$; $p=0.004$). Analysis of neAMD eyes with nfGA is currently underway.

Conclusions: In pseudophakic normal eyes, no correlations were identified between the central CC FD% and the NL-BCVA, LL-BCVAD, and LLVAD measurements; however, in drusen-only eyes, an increase in central CC FD% measurements were correlated with decreased NL-BCVA, decreased LL-BCVA, and increased LLVAD measurements. These correlations suggest that increased CC flow impairment impacts foveal photoreceptor function. The analysis of eyes with nfGA is ongoing.

ABSTRACT BODY:

Purpose: We conducted a genome-wide association study (GWAS) on African ancestry individuals, in order to identify genes associated with primary open-angle glaucoma endophenotypes.

Methods: The Primary Open-Angle African American Glaucoma Genetics (POAAGG) study population consists of self-identified Blacks, aged 35 years or older. Quantitative traits were collected on subjects during ophthalmic exams, including intraocular pressure (IOP), cup-to-disc ratio (CDR), central corneal thickness (CCT), visual acuity (VA), retinal nerve fiber layer (RNFL) thickness, mean deviation (MD), and pattern standard deviation (PSD). Genotyping on 5950 subjects including cases and controls was performed using the Multi-Ethnic Genotyping Array V2 (EX) consortium chip. After standard quality control, samples were imputed to the TOPMED phase 3 reference panel using the TOPMED imputation server, which resulted in ~15M variants at R^2>0.3 filter. Single variant, quantitative trait association tests were performed using generalized estimating equations (GEE) to account for inter-eye correlation, adjusting for sex and age at study enrollment, with the first five PCs included as fixed effects.

Results: Assuming independence of tests, the genome-wide quantitative trait association studies identified 351 significant SNP-trait associations (p-value<5x10-8) in 107 genomic loci. A total of 6 variants reached genome-wide significance for CDR, as well as 26 variants for baseline IOP, 27 variants IOP max, 99 variants for baseline PSD, 180 variants for MD, 7 variants for RNFL thickness, and 6 variants for VA. SNP association results for central corneal thickness (CCT) did not reach conservative genome-wide significance, assuming independence of all phenotypes evaluated in this study. The SNPs implicated in the associations analysis in our study mapped to genes that include SOX5, CSMD1, EVA1C, PHTF2, EXT1, ACE, CPXM2 and others. In silico and functional validation of the implicated SNPs is currently underway.

Conclusions: Our study recruited, genotyped, and deeply phenotyped the largest-ever cohort of African ancestry individuals with glaucoma from a single city, providing much needed genetic architecture for this most affected population. Glaucoma is an inherently complex and heterogenous disease, making this deep phenotyping necessary for understanding the pathophysiology of disease and to study the influence of genetic variations.

TITLE: Novel aspect of epiretinal membrane (ERM) & it clinical significance: internal limiting membrane (ILM) Folds, underneath ERM vs. around ERM

SESSION TITLE: Vitreoretinal surgery/VR Interface/PVR

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Lee, J. Kim, Ophthalmology, Hanyang University Medical Center, Seoul, Seoul, KOREA (THE REPUBLIC OF)|B. Lee, J. Heo, Ophthalmology, Theoneseoul eye clinic, Seoul, Seoul, KOREA (THE REPUBLIC OF)|

Commercial Relationships Disclosure: Byung Ro Lee: Commercial Relationship: Code N (No Commercial Relationship) | Jangwon Heo: Commercial Relationship: Code N (No Commercial Relationship) | Ji Hong Kim: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We previously reported that ILM folds around ERM showed typical radiating hyporeflective lines pattern from margin of ERM, and they were shown excellently on both red-free image of confocal scanning laser ophthalmoscopy (cSLO) and 3D-rendering image of optical coherence tomography (OCT). In this study, we focused on ILM folds underneath ERM and assessed its prevalence, morphologic characteristics, and clinical Implications, which was not reported previously.

