Methods: Manually graded multi-retinal layer segmentation (MLS) was used to generate the ground truth which is defined as the region between RPE and CSJ. The inputs consist of 3 mm OCT patches extracted from five neighboring B-scans along with the attenuation corrected patches. A total of 17,722 training and 10,596 validation data from 603 3x3 mm, 6x6 mm, 9x9 mm, 12x12 mm scans acquired using PLEX® Elite 9000 (ZEISS, Dublin, CA), with eye diseases such as age-related macular degeneration (AMD), were used to train a model. A network was designed with the first half of an autoencoder (encoder) followed by a discrete cosine transform (decoder). In prediction, an uncertainty algorithm detects the low segmentation confidence regions that are replaced by interpolation to generate the complete CSJ surface. 61 6x6 mm and 61 12x12 mm scans from the same eyes with eye diseases such as AMD were used to generate choroidal thickness maps using manual and automated segmentation which are defined as the distance between the MLS Bruch's membrane (BM) and the CSJ. The performance of the algorithm was reported using correlation between manual and automated methods for each sector of the ETDRS grid (Fig 2). Regression and Bland-Altman plots were used for 3 mm, 6 mm and 11 mm zones.

Results: Fig 1 shows five neighboring 3 mm OCT input and ground truth patches, and examples for CSJ segmentation results overlaid on OCT images for different scan FOV. Fig 2 shows the ETDRS and correlation between the manual and automated segmentation in each sector including the regression and Bland-Altman plots for the central 3 mm, 6 mm and 11 mm zones. Most ETDRS sectors show significant correlation (>0.85) between manual and automated measurements. Lower correlation within the ONH vicinity was explained by increased difficulties in the BM segmentation.

Conclusions: We proposed a novel deep learning based CSJ segmentation. The choroidal thickness maps generated by automated and manual segmentation have a strong correlation and good agreement. Automated segmentation may be a valuable diagnostic tool for retinal diseases.

ABSTRACT BODY:

Purpose: Long-lived lens fiber cells require strong cellular protective function against oxidative insults for maintaining their hemostasis and viability; however, the underlying molecular mechanism remainly large elusive. We hypothesize that mechano-activated connexin (Cx) hemichannels (HCs) and glutathione (GSH) transport protect lens fiber cells against oxidative insults.

Methods: Site-directed mutagenesis was used to prepare recombinant RCAS(A) DNA constructs containing different Cx50 site mutations. High-titer recombinant RCAS(A) retrovirus was prepared and used to infect chick embryonic fibroblast cells and lens primary cells to express exogenous Cxs. Western blot was performed to determine expressions of Cxs. Fluid flow shear stress was used to apply mechanical stimulation. Cx HC activity was determined by Lucifer yellow/rhodamine dextran uptake assay. Hydrogen peroxide and ultraviolet B radiation were used to induce oxidative stress. Intracellular GSH and reactive oxygen species were determined by using commercial fluorescence-based kits. Cell apoptosis and necrosis were measured by Annexin V and PI staining. Single lens fiber cells were isolated by enzymatic digestion and cell dissociation.

Results: We found that mechano-activated Cx HCs mediated the transport of GSH into lens fiber cells, leading to the decrease of the accumulation of intracellular reactive oxygen species induced by both hydrogen peroxide and ultraviolet B radiation, and protection of lens fiber cells against cell apoptosis and necrosis. In addition, HCs formed by both homomeric Cx50, Cx46 and heteromeric Cx50/Cx46 were mechanosensitive and facilitated the transport GSH into the cell. Among them, mechano-activated Cx50 HCs showed higher Km than Cx46 HCs (Km: Cx50: 0.72 ± 0.12 mM; Cx46: 0.43 ± 0.14 mM) and Vmax (Cx50: 44.50 ± 2.00 AU/20 min; Cx46: 17.18 ± 1.34 AU/20 min) in transporting GSH. Consistently, deficiency of Cx50 in single lens fiber cells exhibited a higher level of oxidative stress. Moreover, outer cortical short lens fiber cells expressing full length Cxs were more resistant to oxidative injury than central core long lens fibers

Conclusions: Activation of Cx HCs by interstitial fluid flow in lens fiber cells is essential in cellular uptake of reductants and protection of lens fiber cells against oxidative stress-induced cell death.

ABSTRACT BODY:
Purpose: Elucidating principles of vascular permeability will enable development of novel approaches to diagnose and treat retinopathy, which eventually develops in the majority of patients with diabetes. Transforming growth factor b (TGF-β) plays an important role in regulating endothelial (EC) function. We examined the effect of activin A (activin), a member of the TGF-β superfamily, on vascular endothelial growth factor (VEGF) and cytokine-induced permeability.
Methods: High glucose-treated (30 mM D-glucose for at least 10 days) primary human retinal endothelial cells (HG-HRECs) were used for all experiments. Permeability was quantified by electric cell-substrate impedance sensing. VEGF-dependent signaling, and VEGF receptor 2 (VEGFR) half-life was investigated by Western blot analysis.
Results: We discovered that activin A and its biding partner follistatin (FST) influenced the response of HG-HRECs to VEGF. Pretreating HG-HRECs with activin A attenuated VEGF-induced barrier relaxation whereas FST counteracted the effect of activin on VEGF-dependent permeability. We also investigated the mechanism by which activin restrained VEGF-induced permeability. Activin reduced the half-life of activated VEGFR and suppressed VEGF-dependent activation of signaling enzymes. Taken together, these observations suggest that activin accelerates degradation of activated VEGFR and thereby attenuates signaling events and permeability. Finally, activin had no effect on barrier relaxation in response to TNF-α (transforming necrosis factor a) and IL1-β (interleukin 1 b).
Conclusions: Members of the TGF β family such as activin A are capable of contributing to vascular homeostasis by attenuating responsiveness to VEGF, but not to cytokines. The underlying mechanism appears to include accelerated degradation of activated VEGFR2.

ABSTRACT BODY:

Purpose: Corneal nerves and innervation are susceptible to several diseases including diabetes. Despite the clinical need to promote corneal nerve regeneration, few specific therapeutic interventions are available. MSCs and their paracrine effect mediated by exosomes presents an attractive treatment for enhancing nerve regeneration. In this study, we assessed the neuro regenerative potential of exosomes from BM-MSCs cultured in 2D and 3D systems.

Methods: Human BM-MSCs were cultured in 2D monolayer and 3D bioreactor systems. Exosomes were isolated using ultracentrifugation followed by size and concentration measurements utilizing NanoSight and Exoview. Mouse trigeminal ganglia (TG) neurons were isolated from Thy1-YFP mice possessing fluorescent corneal nerves. The neurons were plated in the presence and absence of exosomes derived from 2D or 3D culture systems. Neuronal growth and morphology were monitored over 5 days. Thereafter, the neurons were fixed and immune-stained with β3 tubulin followed by confocal microscopy. Images were analyzed by Neurolucida software to obtain the density and length of the neurites.

Results: The Nanosight tracking analysis revealed significant increase in concentration of exosomes obtained from 3D vs. 2D culture condition (24X fold-change). Exoview analysis showed significantly higher concentration of CD63, CD81 and CD91 exosomal markers in 3D vs. 2D condition. Furthermore, a notable shift towards a more heterogeneous exosome phenotype was observed in the 3D compared to 2D culture systems. Exosomes derived from both 2D and 3D condition significantly induced neurite growth after 5 days in culture compared to untreated control. Neurolucida analysis of the Immunostaining images (β3 tubulin) showed a significant increase in density and complexity of the neuronal growth of TG neurons in 3D vs. 2D condition. Additionally, a significant increase in neuron branching was observed in 3D versus 2D.

Conclusions: Our results demonstrate the distinct effect of BM-MSCs-derived exosomes in neurites growth and elongation. Exosomes obtained from 3D culture system enhanced the neurite complexity and branching compared to the effect of vesicles from 2D culture. This specific property could potentially enhance the therapeutic effect of EVs in vivo and provide new therapeutic interventions for the restoration of damaged corneal nerves.

ABSTRACT BODY:

Purpose: To investigate whether our screening program targeted low socioeconomic neighborhoods in New York City and whether physical disorder and social vulnerability correlate with follow up after ophthalmic screening.

Methods: The TeleOphthalmology Mobile Unit screened 957 participants for cardiovascular risk factors and common causes of blindness. The participants' demographic information and residential addresses were collected at the time of screening. Physical disorder scores were generated using the CANVAS virtual audit system. Google street view was used to evaluate building conditions, building vacancy, graffiti, and litter. Physical disorder ratings were interpolated using ordinary kriging and each participant was assigned a score based on a 500-meter radius around their address. Social vulnerability scores were generated using data from the Centers for Disease Control 2018 Social Vulnerability Index (SVI) database. Each participant was assigned the SVI score of their residential census tract. Multinomial logistic regression was performed to identify predictors of successful follow up (N=156) as compared with lack of follow up (N=160) or inability to contact (N=228).

Results: The mean summary SVI score of the study population recommended for follow up was 0.81 (SD=0.21), with 0 indicating low vulnerability and 1 indicating high vulnerability. Age of participants was inversely correlated with failing to follow up with an ophthalmologist after screening (coefficient=-0.28; p=0.008). Population density of the Census tract was inversely correlated with being unreachable by the researchers (coefficient=-4.77e-06; p=0.042). Per capita income, percentage uninsured, and physical disorder were not significantly different between those who did follow up and those who did not follow up or could not be reached.

Conclusions: Our study participants disproportionately live in Census tracts that are more socially vulnerable than the national average. Older patients were more likely to follow up and may have had more symptomatic disease or more serious diagnoses. Population density was positively associated with follow up, possibly because denser tracts in New York City have more affluent residents and greater access to medical care. Our study demonstrates that the SVI can identify populations in need of eye care and that older patients are more likely to follow up than younger patients.

ABSTRACT BODY:

Purpose: Nonhuman primates are routinely utilized in ocular preclinical research because of their homology to human ocular anatomy. Intravitreal dosing is one the most investigated dose administration routes, and is performed on more than 150 nonhuman primates annually at Labcorp Drug Development, in Madison, WI. In 2018, our preparation method for intravitreal dosing was changed from swabbing the conjunctiva and eyelids with dilute betadine-soaked cotton-tipped applicators (full preparation), to soaking the globe and conjunctiva with dilute betadine for 2 minutes (limited preparation). Both methods are followed by rinsing with saline. It was hypothesized that a limited preparation may reduce adverse events after dosing compared to a full preparation as betadine has a known potential to cause hypersensitivity reactions.

Methods: Control animal data from January 2014-June 2021 for all preclinical toxicology studies with intravitreal dosing was retrospectively analyzed. Data recorded included preparation method, control article composition, number of control animals, number of intravitreal injections, post-injection medications and additional procedures performed. Recorded adverse events included squinting, rubbing, face pressing and periorbital swelling.

Results: Full preparation was used for 96 control animals that were dosed 394 times in total, and limited preparation was used for 107 control animals that were dosed 465 times in total. No differences were noted in control article composition, number of intravitreal injections per study or post-injection medications. However, the number of animals with adverse reactions (Figure 1) and total number of adverse reactions (Figure 2) were reduced using the limited preparation compared to full preparation. Most notably, after changing to a limited preparation method, there was a 68% reduction in the number of animals noted to squint post-dosing, and an 82% reduction in the number of squinting observations.

Conclusions: The change in preparation from full to limited has decreased the number of adverse events. This reduction in adverse events both improves animal welfare and also allows for a more accurate interpretation of post-injection adverse events in test article-treated animals.

ABSTRACT BODY:

Purpose: To gauge the impact of healthcare technology in the management of diabetic retinopathy during the COVID-19 pandemic.

Methods: The study was conducted at EyeCare Consultants of New Jersey's in their two locations in NJ, Woodland Park and Edison. Eye care professionals (ECPs–two ophthalmologists, one optometrist) surveyed 400 diabetic patients during the first year of the pandemic (March 2020- February 2021).

The patients all received previous instructions with CheckedUp, a patient education digital platform utilizing audiovisual and touchscreen to further educate patients, during in-office visits.

The 400 diabetic patients were divided equally into two groups. To ensure the adherence of dietary and behavioral modifications related to diabetes mellitus, Group 1 received traditional phone calls while Group 2 received video calls and supplementary education with CheckedUp.

Both groups had a follow-up in person in September 2021. Surveys elicited responses to gauge consistency of HbA1C management.

Results: Adherence was defined as HbA1C values which remained within a target value lower than or equal to their baseline and/or <7.0% as well as compliance with medications, dietary restrictions, regular physical activity and follow-up visits. The results found a significant difference between educating the patient with a phone call versus a video call and CheckedUp.

At the next follow-up visit in person: Group 1 had an adherence of 48% (96 patients) and had several patients with HbA1C values exceeding the targeted value. Group 2 had an adherence of 69% (138 patients) and were more compliant with a healthier lifestyle. They also stated that their telehealth appointment with CheckedUp helped reinforce the importance of maintaining a normal HbA1C value.

Conclusions: This study illustrates the ability of digital medicine platforms to supplement virtual and in-person consultations to manage diabetic retinopathy, especially during the pandemic. Compliance is an important matter in the management and preventing progression of diabetic retinopathy. Digital tools like CheckedUp assist with optimizing patient care in these unprecedented times.

ABSTRACT BODY:

Purpose: Treatment of chronic, non-infectious ocular inflammation includes corticosteroids, disease modifying anti-rheumatic medications (DMARDs), and biologics. To mitigate adverse effects associated with the use of these medications, routine laboratory test monitoring is recommended throughout treatment. We evaluated the effectiveness of an alert added to the electronic medical record (EMR) to aid in laboratory test monitoring for patients prescribed these high-risk medications.

Methods: A prospective, interventional study assessed the effect of an alert within the EMR on laboratory test ordering at the Division of Ocular Immunology at the Wilmer Eye Institute. The primary outcome measure was the change in number of ordered lab tests at 3, 6, and 12-months after the alert activation compared to pre-interventional levels and overall throughout the study period. The laboratory tests that were monitored included complete blood count (CBC), comprehensive metabolic panel (CMP), dual-energy x-ray absorptiometry (DEXA) scans, fasting lipid panel, hemoglobin A1c, and interferon gamma release assays (IGRA).

Results: The laboratory test orders for 162 patients on high-risk medications were analyzed. Only the frequency of ordering the DEXA and IGRA increased significantly, compared to baseline, throughout the study. Conversely, there was a significant decrease in the frequency of ordering of fasting lipid profiles and hemoglobin A1c at each time point and for CBC and CMP at the 6-month time point.

Conclusions: An EMR alert results in increased laboratory test ordering initially for tests drawn on a yearly basis, but the effect on more frequently ordered tests wanes with time if the alert can be silenced by the provider. Nonetheless, it provides a novel mechanism to increase laboratory ordering in patients on high-risk medications that can be adapted for use in other EMR software. Future studies are needed to assess if physician laboratory test ordering behavior is altered throughout the study period with the use of a non-silenceable alert.

ABSTRACT BODY:

Purpose: To minimize the number and reliance on in-person clinical care and trial visits, many mobile apps for visual acuity (VA) self-assessment have been introduced recently. However, few publications, to our knowledge, have compared near VA with distance VA, routinely tested in clinical practice, using standardized charts. The purpose of this paper is to evaluate the level of agreement between near and distance VA obtained with Early Treatment Diabetic Retinopathy Study (ETDRS) charts in the clinic.

Methods: This study is a multi-site study for 90 participants with neovascular age-related macular degeneration (nAMD) or diabetic macular edema (DME). Patients with nAMD or DME in one eye, aged ≥18 years, VA better than 20/200 were eligible. Each participant had the study eye assessed two times with each chart at both the Baseline (V2) and end of study (V3) visits, using habitual correction for distance VA at 4 m and near VA at 40 cm. Bland-Altman plots with repeated measurements per participant were produced. The 95% limits of agreement (LoA) for the difference between near and distance VA assessment methods are presented, along with 95% confidence intervals (CIs) around the LoAs calculated using the method of variance estimates recovery.

Results: From the preliminary results, 39 participants had completed the V2 visit, of which 34 (87%) had nAMD, mean (±SD) distance VA in the study eye was 0.27 logMAR (0.214), mean (±SD) age was 73.0 (8.4) years and 20 (51%) were female. A total of 35 participants with data at both V2 and V3 visits from the Johns Hopkins University clinical site were included in this analysis. Agreement between BCNVA obtained with the near ETDRS chart in the clinic and BCDVA obtained with the distance ETDRS chart in the clinic observed a mean difference of 0.04 with an upper LoA of -0.22 logMAR (95% CI: -0.29, -0.18) and a lower LoA 0.29 logMAR (95% CI: 0.25, 0.36).

Conclusions: Our results suggest that the LoAs CIs when comparing the VA obtained with the near and distance charts were close to being within a 0.3 logMAR threshold, beyond which typically is considered a clinically relevant change for these diseases. Differences might come from some participants being less optimally corrected with their habitual near correction.

TITLE: Variable contrast flicker in patients with non-advanced age-related macular degeneration: results from the 3rd year follow-up

SESSION TITLE: AMD: Clinical and translational research/AMD therapies (excluding anti-VEGF)

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Gherghel, E. Besinger, K. Dieter, J.D. Rodriguez, G. Wallstrom, M.B. Abelson, Ora Inc, Andover, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Doina Gherghel: Commercial Relationship(s);Code E (Employment):Ora Inc. | Ethan Besinger: Commercial Relationship(s);Code E (Employment):Ora Inc. | Kevin Dieter: Commercial Relationship(s);Code E (Employment):Ora Inc. | John Rodriguez: Commercial Relationship(s);Code E (Employment):Ora Inc. | Garrick Wallstrom: Commercial Relationship(s);Code E (Employment):Ora Inc. | Mark Abelson: Commercial Relationship(s);Code O (Owner):Ora Inc.;Code E (Employment):Ora Inc.

ABSTRACT BODY:

Purpose: The development of effective therapies for non-advanced age-related macular degeneration (AMD) has been hindered by a lack of sensitive, reversible endpoints to be used in clinical trials. Our group has previously reported (1) on the Ora Variable Contrast Flicker (Ora-VCF™) test which has successfully identified differential contrast sensitivity (CS) thresholds for non-advanced AMD patients as compared to matched controls. The present study reports follow-up results from the third longitudinal visit for a cohort of non-advanced AMD patients originally tested in 2017.

Methods: Nine non-advanced AMD patients with visual acuity of 20/25 (at the entry point) and 16 age matched controls were included in this follow-up visit. On a single study visit, all participants completed a battery of visual function assessments, including Ora-VCF™ tests. During the Ora-VCF™ test, patients viewed flickering targets presented via a customized software. Stimuli were presented at three temporal frequencies (low, mid, and high) and two background luminance levels (low- and high-mesopic) as previously reported (1).

Results: Patients with non-advanced AMD had significantly higher contrast thresholds for the intermediate flicker rate (between 10-20 Hz) at both background luminance levels (both $p < 0.03$), as well as a trend for the high flicker rate (> 20 Hz) when presented on the low luminance background ($p = 0.0714$), as compared to matched controls. These results are consistent with patterns observed during prior visits across the duration of the longitudinal study.

Conclusions: The Ora-VCF™ test indicates that, compared to matched healthy subjects, non-advanced AMD patients with good BCVA have higher contrast sensitivity thresholds for flickering images presented at mid- and high-flicker rates – particularly when presented in the low-mesopic luminance range. The general pattern of differentiation between non-advanced AMD patients and matched controls on this test has remained relatively consistent over a 3-year longitudinal period. This suggests a repeatable test over time that can effectively serve as a reliable, reversible functional endpoint for future clinical trials for therapies aimed at treating non-advanced AMD. It also suggests relative stability in visual function for patients with non-advanced AMD over a period of 3 years.

ABSTRACT BODY:

Purpose: High quality, high volume international surgical sites implement a strategy of deskilling, or assigning well-circumscribed care tasks to personnel trained for this limited role, as a means of achieving cost savings. Our previous work has demonstrated personnel costs account for the largest categorical difference in cost of cataract surgery between international and US sites. This paper examines the extent to which deskilling strategies are available to US ophthalmic surgical practices by evaluating state differences in care tasks allowed to be performed by medical assistants. Engaging medical assistants to the full extent of their scope of practice could reduce personnel costs by optimizing care teams for skill mix and efficiency.

Methods: We defined seven central tasks in cataract surgery care, most of which are performed by mid-level ophthalmic providers at international eye hospitals. These tasks include taking a patient's vital signs, administering eye drops, collecting point of care glucose levels, inserting IVs, counseling patients on their surgery, and performing post-op monitoring. Using the American Association of Medical Assistants State Scope of Practice Laws, we determined which of these tasks are allowed, not allowed, and not addressed in regulations governing medical assistants' practice in each state.

Results: States varied in the extent to which each task is allowed to be carried out by lower level providers. New York and Washington have the greatest number of tasks allowed to be performed by medical assistants. The most commonly permitted tasks included IV insertion (48%) and taking vital signs (36%). 6% of states prohibit MAs from administering eye drops, while 28% either explicitly or possibly allow this. A few states remain silent on these issues in the official regulations, which begs the question of whether the services are permitted or excluded in MA scope of practice there.

Conclusions: Significant variation exists in state-by-state regulations of medical assistant activities. Understanding scope of practice of medical assistants in the United States will permit better integration of MAs into delivery of eye care and optimize cost and efficiency of cataract surgery.

ABSTRACT BODY:

Purpose: Normative data for human iris parameters is not well established, resulting in a lack of understanding of the association between quantitative iris features and presence of intraocular disease. The purpose of this study was to quantify iris thickness of pediatric subjects in ultrasound biomicroscopy (UBM) images using an optimized image processing protocol with high repeatability and reliability of measurements.

Methods: Eligible participants' parents were offered consent and subjects were enrolled prior to imaging. 86 images from 26 eyes in 14 healthy pediatric subjects (mean age 2.0+/-1.1yrs, median 1.8yrs, range 0.2-4.1yrs) were analyzed according to a prospective protocol. Two trained observers measured iris thickness on two axial and two longitudinal UBM images per eye in raw format and with image processing using edge detection. Image quality was graded by a trained ultrasonographer. Logistic regression was used to determine association between image features and consistency of measurements. Intraclass correlation coefficient (ICC) between observers was the outcome of interest. Covariates of interest were orientation (axial vs longitudinal), quality (good vs excellent), and processing (raw vs edge detection). Covariates contributing to improved ICC were used in UBM analysis to determine iris thickness stratified by age. Mean values were determined for ages <1yrs, 1-2yrs, and >2yrs. ANOVA was performed to see if there were statistically significant differences in thickness measurements based on age.

Results: Normative data for iris parameters were found to differ significantly by age strata (0-1yrs, 1-2yrs and 2-5yrs). Maximal iris thickness increased with age ($p<0.001$) while minimal and central iris thickness did not vary by age. ICC for these parameters ranged from 0.70-0.97. Preliminary results of multiple linear regression suggest that orientation and image processing were associated with improved ICC. Image quality was not significantly associated with ICC.

Conclusions: Iris measurement consistency is improved by use of longitudinal image orientation and edge detection in image processing. Normative data based on the optimized image analysis protocol suggests that iris thickness varies significantly with age.

TITLE: Contrast Sensitivity with Take-Home SpotChecks Test in Healthy Adults

SESSION TITLE: Fundamental and Applied Psychophysics and Color Vision

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Vu, H. Cheng, University of Houston College of Optometry, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure: Lien Vu: Commercial Relationship: Code N (No Commercial Relationship) | Han Cheng: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: SpotChecks is a newly designed disposable contrast sensitivity (CS) test that has a fine step change of 0.01 logCS and multiple versions. This study evaluated the repeatability of CS with take-home Spot-Checks, in-office Spot-Checks and near Pelli-Robson (PR) charts in healthy adults.

Methods: Thirty-nine healthy adults (age 22-84, mean 43±17, M:F = 21:18) participated in two office visits (7-66 days apart, mean 11±10 days) and an at-home component. Each visit included monocular high-contrast acuity and 12 different CS tests (6 SpotChecks and 6 PR charts in random orders) under the same lighting (luminance 110 cd/m2) all at near in the same eye with habitual correction. SpotChecks consists of 24 rows by 5 columns of 9 mm grey round spots on a white paper with contrast decreasing by 0.01 log units per spot (logCS ranges 0.90 to 2.09). At-home testing was self-administered SpotChecks once a day on six different days using the same eye. Subjects held the SpotChecks at a comfortable reading distance while marking spot positions with guessing encouraged. The third incorrectly marked spot determined threshold. PR charts were read at 40 cm and scored counting 0.05 for each letter read correctly then subtracting 0.15. Repeatability limit for two measurements was calculated as $\sqrt{2}*1.96*Sw$, Sw was within-subject standard deviation determined with one way analysis of variance. Limits of agreement (LOA) between single measurements of SpotChecks and PR were evaluated with Bland-Altman plots considering multiple observations per subject.

Results: Mean high contrast logMAR near acuity was -0.04±0.07, -0.03±0.08 for visit 1 and 2, respectively. Mean logCS from SpotChecks (1.90±0.08 visit 1, 1.92±0.09 visit 2, 1.93±0.09 home) was about 0.10 higher than that of PR (1.80±0.07 visit 1, 1.83±0.07 visit 2). Intravisit repeatability limit of logCS was similar between SpotChecks (0.13 visit 1, 0.14 visit 2) and PR (0.16 visit 1, 0.14 visit 2). Interday repeatability limit for take-home SpotChecks was 0.14, similar to that of intervisit SpotChecks (0.15) and PR (0.19). LOA between SpotChecks and PR was 0.10±0.19 for visit 1 and 0.09±0.20 for visit 2.

Conclusions: Take-home SpotChecks showed similar repeatability as in-office SpotChecks and PR charts. SpotChecks therefore has the potential to be used for self-monitoring of vision between office visits.

ABSTRACT BODY:

Purpose: To investigate if macular optical coherence tomography (OCT)/OCT angiography (OCTA) parameters demonstrate correlation with visual acuity (VA) in glaucoma eyes.

Methods: Pseudophakic primary open angle glaucoma eyes were included in this cross-sectional study. Foveal VD (fVD), parafoveal VD (pfVD), perifoveal VD (perifVD), and whole-image VD (wiVD) of both superficial and deep layers, and their corresponding GCC thicknesses were calculated from OCTA 6x6 mm^2 macular scans. The area and circumferences of foveal avascular zone (FAZ) and foveal density 300 (FD300) were also measured. Univariable and multivariable linear mixed model were performed to characterize the correlation between OCT/OCTA parameters and logMAR VA in different glaucoma severities.

Results: 144 eyes (mean age=80.0 years) were included. VA differed significantly between early (80 eyes, mean logMAR VA=0.05) and moderate-severe (64 eyes, mean logMAR VA=0.11) glaucoma groups (P=0.003). In the multivariable analysis of early glaucoma eyes, none of the OCT/OCTA parameters correlated with VA (P>0.05 for all). In the multivariable analysis of moderate-advanced glaucoma, greater FAZ area (β=0.228, P=0.035) and circumference (β=0.063, P=0.032) were associated with worse logMAR VA (R^2=0.11), but FD300 was not. Lower measurements of almost all GCC thicknesses, including superior hemifield thicknesses, were significantly associated with worse VA (β=0.002-0.003, P<0.05, R^2=0.11-0.33), except for the inferior hemifields of perifGCC and wiGCC. For superficial VD, lower superior hemifield perifVD (β=0.007, P=0.045) and lower superior hemifield wiVD (β=0.008, P=0.042) correlated with worse logMAR VA (R^2=0.11-0.12). For deep VD, only fVD was associated with worse logMAR VA (β=0.004, P=0.049, R^2=0.11).

Conclusions: Some macular OCT/OCTA parameters, particularly GCC thickness, FAZ area and circumference were associated with VA in moderate-advanced glaucoma, but not early-stage glaucoma. Superficial and deep VD showed region-dependent association with VA, indicating the potentially differential involvement of local vasculatures in VA performance.

ABSTRACT BODY:

Purpose: To compare geographic atrophy (GA) area and shape descriptors using fundus autofluorescence (FAF) annotation versus optical coherence tomography (OCT) annotation with complete retinal pigment epithelium and outer retinal atrophy (cRORA) criteria in cases of dry age-related macular degeneration (AMD).

Methods: Retrospective annotation of GA in FAF and OCT in a single timepoint. Primary outcomes: GA area, focality, perimeter, circularity and minimal distance from the center. The primary outcomes were compared between both modalities. Correlations of the primary outcomes on OCT with the difference in GA area between both modalities were analyzed using multivariate regression analysis.

Results: 30 pairs of FAF and OCT scans from 30 eyes of 18 patients with dry AMD were included. The mean total GA area measured 8.77±4.38 mm^2 with FAF and 2.78±3.39 mm^2 with OCT ($P<0.0001$). The mean FAF-OCT area difference was 5.99±4.22 mm^2. Multivariate regression analysis revealed a significant correlation between the FAF-OCT area difference and GA focality and minimal distance from the center on OCT (adjusted $r^2 = 0.66$).

Conclusions: This study quantitatively measured and compared GA area using fundus autofluorescence as compared to OCT. The mean GA area measured on OCT was 3.15 times smaller than that on FAF. FAF-OCT area difference correlated with GA focality and minimal distance from the center on OCT. Further research is needed to establish the clinical application of these findings.

ABSTRACT BODY:

Purpose: The ability to detect progression in eyes with advanced glaucoma is challenging because of known limitations of commonly used structural and functional parameters reaching their minimal measurable limit (floor effect) or increased measurement variability. We examined the ability of inner nuclear layer (INL) thickness measurements to demonstrate change longitudinally in eyes with early and advanced severity glaucoma.

Methods: Subjects with glaucoma and ≥4 visits were included in the study. Subjects in the “Early/Moderate” group (EG) had average circumpapillary retinal nerve fiber layer (cRNFL) thicknesses ≥60µm and subjects in the “Advanced” group (AG) had average cRNFL thicknesses ≤60µm. All subjects had comprehensive ophthalmic examination, Humphrey visual field (Zeiss, Dublin, CA) testing, and spectral-domain OCT (Cirrus HD-OCT; Zeiss) optic nerve head (ONH) and macula scans. Segmentation of the INL was performed using the Iowa Reference Algorithms (Retinal Image Analysis Lab, Iowa Institute for Biomedical Imaging, Iowa City, IA) and segmentation errors were manually corrected by a trained grader. Overall INL thickness along with the superior and inferior hemifields were used for analysis. Rates of progression were estimated from longitudinal OCT and visual field (VF) data using mixed effects models adjusting for baseline age, follow-up duration, and signal strength at each visit.

Results: 23 eyes (23 subjects), 12 with EG and 11 with AG, were included in the study. At baseline, a statistically significant difference between groups was detected in MD, cRNFL, and GCIPL thicknesses (Table 1). In EG eyes, the rate of change was significantly different than a zero slope for cRNFL thickness, C:D ratio, and GCIPL thickness (Table 2). Inferior INL thickness was the only INL parameter showing significant rate of change. However, in the advanced group, all parameters (including both global and sectoral INL thicknesses) showed significant rate of change except for the cRNFL.

Conclusions: Longitudinal measurements of INL thickness may be useful for following disease progression in subjects with advanced-stage glaucoma where cRNFL thickness is no longer useful.

Commercial Relationships Disclosure: Xu Cheng: Commercial Relationship(s);Code E (Employment):Johnson & Johnson Vision;Code P (Patent):Johnson & Johnson Vision | Pete Kollbaum: Commercial Relationship(s);Code F (Financial Support):Johnson & Johnson Vision | Raman Prasad Sah: Commercial Relationship(s);Code F (Financial Support):Johnson & Johnson Vision | Dawn Meyer: Commercial Relationship(s);Code F (Financial Support):Johnson & Johnson Vision | Mona Almaghshi: Commercial Relationship(s);Code C (Consultant/Contractor):Johnson & Johnson Vision | Jing Xu: Commercial Relationship(s);Code C (Consultant/Contractor):Johnson & Johnson Vision | Noel Brennan: Commercial Relationship(s);Code E (Employment):Johnson & Johnson Vision;Code P (Patent):Johnson & Johnson Vision

ABSTRACT BODY:

Purpose: Accommodation of the eye in response to multifocality of a lens may impact the myopia control efficacy of the lens. A soft contact lens (SCL) with the RingBoost^{TM} technology (RB) was designed to maximize myopia control effect without affecting normal accommodation of the eye. The study evaluated accommodative response (AR) of the RB lens by comparing with other SCL and spherical spectacle (SL) corrections.

Methods: The study was double-masked with a cross-over design. AR of 10 adults (18-24 yrs) was assessed with bilateral wear of SL at baseline and four SCLs of different designs in random order: single-vision (SV), dual-focus (DF), center-distance multifocal (MF), and RB. Refractive states (RS) of the subject's right eye under four levels of target vergences (TV) between 0.25 and 4.59 D were determined based on spherical equivalent power measured by an open-field auto-refractor (GS) and Shack-Hartmann wavefront aberrometry (under natural pupils) with three analytical methods: minimum wavefront RMS (minRMS), best-sphere fit to the wavefront (MTR), and paraxial focus (PF). Slopes of accommodative responses (SAR) were obtained from linear fit of RS to TV and compared among lens types.

Results: AR of RB, DF, MF, SV, and SL by four refractive methods are provided in Figure 1. Results varied by method of RS determination and lens type. SARs (D/D) of RB were not significantly different from SV with all four refractive metrics ($p>0.05$) and was statistically larger than SL with minRMS by 0.13 (95%CI: 0.05, 0.21). SARs of DF were statistically smaller than SV with MTR and minRMS but larger than SV and SL with GS ($p<0.05$). SARs of MF were statistically smaller than SV and SL with all four metrics ($p<0.05$) except for PF when compared to SV ($p>0.05$). Compared to DF, SARs of RB were statistically larger by 0.13 (0.05, 0.22) and 0.11 (0.03, 0.19) with minRMS and MTR, respectively, but smaller with GS by 0.09 (0.03, 0.15).

Conclusions: This exploratory study demonstrated interpretation of accommodative response differed by method of RS determination. However, across all metrics, RB lens had similar or better AR than single-vision corrections. AR measured with the open-field auto-refractor provided largely consistent results with those of wavefront-based methods except with DF. Optimal method to quantify RS in myopia control lenses requires further investigation.

Commercial Relationships Disclosure: Christopher Rosenberg: Commercial Relationship: Code N (No Commercial Relationship) | Travis Redd: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Infectious keratitis (IK) is a major cause of blindness. Clinical recognition of the underlying cause of infection is necessary to guide empiric treatment but is often difficult even for cornea specialists. Our prior work showed India-based experts were significantly better than an international cohort at differentiating Indian cases of bacterial and fungal keratitis (BK/FK) on an image-based test. FK is much more common in tropical regions like India compared to more temperate environments like much of the US and Europe. In this secondary analysis, we explored whether this difference in performance could be explained by regional variability in FK burden.

Methods: We used a test set of 100 culture-proven photos of IK, 50 each of FK and BK. 66 cornea specialists from 16 countries (Table 1) graded each image, providing a predicted probability of FK or BK. Area under the curve (AUC) was calculated as the primary performance metric for each respondent. Because FK prevalence data are not available in most regions, the following known risk factors were used as surrogates of FK burden: tropical climate (based on latitude, average annual temperature, and dew point) and agricultural work (based on percent of gross domestic product). These predictors were incorporated into a multivariate linear regression model along with local (Indian) vs. external (non-Indian) practice location to predict respondent AUC.

Results: Bivariate analyses showed significant associations between AUC and Indian practice location ($P<0.01$), latitude ($P<0.01$), agricultural economy ($P<0.01$), dew point ($P=0.01$), and average temperature ($P<0.01$). However, multivariate regression revealed that only Indian practice location was statistically significant after controlling for all other predictors ($P=0.01$).

Conclusions: Local experts remained significantly better at differentiating Indian cases of FK and BK compared to their international counterparts, regardless of regional variability in FK burden. Future work should determine whether similar regional effects occur elsewhere, or if India-based cornea specialists are simply better at this task due to the extraordinarily high volume of IK in their patient population. The results may inform educational efforts to enable earlier initiation of appropriate antimicrobial therapy and improved visual outcomes.

ABSTRACT BODY:

Purpose: The human gut microbiome is a complex ecosystem and refers to the combined genetic material of microorganisms in the gut. The gut microbiome has many important physiological functions, such as promoting digestion and absorption of nutrients, regulating the function of the immune system or synthesizing vitamins and amino acids. Dysbiotic conditions can favor invasion and growth of pathogenic species and can disrupt immune homeostasis, thus potentially induce diseases. In this study we investigated compositional alterations of the gut microbiome in patients with recent onset acute anterior uveitis (AAU).

Methods: Twenty three patients with recent onset AAU without therapeutic intervention were included. Twenty three individuals with no history of uveitis were included. The metagenomic DNA was analyzed in stool samples using the TruSeq DNA PCR-Free Library Preparation kit for library preparation and the Illumina NovaSeq 6000 platform for sequencing. HLA-B*27 genotypes were confirmed by allele-specific PCR.

Results: Mean age of both groups was 46 years with a matched female to male ratio. The taxonomical features and compositional difference between both groups will be presented. To identify taxonomic and functional features with significantly different relative abundances between both groups and to identify associations with clinical metadata, the multivariate association between by linear models (MaAsLin) R package was applied using default settings. A difference was considered to be statistically significant if $q < 0.20$ after adjusting for false discovery rate (Benjamini-Hochberg)

Conclusions: The development of noninfectious anterior uveitis may be influenced by compositional alterations of the intestinal microbiome. Possible mechanisms include antigenic mimicry, destruction of the intestinal barrier and priming of immune cells.

TITLE: The Association Between Glaucoma and Cardiovascular Disease in the Elderly California Medicare Population

SESSION TITLE: Glaucoma epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Emami, University of California Los Angeles David Geffen School of Medicine, Los Angeles, California, UNITED STATES|F. Yu, A.L. Coleman, Ophthalmology, UCLA Stein Eye Institute, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Sara Emami: Commercial Relationship: Code N (No Commercial Relationship) | Fei Yu: Commercial Relationship: Code N (No Commercial Relationship) | Anne Coleman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Glaucoma and cardiovascular disease (CVD) are common in the elderly population. Although a few studies have proposed both conditions to share pathophysiologic mechanisms, inconsistent findings on their relationship exist in the literature. Thus, we performed a cross-sectional study to investigate the association between glaucoma and CVD in the 2019 California (CA) Medicare population.

Methods: Using the 2019 CA Master Beneficiary Summary File and Standard Analytic Files of Part B Carrier Claim data files from the Centers for Medicare and Medicaid Services, patients with International Classification of Diseases, Tenth Revision (ICD-10) diagnosis codes for glaucoma were identified. Inclusion criteria were 65 years or older, CA residence, coverage with both Medicare Part A and B, and at least one Part B claim in 2019. The comparison group included all CA Medicare beneficiaries without glaucoma diagnosis. Demographic characteristics including age, sex, and race/ethnicity were extracted, along with Charlson Comorbidity Index (CCI) that served as an indicator for systemic comorbidities. The main outcome was CVD, which was defined by having at least one ICD-10 diagnosis code for the following: ischemic heart disease, congestive heart failure, valvular disease, angina, arrhythmias, myocardial infarction, stroke, cardiac arrest, or tamponade. Logistic regression models were performed to assess the association between glaucoma and CVD after adjusting for potential confounders mentioned above.

Results: Among 2,717,346 patients who met the inclusion criteria, 411,099 (15%) had a glaucoma diagnosis. Glaucoma beneficiaries were more likely to be between the ages of 70 to 74 (24%), female (60%), white (58%), and had a CCI score of 1 to 2 (36%). Moreover, 188,458 (46%) glaucoma beneficiaries had a CVD diagnosis. On univariate analysis, glaucoma beneficiaries had a statistically significant increased odds of having CVD (odds ratio [OR]=1.38, $P<0.001$) compared to their non-glaucoma counterparts. After adjusting for confounders in the multivariable analysis, the association remained statistically significant (aOR=1.12, $P<0.001$).

Conclusions: This study found glaucoma to be associated with CVD in the 2019 CA Medicare population. Further studies are needed to elucidate the mechanism that links the two diseases, and determine if glaucoma patients may benefit from early interventions for prevention of CVD.

ABSTRACT BODY:

Purpose: Phosphatidylinositol phosphates (or PIPs) have emerged as key regulators of diverse cellular processes including membrane trafficking, receptor tyrosine kinase signaling, and cytoskeleton dynamics. However, the regulation of PIP metabolism in RPE cells has been rarely investigated. We have reported that βA3/A1-crystallin, an ocular moonlighting protein with diverse functions interacts with a phosphatidylinositol transfer protein-PITPβ. In this study, we examined their effect on PIP-metabolism in RPE cells.

Methods: Cryba1 (encoding βA3/A1-crystallin) RPE conditional KO (cKO) mice and Cryba1$^{fl/fl}$ control mice were used in this study. RPE explant cultures isolated from either wildtype C57BL/6J mice or transgenic mice were utilized for in vitro RPE studies. RNA-seq was performed to examine the changes in transcriptome profile in RPE cells overexpressing βA3/A1-crystallin. Immunoprecipitation studies were utilized for detecting the interaction between βA3/A1-crystallin and PITPβ. The expression of proteins involved in EGFR (epidermal growth factor receptor) activation and PLCγ1 (phospholipases C gamma 1) signaling were detected by western blotting. The PIP fraction was isolated from RPE tissue and PIP levels were determined by ELISA.

Results: RPE cells overexpressing Cryba1 have decreased expression of genes involved in inositol phosphate metabolism, such as phosphatidylinositol phosphatases and kinases, and phospholipases. βA3/A1-crystallin interacts with PITPβ in polarized RPE cells, and the binding was more significant when cells were stimulated with EGF. Both PI(4,5)P2 and PI(3,4,5)P3 were significantly reduced, and the EGFR activation was compromised in RPE cells lacking βA3/A1-crystallin. In Cryba1 cKO RPE cells overexpressing βA3/A1-crystallin, EGFR activation was rescued and the PI(3,4,5)P3 level was upregulated, although the PI (4,5)P2 was not increased. PLCγ1 activity was found to be negatively correlated with βA3/A1-crystallin in RPE cells. Moreover, PITPβ overexpression stimulates PLCγ1/PKC activity and inhibits EGFR activation, but RPE flatmounts overexpressing both βA3/A1-crystallin and PITPβ showed no significant changes of PLCγ1/PKC activity or EGFR activation.

Conclusions: The data suggest an important role for βA3/A1-crystallin and PITPβ in the regulation of PIP metabolism, particularly in regulating PLCγ1 activity in the turnover of PI(4,5)P2 in RPE cells.

ABSTRACT BODY:

Purpose: An intact epithelium is key to maintaining corneal integrity and barrier function. Bacterial keratitis and diabetes are among the conditions that can compromise the corneal epithelium leading to impaired wound healing and sight-threatening opacity. Electrical cell-substrate impedance sensing or ECIS® is a non-invasive method to measure real-time cellular behaviors such as barrier function and cell migration. The current study optimizes human corneal epithelial cells as assessed by ECIS® to generate quantifiable measurements that more accurately reflect changes in cell behavior and prove as a more advanced assay to monitor cells in vitro.

Methods: Human telomerase-immortalized corneal epithelial cells (HUCLs) were used to optimize the ECIS® system. Cells were placed in either K-SFM or DMEM+F12 media (37 degrees Celsius, 5% CO_2). Five cell densities (30,000 – 500,000 cells/well of a 96-well plate) were used to determine the optimal seeding density for ECIS® monitoring of cellular behavior over time. Parameters of assessment included: overall impedance (Z), barrier resistance (R), and cell capacitance (C). Mathematical modeling of the R data further generated R_b, α, and C_m values. ARPE-19 cells were used as a control.

Results: Impedance, resistance, and cell capacitance measurements revealed DMEM+F12 at 60,000 cells as the optimal condition for ECIS® assessment. This was further supported by logarithmic curves that reached a cell migration plateau (time to confluency) at 8h with DMEM+F12 compared to 14h with K-SFM; and resistance and capacitance ratios with optimal cell migration slope and plateau achieved with DMEM+F12 at 60,000 cells compared to all other groups. Additionally, ECIS® modeling analysis indicated the contribution of α (basolateral adhesion), R_b (paracellular junctional space), and C_m (membrane capacitance) to overall barrier function were significantly improved for DMEM+F12 compared to K-SFM.

Conclusions: Our results consistently demonstrated that 60,000 cells are an optimal seeding density for ECIS® analysis of HUCLs. Further, DMEM+F12 media provided better growing conditions, allowing for enhanced barrier function compared to widely used K-SFM. This work highlights the sensitivity of the ECIS® biosensor technology and the importance of optimizing not only cell density but media used for in vitro culturing.

ABSTRACT BODY:

Purpose: Staphylococci are among the most frequently reported causative bacteria in ocular infections, and antibiotic resistance in these pathogens can complicate treatment. The Antibiotic Resistance Monitoring in Ocular micRoorganisms (ARMOR) study is a nationwide surveillance study on in vitro antibacterial resistance levels among ocular pathogens now in its 13th year. Here, we examined resistance trends over time among staphylococcal isolates collected from 2009 through 2021 to date in ARMOR.

Methods: Each year as part of ARMOR, Staphylococcus aureus and coagulase-negative staphylococci (CoNS) from ocular infections were collected and sent to a central laboratory for species confirmation. Minimum inhibitory concentrations (MICs) were determined for up to 16 different antibiotics and interpreted as susceptible/resistant based on Clinical and Laboratory Standards Institute methods and breakpoints. Longitudinal trends in resistance were evaluated using Cochran-Armitage tests for linear trends in a proportion.

Results: A total of 2847 S. aureus and 2416 CoNS were included in this analysis. Over the 13-year collection period, methicillin/oxacillin resistance decreased among both S. aureus (39 to 37%; P<0.001) and CoNS (53 to 37% P=0.003). Decreases in resistance were also observed for azithromycin (62% to 53%), ciprofloxacin (39% to 31%), and tobramycin (24% to 12%) among S. aureus, and for ciprofloxacin (46% to 20%) among CoNS (P<0.001 for all). In contrast, increases in resistance were noted for chloramphenicol among S. aureus (6% to 34%; P<0.001) and for trimethoprim among CoNS (26% to 29%; P=0.044). Of staphylococci collected in 2021 specifically, >80% of methicillin-resistant isolates exhibited multidrug resistance (≥3 antibiotic classes). Cumulative besifloxacin MIC_{90}s (1 µg/mL for S. aureus and 2 µg/mL for CoNS) were 4- to 128-fold lower than other fluoroquinolones and comparable to vancomycin.

Conclusions: Analyses of antibiotic resistance among staphylococci collected over 13 years in ARMOR indicate that in vitro resistance has decreased only slightly over this timeframe for several antibiotics and is still prevalent in 2021. Although the clinical relevance of in vitro data is unclear without consideration of the ocular pharmacokinetics of tested antibiotics, these findings warrant attention when choosing empiric therapy for the management of ocular staphylococcal infections.

ABSTRACT BODY:

Purpose: In a randomized trial comparing overminus versus non-overminus spectacles in children with intermittent exotropia (IXT), we found that overminus spectacles improved distance IXT control but also increased myopic shift at 1 year (-0.42D in 189 overminus vs -0.04D in 169 non-overminus participants, respectively; adjusted difference = -0.37D; 95% CI = -0.49 to -0.26). (Chen et al, JAMA Ophthalmol 2021;139(4):464-476) We now report refractive error change over 3 years in a post-RCT subcohort.

Methods: 386 children 3 to 10 years old with IXT and spherical equivalent (SE) refractive error between -6.00 diopters (D) and +1.00D were randomly assigned to overminus spectacles (-2.50D over cycloplegic refraction for 12 months, -1.25D for 3 months, then non-overminus for 3 months) or non-overminus spectacles for 18 months. 221 participants (124 of 196 [63%] in overminus; 97 of 190 [51%] in non-overminus) re-enrolled for 2- and 3-year follow-up, with IXT treatment at investigator discretion. Refractive error was determined by cycloplegic retinoscopy.

Results: The 3-year visit was completed by 83% (103 of 124) of participants in the overminus group and 88% (85 of 97) in the non-overminus group. Between 1 to 3 years, mean myopic shift was -0.37D in both groups (SD = 0.68 in overminus; SD = 0.67 in non-overminus). The mean overall change in refractive error from baseline to 3 years was greater in the overminus group (-0.82D) vs the non-overminus group (-0.46D; adjusted difference = -0.43D; 95% CI = -0.68 to -0.19), with 30% (30 of 101) in the overminus group vs 16% (13 of 83) of the non-overminus group having >1D of myopic shift over 3 years (risk ratio = 1.9; 95% CI = 1.0 to 3.6). Risk ratios for developing >1D of myopic shift over 3 years between overminus and non-overminus groups were 2.7 (95% CI= 1.4 to 6.0; 78% vs 29%) in 46 participants with baseline myopia (SE -0.50D to -6.00D), 2.6 (95% CI = 0.9 to 20.3; 36% vs 14%) in 58 emmetropes (SE -0.375D to +0.375D), and 1.1 (95% CI = 0.2 to 10.9; 7% vs 6%) in 78 with low hyperopia (SE +0.50D to 1.00D) at baseline.

Conclusions: While the greater myopic shift that occurred during 1 year of overminus lens treatment was still present at 3 years, the myopic shift during the 2 years after treatment cessation was similar in both groups. The risk of prolonged myopic shift should be discussed with parents when considering overminus lens treatment.

Commercial Relationships Disclosure: Marc-André Dubois: Commercial Relationship: Code N (No Commercial Relationship) | Charles-Antoine Pelletier: Commercial Relationship: Code N (No Commercial Relationship) | Marc Hébert: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The aim of this project is to replicate the study of Brûlé et al., 2007, which shows a decreased amplitude of electroretinogram in men of about 30%, but this time using much less invasive dermal electrodes than the traditionally used DTL electrodes.

Methods: Full-field photopic and scotopic ERGs were performed with an Espion E3 system (Diagnosys LLC, Lowell, MA). Recordings were obtained in nondilated eyes using self-adhesive skin electrodes (LKC Technologies, Gaithersburg, MD) applied 2 mm below the eyes. ERGs were performed in 25 subjects (16 women [27.1 +/- 4.7 years]; 9 men [28.1 +/- 4.8 years]). The photopic ERG was performed with a background light set at 80 cd/m2 and using 7 white flashes (luminance ranging from 1.33 to 50 cd.s/m2). The scotopic condition was performed after 20 minutes of dark adaptation using 12 green flashes (peak: 509 nm) (luminance ranging from 0. 001778 to 1 cd.s/m2). Each flash intensity was repeated twice (20 flashes per trial) and averaged for both eyes.

Results: In photopic conditions, and at the intensity allowing maximum amplitude (7.5 cd.s/m2), men (M) demonstrated when compared to women (W), an 18% lower cone a-wave amplitude (p=0.017 [M mean=-7.9; s.d.=1,3 mV] [W mean=-9,9 mV; s.d.=2,4 mV]) and a 23% lower cone b-wave amplitude (p=0.002 [M mean=36,6 mV; s.d.=7,2 mV] [W mean=47,6 mV; s.d.=8,8 mV]). In scotopic conditions and at the intensity allowing maximum pure rod response (0.1 cd.s/m2), men demonstrated a 24% lower b-wave amplitude (p=0.001 [M mean=60,8 mV; s.d.=8,4 mV] [W mean=80,2 mV; s.d.=15 mV]. At the maximum intensity used (1 cd.s/m2), men exhibited a 25.5% lower mixed cone and rod b-wave amplitude (p<0.001 [M mean=69,9 mV; s.d.=10 mV] [W mean=93,8 mV; s.d.=14,8 mV]).

Conclusions: The data obtained replicate those shown by Brûlé et al., 2007. More and more researchers are interested in using the ERG to detect biomarkers in mental health. The present project demonstrates the importance of considering biological sex in this field. The difference in ERG amplitudes between men and women increases the variability within groups when not accounted for, reducing the overall statistical power of the projects. The data also validates the use of the less invasive dermal electrodes, as they replicate the results obtained with traditional DTL electrodes, albeit smaller amplitudes are achieved which is not a concern when investigating a normal eye.

TITLE: IL-1β initiates and sustains inflammation between hMC and hRMEC

SESSION TITLE: Cell biology of retinal diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Ontko, Molecular Physiology and Biophysics, Vanderbilt University School of Medicine, Nashville, Tennessee, UNITED STATES|D. Padovani-Claudio, J. Penn, Ophthalmology and Visual Sciences, Vanderbilt University Medical Center, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure: Cayla Ontko: Commercial Relationship: Code N (No Commercial Relationship) | Dolly Padovani-Claudio: Commercial Relationship: Code N (No Commercial Relationship) | John Penn: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Inflammatory cytokines are elevated in the retina/vitreous in DR pathogenesis and levels correlate with retinopathy severity and progression. Human Müller cells (hMC) and human retinal microvascular endothelial cells (hRMEC) are proposed to be sources of inflammatory cytokines, such as TNFα and IL-1β, in DR. Evidence indicates that IL-1β is a multifunctional inflammatory cytokine and a primary trigger of the neuro-inflammatory cascade in DR, and IL-1RA, an IL-1 receptor antagonist, may dampen its effects. This study tests the hypothesis that (1) reactive glia serve as an important source of inflammation in DR and (2) IL-1β, among other inflammatory mediators, acts to both initiate and sustain tissue inflammation in DR.

Methods: Primary hMC were treated in serum-depleted media with 1ng/mL IL-1β or 1ng/mL TNFα for 2h to simulate DR inflammation (n=4). Media were replaced with FBS-containing EBM for 6h to generate conditioned media (CM). hRMEC were pretreated +/- IL-1RA for 2h. hMC derived-CM was transferred onto HRMEC +/- 10ng/mL IL-1RA for 4h. Relative expression of inflammatory mediators was analyzed via qRT-PCR, and ANOVA with Tukey's multiple comparisons test was used to evaluate significant differences among treatment groups.

Results: CM generated by hMC + IL-1β, not hMC + TNFα, caused hRMEC to increase gene expression of inflammatory cytokines TNFα, IL-1β, IL-6 and IL-8, and adhesion molecules ICAM-1, VCAM-1, and E-selectin significantly ($p<0.0001$). IL-1RA significantly reduced expression of TNFα (49%, $p=0.0006$), IL-1β (37%, $p=0.005$), IL-6 (24%, $p=0<0.001$), IL-8 (26%, $p=0.0013$), ICAM (19%, $p=0.0028$) and VCAM (42%, $p=0<0.0001$) in hRMEC treated with IL-1β-stimulated CM, but did not significantly alter their levels in hRMEC treated with TNFα-stimulated CM.

Conclusions: CM from IL-1β-stimulated hMC causes hRMEC to react in a proinflammatory manner, confirming our hypothesis that reactive glia elicit inflammatory responses from retinal endothelium. This was not the case for CM from TNFα-treated hMC, indicating an essential role for IL-1β in initiating inflammatory amplification in hMC and subsequent vascular inflammation. Moreover, IL-1RA significantly decreased the effects of hMC-CM on hRMEC, suggesting that IL-1β contributes a dominant share of the inflammatory capacity of hMC CM. These findings indicate that IL-1β both initiates and sustains retinal inflammation, underscoring its potential as a therapeutic target in DR.

ABSTRACT BODY:

Purpose: The complement system is a well-known modulator of risk for age-related macular degeneration (AMD), a progressive, blinding disease. But few treatments are available because the causal regulatory pathways connecting systemic inflammation, lipids, and AMD are poorly understood. In Mendelian Randomization (MR), reports from independent genome-wide association studies (GWAS) are jointly analyzed to discover exposures that have direct effects on an outcome, and which may not yet be known. Genetic proxies for cholesterol can be statistically tested at a large scale to pinpoint the causal effects of exposures on AMD.

Methods: The MRC IEU OpenGWAS Database was mined for associations between exposure phenotypes containing cholesterol keywords and outcome of advanced AMD from the 2016 International Age-related Macular Degeneration Consortium GWAS. The consortium encompassed 12,711 cases, including the Age-Related Eye Disease Studies (AREDS and AREDS2), and 14,590 controls of European descent. Two studies were used for three exposures (HDL and total cholesterol: 297,626 controls; LDL: 283,251 controls).

Results: All cholesterol phenotypes were found to have strong effects on advanced AMD by MR Egger tests: 47 SNPs were reported for HDL association, 55 for LDL, and 43 for total cholesterol. Overall effect size for HDL was 1.83 (s.e. = 0.37, p = 1.21E-05). Each + mg/dL HDL in blood plasma approximately doubled risk of developing advanced AMD. LDL and total cholesterol were significant but moderated: -0.43 (s.e. = 0.19, p = 3.11E-02), -0.96 (s.e. = 0.35, p = 8.34E-03). One SNP was shared between HDL and LDL: rs429358 in APOE (Apolipoprotein E), an essential metabolizer of triglyceride-rich lipoprotein. In single-SNP MR (LDL, Wald test) this had an effect size of -1.78 (s.e. = 0.13, p = 1.35E-41).

Conclusions: As reported from independent GWASes, genetic instrumental variables for high HDL conferred significant risk to develop advanced AMD, while lowering of LDL or total cholesterol reduced risk. Elevated HDL or too-low LDL may trigger a local inflammatory response causing irreparable macular damage over time. All three types are metabolically interrelated, and it is advisable to consider patient cholesterol levels when evaluating disease risk. MR can decipher the etiology of complex eye diseases by pointing to the most effective targets to lower risk of progression.

ABSTRACT BODY:

Purpose: Previously we have shown that human retinal ganglion cells (hRGC) can be derived from human embryonic stem cells using organoid approach. These neurons survive and grow neurites following subretinal transplantation in mice. The translation of cell therapy relies on the opportunity to cryopreserve large numbers of cells to make them accessible for pre-clinical/clinical studies and further application. There are no gentle protocols available for banking of organoid-derived RGCs.

Methods: Here we selected 7 commercially available DMSO-free cryopreservation agents (CPAs) [Bambanker(BB), ReproCryo, FREEZEstem, Stem-cellbanker(SC), CryoSoFree, CryoScarless, and pZerve) and tested if they can maintain the viability of human stem-cell-derived RGCs and astroglia cells after freeze-thaw. Two DMSO-free (SC and BB) and one DMSO-based [Cellbanker-1(CB)] formulations were used for further investigation. Cell viability, cell recovery, proportion of cells with neurites and neurite length after re-plating in vitro was recorded 48 hours post-thaw. Immediate transplantation of RGCs after thawing was conducted with histological assessment at 3 days for cell quantification and neurite analysis. Non-frozen hRGCs (RGC media) were used as a positive control in all experiments.

Results: Relative to RGC media, the cell count per well was higher in DMSO-based CPA compared to DMSO-free CPA: 147% (CB), 73% (SC), and 65% (BB). Post-thaw RGC viability, however, was comparable across all three CPAs: 54% (BB), 41% (CB), 39% (SC) and 70% (RGC media). Furthermore, a comparable proportion of RGCs recovered their ability to grow neurites when cryopreserved using DMSO-free CPAs or DMSO-based CPA: 80% (SC), 66% (BB), 73% (CB) and 62% (RGC media). Neurite length at 48 hours post-thaw was comparable among all groups:161 µm (SC), 134 µm (BB), 181 µm (CB), and 146 µm (RGC media). Lastly, the xenotransplantation studies highlighted that cryopreserved RGCs survive and grow neurites: RGC media (100% engraftment rate; 64% neurite growth rate), both CB and BB (67% engraftment rate; 33% neurite growth rate), and SC (33% engraftment rate; 0% neurite growth rate).

Conclusions: Early results signify that DMSO-based and DMSO-free CPAs could be an acceptable alternative for RGC cryopreservation as these protocols maintain high cell viability upon recovery and engrafted RGC extend neurites following transplantation.

TITLE: Clinical Outcomes in Exudative Macular Degeneration: A Prospective Study of Patients with Care Delay Due to the COVID-19 Pandemic

SESSION TITLE: Retina epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Janetos, R. Zandi, D. Younessi, G. Johnson, A. Randolph, M. Gill, Ophthalmology, Northwestern University Feinberg School of Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Timothy Janetos: Commercial Relationship: Code N (No Commercial Relationship) | Roya Zandi: Commercial Relationship: Code N (No Commercial Relationship) | David Younessi: Commercial Relationship: Code N (No Commercial Relationship) | Gina Johnson: Commercial Relationship: Code N (No Commercial Relationship) | Amber Randolph: Commercial Relationship: Code N (No Commercial Relationship) | Manjot Gill: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: During the emergeing COVID-19 pandemic, patient care was delayed due to clinic closures and patient hesitancy in seeking necessary care. We aimed to characterize clinical outcomes of exudative macular degeneration (AMD) patients who had delay in their care. As the uncertainly of the pandemic unfolds, this study aims to inform clinical decision making on future care delay decisions.

Methods: Patients with a chart diagnosis of exudative AMD who had an appointment canceled from 3/16/20 through 5/4/20 were selected. This timeframe encompassed the official clinic closure and a time during which many patients self-delayed care. Patients with concurrent macular disease were excluded. Data from each ophthalmology encounter was collected from 3/1/2019 through 7/1/2021. A linear longitudinal multilevel model was used to model best-corrected visual acuity (BCVA) over time. Time varying covariates included injection at visit, presence of subretinal fluid, intraretinal fluid, geographic atrophy, and macular hemorrhage. Baseline covariates included age, race, sex, treatment interval, treatment vs. observation, delay interval, anti-VEGF agent, baseline subretinal fluid, intraretinal fluid, and geographic atrophy, prior PDT, and smoking status.

Results: 161 eyes encompassing 2,555 ophthalmology encounters were selected. An initial model without addition of time varying or baseline predictors show a daily change in BCVA of 0.00151 logMAR ($p = 0.05$) over the study period. The pre-closure BCVA daily change was lower than the post-closure suggesting vision dropped at a faster rate after care delay, however this was not statistically significant (Figure 1). With time varying and baseline covariates added, intraretinal fluid status at baseline was the only statistically significant factor that predicted a larger BCVA slope ($p=0.05$).

Conclusions: Initial data suggests that BCVA fell during the time period, but there was no significant difference between the pre-closure and post-closure data. Patients with intraretinal fluid at baseline may potentially have worse long-term visual outcomes if care is delayed. Further model refinement needs to be undertaken prior to any definite conclusions.

ABSTRACT BODY:

Purpose: This work employs a theoretical model of the human retina to predict blood flow and tissue oxygenation in retinal vessels and tissue for varied levels of intraocular pressure (IOP) and in the presence or absence of blood flow regulation.

Methods: A previously established hybrid model of the human retina, which includes a heterogeneous representation of retinal arterioles and a compartmental representation of capillaries, small venules, and large venules, is adapted here to include blood flow regulation mechanisms in response to changes in mean arterial pressure, shear stress, and metabolism. One of the four main branches of the retinal arterioles is simulated here to reduce computational expense; behavior in the remaining branches is similar. A Green's function method is used to model oxygen transport in the arterioles, and a Krogh cylinder model is used in the capillaries and venules. The model is simulated for a healthy or elevated level of IOP (15 and 25 mmHg, respectively). Additionally, the model is used to simulate retinal tissue oxygenation when all regulation mechanisms are present or absent.

Results: The impact of IOP is depicted in the first and second rows of Figure 1. The model predicts a 6% decrease in tissue oxygenation as IOP is increased from 15 to 25 mmHg. A greater decrease of 11% is predicted in tissue oxygenation when the flow regulation response mechanisms to pressure, shear stress, and metabolism are inhibited, as shown in the first and second columns of Figure 1.

Conclusions: This study demonstrates the utility of a mathematical model of the human retinal vasculature to identify factors that impact the oxygenation and health of the human retina. Specifically, this model demonstrates that both increased IOP and impaired flow regulation mechanisms can cause decreased retinal tissue oxygenation. Importantly, the heterogeneity of the vascular network demonstrates that average values of tissue partial pressure of oxygen (PO_2) levels hide significant localized defects in tissue oxygenation that may be involved in retinal health and ocular disease.

ABSTRACT BODY:

Purpose: To characterize the pupil light reflex (PLR) for small focal chromatic light stimuli in 125 cognitively normal middle-aged subjects at high risk for Alzheimer's disease (AD), due to family history and 61 controls.

Methods: 186 subjects were enrolled, 125 offspring of AD patients (FH+) and 61 age-matched controls (FH-), ages 44-71. Ophthalmic assessments included a Chromatic Pupilloperimetry test and a complete ophthalmologic examination to exclude ocular pathologies. Cognitive assessment, to verify subjects were asymptomatic, included executive function and episodic memory tests. 35 pupilloperimetry features were measured in 54 spots in a 24-2 visual field. Machine learning classification models were trained such that each model was introduced to a single feature type (measured in 54 spots) in the training data, and the same hyperparameters and training protocol were used in all models. Each model was then tested to quantify how well it can discriminate between FH+/FH-. The accuracy of a model was used as an indication of the correlation of a feature type to AD family history, using a standard confidence interval (CI) of 95%.

Results: Chromatic pupilloperimetry-based learning models were highly discriminative in differentiating subjects with and without AD family history, using short focal red (primarily cone-mediated), and dim blue (primarily rod-mediated) light stimuli. Features associated with transient PLR latency achieved Area under the Receiver Operating Characteristic Curve (ROC AUC) of 0.90 ± 0.051 (left-eye) and 0.87 ± 0.048 (right-eye). Parameters associated with the contraction arm of the transient PLR were more discriminative compared to parameters associated with the relaxation arm.

Conclusions: Chromatic pupilloperimetry differentiated between individuals at high risk for AD due to a parental family history from those without AD family history, with high sensitivity and specificity. Subtle changes in pupil contraction latency may be detected decades before the onset of AD clinical symptoms using a simple, non-invasive test.

ABSTRACT BODY:

Purpose: The COVID-19 pandemic caused disruptions in ophthalmic care, and may have negatively impacted some patients more than others. We performed a retrospective, cross-sectional study at our large, tertiary care ophthalmology referral center in the Midwest region of the United States in an attempt to identify patients at risk for worsening ocular health during the COVID-19 shutdowns.

Methods: We completed retrospective Electronic Health Record data extraction of demographic and clinical outpatient encounter-level data for all patients examined in our department from March-May 2019, August-October 2019, March-May 2020 (peak COVID), and August-October 2020 (COVID recovery). Changes in mean logMAR visual acuity (logMAR VA), mean intraocular pressure (IOP), and mean number of procedures per encounter were tested and stratified by age (<18, 18-64, and 65+ years-old), and compared based on associated billing codes.

Results: During peak COVID, there was a 73% decrease in the number of outpatient clinical encounters compared to the control time period in 2019 (6,976 vs. 26,068), and mean patient age was significantly lower during peak COVID (mean age 53.4, 95% CI 52.8-54.0) compared with the other time periods. Documented best-corrected logMAR VA of the right and left eyes worsened for pediatric, adult, and elderly patient age groups; IOP of the right and left eyes worsened when evaluating all patients together; and the mean number of procedures performed per encounter increased by 74% comparing early 2019 to peak COVID months. The billing diagnoses associated with the worst ocular health outcomes during the COVID-related shutdowns include patients with anophthalmia of the fellow eye; infectious keratitis; open, chronic angle closure, and secondary causes of glaucoma; ocular inflammatory disorders; optic neuritis and ischemic optic neuropathies; and vitreoretinal disorders related to diabetes, macular degeneration, and vitreous or retinal hemorrhages.

Conclusions: Patients seen during the COVID-19 pandemic were younger, had worsened logMAR VA, increased IOP, and underwent more procedures compared to the COVID-recovery and 2019 control months. Numerous billing diagnoses were associated with worse measures ocular health. Patients with these ocular disorders may need prioritization during future periods of reduced access ophthalmic care.

ABSTRACT BODY:

Purpose: Low-quality retinal images may impair a clinician’s ability to detect glaucoma and preclude use of deep learning (DL) models for glaucoma identification. The study’s purpose is to assess whether ungradable images can be improved by use of a paired Generative Adversarial Network (GAN) DL model, to yield gradable images.

Methods: 3217 fundus photographs from the Diagnostic Innovations in Glaucoma Study (DIGS) and African Descent and Glaucoma Evaluation Study (ADAGES) datasets were organized into 10,000 image pairs, of one inherently low quality source image and one high quality target image from the same eye. Image quality was calculated by a previously developed quality assessment DL model trained by ground truth of expert graders. The image pairs were used to train a Pix2Pix based GAN to perform image to image translation from low to high quality. The GAN was trained for 30 cycles (epochs) using adam optimizer with learning rate 2e-4, with L1 and adversarial binary cross entropy loss functions.

Results: Generated images from the model had a mean L1 distance of 0.275 and cross entropy of 4.034 from the target high quality images. Generated images had an average brightness increase of 18.30% and contrast increase of 34.31% from the source low quality images, indicating that the GAN tends to increase the brightness and contrast of input images. Qualitatively, the GAN learns quickly, requiring one epoch to improve its output from random noise (fig 1a) to a blurry rendition of the optic nerve head (figure 1b). After 30 epochs, the GAN learns to produce images with

clear retinal vasculature and detail that resembles the target images (fig 1c). The GAN seems to increase brightness and improve contrast of the optic nerve head and vasculature. In some examples, the GAN may insert vasculature into the image (fig 2b). Also, the GAN may insert cropping into the generated image, mimicking the cropping in the ground truth images (fig 2c).

Conclusions: GAN shows promise to improve human gradability of fundoscopic images in the detection of glaucoma. Further investigation must be done to explain unexpected output and assess glaucoma gradability of generated images.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is a leading cause of vision loss among the elderly. Understanding the shared genetic components between metabolites and AMD can provide better insights into the pathogenesis of AMD.

Methods: Leveraging large-scale genetic and metabolomic data, we performed genome-wide association studies for 346 plasma metabolites with a median sample size of 6,610 participants in the Nurses' Health Study, Nurses' Health Study II, and Health Professionals Follow Up Study (NHS, NHSII, and HPFS). AMD GWAS summary statistics from the International AMD Genomics Consortium with 16,144 advanced AMD cases and 17,832 controls were used to investigate the putative causal associations between metabolites and risk of AMD in a bi-directional two-sample Mendelian randomization (MR) framework and Bayesian genetic colocalization analysis. Finally, we develop a metabolome-wide association study (MWAS) pipeline to identify metabolite-AMD associations.

Results: In the NHS, NHSII, and HPFS, we prioritized 41 putative causal associations between metabolites and AMD. Bayesian colocalization analysis revealed 249 shared common causal variants for metabolites and AMD. In the MWAS, we identified 119 metabolites, of which 39 were further prioritized in MR analysis. Pathway analysis revealed that the identified metabolites were mapped to the glycerophospholipid metabolism pathway.

Conclusions: Our results provide genetic evidence that highlights the contribution of metabolites to AMD risk. The shared causal variants and prioritized causal metabolites provide new insights into the pathogenesis of AMD.

ABSTRACT BODY:

Purpose: To evaluate the association between the rate of ganglion cell complex (GCC) thinning and the vision function questionnaire (VFQ) in glaucoma.

Methods: In this longitudinal study, 236 eyes of 118 patients with diagnosed or suspected glaucoma followed up for an average of 4.1 years were enrolled from the Diagnostic Innovations in Glaucoma Study and the African Descent and Glaucoma Evaluation Study. The VFQ was evaluated using the 25-item National Eye Institute Visual Function Questionnaire (NEI-VFQ) at the last follow-up visit. GCC thickness was derived from macular optical coherence tomography scans and averaged within 3 circle areas (3.4-degree, 5.6-degree, and 6.8-degree from the fovea) and superior and inferior hemiregions. Linear mixed-effects models were used to investigate the association between the rate of GCC thinning and Rasch-calibrated VFQ score.

Results: Faster rate of global GCC thinning was significantly associated with higher disability of Rasch-calibrated NEI-VFQ score (-0.31 (95% CI) (-0.57, -0.04) um/year per 100 score; P=.02). When stratified by degrees from the fovea, the 3.4-degree area had the highest association with the composite NEI-VFQ Rasch-calibrated score (-0.52 (-0.91, -0.13) um/year per 100 score: P=.009) followed by the 5.6-degree (-0.34 (-0.62, -0.06) um/year per 100 score: P=.02) and 6.8-degree (-0.16 (-0.32, 0.00) um/year per 100 score: P=.05).

Conclusions: The faster and more central locations of GCC thinning are associated with vision-related quality of life in glaucoma patients. Monitoring macular structure provide useful information in determining the risk of functional impairment in glaucoma.

ABSTRACT BODY:

Purpose: The trabecular meshwork (TM) actin cytoskeleton plays a key role in regulating intraocular pressure (IOP). This study aims at understanding the role of cholesterol in the regulation of actin polymerization in TM.

Methods: Human TM (HTM) cells were treated with SiR-Actin in serum-free media overnight and F-actin changes were recorded using live-cell time-lapse (every 5min) confocal imaging before and during exposure to A) 10mM methyl-β-cyclodextrin (MβCD) (1h) for acute cellular cholesterol removal, B) 100μM cholesterol-saturated MβCD (MβCD-CHOL) (1h) to enrich cholesterol. F-actin changes were calculated, and an unpaired t-test was used for statistical analyses and results were significant if $p<0.05$ with n= 3-4. HTM cells plated on coverslips were treated as mentioned above, C) with 100μM (24h) atorvastatin -cholesterol synthesis inhibitor, D) 10μM cytochalasin D (CYTD) (1h) -actin polymerization disruptor, E) 10μM CYTD (1h) followed by 100μM MβCD-CHOL (1h). Untreated cells acted as the control. After treatments, cells were fixed and immunofluorescence (IF) was performed for cholesterol using filipin, F-actin by phalloidin, focal adhesion (FA) -vinculin and paxillin-localization. Further F/G-actin in vitro assay was performed to quantify the actin polymerization changes under the conditions A–E compared to control.

Results: Imaging analysis showed cholesterol removal significantly decreased F-actin from 20min sustaining up to 1h ($p<0.05$, n=3) and decreased FA distribution. Cholesterol enrichment significantly increased F-actin from 10min sustaining up to 1h ($p<0.05$, n=4) and reorganized FA. IF results showed that atorvastatin decreased F-actin and FA distribution. CYTD disrupted F-actin networks leaving remnant filament ends and decreased FA but cholesterol enrichment increased F-actin branches formed at ~70° angle indicating Arp2/3 activation. These results were confirmed by quantitative F/G-actin ratio decrease and increase upon cholesterol removal/synthesis inhibition and enrichment, respectively. Interestingly, F/G-actin ratio increased under CYTD treatment indicating that CYTD disrupted longer actin filaments but helped polymerization of newly formed actin filaments.

Conclusions: This systematic evaluation of cholesterol modulation on TM actin polymerization identifies the significance of maintaining membrane and cellular cholesterol levels for achieving IOP homeostasis.

ABSTRACT BODY:

Purpose: Inherited retinal degenerations (IRDs) result in blindness due to apoptotic cell death of rods and cones, but spare other retinal neurons, providing a potential that delivery of a light-activated signaling protein to surviving neurons may restore vision. Aspects of vision are restored when mGluR2 is engineered to respond to light by tethering of a photoswitchable agonist. However, as with channelrhodopsins, the system has such low sensitivity that it would require intensifying goggles to work in roomlight. We increasd sensitivity to obtain high acuity vision in dim light.

Methods: Using AAV, we delivered to retinal ganglion cells (RGCs) the gene encoding the GCPR, mGluR2, engineered to contain an N-terminal SNAP domain, to which we could tether a photoswitchable agonist. We increased the sensitivity with a branched photoswitch containing four light-activatable glutamates for each glutamate binding site. Light sensitivity was tested in a Light/Dark box; object recognition in open field under dim light; acuity and abilility to recognize line patterns in motion using standard 500 nit LCD computer screens displaying pairs of lines at different spacings.

Results: 4-branched BGAG SNAP-mGluR2 in all RGCs restores the ability to perform visual tasks in dim room light and using standard LCD computer screens. The system restores line pattern differentiation to approximately the acuity of normal mouse vision and supports pattern recognition at 48^{O}/s of motion.

Conclusions: We achieve high-sensitivity and high-acuity vision that works at high speed of motion and which supports object exploration in dim incidental light. While photopharmacology adds an additional layer of treatment to gene therapy, it provides the dual advantage of upgrade as new photoswitches are developed and the ability to be discontinued at will.

ABSTRACT BODY:

Purpose: Retinal vaso-obliteration is associated with an inability of Endothelial Progenitor Cells (EPCs) to promotes vasculogenesis in oxygen-induced retinopathy (OIR). Because interleukine-1b (IL-1b) is convincingly reported as an important pro-inflammatory factor contributing to vascular degeneration during OIR, we investigated the potential beneficial effects of rytvela (a new non-competitive allosteric (IL)-1 receptor inhibitor) on the post-transcriptional mechanism involved EPC dysfunction during OIR.

Methods: The effect of rytvela on the bioactivity of EPCs subjected to hyperoxia (80% O2) or IL-1b stimulation (100ng/mL), has been examined by senescence, migration and vasculogenic assay. We next profiled micro-RNAs (miRs) expression using next generation sequencing (NGS), in the same condition to identify the post-transcriptional mechanisms associated with EPC dysfunction.

Results: First, we found that EPCs subjected to hyperoxia or IL-1b exhibit a phenotype of early senescence, associated with a significant decrease of their migratory and vasculogenic properties. Interestingly, rytvela inhibits hyperoxia/IL-1b-induced EPC-senescence and rescued their migration and tubulogenic function. At post-transcriptional level, NGS analysis reveal that 26 miRs are significantly modulated by both IL-1b and hyperoxia, and the expression of 9 of these miRs are recovered by rytvela. Interestingly we found that miR-875 - predicted to negatively regulate the expression of FOXF1, a key transcriptional factor for multiple pro-angiogenic genes including CXCR4 – to be upregulated. We next performed a gain-and-loss of function to study the precise role of miR-875 on EPC bioactivity. The result confirms that overexpression of miR-875 in native EPCs leads to downregulation of FOXF1/CXCR4 signaling, that in turn decreases the migratory and vasculogenic properties of native EPCs. Conversely, inhibition of miR-875 protects EPCs functions against OIR conditions by restoring FOXF1/CXCR4 expression.

Conclusions: Altogether, our results suggest that rytvela can protect vasculogenic properties of EPCs in OIR conditions. Bioengineering EPCs with rytvela or antagomiR-875 based-therapy could provide a new potential strategy to preserve vessel integrity in ischemic retinopathies.

ABSTRACT BODY:

Purpose: We investigated the role of sex in the pathogenesis of Congenital Hereditary Endothelial Dystrophy (CHED) in published cases and in a $Slc4a11^{-/-}$ mouse model of CHED.

Methods: Data of age, sex and pre-operative central corneal thickness (CCT) in published cases of individuals with CHED (49 male, 29 female eyes) were collected. CCT of $Slc4a11^{-/-}$ (KO, 100 eyes) and $Slc4a11^{+/+}$ (WT, 88) mice was monitored using AS-OCT. RNAseq analysis of in vivo corneal endothelium (CEn) from 10-week KO and WT mice (3 male and 3 female each) was carried in a 2-genotype by 2-sex matrix. Mitochondrial superoxide (Mito-$O_2^{\bullet -}$) was quantified in ex vivo CEn from KO and WT mice at 10, 24 and 40 weeks (w) by oxidized MitoSOX in LC-MS.

Results: Individuals with CHED and KO mice demonstrated a progressive increase in CCT with age ($p=0.026$ and <0.001). Male individuals with CHED and male KO mice showed greater rate of increase in CCT than females ($p=0.011$ and 0.046), with no difference of CCT between male and female WT mice ($p=0.945$). RNAseq revealed 502 upregulated and 364 downregulated genes in CEn from KO mice compared to WT, controlling for sex. The most upregulated gene, Echdc2, encodes a mitochondrial enzyme in lipid β-oxidation. The two most downregulated genes, Cyp1b1 and Myoc, both have roles in anterior segment dysgenesis. The expression of androgen receptor (Ar) was decreased 6-fold in CEn from KO mice, but the expression of estrogen receptors (Esr1, Esr2) was unchanged. Testing genotype*sex interaction identified 86 genes influenced by Slc4a11 KO in a sexually dimorphic pattern, including an overrepresentation of genes with androgen response elements (ARE) compared to genes with ARE in the mouse genome (42% vs 22%, $p=0.005$). In the 86 genes, there were several regulating factors of lipid metabolism with roles in inducing sex differences: Srebf1, Insig1, Scd1, Scd4, Slc22a14, and Mir22hg. Glucose dependent Mito-$O_2^{\bullet -}$ was significantly increased in CEn from male but not female KO mice at 24w and 40w compared to WT ($p =0.029$ and <0.001). Glutamine dependent Mito-$O_2^{\bullet -}$ was significantly increased in CEn from 40w male but not in female KO compared to 40w WT ($p=0.043$), and not in 10w and 24w mice.

Conclusions: Male sex is associated with more severe phenotype in individuals with CHED and in $Slc4a11^{-/-}$ mice. Sexually dimorphic response to Slc4a11 loss was observed at transcriptomic and functional levels in CEn of $Slc4a11^{-/-}$ mice.

Commercial Relationships Disclosure: Leana Rohman: Commercial Relationship: Code N (No Commercial Relationship) | Marco Ruggeri: Commercial Relationship(s);Code P (Patent):US patent 8,425,037 | Arthur Ho: Commercial Relationship: Code N (No Commercial Relationship) | Jean-Marie Parel: Commercial Relationship(s);Code P (Patent):US patent 8,425,037 | Fabrice Manns: Commercial Relationship(s);Code P (Patent):US patent 8,425,037

ABSTRACT BODY:

Purpose: According to earlier studies utilizing ultrasound, analysis of the dynamics of the lens can provide insights into the lens' mechanical properties and their changes over time, causing presbyopia. This study aims to determine if they are differences in the mechanical microfluctuations of the lens between young and pre-presbyopic subjects.

Methods: Using a custom-built extended depth OCT system (Ruggeri et al., BOE, 2012) and following an IRB-approved protocol, we imaged the lens of the left eye of 3 young subjects (age range: 21 to 25 years; MSE: -0.38 to -3.38 D) and 3 pre-presbyopic subjects (age range: 38 to 45 years; MSE: -0.75 to -4.38 D). We recorded 500 OCT images of the central 2 mm zone of the lens at 50 frames/s (10 s recording session) for each participant at different accommodative demands (young subjects: 0D, 2D, 4D, 7D; pre-presbyopic subjects: 0D, 4D). Each image consisted of 170 A-lines. For each frame, the lens thickness was quantified using a custom-made, semi-automatic MATLAB application. The power spectrum of the lens microfluctuations is calculated by using the Fourier Transform in MATLAB. Then, the microfluctuations are assessed by calculating the area under the power spectrum curve between 0 and 4 Hz.

Results: The amplitude of lens microfluctuations was higher in the accommodated state than in the relaxed state in both age groups. Compared to the relaxed state, the average amplitude of microfluctuations for young subjects is 2.3 times greater at 4D, while for pre-presbyopic subjects it is 1.8 times greater (Fig.1). For young subjects, the microfluctuations of the lens do not increase with increasing accommodation demand once it has reached an accommodative state (Fig. 2).

Conclusions: The results demonstrate the feasibility of quantifying lens thickness microfluctuations using dynamic OCT. Also, the study suggests that the magnitude of lens microfluctuations is larger in the accommodated state and in young compared to pre-presbyopic eyes. Moreover, the amplitude of microfluctuations in the accommodated state is independent of the accommodative response.

TITLE: Innate Immune Mechanisms in Oxidative Retinal Damage

SESSION TITLE: RPE/choroid pathology: oxidative stress, inflammation and neovascularization

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Kerur, A. Kumar, D.H. Biddle, The Ohio State University Wexner Medical Center, Columbus, Ohio, UNITED STATES|D. Banerjee, Aravind Medical Research Foundation, Madurai, INDIA|

Commercial Relationships Disclosure: Nagaraj Kerur: Commercial Relationship(s);Code P (Patent):University of Virginia, University of Kentucky | Daipayan Banerjee: Commercial Relationship(s);Code P (Patent):University of Virginia | Aman Kumar: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Biddle: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Clinical and experimental evidence implicate oxidative stress in the pathogenesis of multiple vision threatening diseases such as age-related macular degeneration (AMD), diabetic retinopathy (DR), and glaucoma. Oxidative stress damages biological macromolecules such as proteins, lipids, and DNA. The pathological consequences of oxidative damage to lipids and proteins in the retina have been well studied. However, whether oxidative damage to DNA – which is elevated in AMD, DR, and glaucoma eye specimens, as well as in experimental animal models – contributes to retinal pathology remains a major gap in the knowledge. The goal of this study is to examine the hypothesis cGAS which is activated by damages self-DNA, plays crucial roles in mediating oxidative retinal damage.

Methods: Human primary RPE and THP1 cells were exposed to oxidative stress by incubating with sodium iodate and cigarette smoke extract. cGAS pathway was blocking by either lentivirus delivered shRNA or CRISPR/Cas9. Activation of cGAS pathway was assessed by examining signaling activity downstream of cGAS by immunoblotting for phospho-STAT2 (pSTAT2), phosphor-ATM (pATM) and phospho-CHK2 (pCHK2).

Results: Exposure to oxidative stress via incubation with sodium iodate and cigarette smoke extract activated type I interferons and DNA damage signaling as demonstrated by induction of pSTAT2, pATM and pCHK2. These signaling activities were dampened in cGAS knockdown and knockout cells.

Conclusions: Our results suggest that cGAS pathway is activated by oxidative stress providing rationale for detailed analysis of role of cGAS in oxidative retinal damage.

ABSTRACT BODY:

Purpose: To investigate effects of acute IOP elevation on structural abnormalities in the post-trabecular aqueous outflow tract of normal cats and cats homozygous for LTBP2 mutation, causal for FCG, prior to spontaneous, sustained IOP elevation.

Methods: 0.4% indocyanine green aqueous angiography (AA) and anterior segment optical coherence tomography (OCT) was performed ex vivo at physiological pressure (15 mmHg) in 14 cannulated eyes from 14 cats at 10-12 wks of age (7 FCG and 7 age-matched control) <2hrs postmortem, imaged by Spectralis HRA+OCT (Heidelberg Engineering). Additionally, 4 eyes per group were imaged 30 mins after IOP elevation (45 mmHg). Images were then exported, and scleral vessel shape was analyzed in 4 different images/quadrant/eye using ImageJ (v1.53n). Eyes were perfusion fixed with 4% PFA for 30 minutes following AA, and were routinely paraffin embedded, sectioned and stained. Morphometric analysis and quantitative assessment of collagen orientation surrounding scleral vessels was performed in each eye in H&E and Picrosirius Red stained sections by polarized light microscopy. Statistical comparisons were performed in GraphPad Prism (v.9.3.1).

Results: All but one cat (an LTBP2 mutant) exhibited homogenous, circumferential AA outflow signal <10mins after tracer perfusion. Scleral lumen minor axis was smaller in LTBP2-mutant FCG eyes relative to controls ($P=0.0004$), and in all feline eyes lumens appeared partially collapsed after acute IOP elevation ($P<0.001$). Scleral vessel lumens in FCG cats appeared significantly collapsed and posteriorly displaced when compared to age matched controls. Scleral collagen orientation differed between FCG and normal cats, especially in anterior perivascular regions.

Conclusions: Differences in perivascular scleral collagen organization, scleral vessel profile and their response to increased IOP were identified in this congenital glaucoma model prior to sustained, spontaneous IOP elevation.

ABSTRACT BODY:

Purpose: Resident surgeons are quoted to take an average of 12 minutes longer when compared to an attending physician. Studies have shown that operative time may impact complications and outcomes in cataract surgery, but this observation is up for debate. This study aims to show the impact of operative time on early postoperative outcomes in resident cataract surgery.

Methods: This retrospective case series includes 100 randomly selected eyes from 100 patients from all PGY-4 resident cataract surgeries performed at a single Veterans Affairs Hospital between March 1, 2018 and March 31, 2020. Eyes with attending as primary surgeon or laser-assisted cataract surgery were excluded. Electronic medical records were reviewed to extract age, nuclear sclerotic cataract grade, and operative factors (use of epinephrine, use of trypan blue, iris expansion device (IED), cumulative dissipated energy (CDE), and operative time). Post-operative outcomes were reviewed, including visual acuity (VA) and intraocular pressure (IOP). Multiple ordinal logistic regression was performed to assess impact of risk factors on post-operative visual acuity.

Results: Operative time (OR=0.95, CI=0.92-0.99, p=0.01) and use of IED (OR= 0.07, CI= 0.01-0.03, p=0.001) are inversely associated with post-operative day one (POD1) pinhole visual acuity when controlling for co-variates as listed above. Other factors including CDE (OR=0.96, CI=0.90-1.03, p=0.29) are not significantly associated. No risk factors are significantly associated with decreased postop week one or month one best corrected visual acuity.

Conclusions: The results suggest that increased resident operative time is a significant risk factor for decreased POD1 pinhole VA, independent of CDE and other operative factors. At the one week and one month, however, resident operative time is not significantly associated with VA, suggesting that resident operative time has minimal effect on long-term VA outcomes. Interestingly, CDE is not significantly associated with decreased VA at any stage in our sample of 100 patients. Understanding effects of resident operative time on early VA outcomes improves understanding of trainee surgery and improves patient counseling when trainees are involved. Safely minimizing intraoperative delays shows promise as a method of improving early post-operative visual outcomes.

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) is a common cause of vision loss among patients with diabetes mellitus, and early diagnosis can reduce the risk of vision loss. In this study, we investigate if remote retinal imaging enables earlier eye care access in patients with newly diagnosed diabetes mellitus in the United States over the past decade.

Methods: We identified patients with newly-diagnosed type II diabetes and at least 1 year and up to 5 years of continuous enrollment between 2011-2020 using the OptumLabs® Data Warehouse (OLDW) – a longitudinal, real-world dataset with de-identified administrative claims and electronic health record data for commercial insurance and Medicare Advantage enrollees in the U.S.. We compared the time from initial diagnosis to the first eye exam by 1) teleretinal screening, defined by Current Procedural Terminology codes for remote retinal imaging (92227 or 92228) or fundus photography (92250) by non-eye care providers, or by 2) in-person eye exam, defined as any encounter with an eye care provider.

Results: We identified 968 846 patients with newly diagnosed type II diabetes who were continuously enrolled for at least 1 year. At year 1, 5 459 (0.6%) patients underwent remote eye imaging and 208 023 (27%) underwent an in-person DR screening. The median time (95% confidence interval) to screening was 2.0 (0-10.9) months for remote imaging and 3.4 (0-11.0) months for in-person visits. Interestingly, 27.5% of remote screenings were performed on the same day of diabetes diagnosis. Excluding same-day screenings, median time to screening was 4.1 months (0.2-11.3) for remote eye imaging and 4.3 months (0.3-11.1) for in-person exams. After year 1, the proportion of eyes that underwent remote imaging remained stable at 0.75% in year 2 and 0.7% in year 5, while the proportion that underwent in-person eye care visits increased slowly to 32.1% and 43.5% at years 2 and 5, respectively.

Conclusions: Teleophthalmology using remote retinal imaging enabled earlier access to eye care among patients newly diagnosed with diabetes, primarily by enabling same-day ophthalmic screening at the time of initial diagnosis. More widespread use of teleretinal screening may enable earlier diagnosis of diabetic retinopathy and prevent vision loss.

ABSTRACT BODY:

Purpose: Anterior segment dysgenesis involves abnormal development of one or more anterior segment structures, including the trabecular meshwork (TM) and Schlemm's canal (SC); this increases risk of developing glaucoma due to elevated intraocular pressure (IOP). We have generated a unique mouse model by deleting activating protein-2β (AP-2β) transcription factor from the developing periocular mesenchyme and its derivatives. The resultant mutant shows a partial angle closure and increased IOP. We hypothesize that the uveoscleral pathway remains functional in this model and thus IOP can be reduced through treatment with prostaglandin analogs such as latanaprost (LTP).

Methods: $MgpCre^{+/-}$ mice were bred with $tfap2b^{+/-}$ mice. Male $MgpCre^{+/-};tfap2b^{+/-}$ offspring were then crossed with female $tfap2b^{lox/lox}$ mice to obtain the final offspring, the $MgpCre^{+/-};tfap2b^{-/lox}$ or AP-2β trabecular meshwork region knockout (TMR-KO) mice, as well as littermate controls. A 40 kDA FITC-conjugated dextran tracer was injected into the anterior segment of mutant and control mice. 0.005% LTP eye drops were used for topical treatment of the eye. The mice were euthanized 10 minutes after injection and eyes were enucleated, fixed, and cryosectioned. RNAscope Hiplex Assay was performed to determine changes in key genes in the mutants that are critical for proper functioning of TM and SC.

Results: In control mice, dextran clumps were observed in the TM region, both with and without LTP treatment (n=6 eyes). This was absent in the mutant mice, likely due to a blocked conventional pathway as demonstrated by previous histological staining. In comparison, dextran was observed along the uveoscleral pathway in the mutants after 5 and 10 minutes of LTP treatment (n=6 eyes). The RNAscope Assay performed in control and mutant mice revealed decreased levels of important SC markers, including Prox1 and Klf4, in the mutant.

Conclusions: Our findings show that while the conventional pathway is blocked in the TMR-KO mutants, the uveoscleral pathway remains functional. Reduction in both Prox1 and Klf4 levels further supports that development of the conventional pathway is altered in the TMR-KO mutants. Since these genes encode pressure-induced transcription factors, it is surmised that lack of aqueous flow through the SC region during development contributed to the phenotype.

ABSTRACT BODY:

Purpose: SARS-CoV-2, the viral infection that causes COVID-19, is known to induce a hypercoagulable state in patients. While there have been isolated reports of retinal vascular occlusion among patients with a pre-existing COVID-19 infection, research into this topic remains scant. Therefore, the purpose of this study is to investigate the short-term prevalence and risk for retinal vascular occlusion between COVID-19 and influenza A patients.

Methods: TrinetX is a national, federated database that was utilized in this retrospective cohort analysis. At the time of the study, electronic medical records from over 80 million patients across 57 healthcare organizations were analyzed to create two cohorts of patients. At the time of the analysis, 1,224,770 patients with a previous history for COVID-19 were compared to 61,555 patients with a previous history for influenza A. Then, 1:1 propensity score matching (PSM) was utilized to balance each cohort by demographics and comorbidities (age, sex, BMI, history of hypertension, chronic lower respiratory disease, diabetes mellitus, nicotine dependence, heart failure, and alcohol related disorders). Adjusted risk ratios (aRR) using 95% confidence intervals (CI) were used to assess risk of retinal vascular occlusion 120 days after initial diagnosis for COVID-19 or influenza A.

Results: Before PSM, COVID-19 patients were at significantly lesser risk for retinal vascular occlusion within 120 days of initial diagnosis than influenza A patients (aRR [95% CI] = 0.58 [0.42,0.8]; $p<0.001$). However, the incidence for influenza patients to develop retinal vascular occlusion was very small (0.1%). After PSM, two balanced cohorts of 61,555 patients were compared to one another and revealed that there is no significant difference in developing a retinal vascular occlusion after a previous diagnosis of COVID-19 or influenza A (0.92 [0.58,1.46]; $p=0.725$). Likewise, the incidence for retinal vascular occlusion remained very small (0.1% between both cohorts) (Table 1).

Conclusions: This is the first large-scale study investigating the risk of retinal vascular occlusion among COVID-19 and influenza A patients. We found that each cohort was at similar risk for developing retinal vascular occlusion within 120 days. Likewise, the incidence for retinal vascular occlusion was miniscule among patients in this study.

ABSTRACT BODY:

Purpose: We have shown that allograft survival in recipients at low-risk (LR) of rejection is sustained by type-1 dendritic cells (DC1) that exhibit potent immunoregulatory function defined by high IL-10 and low IL-12 expression. Herein, we examined the environment-mediated immunostimulatory reprogramming of CD103^{+} DC1 in recipients at high-risk (HR) of rejection

Methods: HR or LR allogeneic corneal transplantation was performed using C57BL/6 mice as donors and BALB/c as hosts. M290-SAP antibody was used to deplete CD103^{+} DC1. Post-transplant, kinetics of CD103^{+} DC1 were assessed. Bone-marrow-derived (BMD) CD11b and naïve CD4 T cells were co-cultured with either FACS-sorted CD103^{+} DC1 from HR recipients, or with BMD induced DC1 (iDC1) pulsed with exogenous IFN-y. Either CD103^{+} DC1 from LR recipients or iDC1 were cultured in a transwell with Th1 cells. Adoptive transfer of iDC1 pulsed with or without IFN-y was performed in HR and LR recipient mice. Readouts include flow cytometry, ELISA, RT-PCR and clinical follow-up

Results: CD103^{+} DC1 numbers were significantly higher in HR compared to LR recipients ($p<0.001$), and these cells expressed lower IL-10 ($p<0.001$), and higher IL-12 ($p<0.001$). While depletion of CD103^{+} DC1 led to 100% graft rejection in LR ($p<0.0001$), it resulted in 40% survival in HR ($p<0.001$). Maturation of BMD CD11b^{+} APC (measured by MHC-II and IL-12) expression and their immunogenic function (assessed by IFN-g production by sensitized Th1 cells) were significantly increased when co-cultured with either HR CD103^{+} DC1 ($p<0.0001$), or IFN-y-pulsed iDC1 ($p<0.0001$). In the presence of IFN-y producing Th1 cells, both LR CD103^{+} DC1 or BMD-iDC1 expressed low IL-10 ($p<0.0001$) and high IL-12 ($p<0.0001$). Finally, adoptive transfer of immunosuppressive iDC1 to HR recipient mice led to 90% allograft survival ($p<0.0001$); while adoptive transfer of IFN-y-sensing iDC1 led to 100% graft rejection in LR recipient mice ($p<0.0001$)

Conclusions: These results demonstrate that the transplant environment alters the function of IFN-y-sensing migratory CD103^{+} DC1. This acquired immunostimulatory function negatively impacts alloimmunity and allograft survival

ABSTRACT BODY:

Purpose: NOVATIVE (NCT00328653) was a randomized phase II/lll trial that evaluated the efficacy and safety of CsA CE in children and adolescents with moderate-to-severe VKC. This analysis examined the time to onset of improvements in signs and symptoms of VKC in CsA CE treated patients.

Methods: 118 patients (mean age, 8.8± 3 y; 81.4% male) were randomized to 4x daily treatment with CsA CE 0.05%, 0.1%, or vehicle eye drops. Rescue treatment (corticosteroids, mast cell stabilizers, or antihistamines) was not allowed. The primary efficacy endpoint was overall rating of subjective symptoms at Day 28. Efficacy was evaluated based on change from Baseline in ratings of subjective symptoms (BenEzra's 5-point scale) and in keratitis as identified by corneal fluorescein staining (CFS) and graded using the Oxford scheme.

Results: All NOVATIVE treatment groups showed improvement in overall subjective VKC symptoms at Day 28; however no statistically significant differences were noted between either CsA CE arm and the vehicle group. Although the primary end-point was not met, patients treated with CsA CE 0.05% and 0.1% showed improvement in subjective itching after 1 week and continued to improve through Month 1. Change from Baseline to Week 1 in the 0.1% treatment group was statistically significant (P=0.049). At Month 1, severe itching was reported by just 5.6% of patients in the 0.1% arm and none in the 0.05% arm vs 11.1% in the vehicle arm. All treatment groups showed improvement in CFS at Week 1; at Month 1 both CsA CE arms showed significantly greater improvements when compared to vehicle (P<0.05). Corresponding decreases in grade severity were also seen over time.

Conclusions: CsA CE 0.1% treatment led to a reduction in signs and symptoms in patients with moderate-to-severe VKC, with efficacy evident 1 week after initiating therapy. These data, along with data from the VEKTIS study, suggest that CsA CE 0.1% may be an effective corticosteroid-sparing VKC treatment.

ABSTRACT BODY:

Purpose: To present cases of punctal and canalicular stenosis following treatment of ocular surface squamous neoplasia with topical 5-fluorouracil 1% eye drops.

Methods: A retrospective chart review of patients with ocular surface squamous neoplasia (OSSN) treated with topical 5FU as primary or adjuvant treatment between 2013 and 2021 was performed. Patients diagnosed with punctal or canalicular stenosis during or after use of topical 5FU were included in the study. Four patients were identified who met these criteria. We report the clinical findings and treatment for each patient.

Results: Five eyes of four patients were included in this study out of a total of 303 charts reviewed for an incidence of 1.3%. For this subset, the mean age at initiation of 5FU was 61 (range 53-69). Most patients were male (75%), white (75%), and non-Hispanic (100%). Five eyes were treated with topical 5FU for a mean of 4.87 cycles (standard deviation, SD 2.0). The most common presenting symptom was epiphora, which presented at a mean of 4.6 months after initiating topical 5FU. Two patients who developed epiphora at 4.3 and 10.3 months after initiating 5FU eye drop therapy underwent surgical intervention (external dacryocystorhinostomy and punctoplasty, respectively) after evaluation by an oculoplastic specialist confirmed punctal and canalicular stenosis, respectively. A third patient developed epiphora of the left eye after two cycles of 5FU. Clinical examination showed mild punctal stenosis and the puncta were dilated in the office with resolution of symptoms. The fourth patient received 5FU in both eyes and reported epiphora at 3.2 months in the left eye and 3.9 months in the right. Fortunately, left eye epiphora resolved after stopping therapy but the right eye epiphora persisted. An oculoplastic evaluation revealed right punctal stenosis. The patient’s symptoms resolved following punctal dilation.

Conclusions: Punctal or canalicular stenosis is a rare adverse effect of topical 5FU eye drops that may require surgical treatment.

ABSTRACT BODY:

Purpose:

Retinal inflammation is associated with vascular degeneration in oxygen-induced-retinopathy (OIR). micro-RNAs (miRs) have been identified as key regulators of genes expression. miR-125 is reported as strongly expressed in the retina, implicated in retinal development and in inflammatory processes. This study aimed to investigate the potential anti-inflammatory properties of miR-125 in a rat model of OIR.