Methods: Retrospective, observational case study was performed in fifty five eyes of 48 patients with ERM. We developed a novel method of obtaining image of ILM folds underneath ERM. Using en face analysis mode of standard OCT macular volume scan, topographic surface images of ILM folds were acquired, then by adjusting frontal surface scan line, images of ILM folds situated underneath ERM and around ERM was acquired, respectively. We classified patterns of ILM folds underneath ERM group and compared them to those around ERM group. The prevalence of each patterns of ILM folds were obtained and compared between the two groups. In the patients with follow-up periods >5 years, anatomical & functional ERM progression was matched to that of the ILM fold patterns.

Results: Pattern of ILM folds were classified as radiating, irregular-random oriented and mixed. Among the 55 eyes, ILM folds around ERM group showed 52 (94.5%) eyes of radiating, 2 (3.6%) eyes of irregular and 1 (1.8%) of mixed pattern. Notably, ILM folds underneath ERM group showed 10(18.2%) eyes of radiating, 30 (54.5%) of irregular, 15 (27.2%) of mixed pattern. Irregular, random oriented pattern of underneath ERM group is composed of multiple gaps between ERM and retina. Immediately after ERM with ILM peeling, the ILM fold disappeared in both group of all eyes. ERM progression showed excellent agreement with ILM fold progression (kappa value [κ]= 1.0, 0.8, respectively in each group).

Conclusions: Our novel images using standard OCT showed that ILM folds underneath ERM has a random oriented, irregular pattern, which is remarkably different from typical radiating ILM folds around ERM. Particularly, this overview of ILM folds and gaps between ERM and retina provides us pre-surgical information and may aid to predict visual prognosis.

TITLE: Exosome release from RPE cells increased by lysosomal compromise

SESSION TITLE: Pathobiology of AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C.H. Mitchell, W. Lu, University of Pennsylvania, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Claire Mitchell: Commercial Relationship: Code N (No Commercial Relationship) | Wennan Lu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Understanding how injured RPE cells communicate trouble to neighboring cells is central. RPE cells are particularly susceptible to lysosomal compromise as they degrade photoreceptor outer segments released each day, and as they are post-mitotic cells, allowing chronic accumulation of toxins in the lysosomes. Given the pathways connecting lysosomes and multivesicular bodies (MVBs), and the role of MVBs in exosome release, we hypothesized that lysosomal compromise alteres exosome release from RPE cells.

Methods: Lysosomal compromise in iPS-RPE or ARPE-19 cells was induced by exposing cells to 20μM chloroquine for 7 days. Immunoblots were performed on vesicles collected from supernatant using ExoQuick. Vesicle size and quantity were analyzed with a Spectradyne system and exosome marker analysis performed with an ExoView chip system. C57BL6J mice received intraperitoneal chloroquine injections 50 mg/kg; 3x/wk for 6 weeks.

Results: Immunoblots showed a rise in exosome marker CD63 in vesicular material from the supernatents of iPS-RPE cells exposed to chloroquine. A similar rise in CD63 was observed in immunoblots from the supernatant of ARPE-19 cells exposed to chloroquine. Quantification of extracellular vesicle size confirmed these vesicles to be exosomes, with a mean diameter of 79.7 ±1.4 nm in control; particle size was not changed after exposure to chloroquine. However, Spectradyne analysis confirmed exosome number was increased by chloroquine. ExoView analysis showed chloroquine induced a differential increase in the number of CD63+ and CD81+ vesicles, with a smaller rise in CD9+ vesicles. Initial trials suggest supernatant from chloroquine-treated ARPE-19 cells reduced viable 661w cells, although chloroquine by itself did not. Increased staining for CD63 was found in RPE cells from mice, and in cultured RPE cells, treated with chloroquine.

Conclusions: These findings suggest lysosomal compromise increases exosome release from RPE cells. Links between exosome release and photoreceptor health require confirmation. Exosome markers CD63 and CD81 were previously identified in drusen from AMD patients; whether reducing lysosomal compromise can reduce these markers in drusen remains to be determined.