Methods: qRT-PCR and western blot were performed to evaluate the expression of miR-125 and inflammatory cytokines. In vitro: miR-125 function was investigated using a miR-125 mimic on activated microglial cells (SIM-A9) by hyperoxia or LPS. The angiogenic effects were analyzed by Matrigel assay and qRT-PCR. In vivo: OIR rat pups were intravitreally injected with miR-125 mimic (10 nmol/kg) or a control-miR at P5 during the cycling OIR model. Retinal tissues were collected at P10 and P14 and the vascular density was analysed by retinal lectin-immunostaining. Apoptosis was analyzed in vitro and in vivo.

Results: miR-125 expression is significantly reduced in the retina of OIR rats compared to control rats, and in SIM-A9 subjected to hyperoxia or LPS. This is correlated with an upregulation of key proinflammatory cytokines including TNF-a, IL-6 and IL-16. Interestingly, we found a significant decrease of TNF-a, IL-6 and IL-16 expression, associated with decreased apoptosis in SIM-A9 transfected with miR-125 before hyperoxic or LPS treatment. Retinal endothelial cells (HRMEC) exposed with the culture medium of SIM-A9 pre-subjected to hyperoxia display a decrease in their angiogenic capacity associated with an increase of apoptosis. Interestingly, overexpression of miR-125 in SIM-A9 reverses the deleterious effects of hyperoxia on their secretome to rescue vasculogenic function of HRMEC. In vivo, OIR rat pups intravitreally supplemented with miR-125 mimic display a significantly decrease of TNF-a, IL-6, IL-16 and activated Caspase-3, associated with lower vasoobliteration area compared to the miR-control group at P10 and P14.

Conclusions: This study suggests that miR-125 acts as an inflammatory and apoptotic suppressor of activated-microglial cells protecting microvascular density during OIR. miR-125-based therapy could potentially constitute a novel anti-inflammatory therapeutic strategy to limit vascular degeneration in the initial step of ischemic retinopathies.

TITLE: Multiple glycinergic subunits mediate inhibitory inputs to mouse ON-OFF Direction Selective Ganglion Cells

SESSION TITLE: Retinal and central processing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C.B. Hellmer, I. Pyle, C. White, M.A. McCall, Ophthalmology and Visual Sciences, University of Louisville School of Medicine, Louisville, Kentucky, UNITED STATES|C. Zhang, University of Washington Department of Biological Structure, Seattle, Washington, UNITED STATES|

Commercial Relationships Disclosure: Chase Hellmer: Commercial Relationship: Code N (No Commercial Relationship) | Ian Pyle: Commercial Relationship: Code N (No Commercial Relationship) | Caitlin White: Commercial Relationship: Code N (No Commercial Relationship) | Chi Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Maureen McCall: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal amacrine cells provide one of two sources of inhibition (GABA or glycine) to ganglion cells (GCs). Various roles for GABAergic inhibition have been discovered. For example, in ON-OFF Direction Selective GCs (ON-OFF-DSGCs), asymmetric GABAergic input restricts sensitivity to objects moving in only one direction. While ON-OFF DSGCs also receive glycinergic input, its function has not been examined. Here we examined GlyRα mediated synaptic inputs and their light evoked currents in WT and GlyRα knockout ON-OFF-DSGCs.

Methods: We pharmacologically isolated glycinergic inputs by eliminating $GABA_A$/$GABA_C$ inputs (PTX and TPMPA) and verified the remaining currents were glycinergic using strychnine. Whole-cell patch clamp recording assessed spontaneous glycinergic currents (sIPSCs) from GFP labeled ON-OFF DSGCs in TRHR mice. GlyRα subunit composition was predicted from known sIPSC decay τ's and tested in mice lacking specific GlyRα subunits (KO mice). Glycinergic light-evoked inhibitory postsynaptic currents (L-IPSCs) were compared between WT and GlyRα KO TRHR cells to evaluate the contribution of GlyRα 2, 3 or 4 inputs at light onset and offset.

Results: Isolating glycinergic inputs reduced the L-IPSC amplitude by ~45% in TRHR ON-OFF DSGCs, indicating that glycine mediates a significant inhibitory input. In WT TRHR GCs, the median sIPSC decay τ was 11.3 ms and this shifted to a slower decay τ of 13.9ms in TRHR/GlyRα3-KO mice. This indicates that the remaining currents should be mediated by GlyRα2 or GlyRα4. The median decay τ was similar in TRHR/GlyRα2-KO and TRHR/GlyRα4-KO GCs, which is inconsistent with their predicted decay τ's (~20 vs 40 msec, respectively). Ongoing studies of glycinergic sIPSCs and L-IPSCs in TRHR double KOs: GlyRα2/GlyRα3 and GlyRα3/GlyRα4 will determine if one or both provide synaptic input.

Conclusions: Our results clearly show that glycinergic currents represent a significant source of inhibition to TRHR ON-OFF-DSGCs. These GCs receive predominant synaptic input via GlyRα3 and an additional input from GlyRα's with slower decay τ's. The different decay kinetics between GlyRα3 (fast τ decays) and GlyRα2 and GlyRα4 (slow τ decays) could lead to subunit specific inhibition in ON-OFF DSGCs on different time scales. Ongoing analyses of light evoked responses will evaluate the functional contributions GlyRα mediated input in ON-OFF DSGCs.

ABSTRACT BODY:

Purpose: Stargardt disease is a progressive inherited retinal disease caused by ABCA4 mutations. Over the years, an increasing number of pathogenic intronic ABCA4 variants has been reported, usually causing splicing alteration at the pre-mRNA level. Antisense oligonucleotides (AONs) are an attractive therapeutic strategy to rescue these splicing defects, yet they are designed to target individual variants. In this study, we experimentally analyze the potential of combined AON-U7snRNA splicing modulation therapy to target multiple intronic ABCA4 variants using midigene-based splice assays in vitro.

Methods: HEK293T cells were transfected with wild-type or mutant ABCA4 midigenes harboring the genomic region where selected intronic variants are located. Twenty-four hours post-transfection, cells were left non-treated (NT) or transfected with single or multiple AON-U7snRNA cassette vectors, including the respective positive (naked AON, 0.5 μM) or negative (single/multiple empty U7snRNA cassette vectors) controls. RNA was isolated after 48 hours and transcripts were detected through RT-PCR (n=2). Levels of correct/aberrant splicing were measured by transcript band semi-quantification of each condition, using one-way ANOVA as statistical analysis.

Results: For an intron 30 variant, aberrant splicing was decreased from 97.95% (SD: 2.9) in NT to 26.17% (SD: 17.44) when transfected with the multiple-cassette vector ($p<0.0001$), whereas its respective single-cassette vector reduced aberrant levels to 17.17% (SD: 10.71 , $p<0.0001$) and naked AON achieved full rescue (0%, SD: 0, $p<0.0001$). In case of an intron 36 variant, aberrant splicing decrease was observed when delivering the naked AON (0%, SD: 0, $p=0.0106$), single (0.51%, SD: 0.72, $p=0.0131$) or multiple-cassette vector (0.87%, SD: 1.23, $p=0.0152$) compared to NT (16.61%, SD: 2.05). No relevant effect was observed after delivering empty controls or single-cassette vectors targeting a different region.

Conclusions: These splice assays showed significant reduction of aberrant ABCA4 transcripts through multiple AON-U7snRNA cassette delivery in vitro, illustrating the therapeutic potential of the system to correct different splicing defects caused by several intronic variants simultaneously. To corroborate the observed results, delivery of the U7snRNA system through AAV in patient-derived photoreceptor cells and retinal organoids is currently ongoing.

ABSTRACT BODY:

Purpose: Doppler optical coherence tomography (DOCT) holds the promise of measuring retinal blood flow (RBF) biomarkers such as average blood velocity, vessel diameter, and flow volume within a single cardiac cycle. Using a recently developed DOCT, we investigated whether there is a difference in RBF biomarkers between the superotemporal and inferotemporal retinal vessels of healthy human eyes.

Methods: Eighteen eyes of 18 healthy subjects, 24 to 61 years old (mean 39 ± 12 years) were included in a cross-sectional study. Vessel diameter (D), average velocity (V) and retinal blood flow (RBF) measurements were assessed at the primary artery (TA) and vein (TV) of the superotemporal (ST) and inferotemporal (IT) arcades using a prototype DOCT flowmeter (3D OCT-1 (Maestro2); Topcon Corp., Tokyo, Japan). Median parameter values from 3 measurements acquired at the same location and similar Doppler angle, were used to ensure reliability and accuracy. RBF biomarkers from the superotemporal and inferotemporal arcades were compared using non-parametric independent t-tests. The association between RBF and D in both arteries and veins was assessed using Spearman rank correlation coefficient. A p-value <0.05 was considered statistically significant.

Results: Comparison of retinal blood flow biomarkers between the ST and IT vessels showed no significant differences. The V (mm/seg), RBF (μL/min), and D (μm) at the ST and IT arteries and veins are shown in Table 1. RBF and D were slightly higher in the inferotemporal region of the retina. Positive correlations were found between RBF and D in arteries (Figure 1A, $r= 0.38$; $p= 0.014$) and veins (Figure 1B, $r= 0.46$; $p= 0.002$).

Conclusions: DOCT is capable of consistent measurement of retinal blood flow biomarkers in healthy subjects, supporting its potential as a clinical tool for the evaluation of retinal blood flow. Establishing normative RBF values with this technology, as provided in this study, will be important for confirming its clinical utility for pathological assessment of conditions such as glaucoma, diabetes, and other retinal vasculopathies.

ABSTRACT BODY:

Purpose: Inherited retinal degenerations (IRDs) are a leading cause of blindness. While a variety of treatments are being developed to address specific IRDs, we currently have a poor understanding of the degenerate retina's ability to reshape, and restore visual function after treatment. Calcium binding protein-4 (CaBP4) is necessary for the normal development of photoreceptor synaptic morphology and visual function. We identified a mutation in CaBP4 in a pedigree of dogs with a progressive IRD. We used the CaBP4-mutant canine model to examine functional and structural recovery following gene therapy.

Methods: Exome sequencing was performed. Visual function and retinal structure of treated and untreated mutant-dogs were assessed in vivo with ERG, visual behavior and SD-OCT. Gene therapy (AAV8(733)-GRK1-CaBP4) was delivered subretinally to 4 eyes (n=3 dogs) at different stages of the disease. Enucleated globes from affected (n=3) and unaffected animals (n=4) were evaluated for structural changes in treated and untreated eyes with histology, IHC and TEM. Antibodies included CaBP4, CtBP2, GPR179, S and M/L opsin, SNAP-25, hCAR, calbindin, RetP1 and PNA. Western blot for CaBP4 was performed on retinal samples.

Results: A missense mutation in CaBP4 was identified. Affected animals exhibited reduced and mislocalized CaBP4 (IHC, Western blot). Photoreceptor synaptic organization was severely disrupted with a thin outer plexiform layer, and synaptic ribbons appearing immature in affected animals. Impaired photoreceptor synaptic transmission in affected animals was shown by a lack of scotopic and photopic ERG b-wave. Gene therapy restored synaptic transmission as shown by the presence of relatively normal ERG b-waves. SD-OCT and histology supported retinal layer preservation. Rescue was maintained for over two years in one dog (both eyes treated). Two dogs with established photoreceptor layer loss also showed vision and ERG rescue. Visual performance assessed with a 4-choice task was improved in scotopic conditions, showing a 4-fold reduction in time to complete the task, and 50% increase in success for treated eyes (n=3 dogs).

Conclusions: CaBP4-mutant dogs have profound photoreceptor synaptic dysfunction and develop a progressive IRD. Gene augmentation therapy is successful in restoring visual function in treated dogs showing photoreceptor synaptic plasticity.

ABSTRACT BODY:

Purpose: In this retrospective study, we used multifocal electroretinogram (mfERG) to evaluate the functional implications of angiographic macular leakage without presence of intraretinal fluid on optical coherence tomography (OCT) in eyes with posterior uveitis.

Methods: The STAnford Research Repository (STARR) database was used to identify subjects with posterior uveitis. Subjects who had fluorescein angiography (FA), OCT and mfERG were included, provided that FA and OCT were done at the same visit and mfERG was done within 1 month of the other two imaging modalities. Macular edema (ME) was defined as evidence of intraretinal fluid on OCT. Macular leakage on FA was referred to as angiographic macular leakage. The study cohort was then divided into two groups based on the presence of angiographic macular leakage and ME: Group 1 (no ME and no angiographic macular leakage) and group 2 (presence of angiographic macular leakage without ME). Baseline data, clinical criteria, and mfERG values were analyzed across both groups.

Results: Twenty-three patients (33 eyes) were included. Mean age was 35.9 (± 21.2) and 73% were female. There were 15 eyes in group 1 and 18 eyes in group 2. Groups 1 and 2 had an average age of 34.9 (± 21.0) and 36.7 (± 21.9), respectively ($p>0.8$). Underlying ocular conditions included retinal vasculitis (70%), panuveitis (26%) and intermediate uveitis (4%).

Mean central macular thickness and logMAR BCVA values were 266.6 (± 26.50) μm and 0.12 (± 0.14), respectively; differences were not statistically significantly between groups 1 and 2 ($p>0.1$ and $p>0.7$, respectively). mfERG ring 2 N1 implicit times were significantly delayed in group 2 as compared with group 1 ($p<0.02$). Other mfERG values did not show statistically significant differences between the two groups. Table 1 shows mfERG values of rings 1 (0^{O}) and 2 (3.5^{O}) for the two groups.

Conclusions: Angiographic macular leakage in posterior uveitis without intraretinal fluid on OCT can be associated with photoreceptor dysfunction detectable in the form of delayed implicit timings of ring 2 N1 waves in mfERG. Angiographic macular leakage can be a marker of disease activity and possibly an indication for treatment even in the absence of ME on OCT.

ABSTRACT BODY:

Purpose: The qualitative, categorical Diabetic Retinopathy (DR) Severity Scale (DRSS) derived from the Early Treatment Diabetic Retinopathy Study (ETDRS) is commonly used to grade the severity of DR in clinical trials. In this study, we correlate this subjective DRSS score with precise quantifications of numbers and surface area of DR lesions on fundus images.

Methods: In this retrospective study, we collected ultra-widefield (UWF) pseudocolor images from adult diabetic patients. Eyes with evidence of retinal diseases aside from DR, history of ocular treatment for DR, or poor-quality images which precluded assessment of DR severity were excluded. A mask corresponding to the area circumscribed by the 7 standard ETDRS fields was applied to the UWF images, and the DRSS grade (no DR, mild, moderate (mod), or severe non-proliferative DR [NPDR], proliferative DR [PDR]) was assessed according to the ICDR protocol by two masked graders. Within the same ETDRS seven-fields, intra-retinal hemorrhages (H), microaneurysms (Ma), intra-retinal microvascular abnormalities (IRMA), and venous beadings (VB) were manually segmented. The numbers and surface area of these lesions were computed and correlated against the DRSS score using ANOVA with posthoc Bonferroni.

Results: Among 258 diabetic eyes (163 patients), 176 eyes (83 right eyes) of 113 patients (68 females) with a mean age of 59.18 ± 15.57 years were included. 4% were graded as no DR, 12.5% as mild NPDR, 69.3% as mod NPDR, 6.3% as severe NPDR, and 8% as PDR. There was strong intergrader agreement for the DRSS (Cohen’s Kappa = 0.95, $p < 0.05$). H/Ma area, H count, Ma count, and IRMA count were generally significantly different ($p < 0.05$) between DRSS levels (Figure 1). Specifically, these DR lesions' counts/area increased with DRSS level up to severe NPDR, but the lesions counts/area then decreased in PDR eyes. There was no significant difference in VB count between the DRSS levels ($p = 0.42$).

Conclusions: While DR lesions counts/area generally show a positive correlation with the DRSS level, lesion counts seem to decrease from severe NPDR to PDR. This seemingly paradoxical reduction in lesions may reflect the impact of progressive capillary nonperfusion.

ABSTRACT BODY:

Purpose: In this retrospective study, we aim to describe the ocular clinical features and long-term visual outcomes of Tubulointerstitial Nephritis and Uveitis Syndrome (TINU).

Methods: Medical records (January 2005 to August 2021) from a tertiary eye care hospital were reviewed. All patients who met the diagnostic Criteria for TINU Syndrome were included. Demographic and clinical data were collected.

Results: Twelve patients (24 eyes) with TINU were included. Median age at onset of uveitis was 13.5 years (9-45). 66.6% (n=8/12) of patients were female. Median follow-up period was 29.5 months (6-89 months). All patients had bilateral anterior uveitis. 41.6% (n=5/12) of patients had biopsy-proven acute interstitial nephritis (AIN); urinary beta-2 microglobulin (Ub2M) measurements were elevated in all tested patients (n=9/9). Posterior segment findings were seen in 66.6% of eyes (n=16/24). Posterior segment findings were including papillitis 58.3% (n=14/24), retinal vasculitis 45.8% (n=11/24), vitritis 33.3%(n=8/24), macular edema 25% (n=6/24), presence of snowballs 16.6% (n=4/24), and chorioretinal lesions 8,3% (n=2/24). 14 eyes had available fluorescein angiography (FA) imaging and of those, 78.5% (n=11/14) revealed retinal capillary leakage, and 71.4% (n=10/14) revealed optic disc staining/leakage. Visual outcomes were favorable in most eyes (n=17/20) except for 3 (one had persistent ME, one with macular scar formation, and one developed amblyopia). 91.6% (n=11/12) patients received systemic treatment. Of those, 75% (n=9/12) received systemic corticosteroid treatment and/or immunomodulatory therapy (IMT), with 41.6% (n=5/12) patients requiring biologics to control intraocular inflammation (IOI). 66.6% (n=8/12) of patients achieved IOI quiescence and of those, 2 achieved drug-free remission during follow-up period. However, one patient in remission developed a recurrence 10 months after discontinuation of IMT. Figure 1 demonstrates fundus and FA findings in a representative patient.

Conclusions: Ub2M is a useful biomarker for the diagnosis of TINU syndrome. Posterior segment manifestations are not uncommon in TINU patients. Therefore, FA is critical for the management of patients with TINU. The majority of patients required systemic treatment in order to control IOI and prevent relapses.

ABSTRACT BODY:

Purpose: Human stem cell-derived retinal organoids (RtOgs) are able to develop matured photoreceptor cells and outer segment structures. Fully functional RtOgs should obtain complete and intact neural pathways between retinal cell layers. The purpose of this study was to apply an advanced electrophysiology testing system for verifying the functionality of matured RtOgs cultured by a customized microfluidic bioreactor platform.

Methods: RtOgs were derived from CRX-GFP genetically modified human embryonic stem cell (hESC) line (Collin et al. 2016, Stem Cells), and cultured on a customized microfluidic bioreactor system (Xue et al. 2021, Lab Chip) from day 103 to 170. On day 170, two RtOgs with outer segment structures were cut into half, with the inner layer retinal cells faced down and seeded on two high-density microelectrode arrays (HD-MEA) wells, respectively. Spontaneous discharge of RGCs and light stimulation on photoreceptor cells were measured using the full scan and network recording modes provided by the MaxOne recording system. The light stimulation experiment used natural light generated from a multi-spectral light source with controlled illuminance (ranging from 20.57 to 883.92 lux). RtOgs were cultured on the HD-MEA system from day 170 to 204 and dark-adapted before the light stimulation experiment.

Results: Spontaneous discharge of retinal cells was observed initially on day 184, the total firing rate, burst frequency, and the number of spikes per burst increased over time. RtOgs' light responsiveness was confirmed by the denser raster scanning plot, increased firing rate, and the number of spikes per burst.

Conclusions: RtOgs cultured by the microfluidic bioreactor system developed functional inner retinal cell and photoreceptor layers, as well as the neural pathway in between. The HD-MEA recording system used in this study achieved in vitro longitudinal live recording of the RtOgs' electrophysiological properties.

ABSTRACT BODY:

Purpose: In a randomized clinical trial comparing bilateral lateral rectus muscle recessions (BLR) with unilateral recess-resect (R&R) for childhood intermittent exotropia (IXT), we previously found no significant difference in cumulative probability of suboptimal surgical outcome by 3 years (46% in BLR and 34% in R&R; difference = 9%; 95% confidence interval (CI): -6% to 23%). (PEDIG, Ophthalmology 2019;126(2): 305-317) We now report outcomes after 8 years of follow-up.

Methods: After a 3-year randomized trial, 123 (64 in BLR and 59 in R&R) of the 197 original cohort (age 3 to <11 years with basic-type IXT 15 to 40 prism diopters (Δ), stereoacuity of 400 arc sec or better and no prior surgery), consented to participate in an additional 5 years of follow up, with treatment at investigator discretion. The primary outcome measure was “suboptimal surgical outcome” by 8 years, defined as any of the following at any visit: exotropia ≥10Δ by simultaneous prism cover test (SPCT) at distance or near; constant esotropia ≥6Δ by SPCT at distance or near; loss of near stereoacuity by ≥2 octaves from baseline; re-operation without meeting any of aforementioned criteria. "Complete or near complete resolution" at 8 years was defined as: any exodeviation <10Δ by SPCT and prism alternate cover test (PACT) at distance and near AND ≥10Δ reduction in baseline angle by PACT at distance and at near (if ≥10Δ at baseline); any ET <6 Δ at distance and near; no decrease in stereoacuity by ≥2 octaves; and no additional treatment for IXT.

Results: The cumulative probability of suboptimal surgical outcome by 8 years was 66% for BLR and 53% for R&R (difference = 13%, 95% CI: -4% to 30%). Complete or near complete resolution at 8 years occurred in 14% (6 of 42) for BLR and 39% (16 of 41) for R&R (difference = -25%, 95% CI: -44% to -5%). The cumulative probability of reoperation by 8 years was 32% for BLR versus 10% for RR (difference = 22%, 95% CI = 7% to 37%).

Conclusions: There was no significant difference in the study-defined suboptimal surgical outcome by 8 years between BLR and R&R for childhood IXT. However, the R&R group had a higher resolution rate and lower rate of reoperation by 8 years. Taken together, our findings suggest that a unilateral recess-resect procedure may provide superior long-term outcomes to bilateral lateral rectus recession for basic-type childhood IXT.

ABSTRACT BODY:

Purpose: Photoreceptors are highly polarized retinal neurons that absorb light and generate an electrical signal through the process of phototransduction. Light-dependent changes in the membrane potential drive glutamate release from the synaptic terminal onto the second order neurons, bipolar cells (BCs) and horizontal cells (HCs). The photoreceptor's synaptic ribbon facilitates a high rate of exocytosis (vesicle fusion), which is complemented by endocytosis (vesicle retrieval). Endocytosis commonly requires the GTPase dynamin, whose two isoforms, Dnm1 and Dnm3, are expressed specifically in neurons. Here, we evaluated the impact of deleting Dnm1 and 3 on rod photoreceptor structure and function.

Methods: Dnm1- and Dnm3-floxed mice were bred with transgenic iCre75 mice to generate rod-specific single ($^{rod}Dnm1^{-/-}$ and $^{rod}Dnm3^{-/-}$) and double knockouts ($^{rod}Dnm1^{-/-}/3^{-/-}$). ERG recordings were used to test photoreceptor function and signal transmission to BCs. Photoreceptor structure was evaluated by immunohistochemistry, confocal microscopy and electron microscopy.

Results: Immunostaining confirmed the conditional deletion of Dnm1 and 3 from rods. In $^{rod}Dnm1^{-/-}/3^{-/-}$ mice, scotopic ERG a-waves were normal at P90, consistent with normal outer nuclear layer thickness and rod outer segment length; whereas scotopic b-waves were significantly impaired, consistent with a thinning of the outer plexiform layer. Immunostaining of photoreceptor synaptic terminals with ribbon synapse-related proteins (RIBEYE and bassoon) and synaptic vesicle-related proteins (VGLUT1 and complexin-3) showed degeneration of rod terminals. Consistent results were obtained by electron microscopy. In contrast, cone pedicles and the cone-driven ERG in $^{rod}Dnm1^{-/-}/3^{-/-}$ mice remained intact. At P90, $^{rod}Dnm1^{-/-}/3^{-/-}$ retinas showed a reduced number of HCs (anti-calbindin) and an increase in neurite sprouting from rod BCs (anti- PKCα). No abnormalities of any sort were observed in single knockouts of either Dnm1 or 3, suggesting that their function in rods is redundant.

Conclusions: Deletion of Dnm1 and 3 from rods causes functional impairment and degeneration of the synaptic terminal. This degeneration is accompanied by structural defects in postsynaptic neurons and loss of light-driven signals in rod BCs. Normal function of rod synapses requires dynamin-dependent endocytosis.

ABSTRACT BODY:

Purpose: We assessed the prevalence of refractive error in a sample of children of Northwest Mexico using the Refractive Error Study in Children protocol of the World Health Organization, which allows the comparison with other global studies.

Methods: A total of 783 students (384 female and 399 male) in Sinaloa's basic school system participated in the study from 2020 to early 2021. Optometrists and student clinicians from the Optometry Program of the Autonomous University of Sinaloa conducted the testing. Tests included visual acuities and static retinoscopy. We did use a cycloplegic agent when the far visual acuity of the students was equal to or worse than 20/40.

Results: The results showed a high prevalence of uncorrected refractive errors. Myopia, defined as a refractive error ≤ -0.50 D, had a prevalence of 24.64% (95% CI: 21.45— 27.58) hyperopia, defined as a refractive error ≥ +2.00 D had a prevalence of 2.04% (95% CI: 1.14— 3.19) and astigmatism, defined as a refractive error with a cylinder ≥ 0.75 D had a prevalence of 19.79% (95% CI: 16.85—22.47). We did not find a significant effect of sex on myopia (Chi square = 0.27, p = 0.60), hyperopia (Chi square = 0.17, p = 0.18) or astigmatism (Chi square = 0.82, p = 0.36).

Conclusions: The prevalence of myopia found in children (24%) is similar with a high prevalence of myopia reported in adolescents worldwide and in Mexico's northern regions (40%). The results suggest that students attending basic school and entering high school should be required to have an optometric eye examination.

ABSTRACT BODY:

Purpose: Use of Atropine to slow myopia is associated with undesirable side effects, particularly, pupil dilation and a decrease in accommodative amplitude. We report changes in pupil diameter (PD) and accommodative amplitude (AA) with Atropine (Atr) used alone and in combination with Caffeine (Caf).

Methods: In a prospective, clinical trial, 96 Vietnamese children with myopia (mean age 10.4±2.0 yrs, -4.1±1.3D) were randomized to nightly use of either 2% Caf, 0.02% Atr with 2% Caf, or 0.02% Atr (Customcare Compounding Pharmacy, Australia) and single vision spectacles during day. Additionally, 86 children with myopia (mean age 10.1 ± 2.1 yrs, -3.3±1.4D) were enrolled in a parallel group to serve as controls with single vision spectacles only (SVL). At baseline, 2 wk, 3, 6, 9 and 12 months, PD (photopic: 300 lux at eye; mesopic: 30 lux; Oculus Park 1, OCULUS GmBH, Wetzlar, Germany) and AA (Royal Near Pt Ruler, push up method with best corrected SVL, -4.0D) was measured. An average of 3 measurements were considered for PD and AA. Change in PD and AA from baseline was averaged over follow-up visits and differences between groups analysed using linear mixed model and logistic regression. Level of significance was 5%.

Results: Compared to baseline and to SVL, Atr and Atr+Caf increased PD and reduced AA (Table). Caf was similar to SVL. Importantly, change in photopic PD with Atr+Caf was significantly lower compared to Atr alone (0.8mm vs 1.2mm, p=0.006) but not different for change in mesopic PD (0.4mm vs 0.6mm, p=0.678) and AA(-2.8D vs -3.5D, p=1.000).Risk of an increase in mesopic PD over time was 1.5X greater with Atr than Atr+Caf (p=0.033). A photopic PD increase of ≥1mm and ≥2mm was 3.3X and 7.0X greater with Atr compared to Atr+Caff (p=0.001 & 0.008 respectively). The probability of having a photopic PD of ≥1.2mm was reduced by ≥45% with Atr+Caff for all ages and visits.

Conclusions: When Caffeine was combined with Atropine, the observed PD change was smaller compared to the PD change with Atropine alone. Caffeine did not affect the slowing of myopia observed with Atropine (seeTran HDM, ARVO abstract 2022). Caffeine has potential in reducing risk of side effects associated with Atropine without affecting its efficacy.

TITLE: Deletion of Zeb1 blocks injury-induced endothelial mesenchymal transition in the mouse corneal endothelium in vivo

SESSION TITLE: Corneal Endothelium

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J.M. Heur, J. Lee, Ophthalmology, University of Southern California, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: J. Heur: Commercial Relationship(s);Code S (non-remunerative):OneLegacy Eye Bank | JeongGoo Lee: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: FGF2-induced mesenchymal transition (MT) in human and mouse corneal endothelium ex vivo leads to Zeb1 activation and subsequent retrocorneal membrane (RCM) formation. We investigated whether Zeb1 deletion can block RCM formation in FGF2-induced MT in the mouse corneal endothelium in vivo following surgical injury.

Methods: Hemizygous UBC-CreERT2 mice were crossed with homozygous mice harboring loxP-flanked Zeb1 alleles ($Zeb1^{flox/flox}$) to generate $Zeb1^{flox/flox}$:UBC-CreERT2 mice. Intracameral injection of 4-hydroxytamoxifen (4-OHT) renders the Zeb1 allele into a loss of function mutant in the corneal endothelium. Corneal endothelium in anesthetized mice was surgically injured in vivo under direct visualization 7 days after intracameral injection of 4-OHT. Gene expression was analyzed by semi-quantitative RT-PCR and by immunoblotting in the mouse corneal endothelium in vivo.

Results: Conditional deletion of Zeb1 by 4-OHT in $Zeb1^{flox/flox}$ mice inhibited FGF2-induced expression of Zeb1 mRNA and protein. FGF2- and surgical injury-induced expression of EnMT-related genes, including fibronectin, vimentin and type I collagen, and suppression of E-cadherin were inhibited by Zeb1 deletion mouse corneal endothelium in vivo. Surgical injury led to corneal edema, 189.0 ± 14.6um (injury) vs 92.3 ± 2.8um (control), and injury-induced edema was significantly reduced by Zeb1 targeting, 182.2 ± 15.5um (injury) vs 106.8 ± 11.1um (injury + 4-OHT), $F = 120.9$, $p < 0.00001$. Moreover, conditional knock-out of Zeb1 also inhibited injury-dependent RCM formation in mouse corneal endothelium in vivo.

Conclusions: Our data show that Zeb1 is key mediator of FGF2- and surgical injury-dependent endothelial mesenchymal transition in mouse corneal endothelium, with Zeb1 regulating type I collagen, fibronectin, and vimentin expression. These results suggest that Zeb1 signaling could be a therapeutic target for inhibiting anterior segment fibrosis.

TITLE: Mental Health and Visual Acuity in Patients with Age-related Macular Degeneration

SESSION TITLE: AMD: Clinical and translational research/AMD therapies (excluding anti-VEGF)

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Fonteh, A.M. Lynch, R. Navo, N. Mandava, M. Mathias, J.L. Patnaik, University of Colorado Denver School of Medicine, Aurora, Colorado, UNITED STATES|

Commercial Relationships Disclosure: Cheryl Fonteh: Commercial Relationship: Code N (No Commercial Relationship) | Anne Lynch: Commercial Relationship: Code N (No Commercial Relationship) | Roxanne Navo: Commercial Relationship: Code N (No Commercial Relationship) | Naresh Mandava: Commercial Relationship: Code N (No Commercial Relationship) | Marc Mathias: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Patnaik: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: There is an established association between visual acuity (VA) loss and depression in patients with AMD. However, there is a paucity of research linking VA with mental health amongst the different subgroups of AMD. The goal of this study was to describe the relationship between VA and mental health questions on the NEI-VFQ-25 questionnaire in patients with different classifications of AMD, and to identify predictors of mental health subscale scores.

Methods: Patients with AMD defined by multi-modal imaging were recruited into a Colorado AMD registry. Habitual VA was obtained by a trained certified ophthalmic technician using the Snellen VA as distance viewing. At enrollments, patients completed the 25-item NEI-VFQ-25, a visual questionnaire that includes 25 questions regarding the patient's visual functionality with regular daily activities. Mean scores on the mental health subscale of the VFQ were calculated by AMD classification and VA groups. Univariate and multivariable general linear models were used to estimate associations between mental health scores and variables of interest.

Results: A total of 875 patients were included in the study. Patients with bilateral both (geographic atrophy and neovascular) scored lowest on the mental health subscales with a mean ± SD of 59.6 ± 29.3. Patients with a habitual VA of 20/200 or worse scored the lowest on mental health subscales scores in both the better and worse seeing eye of 44.8 ± 25.9 and 63.9 ± 28.4 respectively. Patients with a VA of 20/20 or better had the highest scores on the mental health subscales in both the better and worse seeing eye of 85.3 ± 17.7 and 89.1 ± 13.0 respectively (Fig 1). VA of the better and worse seeing eye and AMD classification were significant predictors of mental health subscale scores (all $p<0.0001$ except the worse-seeing eye in multivariable model where $p=0.012$). Patients enrolled during the COVID pandemic had mental health scores that were 2.7 points lower than prior to the pandemic, but this difference was not significant ($p=0.22$).

Conclusions: There is a significant association between mental health questionnaire scores and AMD classification, as well as VA in both the better-seeing and worse-seeing eyes in patients with AMD. It is important for clinicians to recognize feelings of worry/ frustration in these patients, so they can be appropriately diagnosed, referred, and treated for depression and/or anxiety.

ABSTRACT BODY:

Purpose: Glaucoma is the commonest cause of irreversible blindness globally, affecting patients' quality of life. There have been several attempts to evaluate health-related quality of life using different instruments. Here, we assess utility values (UVs) in a cross-section of patients with ocular hypertension and glaucoma at all stages of severity.

Methods: Patients (n=341) requiring treatment for ocular hypertension and open-angle glaucoma (primary open-angle glaucoma, pseudo exfoliative, and normotension glaucoma) were recruited from two clinical sites in London, United Kingdom. UVs were evaluated for patients' health states using the standard gamble for death and standard gamble for blindness. The Mean Deviation from Humphrey visual field analyser of each patient's worse eye was used to classify participants into mild, moderate, and severe visual field loss groups according to Hodapp-Parrish-Anderson Criteria.

Results: Mean UV for the whole patient cohort was 0.77 (standard deviation (SD) 0.27; 95% confidence interval (CI) 0.74 to 0.80) with the standard gamble for blindness; and 0.87 (SD 0.22; 95% CI 0.85 to 0.90) for a gamble of death. Only 43% of patients were willing to risk blindness in return for perfect vision; whereas 60% were willing to risk dying in return for perfect vision.

Mean UV in patients with severe visual field loss was 0.73 (SD 0.27) with standard gamble for blindness and 0.83 (SD 0.25) with standard gamble for death. With each method, mean UV was lower in those with severe visual field loss compared to those with mild visual field loss (0.80 (SD 0.26), and 0.92 (SD 0.18), respectively). The mean difference in UV between mild and severe groups was 0.076 (95% CI 0.010 to 0.142; P = 0.0071) with standard gamble for blindness. In standard gamble for death, the mean difference between mild and severe groups was 0.085 (95% CI 0.031 to 0.140 P = 0.0001).

Conclusions: Most patients requiring treatment for glaucoma and ocular hypertension are willing to risk their lives in return for the hypothetical offer of normal vision. Severity of visual field loss is inversely correlated with quality of life assessed using utility values. This information is useful for cost-utility analysis in clinical trials.

ABSTRACT BODY:

Purpose: The purpose of this study was to identify factors that influence the timing and duration of retinopathy of prematurity (ROP) regression, a variable process in preterm infants. We hypothesize that more inflammatory exposures and slower growth before a corrected gestational age (CGA) of 36 weeks delay and prolong ROP regression.

Methods: This retrospective chart review included infants born ≤ 30 weeks CGA and < 1500 grams previously included in three prospective cohort studies. Baseline characteristics, growth rates, and inflammatory events were collected for 76 infants who developed ROP not requiring treatment. The outcomes of interest were gestational age (GA) at the most severe stage of ROP (GA MSROP), GA at which ROP regression began, GA at the time of complete vascularization (GA CV), and duration of ROP regression. Continuous variables were analyzed with Pearson's correlation coefficients and categorical variables were analyzed with t-tests or analysis of variance ($P<0.05$).

Results: Mean GA was 35.3 weeks at MSROP, 40.0 weeks at time that ROP regression began, and 49.8 weeks at time of CV. Mean duration of ROP regression was 9.5 weeks. As summarized in Tables 1 and 2, later GA MSROP was associated with slower head growth, increased number of positive cultures, increased platelet transfusion volume in the first week of life, increased red blood cell transfusion volume, greater severity of ROP, and iron deficiency (ferritin<40). Later GA CV and prolonged duration of ROP regression were associated with slower length gain, increased number of positive cultures, higher mean total insulin dose in the first week of life, higher total number of inflammatory events, greater severity of ROP, maternal chorioamnionitis, and chronic lung disease (CLD). Increased IL-6 on day of life 5 was associated with prolonged duration of ROP.

Conclusions: This study confirms prior findings that increased severity of ROP is associated with later GA at MSROP and CV and prolonged duration of regression. New associations were found between slower neonatal growth and inflammatory comorbidities and prolonged or delayed ROP regression. These findings suggest that infants with these comorbidities may require longer surveillance for resolution of ROP.

ABSTRACT BODY:

Purpose: Low corneal hysteresis (CH) is a risk factor for glaucoma progression, as well as a combination of thin, stiff corneas. This study investigates viscoelastic and elastic metrics from air puff deformation in Normal (NL) and Primary Open Angle Glaucoma (POAG).

Methods: A prospective study of 107 subjects was done with 110 eyes of 55 NL subjects, age>50 years, 104 eyes of 52 POAG subjects. Viscoelastic response was evaluated with CH from the Ocular Response Analyzer; elastic response was evaluated with Corvis ST corneal metrics: Stress Strain Index (SSI) and stiffness parameter at first applanation (SP-A1). Scleral stiffness at highest concavity (SP-HC) and central corneal thickness (CCT) were included. Ganglion Cell Complex (GCC) from Optovue OCT was acquired. ANOVA was performed for age, CCT and IOPcc, while ANCOVA was used with IOPcc and CCT as co-variates for GCC, CH, SP-A1, and SP-HC. Regressions were performed between viscoelastic and elastic metrics, as well as between GCC and biomechanical metrics. Stepwise regressions with 0.15 entry/exit criteria were performed to predict GCC as a function of biomechanical metrics, and to predict CH as a function of elastic metrics. Statistical analysis was performed using SAS with significance threshold at $p<0.05$.

Results: No difference in age was found. CCT was thinner and IOPcc higher in POAG. GCC was thinner in POAG ($p < 0.0001$), with CH, SP-A1 and SP-HC not different when controlling for CCT and IOPcc. CH was significantly associated with CCT, SP-A1, SP-HC, and IOPcc in both groups. GCC was significantly positively associated with CH and CCT, only in POAG, but not with SP-A1, SP-HC or IOPcc in either group. GCC was predicted in POAG inversely by SSI, and directly by CH and SP-HC. In NL, GCC was predicted by SSI, CCT and IOPcc. CH was predicted in POAG directly by SP-HC, and inversely by corneal stiffness metrics and IOPcc. CH was predicted in NL by SP-HC, corneal stiffness metrics, IOPcc and CCT.

Conclusions: In POAG, thinner GCC was associated with lower CH and greater corneal stiffness, consistent with the literature on risk factors, as well as low scleral stiffness. Although greater cornea or sclera stiffness were associated independently with greater CH in POAG, when all elastic parameters were included in a predictive model, low CH was predicted by a combination of greater corneal stiffness, higher IOP, and lower scleral stiffness.

ABSTRACT BODY:

Purpose: The speed of human vision is expected to be rate-limited by the slowest deactivation reaction of phototransduction. Our high-acuity color vision is mediated mainly by the cones in the central foveal/macular retina. However, the speed of the rate-limiting deactivation reaction of human phototransduction in the macula is not known. To address this gap in knowledge, we analyzed photoreceptor light responses in different geographical regions of the human retina from posterior eyes procured during organ donations.

Methods: Using ex vivo Electroretinogram (ERG) we measured light-evoked photoreceptor responses from Ø0.5mm areas of peripheral and macular punches from eyes recovered < 20 min postmortem from two organ donors. Retinas were maintained in the dark in Ames' media oxygenated with 95% O_2 5% CO_2 and perfused in Ames' containing $BaCl_2$ and DL-AP4 to isolate photoreceptor responses during recordings. Cone responses were isolated by a double-flash stimulus protocol. We plotted the times taken for photoreceptor responses to return 50% (cones) or 30% (rods) from saturation against natural logarithm of the flash intensities, and applied a linear fit to determine the slope (τ_D), i.e. dominant time constant of the phototransduction termination, as described by Pepperberg et al (1992).

Results: We found the average τ_D of macular human cones was 25 ms (±4 ms S.D., n= 6 punches) and macular rods was 313 ms (±54 ms S.D., n =5 punches). In peripheral retina the τ_D of cones was 27 (± 8ms S.D., n = 6 punches) and rods 367 (± 100ms S.D., n = 6 punches). While macular rods had a τ_D >10 fold longer than that of macular cones, we found no significant difference between macular and peripheral cone dominant time constants, nor of the peripheral and macular rods.

Conclusions: These results indicate that the rate limiting step of human macular cone photoreceptors is significantly shorter than the lifetime of activated phosphodiesterase or rhodopsin determined previously in mouse rod photoreceptors. This is expected to contribute significantly to the high temporal resolution of the human high-acuity color vision. Our results demonstrate the potential of using human donor retinas to understanding the physiology of the human macula in health, aging and disease.

ABSTRACT BODY:

Purpose: Lipid peroxidation induces oxidative stress (OS) which is one of the major underlying causes of age-related diseases including AMD. In early AMD, extracellular deposits, cholesterol, lipids, and proteins accumulate between the RPE and the Bruch membrane. Cholesterol content is abundant in the retina and circulating low density lipoprotein (LDL) is taken up by low density lipoprotein receptor (LDLR) in the RPE and Müller cells. Lldr-/- mice develop thickened Bruch membrane and show increased VEGF with high fat diet; however, the role of LDLR in dry AMD has not been systematically investigated. The aim of this study is to determine the role of LDLR in an OS-induced model of dry AMD.

Methods: Confluent RPE cells were treated with150 µM tBH and expression of LDLR was studied using immunofluorescence. Kinetic activation of caspase-3/7 in Ldlr silenced RPE cells co-treated with 300 µM tBH and 10 or 40 µg/ml of an HDL- mimetic HM 10/10 peptide was quantified by live-cell imaging using the Incucyte system. In vivo studies were conducted with male C57BL6/J (7-8 weeks old) and Ldlr $^{-/-}$ mice. OS was imposed in mice with intravenous NaIO3 (20mg/kg BW). On day 7, fundus imaging, OCT and ERG were performed, and retinal thickness was measured from OCT images. Posterior eye cups were processed for histology, TUNEL staining and immunostaining for cleaved caspase 3.

Results: In primary human RPE cells, LDLR is predominantly found in the cytosol and tBH-induced OS altered its expression pattern. tBH markedly increased caspase activation in a time-dependent manner for 24 h in Ldlr silenced RPE cells. Co-treatment with HM-10/10 (10 µg/ml) significantly blocked caspase activation. Severe pathophysiological changes and functional impairment were observed in the retinas of NaIO3-treated Ldlr$^{-/-}$ mice. LDLR deficiency resulted in significant thinning of retina and compromised rod and cone functions with a total abolition of the rod function. Furthermore, RPE/BM was discontinuous with patchy RPE loss and irregular degenerated cell aggregates were more prominent in the NaIO3-treated retina of Ldlr$^{-/-}$ mice. Moreover, the percentage of apoptotic cells and cleaved caspase 3 was significantly elevated in stressed Ldlr$^{-/-}$ mice vs WT mice.

Conclusions: Our data suggest that loss of LDLR impairs retinal function which could play a significant role in the development of AMD.

ABSTRACT BODY:

Purpose: The retinal degenerative disease Macular Telangiectasia (MacTel) is a complex genetic disease with a common metabolic signature, decreased systemic serine and increased deoxysphingolipids (dSLs). Elevated dSLs are toxic to the retina and correlate with disease severity. However, the mechanism of dSL-mediated toxicity is not understood.

Methods: We model dSL toxicity in the retina by adding deoxysphinganine to mature retinal organoids. Toxicity is quantified by assaying cell death in photoreceptors using TUNEL staining. To characterize the retina's cell stress response to dSL toxicity we perform bulk RNAseq and single-cell RNAseq along with targeted and untargeted pathway analyses. We then utilize selective pharmacological inhibitors and activators of cell stress pathways to assay their functional relevance in the dSL toxicity response.

Results: Through bulk RNAseq we identify the Unfolded Protein Response (UPR) as one of the major stress pathways activated in dSL toxicity, with two of the UPR sub-branches, ATF6 and PERK, comprising the majority of the response. Using single-cell RNAseq we then characterize cell-specific dSL toxicity responses, identifying unique cell-type dSL susceptibility. We next determined the functional role of the UPR pathway sub-branches in dSL toxicity. Inhibition of the UPR PERK pathway prevents cell death indicating that apoptosis from dSL toxicity is mediated through PERK. Conversely, inhibition of the UPR ATF6 pathway exacerbates dSL induced cell death, indicating its role in homeostasis. Next, we screen ATF6 activating drugs to identify multiple compounds that alleviate dSL toxicity through the activation of ATF6.

Conclusions: We provide the first characterization of cell stress responses to dSL toxicity in the retina, identifying the UPR as a major cell stress pathway activated by dSL toxicity. Subsequent single cell RNAseq is used to characterize its unique effect in each cell type providing insight to its pathological mechanism in MacTel. We subsequently identify multiple classes of drugs that can prevent cell death as well as promote compensatory signaling pathways to promote cell health and survival through modification of the UPR.

ABSTRACT BODY:

Purpose: Norrin/Fzd4 signaling is indispensable for retinal vascular development and vessel function in humans and rodent models. These studies examined whether a novel Norrin mimetic could promote the regeneration of damaged blood vessels and their functions in diabetic retinopathy animal models.

Methods: We generated an antibody-based bi-specific Norrin mimetic (SZN-413) that targets Fzd4 and low-density lipoprotein receptor-related proteins and evaluated its effects on damaged retinal vessels in mice and rabbit models. In an oxygen-induced retinopathy (OIR) mouse model, SZN-413 was delivered intravitreally (IVT) and the avascular (AV) area and neovascularization (NV) area were measured 5 days later. Furthermore, the impact on vascular leakage by SZN-413 was examined in a VEGF-induced retinal vascular leakage rabbit model, in which the level of fluorescein leakage was measured 3 days after IVT delivery of VEGF together with SZN-413 or vehicle. ANOVA was used for statistical analysis.

Results: Results: In the OIR mouse model, nanogram quantities of SZN-413 significantly reduced the NV area size ($p<0.001$) to a level comparable to the group treated with 60 ug aflibercept. SZN-413 also showed a dramatic reduction in AV area size compared to vehicle ($p<0.001$) and compared to aflibercept ($p<0.01$). In the VEGF-induced retinal vascular leakage rabbit model, SZN-413 significantly reduced retinal vascular leakage by 78%, compared to the vehicle-treated group ($p<0.01$). No observable abnormalities were detected in ocular exams in these studies.

Conclusions: The novel Norrin mimetic, SZN-413, demonstrated anti-NV properties and reduced the avascular area in OIR mice, and reduced VEGF-driven retinal vascular leakage in rabbits. The results strongly suggests that the pathological cellular responses can be modulated by SZN-413, with possible therapeutic implications for diabetic retinopathy.

ABSTRACT BODY:

Purpose: Primary vitreoretinal lymphoma (PVRL) is the most common intraocular lymphoproliferative disorder. The disease is often difficult to diagnose, having an insidious onset that can masquerade as chronic uveitis. Histologic identification remains important for diagnosis, and vitreous biopsy is frequently obtained. Degradation of fragile lymphoma cells after pars plana vitrectomy (PPV) occurs in many cases, and may be impacted by the transition to smaller gauge and very high cut rate vitrectomy. We evaluated the diagnostic yield of PPV, specifically using modern high-cut rate dual-cycle cutters, on in vitro cell viability and diagnostic yield.

Methods: Human Burkitt lymphoma cell line Namalwa was processed by 25-G dual blade guillotine-type vitrectomy at five different cut rates (500, 1000, 4000, 7500, or 15000 cuts per minute [cpm]) at 2x10^5 cells/mL suspended in BSS. The cell viability and diagnostic yield in each subtype group was determined using hemocytometry with trypan blue staining, viable cell count using Cell Counting Kit-8 (CCK-8), and ocular pathologist-guided manual count. Yield was analyzed by regression analysis and ANOVA test.

Results: Linear regression and ANOVA were performed using viable cell concentration as measured by CCK-8 and cut rate (Figure 1). Linear regression analysis of CCK-8 samples demonstrated no significant variation of cellular yield by cut rate (R^2= 0.188, P=0.47). ANOVA found no statistically significant differences (P=0.61). The same were performed for histological cell count as a function of cut rate (Figure 2). Linear regression was not statistically significant (R^2= 0.531, P = 0.16) as well as ANOVA (P = 0.096).

Conclusions: Using a dual blade, high cut rate vitrector system, there was no statistical significance correlating number of viable cells with increasing cut speed. These results suggest that in contrast to prior findings using 20G or 23G vitrectomy for diagnostic vitrectomy, modern vitrectomy systems may be employed at their maximum cut rate without compromising the viability of lymphoma cells and potential PVRL diagnoses.

ABSTRACT BODY:

Purpose: Deep learning (DL) models have transformed medical image analysis, including OCT image analysis. However, these models require copious labeled data for each device of interest, as they do not generalize across devices from different manufacturers. We sought to use Generative Adversarial Networks (GAN) to generalize a DL model trained on Heidelberg OCTs to segment Topcon OCTs.

Methods: We developed an unsupervised GAN model, GANSeg, to segment Topcon 1000 OCTs (domain B) from the UK Biobank while training on 110 labeled 7-layer segmentations from the Duke Heidelberg dataset (domain A). Traditional supervised DL models learn a mapping from A to A_{label} (Figure 1a), and do not generalize to B images. In contrast, GANSeg uses a GAN to apply B style to the contents of A images, while simultaneously making the U-Net segmenter robust to images in both styles (Figure 1b). To validate GANSeg segmentations, three graders manually segmented the 7 layers on 30 OCTs from UK Biobank, and the Intersection over Union (IOU) between the graders, a U-Net trained only on Heidelberg ($U\text{-}Net_{Heidelberg}$) and $U\text{-}Net_{GANSeg}$ are compared on the 30 OCTs.

Results: $U\text{-}Net_{GANSeg}$ significantly outperforms a $U\text{-}Net_{Heidelberg}$ in segmenting Topcon 1000 in all layers (Figure 2). It achieves comparable IOUs, between 60% to 70%, to human graders, all while having no labeled Topcon 1000 data. Moreover, GANSeg retained the ability to segment Heidelberg OCTs after learning to segment Topcon OCTs.

Conclusions: GANSeg achieved comparable IOUs to human graders, and the GANSeg framework enables us to transfer supervised DL algorithms across devices without labeled data, thereby greatly expanding the applicability of DL algorithms.

ABSTRACT BODY:

Purpose: Quercetin (QUE) and resveratrol (RSV), natural occurring polyphenols, have been proven to be a potential new line of treatments for the ocular surface diseases related to oxidative stress. To use these molecules as a topical treatment, a formulation strategy is required due to their low bioavailability.Our aim was to encapsulate QUE and RSV into Elastin-like recombinamer nanoparticles (NPs) and test their biocompatibility and antioxidant activity in vitro on a Human Corneal Epithelial (HCE) cell line and assess their penetration of corneal tissues ex vivo on excised porcine eyes.

Methods: The biocompatibility of the NPs containing QUE, RSV or both with the HCE cells was assessed by the XTT cell viability assay after a 24-hour exposure.To induce oxidative stress, HCE cells were subjected to UV-B light. The antioxidant activity of NPs was evaluated using H_2DCFDA, a fluorescent indicator of reactive oxygen species (ROS). For QUE and QUE/RSV containing NPs the concentration range employed was 5-50 μM, while for RSV NPs this was 25-300 μM.To ex vivo evaluate the permeation through porcine corneal tissues, NPs were loaded with Nile Red, a fluorescent dye used as hydrophobic model drug.All experiments were performed in triplicate (n=3). The statistical analysis of data was performed via ANOVA followed by Games-Howell or Tukey's post-hoc tests.

Results: None of the formulations reduced the viability of HCE cells. At the highest concentration of QUE in the NPs, 79 % ($p<0.01$) of total intracellular ROS was scavenged, while the NPs containing RSV were able to neutralize 70.6 % of ROS ($p<0.05$). NPs encapsulating QUE/RSV showed to be able to decrease the total ROS by 81.16 % ($p<0.05$). Images taken by Fluorescence Microscopy revealed that encapsulated Nile Red was more efficient in permeating ex vivo porcine corneas than the free compound.After 5 minutes of contact the encapsulated Nile Red was observed in the corneal epithelium, while at longer contact times, 30 and 60 minutes, it was observed in the corneal stroma.

Conclusions: Our results show that the ELR NPs containing QUE, RSV or both are biocompatible with HCE cells and possess excellent antioxidant properties in vitro.Improved permeation in ex vivo corneal tissues were noticed when the fluorescent drug model was encapsulated into the ELR NPs.This formulation strategy seems a promising method for topical delivery of QUE/RSV to the ocular surface.

TITLE: Effect of Rapid Alternating and in phase flicker occlusion on Stereopsis

SESSION TITLE: Vision assessment and Clinical applications

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: B. Ramakrishnan, S.B. Stevenson, University of Houston, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure: Bhavatharini Ramakrishnan: Commercial Relationship: Code N (No Commercial Relationship) | Scott Stevenson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Rapid alternating occlusion of the eyes is a relatively new treatment for amblyopia that has shown promise for improving both stereoacuity and visual acuity in some amblyopic subjects. Previously we looked at the effect of alternate and in-phase occlusion on vergence eye movements and found that vergence responses were disrupted by out-of-phase flicker more than in-phase flicker, particularly at lower frequencies. In this current study compared the effect of alternate vs. in phase occlusion of different frequency on stereopsis for normal subjects, to dissociate the effect of flicker per se from the effect of alternate occlusion.

Methods: Disparity thresholds were measured using a 30 trial, 1 up 2 down staircase beginning at 10 arc minutes disparity. Five staircases were obtained from five healthy adult subjects for all combinations of contrast (100%, 50%, 25%) and flicker (2, 4, 8, 16 and 32 Hz, In-phase and out of phase binocular flicker, and no flicker). The stimulus was a filtered noise pattern (1 cpd, 1 octave bandwidth), presented for one second. Horizontal disparity was added to one half of the image, and subjects indicated which half appeared closer. Left and right eye images were displayed side by side on a gamma corrected monitor and viewed through a mirror haploscope while wearing Eyetronix shutter glasses. With shutter glasses open the luminance was 71cd/m^2 ' closed it was 0.53cd/m^2. Testing distance was 97cm.

Results: Flicker elevated stereoscopic thresholds in most subjects. The flicker did not abolish stereopsis, however: subjects were able to detect a few arc minutes of disparity at all but the lowest frequencies of out-of-phase flicker. Two subjects showed almost no effect of flicker on stereo thresholds except at the lowest frequencies of out-of-phase flicker.

Conclusions: The results of this study show that stereopsis thresholds are elevated by both alternate and in phase flicker but are severely impacted only at the lowest temporal frequencies of 2 and 4 Hz. Flicker overall had an impact on three of five subjects. Taken together with our findings on vergence, it appears that the alternating occlusion provides some of the effects of patching, while still allowing binocular function during treatment, but the dramatic flickering may be disruptive for many subjects.

ABSTRACT BODY:

Purpose: The aging population is rapidly increasing in the world and various pathological conditions are associated with aging, for example, the ocular surface becomes more vulnerable to external stimuli, potentially leading to corneal opacity and angiogenesis, resulting in blindness. Dry eye disease (DED) is a common age-related ocular surface pathology. It is unknown whether cellular senescence (a state of permanent cell cycle arrest) influences the ocular surface microenvironment during DED. We, therefore, investigated the presence of senescent cells in young versus old mice before and after exposure to desiccating stress due to lacrimal gland excision (LGE), and we determined the potential role of senescent cells.

Methods: We used our p16-3MR transgenic mice model, which allows the visualization and elimination of senescent cells that express the cell cycle inhibitor and tumor suppressor $p16^{Ink4a}$. Ocular surface, including cornea and conjunctiva, was analyzed using imaging and quantitative reverse transcription in young (4 months) and old mice (24 months). LGE, which triggers dry eye conditions at the ocular surface, was performed, and ocular surface changes were assessed by measuring the expression of $p16^{Ink4a}$, matrix metalloproteinase 9 (Mmp9), and vascular endothelial growth factor (Vegf). To eliminate senescent cells, topical ganciclovir treatment, which enables the elimination of p16-expressing senescent cells through the herpes simplex virus thymidine kinase, was applied to p16-3MR transgenic mice.

Results: Old mice displayed more punctate epithelial damage in the cornea and a significant decrease in goblet cell density in the conjunctiva compared to young mice. In addition, $p16^{Ink4a}$ mRNA levels showed an age-related increase in both the cornea and the conjunctiva. LGE caused punctate corneal damage, accompanied by lower tear secretion. Even though the cornea remained clear in young mice, LGE in old mice caused corneal opacity with severe angiogenesis and an increase in $p16^{Ink4a}$, Mmp9, and Vegf expression. Topical ganciclovir applied to LGE-treated eyes of old mice reduced angiogenesis and corneal epithelial hyperproliferation and downregulated $p16^{Ink4a}$, Mmp9, and Vegf.

Conclusions: We conclude that selective elimination of senescent cells is a potential approach for the treatment of ocular diseases, such as DED, that are associated with aging.

ABSTRACT BODY:

Purpose: The optic nerve head is incompletely developed at birth and continues to grow postnatally. Recent advancements in noncontact handheld optical coherence tomography (OCT) enable us to directly image the optic nerve head at the bedside. Our goal is to quantify optic disc development in preterm infants using OCT-generated disc diameter (DD), disc-fovea distance (DF), and DD:DF (same parameters used to evaluate for the presence of optic nerve hypoplasia).

Methods: In this retrospective cohort study, we analyzed bedside OCT scans of the left eye that were captured during the prospective BabySTEPS study. We included imaging sessions that occurred between 30 and 50 weeks postmenstrual age (PMA), occurred prior to retinopathy of prematurity (ROP) treatment, and captured the fovea and both edges of the Bruch's Membrane Opening (BMO) on a single OCT volume. Graders marked the BMO and fovea using custom infant-specific software. We performed cross-sectional analysis on 36 eyes with OCT scans acquired at 36±1 weeks PMA and longitudinal analysis on 29 eyes with at least three scans between 30 and 50 weeks PMA. We evaluated the change in DD, DF, and DD:DF ratio over time and their associations with the following demographic and ROP characteristics: gestational age, birthweight, sex, maternal race, maternal parity, and ROP stage at imaging.

Results: Mean gestational age (GA) was 27.3±2.6 weeks for the cross-sectional cohort and 26.5±2.3 weeks for the longitudinal cohort. In the cross-sectional analysis, GA was significantly correlated with DF (r=-0.39 [-0.64, -0.07], p=0.02) and DD:DF (r=0.49, 95% [0.20, 0.71], p=0.002). Infants with ROP stage 0-1 had significantly smaller DF (4169±337 vs. 4394±279 μm, p=0.04) and significantly larger DD:DF (0.25±0.03 vs. 0.23±0.02, p=0.02) than those with ROP stage 2-3. In the longitudinal analysis, DD increased by 20.5±0.9 μm/week (p<0.001), DD:DF increased by 0.0044±0.0003 per week (p<0.001), and DD:DF correlated with GA (0.0047±0.0019 per gestational week, p=0.02).

Conclusions: In premature children in the early few weeks of life, DD:DF is frequently less than 0.35 which meets the current definition of optic nerve hypoplasia. However, it slowly increases and normalizes with growth. Future larger studies are necessary to verify these conclusions.

ABSTRACT BODY:

Purpose: Short term endotamponade with perfluprocarbon liquids (PFCL) is used as a surgical technique in treatment of certain vitreoretinal conditions. Controversy exists around its safety, as cases of retinal toxicity and inflammation were described. We present indications for use and results of short term endotamponade with a PFCL, perfluoro-N-octane (PFO) in treating surgical retinal pathology at Sydney and Sydney Eye Hospital (SSEH)

Methods: A retrospective case series of 42 eyes of 42 patients (31 male, 11 female, 10- 87 yr, mean:55.4 yr) who underwent vitrectomy with short term PFO endotamponade at SSEH between September 2019 and June 2021. Patients consented to data use, and their medical records were reviewed retrospectively. We recorded presenting diagnosis, pre-operative best-corrected visual acuity (BCVA), duration of PFO endotamponade, type of subsequent endotamponade used, additional surgeries, complications and final BCVA. Statistical analysis was carried out using R: A Language and Environment for Statistical Computing, version 4.0.5, R Core Team, R Foundation for Statistical Computing, Vienna, Austria.

Results: Preoperative BCVA was available in 37cases (mean:1.42logMAR). Indications included: giant retinal tear (GRT) (n=18); recurrent retinal detachment (RD)(n=7), RD with large or multiple breaks(n=5); penetrating eye injury (n=3). PFO was removed after 3-21days (mean:8.9days) and exchanged to long-acting gas in 58%(100%GRTs). Mean follow-up:177,3 days. Complications included: recurrent RD: n=3, cataract: n=7, significant epiretinal membrane: n=8 (5/8 in recurrent RD), macular oedema: n=7 (5/7 in recurrent RD), PFO in the anterior chamber: n=5, intraocular inflammation: n=2. We did not observe retinal toxicity. Mean final BCVA was 0.85logMAR overall and 0.40logMAR in the GRT group. Where preoperative data was available mean BCVA improved by 0.54logMAR. Visual improvement: 70.3%, deterioration:18.9%. Final BCVA was positively correlated with initial BCVA ($p < 0.001$). Diagnosis was significantly differentiating final BCVA ($p=0.001$).There was no significant correlation between final BCVA and duration of tamponade ($p=0.637$).

Conclusions: Short-term tamponade with PFO provides good anatomical and functional outcomes and can be safely used in selected cases. The final result depends on the complexity of the underlying pathology and initial BCVA, not length of the tamponade.

ABSTRACT BODY:

Purpose: Diabetes mellitus (DM) is a leading cause of blindness in working-age adults. It involves various epigenetic modifications such as altered DNA methylation and miRNA changes. In the cornea, DM causes persistent epithelial alterations including impaired wound healing, which may occur due to the dysfunction of limbal epithelial stem cells (LESC). Previously, we reported hypermethylation of WNT5A at the promoter region and up-regulation of Wnt5a regulating miR-203a in diabetic limbal epithelial cells (LEC) enriched in LESC, resulting in decreased Wnt5a expression. Our purpose was to use DNA demethylation and gene therapy approaches to normalize diabetic corneal epithelial wound healing and limbal stem cell expression by increasing Wnt5a expression.

Methods: Diabetic organ-cultured corneas obtained from postmortem human donor eyes were pre-treated with (A) DMSO control or DNA methylation inhibitor, zebularine (20 μM) for 48 hours or (B) biodegradable nanobioconjugates based on polymalic acid (PMLA) scaffold containing a control scrambled antisense oligonucleotide (AON) or AON to miR-203a (supposed to increase Wnt5a) for 4 days. Corneal epithelial 5-mm wounds were created with 1-heptanol, and wound healing was monitored over time. The healed corneas were embedded in OCT and sectioned (5 μm) for immunostaining to determine the limbal stem cell and diabetic marker expression.

Results: In diabetic organ-cultured corneas treated with 20 μM of zebularine, DNMT1 was significantly inhibited and Wnt5a expression was increased, resulting in the acceleration of corneal epithelial wound healing as compared to DMSO controls. Moreover, this treatment also increased the expression of putative stem cell markers, keratins 15 and 17, as well as diabetic markers, integrin α3β1 and nidogen-1, and activated the wound healing mediator, p-Akt at Ser 473. Similarly, treatment with the nanodrug PMLA-AON miR-203a also increased Wnt5a expression and stimulated epithelial wound healing vs. scrambled AON control. It also increased putative LESC (keratins 15 and 17) and diabetic (integrin α3β1 and nidogen-1) marker expression.

Conclusions: Our study documented for the first time the dual regulation of WNT5A in the diabetic cornea through DNA hypermethylation and miRNA action. Inhibition of DNA hypermethylation and miR-203a action can normalize corneal epithelial wound healing and limbal stem cell expression through the upregulation of Wnt5a.

ABSTRACT BODY:

Purpose: To characterize the vascular phenotypes of an experimental autoimmune retinal uveitis (EAU) model induced by interphotoreceptor retinoid-binding protein (IRBP) using multimodal imaging techniques.

Methods: We systemically administered IRBP or vehicle to adult C57BL/6 mice. Fundus photography, optical coherence tomography (OCT), in vivo live confocal imaging using different tracers, blood flow analysis by OCT angiography (OCTA), and electroretinogram (ERG) were performed after IRBP immunization. Hematoxylin and eosin and immunofluorescent staining were performed to characterize the immune reaction and vascular permeability. Cx3cr1-GFP mice (microglia-reporter mouse) and LysM-GFP mice (neutrophil-reporter mouse) were used for immune cell phenotyping.

Results: EAU mice exhibited perivascular inflammation, vitritis, and superficial retinal inflammation on fundus photography and OCT. H&E revealed immune cell infiltration in the perivascular area of the retina and choroid accompanied by a significant degree of peri-vasculitis that subsequently damaged the photoreceptors 3 weeks post-immunization. Immunofluorescent staining showed subsequent transcytosis induction after local microglial activation followed by neutrophil recruitment at the perivascular area. Transcytosis in the superficial and deep vascular areas was improved by suppressing immune cells (anti-Ly6C- induced neutrophil inhibition and minocycline-induced microglial inhibition). Intravital in vivo confocal imaging showed signs of neutrophil infiltration and obstructive vasculitis with perivascular leakage 3 weeks post-immunization. OCTA revealed a significant decrease in vascular flow in the deep capillary layer of the retina. Function analysis showed that scotopic responses were intact in 2 weeks; however, normal photopic and scotopic responses were hardly detected in EAU mice 3 weeks post-immunization.

Conclusions: Our data suggest that inflammatory cell activation and subsequent transcytosis induction in endothelial cells might be a major pathogenic factor for vascular leakage in uveitis, bring new insights into the pathophysiology of retinal vasculitis in non-infectious uveitis.

ABSTRACT BODY:

Purpose: We have recently demonstrated the pathogenicity of memory $CD4^+$ T cells in a well-characterized murine model of chronic autoimmune uveitis (CAU). Herein, we aim to determine whether chronic inflammation in CAU is associated with tissue and cellular hypoxia and if so, whether hypoxia regulates transcriptional programming of the uveitogenic memory T cells.

Methods: CAU was induced in wild-type C57BL/6 mice by immunization with interphotoreceptor retinoid-binding protein (IRBP) peptides emulsified in complete Freund's adjuvant (CFA), along with Bordetella pertussis toxin injection. Establishment of CAU was confirmed by digital fundus imaging at week 12. CAU mice were then intraperitoneally injected with pimonidazole (Hypoxyprobe^{TM}). After 24 hours, mice were sacrificed, and eyeballs, draining lymph nodes (dLN) and spleen were collected. Tissue cross sections were stained with Red549-anti-pimonidazole, AlexaFluor488-anti-CD3, and DAPI to detect tissue and cellular hypoxia. In addition, $CD44^{hi}CD4^+$ (memory T cells) and $CD44^{-/low}CD4^+$ (control T cells) were isolated using CD4 negative MACS sorting combined with FITC-CD44 FACS sorting. The sorted cells were subjected to qPCR analysis of mRNA genes. Flow cytometric analysis was also performed by staining BV421-CD4, PerCP/Cy5.5-CD44 and PE-hypoxia-inducible factor-1α (HIF-1α).

Results: Local hypoxia was demonstrated in the inflamed retina in CAU, most prominent in the destructed photoreceptor layer (PRL). In addition, significantly more T cells showing hypoxic state were present in the dLN (18.3 ± 0.9 vs 4.3 ± 0.5 per section) and spleen (29.3 ± 2.2 vs 3.5 ± 0.3 per section) in CAU as compared to normal controls. The sorted memory T cells showed ~ 2-fold up-regulation of HIF-1α mRNA expression (no difference in HIF-2α). Consistently, expression of HIF-1α protein in CAU-memory T cells was significantly increased (mean fluorescent intensity: 1496 ± 44 vs 964 ± 34). Finally, genes of HIF-1-associated transcriptional pathways including glycolysis (Hk2, Ldha, Slc2a1, and Slc16a3) and canonical Wnt/β-catenin activity (Ctnnbl1, Axin2, and GSK3b) were up-regulated in memory T cells.

Conclusions: Our data demonstrate that the uveitogenic memory $CD4^+$ T cells in CAU are in hypoxic state and exhibit hypoxia-driven transcriptional activity that is potentially essential for their long-term survival and function.

ABSTRACT BODY:

Purpose: Hypertransmission defects (HTD), one feature of retinal pigment epithelial and outer retinal atrophy (RORA), visible on en face optical coherence tomography (OCT) images, have been suggested as a risk factor for progression to geographic atrophy (GA). We aimed to determine the prevalence of these HTDs in eyes with intermediate age-related macular degeneration (iAMD).

Methods: Choroidal (64-200 µm below Bruch's membrane) en face spectral domain OCT images (Cirrus OCT, Carl Zeiss Meditec, Dublin, CA) of consecutive iAMD patients examined in an ophthalmology clinic setting were evaluated by trained graders for the presence of HTDs. HTD's were defined by the presence of a well-demarcated region of hyperreflectivity on the en face image of at least 80 µm in diameter, with evidence of at least some retinal pigment epithelial alteration on the corresponding B-scan as the explanation for the hypertransmission. By definition, as these were eyes with iAMD (i.e., no late AMD), none of these lesions met criteria for complete RORA or GA. Graders counted the number of HTD in each eye and also measured their greatest linear dimension (GLD).

Results: A total of 137 eyes with iAMD from 121 subjects were identified and included in this analysis. Among this cohort, 22 eyes (16.1%) of 20 participants (16.5%) demonstrated evidence of HTD(s) on the baseline (first available) en face OCT. For this subgroup of patients with HTD, mean (±SD) age was 77.2 (10.9) years, 12 (60.0%) were female and 18 (90.0%) had unilateral HTD. Of the 22 HTD eyes, 19 (86.4%) had a single HTD lesion (mean [range] number of lesions per eye, 1.2 [1-3]). Among the 22 HTD eyes, 13 (59.1%) had a GLD ≥ 250 µm, 5 (22.7%) had a GLD ≥ 125 µm but < 250 µm, and 4 (18.2%) had a GLD ≥ 80 µm but < 125 µm. Only 14 (63.6%) of the HTD eyes fulfilled all criteria of iRORA, of which 11 had a GLD ≥ 250 µm or more.

Conclusions: HTD are present in a significant proportion (~16%) of eyes with iAMD and they overlap partially with iRORA. If longitudinal studies confirm that HTD confer an increased risk for progression to GA, HTD may provide an efficient biomarker for identifying high-risk iAMD patients for enrollment into early intervention therapeutic trials.

ABSTRACT BODY:

Purpose: We published in 2015 a linear Rasch-based scale (Computer Vision Symptom Scale, aka CVSS17) for measuring the computer-related visual and ocular symptoms in workers using video-display terminals. Because Computer adaptive testing (CAT) is currently considered a more efficient and less time-consuming (for test-takers) method than traditional linear questionnaires, we decided to create a new CAT for assessing these symptoms in general population. Therefore, the aim of our study is to identify content for this new CAT and to calibrate the items included in it.

Methods: For content identification, we used three different sources: (1) items from existing instruments, including a review of the item bank developed for the CVSS17; (2) open questionnaires and semi-structured interviews with digital devices users; and (3) review of social media comments. Items emerged from this phase were reviewed and revised by a group of experts before including them in the new item bank. After that, students and staff of the Faculty of Optics and optometry along with workers from a technological company (DXC Technology) were invited to answer the 76 item bank's items. Subjects aged over 18 and using digital devices at least four hours a day were included in the study while those unable to understand the item descriptors were excluded. Responses were analyzed using Partial Credit Model (PCM) with Winsteps 4.5.1, to assess the item bank's reliability, DIF according to sex and age group (presbyopes or non-presbyopes), item point bi-serial correlation and person/item measure Infit and outfit characteristics.

Results: 76 unique items exploring 19 different symptoms were included in the item bank and the responses of 377 participants (70.82% women, median age: 23.00 years, range interquartile of age: 21.00 –47.00). PCM and differential item functioning (DIF) analyses supported the retention of 38 items in the final item bank. The 38 items fitted the Rasch model (mean square Infit and outfit 0.77–1.26) and there was no DIF. Item point bi-serial correlation was (0.41, 0.67) and item difficulty –in logits- ranged from -2.14 to 1.77.

Conclusions: A new item bank for the Digital Eye Strain Computer Adaptive Test (DESCAT) was developed using a systematic approach and all the items included in the DESCAT showed adequate psychometric properties.

ABSTRACT BODY:

Purpose: Evaluating the efficacy of Vyzulta as replacement therapy for latanoprost in primary open angle glaucoma (POAG) patients within a large tertiary care center.

Methods: A retrospective review of patients with POAG, who were treated with Vyzulta as replacement therapy (RT) for latanoprost, was performed from January 1st, 2018 to June 30th, 2021. Noted demographic and clinical data include age, race, gender, systemic diabetes mellitus (DM) or hypertension (HTN), intraocular pressure (IOP), and medical/surgical management. Data was collected prior to the addition of Vyzulta to patients' drop regimen (treated baseline) as well as at 1, 3, 6, and 12 months follow-up from initial Vyzulta start date. Criteria for success of Vyzulta as RT for latanoprost was defined as a percentage reduction of IOP from treated baseline, resulting in IOP between 5 - 21 mmHg at two consecutive follow-up visits, without additional medical or surgical intervention needed within 12 months. Percentages analyzed included 10%, 15%, 20%, and 30% IOP drop from treated baseline, and were defined as loose (LCr), qualified (QCr), moderate (MCr) and stringent (SCr) success criteria, respectively. QCr was chosen as 15% reduction of IOP from treated baseline as 80% of patients had IOP < 24 mmHg; thus success by QCr statistically would best correlate with a clinically meaningful decrease of IOP to within a normal range.

Results: 2611 patient charts reviewed; 65 patients (65 eyes) met inclusion criteria and were analyzed. Mean age (SD) was 72.28 (11.84) years. Demographics included 50.8% male, 84.6% African American, 33.8% with DM, and 75.4% with HTN. Mean baseline IOP (SD) was 22.2 (6.07) mmHg. Success rate of Vyzulta as RT for latanoprost was 40%, 29.2%, 18.5%, and 10.8% based on LCr, QCr, MCr, and SCr, respectively. There is no significant difference in success with any criteria, among patients with or without DM or HTN ($p>0.05$).

Conclusions: In an urban patient population with POAG, Vyzulta as RT for latanoprost is successful in 29% of patients in which goal IOP for treatment is IOP at 15% reduction from treated baseline, resulting in IOP between 5 - 21 mmHg at two consecutive follow-up visits, without additional medical or surgical intervention needed within 12 months.

ABSTRACT BODY:

Purpose: Retinal pathology has been linked to neurodegenerative diseases. Schizophrenia is a neurodegenerative disease with major research gaps and significant burden to society. Discovery of ocular biomarkers could lead to earlier diagnosis and improved outcomes for patients with schizophrenia. Additionally, identifying ocular manifestations of schizophrenia can lead to an improved understanding of the disease pathophysiology. In this study, we sought to examine the link between schizophrenia spectrum disorders (SSD) and vessel density in participant's optic nerve head (ONH) regions of the retina using Optical Coherence Tomography Angiography (OCTA).

Methods: The study included 73 SSD patients and 57 age-matched healthy controls. Schizophrenia diagnosis was confirmed through structured diagnostic interviews. OCTA was used to noninvasively image retinal vessels in the whole retinal thickness (WR) and superficial capillary plexus (SCP) of the ONH region. OCTA images were binarized using the Phansalkar threshold method and subsequently skeletonized in ImageJ (image 1).

Results: The mean binarized vessel densities for the controls and SSD in the WR were 64.1±4.0 and 65.1±3.0, respectively (p=0.12). Skeletonized vessel densities in the WR were 15.5±0.8 in the controls and 15.7±0.6 in SSD (p=0.30). In the SCP, the binarized vessel densities were 61.5±2.8 in the controls and 62.0±3.3 in SSD (p=0.39). The mean skeletonized densities in the SCP were 15.0±0.6 in the controls and 15.0±0.7 in SSD (p=0.74).

Conclusions: Phansalkar binarization and skeletonization of retinal OCTA images did not find significant differences in vessel density in the ONH regions between schizophrenia patients and healthy controls. Vessel density in the ONH region of the retina of patients with schizophrenia may provide an important tool in the diagnosis and further understanding of the disease.

ABSTRACT BODY:

Purpose: To determine the rates of persistent infection, secondary glaucoma and visual acuity outcomes for patients who underwent penetrating keratoplasty (PKP) for an infectious corneal ulcer, as well as determine how timing of therapeutic PKP affects surgical outcomes.

Methods: A retrospective review was conducted of patients who underwent PKP between the years 2014 and 2020 at an academic medical center in Aurora, Colorado. Demographic information, insurance coverage, pre-operative exam findings, infectious organism, and size of transplant were compared for the outcomes of recurrent infection, transplant failure or rejection, secondary glaucoma and visual acuity before and after transplant. Chi-square testing was used for categorical comparisons and the Wilcoxon rank sum test for continuous variables.

Results: 56 patients (56 eyes) underwent PKP for an infectious corneal ulcer during the study period. There were 27 females (48.2%) and 29 males (51.2%) with a mean age of 58.3 (standard deviation 18). The most common infectious organism was bacterial (55.4%) followed by fungal (10.7%), viral (7.1%) and acanthamoeba (7.1%). For patients that had at least 30 days of clinic follow up after PKP (n = 46), 17 (37.0%) had recurrent infection, 16 (34.8%) had transplant failure or rejection, 16 (34.8%) developed secondary glaucoma, 15 (32.6%) required repeat PKP and 16 (35.6%) had post-op vision better than 20/200. Neither the infectious organism nor the size of the ulcer or donor transplant had any impact on post-operative outcomes. Those who developed recurrent infection following PKP had a greater duration of time between ulcer onset and PKP than those who did not (median 60 days from ulcer onset to PKP vs 17.5 days, p= 0.02). Those who developed secondary glaucoma had a greater duration of time between ulcer onset to date of PKP compared to those who did not develop secondary glaucoma (median 60 vs 14 days, p= 0.04).

Conclusions: Neither the infectious organism (bacterial, viral, fungal, acanthamoeba) nor the size of the ulcer or donor transplant had any impact on post-operative outcomes (recurrent infection, transplant failure, secondary glaucoma, visual acuity) following PKP. On average, patients who had recurrent infection and patients who developed secondary glaucoma underwent PKP later following ulcer onset compared to those who did not.

ABSTRACT BODY:

Purpose: Particulate matter (PM) is a primary trigger for the development of acute and chronic ocular surface disease, including allergic conjunctivitis. The purpose of the present study was to develop a novel rabbit model for PM-induced allergic conjunctivitis to facilitate future targeted drug discovery and development.

Methods: Standardized Reference Material (SRM® 2786) consisting of fine atmospheric particulate of < 4 µm diameter was obtained from the NIST. Male and female New Zealand White rabbits (1.5 -2 kg) were exposed to PM by topical instillation (5 mg/ml, TID, 35 µl) for a period of up to 10 days. Ophthalmic lifitegrast solution (5%, formulated as Xiidra®) was administered for a period of 10 days following discontinuation of PM instillations. Ophthalmic examinations were performed by a veterinary ophthalmologist in awake animals and scored using the SPOTS system. Schirmer Tear Test (STT)
was collected using sterile diagnostic test strips. Corneal fluorescein staining was performed under isoflurane anesthesia using fluorescein ophthalmic strips. Images were recorded with a Spectralis HRT system in fluorescein angiography mode. Images were scored using the Oxford scoring system (0 - 5 scale) and the NEI scoring system (0 - 4 scale per quadrant with a maximum score of 16).

Results: Exposure to PM for 7 days caused severe hyperemia; tear volumes showed a small but significant reduction (10 ± 1 mm vs. 7.7 ± 0.8 mm, n = 16 eyes, $P < 0.05$). PM treatment significantly increased median corneal fluorescein staining (+ 2 scores in Oxford grading; n = 15 - 16 eyes, $P < 0.001$ and + 9 scores in NEI grading; n = 15 - 16 eyes, $P < 0.001$). Changes to the tear film and cornea were detectable by anterior segment SD-OCT imaging. Discontinuation of PM treatment did not improve hyperemia or corneal fluorescein staining in untreated eyes after 10 days. In contrast, topical instillation of lifitegrast resolved hyperemia (n = 4 eyes, $P < 0.05$) and significantly reduced corneal fluorescein staining (n = 4, $P < 0.001$). Lifitegrast treatments had no effect on STT.

Conclusions: PM exposure induces ocular surface disease that is responsive to immunosuppressant therapy. To our knowledge this is the first report of a large animal model to study PM-induced ocular surface disease. Our new rabbit model offers a standardized experimental paradigm for the in vivo testing of novel therapeutic approaches targeting PM-induced allergic conjunctivitis.

ABSTRACT BODY:

Purpose: Variants of Activating Transcription Factor 6 (ATF6), a key regulator of the Unfolded Protein Response (UPR), cause severe morphologic and molecular defects in cone photoreceptors leading to achromatopsia (ACHM). ATF6 is expressed in all retinal cell types, and it is unclear how ATF6 disease variants affect retinal cells other than cones. Here, we analyzed the transcriptomes of major retinal cell types in retinal organoids created from induced pluripotent stem cells (iPSC) of ACHM patients carrying biallelic ATF6 disease variants.

Methods: Retinal organoids were generated using iPSCs from ACHM patients with biallelic ATF6[Y567N] variant and from asymptomatic heterozygous family members as controls. Bulk RNAseq was performed on individual organoids at day 290 (n=3 each for patients and controls). Transcriptomic gene sets specifically associated with cones, rods, horizontal cells, bipolar cells, amacrine cells, retinal ganglion cells, and Müller cells (MC) were extracted from 3 RNAseq analyses of non-diseased human retina and retinal organoids (2019 Liang PMID: 31848347; 2019 Menon PMID: 31653841, 2020 Cowan PMID: 32946783). Using these normal human retinal cell type transcriptome profiles, we evaluated expression levels of these retinal cell specific gene-sets in ATF6 mutant ACHM retinal organoids.

Results: Cone photoreceptor-specific genes were significantly down-regulated in ATF6-ACHM retinal organoids (RO) compared to controls (Wilcoxon, $P < 0.001$). In contrast, Muller cell gene expression was increased in ATF6-RO versus controls (Wilcoxon, $P < 0.01$). No significant changes in gene expression were observed in all other retinal cell types in ATF6-ACHM retinal organoids. Last, we identified dysregulation of UPR specifically a significant increase of IRE1-XBP1-regulated genes (Wilcoxon, $P=0.02$) in the ATF6-RO.

Conclusions: Consistent with prior study (2021 Kroeger PMID: 34561305), ATF6-RO showed severely impaired cone photoreceptor-specific gene expression when compared with the 3 new wild-type human retina/retinal organoid transcriptome datasets. Interestingly, Muller cell-specific gene expression was increased in ATF6-RO. The IRE1-XBP1 signaling pathway of the UPR was also upregulated in the ATF6-RO. Our data suggest 2 new potential retinal pathomechanisms that may contribute to ATF6-associated ACHM – Muller gliosis and abnormal activation of the IRE1-XBP1 branch of the UPR.

ABSTRACT BODY:

Purpose: Pediatric uveitic glaucoma is a complex interplay between structural change from the disease process as well as the treatment options. We hypothesize that early treatment and regular monitoring with therapeutic adjustments by a glaucoma and uveitis specialist team will lead to long-term visual acuity, inflammatory, and intraocular pressure stability.

Methods: Records of pediatric uveitic glaucoma patients with at least 5 years of surveillance beginning in 2000 at a single-site center were retrospectively analyzed following Vanderbilt IRB approval (211820). Outcomes including vision, inflammatory presence, and IOP, along with required medical and surgical therapies, were assessed at 5 years and 7 years of follow-up.

Results: 19 children (33 involved eyes) met criteria for inclusion with 14 patients (23 eyes) having data at 7 years. 12.9% and 17.4% eyes had a ≥ 2-line visual acuity decline at 5 and 7 years, respectively. One patient returned legally blind OU after a 7-year hiatus. 77.4% and 91.3% eyes had no observable inflammation at 5 and 7 years, respectively. 83.3% and 78.6% patients were on immunomodulatory therapy, 5.6% and 7.1% patients were on oral steroids, 32.3% and 52.2% eyes were on topical steroids, and 26.3% and 57.1% eyes were on glaucoma meds at 5 and 7 years, respectively. IOP (6-21 mmHg) occurred in 96.8% and 78.3% eyes at 5 and 7 years, respectively. 16 eyes (51.6%) required glaucoma shunt surgery by 5 years. 4 eyes (25%) required repeat surgery.

Conclusions: Historically, patients with uveitic glaucoma had poor outcomes with limited therapies. However, our study indicated that children with inflammatory glaucoma have good long-term outcomes with uveitis and glaucoma team care. Maintaining IOP in our cohort required adjusting glaucoma medication needs and/or surgical intervention. Regular monitoring with therapeutic adjustments for inflammatory and IOP control in pediatric uveitic glaucoma can maintain vision.

ABSTRACT BODY:

Purpose: Few studies have examined the effects of language barriers in ophthalmology. This retrospective observational study explores differences in outcomes between limited English proficiency (LEP) patients and English proficient (EP) patients undergoing combined cataract surgery and Kahook Dual Blade (KDB) goniotomy.

Methods: Patients who underwent cataract surgery between 2014 and 2019 in the University of Colorado Cataract Surgery Outcomes Database were analyzed. We defined LEP as need or preference for an interpreter during medical encounters. Demographic and pre-operative characteristics analyzed included gender, race/ethnicity, intraocular pressure (IOP), logMAR best corrected visual acuity (BCVA), presence of mature cataract, and type of glaucoma. The main outcomes of this study included the complexity of surgery, intraoperative complications, change in BCVA, post-operative IOP, and number of IOP-lowering medications. Comparisons between groups were made using logistic regression analysis with general estimating equations to account for some patients having two eyes included in the study.

Results: A total of 43 LEP and 666 EP patients who underwent combined cataract surgery and KDB goniotomy were analyzed. LEP patients had a significantly higher rate of mature cataracts (4.6%) and complex surgery (46.5%) compared to EP patients (0.3% and 13.8%, respectively; $p < 0.01$ for both). Post-operative change in BCVA was significantly greater in LEP patients compared to EP patients (mean improvement of 0.260 versus 0.157, $p = 0.01$). No differences were observed between groups for pre- or post-operative IOP, number of IOP-lowering medications, or intraoperative complications.

Conclusions: This study highlights healthcare disparities associated with language barriers and suggests delayed access to specialty eye care. Encouragingly, it confirms the benefit of combined cataract surgery and KDB goniotomy in the LEP population. These findings demonstrate the need for outreach to LEP patients to ensure regular ophthalmologic care.

TITLE:

Assessment of systemic and ocular risk factors for the progression of diabetic retinopathy following cataract surgery

SESSION TITLE: Diabetic Retinopathy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P.S. Tetelbom, J. Shin, S. Mahesh, Ophthalmology, New York Medical College, Valhalla, New York, UNITED STATES|P.S. Tetelbom, S. Mahesh, Ophthalmology, Westchester Medical Center, Valhalla, New York, UNITED STATES|

Commercial Relationships Disclosure: Pedro Tetelbom: Commercial Relationship: Code N (No Commercial Relationship) | Joshua Shin: Commercial Relationship: Code N (No Commercial Relationship) | Sankara Mahesh: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Cataract surgery has been known to worsen the progression of diabetic retinopathy (DR), including development of Proliferative diabetic retinopathy (PDR) and its complications. Previous reports explored this relationship and associated systemic risk factors, but studies on ocular factors associated with such progression have been limited. We performed a retrospective study to assess baseline clinic characteristics associated with progression of DR in patients following cataract surgery.

Methods: We conducted a retrospective cohort study consisting of 175 consecutive eyes of 130 diabetic patients undergoing cataract surgery at Westchester Medical Center, Valhalla, NY, between January 2016 and August 2021 with a follow-up period of at least 3 months. Patients had to be at least 18 years old at the time of surgery and were excluded if they had other retinal pathology or uveitis. Patients were assessed for progression as defined by onset or advancement in non-proliferative DR (NPDR) stage, onset of PDR, or development of new neovascular complications on the first 6 months of postoperative follow up. Baseline ocular and systemic factors were compared between patients with documented progression and no progression using chi-square test for categorical variables and non-paired Student's t-test for continuous variables.

Results: Seventeen out of 175 eyes presented with progression. All the eyes that progressed had DR at baseline. We found that younger age, insulin use, history of anti-VEGF use, history of diabetic macular edema (DME), previous pars plana vitrectomy and panretinal photocoagulation were associated with DR progression. Intraoperative posterior capsule rupture or iris manipulation were not associated with DR progression. Within the group of patients with DR at baseline, the stage of DR (mild, moderate or severe NPDR or PDR) was not associated with progression, and history of DME was the only ocular factor that remained statistically significant as a risk factor (P=0.048).

Conclusions: Progression only happened in patients with DR at baseline, and among those, having a history of DME was associated with increased risk. Our findings may assist in identifying patients who require more intensive pre and postoperative surveillance and treatment, as well as in better directing the focus of prospective studies on this subject.

ABSTRACT BODY:

Purpose: The relationship between age-related macular degeneration (AMD), cardiovascular disease (CVD) and stroke has been long sought, with decades of inconsistent results. We demonstrate new, specific strong associations by first separating AMD into its two major intermediate phenotypes, soft drusen (SD) and subretinal drusenoid deposits (SDD), and comparing their associations with certain common high risk vascular diseases.

Methods: Two hundred AMD patients, ages 51 to 100, 121 females were recruited. Retinal imaging, health history questionnaires, and lipid profiles were obtained. Patients were assigned by volume spectral-domain optical coherence tomography (SD-OCT) into two groups, SDD (with or without SD) and SD (SD only). Fundus autofluorescence (AF) and near-infrared reflectance (NIR) imaging were used to confirm the presence of SDD. Self-reported health history questionnaires further classified patients into those with and without these high risk vascular disorders (HRV): 1) cardiac valve defect; 2) cardiac pump defect (myocardial infarction, congestive heart failure, etc); 3) carotid stroke or transient ischemic attack (TIA) with carotid stenosis. Chi-square testing was used for categorical variables. ‘Waikato 222 Environment for Knowledge Analysis (WEKA) Version 3.8.5’ was used to build a multivariate risk model for presence of HRV as a function of SDD status and other covariates.

Results: The prevalence of HRV was 41.24% (40/97) and 6.80% (7/103) in the SDD and SD groups respectively ($p = 0.000000009$). Differences in the prevalence of HRV sub-types in these groups were also significant: valve defects 14/97 in SDD vs. 3/103 in SD ($p = 0.0035$), pump defects 16/97 vs. 3/103 ($p = 0.0011$), stroke/TIA 10/97 vs.1/103 ($p = 0.0038$). A serum HDL < 62 mg/dL was a strong predictor in our total AMD cohort of HRV ($p = 0.0046$). Data modeling showed that the joint presence of SDD and an HDL<62 predicted the presence of HRV with an accuracy of 85%, 95% CI, 77.5 %-90.7 %.

Conclusions: HRV were significantly more prevalent in subjects with SDD than those with SD only. This suggests that SDD specifically are a biomarker of these life-threatening systemic vasculopathies, all of which are likely to compromise ocular perfusion. This in turn suggests a direct vascular mechanism for SDD that merits investigation. Risk modeling shows a potential for saving lives by detecting occult HRV with non-invasive SD-OCT imaging and serum risk factors.

ABSTRACT BODY:

Purpose: To compare the anatomic and functional efficacy of intravitreal anti-vascular endothelial growth factor (VEGF) versus half-dose photodynamic therapy (PDT) treatment in central serous chorioretinopathy (CSC) with flat irregular pigment epithelium detachment (fiPED).

Methods: This retrospective, interventional, comparative study included 72 treatment naive patients with CSC who exhibited fiPED. Among 75 eyes from 72 patients, 42 eyes from 41 patients received anti-VEGF treatment and 33 eyes from 31 patients received half-dose PDT. Treatment outcomes, including the visual acuity, central retinal thickness (CRT), and presence of subretinal fluid (SRF) were evaluated at baseline and 1, 6, 12 and 24 months after treatment and compared between two groups.

Results: There were no differences in baseline characteristics between the two groups. In both groups, a significant improvement of CRT was observed at 1 month after treatment and was maintained throughout the 24-month follow-up period ($P < 0.01$). Whereas 10 out of 42 eyes (23.8%) with anti-VEGF treatment (mean 6.1 injections/ 2 years) required the alternative treatments (6 with PDT and 4 with focal laser), 1 out of 33 eyes (6.0%) with PDT treatment (mean 1.0 treatment/ 2 years) received focal laser treatment. In addition, PDT group showed significantly higher percentage of SRF resolution than anti-VEGF group ($P < 0.05$, PDT : 93.75%, anti-VEGF : 45.24% at 12-month follow-up), with lower recurrence rate of SRF ($P < 0.05$, PDT : 13.8%, anti-VEGF : 68.75% at 24-month follow-up). Likewise, the visual outcome had the similar trend with the anatomic outcomes.

Conclusions: While treatment responses to anti-VEGF and PDT were favorable in CSC with fiPED, PDT treatment showed faster recovery of functional and anatomic outcomes with the lower recurrence, compared with anti-VEGF.

ABSTRACT BODY:

Purpose: To comprehensively describe large publicly available health databases used in published big data research in ophthalmology.

Methods: To identify studies using large publicly available health databases for ophthalmic research, a literature search was formulated by a health sciences librarian and conducted in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines using the PubMed and Embase digital literature databases from inception (1809 and 1947, respectively) through August 1, 2021. Databases were identified from full-text articles. Study selection and data extraction were performed independently by two investigators, and a third investigator arbitrated any disagreements.

Results: In total, 204 databases were identified in the included studies; most (52%; 107/204) were available online. Most were provided by government agencies (52%; 55/106) or academic institutions (30%; 32/106) and were from high-income (87%; 92/106) or English-speaking (68%; 72/106) countries; no publicly available databases were identified from Latin America and the Caribbean, the Middle East and North Africa, or Sub-Saharan Africa. Half were comprised of administrative data (50%; 53/106). Few published details about their sampling methods (23%; 24/106) or study populations (41%; 43/106). Some common requirements to access data included an application requirement (29%; 31/106), training requirement (10%; 11/106), purchase requirement (8%; 9/106), or other requirements such as citizenship or employment (8%; 8/106). One-third were freely available (33%; 35/106).

Conclusions: Big data research in ophthalmology was concentrated on databases based in high-income countries. Access to many publicly available databases was restricted by application, training, purchase, and other requirements. Infrequent disclosure of sampling methods and study populations may impact the quality, transparency, and generalizability of big data research in ophhtalmology.

ABSTRACT BODY:

Purpose: To evaluate the progression of myopia in children wearing novel spectacles with highly aspherical lenslets (HAL) versus conventional single-vision spectacles (SV) in a randomized, double-masked, and cross-over trial.
Methods: 119 Vietnamese children, aged 7 to 13 years with baseline (BL) refractive error ranging from -0.75 to -4.75D, cylinder ≤ 1.50D were assigned to 2 groups to wear either HAL or SV, and after 6 months (Stage 1) crossed over to wear the other lens type for another 6 months (Stage 2). At the end of stage 2, all children (n=105) wore HAL for a further 6 months. Based on the order in which they wore the lenses at each stage, Group I was designated HSH (HAL - SV – HAL) and Group 2 SHH (SV-HAL-HAL). Cycloplegic autorefraction was performed at BL and then every 6 months and axial length (AL) measurements were collected at BL and 3 monthly thereafter. Myopia progression (change in spherical equivalent refractive error (SE) and AL) was compared between groups. A linear mixed model with subject random intercept (adjusted for confounders -age, gender, parental myopia) was used for analysis. Post hoc multiple comparisons were Bonferroni corrected. The level of significance was set at 5%.
Results: During stages 1 and 2, myopia progressed slower with HAL than SV (significant for AL for both stages and SE for Stage 2). In the HSH group, myopia progression with SV during Stage 2 was not different to SV progression observed at Stage 1 SHH group ($p=0.208$ and 0.092 for SE and AL respectively) and indicates no rebound of myopia. In the SHH group, Stage 3 change in SE with HAL was greater compared to stage 2 ($p<0.001$) but not for AL. Children reported long hours of wearing (>13 hrs/day) and there were no subjective issues with lens wear.
Conclusions: HAL spectacles slow myopia. This is evidenced by a) inter-group comparisons at Stages 1 and 2, and b) intragroup comparison when children switched between HAL and SV between stages. Children were compliant with lens wear and in this short-term, cross-over study there was no rebound when children were switched from HAL to SV. The reduced SE change with prolonged wear of HAL (Stage 2 to Stage 3 in the SHH group) needs further exploration.

TITLE: Using Moving instead of Static Stimuli to Extend the Dynamic Range of Perimetry
SESSION TITLE: Visual Fields and Psychophysics
SESSION TYPE: Paper Session
AUTHORS/INSTITUTIONS: S.K. Gardiner, S.L. Mansberger, Discoveries In Sight, Devers Eye Institute, Portland, Oregon, UNITED STATES|
Commercial Relationships Disclosure: Stuart Gardiner: Commercial Relationship: Code N (No Commercial Relationship) | Steven Mansberger: Commercial Relationship: Code N (No Commercial Relationship)
ABSTRACT BODY:
Purpose: Pointwise perimetric sensitivities below ~20dB are unreliable due to excessive variability. Dynamically increasing stimulus size to increase detectability extends this dynamic range, allowing testing in more severe glaucoma. However, larger stimuli overlap multiple nerve fiber bundles so may miss smaller defects; and the bundles being stimulated differ even with perfect fixation. We propose instead using moving stimuli to increase detectability and hence increase the dynamic range of perimetry in glaucoma.
Methods: A Size V moving stimulus was designed that travels parallel to the average nerve fiber bundle orientation at each location, with speed proportional to local magnocellular ganglion cell spacing (Fig 1). 34 locations across the visual field were tested with moving and static stimuli, using an otherwise identical Zippy Estimation by Sequential Thresholding (ZEST) seen / not seen algorithm on a clinical perimeter. 152 subjects with glaucoma / suspects were tested, of whom 52 were retested 6 months later. Resultant pointwise sensitivity estimates were compared using generalized estimating equation (GEE) regression. Test-retest variability for each stimulus was assessed by Bland-Altman plots, with limits of agreement adjusted for within-eye clustering.
Results: The 152 subjects tested had average Mean Deviation -3.1dB from standard perimetry (interquartile range -3.7 to -0.3dB). Sensitivities using moving stimuli were 1.8dB higher; this difference increased with damage and eccentricity (both $p<0.001$, Fig 2A). Test-retest limits of agreement among 52 eyes were narrower for moving stimuli (-6.3 to +6.7dB, Fig 2B) than static stimuli (-12.7 to +7.9dB, Fig 2C), and test-retest variance was significantly smaller ($p<0.001$, F-test). 53% of subjects stated preferring the moving stimulus, vs. 24% who preferred the static stimulus.
Conclusions: Using a moving stimulus for perimetry increases sensitivities, and hence locations stay within the dynamic range longer, allowing reliable testing at locations with more severe damage without the problems caused by increasing stimulus size. Results are more repeatable, and the test is preferred by most subjects. Work is underway to assess the normative range. Since stimulus speed is a continuous variable, a clinical test could either use moving stimuli at all sensitivities, or could increase speed proportional to loss ensuring that early detection would be unaltered.

TITLE: Development of a Code-Free Machine Learning Model for the Classification of Cataract Surgery Phases

SESSION TITLE: Machine Learning: Segmentation and Classification

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Touma, F. Antaki, R. Duval, Ophthalmology, Universite de Montreal Faculte de Medecine, Montreal, Quebec, CANADA|

Commercial Relationships Disclosure: Samir Touma: Commercial Relationship(s);Code F (Financial Support):Bayer | Fares Antaki: Commercial Relationship(s);Code F (Financial Support):Bayer | Renaud Duval: Commercial Relationship(s);Code C (Consultant/Contractor):Alcon, Novartis, Bayer, Roche;Code F (Financial Support):Alcon, Novartis, Bayer, Roche

ABSTRACT BODY:

Purpose: Automated machine learning (AutoML) is a novel tool machine learning research that does not require coding. This study assessed the performance of AutoML in classifying cataract surgery phases from surgical videos.

Methods: Two ophthalmology trainees without coding experience designed a deep learning model in Google Cloud AutoML Video Classification for the classification of 10 different cataract surgery phases. We used two open-access publicly available datasets (total of 122 surgeries) for model training, validation and testing. Overall, 1,280 video segments were used for training and 144 segments for testing. External validation was performed on 10 surgeries issued from another dataset.

Results: The AutoML model demonstrated excellent discriminating performance, even outperforming bespoke deep learning models handcrafter by experts. The area under the precision-recall curve was 0.855. At the 0.5 confidence threshold cut-off, the overall performance metrics were as follows: sensitivity (81.0%), recall (77.1%), accuracy (96.0%) and F1 score (0.79). The per-segment metrics varied across the surgical phases (precision 66.7–100%), recall 46.2–100% and specificity 94.1–100%. Hydrodissection and phacoemulsification were the most accurately predicted phases (100 and 92.31% correct predictions, respectively). During external validation, the average precision was 54.2% (0.00–90.0%), the recall was 61.1% (0.00-100%) and specificity was 96.2% (91.0-99.0%).

Conclusions: A code-free AutoML model created by two ophthalmology trainees can accurately classify cataract surgery phases from surgical videos with an accuracy comparable or better than bespoke deep learning models developed by experts.

ABSTRACT BODY:

Purpose: Ang-2 and vascular endothelial growth factor (VEGF)-A are key drivers of vascular instability in DME. We explored the effect of dual Ang-2/VEGF-A pathway inhibition on vascular stability using preclinical and phase 2/3 clinical data.

Methods: JR5558 mice (spontaneous model of choroidal neovascularization [CNV]) received anti−Ang-2, anti−VEGF-A, dual anti–Ang-2/anti–VEGF-A (VA2), or none/immunoglobulin G (IgG) as controls. Vascular stability was evaluated by analyzing neovascular leakage and subretinal inflammatory cell infiltration (Iba1+, CD11b+, CD45+) at baseline and at 1 week (1W), 3W, and 5W posttreatment. In the phase 2 BOULEVARD trial (NCT02699450), the effect of faricimab, a bispecific Ang-2/VEGF-A neutralizing antibody, on sustained retinal stability (SRS; defined as the achievement and maintenance [< 10% worsening] of central subfield thickness [CST] ≤ 325 µm to week 24) was assessed. Vascular stability with faricimab was also evaluated in the phase 3 YOSEMITE/RHINE trials (NCT03622580/NCT03622593) over 2 years.

Results: In JR5558 mice, CNV lesion leakage was reduced at 1W with anti−Ang-2, anti−VEGF-A, and VA2 versus controls ($P < 0.05$ to $P < 0.001$); at 3W and 5W, this was maintained with anti−Ang-2 and VA2 only ($P < 0.05$ to $P < 0.0001$). Compared with IgG, VA2 treatment reduced Iba1+, CD11b+, and CD45+ cell infiltration at 1W ($P < 0.05$); at 5W, only anti−Ang-2 and VA2 reduced Iba1+ cell infiltration ($P < 0.0001$). In BOULEVARD, SRS was achieved by > 50% of patients receiving faricimab 6.0 mg and 1.5 mg at weeks 8 and 16, respectively, compared with week 20 for patients receiving ranibizumab. During year 1 of YOSEMITE/RHINE, change in CST from baseline consistently favored faricimab over aflibercept, and absence of DME and intraretinal fluid were achieved by a higher proportion of patients treated with faricimab versus aflibercept. Year 2 vascular stability data from YOSEMITE/RHINE will be presented at the meeting.

Conclusions: Preclinical data suggest that Ang-2 inhibition may contribute to reduced inflammation and increased vascular stability. Furthermore, dual Ang-2/VEGF-A blockade with faricimab promoted SRS in BOULEVARD and improved DME disease control in YOSEMITE/RHINE. These data support the role of Ang-2 in vascular stability and the potential for dual Ang-2/VEGF-A inhibition with faricimab to improve outcomes in patients with DME over anti-VEGF alone.

TITLE: Wnt Signaling Regulates Cornea Wound Healing
SESSION TITLE: Corneal epithelial biology and repair mechanisms
SESSION TYPE: Paper Session
AUTHORS/INSTITUTIONS: W. Liang, J. Ma, Physiology, The University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma, UNITED STATES|
Commercial Relationships Disclosure: Wentao Liang: Commercial Relationship: Code N (No Commercial Relationship) | Jian-Xing Ma: Commercial Relationship: Code N (No Commercial Relationship)
ABSTRACT BODY:
Purpose: The regulation of corneal wound healing remains elusive. Wnt signaling is known to mediate cell proliferation, differentiation, and migration. We hypothesize that Wnt signaling may regulate cornea wound healing.
Methods: i) The very low-density lipoprotein receptor (VLDLR) and kallistatin (KS) are negative regulator of the Wnt signaling pathway. VLDLR knock out (VKO) mice and kallistatin-transgenic (KS-Tg) mice were used for experiments. The corneal epithelial layer was removed in anesthetized mice using Algerbrus II Ocular Burr. The abraded region was measured daily after topical application of 0.1% fluorescein solution. The corneal healing rates were also determined in mice following subconjunctival injection of different Wnt signaling inhibitors or activators.
ii) Primary human corneal epithelial cells (HCEC) were treated with Wnt conditioned medium (WCM) and purified KS after 100% confluence. The acellular area was measured after a straight-line scratch across the monolayer.
iii) After being treated with WCM with/without KS, HCEC numbers were evaluated by Trypan blue dye exclusion method.
Results: VKO mice showed higher Wnt/β-catenin signaling activities while KS-Tg mice had lower Wnt signaling in the cornea compared with WT mice. Corneal with wound healing showed increased Wnt signaling activities. Cornea wound healing rate was significantly increased in VKO mice and decreased in KS-Tg mice compared with WT mice. Wnt signaling inhibitors such as adenovirus expressing the soluble VLDLR ectodomain, an LRP6-blocking antibody, and KS protein delayed corneal wound healing in mice. Activation of Wnt signaling in the cornea by adenovirus expressing a constitutively active mutant of β-catenin (Ad-S37A) in which the phosphorylation site Ser37 in β-catenin was substituted by Ala (S37A), and lithium chloride accelerated wound healing. In vitro, WCM enhanced HCEC migration and proliferation, while KS reversed this effect in a dose-dependent manner.
Conclusions: Wnt/β-catenin signaling is activated during corneal wound healing. Wnt signal enhances cornea epithelial cell migration and proliferation and subsequently promotes corneal wound healing.

ABSTRACT BODY:

Purpose: The development of artificial intelligence (AI) algorithms for analyzing retinal pathologies requires training based on well-organized, labeled images. The goals of this project are to develop an AI model to curate 7-field retinal photographs and to explore ways to implement the AI model at the Wisconsin Reading Center (WRC) with high-volume image submissions.

Methods: Stereoscopic 7 modified field images of the retina are used for the evaluation of diabetic retinopathy via the Early Treatment Diabetic Retinopathy Study (ETDRS) Severity Scale as an outcome in clinical trials. The imaging protocol includes 7 pairs of images of the optic disc, macula, and surrounding retinal quadrants along with an image of the anterior part of the eye (red reflex). Each field of the retina is identified by a field designation number (Figure 1). Clinical images submitted to the WRC are often inefficiently organized for the training of AI algorithms. We trained a neural network to differentiate red reflex images from retinal images and to provide the appropriate retinal field designation. Model outputs included classification of the retinal images into 8 classes (7 fields and red reflex) and a probability score (0 – 1) for each class to predict potential classification errors. The AI model was trained and internally validated on 17,529 images from multiple sites and tested on 3004 independent images. The ground truth was generated by 2 WRC graders.

Results: Exact agreement on field designations between graders and the AI model was found for 2651/3004 images (88%, kappa 0.87) (Figure 2). AI probability scores were 0.95-0.99 for labels that matched the human assessment and 0.39-0.84 for labels that did not match. Fields with non-matched labels included images with poor image quality/focus and improper localization of retinal landmarks.

Conclusions: The deep learning model provides an accurate, automated method for curating retinal images. The probability score provides a tool to flag potential errors in AI labels that can be routed for human oversight. Large-scale AI implementation systems need a tiered approach to augment workflow, increase trust in AI models, and to provide a means for continuous model development.

TITLE: Characterization of superficial periocular tissue using Spatial Frequency Domain Imaging

SESSION TITLE: Oculoplastics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Sung, D. Devineni, L.S. Ediriwickrema, Ophthalmology, University of California Irvine School of Medicine, Irvine, California, UNITED STATES|G. Philipopoulos, G. Kennedy, A. Durkin, Beckman Laser Institute and Medical Clinic, Irvine, California, UNITED STATES|G. Kennedy, A. Durkin, Biomedical Engineering, University of California Irvine, Irvine, California, UNITED STATES|L.S. Ediriwickrema, Gavin Herbert Eye Institute, Irvine, California, UNITED STATES|

Commercial Relationships Disclosure: Shijun Sung: Commercial Relationship: Code N (No Commercial Relationship) | Divya Devineni: Commercial Relationship: Code N (No Commercial Relationship) | George Philipopoulos: Commercial Relationship: Code N (No Commercial Relationship) | Gordon Kennedy: Commercial Relationship: Code N (No Commercial Relationship) | Anthony Durkin: Commercial Relationship: Code N (No Commercial Relationship) | Lilangi Ediriwickrema: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The ability to measure markers of inflammation and tissue remodeling in periocular tissue would help better understand disease processes and improve clinical decision making. However, quantitative methods to measure these activities are not well established. We hypothesize that spatial frequency domain imaging (SFDI), a noninvasive, quantitative, multispectral imaging technology, can provide periocular tissue's absorption and scattering characteristics to inform about the tissue composition, hemodynamics, edema, and inflammation.

Methods: SFDI of periorbital regions were obtained in nine healthy volunteers in compliance with an IRB approved protocol. Imaging is performed at eight center wavelengths (471,526,591,621,659,731,851 nm) and 5 spatial frequencies (0-0.2 mm^{-1}, evenly spaced) over 20cm x 15cm field of view, with typical exposure times of 5-60 ms per image. For each pixel, absorption and reduced scattering coefficients (μ_a and μ'_s, respectively) were determined. Regions of interest (ROI) along the superior/ inferior temporal quadrant, and inferior nasal quadrant are selected for analysis, and compared with adjacent maxillary skin (Figure 1). Tissue optical properties are locoregionally correlated. Paired student's t-test was used for statistical analysis.

Results: The periocular region shows several distinct optical property trends. Notably, there is a local increase in the absorption along the inferior temporal quadrant compared to surrounding facial skin (Mean $\mu_{a\ ITQ}/\ \mu_{a\ face}$ at 659nm is 1.38, [CI: 1.23, 0.53], $p < 0.001$). Reduced optical scattering is observed in all three ROIs (19% to 25% reduction in the amplitude of μ'_s across the spectra) Deoxyhemoglobin concentration as well as oxygen saturation can be inferred from multispectral data and skin melanin content.

Conclusions: SFDI provides wide-field assessment of chromophore concentrations of periocular tissue, showing increased absorption by tissue chromophores and decreased scattering. The cutaneous tissue of the periocular region has a thinner epithelium and is devoid of subcutaneous fat, which presents distinct optical properties that optimize SFDI interrogation of inflammatory disease sub-types. Further studies will involve subjects with various etiologies of inflammatory processes in this region using this methodology.

ABSTRACT BODY:

Purpose: Upregulation of retinal endothelial ICAM-1 and subsequent leukostasis promote vascular degeneration in early diabetic retinopathy (DR). Our previous in vitro studies identified lysyl oxidase (LOX)-mediated subendothelial matrix stiffening as a potent regulator of ICAM-1 upregulation in diabetic conditions. Here we determined the extent to which LOX-mediated retinal vascular stiffening promotes ICAM-1-dependent leukostasis and vascular degeneration in a mouse model of early DR.

Methods: Male (8-10 wk old) C57BL/6 mice were divided into three groups (n=8/group) viz. nondiabetic (ND), streptozotocin-induced diabetic (D), and diabetic + LOX inhibitor BAPN (3mg/kg drinking water) (D+BAPN). After 20 weeks of BAPN treatment, fresh retinal vessels (isolated using isotonic method) was used for qPCR analysis while fixed retinal vessels (isolated using trypsin digestion) were used for stiffness measurements with an atomic force microscope (AFM). Leukocyte adhesion to retinal vessels was determined using fluorescein-coupled concanavalin A. Finally, retinal capillary degeneration was assessed at 8 months' duration of diabetes using Periodic acid-Schiff staining.

Results: When compared with ND group, D group exhibited a 2.2-fold increase ($P<0.001$) in retinal vascular LOX mRNA levels that was accompanied with a 2.0-fold increase ($P<0.01$) in retinal capillary stiffness. Importantly, LOX inhibition (D+BAPN) significantly prevented the diabetes-induced retinal capillary stiffening (47% decrease; $P<0.01$ vs D), which was associated with a concomitant inhibition of ICAM-1 mRNA (53% decrease; $P<0.0001$ vs D) and leukostasis (37% decrease; $P<0.05$ vs D). Further, LOX inhibition in long-term diabetic mice (D+BAPN) significantly reduced (16% decrease; $P<0.05$ vs D) retinal capillary degeneration. Since adherent leukocytes exert cytotoxicity toward retinal endothelial cells, we are currently investigating whether and how cell and subendothelial matrix stiffening regulates retinal endothelial apoptosis by adherent neutrophils.

Conclusions: These findings reveal a new and potentially crucial role of LOX-dependent retinal vascular stiffening in inflammation-mediated vascular degeneration in early DR. Importantly, these findings provide the basis to examine LOX-dependent retinal vascular stiffening and its downstream mechanotransduction pathways as new anti-inflammatory targets for effective DR management.

TITLE: Biomechanical Simulation of Compartmental Superior Oblique (SO) Palsy

SESSION TITLE: Eye movements and nystagmus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Q. Wei, Bioengineering, George Mason University, Fairfax, Virginia, UNITED STATES|J.L. Demer, Ophthalmology, University of California Los Angeles, Los Angeles, California, UNITED STATES|J.L. Demer, Neurology, University of California Los Angeles, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Qi Wei: Commercial Relationship: Code N (No Commercial Relationship) | Joseph Demer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Histology and quantitative analysis in the past decade revealed that compartmentalization is a general feature of extraocular muscles (EOMs). Such discovery motivates consideration of strabismus potentially associated with compartmental pathology. We developed a biomechanical model and simulated the strabismus caused by compartmental SO palsy.

Methods: A new model simulating actively controlled pulley mechanics of the horizontal EOMs was developed recently (Wei and Demer, IOVS, 62: 2606, 2021). The orbital (OL) and global (GL) layers of the horizontal rectus EOMs, as well as the pulley sleeves and their suspensions, were explicitly modeled as coupled via elastic strands. The model was elaborated by adding these pulley modeling primitives to the vertical EOMs to enable realistic pulley simulation in tertiary gazes. Two mechanically-independent neuromuscular SO compartments (Suh et al., IOVS, 57:13:5535-5540, 2016) were explicitly modeled. The medial SO compartment tendon inserts more anteriorly and medially than the lateral compartment, while the two compartments share the same path from origin to trochlea. Independent innervations of the two SO compartments were assumed to model compartmental SO palsy. The neural controller minimized simulated eye velocity error and total innervation level during and after saccades. We simulated 25 fixational eye positions formed by 15^{o} horizontal and vertical increments around central gaze. The controller estimated innervations of 11 actuators comprising 2 layers of each rectus EOM, 2 SO compartments, and one inferior oblique unit. Compartmental SO palsy was simulated by zeroing innervation of one SO compartment.

Results: Predicted innervations for fixations (Fig. 1) and saccades were consistent with previous computational work as well as known functions of EOMs and their compartments. Simulation of lateral compartment SO palsy (Fig. 2) predicted greater hypertropia than medial compartment palsy in infraduction, and less excyclotorsion in infraducted adduction, demonstrating differential mechanical functions of the two SO compartments.

Conclusions: An improved biomechanical model implementing realistic actively controlled pulleys and SO compartments provides a computational tool to examine compartmental functions of the SO muscle. Modeling might assist diagnosis of compartmental palsy, and be used to quantitatively predict the effectiveness of selective strabismus surgeries.

TITLE: Soft Contact Lens Prescribing Habits for Patients with Astigmatism in the United States

SESSION TITLE: Contact lens

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Chima, West Point Optical Group, LLC, Ohio, UNITED STATES|S. Rosinski, J. Kwan, Coopervision Inc, Fairport, New York, UNITED STATES|

Commercial Relationships Disclosure: Harmin Chima: Commercial Relationship(s);Code C (Consultant/Contractor):Coopervision, Bausch and Lomb, Alcon | Steve Rosinski: Commercial Relationship: Code N (No Commercial Relationship) | Justin Kwan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Approximately 47% of the population has ≥ 0.75 D of astigmatism in at least one eye. While most contact lens manufacturers have a wide range of parameters in frequent replacement and daily disposable soft toric options, that begins to diminish substantially when considering the needs of higher astigmats that have cylinder powers of more than 2.25 D. The purpose of this work was to understand the current soft toric prescribing habits of eye care professionals (ECP) in the United States (US) for the most prescribed monthly replacement soft toric contact lens, Biofinity® toric (comfilcon A, CooperVision, Inc.).

Methods: CooperVision revenue data by volume for Biofinity® toric (BT) and Biofinity® XR toric (BXRT) from November 2020 to July 2021 were reviewed. BXRT includes cylinder powers from 2.75 to 5.75 D in five degree axis steps. Frequency of power parameters ordered were sorted from highest to lowest and by sphere power, cylinder power (DC), and axes for sub-analyses.

Results: BT axes distribution was 65% with the rule (WTR), 29% against the rule (ATR), and 6% oblique. BXRT was 85% WTR, 12% ATR, and 3% oblique. When considering the sphere component of these soft toric orders, the ratio of myopia to hyperopia to plano was 24.1 to 5.5 to 1.0 respectively. For every 9.1 BT orders, there was 1 BXRT order. For spheres -6.50 D or higher, the percentage of -0.75 and -1.25 DC orders was 47.5% to 52.5%. The 56 most ordered powers were in 0.50 D sphere increments with the 57th being the first 0.25 D sphere increment (-3.75 / -0.75x180). In addition, 0.50 D sphere steps were ordered 3.4 times more than 0.25 D sphere steps. The 32 most ordered powers had axes of 180 or 090.

Conclusions: These data for soft toric orders can be used to optimize selection of powers for diagnostic fit sets, minimize waste of expired trials, and improve the practice and patient experience. The need for extended range cylinder powers beyond 2.25 D is not infrequent as nearly 11% of orders are for Biofinity® XR toric. For the ECP, it's important to note the potential room for more accurate prescribing in the sphere component of these soft toric lenses; 0.50 DS steps may be ordered more often reflecting the US fit set configuration.

ABSTRACT BODY:

Purpose: To evaluate the impact of the COVID-19 pandemic on diabetic retinopathy screening (DRS) to uninsured, predominantly Latino patients at the UC San Diego Student-Run Free Clinic Project (SRFCP).

Methods: A retrospective analysis of the electronic medical records of all diabetic patients seen in the years 2019, 2020, and 2021 (N = 196, 183, and 178 respectively) at the SRFCP was performed. Ophthalmology specialty clinic metrics from before, during, and after the COVID-19 pandemic-related lockdowns were compared to assess the impact of the COVID-19 pandemic lockdowns on DRS rates. All statistical analyses were performed in Microsoft Excel.

Results: In patients with available demographic data (N=164), 92.1% were Latino, 69.5% female, with a mean age of 58.7 years (SD=10.6). A chi-squared test for goodness of fit showed that the distribution of patients seen ($p<0.001$), referred ($p=0.012$), or scheduled ($p<0.001$) in 2020 and 2021 differed significantly when compared to 2019. In 2019, 99 (50.5%) of 196 patients requiring DRS were referred, of which 97 (49.5%) were scheduled, and 89 (45.4%) were seen by the ophthalmology clinic (Figure 1). In 2020, a similar percentage of patients were referred (76/183 patients, or 41.5%), but the number of patients scheduled and seen dropped to 37 (20.2%) and 21 (11.4%), respectively. In 2021, clinic performance recovered with 113 (63.5%) of 178 patients eligible for DRS referred, 100 (56.2%) scheduled, and 82 (46.1%) seen. No-shows and cancellations constituted 12 (12.4%) and 6 (6.2%) of the 97 encounters in 2019. Conversely, of the 37 encounters scheduled in 2020, the no-show (10.8%) and cancellation (40.5%) rates were notably higher.

Conclusions: The COVID-19 pandemic significantly diminished the delivery of eye care to patients at the SRFCP. 2020 saw a meaningful decline from 2019 in all clinic performance metrics which was reversed in 2021. These results show the current need for annual DRS surpassed the ability of the ophthalmology specialty clinic to schedule and deliver care to these patients in all years evaluated, especially in 2020 due to COVID-19 restrictions. SRFCP patients may benefit from telemedicine-based DRS programs such as remote imaging during primary care visits to further improve screening capacity.

TITLE: Glaucoma-associated human Optineurin mutations increase transmitophagy in the Xenopus laevis tadpole optic nerve

SESSION TITLE: Neurodegeneration

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: Y. Jeong, N. Marsh-Armstrong, Ophthalmology, University of California Davis, Davis, California, UNITED STATES|

Commercial Relationships Disclosure: Yaeram Jeong: Commercial Relationship: Code N (No Commercial Relationship) | Nicholas Marsh-Armstrong: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Different mutations in the mitophagy adaptor Optineurin (OPTN) are associated with either glaucoma or Amyotropic Lateral Sclerosis (ALS). The purpose of this research was to investigate whether disease-associated OPTN variants alter the behavior of mitochondria, OPTN or the autophagy receptor LC3b within retina ganglion cell (RGC) axons in the optic nerve (ON).

Methods: Transgenes encoding GFP-LC3b and human mCherry-OPTN variants (Wt, glaucoma-associated mutations E50K, M98K and H486R, ALS-associated mutations E478G, and synthetic mutations F178A and D474N affecting LC3b or ubiquitin binding) were expressed selectively in Xenopus RGCs in a tetracycline inducible manner using the zebrafish Isl2b RGC-specific promoter 3 days prior to imaging. For sparse-labeling studies, small groups of cells were transplanted from transgenic donors to non-transgenic hosts early in eye development. The ONs of 4-6 tadpoles per transgene were live imaged using a spinning disc confocal as 1-minute single plane t-series acquired at 1 Hz, and Z-scan imaging the full thickness of the ON. Imaging data were analyzed using ImageJ, IPLab scripts and Imaris and the movement of mitochondria, OPTN and LC3b measured using kymographs. Vision was assessed in a dot-avoidance assay.

Results: Wt OPTN and LC3b were found to move ortho- and retro-gradely in comparable numbers with very few (~2%) of puncta stalled within the ON, whereas 23-88% of OPTN and LC3b were found stalled after expression of all OPTN mutants. In addition, a greater fraction (~65%) of axonal mitochondria were also found stationary in E50K mutants. In the imaging of sparsely labeled axons, E50K OPTN expression resulted in increased OPTN (5.7% in Wt→21.8% in E50K) and mitochondria (15.2% in Wt→35.8% in E50K) outside of RGC axons. Tadpoles expressing E50K OPTN had normal vision at the time of live imaging but developed vision impairment a week later.

Conclusions: OPTN mutations associated with ALS and glaucoma as well as synthetic mutants perturbing its interaction with damaged mitochondria or autophagosomal machinery all affect the movement of mitophagy machinery (OPTN and LC3). The glaucoma-associated mutations in addition increased the amount of axonal mitochondria and OPTN outside of axons. Visual impairment in the E50K animals subsequent to increased transmitophagy suggests that the increased or dysregulated transmitophagy may be detrimental.

ABSTRACT BODY:

Purpose: Although intraocular anti-vascular endothelial growth factor (VEGF) injection is now considered first-line treatment for diabetic macula edema (DME), 30-50% of patients poorly respond to the treatment, resulting in poor compliance and placing heavy finical burden on patients. We developed a deep-learning (DL) system for predicting anti-VEGF treatment response for eyes with DME using optical coherence tomography (OCT) images, aimed to personalize treatment for patients with DME.

Methods: Training dataset from an OCT device (Spectralis, Heidelberg Engineering, Germany) were collected from patients with center involved-DME (CI-DME) who received 3 injections within 6 months from 3 hospitals in Hong Kong. We extracted macular volumetric scans prior to receive anti-VEGF treatment, obtained with high-resolution 6.3mm × 6.3mm (25 B-scans) and high-speed 6.5mm × 4.9mm (19 B-scans) scanning protocol. A volumetric scan with good response was defined according to the DRCR.Net protocol-defined thresholds: ≥1-line gain on the Early Treatment Diabetic Retinopathy Study letter score or Snellen VA chart and >10% reduction in central subfield thickness. Label of a given volumetric scan was applied to its corresponding B-scans. Treatment response-related features were manually segmented in approximately two representative B-scans of each volumetric scan to train the system to predict robust outcome. A convolutional neural network-based B-scan classifier was established and trained with the volumetric labels. By feeding all B-scans of a given volumetric scan sequentially as input, we took the maximum prediction value among all B-scans as the volume-level result (good or poor response, Fig.1).

Results: 949 OCT volumes (23,356 B-scans) from 679 eyes of 531 patients were included for training (60%), validation (20%) and testing (20%). The DL system achieved dice scores of 0.689, 0.880, and 0.856 for segmentation of sub-retinal fluid, outer-retinal defects, and disorganization of the retinal inner layers. The system achieved AUROC of 0.731 for prediction good or poor response at volume-level.

Conclusions: The DL system could predict anti-VEGF treatment response with good performance. It may optimize treatment modality for an individual’s condition of DME for better compliance and less financial burden.

ABSTRACT BODY:

Purpose: Our previous studies have demonstrated the presence of anti-citrullinated protein autoantibodies (ACPA) in ocular surface washes from patients with autoimmune dry eye disease (DED). Moreover, this pathology was responsive to ocular surface immunoglobulin G (OSIG) treatment. The purpose of this study was to develop a murine model of autoantibody-induced DED to support future mechanistic and pharmacological studies.

Methods: Male C57BL/6J mice (8-10 weeks of age) received four daily instillations (5 µl) of either anti-histone 4 (citrulline R3) antibody (H4R3 ACPA; 100 ng/ml) or anti-histone 4 wildtype antibody (H4 WT; 100ng/ml). Corneal pathology was evaluated at baseline, day 5 and day 8 by fluorescein staining using a hand-held slit lamp with built-in cobalt blue light. Fluorescence was captured using a Spectralis HRT with anterior segment module (Heidelberg Engineering) in fluorescein angiography mode. Fluorescein staining was graded using both the Oxford scoring system and National Eye Institute (NEI) grading system. Data were analyzed by Two-Way ANOVA with Holm-Šídák's multiple comparisons test.

Results: Eyes treated topically with H4R3 ACPA showed significant corneal damage on day 5 (median score: 2.5, range 2 – 4, $n = 6$, $P < 0.01$) and on day 8 (median score: 3.5, range 2 – 4, $n = 6$, $P < 0.01$), when compared with baseline. In contrast, eyes treated with H4 WT antibody showed some signs of corneal damage (median score: 1.5, range: 1 – 2, $P < 0.01$), but pathology was significantly lower than in H4R3 ACPA-treated eyes.

Conclusions: Topical instillation of H4R3 ACPA antiserum results in significant corneal damage in mice mimicking autoimmune DED pathology in patients. The novel model for autoantibody-induced dry eye disease offers a validated and standardized experimental paradigm that will allow for the rigorous testing of targeted therapeutics for autoimmune DED.

ABSTRACT BODY:

Purpose: Transient intraocular pressure spikes (spOHT) are induced by certain activities, including yoga, playing wind instruments, and caffeine intake, and are associated with an increased risk of glaucoma. To understand mechanisms underlying the spOHT-induced retinal ganglion cell (RGC) loss, we examine the role of innate immune response in RGC disfunction in a rodent model of non-ischemic IOP spikes.

Methods: C57BL/6J mice (2-3 month) were challenged by either “spiking” IOP changes (spOHT) or by a steady elevation (stOHT) at 40mm Hg above baseline via cannulation of the anterior eye chamber. For spOHT, the reservoir is elevated 1 minute and then lowered for 1 minute for seven cycles. For steady stress, the column remains raised for 7 minutes. We measured changes in intravitreal IL1-β using ELISA, and monitored activation of GsdmD, NLRP1, caspases-1 in retina by qRT-PCR. Retinal function was measured with pattern electroretinogram (PERG). RGC counts were performed on whole mount retina with RBPMS antibody at 7 days after stress. The role of inflammasome was examined using Caspase 1, NLRP1, and GSDMD null mice. TRPV1 blocker was administered to test the role of mechanical stress signaling. Data were evaluated with ANOVA with multiple comparisons to controls.

Results: Fluorescent label showed caspase 1, caspase 3, and GSDMD activation in RGCs 6 hours after spOHT. IL1β measured in vitreous at 6, 12, and 24 hours post spOHT showed 1, 12, and 13 fold increase. qRT-PCR showed significant transcription increase in retina for casp1, NLRP1, and GSDMD at 24h after spOHT. PERG revealed a decline in amplitude of 31.8% at 1 week following spOHT. RBPMS+ cell counts of retina at 1 week also showed 22.6% reduction in cells per sampled regions. Significant inflammasome markers and functional and structural loss were not observed in the stOHT group. Casp1 knull mice demonstrated reduced loss in PERGamp (1.8%) and RBPMS+ (7.7%) count at 1 week, as did NLRP1 null (10%), (5.9%), and GSDMD null (18%), (4.7%) after spOHT. TRPV4 blocker treatment prior to spOHT ablated singificant deficts in PERGamp (5%) and RBPMS+ (3.1%).

Conclusions: Rapid IOP fluctuations drive innate immune responses in retinal ganglion cells, leading to functional disruption and cell loss. Ablation of inflammation-initiating proteins, as well as blockade of pressure-sensitive TRPV4 channel protected from functional disruption.

ABSTRACT BODY:

Purpose: X-linked retinitis pigmentosa (XLRP) is caused by mutations in the retinitis pigmentosa GTPase regulator gene, RPGR, which leads to progressive night blindness, loss of peripheral vision, and eventually central vision loss. This is a follow-up report of macular structure analysis from an ongoing, phase 1/2, open label, dose escalation clinical trial using a recombinant adeno-associated viral (rAAV) vector to deliver a functioning gene copy of RPGR via subretinal injection.

Methods: Male participants (n=29), age ≥6, were assigned to five dose groups and received subretinal injection of AGTC-501 (rAAV2tYF-GRK1-RPGR) into the central or peripheral region of the study eye. Primary outcome was safety. Among the 21 centrally dosed patients analyzed in this study, the secondary outcome was macular structure (OCT) and function (MAIA microperimetry and best-corrected visual acuity (BCVA) as assessed by ETDRS). Up to 18 months post-treatment data were analyzed.

Results: Subretinal administration of AGTC-501 was well-tolerated across a wide dose range. The majority of adverse events were mild-moderate in severity, consistent with the subretinal injection and vitrectomy procedures, and/or concomitant prophylactic steroid regimen used to mitigate inflammation. Of the 21 patients who received a subretinal injection within the macula of the study eye, 13 had visible foveal ellipsoid zone (EZ) on OCT at baseline. Post-injection, the macular EZ recovered by 3-6 months in 9 eyes (69%). Of these eyes, six (67%) subsequently showed improvement of EZ line area and reflectivity compared to baseline by month 12, which was sustained to month 18. Treated eyes with EZ improvement had improved macular function on MAIA ($p = 0.003$) and stable foveolar thickness on OCT ($p = 0.0003$) compared to eyes without EZ improvement.

Conclusions: Consistent safety and efficacy signals in the study eyes that underwent subretinal administration of AGTC-501 were observed up through month 18. Of the study eyes with visible EZ at baseline, most showed recovery of foveal EZ after macular injection, and nearly half had improved EZ appearance which correlated with improvement in macular sensitivity. Follow-up is ongoing through 5 years to assess long-term safety and durability of response.

TITLE: Mutation-independent RNA replacement approach based on RHO-targeting ribozyme rescues rod photoreceptor function in mice model of autosomal dominant Retinitis pigmentosa (adRP)

SESSION TITLE: Photoreceptors and disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Kim, S. Lee, R&D, Rznomics, Seongnam si, 253, Pangyo-ro / Bundang-gu, KOREA (THE REPUBLIC OF)|

Commercial Relationships Disclosure: Ji Hyun Kim: Commercial Relationship(s);Code E (Employment):Rznomics | Seong-Wook Lee: Commercial Relationship(s);Code O (Owner):Rznomics

ABSTRACT BODY:

Purpose: Rhodopsin (RHO) mutations account about 25~30% of adRP. Although a single P23H mutation in the RHO gene is known to be the most common cause of adRP in USA, more than 150 mutations have been identified. Group I intron-based trans-spicing ribozyme enables to reprogram target RNA into gene of interest through RNA replacement. Here, we developed a mutation-independent therapeutic strategy based on specific trans-splicing ribozyme that can replace, and thus edit mutant RHO RNA with functional RHO RNA using AAV delivery system.

Methods: Target site of RHO RNA was first identified by in vitro mapping. To improve the trans-splicing specificity and efficacy, we optimized RHO-targeting ribozyme through modification of ribozyme structure. To verify in vivo function, AAV vector encoding the optimal ribozyme was constructed and delivered by subretinal injection into the eye of human P23H knock-in mice. After administration, scotopic ERG was measured on dark-adapted mice and retinas were dissected and processed for H&E staining, RT-PCR, and qPCR.

Results: Sequencing analysis of trans-splicing sites through mapping revealed that the most efficient target site occurred at the 5’ UTR of RHO RNA. We modified and optimized the structure of the ribozyme targeting the most accessible site of target RHO RNA. We observed that various mutant RHO RNAs were successfully targeted and replaced with WT RHO RNA by the optimized ribozyme. When assessed the electrical response function of eye in human P23H knock-in mice model, the b-wave amplitudes significantly increased in eyes injected by AAV encoding the ribozyme as compared to those of control-injected eyes. Molecular and cellular analysis of retina tissue showed that P23H RNA is replaced with WT RHO with high efficacy and fidelity and ONL appears significantly thicker in the ribozyme-treated eyes.

Conclusions: Various mutant RHO RNAs were trans-spliced with high fidelity and restored to WT RHO by RHO-targeting ribozyme in cells. The ribozyme effectively prevents the degeneration of photoreceptor cells and preserve their electrical response function in P23H knock-in mice through specifically targeting and trans-splicing of target RHO RNA. These results suggest that RNA replacement based on RHO-targeting ribozyme could be potent and mutation-independent therapeutic strategy for RHO-adRP.

ABSTRACT BODY:

Purpose: Retinal vessels reflect the alteration of physical status related to hypertension and arteriosclerosis. Previously, we reported a deep learning algorithm to detect retinal vessels full-automatically and to measure the total retinal vascular area in fundus images (Fukutsu et al. Ophthalmology Science. 2021). In the present study, we investigated the relationship between the total retinal vascular area and brachial-ankle pulse wave velocity (baPWV), which is known as a gold standard for arterial stiffness assessment in clinical practice.

Methods: Retinal photographs (n=696) obtained from 372 individuals who visited Keijinkai Maruyama Clinic for a regular health checkup were used to analyze the total retinal vascular area. PWV was also measured in each patient. Automatic retinal vessel segmentation was performed using our deep learning algorithm, and the total arteriole area (AA) and the total venule area (VA) were measured. The correlation between PWV and several parameters including AA and VA were assessed.

Results: The baPWV correlated negatively with AA ($R = -0.40$, $n = 696$, $P < 2.2e-16$) and VA ($R = -0.36$, $n = 696$, $P < 2.2e-16$). Each of the independent variables (AA, gender, age, and systolic blood pressure) selected using the stepwise method showed a significant correlation with the value of baPWV. The predicted value of baPWV, calculated from regression equation using the variables including AA, showed a better correlation with the measured baPWV value ($R=0.70$, $n=696$, $P < 2.2e-16$) than the predicted value without AA ($R=0.68$, $n = 696$, $P < 2.2e-16$).

Conclusions: AA and VA showed a significant correlation with baPWV. In addition, the predicted value of baPWV using AA well correlated with the actual baPWV value. The present data indicate that the retinal vascular area serves as an alternative biomarker for evaluating arteriosclerosis.

ABSTRACT BODY:

Purpose: Intraretinal hyperreflective foci (IHRF) have been identified as an important optical coherence tomography (OCT) biomarker for progression of age-related macular degeneration (AMD). In this study, we evaluate the impact of reducing B-scan density on the sensitivity for detecting IHRF on spectral domain OCT (SD-OCT) volumes in eyes with intermediate AMD.

Methods: A total of 165 eyes from 106 patients with intermediate AMD and IHRF enrolled in the Amish Eye Study were evaluated in this retrospective analysis. For each case, raw SD-OCT (Cirrus OCT 512x128, 6x6mm, fovea centered) volumes were imported into 3D-OCTOR software. The number of IHRF was assessed on all 128 B-scans (spaced 47 μm apart) using a categorical scale (graded as 1-4, 5-9, 10-14, 15-19, and >20). Additionally, B-scan densities in the volume were lowered to 64 B-scans (spaced 94 μm apart), 43 B-scans (spaced 140 μm apart), and 32 B-scans (spaced 188 μm apart), respectively, by removing intervening B-scans prior to presenting the volume to the grader. The number of eyes with any IHRF and the number category of IHRF were used to compare the sensitivity at each reduced B-scan density against the reference 128 B-scan volume.

Results: In the reference 128 B-scan volume, there was a median IHRF score of 1-4 IHRF/eye. For the primary analysis of qualitative presence or absence of IHRF, the sensitivity decreased with decreasing B-scan density from 98.2% ($p= 0.0819$) at 64 B-scans, 92.7% ($p<0.0001$) at 43 B-scans, and 75.2% ($p<0.0001$) at 32 B-scans. With regards to the number of IHRF/eye, there was no significant difference in the numerical category when the density was reduced to 64 B-scans ($P=0.0753$) but was significantly different (with a lower level on the scale chosen) when the B-scan density was reduced to 43 or 32 B-scans ($p<0.0001$ and $p<0.0001$, respectively).

Conclusions: Increasing the inter B-scan spacing from 47 to 188 microns significantly reduced the ability to accurately determine whether IHRF were present in an eye. For quantification of the severity of IHRF within an eye, even an increase in inter B-scan spacing to 140 microns, was associated with a significant misclassification of the IHRF quantity. These findings may be of relevance in the design of OCT scanning protocols for studies utilizing biomarkers for AMD progression.

ABSTRACT BODY:

Purpose: To report quantitative and quantitative analysis of Haller vessel layer using 3-dimensional (3-D) model of choroidal vasculature in healthy subjects.

Methods: A retrospective study of patients (n = 14) of healthy subjects with no history of previous retinal disease underwent swept-source optical coherence tomography. Previously validated algorithm was used to create a 3-D Haller vessel reconstruction was constructed. Two independent personnel evaluated the images of the Haller vessels via a three dimensional representation on MeshLab® and graded them on qualitative criterias including symmetry, hot areas showing thicker vessels, branching, rarefaction, and focal constriction. Quantitative analysis was performed using heat maps which included mean, relative distribution (range) of radius, quadrant analysis and curvature analysis.

Results: The average age of the patient was 38.4 ± 16.2. The average of the minimum (15.0 ± 1.2 μm) and maximum (174.1± 6.6 μm) of the vessels was calculated. Qualitative analysis on Haller vessels based on symmetricity (100% symmetric), branching (42.9% occasional; 57.1% moderate), rarefaction (50.0% absent; 42.9% mild-moderate; 7.1% severe), focal hot area (28.6% absent; 57.1% few; 14.3% absent), course of vessels i.e., parallel to each other (92.9% yes; 7.1% no), and focal vascular constriction (14.3% yes; 85.7% no) was performed. Further analysis on other quantitative parameters is underway.

Conclusions: Healthy subjects largely had symmetric distribution with parallel arrangement of Haller layer blood vessels with mild branching and rarefaction with few focal hot areas and focal constriction. Normative database for different age groups for Haller vessel analysis will be established.

ABSTRACT BODY:

Purpose: Neural processing of sensory input in the brain takes time, due to the time taken for neural transmission and sensory integration. This creates a potential challenge for the visual system to accurately localize moving objects. One way the brain might overcome this is through motion extrapolation: using the past trajectory of a moving object to predict its future position. In this study we wanted to investigate (i) whether such extrapolation mechanism operate between the eyes in normally sighted observers; and (ii) whether extrapolation processes could be defective in the amblyopes as these patients exhibit an interocular processing delay.

Methods: To measure interocular extrapolation we used a dichoptic flash-lag effect (FLE) paradigm. Twelve adults amblyopes and 12 control subjects participated in the experiment. We measured the FLE magnitude of the subjects under binocular, monocular and dichoptic conditions.

Results: In controls, the FLE magnitude of binocular viewing was significantly smaller than that of monocular and dichoptic viewings ($P \leq 0.023$), but there was no difference between monocular and dichoptic conditions. Amblyopes exhibited a smaller FLE magnitude in the dichoptic condition when the moving bar was presented to the amblyopic eye and the flash to the dominant eye (DA condition) compared to the opposite way around (DF condition), consistent with a delay in the processing of the amblyopic eye ($P = 0.041$).

Conclusions: Our observations confirm that trajectory extrapolation mechanisms transfer between the eyes of normal observers. However, such transfer may be impaired in amblyopia. The smaller FLE magnitude in DA compared to DF in amblyopes could be due to an interocular delay in the amblyopic visual system. The observation that normal controls present a smaller FLE in binocular conditions raises the question whether a larger FLE is or is not an indicator of better motion processing and extrapolation.

ABSTRACT BODY:

Purpose: The effects of COVID-19 on the retina have been debated since the start of the pandemic. This study aims to assess how COVID-19 may alter retinal microvasculature using wide-field swept-source optical coherence tomography angiography (WF SS-OCTA).

Methods: This prospective, cross-sectional, observational study included patients with a positive COVID-19 polymerase chain reaction (PCR) test who underwent WF SS-OCTA imaging from August 2020 to November 2021. The mean days from PCR diagnosis to imaging was 175.6. Age-matched controls included healthy eyes and fellow eyes of retinal detachment, retinal tears, retinal artery occlusion, and retinal vein occlusion. Patients with diabetes, uncontrolled hypertension, retinal disease, prior retinal surgery, and a positive COVID-19 test >365 days before imaging were excluded. Vessel density (VD) and vessel skeletonized density (VSD) were calculated (Macular Density Algorithm v0.7.3.3, ARI Network) for the superficial capillary plexus (SCP), deep capillary plexus (DCP), and whole retina using 3x3, 6x6, and 12x12 mm scans centered on the fovea. A mixed-effect multivariate multilevel linear regression model was used to identify any difference between controls and COVID-19 groups.

Results: 34 eyes of 29 patients with COVID-19 and 54 eyes of 45 controls were included. Generalized reductions in VD and VSD were seen in COVID-19 eyes compared to controls (Fig 1). Controlling for age, COVID-19 was associated with a statistically significant overall reduction in VD in the SCP and whole retina in 3x3 mm and DCP of 6x6 mm scans as well as decreased VSD in the DCP in 6x6 mm scans (Table 1). Looking at changes by region, COVID-19 eyes had significant reductions in superior sectors in VD across all scan sizes and layers except the whole retina in 6x6 mm scans, and in VSD across all scan sizes and layers except the SCP in 3x3 and 6x6 mm scans and whole retina in 6x6 mm scans. Additional region-specific reductions in VD and VSD were seen in the DCP in 6x6 and 12x12 mm scans, whole retina in 12x12 mm scans, and SCP in 12x12 mm scans.

Conclusions: Patients with COVID-19 showed reduced VD and VSD compared to controls. This may indicate that there are some retinal microvasculature changes in patients with prior COVID-19 infection.

ABSTRACT BODY:

Purpose: Individuals with neuropathic ocular pain (NOP) have poor response to conventional topical therapies targeting the ocular surface. Common descriptors of NOP such as chronic pain, burning sensation, photoallodynia, and hyperalgesia to wind elucidate somatosensory dysfunction. We performed a prospective, open, single-arm pilot study without randomization to quantify changes in chronic ocular pain and corneal nerve density in sub-basal plexus after long-term use of trigeminal nerve stimulation (TNS).

Methods: During January-December 2021, seven subjects with NOP were identified as candidates for daily 20-minute TNS sessions at home for six months. Participants gave subjective scores on a 0-10 scale to questions evaluating severity of pain, dryness, burning sensation, sensitivity to light and wind before and after a 20-minute in-clinic TNS trial. The same questions and scale were used to monitor changes in symptom severity monthly. In vivo confocal microscopy (IVCM) was performed prior to initiating TNS therapy and measurements were repeated every two months to quantify changes in corneal nerve density for a total of six months.

Results: Paired t-tests were performed comparing baseline measurements vs. in-clinic TNS trial, response at three and six months. In-clinic TNS trial showed overall decrease in symptom severity. Reduction of ocular pain and sensitivity to wind were statistically significant ($p=0.014$ and $p=0.048$, respectively). Follow up at three months, maintained the same trend with an important decline in wind hyperalgesia ($p = 0.002$). 6 month follow up showed a clinically significant reduction in ocular pain of 24% ($p = 0.025$) and decrease in wind sensitivity by 18% ($p= 0.019$). IVCM did not show changes in corneal nerve density in the subbasal plexus.

Conclusions: Six months of TNS therapy significantly reduces chronic ocular pain and wind hyperalgesia exhibiting its potential use as adjunctive therapy for NOP. TNS does not modify corneal nerve density.

Commercial Relationships Disclosure: Chrysanthi Stevens: Commercial Relationship: Code N (No Commercial Relationship) | Jing Xu: Commercial Relationship: Code N (No Commercial Relationship) | Alex Bowers: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In the majority of states, drivers with reduced visual acuity are permitted to drive with a bioptic telescope which magnifies distant objects. Advanced driver assistance systems (ADAS) have become widely available in new cars and may be helpful for drivers with impaired vision, but little is known about whether bioptic drivers use these systems. We conducted a survey to quantify usage of ADAS by bioptic compared to normal vision (NV) drivers.
Methods: The telephone survey included questions pertaining to subjects' demographics, vision, vehicle, driving habits, experience, and use of 8 ADAS: forward collision warning, forward collision avoidance, blind spot warning, lane departure warning, rearview camera, adaptive cruise control, cruise control, and GPS navigation.
Results: 46 bioptic drivers (25 male; median age 53, range 24-84 years) and 47 NV drivers (25 male; median age 55, range 24-89) completed the survey. Weekly mileage (median 50 miles) and days per week driving (median 5) did not differ between the two groups. Yet, bioptic drivers had overall newer cars (medians 4 vs. 7 years, p =0.041) and used more ADAS (medians 3 vs. 2, p = 0.113) than NV drivers. For bioptic drivers, the most commonly used ADAS were GPS (89% bioptic, 91% NV), rearview camera (61% bioptic, 49% NV) and blind spot warning (50% bioptic, 23% NV). Forward collision warning (p=0.038), blindspot warning (p=0.009), and rearview camera (p = 0.026) were used more by bioptic than NV drivers. The ADAS most commonly believed to improve safety were blind spot warning (89% bioptic, 83% NV) and rearview camera (74% bioptic, 83% NV). The majority (83%) of bioptic drivers reported that GPS compensated for their reduced vision (compared to < 57% for other ADAS) and 50% commented that it replaced the need to read road signs. However, 37% of bioptic drivers reported difficulty using GPS because of their vision.
Conclusions: Bioptic drivers have newer cars and use ADAS more than NV drivers, most notably forward collision warning, blind spot warning, and rearview camera. For bioptic drivers, blind spot warning was reported to be most likely to improve safety and GPS was most likely to compensate for vision impairment, even though they experienced visual difficulties when using GPS and believed other ADAS to have greater potential to improve driving safety.

ABSTRACT BODY:

Purpose: To examine optic nerve head (ONH) and retinal nerve fiber layer (RNFL) structure and its relationship to optical coherence tomography angiography (OCTA) biomarkers of hemodynamics in open angle glaucoma (OAG) patients of African (AD) and European descent (ED).

Methods: In a cross-sectional analysis, thirty one patients with OAG (13 AD, 18 ED) were assessed for visual field (VF), intraocular pressure (IOP), ONH and RNFL structure and hemodynamics via OCTA for radial peripapillary capillary vessel density (VD) of all the vessels (ALL) and small blood vessels (SV) (AngioVue Imaging System, RTVue XR Avanti, Optovue Inc., Fremont, CA, USA). Age-adjusted nonparametric tests and Spearman correlations were used to identify differences and associations between measurements, with $p<0.05$ considered statistically significant.

Results: OAG patients of AD and ED demonstrated significant differences between hemodynamics and structure even with statistically similar IOP and VF biomarkers ($p>0.05$). Strong and positive correlations were found between average global RNFL thickness and vascular parameters in OAG patients of ED, while these correlations were weak in AD (correlations between RNFL thickness and peripapillary VD SV: ED r=0.90, AD r=0.34, p=0.019; inferior hemisphere (IH) VD SV: ED r=0.88, AD r=0.29, p=0.025; whole image VD ALL: ED r=0.85, AD r=0.25, p=0.038; peripapillary VD ALL: ED r=0.90, AD r=0.26, p=0.010; IH VD ALL: ED r=0.85, AD r=0.02, p=0.009). Moderate to strong negative correlations were found between ONH structural parameters and hemodynamic biomarkers in OAG patients of AD, with positive associations identified in ED patients (correlation between cup to disc horizontal ratio and inside disc VD ALL: AD r=-0.30, ED r=0.62, p=0.029; between cup volume and whole image VD SV: AD r=-0.63, ED r=0.27, p=0.032; IH VD SV: AD r=-0.78, ED r=0.06, p=0.020; inside disc VD ALL: AD r=-0.65, ED r=0.18, p=0.043; and IH VD ALL: AD r=-0.76, ED r=0.06, p=0.026).

Conclusions: In this cohort, vascular biomarkers in OAG patients of AD were more strongly associated with structural damage at the level of the ONH, while in OAG patients of ED hemodynamic parameters were more strongly associated with RNFL thickness. Large well-designed longitudinal studies are required to investigate how differences in hemodynamic biomarkers may affect the risk for OAG onset and progression.

ABSTRACT BODY:

Purpose: The effect of preoperative lens status (phakic, pseudophakic, aphakic) on outcomes in glaucoma drainage implants (GDI) remains unclear. We compared visual acuity (VA), intraocular pressure (IOP), and medication use outcomes in patients undergoing GDI placement by the lens status.

Methods: Patients undergoing Baerveldt GDI surgery were reviewed retrospectively from 2015-2021. Inclusion criteria were primary and secondary glaucomas, and a minimum follow up of six months. We excluded pediatric patients <18 and fellow eyes in patients with previous surgery. Main outcome measures were LogMAR VA, IOP, and number of medications at final visit. Failure was defined as IOP < 6 or > 21 at two consecutive visits after postoperative month three, IOP not < 20% from baseline, need for subsequent glaucoma filtration surgery, or loss of light perception vision. 160 eyes in 160 patients undergoing both 250 and 350 mm2 Baerveldt GDI were eligible up to two years post-operatively. A two-way ANOVA was conducted to investigate the effect of Baerveldt GDI surgery and lens grouping on these measures.

Results: Mean follow-up time was 11.6 months. All patients showed significantly lower mean IOP pre vs. postoperatively (26.4 vs. 14.5, p<0.01) and fewer number of medications (3.7 vs. 2.4, p<0.01), however there was no difference in these outcomes based on lens status. No significant difference was seen between pre and postoperative visual acuity by LogMAR in any groups. Aphakic patients had the greatest decrease in mean pre vs. postoperative medications (3.57 vs. 1.86), followed by pseudophakics (3.48 vs. 2.23), and then phakics (3.78 vs. 2.53). 21 patients met failure criteria of which there was a higher rate in 15 phakic patients (15.6%) vs. 6 pseudophakic patients (10.5%); however, this was not significant (OR=1.57, p=0.39). Four of these 21 patients required repeat filtration surgery, all of whom were phakic preoperatively.

Conclusions: No significant difference was found between pre and postoperative IOP and number of medications in patients undergoing Baerveldt GDI on the basis of lens status. Aphakics showed the fewest number of medications postoperatively. Phakic patients showed a slightly higher, but not significant, rate of Baerveldt GDI failure. Further studies are needed to confirm the characteristics of patients that confer both greater IOP lowering response, and higher risk of failure.

ABSTRACT BODY:

Purpose: To examine the age-adjusted differences in biomarkers of ocular blood flow and oxygen metabolism between patients with open angle glaucoma (OAG) and healthy controls.

Methods: 143 patients (102 with OAG; 41 healthy) were assessed in a cross sectional analysis for: intraocular pressure (IOP), blood pressures (BP), ocular perfusion pressure (OPP), visual field (VF mean deviation (MD), pattern standard deviation, (PSD); VF index, (VFI)); retinal photographic oximetry (Oxymap); optic nerve head (ONH) and retinal nerve fiber layer (RNFL) and ganglion cell complex (GCC) structure and vascular biomarkers via optical coherence tomography angiography (OCTA, Optovue). Age-adjusted chi-square tests, two-sample t-tests and nonparametric tests were used to test for differences with $p<0.05$ considered statistically significant.

Results: Compared to healthy controls, patients with OAG had lower vascular biomarkers of: peripapillary small vessel density (mean, standard deviation): (46.11, 6.30 vs. 51.67, 4.12; p=0.008), superior hemisphere small vessels density (46.89, 6.36, vs. 51.75, 4.75; p=0.016), whole image all vessels density (50.14, 4.30 vs. 55.28, 3.18; p=0.025), peripapillary all vessels density (51.60, 6.24 vs. 57.60, 4.09; p=0.002), superior hemisphere all vessels density (52.49, 6.25 vs. 58.01, 4.38; p=0.011), and inferior hemisphere all vessels density (50.58, 7.12 vs. 57.21, 4.12; p=0.038). In addition, OAG patients had lower oxygen saturation in the superior nasal vein (57.57, 10.46) compared to controls (60.49, 9.47); (p=0.018) leading to a significant difference in the supero-nasal arterio-venous difference (p=0.045). The lower vascular biomarkers occurred despite higher mean OPP in patients with OAG (89.2, 16.3) compared to controls (79.6, 13.3); (p=0.002).

Conclusions: OAG patients had significantly lower vascular and metabolic biomarkers compared to healthy controls. Importantly, these differences were present despite higher OPP in the OAG group. Our data suggest localized reductions in blood flow may occur despite higher perfusion pressures and/or occur from autoregulation deficits present in patients with glaucoma.

ABSTRACT BODY:

Purpose: Telemedicine allows physicians to provide care virtually, limiting patient exposure during the COVID-19 pandemic. As a follow up to a previous analysis (Gore R, et al. IOVS 2021;68:ARVO E-Abstract 146), we performed a retrospective chart review on a separate patient cohort to test whether virtual visual acuity (VA) tests are a reliable means of screening vision in a pediatric population.

Methods: Families screened were sent instructions and an Early Treatment Diabetic Retinopathy Study (ETDRS) eye chart calibrated for 5 feet. Volunteer screeners instructed children over the phone, and those who failed the screen were referred to Wills Eye Hospital (WEH) for further evaluation. The institutional review board at WEH approved the current study. Demographic characteristics and VA screenings (virtual and in-person) were analyzed and compared using Pearson correlation coefficients. Bland-Altman plots were constructed to visualize this comparison.

Results: A total of 242 eyes of 121 patients were included. The mean ± SD age was 11.7±3.1 years. Using Pearson correlations, the in-person and virtual VA measurements were moderately correlated in both the right eye (OD: $r=0.506$, $p<0.001$) and left eye (OS: $r=0.610$, $p<0.001$). Comparing in-person to virtual settings, the mean ± SD LogMAR of VA of the right eye (OD) was 0.37±0.36 (Snellen 20/46) vs. 0.55±0.30 (Snellen 20/70), respectively ($p<0.001$). The mean ± SD LogMAR of VA of the left eye (OS) was 0.38±0.43 (Snellen 20/47) in-person vs. 0.52±0.30 (Snellen 20/66) in the virtual setting ($p<0.001$). However, when the VA range was classified based on the median of in-person VA (LogMAR 0.3, Snellen 20/40), there was no significant difference between in-person and virtual VA measurements in VA >20/40 OD (0.70±0.30, 20/100 vs. 0.67±0.29, 20/93, $p=0.538$) and OS (0.76±0.45, 20/115 vs. 0.70±0.29, 20/100, $p=0.274$) (Table 1). Compared to in-person VA measurement (gold standard), the Bland-Altman plot shows a mean difference of 0.17 LogMAR with virtual VA measurements OD (Fig 1A) and a mean difference of 0.14 LogMAR with virtual VA measurements OS (Fig 1B).

Conclusions: An ETDRS VA test delivered at home demonstrated good correlation with a standard ophthalmologist-administered VA test in a pediatric population. Virtual screening may underestimate vision in patients with good vision at the in-person visit, but the virtual screening does not fail to detect poor vision.

ABSTRACT BODY:

Purpose: Local tissue ischemia has been shown to cause retinal ganglion cell death, but the translation of vascular biomarkers into predictors of open angle glaucoma (OAG) has been challenging. Oximetry and hemodynamics data were collected in OAG and healthy subjects to identify correlations between biomarkers of blood flow and visual function. Mathematical modeling of blood flow and oxygen transport was used to reveal differences in localized tissue oxygenation despite similar measured levels of arteriolar and venous saturation.

Methods: Clinical data from a prospective cross-sectional study included matched examples of healthy and OAG individuals with evaluations of: IOP, blood pressure, visual field (VF) mean defect (MD), pattern standard deviation (PSD), visual field index (VFI), and retinal oxygenation via retinal photographic oximetry. Our mathematical model of the human retinal vasculature was used to predict the arteriolar tissue oxygenation in one quadrant of the eye given an assumed pressure drop across the retinal vasculature of 25 mmHg and an intraocular pressure (IOP) of 15 mmHg.

Results: Healthy (VFI: 99%; MD: 0.29 decibel; PSD: 1.62 decibel) and OAG (VFI: 90%; MD: -5.47 decibel; PSD: 4.83 decibel) samples (both male and Hispanic) exhibited similar IOP and arterial saturations yet had very different clinical outcomes. The model predicted similar disparate outcomes; the two red stars in Fig. 1A highlight two tissue positions where PO_2 = 62 mmHg and PO_2 = 45 mmHg despite identical arterial saturation entering that retinal branch. The histogram in Fig. 1B gives the predicted values of all tissue PO_2, ranging from 35 to 70 mmHg.

Conclusions: This analysis demonstrated that average values frequently reported as mean global values obscure the possibility of regional hypoxia and/or ischemia in some individuals. Developing methodology to discriminate localized tissue metabolic disturbances from global averages may improve translational use of vascular biomarkers in glaucoma and identify patients at elevated risk for progression.

ABSTRACT BODY:

Purpose: Progressive retinal degeneration has been demonstrated in classic CLN2 disease, particularly loss of central retinal thickness with symmetrical bilateral onset and progression. However, changes in the outer retina, especially the ellipsoid zone (EZ), have not been described in detail. This retrospective, observational clinical study was therefore undertaken to examine whether longitudinal observations are possible between low- and high-resolution SD-OCT scans in children with classic CLN2 disease.

Methods: SD-OCT macular cubes (8.8 x 7.8 mm, 61 B-scans, low resolution) were collected in 23 classic CLN2 patients, ages 24 to 122 months. In a subset of subjects, both low- and high-resolution macular cubes consisting of 241 B-scans were also collected on the same day. The contour of EZ loss was marked manually where the EZ band became indistinguishable from retinal pigment epithelium in cross-sectional B-scans and EZ area loss was measured using Heidelberg Eye Explorer (V1.9.10). In subjects with both low- and high-resolution scans acquired, EZ area loss was measured in both resolutions from the same eye for analysis of agreement. EZ loss from the same scans were assessed again after a 2 day washout period for estimation of repeatability. Bland-Altman analyses were used to determine the cutoffs in agreement and precision. Outer nuclear layer (ONL) thickness was measured using the standard ETDRS grid. Longitudinal data were analyzed when available.

Results: Repeatability between EZ loss measurement by the same reader in the same scan was -0.28 to 0.25 mm^2. EZ area loss measured with both low- and high-resolution scans showed strong correlation (Pearson's correlation coefficient = 0.999, $p < 0.01$, with limits of agreement of -0.43 to 0.22 mm^2). The area of EZ loss increased with disease progression and was associated with the magnitude of ONL reduction.

Conclusions: Strong correlation and agreement in measurement of EZ loss between low- and high-resolution scans indicated the method is reliable, while low test-retest variability suggests it is repeatable. This allows comparison of EZ area loss between scans of different resolutions. Additional longitudinal data are needed to understand the pattern of EZ loss in CLN2 disease and its relationship with degeneration of other photoreceptor layers.

ABSTRACT BODY:

Purpose: Currently, utilization of choroidal thickness (CT) in the management of glaucoma is inhibited by its lack of translation in clinical applications. Here, we use Transfer Learning (TL) applying outcomes from glaucoma progression data to analyze a prospective cross-sectional study in patients with OAG and healthy controls.

Methods: We applied Fuzzy c-Means (FCM) clustering to a prospective cross-sectional dataset (Indianapolis Glaucoma Progression Study (IGPS): n=115) enhanced with hemodynamic variables predicted by a validated mathematical model (Guidoboni et al, IOVS, 2014). The model specifically uses intraocular pressure (IOP-Goldmann), blood pressure (BP-automated) and heart rate (HR-automated) as individualized inputs. The 3 clusters identified via FCM on IGPS are then applied to categorize the cross-sectional dataset (n=45 healthy, 11 OAG) based on the mean arterial pressure (MAP) and IOP measured on each subject. CT measured via optical coherence tomography angiography (OCTA) using enhanced depth imaging (EDI) is analyzed by (i) distinguishing between healthy and OAG subjects, and then (ii) sectioning each group by the 3 established IGPS-based clusters.

Results: Figure 1 displays data categorized via the FCM-based clusters and the CT medians, 25th, and 75th percentiles. Overall, CT in OAG eyes is found to be 29% lower than in healthy eyes ($p<0.01$). When further sub grouped, the difference in CT between OAG and healthy eyes was found to be 58% in Cluster 1 ($p=0.03$) and 35% in Clusters 3 ($p<0.01$) (p values obtained with the 2-sample Wilcoxon signed rank test for medians).

Conclusions: TL reveals significantly lower CT in patients with OAG compared to controls as separated into clusters by a hemodynamic and IOP input-based model. FCM applications of clinical datasets combined with transfer learning have the ability to discriminate patients with OAG into those where CT is lowest and patients may be at highest risk for progression compared to healthy controls. These differences were previously unseen when solely comparing OAG and healthy eyes, without the TL-informed subgrouping.

ABSTRACT BODY:

Purpose: To investigate the relationships between choroidal thickness (CT), age, hemodynamic and structural parameters measured by optical coherence tomography angiography (OCTA) in open-angle glaucoma (OAG) patients and healthy controls.

Methods: In a prospective cross-sectional analysis, 48 eyes (13 OAG and 35 healthy) underwent OCTA (Optovue) assessment of: subfoveal CT, retinal nerve fiber layer (RNFL) thickness, cup-to-disc vertical ratio (C/D), average ganglion cell complex (GCC) thickness, and radial peripapillary capillary (RPC) vessel density percentages (VD%). Using enhanced depth imaging (EDI) and a defined anatomical landmark protocol, CT was assessed perpendicularly from the outer edge of the hyper-reflective retinal pigment epithelium to the inner sclera at the fovea. Intra-operator repeatability and inter-operator agreement were evaluated using intraclass correlation coefficients (ICC) and Bland-Altman plots. Associations were calculated across all patients, as well as by presence or absence of OAG, using Pearson’s correlation coefficient and two-tailed, two-sample T-tests assuming unequal variances, repeated before and after adjustment for age.

Results: Mean age was significantly higher in OAG group compared to control group (65.5+/-16.6 years vs. 40.3+/-17.9, $p<0.001$). In all subjects, after adjusting for age, CT was positively correlated with average RNFL thickness ($r=0.39$, $p=0.040$), GCC thickness ($r=0.36$, $p=0.046$), and peripapillary RPC VD% ($r=0.38$, $p=0.0035$), and negatively correlated to vertical C/D ($r=-0.47$, $p=0.013$). CT also had a strong positive correlation with peripapillary RPC VD% ($r=0.90$, $p=0.010$) only in OAG patients. Mean CT was significantly lower in OAG eyes only prior to age adjustment (166.6+/-80.4 µm vs. 266.6+/-85.9 µm, $p=0.001$; after adjustment $p=0.077$). The inter-operator agreement of three independent operators was 0.90.

Conclusions: CT was positively correlated with RNFL thickness, GCC thickness, and peripapillary RPC VD%, and negatively correlated with vertical C/D. CT also had a strong positive correlation with retinal peripapillary capillary density in OAG subjects. After adjusting for differences in age, average mean CT was not statistically significantly different between OAG patients and controls.

ABSTRACT BODY:

Purpose: Lower retinal arterio-venous oxygen saturation (A/V-diff) has been reported in patients with open angle glaucoma (OAG). However, utilization of biomarkers of reducted oxygen extraction in retinal tissues is complex. This analysis applies Transfer Learning (TL) of glaucoma progression data outcomes to analyze a prospective cross-sectional sample of OAG and healthy controls retinal photographic oximetry images.

Methods: Fuzzy c-Means (FCM) clustering is applied to a prospective glaucoma progression dataset (n=115) enhanced with hemodynamic variables predicted by a validated mathematical model (Guidoboni et al, IOVS, 2014). The model specifically uses intraocular pressure (IOP), blood pressure (BP) and heart rate (HR) as individualized model inputs. The 3 FCM-based clusters are then applied to categorize cross-sectional data (n=45 healthy, 11 OAG) based on subjects mean arterial pressure (MAP) and IOP. Optical coherence tomography (OCT) biomarkers of retinal nerve fiber layer thickness (RNFL) and the optic nerve head and oximetry biomarkers were analyzed by (i) distinguishing between healthy and OAG subjects and then (ii) sectioning each group by the 3 FCM-based clusters.

Results: Table 1 displays the FCM TL data for patients with OAG and healthy controls. Structural markers are worse in OAG than healthy eyes in both analyses (i) and (ii). Superior temporal (ST) A/V-diff reveal a 7% increase from healthy to OAG eyes (p=0.12) while inferior temporal (IT) A/V-diff display a 15% increase (p=0.07). When further sectioned, there was an increase in the ST A/V-diff in cluster 1 by 12% (p=0.21), but in cluster 3 there was no change (p=0.63); IT A/V-diff shows a 10% decrease (p=0.46) in cluster 1, but a 9% increase (p=0.09) in cluster 3 (p values via 2-sample Wilcoxon signed rank test for medians).

Conclusions: Specific clustering from TL confirms worse OCT structural markers for OAG eyes in all clusters. It further reveals A/V differences among clusters that were masked when subgrouping was not considered, with no change in cluster 3 for ST A/V-diff, and a decrease in cluster 1 for IT A/V-diff. TL and FCM clustering of clinical inputs may improve specificity of individualized risk assessment.

ABSTRACT BODY:
Purpose: Patients may be fit with scleral lenses (SLs) for indications such as ocular surface disease or irregular corneal astigmatism. Patients wearing SLs often report improved vision and comfort, but some experience mid-day fogging, which may require removal and reapplication of their SLs due to blurry or hazy vision.

The purpose of the present study was to document high contrast visual acuity pre- and post-scleral lens removal in patients with (foggers) and without (non-foggers) subjective mid-day fogging.
Methods: Scleral lens wearers who had worn SLs for a minimum of six months were recruited from five clinical sites. Subjects who wore SLs for at least 2 hours prior to follow-up examinations were asked to participate. Informed consent was obtained, and the following information was collected: patient demographics, subjective complaint of mid-day fogging, and high contrast Freiburg Visual Acuity and Contrast Test (FrACT) pre- and post- scleral lens removal. Descriptive statistics are reported, and comparisons were made by t-test.
Results: Thirty established scleral lens wearers (53 eyes) participated in this study with a mean age of 46 ± 14.6 years (range 24-76 years). Subjects reported a mean SL wear time of 12.5 + 3.2 hours per day (range: 5-17 hours) and 6.5 + 0.8 days per week (range: 4-7 days). 57% (17/30) of subjects reported mid-day fogging.

Mean FrACT acuity in foggers was 0.23 + 0.3 logMAR (range: -0.09-0.94 logMAR, n=13) for right eyes and 0.08 + 0.2 (range: -0.23-0.32 logMAR, n=12) for left eyes. There was no statistically significant difference in FrACT acuity pre- or post-scleral lens removal in foggers for the right (p=0.5) or left (p=0.3) eyes. There was a barely significant difference in FrACT acuity between foggers and non-foggers in the right eye (p=0.05) but not in the left (p=0.3) eye with over two hours of lens wear.
Conclusions: Over half of the subjects in this study reported mid-day fogging but there was no difference in high contrast visual acuity pre-and post-scleral lens wear and minimal to no difference between foggers and non-foggers. Further analysis may provide more insight into the correlation between the subjective complaint of mid-day fogging and clinician observed findings.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is a progressive retinal disease which causes irreversible blindness in elderly. Studies indicate a prominent role of inflammation in the pathogenesis of AMD. Both the cellular and non-cellular components of the innate immune system including cytokine production have been extensively studied to understand the pathophysiology of the disease.

We utilize a novel strategy to address severe chronic “non-resolving” inflammation via the body’s own self recognition system. Our lead asset is a glycan-coated nanoparticle exhibiting dual function in regulating the immune system. It directly modulates the self-pattern recognition receptors on the immune cells, Siglecs (sialic acid binding immunogloblulin like lectins), by dampening the activity of inflammatory cells and enhancing the activity of complement factor H.

Methods: We performed cell-based assays using our proprietary asset in two cell types; THP-1-derived macrophages and PBMC-derived macrophages to characterize the biological activities. Cytokine release as pro-inflammatory markers and complement factor H levels were measured 24 hours post treatment.

Results: Our glycan-coated nanoparticle significantly reduces the production of pro-inflammatory markers (TNF-a) by 2 folds in THP-1-derived macrophages and 2-fold increase in complement factor H levels in PBMC derived M1 macrophages compared to the cells treated with a negative control

Conclusions: Our glycan coated nanoparticle leads to a significant reduction in pro-inflammatory markers and an increase in CFH levels. Our approach for the treatment of non-exudative AMD is to selectively repolarize the macrophage into a resting state. These preclinical studies provide evidence that our molecule targets both cellular and complement mediated aspects of the innate immune system, which are believed to be involved in the pathogenesis of non-exudative AMD and support the advancement of our glycan coated nanoparticle for further development.

Commercial Relationships Disclosure: Rachael Warrington: Commercial Relationship: Code N (No Commercial Relationship) | Timothy A Blenkinsop: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Proliferative vitreoretinopathy (PVR) is an abnormal wound healing response following retinal tears. Cellular membranes form on the subretinal and/or epiretinal surface of the retina resulting in scarring, which can be contractile causing retinal detachments and vision loss. The most aggressive forms of PVR derive from retinal pigment epithelial (RPE) cells. The cytokines TGFβ and TNFα have been shown to play a role in PVR. An in vitro model of PVR combined these cytokines (referred to as TNT), inducing contractile membranes in RPE. A p38 inhibitor (Comms Bio 2019; 2: 1-14) and nicotinamide (Stem Cell Rep 2020; 14: 631-647) prevented these aggressive contractile masses in RPE. Additional tests on patient derived PVR membranes would validate the TNT model, confirming the anti-PVR effects of p38 inhibition and nicotinamide.

Methods: A patient-dissected membrane was divided for immunofluorescence or digestion with collagenase II. The isolated cells were cultured, expanded and assessed for their ability to contract under the TNT conditions of the in vitro PVR model, as well as determine if p38 inhibition and nicotinamide can prevent TNT induced contraction.

Results: The PVR membrane contained RPE and glia, along with markers for epithelial to mesenchymal transition (EMT), motility and extracellular matrix (ECM). Isolated cells from the patient-dissected PVR membrane may have undergone mesenchymal to epithelial transition (MET), as EMT markers were only present in TNT conditions. TNT induced the cells to undergo EMT forming contractile masses. The p38 inhibitor and nicotinamide prevented contraction, however, EMT was not fully reversed as EMT markers (αSMA and SNAI1) positively labelled cells. Motility and ECM markers were present in all conditions, with TNT treatment having the highest expression. Cells treated with the p38 inhibitor or nicotinamide exhibited decreased motility (ACTG2) and ECM (COL1a2 and Laminin) protein production compared to TNT treatment.

Conclusions: Both the p38 inhibitor and nicotinamide prevented membrane contraction showing promise to become a therapeutic treatment for patients at risk of developing PVR and individuals with already formed membranes, both treatments warrant further study in an in vivo model of PVR.

ABSTRACT BODY:

Purpose: More than 50% of children with chronic anterior uveitis (CAU) fail standard methotrexate (MTX) and conventional tumor necrosis factor α inhibitors (cTNFi) therapy. Data are lacking on optimal next therapy. Our aim is to compare the characteristics of children treated with MTX, cTNFi, and alternative biologic agents (ABT) for CAU.

Methods: We reviewed records of 52 children. We grouped based on therapy required to control CAU for ≥3 months. CAU control was defined by all: 1) inactive per SUN criteria, 2) no vitreous haze or uveitis activity by dilated exam or imaging, 3) ≤2 drops of prednisolone acetate 1% or equivalent/day, and 4) no oral corticosteroid.

Results: Of 52 children, CAU was controlled by MTX monotherapy in 15/52, cTNFi in 28/52, and ABT in 9/52 (abatacept-1, tocilizumab-3, and/or golimumab-5). All patients requiring ABT were ANA positive compared to MTX (67%) and cTNFi (71%) groups but not significantly different (NS) (Table 1).

Comparing 28 children controlled on adalimumab (ADA) to 9 who escalated to ABT, the ADA dose, non-biologic DMARD use, and treatment duration were similar. Neutralizing anti-ADA antibodies occurred in 1 patient on ADA compared to 4 on ABT ($p<0.005$).

Comparing 36 children controlled on infliximab (IFX) to 3 who escalated to ABT, IFX was given every 4 weeks at 10 mg/kg/dose (IQR 9.6-11.5) in those on cTNFi, and 7.5 mg/kg/dose (IQR 5-10) on ABT (NS). Infusion reactions occurred in 2 of 3 escalating to ABT. Human anti-chimeric antibodies occurred in 2 patients on ABT compared to 0 on cTNFi despite MTX (NS).

Ocular complications at presentation were similar among all groups. Those on MTX were less likely to develop synechiae, cataracts, ocular hypertension and glaucoma compared to those on cTNFi or ABT (Table 2). Total ocular complication rate (3.4 per person) was higher in those on ABT compared to MTX (0.7 per person) ($p<0.001$) and cTNFi (1.5 per person) ($p<0.001$). Patients on ABT were more likely to have used intraocular pressure-reducing agents prior to ABT compared to cTNFi ($p=0.011$).

Conclusions: Abatacept, golimumab, and tocilizumab may be useful in CAU children who fail MTX and cTNFi. Patients that required ABT had more complications, and anti-cTNFi neutralizing antibodies. The higher incidence of complications may reflect prolonged duration of poor CAU control prior to initiation of ABT.

ABSTRACT BODY:

Purpose: We have recently shown that spectacle lenses with concentric rings of contiguous highly aspherical lenslets (HAL) and slightly aspherical lenslets (SAL) reduce myopia progression in Chinese children. The purpose of this analysis was to evaluate the two-year effect of these lenses on the retinal shape.

Methods: In this randomized, controlled, double-masked clinical trial, 156 children (age 8 to 13 years, myopia between -0.75 D and -4.75 D) were randomized into three groups wearing either HAL, SAL, or single vision (SVL) lenses for 24 months. The central and peripheral axial length of the right eye (between 30 degrees nasally and temporally in 15 degrees steps) were acquired at the baseline and every six months. Individual peripheral eye length data were fitted with a quadratic function, and the quadratic coefficient served as an indicator of the retinal shape per child per study visit. These values were subjected to a between-group comparison using Fisher's LSD-adjusted paired comparisons. The relationship between two-year myopia progression and retinal shape changes was evaluated using Pearson's correlations.

Results: The quadratic function fit well the data (mean $r^2 = 0.94$). As expected, the eyes in the SVL group have become progressively more prolate indicated by the mean two-year decrease of the quadratic term by $-1.96 \pm 2.25 \times 10^{-4}$ mm/deg^2. This trend was significantly weakened in the SAL group ($-0.96 \pm 1.84 \times 10^{-4}$ mm/deg^2; $p < 0.01$) and completely absent in the HAL group ($0.28 \pm 2.00 \times 10^{-4}$ mm/deg^2; $p < 0.001$). The changes in the quadratic coefficient were negatively correlated with the two-year changes in axial length in all groups (all $r < -0.321$, $p < 0.02$).

Conclusions: Wearing HAL lenses abolished the characteristic retinal shape changes associated with increasing myopia. In the SAL group, this trend was also present but less prominent. From the clinical perspective, these findings are important and indicate that myopia control with lenses with aspherical lenslets may provide an additional benefit besides a "simple" reduction of the axial elongation and refractive error.

TITLE: A mouse model of acute retinal necrosis to study innate immunity of the retina

SESSION TITLE: Infection and Immunity

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Conrady, S. Fan, University of Nebraska Medical Center, Omaha, Nebraska, UNITED STATES|

Commercial Relationships Disclosure: Christopher Conrady: Commercial Relationship: Code N (No Commercial Relationship) | Shan Fan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The innate immune response activated by acute retinal necrosis, a rapidly progressive herpes virus infection (herpes simplex virus [HSV] -1 or -2, or varicella-zoster virus) of the retina, is poorly understood. We aimed to create an experimental mouse model of acute retinal necrosis in which the retina is directly infected with herpes virus and that mimicks human disease.

Methods: Using both male and female C57Bl/6J mice between 6-8 weeks of age consisting of 2 experiments of 2-3 mice per group. Mice receiving subretinal HSV-1 were compared 1, 3, and 5 days post-infection to subretinal sterile saline controls. Histology, OCT, fundus imaging and viral plaque assays were evaluated. A student's t test was then used to compare the two groups with statistical significance defined as a p value less than 0.05.

Results: Following subretinal injection of herpes simplex virus -1, retinal whitening insues and results in full thickness retinal necrosis with overlying vitreous inflammation on OCT, histology, fundus imaging within 3 days of infection and progressively expands in size (n = 2-5 mice / group consisting of 2 independent experiments) [FIGURE]. Viral load was then compared at 5 days post infection and was significantly elevated when compared to PBS controls (3.94±0.332 versus 0±0; $p < 0.01$) [FIGURE].

Conclusions: We have created a reproducible mouse model of acute retinal necrosis similar to human disease and in which replicating virus can be isolated from the retina. This model will help us better understand the innate immune response to HSV infection of the retina and could be utilized to better understand innate immunity to other bacterial, viral, or viral-vector pathogens.

ABSTRACT BODY:

Purpose: With recent technical advances, visible light OCT has revealed previously unseen retinal bands in the living human retina and enabled quantification of other bands for the first time. Here, we investigate outer retinal band 2, referred to as the ellipsoid zone or inner segment / outer segment (IS/OS) junction, with 1 micron axial resolution visible light OCT.

Methods: Spectral/Fourier domain visible light OCT, with 1 micron axial resolution, was performed along the horizontal meridian from the fovea to the periphery in 2 male subjects aged 27 and 40. Data from a single subject (27 year-old Asian male with brown iris) is shown. A noise-corrected transverse cross-correlation matrix of the flattened volumetric OCT intensity data sets, displayed as an image, was employed to examine associations between various axial positions in the outer retina. The logarithm of the p value (not corrected for multiple comparisons) was also examined. All findings were confirmed qualitatively in the second subject (not shown).

Results: Band 2 appeared as a single entity in the fovea, yet was clearly split into nominal bands 2a and 2b in the peripheral retina (Figure 1). The cross-correlation matrix showed that band 2a is associated with band 3 (Figure 2), referred to as the cone outer segment tips (COST) or cone interdigitzation zone (CIZ). On the other hand, band 2b was not associated with band 2a or band 3, though it was weakly associated with the rod IZ or rod OST in band 4 (Figure 2).

Conclusions: Visible light OCT revealed a split band 2 in the human peripheral retina. The topography and transverse intensity variations of the outermost band 2b suggest an association with rods. Band 2b may relate to the rod IS/OS or ellipsoid zone which has been reported in various animal models.

ABSTRACT BODY:

Purpose: To identify the missing heritability of ABCA4-related retinopathy in a Chinese cohort.

Methods: 33 unrelated patients with ABCA4-related retinopathy carrying a monoallelic variant in ABCA4 were recruited. All patients underwent ophthalmic examinations. Next-generation sequencing of the whole ABCA4 sequence, including coding and non-coding regions, was performed to detect deep intronic variants (DIVs) and copy number variations (CNVs).

Results: Eight missing pathogenic ABCA4 variants were identified including five DIVs and three CNVs in 20 patients (60.6%). The five DIVs, including four novel (c.1555-816T>G, c.2919-169T>G, c.2919-884G>T, and c.5461-1321A>G) and one reported (c.4539+1100A>G), accounted for the missing alleles in 51.5% of the patients. Minigene assays showed that four novel DIVs activated cryptic splice sites leading to the insertions of pseudoexons. The three novel CNVs consisted of one gross deletion of 1273 bp (exon 2), and two gross duplications covering 25.2 kb (exons 28–43) and 9.4 kb (exons 38–44). Three microhomology domains were identified at the breakpoints and revealed the potential mechanisms of CNV formation.

Conclusions: DIVs and CNVs explained about two-thirds of the unresolved Chinese cases with ABCA4-related retinopathy. Combining results from phenotypic screening, targeted the whole ABCA4 sequencing, and in silico tools can help to identify the missing heritability and lay the foundation for future drug and gene therapy.

TITLE: Validation of portable slit lamp videos and anterior segment photographs as telemedicine modalities

SESSION TITLE: New improvements in imaging and development of biomarkers

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Schott, A. Zhu, Medical Student, Rutgers New Jersey Medical School, Newark, New Jersey, UNITED STATES|B. Szirth, M. Habiel, Ophthalmology, Rutgers New Jersey Medical School, Newark, New Jersey, UNITED STATES|

Commercial Relationships Disclosure: Brian Schott: Commercial Relationship: Code N (No Commercial Relationship) | Aretha Zhu: Commercial Relationship: Code N (No Commercial Relationship) | Bernard Szirth: Commercial Relationship: Code N (No Commercial Relationship) | Miriam Habiel: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The COVID-19 pandemic has highlighted the need for telemedicine across all specialties. Though its utilization has increased since the start of the pandemic, ophthalmology has been reported to be among the specialties least likely to utilize telemedicine in practice. We evaluated the potential utility of portable slit lamp exam (SLE) videos and anterior segment photos as telemedicine modalities by comparing the findings from these modalities to those identified in-person in the clinic.

Methods: Data was collected from 98 subjects at Rutgers Institute of Ophthalmology and Visual Science by non-ophthalmic trained staff, which included portable SLE videos and anterior segment photos, collected with Microclear digital hand-held slit lamp (Suzhou, China) and Canon non-mydriatic retinal camera CR-2 Plus AF (Tokyo, Japan), respectively. Analysis included anterior segment photos taken from 92 patients (183 eyes) and SLE videos taken from 91 patients (177 eyes), which were interpreted and compared to exam findings identified in-person in the clinic. Sample t-tests were used for statistical analysis.

Results: Nuclear sclerotic cataract (NSC) had the most agreement between telemedicine interpretation and in-person exam (photo 93.8%, video 93.75%). Cortical cataract showed less agreement (photo 65.63%, video 45.16%) and posterior subcapsular cataract (PSC) showed the least agreement (photo 8.33%, video 0%) among cataract findings. Cornea findings were among those least likely to be identified (photo 12.5%, video 14.86%). Findings that showed statistically significant differences between photo and video included pinguecula ($p=0.00032$). PSC ($p=0.044$) and posterior capsule opacification ($p=0.00098$) showed statistically significant differences regarding identifying findings on telemedicine interpretation that were not documented in clinic.

Conclusions: Portable SLE videos and anterior segment photos may have potential for utility as means of telemedicine, particularly for NSC. Portable SLE requires more training to display a full ophthalmic exam whereas photographs can easily be done by non-ophthalmic trained staff, displaying similar findings. Differences in exam findings may be attributed to lack of documentation when patients present to the clinic for more urgent concerns and lack of focus on slit lamp videos by non-ophthalmic trained staff.

TITLE: Kidney Injury after Intravitreal Anti-Vascular Endothelial Growth Factor Injection: A Multi-Center Study Using Electronic Health Records

SESSION TITLE: Anti-VEGF in AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Mosenia, A. Shahlaee, J. Schallhorn, Ophthalmology, University of California San Francisco, San Francisco, California, UNITED STATES|A. Shahlaee, Wills Eye Hospital, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Arman Mosenia: Commercial Relationship: Code N (No Commercial Relationship) | Abtin Shahlaee: Commercial Relationship: Code N (No Commercial Relationship) | Julie Schallhorn: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: An increasing number of cases of acute kidney injury (AKI) have been reported after intravitreal anti-Vascular Endothelial Growth Factor (anti-VEGF) injections. The purpose of this study was to evaluate the real-world evidence for AKI in a large cohort of patients receiving anti-VEGF therapy using routinely collected electronic health records.

Methods: De-identified data from over 6 million patients treated across University of California Health system from 2012 to 2021 were queried. All patients with a creatinine measurement within 6 months prior to and 14 days after the intervention were considered, and those with a baseline creatinine ranging from 0.4 to 4.0 were included. Rate of acute kidney injury (a rise of creatinine by 0.3 mg/dl within 48 hours or 150% within two weeks) was calculated after the patients first record of anti-VEGF injection (intervention group) or posterior segment optical coherence tomography scan without anti-VEGF injection (OCT, control group). The χ^2 test was used to assess statistical significance (α = 0.05). Information on a pre-existing diagnosis of diabetes mellitus (DM) was also included.

Results: A total of 191,211 and 9,149 unique patients in the database received OCT and intravitreal anti-VEGF, respectively. Pre- and post-intervention creatinine were available for 7,367 (control) and 347 (intervention). Baseline creatinine was similar between the two cohorts. Rate of AKI in anti-VEGF group was 2.88%, which was not significantly different from the control group (1.87%, p=0.18). Creatinine data availability was significantly higher in the subset of patients with a previous diagnosis of DM ($p < 0.0001$). However, in those with DM, creatinine availability was similar between the two cohorts ($p = 0.06$), and rate of AKI was not significantly different (Anti-VEGF: 4.76% vs OCT: 2.50%, p=0.0503).

Conclusions: The rate of AKI after intravitreal anti-VEGF was low and not statistically different from the control group, even in those with a prior diagnosis of DM. Future analyses will attempt to investigate whether other patient characteristics impact the risk of kidney injury in those receiving this treatment.

ABSTRACT BODY:

Purpose: The purpose of this study is to assess the photoreceptor mosaic in patients diagnosed with idiopathic macular hole (MH) before and after surgical repair using adaptive optics enhanced retinal imaging (AO).

Methods: This is a REB-approved, prospective case series, performed at Kensington Eye Institute. Subjects presenting with idiopathic MH treated with pars plana vitrectomy (PPV) between May and December 2021 were included. AO imaging was performed preoperatively and at 3 months after successful macular hole repair using the RTX1 camera (Imagine Eyes, Orsay, France). All images were manually assessed for quality and images without a clearly resolvable cone mosaic were excluded from the analysis. Cone density, packing regularity, and dispersion were measured at 2 and 4 degrees of eccentricity in all 4 quadrants (superior, inferior, nasal, and temporal) using the manufacturer's software with manual correction. After correction for axial length, mixed effects modeling with repeated measures were used to identify significant changes.

Results: 8 patients (8 eyes) with idiopathic MH and with a successful surgical closure were analyzed. Mean cone density at 2° was 13407 mm^3 preoperatively and 12154 mm^3 postoperatively (95% CI= [-1227.77, 3734.21]); at 4°, cone density was 13542 mm^3 preoperatively and 11807 mm^3 postoperatively (95% CI= [892.68, 2577.80]). Mean regularity at 2° was 86.2% preoperatively and 83.6% postoperatively (95% CI= [-1.22, 6.57]); at 4°, was 87.7% preoperatively and 84.9% postoperatively (95% CI= [-3.04, 8.59]). Mean dispersion at 2° was 19.8% preoperatively and 22.6% postoperatively (95% CI= [-8.77, 3.22]); at 4°, was 20.09% preoperatively and 21.6% postoperatively (95% CI= [-4.83, 1.71]). There is no significant change to cone density ($F_{(1,29)}$ = 0.02, p =0.87), cone regularity ($F_{(1,24)}$ = 0.29, p =0.60) or cone dispersion ($F_{(1,17)}$ = 0.001, p =0.97) at either 2° or 4° eccentricity.

Conclusions: Adaptive optics imaging allows quantitative assessment of the photoreceptor mosaic before and after successful PPV in patients with idiopathic macular hole. This will enable further investigation of the photoreceptor remodeling process and microstructural changes following surgery.

TITLE: Deletion of FATP4 in Rpe65-null rd12 mice improves cone vision but not rod vision

SESSION TITLE: Animal models of human ocular disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Li, M. Jin, Neuroscience Center of Excellence, LSU Health New Orleans, New Orleans, Louisiana, UNITED STATES|M. Jin, Department of Ophthalmology, LSU School of Medicine, LSU Health New Orleans, New Orleans, Louisiana, UNITED STATES|

Commercial Relationships Disclosure: Songhua Li: Commercial Relationship: Code N (No Commercial Relationship) | Minghao Jin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We recently showed that deletion of fatty acid transport protein-4 (FATP4) significantly promotes cone opsin solubility, cone photoreceptor survival, and cone-mediated vision in the RPE65 R91W knock-in mouse model of Leber congenital amaurosis (LCA). The purpose of this study was to test whether FATP4-deficiency can improve cone survival and function in RPE65-null rd12 mice.

Methods: Using rd12 and Fatp4$^{-/-}$;Ivl-Fatp4$^{tg/+}$ (shown as Fatp4$^{-/-}$ hereafter) mice, we generated rd12;Fatp4$^{-/-}$ mice. Key visual cycle enzymes and FATP4 in the retinal pigment epithelium (RPE) of these mice were detected by immunoblot analysis. Synthesis of 11-cis-retinal (11cRAL) in dark adapted mice were analyzed by high-performance liquid chromatography. Retinal degeneration was assessed by immunoblot and immunohistochemical analyses of rod and cone specific proteins. Visual functions of rod and cone photoreceptors were determined by scotopic and photopic electroretinographies (ERG) evoked with various flash intensities of white, 530-nm green or 360-nm UV light. For recording cone ERGs, animals were light adapted for 10 min by exposing to 40 cd/m^2 white light.

Results: RPE65 was undetectable in the both rd12 and rd12;Fatp4$^{-/-}$ RPEs while FATP4 was expressed only in the rd12 RPE. Expression levels of lecithin:retinol acyltransferase in the rd12 RPE were similar to those in age matched rd12;Fatp4$^{-/-}$ RPE. Similar to rd12 mice, dark adapted rd12;Fatp4$^{-/-}$ mice contained undetectable 11cRAL. Both immunoblotting and immunohistochemistry showed that the expression levels of rhodopsin in 2- and 4-month-old rd12 mice were similar to those in age-matched rd12;Fatp4$^{-/-}$ mice whereas the expression levels of M-opsin and cone arrestin in the rd12;Fatp4$^{-/-}$ mouse retina were significantly higher than those in the rd12 retina. Consistent with these results, rd12 and rd12;Fatp4$^{-/-}$ mice exhibited comparable scotopic ERG responses whereas green light-evoked ERG responses of M-cones were clearly greater in rd12;Fatp4$^{-/-}$ mice as compared to rd12 mice.

Conclusions: Our results indicate that 1) cone survival and function are supported by a RPE65-independent mechanism(s) that may be an important therapeutic target for LCA caused by loss of RPE65 function; and 2) FATP4 negatively regulates this RPE65-independent pathway.

TITLE: Can Serum Drops Containing Doxycycline Provide Potential Anti-Bacterial Effect in the Treatment of Bacterial Keratitis?

SESSION TITLE: Corneal epithelial biology and repair mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Mora-Boellstorff, K. Matharu, V. Jhanji, R.P. Kowalski, The Charles T. Campbell Ophthalmic Microbiology Laboratory, Department of Ophthalmology, UPMC, Pittsburgh, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: David Mora-Boellstorff: Commercial Relationship: Code N (No Commercial Relationship) | Kanwal Matharu: Commercial Relationship: Code N (No Commercial Relationship) | Vishal Jhanji: Commercial Relationship: Code N (No Commercial Relationship) | Regis Kowalski: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Systemic doxycycline has been prescribed to enhance corneal healing in the setting of bacterial keratitis. Topical autologous serum drops containing doxycycline via oral supplementation may additionally confer an anti-bacterial effect. The potential of this treatment supplementation was evaluated by determining the in vitro susceptibility of bacterial keratitis isolates to doxycycline.

Methods: The minimum inhibitory concentrations (MICs) to doxycycline of 100 bacterial keratitis isolates submitted to the Charles T. Campbell Ophthalmic Microbiology Laboratory at the University of Pittsburgh Medical Center were determined using Etests. Twenty-seven (27%) Staphylococcus aureus, 10 (10%) coagulase-negative Staphylococci, 6 (6%) Streptococcus pneumoniae, 7 (7%) Streptococcus viridans group, 7 (7%) other Gram-positive bacteria, 19 (19%) Pseudomonas aeruginosa, 8 (8%) Serratia marcescens, 4 (4%) Moraxella spp., 2 (2%) Haemophilus spp., and 10 (10%) other Gram-negative bacteria isolates were tested. MICs to doxycycline were compared to a serum standard concentration of doxycycline (SD) of 4 µg/ml as well as concentrations of doxycycline in serum drops at 50% SD (2 µg/ml) and 20% SD (0.8 µg/ml) as would be found in clinical preparations of autologous serum 50% and 20% drops, respectively. MICs equal or less than these values were deemed susceptible.

Results: For Gram-positive bacteria, susceptibilities to SD, 50% SD, and 20% SD were respectively, 86%, 65%, and 60%. For Staphylococcus aureus, susceptibilities to SD, 50% SD, and 20% SD were respectively, 92.6%, 85.2%, and 77.8%. For Gram-negative bacteria, susceptibilities to SD, 50% SD, and 20% SD were respectively, 37.2%, 23.3%, and 11.6%. Pseudomonas aeruginosa tested resistant to doxycycline at all concentrations. For the composite dataset of bacterial keratitis isolates, susceptibilities to SD, 50% SD, and 20% SD were respectively, 65%, 47%, and 39%. Chi-squared analyses comparing Gram-positive and Gram-negative susceptibilities showed significantly greater susceptibility of Gram-positive bacteria at all three tested MICs (<.0001, <.0001, <.0001).

Conclusions: Our data suggests that serum drops containing doxycycline may have a select advantage for treating Gram-positive bacterial keratitis, especially Staphylococcus aureus, over Gram-negative bacterial keratitis.

ABSTRACT BODY:

Purpose: We desired to develop a new topical ocular anesthetic with good bioavailability in anterior segment tissues. As well, given concerns about contamination and sterility in multi-dose products, we selected a unit-dose, non-preserved presentation in blow-fill-seal containers (similar to currently marketed pharmacological therapies for dry eye disease). The primary objective of these two Phase 3, randomized, placebo-controlled, double-masked, parallel design studies in healthy subjects was to evaluate anesthetic efficacy of AG-920. The secondary objectives included and the safety and tolerability of AG-920.

Methods: In each study, 120 subjects were randomized to receive a single dose of AG-920 or identical looking placebo into one (study) eye (2 drops 30 seconds apart). Subjects underwent a conjunctival pinch procedure and the pain associated with the pinch assessed. A priori, the primary endpoint was “no pain at 5 minutes”.

Results: AG-920 provide a rapid onset of local anesthesia (less than one minute) with clinically and statistically significantly greater effect in AG-920 (68% and 83%) than placebo (3% and 18%, for Study 1 and Study 2, respectively, $p < 0.0001$). The most frequently adverse event was instillation site pain (27% vs 3%), followed by conjunctival hyperemia (probably related to the pinch, 9% vs 10%) in the AG-920 and placebo groups, respectively.

Conclusions: A single dose of AG-920 (two drops 30 seconds apart) resulted in local ocular anesthesia in a short period of less than half minute and lasting up to approximately 15 minutes or longer. Other than mild conjunctival hyperemia, there were no clinically significant safety findings.

ABSTRACT BODY:

Purpose: We previously showed that topical application of RCI001 had excellent anti-inflammatory and antioxidant effects in dry eye disease and ocular chemical burn model. In this study, we investigated the inhibiting effects of RCI001 on Rac1 and NLRP3 inflammasome in vitro and in vivo model.

Methods: We confirmed Rac1 activity by RCI001 treat in RAW264.7 cells and Swiss 3T3 cells by GST (glutathione-S-Transferase) pull-down assay and G-protein activation assay kit. And the production and gene expression changes of IL-1β, IL-6 and TNF-α by RCI001 were quantified by ELISA and real-time PCR on RAW264.7 cell stimulated by LPS. In the mouse ocular alkali burn model, RCI001 was administered via eye drop (10mg/ml, twice daily) for 5 days. As a positive control, prednisolone acetate (PDE) ophthalmic suspension 1% was used. Corneal epithelial integrity (on Day 0, 3, 4 and 5) and histological changes were compared between RCI001 and PDE. Gene and Protein levels of Rac1, NLRP3, Caspase-1 and IL-1β were quantified by real-time PCR and western blotting in corneal tissues collected on day 3 and 5.

Results: RCI001 inhibited Rac1 activity and various inflammatory cytokines dose-dependently in LPS-stimulated murine macrophage. Additionally, RCI001 restored corneal epithelial integrity and thickness faster than PDE in chemically injured cornea. Activation of Rac1 and NLRP3 inflammasome/ IL-1β axis was suppressed in RCI001 group compared with saline group especially in early phase of ocular alkali burn model.

Conclusions: Topical RCI001 suppressed expressions of activated Rac1 and inflammatory cytokines in vitro and restored injured cornea quickly by inhibiting the activation of Rac1 and NLRP inflammasome/ IL-1β axis in vivo. We believe that RCI001 could be a promising therapeutic agent for ocular surface disease.

TITLE: Correction of involutional lower lid entropion without retractor reinsertion in Asians
SESSION TITLE: Oculoplastics
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: P. Lee, Department of Ophthalmology, Kaohsiung Medical University Chung Ho Memorial Hospital, Kaohsiung, TAIWAN|P. Lee, Department of Ophthalmology, Chi Mei Medical Center, Tainan, TAIWAN|
Commercial Relationships Disclosure: Po-Yen Lee: Commercial Relationship: Code N (No Commercial Relationship) | Po-Yu Lee: Commercial Relationship: Code N (No Commercial Relationship)
ABSTRACT BODY:
Purpose: Involutional entropion correction usually involves lower lid retractor plication/reinsertion. In Asian patients, congenital entropion associated with epiblepharon has been corrected with modified Hotz procedure, without reinforcement of retractor. This method avoids the unwanted postoperative lower lid crease from aesthetic aspect. The enhanced adhesion between tarsal plate and subcutaneous tissue may also increase the stiffness of tarsus and help to overcome orbicularis muscle tone. Besides, aging lower retractors in Asians are usually thin, atrophy and not sufficient to rotate the direction of the lashes. Excessive tightening of the retractors can instead cause lid retraction. We investigate the outcome of this single method without combination of retractor reinsertion and lid tightening.
Methods: Retrospective chart review. Modified Hotz procedure was performed soley. Pretarsal skin and orbicularis muscle were partially removed along subciliary incision. Several rotational sutures then anchor the subcutaneous tissue just beneath the lash base onto tarsal plate to evert the lash line.
Results: From January 2019 to December 2021, 43 patients with 57 eyes were included (mean age: 67.89, range: 55-95 years old). The mean follow-up period was 10.56 months. (Range: 6-29months). After operation, immediate improvement of irritation, tearing and discharge were observed in all patients. 5 (8.7%) eyes presented slightly increased scleral show within 2mm. No patient presented ectropion due to overcorrection. Only one patient (one eye) recurred during the period of follow-up (7 months after surgery). This was mainly due to excessive lid laxity and after receiving lateral tarsal strip procedure, she achieved symptom relief. At the final follow-up, all patients were satisfied with the results. While 51 eyes (89.4%) reported complete remission, 6 eyes (10.5%) reported mild and easily tolerated symptoms.
Conclusions: Involutional lower lid entropion can be corrected without retractor plication/reinsertion in certain Asian patients. It prevents from forming lower lid crease and may reduce tendency of overcorrection. The tarsal plate stability may be increased due to scar formation. Lower lid laxity should be evaluated before surgery with consideration of adding a lid tightening procedure. More case studies are needed to assess the outcomes and complications.

ABSTRACT BODY:

Purpose: Neovascularization is the vision-threatening vascular pathology that develops in diabetic retinopathy (DR) and retinopathy of prematurity (ROP). This pathological process is primarily driven by angiogenic factors such as vascular endothelial growth factor (VEGF), which cause retinal vessels to become proliferative and leaky. Inflammation drives the development of neovascularization and features the activation of retinal microglia, resident immune cells of the retina. However, circulating immune cells, such as leukocytes and lymphocytes, can enter the retina due to breakdown of the blood-retinal barrier, further exacerbating inflammation. Neutrophils are the most abundant type of leukocytes and are found in the vitreous of DR patients, but their role in neovascularization is largely unknown.

Methods: Two robust models of retinal inflammation and vasculopathy were studied: oxygen-induced retinopathy (OIR) and streptozotocin (STZ) type-1 diabetes. OIR was induced by exposing C57BL6/J mice at postnatal day (P) 7 to 75% oxygen for 5 days and then room air (21% oxygen) until P18. Comparisons were made to mice housed in room air. A neutrophil depletion antibody (anti-Ly6G, 100µg) was given via IP injection every 3 days from P7, and controls received an isotype antibody. To induce DR, 6-7 week old C57BL6/J mice were administered STZ and studied for 26 weeks. Comparisons were made to non-diabetic mice administered vehicle. Twelve to 24 animals were studied per group, and data analyzed by unpaired t-tests or one-way ANOVAs. Statistical significance was defined as $p<0.05$.