ABSTRACT BODY:

Purpose: Eyesi Surgical is an ophthalmologic microsurgery simulator that allows users to practice abstract microsurgical skills as well as more specialized clinical skills relating to cataract and vitreoretinal surgery. Currently, the simulator is usually introduced during residency or fellowship training for ophthalmologists. This study assessed the inclusion of microsurgical simulation training in the medical school ophthalmology clerkship.

Methods: 79 German medical students in their 10^{th} semester of undergraduate education were given the opportunity to complete up to two days of training on the simulator during their ophthalmology clerkship. They began with abstract modules which focused on instrument handling and microscope use and progressed to more ophthalmology-specific modules. They received an objective numeric score based on simulator performance and completed pre and post training subjective questionnaires.

Results: There was no relationship found between students' Eyesi Surgical performance scores and their specialty interests ($p=.790$). The majority of students (73.4%) subjectively rated their microsurgical skills to be higher after simulator training than before training ($p<0.001$). 92.4% of students found the Eyesi Surgical to be a useful component of the ophthalmology clerkship. Additionally, 15.2% of students indicated an interest in more simulator training during the clerkship than that which was offered. Objective scores from Navigation Training Level 1 showed that students achieved better results in the criteria categories of Completing Objects and Tissue Treatment than in the categories of Instrument and Microscope Handling. The mean Total Score was 25.71 out of a possible 100 points. A trend was found ($p=.078$) in the correlation between self-rated microsurgical ability and Navigation Level 1 total score on the Eyesi Surgical.

Conclusions: The inclusion of surgical simulation in the ophthalmology clerkship curriculum led to increased levels of confidence in the microsurgical skills of medical students. Offering surgical simulation training to medical students prior to residency can help to expose students to surgical fields, identify those that have particular talent and aptitude for surgery, and assist them in deciding which specialty to pursue in residency.

ABSTRACT BODY:

Purpose: To determine the neuroprotective effects of chaperone peptides (peptain-1 and peptain-3a) against retinal ganglion cell (RGC) death in vitro and two mouse models of ocular hypertension.

Methods: Rat primary RGCs were treated with peptain-1 or peptain-3a in the absence of trophic factors, and the apoptotic and dead cells were counted. Microbeads were injected into the anterior chamber of mice, and after 3 weeks, IOP was elevated. Peptains were injected intravitreally at 1 µg each in PBS and subsequently once a week for 3 weeks. Silicone oil was injected into the anterior chamber to elevate IOP and after 2 weeks the oil was removed and peptains were injected intravitreally at 1µg each in PBS.

Results: Peptains exhibited robust anti-apoptotic activity against neurotrophic factor deprivation in primary RGCs. The microbead-injected eyes had significantly higher IOP levels over a 6-week follow-up than the contralateral control eyes. The number of RGCs decreased by 31% following microbead injection, but peptain-1 and peptain-3a significantly decreased RGC death; to only 4% and 12%, respectively. IOP elevation reduced the anterograde transportation along the length of the optic nerve, but peptains ameliorated this effect. In eyes injected with silicone oil, RGC counts decreased by 39% after 2 weeks. Two weeks after silicone oil removal, the injection of peptain-1 and peptain-3a significantly reduced the RGC loss by 27% and 25%, respectively.

Conclusions: Peptain-1 and peptain-3a protect RGC somas and axons against ocular hypertension in mice. Our results suggest that they could be developed as neuroprotective agents for the treatment of glaucoma.

ABSTRACT BODY:

Purpose: Personalized screening policies for diabetic retinopathy (DR) can be effective in detecting DR while incorporating more accessible screening technologies such as teleretinal imaging (TRI) as a precursor to clinical screening (CS). This study conducts cost-effectiveness analysis comparing personalized and standardized screening policies for an urban, safety-net hospital system.