Results: Neutrophils (flow cytometry, $CD45^{+}CD11b^{+}Ly6G^{+}$) increased in the blood and lymphoid organs of OIR mice from P9 to P18, and in DR mice at 13 and 26 weeks post-STZ, coinciding with the presence of retinal inflammation and vasculopathy. In OIR, the depletion of neutrophils reduced retinal vasculopathy including neovascularization, vascular leakage and VEGF levels compared to controls. In OIR, depletion of neutrophils reduced the recruitment of leukocytes to the retina, suggesting that neutrophils are major contributors to retinal inflammation.

Conclusions: Neutrophils are one of the first responders to retinal injury in OIR, and they contribute to the development of inflammation and vasculopathy including neovascularization. Drugs targeting neutrophils may be beneficial for treating and preventing leading causes of blindness, such as DR and ROP.

ABSTRACT BODY:

Purpose: Diabetic Retinopathy (DR) is a leading cause of blindness in the United States. While many studies have assessed incidence and prevalence of DR, understanding of odds of transitions between mild, moderate, severe, and proliferative DR is limited. We generate a Markov Model to quantify DR progression and regression, and highlight disparities in DR course based on patient characteristics.

Methods: We identified patients with a new diagnosis of mild non-proliferative diabetic retinopathy (NPDR), moderate NPDR, severe NPDR, or proliferative diabetic retinopathy (PDR) in 2016 in the IRIS Registry database. Within each category, we analyzed the percentage of eyes whose DR progressed (to more severe disease) or regressed (to milder disease) over a two-year period from disease onset. We stratified analyses by patient characteristics, including age, sex, race, and insurance.

Results: In 2016, 202,777 eyes had a new diagnosis of mild NPDR, 92,319 moderate NPDR, 32,471 severe NPDR, and 125,289 PDR. Within two years, 1.57% of mild NPDR eyes developed PDR, 4.56% of moderate NPDR developed PDR, and 9.64% of severe NPDR developed PDR. 5.43% of eyes with PDR regressed to NPDR within two years. Among eyes with moderate DR, 5.93% regressed to mild NPDR and 7.87% progressed to severe NPDR or PDR. Among eyes with severe NPDR, 10.01% regressed to mild/moderate NPDR and a 9.64% progressed to PDR. Greater progression from NPDR to PDR was observed in patients with Hispanic race (2.48%), age 21 to 40 years (2.27%), and Medicaid insurance (2.12%). Less progression was observed in those of white race (1.37%), age 81-100 years (1.04%), and commercial insurance (1.60%). Regression from PDR to NPDR was most frequent in Asians (7.38%), ages 61-80 (5.78%), and VA insurance (6.20%), and least frequent in black patients (4.77%), ages 21 to 40 (3.91%), and Medicaid (4.76%) insurance.

Conclusions: We identified four key findings: (1) patients with more advanced NPDR more often progress to PDR (6x more often in severe NPDR vs. mild NPDR); (2) The vast majority of eyes neither progressed nor regressed over 2 years; (3) Moderate NPDR progressed 32% more often than it regressed, whereas severe NPDR regressed 4% more often than progressed; (4) Hispanics, ages 21-40, and Medicaid patients most often progressed, while Asians, ages 61-80, and VA insurance patients most often regressed.

TITLE: Binocular Disparity Selectivity and Orientation Tuning in Mouse V1

SESSION TITLE: Retinal and central processing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Fu, Neuroscience Graduate Program, University of Virginia, Charlottesville, Virginia, UNITED STATES|S. Tanabe, J. Cang, Psychology, University of Virginia, Charlottesville, Virginia, UNITED STATES|J. Cang, Biology, University of Virginia, Charlottesville, Virginia, UNITED STATES|

Commercial Relationships Disclosure: Jieming Fu: Commercial Relationship: Code N (No Commercial Relationship) | Seiji Tanabe: Commercial Relationship: Code N (No Commercial Relationship) | Jianhua Cang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The brain combines 2-dimensional images collected by the eyes to form a 3-dimensional representation of its surroundings. This process of stereopsis arises from the binocular integration circuitry in the primary visual cortex (V1) that include neurons tuned to certain disparities between visual stimuli viewed by the two eyes. V1 neurons are also known to be tuned to orientations of visual stimuli. We examined whether these two well-known properties of V1 neurons are related in the mouse, expecting cells tuned to vertical orientations to have the strongest disparity selectivity tuning.

Methods: Adult C57BL/6 mice were surgically fitted with a headplate and had a craniotomy performed over the binocular zone of V1 to facilitate in vivo electrophysiological recording in awake animals. A combined projector and polarizing alternator system was used to display dichoptic visual stimuli. The stimulus set consisted of drifting gratings, in which each binocular condition consisted of a specific combination of orientation and phase disparity, and the associated controls were two monocular conditions at the same orientations. Binocular and monocular conditions were displayed in a randomly interleaved order. A high density 64-channel silicon probe was inserted to collect extracellular voltage signals, which were later sorted into single unit spikes for further analysis.

Results: We acquired a total of 338 single units across 15 animals. Of this population, 107 were significantly responsive to our set of drifting gratings (random permutation test $p<0.05$). For each neuron, we measured its tuning in the joint parameter space of orientation and phase disparity, as well as its orientation tuning for monocular stimulation. The strength of tuning along the phase disparity axis was quantified using a selectivity index (gPDSI), and orientation corresponding to highest gPDSI was determined. The distribution of orientations corresponding to highest gPDSI was not equally spread among the 4 orientation conditions in the stimulus set ($\chi^2(3)=8.238$, $p=0.041$). However, there was also no significant correlation between gPDSI and preferred orientation ($R^2=0.001$, $F_{(107,105)}=0.065$, $p=0.8$).

Conclusions: Binocular disparity selectivity in mouse V1 is not significantly stronger in cells tuned to vertical orientations. Studies utilizing only vertical gratings in their stimulus set may be mis-estimating the prevalence of disparity selective cells in binocular V1.

ABSTRACT BODY:

Purpose: Subretinal fibrosis causes irreversible vision loss in patients with neovascular age-related macular degeneration (nAMD). Ophthalmic imaging techniques allow detection of fibrosis with limited efficiency and there is a clinical need for novel tools to monitor fibrosis-related changes. We report in vivo imaging of active fibrosis using collagen-hybridizing peptides (CHPs), small molecules that bind to single α-chain collagen structures, allowing identification of collagen remodeling (a hallmark of active fibrosis) in the subretinal space.

Methods: Using 2 independent mouse models (laser-induced choroidal neovascularization [CNV]; JR5558 spontaneous CNV), we investigated the effectiveness of sCy7.5-labeled CHPs to image active fibrotic lesions in vivo. Validation studies assessed correlation between CHP and epithelial mesenchymal transition (EMT) markers, laser intensity and CHP binding in vivo, and between in vivo and ex vivo CHP quantification of active collagen. The antifibrotic effects of a bispecific angiopoietin-2/vascular endothelial growth factor-A antibody (VA2) were examined in vivo by assessing CHP binding in 42-day-old JR5558 mice after 3 weekly VA2 injections versus IgG control (10 mg/kg body weight; days 21, 28, 35; sCy7.5-CHP injected on day 37).

Results: Integration of retinal pigment epithelium (RPE)/choroid flatmount images of JR5558 eyes showed coexpression of CHPs with fibrosis and EMT-related markers, correspondence between sCy7.5-labeled and sCy3-labeled CHP binding, and increased CHP binding in RPE/choroid with age. After laser-induced scarring, sCy7.5-CHP binding in vivo correlated to the intensity of laser and ex vivo CHP ($r = 0.76$; $P = 0.03$) and fibronectin ($r = 0.69$; $P = 0.058$) binding. In laser-induced CNV, there was decreased CHP binding in vivo and ex vivo at 8 weeks (stabilized scars) versus 1 week after injury. In JR5558 mice treated with VA2, CHP integration detected significantly decreased collagen remodeling (CHP binding in vivo and ex-vivo; $p < 0.01$) versus IgG control.

Conclusions: CHPs bound specifically to active fibrosis and detected increased collagen remodeling in JR5558 mouse eyes in vivo as they aged, in contrast to reduced binding over time in laser-induced scarring. The antifibrotic effects of dual Ang-2/VEGF-A inhibition were clearly demonstrated using this method, which has potential to support clinical development of nAMD treatments.

ABSTRACT BODY:

Purpose: This study aimed to confirm the potential of novel peptide with anti-angiogenic effect, as a therapeutic agent for retinal vascular disorders such as wet age-related macular degeneration (w-AMD) and retinopathy of prematurity (ROP) using mouse and monkey models.

Methods: The novel peptide and aflibercept as a positive control were intravitreally injected in laser-induced choroidal neovascularization (CNV) mouse and monkey model of w-AMD and oxygen-induced retinopathy (OIR) mouse model of ROP. The analysis of vascular leakage by fundus fluorescein angiography (FFA) and CNV lesions by Optical coherence tomography (OCT) to evaluate efficacy was conducted in laser-induced CNV mouse and monkey models. Retinal neovascularization in OIR model was evaluated by retinal flat mount stained with isolectin B4 for blood vessels.

Results: In CNV mouse model, the vascular leakage and CNV volume were statistically reduced by 38.1% and by 23.5% in the novel peptide injected eyes compared with that of control of PBS injected. The mean vascular leakage and retinal thickness were reduced 13.9% and 48.5% ($P<0.05$ vs. Control) in CNV monkey model for 28 days after a single injection of novel peptide injection. The vessel tuft area in OIR mouse eye exhibited markedly decreased by 54.3% after novel peptide treatment compared to the control group.

Conclusions: Intravitreally injected novel peptide showed significant efficacy in pathological angiogenesis in three types of animal models of retinal disease. Especially in CNV mouse model, the novel peptide was shown the equivalent reducing CNV compared with aflibercept. These findings suggest that novel peptide has potential as a therapeutic agent for the wet AMD by preventing vascular leakage and increase in the retinal thickness.

ABSTRACT BODY:

Purpose: To validate a machine learning model from spectral-domain optical coherence tomography (Cirrus, Carl Zeiss Meditec, Dublin, CA) data along with patients' background information for glaucoma detection and assess its external validity.

Methods: In this cross-sectional study, 514 Asians (257 glaucoma and 257 controls) were enrolled to construct a machine learning model for glaucoma detection, which was then tested on an independent dataset of 356 Asians (183 glaucoma and 173 controls) and an external dataset of 138 Caucasians (57 glaucoma and 81 controls). The machine learning model was also compared to the existing multivariate-adjusted retinal nerve fiber layer (RNFL) thickness compensation model and Cirrus-generated (measured) RNFL model. The area under the receiver operating characteristics curve (AUC) for glaucoma detection was calculated.

Results: The machine learning-based model (AUC=0.97) outperformed both the compensation model (AUC=0.93; P<0.001) and the measured RNFL model (AUC=0.93; P<0.001) for glaucoma detection in the Asian dataset. However, in the Caucasian dataset, the compensation model (AUC=0.90 to 0.93) outperformed both machine learning-based (AUC=0.85; P<0.001) and measured RNFL (AUC=0.82; P<0.001) models, and there was no significant difference in the AUC between the machine learning-based model and measured RNFL model (P=0.174) for glaucoma detection.

Conclusions: While the machine learning model detected glaucoma at a higher accuracy as compared to the compensation model or measured RNFL model in the internal dataset, this finding was not fully replicated in the external validation with the Caucasian dataset. Care must be taken when machine learning models are applied to patient cohorts of different ethnicities.

ABSTRACT BODY:

Purpose: Heat shock protein 90 (HSP90) plays fundamental role in protecting various biological systems from stress condition and also from pathogenesis. Previous studies have shown that HSF1 plays an important role in regulating expression of HSP90. Whether other transcription factors also play essential roles in regulating expression of HSP90 remains largely unknown. In the present study, we have demonstrated that except for HSF1, the SP family transcription factors including SP1/SP3/SP4 also play essential roles in regulating HSP90β transcription in lens epithelial cells.

Methods: Gel mobility shifting assays were used to determine binding of SP family transcription factors to various HSP90β gene promoter and enhancer regions. ChIP assays were used to confirm the binding of different SP factors to the HSP90β gene promoter and enhancer regions. Various reporter gene constructs driven by different promoter and enhancer regions of the HSP90β gene were generated and used to assay the relative strength of different HSP90β gene promoter and enhancer regions. CRISPR/Cas9 technology was used to create various mutants. QRT-PCR and Wes were used to analyze mRNA and protein expression levels.

Results: In the proximal promoter and downstream enhancer regions, numerous SP1/SP3/SP4 binding sites were identified. These cis-elements were able to mediate binding by SP family transcription factors via EMSA and ChIP, and most of these elements also provide positive regulation on the expression of HSP90β. The cis-elements in different promoter and enhancer regions have differential strength in mediating control of HSP90β expression.

Conclusions: The SP family transcription factors play an important role in regulating transcription of the major heat shock protein HSP90β in lens epithelial cells. Among different SP family transcription factors, SP1 is the most important factor in regulating HSP90β expression. ABSTRACT BODY:

Purpose: Split-tendon medial transposition of lateral rectus (STMTLR) for complete oculomotor palsy can correct large angles of exotropia in adults, but outcomes are variable and complications are frequent. Although outcomes in pediatric cases have been reported, further insight is needed to assess the child’s ability to gain sensory function and/or demonstrate neuroplasticity post-surgically. The purpose of our study is to report the outcomes of this technique in pediatric cases of complete oculomotor palsy.

Methods: A retrospective review of outcomes was conducted on 5 consecutive patients with complete oculomotor palsy treated with STMTLR by a single surgeon between 2012-2019 at a tertiary pediatric referral center. All patients underwent unilateral surgery utilizing the same technique. Primary outcome was postoperative horizontal alignment, and secondary outcome was demonstration of gain-of-function activity in the field of action of the paretic medial rectus muscle.

Results: Patients averaged 5.3 years old (range 10m-16y). Two were female. Etiologies were heterogeneous, with two subjects possessing bilateral disease secondary to miliary tuberculosis with CNS involvement, two with congenital unilateral palsy, and one iatrogenic case resulting from a pineal gland tumor extraction. All presented with oculomotor palsy with a mean preoperative exotropia of 75 ± 33.96 prism diopters (PD, range 35 to >120). Mean surgical decrease in exotropia was 49 ± 15.47 PD (range 37.5 to 75). Both patients with congenital oculomotor palsy regained convergence.

Conclusions: STMTLR was a safe and effective approach for the surgical correction of pediatric oculomotor palsy in our case series. If performed early, pediatric patients may additionally benefit in potential gain-of-function activity in the transposed lateral rectus muscle owing to the adaptive neuroplasticity of childhood.

ABSTRACT BODY:

Purpose: Published diagnostic sensitivity of cytology, the gold standard in vitreoretinal lymphoma (VRL) diagnosis varies greatly from 45-87% and is dependent on the cytologist's experience. This study aims to determine the diagnostic accuracy of single cell MYD88^{L265P} mutation and Immunoglobulin (Ig) H gene rearrangement analysis in comparison to specialised cytology with the purpose of improving VRL diagnosis rates.

Methods: This study was performed with informed consent and institutional review board approval. A total of 12 patients with clinically proven VRL and 7 patients with chronic inflammatory vitritis were recruited. Vitreous cytology was analysed by experienced ophthalmic and lymphoma pathologists. Single cell (sc)-MYD88L265P and sc-IgH rearrangement analysis was performed using DEPArray™ Nxt single cell selection, followed by Whole Genome Amplification (WGA) and specific targeted sc-PCR. Measures of diagnostic accuracy included sensitivity and specificity using receiver operating characteristic (ROC) curve analysis.

Results: In our lab, cytology analysis by experienced ophthalmic pathologists and hematopathologist had a higher diagnostic sensitivity (88.9%) than most published diagnostic rates, however, specificity was only 66.7% for diagnosing VRL. Using a cut-off of >2.3% homozygous MYD88^{L265P} to define the presence of a MYD88^{L265P} mutation, this test was more sensitive (100%) and specific (83.3%) test than cytology. However Sc-IgH gene re-arrangement analysis was the most sensitive (100%) and specific (100%) test for VRL diagnosis when a cut off > 74% was used to define a dominant clone.

Conclusions: Although vitreous cytology remains highly sensitive for VRL diagnosis when analysed by experienced ophthalmic and lymphoma pathologists, the use of sc-MYD88^{L265P} mutation and/ or sc-IgH gene rearrangement analysis can improve the sensitivity and specificity of VRL diagnosis.

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) is one of the leading causes of blindness and vision impairment in 2020. Apart from vasculopathy, DR has been found to involve retinal neurons including amacrine cells and retinal ganglion cells. Recent literature also suggested that photoreceptors secret proinflammatory molecules and produce reactive oxygen species that contribute to the development of DR. The effect of hyperglycemia on photoreceptors is not well understood. Here, we aimed to investigate the high glucose-induced changes in the proteomic profile of 661w photoreceptor-like cell line with data-independent Sequential Window Acquisition of all Theoretical Mass Spectra (SWATH) based proteomic analysis.

Methods: 661w cells were incubated in normal glucose (5.5mM glucose) and high glucose (55mM glucose) conditions for 48 hours. The sample (n=3 in each group) were then processed with S-Trap™ Micro Spin Column Digestion (S-Trap) protocol according to the manufacturer's guideline. The MS data were acquired using a hybrid quadrupole time-offlight TripleTOF 6600 mass spectrometer (SCIEX) with Analyst TF 1.7 software. Data obtained were exported and analyzed using ProteinPilot 5.0.1, PeakView 2.2, MarkerView 1.3 software, and OneOmics cloud-based platform (SCIEX). Pathway analysis was conducted with Ingenuity® Pathway Analysis (IPA).

Results: A total of 625 proteins out of 3,613 proteins was found to be differentially expressed ($p<0.05$, Fold-change ≥ 1.5 or ≤ 0.667) in the 661w cells under high glucose condition compared to normal glucose condition. Three hundred thirteen proteins were found to be up-regulated, while 312 proteins were found to be down-regulated. The top three enriched pathways revealed by IPA included 1) Protein Ubiquitination Pathway, 2) Mitochondrial Dysfunction, and 3) Oxidative Phosphorylation.

Conclusions: Our data suggested that high glucose condition may trigger changes in these three metabolic pathways in photoreceptor cells. These changes may have led to compromised mitochondrial function and increased cell apoptosis in the 661w cells previously reported by our team. The alternation of these three pathways has also been shown to affect the physiology of other retinal cell types under simulated hyperglycemia. The underlying molecular changes and their role in the pathogenesis of DR warrant further investigation.

ABSTRACT BODY:

Purpose: Patients of diabetes mellitus suffer from high incidence of corneal epithelial defects, ocular surface infections and dry eye disease. Ocular surface glycocalyx, mucins and goblet cells play a critical role to keep the ocular surface hydrated and protected from pathogens. We have previously shown that hyperglycemia can compromise ocular surface epithelial barrier function. The goal of the present study was to investigate the effect of diabetes mellitus on tear film, glycocalyx, mucins and goblet cells and to test whether restoration of euglycemia by insulin treatment has ameliorative effects on hyperglycemia-mediated ocular surface damage.

Methods: Streptozotocin-induced and db/db mouse models of type 1 and type 2 diabetes were used. Tears were quantified using phenol red thread and corneal keratopathy was visualized with slit lamp after fluorescein staining. Eyes were harvested at week1, 2 and 4 after diabetes. Glycocalyx was stained with wheat germ agglutinin and whole cornea mounts were imaged using confocal microscope. Tissue sections were used for goblet cell staining with PAS and imaged using brightfield microscope. Mucin gene expression was quantified in corneal tissue using real time PCR. Mice were implanted with subcutaneous insulin pellets. Effect of insulin treatment on diabetes-associated changes in tear film, glycocalyx, goblet cells and mucins were examined.

Results: Our data shows that type 1 and type 2 diabetes caused a 60% and 30% decrease in tear film volume and resulted in corneal keratopathy score of 10 and 8, respectively. A 65% and 45% decrease in glycocalyx area was noted in the corneas of type 1 and type 2 diabetic mice. Goblet cell number was decreased by 40% and 16%. Diabetes mellitus also modulated gene expression of membrane-tethered mucins. Treatment of diabetic mice with insulin pellets restored blood glucose levels to euglycemia. Insulin treatment reduced the severity of diabetes-mediated corneal keratopathy and remarkably prevented diabetes-mediated decrease in tear secretion, glycocalyx area and goblet cell number.

Conclusions: Diabetes mellitus causes damage to ocular surface and more detrimental effect was observed with higher levels of hyperglycemia due to type 1 diabetes as compared to type 2 diabetes mellitus. Restoration of euglycemia by insulin treatment remarkably prevented diabetes-mediated damage to tear film and ocular surface.

ABSTRACT BODY:

Purpose: The cGAS-STING pathway plays an important role in innate immunity. Previous studies have shown that activation of cGAS-STING is implicated in AMD pathogenesis. Whether this pathway is implicated in cataractogenesis remains to be studied. In the present study, we have analyzed the expression patterns of the major signal components of the cGAS-STING pathway in normal human lens and cataract patients.

Methods: Normal human lens were collected from Guangdong Province Eye Bank. Cataract capsular epithelia were harvested during surgical operation with consent of cataract patients. Micro-Western blot analysis (Wes) was used to detect the expression levels of cGAS, STING, TBK1 and IRF3.

Results: From normal human lens to cataractous lens, cGAS protein was significantly downregulated. Among different age groups of cataract patients, cGAS was upregulated from 50s to 60s, and then returned to the similar level of 50s in both 70s and 80s. Different from cGAS, the STING protein level in normal human and cataract patients lenses of 60-year old was similar. In different groups of cataract patients, STING became downregulated from 60s to 80s. For TBK1 and IRF3, they were barely detectable in normal human lens. In cataract patients, both TBK1 and IRF3 were easily detected. From 60s to 80s, however, they were downregulated.

Conclusions: The major components of the cGAS/STING pathway were differentially expressed from normal human lens to cataractous lens. The cGAS/STING pathway may play a protective role against cataractogenesis.Supported by National Natural Science Foundation of China (Grants 81970787, 82000876, 81770910) and Natural Science Foundation of Guangdong Province and Guangdong City Joint Program of China (2019B1515120014)，and the Fundamental Funds, 3030901010110 of the State Key Laboratory of Ophthalmology of Zhongshan Ophthalmic Center.

ABSTRACT BODY:

Purpose: Adaptive optics scanning light ophthalmoscopy (AOSLO) can image single blood cells in the retina. AOSLO can serve as a new platform to study the cellular components of whole blood in vivo. Here, we demonstrate an imaging-based method to study two rare blood cell types in the retinal circulation of living mice.

Methods: Two sparse populations of white blood cells (WBCs) were imaged in the living retina: circulating GFP-labeled monocytes (CX3CR1, Jackson Labs stock 005582), and CD8+ T-cells harvested from a GFP donor mouse (stock 006567) and adoptively transferred into a healthy C57BL/6J (stock 00664) mouse via intraperitoneal injection. A single retinal arteriole and a single venule from each mouse were imaged with a custom-built AOSLO with reflectance (796 nm) and fluorescence (488 nm ex/520Δ35 nm em) capabilities. Circulating cells were imaged using a 15kHz point scanned obliquely across a vessel, which simultaneously images the red blood cells and fluorescent WBCs. Cell velocities were quantified using the automated Radon approach previously described (Joseph et al., 2019). Total imaged blood volume was approximated by flow speed x π x radius^2 of the blood vessel. Fluorescent WBC populations were automatically counted and manually validated.

Results: In CX3CR1+ mouse, we observed the passage of labeled monocytes at rates of 27.7 cells/min in the arteriole and 14.0 cells/min in the venule. Based on the estimated blood volume imaged, this represents monocyte density of 244 cells/μL in the arteriole and 95 cells/μL in the venule. These counts in vivo were within an order of magnitude of the expected density of monocytes in circulation (van Furth & Sluiter, 1986). In the T-cell recipient mouse, we detected an average of 328 cells/min in the arteriole and 204 cells/min in the venule. Scaled by the blood volume imaged relative to total blood volume, we estimate 1.01-1.61 million CD8+ T-cells in systemic circulation. The total number of cells injected into the peritoneum was estimated to be 10 million cells, indicating 10 to 16% of the cells entered systemic circulation.

Conclusions: Here we demonstrate the ability to count and measure the speeds of monocytes and T-cells in high flow vessels in the body. Such capability provides the foundation for studying rare immune cells of interest that fight inflammation, infection and even mediate cutting-edge therapies that use adoptively transferred immune cells.

ABSTRACT BODY:

Purpose: The cGAS-STING pathway plays an important role in innate immunity. Previous studies have shown that activation of cGAS-STING is implicated in AMD pathogenesis. Whether this pathway plays a role during lens development remains elusive. In the present study, we have analyzed the developmental expression patterns of the major signal components of the cGAS-STING pathway and revealed its potential role in governing lens development.

Methods: Normal mouse embryos of different stages and adult mice were used for isolation of eye tissues. RT-PCR and in situ hybridization were used to analyze the mRNA expression levels of cGAS, STING, TBK1 and IRF3. Immunohistochemistry was used to detect the protein expression levels of the above components.

Results: At the mRNA level, cGAS and TBK1 mRNAs were detected at ED 14.5, reached the highest expression levels in the newborn lens and then were downregulated to 60-70% in the mature lens, and were further downregulated during aging in 7- to 8-month. In contrast, expression of the STING mRNA was low at the ED14.5, and gradually upregulated in newborn and adult mouse lenses and further upregulated in the aging lens. Different from cGAS, TBK1 and STING, the IRF3 mRNA was low at the ED 14.5, then upregulated in the newborn lens and maintained at this level in the mature and aging lens. At the protein level, the cGAS signal was relatively weak. The STING signal was very strong from ED 11.5 to newborn mice, and the IRF3 signal was intermediate between cGAS and STING.

Conclusions: The signal components of the cGAS/STING pathway are clearly expressed during lens development. Activation of this pathway may be important to protect lens development. Supported by National Natural Science Foundation of China (Grants 81970787, 82000876, 81770910) and Natural Science Foundation of Guangdong Province and Guangdong City Joint Program of China (2019B1515120014)，and the Fundamental Funds, 3030901010110 of the State Key Laboratory of Ophthalmology of Zhongshan Ophthalmic Center.

TITLE: Neuronal firing between retinal ganglion cells and coupled amacrine cells in the mouse retina

SESSION TITLE: Retinal circuits

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: Q. Wang, C. So, F. Pan, School of Optometry, The Hong Kong Polytechnic University, Hong Kong, HONG KONG|Q. Wang, F. Pan, Centre for Eye and Vision Research Limited, Hong Kong, HONG KONG|

Commercial Relationships Disclosure: Qin Wang: Commercial Relationship: Code N (No Commercial Relationship) | Chung Him So: Commercial Relationship: Code N (No Commercial Relationship) | Feng Pan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Gap junctions between retinal ganglion cells (RGCs) and amacrine cells (ACs) are important in visual information transmission. In the mouse retina, ON αRGCs are coupled to displaced ACs, and OFF αRGCs are coupled to conventional ACs and other OFF αRGCs. This study is to investigate the role of gap junctions in synchronization and cell driving activities in the mouse retina.

Methods: Adult C57BL/6J wild-type mice were used. Electrical activities of RGCs or ACs in the retina were recorded by patch-clamp. In the first part, two cells activities were recorded by green (525 nm) light stimuli. SKF38393 (10μM) and SCH23390 (5μM), which are agonist and antagonist for dopamine receptor 1 (D1), were applied to study the effect of ACs coupling to RGCs synchronization. Currents were injected into one cell in whole-cell mode, and the other cell activity was recorded. In the second part, viral vectors carrying a fusion construct of channelrodopsin2 (ChR2) and green fluorescent protein (GFP) were injected into the intravitreal space of both eyes and kept for 5 days before euthanized. A blue (460 nm) light was used as stimulus. The electrical recordings were performed between one ChR2-expressed cell and one non-ChR2-expressed cell.

Results: The synchronous firings in ganglion cells layer: ON αRGCs, OFF αRGCs and ON αRGC-displaced AC were investigated. The synchrony between these couplings could be abolished by gap junction blocker-MFA (50 μM) or 18β (30 μM). D1 agonist decreased the correlations of synchrony, while D1 antagonists increased the correlations. This suggested coupling between ACs decreased the synchronous correlations of RGCs. Injecting currents into one cell could induce spikes in the coupled cell. After virus transduction, the ChR2-expressed cells could fire without chemical input. More importantly, light-evoked spiking activity of a ChR2-expressed AC drove the activity of a non-ChR2 expressed RGC, gap junction blocker MFA diminished this activity.

Conclusions: Coupling of ACs affected synchronization between ON or OFF αRGCs. ACs could drive RGCs firing through gap junctions and vice versa. Gap junctions underlie the arbitrary manipulation of one cell by the other cell or external stimuli.

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) is the most common long-term complication to diabetes mellitus and the most common cause of visual loss in the working-aged population. In a national 5-year register-based cohort study, we aimed to identify demographic and clinical characteristics of patients, who later developed proliferative diabetic retinopathy (PDR) compared to patients who did not.

Methods: The study population includes all Danish diabetes patients above 18 years who attended the Danish DR-screening program. We included 147,802 patients from the Danish Registry of Diabetic Retinopathy followed from the 2th of January 2013 to the 30th of December 2018.

We used the first screening episode as index date and included both eyes of patients with and without subsequent development of PDR. We linked data with various national databases in order to investigate relevant clinical and demographic parameters.

A multivariable Cox regression model was performed to measure the hazard ratio (HR) for incident PDR for all relevant demographic and clinical parameters. We used the k-sample test on equality-of-medians and chi-square test for continuous and categorical variables to test for baseline differences between patients with and without incident PDR-progression.

Results: Subsequent progression to PDR was identified in 1.741 (1.2 %) patients. 5-year rates of progression to PDR were 0.2%, 3.4% and 20.8% for eyes with DR-levels 0, 1, 2, and 3, respectively.

The HR for incident PDR were duration of diabetes (HR 4.40 per 10 years; 95% confidence interval (CI) 3.61 to 5.35), type 1 diabetes (HR 13.16; 95% CI 10.84 to 15.97), Charlson Comorbidity Index score >0 (Score 1 = HR 4.93; 95% CI 4.20 to 5.79; score 2 = HR 2.01; 95% CI 1.51 to 2.68; score ≥3 = HR 3.09; 95% CI 2.16 to 2.68), use of insulin (HR 4.84; 95% CI 3.84 to 6.11), use of anti-hypertensiva (HR 2.35; 95% CI 1.88 to 2.94) and compared to DR-level 0, the risk of progression was increased with DR-level 1 (HR 11.15; 95% CI 8.92 to 13.93), DR-level 2 (HR 23.88; 95% CI 18.63 to 30.61) and DR-level 3 (HR 77.72; 95% CI 57.59 to 104.89).

Conclusions: In a 5-year longitudinal DR-screening study of an entire nation, longer duration of diabetes, type 1 diabetes, systemic comorbidity, use of insulin and blood pressure lowering medicine, as well as increasing baseline level of DR, independently predicted progression to PDR.

ABSTRACT BODY:

Purpose: Retinal vasculitis (RV) is a sight-threatening condition that can be idiopathic or associated with local or systemic inflammation due to infectious, neoplastic, or autoimmune diseases. While the structural changes associated with RV, as seen on ophthalmoscopy, angiography, optical coherence tomography, and other imaging modalities have been well documented, functional changes as may be seen on electrophysiology have not been well characterized. This retrospective study examines the Diopsys® Flicker Electroretinogram (ERG) findings present in cases of RV and tests whether these findings correlate with RV severity.

Methods: All retinal vasculitis cases seen by the uveitis service at a tertiary care center over a 14-month period were retrospectively reviewed and screened for inclusion in the study. Eyes with retinal vasculitis were included if there was at least one pair of Diopsys® flicker ERG recording and corresponding Fluorescein Angiogram (FA) within 2 months of each other for that eye. Eyes with other confounding retinal diagnoses were excluded. Each FA was scored for retinal vasculitis severity by two independent graders using the semi-quantitative Angiography Scoring
for Uveitis Working Group FA scale and the mean RV severity score was compared to the corresponding Diopsys® Flicker ERG findings (phase and magnitude values) across eyes and time points.

Results: A total of 50 eyes from 33 patients (mean age 26.3 years) were included. There was a moderate, highly significant correlation between retinal vasculitis severity and the Diopsys® flicker ERG Phase, both for Fixed-Luminance (FL) (-0.65, $p<0.001$) and for Multi-Luminance (ML) ERG settings (-0.63, $p=<0.001$) (Figure). Similarly, there was a mild correlation between RV severity and ERG Magnitude for both FL (-0.26, $p=0.04$) and ML (-0.33, $p<0.001$).

Conclusions: Increasing retinal vasculitis severity is associated with increasingly abnormal flicker ERG findings suggesting progressive dysfunction of the cone photoreceptor pathway.

ABSTRACT BODY:

Purpose: To test ocular toxicity and long-term analgesic efficacy of two novel ocular formulations of Substance P receptor antagonist Aprepitant in comparison with Diclofenac and Oxybuprocaine.

Methods: 7/8-week-old male C57BL/6N mice received topical (eye) treatment as follows: formulation A vehicle (n=18), formulation A 0.005% (n=7), 0.05% (n=7), and 0.5% (n=7); formulation B vehicle (n=18), formulation B 0.05% (n=7), and 0.5% (n=7); 0.4% Oxybuprocaine (n=7), 0.1% Diclofenac (n=7), and saline (n=6). Eye-drops were applied 3 times/day for 90 days. The animals were monitored by in vivo slit-lamp microscopy imaging. At days 0, 45, and 90 the eye-wiping test and corneal sensitivity measure were performed immediately after the last treatment to evaluate corneal nociception and sensitivity. At day 90, mice were euthanized and corneas were dissected to assess nerve density and leukocyte infiltration by immunofluorescence and to evaluate inflammation/pain-associated markers (TNF-α, IL-6, IL-1β, and Neurokinin-1 receptor) by RT-PCR.

Results: We found that both formulations A and B did not induce any significant epithelial damage or change in corneal transparency and nerve density. However, the Diclofenac group displayed a significant reduction in corneal nerve density after 90 days of treatment ($p<0.01$). Formulation A groups showed increased CD45+ infiltration ($p<0.01$) and up-regulation of inflammatory markers ($p<0.05$), which was not observed in formulation B groups. Both formulation B groups significantly reduced nociception ($p<0.05$) and corneal sensitivity ($p<0.01$) after 45 and 90 days. Similarly, Diclofenac significantly decreased nociception only after the first administration (day 0) ($p<0.05$) and sensitivity at all time points ($p<0.001$). As expected, the anesthetic medication Oxybuprocaine was the most effective in preventing pain ($p<0.001$) and in reducing corneal sensitivity ($p<0.0001$) at all time points. Finally, formulation A candidates were effective only at day 90 ($p<0.05$).

Conclusions: Both formulations B (0.05% and 0.5%) exhibit analgesic efficacy at day 45 and 90, differently from 0.1% Diclofenac, which is effective only at day 0. Differently from Diclofenac, both formulation B groups are not toxic for corneal nerves even after long-term (90 days) administration.

ABSTRACT BODY:

Purpose: The SP family transcription factors including SP1/SP3/SP4 play essential role in regulating lens differentiation through control of various crystallin genes [Gong et al., 2014. Proc. Natl. Acad. Sci. USA]. In our most recent studies, we also found that the SP family transcription factors also play an important role in the regulating transcription of the major heat shock protein HSP90β in lens epithelial cells. Whether these transcription factors are implicated in cataractogenesis remains to be further studied. In the present studies, we have analyzed the differential expression patterns of SP1/SP3/SP4 in normal human lens and cataract patients.

Methods: Normal human lens were collected from Guangdong Province Eye Bank. Cataract capsular epithelia were harvested during surgical operation with consent of cataract patients. Micro-Western blot analysis (Wes) was used to detect the expression levels of SP1/SP3/SP4.

Results: From normal human lens to cataractous lens, all SP1 family transcription factors were down-regulated. Among the different age groups of cataract patients, SP1 was upregulated over 50% from 50s to 60s. From 60s to 70s, however, SP1 was down-regulated more than 80%. From 70s to 80s, SP1 was upregulated to the level between 50s and 60s, but down-regulated over 80% again from 80s to 90s. In contrast, SP3 and SP4 remain relatively stable from 50s to 70s.

Conclusions: The SP family transcription factors display clearly differential expression patterns. Such patterns are consistent with the down-regulated expression of the major heat shock protein, HSP90β in lens epithelial cells. These results suggest that down-regulation of the SP family transcription factor level is implicated in cataractogenesis.Supported by National Natural Science Foundation of China (Grants #81970787, #82000876, #81770910) and Natural Science Foundation of Guangdong Province and Guangdong City Joint Program of China (Grant # 2019B1515120014), and the Fundamental Funds, 3030901010110 of the State Key Laboratory of Ophthalmology of Zhongshan Ophthalmic Center.

ABSTRACT BODY:

Purpose: Environmental cell conditions can promote extracellular vesicles (EVs) release. EVs are nanovesicles produced by most human cells containing numerous products including mRNA, microRNA (miRNAs), proteins and signaling molecules that have a crucial role in cell-to-cell communication. miRNAs are noncoding RNAs about 22 nucleotides long. They are considered post-transcriptional regulators of gene expression that influence the expression of hundreds of genes simultaneously. They are involved with up and downregulation is associated with many pathologies. Diabetic retinopathy (DR), age-related macular disease (AMD) and cancers are characterized by neovascularization processes. Oxidative damage increases the EVs release regulating angiogenesis. It has been proved that miR-302a-3p inhibits vessel formation targeting VEGFA via zinc finger protein 91 (ZFP91) and hypoxia induced factor 1α (HIF-1 α).

Methods: Our objective was to demonstrate that oxidative stress stimulates EVs release, down regulating miR-302a-3p and increasing angiogenesis. We used arising Retinal Pigment Epithelial cell line (ARPE-19) treated with 600 μM H_2O_2 or 4mM N-Acetylcysteine (NAC). Then, Human Vein Endothelial Cells (HUVEC) were grown indifferent conditions with or without EVs from control media, H_2O_2 or NAC media collecting EVs and isolating miRNA in order to confirm the results.

Results: H_2O_2 and H_2O_2-induced EVs exposure increases reactive oxygen levels (ROS) levels and decreases cell viability in ARPE-19 overexpressing VEGFA mRNA levels, those changes were reverted with NAC. miR-302a-3p mimic exposure decreased H_2O_2 induced VEGFA mRNA expression similarly to NAC addition. It is known that miR-302a-3p decreases vascular processes. Control-released EVs significantly downregulated the new vessels formation. More EVs were released after miR-302a-3p mimic addition and it was correlated with a stronger angiogenesis inhibition, showing a relationship between them. The use of miR-302a-3p inhibitor abolishes the effect. On the other hand, the miR-302a-3p mimic inhibitor restored VEGFA mRNA expression to control levels.

Conclusions: Oxidative stress promotes EVs release with proangiogenic properties. Those are inhibited by miR-302a-3p and promoted by ROS. This opens a new strategy against oxidative- induced angiogenesis by promoting miR-302a-3p as VEGFA mRNA repressor.

ABSTRACT BODY:

Purpose: Balance control is vital for safe ambulation among older adults, especially under challenging environments like dual task paradigm and unstable surfaces. Our study aimed to assess older adults' perturbed balance in simulated real-life scenarios during visual searching and negotiating unstable surfaces. We hypothesized that experimental conditions with more challenging visual tasks and unstable surfaces would result in a decline in postural stability and longer latency among older adults.

Methods: Eighteen participants (age: 65.8±4.0 years; F/M: 15/3) without any systemic or eye diseases were recruited. All participants were instructed to stand on a perturbed force-plate on their bare-feet and complete balance assessments using Bertec Balance Advantage™ system for the following conditions: 1) standing surface (firm/ foam surface) and 2) visual task (fixating on a stationary target/ visual searching [1 target/ 3 targets]). All measurements were repeated 3 times. Reactive balance control in terms of latency reacting to perturbation (randomly moved forward and backward) and root mean square (RMS) sway of Center of Pressure (CoP) for dominant leg in anterior-posterior (AP) and medial-lateral (ML) directions were measured. Independent t-test and one-way analysis of variance (one-way ANOVA) were used to analyze the data.

Results: Contrary to our hypothesis, the effect of visual task showed non-significant influence on latency and RMS sway of the participants ($F<3.682$, $p>0.10$). Latency for the conditions with foam surface was not significantly different from firm surface ($p>0.10$). Instead, the RMS sway on the foam surface in ML direction was significantly lower than firm surface ($p<0.05$), but not in AP direction. The interaction effect of visual task and standing surface showed that RMS sway in ML direction reduced further when standing on the foam surface and conducting visual tasks ($F>3.682$, $p<0.01$).

Conclusions: Opposing to our hypothesis, the effect of visual task and standing surface on latency and RMS sway were weak. Surprisingly, the RMS sway on the foam surface was significantly less than firm surface. The results may be explained by posture priority. Older adults will take posture as the priority, mainly for safety reasons. They may sacrifice their attention on the visual task. Alertness may also alter the performance, therefore standing on foam may create less sway.

ABSTRACT BODY:

Purpose: Tet3 is a member of the ten-eleven translocation enzymes, which include also Tet1 and Tet2. Their canonical function is the oxidation of the 5-methylcytocine (5mC) on the DNA into 5-hydroximethylcytosine (5hmC), and subsequent oxidative states, thereby promoting increased gene expression. Tet3 is expressed in the mouse retina from early postnatal stages, implying its role during the same time window in which retina cells develop and mature. Although Tet3 is the most abundant member in brain and retina, its role in the latter has not been addressed.

Methods: Mutations in the Tet3 catalytic domain has been previously identified and linked to neurological, but also ophthalmological defects. Using a Rax-Cre driver line and a Tet3 floxed mouse, we generated conditional mutant (cMut) mice lacking part of the Tet3 catalytic domain in retinal progenitors and their progeny. Mice have been characterized using a variety of techniques ranging from immunohistochemistry with cell specific markers, ultrastructural analysis of cell morphology by electron microscopy (EM) and electroretinography (ERG) to assess retinal functionality.

Results: Cone photoreceptors, responsible for diurnal and color vision, are of two subtypes in the mouse retina. S-cones, sensitive to blue light, have an increasing dorsal to ventral gradient. M-cones, responsive to green light, are more evenly distributed, although less abundant in the ventral part. Except for the dorsal retina with a prevalence of M-cones, many cones are hybrid and express both S and M photopigments. Preliminary results show that cMut mice have an increased number of cones and altered cone subtype distribution. In fact, S opsin-positive cones are higher in numbers and lack the characteristic dorsal to ventral gradient. As a consequence, all the cones of Tet3 mutant mice appear to be hybrid. The increased cone number is accompanied by a reduction in the total cell number of the inner nuclear layer affecting the functionality of the retina and the propagation of the light stimulus as shown by ERG b-wave measurements. This altered functionality seems not be linked to missing or defective synaptic components as revealed by EM analysis.

Conclusions: These results suggest that Tet3 has a selective role in retinal development and/or lineage specification. Elucidating the mechanisms downstream of Tet3 will improve our understanding of retinal homeostasis under physiological and pathophysiological conditions.

ABSTRACT BODY:

Purpose: To longitudinally examine the transitions in diabetic retinopathy (DR) severity over time and determine which state deteriorates rapidly in an Asian population with diabetes.

Methods: We analysed 20453 clinic visits by 9481 Chinese, Malay and Indian adults diagnosed with diabetes who attended the annual DR screening visits in primary care clinics as part of the Singapore Integrated Diabetic Retinopathy Screening (SiDRP) programme from 2010-2015 and linked to death data at Ministry of Health. DR was assessed from retinal photographs and graded for severity by professional graders. We applied a multistate Markov model to estimate the annual transition probabilities between states (none, mild, moderate and severe/proliferative DR and the absorbing state, death), and the expected waiting time in each state (sojourn time) adjusted for risk factors including age, sex, systolic blood pressure (SBP), duration of diabetes, HbA1c, and body mass index (BMI).

Results: The median time between assessments was 12 months, and the majority of patients had at least 3 assessments. The annual transition probability from none-to-mild, mild-to-moderate and moderate-to- severe in the adjusted model were 6.1%, 7.0% and 19.1% and of death from each state were 1.2%, 2%, 19.1%, and 29.8%; mean time spent in each state (sojourn time) were 8.2, 0.8, 0.8 and 2.2 years. While 0.1% progressed from none-to-severe DR, 1.9% progressed from mild-to-severe DR; Probability of regression from mild-to-none, moderate-to-mild and severe-to-moderate DR were: 55.4%, 17.1% and 4.3%. While 12.4% regressed from moderate-to-none, 0.4% regressed from severe DR-to-none. Higher levels of HbA1c and SBP were associated with progression of none-mild and mild-moderate DR and duration of diabetes with no-mild and moderate to severe/proliferative DR. Lower levels of HbA1c were associated with regression from mild-to-none and moderate-to-mild; higher BMI with mild-to-none DR.

Conclusions: Our results suggest that the mean time to develop mild DR was long (~8 years), while transitions from mild or moderate states were faster within a year. Moderate/above DR greatly increases the probability of progression and death as compared to mild DR/below. HbA1c was associated with both progression as well as regression.

ABSTRACT BODY:

Purpose: Within the MyCAL (Myopia Control with Aspherical Lenslets) clinical trial, to analyse the impact of wearing time on the myopia control efficacy of two spectacle lenses with aspherical lenslets, compared with single vision lenses (SVL).

Methods: In this prospective, randomized, double masked clinical trial, 170 children were randomized to wear either spectacle lenses with highly aspherical lenslets (HAL), spectacle lenses with slightly aspherical lenslets (SAL) or control SVL. Daily wearing time of glasses was assessed over two years through 6-monthly questionnaires. Average wearing time over the full duration of the clinical trial in hours per day (WT) was used for analysis. Influence of WT on change of spherical equivalent of cycloplegic autorefraction (SER) and axial length (AL) were analysed for two WT categories: full-time wearers (at least 12 hours per day, every day) and part-time wearers (less than 12 hours per day or not every day) and through cumulative minimum WT.

Results: WT was analysed for the 157 children who completed all 6-monthly visits. For SVL, full- (n=34)/part-time (n=16) wearing did not impact change in SER (p=0.76) or AL (p=0.92). Myopia progression and axial elongation decreased with increasing minimum WT for HAL and SAL. For both HAL WT groups, SER and AL progression were significantly slower than for SVL ($p<0.01$). HAL full-time wearers (n=32) experienced significantly higher myopia control efficacy compared with SVL group for both SER (0.99±0.12D) and AL (0.41±0.05mm) than HAL part-time wearers (n=22, 0.54±0.15D, p=0.01; 0.26±0.07mm, p=0.03 respectively). For SAL, myopia control efficacy was comparable for full- (n=30, SER: 0.51±0.13D; AL: 0.23±0.06mm) and part-time wearers (n=23, SER: 0.31±0.15D, p=0.11; AL: 0.12±0.06mm, p=0.10).

Conclusions: Myopia control efficacy increased with wearing time for spectacle lenses with highly aspherical lenslets, reaching 0.99D less myopia progression and 0.41mm less axial elongation over two years for full-time wearers.

ABSTRACT BODY:

Purpose: Diabetic retinopathy is preceded by subtle neurodegenerative changes, including retinal nerve fiber layer (RNFL) thinning. Presently it remains unclear whether potentially modifiable risk factors may be determinants of RNFL thinning. We investigated, using prospectively-collected cross-sectional data from an observational cohort study, whether potentially modifiable risk factors were associated with RNFL thickness.

Methods: We used cross-sectional data from The Maastricht Study (up to 5,255 participants,49.0% men,mean±SD age59.5±8.7 years, and 23.3% with type 2 diabetes [T2D; T2D oversampled by design]). We assessed RNFL thickness with optical coherence tomography (i.e. mean peripapillary RNFL thickness of both eyes). We used linear regression analyses with adjustment for potential confounders; and tested for interaction by sex and T2D (yes/no).

Results: After full adjustment, greater HbA1c and lower healthy diet score were significantly associated with lower RNFL thickness (per SD, standardized beta [95% CI], -0.05 [-0.08; -0.02] and -0.03 [-0.06; -0.00], respectively); high (>2 units/ day for men or >1 unit/day for women) versus none alcohol consumption was significantly associated with lower RNFL thickness (-0.09 [-0.18; -0.00]); antihypertensive medication use was significantly associated with lower RNFL thickness (-0.12 [-0.19; -0.05]); and greater 24-hour ambulatory systolic blood pressure and greater total cholesterol were, respectively, significantly associated with lower and greater RNFL thickness in individuals with, but not in individuals without, T2D (in individuals with T2D, -0.06 [-0.13; 0.00]; 0.09 [0.03; 0.16]). Smoking,cardiorespiratory fitness, accelerometer-assessed physical activity, and waist circumference were not associated with RNFL thickness. Sex did not modify associations under study.

Conclusions: This population-based study found that a higher level of glycemia, lower adherence to a healthy diet, high alcohol consumption, and a history of hypertension, estimated from the use of antihypertensive medication, were

associated with a lower RNFL thickness. Hence, early-stage prevention of these adverse factors may contribute to the prevention of RNFL thinning, and, ultimately, diabetic retinopathy.

Commercial Relationships Disclosure: Jan Kremers: Commercial Relationship: Code N (No Commercial Relationship) | Avinash Aher: Commercial Relationship: Code N (No Commercial Relationship) | Neil Parry: Commercial Relationship: Code N (No Commercial Relationship) | Nimesh Patel: Commercial Relationship: Code N (No Commercial Relationship) | Laura Frishman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To study ERGs elicited by temporal white noise (TWN) stimuli that excite only the L- or the M-cones or all photoreceptors in concert.

Methods: ERGs were recorded from the right eyes of five anesthetized macaques (Macaca mulatta ; three males, two females). Stimuli were created with a 4-colour ganzfeld stimulator. The stimuli were luminance (22% contrast), selective L-cone excitation and selective M-cone excitation (both 22% cone contrast). Cone isolating stimuli were generated using triple silent substitution. The stimuli had equal amplitudes at all frequencies between 0 and 512 Hz. Inverse Fourier transform resulted in a TWN stimulus with a Gaussian luminance or cone excitation distribution. All ERG measurements were performed twice to study reproducibility and correlations.

Results: The repeated measurements showed that the measured ERGs were reproducible. The responses to identical stimuli measured in different animals were correlated but less strongly as the responses to the same stimuli in the same animals. A cross-correlation between ERG responses and stimuli resulted in impulse response functions (IRFs) for luminance stimuli that were similar to flash ERGs in having an a-wave-like negativity and a b-wave-like positivity, but lacked oscillatory potentials and showed a late (after 40 ms) positive wave. L-cone driven IRFs were similar to luminance IRFs albeit smaller. The a- and b-wave-like components were absent in the M-cone driven IRFs. The M-cone driven late positivity was of similar amplitude as those obtained for L-cone isolating stimuli.

Conclusions: ERGs elicited with temporal white noise are reproducible. The a-like and b-like waves of the luminance IRF are L-cone dominated as previous seen for ERG responses in humans and macaques to sine wave, square wave and sawtooth stimuli. A late positive wave, present in luminance, L- and M-cone IRFs but not visible in conventional flash ERGs may provide a new measure of retinal function.

ABSTRACT BODY:

Purpose: Application of tailored MRI sequences should improve diagnostic accuracy in acute optic neuritis (ON) and chronic optic neuropathy. This retrospective, observational study compares short tau inversion recovery (STIR) and 3D-fluid attenuation inversion recovery (FLAIR) in acute and chronic ON and correlates radiographic metrics to vision function and optical coherence tomography (OCT) structure.

Methods: Orbital MRIs of 57 patients (56% female; mean age 50.8±16.7 years) with acute ON (n=15), chronic ON (n=31), or clinically normal (n=11) were retrospectively analyzed by masked neuroradiologists (2) and neuro-ophthalmologist (1) for presence of lesion, lesion signal normalized to normal frontal white matter, and lesion length. Clinical data included visual acuity (VA), OCT retinal nerve fiber layer (RNFL) and ganglion cell layer (GCL) thickness, and automated perimetry mean deviation (MD) at presentation and outcome.

Results: The diagnostic accuracy per reader for acute and chronic ON were 73-100% and 58-71%, respectively, for STIR and 87-100% and 48-71%, respectively for 3D-FLAIR. Diagnostic accuracy for chronic ON was lower than acute ON for one reader on STIR and both readers on 3D-FLAIR ($p=0.02$). Average ROI of acute and chronic ON lesions were higher than clinically normal cases on STIR ($p=0.01$ and $p<0.01$, respectively) and 3D-FLAIR ($p=0.07$ and $p=0.08$, respectively). Presenting LogMar VA for acute ON correlated with mean lesion length ($r=0.55$) and ROI ($r=0.54$) on STIR ($p<0.05$). The mean lesion length on STIR correlated to presenting ($r=-0.67$) and final ($r=-0.92$) GCL in acute ON ($p<0.01$) and to RNFL ($r=-0.44$) and GCL ($r=-0.48$) in chronic ON cases ($p<0.05$). In acute ON, the mean lesion length on FLAIR correlated with the presenting GCL ($r=-0.69$, $p<0.01$); and the outcome GCL with the mean lesion ROI on STIR ($r=-0.67$, $p<0.05$). No MRI features correlated with final VA or MD for acute or chronic ON.

Conclusions: 3D-FLAIR and STIR have similar detection rates for ON lesions, but FLAIR had slightly greater sensitivity for acute ON. Use of a normalized quantitative ROI increased diagnostic accuracy for detecting abnormal signal. In acute ON, longer lesions and increased signal on STIR corresponded to worse presenting VA and greater structural loss reflected by OCT GCL and RNFL thinning, suggesting MRI might help predict outcome neuronal loss in acute ON.

Commercial Relationships Disclosure: Bernhard Baumann: Commercial Relationship: Code N (No Commercial Relationship) | Conrad Merkle: Commercial Relationship: Code N (No Commercial Relationship) | Marco Augustin: Commercial Relationship: Code N (No Commercial Relationship) | Martin Glösmann: Commercial Relationship: Code N (No Commercial Relationship) | Gerhard Garhofer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal tissue structures are subject to rhythmic movements caused by pulsatile ocular blood flow. Alterations of ocular pulsatility and mechanical tissue properties have been associated with some of the most sight-threatening eye diseases. Currently available methods for the visualization and quantitative assessment of fundus pulsations have been limited to one or two spatial dimensions. Here we present volumetric imaging of pulsatile tissue dynamics in the murine retina and choroid based on 4D optical coherence tomography (OCT).

Methods: A spectral-domain OCT ophthalmoscope optimized for rodent retinal imaging was used to investigate pulsatile motion patterns in the posterior eyes of mice. The system operated in the 840-nm wavelength band and provided an axial resolution of 3.8 µm. Volumetric OCT data sets comprising 2,000 B-scans across a field of view of roughly 1 mm x 1 mm were acquired in the posterior eyes of wildtype mice and a mouse model of retinal neovascularization. An analysis of the complex-valued OCT data was performed in order to detect changes of the signal phase between successive B-scans. Using the photoreceptor layer as a reference, tissue deformation patterns were visualized and quantified with high volumetric resolution.

Results: Pulsatile tissue displacements in the ±20 µm/s range were visualized and charted with a frame rate of 130 Hz. Volume scans enabled sampling motion patterns during the murine pulse cycle with ~15 volumes per cycle. Pronounced pulsatile displacements in the in vivo imaging data were localized in the vicinity of retinal vessels as well as in the choroid (see Figure 1). Increased pulsatility was observed in the outer retina of the mouse model at locations exhibiting high reflectivity associated with neovascular lesions.

Conclusions: The concept of fundus elastography (FUEL) was demonstrated based on high-speed 4D-OCT imaging and proved capable of visualizing subtle tissue deformation dynamics related to ocular pulsation. This high-resolution retinal elastography technique may enable a new paradigm of OCT based measurements and image contrast.

TITLE: Strain dependent influence of UVA-based corneal crosslinking (CXL) on corneal immune cell populations

SESSION TITLE: Corneal Immunology and Neovascularization

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Deng, W. Zhang, A.P. Schönberg, F. Bock, C. Cursiefen, Department of Ophthalmology, Universitat zu Koln, Köln, Nordrhein-Westfalen, GERMANY|

Commercial Relationships Disclosure: Shuya Deng: Commercial Relationship: Code N (No Commercial Relationship) | Wei Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Alfrun Schönberg: Commercial Relationship: Code N (No Commercial Relationship) | Felix Bock: Commercial Relationship: Code N (No Commercial Relationship) | Claus Cursiefen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Corneal collagen crosslinking (CXL) is an established technique to halt the progression of keratectasia and was recently shown to also regress mature pathologic corneal blood and lymphatic vessels in inflamed corneas. However, the effect of UVA-based CXL on corneal immune cells remains unknown. This study investigates the early and strain dependent influence of CXL on corneal immune cell populations.

Methods: After corneal abrasion, BALB/c mice and C57BL6/N mice received a 9 minutes topical application of 0.1% riboflavin in 20% dextran phosphate sodium followed by a 9 minutes UVA irradiation (370 nm, 3 mW/ cm^2) using the CCL- vario CXL system. The corneal limbus was protected by a light-preventing plastic shield. Fresh eyeballs were collected at day 1, 4, 7 (each n=5) after CXL for cryosection. Stainings for F4/80, MHC-II, CD11c were analyzed with a fluorescence microscope.

Results: A significantly reduced amount of $F4/80^+$ cells was observed in BALB/c mice on day 1 ($p=0.012$) and day 4 ($p<0.001$) after treatment compared to C57BL6/N mice. $F4/80^+$ $MHC\text{-}II^+$ cells in BALB/c ($p<0.001$, compared to BALB/c naïve mice) significantly went down at day 1 after CXL, whereas C57BL6/N mice showed a significant decrease ($p=0.014$, compared to C57BL6/N naïve mice) only at 4 days after CXL. $F4/80^+$ $MHC\text{-}II^+$ cells in BALB/c mice reversed to baseline on day 7. Interestingly, $F4/80^+$ $MHC\text{-}II^+$ cells in C57BL6/N mice remained at very low levels on day 7 after CXL.

On day 1 also the percentage of $CD11c^+$ MHC -II^+ mature dendritic decreased significantly in BALB/c group (23.76%, $p=0.006$) compared to naïve mice (57.23%) but not in the C57BL6/N group (43.55%). On day 7 the proportion of mature dendritic cells increased in both the BALB/c group (91.02%) and C57BL6/N group (86%) equally.

Conclusions: Our results show a strain dependent influence of CXL on corneal immune cell populations in BALB/c and C57BL/6N mice. This suggests individually different immune responses of patients after UVA-based CXL treatment and sheds light on the heterogenous outcomes of this treatment strategy.

ABSTRACT BODY:

Purpose: To create and validate automated deep learning models for DR that are trained on UWF images obtained from a DR teleophthalmology program.

Methods: AutoML Vision (Google) models were generated based on nonmydriatic UWF images from the Joslin Vision Network (JVN). Image labeling was based on standardized evaluation by the JVN reading center following the clinical Early Treatment Diabetic Retinopathy Study Severity Scales (ETDRS-SS). Images for the initial model were split 8-1-1 for training, validation and testing to detect referable DR [(refDR), defined as moderate nonproliferative DR (NPDR) or worse]. External testing of the autoML model was performed using a published image set with matching nonmydriatic UWF, clinical exam and standard 7-Field ETDRS photos (N=192 eyes). Sensitivity and specificity (SN/SP) for refDR were calculated. Based on published FDA requirements, prespecified performance thresholds were defined at 0.85/0.825 for SN/SP.

Results: Distribution of ETDRS-SS in training set (N=3,999 images): no DR 33.8%, mild 16.2%, moderate 29.4%, severe NPDR 5.0%, PDR 16.6%, RefDR was present in 50.0% of images. Area under the precision-recall curve (AUPRC) was 0.947 (figure 1). The model's overall accuracy for RefDR was 92.2%. External testing set distribution of ETDRS-SS by UWF/clinical exam/ETDRS photos: no DR 10.9/8.9/12.5%, mild NPDR 22.9/18.7/22.9%, moderate NPDR 33.8/33.8/29.7%, severe NPDR 10.9/12.0/8.3%, PDR 21.3/26.6/26.6% with RefDR was present in 66.1/72.4/64.6%. SN/SP for refDR on the external test set was 0.79/0.83 for UWF, 0.76/0.90 for clinical exam, 0.79/0.81 for ETDRS photos. Table 1 shows a comparison with reported metrics from FDA approved and UWF algorithms.

Conclusions: Despite the increasing adoption, there are no commercially available artificial intelligence DR algorithms for UWF images. This study demonstrates feasibility of using autoML models for the identification of refDR from UWF obtained in a teleophthalmology program. Despite the large image size and complexity of UWF compared to standard retinal images, the performance approaches published diagnostic accuracy metrics of commercial models used for DRSP. This proof of concept use emphasizes the broad future potential by allowing programs with large image datasets to address emerging clinical needs with AI applications

ABSTRACT BODY:

Purpose: The main purpose of this study is to describe the fundoscopic alterations and retinal vessel caliber measurements in SARS-CoV2 positive patients admitted to a tertiary referral hospital in Madrid (Spain) and to correlate the retinal vessel caliber with the severity of the disease.

Methods: A single-center cross-sectional observational study to document the retinal vascular findings in SARS-CoV2 patients admitted to a tertiary Hospital during the first wave in Madrid, Spain. Fundoscopy was performed in both eyes (when possible) with a manual retinography Zeiss Visuscout 100. All patients signed a consent form to participate in the study. Pharmacological mydriasis prior to retinography was achieved by applying one drop of tropicamide 1% in each eye. Data collected included previous medical and ophthalmic history, prescribed medical and postural treatments, and laboratory findings at the time of admission. All cases were classified according to their outcome as per the WHO clinical progression scale on a scale of 0 to 10, with being 0 the uninfected state and 10 being death. All the retinal images were analysed by two medical retina experts independently. Retinal vessel calibers were measured by a single masked grader using a validated research software with high reproducibility.The relationship between the WHO clinical progression scale and retinal vessel caliber was assessed by Kruskal-Wallis test for independent samples.

Results: In total, 81 patients and 154 eyes were included in the study. The fundus retinal assessment disclosed signs of hypertensive retinopathy in 8 right eyes (OD) (8/77) and 9 left eyes (OS) (9/77); vascular tortuosity was present in 13 OD (13/77) and 13 OS (13/77); age-related macular degeneration was found in 13 OD (13/77) and 12 OS (12/77); myopic retinopathy in 3 OD (3/77) and 3 OS (3/77); finally incidental choroidal nevi were found in 4 OD (4/77) and 2 OS (2/77). The retinal microvascular caliber assessment was performed in a total of 72 eyes from 72 subjects, the right eye was used in 61 cases, left eye in the rest. There was no statistically significant difference according to vessel caliber and WHO outcome score.

Conclusions: COVID-19 has been linked to an increase risk of cardiovascular events. However, we could not find a correlation among retinal vascular findings and clinical outcome in our cohort.

ABSTRACT BODY:

Purpose: Primary angle closure glaucoma (PACG) is one of the leading causes of blindness worldwide with a complex genetic aetiology. For complex genetic disorders, copy number variation (CNV) is anticipated to play an essential role in disease vulnerability. The impact of CNVs on PACG has not been studied yet. In India, ~30% of people show narrow angles but 0.5-1% of people actually develop PACG. To exclude heterogeneity, we compared genome-wide CNVs between older (age ≥60 years) anatomically suspects (PACS) showing narrow angle <15° and PACG individuals having age ≤50 years. In doing so we would therefore be able to identify genes that are involved in the glaucomatous neurodegeneration, which we believe will be separate from genes controlling angle-related parameters.

Methods: Genome-wide genotyping was performed on 148 PACG (40.15 ± 6.62 years) and 92 PACS (68.03 ± 7.56 years), followed by CNV calling using the PennCNV package's Hidden Markov model-based approach. For all deletions and duplications, CNV frequencies were analyzed statistically through the Wilcoxon test between PACG and PACS. The significant genomic regions were subjected to validation by qPCR and subsequently, bioinformatic analyses were carried out to determine the role of PACG pathophysiology.

Results: There is no significant deletion was found between two groups but in amplification, we discovered that NLGN1 genic region (Gr37Chr3; bp:173239453-173246813) was overrepresented in PACG (P = 0.008413). That genic area of NLGN1 was successfully validated in qPCR by SYBR green assay. In PACG, the mean Ct values were significantly lower than in PACS (P= 0.079).NLGN1 is highly expressed retinal ganglion cells (PLIER: 44.3257). Gene network analyses showed that the NLGN1 are associated with many neurodegenerative and eye diseases. Moreover, genotype-phenotype correlation revealed that NLGN1 is linked to the assessment of a greater optic-cup area that is positively correlated with glaucomatous neurodegeneration.

Conclusions: NLGN1 is involved in regulating the activity of NMDA receptors. Amplification of NLGN1 may promote more synaptic clustering of NMDARs in retinal ganglion cells (RGCs). The overexpression of these NMDARs leads to mitochondrial dysfunction of the RGCs. That eventually leads to the death of RGCs and subsequent glaucomatous neurodegeneration.

ABSTRACT BODY:

Purpose: Heterochromatin alterations is a hallmark of aging process. This study is aimed to investigate structure and distribution of heterochromatin on retinal pigment epithelial (RPE) cell premature senescence induced by oxidative stress exposure or X-ray irradiation, and to explore the effects of heterochromatin in regulating senescence-associated secretory phenotype (SASP) gene expression during RPE senescence.

Methods: Heterochromatin structure was assessed by confocal microscopy and transmission electron microscope. Genome-wide heterochromatin distribution was studied by chromatin immunoprecipitation (ChIP)-seq analysis. ARPE-19 cells were continually exposed to tert-Butyl hydroperoxide (t-BHP) or X-ray irradiation to induce cell senescence, which was confirmed by senescence-associated ß-galactosidase (SA ß-gal) staining, senescent-associated gene expression and RPE barrier function analysis. Chromatin structure on SASP gene locus was assessed by formaldehyde-assisted isolation of regulatory elements (FAIRE), and the occupancy of heterochromatin there was determined by quantitative ChIP (q-ChIP) analysis. Heterochromatin was disrupted by chaetocin treatment. Expression of inflammatory cytokines were examined by qRT-PCR and cytokine protein array.

Results: Heterochromatin mark H3K9me3 was enriched in SASP gene locus. A prominent nuclear peripheral heterochromatin loss was found in senescent RPE cells. Decreased chromatin compaction was detected in proinflammatory genes upregulated during RPE senescence. Disruption of heterochromatin led to robust upregulation of SASP genes.

Conclusions: Heterochromatin represses SASP gene expression during RPE senescence. Our data suggest a potential role for targeting heterochromatin in the treatment of retinal diseases related to RPE senescence, such as age-related macular degeneration (AMD).

ABSTRACT BODY:

Purpose: With emerging therapies for GA, little is known about how GA is evaluated. A Delphi survey was conducted to determine consensus among healthcare professionals (HCPs), specifically retina specialists, on GA diagnosis and management.

Methods: Initial consensus was developed by 8 retina specialists, serving as a steering committee, with an electronic questionnaire (round 1) sent to 175 randomly selected retina specialists globally. In round 2, 125 HCPs (selected from the same respondents) were probed further on question areas that did not achieve consensus in round 1. Questions were open ended, multiple choice, rank order, level of agreement (Likert scale). Consensus (defined as ≥75% agreement for a response) was sought in areas relating to GA diagnosis and current patient management.

Results: Reading difficulties (93% agreement) and impaired ability to recognize faces (84%) are the most elicited symptoms during an initial clinical visit by HCPs. The most often used functional measures for GA are best corrected visual acuity (94%) and the Amsler grid (86%). Optical coherence tomography (OCT) is the most regularly used imaging modality (98%), followed by fundus autofluorescence (81%), and color fundus photography (77%). OCT was ranked as the first or second most important imaging modality (out of 6) for GA diagnosis and monitoring by 85% and 82% of HCPs, respectively. There is consensus among HCPs (76%) that foveal involvement is the most important variable for determining GA prognosis. Impact on daily living (89%) and visual-aid options (75%) are important topics

to discuss with newly diagnosed patients. Most (90%) felt a GA treatment option would have a significant positive effect on patient quality of life. Low vision aids (90%), smoking cessation (86%), and vitamin supplementation (75%) are thought to be beneficial for GA. Active neovascular age-related macular degeneration (in either eye) was selected as the most common circumstance requiring a patient with GA to be followed more closely (76%). Most (82%) of HCPs agreed that patients with choroidal neovascularization controlled by anti-vascular endothelial growth factor therapy can continue to experience vision loss due to atrophic lesions.

Conclusions: There was agreement among HCPs that GA is a significant burden, meriting close management. In lieu of treatment options, HCPs also agreed on general clinical management approaches.

ABSTRACT BODY:

Purpose: Genetic variants in complement genes are associated with age-related macular degeneration (AMD). However, the functional impact of the majority of missense variants is unknown. We evaluated spatial placement on protein structure, using the International AMD Genomics Consortium(IAMDGC) data(16,144 cases/17,832 controls).

Methods: The IAMDGC data was imputed using the HRC, with a 30% improvement over the original. Missense variants were extracted for CFH,CFI,CFB,C9,& C3 genes. We evaluated variants' placement in protein structure space: spatial proximity in the protein, and AMD association. We compared the spatial proximity of known AMD variants(KAV) to unassociated, assessed variants' likelihood of protein destabilization, and performed gene-based testing. Gene-based tests included: all variants; variants near KAV; and variants predicted to destabilize proteins. SKAT testing was used to confirm spatial associations. Logistic regression on KAV in CFI identified variants leading to >50% reduction in protein expression compared to wild type in vitro. These results were compared to functional impact scores, showing if a variant has a functional impact genome wide.

Results: Multiple destabilizing variants were found. Gene-based tests using all variants identified significant associations of the C3,C9,CFB,andCFH genes with AMD risk after controlling for age and sex($P=3.22\times10^{-5}$;7.58×10^{-6};2.1×10^{-3};1.2×10^{-31}). Filtering on protein destabilization and SKAT-O tests found several missense variants in CFI and CFH associated with AMD(P=CFH:0.05,CFI:0.01, threshold<0.05).We identified spatial associations for AMD risk in structures for C3,C9,CFB,CFH,and CFI at P<0.05. Both structural and functional scores were predictive of reduced CFI protein expression, and ROC curve analyses suggest structural scores are a better predictor(AUCs of 0.76 and 0.69).

Conclusions: We demonstrate missense variants in complement genes cluster spatially and are associated with AMD status. Using this method, we can identify CFI and CFH variants previously classified as unknown significance, but are predicted to destabilize proteins. This method can predict in-vitro tested CFI protein expression changes, indicating that it is a useful tool for selecting variants for functional follow-up. Further investigation is needed to validate the models for additional variants in other complement and AMD-associated genes.

ABSTRACT BODY:

Purpose: Manual analysis of fundus images in diabetic retinopathy screening programme is time consuming due to the large number of patients and limited resources. We propose an end-to-end deep learning framework for automatic Diabetic Retinopathy (DR) grading.

Methods: To perform the experiments, we used the largest public retinal image dataset provided by EyePACS for the Diabetic Retinopathy Detection with 35,126 images meant for training and 53,576 for testing and included a real-world scenario with images affected by noise. We randomly selected 10% of the images and used 18,860 images for training, 2,096 images for validation and 32,017 for testing. Only images with enough quality for analysis underwent the DR grading stage. 35,729 images were discarded and, therefore, 52,973 images were used for subsequent analysis.

The approach done by our group is based on an attention mechanism which performs a separate attention of the dark and the bright structures of the retina. The framework includes an image quality assessment stage and additional deep learning-related techniques such as data augmentation, transfer learning and fine-tuning. The architecture Xception as feature extractor and the focal loss function to deal with data imbalance was used. The Kaggle DR detection dataset was used for method development and validation.

Results: The Quadratic Weighted Kappa (QWK) achieved with the proposed method was 0.78 on the test set, which corresponds to 83.7% accuracy. However, when dealing with class unbalance, QWK is dominated by the most representative classes, which is the class of No DR in our dataset. This is the reason why the confusion matrix is also important to evaluate the results.

First, the class of No DR was detected with high accuracy: only 2.9% (706 out of 23,962) of the R0 images were over-diagnosed. More importantly, only 0.0005% (12 out of 23,962) of them were rated as severe or very severe. Conversely, the class Mild DR was easily misguided with the classes no DR and mild to moderate. Finally, poor detection accuracy for class R4 was obtained.

Conclusions: Our results suggest that our framework could be a diagnostic aid for the early detection and grading of DR. Further validation and comparative studies are needed.

Commercial Relationships Disclosure: Therese Cronin: Commercial Relationship(s);Code C (Consultant/Contractor):SpliceBio | Lyse Libeau: Commercial Relationship: Code N (No Commercial Relationship) | Joanna Demilly: Commercial Relationship: Code N (No Commercial Relationship) | Séverine Remy: Commercial Relationship: Code N (No Commercial Relationship) | Mikaël Croyal: Commercial Relationship: Code N (No Commercial Relationship) | Ignacio Anegon: Commercial Relationship: Code N (No Commercial Relationship) | Oumeya Adjali: Commercial Relationship(s);Code C (Consultant/Contractor):SpliceBio

ABSTRACT BODY:

Purpose: We investigated the most common mutation underlying a mild to moderate Stargardts disease (STGD1) phenotype in a rat model carrying the paralogue to the ABCA4 G1961E mutation. By crossing with another rat line that lacks ABCA4 protein we reveal a phenotype in line with that described for STGD1 patients carrying this mutation in compound heterozygosity. The model is used to test the potential of therapies such as the CFTR corrector Lumacaftor.

Methods: Following in silico modelling, the rat Abca4 gene was targeted for disruption by SpCas9 RNP microinjection into the pronucleus of intact Sprague-dawley rat zygotes in complex with a guide RNA targetting the nuclease to exon 42 of Abca4 as well as a 112-nt ssDNA oligo carrying the required G-to-E substitution to generate the knock-in Abca4$^{E/E}$ line. The functional consequences of the mutation on ABCA4 protein purified from ocular extracts was tested by mass spectrometry, ATPase and flippase assay in the presence or absence of lumacaftor. The ocular phenotype was assesed by in vivo imaging and ERG.

Results: Surprisingly, an increase in the protein levels was determined in the retinas of Abca4$^{E/E}$ rats including an increase in a residual mislocalised cytosolic fraction. Bisretinoid analysis shows an increase of 2-fold and 3.5-fold in A2E dimers for the Abca4$^{E/E}$ and Abca4$^{E/-}$ lines respectively. The structure and function of the knockin Abca4$^{E/E}$ rat retina is normal while being moderately impacted in the double transgenic Abca4$^{E/-}$ rat. At the same time ABCA4 purified from Abca4$^{E/E}$ rat eyes and reconstitued onto artificial liposomes shows a drop of ATP hydrolysis and of flippase activity across the membrane in the presence of an excess of retinal. This can potentially be rescued by the small molecule corrector VX-809.

Conclusions: The Abca4$^{E/E}$ and Abca4$^{E/-}$ rats display a disruption in retinoid metabolism that make them suited to testing novel STGD1 therapies that aim at restoring normal ATPase function. One such therapy investigated here using these novel models is the CFTR small molecule corrector VX-809. Changes in ATPase activity of the ABCA4 protein in the Abca4$^{E/E}$ rat retina can be corrected through this approach.

ABSTRACT BODY:

Purpose: Effective treatment of uveal melanoma (UM) patients with metastatic disease is unfortunately not yet available. Twenty percent of UM harbors a mutation in splicing factor gene SF3B1, suggesting that an aberrant spliceosome function plays a vital role in tumorigenesis. Inhibiting the spliceosome could prevent formation of aberrant transcripts. Splicing inhibitors (e.g. E7107) have been shown to exploit the preferential sensitivity of spliceosome compromised cells to these compounds. E7107 targets the SF3B subunit 1 and interferes with splicing by binding non-covalently to the SF3B subunit of the U2 snRNP complex. This prevents the U2 snRNP complex to bind to the pre-mRNA branch point. We have studied the effect of E7107 using UM cell lines (Mel202 and 92.1) and SF3B1 and BAP1 mutated primary ex vivo tumor slices.

Methods: Cell lines and ex vivo tumor slices were exposed for 24h to different concentrations of E7107. Tumor slices were stained with H&E, BAP1, MelanA, MIB-1 and caspase-3 antibodies. RNA was isolated for transcriptome and gene expression analysis. The type and number of alternative and aberrant transcripts was evaluated after exposure to E7107 with the MISO and FRASER analysis, respectively.

Results: Of twenty UM slices were included from September 2018-2021. E7107 exposed on UM cell lines showed decreased cell viability and increased apoptosis. This effect was significant in SF3B1 mutated cells compared to SF3B1 wild-type cells ($p = 0.0004$). A similar effect was observed in UM tumor slices. A decrease in MIB-1 (proliferation) positive cells and increase in caspase-3 (apoptosis) positive cells was observed. Furthermore, a decrease in mainly aberrant transcript formation was observed after E7107 exposure, especially at a concentration of 5 nM E7107. Ninety-seven transcripts had a decrease in aberrant transcripts after E7107 exposure, and this effect was mostly in exon skipping/intron retention.

Conclusions: This study demonstrates that SF3B1 mutated UM cells are more sensitive to splicing inhibitor E7107 compared to SF3B1 wild-type UM cells. Splicing inhibitors such as E7107 have therapeutic potential in SF3B1 mutated UM. Further research is recommended to assess and maximize the efficacy of E7107 as well as other potential splicing inhibitors in a therapeutic setting. An optimal dose should be determined with no serious adverse events but high enough for an increased effect in mutated cells.

ABSTRACT BODY:

Purpose: Trehalose is a naturally occurring bioprotective disaccharide in non-mammalian species, allowing survival in unfavourable environments. It acts as a signalling molecule by activating autophagy and reducing cell death associated with apoptosis and inflammation. It is currently used clinically in ocular surface disease and is shown in vivo to be neuroprotective in neurodegenerative disease including Parkinson's Disease, Huntington's Disease and Amyotrophic Lateral Sclerosis. Its potential as a neuroprotective agent in glaucoma has also therefore been postulated. We hypothesised that trehalose could be demonstrated in vitro and in vivo to have a neuroprotective effect in neurodegenerative insults.

Methods: Trehalose solution was formed by dissolving trehalose in phosphate buffer solution. Toxicity of trehalose was assessed by investigating the cell viability of increasing concentrations of trehalose co-incubated with retinal cells. Cultured retinal cells were treated with insults of cobalt chloride, glutamate, paraquat and homocysteine. They were then co-incubated with either 70 mM trehalose solution or culture media only for 24 hours. Assessment of trehalose-mediated neuroprotection in vitro was achieved using an alamarBlue cell-viability assay. Direct application of trehalose to the optic nerve was used in an optic nerve crush mouse model of neurodegeneration with primary endpoints after 1 week of DARC (Detection of Apoptosing Retinal Cells) imaging and whole retinal RBPMS histology.

Results: Toxicity studies demonstrated that trehalose was not toxic to retinal cells up to its maximal solubility of 50 mg/mL (146 mM). 70mM trehalose was significantly neuroprotective in vitro in insults of cobalt chloride; IC50 trehalose 520.9μM vs vehicle 390.24μM ($p<0.05$); and in glutamate; IC50 trehalose 4.761mM vs vehicle 3.231mM ($p<0.01$). There was no significant neuroprotective effect in paraquat and homocysteine insults. Trehalose was not neurotoxic after 1 week of in vivo study and displayed no adverse effects systemically or locally.

Conclusions: This work demonstrates that trehalose is safe at high concentrations, is neuroprotective in vitro and not neurotoxic in vivo. Its efficacy in cobalt chloride and glutamate insults suggests a mechanism of action of trehalose which interferes with HIF-1α and calcium excitotoxicity pathways.

ABSTRACT BODY:

Purpose: Vitreous opacities, also known as floaters, are a common phenomenon in most people’s lives. For those who suffer from a more severe amount of these floaters, laser vitreolysis is one treatment option. But due to the manual handling of the procedure, there is a significant risk to misguide the laser into critical areas near retina or lens. To enhance the safety for the patient and simplify the handling for the physician we introduce a method to visualize and segment vitreous opacities via optical coherence tomography for an improved computer-guided procedure. Moreover, we present an easy method to build eye models for training and testing purposes in ophthalmology.

Methods: We developed a Swept Source OCT setup that is specialized to capture the vitreous volume inside a silicone model eye with a high volume per second rate. Our lens setup allows us to shift the laser focus through the whole eye, thus no change of the patient contact interface is necessary. Our custom-made software segments and visualizes floaters in the two- and three-dimensional space, optimized for the high-speed B-Scan rate of the OCT. To adapt the eye model to reality, we also developed a new procedure to create hollow silicone eyes that are suitable for clinical patient contact interfaces and can be filled with a viscous floater solution.

Results: The combination of a patient contact interface and our silicone eye model enables a clear view inside the eye for camera and OCT view. We are able to segment single B-Scans in under 10 milliseconds. The software highlights the floater material and provides suitable coordinates for the laser treatment. To prevent treatment near critical structures like retina and lens, their distance from the floater material can be measured.

Conclusions: We introduced a simple method to create silicone eyes that could be used for other training purposes in the field of ophthalmology as well. With our OCT setup and software, we present a way to improve the safety for the patient and simplify the procedure for the physician.

ABSTRACT BODY:

Purpose: Accumulation of cytosolic DNA has been found during cell senescence, a terminal cell cycle arrest and usually associated with pro-inflammatory responses. Aging is one of the highest risk factors for age-related macular degeneration (AMD) and other degenerative eye diseases. The functional significance of cytosolic DNA during retinal cell senescence is largely unexplored. Here, we are aimed to investigate the distribution, composition and pro-inflammatory effect of cytosolic DNA during RPE and photoreceptor cell senescence.

Methods: Hydrogen peroxide (H_2O_2, 600 μM, 2 h) was used to induce cell senescence in human RPE cell line ARPE-19 and in mouse photoreceptor cell line 661W. β-galactosidase (β-gal) analysis and Western blot (WB) analysis confirmed cell senescence upon oxidative stress. Immunofluorescence determines DNA leakage, DNA damage and enriched chromatin marker in cytoplasm. To determine the potential pro-inflammatory of cytosolic DNA, genomic DNAs were extracted from ARPE-19 cells with or without H_2O_2 exposure. The obtained DNA was then transfected into ARPE-19 cells. Inflammatory factors were determined by qRT-PCR analysis at 16 h post transfection.

Results: Oxidative stress leads to senescence of RPE and 661W cells. Leakage of nuclear DNA into cytosol and formation of micronuclei were evident in those senescent cells. The cytosolic DNA contains unrepaired fragment as evidenced by positive staining of DNA damage marker γH2AX, which is achieved by extrusion of chromatin through lamina/C-coated nuclear envelope. Transfection of genomic DNA derived from senescent cells lead to significant higher expression of IL6, IL1β and INFβ as compared to untreated normal cells.

Conclusions: Together, our results demonstrate RPE and photoreceptor senescence is accompanied by accumulation of cytosolic DNA, which may initiate a pro-inflammatory response in age-related eye diseases.

ABSTRACT BODY:

Purpose: Different signs of inflammation have been described in the brains of COVID-19 patients. In the retina, the fundus eye exam of these patients shows cotton wool spots, microhemorrhages, and a decrease in vascular density. However, morphological alterations of retinal cells in these patients are unknown. Thus, the aim was to analyze the morphological changes of the retinal cells from human donors with COVID-19 to establish several stages of response to damage in these cells and to define correlations with clinical parameters.

Methods: The retinas of human donors with COVID-19 (n = 16) and control subjects (n = 12) obtained from the General University Hospital Consortium of Valencia were analyzed. Immunohistochemical stainings were performed on transversal sections or flat-mount retinas to study photoreceptors, microglial cells, Müller cells, astrocytes, and the presence of ACE2. TUNEL assays and confocal microscopy imaging were carried out. Correlations were calculated between retinal and clinical parameters.

Results: Mean age of COVID-19 and control group were 80±10 and 70±8 years respectively. Müller cells, outer segment of cones and retinal pigment epithelium presented ACE2 staining. Larger staining of ACE2 and CRALBP was observed in cell bodies of Müller cells in COVID group. Disorganization of honeycomb-like pattern formed by Müller cells in the outer nuclear layer and disruption of external limiting membrane was found in the 81.3% of COVID patients. The 56.3% of COVID patients showed gliosis compared to controls (40%). COVID-19 retinas also presented epiretinal membranes and astrocytes protruding to vitreous humor. The 93.8% of COVID-19 patients had activated or ameboid-shape microglia. Microglial nodules around vessels and a reduction of the area occupied by microglia in these retinas were observed. COVID-19 group showed a more severe degeneration of cones. Cone degeneration correlated with Müller cell activation. Age of COVID patients correlated inversely with total retinal degeneration.

Conclusions: Morphological alterations in the cone photoreceptors as well as glial activation showing an inflammatory state of the retina were observed in COVID-19 patients.

ABSTRACT BODY:

Purpose: To characterize the two-year progression of neurodegeneration in different diabetic retinopathy (DR) risk phenotypes in type 2 diabetes.

Methods: A prospective longitudinal cohort study (CORDIS, NCT03696810) was conducted with 3 visits (baseline, 6-months and one-year). Demographic and systemic data included age, sex, diabetes duration, lipidic profile and hemoglobin A1c (HbA1c). Ophthalmological examinations included visual acuity (BCVA), color fundus photography (CFP) and optical coherence tomography (OCT and OCTA). Phenotype classification was performed, at 6-month visit, based on microaneurysm turnover (MAT, on CFP) and central retinal thickness (CRT, on OCT). Only risk phenotypes B (MAT<6 and increased CRT) and C (MAT≥6 with or without increased CRT) were included. ETDRS grading was performed at the baseline and last visit based on 7-fields CFP.

Results: Of the 133 T2D individuals included in the study, 81 (60%) eyes were classified as phenotype B and 52 (40%) eyes as phenotype C. Of these, 127 completed the two-year follow-up, with 24 (19%) developing central involved macular edema (CIME) and 2 (1.6%) clinically significant macular edema (CSME).
Neurodegeneration represented by thinning of the GCL+IPL was present in both phenotypes showing no differences between these phenotypes. Furthermore, GCL+IPL thickness decreased with time (average of -0.605 µm/year; p=0.010). This decrease remained statistically significant (ß=0.624, p=0.006) when controlling for age, sex, diabetes duration and HbA1c. Changes in time for GCL+IPL thickness are also associated with longitudinal changes in FAZ area, FAZ perimeter and deep capillary plexus vessel density particularly in phenotype C. No correlation was found between the presence of increased neurodegeneration and the development of CIME.

Conclusions: In the two-year period of follow-up both phenotypes B and C showed similar progression in retinal neurodegenerative changes. The neurodegeneration is associated with microvascular related variables indicative of capillary closure. There is no association between the progression in neurodegeneration and development of CIME.

ABSTRACT BODY:

Purpose: To study thickness of intraretinal segmentations at the fovea and parafovea in dyslexic individuals and controls.

Methods: 22 dyslexic participants and 22 non-dyslexic controls had OCT scans of the macula using the 8x8 posterior pole algorithm. The sixteen most centrally-located superpixels of the grid, corresponding to the fovea and parafovea (4x4 grid), were considered in the these segmentations: complete retina, outer retina, inner retina, outer nuclear layer + outer plexiform layer + inner nuclear layer (ONL+OPL+INL, in other words, middle retinal layers) and ganglion cell complex (GCC). The results of the right and left eyes were compared between groups with unpaired t test.

Results: Significant increases of thickness in the superpixels of the studied 4x4 grid were found in the dyslexic group in right an left eyes, mainly in ONL+OPL+INL (13 thicker cells in the right eye and 16 in the left one in the dyslexic group, with mean superpixel thickening ranging from 4.95 to 11.15 microns) but also in complete retina (4 thicker superpixels in the right eye and 8 in the left one in the dyslexic group, with mean superpixel thickening ranging from 7.80 to 11.30 microns) and inner retina (6 thicker superpixels in the right eye and 10 in the left one in the dyslexic group, with mean superpixel thickening ranging from 6.50 to 12.4 microns). In contrast, GCC only showed one thicker superpixel in the dyslexic group (in the left eye, with mean superpixel thickening of 4.33 microns, but none in the right eye) and outer retina did not show any significant difference in the superpixels of right or left eyes between groups.

Conclusions: Middle retinal layers are thicker at the fovea and parafovea in dyslexia. This fact allows to consider that the fovea and parafovea could play a role in dyslexia.

TITLE: All-trans retinoic acid function in multiocular organoids early development: effects in pigmentation, neuroretina maturation, and corneal transparency

SESSION TITLE: Mechanisms of Refractive Error and Eye Development

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Isla, M. Zufiaurre, J. García-Arumí, A. Duarri, Ophthalmology, Vall d'Hebron Institut de Recerca, Barcelona, Catalunya, SPAIN|

Commercial Relationships Disclosure: Helena Isla: Commercial Relationship: Code N (No Commercial Relationship) | Maddalen Zufiaurre: Commercial Relationship: Code N (No Commercial Relationship) | José García-Arumí: Commercial Relationship: Code N (No Commercial Relationship) | Anna Duarri: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: All-trans retinoic acid (ATRA) plays an essential role during human eye development, being temporally and spatially adjusted to create gradient concentrations. Perturbations in ATRA signaling can result in severe ocular developmental diseases including microphthalmia, anophthalmia, or coloboma. However, the effects of ATRA in the different ocular tissues during embryonic development of the eye remain unknown. Here we performed a preclinical study to test the effects of high and low ATRA concentrations on early development and maturation of ocular tissues using an in vitro model of human induced pluripotent stem cells (hiPSC) derived multiocular organoids.

Methods: The differentiation protocol started by multizone ocular progenitor cells generation from hiPSC in 2D, and lifted at day 30, to generate 3D ocular organoids consisting of retina, retinal pigment epithelium (RPE) and cornea. Organoids in suspension were cultured in medium containing low or high ATRA concentrations from days 30 to 90. Histology, immunochemistry, PCR and WB were used to study gene and protein differential expression among groups. Unpaired two-tailed Student’s t-test was applied to determine statistical significance between high and low ATRA concentrations groups. For more than two groups, 2-way ANOVA with Bonferroni posttest was used.

Results: Significant differences were observed between tested groups revealing some effects of ATRA during early eye development. The presence of high ATRA concentration promotes transparent corneal organoids and neuroretinal development in retinal organoids while inhibiting the pigmentation of RPE organoids and the maturation of photoreceptors (PR). By contrast, low ATRA concentrations enhanced pigmentation of RPE organoids, the opacity of corneal organoids - due to an increase of collagen type IV in the stroma– and PR maturation in retinal organoids.

Conclusions: ATRA modulates the corneal epithelial integrity and transparency, promotes PR development and maturation of the RPE in a dose-dependent manner. These results demonstrate the relevance of ATRA during ocular tissue development and suggest a potential new strategy to better modulate the development and maturation of ocular organoids by controlling ATRA concentrations temporally and spatially.

ABSTRACT BODY:

Purpose: To develop an interpretable machine learning model to predict anti-VEGF treatment requirements for previously treated patients with nAMD.

Methods: 547 patients from the ranibizumab 0.5 and 2.0 mg as-needed arms of HARBOR (NCT00891735) were included. 144 (26%) patients had a high treatment requirement (≥ 6 injections from 9 visits between month [M] 9 and M17). Boundaries of 5 retinal layers and 4 pathological features (intra- and subretinal fluid [IRF, SRF], subretinal hyperreflective material, pigment epithelial detachment [PED]) were automatically segmented from spectral-domain OCT (SD-OCT) scans acquired at M9 and M10. Segmentations were used to extract quantitative features (69 for layers, 36 for the 4 pathologies per visit). Extreme gradient-boosting model was used for binary classification using stratified 5-fold cross-validation repeated 10 times. The experiment was run separately for each feature group (4 pathologies and layers) and on the combined set of all features. Feature importance was analyzed using SHapley Additive exPlanations (SHAP).

Results: The best performance was achieved with retinal layers (area under the receiver operating characteristic curve [AUC], 0.76 ± 0.04 with M9 only and 0.79 ± 0.05 with M9 and M10 data) and was very close to the performance with the combined set of all features. For all experiments, adding M10 data only improved the results marginally. The layer features also contain information about the presence of pathologies such as fluids and cysts (thickness and volume increase), and therefore achieved better performance than individual pathological feature groups (Figure 1). However, good performance was observed for the SRF alone (AUC > 0.70), as well as for the PED features (Figure 1, Table 1). Predictive value of SRF and PED was confirmed by SHAP analysis (Table 1), where they were among the most important features.

Conclusions: This exploratory study showed the feasibility of identifying future high treatment requirements for previously treated patients with nAMD using automatically segmented SD-OCT. Further confirmation of model performance will contribute to future development of personalized health care algorithms.

ABSTRACT BODY:

Purpose: Ultraviolet B (UVB) irradiation may induce DNA lesions in all directly exposed tissues. In the human body, only two tissues are chronically exposed to UV: the skin and the cornea. The cornea lacks some of the phsycical barrier properties that the skin has, this makes the cornea particularly vulnearable damage. The induction of autophagy, a process that removes damaged cytoplasmic components, is of great importance in the cornea and extremely so in the stem cells that maintain the cornea. Here, we aim to characterise autophagy in isolated corneal epithelial stem cells (CESC) exposed to UV.

Methods: Epithelial cells were extracted from the limbus of discarded donor cornea (n=3). The cells were sorted to remove any fibroblasts. Cells were irradiated with 0.05J/cm^2 UVB. Autophagy and stem cells markers were observed using qPCR and immunofluorescent imaging. UVB damage was confirmed using DNA-lesion immunofluorescence assay.

Results: The putative stem cell character was assessed with ABCB5 and p63a. In culture, p63a+ epithelial cells have a high expression of mTOR that decreases by -0.96±0.6 log2 fold with UVB irradiation. Additionally, phosphrylated-mTOR (p-mTOR) position changes in CESC after irradiation, concentrating at the nucleus. Other assayed autophagy controllers had increased expression following UVB irradiation. ATG5 expression increased by 6.9±0.08 log2 fold, ATG7 expression increased by 7.7±2.9 log2 fold, ATG12 expression increased by 2.9±0.4 log2 fold, and LC3B expression increased by 1.05±0.3 log2 fold.

Conclusions: The decrease in expression of mTOR expression as well as the relocalisation of p-mTOR to the nucleus suggests that autophagy in CESC cytolasm is no longer inhibited. Additionally, both higher expression and visible presence of key autophagy controllers ATG5, ATG7, ATG12, and LC3B strongly suggests that short UVB exposure triggers autophagy in CESC.

ABSTRACT BODY:

Purpose: The cornea is physiologically free of blood and lymphatic vessels ([lymph]angiogenic privilege). However, injury or inflammation may lead to an ingrowth of these vessels. Recently, corneal lymphangiogenesis (LA) has been implicated to play a role in the regulation of corneal edema and inflammation resolution. Nuclear factor of activated T-cells 5 (NFAT5/TonEBP) has recently been identified as an important transcription factor that regulates LA and fluid homeostasis in skin. Here, NFAT5 enhances the expression of pro-lymphangiogenic vascular endothelial growth factor C (VEGF-C) in skin macrophages (MΦ), resulting in increased LA. So far, it has not been investigated whether NFAT5 is expressed in the cornea and which role it plays in the inflammatory response after corneal injury.

Methods: The corneal expression pattern of NFAT5 was investigated by immunofluorescence staining (IF) and qPCR in naïve and injured mouse corneas using a perforating corneal injury model to induce inflammation, LA and edema. The role of NFAT5 in corneal inflammation and the resolution of corneal edema was investigated using a tamoxifen-inducible NFAT5 knockout (KO) (Ubc-Cre/NFAT5$^{fl/fl}$) mouse model. Corneal thickness and resolution of corneal edema was measured by optical coherence tomography (OCT). Inflammation and LA were analyzed using IF.

Results: In naive corneas, NFAT5 was mainly expressed in corneal fibroblasts. After injury, NFAT5 expression in fibroblasts was downregulated and mainly expressed by MΦ (Correlation coefficient of TonEBP^{+}/Vimentin^{+}: 0.446±0.111 in naive corneas vs 0.153±0.024 after injury [p<0.0001]); TonEBP^{+}/F480^{+}: 0.113±0.032 in naive cornea vs. 0.446±0.018 after injury [p<0.0001]). In uninjured corneas, NFAT5 KO did not lead to changes in corneal thickness, however, the number of MΦ was significantly increased (24.76±3.54% in KO vs. 16.14±0.36%; p=0.0094 of corneal area covered by F480^{+} cells). After injury, the resolution of corneal edema was enhanced in NFAT5 KO mice (corneal thickness: 97.1±10.0 µm in KO vs. 137.1±28.8 µm [p=0.002]).

Conclusions: Our results demonstrate that NFAT5 is highly expressed in the cornea and its expression shows considerable changes after injury. Furthermore, our data indicate that the loss of NFAT5 leads to a faster resolution of corneal edema. The suppression of NFAT5 might be a promising strategy for the treatment of diseases associated with corneal edema.

ABSTRACT BODY:

Purpose: Bilateral acute iris transillumination (BAIT) is characterized by conjunctival injection and photophobia, with clinical findings of bilateral severe iris transillumination, pupils that are fixed and mid-dilated, and anterior chamber pigment dispersion. BAIT has a documented association with antibiotic use, in particular systemic moxifloxacin. The data regarding predisposing factors and demographic characteristics in the Latino population is limited. Our retrospective study aims to report the clinical and demographic characteristics and identify risk factors leading to BAIT in our population.

Methods: A retrospective review of patients diagnosed with BAIT was performed in two private ophthalmology practices in San Juan, Puerto Rico. All the patients were personally examined by either of two uveitis specialists who established the BAIT diagnosis. Prior to the diagnosis, all patients underwent an extensive systemic workup to rule out other possible etiologies such as HSV, syphilis, tuberculosis, and sarcoidosis; no evidence of these or other systemic conditions to explain the diagnosis of BAIT was found.

Results: A total of 72 eyes of 36 patients with BAIT were identified. The total antibiotic use within our BAIT cohort was 83%, of which 66% reported the use of moxifloxacin. The median age at presentation was 53 years; 80% of the patients were female. The most common systemic conditions were hypertension (31%) and chronic obstructive pulmonary disease (17%). Seventy-two percent of eyes had a best-corrected visual acuity greater than or equal to 20/50. At presentation, the median intraocular pressure (IOP) was 18 mmHg (range 8-50); 20 eyes (27%) had IOP greater than 21 mmHg, and 18 had IOP greater than or equal to 30 mm Hg. Anterior uveitis and pigmented cells in the anterior chamber, both observed in 38% of eyes, were the most prevalent associated ocular findings. Transillumination was diffuse in 59% of patients, and 63% also had pupillary sphincter atrophy.

Conclusions: As reported in prior studies, within our cohort, BAIT was more common in women, and the most common antibiotic predisposing to BAIT was moxifloxacin. To our knowledge, this is the first retrospective epidemiologic study of BAIT in the Puerto Rican population.

ABSTRACT BODY:

Purpose: Attendance for diabetic retinopathy screening (DRS) in young adults (YAs) is consistently below recommended levels. We used a behavioural approach to develop intervention strategies to improve uptake that target YAs, healthcare professionals (HCPs) and the healthcare system.

Methods: We identified barriers/enablers to DRS uptake through a process of qualitative interviews and online surveys with YAs (18-34 years) and HCPs. Data were collected and analysed using the Theoretical Domains Framework (TDF) to explore potential individual, sociocultural and environmental influences on attendance. Barriers/enablers were mapped to behaviour change techniques (BCTs) to identify potential intervention components to increase attendance. We then undertook a Knowledge Exchange process with stakeholders to prioritise and discuss the acceptability and feasibility of delivering the proposed interventions.

Results: Barriers to attendance reported by YA in 29 qualitative interviews included: not understanding reasons for attending DRS or available treatments (22/29), lack of support after receiving results (12/29) and lack of appointment flexibility (14/29). Social support of family and the diabetes team was a key enabler (14/29). Reported HCP barriers by 140 survey respondents included poor communication between HCPS involved in diabetes care (62.9%) and 46.1% of DRS providers lacked a dedicated strategy to improve screening uptake in YAs. Strategies perceived by stakeholders to be most likely to improve screening uptake included: tailored health information packages emphasising the positive outcomes of DRS, a more flexible appointment booking system and integration of DRS with other aspects of diabetes care.

Conclusions: Using a method that combines behavioural theory with user involvement, we have identified a number of strategies to support DRS attendance in YAs. Interventions are more likely to be effective if they include components that specifically target the empirically identified modifiable determinants of behaviour and behaviour change. Interventions need to be targeted at both individual and organizational levels and are likely to vary in scope and intensity.

TITLE: FOXD1 is involved in uveal melanocyte development and associated with high-risk uveal melanoma

SESSION TITLE: Where art thou tumor? - Ocular tumor physiology and metastases

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: Q.V. Bosch, J. Nguyen, T. Brands, D. Paridaens, N. Naus, E. Kilic, Ophthalmology, Erasmus Universiteit Rotterdam, Rotterdam, Zuid-Holland, NETHERLANDS|T. van den Bosch, R. Verdijk, Pathology, Erasmus Universiteit Rotterdam, Rotterdam, Zuid-Holland, NETHERLANDS|Q.V. Bosch, T. Brands, A. de Klein, E. Brosens, Clinical Genetics, Erasmus Universiteit Rotterdam, Rotterdam, Zuid-Holland, NETHERLANDS|

ABSTRACT BODY:

Purpose: Uveal melanoma (UM) arises from melanocytes located in the uveal tract and is the most common primary intraocular malignancy. Driver mutations are mainly found in GNAQ and GNA11, followed by mutually exclusive mutations in BAP1, SF3B1 and EIF1AX which predicts prognosis. (Fig.1A) BAP1-UM is known to be highly aggressive, although the mechanism remains unclear. Multiple studies used transcriptomics to study BAP1-UM and implicate a more stem-like profile in BAP1-UM with an unique immune-landscape compared to SF3B1- and EIF1AX-UM. We hypothesized that BAP1-UM reactivate genes involved in uveal melanocyte development to increase aggressiveness. To identify transcripts involved in uveal melanocyte development, we used public scRNA-seq datasets of zebrafish and human and validated our finding in RNA-seq datasets of UM

Methods: To gain insights in uveal melanocyte transcriptomes, we utilized embryonic zebrafish scRNA-seq datasets lacking the eyes and used genes found in melanocytes as a filter against whole zebrafish scRNA-seq. Similarly, we used postnatal human skin scRNA-seq dataset as a filter against human eye to identify uveal melanocyte genes. Uniquely found transcripts in ocular melanocytes were then validated in 106 UM samples (Fig.1B)

Results: After filtering the zebrafish dataset, cluster 199 was identified as uveal melanocytes. Expression of melanocyte core genes (Fig.2A) and ocular genes pmelb and otx1 (Fig.2B) were expected, yet interestingly we uniquely found foxd1 to be involved in this cluster. We were unable to detect FOXD1 in healthy human scRNA-seq, suggesting spatial expression during embryonic vertebrate development. This prompted us to study FOXD1 in UM and found near exclusive expression in the BAP1-UM (Fig.2C), which is correlated to poor prognosis (Fig.2D)

Conclusions: Using a multi-species scRNA-seq approach we found genes involved ocular pigmentation and identified foxd1 in embryonic zebrafish melanocytes. Absence of FOXD1 transcripts in healthy human ocular melanocytes suggested spatial expression of FOXD1 as the human dataset consists of postnatal tissue. In UM we found expression of FOXD1 in BAP1-UM, which is correlated to poor prognosis. This study identified FOXD1 as a novel gene involved in high-risk UM

TITLE: Does vision correlate with overall development in children with cerebral visual impairment?

SESSION TITLE: Pediatric ophthalmology and imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R.S. Chakram, P. Satgunam, LV Prasad Eye Institute, Hyderabad, Telangana, INDIA| R.S. Chakram, A. Subramanian, M. Conway, City University of London, London, London, UNITED KINGDOM|L. Lingappa, P. Errolla, S. Naraganti, U. Hyndavi, Rainbow Children's Hospital Banjara Hills, Hyderabad, Telangana, INDIA|

Commercial Relationships Disclosure: Rebecca Chakram: Commercial Relationship: Code N (No Commercial Relationship) | PremNandhini Satgunam: Commercial Relationship: Code N (No Commercial Relationship) | Ahalya Subramanian: Commercial Relationship: Code N (No Commercial Relationship) | Miriam Conway: Commercial Relationship: Code N (No Commercial Relationship) | Lokesh Lingappa: Commercial Relationship: Code N (No Commercial Relationship) | Premalatha Errolla: Commercial Relationship: Code N (No Commercial Relationship) | Somasekhar Naraganti: Commercial Relationship: Code N (No Commercial Relationship) | Usha Hyndavi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A significant portion of a child's early overall development is accomplished through visual learning. Children with neurological conditions such as cerebral visual impairment (CVI) are likely to have visual concerns as well as developmental delays in areas such as motor, cognition and speech. Through this study, we aim to determine the correlation between vision loss and the overall development of children with CVI.

Methods: A prospective cross-sectional study was conducted on children with CVI visiting a paediatric neurology unit in India. Grating acuity (Teller Acuity Cards), contrast sensitivity (Ohio Contrast Cards), functional vision (Lantzy's CVI range; phase 1=building visual behaviour, phase 2=integrating vision with functions, phase 3=resolution of CVI characteristics) and developmental quotient (DQ) (Denver Developmental Screening Test-II) were assessed.

Results: Forty-seven children (males: 35) with CVI were included with a mean chronological age of 2.9±1.7 years (range= 9 months to 6.8 years). The mean binocular grating acuity was 1.35±0.67 logMAR (range=2.27 to 0.37 logMAR) and mean binocular contrast sensitivity was 0.49±0.56 logCS (range=0.0 to 1.66 logCS). Grating acuity ($r=-0.36$, $p=0.01$), contrast sensitivity ($r=0.41$, $p<0.01$) and functional vision score ($r=0.5$, $p<0.01$) were significantly and moderately correlated with DQ. Using linear mixed model (age adjusted), the outcome parameters of grating acuity, contrast sensitivity and DQ were compared to the CVI phases. Significant difference was noted across the 3 phases of CVI for grating acuity ($p<0.01$). There was no significant difference between phase 1 and 2 for contrast sensitivity and DQ ($p=0.09$), however phase 3 showed significant difference when compared with other two phases ($p<0.01$).

Conclusions: Vision parameters correlate with DQ in children with CVI. Although there is no separate vision domain in most developmental screening tools, psychologists could consider referring children particularly with lower DQs for vision assessment. Eye-care personnel should also ensure providing referrals to therapists for child's overall development particularly during the early years. The results do not establish any causation between the 2 parameters (visual vs. DQ) and can be further explored by studying the DQs of children having ocular visual impairment and no additional developmental delays.

TITLE: Assessment of the bivariate contour ellipse area (BCEA) as a marker of microperimetry reliability

SESSION TITLE: Fundamental and Applied Psychophysics and Color Vision

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.S. Josan, L. Taylor, R.E. MacLaren, University of Oxford Nuffield Laboratory of Ophthalmology, Oxford, Oxfordshire, UNITED KINGDOM|A.S. Josan, T.M. Buckley, L. Taylor, R.E. MacLaren, Oxford Eye Hospital, Oxford, Oxfordshire, UNITED KINGDOM|

Commercial Relationships Disclosure: Amandeep Josan: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Buckley: Commercial Relationship: Code N (No Commercial Relationship) | Laura Taylor: Commercial Relationship: Code N (No Commercial Relationship) | Robert MacLaren: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Microperimetry has increased the accuracy in measurement of retinal sensitivity compared with standard perimetry. It is increasingly utilised in assessing the effects of novel therapies. However, errors from loss of fundus tracking has not been quantified resulting in a lack of understanding of the limitations and reliability of any given examination, particularly in those with poor fixation. The currently used measure, fixation losses, only samples the optic nerve approximately once every minute and may lead to erroneous conclusions about reliability. This study quantifies reliability using fixation data gathered in the form of the 63% and 95% fixation bivariate contour ellipse areas (BCEA63 and BCEA95).

Methods: A custom grid of 181 densely arranged points was constructed using the Macular Integrity Assessment System (MAIA; CenterVue, Padova, Italy), (see fig 1). This grid was centred on the optic nerve of 16 healthy participants and the scotoma mapped. The test was repeated with the participant's gaze directed away from the fixation target in an attempt to reduce fixation performance. Number of false positives and BCEA63 and BCEA95 values extracted for each participant.

Results: Of the 16 participants, four were rejected due to small pupils. A linear mixed effects model with BCEA as the fixed effect independent variable and participant ID as the random effect variable demonstrated a significant ($p = 0.006$) linear correlation between the number of false positives and the BCEA. A value of 30 percent false positives corresponds to a BCEA95 of 143 degrees^2 and a BCEA63 of 48 degrees^2.

Conclusions: The MAIA microperimeter gathers a significant amount of fixation information during testing. We have shown for the first time that this fixation data is significantly correlated to the reliability of any given examination with BCEA providing a surrogate marker for test accuracy. Further investigations is warranted to determine what an acceptable false positive value should be as the current value of 30% derives largely from historical static perimetry glaucoma studies. This study suggests any examination with a BCEA63 or BCEA95 of greater than 48 and 143 degrees^2 respectively should be viewed with caution and considered potentially unreliable regardless of the quoted level of fixation losses.

ABSTRACT BODY:

Purpose: To evaluate the effectiveness of citicoline (Cebrolux ®), Vitamin C and docosahexaenoic acid (Brudypio ®) on the visual function of glaucoma patients.

Methods: This ongoing study is a prospective, randomized and controlled study. On December 2021, 67 patients had finalized the study. All participant persons had chronic glaucoma with structural damage as measured by OCT and visual-field damage compatible with glaucoma, mean defect (MD) between – 4 dB and -20 dB at least in one eye, a minimum of 3 reliable fields before baseline and 3 after baseline and, age between 50 and 75 years old. Persons were excluded if they were taken vitamins or nutraceutical treatments, or suffered pathologies that could alter visual fields, or had hypersensitivity to acetylsalicylic acid or fish proteins, or prior glaucoma surgery. Persons were randomly assigned receive vitamin C (VC), docosahexaenoic acid (DHA), Citicoline (C) or C + DHA. MD and Visual Field Index (VFI) slopes were calculated and a minimum positive slope-change ≥ 0,5 dB/month (MD) or ≥1.5 %/month (VFI) were considered clinically significant. Percentage of persons with positive slope-change was calculated and its association with a certain treatment was analyzed with Chi-squared test. Mann Whitney Test and T test were used to compare MD and VFI slopes, pre and post-treatment in every group.

Results: Table 1 shows mean ± sd of slopes by group:

Chi-squared test showed association with slope improvement of 0.5 dB/month in MD (p=0.003) and 1.5 %/month in VFI (p=0.02) for group 4 only. Furthermore, only group 4 showed significant improvement in MD (p=0.001) and VFI slopes (p=0.003) after 3 months of treatment.

Conclusions: C + DHA treatment improved visual field results of persons with glaucoma at short term. A larger, longer and multicenter study would be advisable to confirm these results.

ABSTRACT BODY:

Purpose: To understand measurements variability between 2 different OCTA devices and to develop a conversion model that translate vascular metrics into a standardized and comparable value in patients with different stages of DR.

Methods: A cross-sectional study was conducted in 55 patients (n=108 eyes) with diabetes type 2 (68.1±9.3yrs), 37(67%) were males.

Each eye underwent 3x3mm OCTA scans in AngioVue (Optovue RTVue,Optovue Inc) followed by 3x3mm OCTA scans in Angioplex (Cirrus HD-OCT 5000,Zeiss Meditec Inc) both centred on fovea. The Foveal Avascular Zone(FAZ) area and perimeter and the binarized Vessel Density(bVD) in the Central area, Inner Ring (3mm ø centred on fovea) and full 3mm^2 area were collected from the Superficial Capillary plexus(SCP) images of both equipments. Agreement between AngioVue and Angioplex measurements was assessed by Intraclass Correlation Coefficient(ICC) and Bland-Altman plots. A conversion equation was established to transform bVD values from Angiovue in Angioplex-equivalent values. This equation was built using repeated-measures models with generalized estimating equations to account for the correlation in participants with 2 study eyes, with Angioplex measurement as the dependent variable and AngioVue measurement as the independent variable.

Results: Binarized VD values measured by AngioVue were significantly higher than those by Angioplex (inner ring: 42.9±4.8vs35.6±3.3; $p<0.001$). However, a good ICC between both equipments was found for FAZ metrics (0.66 (0.52-0.77) for area and 0.59 (0.45–0.70) for perimeter), showing a good agreement of these metrics independently of the device.

Regarding the conversion model between devices, the following equation was derived: Angioplex bVD=(Angiovue bVD x 0.45) + 16.3. With this equation,84% of the Angioplex-equivalent bVD values fell within 10% of the real measurements using Angioplex. The obtained difference between converted and real values of bVD was <7.21.

Conclusions: Despite the use of distinct algorithms to detect binarized retina VD between different OCTA equipments, we propose a conversion model to obtain comparable bVD measurements between AngioVue and Angioplex devices in diabetic eyes with distinct levels of severity. This conversion model opens important possibilities for clinical trials to pool data from different OCTA instruments, allowing comparison of results within and between groups that are using distinct instruments.

ABSTRACT BODY:

Purpose: Cerebral visual impairment (CVI) is a common cause of pediatric visual impairment globally. Children with CVI can have additional developmental delays in areas such as motor, cognition and speech. The location/extent of brain damage, frequency of seizures, medication can all contribute to the variability of clinical measurements in these children. Therefore it will be important to identify clinical tools with good repeatability to monitor and manage this condition. In this study, we aimed to determine the repeatability indices of 2 important clinical tests: grating acuity [Teller acuity cards (TAC), Peekaboo Vision app (PV)] and contrast sensitivity [Hiding Heidi cards (HH) and Ohio contrast cards (OCC)] tests in children with CVI.

Methods: A cross-sectional, prospective study was conducted on children with CVI visiting a paediatric neurology clinic in Hyderabad, India. Informed written consent was taken from parents. Grating acuity and contrast sensitivity tests were administered in a randomized sequence and testing time was recorded. Test-retest repeatability was carried out within 3.5 months on average.

Results: Thirty-two children (males: 22) with a mean age of 2.6±1.7 years (range: 9 months to 6.8 years) were recruited. Significantly different acuities were obtained with PV and TAC ($p<0.01$, 95% limits of agreement (LoA): -0.67 to 0.33 logMAR). Teller acuity cards (Coefficient of Repeatability (CR): 0.3) had better repeatability when compared to PV (CR: 0.83). Testing time with both acuity tests was found to be comparable ($p=0.76$). Significantly different contrast sensitivities were obtained with HH and OCC ($p=0.02$, 95% LoA: -0.31 to 0.47 logCS). Ohio contrast cards (CR: 0.32) had better repeatability when compared to HH (CR: 0.5). Significantly lesser time was taken to administer HH compared to OCC ($p<0.01$).

Conclusions: Repeatability was found to be better for TAC and OCC in measuring grating acuity and contrast sensitivity respectively. Differences in thresholding paradigms, number of cards depending on the step sizes measured and different types of stimuli could be the possible reasons for poor agreement between the tests. Choice of visual function tests for children with CVI should consider the repeatability measure, especially for longitudinal follow-ups.

ABSTRACT BODY:

Purpose: Inflammation, oxidative and nitrosative stress are involved in neovascular retinopathies (NR). Nitro-fatty acids are important electrophilic signaling mediators with anti-inflammatory, antioxidant and cytoprotective properties. Therefore, our aim is to evaluate the effect of Nitro-oleic acid (NO_2-OA) in a mouse model of oxygen-induced retinopathy (OIR).

Methods: OIR mouse model was used. Briefly, C57BL/6 mice (n=35) were exposed to 75% O_2 from P7 to P12, after which they were brought to room air (RA) for additional five (P17) or fourteen days (P26). Age-match mice maintained in RA (n=25) were used as controls. OIR mice were intraocular (i.o.) injected with 5 µM of NO_2-OA (n=22) or vehicle (n=13) at P12 and intraperitoneal (i.p) with 15 mg/Kg of NO_2-OA or vehicle at P14, P17, P20, P23. At P17 or P26 mice were sacrificed. Some eyes were fixed for whole mount staining of retina and microscopy and other retinas were used for Western blot or RT-PCR assays. Retinal functionality was assessed by scotopic electroretinography (ERG) in dark-adapted mice. Amplitudes and latencies of a- and b-waves from ERG were recorded at P17 or P26. Finally, the NO_2-OA effect on neovascularization was evaluated by tube formation assay in bovine aortic endothelial cells (BAEC). GraphPad Prism was used for statistical analysis.

Results: NO_2-OA induced vascular regrowth ($p<0.05$) and decrease pathological neovascularization ($p<0.001$) at P17 OIR. Interestingly, RT-PCR revealed a significant increase in VEGF levels in OIR mice respect to RA mice ($p<0.0001$), but not difference was found between NO_2-OA treatment and vehicle ($p=0.9978$). In addition, WB of neural retinas showed that NO_2-OA prevented glial stress by decreasing GFAP ($p<0.0001$) in OIR model at P17 ($p=0.3160$). In the other hand, NO_2-OA did not modify the ($p=0.0177$) levels of GS at P17 ($p=0.0003$). At P26, ERG shown that NO_2-OA treated mice prevented the decrease in b-wave amplitude ($p=0.1362$) as well as increasing the expression of total Caspase-3 ($p=0.0004$) as a marker of cellular protection. Finally, it was observed that NO_2-OA affected neovascularization by decreasing the total segment length ($p<0.0001$) and number of tubular structures ($p<0.0001$) in BAEC cells.

Conclusions: These findings suggest that NO_2-OA could be beneficial for retinal cells in order to attenuate vascular and non-vascular alterations in NR.

ABSTRACT BODY:

Purpose: To characterize the two-years progression of two diabetic retinopathy (DR) risk phenotypes in type 2 diabetes (T2D).

Methods: A prospective longitudinal cohort study (CORDIS, NCT03696810) was conducted with 4 visits (baseline, 6-months, one-year and two-year). Demographic and systemic data included age, sex, diabetes duration, lipidic profile and hemoglobin A1c (HbA1c). Ophthalmological examinations including visual acuity (BCVA), color fundus photography (CFP) and optical coherence tomography (OCT and OCTA), identified the presence of nonproliferative diabetic retinopathy (NPDR). Phenotype classification was performed, at 6-month visit, based on microaneurysm turnover (MAT, on CFP) and central retinal thickness (CRT, on OCT). Only risk phenotypes B (MAT<6 and increased CRT) and C (MAT≥6 with or without increased CRT) were included. ETDRS grading was performed at the baseline and last visits based on 7-fields CFP.

Results: 133 T2D individuals were included in the study, 81 (60%) eyes classified as phenotype B and 52 (40%) eyes as phenotype C. Of these, 127 completed the two-year follow-up, 24 (19%) developed central-involved macular edema (CIME) and 2 clinically significant macular edema (CSME) (1.6%). In the two-year period, two-step severity progression (ETDRS) occurred only in one eye with phenotype C.

At baseline, eyes with phenotype C showed more capillary closure in the superficial capillary plexus (SCP), deep capillary plexus (DCP) and full retina (FR, p<0,001) and increased FAZ area (p<0,001), indicating more advanced microvascular disease and confirming the ischemia phenotype. During the two-year period both phenotypes, B and C, showed progression in GCL+IPL thinning (p<0,001) and decrease in vessel density in the DCP (<0,001). When analyzing the two-year progression of each phenotype, only phenotype C revealed significant decrease in BCVA (p=0,02) and enlargement of the FAZ (p=0,03). CSME developed only in phenotype C whereas CIME occurred in both risk phenotypes.

Conclusions: In the two-year period of follow-up both phenotypes B and C showed progression in retinal neurodegeneration associated with progression in capillary closure identified by progressive decrease in vessel density of the DCP. CIME developed in both phenotypes and CSME only in phenotype C.

ABSTRACT BODY:

Purpose: Structural and functional studies have implicated vitronectin (VTN), a human blood and extracellular matrix (ECM) protein, in the complex pathogenesis of age-related macular degeneration (AMD). Our aim was to further explore the role of this protein in AMD and the functional impact of the non-synonymous polymorphism rs704C>T in the VTN gene, significantly associated with AMD in a genome-wide association study (GWAS).

Methods: Based on the largest AMD GWAS dataset of the International AMD Genomics Consortium (IAMDGC), we performed an association analysis to refine the relationship of rs704 with AMD clinical subtypes in 16,144 cases and 17,832 controls. In vitro studies including protein interaction and activity assays, western blot analysis and immunofluorescence staining were conducted to investigate the effects of rs704 on VTN function, with a focus on the interaction of recombinant VTN isoforms (AMD risk-associated VTN_rs704:T and non-risk-associated VTN_rs704:C) with the binding partner and angiogenic regulator plasminogen activator inhibitor 1 (PAI-1), and their influence on PAI-1 production by cultured endothelial and retinal pigment epithelium (RPE) cells. In addition, a large-scale gene expression analysis was performed based on our retinal gene expression database (n=311) and the Genotype-Tissue Expression (GTEx) project (n=556).

Results: Our statistical analysis revealed an association of rs704 only with neovascular AMD (NVAMD; Q value <0.05). In in vitro assays, VTN_rs704:T showed a stronger binding to PAI-1 than VTN_rs704:C (1.50 ± 0.61-fold increase, p <0.05), while both isoforms equally sustained PAI-1 activity. Interestingly, exposure of endothelial and RPE cells to VTN isoforms resulted in a large accumulation of PAI-1 in the ECM compared to control-treated cells (p <0.05). In silico, gene expression of VTN and PAI-1 showed positive correlations and a statistically significant increase in human retinal and blood tissues aged 60 years and older.

Conclusions: Our findings link VTN function to the progression of NVAMD and suggest a mechanism whereby ageing and the AMD-associated rs704 variant may concomitantly alter angiogenesis-related processes regulated by VTN and PAI-1. This provides novel cues to understand NVAMD, eventually facilitating the development of target-based therapeutic options to prevent and cure the vascular complications in AMD.

ABSTRACT BODY:

Purpose: Pachychoroid neovasculopathy (PNV) have been recently noticed as a new clinical entity. On the other hand, PNV could not be a completely independent entity from the previous neovascular age-related macular degeneration (AMD) types, such as typical AMD, polypoidal choroidal vasculopathy (PCV), and retinal angiomatous proliferation (RAP), but some of each type might be determined to be PNV. In the current study, we retrospectively reviewed the clinical records of AMD patients and re-classified the AMDs to determine the prevalence of PNV.

Methods: One hundred and ten eyes of 100 consecutive patients diagnosed previously with AMD at Tokyo Women's Medical University Hospital were studied. All patients were Japanese over 50 years old, and the mean age was 75.6 years (72 males and 28 females). PNV was defined with macular neovascularization (MNV) detected just above the dilated choroidal vessels (Pachy-vessels), and choroidal thickness was not included in the definition. Locations of choroidal vessels, horizontal symmetric vortex vein, and watershed zone were evaluated on indocyanine green angiography (IA, HRA2, Heidelberg) and/or en face optical coherence tomography (OCT, Elite 9000, Zeiss). When polypoidal lesion was identified in IA, it was determined to be PCV. Subfoveal choroidal thickness (SCT) was also manually measured on OCT.

Results: Based on the current criteria, twenty-six patients (26.0%, 26 eyes) were diagnosed with PNV, 38 patients (38.0%, 44 eyes) with PCV, 29 patients (29.0%, 31 eyes) with typical AMD, and 7 patients (7.0%, 10 eyes) with RAP. All PNV cases (26 patients) diagnosed as typical AMD on the previous criteria. Asymmetric vortex vein and watershed zone shift were observed in 80.8% of PNV cases, which was significantly higher than in 40.0% of non-PNV cases ($P<0.01$). There was no significant difference in mean SCT between PNV and non-PNV cases (277±88μm vs 252±95μm, $P=0.21$).

Conclusions: According to our criteria, including the new entity of PNV, which excludes choroidal thickness as diagnostic index, PNV was identified in 26% of neovascular AMD in Japanese patients. The results of this study may have a significant impact on the treatment strategy for Japanese patients with MNV.

ABSTRACT BODY:

Purpose: Protocols for the primary culture of human corneal endothelial cells (hCECs) have several limitations: cultures are heterogeneous, have a limited capacity to grow without negatively affecting the cells, are only successful if derived from donors younger than 40, and there is a lack of markers to identify the high quality from inferior cells. We hypothesized that by gaining transcriptomic information from individual cells, markers to enrich for high quality clinical-grade CECs can be identified and protocols improved using the molecular pathway–level information gained.

Methods: Four human donor corneas, with ages ranging from 24 to 34 years were used for this study. hCECs were isolated and cultured as described by Peh et al. 2015. hCECs from all donors at culture time points day 2 (passage 0), day 5 (passage 0), day 14 (passage 0), day 30 (passage 1) and day 46 (passage 2) were sequenced with 10x Genomics 3’ V3.1 protocol. The data from all samples were loaded in R (v.3.6.2), processed with Seurat package (v.3.2.0), and cells clustered using graph-based clustering.

Results: Approximately 85,000 hCECs were loaded to 10x genomics. Data of 62,000 sequenced cells revealed the main clusters observed during primary expansion of hCECs. The sequenced cells expressed typical endothelial markers such as ALCAM, PRDX6, TJP1, and ATP1A1. Pseudotime analysis revealed the dynamics and variations in hCEC during primary expansion. Differential expression analysis will be used to identify the major differences between cell clusters at early and late time points. This will allow the identification of markers to differentiate high quality to lower quality hCECs. Furthermore, differential analysis will allow the identification of altered pathways during primary expansion of hCECs.

Conclusions: This work provides the first single cell analysis of primary cultured hCECs depicting their heterogeneity. This research allows deep understanding on the process of primary expansion of hCECs and sets the basis for further improvement of protocols and therapies based on primary hCECs.

ABSTRACT BODY:

Purpose: Including the fovea in the treatment spot during half-dose photodynamic therapy (PDT) in chronic central serous chorioretinopathy (cCSC) still is a topic of controversy, since a risk of developing foveal atrophy after PDT has been previously suggested. We performed a retrospective study with data from prospective randomized controlled trials, to assess the risk of foveal atrophy, as well as the likelihood of structural and functional improvement on OCT, after half-dose PDT treatment of cCSC that included the fovea.

Methods: In the randomized controlled trials PLACE and SPECTRA, a total of 57 cCSC patients received half-dose PDT with a treatment spot that included the fovea at least partially, and were included in the current study. Optical coherence tomography (OCT) scans were analyzed for signs of foveal atrophy, as well as structural improvement, at baseline visit, at 8-12 weeks, 1, and 2 years after half-dose PDT. Fluorescein angiograms (FA) at baseline visit and at 8-12 weeks were analyzed for the presence of an RPE window defect. Main outcome measures were integrity of the external limiting membrane (ELM) and the ellipsoid zone (EZ). Secondary outcomes involved best-corrected visual acuity (BCVA) in Early Treatment of Diabetic Retinopathy Study (ETDRS) letters, and retinal sensitivity on microperimetry.

Results: The ELM was considered intact at baseline in 21/57 (36.8%) of patients, increasing to 56/57 (98.2%; $p<0.001$) at 1 year, and 50/51 (98.0%; $p<0.001$) at 2 years. The EZ was intact at first visit after SRF resolution in 5/57 (8.8%). At 1 year after half-dose PDT, 30/57 (52.6%) of patients had regained an EZ with a completely normal aspect ($p<0.001$), which increased to 32/57 (56.1%) at 2 years after baseline visit ($p<0.001$). None of the patients showed a deterioration of the foveal ELM or EZ after treatment. No window defects on FA were seen foveally either before- or after treatment. Mean BCVA and retinal sensitivity improved significantly at 1 year after treatment (+6.72 ±7.34 ETDRS letters, $p<0.001$, and +3.88 ±2.22 dB, $p<0.001$, respectively), compared to baseline.

Conclusions: In patients with cCSC who received half-dose PDT with inclusion of the fovea in the treatment spot, a significant improvement in structural and functional parameters was seen at 2 years of follow-up. None of the patients had evidence of development of PDT-associated foveal atrophy.

ABSTRACT BODY:

Purpose: Gene replacement therapy has shown great promise in treating inherited retinal dystrophies, but its application to dominant diseases is limited. CRISPR-Cas9 base editing presents an alternative approach to correct dominant single nucleotide variants. We tested in vitro adenine and cytosine base editors (ABE, CBE) utilizing S. aureus Cas9 to treat the dominant RHO c.541G>A (p.E181K) mutation.

Methods: Available PAM sites were searched for the SaABE8e (Addgene #138500), KKH-SaABE8e (#138502) and the CBE SaBE4 (#100805), with single guide RNAs C[G>A]AGGGCCTGCAGTGCTCGTGtggaat and CAGGTACATCCCC[G>A]AGGGCCtgcagt; PAM sites in lower case letters. Transfections in HEK293 or patient fibroblasts with 700 ng base editor and 200 ng guide were performed using FuGene or Neon Electroporation kit. Editing efficiencies were determined 120h post-transfection by analyzing the sequencing data with EditR. Non-transfected cells and published guides were used as negative and positive controls.

Results: The RHO gene was successfully edited in HEK293 cells using SaABE8e and SaKKH-ABE8e constructs. For the SaABE8e, 45% editing efficiency was observed in guide position 12 and the SaKKH-ABE8e variant achieving 22% and 26% editing efficiencies of adenines at positions six and eight, respectively. However, editing at the adenine adjacent to the mutation site in each target sequence was not detected. The SaBE4 was confirmed to be active, achieving 19% editing with a published guide. Attempts were then made to introduce a mutant-allele specific stop codon by converting the C at guide position 11 into a T, thus converting a glutamine codon “CAG” into a stop codon “TAG”. Despite validation of both the SaBE4 construct and the guide, editing at the RHO locus was not detected in either HEK293 cells or patient fibroblasts.

Conclusions: The tested ABEs produced high editing efficiencies of the RHO gene. However, absence of editing at the adenine adjacent to the mutation site suggested the target base does not fall within the constructs’ editing window. Further optimizations for the guides or choosing alternative ABE with different PAM site are needed to correct the RHO c.541G>A mutation. The tested CBE did produce editing with a published guide, but need further optimization to efficiently edit the RHO locus.

ABSTRACT BODY:

Purpose: To report the outcomes of focal thermal laser photocoagulation in polypoidal choroidal vasculopathy (PCV) patients from a Dutch referral center.

Methods: We describe a retrospective series of 24 eyes with indocyanine green angiography (ICGA)-proven PCV who had received focal laser photocoagulation. Inclusion criteria were: 1) the presence of either one or a cluster of extrafoveal polyps in the early phase of ICGA, with or without a co-existing neovascular network, 2) the presence of visual symptoms, and 3) the performance of focal laser photocoagulation, but no intravitreal injections with anti-vascular endothelial growth factor (VEGF) medication for at least 6 weeks before laser photocoagulation.

Results: Twenty-four eyes of 22 patients were included. The mean age of patients was 72 years, with a female predominance (82%). The most common clinical features at presentation were exudates (88%), either serous or hemorrhagic pigment epithelial detachments (PEDs) (58%), and (sub)retinal hemorrhages (46%). During the mean total follow-up of more than 2 years, focal laser photocoagulation was applied once in 14 eyes (58%), and multiple times in 10 eyes (42%). Three months after laser photocoagulation, exudates were only seen in 17% of cases, serous or hemorrhagic PEDs in 4%, and hemorrhages in 4%. Over the first 3 months following laser photocoagulation, best-corrected visual acuity (BCVA) in Snellen improved 2 lines or more in 10 eyes (42%), decreased 2 lines or more in 4 eyes (16%), and remained stable (≤1 line change) in 10 eyes (42%). Only 5 remaining polyps were observed at the visit at 3 months after treatment and only 1 polyp was seen at 1 year after treatment. During the mean follow-up of 27 months, 7 of the 24 eyes (29%) had a polyp recurrence.

Conclusions: We observed a marked decrease of exudates, PEDs, and subretinal hemorrhages after focal laser photocoagulation in eyes with extrafoveal PCV, with a recurrence of polyps in only 25% of our cases, with a mean follow-up of 2 years. Visual acuity improved or stabilized in the majority of eyes. Monotherapy with focal laser photocoagulation may therefore still be a treatment option in PCV patients for whom photodynamic therapy or anti-VEGF medication is not available or for whom an intravitreal anti-VEGF injections treatment regimen is too intensive.

ABSTRACT BODY:

Purpose: Stargardt disease due to bi-allelic variants in ABCA4 (STGD1) is the leading cause of inherited maculopathy, yet ~35% of cases remain genetically unsolved with traditional sequencing methods. We hypothesize that the missing heritability is due to undiscovered RNA defects in ABCA4. We explore this hypothesis through induced pluripotent stem cell (iPSC)-disease modelling to derive a biologically relevant RNA source for long-read RNA sequencing (LRS).

Methods: iPSCs were generated from two monoallelic [CF1] cases with the complex heterozygous allele c.[5461-10T>C;5603A>T]. Whole genome sequencing (WGS) was conducted to exclude potential phenocopies. Resulting iPSC lines were differentiated alongside a bi-allelic STGD1 case (c.4892T>C and c.4539+2001G>A) and unaffected control using published 3D retinal organoid (RO) protocols to produce a biologically relevant in vitro model of STGD1 (n=2). ROs were characterised during development using immunostaining and quantitative PCR for common markers of the developing retina. ABCA4 expression was confirmed using Western blotting. Fluorescence was quantified using Image J (n=5 images/sample) with statistical analyses performed via two-tailed paired t-test (mean ± SEM).

Results: WGS on Patient 2 did not report any additional candidate variants in ABCA4 nor in other IRD-associated genes. However, c.5603A>T was identified in trans in Patient 1. All samples produced ROs with the major retinal cells present. A photoreceptor outer segment (POS) brush border formed apically on the RO, which increased from Day 180 onwards. ABCA4 protein was also visualised in the sample at the POS. At Day 120, a proportion of Recoverin^{+} photoreceptor cells in STGD1 were displaced towards the centre of the RO. Mislocalised expression was mirrored by rod and cone photoreceptors (Rhodopsin^{+} and OPN1MW/LW^{+} cells) which did not resolve by Day 230. Immunostaining with Caspase-3 reveals that this phenotype was not correlated with apoptosis.

Conclusions: We generated STGD1 ROs which develop POS and express ABCA4, validating the use of this model as a source of tissue-specific RNA. We report a novel disease-specific phenotype of mislocalised photoreceptors, occurring independent of apoptosis. Further work is required to characterise this model, but we believe it will aid with the drug-discovery process for STGD1. We are currently applying LRS to unveil the missing inheritance of remaining monoallelic cases in this study.

ABSTRACT BODY:

Purpose: The UK Biobank (UKBB) study is a large, prospective cohort study including adults registered with the National Health Service. The aims of the present study were to describe the grading methods and baseline characteristics for participants who underwent retinal imaging, and to characterise individuals with retinal features suggestive of age-related macular degeneration (AMD), glaucoma and diabetic retinopathy (DR).

Methods: Non-mydriatic colour fundus photographs and macular optical coherence tomography (OCT) scans were acquired using a Topcon 3D OCT-1000 Mark II system (Topcon, Japan). Grading was performed by trained and certified graders and quality assured by clinicians of the Network of Ophthalmic Reading Centres UK (NetwORC UK – Belfast, Liverpool, and Moorfields Ophthalmic Reading Centres). Study-specific grading forms were created to capture retinal features including those associated with any AMD (at least one definite drusen on either imaging modality), glaucoma (based on colour fundus photographs only; ≥0.7 cup-disc ratio, ≥0.2 cup-disc ratio difference between the eyes, abnormal disc features (notching, inferior rim thinning or both) and/or disc haemorrhage in either eye) and DR (microaneurysms with or without other characteristic features of DR). Suspected cases of these conditions were

compared against the information provided by UKBB self-reported (verbal interview), linked hospital episode statistics and available primary care records.
Results: Among 68,517 UKBB participants who underwent retinal imaging, the median age at imaging was 58 years (interquartile range 51-64), 45.7% were men and 90.6% were of white ethnicity. Altogether, 64,266 (93.8%) participants had gradable colour fundus photographs and 68,465 (99.9%) had gradable OCT scans in at least one eye. Retinal features suggestive of any AMD, glaucoma and DR were identified in 15,178 (22.2%), 2,183 (3.2%) and 265 (0.4%) participants, of whom 125 (0.8%), 218 (10.0%) and 132 (49.8%) respectively had a recorded diagnosis.
Conclusions: The outcomes of grading of baseline images represents a rich resource that will aid detailed phenotyping of UKBB subjects and yields diagnostic information not captured by self-report and healthcare data linkage. Judicious use of the image analysis information generated will accelerate research across a range of areas including genetics and artificial intelligence.

ABSTRACT BODY:

Purpose: To evaluate the synergetic impact of high-intensity light (HL) and optical refocus (RF) on lens induced hyperopia (LIH) in a chicken model.

Methods: One-day-old chicks (n=130) were assigned to 10 groups of 13 chicks each. Chicks were housed for 8 days in a 12/12h light-dark cycle (150 lux). In all groups, hyperopia was induced randomly in one eye from day 1 post-hatching (D1) until D8 using +10D lenses. The fellow eyes acted as uncovered control. Nine groups were exposed daily to continuous 2 hours (h), 4h or 6h of either HL (15,000 lux); RF (removal of +10D lens); or both (HL+RF). One control group remained without HL or RF interventions. Ocular axial length (AL), refractive error and choroidal thickness (CT) were measured on D1, D4 and D8 using ultrasonography, infra-red refractometry and optical coherence tomography. Outcome measures are expressed as inter-ocular difference (IOD=experimental-control eye) ± SEM and compared between groups and intervention durations using a 2-way ANOVA.

Results: By D8, LIH led to a significant decrease in AL (-0.42±0.03 mm), increased hyperopic refraction (+3.48±0.32 D) and choroidal thickening (+85.8±35.2 µm) in the control group (all, $P<0.001$). Exposure to 2h of HL, RF or HL+RF did not significantly affect outcome measures of LIH. HL was associated with an additional, duration-dependent, increase in hyperopic refraction, while only 6h of HL significantly decreased AL ($P=0.02$). RF caused a duration-dependent increase in AL, and decrease in hyperopic refraction (Fig. 1). When interventions were 2h or 4h long, HL+RF had a similar impact as RF on the AL and refraction of eyes with LIH. Conversely, 6h of HL significantly reduced the impact of RF on AL (HL+RF vs RF, $P<0.05$, Fig.1A). HL increased CT compared to RF ($P=0.007$) and HL+RF ($P=0.03$).

Conclusions: In eyes developing LIH, daily exposures to HL promotes axial shortening and hyperopia in a duration-dependent manner, whereas, RF promotes emmetropization and slows the development of LIH. Exposure to 6h of HL can modulate the drive of RF potentially through changes involving CT.

ABSTRACT BODY:

Purpose: Glaucoma is known as multifactorial neurodegenerative disorder with autoimmune components. One of these autoimmune phenomena targets the ß2 adrenergic receptor (ß2-AR; i.e. agonistic autoantibodies; ß2-agAAb) and is linked to the elevated IOP and an impaired retinal microcirculation. As the neurodegenerative disorder, Alzheimer's Disease (AD), is postulated to share a common molecular mechanism with glaucoma, the aim of the present study was to investigate autoimmune phenomena targeting the ß2-AR in patients with AD.

Methods: Sera of 11 subjects with AD and 18 subjects with primary open-angle glaucoma were analyzed for a seropositivity of functional autoantibodies against ß2-AR. AAbs were analyzed by frequency modulation of a specific rat cardiomyocyte bioassay in vitro. In addition, different species of amyloid beta (Aß) monomers were tested (Aß1-14, Aß10-25, Aβ10-37 Aß1-40, Aß1-42, Aβ28-40, and [Pyr]-Aß3-42). The study was approved by the local ethics committee and was done in accordance with the tenets of the Declaration of Helsinki. Informed consent was achieved.

Results: The results demonstrate that the long-chain [Pyr]-Aß3-42, representing a major neurogenic plaque component, exerted an activation in the bioassay, which was blocked by ICI118.551, indicating that the effect was realized via the ß2-AR. Contrary, none of the short-chain Aß (Aß1-14, Aß10-25, or Aβ28-40) showed any inhibitory or agonistic effect on ß2-AR. The long chain Aß1-40, Aβ1-42, and Aβ10-37, yet not the short-chain Aß peptides prevented the clenbuterol induced desensitization of the ß2-AR. In addition, we identified a seropositivity of functional AAb in AD patients, activating the ß2-AR like the ß2-agAAb found in patients with glaucoma.

Conclusions: As autoimmune mechanisms were reported to be involved in the pathogenesis of neurodegenerative disorders, we postulate that an overstimulation of the ß2-AR pathway can induce an adrenergic overdrive. This might play an important role in the multifactorial interplay of glaucoma and Alzheimer's Disease.

ABSTRACT BODY:

Purpose: To evaluate US glaucoma fellow surgical experience with traditional filtering and microinvasive glaucoma surgeries (MIGS).

Methods: Association of University Professors of Ophthalmology (AUPO) case log data from 2008-2019 was reviewed and analyzed for year-to-year trends.

Results: From 2008 to 2019, mean primary trabeculectomy surgeries among glaucoma fellows decreased 17.6% from 30.1 to 24.8, which represented a 0.8% decrease per year (P=0.67). During the same time period, mean primary glaucoma drainage implant (GDI) surgeries increased 56.3% from 30.2 to 47.2, which represented a 4.3% increase per year (P<0.01). From 2014 to 2019, mean iStent cases increased from 3.7 to 11.7, which represented a 24.1% increase per year (P=0.03). Mean goniotomy cases from 2014-2019 increased from 0.2 to 8.6, which represented a 55.5% increase per year (P<0.01). From 2016 to 2019, mean Trabectome cases increased from 2.7 to 3.7, which represented a 16.3% increase per year (P=0.69), and mean gonioscopy-assisted transluminal trabeculotomy (GATT) cases increased from 1.7 to 4.7, which represented a 49.8% increase per year (P=0.24).

Conclusions: There are steadily increased cases of GDI, iStent, and goniotomy surgeries among US glaucoma fellows. The cases of primary trabeculectomy surgeries have been fluctuating with a possible downtrend.

ABSTRACT BODY:

Purpose: Rhegmatogenous retinal detachment leads to fluid between the photoreceptor outer segments and retinal pigment epithelium (RPE). Knowledge of the protein composition in this fluid may provide clues to retinal diseases such as age-related macular degeneration, which is believed to involve dysregulated lipid transfer between photoreceptors, RPE, and choroid.

Methods: Intact proteins were extracted from the subretinal fluids of five patients with rhegmatogenous retinal detachment and analyzed by tandem mass spectrometry. A publicly available retinal gene expression database was searched. Two human donor eyes with normal maculas were immunoprobed for transthyretin (TTR) with appropriate controls.

Results: Albumin, TTR, and apolipoprotein A-I were the three most abundant proteins in subretinal fluid. Remarkably, TTR relative to the other proteins was more abundant than its serum counterpart, suggestive of TTR being predominantly synthesized locally. Six post-translationally modified protein forms (proteoforms) of TTR were detected, with the relative amount of glutathionylated TTR being much higher in the subretinal fluid (12 - 43%) than values reported for counterparts in serum (< 5%) and cerebrospinal fluid (0.4 - 13%). Moreover, a putative TTR dimer of 32,428, most likely with glycosylation modifications, was detected as the fourth most abundant protein. The high abundance of TTR and putative TTR dimer in subretinal fluid was supported by single-cell RNA sequencing analysis, which showed strong signal for TTR in RPE. Immunohistochemistry further showed strong diffuse TTR immunoreactivity in choroidal stroma that contrasted with vertically aligned signal in the outer segment zone of the subretinal space and negligible signal in RPE cell bodies. Lower relative amounts of glutathionylated TTR and a putative TTR dimer in one AMD eye merits further investigation in more samples.

Conclusions: The high percentage of glutathionylated TTR suggests that glutathionylation is crucial for normal TTR function in the retina. RPE expression of TTR gene and compartmentalized immunoreactivity suggests that TTR is made intraocularly as well as in the liver for plasma. Lipid carriers like TTR may participate in pathways that when dysregulated lead to subretinal drusenoid deposit. Subretinal fluid from patients undergoing retinal detachment repair is a rich biofluid for discovery.

ABSTRACT BODY:

Purpose: Recent work suggests that the vitamin B3 derivative nicotinamide (NA) ameliorates an age-related macular degeneration (AMD) phenotype in retinal pigment epithelium (RPE) cells derived from induced pluripotent stem cells (iPSCs) (Saini et al., 2018). While NA is a frequent supplement in RPE culture media for its property to enhance iPSC-RPE differentiation, it may inadvertently disguise molecular phenotypes in cellular models of RPE pathologies. We therefore aimed to investigate the effects of NA depletion on RPE cell integrity and functionality as well as oxidative stress susceptibility in iPSC-RPE cell lines categorized into extremes of high or low genetic risk for AMD.

Methods: iPSC-RPE cells were cultivated on transwell inserts and depleted of NA one week after seeding. Oxidative stress was induced by sodium iodate (SI) treatment. RPE cell layer integrity and functionality was analyzed by transepithelial resistance (TEER) measurements, immunocytochemistry and a photoreceptor outer segment (POS) phagocytosis assay. mRNA expression of markers for RPE cell faith, complement cascade and oxidative stress response was measured by qRT-PCR and verified by Western Blot and ELISA.

Results: NA depletion had no influence on RPE monolayer integrity as shown by immunocytochemistry and TEER measurement. Upon NA depletion RPE markers BEST1 and RPE65 were down regulated, whereas expression of complement markers CFH and C3 and oxidative stress markers HMOX1 and NQO1 were increased. These changes were reversible by reintroducing NA. Intriguingly, cells depleted of NA showed an increased uptake of POS. Oxidative stress was induced by SI treatment. Cells depleted of NA did not show a more pronounced stress response than cells cultivated in presence of NA. Cell lines with different genetic AMD risk scores did not show differences for any of the parameters addressed.

Conclusions: While NA decreases baseline expression of oxidative stress response and complement cascade marker genes in iPSC-RPE the cellular responses to SI mediated oxidative stress remain unmodified. Additionally, RPE cells depleted of NA showed a much higher POS phagocytosis than cells cultivated with NA. It thus remains elusive if the beneficial effect of NA on oxidative stress and complement regulation makes it a suitable therapeutic agent for AMD.

TITLE: Anxiety and depression in patients treated for proliferative diabetic retinopathy.

SESSION TITLE: Diabetic retinopathy epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: V. Ponnusamy, P. Le, Y. Zhang, Ophthalmology, University of North Carolina System, Chapel Hill, North Carolina, UNITED STATES|

Commercial Relationships Disclosure: Vikram Ponnusamy: Commercial Relationship: Code N (No Commercial Relationship) | Patrick Le: Commercial Relationship: Code N (No Commercial Relationship) | Yang Zhang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Diabetic retinopathy is associated with higher rates of anxiety and depression. We performed a retrospective case-control study to quantify the association between different interventions for the treatment of proliferative diabetic retinopathy (PDR), and anxiety and depression.

Methods: Medical records from The University of North Carolina Hospital System (2014-2020) were reviewed to identify patients diagnosed with PDR (n = 3572) , anxiety, and depression using ICD-9 and 10 codes. Furthermore, PDR patients that received treatment with intravitreal injection (IVI), pan-retinal photocoagulation laser (PRP), pars plana vitrectomy (PPV), retinal detachment repair (RDR), complex RDR, and removal of silicone oil were identified by CPT codes. Multiple logistic regression analysis was used to calculate the effect size of an odds ratio (OR) between each mental illness and PDR treatment. X^2 test of homogeneity and Fischer-exact test were used to determine statistical significance between groups. All P values received Bonferroni correction for multiple comparisons.

Results: Out of 3572 PDR patients, 648 had anxiety and 979 depression. IVI had lower odds of comorbid anxiety when compared to untreated PDR patients (OR 0.835, 0.738-0.944, P < 0.001). Similarly, there were reduced odds for comorbid depression when comparing between patients who received IVI (OR 0.584, 0.525-0.650, P < 0.001), PPV with endolaser (OR 0.725, 0.604-0.870, P < 0.001), or PRP (OR 0.589, 0.513-0.678, P < 0.001) to patients who had no intervention for PDR. However, RDR (OR 1.759, 1.044-2.966, P < 0.001) and complex RDR (OR 1.451, 1.032-2.040, P < 0.001) were associated with increased odds of comorbid anxiety when compared to patients with untreated PDR.

Conclusions: These findings further elucidate the relationship between mental health and diabetic retinopathy. Patients receiving surgical and non-surgical interventions for PDR have decreased odds of having comorbid anxiety and depression, with the exception of retinal detachment repair, which is associated with higher odds of anxiety. These findings emphasize the importance of multidisciplinary care in managing patients with diabetic retinal detachments.

ABSTRACT BODY:

Purpose: Mutations within the retinitis pigmentosa GTPase regulator (RPGR) are the most frequent cause of X-Linked Retinitis Pigmentosa (XLRP), a common and severe form of inherited retinal disease. XLRP is characterised by the progressive degeneration and loss of photoreceptors, leading to visual loss and, ultimately, bilateral blindness. Unfortunately, treatments for RPGR-associated XLRP are non-existent. Therefore, we sought to investigate the efficacy of $RPGR^{ORF15}$ gene supplementation in human RPGR-deficient retinal organoids (ROs).

Methods: Isogenic RPGR knockout (KO) induced pluripotent stem cells (iPSCs) were generated using established CRISPR/Cas9 gene editing methods. RPGR-KO iPSCs were differentiated into 3D ROs, which were utilised to test the RPGR clinical vector construct. Molecular, structural, and functional readouts included RPGR quantification, RPGR photoreceptor localization, RPGR glutamylation and ciliation assessment.

Results: Successful differentiation of RPGR-KO iPSCs was confirmed by qPCR and immunocytochemistry of major retinal and phototransduction markers. Viral transduction of RPGR-KO ROs with AAV-RPGR led to restoration of RPGR expression in human rods and cones. RPGR was localised at the photoreceptor cilium and led to marked improvements in several molecular readouts.

Conclusions: The RPGR transgene was correctly expressed, processed, and localised in human rods and cones following viral transduction of RPGR-deficient human ROs. These data agree with the reported Phase I/II trial positive results in patients with RPGR-associated XLRP.

ABSTRACT BODY:

Purpose: Variants in the OPN1LW/OPN1MW gene cluster cause X-linked color vision deficiencies, such as the frequently occurring protanopia and deuteranopia or the more rare Bornholm eye disease and blue cone monochromacy. Genetic analysis of the cluster is extremely difficult, first due to the ~98% homology of the OPN1LW and OPN1MW genes, second because only the first two opsin genes in the cluster are clinically relevant, while the cluster can contain zero to as many as six gene copies and third because of the broad spectrum of causal variants.

Methods: A genetic assay was developed for the OPN1LW/OPN1MW gene cluster combining copy number analysis using multiplex ligation-dependent probe amplification (MLPA) and sequencing analysis using long-read circular consensus sequencing. The assay was tested on 50 clinical cases analyzed to confirm clinical diagnosis (n=43) or determine carrier status (n=7).

Results: Using the developed assay a broad range of pathogenic variants were detected, such as deletions of the LCR, hybrid genes, single variants (including 7 novel variants) and combinations of variants. In all 43 male cases in which a genetic confirmation of diagnosis was requested the genetic composition of the clinically relevant first and second gene in the OPN1LW/OPN1MW gene cluster could be determined. In 39 of these 43 cases the clinical diagnosis was genetically confirmed, in two cases it was unclear whether the detected variants were causal and in two causes no causal variants were detected. In the latter two cases the causal variants are most likely outside the OPN1LW/OPN1MW gene cluster. Indeed, in one of these cases variants in the ZNF644 gene were detected. In seven female samples carrier status could be determined, although in two samples parental samples were requested and analyzed to definitely conclude carrier status. Interestingly, in 4 of the 7 cases the causal allele arose de novo in the affected child.

Conclusions: The developed genetic assay for the OPN1LW/OPN1MW gene cluster is the first available diagnostic assay that can detect both structural and nucleotide variants with a straightforward analysis, as MLPA is a fast and efficient method for copy number analysis and the long read sequencing approach makes it possible to determine the genetic composition of the entire OPN1LW or OPN1MW gene in single sequencing reads.

ABSTRACT BODY:

Purpose: Neovascular age-related macular degeneration (nAMD) is a degenerative retinal disease that when untreated leads to severe visual loss. Prompt detection of the disease may achieve better therapeutic outcomes. This study aimed to ascertain the presenting symptoms of nAMD in 2 different population groups and examined how awareness interacts with clinical variables.

Methods: In this bicentre, cross-sectional study conducted from September to December 2021 in Milan and Dublin, patients with nAMD attending the intravitreal injection service were included. Four age-subgroups were considered: 60-69, 70-79, 80-89, >90. The patients completed an interviewer-administered questionnaire regarding their symptoms at the time of nAMD onset. Individuals were divided into group A composed of Italian patients and group B consisted of Irish patients. The 2 groups were compared using the Chi-square test with Yates correction for categorical variables (univariate analyses). P-values <.05 were considered statistically significant.

Results: 152 patients with nAMD were included in the study, 56 in group A and 96 in group B.

The most common age-subgroup was 80-89 years (46.7%); 95(62.5%) patients were females, while 57(37.5%) were males. The most frequent symptom at presentation was difficulty when reading (n=57,37.5%), followed by both drop in central vision in one eye (n=52,34.2%) and distortion (n=52,34.2%). Other presenting symptoms were a transient shadow upon wakening (n=26,17.1%), difficulty in going from light to dark (n=9,5.9%), and also in recognizing faces (n=6,3.9%). Notably, 44 patients (28.9%) were asymptomatic. Univariate linear regression analyses didn't reveal a significant association of awareness of the disease with age and sex. Interestingly, group A was more likely to be aware of the disease onset compared to group B X^2 (1,N=152)=4.483, p=.0342.

Conclusions: These findings show that almost a third of patients with nAMD are asymptomatic at the time of their first presentation. Symptom awareness was higher among the Italian cohort compared to the Irish group. nAMD patients should attend regular ophthalmic/optical coherence tomography monitoring rather than rely on subjective symptoms.

ABSTRACT BODY:

Purpose: An increasing variety of myopia control spectacle lens (MCSL) designs are emerging. However their optical features potentially create distortion in the field of view affecting tolerance and compliance. The aim was to develop a novel bench device to measure this distortion and evaluate commercially available MCSLs.

Methods: An opto-electro-mechanical Lens Distortion Tester (LDT) was developed for evaluating Static Field (SF) and Horizontal Smooth Pursuit (HSP) distortion. The LDT includes a colour camera with a focusing lens, a test lens mount on an automatic pivoting arm, and a monitor to present a target object. The LDT can resolve micro to macro levels of distortion by adapting the optical layout.

Targets were black and white linear gratings in a range of spatial frequencies. Custom software controlled a pivoting arm for transverse angular lens movements to capture a sequence of output images. Post-processing analysis software was developed in Matlab whereby edge detection and deviation due to distortion was quantified by decomposition into frequency components.

Four commercially available spectacle lenses were evaluated; Hoya Single Vision (SV), Zeiss MyoVision, Hoya Miyosmart, and Essilor Stellest. Output of the distorted target edge was assessed using histogram plots. The frequency and magnitude of distortion was quantified across the field of view.

Results: The results presented in Fig.1 & 2 suggest consistent trends between SF and HSP:

— SV had the least amount of distortion spread evenly across the field, as represented by low magnitudes for all frequencies.

— MyoVision had the largest amount of low frequency (blue) distortion which increased to the peripheral field (i.e. peripheral drift).

— Miyosmart had a medium amount of distortion spread evenly across the field shown by low-medium (light blue) and medium (orange) frequencies (i.e. small jitter) in SF and HSP respectively.

— Stellest had a large amount of distortion increasing to the peripheral field with medium (orange) and low-high (light blue to green) frequencies (i.e. large jitter) in SF and HSP respectively.

Conclusions: The LDT can distinguish distortion characteristics between the various MCSL technologies. Each MCSL technology type (progressive power and lenslet) offers differing qualities and amounts of distortion. Miyosmart lenslets create the least distortion magnitude and change across the field of view when compared to other MCSL types.

ABSTRACT BODY:

Purpose: To evaluate the clinical results obtained with the new PhysIOL Isopure 123: using an isofocal optical design to achieve functional intermediate vision

Methods: An observational study of patients with a isofocal IOL (PhysIOL Isopure 123) implanted between December 2020 and October 2021. Visual outcomes were assessed 1 month postoperatively; uncorrected and best-corrected distance visual acuity using logMAR at 4 metres, uncorrected and corrected intermediate (70cm) and reading/near visual acuity using a Jaeger chart

Results: Nineteen eyes of 18 patients were analysed. Mean preoperative distance visual acuity was 0.66 ± 0.71 logMAR. At the one-month post-operative follow-up visit, uncorrected distance visual acuity was 0.17 ± 0.17 logMAR and corrected distance visual acuity was 0.07 ± 0.12 logMAR. Two thirds (66%, n=12) of patients achieved uncorrected intermediate visual acuity (70cm) of N12 or better. Wearing their auto-refraction correction, sixty-six achieved N12 or better at 70cm and over half (53%) could read N10 or better at their comfortable near distance. There were no intra or post-operative complications of note. Mean post-operative spherical equivalent was -0.06 ± 0.04.

Conclusions: The results demonstrated that the PhysIOL Isopure 123 is able to restore near, intermediate, and distance visual function.

ABSTRACT BODY:

Purpose: To develop a deeper understanding of the progression of Retinitis Pigmentosa (RP), for the successful design of clinical trials assessing novel therapeutics.

Methods: PHENOROD2 is an ongoing prospective, multicentric, natural history study documenting functional and structural changes in patients with RP due to mutations in RHO, PDE6A, or PDE6B. An interim analysis was performed at baseline and 12 months in the first 44 patients enrolled at the national reference center for rare diseases (REFERET) of the Centre Hospitalier National d'Ophtalmologie des Quinze-Vingts (Paris, France). One patient was lost to follow-up and was excluded from the analysis. Population demographics, visual acuity (VA), and kinetic visual field (V4e) were analyzed in the entire cohort and per genotype.

Results: Out of 43 patients, 32 (75%) carried a mutation in RHO, 7 (16%) in PDE6A, and 4 (9%) in PDE6B. Mean age at inclusion was 46 (12.2) years, and gender distribution was 53.5% males, 46.5% females.

At baseline, VA ranged between 20/13 and 20/800, with a mean of 0.14 (0.19) LogMAR (20/28) and 0.17 (0.22) LogMAR (20/30) in OD and OS, respectively. At 12 months, no significant changes were reported, although subjects with PDE6 variants showed a slight trend towards mild VA loss (+0.08 and +0.04 LogMAR in OD and OS, respectively).

At baseline, a mean visual field area of 5,532.4 (5,151.9) mm^2 was reported in both eyes of all patients (6,320.6 mm^2 in RHO patients, 2,675.2 mm^2 in PDE6A patients, and 4,226.9 mm^2 in PDE6B patients). At 12 months, a mean loss of -345.8 (1,572.8) mm^2 (-6.3%) was observed in all patients: -323.2 mm^2 (-5.1%) in RHO patients, -591.6 mm^2 (-22.1%) in PDE6A patients, and -96.85mm^2 (-2.3%) in PDE6B patients.

The small numbers of PDE6A and PDE6B patients did not allow for statistical analysis across groups.

Conclusions: Virtually no decrease in VA was observed after 12 months of follow-up in this population of patients with relatively spared VA at baseline, in alignment with the documented natural history of RP. However, a loss of visual field was reported over the same period. This suggests that visual field assessment may be more appropriate to monitor disease progression in the early stages. Future interim analyses including the entire PHENOROD2 cohort will help validate these preliminary observations.

Commercial Relationships Disclosure: Elio Herzog: Commercial Relationship: Code N (No Commercial Relationship) | Irene Keller: Commercial Relationship: Code N (No Commercial Relationship) | Sebastian Wolf: Commercial Relationship: Code N (No Commercial Relationship) | Martin Zinkernagel: Commercial Relationship: Code N (No Commercial Relationship) | Denise Zysset-Burri: Commercial Relationship: Code N (No Commercial Relationship)
ABSTRACT BODY:
Purpose: Since the ocular surface is continuously exposed to the environment, an important role of its microbiome is to protect the underlying tissue against colonization of pathogens. If left unchecked, the ocular surface microbiome (OSM) may itself cause disease by uncontrolled immune responses resulting in inflammatory processes. Due to the low abundance of microbial relative to host DNA, the generation of stable and reproducible sequencing data to characterize the human OSM is challenging.
Methods: To characterize the OSM by whole-metagenome sequencing, swabs of the lower conjunctiva were collected using standard cotton swabs compared to flocked nylon swabs. Total DNA was extracted by either the E.Z.N.A. MicroElute Genomic DNA (Omega) or the QIAamp DNA Microbiome (Qiagen) kit. The latter includes a mechanical lysis and host DNA depletion step. Samples were prescreened for bacterial DNA using RT-qPCR of 16S rRNA genes.
Results: More DNA was isolated using flocked swabs ($p=0.0378$, $n=21$). The majority of the identified taxa were bacteria (96.60 ± 1.74%), whereas 1.86 ± 1.38% and 1.54 ± 0.75% (SD) were viruses and eukaryotes, respectively. Using the Qiagen kit, a total of 112 species belonging to 71 genera in eight phyla were found compared to eleven species belonging to nine genera in three phyla isolated with the Omega kit (Fig. 1). The most abundant phyla were Proteobacteria and Actinobacteria, additionally Firmicutes if using the Qiagen kit. Extraction kits output differed in both, microbial composition and resolution (Fig. 2).
Fig. 1: Detected microbial phyla, genera and species using the E.Z.N.A. MicroElute Genomic DNA kit (Omega) vs. the QIAamp DNA Microbiome kit (Qiagen). The same three patients were sampled on consecutive days.
Fig. 2: The microbial composition on phylum (A) and species (B) level. The lower six samples are the same three subjects sampled on consecutive days extracted with either with the Omega (yellow) or Qiagen (green) kit.
Conclusions: Despite low microbial abundance of the OSM, preliminary data showed that robust sequencing data can be generated using flocked swabs to increase the DNA input and without 16S rRNA amplification to eliminate amplification bias and to include viral and fungal in addition to bacterial DNA. Microbial diversity depended on the DNA extraction kit, therefore positive controls with known microbial composition will be included in validation studies.

ABSTRACT BODY:

Purpose: It is possible to find biomarkers in the retina that inform about the pathological state of other parts of the body. Neurodegenerative diseases could be diagnosed early by high-precision retinal imaging. However, many cells in the inner retina are too transparent to be detected by existing techniques. We have shown how multi-offset detection in Adaptive Optics Scanning Laser Ophthalmoscopy (AO-SLO) can capture variations in refractive index between retinal cells leading to images of ganglion and microglial cells in humans in vivo. A detector with the same offset distance was installed on a custom-modified AO-SLO Optical Coherence Tomography (OCT) device. The aim of this project was to detect transparent cellular biomarkers on patients suffering from multiple sclerosis (MS).

Methods: Images were acquired with the AO-SLO-OCT using a split-detector at 10 ADD offset distance. We imaged a total of 35 participants, 10 controls and 25 patients with MS. From the 25 patients, 20 were included in a therapeutic protocol, targetting patients with optic neuritis (ON) who received an electrical stimulation of the optic nerve; the other 5 patients (4 without ON) were included in an observational protocol. Patients were followed over several months and were imaged over different time periods. Quantitative biomarkers such as cell density, cell size and motion speed were extracted over time. AOSLO images were co-localized with simultaneously acquired AO-OCT cross sections to determine the retinal depth of cells.

Results: Inflammatory cells were detected on the retinal ganglion cell layer (GCL) in MS patients. We determined their depth through AO-OCT where highly reflective spots corresponded to the cells observed on the AOSLO images. The cell density peaked right after the ON and decreased over the following weeks. Cells were also detected on the control eye with no ON from the patients undergoing therapy and a few isolated cells were detected on some observational patients.

Conclusions: These cells specifically detected in the GCL which is targeted by MS degeneration, with a density that varies over time in relation to symptomatic attacks of the disease are a quantifiable biomarker of the state of the inflammation and could be correlated with other changes in this layer caused by MS. We aim to use this biomarker to evaluate the influence of the inflammatory response in MS on the demyelination process.

TITLE: Devaluing privacy: medicine for AI in the public domain
SESSION TITLE: Public Health I
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: S.I. Marks, G.W. Armstrong, D.S. Friedman, Ophthalmology, Harvard Medical School, Boston, Massachusetts, UNITED STATES|S.I. Marks, G.W. Armstrong, D.S. Friedman, Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|
Commercial Relationships Disclosure: Samuel Marks: Commercial Relationship: Code N (No Commercial Relationship) | Grayson Armstrong: Commercial Relationship: Code N (No Commercial Relationship) | David Friedman: Commercial Relationship: Code N (No Commercial Relationship)
ABSTRACT BODY:
Purpose: Advocate and demonstrate a public domain methodology for the collection, analysis, and use of medical data. This is as opposed to keeping patient data private and siloed; the norm. Although privacy is attractive, we posit insufficient attention is targeted on the advantages of its inverse: the public domain. Public domaining medical information enables the advance of knowledge and understanding (through data-pooling and disparate expert analysis), and its sharing, regardless of financial and physical positions.
Methods: Recruit ophthalmologists who are department directors to allow their patients to be screened without the siloed gatekeeper approach. Each individual patient must explicitly give their informed consent, and, following a grace period of 2 months, be unable to withdraw their consent. New public-domain software systems are designed to facilitate this process. The medicolegal and other bureaucratic requirements for running these studies will also be placed in the public domain to aid replication.
Results: Initiating two studies at two departments at a major top-tier eye \& ear hospital in the United States, specifically: its ophthalmic emergency and glaucoma departments. Over 1,000 new patient records are expected to be collected and public-domained every month.
Conclusions: The culmination of patient data from disparate locations is greater than the sum of its parts… being a great boon for everything from epidemiological analyses to automated diagnoses through Machine Learning and Artificial Intelligence. Long term we hope others follow suit with the public domain methodology.

ABSTRACT BODY:
Purpose: There are currently no large-mammal surgical models for geographic atrophy with choroidal neovascularization (CNV). Our goal was to develop a porcine surgical RPE (retina pigment epithelium) debridement model to study the time course of photoreceptor cell loss and choroidal remodeling. This model was developed to study the therapeutic potential of RPE sheet transplantation, delivered using erodible fibrin scaffolds in mitigating the effects of acquired RPE cell loss.
Methods: This research is compliant with the ARVO Statement for the Use of Animals in Ophthalmic and Vision Research. Six 2-month-old female domestic pigs (Sus scrofa domesticus), purpose-bred for medical research were used for this study. Animals were screened for overall health by a veterinarian and underwent pre-surgical ophthalmological examination to assure that the cornea and lens were clear and that there was no evidence of retinal dialysis or detachment in the operative eye. Three-port triamcinolone-assisted 25-gauge pars plana vitrectomy was performed with careful separation of the posterior hyaloid in the area centralis. A 41-gauge needle was used to create a retinal bleb, detaching the area centralis outside of the tapetum. Endodiathermy was applied along the proximal bleb and a 2mm retinotomy was created with vertical scissors. A nitinol wire or 5-0 proline loop was used to gently debride and remove a 5mm diameter region RPE cells without rupturing Bruch’s membrane. Fluid-air exchange was performed and 20% SF6 gas was injected. Animals underwent color fundus photos at 2 weeks post-op. Fundus photos, OCT and OCT angiography (OCTA) were also performed at 1,2,3,4 and 6 months post-op. Retinal histology was obtained at 2, 4 and 6 months, post-op.
Results: Debridement of RPE resulted in geographic atrophy with progressive loss of photoreceptors and rapid loss of choriocapillaris within 2 months in all eyes. Pachychoroidal changes were also observed in Sattler and Haller layers. OCTA revealed non-exudative type 1 CNV, initially at the edges of the debridement zone by 2 months. At six months, non-exudative filamentous type 1 CNV progressed toward the center of the debridement zone.
Conclusions: Surgical debridement of the RPE results in geographic atrophy and CNV, reproducing both forms of advanced AMD. This surgical model is useful as a means of testing the role of RPE and other cell replacement in treating advanced AMD.

ABSTRACT BODY:

Purpose: Leber congenital amaurosis type 10 is a retinal degenerative condition that causes severe visual impairment. To restore vision, we developed EDIT-101, an adeno-associated virus type 5 encoding Staphylococcus aureus Cas9 (SaCas9) expressed under the photoreceptor-specific GRK1 promoter and two guide RNAs designed to excise the disease-causing CEP290 mutation, c.2991+1655A>G (CEP290-IVS26). Safety and tolerability of EDIT-101 is being evaluated in the ongoing BRILLIANCE (NCT03872479) trial, an open-label, Phase 1/2 single ascending dose study enrolling adults and children. Viral shedding in body fluids of EDIT-101 treated subjects is a key exploratory safety endpoint in the trial. To monitor this key safety assessment, a SaCas9-based real-time quantitative polymerase chain reaction (qPCR) assay was developed and validated.

Methods: We developed a qPCR assay to quantify EDIT-101 vector genomes in blood and tears by targeting the SaCas9 transgene. Assay validation was performed to establish linearity, reproducibility, limits of detection, biological matrix effects, and acceptance criteria for EDIT-101 detection in samples collected throughout the BRILLIANCE trial.

Results: The validated assay for blood and tears has a lower and upper limit of quantification (LLOQ & ULOQ) of 25 to $1x10^7$ double stranded EDIT-101 vector genomes, respectively, and a lower limit of detection (LLOD) of 10 vector genomes. No matrix effect or amplification above the LLOD was observed in the absence of EDIT-101. The assay is highly reproducible and specific with an efficiency of 92% to 103% and a $R^2 \geq 0.998$.

EDIT-101 vector genomes were only detected in a small number of clinical samples. The highest levels were observed the day after treatment, then rapidly dropped below the LLOQ. Vector genomes were only identified in tears collected from inside the lower eyelid of the treated, but not the untreated eye. Of the blood and tear samples tested, fewer blood samples contained detectable vector genomes. Levels of vector shed were minimal compared to the initial dose, indicating low risk to the patient or environment.

Conclusions: We developed a SaCas9-specific qPCR assay to evaluate viral shedding in the BRILLIANCE trial. Our data suggests observed EDIT-101 shedding is transient and at low levels of detection, with no risk of systemic viral persistence.

TITLE: Characterization of associations between macular atrophy and subretinal fibrosis in treated neovascular AMD : 7 year findings from the IVAN trial

SESSION TITLE: Anti-VEGF in AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: U. Chakravarthy, Ophthalmology, Belfast Health and Social Care Trust, Belfast, Belfast, UNITED KINGDOM|

Commercial Relationships Disclosure: Usha Chakravarthy: Commercial Relationship(s);Code C (Consultant/Contractor):Apellis, Iveric Bio, Boehringer Ingelgheim;Code E (Employment):Hoffman La Roche

ABSTRACT BODY:

Purpose: To describe the frequency of fibrosis and macular atrophy (MA) detected by optical coherence tomography (OCT) and to characterize associations with visual acuity (VA) after exit from the inhibition of VEGF in age-related choroidal neovascularization (IVAN: ISRCTN92166560) trial.

Methods: Participants in the IVAN trial were randomized to either ranibizumab or bevacizumab and after exit received usual care consisting of treatment with licensed anti VEGF agents and followed for up to 7 years after enrolment. Visual acuity (VA) and image grading of the most recent OCT in 372 surviving participants were obtained from a study visit or from usual care records. Fibrosis was inferred from presence of hyperreflective material (HRM) on OCT and location categorized into none, subretinal only , subretinal pigment epithelial (sub-RPE) only, or combined (subretinal plus sub-RPE) Figure 1. Graders assigned the latter two categories only when they detected an intact RPE layer with HRM on its outer and or inner aspect. MA was identified from subsidence of the inner nuclear and or outer plexiform layer, thinning of the outer nuclear layer, or a band of hypertransmission of OCT signal. Observations were excluded from VA descriptives when VA was unavailable within 30 days of the OCT image.

Results: Tabulations of MA and HRM shown in Figure 1. MA was present in 90%, HRM in 82% and either in 96%. When MA was absent (n = 39) one third of study eyes had no HRM. Whereas when MA was present (n = 333) around one-fifth had no HRM. When HRM was subretinal, MA was detectable in 95.4% and absent in 4.6%. When HRM was sub-RPE only, MA was present in 85.8% and absent in 14.2%. Both VA and OCT were available in 319 (86%) study eyes. Examining associations of MA and HRM with VA, VA was best when MA was present with no HRM (median VA 65.0, IQR 45.0, 75.0) or MA present with HRM sub-RPE only (median VA 64.5, IQR 43.0, 72.0). In eyes with MA when HRM was subretinal, median VA was 33.0 letters (IQR 18.0, 62.0). In the absence of MA, VA was similar across the HRM groups.

Conclusions: High proportions of neovascular AMD eyes treated with anti VEGF agents over a sustained period that have subretinal fibrosis exhibit MA. A visible RPE layer was associated with a lower risk of an eye having MA and better VA.

ABSTRACT BODY:

Purpose: Sulfur mustard (SM), a chemical warfare agent, can cause severe corneal inflammation and permanent damage in vision in exposed individuals. We have demonstrated that topical treatment of HDL NPs can attenuate inflammation resulting from chemical burns. We also have shown that systemic treatment with vitamin D3 can attenuate skin inflammation induced by UV irradiation. In this study, we tested the potential of topical application of HDL NPs and vitD3 as novel therapeutics in ocular injuries induced by nitrogen mustard (NM), which is an analog of SM and can mimic perturbations caused by SM.

Methods: Mouse corneas were exposed to 0.5% NM for 1min. Corneas were treated 1hr post wounding, topically with HDL NPs, or HDL NP complexed with vitamin D3 daily for 4 weeks. To evaluate corneal clarity, mouse corneas were imaged for haze scoring. To determine epithelial integrity, corneas were stained with fluorescein and imaged. RT-qPCR was performed to examine expression of pro-inflammatory genes (e.g., Il1b, Ccl2, Inos). Whole mount staining using CD31 was conducted to visualize vessel egress into the cornea.

Results: NM exposure caused perturbations in the anterior segment including corneal haze, epithelial cell death, severe inflammation (e.g., increased expression of Il1b, Ccl2, Inos), extensive corneal neovascularization, and conjunctivalization (e.g., goblet cells in cornea) in the central cornea. This suggests a compromise in the limbal epithelial stem cell niche and can lead to limbal epithelial stem cell deficiency. After NM injury, topical treatment with HDL NPs (1μM) significantly attenuated NM-induced detrimental effects, such as corneal haze and increased expression of pro-inflammatory genes. Interestingly, HDL NP- Vit D3 treatment further reduced: (i) the amount of corneal fluorescein staining; (ii) degree of haze; and (iii) pro-inflammatory cytokine and chemokine expression. This indicates that Vit D3 in combination with HDL NPs have a synergistic effect in the alleviation of NM-induced corneal damage.

Conclusions: We have established a mouse model mimicking SM injured cornea. Our findings strongly suggest that topical delivery of HDL NPs and HDL NP-Vit D3 to the cornea and limbus have vast treatment potential for corneal mustard keratopathy.

TITLE: STZ is toxic to rat retinal progenitors and suppresses their expansion

SESSION TITLE: Stem cells and disease modeling in vitro

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Lin, X. Ren, D. Chen, Sichuan University West China Hospital, Chengdu, Sichuan, CHINA|

Commercial Relationships Disclosure: Yu Lin: Commercial Relationship: Code N (No Commercial Relationship) | Xiang Ren: Commercial Relationship: Code N (No Commercial Relationship) | Danian Chen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: STZ is toxic to pancreatic b cells and thus can induce type 1 diabetes, but if it has any direct effects on retinal cells is unknown. The purpose of this study is to investigate the effects of systemic administered STZ on the retina of neonatal rats.

Methods: STZ or citrate buffer (control) were subcutaneously injected into neonatal rats at postnatal day 1, 3, and 5 (P1/3/5). Electroretinogram (ERG), hematoxylin and eosin (H&E) staining, immunofluorescent staining, flow cytometry, and RNA sequencing were performed to evaluate the effects of STZ on retinal function and structure, and retinal cell differentiation at different time-points after STZ administration, from P2-P70.

Results: At P21, STZ reduced the amplitudes of dark-adapted a wave and b wave, as well as the total oscillatory potentials (OPs) energy. HE staining showed abnormal retinal structures from P5, including rosettes at the peripheral retina and ONL extrusions at the central retina. The retina is much thinner, including ONL and INL. Immunofluorescent staining revealed that the numbers of early-born retinal cell types (ganglion cells, cone, horizontal cells and amacrine cells) were not changed, but the late-born retinal cell types (rod, bipolar cells and Müller cells) were significantly reduced. STZ induced cell death ($TUNEL^+$ or active $caspase\ 3^+$) of retinal progenitor cells (RPCs), from P2-P5 (mainly at P3-P4). EdU labeling and Ki67 staining found that STZ suppressed the proliferation of RPCs and delayed the cell cycle exit of RPCs. Flow cytometry showed that the G2/M phase of STZ rats reduced significantly. STZ also delayed the development of retinal deep vascular plexus (DVP) at P10.

Conclusions: STZ is toxic to rat RPCs, induces cell death and cell cycle arrest of this cell type.

ABSTRACT BODY:

Purpose: ADOA is the most common inherited optic neuropathy, starting in the first decade of life and resulting in severe and progressive visual decline due to loss of RGCs. Most patients harbor loss-of-function mutations in the OPA1 gene that lead to haploinsufficiency. Reduced OPA1 protein levels result in impaired mitochondrial function in RGCs leading to cell death. Currently, there is no treatment for patients with ADOA. Targeted Augmentation of Nuclear Gene Output (TANGO) ASOs, such as STK-002, reduce the inclusion of a non-productive, alternatively spliced exon in OPA1, and leverage the wild-type allele to increase productive OPA1 mRNA and protein. We previously demonstrated that TANGO ASOs can increase OPA1 protein levels in human cell lines, rabbit retina, and ADOA patient fibroblasts. In this study, we evaluated ASO localization and OPA1 protein levels in the retina following intravitreal administration of STK-002 to NHPs.

Methods: Cynomolgus monkeys (N=22) received bilateral intravitreal injections of vehicle or STK-002. Eyes were collected at 4 or 8 weeks after injection. Retinas were isolated for molecular analyses and whole globes were prepared for histology. Retinal OPA1 mRNA and protein were measured using qPCR (Taqman) and enzyme-linked immunosorbent assay (ELISA), respectively. A hybridization ELISA (HELISA) method was used to quantitate STK-002 levels in retina. Whole globes were sent for custom assay development and detection of STK-002 by miRNAscope™ in situ hybridization (ISH), and detection of OPA1 protein by immunofluorescence (IF).

Results: Retinal exposure of STK-002 increased in a dose-dependent manner and remained high at the last timepoint evaluated (Week 8). STK-002 also dose-dependently increased protein levels at Week 4, ranging from 31 to 47% compared to vehicle, and levels were maintained at Week 8. ISH and IF analysis demonstrated that both STK-002 and OPA1 protein levels increased in RGCs, the target cells for ADOA.

Conclusions: STK-002 produced a dose-dependent and persistent increase in OPA1 protein expression in the retinas of NHPs. ASO-induced increase in OPA1 protein levels in RGCs represents a potentially disease-modifying therapy for patients with ADOA.

ABSTRACT BODY:

Purpose: The capacity for endogenous regeneration of retinal neurons after injury varies greatly among vertebrate species. For example, zebrafish Müller glia can regenerate all major retinal cell types after injury, while those in mice appear to lack this ability. The neurogenic potential of retinal glia in other mammalian model organisms is currently unknown. In this study, we aimed to identify genes and transcriptional networks involved in regulating neurogenic competence in a rabbit model of retinal injury.

Methods: Animal procedures were conducted in accordance with the ARVO Statement for the Use of Animals in Ophthalmic and Vision Research and were approved by the Johns Hopkins Animal Care and Use Committee. Unilateral retinal injury was induced in Dutch Belted rabbits by vitrectomy, retinotomy, retinal detachment, platelet-rich plasma injection, and cryotherapy. At different time points after injury, extracted retinas were dissociated and processed to assess the transcriptional profile by single cell RNA sequencing (sc-RNAseq). Fellow eyes were used as non-injury controls.

Results: Retinas were harvested at time points ranging from six hours to 35 days after injury induction. We profiled >70,000 single cells in this study. All major retinal cells including neurons, glia, and retinal pigment epithelium cells were identified in the data sets using selected marker genes. We identified two trajectories of glial cells post-injury: the first expressing classical fibrotic markers (ACTA2 and COL1A1) and the second expressing several genes that are known to promote proliferation (MKI67, MYBL2, UBE2C, TOP2A and HMGA2) and neurogenic competence (ASCL1, GADD45G, KLF6, MSX2, OLIG2, HES6, BHLHE22 and NEUROG2).

Conclusions: Our high throughput transcriptomic analysis identified known fibrotic and neurogenic genes that were differentially expressed between control and injury states in the rabbit model. These findings may facilitate further research in large mammalian models on molecular pathways that could be targeted to induce neurogenesis in human Müller glia following retinal injury.

ABSTRACT BODY:

Purpose: This study describes the application of deep learning methodology to identify the pupil, limbus, and eyelid boundaries in images from a variety of commercially available topographers with a single unified software approach.

Methods: 604 de-identified unique grayscale infrared iris images were obtained from a variety of commercially available topographers. All images had the boundaries delineating the pupil and visible iris annotated by hand using software tools. A custom pupil warping method was utilized to produce augmented copies of each image with the iris “stretched” to varying pupil shapes and sizes. A deep convolutional neural network based on the U-Net architecture was trained to label pixels from these images as belonging to the pupil, iris or neither. An active contours algorithm was developed to post-process the U-Net output into geometric curves and infer eyelid interference based on the shape of the iris contour. Performance was evaluated through two-fold cross-validation based on geometric center accuracy and dice coefficient (F1 score) of the final curve-bounded regions.

Results: The pupil and limbus were correctly identified in 603 of 604 unique eyes for a success rate of 99.8%. The pupil center error – defined as the Euclidean distance between the center-of-mass of the hand-labeled pupil region and the center of the best-fit ellipse to the identified pupil curve – was below 5 pixels in 98.7% of cases, below 10 pixels in 99.5% of cases, and below 15 pixels in 99.7% of cases (pixel scaling varies from approximately 0.03 to 0.045 mm per pixel). The similarly defined limbus center error was below 5 pixels in 69.2% of cases, below 10 pixels in 95.0% of cases, and below 15 pixels in 99.8% of cases. Dice coefficients measured above 0.95 in 95.6% of cases for the pupil, 98.2% for the composite iris region (including the pupil area), and 92.0% for the exclusive iris region (excluding the pupil area).

Conclusions: Modern deep learning technology is capable of segmenting iris images from a wide variety of diagnostic devices under a unified software approach, with a standardized image resizing scheme serving as the only device-specific operation. This technological advance has significant implications for device interoperability, as it can enable device software to handle images from multiple additional input devices with little or no modification.

SUBMITTER (NAME ONLY): Darren Lee

TITLE: A novel and distinct TIGIT-dependent Treg subset provides resistance to relapsing uveitis through suppression of Th17 cells

SESSION TITLE: Uveitis: Human and Murine Experimental Medicine Studies

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: D.J. Lee, T. McDonald, K. Peters, Ophthalmology/Dean McGee Eye Institute, The University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma, UNITED STATES|D.J. Lee, Microbiology and Immunology, The University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma, UNITED STATES|

Commercial Relationships Disclosure: Darren Lee: Commercial Relationship: Code N (No Commercial Relationship) | Trisha McDonald: Commercial Relationship: Code N (No Commercial Relationship) | Kayleigh Peters: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Experimental autoimmune uveitis (EAU) is used to gain a better understanding of human autoimmune uveitis. EAU-resolution is in part due to emergence of ocular antigen specific regulatory T cells (Tregs) that express T cell Immunoreceptor with Ig and ITIM domains (TIGIT). We have previously published that post-EAU TIGIT^{+} Tregs are distinct from post-EAU PD-1^{+} Tregs, and that Treg induction of PBMCs from uveitis patients induces significantly fewer TIGIT^{+} Tregs compared to controls. The role for TIGIT on Th17 cells over the course of EAU is not well understood.

Methods: IL-17-GFP and Foxp3-GFP reporter mice given TIGIT blocking antibody (Ab) at the onset of EAU and post-EAU mice were reimmunized for EAU. Flow cytometry analysis of TIGIT expression on Th17 and Tregs was done at the onset of EAU. Slit lamp examination and infiltration of Th17 and Tregs into the eye was done throughout disease and following reimmunization.

Results: We observed Th17 cells emerge in the eye beginning at the onset of EAU and diminish as EAU resolved. At the onset of EAU flow cytometry analysis of ocular T cells revealed 2-5-fold more TIGIT^{+} T cells in the FoxP3 compartment compared to the Th17 compartment. The reporter mice confirmed a persistence of Tregs in the eye compared to a decrease in Th17 cells as resolution of EAU occurred. Mice administered TIGIT blocking Ab showed no difference in the course of disease compared with control EAU mice. Reimmunization of EAU resulted in a significant increase in EAU of mice that received TIGIT blocking Ab compared to control EAU mice that received isotype Ab. Reimmunization of reporter mice that received TIGIT Ab showed diminished Tregs, and an increase of Th17 cells in the eye. In contrast, control reporter mice that received isotype had an increase in Tregs, and a decrease in Th17 cells in the eye.

Conclusions: This work suggests that TIGIT is needed for the induction of Tregs that emerge and persist in the eye over the course and resolution of EAU. Additionally, TIGIT signaling limits the migration of Th17 cells into the eye as resolution of EAU occurs. We also provide evidence that relapse of EAU may be due to an expansion of Th17 cells in the eye, and this expansion may be limited by TIGIT-dependent Tregs. The implication of this work is that TIGIT signaling may be an important mechanism that provides resistance to relapsing autoimmune uveitis.

ABSTRACT BODY:

Purpose: To evaluate the presence of specific aqueous humour (AH) biomarkers in eyes affected by uveal melanoma (UM) and to correlate them with tumor genetic and clinical characteristics.

Methods: Seventy-two eyes affected by primary UM were included. Tumor thickness, serous detachment and largest basal diameter were specific clinical characteristics. During brachytherapy AH sample collection and transscleral fine needle aspiration biopsy were performed. AH samples were analyzed by microarray and western blotting techniques to quantify selected proteins. Cytologic material underwent fluorescence in situ hybridization for chromosome 3. The AH of thirty-six normal eyes, scheduled for cataract surgery, was used as control.

Results: Compared with the control group, significantly higher levels of Somatostatin Receptor Type 1 (SSTR1; p=0.027), Splicing Factor 3B subunit 1 (SF3B1; p=0.026), BRCA1 Associated Protein 1 (BAP1; p=0.012), Guanine nucleotide binding protein [G protein], q polypeptide (GNAQ; p=0.024), Human Melanoma Black (HMB45; p=0.017), Interleukin-6 (IL-6; p=0.049), IL-8 (p=0.007), Regulated upon Activation Normal T cell Expressed and Secreted (RANTES; p=0.009), Pigment Epithelium-Derived Factor (PEDF; p=0.049), Osteopontin (p=0.049), Epidermal Growth Factor (EGF; p=0.042), basic Fibroblast Growth Factor (bFGF; p=0.018), Macrophage Inhibiting Factor (MIF; p=0.008), Monocyte Chemoattractant Protein (MCP; p=0.022) were detected in UM group. A positive significant correlation was found between: tumor thickness and IL-8($p = 0.032$) and VEGF($p = 0.032$), degree of serous retinal detachment and IL-6 ($p = 0.021$), largest basal diameter and RANTES ($p = 0.031$). Monosomy 3 was detected in 34 cases (47%) and disomy 3 in 38 cases (53%). Statistically significant higher levels of inflammatory proteins were detected in eyes with monosomy 3 UM (p=0.049).

Conclusions: Selected biomarkers may be identified in the AH of eyes affected by UM. These findings not only confirm in vivo the possibilities offered by AH analysis in UM eyes, but suggest that AH evaluation may represent the liquid biopsy approach in UM diagnosis, prognosis and follow-up.

TITLE: APOE4 impairs the response of neurodegenerative microglia and prevents neuronal loss in glaucoma

SESSION TITLE: Neurodegeneration

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: M. Margeta, K.M. Pitts, Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|O. Butovsky, Brigham and Women's Hospital, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Milica Margeta: Commercial Relationship(s);Code P (Patent):G3P | Kristen Pitts: Commercial Relationship: Code N (No Commercial Relationship) | Oleg Butovsky: Commercial Relationship(s);Code P (Patent):G3P

ABSTRACT BODY:

Purpose: The apolipoprotein E4 (APOE4) allele is associated with an increased risk of Alzheimer's disease and a decreased risk of glaucoma and age-related macular degeneration, but the underlying mechanisms remain poorly understood. Prior research has demonstrated that Apoe is a critical regulator of the microglial neurodegenerative (MGnD/DAM) molecular signature in disease. The goal of this study was to investigate the effect of human APOE alleles, APOE3 and APOE4, on microglial molecular signature and retinal ganglion cell (RGC) survival in glaucoma in order to test the hypothesis that the APOE4 allele is protective in glaucoma.

Methods: We investigated the microglial molecular signature in humanized APOE3 and APOE4 mice using the microbead (MB) glaucoma model. Retinal microglia were isolated one month after MB injection as CD11b+/Ly6C-/FCRLS+ cells and underwent Smart-Seq2 RNA sequencing. RGC survival was assessed in MB-injected APOE3 and APOE4 humanized mice using Brn3a+ cell body and PPD axon counts. As Galectin-3 (Lgals3) was found to be one of the strongly differentially expressed genes between APOE3 and APOE4 microglia, RGC survival was also evaluated in MB-injected Lgals3$^{-/-}$ mice and in wildtype mice intravitreally treated with Galectin-3 inhibitor TD139. Human retinal postmortem samples were genotyped for APOE and immunostained for Iba1 and Galectin-3.

Results: We have found that MB-injected APOE3 animals experience significant RGC loss and their microglia transition to MGnD molecular phenotype, characterized by upregulation of inflammatory cytokines, complement, and Lgals3. In contrast, MB-injected APOE4 animals were protected from RGC degeneration, and their microglia did not upregulate MGnD genes despite IOP elevation. Genetic and pharmacologic targeting of Galectin-3, the downstream effector of Apoe, also ameliorated RGC degeneration. Finally, Galectin-3 was upregulated in microglia in human APOE3 glaucoma samples, and its expression was attenuated in APOE4 glaucomatous retinas.

Conclusions: In this study we demonstrate that APOE4 impairs the response of neurodegenerative microglia and protects RGCs from glaucomatous degeneration. These results provide an explanation as to why the APOE4 allele is associated with a decreased risk of glaucoma and show that the APOE-Galectin-3 signaling pathway can be targeted to develop novel neuroprotective therapies for this blinding disease.

TITLE: Low in vitro Serratia marcescens Adhesion to Lehfilcon A Contact Lenses
SESSION TITLE: Contact lens
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: R. Pifer, V. Harris, M. Crary, P. Shannon, Alcon Research Institute, Fort Worth, Texas, UNITED STATES|
Commercial Relationships Disclosure: Reed Pifer: Commercial Relationship(s);Code E (Employment):Alcon Research | Valerie Harris: Commercial Relationship(s);Code E (Employment):Alcon Research | Monica Crary: Commercial Relationship(s);Code E (Employment):Alcon Research | Paul Shannon: Commercial Relationship(s);Code E (Employment):Alcon Research
ABSTRACT BODY:
Purpose: Lehfilcon A is a new monthly replacement contact lens with a silicone hydrogel core and a Celligent® Technology water gradient surface with a ≥90% surface water content. The surface polymer, 2-methacryloyloxyethyl phosphorylcholine (MPC), creates a nanofiber structure on the lehfilcon A lens surface. MPC coatings protect against fouling by foreign substances, including microorganisms. Therefore, in this in vitro experimental study, we examined the ability of Serratia marcescens to adhere to lehfilcon A and leading monthly or bi-weekly replacement contact lenses.
Methods: We performed quantitative adhesion assays to evaluate the adherence of S. marcescens to seven contact lens materials (lehfilcon A, comfilcon A, senofilcon A, omafilcon B, fanfilcon A, balafilcon A, and senofilcon C). Individual contact lenses were incubated in the presence of S. marcescens and gently rinsed to remove non-adherent bacteria. Adherent bacteria were eluted from lenses via sonication and bacterial colony forming units (CFU) were enumerated by plating. CFUs were normalized to the surface area of each lens. Statistical analyses were performed as t-tests for differences in the mean log CFU/mm^2 between lens types without assuming equal standard deviation between groups. Bonferroni correction was used to account for multiple comparisons.

We performed fluorescent microscopy to qualitatively evaluate bacterial adherence to lehfilcon A and comparison lenses. The cell surface of live S. marcescens was stained with a protein-conjugating dye, 5(6)-Carboxytetramethylrhodamine succinimidyl ester (TAMRA-SE). Labeled bacteria were used in adhesion assays as described above, fixed with paraformaldehyde, and contact lenses were imaged using a TRITC filter.
Results: We observed lower densities of S. marcescens adhered to lehfilcon A (2.6 ± 0.3 log CFU/mm^2) relative to the next best performing lens material, comfilcon A (4.6 ± 0.3 log CFU/mm^2; $p < 0.0001$). This difference corresponds to ≥99.0% lower adhesion to lehfilcon A. In agreement, fluorescent microscopy visually demonstrated lower levels of bound bacteria to lehfilcon A vs alternative lens materials.
Conclusions: Our in vitro data suggests that S. marcescens adheres to lehfilcon A at low levels relative to comparable marketed contact lenses. These results add to the body of evidence that MPC coatings confer anti-fouling properties to medical devices.

ABSTRACT BODY:

Purpose: The ocular surface is a defined route of entry of several viral pathogens. Conjunctival epithelial cells, which express viral entry receptors ACE2 and TMPRSS2, constitute the largest exposed epithelium of the ocular surface tissue, and may represent a relevant viral entry route. An important unresolved question is whether SARS-CoV-2 can infect the conjunctival epithelial cells.

Methods: Adult human eyes from three female donors of 52, 78, and 80 years old were donated for research following informed consent. All tissue was provided by NHS Blood and Transplant Tissue and Eye Services or the Newcastle NHS Trust following ethical approval (18/YH/04/20). Conjunctival epithelial progenitors were expanded on 3T3 mitotically inactivated feeder cells and differentiated using an air-liquid interface (ALI) method. Single cell RNA-Seq, with complementary imaging and virological assays were used to define the cellular permissiveness of various epithelial cell types in the conjuctiva and determine the cell type specific innate immune response to SARS-CoV-2 infection.

Results: We generated an organotypic ALI model of conjunctival epithelium, composed of progenitor, basal and superficial epithelial cells and fibroblasts, which could be maintained successfully up to day 75 of differentiation. Using single-cell RNA Seq, with complementary imaging and virological assays, we observed that while all conjunctival cell types were permissive to SARS-CoV-2 genome expression, a productive infection did not ensue. The early innate immune response to SARS-CoV-2 infection in conjunctival cells was characterised by a robust autocrine and paracrine NF-Kβ activity, without activation of antiviral interferon signalling.

Conclusions: The data presented herein show that conjunctival epithelium is permissive to SARS-CoV-2 infection, but without evidence of productive viral replication. This study was performed in organotypic models derived from three different patients, with single cell RNA-Seq data obtained from the peak infection interval. Future work should assess changes in transcriptome of each conjunctival cell type in frequent intervals after infection and in a larger number of donors to get deeper insights into the refractory nature of these cell to viral propagation.

ABSTRACT BODY:

Purpose: Perfluorohexyloctane (PFHO, NOV03) is under clinical investigation for the treatment of dry eye disease (DED) associated with meibomian gland dysfunction. We evaluated the physical properties of PFHO along with its in vitro effect on meibum from a human volunteer.

Methods: PFHO structure and interactions with standard lipid esters (LEs), a wax ester (WE), and with meibum from a 68-year old Caucasian volunteer without DED were studied using absorbance spectroscopies. Lipid composition and concentrations in the collected meibum were measured using nuclear magnetic resonance (NMR) spectroscopy. Evaporation rates were measured gravimetrically.

Results: PFHO is a liquid between -30°C and 70°C and evaporates at a rate of 0.137 ± 0.003 μm/min. When layered on top of physiological saline, PFHO inhibited the evaporation rate of saline by 84% ($P < 0.0001$). Stearylpalmitate and cholesterylstearate, two ordered LEs, were visibly insoluble in PFHO, whereas oleyloleate, a fluid WE, was soluble in PFHO. Addition of PFHO had a minimal effect on ordered LEs but increased the fluidity of the WE by 64%. Addition of PFHO to meibum (19:1, g:g) significantly increased the magnitude of the phase transition and decreased the cooperativity and minimum frequency of the phase transition of meibum but did not change the order of the lipids at physiological temperatures.

Conclusions: PFHO is a potential replacement for the tear film lipid layer in patients with DED: it significantly decreases the rate of evaporation, a property related to tear film stability. However, PFHO did not change the lipid order in meibum from a healthy volunteer. We speculate that PFHO could form a protective layer on the tear film surface that enhances tear film spreading as well as decreasing the rate of evaporation. Further in vitro rheological and in vivo evaporation rate studies are warranted along with interaction studies with meibum from DED patients.

ABSTRACT BODY:

Purpose: Risuteganib (RSG) is a synthetic peptide that has shown promising efficacy in an intermediate dry age-related macular degeneration (AMD) phase 2 clinical study. We previously reported that RSG protected against retinal pigment epithelial (RPE) cell injury induced by hydroquinone (HQ), a major oxidant in cigarette smoke and atmospheric pollutants agents implicated in AMD pathogenesis. Herein, we investigate whether RPE cells take up RSG.

Methods: Cultured human RPE cells were transduced overnight with late endosome-GFP, mitochondria-GFP, or endoplasmic reticulum-GFP using CellLight Reagents (BacMam 2.0) at 40 particles per cell. Cells were washed, incubated with Alexa Fluor™ 555 alkyne, triethylammonium salt (AF555, 50uM, control) or RSG-Alexa Fluor™ 555 (RSG-AF555, 50uM, synthesized using Fmoc [the fluorenylmethoxycarbonyl protecting group] solid-phase peptide synthesis and N-Hydroxysuccinimidyl ester-amine reaction) for various times at 37°C or for 2.5 hours at 4°C. RSG co-localization with cell organelles were examined by confocal microscopy.

Results: A large amount of cytoplasmic dot-like staining was detected in RSG-AF555-treated cells while little staining was seen in AF555-treated cells 2.5 hours post-treatment. The cytoplasmic dot-like staining pattern in RSG-AF555-treated cells was dramatically reduced at 4°C when compared to 37°C at 2.5 hours post-treatment. RSG-AF555 accumulated in the cells as early as 30 minutes and remained for at least 21 hours. In RSG-AF555-treated cells, some RSG-AF555 dots were co-stained with late endosome and additional RSG-AF555 dots were co-stained with mitochondrial and endoplasmic reticulum 2.5 hours post-treatment.

Conclusions: Experiments at temperatures that permit and inhibit endocytosis suggest that cultured RPE cells take up RSG via endocytosis. Co-localization of RSG with cell organelles may be involved in RSG's protection against HQ-induced cell damage.

ABSTRACT BODY:

Purpose: Treatment for ocular inflammation includes intravitreally administered corticosteroid treatments which are plagued by inconsistent delivery and inability to maintain significant level of drug for a long period of time. This study proposes that sustained release of dexamethasone via a polymeric implant is an ideal solution for long term (> 6 months) delivery to treat chronic inflammation. This study demonstrates dexamethasone release from an EVA implant and highlights the ability to tune the release rate of a therapeutic with various loading percentages and polymer grades.

Methods: Powdered EVA with vinyl acetate contents of 28% and 40% were blended with dexamethasone at loading levels of 20% and 50%. These blends were compounded via hot melt extrusion (HME) on a 11mm twin screw extruder to produce four formulations. For each formulation, implants (N=6) were cut and weighed before placing them into Eppendorf conical tubes containing 5 mL buffer solution (pH =7.4). The tubes were placed into temperature-controlled incubators at 37 °C and 100 rpm. Samples were pulled at 1, 2, 7, 14, 21, 28 days and release were calculated via ultra-performance liquid chromatography (UPLC) method with thermo Fisher Scientific Vanquish UPLC equipped with an Ultra C18 column at 23 °C.

Results: All formulations demonstrated dexamethasone release at day one. 50% loaded formulations released dexamethasone at a higher concentration when compared to 20%-loaded formulations. EVA with 40% VA and 50% loaded with dexamethasone released 2.36 mg dexamethasone compared to 1.21 mg for EVA with 28% VA and loaded 20% at 28 days.

Conclusions: An EVA implant achieves sustained release of dexamethasone. Altering VA content is a tunable implant parameter that can be used to achieve the desired release profile of dexamethasone. The loading percentage has a larger effect on the release rate compared to the VA percentage in EVA. The demonstrated 1-month release rate, in tandem with modeling, provides evidence that an EVA implant can deliver dexamethasone for greater than 6 months.

ABSTRACT BODY:

Purpose: Diopsys® NOVA is a novel electroretinography (ERG) system that can perform flicker ERG testing. In this cross-sectional study, we assess the correlation between Diopsys® NOVA fixed-luminance flicker ERG phase and Diagnosys® Espion 2 flicker ERG implicit time measurements.

Methods: This study was a retrospective evaluation of patients with various retinal pathologies who underwent Diopsys® NOVA fixed-luminance and Diagnosys® Espion 2 flicker testing over a period of seven months. Patients who had an interim period of three or more months between the two tests were excluded. Patients who had any surgical intervention or change in disease activity between the two tests were excluded. Baseline patient characteristics including age, sex, and underlying diseases were collected. Pearson correlation coefficient was used for correlation analysis of values measured by the Diopsys® NOVA and the Diagnosys® Espion 2 flicker tests.

Results: The average Diopsys® phase measurement was 301.76 ± 38.02° while the average Diagnosys® implicit time measurement was 30.64 ± 4.28 milliseconds. A significant, strong negative correlation (r= -0.814, P<0.001) was observed between phase and implicit time measurements (Figure 1). Mean age of patients was 53.3 ± 24.1 years. 58% (n=7/12) of patients were female. Best corrected visual acuity ranged from 20/20 to hand motion. Ocular conditions included retinal vasculitis (n=7/22 eyes, 32%), melanoma associated retinopathy (n=2/22 eyes, 9%), panuveitis (n=2/22 eyes, 9%), autoimmune retinopathy (n=2/22 eyes, 9%), autoimmune optic neuropathy (n=2/22 eyes, 9%), non-proliferative diabetic retinopathy (n=2/22 eyes, 9%), age-related macular degeneration (n=2/22 eyes, 9%), tuberculous choroiditis (n=2/22 eyes, 9%), and retinal vein occlusion (n=1/22 eyes, 5%). Five patients (42%) had significant systemic associations including metastatic cutaneous melanoma, HLA-A29 positivity, tuberculosis, breast cancer, multiple sclerosis, and autoimmune hepatitis.

Conclusions: Higher Diopsys® NOVA fixed-luminance flicker ERG phase values are strongly correlated with lower Diagnosys® Espion 2 flicker ERG implicit time values. Our results suggest that Diopsys® NOVA fixed-luminance flicker ERG phase is consistent with Diagnosys® Espion 2 flicker ERG implicit time.

ABSTRACT BODY:

Purpose: Genome editing takes center stage in the development of new therapeutic applications for the treatment of inherited diseases. While a lot is known with regard to DNA repair processes and necessary modifications upon induction of a double strand break (DSB) at the target site in dividing cells in vitro, hardly anything is known in nondividing cells of different tissues in vivo, such as neurons. Therefore, the aim of the present study was to analyze the influence of template DNA quantity on the activity of nonhomologous endjoining (NHEJ) and homology directed repair (HDR) of DSBs in photoreceptor cells in vivo.