Methods: A partially observable Markov decision process model (POMDP) determined semi-annual personalized recommendations of either wait and watch (WW), TRI, or CS based on a patient's risk of having proliferative DR and screening compliance. A Monte Carlo discrete event simulation model was then utilized to compare the model-based personalized policy to standardized policies including annual CS (ACS), biennial CS (BCS) and annual TRI (ATRI) for a hypothetical cohort over their lifetimes. DR progression rates and patient-specific CS compliance were obtained from literature while patient-specific TRI compliance was derived from the TRI screening program at the Harris Health System, Houston, TX. Sensitivity analysis was conducted to examine cost-effectiveness of the screening policies across different A1C levels.

Results: For a base case population with an A1C level of 7% and TRI and CS compliance rates of 68.4% and 35%, respectively, the model-based personalized policy included 3.65% WW, 86.72% TRI and 9.62% CS (95% CI +/- 0.02%) on average during a patient's lifetime. The personalized policy was found dominant in 57.23%, 80.02%, and 67.75% (95% CI +/- 0.04%) for patients who followed them compared to ACS, BCS and ATRI, respectively (See Fig 1). At an A1C level of 13%, the personalized policy on average included 0.23% WW, 64.67% TRI, and 35.10% CS (95% CI +/- 0.03%). For this cohort, the personalized policy was found dominant for 71.99%, 94,53%, and 83.36% (95% CI +/- 0.04%) of patients compared to ACS, BCS and ATRI, respectively (See Fig 2).

Conclusions: For the majority of patients, following the model-based personalized screening policy provided more QALYs and was less costly when compared to other standardized policies, highlighting the potential benefit of personalized screening recommendations. This benefit increases for more at-risk patients, such as those with high A1C levels.

ABSTRACT BODY:

Purpose: Individual retinal pigment epithelium (RPE) cells host hundreds of granules with AF properties (PMID: 32433758). Here, we characterized RPE cells in healthy and age-related macular degeneration (AMD) affected eyes by their AF spectra and correlate individual wavelengths with the amount of autofluorescent granules (lipofuscin, melanolipofuscin) per RPE cell body (RPECB).

Methods: Twenty-two RPE flat mounts of human donor eyes (7 AMD-affected (3 early AMD, 1 geographic atrophy, 3 neovascular) and 15 w/ unaffected macula (8<51 yrs; 7>80 yrs)) were imaged at three locations (fovea, perifovea, near periphery) using en face confocal AF (exc. 488 nm) and high-resolution structured illumination microscopy. Up to 110 cells/location/eye were marked manually and emission spectra were extracted (490-695 nm; 8.9 nm spectral channel width) from a projection image of each cell and stratified by disease status and location. Granules/cell were manually quantified and classified with computer-assistance. Mixed linear models were used to correlate spectra with the number of intracellular granules.

Results: Spectra of 5.549 RPE cells (<51yrs: 2.353, >80yrs: 2.053, AMD: 1.143) were included. Spectra of healthy cells showed similar emission spectral curves that peaked at 580 nm for the fovea and perifovea and between 575 and 580 nm for the near periphery. Compared to healthy, AMD spectral curves showed a 10 nm-shift towards shorter wavelengths (further statistical analysis in progress). The effect was strongest for the fovea and perifovea. Spectral curves at the perifovea appeared to be flattened at nAMD stage. Mixed linear models showed no statistically significant differences between the coefficients for wavelengths and granule load.

Conclusions: With the help of different microscopy techniques, identification of cellular (spectral AF) and subcellular (granules) properties of RPE cells allow to distinguish healthy from diseased RPE, especially at fovea and perifovea,

areas highly impacted by AMD related sub-RPE deposits A spectral shift in AMD in this large series of RPE cells confirms earlier microscopy findings (PMID: 12091448) from tissue cross sections. Future studies will examine the impact of individual granule spectra on the total RPE spectrum. Overall, our results will help to interpret the RPE's AF in studies using in vivo single cell imaging.