Methods: Sixteen hemizygous male or homozygous female mice (age: 2 months) of the C57BL/6-RPGR.^{tm1Sti} mouse line were injected subretinally with AAV2/8 vectors harboring the ISce-I homing endonuclease and a GFP frame linked by a T2A linker under the control of the rhodopsin kinase (Rk) promoter alone or together with a template (changing the ISce-I target site into a HindIII site) either in an all-in-one vector, or as two vectors at the ratio of 1:1 or 1:10 (endonuclease : template). Following euthanasia, GFP positive cells were enriched by FACS, and consequences of DNA repair activity studied at the target site by sanger sequencing and TIDE analysis.

Results: Between 10% (ISce-I vector alone), 15 and 17% (ISce-I and template all in one or 1:1 ratio, respectively) and 25% (ISce-I and template at 1:10 ratio) total editing activity was observed in targeted photoreceptor cells. While the NHEJ activity declined slightly from 10% (ISce-I vector alone) to 8% for the all in one vector and 6% for both vector combinations, the HDR activity increased from 8 and 9% for all in one vector and 1:1 ratio to 19% for the 1:10 ratio vector combination. Deletions and substitutions outnumbered insertions in NHEJ repair events and appeared to occur more often at the 5' site of the DSB.

Conclusions: Targeted DNA editing is possible in photoreceptor cells using the ISce-I homing endonuclease in vivo. The rate of HDR increases significantly with higher amounts of template. This correlation, which is known from in vitro experiments, has important implications in the design of therapeutic applications and may contradict the notion that all in one vectors are more efficient in gene transfer for genome editing applications.

ABSTRACT BODY:

Purpose: High Magnification Module (HMM™, Heidelberg Engineering, Heidelberg, Germany) imaging is a novel technique, designed to visualize the retina at a cellular level. To assess the potential of HMM™ metrics as clinical endpoints for future trials, we evaluated correlations between structural HMM™ metrics, spectral-domain OCT (SD-OCT, Heidelberg Engineering, Heidelberg, Germany) and retinal sensitivity on MAIA microperimetry (MP, CenterVue, Padova, Italy) in healthy subjects and p.arg142trp PRPH2-associated Central Areolar Choroidal Dystrophy (CACD) patients.

Methods: We projected a default 10° MP grid on composite HMM™ images and performed automated cone density (CD), intercell distance (ICD) and nearest neighbor distance (NND) analysis at stimuli located at 3 and 5° retinal eccentricity. We averaged HMM™ metrics and MP sensitivity of each participant if located at similar eccentricity (3 or 5°) and meridian (superior, inferior, temporal or nasal) and calculated Pearson correlation coefficients. We manually measured outer retinal thickness (ORT) on SD-OCT in absolute scotomas and relative scotomas, outside of focal atrophy. We defined ORT as the distance between RPE/Bruch membrane and the external limiting membrane (ELM).

Results: We included 15 genetically confirmed CACD patients and 5 healthy subjects. All correlations of HMM™ metrics and MP sensitivity at 3° reached statistical significance and are depicted in table 1. With exception of the inferior meridian with a Pearson r of -0,577 (p= 0,015396) for ICD, we were unable to find significant correlations at 5°. We found ORT in absolute scotomas to be statistically significant thinner (p=0.033) compared to relative scotomas of the same subject and retinal eccentricity, while CD of the corresponding areas did not differ significantly (p=0.945).

Conclusions: We have established significant correlations between multiple structural metrics on HMM™ imaging and retinal sensitivity on MP in healthy subjects and p.arg142trp PRPH2-associated CACD patients. A multimodal approach combining SD-OCT with HMM™ imaging and MP may allow for detailed mapping of retinal photoreceptor integrity, which may be used as biomarkers in future clinical trials.

ABSTRACT BODY:

Purpose: Dual inhibition of the angiopoietin-2 and vascular endothelial growth factor (VEGF)-A pathways with faricimab may extend treatment durability beyond current anti-VEGF therapies for diabetic macular edema (DME). The PTI algorithm in the phase 3 YOSEMITE/RHINE trials was a protocol-driven treat-and-extend regimen, designed to test the durability of faricimab by tailoring dosing intervals to individualized treatment response.

Methods: YOSEMITE/RHINE (NCT03622580/NCT03622593) were randomized, double-masked, active comparator–controlled trials of faricimab for center-involving DME. Patients were randomized 1:1:1 to faricimab 6.0 mg per PTI after a minimum of 4 initial every-4-week (Q4W) doses, faricimab 6.0 mg Q8W after 6 initial Q4W doses, or aflibercept 2.0 mg Q8W after 5 initial Q4W doses. In the PTI arms, patients received faricimab Q4W until central subfield thickness (CST) < 325 μm was achieved at or after week 12. Once CST < 325 μm was achieved, treatment intervals could be extended by 4 weeks (up to Q16W), maintained, or reduced by 4 or 8 weeks (as low as Q4W), based on prespecified CST and best-corrected visual acuity (BCVA) criteria. To maintain masking, all patients received sham injections at non–active dosing visits; however, CST and BCVA at sham injection visits were not used to determine PTI dosing intervals. Treatment intervals in the faricimab PTI arms were assessed through week 100.

Results: Among 1891 patients enrolled in YOSEMITE (N = 940) and RHINE (N = 951), 313 and 319 patients, respectively, were randomized to the faricimab PTI arms. At week 52, > 50% of patients in the PTI arms achieved Q16W dosing and > 70% achieved Q12W or Q16W dosing. Approximately two-thirds of patients achieved Q12W or Q16W dosing without an interval reduction below Q12W through week 52 (YOSEMITE, 68%; RHINE, 64%). The majority of patients who rapidly achieved Q16W dosing at week 32 (ie, the first timepoint that a patient could be extended to Q16W dosing) subsequently completed a full Q16W dosing cycle and remained on Q16W dosing at week 52. Faricimab treatment intervals through week 100 and PTI case studies will be presented at the meeting.

Conclusions: Treat-and-extend–based PTI dosing in YOSEMITE/RHINE optimized treatment intervals and demonstrated the durability of faricimab to meet the heterogeneous needs of patients with DME.

ABSTRACT BODY:

Purpose: Long-term exposure to benzalkonium chloride (BAK) causes toxicity reactions on the ocular surface. Sodium hyaluronate (SH) has been postulated as a potential neutralizing agent for BAK-induced toxicity. The goal of this work was to evaluate the protective effect of SH on BAK-induced toxicity using an in vitro model.

Methods: The NAV14 cell line (SV40-immortalized murine conjunctival epithelium) was used. Cell monolayers were exposed to different concentrations of BAK (0.001%; 0.005%; 0.01%) and SH (0.2%; 0.3%; 0.4%) for 15 minutes; then, the cells were washed, and fresh culture media was added. Cell viability was evaluated after 2 h by resazurin reduction and lactate dehydrogenase (LDH) enzyme release. Also, cell migration and proliferation over 24 hours were determined by the scratch wound-healing assay. Data was analyzed by two-way ANOVA and is shown as mean±SD of two independent experiments with 4-6 replicates each. Statistical significance was defined as $p<0.05$.

Results: BAK induced a concentration-dependent decrease on cell viability (BAK 0.001%: 91±14%, BAK 0.005%: 45±9% and BAK 0.01%: 22±10% of control cells, $p<0.001$) and an increase in LDH release (no BAK: 0.22±0.02, BAK 0.001%: 0.31±0.02, BAK 0.005%: 1.14±0.05 and BAK 0.01%: 1.21±0.05, $p<0.001$). Conversely, SH neutralized these effects also in a concentration-dependent manner ($p<0.001$). In the presence of SH 0.4% (highest effect), cell viability was BAK 0.001%: 104±22%, BAK 0.005%: 109±9% and BAK 0.01%: 75±13% of control cells ($p<0.001$ for BAK 0.005-0.01%) while LDH release was no BAK: 0.24±0.03, BAK 0.001%: 0.26±0.01, BAK 0.005%: 0.37±0.02 and BAK 0.01%: 0.49±0.22, (vs no SH: $p<0.001$ for BAK 0.005-0.01%). BAK also reduced wound closure in vitro (after 24 h, no BAK: 76±14%, BAK 0.001%: 42±12%, BAK 0.005%: 17±16% and BAK 0.01%: 0.0% wound closure, $p<0.001$ for all BAK). Conversely, SH neutralized this effect in a concentration-dependent fashion ($p<0.001$). In the presence of SH 0.4% (highest effect), wound closure at 24 h was: no BAK: 81±15%, BAK 0.001%: 58±6%, BAK 0.005%: 63±10%, BAK 0.01%: 60±8% (vs no SH: $p<0.001$ for BAK 0.005-0.01%).

Conclusions: SH neutralized BAK toxicity on conjunctival epithelial cells in a concentration-dependent manner. SH 0.4% was even protective at the highest preservative concentration. These findings support the use of SH to mitigate BAK toxicity in patients, although more studies are needed.

ABSTRACT BODY:
Purpose:

High myopes experience lower contrast sensitivity (CS). A fast and easy way to test for CS has been developed by the RCCST; however, baseline CS measurements using this system in patients with high myopia remain unknown. This study tested the hypothesis that CS will be lower in high myopic patients compared to emmetropic individuals.
Methods: Cross-sectional, comparative study. Twenty-five patients with high myopia (less than or equal to 6 D and/or >26.5mm axial length) aging between 18 and 50 years with a BCVA equal or better than 20/40 were enrolled. Postoperative patients or with any ophthalmological disease associated with myopia were excluded. RCCST, and A-mode ultrasound measurement of the axial length were performed in all participants. RCCST results were expressed in logarithmic units. Obtained data was later compared with our previous CS reports of emmetropic individuals. Mann-Whitney U test and Spearman's correlation were used for statistical analysis.
Results:

Twenty-five patients were included in group A (high myopic), of which 14 were women and 11 were men. This group had a mean age of 26.6 years, standard deviation (SD): 5.46, range: 18 - 36 (95% CI: 24.34 - 28.85) . The mean CS was 1.56, SD: 0.21, range: 0.90 - 1.75 (95% CI: 1.47 - 1.64).
Group B (emmetropic patients) was composed of 76 patients, with a mean age of 25.78 years, SD 4.69, range 18 - 39 years. Mean CS for group B was 1.62, 0.09 SD, 95% CI 1.60 - 1.65 (range: 1.25 - 1.98).
A comparison of mean CS using Mann-Whitney U Test, resulted in a non-significant Z-score of -0.422 (P= 0.673).
Spearman’s correlation between age and CS was performed for group A, resulting in a small, negative correlation, without statistical significance (Correlation Coefficient: -0.211; P= 0.311).
Group A presented a mean axial length of 27.11 mm, SD: 1.43, range: 25.41 - 31.01 (95% CI: 26.51 - 27.70).
Spearman’s test between contrast sensitivity and axial length resulted in a small, negative, non-significant correlation (correlation coefficient: -0.053; P= 0.801).
Conclusions: Our results are consistent with our hypothesis, CS in high myopic patients appear to be lower than in emmetropic patients, however the difference was not statistically significant. There is a small negative correlation between axial length and CS suggesting that high axial lengths may present lower CS.

ABSTRACT BODY:

Purpose: Dry eye (DE) is a common condition that can profoundly impact patient (pt) quality of life. Pathogenesis is multifactorial, yet most therapies only address inflammation or tear film instability. Neurosensory abnormalities have been increasingly recognized as a key DE feature. A therapeutic agent targeting this etiology would be of great value as improving nerve health may be critical to restoring ocular homeostasis. This study evaluated the efficacy and safety of rhNGF in pts with DE.

Methods: This phase 2, randomized, vehicle (VEH)-controlled study enrolled pts ≥18 years with moderate-to-severe DE for ≥6 months. Pts were randomized 1:1:1 to receive the following drops in both eyes for 4 weeks (wks) + 12 wks follow up: 20 µg/mL rhNGF 3x/day (TID), 20 µg/mL rhNGF 2x/day (BID) + VEH 1x/day, or VEH TID. Primary endpoint was change from baseline in Schirmer test I without anesthesia at wk 4. Secondary endpoints included change in Symptom Assessment in Dry Eye (SANDE) scores. Treatment (tx)-emergent adverse events (TEAEs) were assessed throughout the study.

Results: In total, 261 pts were randomized to rhNGF TID (N=87), rhNGF BID (N=86), or VEH (N=88) arms. In the full analysis set, mean (SD) change from baseline in Schirmer test I at wk 4 was higher in the rhNGF BID than VEH arm (4.0 [8.1] vs 1.7 [5.8] mm, P=0.037). Rates of responders (score >10 mm/5 minutes) at wk 4 were also higher in the rhNGF TID (25.9%) and rhNGF BID (29.3%) arms compared with the VEH (11.9%) arm (P=0.028 and P=0.007, respectively). During follow up, the rhNGF TID arm had significantly greater mean (SD) SANDE score reductions, indicating greater symptom improvement, than the VEH arm at wk 8 (-27.2 [25.8] vs -16.9 [20.4], P=0.006), wk 12 (-27.9 [25.6] vs -16.4 [19.6], P=0.002), and wk 16 (-26.5 [25.7] vs -16.7 [19.7], P=0.008). More pts in the rhNGF arms than VEH arm reported ≥1 ocular TEAE in wks 1-4 (69.4% rhNGF TID, 65.5% rhNGF BID, 13.6% VEH); the most common was eye pain (63.5% rhNGF TID, 46.4% rhNGF BID, 4.5% VEH), which was mild and transient in most pts. No study drug-related serious AEs were reported.

Conclusions: After 4 wks of tx, rhNGF improved Schirmer test I scores and appeared to have clinically relevant enduring effects, with significantly improved DE symptoms up to 12 wks post-tx completion in the rhNGF TID arm. rhNGF was generally well-tolerated, and most TEAEs were mild.

TITLE: Progression dynamics of early versus advanced atrophic lesions in non-neovascular AMD using AI-based OCT analysis

SESSION TITLE: AI in the Retina

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Coulibaly, P. Fuchs, D. Lachinov, O. Leingang, H. Bogunovic, G.S. Reiter, U. Schmidt-Erfurth, Ophthalmology, Medizinische Universitat Wien, Wien, Wien, AUSTRIA|

Commercial Relationships Disclosure: Leonard Coulibaly: Commercial Relationship: Code N (No Commercial Relationship) | Philipp Fuchs: Commercial Relationship: Code N (No Commercial Relationship) | Dmitrii Lachinov: Commercial Relationship: Code N (No Commercial Relationship) | Oliver Leingang: Commercial Relationship: Code N (No Commercial Relationship) | Hrvoje Bogunovic: Commercial Relationship: Code N (No Commercial Relationship) | Gregor Reiter: Commercial Relationship: Code N (No Commercial Relationship) | Ursula Schmidt-Erfurth: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Atrophic lesion growth rates can vary during the progression of non-neovascular age-related macular degeneration (AMD) which might have potential influence on the use of complement inhibition. The purpose of this study is to investigate the progression of atrophic lesions as early as they arise in order to set a standard for the optimal time of first intervention.

Methods: Patients which had recently converted to atrophic late AMD were included and prospectively imaged using optical coherence tomography (OCT). The respective total areas of external limiting membrane (ELM) disruption and retinal pigment epithelial (RPE) loss on longitudinal OCT volumes were quantified using artificial intelligence (AI) algorithms. Freshly converted eyes were compared to eyes with advanced disease status using mixed effect models.

Results: Eighty-two eyes from 53 patients were included. The first cohort consisted of 30 eyes from 25 patients with a recent conversion to complete retinal pigment epithelium and outer retinal atrophy (cRORA) within 6 months. The second cohort consisted of 52 eyes from 28 patients with a conversion to cRORA at least two years prior to the first study visit. The study period encompassed two years with scheduled visits every 6 months. Mean (95%CI) square root progression of recent atrophy was 123.92 µm [76.88 – 170.86] and 126.08 µm [80.18 – 171.94] per year for ELM disruption and RPE loss, respectively. Mean square root progression of advanced lesions was 220.2 µm [187.46 – 252,68] and 219.2 µm [187 – 251.06] per year for ELM disruption and RPE loss, respectively. A significant difference regarding progression of ELM disruption (p=0.001) and RPE loss (p=0.001) between converted and advanced lesions was found.

Conclusions: Data on early disease progression in atrophic AMD is rare. Atrophic lesions from recently converted patients have a slower growth rate in comparison to patients in an advanced disease stage. These findings might play a crucial role in planning future treatments using complement inhibition. Individual disease monitoring in early AMD supported by AI-quantifications is necessary to capture the ideal point of care in non-neovascular AMD.

TITLE: Fluorescence lifetimes of subretinal pigment epithelial depositions are prolonged in a primary RPE cell culture model

SESSION TITLE: Pathobiology of AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R.S. Schultz, D. Meller, M. Hammer, Clinic for Ophthalmology, Universitatsklinikum Jena, Jena, Thüringen, GERMANY|

Commercial Relationships Disclosure: Rowena Schultz: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Meller: Commercial Relationship: Code N (No Commercial Relationship) | Martin Hammer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Fluorescence lifetime imaging ophthalmoscopy (FLIO) is used to specify fundus autofluorescence of pathologic lesions such as drusen in AMD. However, the identification and full characterization of disease-related fluorophores in vivo is difficult. The purpose of this study was to measure fluorescence spectra and lifetimes of RPE and drusen-like sub-RPE deposits in an established in vitro model of primary RPE cell culture[1], which will enable down-stream fluorophore characterizations for a better understanding of in vivo FLIO findings.

Methods: Retinal pigment epithelium cells isolated from freshly enucleated porcine eyes were cultured on Transwell membranes for up to 8 weeks in Miller medium[2] supplemented with 0.5% and 1.5% human serum (upper and lower well, respectively). Two-photon-excited autofluorescence emission spectra and time-resolved autofluorescence measurements (500-700 nm, λ_{ex} = 960 nm) were recorded from the RPE cells as well as deposits generated by them. Decays were approximated by a series of three exponentials, with the amplitude-weighted mean (τ_m) utilized as the main parameter for statistical analysis (Wilcoxon test of deposits vs. surrounding RPE cells).

Results: Primary porcine RPE cells cultured with human serum survived 8 weeks and produced sub-RPE deposits (size: 693±292 μm^2, n=9) when cultured on 10-µm-thick Transwell membranes with 0.4-µm-diameter pores. The autofluorescence emission peak maximum of deposits was green-shifted compared to RPE (Median (IQR): 569 (0) nm vs. 636 (2.5) nm, Z = -2.9, p = 0.004) and the lifetimes were significantly prolonged (534 (583) ps vs. 81 (49) ps, Z = -2.8, p = 0.005).

Conclusions: The data suggest that sub-RPE deposit formation, initiated by porcine RPE cultured with human serum, leads to deposits with prolonged lifetimes comparable to drusen as seen in AMD histology.[3] This cell culture model of early AMD lesions provides a system for analysis of the fluorophore-composition of sub- RPE deposits and will help to better interpret FLIO imaging results.

ABSTRACT BODY:

Purpose: Plane-wave (PW) ultrasound with a linear array probe is capable of visualizing and measuring retrobulbar blood-flow. The goal of this study was to determine if PW ultrasound could be used to image and measure retorbulbar blood-flow velocities in preterm neonates and assess the association of these velocities with retinopathy of prematurity (ROP) stages and zone.

Methods: Ultrafast PW imaging of the perioptic region was performed with a Verasonics Vantage 128 ultrasound system using an 18 MHz linear array probe. Both eyes of 26 low-birthweight subjects at risk for ROP were scanned in the neonatal intensive care unit. Each scan was compounded from six scan angles, at a rate of 3000 compound scans/sec for 1.5 seconds, capturing at least two cardiac cycles. 16 subjects were scanned twice bringing the total number of eyes scanned to 84. All subjects had a birth-weight of less than 1500 g and a gestational age of less than 30 weeks. PW data were post processed to form color-doppler images and flow-velocity was measured in the central retinal artery (CRA), central retinal vein (CRV) and short posterior ciliary artery (SPCA) using spectrogram analysis. Findings were compared to ophthalmoscopic grading, with ultrasound and ophthalmoscopic findings masked until completion.

Results: Minimal change in arterial or venous flow was observed in stage 1 and 2 ROP, but systolic and diastolic flow velocities increased significantly ($p<.001$) compared to non-ROP at stage 3 in the CRA (from 39±14 mm/sec to 64±20 mm/sec systolic) and CRV (from 19±6 mm/sec to 31±12 mm/sec systolic) Systolic flow velocity increased as well in the SPCA (from 45±14 mm/sec to 58±15 mm/sec, $p=.007$). Resistance indices did not change significantly. Five stage-3 subjects with pre-plus disease did not have significantly different flow velocity than other stage-3 subjects. There was no correlation between flow velocity and blood pressure.

Conclusions: Flow velocities in the major orbital vessels increased at ROP stage 3. If plus disease is caused by high retinal flow velocities, its detection by PW ultrasound may represent a valuable tool to assess ROP risk in low birthweight neonates, especially because the exam can be performed more frequently than dilated ophthalmoscopy. With few pre-plus and no plus disease in this series, this hypothesis remains to be explored in a larger cohort.

TITLE: Low in vitro Pseudomonas aeruginosa Adhesion to Lehfilcon A Contact Lenses

SESSION TITLE: Contact lens

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: V. Harris, R. Pifer, P. Shannon, M. Crary, Alcon Research Institute, Fort Worth, Texas, UNITED STATES|

Commercial Relationships Disclosure: Valerie Harris: Commercial Relationship(s);Code E (Employment):Alcon | Reed Pifer: Commercial Relationship(s);Code E (Employment):Alcon | Paul Shannon: Commercial Relationship(s);Code E (Employment):Alcon | Monica Crary: Commercial Relationship(s);Code E (Employment):Alcon

ABSTRACT BODY:

Purpose: Pseudomonas aeruginosa is the most common causative agent implicated in microbial keratitis. During contact lens wear, pathogens may be introduced into the ocular environment, which might cause adverse events. Lehfilcon A is a newly marketed contact lens with a water gradient surface composed of polymeric 2-methacryloyloxyethyl phosphorylcholine (MPC). MPC is reported to impart anti-biofouling properties onto coated substrates. Therefore, in this in vitro experimental study, we evaluated the ability of lehfilcon A to resist adhesion by P. aeruginosa.

Methods: Quantitative bacterial adhesion assays using five strains of P. aeruginosa were conducted to compare the adherence properties of lehfilcon A to five currently marketed contact lenses (comfilcon A, senofilcon C, samfilcon A, senofilcon A, fanfilcon A). Individual contact lenses were incubated in the presence of P. aeruginosa followed by gentle rinsing to remove non-adherent bacteria. Adherent bacteria were recovered from lenses by vigorous vortexing and eluted bacterial colony forming units (CFU) were enumerated by plating. CFUs were normalized to the surface area of each lens. Statistical analyses were performed as t-tests for differences in the mean log CFU/mm^2 between lens types without assuming equal standard deviation between groups. Bonferroni correction was used to account for multiple comparisons. Adherence of GFP-positive P. aeruginosa to contact lenses was qualitatively evaluated by fluorescent microscopy.

Results: Across five strains of P. aeruginosa, lehfilcon A allowed an average of 1.1 ± 0.1 log CFU/mm^2 fewer bacteria to bind to the lens compared to the next best performing contact lens material, senofilcon C. Across all strains, this corresponds to an average of 92.0% lower adherence by lehfilcon A compared to all lenses tested, or a difference greater than $2.2x10^5$ live bacteria per lens. Results from fluorescent imaging experiments support the quantitative results, with a clearly greater mass of P. aeruginosa adhering to non-MPC coated lenses.

Conclusions: Lehfilcon A has reduced P. aeruginosa adhesion relative to currently marketed monthly and bi-weekly contact lenses. Contact lenses that limit microbial adhesion coupled with effective contact lens care solutions may be an effective approach to reducing contact lens contamination.

ABSTRACT BODY:

Purpose: Retinal degeneration occurs in Alzheimer's disease (AD), but its temporal association with intracranial pathology is unknown. This study investigated the association between OCT-derived retinal layer thickness and intracranial diffusion tensor imaging (DTI) measures of optic tracts among subjects with an Autosomal Dominantly inherited form of AD (ADAD).

Methods: Carriers of ADAD mutations (A431E_PSEN1 or V171I_APP or F388S_PSEN1) or non-carriers of the mutation from the same family were recruited from an NIH funded longitudinal study of ADAD. Outer nuclear layer (ONL), Ganglion Cell Layer (GCL), Inner Plexiform Layer (IPL) and GCIPL thickness were obtained using SD-OCT (Heidelberg Spectralis). The retinotopically mapped white matter tract integrity was measured along the optic tracts using previously described DTI measures including fractional anisotropy (FA), radial diffusivity (RD), mean diffusivity (MD), axial diffusivity (AD). The correlation between the retinal layer thickness and the DTI measures was assessed using generalized estimating equations to adjust for correlation between retinal measurements from two eyes of the same subject.

Results: Fifteen subjects with ADAD mutations (9 males, mean age 36yrs) and 4 non-carriers (1 male, mean age 37yrs) were recruited into the study. Six subjects with ADAD mutations were asymptomatic. FA was positively correlated with GCL (β=0.0017, P=0.01) and GCIPL complex (β=0.0008, P=0.03) thickness. RD was negatively correlated with GCL (β=-0.0105, P=0.002) and GCIPL complex (β=-0.0071, P=0.001) thickness. MD was negatively correlated with GCIPL complex (P=0.001) thickness. AD was positively correlated with GCL and GCIPL complex but not significant (P>0.05). The correlations between ONL thickness and DTI measures (FA, MD, AD and RD) were not significant (P>0.05).

Conclusions: GCIPL thickness was significantly associated with DTI measures of optic tract integrity. These findings support the hypothesis that the degeneration of ganglion cells in the retina is concurrent with a decrease in white matter integrity of the optic tracts in ADAD. The causal chain of events is a topic of further investigation.

ABSTRACT BODY:

Purpose: PFV is a rare disease with limited treatment options, where the hyaloid artery does not regress normally after birth, potentially causing blindness in an otherwise normal child. We have shown that astrocytes in Nuc1 mutant (spontaneous mutation in Cryba1 gene that encodes for βA3/A1-crystallin) rats abnormally migrate and ensheath the hyaloid artery, likely due to abnormal lysosomal function and activated EGFR/mTORC1 signaling. Different astrocyte populations with anti/pro-inflammatory properties have been identified in human diseases and are linked to protective/neurodegenerative changes, respectively. Herein, we evaluated the importance of different astrocyte populations in our rat model, determining the roles of their underlying signaling pathways in the pathogenesis of PFV disease.

Methods: We performed scRNAseq analysis on optic nerve astrocytes from Nuc1 and WT rats. Western blot analysis evaluated the levels of mTOR and inflammatory signaling proteins. Astrocyte cell migration (wound healing assay), proliferation (Ki-67 expression) and phagocytosis (pHrodo internalization assay) were also assessed. βA1-mCherry construct was generated to overexpress the protein in astrocytes in vitro.

Results: scRNAseq analysis revealed two distinct astrocyte populations- astrocyte clusters 1 and 2 (AC1 and 2) in Nuc1 rats, but not in WT. AC1 showed increased expression of mTORC1 components like Raptor and downregulation of mTORC2 components like Rictor, with no increase in the levels of inflammatory genes. However, AC2 showed activation of both mTORC1/2 components and inflammatory mediators like CXCL14 and IL-2a. Interestingly, Lrp2 gene, which is linked with astrocyte activation in Parkinson's disease, as well as glial and cancer cell activation/migration, also was upregulated in AC2 but not in AC1 cells. These results were confirmed by western blots and the changes were rescued upon βA1-crystallin overexpression in AC2 cells. Induction of cell migration/proliferation and a reduction in phagocytic activity, known phenotypic changes during astrocyte activation in PFV disease were significant in AC2 cells and were rescued by βA1-crystallin overexpression.

Conclusions: We have identified a specific population of astrocytes which might be responsible for the pathogenesis of PFV disease: overexpression of βA1-crystallin in these astrocytes could have therapeutic importance for treating PFV disease.

ABSTRACT BODY:

Purpose: Epigenetic factors are known to influence neural development, functionality, and their response to pathophysiology. In recent times, electrical stimulation (ES) of cell and animal models have shown promising results in neural regeneration and recovery. However, the underlying mechanisms remains elusive. Our study will investigate if ES holds the promise to regulate DNA demethylation, a vital epigenetic event known to influence neuronal regeneration, using an in-vitro cell model.

Methods: PC12 cells acquired from ATCC were cultured and the effect of ES on DNA demethylases (ten-eleven translocation (TETs) proteins (TET1, TET2 and TET3)) was studied using qPCR. PC12 cells were incubated with 0, 5 and 100 ng/ml of nerve growth factor (NGF), a known inducer of neuronal differentiation, for 5 days and were also electrically stimulated for 20 min at 100 µA. Non-electrically stimulated cells were maintained as control. RNAs were collected 16 h post procedure and the changes in TETs gene expression were analyzed using qPCR. Additionally, lactate dehydrogenase (LDH) estimation assay was carried out to evaluate cytotoxicity in the experimental groups. Two-tailed Student's t-test was used for statistical analysis.

Results: qPCR revealed increased TET1 gene expression in cells exposed to ES relative to control cells. TET2 and TET3 amplification did not change significantly. LDH assay demonstrated no significant cytotoxicity in any treatment groups. Interestingly, increasing NGF concentration in PC12 cells exhibited similar induction of TET1 but not TET2 or TET3 expression, suggesting a possibly shared epigenetic event in ES and NGF-induced neuronal differentiation process.

Conclusions: Our results point to a possible regulation of TET1, a DNA demethylase, by ES in neurons. A comprehensive understanding of epigenetic regulation following ES in neuronal differentiation, development and homeostasis will help us unravel novel molecular pathways and pave the way to design blueprints for effective therapeutics to address neuronal protection, repair, and regeneration.

ABSTRACT BODY:

Purpose: To describe a new method to estimate the frequency distribution of optic nerve Disc Area, using digital retinographic images. Disc Area influences other morphological indices such as cup and rim, of interest in glaucoma (1). The immediate goal is to use this method in the Laguna ONhE application that allows estimation of hemoglobin distribution in the normal and glaucomatous optic nerve (2).

Methods: We analyzed 492,023 fundus images obtained with 7 fundus cameras (Table), mainly in Caucasian subjects. They were grouped by resolution and zoom. They were automatically segmented by identifying the inner edge of the Elschnig scleral ring. For this purpose, a neural network trained by Deep Learning previously described (3) was used. The number of pixels contained within the segmentation and their frequency distribution were calculated. The results of each camera, using different number of images, were compared with the global results using the Kolmogorov-Smirnov test to confront frequency distributions.

Results: The frequency distribution was Non-Gaussian, more limited in the small sizes than in the large ones. If the median is assigned a theoretical value of 1.95 mm^2(4) the 1^{th}, 5^{th}, 25^{th}, 50^{th}, 75^{th}, 95^{th} and 99^{th} percentiles would correspond to 1.29, 1.46, 1.73, 1.95, 2.20, 2.64 and 3.03 mm^2 in the whole data set (Figure 1). The overall differences were significant for the smaller series, but for each percentile their mean value was only 0.01mm^2 and the maximum 0.10mm^2, so they can be considered similar for practical purposes in all cameras. (Table).

Conclusions: By automatically segmenting the edges of the optic nerve and observing the frequency distribution of the number of pixels it delimits, it is possible to estimate the frequency distribution of the Disc Area in the population as a whole and that of each individual case.

ABSTRACT BODY:

Purpose: To quantitatively analyze choriocapillaris alterations using swept-source optical coherence tomography angiography (SS-OCTA) in eyes presenting with severe hydroxychloroquine (HCQ) retinopathy and to compare it with patients taking HCQ without toxic retinopathy and healthy controls.

Methods: In this cross-sectional study, macular 6x6 mm SS-OCTA scans were analyzed in eyes with either severe HCQ toxic retinopathy, or under HCQ without retinal toxicity, as well as in healthy age and sex-matched controls. The choriocapillaris en face slabs were extracted from the SS-OCTA device. En face choriocapillaris flow images were compensated with en face choriocapillaris structure images, followed by Phansalkar local thresholding using window radius 4 and 8 pixels. Percentage of flow deficits (FD %), as well as FD number, size, and total area, were computed for comparison.

Results: Seventy-six eyes of 38 patients under HCQ (mean age 49.89±11.68 years) and sixty eyes of 34 age-matched controls (mean age 54.30±14.85 years) were included in this study. Among the patients under HCQ, fourteen eyes (7 patients) presented with severe HCQ toxicity, while sixty-two eyes (31 patients) had no signs of toxicity. FD%, the average size of FDs, and the number of FDs were significantly different between the severe HCQ toxicity, no HCQ toxicity, and controls (p-value < 0.001 for all comparisons, for both radius 8 and 4 pixels). Compared to controls and eyes with no HCQ toxicity, the eyes with severe HCQ toxicity had a significantly higher FD% (p-value 0.009 and <0.001 for radius 8 pixels, p-value <0.001 and <0.001 using radius 4 pixels, respectively), a significantly lower number of FDs (p-value 0.005 and <0.001 using radius 8 pixels, p-value 0.005 and <0.001 using radius 4 pixels).

Conclusions: Our results suggest an involvement of the choriocapillaris in severe HCQ retinal toxicity, therefore expanding the current knowledge of the (inner) choroidal involvement in the pathogenesis of HCQ retinopathy.

ABSTRACT BODY:

Purpose: Ultra-Low Vision is defined as visual acuity ≤ 20/1600. Currently, there are no standardized tools available to assess hand-eye coordination in individuals with vision in the ULV range. The purpose of this study was to develop and validate a test to assess hand-eye coordination for people with ultra-low vision (ULV).

Methods: Eleven participants with ULV went through task stimulations requiring hand-eye coordination, such as flipping a light switch or placing silverware on a dinner table, using the VR Headset. Using a Leap Motion hand tracker, each participant was able to visualize their hand as they went about performing a task. The same task was presented at different visibility levels (high, medium, and low). Tasks were to be completed in 5 pre-defined steps (e.g., 5 defined steps to make a pancake). The results were then analyzed using the method of successive dichotomizations, a polytomous Rasch model, to estimate person measures (person ability) and item measures (task difficulty).

Results: Estimated item measures ranged from -3.49 to 3.97 logits with a mean of zero (by convention) and a SD = 1.8 logits (Fig 1). The most difficult item was sorting pills (3.97 logits) and the least difficult item was building a tower from high contrast blocks in decreasing size (-3.49 logits). Person measures ranged from -2.9 to 4.3 logits with a mean (SD) of 1.06 (2.09) logits. A t-test showed that the means of the distributions were not significantly different ($p = 0.2$). The items (tasks) were therefore well-targeted to the sample of persons.

Conclusions: The results show a mix of items with good spread of difficulty levels that can be used to assess hand-eye coordination in individuals with ULV with different levels of functional ability. We will continue testing in a larger sample of people using a reduced set of items by eliminating items with similar item measures to reduce redundancy and cut down testing times.

ABSTRACT BODY:

Purpose: To examine the frequency and risk factors for ocular pain after laser assisted in situ keratomileusis (LASIK) and photorefractive keratectomy (PRK).

Methods: Prospective study of individuals undergoing refractive surgery. All individuals were seen prior to surgery and 3 months after surgery. Questionnaires regarding dry eye and ocular pain symptoms were completed at both time points. In addition, a comprehensive ocular surface assessment was performed at 3 months. The primary outcome measures were the frequency of ocular pain 3 months after surgery and risk factors for peristent pain. The latter were examined using multivariable forward stepwise logistic regression analyses.

Results: 58 individuals were enrolled into the study, with a mean age of 33±9 years (range 23 to 57); 65.5% (n=38) self identified as female, 74% as white, and 43% as Hispanic. The majory of individuals underwent bilateral (n=57) LASIK (n=52). Prior to surgery, 15.5% (n=9) of individuals indicated that they had any ocular pain (>0 rating of average pain intensity over a 1 week recall, range 0-10), with the majority reporting mild pain (n=7 with a score of 1). At 3 months, 33% (n=19) of individuals reported ocular pain (average intensity of pain over a 1 week recall >0), 10 with a score >1. This included 12 individuals (63%) who developed new ocular pain after surgery. The two factors that significantly predicted ocular pain after surgery (score>0) were ocular pain (odds ratio (OR)=3.15, 95% confidence interval (CI) 1.28-7.71, p = 0.01) and dry eye symptoms (Ocular Surface Disease Index, OR=1.12, 95% CI 1.0-1.26, p=0.05) before surgery. Pre-operative contact lens use (OR=0.16, 95% CI 0.03-0.90, p = 0.04) was protective against post-operative pain. When considering factors associated with pain intensity >1 at 3 months, pre-operative pain scores again predicted post-operative pain (OR=2.90, 95% CI 1.37-6.14, p=0.005) along with higher depression scores pre-surgery (Patient Health Questionniare-9, OR=1.38, 95% CI 1.08-1.75, p=0.01). Importantly, the majority (94%) of individuals were completely (70%) or somewhat (24%) satisfied with the results of their surgery.

Conclusions: A significant proportion of individuals report mild or greater post-operative pain 3 months after refractive surgery, with ocular pain prior to surgery being the most significant predictor for pain after surgery.

ABSTRACT BODY:

Purpose: To isolate extracellular vesicles (EVs) from human conjunctival mesenchymal stromal cells (Conj-MSCs) and analyze their effect on conjunctival epithelium.

Methods: Conjunctival stromal cells isolated from cadaveric donor tissues were cultured and analyzed to determine whether they could be defined MSC (n=5). Expression of MSC markers was analyzed by flow cytometry. Cells were cultured in adipogenic, osteogenic, and chondrocyte differentiation media, and stained with Oil Red, Von Kossa, and Alcian Blue, respectively, to determine multipotent capacity. Cells were grown at 70% confluence, secretome was collected after 48h with EVs-depleted FBS-supplemented medium and EVs were isolated by differential ultracentrifugation. EV morphology was evaluated by atomic force microscopy, size distribution analyzed by dynamic light scattering, and EVs were individually characterized by nanoflow cytometry. To analyze the effect on oxidative stress, the human conjunctival epithelial cell line IM-HConEpiC was exposed to 50 µg/ml Conj-MSCs-derived EVs for 3h (n=3), then loaded with 2′,7′-Dichlorofluorescin diacetate (30 min, 37°C) and finally exposed to 200 µM H_2O_2 to induce oxidative stress. Fluorescence was measured to quantify reactive oxygen species (ROS). Cell viability was determined by alamarBlue assay. Data were shown as mean ± standard deviation. One-way ANOVA was done to analyze differences.

Results: Cultured stromal cells fulfilled the criteria of MSCs: they adhered to plastic; expressed CD90 (99.95±0.03% positive cells), CD105 (99.04±1.43%), CD73 (99.99±0.19%), CD44 (99.93±0.05%), and lacked CD34, CD11b, CD19, CD45 and HLA-DR (0.82±0.91%); and differentiated in vitro into different lineages. Conj-MSCs EVs were morphologically round. Main EV subpopulations were <300nm, but larger differential subpopulations were also observed. EVs expressed CD9, CD63, CD81, and CD147 markers. H_2O_2 increased ROS by 1.61+0.31-fold ($p=0.0061$) compared to untreated cells set as 1, and Conj-MSC EVs decreased it to 0.42±0.46 ($p<0.0001$), in similar levels than adipose tissue-MSC-derived EVs (0.65±0.50; $p=0.0002$) and 250 µM ascorbic acid (0.50±0.59; $p<0.0001$), used as control. EVs did not affect cell viability.

Conclusions: Conj-MSC-derived EVs show no toxicity and promising antioxidant activity on conjunctival epithelial cells, warranting further research to determine their potential therapeutic effect.

ABSTRACT BODY:

Purpose: We reported that aged C57BL/6 (B6) had increased lacrimal gland (LG) lymphoid infiltrates that are suggestive of ectopic lymphoid structures. However, B6 mice are T helper 1 prone mice. This study investigates the presence and composition of LG infiltrates in aged mice. We also analyse the diversity of mice with different genetic background.

Methods: Female B6 mice were used at 2-4, 12, and 24months (M) of age (n=10/age). A separate group of diversity outbred mice (DO, Jackson strain 009376) were used at 2-4 and 24M of age (n=9-10/age/sex). LGs were excised and used for histology, bulk RNA sequencing, or gene expression analysis using qPCR. Flow cytometry investigated B cell frequency. Eyes were excised for goblet cell density evaluation using PAS staining. The number of inflammatory foci (>50 cells) was counted under a 10X microscope lens. H&E-stained LGs were scanned, photographed, and image analysis calculated the focus score. The expression of B-cell-related genes was investigated by real-time PCR.

Results: Bulk RNA seq of aged B6 LGs showed upregulation of many inflammatory pathways. B-cell-related genes were among the top hits. A significant increase in B220+ cells was seen with aging from 8 to 12 to 24M in the LG (3, 20, and 38% among live cells, $P<0.05$). qPCR validation showed a significant increase in Cd19 (70 and 151-fold), Cd22 (46 and 138-fold) Cxcl13 (5 and 11-fold), Ltb (9 and 7-fold), Lta (4 and 5-fold), Glycam-1 (915 and 3095-fold), Ccl19 (11 and 15-fold) at 12 and 24M compared to young (all $P<0.05$ or lower). T helper follicular genes were also upregulated with aging: Cxcr5 (3 and 3-fold), Ccr7 (8 and 4-fold), Il21 (27 and 24-fold) (all $P<0.05$ or lower). Aged female DO mice have increased immune infiltrates in aged LGs (3.2±3.5 vs 0 focus score/4mm^2, $P<0.01$), but male DO mice do not (1.6±2 vs 0 focus score/4mm^2, $P>0.05$). Interestingly, female and male DO mice have decreased goblet cell density with aging (~35% loss compared to young DO, $P<0.01$ for both sexes).

Conclusions: Many pathways are altered in the aged LG in B6 mice, including B cell infiltration. There is an upregulation of B and T helper follicular-related genes as early as 12M of age. In addition, LG immune infiltrates preferentially accumulate in female mice, while goblet cell loss is observed in both sexes. These results show that age-related dry eye and LG infiltration is not exclusive of a mouse genotype.

TITLE: Sox8 and Sox9 dominant-negative constructs promote photoreceptor specification while inhibiting generation of inner retinal cell types.

SESSION TITLE: Retina Development and Regeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Pannullo, C.P. Santiago, M. Gimmen, L. Duncan, S. Blackshaw, Neuroscience, Johns Hopkins University School of Medicine, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Nicole Pannullo: Commercial Relationship: Code N (No Commercial Relationship) | Clayton Santiago: Commercial Relationship: Code N (No Commercial Relationship) | Megan Gimmen: Commercial Relationship: Code N (No Commercial Relationship) | Leighton Duncan: Commercial Relationship: Code N (No Commercial Relationship) | Seth Blackshaw: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Sox8 and Sox9 are highly and specifically expressed in late-stage retinal progenitor cells (RPCs) and mature Muller glia (MG) and are predicted to repress proliferative and neurogenic competence in these cell types. We have developed dominant negative (DN) constructs of Sox8 and Sox9 to test their ability to alter the developmental trajectory in the murine retina. Constructs that promote an early-stage RPC cell fate and/or production of early-born retinal cell types will be used to reprogram adult Muller glia to early-stage RPCs that are competent to produce cone photoreceptors upon retinal injury in vivo.

Methods: DNs for Sox8 and Sox9 consisting of the DNA binding domain (DBD) only, DBD fused with a KRAB repressor (DBD+KRAB), and DBD fused with a VP48 activator (DBD+VP48) were designed. DNs were expressed in a pCAGIG construct downstream of a CAG promoter and upstream of an eGFP under the control of a bicistronic IRES element. Retinal explants were electroporated ex vivo to screen the DN constructs for their ability to alter the developmental trajectory in the retina. Retinal explants were electroporated with the DN constructs during late-stage retinal development (postnatal day(P)0-P8). The resulting phenotypes were analyzed using both scRNA-seq and immunohistochemistry.

Results: Retinal explants electroporated with the DBD and DBD+KRAB DN constructs at P0 showed phenotypes at P8 that were consistent with the known or predicted genetic loss of function of each cluster of paralogous genes, including a reduction in MG, bipolar and amacrine cell generation, and an increase in photoreceptor generation. Notably, these constructs also induce formation of a small number of cells expressing markers of cone photoreceptors.

Conclusions: These results suggest that suppression of Sox8 and Sox9 function is sufficient to shift the developmental trajectory of the retina to promote photoreceptor specification and induce expression of cone-specific markers. Since adult MG express many of the same TFs as late-stage RPCs, these DN constructs are potentially promising candidates for reprogramming MG to early-stage RPCs that are competent to produce cone photoreceptors upon retinal injury in vivo.

ABSTRACT BODY:

Purpose: Previous studies have shown that ocular anatomy may differ amongst ethnic groups. However, there are limited data on ethnic differences in corneal pachymetry and anterior chamber dimension. This study utilizes Pentacam data to compare corneal pachymetry and anterior chamber dimension between Hispanic and non-Hispanic White groups.

Methods: In this retrospective study, we analyzed Pentacam data from patients 50 years or older who underwent surgery for senile cataract. We included patients who were self-identified as Hispanic White or non-Hispanic White. Exclusion criteria included non-White race or multiethnic groups, history of surgery or trauma of cornea or anterior segment, or any abnormalities in these structures. The following parameters were compared between Hispanic Whites or non-Hispanic Whites: pupil center pachymetry, pachymetry at vertex, thinnest location, corneal volume, anterior chamber volume, and anterior chamber depth.

Results: This study consisted of 200 patients, including 103 Hispanic White individuals and 97 non-Hispanic White individuals. The mean age was 69.9 ± 7.4 years (range, 50-88 years), and there were 68 men and 132 women. There was no significant difference between Hispanic White and non-Hispanic White groups regarding age. There were no statistically significant differences between these two groups regarding pupil center pachymetry (546.2 ± 35.6 μm vs 548.2 ± 34.6 μm, P= 0.85), pachymetry at vertex (546.5 ± 35.3 μm vs 549.2 ± 34.7 μm, P=0.69), thinnest location (541.3 ± 36.1 μm vs 544.0 ± 33.5 μm, P=0.58), or corneal volume (59.4 ± 4.0 mm^3 vs 59.4 ± 3.8 mm^3, P=0.98). However, there were significant differences between Hispanic White and non-Hispanic White groups regarding anterior chamber volume (130.0 ± 45.6 mm^3 vs 146.6 ± 38.0 mm^3, respectively, P<0.001) and anterior chamber depth (2.6 ± 0.5 mm vs 2.7 ± 0.4 mm, respectively, P=0.01).

Conclusions: Although no significant differences exist in corneal pachymetry between Hispanic Whites and non-Hispanic Whites, anterior chamber depth and volume are significantly lower in Hispanic Whites compared with non-Hispanic Whites. Such anatomical differences should be considered during intraocular surgeries.

ABSTRACT BODY:

Purpose: The aim of the study was to analyse structural and functional ophthalmological outcomes at six years of age in a population of children born with ≤32 weeks of gestational age (GA) and/or ≤1000grams of birth weight (BW) at the A. Gemelli University Hospital in Rome.

Methods: Per protocol, all preterm babies screened for acute ROP (following ICROP criteria) undergo at six year of age a full ophthalmologic and orthoptic examination. Different neurodevelopmental aspects were assessed By means of the Wechsler Intelligence Scale for Children (WISC) . A standard score below 79 was considered below average. Recently wide-field fundus retinography and oral ultra wide-field fluorescein angiography (UWFFA, OPTOS Inc USA) and OCT and OCT-A (Carl Zeiss, D) imaging were introduced in the protocol. Peripheral retinal vascular features highlighted by UWFFA were classified by three different graders and correlated with to clinical parameters such as BW, GA and acute ROP severity. Peripheral avascular retina (PAR) was also observed and classified form 1 to 3 based on its extent. Foveal Avascular Zone (FAZ) was observed with both OCT-A and UWFFA and correlated with visual acuity (VA).

Results: 45 preterm infants, 28.5% of the preterm population screened for ROP from January 2013 untill December 2014 were examined at a mean age of 6 years and 5 months. 72 eyes were previously diagnosed by various ROP stages. Mean age at examination was 6.14 years. 13 babies showed various degree of neurological disabilities and 17 various form of strabismus. ETDRS LogMar visual acuity ranged from 2 to 0. Peripheral retinal vasculature showed at WFFA a dichotomous pattern in 67% (n=55, shunting pattern in 21% (n=17) and finger-like pattern in 12% (n=10). One eye only showed a light leakage at the junction between vascular and avascular retina. PAR was present in 63% (n=29). FAZ was absent on 28,5% (n=24) of the OCTA images with a good accordance with WFFA images. No significant correlation was found with VA.

Conclusions: Dichotomous branching pattern and PAR are common peripheral vascular features in our population. These findings suggest the importance of a long term follow up in preterm children, especially those with specific peripheral vascular retinal features.

ABSTRACT BODY:

Purpose: To develop an in vitro eye model using a novel 3D bioprinting method for testing the release of ophthalmic formulations to the posterior ocular region.

Methods: The eye model was designed using CAD software and includes both an anterior aqueous chamber and a posterior vitreous chamber. The vitreous chamber is surrounded by a blood chamber to mimic vessels that can be used to transport a blood-like substance. Three inlet ports control the flow of fluid into the chambers and the blood channels, and the three outlet ports allow fluids to exit these compartments. The eye model was 3D printed on a commercial mSLA printer (Photon Mono X, AnyCubic), which was retrofitted with a humidity and temperature control module to create a printing environment at 37°C and >80% humidity. The bioink formulation consisted of 10% gelatin methacrylate (GelMa). After printing, the models were incubated at 37°C to remove any uncured GelMa within any hollow compartments. For this study, phosphate-buffered saline was used as an aqueous and vitreous humour mimic. To evaluate the diffusion of a small hydrophilic molecule on the eye model, a contact lens (Air Optix) was soaked with a water-soluble red food dye for 1 hour and then placed on the eye model. The amount of dye in the anterior chamber, posterior chamber, and blood channels was measured using UV spectrophotometry after 24 hours.

Results: The entire model can be printed without any support structures within approximately 3 hours. The 3D printed eye model can also be autoclaved for testing that requires sterility. Because there were no diffusion barriers present in the current model, the red dye was detected in all three chambers after 24 hours. The highest concentration of dye was found in the anterior chamber, followed by the blood chamber and then the posterior chamber.

Conclusions: The prototype developed in this study can be used as a starting point to develop enhanced 3D printed eye models to test drug release kinetics of various devices and formulations. Future work will focus on adding the appropriate diffusion barriers to better simulate drug diffusion through ocular tissues.

TITLE: Cas9 targeted long-read nanopore sequencing of ABCA4 and the OPN1LW/OPN1MW gene array for investigation of inherited retinal disease

SESSION TITLE: Genetic variants in human ocular disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Arno, N. Jurkute, M. Michaelides, O.A. Mahroo, A.R. Webster, Institute of Ophthalmology, University College London, London, London, UNITED KINGDOM|G. Arno, N. Jurkute, M. Michaelides, O.A. Mahroo, A.R. Webster, Moorfields Eye Hospital NHS Foundation Trust, London, London, UNITED KINGDOM|T. Boles, Sage Science Inc., Beverly, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Gavin Arno: Commercial Relationship: Code N (No Commercial Relationship) | Neringa Jurkute: Commercial Relationship: Code N (No Commercial Relationship) | T. Christian Boles: Commercial Relationship(s);Code E (Employment):Sage Science Inc. | Michel Michaelides: Commercial Relationship: Code N (No Commercial Relationship) | Omar Mahroo: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Webster: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Short, paired-end sequencing (next generation sequencing, NGS) enables interrogation of up to ~95% of the human genome. Several clinically relevant genes for inherited retinal disease (eg: OPN1LW/OPN1MW) and variants (eg: complex rearrangements) cannot be resolved by NGS technology including whole genome sequencing (WGS). We sought to investigate the use of Cas9 targeting of chromosomal segments (CATCH) with Oxford Nanopore Technologies (ONT) long-read sequencing for a WGS-intractable suspected ABCA4-retinopathy case and to sequence the NGS-intractable OPN1LW/OPN1MW gene array.

Methods: CATCH was performed for ABCA4 and the OPN1LW/OPN1MW array using CRISPR guide RNAs flanking the regions of interest followed by separation of high molecular weight DNA fragments using the SageHLS system (SAGE science). ONT MinION long-read sequencing was performed on resultant enriched DNA fragments.

Results: One patient with Stargardt disease was unresolved following WGS. A single heterozygous variant was identified (c.5715+5G>A) with no candidate non-coding or structural variants that could account for the second allele. CATCH-nanopore sequencing using CRISPR-guides flanking ABCA4 generated 337 on-target reads (chr1:93,992,834-94,121,148) and a maximal read depth of 50x. Interrogation of reads revealed a complex structural rearrangement comprising insertion of 689bp from the long non-coding RNA, LINC01500 at chr14q23.1, and an ~800bp long interspersed nuclear element (LINE) into intron 1 of ABCA4. Splice prediction (nnsplice) showed a potential 14bp pseudoexonwithin the inserted sequence.

Sequencing ofthe OPN1LW/OPN1MW gene array following CATCH enrichment for a control female subject generated a maximal read depth of 36x, and for a control male, 25x read depth, including full-length reads of up to ~233kb spanning the entire fragment enabling accurate haplotyping of the opsin arrays.

Conclusions: This study demonstrates that CATCH-nanopore sequencing is effective for cases intractable to NGS. We were able to generate significant enrichment for target regions and ultra-long reads spanning the entire targets. This study identified a complex structural rearrangement, missed by short-read WGS, in ABCA4 that may lead to cryptic splicing. Effective sequencing of the NGS-intractable OPN1LW/OPN1MW gene array is possible for variant detection in males with blue cone monochromacy.

ABSTRACT BODY:

Purpose: To report the prevalence and clinical characteristics of polypoidal choroidal vasculopathy (PCV) at 3 tertiary referral centers, focusing on racial differences in Caucasians, African American, and Asian subjects.

Methods: We reviewed the medical records of patients diagnosed with treatment naïve exudative AMD between January 2016 and December 2020 at the following institutions: Northwestern University, University of Chicago, and Hyogo College of Medicine. We diagnosed PCV in this cohort based on fundus photos and OCT characteristics, defined as the presence of: two of the following three characteristics: sub-retinal pigment epithelium (RPE) ring-like lesion, complex RPE elevation, or sharp-peaked pigment epithelium detachment. We also report the visual and anatomic outcomes in patients who completed longitudinal follow-up of 12 months.

Results: A total of 123 patients with treatment-naïve PCV— 21 Caucasians, 18 African Americans, and 84 Asians— were identified. PCV prevalence in the overall AMD cohort was 6.89 % among Caucasian subjects, 33.3 % in African Americans, and 36.68 % in Asians. The prevalence of hard exudates and subretinal hemorrhage was highest in African American patients (55.6% and 72.0%) and considerably lower in Asians (32.1% and 38.1%) and Caucasians (14.3% and 33.3%). Baseline BCVA was also worse in African American patients (mean Log MAR: 0.793). Caucasian patients had significantly lower incidence of pachyvessels (28.6%) and more soft drusen (66.6%) compared to African Americans and Asians. Ninety-four patients — 20 Caucasian, 11 African American, and 63 Asians— were followed for more than one year. Mean BCVA (LogMar) improved significantly from baseline to month 12 (0.394 to 0.211) in the overall cohort (P<0.001), though this did not hold true for the Caucasian subgroup ((0.362-tp 0.361; P = 0.56).

Conclusions: We found significant differences in the prevalence and clinical characteristics of PCV amongst the three racial groups. These pathophysiologic differences deserve further study since they can have important impact on prognosis and treatment outcomes.

ABSTRACT BODY:

Purpose: We compare the ability of resident ophthalmologists to identify neovascularization (NV) in patients with proliferative diabetic retinopathy (PDR) using widefield (WF) swept source (SS) optical coherence tomography angiography (OCTA) and fluorescein angiography (FA) to help examine how easily this new technology could be more widely deployed to less experienced users.

Methods: Eyes with PDR based on clinical examination were imaged with 15mm x 15mm WF SS-OCTA and FA no more than 1 week apart. These images were scrambled to create a grading set consisting of anonymized SS-OCTA images of the retina slab with the corresponding B-scans (hereby referred to as SS-OCTA with corresponding B-scan), SS-OCTA images of the retina slab and the vitreoretinal interface (VRI) angio slab (hereby referred to as the VRI slab), and FA image set consisting of an early phase image and a late phase image (hereby referred to as FA) for each eye. After IRB approval, participants were asked to identify NV in each image and scored on the number of NV identified correctly. Additionally, participants were timed on how long they spent on each FA and VRI slab.

Results: 10 eyes from 10 patients were included in the study for a grading set consisting of 30 images. The mean number of neovascularization per image was 2.03. 11 resident physicians participated in the study. Overall, resident physicians correctly identified 65.6% of NV using FA, 50.8% of NV using SS-OCTA with corresponding B-scan, and 78.0% of NV using the VRI slab. There was no statistically significant difference in resident physician’s ability to detect NV across the three imaging modalities (P = 0.12). Participants spent an average of 4.8 seconds less for each VRI slab compared to FA (13.5 seconds versus 18.3 seconds, P = 0.04).

Conclusions: Detection rates of NV by resident physicians using SS-OCTA was comparable to that of using FA. Additionally, resident physicians were able to identify NV more quickly on VRI slab compared to FA. Our results suggest that SS-OCTA may be an appropriate imaging modality for the detection of NV in PDR patients, even with less experienced OCTA graders.

TITLE: The novel secretome ST266 promotes survival of oxidant-stressed human RPE by a mechanism involving the Akt/mTOR/p70S6k/GSK-3b pathway

SESSION TITLE: Cell biology of retinal diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Trimpey-Warhaftig, N. Besley, S. Lallier, P. Yang, G.J. Jaffe, Ophthalmology, Duke University School of Medicine, Durham, North Carolina, UNITED STATES|H. Wessel, L. Brown, Noveome Biotherapeutics Inc, Pittsburgh, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Rose Trimpey-Warhaftig: Commercial Relationship: Code N (No Commercial Relationship) | Nicholas Besley: Commercial Relationship: Code N (No Commercial Relationship) | Scott Lallier: Commercial Relationship: Code N (No Commercial Relationship) | Ping Yang: Commercial Relationship: Code N (No Commercial Relationship) | Howard Wessel: Commercial Relationship(s);Code E (Employment):Noveome Biotherapeutics, Inc | Larry Brown: Commercial Relationship(s);Code E (Employment):Noveome Biotherapeutics, Inc | Glenn Jaffe: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Oxidative stress contributes to dysfunction and loss of retinal pigment epithelial (RPE) cells observed with age-related macular degeneration (AMD). ST266 is the biological secretome produced by a novel population of amnion-derived multipotent progenitor cells. We have previously shown that ST266 increases RPE cell survival and mitochondrial function after cells were treated with hydroquinone (HQ), hydrogen peroxide (H_2O_2), oxidants related to cigarette smoke, or all-trans Retinal (atRal), a pro-oxidant component of the retinoid cycle. Herein, we aim to determine the mechanism by which ST266 confers protection.

Methods: Cultured human RPE cells were pre-treated for 1h in the presence or absence of MK-2206, a known protein kinase B (Akt) inhibitor, treated with varying concentrations of H_2O_2, HQ, or atRal alone in serum-free media (SF-MEM) for 1.5h at 37^oC for WST-1 assay, followed by 1h or 24h treatment with STM100 (the media in which the amnion progenitor cells are grown) or ST266 (20% in STM100) for Western blot or WST-1 assay, respectively. Western blot analysis was performed to determine phosphorylation of Akt and its downstream targets p70 ribosomal S6 kinase (p70S6K), mammalian target of rapamycin (mTOR), and glycogen synthase kinase 3 beta (GSK-3B). Cell viability was measured with WST-1 reagent.

Results: ST266 significantly increased levels of phosphorylated Akt as well as its downstream targets p70S6k, mTOR, and GSK-3B ($p<0.05$). Addition of MK-2206 to STM100-treated cells virtually eliminated Akt phosphorylation, while the addition of MK-2206 to ST266-treated cells reduced Akt phosphorylation to near basal levels. ST266 significantly improved cell viability on average by 38%, 20%, and 29% in HQ-, H_2O_2-, and atRal-treated cells respectively compared to STM100 treated cells. This improved viability with ST266 was significantly reduced when MK-2206 was added to 17%, 7%, and 10% in HQ-, H_2O_2-, and atRal-treated cells respectively compared to STM100 treated cells ($p<0.05$).

Conclusions: When RPE cells were exposed to ST266, Akt phosphorylation increased as well as its downstream targets. ST266 improved cell viability after exposure to various oxidants, an effect that was significantly reduced when Akt activation was blocked. These data suggest that Akt is involved in the mechanism by which ST266 improves cell survival in oxidant-treated human RPE cells.

ABSTRACT BODY:

Purpose: Risk stratification for early detection of primary open-angle glaucoma (POAG) may mitigate severe disease outcomes, including irreversible vision loss, for millions globally. Genetic risk scores (GRS), which sum allelic effects, promise clinical utility for prediction of many complex diseases but are not generalizable across different ancestral groups. Moreover, although POAG burden is higher in Hispanic (HIS) individuals, most POAG genetic studies have been reported in individuals of non-HIS European ancestry (EUR). We aimed to evaluate POAG GRS performance in HIS Veterans in the Million Veteran Program (MVP).

Methods: We calculated GRS based on 127 published POAG-associated variants in HIS (382 cases and 2965 controls) and EUR (3382 cases and 58811 controls) Veterans in the MVP. Ancestry was defined using the Harmonized Ancestry and Race/Ethnicity (HARE) algorithm. We tested for association between the 127-variant (unweighted and weighted by published cross-ancestry effect estimates) GRS and POAG via logistic regression-based analyses with unadjusted and adjusted (age, sex, and 10 sample-specific principal components) models. We compared POAG case classification across GRS deciles and evaluated GRS model performance with receiver operator characteristic (ROC) curves and area under the curve (AUC) estimates. We also performed subset analyses of HIS with <50% EUR global genetic ancestry (GGA; determined via ADMIXTURE program).

Results: Unweighted and weighted GRS were significantly associated with POAG in HIS and EUR Veterans ($p<0.05$). Between the top decile and bottom 90%, we observed ~3-fold higher odds of POAG case classification for unweighted (odds ratios [OR], 95% confidence intervals [CI]: HIS: 2.70 [2.03-3.56]; EUR: 2.74 [2.51-2.98]) and weighted (HIS: 3.11 [2.35-4.07]; EUR: 3.03 [2.78-3.29]) GRS. We detected no statistically significant difference between GRS performance in ROC comparisons between HIS and EUR Veterans (AUC range 0.65-0.67). In GGA subset analyses of 220 cases and 1486 controls, ROC curves were comparable to the full HIS dataset.

Conclusions: POAG studies prioritizing diverse, non-EUR groups are crucial to ensure equitable clinical introduction of GRS for POAG prediction. We confirmed that a GRS of 127 POAG risk variants performed similarly in HIS and EUR MVP Veterans, regardless of majority EUR/non-EUR GGA.

TITLE: Predicting one-day post-cataract surgery intraocular pressure spikes using machine learning methods

SESSION TITLE: Using Technology for Care Delivery and Improvement

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: L. Bonnell, K.L. Christopher, N. Mandava, A.M. Lynch, J.L. Patnaik, Ophthomology, University of Colorado, Denver, Colorado, UNITED STATES|

Commercial Relationships Disclosure: Levi Bonnell: Commercial Relationship: Code N (No Commercial Relationship) | Karen Christopher: Commercial Relationship: Code N (No Commercial Relationship) | Naresh Mandava: Commercial Relationship: Code N (No Commercial Relationship) | Anne Lynch: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Patnaik: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Transient one-day postoperative intraocular pressure (IOP) spikes following cataract surgery are adverse outcome of cataract surgery and can lead to pain, corneal edema, glaucomatous nerve damage, anterior ischemic optic neuropathy, and vision loss. To our knowledge, no studies have combined known and unknown risk factors to predict IOP spikes. We performed a retrospective, observational cohort study to build a clinical prediction rule for one-day postoperative intraocular pressure spikes based on demographic, clinical, and ophthalmic data using machine learning methods.

Methods: First eye phacoemulsification cataract surgeries between January 2014 and June 2020 from the University of Colorado Cataract Outcomes Registry were included. Exclusion criteria were the absence of documented postoperative IOP. The presence of a one-day IOP spike was defined as an IOP ≥ 30 mmHg at the first day post-operative visit. The data were randomly split into two independent sets: a training set (80%) for development and tuning of the model and a test set (20%) to determine the final fit of the model. Random forests were used to build the clinical prediction model.

Results: A total of 7,676 first eye phacoemulsification cataract surgeries were included in the analyses. A random forest model with 75 variables produced the largest area under the receiver operator curve (0.80) in the training set and 0.71 (95% confidence interval 0.66, 0.79) in the test set, where 0.50 is no predictive power. Among the most influential predictors were surgery characteristics (cumulative dissipated energy, length of surgery, complex case, combined surgery), eye characteristics (eye diseases and measurements), baseline IOP, and race and sex of patient. The optimum operating point had a sensitivity of 0.78, specificity of 0.55 and a positive predictive value of 0.84.

Conclusions: A clinical prediction rule for postoperative IOP spikes can identify at-risk patients immediately after the surgery, allowing the surgeon to mitigate risk by providing prophylactic IOP lowering drops, ultimately reducing short-term pain and long-term sequalae. We also identified several novel risk factors for IOP spikes that warrant follow-up.

ABSTRACT BODY:

Purpose: The role of Caveolin-1 (Cav1), the signature protein of caveolae, in regulation of innate immune response seems controversial, since Cav1 can either promote or suppress immune response in a cell-context manner. We speculate that caveolar and non-caveolar localization of Cav1 in different cells accounts for this paradoxical immune regulatory role. Here, we show that non-caveolar Cav1 in Müller glia enhance lipopolysaccharide (LPS)-induced interleukin-6 (IL-6) response, which can be blunted by either Cav1 silencing or sequestration into caveolae

Methods: To investigate the role of non-caveolar Cav1 in immune regulation, we either silenced Cav1 using Cav1-shRNA, or sequestered Cav1 into caveolae by expressing Cavin1/PTRF in MIO-M1 Müller glia and measured IL-6 response in tissue culture media by ELISA, with or without LPS stimulation. We used quantitative proteomics to identify immune-related pathways enriched in Cav1 immunoprecipitates from control and Cavin1/PTRF-expressing MIO-M1 Müller glia. Additionally we performed immunocytochemistry staining of MIO-M1 Müller glia using fluorescently labeled phalloidin to evaluate changes in filamentous actin (F-actin) when Cavin1/PTRF is expressed

Results: LPS stimulation of MIO-M1 Müller glia significantly increased IL-6 secretion into tissue culture media. Surprisingly, both Cav1 silencing or Cavin1/PTRF expression in MIO-M1 Müller glia significantly suppressed LPS-induced IL-6 response. Analysis of mass spectrometry data revealed significant differential association of different proteins with Cav1 when Cavin1/PTRF is expressed. Interestingly, we identified 18 genes in 11 of the 30 most enriched pathways for proteins with significantly increased association with Cav1 that were associated with immune-related pathways. These were distributed among seven distinct immune-related gene ontology (GO) functional categories including neutrophil activation, neutrophil degranulation, immune effector process and immune response. Furthermore, expression of Cavin1/PTRF in MIO-M1 Müller glia significantly reduced F-actin staining intensity

Conclusions: Our results suggest that non-caveolar Cav1 in MIO-M1 Müller glia enhance LPS-induced innate immune response. Expression of Cavin1/PTRF sequesters Cav1 into caveolae, which alters critical pathways involved in immune regulation, with remodeling of actin cytoskeleton as a potential mechanism

ABSTRACT BODY:

Purpose: To examine relationships between serum brain-derived neurotrophic factor (BDNF) and symptoms and signs of corneal nerve function.

Methods: Prospective study of individuals seen in the Miami Veterans Affairs eye clinic. All individuals completed questionnaires regarding ocular pain symptoms and underwent a comprehensive assessment of the ocular surface, including confocal microscopy. All individuals provided a blood sample which was analyzed for BDNF using R&D Free BDNF Quantikine ELISA Kit. Our primary goal was to examine relationships between neuropathic ocular pain symptoms and confocal microscopy findings and serum BDNF levels. These relationships were examined by correlational analysis, followed by multivariable forward stepwise linear regression analysis.

Results: 35 individuals were enrolled into this prospective study, with a mean age of 54±4 (range 48 to 63 years); 97% (n=34) self-identified as male, 60% as white, and 43% as Hispanic. BDNF levels ranged from 11.6 ng/ml to 50.5 ng/ml, with a mean of 30.5 ng/ml (standard deviation 9.0). BDNF levels were positively associated with Neuropathic Pain Symptom Inventory-modified for the eye (NPSI-E) scores ($r=0.33$, $p=0.05$) and corneal nerve beading density ($r=0.41$, $r=0.02$). When considering demographics, ocular symptoms, signs, and nerve metrics in a forward multivariable regression model, elevated levels of BDNF were associated with higher neuropathic pain symptoms (NPSI-E, standardized β 0.64, $p<0.005$) and higher corneal nerve beading density (minimum value of 6 scans from both eyes, standardized β 0.69, $p<0.005$). Elevated levels of BDNF were also associated with lower corneal sensation (measured with a cotton swab, standardized β -0.52, $p=0.001$) and corneal nerve fiber area (standardized β -0.40, $p=0.01$). This model explained 59% of variability in systemic BDNF levels. Of note, demographics and tear film metrics were not related to BDNF levels.

Conclusions: BDNF levels are related to higher neuropathic ocular pain symptoms and beading density (a measure associated with nerve metabolic activity).

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) results from a complex interaction of environmental and genetic risk factors. Genetic studies have shown complement genes are strongly associated with AMD. Rodent models based on expression of human genetic risk variants in complement genes have exhibited only limited phenotypic similarity to human disease. In the present study we have compared complement Factor H (CFH) and complement component 3 (C3) mRNA expression in different species eye (e.g. mouse, rat and human).

Methods: Paraffin sections or cryosections of mouse, rat and normal human donor eyes were used for in situ hybridization assay to determine the CFH and C3 expression. Manufacturer's (Advanced Cell Diagnostics) instructions were followed for RNAscope® experiments. CFH and C3
probes for different species were applied. Negative controls, e.g. DapB and positive probes or tissues (Liver), were included.

Results: In rodent eye (both rat and mouse), CFH mRNA is strongly expressed in the retinal pigment epithelium with some expression also found in inner nuclear (INL) and retinal ganglion cell (RGC) layers of the retina. C3 mRNA is expressed mainly in RGC, INL of retina, ciliary body, corneal epithelium with some expression is also found in rodent retinal pigment epithelium layer. However, in human eye, CFH and C3 mRNA are strongly expressed in the choroid. Some expression is also found in RGC, INL layer of retina, ONH, sclera, cornea endothelial and stroma; and ciliary body. There is no C3 or CFH signal detected in RPE cells.

Conclusions: The complement genes are present in ocular tissues, where they could play an important role in the pathogeneses of age-related macular degeneration. Our results show that complement factor H and C3 expression localization are quite different between human and rodent eyes. Rodent animal models based on manipulating CFH or C3 expression might not represent human disease because of these anatomic differences.

ABSTRACT BODY:

Purpose: Rhesus macaques (Macaca mulatta) are a valuable model in ophthalmology research, exhibiting visual systems that share many anatomical similarities with those of humans. The purpose of the current study is to investigate the effects of age on ocular features of a large cohort of free ranging rhesus macaques derived from animals originally introduced to Cayo Santiago/Puerto Rico in 1938.

Methods: A total of 172 animals (83 males and 89 females) from all ages (mean 13.1±5.7; range 0.7 to 26.2 years old) and mean weight of 16.0±7.6 pounds underwent a comprehensive eye exam, including slit-lamp biomicroscopy (HSL-600, MicroClear, Jiangsu, China), pachymetry (Pachmate 2, DGH Technologies, Exton, USA), axial length (vuPad, Sonomed Escalon, Lake Success, USA), and automated refraction (Topcon KR 7000S, Topcon, Tokyo, Japan). Each outcome variable was modeled as a function of age using multilevel mixed-effects models adjusted for animal sex and weight.

Results: Cataract of any degree (no evidence of traumatic cataract) was observed in 19 animals (11 unilateral and 8 bilateral cases) representing a frequency of 11.05% (95% CI: 6.78 – 16.71%). The mean pachymetry, axial length, and spherical equivalent were, respectively, 474.43±32.21 mm (median: 473.00), 19.49±1.24 mm (median: 19.46), and 0.30±1.70 D (median: 0.38). Age was significantly associated with cataract occurrence, pachymetry, axial length and spherical equivalent. For each 1 year increase of age, the odds of having cataract increased by 18% (OR= 1.18; 95%CI: 1.06 – 1.31; p=0.001), the pachymetry decreased by 1.11 mm (Coef.= -1.11; 95%CI: -2.00 to -0.23; p=0.013), the axial length increased by 0.03 mm (Coef.= 0.03; 95%CI: 0.01 to 0.05; p<0.001), and the spherical equivalent decreased by 0.12 D (Coef.= -0.12; 95%CI: -0.22 to -0.02; p=0.015).

Conclusions: Rhesus macaques have age-related ocular changes similar to those observed in human aging, including higher occurrence of cataract, decreasing corneal thickness, increasing axial length, and myopic shift. Our results are from a natural free-ranging population without medical intervention, which represents an excellent population for studying naturally occurring age-related eye diseases.

SUBMITTER (NAME ONLY): Megan Cavet

TITLE: National physician survey on clinical practice patterns for the treatment of noninfectious uveitis

SESSION TITLE: Clinical Uveitis and Scleritis: Therapies and Outcomes

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.E. Cavet, Medical Affairs, Bausch + Lomb, Rochester, New York, UNITED STATES|S. Hancock, T.A. Ciulla, Clearside Biomedical Inc, Alpharetta, Georgia, UNITED STATES|

Commercial Relationships Disclosure: Megan Cavet: Commercial Relationship(s);Code E (Employment):Bausch + Lomb;Code I (Personal Financial Interest):Bausch + Lomb | Shelley Hancock: Commercial Relationship(s);Code E (Employment):Clearside Biomedical Inc;Code I (Personal Financial Interest):Clearside Biomedical Inc;Code P (Patent):Clearside Biomedical Inc | Thomas Ciulla: Commercial Relationship(s);Code E (Employment):Clearside Biomedical Inc;Code I (Personal Financial Interest):Clearside Biomedical Inc

ABSTRACT BODY:

Purpose: Noninfectious uveitis (NIU) often manifests as a persistent relapsing disease that may be challenging to treat. This survey was conducted to evaluate current treatment patterns for chronic and acute NIU among retina specialists and identify unmet needs associated with therapy for NIU and associated macular edema (ME).

Methods: An anonymized online survey on NIU practice patterns was designed and sent to ophthalmologists throughout the US. Screening questions limited respondents to retina specialists with retina/uveitis fellowship training and intravitreal injection experience. The survey consisted of questions related to respondent's location and specialty, occurrence of ME in association with NIU, NIU treatment patterns and therapeutic unmet needs. Responses were analyzed using descriptive statistics.

Results: Survey respondents (N=150) were evenly distributed geographically. Respondents reported ME secondary to 31% and 61% of acute and persistent NIU cases respectively, with an overall rate of 47%. Corticosteroids were the most common initial treatment for acute NIU (>90% of cases), mostly administered topically. Proportions of patients with unilateral/bilateral acute NIU receiving topical corticosteroids were 93%/91%, 51%/47% and 47%/46% for anterior, posterior and pan NIU, respectively. In persistent NIU, therapy was typically changed to another corticosteroid and/or a non-steroidal immunosuppressant. Among patients receiving corticosteroids for persistent NIU, periorbital delivery was the most common route of administration for unilateral/bilateral anterior NIU (59%/55%), while intravitreal delivery was most common for posterior NIU (64%/59%) and pan NIU (68%/63%). Respondents refrained from using corticosteroids in 20% of patients due to concern over elevated intraocular pressure (IOP) and considered elevated IOP, glaucoma and cataract risk to be moderately high concerns when selecting therapy (ranking of 4.0, 3.9, 3.5, respectively, on a 1-5 scale). A lower risk of IOP elevation was ranked as the greatest unmet need for corticosteroid therapies.

Conclusions: Survey results indicate that ME is commonly associated with NIU, and local corticosteroids are typically used first-line. However, physicians may limit use of corticosteroids due to risk of associated side effects such as cataract and IOP elevation; effective therapies with lower incidence of these adverse reactions are warranted.

ABSTRACT BODY:

Purpose: ADOA is the most common inherited optic neuropathy, resulting in severe and progressive visual failure due to loss of retinal ganglion cells (RGCs). Most patients harbor loss-of-function mutations in the OPA1 gene that lead to haploinsufficiency. Reduced OPA1 protein levels result in impaired mitochondrial function in RGCs leading to cell death. Currently, there is no treatment for patients with ADOA. TANGO ASOs reduce inclusion of a non-productive, alternatively spliced exon in OPA1, and leverage the wild-type (WT) allele to increase productive OPA1 mRNA and protein. To test TANGO ASOs on OPA1 expression and function in RGCs in a human ADOA model, we generated OPA1 haploinsufficient iPSCs for differentiating into retinal neurospheres.

Methods: OPA1 mutations were introduced in a WT human iPSC line using CRISPR-Cas9. Clones were assessed for karyotype, pluripotency, heterozygous mutation status, and OPA1 expression. Mutant and isogenic control WT retinal neurospheres were generated over 45 days of differentiation (PMID: 25640818). RGCs were assessed by immunofluorescent microscopy and single-cell RNA sequencing. Relative levels of OPA1 were assessed by qPCR, quantitative western, in situ hybridization, and immunohistochemistry. Reactive oxygen species (ROS) and viability of RGCs were assessed by flow cytometry. We evaluated neurospheres treated with TANGO ASOs by gymnotic delivery.

Results: Haploinsufficient OPA1 iPSC clones were generated with normal karyotype and pluripotency. Both OPA1 mutant and WT control neurospheres were generated with approximately 10-20% RGCs. OPA1 mutant cells had similar viability and increased cellular ROS levels compared to controls. ASO treatment of neurospheres increased OPA1 mRNA expression and OPA1 protein while reducing non-productive OPA1 mRNA.

Conclusions: iPSC-derived RGC-containing neurospheres provide a useful in vitro model to evaluate TANGO ASOs. TANGO ASOs were able to partially correct RNA and protein deficiencies in OPA1 mutant retinal neurospheres. Our results support that TANGO ASOs can potentially be used to treat ADOA caused by OPA1 haploinsufficiency.

TITLE: Ophthalmologists' Familiarity and Anticipated Use of Biosimilars Prior to the Launch of the First Biosimilar in Ophthalmology

SESSION TITLE: AMD and diabetic retinopathy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Ferguson, Ophthalmology, Spherix Global Insights, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Chrystal Ferguson: Commercial Relationship(s);Code E (Employment):Spherix Global Insights

ABSTRACT BODY:

Purpose: The aim of this study is to assess, through a wirtten questionaire, ophthalmologists' knowledge, attitudes, current market use (bevacizumab biosimilars; not authorized in retinal conditions) and future market use (ranibizumab and aflibercept biosimilars) of biosimilars in ophthalmology.

Methods: In November 2021, US ophthalmologists (n=75) completed a 40-minute on-line survey. Ophthalmologists were required to be in practice between 2 and 40 years, spend at least 50% of their professional time in clinical practice seeing patients, and not be pediatric-focused.

Results: 61% of ophthalmologists are neutral towards biosimilars, while 24% are in-favor and 15% are against. 23% of respondents report their opinion has become more positive in the last two years, while only 6% report their opinion has become more negative. 29% of ophthalmologists surveyed are extremely familiar with the FDA biosimilar approval pathway while 44% are moderately familiar, and 27% are not familiar; 31% and 28% are extremely comfortable with the concepts of extrapolation and interchangeability respectively. 61% and 56% are aware of approved bevacizumab biosimilars (ABP 215 and PF-06439535 respectively) when given the options but reported use is only 2% (ABP 215) and 1% (PF-06439535) given bevacizumab is used off label and therefore retinal diseases would not qualify for extrapolation. 61% of surveyed ophthalmologists report low familiarity with SB11 (ranibizumab biosimilar and the first FDA approved biosimilar studied in retinal conditions) and only 16% were aware of the launch date in 2022. Respondents estimate a mean of 26% of ranibizumab patients will be switched to SB11 for any condition when it becomes available, but only estimate switching 10% of aflibercept patients to the biosimilar. 21% report being extremely likely to prescribe SB11 over ranibizumab while 12% report the same for aflibercept; however, 36% are not likely to prescribe SB11 over ranibizumab while 61% are not likely to prescribe the biosimilar over aflibercept.

Conclusions: Ophthalmologists are predominantly neutral towards biosimilars currently, and familiarity of the FDA approval pathway is modest. Bevacizumab biosimilars are not supported by ocular data influencing familiarity, comfort, and uptake. Biosimilars investigated in ophthalmologic conditions have potential for greater utility.

Commercial Relationships Disclosure: Alexander Neugebauer: Commercial Relationship: Code N (No Commercial Relationship) | Katarina Stingl: Commercial Relationship: Code N (No Commercial Relationship) | Iliya Ivanov: Commercial Relationship(s);Code E (Employment):Carl Zeiss Vision GmbH | Siegfried Wahl: Commercial Relationship(s);Code E (Employment):Carl Zeiss Vision GmbH

ABSTRACT BODY:

Purpose: Gaze training describes the method of encouraging a more effective gaze behavior in persons living with impairments to the visual field - such as Retinitis pigmentosa - through specifically designed visual tasks, thus improving the visual performance in everyday life. Recent advancements in the field of virtual reality in both technology and accessibility motivate new and adapted gaze training approaches. In this study, we aim to evaluate the potential of utilizing virtual reality devices in gaze training.

Methods: For this, a gaze training application for a wireless virtual reality headset was designed and developed. Seven visually healthy participants (aged 19-29, average 22.9±3.1) with simulated tunnel vision used the application over the course of two weeks for unsupervised at-home gaze training. The training consisted of three different visual tasks – navigation, target search and simultaneous tracking of multiple moving targets – each designed to encourage increased gaze movement. The results were analyzed using Linear Mixed Models. Participants were further asked to fill questionnaires regarding their experience with the training application and virtual reality device throughout the two-week training phase.

Results: Participants display an increase in effective gaze movements – measured by the perceived visual area over a fixed amount of time - over the course of the study, with an average linear increase of 14.3% in the navigation task and 19.0% in the search task from first to tenth session ($p<0.01$ in both tasks). In addition, it is found that increased effective gaze movements correlate with the performance in the navigation task ($p<0.01$). According to the questionnaires, the developed virtual-reality gaze training is intuitive, not straining and initially enjoyable, however the reported motivation during training decreases over the course of the study.

Conclusions: The improvements in gaze behavior and visual performance displayed by the participants with simulated tunnel vision suggest that similar results may be achieved in Retinitis pigmentosa patients, though it remains to be assessed whether these effects translate to real-world situations. Further, the complication-free execution of a two-week training phase and positive user feedback regarding ease-of-use of the application and virtual reality setup show their feasibility for unsupervised at-home training.

TITLE: Conditional late deletion of IRBP causes loss of retinal function and a slow retinal degeneration without myopic eye elongation

SESSION TITLE: Animal models of human ocular disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Getz, M. Chrenek, C. Reid, D. Shelton, V. Summers, J.H. Boatright, J.M. Nickerson, Emory University, Atlanta, Georgia, UNITED STATES|

Commercial Relationships Disclosure: Tatiana Getz: Commercial Relationship: Code N (No Commercial Relationship) | Micah Chrenek: Commercial Relationship: Code N (No Commercial Relationship) | Chloe Reid: Commercial Relationship: Code N (No Commercial Relationship) | Debresha Shelton: Commercial Relationship: Code N (No Commercial Relationship) | Vivian Summers: Commercial Relationship: Code N (No Commercial Relationship) | Jeffrey Boatright: Commercial Relationship: Code N (No Commercial Relationship) | John Nickerson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Germline knockout of IRBP (i.e., RBP3) results in severe myopia starting early in development (P7) followed much later by retinal degeneration (P25+). Here, we test the hypothesis that late deletion of IRBP expression should cause loss of photoreceptor function and retinal degeneration without an increase in eye axial length.

Methods: To conditionally delete IRBP late in rod photoreceptors specifically, we used Rho-iCRE75. Littermate controls without the Rho-iCRE75 driver, but with the $RBP3^{lox/lox}$ gene, were used for comparison. IRBP mRNA levels were measured by digital droplet RT-PCR. Retina function was measured with electroretinograms (ERGs). Fundus imaging and SD-OCT evaluated retina morphology in vivo. Eye axis and circumference dimensions were measured with noncontact micrometers at sub-micron accuracy and precision. ONL counts were conducted on H&E stained sections.

Results: By P30, IRBP gene expression levels were significantly decreased by about 90% in the Rho-iCRE75 $RBP3^{lox/lox}$ mice vs the $RBP3^{lox/lox}$ mice ($p<.0001$). At P60, the ERGs showed significant decreases in a-wave (~34%; $p<0.01$) and c-waves (~21%; $p<0.05$) for the Rho-iCRE75 $RBP3^{lox/lox}$ mice, while the b-wave trended about 13% lower but was not statistically significant. Fundus photographs and SD-OCT imaging showed no obvious pathology in any group. Eye axial length, equatorial width, fit diameter, and roundness were not significantly different between genotypes at either age group. Retinal arc lengths were not different at either age group. Interestingly, outer nuclear layer counts at P30 showed an 8% significant decrease of nuclei in Rho-iCRE75 $RBP3^{lox/lox}$ versus $RBP3^{lox/lox}$ mice ($p<0.05$).

Conclusions: 1. Loss of IRBP late (after rapid early eye growth is mostly complete) was not associated with myopic eye growth. 2. The eye may already be incompetent to experience abnormal eye elongation when IRBP was lost late. 3. Selectively early IRBP expression was sufficient to allow normal emmetropia in the mouse eye. 4. However, the late loss of IRBP profoundly decreased photoreceptor number and function soon after IRBP mRNA was lost. This suggests that IRBP independently controls photoreceptor maintenance and emmetropic eye growth, implying at least two different and independent mechanistic roles for IRBP.

ABSTRACT BODY:

Purpose: To assess how key stakeholders, including visually impaired individuals and ophthalmic professionals, perceive potential challenges and effects on visually impaired users navigating the built environment

Methods: Semi-structured interviews were conducted with 20 stakeholders including 3 town planners, 4 architects, 3 visually impaired individuals, 6 ophthalmic professionals including ophthalmologists and optometrists and 4 sight loss charities. All transcripts were analysed using NVivo version 11 and random transcripts from each category were analysed by a secondary analyst, to agree on themes and sub-themes. A senior researcher adjudicated themes and subthemes.

Results: Four main themes and twenty-three subthemes were identified (table 1). The main themes included barriers and enablers of the built environment, the impact of living with visual impairment, policy, regulation and guidance and future solutions and innovations. The issues mentioned most were isolation and loneliness (33 times), confidence (21 times), mental health (19 times), independence (13 times). This was echoed by all stakeholders with planning professionals stating, ‘it must restrict them going out psychologically which leads to a lack of interaction, makes them homebound which impacts their physical and mental health and wellbeing’. Charities stated that ‘People [feel] cut off from the rest of society stuck at home’. In addition, some of the biggest barriers and enablers to navigating the built environment were issues with pavements (58 times), street furniture (36 times), lighting (25 times), shared space (18 times) and pedestrian crossings (17 times). Visually impaired individuals felt that ‘we give so much space to cars and everyone else has to jostle on the pavement in fear of their death’. Town planners and architects echoed these concerns commenting ‘far too much space has been given over to the motor vehicle and now the space on footways in restricted’.

Conclusions: This study showed that there are potential challenges for people with a visual impairment when navigating the built environment, many of which ophthalmic professionals, built environment professionals, charities and visually impaired people agreed on. The results also showed how big an impact having visual impairment can have on moving around towns and cities and its effect on mental and physical health.

SUBMITTER (NAME ONLY): Varsha Venkata Srinivasan

TITLE: Macula Ganglion Cell Inner Plexiform Layer and Circumpapillary Retinal Nerve Fiber Layer Thicknesses from Widefield Imaging are similar to Standard Scans

SESSION TITLE: Multidisciplinary Ophthalmic Imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: V. Venkata Srinivasan, S. Das, N.B. Patel, University of Houston College of Optometry, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure: Varsha Venkata Srinivasan: Commercial Relationship: Code N (No Commercial Relationship) | Siddharth Das: Commercial Relationship: Code N (No Commercial Relationship) | Nimesh Patel: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Optical coherence tomography (OCT) inner retinal thickness measures of the macula and circumpapillary regions are important for determining onset and progression of experimental glaucoma in the non-human primate (NHP). Standard raster and circumpapillary scans have excellent repeatability but sample a limited region of the posterior pole. The purpose of this experiment was to determine the agreement and repeatability of inner retinal thickness measures from widefield imaging compared to standard scans

Methods: OCT scans (Spectralis HRA+OCT) were acquired from 30 NHPs with healthy eyes. 11 of these animals were imaged on at least 4 separate days to assess repeatability. Standard scans included a 20x20° raster scan centered on the macula, and a 12° diameter circular scan centered on the optic nerve head. Widefield imaging protocol included a 217 line, 55x45° raster scan centered on the macula. Scans were imported into MATLAB, and the inner retinal borders were delineated using a neural network-based image segmentation algorithm. For comparison, retinal nerve fiber layer (RNFL) thickness was determined from an interpolated 12° scan path from widefield thickness maps. For both standard and widefield scans, the ganglion cell inner plexiform layer (GCIPL) thickness was determined for a region of 16 degrees in diameter centered on the fovea.

Results: The average GCIPL thickness from standard raster scans was 72.7±4.3μm, and 73.7±3.7μm from widefield images (bias = -1.0μm, 95% LOA -4.4 to 2.4μm). Average circumpapillary RNFL thickness from the standard circular scan was 113.2±7.3μm, and 114.2±5.8μm for a similar interpolated path from widefield scans (bias = 1.0μm, 95% LOA -6.5 to 8.6μm). Repeatability (2.77xSw) for GCIPL thickness was 2.7μm and 3.2μm, and for RNFL thickness 5.2μm and 4.5μm, for standard and widefield scans respectively.

Conclusions: Inner retinal thickness measures from widefield imaging have good repeatability and are comparable to those measured using standard scans. One of the major advantages of using widefield imaging is that it encompasses most of the visual field sampled in perimetry.

ABSTRACT BODY:

Purpose: To evaluate the anatomic and functional outcomes of eyes presenting with early onset versus delayed RDs following acute PVD.

Methods: This was a retrospective, comparative, interventional cohort study of patients who presented with delayed RDs (>42 days after initial presentation to a retinal specialist with acute PVD) compared to an age- and gender-matched control cohort who presented with early onset RDs (PVD and RD at initial visit to a retina specialist). All eyes underwent retinal detachment repair from October 1, 2015 to March 31, 2020. The primary outcome was the final attachment rate and single surgery anatomic success (SSAS) at 3 months.

Results: Seventy-one patients presented with delayed RDs and 147 matched controls presented with early onset RDs. Patients with delayed RD had a mean (SD) baseline logMAR VA of 0.20 (0.37) [Snellen, 20/32] at the initial presentation with an acute PVD, which then decreased to 0.50 (0.70) [Snellen, 20/63] at the time of RD diagnosis ($p<0.001$). The mean VA of the early onset RD group was 1.03 (0.92) [Snellen, 20/214]. There was a significant difference between the mean VA of these groups at the time of RD presentation ($p<0.001$). The mean VA was better at month 1 and 3 post-RD repair in the delayed RD group compared to that of the control group ($p=0.004$ and 0.03, respectively). No significant difference was found when comparing the mean VA at 6-months post-repair, 12-months post-repair, or at the final visit ($p=0.43$, 0.32, and 0.21 respectively). SSAS was 59/71 (83.1%) for the delayed RD group and 117/147 (79.6%) for the early onset RD group ($p=0.54$). In the delayed RD group, 31/71 (43.7%) eyes had a macula-off RD while in the control group 98/147 (67.5%) eyes were macula-off ($p=0.002$).

Conclusions: Delayed RDs occurring more than 6 weeks after initial presentation with an acute PVD generally had better VA at the RD diagnosis visit and faster post-surgical visual recovery compared to RDs diagnosed at the initial presentation to a retina specialist. While no significant difference in anatomic outcomes was seen between the two groups, a greater proportion of patients presented with macula on RDs in the delayed RD group, perhaps suggesting that RD warnings given at earlier visits may be beneficial.

ABSTRACT BODY:

Purpose: Although vascular endothelial growth factor (VEGF) drives vascular dysfunction in both non-diabetic (neovascular AMD) and diabetic (DME and PDR) settings, it remains an open question if hyperglycemia (a key element of the diabetic setting) influences VEGF-mediated permeability. The purpose of this study was to begin to address this question.

Methods: We studied the contribution of the renin-angiotensin-aldosterone system (RAAS) to VEGF-induced permeability in primary human retinal endothelial cells (HRECs), which were cultured for 10 days in either normal glucose (NG; 5 mM), or high glucose (HG; 30 mM) media, using transendothelial electrical resistance assay (TEER). Additionally, RNAseq analysis was performed on HRECs cultured in normal and high glucose conditions for 10 days.

Results: RNAseq analysis indicated that HG alone altered expression of over 2000 genes. Furthermore, VEGF altered expression of almost twice as many genes in HG versus NG cells. While many of the VEGF-regulated genes and pathways were unique to one glucose concentration, a small subset was altered by VEGF in both NG and HG cells. Follow-up laboratory-based experiments indicated that these common genes/pathways were probably not governing VEGF-driven permeability. Consequently, we considered if VEGF-mediated permeability was different between NG and HG cells. Indeed, it was. HG cells were more sensitive to VEGF-induced permeability. Furthermore, VEGF-induced permeability was in part dependent on RAAS in HG, but not NG cells. Our ongoing studies are focused on elucidating the underlying mechanism by which RAAS contributes to VEGF-induced permeability.

Conclusions: Hyperglycemia alters the way VEGF induces permeability in retinal endothelial cells. This realization, along with the underlying mechanism of this phenomenon, will guide development of individualized therapeutics for retinopathies in and outside the context of diabetes.

ABSTRACT BODY:

Purpose: The PDS is an innovative drug delivery system approved for neovascular age-related macular degeneration (nAMD) in the United States that includes an ocular implant for continuous delivery of a customized formulation of ranibizumab (RBZ) into the vitreous. The Archway trial (NCT03677934) evaluated safety and efficacy of the PDS for nAMD through 96 weeks (W).

Methods: Archway was a phase 3, randomized, active treatment–controlled trial. Patients (pts) with nAMD previously treated with and responsive to a mean of 5 anti–vascular endothelial growth factor injections were randomized 3:2 to PDS with RBZ 100 mg/mL with fixed 24W refill-exchanges (PDS Q24W), or intravitreal RBZ 0.5 mg injections every 4W (monthly RBZ) through W96. The trial evaluated noninferiority (NI) and equivalence of PDS Q24W versus monthly RBZ on a primary endpoint of best-corrected visual acuity (BCVA) change from baseline (BL) averaged over W36/40 (NI margin, –4.5 letters; equivalence margin, ±4.5 letters; previously presented) and key secondary endpoints of BCVA change from BL averaged over W60/64 and W88/92 (NI margin, –3.9 letters).

Results: PDS Q24W was noninferior to monthly RBZ at W60/64 and W88/92, with differences in adjusted mean (95% CI) BCVA change from BL of 0.4 (–1.4, +2.1) and –0.6 (–2.5, +1.3) letters between arms, respectively. Change in adjusted mean BCVA from BL averaged over W60/64 and W88/92, respectively, was –0.4 and –1.1 letters in the PDS Q24W arm and –0.8 and –0.5 letters in the monthly RBZ arm. Adjusted mean center point thickness change from BL was generally similar between arms through W96. During each of the 4 Q24W PDS treatment intervals, 98.4%, 94.6%, 94.8%, and 94.7% of PDS pts assessed did not receive supplemental RBZ treatment, respectively. The ocular safety profile of the PDS was generally unchanged from the primary analysis, with no new safety signals.

Conclusions: Archway end-of-study results support the continued efficacy of the PDS over 2 years. Archway BCVA results averaged over W60/64 and W88/92 were consistent with the primary analysis, with PDS Q24W noninferior to monthly RBZ. Through each of the 4 Q24W PDS treatment intervals, ~95% of PDS pts assessed did not receive

supplemental RBZ. Adverse events related to PDS procedures were well understood and manageable, with learnings continually implemented to optimize pt outcomes.

ABSTRACT BODY:

Purpose: Congenital stationary night blindness (CSNB) is known to be associated with high myopia. However, there is only limited information on the natural history of refractive error and the variability by causal gene in patients with CSNB. We performed a multi-center, retrospective study to better characterize refractive error in CSNB.

Methods: In this multinational study 138 patients with a clinical and molecular diagnosis of CSNB age 1-20 years were included from 8 sites We conducted a retrospective longitudinal chart review including data on age, refractive error, and genotype. Refractive error was defined as spherical equivalent of refraction (SER). Inclusion criteria were at least 2 longitudinal SER measurements and a known genetic variant. Unpaired t-tests were used to evaluate the differences in SER and age of measurement between genes.

Results: The mean ± SD age in years at the youngest measurement was 6.70 ± 4.18, 5.03 ± 2.87, 3.88 ± 3.18, 3.80 ± 3.76, and 4.40 ± 2.80 for CACNA1F, NYX, TRPM1, GRM6, and GPR179 respectively. The mean ± SD age in years at the oldest measurement was 12.06 ± 4.79, 8.85 ± 8.62, 9.75 ± 4.84, 8.20 ± 5.11, and 8.80 ± 3.71 for CACNA1F, NYX, TRPM1, GRM6, and GPR179 respectively. The mean ± SD SER for the youngest measurement was -3.50D ± 5.01D, -6.51D ± 3.44D, -5.44D ± 3.14D, -5.28D ± 5.81D, -7.40D ± 2.26D for CACNA1F, NYX, TRPM1, GRM6, and GPR179 respectively. The mean ± SD SER for the oldest measurement was -4.79D ± 5.89D, -6.51D ± 3.44D, -7.54D ± 4.43D, -6.60D ± 6.54D, and -9.00D ± 3.56D for CACNA1F, NYX, TRPM1, GRM6, and GPR179 respectively. The two X-linked genes were CACNA1F and NYX. Age at the youngest measurement was not significantly different for CACNA1F vs NYX (p=0.120). Age at the oldest measurement was significantly older for CACNA1F vs NYX (p=0.032). The SER for NYX was significantly more myopic than CACNA1F (p=0.017, p=0.009) for the youngest and oldest measurements respectively.

Conclusions: Average age at the first measurement was not significantly different whereas the average age at the last visit was higher in CACNA1F than NYX. Despite that myopia increased as age increased, NYX had significantly higher myopia than CACNA1F at both the first and last measurement.

ABSTRACT BODY:

Purpose: Phase-contrast adaptive optics scanning light ophthalmoscopy (AOSLO) enhances the visibility of translucent cells in the living retina. A model by Guevara-Torres suggests that the contrast is generated by the steering of light as it passes through refractive retinal cells that act as microscopic lenses. Here, we show for the first time, evidence that light is indeed bent by single retinal cells and laterally shifted at deeper retinal layers. This measurement provides information for detection optimization. Aperture patterns that favorably collect such steered light, can increase the contrast of translucent cells in the retina.

Methods: A digital micromirror device (DMD) was placed in the detection plane of a mouse AOSLO to image the light distribution in the retina. 796 nm light (241uW) was focused in the outer nuclear layer, while the detection plane was positioned conjugate to the deeper photoreceptor (PR)/RPE complex. The light distribution at the detector plane was imaged by turning on/off DMD facets to create a “flying” pinhole (~4.3 Airy disc diameter). A gradient descent algorithm optimized the aperture pattern by maximizing retinal image contrast (Brenner gradient, BG). Aperture pattern was trained on in vivo data from 3 adult C57BL/6J mice and was tested on a 4^{th} mouse.

Results: The light distribution was laterally shifted at deeper layers by as much as 6 μm consistent with a positive lens, showing that single translucent cells can lens and steer light (Fig.1). With the light distribution imaged, we could optimize the image contrast with an aperture pattern that highlights the lateral differences induced by cell steering. Starting from a random pattern, our algorithm iterated the aperture patterns to enhance the image contrast, which converged in 10 iterations (Fig. 2). Optimizing the BG in the horizontal direction, the trained aperture converged to an asymmetric pattern that resembled a split detector aperture that matched the differential light distribution seen by cell steering.

Conclusions: This strategy shows the first images of the directional steering of light by single retinal cells as light propagates to deeper retinal layers. We find that by optimizing the aperture this distribution of light can provide a further contrast improvement with the ultimate goal of providing intrinsic contrast for translucent cells in the retina.

ABSTRACT BODY:

Purpose: Tau is a neuron-restricted microtubule-binding protein whose aggregation is pathognomonic of neurodegenerative diseases (tauopathies). Tau miss-sorting and accumulation has been proposed to be associated with glaucoma pathogenesis. Recently, tauopathies have been reported to display a distinguishable pattern of Tau ubiquitylation that affects protein sorting and aggregating fibril diversity. The conjugation of ubiquitin (Ub) to lysine (K) residues is a conserved post-synthetic modification each protein can be decorated within living cells, which regulates substrate sorting or clearance through the proteasome. Here we report identification of Ub-proteins and Tau proteoforms in the aqueous humor (AH) of healthy and glaucoma subjects and the characterization of the kinetics of digestion of enzymatically and semi-synthetically produced mono-Ub-Tau species by the 20S proteasome in vitro.

Methods: Western blotting and proteomics studies were applied to interrogate the repertoire of Ub-proteins and to identify Tau proteoforms in the AH of healthy (cataract) and glaucoma subjects (n=15). The Microtubule Binding Domain (MBD) of Tau has been conjugated to Ub (mono-) at different lysine residues, recapitulating proteoforms described in brain tissues post-mortem, through a semisynthetic strategy and fed to the 20S to figure out the dynamics of catalytic processing.

Results: Total Ub-proteins were frequent in the AH and display an average 2-fold increase in glaucoma vs healthy subjects ($p<0.0001$). Tau shows up as different proteoforms, including Ub-positive species matter of further investigation, in the AH of glaucoma subjects. Site-specific mono-ubiquitylated Tau-MBD species show greatly divergent kinetics of processing by the 20S.

Conclusions: Double the amounts of Ub-proteins are immune-detectable in the AH of glaucoma subjects compared to healthy controls. If confirmed on a larger sample size, the accumulation of specific Tau proteoforms, especially individual Ub-Tau species, may elucidate the mechanisms of metabolism within the retina and identify novel biomarkers for improved glaucoma management. The divergent pathogenicity of individual Ub-Tau proteoforms may also be associated with their dynamics of interaction with the 20S and differential propensity toward intrinsic resistance or optimized clearance to proteolysis

ABSTRACT BODY:

Purpose: Congenital stromal corneal dystrophy (CSCD) is a rare congenital, dominantly inherited disorder characterized by diffuse stromal opacification. CSCD is associated with mutations in the decorin gene (DCN), which encodes one of the highly expressed small leucine rich proteoglycans in the extracellular matrix of the corneal stroma. As only 5 families with genetically confirmed CSCD have been reported, the identification of a novel pedigree provides the opportunity to better characterize the phenotype, ultrastructural features, clinical course and underlying genetic basis.

Methods: We report a novel Armenian family with affected individuals in 4 consecutive generations demonstrating clinical features consistent with CSCD. Consented individuals underwent slit lamp examination, optical coherence tomography and confocal microscopy. Genomic DNA was collected from saliva and all coding and adjacent intronic regions of DCN underwent PCR amplification and Sanger sequencing. In silico analysis was performed for identified mutations. Corneal tissue excised at the time of corneal transplantation underwent immunohistochemical and electron microscopic evaluation.

Results: Slit lamp examination of affected individuals showed bilateral, diffuse, panstromal corneal opacification. Two of the 6 individuals diagnosed with CSCD based on history and/or examination underwent genetic analysis; both demonstrated a novel heterozygous frameshift deletion in exon 8 of DCN (c.948delA (p.His317Thrfs*11)), predicted to cause a 33 amino acid truncation. The mutation was predicted to be damaging and disease causing by SIFT and Mutation Taster. Electron and light microscopic examination of an excised cornea demonstrated increased corneal thickness, stromal scarring, keratocyte loss and an irregularity of lamellar collagen spacing and fibril formation.

Conclusions: We report only the sixth affected pedigree with genetically confirmed CSCD, associated with a novel DCN frameshift mutation in an Armenian family. The clinical evaluation, multimodal imaging, and histopathological assessment of this family with CSCD broaden our understanding of the rare corneal disease.

ABSTRACT BODY:

Purpose: Earlier studies report an association of refractive error (RE) with retinal and choroidal thickness (RT and ChT respectively). However, it is not known whether these differences are present before the development of RE in children or develop as a consequence of the RE. We evaluated longitudinal changes in RT and ChT in young children who are at high or low risk of developing myopia as part of the Preventing myopia: Investigating Contributing factors to Nearsightedness In Children (PICNIC) study.

Methods: Children (n=23, age=7.6±0.9 years) were categorized as low risk (LR) (n=12, age=7.9±0.8 years, axial length, AXL=22.8±0.3mm, RE=1.1±0.3D) and high risk (HR) (n=11, age=7.4±1.0 years, AXL=22.5±0.8mm, RE=0.8±0.5D) for myopia, based on parental history and cycloplegic autorefraction at baseline. Wide-field SD-OCT (Spectralis, Heidelberg) radial scans centered on the fovea (55°, 12 lines) were collected at 3 points in time: baseline, 6 and 12 months. Images were processed in a custom Matlab program and corrected for lateral magnification using biometric data (Lenstar). RT and ChT were evaluated for retinal eccentricities of 1, 3, 5, 8 and 12 mm.

Results: At 12 months, AXL increased and RE decreased (less hyperopic) in the HR group ($p<0.05$ both) while only AXL increased in the LR group ($p<0.05$). At baseline, RT and ChT were not significantly different between the two groups at any eccentricity, although there was a trend for thicker choroid in the LR compared to the HR group at all eccentricities. There was also a significant increase in RT for the HR group at 1, 3 and 5 mm eccentricities, while RT increased at the central 1 mm only for the LR group ($p<0.05$ all). ChT increased significantly at all eccentricities for both groups, greatest superiorly (27.9±29.0 µm) and smallest nasally (19.9±20.7 µm) ($p<0.05$ both). Subfoveal ChT at 12 months increased significantly only in the LR group (26.2±27.8 µm, $p<0.01$).

Conclusions: At 12 months, there was greater ocular elongation and decreased hyperopia in children for HR of myopia, as predicted. Additionally, there were significant increase in RT and ChT, with different patterns of thickening for the HR and LR groups, which suggests differences in ocular growth patterns prior to myopia development. We will continue to follow up these children for 3 years, which will provide an understanding of changes associated with myopia development.

ABSTRACT BODY:

Purpose: To investigate a multi-modal approach to automatically generate natural-language diagnostic reports for macular diseases, by detecting varied lesions and diseases from color fundus photographs (CFP) and optical coherence tomography (OCT) images and accordingly synthesizing descriptions using natural-language processing (NLP) techniques.

Methods: Three pre-trained deep neural networks were used to detect variable retinal lesions from the CFP / OCT images and predict diagnosis from both modalities independently. A sanity check was performed to ensure the coherence between the detected lesions and the predicted diagnosis. Then a rule-based NLP algorithm descripted the lesions, reported diagnosis and recommended treatment (Fig. 1). A test set of 172 eyes from 127 subjects were successively acquired from July 2020 through September 2020 in our clinic, including 113 normal eyes and 59 abnormal eyes with epiretinal membrane (ERM), dry age-related macular degeneration (AMD), wet AMD and diabetic retinopathy (DR). Each eye consisted of one CFP and 12 radial OCT B-scans. Evaluation of the generated reports was conducted by comparing with the performance of two junior ophthalmologists. A questionnaire was designed and cooperatively judged by two retina specialists to quantitatively grade each report’s readability, correctness of diagnosis and recommendations (Fig. 1). All reports were anonymized to avoid potential bias. Sensitivity and specificity per class was also analyzed.

Results: AI-based NLP reports achieved higher grades in correctness of diagnosis (9.13 vs 9.03 points,) and recommendations (8.55 vs 8.50 points) compared to the junior ophthalmologists, but there was no statistically significance (P=0.43 and 0.85, respectively). For readability, both groups had a satisfactory performance (9.87 vs 9.88 points, P=0.87). Sensitivity of AI-reports and junior ophthalmologists was 0.74 (95% CI, 0.66 - 0.82) and 0.75 (95% CI, 0.67 - 0.83), respectively. Specificity of AI-reports and junior ophthalmologists was 0.94(95% CI, 0.91 - 0.98) and 0.97 (95% CI, 0.95 - 0.99), respectively (Fig. 2).

Conclusions: NLP algorithms-generated diagnostic reports for macular diseases based on multi-modal AI system can achieve similar performance as junior ophthalmologists, suggesting this emerging concept's potential in primary eye service.

TITLE: Anterior Eye Segment Imaging System for Teleophthalmology

SESSION TITLE: Telehealth

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Diego, M. Abou Shousha, Ophthalmology, University of Miami Health System Bascom Palmer Eye Institute, Miami, Florida, UNITED STATES|A. Diego, Biomedical Engineering, University of Miami, Coral Gables, Florida, UNITED STATES|

Commercial Relationships Disclosure: Ana Diego: Commercial Relationship: Code N (No Commercial Relationship) | Mohamed Abou Shousha: Commercial Relationship(s);Code I (Personal Financial Interest):Heru, Inc.

ABSTRACT BODY:

Purpose: Teleophthalmology increases access to ophthalmic care, lowers screening barriers, and facilitates follow-ups. However, there is a need to develop better systems to evaluate diverse conditions remotely. This study aims to compare a portable anterior eye segment imaging system with the current standards method for ophthalmology examination.

Methods: The new imaging system consisted of two IMX219 Arducam autofocus sensors (Arducam, China, Nanjing) for Raspberry Pi V2 camera module connected to a Raspberry Pi Zero W (Raspberry Pi Foundation, UK, Cambridge) that clips to a HoloLens 2 (Microsoft, Redmond, WA). Twenty subjects from the Bascom Palmer Eye Institute clinic participated in the study. Anterior eye segment videos were recorded with the new system and a 720p FaceTime HD camera (Apple, Cupertino, CA). Afterward, an ophthalmologist evaluated the videos using a clinical eye examination form. This questionnaire assessed the presence of pathologies for the different eye structures and graded video quality based on identifying emergent findings. The video evaluations were compared with the standard slit-lamp clinical evaluation performed during the patient's visit.

Results: Thirty-five eyes were evaluated. The percentage sensitivity and specificity were 31.4% and 81.1%, respectively, for the HoloLens-RBPi videos and 13.7% and 39.9% for the web camera videos. Ocular structures such as the cornea, anterior chamber, iris, and lens were better evaluated with the HoloLens-RBPi videos (specificity 50%-88.5%, sensitivity 18.2%-40%). Conjunctiva and sclera had the highest sensitivity percentage for both modalities (73.3% HoloLens-RBPi and 66.7% Web Camera). The average grade for the HoloLens-RBPi videos was 3.17, and the web camera videos averaged 1.35 out of a 5 point scale.

Conclusions: Specificity percentages were higher than sensitivity percentages in both imaging modalities, indicating that video evaluations are less accurate for pathologies screening. Nevertheless, HoloLens-RBPi evaluations were statistically significantly better than the webcam evaluations. This study presented an alternative system to assess eye conditions for telemedicine, a system that provides more details than the current standard for eye evaluation performed through a webcam. Further developments will include improving camera and illumination quality, obtaining fundus images, automating camera positioning, and creating a program to access livestream images.

ABSTRACT BODY:

Purpose: For the task of segmenting the double layer sign (DLS), an important feature of type 1 macular neovascularization (MNV) in age-related macular degeneration, we applied a Vision Transformer (ViT)-based model, which is now state of the art in many computer vision tasks. The ViT is convolution-free transformer architecture that can capture global interactions between elements of a scene and make better use of long-range dependencies.

Methods: Eyes were imaged using swept-source OCT angiography (SS-OCT, PLEX Elite 9000, Carl Zeiss Meditec, Dublin, CA) 6x6mm scans. The scans consisted of 500 A-scans per B-scan; each B-scan repeated twice at each of 500 B-scan positions along the y-axis. The SS-OCTA structural B-scans were manually annotated for the presence of a DLS and drusen (Dr) and used for training. We built a multi-region segmentation ViT that labelled both DLSs and Dr on a single B-scan image. In order to extend ViT from image classification to semantic segmentation, we depended on the output embeddings corresponding to image patches and obtained class labels from these embeddings with a pointwise linear decoder. For comparison, a convolutional (CNN) model was trained on the same dataset.

Results: A total of 251 eyes (211 patients) were included; 188 eyes with DLS and 63 eyes with drusen only (Dr) as controls. Our ViT model had 12 layers, 768 token sizes, and 12 heads. Mean Intersections over Union (IoU) between predicted and annotated masks for DLSs and Dr were 59.7%, 62.4% for the ViT model, and 44.9%, 52.8% for the CNN model, respectively. The transformer-based model significantly outperformed the CNN-based model.

Conclusions: We present a network that can detect DLS from structural B-scans alone using a purely transformer-based model and have applied it to a dataset with coarse annotations. To our knowledge, this is the first application of ViT segmentations in ophthalmic imaging.

TITLE: Development of a minicircle gene therapy system for expanding treatment options of inherited retinal disease

SESSION TITLE: Retinal Degenerations, Gene Therapy, Transplantation, and Prostheses

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F. Staurenghi, M.E. McClements, A. Salman, R.E. MacLaren, Department of Clinical Neurosciences, University of Oxford, Oxford, Oxfordshire, UNITED KINGDOM|M.E. McClements, R.E. MacLaren, Oxford University Hospitals NHS Foundation Trust, Oxford, Oxfordshire, UNITED KINGDOM|

Commercial Relationships Disclosure: Federica Staurenghi: Commercial Relationship: Code N (No Commercial Relationship) | Michelle McClements: Commercial Relationship: Code N (No Commercial Relationship) | Ahmed Salman: Commercial Relationship: Code N (No Commercial Relationship) | Robert MacLaren: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: DNA minicircles (MC) are transgene DNA vectors produced as circular expression cassettes devoid of any bacterial plasmid DNA backbone. One or more transgenes can be expressed without the theoretical risk of immunogenic responses against the bacterial backbone sequence in the common plasmids. Their smaller size facilitates expansion of their cloning capacity and improves their delivery into cells; indeed, this technology offers a potential solution for the reduction in transfection efficiency translational barrier in gene therapy. The overriding aim was to study a novel gene therapy application, Minicircle (MC) DNA, that has not yet been fully explored as a possible promising treatment for genetic diseases in the eye.

Methods: Minicircles and plasmids carrying a CAG.GFP.WPRE.pA transgene were prepared with different transfection reagents used (FuGene and ViaFect) to identify optimal transfection conditions. HEK293 cells (Human Embryo Kidney cell line) and ex vivo retinal explants from wild-type (WT) mice were transfected with the MC and plasmid constructs and GFP expression was monitored by live cell imaging. Subretinal injections in WT mice assessed transfection reagent toxicity and transfection success of MC-treated eyes. Eyes were imaged using Scanning Laser Ophthalmoscope (SLO) and Optical Coherence Tomography (OCT) then harvested at 8 weeks post-injection.

Results: HEK293 cells maintained GFP expression from both MC and plasmid transfections for over a week post-treatment. Ex vivo retinal explants achieved GFP expression up to one week post-transfection, which was limited to MC treated samples. In vivo SLO assessments did not present any signs of toxicity in the retina up to 8 weeks post-injection. Similarly, OCT scans identified no significant differences in photoreceptor layer thickness of either inferior and superior retina between injection groups.

Conclusions: MC transfections achieved better outcomes in ex vivo studies than equivalent plasmid transfections. In vivo, neither the transfection reagents or the MC DNA induced retinal toxicity at the doses used. However, consistent evidence of reporter expression has yet to be achieved in vivo, indicating further investigations into the delivery method of MC DNA to the retina are required.

TITLE: The Obesity Paradox in Uveal Melanoma: Body Mass Index >30 is associated with lower metastatic risk

SESSION TITLE: Intraocular tumors - Uveal melanoma and retinoblastoma

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Sabazade, A.H. Opalko, V. Gill, C. Herrspiegel, G. Stålhammar, Clinical Neuroscience Eye/Vision, Karolinska Institutet, Stockholm, Stockholm, SWEDEN|

Commercial Relationships Disclosure: Shiva Sabazade: Commercial Relationship: Code N (No Commercial Relationship) | Adrianna Opalko: Commercial Relationship: Code N (No Commercial Relationship) | Viktor Gill: Commercial Relationship: Code N (No Commercial Relationship) | Christina Herrspiegel: Commercial Relationship: Code N (No Commercial Relationship) | Gustav Stålhammar: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To examine the association between metabolic factors and the risk of metastasis in uveal melanoma.

Methods: Data on patient body mass index, cardiovascular diseases, diabetes, use of anticoagulants, antihypertensives, diuretics, statins and hypothyroidism replacement therapy at the time of diagnosis were collected from all patients diagnosed with uveal melanoma at St. Erik Eye Hospital, Stockholm, Sweden from January 2009 through December 2017. The hazard ratio (HR) for metastasis was then calculated with Cox regressions. Obesity was defined as a BMI of 30.0 or above.

Results: Data on the presence of cardiovascular diseases, use of anticoagulants, antihypertensives and hypothyroidism replacement therapy was available for 683 patients. For 581 of these, body mass index (BMI) was available and for another 200, we also had data on the presence of diabetes type 1 and 2 and the use of statins, diuretics, metformin and insulin. A total of 465 patients (80%) were non-obese and a total of 116 patients (20%) were obese. In univariate Cox regression, tumor diameter (HR 1.2 per increasing mm, $p<0.0001$) and diabetes type 1 or 2 (HR 1.9, $p=0.05$) were associated with metastasis. Obesity was negatively correlated (HR 0.6, $p=0.04$). In multivariate Cox regression, tumor diameter (HR 1.2, $p<0.0001$) and obesity (HR 0.4, $p=0.006$) retained their significance

Conclusions: Obesity is associated with lower metastatic risk in uveal melanoma, independent of tumor size and diabetes.

ABSTRACT BODY:

Purpose: While there have been multiple automatic segmentation techniques for different types of fundus images, few target specifically optical coherence tomography angiography (OCTA) images due to the difficulty of manual annotation during the data collection process, despite its importance in the diagnosis and treatment of various ophthalmic diseases. We developed and tested a deep learning approach to automatically segment the vascular structures in OCTA scans without the need for a large amount of manually traced images for training.

Methods: We pre-trained a deep learning-based image segmentation model, ResUNet, to automatically segment the axons and dendrites in retinal ganglion cell (RGC) images. A total of 110 RGC scans with manual annotations from human experts were used to develop this model, where 90 scans were used for training and the remaining 20 images were reserved as testing data. Next, transfer learning was applied by fine tuning the model on 4 manually annotated OCTA images, while 4 additional OCTA images were used for evaluation. Pre-processing and post-processing steps were applied to adjust the brightness and contrast of input images and segmentation outputs from the model.

Results: Our model can effectively and automatically segment the structures in both RGC and OCTA images. Quantitatively, our segmentation model achieves average foreground, background and overall accuracy of 0.689, 0.998 and 0.997 for the RGC images, and 0.662, 0.968 and 0.955 on the OCTA images, respectively.

Conclusions: Our model can successfully adapt the prior knowledge learned from axon and dendrite segmentation of RGC images to the segmentation of vascular structures in OCTA images.

ABSTRACT BODY:

Purpose: To train and validate an automated deep learning system (DLS) on classifying high-resolution digital retroillumination images of posterior capsule opacification (PCO) and to discriminate between clinically significant and non-significant PCO.

Methods: For this retrospective register study, three expert observers graded two independent datasets totalling 279 images with no to severe PCO providing binary labels for clinical significance. The automated DLS was trained and internally validated with 179 images and externally validated with 100 images using Google Cloud AutoML Vision Application.

Results: Intraobserver variability κ (95% CI) for the three gradings for observer 1, 2 and 3 were 0.90 (0.86, 0.95), 0.94 (0.90, 0.97), and 0.88 (0.82, 0.93) respectively. Interobserver κ for the final grading for all three observers was 0.84 (0.78, 0.89) and for all nine gradings was 0.82 (0.76-0.86). Interobserver agreement was generally high, ranging from 0.85 (0.79-0.90) between observers 1 and 2 to 0.90 (0.85-0.94) for observers 1 and 3. On the internal validation dataset, sensitivity of the DLS was 0.89 at a specificity of 1 and the AUC was 0.98 (0.92-1). The external validation dataset consisted of 100 images, of which 63 were visually significant PCO. On external validation, sensitivity was 0.84 and specificity was 0.92. The AUC was 0.97 (0.93-0.99).

Conclusions: This automated DLS can provide highly accurate discrimination between clinically significant and non-significant PCO equivalent to human expert graders. The clinical value of this DLS as a potential decision support tool in different models of care warrants further clinical research.

ABSTRACT BODY:

Purpose: Nitrogen mustard (NM) is a cytotoxic and alkylating agent with no antidote. As a potent vesicant, it causes debilitating eye injury in the anterior segment. However, its effect on the retina is unknown despite evidence of retinal deficits in humans exposed to the agent. Here, we studied NM's pathological effects in murine cornea and retina. We hypothesized that NM will cause degeneration of corneal Schwann cells (cSCs) and axons, and induce reactive gliosis and citrullination in injured mice retinas.

Methods: Adult C57LB/6 wild-type (WT) mice and PLP-eGFP transgenic (TG) mice were used (Bargagna-Mohan et al., J. Neurosci. Res., 2020). After sedation, 5 µL of 0.2% or 1.0% NM was applied for 5 min in the right eye to induce injury, and flushed with 5 mL of sterile saline. The left eye was used as control. Mice were euthanized at 5 and 14 days post-injury. TG mice eyes were dissected for immunohistochemical (IHC) analyses of whole mount corneas (WMCs) and cryosectioned posterior eye cups (PECs). Whole eyes of WT mice were cryosectioned for IHC analyses. WMCs were stained for axonal β3-tubulin and imaged for eGFP of cSCs, while PEC tissues were co-stained for GFAP and citrullination (F95 antibody). Epifluorescence microscopy was used for imaging.

Results: We found that 0.2% and 1.0% NM caused corneal injury and regression of stromal cSCs and axons, with no notable changes in the uninjured cornea. These findings were evident in the central and peripheral zones of the cornea, and were observed at both 5 and 14 days post-injury. In the injured retina, a global increase in reactive Muller glia with ample staining for GFAP was observed. Notably, the F95 antibody revealed increased citrullination in Muller glia at both 5 and 14 days post-injury time points at the 1.0% NM dose. Although the 0.2% NM dose caused corneal injury, retinal gliosis and increased citrullination were not observed. The cornea and retina responses to NM is consistent with our lab's findings from previous models of corneal injury.

Conclusions: Our initial results suggest that NM causes loss of corneal nerves leading to reduction in overall density, and increases Muller cell gliosis and citrullination of GFAP filaments in murine retinas. Our novel in vivo NM corneal injury model potentially supports real-life exposure and provides the first evidence that NM-induced retinal gliosis and hypercitrullination may be involved in retinal degeneration.

ABSTRACT BODY:

Purpose: This study assesses the transretinal penetration of intravitreally injected retinal tissue-derived naïve exosomes and the enhanced targeting of choroidal neovascularization (CNV) after decorating them with Arg-Gly-Asp (RGD), a well-known ligand for integrins which are essential in VEGF signaling in CNV.

Methods: Exosomes were recovered from either mouse Müller glial cell or whole mouse retina using differential ultracentrifugation. Their size, number, and morphology were characterized using nanoparticle tracking analysis (NTA) and transmission electron microscopy (TEM). Exosome markers were confirmed using an exosome detection antibody array. Intravitreal injection of fluorescent-labeled naïve or RGD-conjugated exosomes (5.3×10^7 exosomes/μl) were given to wild type (n =9) or laser-induced CNV mouse model (n= 9). Retinal uptake of exosomes was assessed by in vivo retinal imaging microscopy and fluorescent staining with DAPI, GSA, and anti-integrin α_v antibody of retinal sections or choroid/RPE flat mounts. Active targeting of CNV was assessed by comparing retinal uptake between areas with and without CNV and by colocalization analysis of RGD-conjugated exosomes with integrin α_v within CNV.

Results: We recovered an average of 2.1×10^9 particles/ml with a peak size of 140 nm from 10 whole mouse retinas, and 4.2×10^8 particles/ml with a peak size of 147 nm from the supernatant of primary cultured mouse Müller glia. Rapid retinal penetration of intravitreally injected exosomes was confirmed by retinal imaging microscopy at 3 and 24 hours post-injection. Intravitreally injected naïve and RGD-conjugated exosomes penetrated into inner and outer retinal layers including IPL, INL, OPL, and ONL at 1 and 7 days after injection. Intravitreally injected RGD-conjugated exosomes were exclusively delivered to the area of CNV including ONL, RPE, and choroid in laser-induced CNV mouse model with 89.5% of colocalization with integrin α_v. Exosomal origination between mouse Müller glia cell and whole mouse retina did not show differences in retinal penetration.

Conclusions: Intravitreally injected exosomes demonstrated good penetration in both inner and outer retina. Further, intravitreally injected RGD-conjugated exosomes were selectively delivered to the area of CNV. This suggests that RGD-conjugated exosomes have a great potential to serve as an intraocular drug delivery vehicle, allowing an active targeting strategy.

ABSTRACT BODY:

Purpose: Glaucoma is classically viewed as a genetic and age-related disease and has rarely been associated with congenital infections. However, during the recent epidemics in Brazil, Zika virus (ZIKV) infection during pregnancy has been linked to cause glaucoma in infants. The aim of this study is to investigate the pathobiology of ZIKV induced glaucoma.

Methods: C57BL/6 wild type (WT) and IFNAR1$^{-/-}$ adult mice and pregnant dams were challenged with ZIKV strain PRVABC59 by anterior chamber (AC) and subcutaneous (s.c.) injections respectively. Intraocular pressure (IOP) was recorded at various time-points post-ZIKV infection. Trabecular meshwork (TM), retinal ganglion cells (RGCs) infectivity and cell death were assessed using immunofluorescence and TUNEL staining respectively. Axonal transport was measured by intravitreal injection of cholera toxin subunit B (CTB) and optic nerve imaging. For in vitro studies, human primary TM cells (HTMC) and GTM3 cell line were challenged with ZIKV at multiplicity of infection (MOI) 1 followed by measurements of innate antiviral responses using qPCR

Results: ZIKV infection caused increased IOP and the development of chorioretinal atrophy in both WT and IFNAR1$^{-/-}$ mouse eyes. AC inoculation of ZIKV caused infectivity in iridocorneal angle and TM, leading to the death of TM cells in the mouse eyes. ZIKV challenge resulted into RGC death and loss in the infected mice and neonate pups born from infected dams. ZIKV infection in IFANR1$^{-/-}$ mice caused optic nerve infectivity and disruption of anterograde axonal transport. ZIKV infection in mice induced autophagy in the anterior segment tissue, and autophagy inhibition using an FDA approved drug- Hydroxychloroquine (HCQ) attenuates ZIKV induced ocular pathology. HTMC and GTM3 cells were found to be permissive to ZIKV and evoked an innate antiviral response.

Conclusions: Our study for the first time showed experimental evidence of ZIKV induced glaucoma. Because of the similarity in glaucomatous pathologies in our study and other experimental glaucoma models, ZIKV infection can be used to study infectious triggers of glaucoma, currently, an understudied area of investigation.

TITLE: Success of non-absorbable versus absorbable suture material for posterior fixation (Faden procedure) of the medial rectus

SESSION TITLE: Strabismus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E.M. NaPier, Y. Schein, A. Spiller, G. Binenbaum, The Children's Hospital of Philadelphia Division of Ophthalmology, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Erin NaPier: Commercial Relationship: Code N (No Commercial Relationship) | Yvette Schein: Commercial Relationship: Code N (No Commercial Relationship) | Alyssa Spiller: Commercial Relationship: Code N (No Commercial Relationship) | Gil Binenbaum: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Esotropia with a high accommodation to convergence ratio (AC/A) is commonly treated with medial rectus recession and/or posterior fixation sutures (Faden procedure). Posterior fixation sutures traditionally involve suturing the rectus muscle to the sclera at a point posterior to the insertion. This shortens the muscle's arc of contact and limits the muscle's movement through its soft-tissue pulley. The literature on posterior fixation sutures describes the use of non-absorbable sutures for fixation. We sought to compare the success rates and complication rates of non-absorbable versus absorbable suture materials for posterior fixation.

Methods: Retrospective cohort study of children who underwent a posterior scleral fixation procedure of medial rectus muscle for high AC/A strabismus. Exclusions included <3 months follow up and fixation performed by suturing to the surrounding pulley fascia. Children were divided into groups based on the use of non-absorbable and absorbable suture material, both with spatulated needles. The primary outcome was surgical success, defined as a reduction in high AC/A esotropia without the use of bifocal glasses.

Results: We studied 16 children who had a posterior fixation procedure (median age 5.1 years, range 2 to 8.5; median follow up 1.7 years, range 0.3 to 6.7). Seven (44%) children had fixation using a non-absorbable 5-0 Merseline suture and 9 (56%) children had fixation using an absorbable 6-0 Vicryl suture. Three of 7 (43%) treated using non-absorbable suture had surgical success, compared to 6 of 9 (67%) children treated with using absorbable suture (p=0.61, Fisher exact). There was 1 (17%) complication among the 7 children in the non-absorbable group and 0 among the 9 children in the absorbable group.

Conclusions: Absorbable sutures are as clinically effective as non-absorbable sutures when used for scleral posterior fixation of rectus muscles. Absorbable sutures obviate the need for placement of a long-lasting foreign material on the eye and provide surgeons with additional choice of suture material and accompanying spatulated needles.

ABSTRACT BODY:

Purpose: Cancer screening can lead to early detection and reduced mortality. Due to barriers in reading, driving, and ambulating, individuals with visual impairment (VI) may participate in cancer screening less often than those without VI. This cross-sectional study compared participation rates in government-funded screening for breast, cervical and colorectal cancer in Canadians with and without VI, and examined associated sociodemographic factors.

Methods: Self-reported data on vision status and participation in mammography, pap smear, and fecal occult blood test was analyzed from the Canadian Community Health Survey 2013/2014 and 2017/2018. Participation in screening at the recommended age and time interval was compared between individuals with and without VI. Screening rates were also compared by level of household income and education, and having a family physician.

Results: Canadians with VI had lower participation rates in breast (53.0% [95% confidence interval [CI] 36.3-69.7%] vs. 67.0% [95% CI 64.5-69.4%]) and cervical (53.8% [95% CI 29.3-78.3%] vs. 76.2% [95% CI 74.0-78.3%]) cancer screening versus those without VI in 2013/2014. Colorectal cancer screening rates were similar for participants with and without VI (25.7% [95% CI 17.3-34.1%] vs. 24.7% [95% CI 23.7-25.6%]). Differences between the VI and non-VI groups across the three cancer screening categories persisted despite having a family physician. Lower levels of household income and education were associated with lower screening rates in the VI group for all cancer screenings examined. The 2017/2018 data similarly revealed a lower breast cancer (61.9% [95% CI 55.7-68.2%] vs. 69.4% [95% CI 66.3-72.5%]) and a comparable colorectal cancer screening rate (40.7% [95% CI 37.0-44.5%] vs. 38.0% [95% CI 36.4-39.5%]) in Canadians with versus without VI. Information on cervical cancer screening was unavailable in 2017/2018.

Conclusions: Canadians with self-reported VI appear to have lower participation rates in breast and cervical cancer screening than those without VI. Having a family physician did not impact the noticed lower participation rate. Smaller sample sizes in individuals with VI are likely responsible for the wide CI and non-significant differences observed. Policy-makers, organizations and clinicians should understand the unique barriers faced by individuals with VI, and facilitate adherence to screening guidelines.

ABSTRACT BODY:

Purpose: To analyze mesopic and dark-adapted (DA) retinal sensitivity changes based on fundus-controlled perimetry (FCP) test patterns designed to the shape of geographic atrophy (GA).

Methods: A total of 40 patients (75.8 ± 8.5 years old; 21 females) were prospectively examined by mesopic, DA cyan, and DA red FCP with the S-MAIA device (CenterVue, Padua, Italy). Test points were placed along iso-hulls (i.e., contour lines) at even distances surrounding the GA boundary at −0.645°, 0.43°, 0.86°, 1.29°, 2.15°, and 3.01° with customized software. Retinal sensitivity was assessed in 40 eyes, with longitudinal data for 29 eyes with a median [IQR] of one follow-up visit [0;2] spanning 2.1 [1.9;2.3] years. Linear mixed model analysis was applied to estimate the change in sensitivity over time with “test point nested in eye” as a random effects term.

Results: At baseline, mesopic, DA cyan, and red testing showed a curvilinear relationship between sensitivity and distance to GA with more severely reduced light sensitivity in the proximity to GA (Figure 1). In the longitudinal analysis (Table 1), for mesopic testing, the estimated marginal mean [95% CI] for sensitivity change was -2.29 [-3.27;-1.31] dB/y at 0.43° and gradually less for more distant test points. For DA cyan testing, the most severe decline in sensitivity was observed for more peripheral loci at 2.15° with -1.38 [-2.09;-0.67] and at 3.01° with -1.38 [-2.09;-0.68] dB/y, due to a floor effect for DA cyan testing at 0.43°. The pattern of decline in DA red sensitivity paralleled the changes in mesopic sensitivity.

Conclusions: Individualized, lesion-tailored mesopic and DA cyan and red FCP testing in eyes with dry AMD detect advancing functional loss prior to GA development. Differential patterns of decline in sensitivity over time - depending on the distance from the GA border and on the mode of FCP testing - reveal a dynamic functional “fingerprint”: Early, pronounced rod-related sensitivity loss in a certain distance to the actual atrophic lesion along with late, pronounced mesopic sensitivity decline colocalizing with the atrophic lesion border. This data demonstrates in vivo the dynamic functional consequences of localized pathobiological processes in advancing GA progression.

ABSTRACT BODY:

Purpose: Safe mobility is difficult with peripheral field loss. Perimetry maps the field loss but cannot determine the effectiveness of residual field or visual aids in daily life, where multiple hazards may be on colliding and non-colliding paths. Simplistic collision detection tests included a single approaching pedestrian over a simple background. Realistic collision detection tests need to simulate complex real-world scenarios.

Methods: We reviewed videos of real-world walking in busy shopping malls to identify walking paths of pedestrians. These behaviors were modeled mathematically and implemented in a video-based pedestrian collision detection test using Unity 3D engine for patients with homonymous hemianopia (HH).

Results: A patient and a pedestrian walking straight on a collision course at constant speeds are defined by the initial bearing angles (α and β) from their walking paths (Fig. 1). If β is in the HH patient's blind side, the colliding pedestrian is not visible. We implemented colliding pedestrians: 1) approaching face-to-face colliding pedestrian (α<90°), where patient and pedestrian share social responsibility for avoiding a collision, and 2) overtaken colliding pedestrian (α>90°), in which the patient is solely responsible for avoiding the collision because the patient is outside the normal visual field of the overtaken colliding pedestrian (walking slower than the patient).

The first-person view of shopping mall walking with modeled pedestrians is displayed on a large screen matching the real-world perspective. In each trial, a lead child who guides the patient along the walking path and multiple non-colliding pedestrians (passing either in front of or behind the patient) are deployed with or without a colliding pedestrian (Fig. 2).

Conclusions: We characterized colliding/non-colliding pedestrian paths and developed the test, which may provide objective outcome measures for any type of field loss patients with and without field expansion aids.

ABSTRACT BODY:

Purpose: To characterize the contents of diabetic (DM) and normal (N) primary limbal epithelial cell (LEC)-derived exosomes (Exos) using both genomic and proteomic analyses, and to identify their cargo differences.

Methods: Exos were isolated from age-matched human normal and DM LEC-conditioned media by ultracentrifugation. Total Exos RNA was isolated and subjected to Next Generation Sequencing (NGS) analysis. MiRNA libraries were prepared, sequenced, and aligned to GeneGlobe Data Analysis Center (Qiagen, Germantown, MD) followed by miRBase (release v21) mature and hairpin databases sequentially using Bowtie v1.2 (Langmead et al., 2009). For proteomics analysis, LEC-derived Exo lysates were reduced, alkylated, digested, and then labeled using 10-plex TMT isobaric tags and analyzed by tandem mass spectrometry. Pathway analysis was used to profile the molecular activities of the differentially expressed genes (DEG)/proteins cargos.

Results: The supervised analysis of NGS data identified a total of 2759 small RNAs including miRNA, piRNA, and snoRNA in all samples with the average threshold of more than one unique molecule identifier (UMI). Among these entities, 2422 were known miRNAs. A set of 87 (23 upregulated and 64 downregulated) miRNAs was identified as differentially expressed in DM-Exos vs. N-Exos (FC > 1.5 adjusted $p < 0.1$). Ingenuity pathway analysis of differentially expressed miRNA showed significant differences in insulin receptor signaling, cell cycle, regulation of EMT, chemokine, VEGF, planar cell polarity, and CXCR4 signaling pathways. Proteomics analysis showed a total of 2648 proteins associated with Exos in all samples. A set of 280 (26 upregulated and 254 downregulated) proteins was identified as differentially expressed in DM-Exos vs. N-Exos (FC > 2, $p < 0.05$). Pathway analysis of differentially expressed proteins showed significant differences in VEGF signaling, apoptosis, translation, metabolism, and cellular responses to stress pathways.

Conclusions: We identified normal and DM LEC-derived Exos' small RNAs and protein cargos and differentially expressed miRNAs and proteins in DM-Exos, which may have roles in disease state. Further studies are required to determine their functions in normal and diabetic cornea, which may help in developing more effective therapeutic approaches for corneal diseases such as diabetic keratopathy.

TITLE: Effect of reticular pseudodrusen on progression to late age-related macular degeneration alongside traditional severity scales

SESSION TITLE: AMD: Clinical and translational research/AMD therapies (excluding anti-VEGF)

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Agron, T.D. Keenan, E.Y. Chew, National Eye Institute, Bethesda, Maryland, UNITED STATES|T.E. Clemons, The Emmes Company LLC, Rockville, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Elvira Agron: Commercial Relationship: Code N (No Commercial Relationship) | Tiarnan Keenan: Commercial Relationship: Code N (No Commercial Relationship) | Traci Clemons: Commercial Relationship: Code N (No Commercial Relationship) | Emily Chew: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate reticular pseudodrusen (RPD) as a risk factor for progression to late age-related macular degeneration (AMD)

Methods: Color fundus photographs (CFP) of participants enrolled in the Age-Related Eye Diseases Study (AREDS) from annual study visits were graded for large drusen, pigmentary abnormalities, and late AMD. RPD presence was determined by deep learning grading of CFP. Proportional hazards regressions were performed that included traditional AMD severity scales (simplified severity scale (person) and 9-step scale (eye)) based upon the presence of drusen and pigmentary changes and RPD presence together. Outcomes were late AMD, geographic atrophy (GA) and neovascular AMD (NV).

Results: For the 9-step scale analyses 6959 eyes (3780 participants) with no late AMD at baseline were analyzed. For late AMD by eye, in a model including this scale and RPD together, the hazard ratio (HR) for RPD was 2.5 (95% confidence limit (CL): 2.1-3.1). In stratified models by the scale the RPD HRs were 5.1 and 1.8 for levels 1-6 and 7-8, respectively. For GA, the RPD HRs were 2.6 (2.2-3.4) (not stratified), 5.9 and 1.9 for levels 1-6 and 7-8, respectively. For NV, the HRs were 1.7 (1.3-2.2) (not stratified), 3.7 and 1.1 for levels 1-6 and 7-8. For the simplified scale analyses 3182 participants with no late AMD at baseline in either eye were analyzed. For late AMD, in a model including this scale and RPD together, the HR for RPD was 2.2 (1.8-2.6). In stratified models by the scale the RPD HRs were 3.2, 3.8, 2.3, and 1.6 for levels 0-1, 2, 3 and 4, respectively. For GA, the RPD HRs were 2.6 (2.1-3.2) (not stratified), 3.5, 4.9, 3.1 and 1.9 for levels 0-1, 2, 3 and 4, respectively. For NV, the HRs were 1.3 (0.9-1.8) (not stratified), 2.9, 3.03, 1.1 and 0.9 for levels 0-1, 2, 3 and 4. The Table includes the 95% CL of the models performed.

Conclusions: RPD represents an important third risk factor for progression to late AMD. This is true for both subtypes of late AMD, particularly for GA. However, the excess risk associated with RPD varies markedly by severity level. It carries highly increased risk at lower/moderate levels and less increased risk at higher levels. RPD status should be included in updated AMD classification systems, risk calculators, and clinical trials.

ABSTRACT BODY:

Purpose: Uncorrected refractive error is treatable but it causes vision impairment in millions of people worldwide, due to lack of vision care resources. This study evaluate a low-cost Refractive Kit (RK) for measuring refractive error in people with myopia by lay persons, and effect of vision correction based on RK.

Methods: The RK is a booklet with 16 pages of Tumbling E letter chart and a tape measure which measures the far point of the myopic eye from -1.0 to -8 with 0.5 gap between each page. The distance is converted to spherical equivalent refractive error. 30 participants between the age of 18 to 40 years old were tested with RK and also standard non-cycloplegic subjective refraction. In addition, 71 participants in Mali were tested in a vision screening for Visual Acuity (VA) with and without spherical lens determined by a lay person using the RK.

Results: In the accuracy test, the refractive error according to standard test ranged from -7.25D to 0.5D with a mean of -3.0D. There were 11 eyes, with astigmatism of -1.75 CYL and worse, which were not able to read any of the RK chart. Excluding these eyes, the Pearson correlation coefficient between standard and RK measurement was 0.97. The mean of absolute error was 0.39, and the standard deviation of the absolute error is 0.37. Participants had a mean uncorrected Visual Acuity (VA) of 0.8, lowest VA of 1.30. Wearing spherical correction lens according to RK, corrected VA was improved to -0.04 significantly ($p < 0.001$). Among the 71 participants received vision screening in Mali, 23 were diagnosed with myopia, with uncorrected visual acuity of as low as 0.70 with average of 0.16. The measured refractive error using RK ranged from -1 to -5.5 diopters. The mean VA of these participants was improved to 0.03 ($p < 0.001$) with worse VA of 0.15 with spherical lens according to RK.

Conclusions: RK measurements were highly correlated with the measurement standard clinical refraction method for myopic eyes without strong astigmatism. While there is an error in RK measurement, spherical prescription based on low-cost RK can correct most eyes with impaired vision due to refractive error to normal range. RK has a potential to address the issue of uncorrected refractive error in areas lacking access to eyecare professionals.

Mark Petrash: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Dry eye disease affects millions of people worldwide and is prevalent in older people, females, contact lens wearers, and increasingly in the general population due to excessive use of visual display devices. Tear instability is the characteristic pathophysiology of the disease due to the inability of tears to form a stable film on the ocular surface, which leads to drying of the ocular surface. Enhancing tear stability is known to relieve symptoms of dry eye. Human breast milk (HBM) has been shown to contain proteins that enhance ocular surface healing following injury. In healthy tears, tear proteins increase tear stability by showing surface-active properties. The aim of this project was to study the biophysical characteristics of HBM proteins and compare them with the proteins found in tears as a first step to explore the use of HBM constituents for treatment of dry eye.

Methods: HBM samples were fresh frozen, then thawed, centrifuged, and aqueous recovered for lyophilisation. The aqueous containing proteins was used in the experiments. Pressure-area profiles and rheology of surface films of HBM proteins and tear proteins, namely, lysozyme and lactoferrin were studied using Langmuir trough technology on an artificial tear solution at the physiological pH and temperature of tears.

Results: Pressure-area profiles indicated that HBM proteins formed a highly compressible, non-collapsible surface film with a maximum surface pressure of 32mN/m. The surface films of lysozyme and lactoferrin were also compressible with the maximum surface pressures of 23mN/m and 17mN/m, respectively. Hysteresis was observed in all proteins with smallest in lactoferrin and highest in lysozyme.

Conclusions: HBM proteins are surface active and capable of reducing surface tension to increase the film stability. They are effective in smaller amounts, show higher surface pressure, and wider surface coverage than tear proteins lysozyme and lactoferrin. Overall, the biophysical experiments indicate that HBM proteins in smaller amounts would provide better protection to the tear film than the natural proteins of the tear film and can be effective in enhancing tear stability in dry eye.

ABSTRACT BODY:

Purpose: HPV-derived Virus Like Particles (VLPs) have been previously described to have the ability to selectively target a large panel of solid tumor types by binding to specifically modified heparan sulphate proteoglycans (HSPGs) on the tumor cell surface. The investigational VDC, belzupacap sarotalocan (AU-011), is composed of a modified VLP conjugated to a novel photosensitizer and is currently in phase 2 clinical trials for the treatment of primary choroidal melanoma. Upon light activation, AU-011 causes membrane disruption leading to acute cellular necrosis, tumor regression and an anti-tumor immune response in murine tumor models. With the ability to target a broad range of tumor types, AU-011 has the potential to treat tumors that metastasize to the choroid using the same treatment paradigm. We have previously shown anti-tumor activity of AU-011 in mouse models of breast and lung cancer. The purpose of this study was to expand to other cancer types that metastasize to the choroid as well as to explore the dose response.

Methods: In vitro efficacy was evaluated in a panel of cancer cell lines. Cells were treated with AU-011, and cell binding and cell killing were evaluated by flow cytometry. HSPG targeting was assessed by inhibiting HSPGs binding with exogenous heparin. In vivo efficacy was evaluated by utilizing EMT6 (breast), CT26 (colon) and RENCA (renal) syngeneic mouse models. Subcutaneous tumors were treated when they reached a size of ~50 mm^3. Treatment consisted of a single intravenous administration of AU-011 followed 12 hours later by external exposure to near-IR light. Tumor volumes were measured over time.

Results: In all cancer cell lines tested, the in vitro cell binding and cell killing potency were under 100pM. Cell binding and subsequent AU-011 mediated cell death was inhibited by heparin, demonstrating that AU-011 can bind to these tumor cell types in an HSPG-dependent manner. In vivo, AU-011 treatment demonstrated dose dependent activity and delay of tumor growth in EMT6, CT26, and RENCA murine tumor models.

Conclusions: These data demonstrate that AU-011 can bind to, and kill, cells derived from cancer types known to metastasize to the choroid. Furthermore, AU-011 showed dose dependent activity in vivo using cognate tumor models. The studies herein support further development of AU-011 for choroidal metastasis.

ABSTRACT BODY:

Purpose: RP59 (OMIM# 613861) is caused by mutations in the dehydrodolichyl diphosphate synthase (DHDDS) gene. We previously reported that knock-in mice with K42E and T206A DHDDS mutations do not exhibit overt retinal degeneration, but exhibit a “negative ERG” [normal a-wave and reduced (scotopic and photopic) b-wave amplitudes]. Here, we describe further characterization of two RP59 mouse models.

Methods: $Dhdds^{T206A/T206A}$ and $Dhdds^{T206A/K42E}$ knock-in mice (Nguyen et al., ARVO 2021) vs. age-matched WT ($Dhdds^{+/+}$) mice were assessed by quantitative retinal morphometry (SD-OCT) and electroretinography (ERG; 500 nm LED stimulus). Visual acuity (VA; spatial frequency) was assessed by OKR under scotopic and photopic conditions. Statistical significance (Student’s t-test) threshold was $p \leq 0.05$ ($N \geq 3$ SD-OCT, $N \geq 8$ ERG, $N \geq 3$ OKR).

Results: From PN 1- to PN 12-mo, neural retina full thickness declined <5% ($p \leq 0.05$), while INL thickness declined by 27% in $Dhdds^{T206A/T206A}$ and 30% in $Dhdds^{T206A/K42E}$ ($p \leq 0.01$), vs. WT mice. ERG b-to-a-wave amplitude (b/a) ratios declined (at 3-mo intervals) over the same time. At PN 12-mo: scotopic b/a ratios were reduced by ~25% in $Dhdds^{T206A/T206A}$ and by ~35% in $Dhdds^{T206A/K42E}$ mice, vs. WT values ($p \leq 0.01$). Photopic b/a ratios were also declined by ~33% in $Dhdds^{T206A/T206A}$ and by ~41% in $Dhdds^{T206A/K42E}$ mice, vs. WT values ($p \leq 0.01$). ERG c-wave amplitudes were like WT at PN 6-mo; however, at PN 12-mo, c-wave amplitudes were reduced by ~35% in both mutants, vs. WT mice ($p \leq 0.01$), and ERG d-wave amplitudes were reduced by ~35% in $Dhdds^{T206A/K42E}$ mice, vs. WT values ($p \leq 0.05$). Scotopic VA was reduced by ~15% and ~10%, respectively, in $Dhdds^{T206A/T206A}$ and $Dhdds^{T206A/K42E}$ mice, and photopic VA was reduced by ~15% and ~20.5%, respectively, in $Dhdds^{T206A/T206A}$ and $Dhdds^{T206A/K42E}$ mice, vs. WT values.

Conclusions: These results are consistent with defective rod- and cone-to-bipolar cell synaptic transmission (normal a-wave, reduced b- and d-waves) and compromised RPE and/or Müller cell responses (reduced c-wave) in these Dhdds mouse mutants.

ABSTRACT BODY:

Purpose: Microvascular complications of DM (retinopathy, nephropathy and neuropathy) are closely interrelated and are an important cause of patient morbidity and mortality. We aim to evaluate the relationship between WF SS-OCTA quantitative metrics and the presence of albuminuria and serum creatinine in DM patients.

Methods: In this cross-sectional observational study between January 2019 and April 2021, 380 eyes of 234 patients were imaged on 100kHz WF SS-OCTA using 12x12mm angiogram centered on fovea. The ARI Network (Zeiss Portal) was used to calculate vessel density (VD), vessel skeletonized density (VSD), foveal avascular zone area, circularity, and perimeter; and ImageJ for non-perfusion area (NPA), Figure 1. We recorded glycosylated hemoglobin (HbA1c), serum urea, creatinine and urine albumin to creatinine ratio (ACR) within one year of imaging.

Results: The median patient age was 58.5 (50-65) years and 125 (53.4%) were males. Subjects had a median HbA1c 8.1 (7-9.3) %, median creatinine 0.98 (0.80-1.33) mg/dL and 111 (47.4%) patients had albuminuria (urine ACR >30mg/g). Using serum creatinine, estimated glomerular filtration rate (eGFR) was calculated, and 74 (31.6%) patients had chronic diabetic kidney disease (CDKD) i.e., eGFR <60mL/min/1.73m^2 (Figure 2). Using mixed effects multiple logistic regression model adjusting for age, smoking status, HbA1c, mean arterial blood pressure and duration of diabetes; NPA (Odd's ratio (OR)=1.14, 1.03-1.27; p=0.02) and whole retina VSD (OR=0.26, 0.08-0.10; p=0.02) were significantly associated with the presence of albuminuria. None of the OCTA metrics were significantly associated with serum creatinine. Also, NPA (OR=1.11, 1.00-1.23, p=0.047) and superficial VSD (OR=0.61, 0.37-0.99, p=0.047) were significant predictors for the presence of CDKD.

Conclusions: Herein, we see that NPA can serve as a potential imaging biomarker associated with deteriorating renal function (presence of albuminuria and CDKD). Due to OCTA having high-resolution and being depth resolved, quantitative OCTA metrics can leverage the changes at the retinal capillary level in patients with kidney damage.

Hence, this safe non-invasive device can be potentially useful for diagnosis and early management of various microvascular complications of DM.

ABSTRACT BODY:

Purpose: A key epigenetic regulator of gene expression is gene silencing through DNA methylation at specific cytosines (mCG). mCG methylation governs chromatin configurations and DNA accessibility changes that modulate transcription factor function. It is well established that mCG methylation regulates the activities of individual genes and their cognate transcription factors but few studies have examined its role in global biological processes or employed it as a tool to predict key transcription factors. Here, we employed a multiomics analysis to establish a requirement for mCG methylation in gene expression events that hallmark lens cell differentiation.

Methods: The genome-wide relationships between mCG methylation, chromatin accessibility and transcript levels were compared between lens epithelial cells and fiber cells of embryonic day 13 chick lenses through integrated analysis of bisulfite sequencing, ATAC Seq and RNA Seq data. Bioinformatic interrogation of the data was used to predict functional DNA regulatory sites and transcription factor consensus representation across the chick genome.

Results: 7621 genomic loci exhibiting significant differences in mCG levels between lens epithelial and fiber cells were correlated with the differentiation state-specific expression of 1285 genes preferentially expressed in either lens fiber or lens epithelial cells (Pearson $r = -0.37$, $p < 1x10^{-42}$). mCG levels were inversely correlated with chromatin accessibility as determined by Assay for Transposase-Accessible Sequencing (ATAC-seq) (Pearson $r = -0.86$, $p < 1x10^{-300}$). Genes exhibiting altered regions of DNA methylation, chromatin accessibility and gene expression levels in fiber cells relative to epithelial cells include crystallins (CRYBA4, CRYBB1, CRYGN, CRYBB2), lens beaded filament proteins (BFSP1, BFSP2), transcription factors (HSF4, SOX2, HIF1A), and Notch signaling. Regions exhibiting cell-type specific DNA methylation changes were enriched with transcription factor binding sequences including HIF1A, SOX2, and the MAF family of transcription factors.

Conclusions: The results demonstrate that gene silencing through mCG methylation changes control chromatin accessibility and gene expression events that are required for lens differentiation. They also point to a role for mCG methylation in the regulated binding of transcription factors important for lens cell differentiation.

ABSTRACT BODY:

Purpose: Despite widespread use for major ocular vasculature diseases, use of anti–vascular endothelial growth factors (VEGF) as primary treatment for nonproliferative diabetic retinopathy (NPDR) is debated. This study synthesized key efficacy results from pivotal clinical trials investigating anti-VEGF for primary treatment of DR.

Methods: A systematic literature search was conducted using Cochrane, PubMed, and clinical trial registers to identify clinical trials of DR that compared anti-VEGF monotherapy vs laser photocoagulation (any type), sham treatment, or clinical observation. Standard methodologies were used to identify, select, extract data from, and assess quality of the studies. Results of patient (pt) outcomes related to visual acuity (VA) and DR progression on Diabetic Retinopathy Severity Scale are reported.

Results: Among 975 publications, 13 met inclusion criteria for proliferative DR (PDR; n=5), diabetic macular edema (DME; n=6), and NPDR (n=2). At 2y, anti-VEGF resulted in better VA outcomes vs laser and sham in pts with PDR with or without DME, and pts with DME with variable baseline (BL) DR severity. In pts with NPDR without BL DME, anti-VEGF did not result in significant VA improvements vs sham. At longest follow-up across trials and indications, pts who received anti-VEGF generally showed higher rates of ≥2-step DR improvement on DRSS vs pts who did not (NPDR without BL DME at 2y, 52% vs 13%; PDR with or without DME at 5y, 46% and not evaluable; DME with variable BL DR severity at 3y, 38% vs 22%). Further, pts who received anti-VEGF showed lower rates of ≥2-step DR progression vs pts who did not (NPDR without BL DME at 2y, 4% vs 16%; PDR not reported; DME with variable BL DR severity at 3y, 3% vs 9%). In pts with NPDR without DME at BL, anti-VEGF injections were associated with lower rates of development of PDR and central-involved DME vs sham at 2y (4% vs 11%; 9% vs 21%).

Conclusions: A growing body of clinical trials shows that anti-VEGF injections can regress DR severity in moderately severe NPDR and PDR and reduce rates of PDR progression and DME development in NPDR without DME at BL. The strongest predictor of anti-VEGF efficacy on DR improvement is BL DR severity, which is independent of BL DME presence/absence; however, anti-VEGF effect on VA depends on BL DME presence/absence. This review supports future research on anti-VEGF for primary treatment of DR with or without DME.

ABSTRACT BODY:

Purpose: Evaluation of long-term visual acuity (VA) and performance of a monitoring strategy that includes a self-operated artificial intelligence enabled home monitoring system in conjunction with standard care for early detection of neovascular age related macular degeneration (nAMD) (ForeseeHome (FSH), Notal Vision Monitoring Center)

Methods: A retrospective review was performed of all iAMD patients monitored with FSH from 5 clinics from 8/2010-07/2020. Data included visual acuity (VA) at baseline, VA at conversion to nAMD during the monitoring period, VA at most recent visit, frequency of use, duration of monitoring, modality of CNV diagnosis (system alert vs detection by standard care means), and duration and number of treatments since conversion to most recent visit.

Results: 3334 eyes of 2123 patients were reviewed with a mean (SD) age of 74(8) years, monitored for mean (SD) duration of 3.1(2.4) years, with a total of 1,706,433 tests in 10,474 eye-monitoring years. A Kaplan-Meyer survival analysis predicted a mean (95%CI) 4.5(4.3-4.7) years of monitoring. The mean (SD) weekly FOU per patient was 5.2(3.4) and it was persistent over the usage period. 285 eyes converted while monitored at an annual rate of 2.72% and were treated with mean (SD) 17.3(16.5) injections over mean (SD) 2.7(2.0) years, with 6.4(3.1) injections per year for eye treated for > 1 year. The median VA at baseline and recent visit for eyes that did not convert were 20/27 and 20/34 with a median change of 0.0 letters. The median VA at baseline, conversion and recent visit for eyes that converted during the monitoring period were 20/30, 20/39 and 20/32 with a median change from baseline to conversion, baseline to recent and conversion to recent of -4, -4 and 0 letters, respectively. 52% of the conversions detected had a system alert prior to conversion. 48% of patients were detected by symptoms or routine visit. Patients experienced a non-nAMD alert on average every 4.6 years. At conversion and at recent visit the proportion (95% CI) of eyes that maintained ≥20/40 was 84%(78%-88%) and 82%(76%-86%) respectively.

Conclusions: Patients in the FSH monitoring program showed excellent long-term visual acuity years after conversion to nAMD, emphasizing the importance of early detection.

ABSTRACT BODY:

Purpose: Retinal laser therapy requires precise control of the temperature rise during the procedure, especially for the relatively narrow therapeutic window of the non-damaging thermal therapy. Heat deposition is primarily governed by the melanin concentration in the retinal pigment epithelium and pigmented choroid, which can vary locally within the retina and from patient to patient. It is therefore important to precisely determine the local absorption coefficients prior to the treatment. Here, we present a method for determining the optical and thermal properties of the retina, using phase-resolved optical coherence tomography (pOCT).

Methods: Optical path length changes (ΔOPL) following laser-induced heating and thermal expansion are measured using line-scan spectral-domain phase-resolved OCT. The sample is illuminated with a line field and the backscattered spatial profile is then imaged via an anamorphic configuration onto a high-speed camera, yielding B-scans, recorded at a maximum frame rate of 10 kHz. For the tissue heating, a 450-nm laser is used with 1-ms pulse duration.

Results: The method is demonstrated on a model retina (a multi-layer polymer-based tissue phantom) heated with a laser pulse focused onto an absorbing layer buried 60 μm below the surface. We monitor the thermal expansion as changes in the OPLs between multiple layers (e.g., the top and the absorbing surface planes), where both, the decrease of refractive index with temperature and the layers displacement contribute to ΔOPL. The absorption coefficient, the heat conductivity, and the thermal expansion coefficient of the model retina are determined by fitting a thermomechanical model to the experimental data, using the full lateral and temporal extent of the thermal deformations.

Conclusions: With this method, we demonstrate that the absorption coefficient can be determined with a precision of 2.5% and the temperature rise with a precision of about 0.2°C from a single 1 ms-long laser exposure, while the peak did not exceed 8°C during the pulse, which is well within the tissue safety range. We further discuss the temperature determination precision in the living eye with the present method.

ABSTRACT BODY:

Purpose: Though a non-uniform glycocalyx layer covers the endothelium of the trabecular outflow pathway in bovine and human eyes, the differences in glycocalyx morphology between regions of different flow types in normal and diseased eyes have not been explored. This study examined glycocalyx morphology in high- and low-flow regions in normal and laser-induced ocular hypertensive monkey eyes.

Methods: YAG laser photocoagulation burns were created along ~270 degrees of the trabecular meshwork (TM) of one eye (n = 6) or both eyes (n = 2) of each monkey, reducing outflow in these regions, until a consistent rise in intraocular pressure was noted. Portions of the TM were not lasered, allowing outflow. Unlasered eyes (n = 6) served as controls. Monkeys were euthanized ≥60 months after the last laser treatment. Eyes were enucleated and perfused at 15 mmHg to measure outflow facility, outflow pattern was labeled with fluorescein, then eyes underwent perfusion-fixation for glycocalyx labelling. Anterior segments were cut into ~36 radial wedges and processed for electron microscopy. Coverage and thickness of the glycocalyx were measured in the TM, Schlemm's canal (SC), collector channels (CCs), intrascleral veins (ISVs), and episcleral veins (ESVs) in non-lasered regions of laser-treated eyes and high- and low-flow regions of controls.

Results: Median outflow facility was significantly less in laser-treated eyes compared to controls ($P = 0.02$). A trend of increasing glycocalyx thickness from the TM to ESVs was noted in non-lasered regions of lasered eyes and controls. No significant differences were found in glycocalyx coverage and thickness between high- and low-flow regions of controls. In non-lasered regions of lasered eyes, glycocalyx thickness was less when compared to high-flow regions in SC and CCs and low-flow regions in CCs ($P < 0.05$), and coverage was less when compared to high-flow regions in TM and SC and low-flow regions in SC ($P < 0.05$). In lasered regions of laser-treated eyes, TM, SC, and CCs were partly to completely obliterated, and ISVs and ESVs rarely showed glycocalyx labeling.

Conclusions: Laser treatment of the TM resulted in a decrease in glycocalyx coverage and/or thickness in lasered and non-lasered regions. Whether these changes contribute to decreased outflow facility needs further investigation.

ABSTRACT BODY:

Purpose: To present application of the modified Knox-Thompson phase-based method for extraction of the light-evoked functional responses of human retina imaged with optical coherence tomography (OCT).

Methods: The human volunteers were imaged in vivo with a clinical-grade OCT retinal imaging system, equipped with a controlled light stimulator, to allow ORG experiments. Before the testing volunteers were dark-adapted for over 5 minutes. The clinical-grade OCTs cannot resolve individual photoreceptors and instead probe a group of cells, resulting in limited phase information due to temporal speckle decorrelation. Implementation of the modified Knox-Thompson method allowed us to successfully extract phase-based ORG signals from the outer segment band (between IS/OS and COST).

Results: The phase-based ORG signals extracted from the same data sets, although more sensitive to retina motion and more computational demanding than ORG intensity-based methods, provided an order of magnitude higher sensitivity of detecting changes in retina layers positions. The cross-correlation of the phase difference between the measured layers of the object allowed identification of the intervals with strong phase correlation, thus allowing extraction of the ORG signal in a clinical setting.

Conclusions: Successful implementation of phase-based ORG signal analysis provided an order of magnitude higher sensitivity of detecting changes in retina layer positions. ORG signal analysis using clinical-grade raster scanning OCT systems is now possible, which should open a path to clinically friendly ORG probing.

ABSTRACT BODY:

Purpose: Chronic inflammation and tissue senescence have been implicated in the onset of dry age-related macular degeneration (AMD), but the role of choroidal fibroblasts in AMD pathogenesis is not well understood. To better understand the role of choroidal fibroblasts in AMD pathogenesis, we established an in vitro 3D bioprinted outer blood-retinal barrier (oBRB) model utilizing either iPSC fibroblasts or senescent adult fibroblasts and analyzed their effects on choroidal maturation and RPE functionality.

Methods: A 3D bioprinting system generated a model choroid tissue consisting of pericytes, endothelial cells (EC), and either iPSC-derived or senescent fibroblasts deposited on a PET transwell membrane. After 1 week of maturation, an iPSC-derived RPE monolayer was deposited on the opposite side of the PET membrane to complete the oBRB model. After 4 further weeks of maturation, the effects of iPSC-derived or senescent fibroblasts were evaluated using vasculature network area, transepithelial resistance (TER), PLVAP expression and Luminex analysis for tissue cytokine secretions in media. Two-way ANOVA and Tukey's Multiple Comparisons Test were utilized for analysis.

Results: Vasculature network area was significantly increased in iPSC versus senescent fibroblast tissues ($P \leq 0.0001$). Senescent fibroblasts increased PLVAP/GFP Colocalization in EC, indicating increased potential for fenestration formation in EC. TER values in RPE were significantly increased in iPSC vs. senescent tissues ($p \leq 0.0001$). The inclusion of senescent fibroblasts in tissues caused a significant increase in IL-1B, IL6 and IL8 in media.

Conclusions: Senescent choroidal fibroblast tissues have decreased choriocapillaris development and worsened RPE maturation and functionality compared to iPSC-derived tissues. Our work indicates a critical role of fibroblasts in RPE and choriocapillaris degeneration and in inflammatory processes associated with AMD pathogenesis.

ABSTRACT BODY:

Purpose: Proliferative Vitreoretinopathy (PVR) is characterized by the proliferation of retinal pigment epithelial (RPE) cells. In PVR, RPE cells undergo transformation into fibroblast-like cells by epithelial to mesenchymal transition (EMT). The purpose of this study was to investigate the role of αB crystallin (αBC) peptide on epithelial EMT in experimental PVR.

Methods: Subconfluent primary human RPE (hRPE) cells were stimulated by TGFβ2 (10 ng/ml) with or without αBC peptide (50 or 75 µg/ml) for 24h or 48h EMT/MET-associated markers were examined by RT-PCR and WB analysis. The effect of TGFβ2 on glycolysis and oxidative phosphorylation was determined in hRPE cells using Seahorse XF96 analyzer. PVR was induced in 6-8 week old male C57BL/6J mice by intravitreal administration of dispase (10 mg/ml) and PVR progression was studied on day 21. Expression of αSMA, E-cadherin (E-C), fibronectin (FN), and RPE65 in control and dispase-treated retina was determined by immunostaining on day 21.

Results: The EMT-associated αSMA and vimentin showed a significant upregulation with TGFβ2 stimulation at the gene (3- and 1.5-fold) and protein (2.5-fold) level. The protein expression of these markers was significantly suppressed by co-treatment with αBC peptide ($p < 0.05$ vs TGFβ2 alone). The mesenchymal epithelial transition (MET)-associated genes and proteins, E-C and SIRT1 were significantly downregulated by TGFβ2 (> 2-fold) and were restored by αBC peptide cotreatment. Mitochondrial oxygen consumption rate (OCR, pmol/min/total DNA) increased with TGFβ2 treatment for 24h or 48h and αBC peptide co-treatment caused a further increase in OCR for both time points. An increased deposition of αSMA and FN and a decreased expression of E-C and migration of RPE65 was observed 3 weeks after dispase administration by immunofluorescence.

Conclusions: Our findings suggest that αBC peptide may have therapeutic potential in preventing the proliferation of PVR by reversing the phenotype of EMT/MET and improving the mitochondrial function in RPE cells.

ABSTRACT BODY:

Purpose: To determine how high myopia impacts pharmacological pupillary dilation, and to evaluate the relationship between the rate and extent of pharmacological pupillary dilation and axial length (AL).

Methods: Patients were recruited from Shiley Eye Institute at the University of California San Diego, and grouped into high myopes, defined as one or both eyes having a spherical equivalent (SE) refraction greater than -6 diopters (D) or AL>26mm, and controls (SE less than -6 D and AL<26mm). Inclusion criteria were: phakic, aged 21 to 100, and planning to get pharmacological pupillary dilation as part of their eye exam. Exclusion criteria were: current use of eye drops other than artificial tears, prior intraocular or refractive surgery, iris or angle abnormalities, history of eye inflammation, previous adverse reaction to dilating drops, or diabetes. Dilation was achieved with 1 drop of tropicamide 1% and phenylephrine 2.5% in each eye. Pupil size was measured utilizing a Colvard pupillometer and the Cirrus HD-OCT (manual measurement on anterior segment scans) at full and dim light prior to dilation, then 15 and 30 minutes after dilation. AL and keratometry were measured using the Zeiss IOLMaster 700. Two-sample t-tests and generalized estimating equations (GEE) models were performed using R software.

Results: Thirty-four patients (68 eyes) participated in the study. The average age was 49 years and 70.5% were females. Sixteen patients were high myopes (average SE -7.14 D, range -4.75 to -11) and 18 were controls (average -1.06 D, range +2 to -5.5). Fully dilated pupil size at 30 minutes was significantly correlated with both SE refraction ($r=-0.59$, $p < 0.001$) and AL ($r=0.44$, $p < 0.001$), indicating eyes with higher myopia, as measured by both AL and refractive error, dilated more. When grouped by AL, 16 eyes had AL>26 mm (range 26.03-28.58mm) and 48 eyes had AL<26 mm (range 22.77-25.99mm), with eyes>26mm dilating to a greater extent than eyes<26mm at both 15 ($p = .05$) and 30 minutes ($p < .0005$).

Conclusions: Highly myopic patients dilate to a larger pupillary size compared to other patients. The positive correlation between dilation and axial length may be explained by the difference in elasticity of the sclera and thickness of the iris in highly myopic eyes. Predicting dilation based on extent of myopia could facilitate intraocular surgery planning and reduce clinic wait times for myopic patients.

ABSTRACT BODY:

Purpose: The hazardous effects of air pollution on the lungs and heart are well established. The effects on the eye, which is directly exposed to air pollution, are less known. The purpose of our study was to synthesize the existing evidence on the global associations of ambient air pollutants with glaucoma.

Methods: This work was conducted in accordance with the standards and guidelines of Preferred Reporting Items for Systematic Reviews and Meta Analyses (PRISMA). MEDLINE, EMBASE, and Scopus were searched for articles until September 30, 2021. Inclusion criteria included studies of adults, aged 40+ years, that provided measures of association between nitrogen dioxide (NO_2), carbon monoxide (CO), sulfur dioxide (SO_2), ozone (O_3), particulate matter (PM) less than 2.5μm in diameter ($PM_{2.5}$), and PM less than 10μm in diameter (PM_{10}) and glaucoma. Articles were screened, extracted, and graded for certainty of the evidence by two independent reviewers. Pooled odds ratio (OR) estimates and 95% confidence intervals (CI) were calculated using a random-effects meta-analysis model in which study weights were inversely related to the total variance and between-study variability was estimated using restricted maximum likelihood. PROSPERO registration ID: CRD42021250078.

Results: A total of 403 articles were identified. Of these, 4 studies including 181,801 people met the criteria for inclusion in our systematic review and meta-analysis. Consistent evidence for an association was found between $PM_{2.5}$ and glaucoma with 4 out of 4 studies reporting a positive association. The pooled OR for each 10 $\mu m/m^3$ increase of $PM_{2.5}$ on glaucoma was 1.18 (95% CI: 0.95-1.47). Inconsistent evidence was found for the associations between the other pollutants and glaucoma.

Conclusions: Current evidence suggests there may be an association between $PM_{2.5}$ and glaucoma. Strengths of the current study included the use of recent evidence in which large sample sizes were utilized while limitations included low response rates, the use of self-reported glaucoma measures, and cross-sectional study designs. More studies, especially those using longitudinal data, are needed and potential mechanisms should be explored by investigating interactions with genetic factors or inflammatory markers that may be involved in the causal pathway.

TITLE: Association of hyperreflective foci with disease severity and functional impairment in age-related macular degeneration

SESSION TITLE: Imaging of posterior segment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Duic, K. Hess, A. Thavikulwat, H. Wiley, T.D. Keenan, E.Y. Chew, C.A. Cukras, National Eye Institute, National Institutes of Health, Bethesda, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Cameron Duic: Commercial Relationship: Code N (No Commercial Relationship) | Kristina Hess: Commercial Relationship: Code N (No Commercial Relationship) | Alisa Thavikulwat: Commercial Relationship: Code N (No Commercial Relationship) | Henry Wiley: Commercial Relationship: Code N (No Commercial Relationship) | Tiarnan Keenan: Commercial Relationship: Code N (No Commercial Relationship) | Emily Chew: Commercial Relationship: Code N (No Commercial Relationship) | Catherine Cukras: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To analyze the presence of hyperreflective foci (HRF) across different severities of age-related macular degeneration (AMD) as well as to examine its correlation with other structural and functional AMD features, including reticular pseudodrusen (RPD), increased pigment and rod intercept time (RIT).

Methods: Participants older than 50 years with varying AMD severities (including no AMD) with multimodal imaging were included in this longitudinal single-center study (NCT01352975). Color fundus imaging was used to assess AMD severity and presence of increased pigment. Presence of RPD and HRF were detected on OCT volumes. One study eye per participant underwent dark adaptation (DA) testing measuring rod intercept time (RIT). The correlation of HRF with additional features of AMD were evaluated using linear and logistic mixed-effects models. HRF comparison at first and last visit was used for longitudinal analysis on AMD severity and RIT.

Results: A total of 1332 visits of 158 participants (292 eyes) with a mean baseline age of 72.3±9.14 years were included. HRF were detected more frequently in higher AMD severities. In a multivariable model, the presence of HRF was significantly associated with the presence of increased pigment (Odds ratio 397.42, $p<0.001$) and RPD (Odds ratio 10.38, $p=0.007$). Eyes with HRF demonstrated greater delays in DA (median 27.3 [IQR=16-40] mins), compared to eyes without HRF (13.5 [10-22] mins) but less than eyes with RPD only (40 [28-40] mins). The highest RIT values were found in eyes with both HRF and RPD present (40.0 [40-40] mins). Using linear mixed models, age and HRF explained a similar portion of the RIT variability in our cohort as age and RPD. Eyes that developed HRF demonstrated baseline RITs that were closer to eyes that had HRF at baseline compared to those that never developed HRF (29.2 [16-38], 38.45 [23-40] vs 12.8 [10-22] mins; Kruskal-Wallis). They also exhibited a greater change in AMD severity than those that did not change HRF grades.

Conclusions: The progressively increased presence of HRF in later AMD stages, in addition to its correlation with previously associated AMD biomarkers suggests that HRF is an important OCT feature adding to the understanding of disease progression. The presence of HRF was associated with delays in DA lending support that HRF is a marker for retinal pigment epithelium and photoreceptor dysfunction.

ABSTRACT BODY:

Purpose: The development of generic ophthalmic drug products is challenging due to the complexity of the ocular system, difficulties with clinical measurements of drug concentrations at the site of action, and a lack of sensitive testing to evaluate the interplay of physiology with ophthalmic formulations. The rabbit eye physiology is comparable to human eye physiology and is commonly used as a preclinical model to investigate the impact of formulation changes on the ocular exposure of an Active Pharmaceutical Ingredient (API). The purpose of this study is to demonstrate the utility of an ocular physiologically based pharmacokinetic (PBPK) model for translation of ocular exposure from rabbit to human. Ophthalmic moxifloxacin (Mox) solution is presented as a case study.

Methods: The Ocular Compartmental Absorption and Transit (OCAT™) model within GastroPlus® v9.8.2 was used to build a PBPK for Mox ophthalmic solution that accounts for nasolacrimal drainage, ocular absorption, and distribution in the rabbit eye. The model was subsequently used to predict Mox exposure after ocular solution administration in humans. Drug-specific parameters were used as fitted and validated in the rabbit. The physiological parameters were adjusted to match human ocular physiology. Simulated human ocular PK profiles were compared with observed cornea and aqueous humor (AH) concentration data to assess the OCAT models' ability to predict human ocular exposure based on preclinical data.

Results: OCAT model simulations for rabbit well described the observed concentrations in the anterior segment (cornea, AH) of the eye following Mox solution administration of different doses and various administration schedules. After adjustment of physiological parameters to represent the human eye, the clinical ocular exposure (cornea, AH) following ocular administration of Mox solution at different doses and various administration schedules was predicted within 2-fold of observed exposures.

Conclusions: The OCAT model reasonably predicted Mox ocular exposure in humans. Even though more case studies for different types of APIs and formulations will be needed, the positive clinical extrapolation outcomes of Mox solution from this study represents an important step in the validation process of the extrapolation method used to predict human ocular exposure for other ophthalmic drug products using PBPK models.

ABSTRACT BODY:

Purpose: To explore the origin of Crygs expression in the retina and assess its role against neuroinflammation

Methods: Retinal $CD45^{+}$ $CD11b^{+}$ cells from C57BL/6 mice were sequenced using single-cell RNAseq after inflammatory insult. Crygs expression was assessed using $CX3CR1^{+/EGFP}$ mice with immunohistochemistry and flow-cytometry. The function of Crygs was evaluated in $Crygs^{-/-}$ or wild-type mice that received recombinant murine Crygs (rCrygs) injection in the eye following acute retinal inflammation induced by ocular injection of LPS (10ng/mL) or ocular surface injury with NaOH. qPCR was used to quantify retinal inflammatory cytokines. The neutralizing effect of exogenous Crygs in LPS-mediated retinal inflammation was evaluated ex vivo in $CX3CR1^{GFP/+}$ mice using flow cytometry and immunofluorescent microscopy. Retinal lysates from AMD patients and healthy control were also analyzed by Western blot for Crygs expression

Results: Single cell RNAseq identified a subset of $CD45^{+}$ $CD11b^{+}$ retinal immune cells with compensatory expression of Crygs in response to inflammation. Studies in $CX3CR1^{GFP/+}$ mice showed that activated microglia express Crygs in response to injury. Administration of rCrygs in LPS injected mouse eyes led to significant suppression of TNF-α (65% suppression), IL-1β (60% suppression), and Crygs (95% suppression) within 24 hours, and reduced MHC-II expression in microglia from 51.6% to 12.27%. rCrygs was shown to mediate neuroprotection by physically binding to LPS, thereby disrupting its biologic activity. In a separate model of ocular alkali burn, deletion of Crygs gene exacerbated retinal TNF-α and IL-1β expression after injury while restoration of the gene in $CX3CR1^{+}$ cells by adoptive transfer suppressed inflammation in injured $Crygs^{-/-}$ mice. Lastly, we were able to detect expression of Crygs by Western blots in retinal extracts from patients with AMD, a condition known to have activated microglia, but not in normal controls.

Conclusions: Here we show for the first time that Crygs is expressed in retinal microglia during retinal inflammation or pathology. Its expression is compensatory in nature, leading to suppression of inflammation and associated retinal neurodegeneration. Further studies are required to assess the functional and therapeutic roles of Crygs in other retinal and CNS pathologies

ABSTRACT BODY:

Purpose: There is a paucity of data on the molecular mechanisms driving the local recurrence of uveal melanoma after enucleation, a rare event with devastating consequences. The purpose of this study was to characterize the tumor genetic profile in a patient with local recurrence of uveal melanoma in the intraorbital optic nerve in an anophthalmic orbit seven years after secondary enucleation.

Methods: Relevant clinical data and MRI imaging were reviewed. Biopsy of the recurrent tumor in the anophthalmic orbit was carried out. Archived primary tumor samples from prior enucleation and biopsy samples of the secondary recurrent tumor were obtained for histopathological analysis. Targeted next-generation sequencing (NGS) of biopsy samples of the secondary recurrent tumor was carried out using the Oncomine (Waltham, MA) Assay Targeted NGS Cancer Gene Panel to evaluate for DNA mutations and/or amplifications in 146 cancer-related genes as well as the presence of gene fusion mRNA transcripts involving 44 oncogenic driver genes.

Results: Primary tumor samples from the prior enucleation showed a uveal melanoma of mixed spindle and epithelioid cell types without extra-scleral extension or optic nerve invasion. Biopsy of the recurrent tumor showed mixed spindle and epithelioid cell types positive for MelanA and SOX10 on immunohistochemistry, consistent with malignant melanoma. Targeted NGS revealed somatic mutations in GNAQ (Q209L) and the telomerase gene (TERT) promoter (c.1-124C>T). No other mutations were detected in the remaining genes tested including BAP1 and SF3B1.

Conclusions: This is the first report of an activating TERT promoter mutation in local uveal melanoma recurrence. Future studies on genetic biomarkers in recurrent tumors may lead to rational strategies to reduce the local recurrence of uveal melanoma.

ABSTRACT BODY:

Purpose: Brain MRI for optic disc edema (ODE) is indicated in cases of presumed optic neuritis or suspicion for elevated intracranial pressure (ICP). The utility of brain MRI in pediatric patients with uveitis and optic disc edema is unknown and there are no guidelines for ordering neuroimaging in this setting. We conducted a retrospective review of 12 pediatric uveitis patients with ODE to assess the diagnostic yield of MRI in this population.

Methods: We identified pediatric patients with uveitis and ODE under the care of 2 uveitis specialists and 2 pediatric rheumatologists at the University of Minnesota between 2014 and 2021. Inclusion criteria were diagnosis of uveitis, clinically identified ODE, and an MRI performed within 60 days of identification of ODE. We reviewed retinal nerve fiber layer thickness by optical coherence tomography (RNFL-OCT), neurological symptoms, concurrent ocular medications, MRI findings, and whether MRI results impacted treatment.

Results: Twelve subjects met inclusion criteria. Nine (75.0%) had bilateral and three (25.0%) had unilateral ODE. Average age was 11 (range: 6-18 years). Neurologic symptoms manifested in 8 (66.7%) subjects. Brain MRI identified abnormalities in four (33.3%) subjects. Two of these individuals had elevated ICP treated with optic nerve sheath fenestration, one had pituitary enlargement unrelated to ODE, and one had nonspecific white matter hyperintensities. All subjects with abnormal MRI findings had bilateral ODE. Average RNFL thickness for the affected eye(s) was found to be 171 microns for those with negative MRI, 145 microns among those with abnormal MRI, and 124 microns for those with increased ICP. Uveitis was the presumptive cause of ODE in 11 (91.6%) of subjects.

Conclusions: Pediatric uveitis patients with optic disc edema may have an abnormal brain MRI even without substantial RNFL thickening or normal brain MRI even with significant RNFL thickening. This suggests that uveitic disc edema in pediatric patients is more nuanced and the decision to pursue neuroimaging cannot be dictated solely by RNFL OCT thickness.

TITLE: Selective autophagy regulates limbal epithelial differentiation via controlling Notch1 protein degradation

SESSION TITLE: Corneal cell and molecular biology | Corneal Development

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: H. Peng, N. Kaplan, M. Liu, W. Yang, R.M. Lavker, Northwestern University Feinberg School of Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Han Peng: Commercial Relationship: Code N (No Commercial Relationship) | Nihal Kaplan: Commercial Relationship: Code N (No Commercial Relationship) | Min Liu: Commercial Relationship: Code N (No Commercial Relationship) | Wending Yang: Commercial Relationship: Code N (No Commercial Relationship) | Robert Lavker: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Selective autophagy, a highly regulated pathway specifically degrades certain cytosolic components that are recognized by selective adaptors. For example, selective autophagy degrades Notch1 protein via specific adaptors p62, which leads to inhibition of stem/progenitor cell differentiation in various tissues including neural cells. However, the role of selective autophagy in corneal/limbal epithelia remains unclear.

Methods: To determine the differentiation status of limbal epithelium, expression of differentiation markers (e.g., mucin1, PAI-2) as well as putative limbal epithelial stem cell markers (e.g., N-cad, K15) were determined by immunoblotting and immunostaining. 3D organotypic raft cultures of HLECs, a stratified limbal epithelial equivalent, were used to investigate the expression of differentiation markers (e.g., IVL, mucin1).

Results: Stem/TA cell-enriched HLECs were induced to differentiate by increasing the calcium concentration from 0.07mM to 1.6mM. Such calcium modulation reduced the expression of LC3II, as well as increased p62, indicating an inhibition of autophagy flux. Knockdown of autophagy-related genes (e.g., Beclin1, Atg5) enhanced HLEC differentiation as evidenced by increased expression of mucin1 and PAI-2 and reduced N-cad. This observation was confirmed using 3D organotypic raft cultures, which demonstrated that activation of autophagy by rapamycin inhibited the expression of IVL and mucin 1. To explore how autophagy regulates stem/TA cell-enriched HLEC differentiation, our single cell RNA seq investigation identified a group of novel stem/TA cell regulators including Bmal1 and Wdfy1. Inhibition of autophagy decreased stem cell regulators, Bmal1 and Wdfy1 in vitro and in vivo. Furthermore, knockdown of Bmal1 or Wdfy1 enhanced HLEC differentiation. Significantly, inhibition of Notch signaling, which is specifically and negatively regulated by selective autophagy, increased Wdfy1 expression. This suggests that attenuated autophagy induces differentiation of stem/TA cell-enriched limbal epithelial basal cells via controlling novel stem/TA cell regulators including Bmal1, Notch/Wdfy1.

Conclusions: Our observations suggest that a decrease in selective autophagy triggers the differentiation of stem/TA cell-enriched limbal epithelium into more differentiated limbal epithelial superficial cells.

ABSTRACT BODY:

Purpose: The 2-photon (2P) effect in vision occurs when light incident on the retina causes a direct photoisomerization of photoreceptor pigments involving two photons at a given wavelength, creating a percept of light corresponding to a 1-photon (1P) process at half that wavelength. Thus, a 2P effect elicited by 940-nm light may appear similar to 470-nm light. Typically, such an effect is achieved using pulsed lasers which compress photons in time. However, with adaptive optics (AO), we can also compress photons in space, further increasing the likelihood of 2P photoisomerization. We investigate the impact of AO correction on the 2P effect.

Methods: We scanned a focused spot of 940-nm light in a 0.9° x 0.9° raster pattern using an AO scanning laser ophthalmoscope. A supercontinuum light source was used with a ~20-ps pulse and an average power of 198.2 μW. We varied the focusing depth of the raster in and out of the plane of best focus and had subjects make a color and luminance match by tuning the color of a projector-generated square, thereby revealing the 2P effect's benefit from an AO correction.

Results: Subjects' matching data showed a clear increase in luminance and blue hue when the AO-corrected raster was focused on their photoreceptors. Their matches can be interpreted as having a relatively constant red component corresponding to 1P isomerizations at 940 nm superimposed with blue and green components that increase greatly as the raster comes into focus. For 3 subjects, a retinal irradiance of 0.29 W/cm^2 of 940-nm light elicited a percept equivalent to an irradiance of 94 nW/cm^2 of 470-nm light at best focus. Analysis of matching data yielded an average 1P luminance of 0.14 cd/m^2 with the luminance of the 2P effect peaking at 0.57 cd/m^2.

Conclusions: 2P vision was greatly enhanced by AO. As AO was used to focus a faintly-visible 940-nm scanning raster onto the retina, the raster appearance changed from red to blue, as if it were a mixture of 940- and 470-nm light. This effect was readily visible, despite our laser using pulses that are quite long compared to the conventional short-pulsed lasers used in 2P imaging (20 ps vs 200 fs). Our results are consistent with the hypothesis that this is a 2P isomerization process by the color appearance and by the strong focus dependency. These data set the technical specifications for future systems that aim to elicit even brighter color appearances via direct 2P activation of human photopigments.

ABSTRACT BODY:

Purpose: Topical Povidone-Iodine (PI) is a widely used ocular surface antiseptic for intravitreal injections and is associated with significant ocular discomfort in some patients. In limited studies, aqueous chlorhexidine (CHX), as an alternative antimicrobial to PI, has been associated with a low post-injection endophthalmitis (PIE) rate and less ocular discomfort compared to PI. This study compares the rates and outcomes of PIE for patients pre-treated with 5% PI and 0.05% CHX.

Methods: This was a retrospective, single center, comparative cohort study of patients receiving intravitreal anti-VEGF injections from January 1, 2019, to November 30, 2021. Injection preparation with PI or CHX and cases of PIE were compiled using electronic health records and billing code data. The primary outcomes were the rate of endophthalmitis, culture results, and visual acuity. LogMAR visual acuity was determined at the time of causative anti-VEGF injection, endophthalmitis presentation, and 3-month follow-up.

Results: A total of 68,334 intravitreal injections were administered by 13 retinal specialists during the study period. 13 of 33,064 (0.0393%; 1 in 2,543 injections) cases of presumed endophthalmitis occurred in the PI group, and 9 of 35,270 (0.0255%; 1 in 3,918 injections) cases in the CHX group (OR=0.65; 95% CI 0.27–1.52; p=0.319; Table 1). For the PI group, there were 2 culture-positive endophthalmitis cases (0.00605%, 1 in 16,532), compared to 2 cases in the CHX group (0.00567%, 1 in 17,635) (OR=0.94; 95% CI 0.13–6.66; p=0.949; Table 1). No significant difference was observed in visual acuity between PI and CHX at causative injection (p=0.41), endophthalmitis encounter (p=0.45), and 3-month follow-up (p=0.45; Table 2).

Conclusions: There was no significant difference in the rate of PIE and visual acuity in the CHX group compared to the PI group. Further multicenter studies are needed to further evaluate the efficacy and safety of CHX compared to PI for intravitreal injection preparation.

ABSTRACT BODY:

Purpose: Astrocytes closely associate with retinal ganglion cells (RGCs) in the nerve fiber layer of the retina and optic nerve, where they provide support for RGCs but can contribute to RGC neurodegeneration in a glaucomatous state. However, the mechanisms by which astrocytes promote neurotoxicity and contribute to neurodegeneration remain unclear. Importantly, human pluripotent stem cells (hPSCs) can serve as powerful tools for the in vitro analysis of human neurodegenerative diseases, including neuron-glia interactions.

Methods: Using hPSC-derived RGCs and astrocytes, we explored how reactive astrocytes contribute to RGC degeneration. Human pluripotent stem cells were differentiated into 3D retinal organoids or forebrain organoids for the subsequent isolation of retinal ganglion cells (RGCs) and astrocytes, respectively. The induction of a reactive astrocyte phenotype (“A1”) was promoted through incubation with a cocktail of recombinant proteins including C1q, TNFα and IL1α.

Results: Reactive astrocytes displayed profound morphological alterations exhibiting a hypertrophic profile and increased expression of reactive astrocyte-specific markers such as complement C3. Transcriptional analyses of reactive astrocytes revealed an upregulation of genes associated with the inflammatory pathway as well as cytokine signaling. Functionally, reactive astrocytes affected blood-brain barrier properties by reducing transendothelial electrical resistance and increasing barrier permeability. Moreover, the secretion of several pro-inflammatory cytokines was increased in reactive astrocytes. Consequently, the neurotoxic potential of reactive astrocytes was determined through co-cultures with hPSC-derived RGCs, in which reactive astrocytes promoted marked morphological alterations including neurite retraction and reduced neurite complexity.

Conclusions: The results of this study demonstrate that hPSC-derived astrocytes can be induced to acquire a reactive and dysfunctional profile with a predominant inflammatory and neurotoxic phenotype which leads to RGC neurodegeneration. Thus, the modulation of reactive astrocytes could offer a novel therapeutic strategy for glaucoma by restoring a more homeostatic state and reducting RGC neurodegenerative phenotypes.

ABSTRACT BODY:

Purpose: Dry eye (DE) is a multifactorial disease with numerous presenting phenotypes and potential contributors. In order to deliver precision medicine, a better understanding of an individual's contributors to disease is needed. Genetic polymorphisms have previously been shown to influence disease presentation and course in diseases relevant to DE, such as in chronic pain syndromes. However, the impact of genetic polymorphisms on DE presentation and treatment response have not been well characterized. A previous study examined the impact of rs1800693 (chr12, alleles: T/C), a single nucleotide polymorphism (SNP) within the tumor necrosis factor receptor 1 (TNFR1) gene. Individuals with DE and homozygous alternate CC alleles were found to have a better symptomatic response to OCS-02 (a topical TNFα antibody) compared to those with a TC or TT alleles. Building on this data, in the current study, we examine the frequency of a CC genotype in a novel population, South Florida veterans, and investigate whether the presence of this genotype impacts disease phenotype and response to anti-inflammatory therapy.

Methods: Prospective study of 328 individuals with a variety of DE symptoms and signs who underwent genetic profiling for rs1800693 (TT, TC, CC). The frequency of genotype CC was examined as were relationships between genotype and phenotype and response to an anti-inflammatory agent.

Results: The mean age of the population was 61.7±9.8 years, 92% self-identified as male, 56% as white, and 21% as Hispanic. 13% (n=42) individuals had a CC genotype, which was equally distributed between races but was less common in Hispanics. The presence of a CC genotype (as compared to TT and TC) did not influence the DE phenotype with similar DE symptoms and signs between the groups. In all, 30 individuals (4 with CC) were treated with an anti-inflammatory agent. There was a trend for individuals with CC genotype to have a partial or complete response to treatment compared to the other two groups (100% vs 38.5%, p=0.07).

Conclusions: The presence of homozygosity of risk allele C (CC genotype) in a SNP within TNFR1 was noted in a minority of individuals with various aspects of DE. However, this genotype did not relate to DE phenotype but did impact treatment response. These finding suggest that current phenotyping strategies in DE are not sufficient to identify underlying contributors to disease, including potential genetic contributors.

ABSTRACT BODY:

Purpose: To compare the diabetic retinopathy severity level determined when considering only the ETDRS 7-Field region versus the entire ultrawide field (UWF) image

Methods: In this retrospective, cross-sectional study, UWF images (Optos 200Tx) were obtained from diabetic patients presenting to the retina clinic. An ETDRS 7-field overlay was superimposed on these UWF images to define the region covered by the ETDRS 7 standard fields. The images were graded on Eyenuk's web-based grading portal for the severity of DR, based on the region within the ETDRS 7-fields as well as based on the entire UWF image, using both the ICDR severity scale and the modified ETDRS DRSS scale from DRCR.net Protocol AA. In addition, the grader also determined whether the lesions were predominantly central lesions (PCL) or predominantly peripheral lesions (PPL) using both a single-field (PPL was assigned if any one peripheral field had more lesions than the corresponding ETDRS field) method and a global method (if entire region outside ETDRS 7-fields had more lesions than within ETDRS 7-fields).

Results: A total of 125 eyes from 81 patients were included in this analysis. The distribution of DR severity levels as assessed by ICDR is shown in Table 1, and by ETDRS DRSS in Table 2. Only 3 (2.4%) eyes had a discrepancy in DR severity level between the ETDRS 7-field region and the entire UWF region when using the ICDR classification system. Six (4.8%) eyes had a discrepancy in DR severity level between the ETDRS 7-field region and the entire UWF region when using the ETDRS DRSS Protocol AA classification system. The discrepancy was due to the presence of lesions [hemorrhages (n=1), neovascularization (n=2), scatter laser scars (n=2), and pre-retinal hemorrhage (n=1)] in the peripheral fields which were not identified in the ETDRS 7-fields. Thirty percent of the eyes were PPL by the single-field method and 10.5% were PPL by the global method.

Conclusions: Although, considering regions outside of the ETDRS 7-fields altered the DR severity level assessment in < 5% of cases in this cohort (which only had a proportion of patients with PPL), significant potential vision-threatening lesions including neovascularization and pre-retinal hemorrhage were missed. This highlights the importance of evaluating the entire UWF region when assessing patients with diabetic retinopathy.

Commercial Relationships Disclosure: Yingchen He: Commercial Relationship: Code N (No Commercial Relationship) | Dana Kang: Commercial Relationship: Code N (No Commercial Relationship) | Christian Larson: Commercial Relationship: Code N (No Commercial Relationship) | Colin Flowers: Commercial Relationship: Code N (No Commercial Relationship) | Gordon Legge: Commercial Relationship(s);Code P (Patent):Precision Vision | Stephen Engel: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Text remapping has been proposed to improve reading with central-field loss, where letters occluded by the scotoma are shifted in real-time to a location outside of the scotoma. However, remapped text deviates from horizontal lines, which may negatively affect reading. This study aims to test the feasibility of text remapping by evaluating letter and word recognition performance along unusual trajectories.

Methods: Stimuli were triplets of random letters (trigrams) and words of 3-8 letters (x-height = 1°), presented for 100 ms along trajectories of 13 letter positions. Two groups of college students respectively read trigrams (N = 16) and words (N = 12). Baseline performance was measured with a typical horizontal linear text trajectory passing through the fovea (0°). Four other trajectories were designed assuming a scotoma covering the central 5 letters: 1) Lowered-line: the entire line was lowered by 3.8°. 2) Step-down: the leftmost 4 letters remained at 0° but the rest were lowered by 3.8°. 3) V-shaped: the central 5 letters were lowered then raised along a diagonal, circumventing the scotoma. 4) Horizontal-gap: the line remained at 0° but skipping the central 5 letter positions. Recognition performance was normalized as a percentage of baseline. A linear mixed-effect model was fitted where Stimulus type (trigrams/words) and Trajectory were fixed effects and Participant was the random effect.

Results: Recognition of remapped text only reached 69.7% to 93.9% of baseline performance, consistent with the slower reading with central-field loss. The main effect of Trajectory was significant ($F_{3,72} = 117.58$, $p < .001$): Compared to the Lowered-line trajectory, the performance of the V-shape trajectory was significantly better whereas that of the Horizontal-gap trajectory was significantly worse (adjusted p's < .001). While contextual benefits were observed during word recognition at baseline, the effect of Stimulus type was not significant after normalization ($F_{1,24} = 0.075$, $p = .79$). No significant interaction was found ($F_{3,72} = 1.26$, $p = .30$), indicating that the trajectories affected letter- and word-recognition similarly.

Conclusions: A V-shaped trajectory produced better performance than horizontal trajectories in peripheral vision despite the unusual text arrangement. Text remapping may be a feasible way to improve reading in people with central-field loss by customizing text arrangements to make more effective use of peripheral vision.

ABSTRACT BODY:

Purpose: RPE basal infoldings are microvillous membrane specializations to optimize surface area for ion transport and exchange of metabolites with the choroidal circulation. The fovea is supplied by the choroid, while mixed rod-cone areas are supplied additionally by the retinal circulation. We hypothesize that the basal RPE will differ in areas with differing photoreceptor content. We investigated basal infoldings (BI) in foveal and parafoveal regions of human RPE.

Methods: Rapidly preserved foveal (~160 µm eccentricity) and parafoveal (~850 µm eccentricity) tissue from 21-year-old and 53-year-old organ donors, respectively, were vertically sectioned using scanning block-face EM at 5 x 5 x 50 nm voxel resolution. BI were manually reconstructed in 7.5 x 7.5 µm sampling regions at the basolateral RPE using TrakEM2. Morphometric analysis of density (# per mm of basal lamina) and surface area (mm^2 per sampling region) were performed using ImageJ and Dragonfly 2020.2 (Object Research Systems).

Results: BI resemble elongated filopodia that appear to originate and extend from a consistent level of the cell body and extend towards the RPE basal lamina (Figure). Foveal BI had fine ridge-like profiles (A1). Parafoveal BI were elaborate (D1) with whorls that extended as far as the nuclear envelope (D2, E2), in contrast to straighter and non-convoluted infoldings under the nuclei of foveal RPE (A2, B2). The density of BI was higher in the fovea than parafovea (4624 ± 594 vs. 2784 ± 359 infoldings/ mm, $P < 0.001$). The surface area was 39% higher in the fovea compared to parafovea (838.9 vs. 602.3 μm^2). We also identified electron-dense punctate material that tend to localize at the basal RPE cell body, in a regularly-spaced pattern (B2). The internal structure of this material resembled disorganized cristae of mitochondria.

Conclusions: Our initial findings suggest that the exchange capacity of foveal RPE may be significantly higher than parafoveal RPE. However, we cannot exclude that age difference in our samples could also be a factor in these morphological differences. To answer this question, ongoing studies will match regions and ages to the current samples (fovea of 21-year-old and parafovea of 53-year-old) and expand sample size with deep-learning assisted methods.

ABSTRACT BODY:

Purpose: Medicare reimbursements for glaucoma procedures have declined on average by 21% since the year 2000. These trends can help guide changes to Medicare policies and may explain the change in glaucoma practice patterns over time.

Methods: Reimbursement data from the Physician Fee Schedule look-up tool from the Centers for Medicare and Medicaid Services was compiled for Glaucoma procedures. Compensation trends for each CPT code were investigated after adjusting for inflation in 2020 US dollars from the unadjusted data between 2000 to 2020.

Results: The average adjusted reimbursement for the analyzed procedures decreased by 20.5% (95% confidence interval [CI], -15.4% to -25.6%) over the twenty-year period. On average, there was a 1.03% decrease in reimbursement rates per year (95% confidence interval [CI], -0.74% to -1.33%) with an adjusted CAGR of -1.35% (95% confidence interval [CI], -1.07% to -1.64%). Procedures with the largest decrease in reimbursement over the study period included CPT codes 65855 (Trabeculoplasty by laser surgery, 48.9%), 66761 (Iridotomy/iridectomy by laser surgery, 37.0%), and 66700 (Destruction ciliary body by diathermy, 32.37%). The only CPT code for which an increase in reimbursement rate was observed was 66762 (Laser iridoplasty by photocoagulation, 1.89%). These results show an overall declining rate in reimbursement for the glaucoma procedures analyzed in this study.

Conclusions: Medicare reimbursement for glaucoma procedures showed a significantly declining trend between 2000 to 2020. The varying trends seem to closely reflect the political and economic climate of the times. The declining trends previously led to some physicians refusing to take new Medicare patients. However, the legislative impact of the Consolidated Appropriations Act of 2020 brings hope for a future of rising Medicare reimbursement rates for Ophthalmology, and other medical specialties.

ABSTRACT BODY:

Purpose: To maintain tissue transparency, the ocular lens is avascular and operates a microcirculation that delivers nutrients and removes waste products from the lens nucleus. Breakdown of lens structure or function can lead to lens cataract. Globally, lens cataract is the leading cause of preventable blindness, yet the only ‘cure’ is surgical implantation of a synthetic lens. MALDI imaging mass spectrometry (IMS) has been used to map uptake of exogenous molecules to inform development of novel pharmaceutical approaches to delay or prevent the onset of cataract.

Methods: Bovine lenses were incubated from 5 min-20h in artificial aqueous humour containing stable isotopically-labelled (SIL) lens nutrients (glucose, glutathione) or pharmaceuticals. Axial cryosections (20mm) were analysed by negative and positive mode MALDI-FT-ICR IMS, respectively. Identical samples were microdissected into epithelium, outer cortex, inner cortex and nucleus regions. Gas chromatography mass spectrometry was then used on extracts of these lens regions to validate spatial distribution patterns observed by IMS, and confirm identities of small molecules observed by IMS. Liquid chromatography tandem mass spectrometry-based proteomics and immunohistochemistry were used to detect and localise specific small molecule transport proteins throughout the lens.

Results: For SIL lens nutrients, MALDI IMS showed signal first appeared in the peripheral epithelium and lens equator. Several members of the solute carrier family of integral membrane proteins (e.g. GLUT1, GLUT3) were also detected by proteomics and immunohistochemistry in this region. In contrast, uptake profiles for pharmaceuticals were less spatially directed than for lens nutrients. Rates of transport of pharmaceuticals throughout the lens were also different between pharmaceuticals with different physicochemical properties.

Conclusions: A combination of mass spectrometry techniques for protein, metabolite and pharmaceutical detection and mapping can be utilised to aid development of future therapeutic interventions that exploit lens physiological biochemistry to delay the onset of cataract.

TITLE: Mobile-RetinaNet : A Computationally Efficient DeepNet for Retinal Fundus Image Segmentation for Use in Low-resource Settings

SESSION TITLE: Machine Learning: Segmentation and Classification

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Karmakar, S. Nooshabadi, Electrical and Computer Engineering, Michigan Technological University, Houghton, Michigan, UNITED STATES|A. Eghrari, Ophthalmology, Johns Hopkins University School of Medicine, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Ranit Karmakar: Commercial Relationship: Code N (No Commercial Relationship) | Saeid Nooshabadi: Commercial Relationship: Code N (No Commercial Relationship) | Allen Eghrari: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal fundus photography is used by physicians to detect and track different eye diseases such as glaucoma and diabetic retinopathy (DR). Manual segmentation is time-consuming and may introduce observational bias. This work presents a computer-aided automatic segmentation model for the retinal blood vessels and optic disc in retinal fundus images. Accurate automatic detection of these image features will reduce the manual effort while producing consistent results in clinical settings instantaneously.

Methods: The efficient use of bottleneck residual blocks on the U-Net like encoder-decoder convolutional neural network (CNN) architecture requires a significantly lesser number of floating-point operations (FLOPs) to achieve the desired accuracy. The model has been trained and tested on two publicly available retinal datasets, digital retinal images for vessel extraction (DRIVE) and child heart and health study in England (CHASE). The model's performance is compared with the prior art using widely used accuracy, sensitivity, specificity, and the area under the curve (AUC). For the OD segmentation, we proposed a fully automatic segmentation that uses classical image processing to localize the OD and then our network to do the semantic segmentation.

Results: For retinal vessel segmentation, we achieved an AUC score of 0.968 for the DRIVE dataset and 0.985 for the CHASE dataset which for the state-of-the-art is 0.986 and 0.991 respectively. With this small degradation in performance, our model needs 2.5 times a lesser number of parameters and 4.5 times fewer FLOPs. For OD segmentation, we achieved an AUC score of 0.950 and 0.981 for the DRIVE and CHASE datasets respectively

Conclusions: While deep learning models can be high resource-consuming, successfully developed a model that achieves very high efficiency for medical image segmentation task without loosing much accuracy.

SUBMITTER (NAME ONLY): Stephen Hunter

TITLE: Evaluating the effectiveness of the PlusoptiX S12C photoscreener in detecting amblyopia risk factors in preschool children within one year of a mobile community vision screening program

SESSION TITLE: Amblyopia

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Hunter, D. Suh, J. He, University of California Irvine, Irvine, California, UNITED STATES|

Commercial Relationships Disclosure: Stephen Hunter: Commercial Relationship: Code N (No Commercial Relationship) | Donny Suh: Commercial Relationship: Code N (No Commercial Relationship) | Jody He: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To reduce the disease burden and increase early detection of amblyopia, the US Preventive Services Task Force recommends at least one vision screening for all children aged 3 to 5 years. The UCI EyeMobile for Children Program is a mobile community vision screening program designed to detect amblyopia or its risk factors in preschool children, and provide further eye care services including referral to ophthalmology if needed. We performed retrospective chart review to determine the effectiveness of our screening device in detecting amblyopia or its risk factors.

Methods: Children aged 30 to 72 months from 37 Orange County preschools underwent vision screening at their schools during the 2019 - 2020 school year. All screenings were conducted with the PlusoptiX S12C by two trained screeners using ROC 3 referral criteria. Children who failed the vision screening were given an appointment for a comprehensive eye examination on the UCI EyeMobile. Excluded from this group were those students absent from the school on the dates screening took place and those who had not provided signed consent forms. Amblyopia RF were determined using 2013 American Association for Pediatric Ophthalmology and Strabismus Vision Screening Committee Guidelines.

Results: A total of 5,226 children were screened during the 2019 - 2020 school year. 10.4% (546/5226) failed the photoscreening. 27.3% (149/546) were no-shows. 397 children were seen by an optometrist, of which 246 received complete comprehensive examinations including cycloplegic retinoscopy. 149 of these children were found to have at least one ARF, corresponding to a device positive predictive value (PPV) of 60.6% for detecting ambylogenic risk factors in the dilated group. Of the 151 children who were examined but did not undergo cycloplegic retinoscopy, 61 were found to have at least one ARF, corresponding to a PPV of 40.4% in the undilated group. The PPV for all 397 children examined was 52.9%.

Conclusions: Vision screening is crucial for the early detection and treatment of ambylopia. With a PPV of 52.9% for the detection of ambylopia and its risk factors, the PlusoptiX S12C is an adequate screening device for our program. We will consider modifying the device referral criteria as other studies have demonstrated this may lead to increased specificity and PPV.

ABSTRACT BODY:

Purpose: The only modifiable risk factor for primary open-angle glaucoma, elevated intraocular pressure (IOP), is regulated by trabecular meshwork (TM)-related aqueous humor outflow. Estrogen signaling may play a role in lowering IOP. We sought to determine if 17β-estradiol (E2) treatment of primary human TM (HTM) cells could reverse the transcriptional profile induced by ocular hypertension (OHT)-inducing TGFβ2.

Methods: Primary HTM cells from 10 donors were cultured for >24 hours in estradiol-free medium before treating in the following groups: medium only, DMSO, 50nM E2, 10ng/mL TGFβ2, and 50nM E2 + 10ng/mL TGFβ2. For each cell line, treatments were performed simultaneously on cells cultured statically on plastic 6-well plates and cells undergoing cyclical stretch (1 cycle/sec) on a Flexcell Tension System for 24 hours. qRT-PCR was performed to assay the expression of 17 selected TGFβ2-responsive genes. The $\Delta\Delta C_t$ method followed by one-way ANOVA was used to calculate expression changes in response to treatments normalized to ACTB expression. Using relative fold changes, a linear mixed effect model was used to test for the overall effects of stretch and sex on gene expression, using treatment, stretch, and sex as covariates.

Results: Of the 17 TGFβ2-responsive genes profiled, TGFβ2 treatment significantly altered the expression of 4 genes in static and 8 genes in stretched HTM cells. Conversely, E2 treatment significantly altered the expression of 11 genes in static and BMP1 in stretched HTM cells. In several cases, genes that were significantly downregulated in response to TGFβ2 were significantly upregulated in response to E2 (e.g., SMAD2 and SMAD3 in static cells and BMP1 in stretched cells). Furthermore, in cells treated with both E2 and TGFβ2, E2 lessened or reversed the effects of TGFβ2 for several genes (e.g., NFATC1 and SMAD2 in static cells and BMP1, FST, GREM1, LAMC1, NFATC1, SMAD2, and SMAD3 in stretched cells). In addition to treatment response, nine genes were significantly impacted by stretch while two genes were significantly impacted by the sex of the cell donor.

Conclusions: TGFβ2 had more significant effects under stretch, suggesting that stretch may exacerbate TGFβ2 effects. In many cases, E2 was able to mitigate or reverse the transcriptional effects of TGFβ2. Therefore, E2 may ameliorate the effects of OHT-inducing TGFβ2 to reduce IOP, especially under conditions of mechanical stress.

ABSTRACT BODY:

Purpose: Oxidative stress is considered the central pathogenesis of age-related cataractogenesis. Aged and cataractous human lenses manifest with increased reactive oxygen species (ROS) formation, elevated lipid peroxidation, and accumulative intracellular redox-active iron. Interestingly, ample evidence suggests that there is no remarkable apoptosis present in aged and cataractous human lenses despite the profound disruption of redox homeostasis, raising an essential question regarding the existence of other cell death mechanisms. Here we sought to explore the role of lipid peroxidation in lens epithelial cell death.

Methods: Cell death pathways were explored using both in vitro cell aging model and ex vivo mouse lens capsule aging model. Lipid peroxidation and cell apoptosis markers were determined. Gene expression was performed by the deep sequencing approach.

Results: Here we show that the aging lens epithelium is susceptible to ferroptosis-mediated cell death via lipid peroxidation. We show that very low concentrations of system X_C^- inhibitor Erastin (0.5uM) and glutathione peroxidase 4 (GPX4) inhibitor RSL3 (0.1uM) can drastically induce human LEC (FHL124) ferroptosis in vitro and mouse lens epithelium ferroptosis ex vivo. Depletion of intracellular glutathione (GSH) in human LECs and mouse lens epithelium significantly sensitizes ferroptosis, particularly under the RSL3 challenge. Intriguingly, both human LECs and the mouse lens epithelium demonstrate an age-related sensitization of ferroptosis. Transcriptome analysis indicates that clusters of genes are up-or down-regulated in aged LECs, impacting cellular redox and iron homeostases, such as downregulation of both cystine/glutamate antiporter subunits SLC7A11 and SLC3A2 and iron exporter ferroportin (SLC40A1).

Conclusions: Here, for the first time, we are suggesting that LECs are highly susceptible to ferroptosis. Moreover, aged and cataractous human lenses may possess more pro-ferroptosis criteria than any other organ in the human body.

TITLE: Transient PERG extracted from Steady-State PERG in Glaucoma suspects

SESSION TITLE: Electroretinography: basic mechanisms and disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Alba, V. Porciatti, University of Miami Health System Bascom Palmer Eye Institute, Miami, Florida, UNITED STATES|J. Toft-Nielsen, Jörvec Corporation, Miami, Florida, UNITED STATES|

Commercial Relationships Disclosure: Diego Alba: Commercial Relationship: Code N (No Commercial Relationship) | Jonathon Toft-Nielsen: Commercial Relationship: Code N (No Commercial Relationship) | Vittorio Porciatti: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To use the Continuous Loop Averaging Deconvolution (CLAD) technique to extract a per-stimulus PERG (Transient) from steady state (SS) PERG at jittered high-frequency stimulation rates, and compare CLAD PERG data from a pool of glaucoma suspects (N=23) with those of age matched controls (N=16).

Methods: PERG were recorded in response to contrast-reversal of horizontal gratings (LED display JÖRVEC Corp, mean luminance 800 cd/m^2, contrast ratio 99%) presented under 3 conditions: Conventional transient PERG at 3.91 rev/sec, conventional SS-PERG at 15.63 rev/sec, and jittered 'quasi' steady state (Q-SS) PERG at 15.63 mean rev/sec. Q-SS responses were deconvolved using CLAD (PMID: 25477321; 24618216), extracting the equivalent per-stimulus transient response at 15.63 rev/sec, obtaining a response with peaks and troughs similar to a conventional transient PERG. For conventional and deconvolved transient responses, waveform peaks (N35, P50, N95) were identified and latencies and amplitudes were measured. For conventional SS-PERG responses, analysis was done in the frequency domain, by looking at the phase and magnitude of the response at the frequency bin corresponding to the rate of stimulation (15.63 rev/sec).

Results: In all three conditions, there was a significant difference between the control and glaucoma suspect groups ($p<0.05$), with the CLAD deconvolved response having the most significant difference between the two groups. Receiver operator curves (ROC) generated for the three cases resulted in area under the curve (AUC) values of 0.789 for conventional transient responses (P50 to N95 amplitude), 0.683 for conventional SS PERG (SS magnitude) and 0.897 for deconvolved Q-SS responses (P50 to N95 amplitude).

Conclusions: Results show that while all the methods were effective differentiating between control and glaucoma suspect groups, the CLAD deconvolved responses had the highest specificity, suggesting that the CLAD technique unveils some clinically relevant information that is obscured in the SS response when using conventional analysis techniques. This has the potential to greatly expand the diagnostic utility of the PERG response.

TITLE: Distribution of gamma-glutamyltranspeptidase, aldose reductase, and biomarkers of oxidative stress in STZ-induced diabetic rat lens

SESSION TITLE: Lens proteins and cataracts

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.P. Langford, T.B. Redens, Ophthalmology, LSU Health Shreveport, Shreveport, Louisiana, UNITED STATES|R. Eshaq, N. Harris, Molecular and Cellular Physiology, LSU Health Sciences Center, Shreveport, Louisiana, UNITED STATES|

Commercial Relationships Disclosure: Marlyn Langford: Commercial Relationship: Code N (No Commercial Relationship) | Rhanda Eshaq: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Redens: Commercial Relationship: Code N (No Commercial Relationship) | Norman Harris: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate gamma-glutamyl transpeptidase (GGT, critical to glutathione recapture and cysteine-dependent cell proliferation), Xc- antiporter, (xCT, cysteine transporter), aldose reductase (AR, hyperglycemic oxidative stress marker), oxidized DNA [8-hydroxy-2'-deoxyguanosine (8-OHdG), and annexin V (marker of apoptosis) expression in streptozotocin (STZ)-induced diabetic cataractous and normal rat lens.

Methods: Gross ocular examinations were performed, and blood glucose levels were determined on control and diabetic rats. Bilateral eye enucleations were performed post euthanasia at 8 weeks and the eyes placed in 70% ethanol. Histopathology was determined on paraffin-embedded sections stained with hematoxylin and eosin. DAPI-treated sections were reacted with antibody to AR, GGT, 8-OHdG, and/or annexin V. The lens distributions were visualized using the immunohistochemical and immunofluorescent antibody methods, and digital images captured for comparative analysis.

Results: Cytopathological changes consistent with lens epithelial cells disorganization and lens cell hyperplasia were noted in hyperglycemic rat cataractous lenses. GGT was expressed by epithelial cells and diminished to undetectable levels within 1 mm of the control rat lens surface. AR and oxidized DNA (8-OHdG) were detected in normal lens beneath the lens cortex within lens fibers (1 mm from the surface). Xc-antiporter (xCT) expression was reduced in diabetic lens. Weak annexin V reactivity was detected in the lens epithelium. In the diabetic rat lens, GGT expression in epithelial cells was decreased, while GGT was detected on sub-capsular hyperplastic lens cells. Increased AR expression and oxidized DNA (8-OHdG) were detected in the sub-capsular hyperplastic lens fiber cells of diabetic rat lens. Oxidized DNA was detected in annexin V-positive lens epithelial cells of some diabetic lenses.

Conclusions: The sub-capsular cataractogenic changes in STZ-induced hyperglycemic diabetic rats were associated with increased expression of AR and GGT with oxidized DNA-positive hyperplastic lens fiber cells. The results support hyperglycemia-induced inhibition of epithelial-to-mesenchyme lens fiber cell differentiation and oxidative epithelial cell death as evidenced by annexin V expression.

ABSTRACT BODY:

Purpose: Exfoliation syndrome (XFS) is a systemic disease in which extracellular matrix deposits (exfoliation material, XFM) are found in the anterior segment of the eye. Prior studies suggest that ocular UV radiation in early life is a risk factor for XFS. We performed a clinical survey study to assess the relationship between UV exposure in early life with XFS using UV-associated carcinomas [basal cell carcinoma (BCC), and squamous cell carcinoma (SCC)] history in specific regions of the body as a proxy for UV exposure.

Methods: Subjects were recruited for a one-time cross-sectional interview survey assessing age, sex, medical history, XFS diagnosis, eye color, hair color, likelihood of tanning or burning in early life, and history of BCC and/or SCC. Multivariate models adjusting for these covariates were performed.

Results: 321 subjects were recruited for the study (52.6% female, 96.2% white ethnicity, mean age: 72.6 years). 98 (30.5%) patients had XFS/XFG, 117 (36.5%) had primary open-angle glaucoma (POAG) and 106 (33.0%) were non-glaucomatous controls (Tbl. 1). After adjusting for the covariates, there was a 2-fold risk for having XFS with any history of BCC/SCC in the head and neck region versus POAG + controls (odds ratio (OR) = 2.05, 95% confidence interval (CI) = 1.04 – 3.89). Additionally, we observed a dose-response association where the chance of having XFS was higher by 67% with every BCC/SCC occurrence versus POAG + controls (OR = 1.67, 95% CI = 1.09 – 2.56). XFS versus control groups showed a 2.8-fold risk for XFS with any history of head/neck BCC/SCC (OR = 2.80, 95% CI = 1.12 – 7.02), and a 2-fold risk for each additional count of UV-related carcinomas (OR = 1.97, 95% CI = 1.09 – 3.58).

When BCC/SCC located anywhere on the body was considered, there were non-significant increased odds of XFS (OR = 1.65, 95% CI = 0.88 – 3.09).

There were no associations between head and neck BCC/SCCs and POAG compared to controls (OR = 1.15, 95% CI = 0.58 – 3.48).

Conclusions: Having BCC/SCC specifically in the head and neck region is associated with a 2-fold increase in risk for XFS/XFG. These findings support prior evidence that UV exposure may be a significant risk factor for XFS. In addition, these results provide further support for in vitro studies analyzing the effects of UV exposure in generating XFM and also strengthen recommendations for UV protection.

ABSTRACT BODY:

Purpose: The Postnatal Growth and ROP Studies (G-ROP-1&2) developed new ROP screening criteria with 100% sensitivity for type 1 and 30% fewer infants requiring exams. However, the criteria are slightly less sensitive for type 2. Currently under conventional screening criteria, outlier infants are identified with a subjective criterion of neonatologist judgment of a “poor postnatal course.” We identified risk factors for developing stage 2 and 3 in infants who were older, larger, or had faster weight gain than the G-ROP criteria to help neonatologists identify these outlying infants.

Methods: Secondary analysis of 2312 of 7483 infants in G-ROP-1 who did not meet the proposed G-ROP criteria. 5(0.2%) had stage 3; 57(2.5%) had stage 2. Medical and surgical comorbidities of prematurity during the first 28 postnatal days were evaluated using multivariable analysis.

Results: Factors associated with stage 2 or 3 ROP were no enteral feeding in first 3 weeks (aOR 5.6, 95% CI 2.6-12.1; 9 or more days on supplemental oxygen in first 4 weeks (aOR3.34, 2.0-5.6); NEC (aOR 4.2, 1.0-17.5); and IVH grade III/IV (aOR 2.6, 0.9-7.6). Risk of stage 2 or 3 increased with number of risk factors: 20/1575(1%) for 0; 34/636(5%) for 1; 7/51(14%) for 2; 1/3(33%) for 3.

Conclusions: NEC, IVH grade III/IV, 9 or more days on supplemental oxygen in first 4 weeks, and no enteral feeding in first 3 weeks are associated with increasing risk of stage 2 or 3 ROP. Counting the number of factors may help identify outlier infants requiring ROP examinations.

ABSTRACT BODY:

Purpose: Ionotropic purinergic receptors (P2XRs) are formed as hetero- or homotrimers from seven subunits, and are activated by extracellular nucleotides such as ATP. Upon activation, the P2XRs become permeable to cations, leading to activation of intracellular signaling pathways and an increase in cytosolic free calcium ($[Ca^{2+}]_i$). All P2XRs are present on cultured rat conjunctival goblet cells (CGCs). The purpose of this study was to investigate the source of the free cytosolic calcium in CGCs after the stimulation with ATP and the ATP analogues BzATP and 2MeSATP.

Methods: Goblet cells were cultured from rat conjunctival explants. First passage CGCs were incubated with the ratiometric fluorescent dye Fura 2-AM in: 1. buffer containing calcium or in calcium free buffer with or without 2 mM EGTA, or 2. calcium-containing buffer with or without the sarco/endoplasmic reticulum Ca^{2+}-ATPase (SERCA) inhibitor thapsigargin (10^{-6} M) that depletes ER Ca^{2+} stores. The CGCs were then stimulated with the non-specific P2XR agonist ATP (10^{-7}-10^{-5} M) or the ATP analogues BzATP (10^{-7}-10^{-4} M) or 2MeSATP (10^{-7}-10^{-5} M), and $[Ca^{2+}]_i$ measured.

Results: $[Ca^{2+}]_i$ was significantly increased from baseline when stimulated with ATP (10^{-7}-10^{-4} M), BzATP (10^{-7}-10^{-4} M) or 2MeSATP (10^{-7}-10^{-5} M), with a maximal response for ATP at 10^{-5} M, BzATP at 10^{-4} M and 2MeSATP at 10^{-5} M in buffer containing calcium. The change in peak $[Ca^{2+}]_i$ was not significantly different in calcium free buffer, but was significantly reduced in the presence of 2 mM EGTA. The $[Ca^{2+}]_i$ increase in CGCs preincubated with thapsigargin was completely reduced for ATP at 10^{-4} M, BzATP at 10^{-4} M and 2MeSATP at 10^{-5} M.

Conclusions: We conclude that ATP and the ATP analogues BzATP and 2MeSATP increase $[Ca^{2+}]_i$ mainly through releasing ER calcium stores.

TITLE: Oncostatin M reduces hypoxia-induced retinal neovascularization through Müller cell activation

SESSION TITLE: Blood flow and ischemia

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: F. Bucher, J. Rapp, P. Liang, G.R. Schlunck, H.T. Agostini, Eye Center, Medical Center, Faculty of Medicine, University of Freiburg, GERMANY|

Commercial Relationships Disclosure: Felicitas Bucher: Commercial Relationship(s);Code F (Financial Support):Hoffman-La Roche, Bayer, Novartis | Julian Rapp: Commercial Relationship: Code N (No Commercial Relationship) | Paula Liang: Commercial Relationship: Code N (No Commercial Relationship) | Gunther Schlunck: Commercial Relationship: Code N (No Commercial Relationship) | Hansjüergen Agostini: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal neovascularization (NV) represents a common hallmark of retinal ischemic diseases in the context of diabetes or retinal vascular occlusion. While hypoxia is known to be a main driver of vascular endothelial cell proliferation and retinal neovascularization, it becomes more apparent that the inflammatory microenvironment and associated signaling pathways modulate hypoxia driven angiogenesis. In this study, we analyze the effect of Oncostatin M (OSM), a strong STAT3 activator with well-documented pro-angiogenic properties outside the eye, in a mouse model of hypoxia-induced retinopathy.

Methods: In the mouse model of oxygen-induced retinopathy (OIR) Bl6/J pups were subjected to hyperoxia between postnatal day (P) 7 and 12. Upon return to room air at P12 mice received intravitreal injections with 0.5µL of 100ng/µl OSM or PBS control. Retinal vascular phenotype following treatment was quantified at P17. Western blot analysis and immunohistochemical stainings on retinal cryosections for pSTAT3 were performed 12h post injection. Retinal vascular endothelial cells were isolated at P17 via cell sort using a CD31+/CD45- gating strategy and submitted for RNA sequencing.

Results: OSM reduced retinal NV in the OIR model by 65,2% compared to PBS-treated controls (N=11 mice, $p<0.05$). Western blot analysis showed a clear increase in pSTAT3 levels in retinal lysates 12 h post treatment. Immunohistochemical analysis visualized a positive pSTAT3 signal in the inner nuclear layer as well as GFAP upregulation in Müller cells suggesting a primary Müller cell response to OSM treatment. RNA sequencing of sorted vascular endothelial cells at OIR P17 revealed a downregulated angiogenic profile following OSM treatment (GSEA: GO angiogenesis, enrichment score 0.287 $p<0.05$).

Conclusions: OSM possesses therapeutic potential by a primary activation of Müller cells resulting in downregulation of angiogenic drivers in vascular endothelial cells.

TITLE: A Contralateral Comparison of a Trifocal vs a Multifocal +3.25 IOL: Pt Preference, Visual Performance, & Predictors of Overall Satisfaction

SESSION TITLE: Cataract surgery 1

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F.A. Bucci, Bucci Laser Vision, Wilkes Barre, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Frank Bucci: Commercial Relationship(s);Code F (Financial Support):Johnson and Johnson

ABSTRACT BODY:

Purpose: To compare pt preference, visual performance, and overall satisfaction in pts receiving a trifocal (PanOptix) in one eye and a multifocal (Tecnis +3.25) in the opposite eye. To identify by regression analysis patient variables that predict pt preferences and overall satisfaction.

Methods: 30 KPE pts (60 eyes) were prospec. randomized to receive a PANO in one eye and a TMF +3.25 in the other eye. A pt questionnaire was administered to evaluate distance,intermediate, and near vision,halos,glare,and starbursts, and overall pt satisfaction. The M&S Clinical Trial Suite was used to assess letter acuity, sine wave, and bullseye contrast sensitivity. Metrics such as uncorrected visions, residual sph and cyl, angle kappa, HOAs, and pupil size were also evaluated. Regression analysis was used to identify objective and subjective variables acting as significant predictors of overall pt satisfaction and IOL preference.

Results: Pts signif preferred (p=.028) the TMF(18) to the PANO(7), and no preference(5). “Overall Satisfaction” was sig greater (4.70/5.00) for TMF vs (4.43/5.00) PANO (p=.05). Uncorrected distance vision was sig greater (p=.032) and best corrected dist acuity trended better (p=.059) for TMF eyes. The questionnaire revealed sig better (p=.05) responses for “frequency of glasses use at distance” and trended (p=.10) for “ability to function at distance without glasses” for TMF eyes. The objective varaibale of intermed (Jaeger) vision was sig better (p=.034) in PANO eyes. However, the subjective variable “frequency glasses use at intermed” trended (p=.10) for TMF eyes. For both TMF and PANO eyes, regression revealed that variables related to reading fine print and intermediate (Jaeger) vision were sig predictors of overall patient satisfaction. But for the PANO eyes only, 2 sine wave contrast sensitivity variables – “sine wave contrast sensitivity with glare” and “sine wave contrast sensitivity without glare” were both highly sig predictors of overall satisfaction in just the PANO eyes.

Conclusions: TMF was sig preferred to PANO (18 TMF,7 Pano,5 no pref). The “overall pt satisfaction” score by pt questionnaire was sig greater (p=.05) for TMF. Regression analysis strongly suggests that issues related to contrast sensitivity both with and without glare may be responsible for the significant preference for the TMF IOL.

TITLE: Shear stress-induced autophagy regulates endothelial nitric oxide synthase (eNOS)/nitric oxide (NO) production via primary cilia in Schlemm's canal cells

SESSION TITLE: Aqueous humor dynamics and Trabecular Meshwork

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Sim, K.M. Perkumas, W.D. Stamer, P.B. Liton, Duke University Department of Ophthalmology, Durham, North Carolina, UNITED STATES|

Commercial Relationships Disclosure: Myoungsup Sim: Commercial Relationship: Code N (No Commercial Relationship) | Kristin Perkumas: Commercial Relationship: Code N (No Commercial Relationship) | William Stamer: Commercial Relationship: Code N (No Commercial Relationship) | Paloma Liton: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Changes in intraocular pressure (IOP) are "sensed" by stretching of trabecular meshwork (TM) cells and shear stress on Schlemm's canal (SC) cells. We previously reported stretch-induced primary cilia (PC)-mediated activation of autophagy as a crucial physiological response for regulating IOP homeostasis in TM cells. Here we investigate the role of autophagy upon shear stress in SC cells.

Methods: Primary human SC cells (6 strains) and human umbilical vein endothelial cells (HUVECs) were subjected to shear stress (1~10 dyne/cm^2) for up to 24 h. Autophagy activation was monitored by measuring LC3-II and SQSTM1 levels, tandem fluorescent-tagged LC3 (tfLC3) or SQSTM1-RFP using western blot or live cell imaging. PC were detected by PC markers (acetylated-TUBA4A, IFT88 and 5HT$_6$-mcherry) and disrupted by chloral hydrate (2 mM for 3 day). The expression and activity of eNOS were measured by GFP under the control of eNOS promoter (eNOSpd-GFP) and phosphorylated eNOS (S1177). Autophagy was inhibited by bafilomycin A (50~100 nM) or siRNA targeting LC3B.

Results: Autophagy marker proteins (LC3 II and SQSTM1) significantly increase by approximately 2 fold ($p<0.05$, $n=6$) upon flow application (10 dyne/cm^2 for 24 h) in the SC cells. Time-lapse live imaging of tfLC3 and SQSTM1-RFP showed that autophagic activity increases and SQSTM1 is aggregated and continuously removed by autophagic vacuole-like structures upon shear stress. Immunochemical and live cell imaging analyses revealed the presence of PC in SC cells. Deciliation significantly prevented the increase in LC3-II levels by shear stress in SC cells (CNT vs deciliated: 2.36±0.58 vs 0.78 ±0.62, $n=4$, $p<0.05$). Time-lapse live imaging of eNOSpd-GFP and western blot showed that the transcription and phosphorylation of eNOS increase by shear stress, and removal of PC decreased eNOS phosphorylation in SC cells. Intriguingly, bafilomycin treatment decreased eNOS protein levels in HUVECs in a concentration-dependent manner, and LC3 knockdown decreased eNOS protein level of HUVECs in static and shear stress conditions (10 dyne/cm^2 for 24 h).

Conclusions: We demonstrate here for the first time the PC-mediated autophagy activation in response to physiological levels of shear stress in SC cells. Moreover, our data strongly suggest that the shear stress-induced autophagy regulates eNOS/NO production in SC cells.

TITLE: Single cell RNA sequencing reveals the role of Myelin regulatory factor (MYRF) in regulating melanogenesis and cell structure during retinal pigment epithelial development.

SESSION TITLE: Single cell analysis in retinal research in health and disease

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: L. Prasov, S.Q. Wang, Ophthalmology and Visual Sciences, University of Michigan, Ann Arbor, Michigan, UNITED STATES|L. Prasov, M.L. Brinkmeier, A. Yakoo, L.Y. Cheung, Human Genetics, University of Michigan, Ann Arbor, Michigan, UNITED STATES|

Commercial Relationships Disclosure: Lev Prasov: Commercial Relationship: Code N (No Commercial Relationship) | Michelle Brinkmeier: Commercial Relationship: Code N (No Commercial Relationship) | Su Wang: Commercial Relationship: Code N (No Commercial Relationship) | Athera Yakoo: Commercial Relationship: Code N (No Commercial Relationship) | Leonard Cheung: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Variants in the transcription factor MYRF have been described in a cardiac urogenital syndrome and familial and sporadic nanophthalmos, but the mechanism of pathogenesis is unclear. Using a conditional mouse model of Myrf loss of function (Myrf fl/fl) in the early eye cup (RxCre), we previously showed that loss of Myrf leads to retinal degeneration and loss melanin pigment in the retinal pigment epithelial (RPE). Here, we identify specific gene expression changes caused by MYRF deficiency using single cell RNA sequencing (scRNAseq).

Methods: scRNAseq was conducted at 3 developmental timepoints (E13.5, E15.5, P0) using pools of eye cups from RxCre Myrf fl/fl or matched Myrf fl/fl littermates, and data were processed using CellRanger and Seurat. Histology, RNAscope in situ hybridization, and electron microscopy (EM) were used to validate gene expression findings.

Results: Cell clustering revealed that Myrf deficiency altered cell type distributions with reductions in RPE cells at all timepoints. Cell cycle dynamics were stable, consistent with increased cell death in mutants. There was also a compensatory increase in retinal progenitor (RPC) population at P0, without alteration in overall cell cycle dynamics. Differential gene expression analysis and PANTHER gene ontology-term analysis revealed down regulation of key pathways in mutant RPE cells, including melanosome biogenesis, cytoskeleton, and extracellular matrix. EM analysis and immunofluorescence staining of RPE flatmounts confirmed structural defects in RPE and disorganization of photoreceptor outer segments, loss of melanosomes, and alterations in novel structural proteins in the apical RPE. Compensatory upgregulation of Prss56, another gene implicated in nanophthalmos, was found in the RPC population.

Conclusions: These results suggest that MYRF plays a critical role in regulating RPE structure and function during development, which likely contributes to abnormal outer segment morphology and retinal degeneration in RxCre Myrf fl/fl mice. Compensatory gene expression changes in the retina may act maintain proper ocular size in mice. These studies inform molecular mechanisms of nanophthalmos and support a role for RPE in this condition.

Commercial Relationships Disclosure: Michael Foster: Commercial Relationship: Code N (No Commercial Relationship) | Catherine Urbano: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Maatouk: Commercial Relationship: Code N (No Commercial Relationship) | Mark Bui: Commercial Relationship: Code N (No Commercial Relationship) | Grant Hom: Commercial Relationship: Code N (No Commercial Relationship) | Blanche Kuo: Commercial Relationship: Code N (No Commercial Relationship) | Rishi Singh: Commercial Relationship: Code N (No Commercial Relationship) | Katherine Talcott: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Studies on long-term outcomes of neovascular age-related macular degeneration (nAMD) eyes on anti-vascular endothelial growth factor (anti-VEGF) injections are limited, especially if there is baseline macular atrophy (MA). This study aims to understand the long-term outcomes of nAMD eyes with baseline MA undergoing anti-VEGF injections.

Methods: This was a retrospective chart review of nAMD patients receiving at least twice-yearly anti-VEGF injections for nAMD for at least 5 years at Cole Eye Institute from 2012 to 2019. Measurements for sub-RPE illumination (SRI), foveal distance to atrophy (FDA), best visual acuity (BVA), and intraocular pressure (IOP) were collected annually. Eyes were excluded if subretinal fluid precluded reliable measurements or if one-year change in SRI or FDA was greater than 2 standard deviations from the cohort mean. 5-year change in BVA was regressed on combinations of six patient characteristics and baseline measures.

Results: A total of 232 eyes of 232 patients (83.9±9.0 years, 64% female) with nAMD and at least 5 years of follow-up (mean 6.0 years) with anti-VEGF injections were identified. 76% (n=178) had baseline MA. Baseline BVA was 67.2±13.9 letters for those with MA and 70.8±11.6 without MA (p=0.0971). Both groups experienced an initial non-significant improvement in average BVA before BVA began to decline (Table 1). Average BVA for patients with no MA peaked in year 1 (+3.0 from baseline, p=0.2289) while average BVA in patients with MA peaked in year 2 (+1.3 from baseline, p=0.0947). Additionally, differences in annual BVA change or BVA change from baseline are not statistically significant between groups without and with baseline MA (Table 1, p≥0.1324). Multiple linear regressions found baseline SRI (p=0.0026) and gender (p=0.0401) to be statistically significant regressors for 5-year change in BVA. Age, baseline FDA, baseline BVA, and baseline IOP were not significant regressors.

Conclusions: In nAMD patients treated with anti-VEGF injections, there was an initial non-significant improvement in vision before decline after two years of treatment. Differences in annual BVA change or BVA change from baseline are not statistically significant between groups without and with baseline MA, but gender and baseline SRI were found to be significant predictors of 5-year BVA change. Larger studies are needed to further explore these trends.

ABSTRACT BODY:

Purpose: To characterize the guinea pig contact lens (CL) induced myopia model, the temporal profile of short-term ocular changes both during induction and after treatment is terminated.

Methods: To induce myopia, 2-week-old pigmented guinea pigs (New Zealand strain, n = 8) wore monocular -10 D rigid gas-permeable (RGP) CLs for one week, while the fellow eye served as a control. Ocular measurements were made at baseline, 3, and 7 days after initiation of CL wear. The CL treatment was then terminated on day 7, and additional measurements were made 3, 7, and 14 days later. Measurements included retinoscopy (spherical equivalent refractive error; SE), noncontact optical biometry (axial length, AL), and spectral-domain optical coherence tomography (choroidal and scleral thicknesses; ChT & ScT).

Results: Mean interocular differences (treated - fellow) in SE and AL were significantly different from baseline after 3 and 7 days of CL wear ($p < 0.0001$). ChT was also significantly reduced by day 7 of CL wear ($p = 0.004$). Interestingly, while both SEs and ALs of treated eyes recovered fully within 7 days of CL removal, the earlier ChT thinning, during the induction phase, was replaced by sustained thickening compared to baseline values, remaining significantly so on day 7 ($p = 0.009$), but returning to the normal by day 14. While ChT changes would have contributed to AL changes, they were much smaller in magnitude than AL changes in both phases. Interocular differences in ScT showed no significant changes.

Conclusions: The above patterns of myopia induction and recovery validate this negative RGP-CL model as an alternative to traditional spectacle lens models, at least for guinea pigs. The scaling mismatch between ChT and AL changes warrants further investigation in relation to underlying mechanisms.

ABSTRACT BODY:

Purpose: Fuchs' endothelial corneal dystrophy (FECD) is the most common corneal endothelial dystrophy and a major cause of visual impairment. FECD patients are at increased risk of endothelial cell density (ECD) loss during cataract surgery, requiring careful surgical consideration. We examine the predictive factors for corneal decompensation and the proportion of FECD patients requiring corneal transplant following conventional phacoemulsification surgery.

Methods: We retrospectively included all patients with FECD undergoing phacoemulsification and intraocular lens implantation by a single surgeon (FF) during 2015–2021 in a UK tertiary hospital, all conducted with soft-shell technique using DuoVisc®. We collected best-corrected visual acuity (BCVA), specular microscopy, and pachymetry measurements pre- and post-operatively, as well as complications and need for further corneal transplant. We excluded patients without pre- and post-operative specular microscopy measurements and those with follow-up of less than 2 months.

Results: 64 eyes of 51 patients were included. The mean age was 73 years (SD=9), 59% female. Median follow-up was 32 months (IQR=18). 13 (20.3%) eyes required Descemet Stripping Automated Endothelial Keratoplasty (DSAEK) after cataract surgery, nine planned on listing and four unplanned. Median time between operations was 3 months (IQR=4). Of the 51 eyes not needing DSAEK, there was a significant change in mean BCVA (−0.13 logMAR, P=0.01) and central corneal thickness (CCT; +19.9μm, P<0.001) following cataract surgery. There was no significant change in ECD (−14%, P=0.16), hexagonality (−3%, P=0.23), or mean cell area (P=0.30). Using multilevel logistic regression adjusted for age, sex, and inter-eye correlation, we find that pre-operative CCT significantly predicts the risk of corneal decompensation (OR 1.01/μm, 95% CI 1.00–1.03, P=0.02) and need for corneal transplant post-cataract surgery (OR 1.04/μm, 95% CI 1.02–1.08, P=0.002). Kaplan-Meier analyses identify pre-operative CCT as a predictor of time-to-transplantation (P<0.001) with an optimal cutpoint value of 591μm.

Conclusions: Conventional phacoemulsification surgery with soft-shell technique has favourable visual outcomes in FECD. Careful counselling of FECD patients before cataract surgery is important with high pre-operative CCT being a significant risk factor for post-operative corneal decompensation and need for corneal transplantation.

ABSTRACT BODY:

Purpose: Xenotransplantation in animal models is a necessary step to reach clinical trials in humans. However, transplantation of human cells into animal models results in severe immune rejection responses. To determine the mechanisms underlying xenotransplant rejection in porcine models, we tested the hypothesis of the potential presence of pre-existing anti-human antibodies that could be responsible for immediate recognition and rejection of transplanted human cells.

Methods: Transplants containing neural retina and retinal pigmented epithelium (RPE) cells derived from human induced pluripotent stem cells (hiPSCs) were implanted in the subretinal space of P23H transgenic and Yucatan pigs. Blood was collected before transplantation (basal level) and weekly for 6 weeks post transplantation. Serum derived from blood was used as a probe in dot blot and western blot assays to attempt to quantify and identify the presence of porcine antibodies against human neural retinal cells, RPE cells, and undifferentiated hiPSC in the weeks prior to and post-surgery. Protein bands identified in western blots are currently being analyzed by mass spectrometry.

Results: Serum collected throughout the 6 weeks post transplantation resulted in positive dot blot signals of relatively equal intensity, inconsistent with a gradually increasing immune rejection process. Furthermore, positive signals were identified from naive serum, collected prior to transplantation, suggesting that the animals expressed pre-existing anti-human antibodies. Further analysis revealed a discrete number of distinct bands in samples corresponding to human neural retina, RPE, and hiPSC, suggesting that pigs expressed antibodies against specific human proteins. Naïve serum from both P23H transgenic and Yucatan pigs recognized equivalent molecular weight bands in neural retina (90kD, 70kD, and 45kD), RPE (70kD, and 45kD), and undifferentiated hiPSC (90kD, and 70kD) samples.

Conclusions: These studies suggest that xenotransplantation of hiPSC-derived retinal transplants in pigs is challenged by the presence of pre-existing anti-human antibodies in the naïve animal model. Follow-up studies will aim at identifying the specific human proteins against which pigs possess pre-existing immunity. Identification of these proteins would be instrumental in devising appropriate strategies to prevent xenotransplant rejection in pre-clinical porcine models.

ABSTRACT BODY:

Purpose: This study investigates adherence rates to immunosuppressive therapy (IMT) for treatment of chronic noninfectious inflammatory eye disease (IED), the relationship between adherence to IMT and disease control, and factors associated with nonadherence in a tertiary care uveitis clinic.

Methods: Retrospective review of medical charts from 2015-2020 was conducted on patients with IED at 6 months, 1 year, and 2 years after initiation of IMT. Demographics and clinical characteristics regarding comorbidities, additional specialists, and medications were collected. Adherence rates and reasons for nonadherence were determined by review of chart notes and lab data. Exam findings were used to assess quiescence. A generalized linear mixed effects model was run to investigate the relationship between adherence and disease control.

Results: During the study period, 183 patients initiated IMT, with 178 included at 6 months, 170 at 1 year, and 126 at 2 years. The mean age was 44, 69% were female, 40% were Black/African American, and 39% had commercial insurance. Diagnoses included anterior uveitis (31%), intermediate uveitis (7%), posterior uveitis (13%), panuveitis (32%), and scleritis (17%). Types of IMT included Methotrexate (57%), Mycophenolate (26%), Adalimumab (6%), other (6%), and combination therapy (5%). More than one quarter of patients had at least one systemic comorbidity (27%) and took more than eight medications (26%). The adherence rate at 6 months and 1 year was 70% but dropped to 58% by 2 years. By 6 months, 46% of patients achieved quiescence, 56% by 1 year, and 64% by 2 years. Of patients who achieved disease control, 82% were adherent at 6 months, 78% at 1 year, and 65% at 2 years. Adherent patients have a 1.86 (95% CI 1.09, 3.20) times greater likelihood for disease control compared to nonadherent patients. At all time intervals, the primary reason for nonadherence was patient self-discontinuation due to insurance coverage issues or running out of medication. No specific demographic factors were significantly associated with nonadherence.

Conclusions: Patients on IMT for IED had steady adherence rates at 6 months and 1 year, with decreased adherence at 2 years. Patient adherence to IMT significantly correlates with disease quiescence, and nonadherence with uncontrolled ocular inflammation. Patient-centered interventions targeted to improving adherence may improve disease control in IED.

ABSTRACT BODY:

Purpose: Spaceflight exposes humans to stress of microgravity and radiation, leading to immunosuppression, muscle atrophy, cardiovascular damage, and visual disturbances. Minimizing or mitigating these pathological changes is necessary for future deep space missions. Several spaceflight-related pathologies are associated with the altered expression of 13 miRNAs. Previously, we found increased expression of these spaceflight-associated miRNAs in rodents exposed to either simulated or real spaceflight and partial conservation in the space-flown twin of the NASA Twins Study. Moreover, small molecule inhibitors (antagomirs-Ag) targeting 3 spaceflight-associated miRNAs reduced vascular inflammation in human tissue exposed to simulated spaceflight. Here, we examined the effects of inhibiting these 3 spaceflight-associated miRNAs in mice before exposure to simulated spaceflight conditions.

Methods: We used 6 groups of 20 female mice: control, control + Ag, simulated gamma-cosmic rays (GCRs), GCRs + Ag, simulated space particle event (SPE), and SPE + Ag. Half of each group was housed with hindlimb unloading to simulate microgravity. Ag-treated mice were treated every 3 days, with the last treatment 24 hours before irradiation. We harvested the vertebral column and eyes. We isolated total RNA and used RT-qPCR to measure expression levels of 13 candidate genes.

Results: We identified 13 gene targets of 3 miRNAs via mirNET, mirWalk, and Cluepedia databases (Figure). Differences in relative expression of 13 genes was analyzed via Welch's unpaired t-test and two-way ANOVA. We found changes in spinal cord expression of 9 genes when treated with spaceflight-associated miRNA Ag ($p < 0.05$), several of which are involved in mitotic function, membrane organization, and phosphatase regulation. Conversely, in eyes we found that Ag treatment only changed expression of one gene (Zcchc9; sham vs SPE + Ag, $p< 0.05$; sham vs Sham + Ag $p< 0.05$), that encodes a zinc-finger containing protein phosphatase. However, simulated-spaceflight radiation and microgravity alone did not influence expression of the 13 target genes in the eye or spinal cord.

Conclusions: Our study demonstrates that inhibition of miRNAs in preclinical models of simulated spaceflight has potential for preventing biological damage.

ABSTRACT BODY:

Purpose: Spatial localization refers to the ability to determine the location of people and objects in relation to oneself. In previous psychophysical studies we have investigated the effect of vision and/or hearing impairments on spatial localization behavior. However, it is not known how people with sensory impairment judge the difficulty of spatial localization in real-life situations. We developed a spatial localization survey to assess participants' perceived difficulties in visual and auditory localization, as well as their sensory integration strategies in real-life scenarios.

Methods: The survey included 35 real-life scenarios with visual and auditory cues, e.g., "You are walking along a city sidewalk. A police vehicle is approaching with a siren sound and flashing lights. You need to determine which direction the police car is coming from". For each scenario, participants reported their perceived difficulties in completing the task solely by vision and solely by hearing, using a scale from 1-5 (1 = very easy; 5 = very difficult), and which sense (vision or hearing) they would primarily rely on. Data were collected from three groups—vision impairment (VI, N = 24); dual sensory impairment (vision and hearing/DSI, N = 15); and healthy controls (N = 26). Their mean acuities were 0.75, 0.52 and 0.0 logMAR; and mean hearing levels were 6.2, 30 and 5.8 dB, respectively.

Results: The VI and DSI group reported significantly higher visual difficulty scores than the control group. However, the DSI group did not show higher hearing difficulty scores than the control or VI group. When asked which sense the participants primarily relied on, the control group was consistently "vision dependent", while the VI and DSI groups had more participants who were "hearing dependent". Participants were primarily "vision dependent" until their acuity reached 1.0 logMAR (20/200), after which they were more likely to be "hearing dependent".

Conclusions: Vision impairment resulted in higher overall perceived difficulty in visual localization, while hearing impairment did not significantly affect the perceived difficulties in auditory localization. While healthy controls were primarily vision dependent, participants with VI or DSI adjusted their sensory dependence pattern in coping with vision impairment. Our survey provides a unified framework for assessing participants' reported vision and hearing function in daily activities.

ABSTRACT BODY:

Purpose: The cytokine interleukin-6 (IL-6) has two major signaling modalities, classical signaling and trans-signaling, which are generally considered anti-inflammatory and pro-inflammatory, respectively. IL-6 classical signaling is limited to cells expressing the membrane-bound IL-6 receptor (IL-6Rα), whereas trans-signaling is mediated through a soluble form of IL-6 receptor. To characterize the role of IL-6 signaling in retinal Müller glia, we generated a Müller-cell-specific Il6ra knockout (KO) mouse (Pdgfra-Cre Il6ra$^{fl/fl}$). In this study, proteomic analysis of Müller glial cells (MGCs) with and without IL-6Rα was performed to reveal the autocrine functions of IL-6 classical signaling in-vitro.

Methods: MGCs were isolated from wildtype C57BL/6J (WT) and KO mouse pups and cultured in-vitro. Comprehensive proteomic profiling of cell lysates from both groups was conducted using liquid chromatography-tandem mass spectrometry (LC-MS/MS).

Results: Proteomic profiling identified a total 1066 proteins, of which 79 proteins were significantly altered (33 upregulated and 46 downregulated) in MGCs from KO mice relative to WT. The top five upregulated proteins include PDZ and LIM domain protein 1 (Pdlim1: 5.25-fold), glycogen phosphorylase (Pygb: 3.36-fold), procollagen-lysine,2-oxoglutarate 5-dioxygenase 2 (Plod2: 3.24-fold), transgelin (Tagln: 2.87-fold), and acyl-coenzyme A thioesterase 9 (Acot9: 2.5-fold). The top five downregulated proteins include neprilysin (Mme: 0.12-fold), metalloreductase STEAP4 (Steap4: 0.17-fold), transmembrane glycoprotein NMB (Gpnmb: 0.19-fold), ectonucleotide pyrophosphatase/phosphodiesterase family member 5 (Enpp5: 0.26-fold), and alcohol dehydrogenase 1 (Adh1: 0.27-fold). Mitochondrial structure, cell metabolism, cytoskeletal structure, glycolysis, actin cytoskeletal signaling, and endoplasmic reticulum stress response were highly enriched gene ontology (GO) terms in the 79 altered proteins.

Conclusions: Elimination of IL-6 classical signaling via IL-6 receptor knockout in MGCs produced significant alterations in protein expression. This characterization reveals the autocrine functions of IL-6 classical signaling in-vitro and lays the groundwork for future experiments involving the functions of IL-6 in MGCs.

ABSTRACT BODY:

Purpose: Our recent studies in human retinal endothelial cells and diabetic mice indicate that the damaging effects of interleukin-6 (IL-6) in diabetic retinopathy (DR) are primarily mediated by IL-6 trans-signaling through its soluble IL-6 receptor (sIL-6R). The effects of IL-6 trans-signaling in Müller glial cells (MGCs) remain unclear, as MGCs also express the membrane-bound IL-6 receptor (IL-6Rα) and are thus capable of both classical and trans-signaling, making it difficult to discern the distinct effects of each signaling mechanism. To address this problem, we have generated a Müller-cell-specific Il6ra knockout (KO) mouse to eliminate IL-6 classical signaling in MGCs.

Methods: This conditional knockout mouse was created by crossing a mouse expressing a Müller-cell-specific Cre recombinase (C57BL/6-Tg(Pdgfra-cre)1Clc/J) with a floxed Il6ra mouse (B6;SJL-Il6ra$^{tm1.1Drew}$/J). Knockout specificity in MGCs was evaluated by immunohistochemistry of retinal sections. Visual function testing and live retinal imaging were performed using Phoenix MICRON™ Ganzfeld ERG system. Primary MGCs were isolated from wildtype (WT) and KO mice, and Il6ra KO was confirmed by RT-PCR, western blotting, and immunofluorescence staining.

Results: After successful breeding and genotyping, ~75% of F3-generation mice were positive for Cre recombinase and homozygous for floxed Il6ra. IL-6Rα protein expression was detected in WT Müller glia by immunofluorescence staining and confirmed to be absent in the KO mouse retina. Further, mRNA expression of the exon 5-6 region of the Il6ra gene, the region flanked by loxP sites, was not detected in KO MGCs. Western blotting and immunofluorescence staining for IL-6Rα confirmed its presence in WT MGCs and its absence in KO MGCs. Finally, we confirmed via H&E staining of retinal sections that KO mice possess normal retinal morphology. Preliminary visual function testing by ERG at 12 weeks of age showed a normal response to visual stimulus in KO mice, and fundus examination also showed no evidence of retinal lesions.

Conclusions: We have successfully generated a novel tissue-specific knockout mouse to isolate the specific effects of IL-6 trans-signaling in Müller glial cells. Use of this model will provide critical knowledge of the seemingly opposite roles of the two major IL-6 signaling modalities within the retina and retinal pathology.

ABSTRACT BODY:

Purpose: Microglial activation has emerged as a critical event contributing to retinal ganglion cell loss in glaucoma. Apolipoprotein E (APOE), the major apolipoprotein in the brain, and Galectin-3 (Gal-3), a secreted carbohydrate-binding lectin, have been identified as molecules critical for microglial cytotoxicity in mouse models of glaucoma. In this study, we aim to examine the role of APOE and Gal-3 in human disease by analyzing their concentrations in aqueous humor (AH) collected from glaucoma patients and healthy controls.

Methods: AH was collected from 71 patients at the start of surgery, including 57 glaucoma patients undergoing various ophthalmic procedures and 14 control patients undergoing routine cataract surgery. APOE and Gal-3 levels were quantified by enzyme-linked immunosorbent assay and total protein concentration by bicinchoninic acid (BCA) assay. Patients' medical records were carefully reviewed to collect relevant preoperative data. Descriptive statistics, Pearson's correlation coefficient, and multivariate linear regression analyses were conducted to characterize associations between clinical and demographic variables and APOE and Gal-3 levels.

Results: APOE and Gal-3 levels were significantly elevated in the AH of glaucoma patients (1.64 +/- 1.45 µg/mL and 2.33 +/- 2.09 ng/mL, respectively) compared to controls (0.40 +/- 0.19 µg/mL, 0.92 +/- 0.81 ng/mL) [$p<0.001$; $p=0.004$]. APOE and Gal-3 levels were moderately positively correlated across the entire cohort ($r=0.65$, $p<0.001$). No association was observed between APOE and total protein or Gal-3 and total protein, indicating that APOE and Gal-3 levels were not increased in glaucomatous AH due to nonspecific protein accumulation ($p>0.3$). Multivariate linear regression analyses revealed significant associations between Gal-3 and maximum recorded intraocular pressure measurement ($p=0.009$), and between APOE and number of past ophthalmic surgeries ($p=0.031$).

Conclusions: Our findings demonstrate that APOE and Gal-3 are increased in the AH of glaucoma patients and significantly correlate with clinical measures of glaucoma severity. Thus, these molecules could serve as biomarkers to identify patients who may benefit from microglia-based neuroprotective glaucoma therapies.

ABSTRACT BODY:

Purpose: Retinopathy of prematurity (ROP) and diabetic retinopathy (DR) are leading causes of blindness. Retinal hypoxia, inflammation, and pre-retinal neovascularization characterize both conditions. Pregnancy, poor glycemic control, and diabetes mellitus (DM) duration are associated with worsening DR. On the other hand, low gestational age (GA), low birth weight (BW) and exposure to comorbidities like necrotizing enterocolitis (NEC) are risk factors for ROP progression. Pathologic similarities between ROP and DR posit that maternal DM (in-utero hyperglycemia) may increase a premature infant's risk of retinopathy progression to vision-threatening stages (Stage 3-5). However, the few studies that address this question describe conflicting results and no studies have reported data on specific maternal DM sub-types. Our study further explores the contribution of maternal DM-type to this potential association.

Methods: This retrospective cohort study included infants born between January 2004 and December 2017 with GA between 22 weeks 0 days and 30 weeks 6 days or with BW <1500g, who had documented staging on ROP screening, and who survived to at least day-of-life 30 and to 40 weeks corrected GA. The study investigated the association between Stage 3-5 ROP and maternal DM using multivariate analysis including GA, BW, year of birth, and NEC. A two-sided t-Test with $p<0.05$ was used for statistical significance.

Results: 2386 of 17066 infants met inclusion criteria. Of these 2386 infants, 1612 (67.5%) had Stage 0 (no ROP controls) and 242 (10.1%) had Stage 3-5 ROP. Maternal DM was found in 131 infants (8.1%) with Stage 0 ROP and 17 infants (7%) with Stage 3-5 ROP. In the multivariate analysis, a positive association with OR of 2.2 (95% CI: 1.0-4.3, p=0.03) was detected between Stage 3-5 ROP and maternal DM. Sub-analysis by DM-type suggested a significant association between Stage 3-5 ROP and maternal Type 2 DM (OR 3.7, 95% CI 1.3-10.1, p=0.012), but not with Type 1 DM (OR 5.9, 95% CI: 0.7-33, p=0.06) or with gestational DM (OR 1.1, 95% CI 0.4-3.0, p=0.859).

Conclusions: Our results suggest that maternal diabetes, particularly Type 2 DM, may confer an increased risk of developing vision-threatening ROP. Incorporating this risk factor to screening decisions may be valuable to preserve vision in at-risk infants.

ABSTRACT BODY:

Purpose: Posterior capsule opacification (PCO) is a frequent complication after cataract surgery, and advanced PCO requires YAG laser (Nd: YAG) capsulotomy, which often gives rise to more complications. Lens epithelial cell (LEC) proliferation and transformation (i.e., epithelial-mesenchymal transition (EMT)) are two key elements in PCO initiation and progression pathogenesis. While PCO marginally impacts aged cataract surgery patients, PCO incidences are exceptionally high in infants and children undergoing cataract surgery. The epigenetics of lens epithelial cell aging and its role in the discrepancy of PCO prevalence between young and older people have not been fully studied.

Methods: Here, we conducted a comprehensive differentially expressed gene (DEG) analysis of the young and aged lens epithelial cells (LECs) that originated from a cellular aging model. In vitro TGFb2 cell treatment and in vivo mouse cataract surgical models were used to validate our findings.

Results: We found that aged LECs decelerated rates of cell proliferation accompanied with dysregulation of cellular immune response and cell stress response. Surprisingly, we found that LECs systematically downregulated epithelial-mesenchymal transition (EMT)-promoting genes. The protein expression of several EMT hallmark genes, e.g., fibronectin, aSMA, and cadherin 11, were gradually decreased during LECs aging. We then confirmed these findings in vitro and found that aged LECs markedly alleviated TGFb2-mediated EMT. Importantly, we explicitly confirmed the in vitro findings from the in vivo mouse cataract surgery studies.

Conclusions: We propose that both the high proliferation rate and EMT-enriched young LECs phenotypic characteristics attribute to unusually high PCO incidence in infants and children.

ABSTRACT BODY:

Purpose: TMEM97 (Sigma-2 receptor) is a transmembrane protein that has been implicated in cell proliferation and death, cholesterol homeostasis and lipoprotein uptake. Its distribution and role in the retina are not well understood. Here, we examined TMEM97 distribution in the adult mouse retina.

Methods: Eyes from adult C57BL/6J wildtype (WT) and Tmem97 knockout (KO; Shen et al., 2021) mice were fixed in 4% paraformaldehyde/PBS, and cryosections (O.C.T.) were collected on glass microscope slides for immunohistochemistry (IHC) and probed with rabbit anti-TMEM97 (Invitrogen #PA5-2300 or Novus Biologicals #NBP1-30437), followed by fluorochrome-conjugated secondary antibodies (Abs), and examined by confocal fluorescence microscopy. Non-immune (normal) rabbit IgG (Sigma/Aldrich) served as a negative control. Markers of rod outer segments (ID4 anti-opsin), Müller glia (anti-glutamine synthetase (GS); BD, Clone 6 #610517), mitochondria (COX4-I1; #AF5814, Bio-Techne), cilia (chicken anti-rootletin; Tiansin Li, NEI), ECM (anti-IMPG1, #SC-377366) also were probed, using suitable secondary fluorochrome-conjugated Abs, and DAPI counterstain. Alternatively, WT mouse eyes were fixed in buffered mixed aldehydes, then embedded in LR White resin, and processed for immunoelectron microscopy, applying anti-TMEM97 Abs in combination with Nanogold-conjugated anti-rabbit Ab and silver enhancement (Wolfrum & Schmitt, 2000). Western blots (WB) of mouse neural retinas were probed with anti-TMEM97 Abs (ECL detection).

Results: WB analysis of retina lysates showed a single anti-TMEM97-positive band (M_r ~21 kDa), consistent with TMEM97. Prominent TMEM97 immunofluorescence labeling was found in the photoreceptor layer of the mouse retina, but no colocalization with rod opsin, COX4, GS, or IMPG1 was observed; occasional co-localization with rootletin in rods and RPE cells was observed, otherwise little or no RPE labeling. Focal and more diffuse labeling was observed in the OPL, IPL, and GCL. In both the INL and GCL we observed elongated staining that co-localized with rootletin. Tmem97 KO retinas exhibited no Tmem97 immunostaining. Immunoelectron microscopy confirmed TMEM97 localization in rod ciliary rootlets, and periciliary and centriolar material of retinal cells.

Conclusions: These findings are consistent with TMEM97 having a role in the structure and function of primary cilia in neural retina (especially photoreceptors) and RPE centrosomes.

ABSTRACT BODY:

Purpose: Mean contrast sensitivity (CS) and area under the log CS function (AULCSF) parameters may help evaluate visual function in patients with glaucoma, yet they are rarely performed in routine clinical care. The quick CS function (qCSF) test (Adaptive Sensory Technology, San Diego, CA, USA) is a Bayesian adaptive procedure that estimates AULCSF by measuring CS at different spatial frequencies and modeling log CS as a function of stimulus size. We analyzed the relationship between qCSF test outputs and visual field mean deviation (MD).

Methods: In this observational study, subjects with visual acuity 20/40 or better and a diagnosis of glaucoma or glaucoma suspect performed the qCSF test. All subjects were reliable, experienced HFA testers. qCSF reports AULCSF and the individual CS recorded at 1.0, 1.5, 3.0, 6.0, 12.0 and 18.0 cycles per degree (CPD). We created a scatterplot with AULCSF as a function of each subject's MD and fit linear regression at each CPD to evaluate the effect of MD on CS, then adjusted for intraocular lens status.

Results: MD averaged -3.16 (± 3.90) dB for 54 eyes of 54 subjects with mean age 61 years (range 30-71) and was not correlated with AULCSF (P = 0.15, Figure 1). Better MD was associated with better CS at 1.0, 1.5, and 3.0 CPD (Figure 2), but these correlations were weak. When intraocular lens status was added to the model, it was correlated with CS at 1.0 and 1.5 CPD, and MD was no longer correlated with CS.

Conclusions: HFA MD and AULCSF were not correlated in this population with mostly early or no VF defects. MD was correlated with CS at lower CPD (1.0, 1.5, 3.0). This association was no longer statistically significant when adjusting for intraocular lens status. The mild glaucoma severity in this cohort may have limited the ability to detect a relationship between CS and MD, and any relationship was overshadowed by intraocular lens status. At higher CPD, CS is less correlated with MD and intraocular lens status. The results of this preliminary study were limited by the overall healthy population and apply only within the bounds of the tested cohort.

ABSTRACT BODY:

Purpose: Gene expression varies among individuals and between tissues in the same person. Gene expression analyses in disease-affected tissues can help ascribe function to previously associated disease susceptibility variants in complex disorders such as age-related macular degeneration (AMD). We aimed to uncover patterns of differential gene expression between different disease stages to uncover the pathogenesis of AMD.

Methods: Utilizing well-characterized fresh human donor tissue from rapidly autopsied eyes, phenotyped and dissected according to a standardized protocol; the macula of the neural retina and separately the macula of the RPE/choroid. Analysis was performed on 27 donors (12 normals, 10 intermediate AMD and 5 neovascular AMD) that underwent poly A tail RNA-sequencing to identify differentially expressed genes (DEG) between the AMD subtypes.

Results: Following principal component analysis, DESeq2 pipeline analysis and correction with Benjamini -Hochberg, significant DEG within the macular RPE/choroid tissues was observed for 40 genes between intermediate AMD and normal eyes, 1,204 genes between neovascular AMD and normal eyes, and 1,194 genes between intermediate and neovascular AMD. Within the macular neural retina, 30, 41, and 50 genes were differentially expressed when comparing the same respective groups. Among genes associated with AMD from prior GWAS and candidate gene studies, expression was significantly higher for ABCA4, ABCA7, RORA and VTN in neovascular AMD versus normal macular RPE/choroid tissue; significantly lower for ABCA4, ABCA7, SPEF2 and significantly higher for TNFRSF10B and TRPM1 in intermediate versus neovascular AMD macular RPE/choroid. There was no overlap between significant DEG and tissue type. 16 pathways in the GSEA Hallmark collection were significantly enriched; 14 unique to the comparison of intermediate with normal eyes and 10 of those specific to the RPE/choroid tissue.

Conclusions: Our analysis demonstrates differential patterns of gene expression between AMD phenotypes in macula retina and RPE/choroid tissue with the later demonstrating greater variability underscoring the importance of assessing expression in a cell-type specific manner. Several genes and pathways were differentially expressed between phenotypes suggesting that clinical AMD may represent a spectrum of molecular pathophysiology.

ABSTRACT BODY:

Purpose: Many circulating metabolites including lipids and fatty acids may be involved in the pathogenesis of age-related macular degeneration (AMD). However, conflicting results about their association with AMD have been reported and the relationship between metabolites and AMD remains largely unknown. Here we aim to provide an integrated perspective on the relationship and genetic basis of metabolites and AMD by leveraging the results of published genome-wide association studies (GWAS).

Methods: We curated published GWAS of human serum and plasma metabolites which identified quantitative trait loci for 300 metabolites (mQTLs). Summary statistics of AMD GWAS were derived from the International AMD Genomics Consortium. Two-sample Mendelian randomization (MR) was used to infer causal associations between metabolites and AMD using mQTLs as instrument variables.

Results: We built a metabolites network of AMD by cross-linking different metabolites with their shared SNP associations with AMD (P<5e-8). We found that four AMD risk loci near LIPC, CETP, APOE and MMP9 (PMID 20385826, 20888482, 21139980, 21447678) showed high pleiotropic effects on metabolites and each locus was associated with 20 metabolites on average. Some metabolites were related to multiple AMD risk loci, but the direction of association between metabolites and AMD conflicted at different loci. For example, rs17231506 in CETP was positively correlated with AMD (P=1.7e-8) and extra-large sized HDL (xl-HDL, P=6.7e-15), suggesting that xl-HDL was positively correlated with AMD. However, rs2070895 in LIPC was negatively correlated with AMD (P=1.8e-11) but positively correlated with xl-HDL (P=1.7e-9), suggesting that xl-HDL was negatively correlated with AMD. Results point to key regulatory genes that may balance levels of metabolites in AMD. MR analysis also showed that increased levels of Lyso-phosphatidylethanolamine (Beta=0.46, P=1.1e-18), docosatetranoic acid (Beta=1.4, P=3.5e-15), and m-HDL (Beta=0.67, P=6.9e-5) were associated with increased risk of AMD, and increased level of LDL, VLDL, and IDL (Beta=-0.37, P=4.6e-6) were associated with decreased risk of AMD.

Conclusions: Results provide evidence supporting potentially causal effects of many circulating metabolites on AMD, and pinpoint key regulators which may balance the metabolites network underlying AMD pathogenesis. Therefore, these findings may support new targets for AMD therapies.

ABSTRACT BODY:

Purpose: Idiopathic macular holes are generally a surgical disease. While small, early macular holes may rarely close spontaneously, most require surgery for repair. Edema surrounding the edge of the hole is thought to be contributory and treating the edema is thought to possibly be able to close the hole. Herein, we report our experience with a non-surgical approach to repairing macular holes.

Methods: A retrospective chart review of 13 consecutive patients with macular holes from 2018-2021. Topical therapy consisted of a steroid, a non-steroidal and a carbonic anhydrase inhibitor. The setting was a solo retinal surgeon's practice. Follow-up ranged from 6 months to 2 years.

Data collected included size, stage and duration of macular hole, topical agents used and duration, grading scale of macular edema present, lens status and complications from topical or surgical therapy. The grading scale ranged from 0 (no intraretinal edema at all) to 4 (maximum, large amount of edema). If the hole failed to close after 3 months of topical therapy, intravitreal Ocriplasmin (Jetrea) was offered and / or vitrectomy with membrane peeling and fluid gas exchange. Best corrected visual acuities (BCVA) were converted to logMAR pre and post hole closure with topical therapy or surgery. SD-OCT images were captured of all patients.

Results: Seven of the 13 (54%) eyes initially treated topically experienced successful macular hole closure. Small holes (less than 230 microns) with better initial vision (0.474 vs 0.796 logMAR) were more likely to respond favorably to topical therapy (121 microns vs 499 microns). Additionally, holes with less surrounding edema responded better. Of the holes not responding to topical therapy, all were subsequently closed with pars plana vitrectomy (PPV), membrane peel and fluid / gas exchange.

Conclusions: Topical therapy is a reasonable first line treatment for macular holes with a better than 50% success rate. This is especially true for small, early onset holes with minimal or no edema. There was no apparent deleterious effect of a 1-3 month delay while treating with eye drops as surgery still had a very high success rate.

ABSTRACT BODY:

Purpose: Data science research is dependent on large, well-compiled datasets. However, these datasets are difficult to acquire, and there are currently no best practices for sharing these data. An open dataset could address this gap, allowing researchers to investigate new hypotheses and develop more generalizable studies. This abstract describes factors considered in constructing such a dataset.

Methods: A dataset containing medical record numbers (MRNs) of glaucoma patients, providers and their specialty departments, visit identifiers and dates, raw progress notes and medication lists extracted from the EHR, and statistical analysis from a previously published manuscript was used (Chen et al, Ophthalmology Science, 2021). These progress notes and medication lists were previously manually annotated for medications names, frequency, route, and indication. Each dataset element was reviewed for protected health information (PHI). If PHI was present, a decision was made to remove or de-identify the data field. Example data fields, including PHI, and their rationale for inclusion/exclusion are described in Table 1.

Results: Patient MRNs, visit identifiers, and visit dates were the only data fields specifically with PHI, and were de-identified using an R library, anonymizer, which uses hash functions to encode identifying variables. Visit dates were shifted and truncated. Provider data was removed, and department data was included as is. Annotated medication data were paired with all data fields as a CSV and statistical code was included without modification. While medication lists were included as is, progress notes potentially contained PHI and required de-identification using a natural language processing algorithm, Philter (Python), with results verified by a clinician (JSC). These data could be uploaded to online data repositories such as Dryad or Figshare (Table 2), published as a Data Descriptor Article (Zarbin et al, TVST, 2021), and potentially used to develop or validate text-processing algorithms involving medication data.

Conclusions: Processing and uploading datasets for open-source dataset publication is a feasible, inexpensive process and could become standard practice to increase collaboration as well as dataset accessibility in vision research.

ABSTRACT BODY:

Purpose: Previous studies have reported an association between vision impairment (VI) and cognitive health. Specifically, VI is associated with the development of cognitive impairment, a clinical precursor to dementia. However, most older adults with VI will not develop cognitive impairment or dementia. This study sought to determine whether the association of VI with incident cognitive impairment varies by ε4 carrier status of the Apolipoprotein E gene, a strong genetic risk factor for cognitive decline and dementia.

Methods: We used data from the population-based Aging, Demographics and Memory Study (ADAMS), which included adults aged 70 years and older. Vision impairment was defined as vision worse than 20/40 in the better seeing eye. Participants underwent a consensus panel assessment of cognitive function and were categorized as cognitively normal, cognitive impairment no dementia (CIND), or dementia. We constructed a Cox proportional hazards model to estimate the joint effects of VI and APOE-ε4 on the development of CIND among participants who were cognitively normal at baseline. Models were adjusted for age, sex, education, medical comorbidities, and for the competing risk of death.

Results: There were 196 participants included in this analysis. Both VI (HR=2.0, 95% CI 1.3-3.2) and APOE-ε4 (HR=1.7, 95% CI 1.2-2.6) were independently associated with incident CIND. The joint effect of VI and APOE-ε4 on incident CIND (HR=5.7, 95% CI 2.8-11.6) was significantly elevated compared to having no VI and no APOE-ε4 allele. However, there was no increase in the hazard of CIND among those with only VI or the APOE-ε4 allele (Figure).

Conclusions: The hazard of incident CIND among older adults with VI was elevated only among those who were carriers of the APOE-ε4 gene variant. These findings may be important for risk stratification and for targeting interventions to those at greatest risk.

ABSTRACT BODY:

Purpose: REFLECT is a Phase III randomized trial assessing the efficacy and safety of a bilateral intravitreal injection of lenadogene nolparvovec gene therapy for the treatment of Leber hereditary optic neuropathy (LHON) caused by the m.11778G>A mitochondrial DNA mutation in the MT-ND4 gene.

Methods: 98 LHON subjects carrying the m.11778G>A mutation, who were ≥ 15 years old at onset and with vision loss ≤ 365 days at enrollment, received a single intravitreal injection of lenadogene nolparvovec (9E10 viral genomes in 90 µL per eye) in the first-affected eye. The second-affected eye was randomly allocated to either gene therapy or placebo. Functional and structural parameters were monitored up to 2 years after treatment administration.

Results: 48 subjects were assigned to bilateral treatment with gene therapy and 50 to unilateral treatment (with the first-affected eye injected with lenadogene nolparvovec and the second-affected eye injected with placebo). Two years after injection, a statistically significant improvement in best-corrected visual acuity (BCVA) was reported from baseline in treated eyes. A significant improvement from the nadir was observed in all eyes, reaching +20 and +17 ETDRS letters in the first- and second-affected eyes, respectively, for bilaterally treated patients ($p<0.0001$), and +19 and +14 ETDRS letters in the first-treated and second-placebo eyes, respectively, for unilaterally treated patients ($p<0.0001$). A better average final BCVA was reported in subjects treated bilaterally compared to subjects treated unilaterally (+6 letters). A clinically meaningful improvement from the nadir of at least -0.3 LogMAR (+15 ETDRS letters) was reported in 73% of bilaterally treated subjects and 66% of unilaterally treated subjects, and 77% of bilaterally treated patients moved from off-chart BCVA at baseline to on-chart BCVA at 2 years.

Conclusions: The statistically significant improvement of BCVA from baseline and the nadir reported at 1.5 years post administration of lenadogene nolparvovec was maintained at 2 years. The improvement observed in placebo-treated eyes is consistent with the contralateral effect of a unilateral injection of lenadogene nolparvovec reported in the phase III trials RESCUE and REVERSE. The REFLECT results suggest a dose effect with bilateral injection of lenadogene nolparvovec.

ABSTRACT BODY:

Purpose: For assessing corneal biomechanics, resolving spatial heterogeneity both in depth and over a wide lateral field of view is advantageous to observe the effects of crosslinking procedures and diseases such as keratoconus – both of which vary as a function of corneal depth and lateral position. Phase decorrelation optical coherence tomography (PhD-OCT) is able to resolve the varying depth-dependent effects of different corneal crosslinking protocols and, through the use of a conical scanner, an improved ability to scan a wide field of view.

Methods: Ex vivo porcine corneas were imaged with both a typical telecentric scanner and the conical scan sample arm (following Beer et al., 2017) in conjunction with a 1310nm spectral domain OCT system. M-B scans were acquired and processed to extract the short-time complex decorrelation, as described in prior work (Blackburn et al., 2019). Crosslinking protocols were applied, including the Dresden protocol and accelerated protocols.

Results: Using the conical scanning system, there is no substantial degradation of image quality in the periphery and thus no corresponding degradation of the decorrelation signal. The preserved signal quality allows for decorrelation analysis further from the central cornea. Differences in the depth-profiles that were observed between varying crosslinking protocols correspond well with theory. The use of supplemental oxygen in accelerated protocols enhanced the crosslinking effect.

Conclusions: Conical focal plane scanners offer significant advantages for noise-sensitive OCT processing methods such as PhD-OCT to reliably extend their reach into the periphery of the cornea. PhD-OCT is demonstrated to provide depth-dependent information about crosslinking state.

ABSTRACT BODY:

Purpose: The retinal fovea is responsible for high acuity vision. Within the primate fovea, each cone photoreceptor contacts a pair of ON and OFF midget bipolar cells (MBCs), forming the first synapses of the midget pathway. Foveal cone loss in retinal degenerative diseases such as macular degeneration is a major cause of blindness. Restoring vision in the fovea using cell-based therapies requires proper synaptic integration of new photoreceptors into the surviving midget circuitry. Thus, understanding how mature foveal circuits remodel after cone loss will be helpful for strategizing future therapies. Here, we used serial block face scanning electron microscopy (SBFSEM) to determine the connectivity of surviving foveal cones adjacent to regions of acute photoreceptor loss.

Methods: A region (200 µm by 500 µm) adjacent to the foveal pit of anesthetized 4-year-old Macaca fascicularis monkey was photocoagulated using a PASCAL laser (Topcon). The animal was euthanized 6 months later, the eye enucleated and the eyecup fixed in 4% glutaraldehyde in 0.1M cacodylate buffer. An unlasered retina from a 5-year-old Macaca fascicularis monkey served as a control. Samples were prepared for SBFSEM as previously described (Della Santina et al., 2015, Current Biology 26:2070-2077), and imaged using the VolumeScope (Thermo-Fisher). The samples, located 650 µm from the foveal center, were reconstructed using TrackEM2 software (NIH). Statistical analysis was carried out using Mann-Whitney U test.

Results: A single cone (n=10 cones) contacted a pair of ON and OFF MBCs in the control retina. A cone pedicle deprived zone (PDZ) was clearly visible 6 months after photocoagulation. As in control retina, ON and OFF MBCs within and adjacent to the PDZ were identified by their axonal stratification. At the PDZ border, ON MBCs (n=8) synapsed with single cones as in the control, whereas OFF MBCs (n=10) sometimes connected with 2 cones (average 1.6 ± 0.52; p=0.005 compared to control). Connectivity of individual cones with ON MBCs (0-3, average 1.07 ± 0.62, n=14 cones, p=0.041) and OFF MBCs (1-3, average 1.73 ± 0.90, n=11 cones, p=0.00006) increased significantly compared to the control.

Conclusions: The mature midget pathway in the primate retina rewires after acute cone loss. The extent of remodeling appears to differ between the ON and OFF pathways.

TITLE: Sensitivity and specificity for the detection of Demodex mites with slit-lamp in patients with blepharitis.

SESSION TITLE: Ocular surface health and conjunctiva

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. ESKENAZI, N. Kahuam-López, A. Navas, C.A. Müller-Morales, E.O. Graue-Hernandez, cornea, Instituto de Oftalmologia Fundacion Conde de Valenciana IAP, Mexico City, Mexico City, MEXICO|

Commercial Relationships Disclosure: RUTH ESKENAZI: Commercial Relationship: Code N (No Commercial Relationship) | Nicolás Kahuam-López: Commercial Relationship: Code N (No Commercial Relationship) | Alejandro Navas: Commercial Relationship: Code N (No Commercial Relationship) | Carlos Müller-Morales: Commercial Relationship: Code N (No Commercial Relationship) | Enrique Graue-Hernandez: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Demodex mites are the most common microscopic ectoparasite found in human skin, affecting 84% of the population older than 60 years. It is a common cause of chronic blepharitis. The gold standard for diagnosing a Demodex infestation is the visualization of the mite with light-microscopy examination. We tested the hypothesis that the detection of Demodex infestation in blepharitic patients by silt-lamp is a comparable tool for the detection of the pathogen.

Methods: Demodex infestation was evaluated in 22 patients with blepharitis. Two lashes with cylindrical dandruff were epilated from each lid. They were mounted on a glass slide with a drop of saline, a coverslip was mounted on each slide then placed on a strip of white paper and examined on a slit lamp (magnification x25) with a 90D lens attached. Mites were identified by their morphology and movement patterns. The number of mites per lash were documented. Thereafter the slides were transferred to the pathology laboratory to examined them under a light microscope, and the results were documented. The same procedure was followed with a control group (22 patients). The results were evaluated both per lash and per patient. The findings were expressed in number of mites and in positive (at least 1 mite identified per lash) or negative (no mite identified).

Results: 22 patients were included in the cohort, 11 men and 11 women with an average age of 54.8 years. A total of 176 epilated lashes were examined. The mean total Demodex count per lash was 0.9 ±1.3 mites by slit-lamp examination and 1.22 ±1.73 mites by light-microscopy. Corresponding values per patient were 7.3 ±4.4 and 9.7 ±7.18. The correlation between Demodex counts by using the slit lamp and light microscopy was midly-positive and statistically significant per patient (8 lashes, $r= 0.69$, $P<0.001$). Analysis of positive/negative results yielded 43.2% with a positive result for slit lamp and 51.7% for light-microscopy. The sensitivity of the slit lamp examination for the presence of Demodex per patient was 96.6%, with a specificity of 90.9%; the positive predictive value was 91.6% and the negative predictive value was 95.2%.

Conclusions: Our results are consisting with our hypothesis that Demodex infestation in patients with blepharitis and cylindrical dandruff can be confirmed using a slit lamp, and this technique is non-inferior than the light-microscopy examination.

ABSTRACT BODY:

Purpose: Variability across individuals is rarely explored in perceptual and physiological research. We tested the hypothesis that inter-subject differences in the biomechanics of the human lens could be measured in vivo.

Methods: Inclusion criteria- age 44 through 55 years; best-corrected visual acuity (BCVA) of 20/20 or better in each eye; no abnormalities of the cornea, pupil or lens; no history of ocular trauma or surgery; and no sign of cataract in the undilated eye. Along with standard clinical exams, the test measures included distance-corrected near visual acuity (DCNVA), accommodative amplitude (AA) and the Near Acuity Visual Questionnaire (NAVQ, higher scores indicate greater difficulty with tasks such as reading small print). Longitudinal scans of the lens were performed with the Brillouin Optical Scanning System (BOSS^{TM}, Intelon Optics), to measure the axial thickness and elasticity ("longitudinal elastic modulus", LEM) of the lens.

Results: Of 33 subjects, binocular LEM values were obtained from 28 subjects (9 males) and monocular values from a further 4 (2 males). Subject age (mean±SD of 49.8±3.3 years) was significantly correlated with vertical cup-to-disc ratio (CDR), AA and DCNVA ($P \leq 0.001$). DCNVA also correlated with CDR and AA ($P < 0.001$). With eyes grouped by the degree of presbyopia (based on DCNVA, mild= 20/25 or 20/32; moderate= 20/40 or 20/50; severe= 20/63 or 20/80), analysis of variance tests showed the following significant differences in the clinical data: smaller CDR and greater AA for the mild group than the other two groups ($P < 0.001$) and higher IOP in the severe group than the moderate ($P = 0.007$). The NAVQ scores ranged from 0 to 100 (out of 100) and were significantly correlated only with DCNVA ($P = 0.006$). Compared with the clinical measures, LEM was positively correlated with AA ($P = 0.005$) and negatively correlated with DCNVA ($P = 0.02$) and spherical equivalence ($P = 0.03$). The BOSS data showed good repeatability within subjects (median variability within each eye of ≤6.1% for LEM and thicknesses) but varied considerably across subjects.

Conclusions: Across this small range of participant ages and BCVAs (20/15 to 20/20), differences were found between individuals in terms of self-reported difficulty with near vision and in lens elasticity and size, even for those of the same age and/or DCNVA. Thus, BOSS scans provide a non-contacting measure of individual differences in lens biomechanics.

ABSTRACT BODY:

Purpose: Glucose acts as a competitive inhibitor for vitamin C to cross the blood retinal barrier. Hyperglycemia reduces vitamin C levels in the eyes. Vitamin C acts as a cofactor for the Ten Eleven Translocation Oxidase (TET) enzymes, which are required for active DNA demethylation. Experiments were performed using primary, human retinal endothelial cells to elucidate the effects of vitamin C deficiency on the breakdown of the blood retinal barrier in diabetic retinopathy.

Methods: Primary human retinal endothelial cells were treated either with or without 50 micromolar vitamin C and RNA was extracted. Whole transcriptome sequencing (RNA-seq) was used to determine transcription changes genome wide. Pathway analysis was performed using EnrichR, GOrilla, and Gene Set Enrichment Analysis (GSEA).

Results: After treatment with vitamin C, 437 genes were found to have upregulated transcription and 308 genes were found to have downregulated transcription. Pathway analysis highlighted changes in several pathways that may elucidate changes that occur in retinal endothelial cells that may contribute to the pathogenesis of diabetic retinopathy, such as Insulin-like growth factor 1 (IGF-1) signaling, which was reduced after treatment with vitamin C. Although the contribution of IGF-1 to diabetic retinopathy has been largely attributed to stimulation of production of vascular endothelial growth factor A (VEGFA) in retinal pigment epithelial cells (RPE), knockout of IGF-1 receptors in retinal vascular endothelial cells was shown to reduce neovascularization in an oxygen-induced retinopathy mouse model. Additionally, VEGFA-VEGFR2 signaling pathways were reduced after treatment with vitamin C. New blood vessels from proliferative diabetic retinopathy have been found to regress after anti-VEGF treatments, and anti-VEGF is similar in efficiency to panretinal photocoagulation.

Conclusions: These data suggest that local vitamin C deficiencies in the eyes of diabetics affect signaling in the retinal endothelial cells which may contribute to the breakdown of the blood-retinal barrier in diabetic retinopathy. Specifically, vitamin C reduces IGF-1 signaling and VEGF signaling in retinal endothelial cells.

ABSTRACT BODY:

Purpose: While much is known about the timeline of retinal vascular development in preterm infants, little is known about the developmental trajectory of the choroid. We characterized changes in choroidal thickness from 30 to 60 weeks postmenstrual age (PMA) using optical coherence tomography imaging (OCT) in preterm infants.

Methods: Infants underwent imaging with investigational hand-held OCT as part of the prospective, observational, IRB-approved Study of Eye Imaging in Preterm InfantS (BabySTEPS). Average choroidal thickness across the central subfoveal 1 millimeter in each eye at each time point was measured using custom segmentation software. Eyes imaged at three or more distinct time points between 30 and 60 weeks PMA were included in the analysis. A segmented mixed model was used to analyze the change in choroidal thickness as a function of PMA.

Results: We included 1159 imaging sessions of 85 preterm infants (166 eyes). Average gestational age was 27.7 ± 2.6 weeks. Between 30 and 60 weeks PMA, choroidal growth follows a biphasic model, with a linear growth rate of 13.9 µm per week (95% confidence interval 12.8-14.0 µm) from 30 weeks until 38.2 weeks then cessation of growth, with a growth rate of -0.20 µm per week (95% confidence interval -1.48 to 1.07 µm) from 38.2 weeks to 60 weeks. Mean (±standard deviation) of choroidal thickness was 151.8 ± 38.9 µm at 31±1 weeks, 274.1 ± 86.0 µm at 41±1 weeks, and 301.0 ± 82.4 µm between 50 and 60 weeks.

Conclusions: The choroid experiences rapid linear growth from 30 weeks PMA until 38 weeks PMA, at which time the choroidal thickness is similar to that of a healthy adult. These foundational measurements will be essential as we learn more about choroidal development in preterm infants and the role of the choroid in ocular and retinal health.

ABSTRACT BODY:

Purpose: CRYßA3/A1 is a lens-specific structural protein. However, in the RPE, recent evidence suggests that CRYßA3/A1 is also a lysosomal-resident protein where it controls autophagy and phagocytosis by regulating endolysosomal acidification via modulating the V-ATPase proton pump. G91-deletion (βA3ΔG91) is a common mutation in CRYßA3/A1 that causes autosomal dominant congenital cataract in humans. In this study, the purpose was to explore the molecular mechanism of βA3ΔG91-induced congenital cataract development.

Methods: We generated a βA3ΔG91 mouse model using CRISPR-Cas9 methodology at the UAB Transgenic & Genetically Engineered Models Core (TGEMs) facility. Comparative phenotypic- and biochemical characterizations of lenses from 1-month-old βA3ΔG91- and wild-type (WT) mice were performed. The methodologies used were non-invasive slit lamp examination, cellular migration assay, hematoxylin and eosin (H&E) staining, immunohistochemical (IHC) and western blot analyses and TUNEL assay. During the analyses, anti-βA3-, anti-p62-, anti-LC3- and anti-GAPDH antibodies were utilized.

Results: Slit-lamp examinations of lenses of 15-days- and 1-month old lenses showed that the βA3ΔG91 mice developed nuclear cataract and microphakia relative to age-matched WT mice. Scratch assay showed that βA3ΔG91 LECs had a relatively slower cellular migration rate than the WT cells. Comparative H&E- and Hoechst staining exhibited abnormally high number of nuclei and their debris in the inner and outer cortex of lenses of βA3ΔG91 than WT mice, suggesting an impaired nuclear degradation process. The IHC analyses showed ring-shaped overlapping expressions of LC3 A/B and CRYßA3 that were limited to the inner cortex of the βA3ΔG91 lenses. Additionally, βA3ΔG91 lenses also exhibited relatively higher p62 expression, lower CRYßA3 expression and greater apoptotic cells in the lens cortex in the TUNEL assay. These findings were further confirmed by western blot analyses.

Conclusions: The study shows an association of impaired autophagy in βA3ΔG91-lenses relative to WT lenses. It is probable that the presence of the greater autophagic cargo might be due to G91-deletion in βA3-crystallin and a lysosomal defect.

ABSTRACT BODY:

Purpose: Choroideremia (CHM) is a progressive, blinding X-linked chorioretinal dystrophy caused by mutations in the CHM gene encoding Rab escort protein-1. The purpose of our ongoing study (NCT02994368) is to evaluate the rate of progression of CHM using functional and anatomical assessments and to establish valid endpoints for future interventional trials.

Methods: Key eligibility criteria for this observational study include males age ≥ 14 years with a clinical and molecular diagnosis of CHM; best-corrected visual acuity (BCVA) score ≥34 ETDRS in the worst eye; presence of preserved ellipsoid zone (EZ) and outer nuclear layer within the central 10^{o} (using SD-OCT); and measurable visual fields. Each eye's disease stage was characterized based on preserved visual fields (VF) using the Goldmann III_{4e} spot size or equivalent; Type 1 is advanced with < 30 degree VF and Type 2 is early/intermediate with ≥ 30 degree VF. Both eyes were followed with semi-annual assessments for 24 months. Study assessments included BCVA, preserved fundus autofluorescence area (PFAF), and static perimetry (SP) with mean sensitivity, total hill of vision (V_{TOT}) and central vision (V_{30}) analyses. A central reading center graded PFAF images and visual fields.

Results: Subjects (n=55) were enrolled at 5 sites in the US and Canada; 4 subjects discontinued after the screening visit. The majority were non-Hispanic White (92.7%). Mean age ± SD was 32.8 ± 11.2 years. Most eyes at screening were assessed as Type 2 (81%); analysis by disease stage was limited due to the small proportion of Type 1 eyes (14%) enrolled. Subjects who completed the 24-month follow up visit (n=47, 85%) were included in the analysis. Baseline values and annualized rates of change are shown in Table 1. Correlations with PFAF area for SP mean sensitivity, SP V_{TOT}, and SP V_{30} at baseline are shown in Table 2. Analysis based on disease stage or pooled sample yielded similar results.

Conclusions: Similar to previous reports, BCVA remained stable, but PFAF and visual field parameters declined significantly over 24 months. Strong correlations were observed between PFAF area and visual field parameters at each visit. These findings have important implications for quantification and monitoring of structural and functional disease progression in CHM future interventional treatment trials.

ABSTRACT BODY:

Purpose: To determine the genotype-phenotype correlation in patients with RPGR retinal dystrophy, the commonest form of X-linked and recessive retinitis pigmentosa. Post-translational glutamylation of photoreceptor-specific RPGR ORF15 by TTLL5 enzyme is essential for its function. TTLL5 needs to bind to ORF15 via the C-terminus to glutamylate RPGR. Since TTLL5 loss leads to cone-rod phenotype, in which normal RPGR would not be glutamylated, we hypothesise that the phenotype of distal RPGR mutations would merge with TTLL5 retinal dystrophy.

Methods: We conducted a retrospective study of 102 male patients with RPGR disease at three specialist centres and recorded results of ophthalmic examination, retinal imaging, microperimetry and molecular genetic analysis by next-generation sequencing. In vitro assays were performed to assess the level of RPGR glutamylation in distal mutations and analyse the level of interaction with TTLL5 in these mutant constructs compared to wild-type RPGR.

Results: Of 102 male patients with genetically confirmed RPGR variants, 99 were deep phenotyped. 13 patients had advanced disease with pan-retinal photoreceptor dysfunction. 64 out of remaining 86 patients (74%) had predominant rod-cone phenotype, 18/86 (21%) had cone-rod, 3/86 (3%) had cone only phenotype and 1/86 (1%) patients had mixed cone and cone-rod phenotype. Most mutations associated with cone-rod phenotype were in the distal part of the ORF15 region and those with cone only phenotype were in the very distal part including the basic domain. In-vitro glutamylation assay showed that all tested truncating mutations with a predominant cone phenotype (n=3) had reduced levels of glutamylation, with variable degree of interaction with TTLL5 enzyme.

Conclusions: Mutations found at the proximal N-terminus of RPGR are associated with predominant rod-cone phenotype, with increasing cone involvement towards the distal C-terminus and a predominant cone phenotype associated with the very distal mutations. In-vitro studies demonstrate the importance of glutamylation for normal functioning of RPGR, as the very distal mutations that result in almost full-length normal RPGR, reduce glutamylation and lead to retinal disease with cone phenotype. The application of RPGR with reduced glutamylation in gene therapy clinical trials may convert a rod-cone dystrophy into a cone dystrophy phenotype.

ABSTRACT BODY:

Purpose: To investigate the association of common systemic medication use with intraocular pressure and glaucoma prevalence in the European population.

Methods: We examined associations of systemic medication use with intraocular pressure and glaucoma prevalence in a meta-analysis of multiple cohort studies of the European Eye Epidemiology (E3) consortium. IOP measurement method and glaucoma ascertainment were according to individual study protocols. Multivariable regression (linear for IOP and logistic for glaucoma prevalence) was carried out in each study and results pooled using random effects meta-analysis. Age, sex, body-mass index and diabetes were included as co-variables. Associations of antidiabetic medications were evaluated only in diabetic subjects.

Results: A total of 46,845 participants from 11 population-based studies from the E3-consortium were included. In the meta-analysis of our fully-adjusted multivariable models, beta-blocker usage was associated with a lower IOP (all beta-blockers: Beta=-0.33 mmHg, 95% confidence interval (CI)=-0.58 to -0.08; non-selective betablockers: Beta=-0.56, 95% CI=-0.92 to -0.21; selective betablockers: Beta= -0.40, 95% CI=-0.64 to -0.16). In the meta-analysis of our fully-adjusted multivariable models, usage of calcium-channel blockers was positively associated with a higher glaucoma prevalence (all calcium-channel blockers: OR=1.25, 95% CI=1.05 to 1.50; selective calcium-channel blockers with mainly vascular effects: OR=1.27, 95% CI=1.05 to 1.53; selective calcium-channel blockers with direct cardiac effects: OR=1.54, 95% CI=1.07 to 2.21). Usage of RAS-inhibitors, diuretics, alpha-agonists, statins, fibrates,

non-selective monoamine reuptake inhibitors, selective serotonin reuptake inhibitors, and antidiabetic medications was not associated with IOP or glaucoma.

Conclusions: Our study supports and quantifies the known IOP-lowering effect of systemic beta-blockers, but there was no evidence of an IOP-lowering effect of other commonly used systemic medications. The usage of calcium-channel blockers (both with vascular and direct cardiac effects) was associated with a higher prevalence of glaucoma but not with higher IOP. Further studies are required to probe whether this harmful association of calcium-channel blockers with glaucoma is causal.

ABSTRACT BODY:

Purpose: The aim of this study was to investigate expression and regulation of two of several receptors for PEDF, patatin-like phospholipase 2 gene product/PEDF-R and laminin receptor (LR), in serum-starved RGCs under hypoxia, which is a relevant pathological condition in retinal neurodegenerative diseases such as glaucoma or ischemic retinopathies, and explore their involvement in the survival of retinal neuronal cells. Changes in the expression of some neuroprotective factors (PEDF, VEGF, BDNF) and anti-apoptotic Bcl-2 family members (Bcl-2, Bcl-x_L), when reducing the expression of PEDF receptors. In addition, we have also evaluated whether ERK1/2 signaling pathway was involved in the process which PEDF exerts pro-survival effects on retinal ganglion cells.

Methods: Using RGCs isolated from mice eyeballs and the immortalized retinal cell line R28 as the main research objects. Immunocytochemical Staining, RNA Interference, qPCR, and western blot techniques, were used to detect the expression levels of PEDF-R and Laminin-R under different stimulations. After knocking out PEDF-R and LR genes with interfering RNA, the expression level of neuroprotective factors and anti-apoptotic Bcl-2 family-related factors were detected. Western blot technology was also used to explore the phosphorylation level of ERK1/2 signaling pathway.

Results: RGCs and R28 cells express both PEDF-R and LR. PEDF and VEGF exposure, as well as the presence of Müller cells, enhance the expression of both receptors. These expression trends were the same under hypoxic conditions. After knocking down PEDF-R and LR, the anti-apoptotic Bcl-2 family members' (Bcl-2, Bcl-x_L) and neuroprotective mediators' (PEDF, VEGF, BDNF) expression was significantly reduced. PEDF treatment enhanced the phosphorylation level of ERK1/2 in R28 cells.

Conclusions: The enhancement of PEDF-R and Laminin R under hypoxia sensitizes retinal neurons to interaction with PEDF, which leads to increased cell viability through induction of anti-apoptotic Bcl-2 family members, expression of secretable pro-survival factors, and suppression of apoptosis. ERK1/2 signaling pathway might be involved in the PEDF's action. Elucidating PEDF-R, Laminin R function and signaling pathways regulating receptor-promoted RGC survival may be helpful in developing more efficient treatment options for retinal neurodegenerative diseases.

ABSTRACT BODY:

Purpose: To investigate the dominant source of the laser speckle flowgraphy (LSFG) signals using optical coherence tomography (OCT) derived retinal and choroidal metrics.

Methods: LSFG, OCT and OCT angiography (OCTA) imaging were performed using a custom-designed LSFG system and a commercial swept-source OCT (SSOCT) system. Mean LSFG map was obtained to enhance the signal-to-noise ratio by averaging individual LSFG maps over multiple cardiac cycles. Standard 6-by-6 mm OCTA map of the retina was generated by the SSOCT system. Choroidal vasculatures were visualized from OCT scans using an attenuation correction method. Large retinal vessels were identified using the retinal OCTA image and the corresponding vessel areas were excluded from LSFG, retinal and choroidal data, leaving the background area for analysis. Two-dimensional metrics maps, including retinal thickness (RT), vessel area density (VAD), vessel skeleton density (VSD), vessel complexity index (VCI), vessel diameter index (VDI), and vessel perimeter index (VPI) of the retina, and choroidal thickness (CT), choroidal vessel volume (CVV), and choroidal vessel index (CVI), were obtained for the quantification analysis. Topographic correlation analysis was then performed between the maps of LSFG and the retinal and choroidal metrics.

Results: 10 normal subjects (6 females and 4 males, age range: 24~35 years old) without any known eye diseases were involved in this study. The mean LSFG map exhibited good accordance with the CT and CVV maps. In comparison, the retinal metrics presented generally homogenous distribution of values which was different from the mean LSFG map (Figure 1). Statistically, LSFG signals were significantly correlated with CT and CVV (Spearman's correlation coefficient, $\rho > 0.6$ and p-value < 0.01), but were generally not correlated with all the retinal metrics and CVI ($|\rho| < 0.5$ and p-value > 0.05).

Conclusions: LSFG signals were correlated with the choroidal thickness and vessel volume, suggesting the choroidal blood flow are the dominant source of the LSFG signal.

ABSTRACT BODY:

Purpose: Glaucoma is a group of complex optic neuropathies, which cause vision loss in more than 70 million people worldwide. Its pathophysiology is not fully understood. Since retinal ganglion cells (RGCs) have a high energy demand, suboptimal mitochondrial function may put the survival of these neurons at risk. In the present study, we explored if peripheral blood lymphocytes (PBL) mitochondrial DNA (mtDNA) quantity or quality could reflect a role for mitochondrial impairment in development of primary open angle glaucoma (POAG).

Methods: We have selected four age- and sex-matched groups, namely POAG patients with high intraocular pressure at diagnosis (high tension glaucoma: HTG; n=98), normal tension glaucoma patients (NTG, n=37), ocular hypertensive controls (n=9), and cataract controls (n=32), all without remarkable comorbidities. PBL DNA was isolated and mtDNA copy number was assessed by qPCR quantification of mitochondrial D-loop and nuclear B2M gene. MtDNA copy number comparison between the groups was conducted using Kruskall-Wallis test combined with Dunn's multiple comparison test in GraphPad Prism and R software (V4.1.2). In addition, the presence of the common 4,977 base pair mtDNA deletion was assayed by a sensitive PCR, which amplified the region containing the specific breakpoints in the mitochondrial genome.

Results: Analysis of the mtDNA copy number revealed a significant reduction in HTG patients (median mtDNA copies per cell: 60.82, interquartile range (IQR): 47.75-80.26) compared with NTG patients (median mtDNA copies per cell: 76.77, IQR: 62.30-99.54, p-value < 0.01) and cataract controls (median mtDNA copies per cell: 85.90, IQR: 71.82-105.1, p-value < 0.001), but not with ocular hypertensive controls (median mtDNA copies per cell: 77.22, IQR: 67.98-109.8). The common 4,977 base pair mtDNA deletion was not detected in any of the participants.

Conclusions: The mtDNA copy number was reduced in PBL-DNA of HTG patients. Most likely, this reflects a suboptimal mitochondrial function, which together with ageing and/or high intraocular pressure, may lead to mitochondrial dysfunction during life in RGCs and may contribute to glaucoma pathology in some HTG patients. These patients may be amenable for a mitochondria-targeted drug treatment.

ABSTRACT BODY:

Purpose: To report on the presence of both dominant and recessive RP1-related retinitis pigmentosa in different members of the same non-consanguineous family.

Methods: In this case series, three members of the same family - the daughter, father and mother - were investigated. They underwent clinical assessment by dilated fundus examination and multimodal imaging. Molecular analysis of 111 genes associated with retinitis pigmentosa and retinitis pigmentosa-like phenotypes was undertaken probing the RP1 gene capturing the coding exons and 10 base pairs of the flanking introns of the 111 genes. Putative pathogenic variants were confirmed by Sanger sequencing.

Results: The 38-year-old father was diagnosed with an asymptomatic mild phenotype of rod-cone dystrophy detected by his optometrist, which was subsequently confirmed to be caused by a previously described dominant RP1 c.2613dupA mutation. He was reassured that his 11-year old daughter had a 50% chance of inheriting the same mutation and that the condition, if she had it, would most likely be mild. Clinical phenotyping of his daughter however showed a severe case of early onset cone-rod dystrophy. The mother was asymptomatic and clinically normal. Sanger sequencing of the RP1 gene in the daughter confirmed the presence of biallelic mutations – the dominant c.2613dupA variant from her father and a novel c.3843dupT truncating variant inherited from her mother, both located in exon 4 of the RP1 gene.

Conclusions: Mutations in exon 4 of RP1 are known to cause differential dominant and recessive disease. The novel c.3843dupT variant is likely to act in an autosomal recessive manner, since the heterozygous mother is clinically unaffected. Its pathogenicity is also supported by the previously reported c.3843delT mutation at the same nucleotide and results in a similarly truncated RP1 protein. The father is mildly affected by a known dominant variant which truncates the RP1 protein more proximally. However, inheritance of both variants in a compound heterozygous state in the daughter resulted in a much more severe, early onset cone-rod phenotype, in a pattern akin to recessive disease. This raises challenges for genetic counselling and development of gene-based therapies for RP1 mutations.

ABSTRACT BODY:

Purpose: High resolution optical coherence tomography (HR-OCT) provides unprecedentedly detailed views of retina and choroid. Small perturbations of retinal pigment epithelium-basal lamina-Bruch's membrane band (RPE-BL-BrM) represent earliest stages of AMD. To inform the interpretation of HR-OCT-anchored multimodal imaging, we identified small drusen by histology and fluorescein angiography.

Methods: We surveyed Project MACULA (https://projectmacula.org/) an online resource of epoxy-resin histology of human donor eyes (N=54, aged-normal; N=24 early-intermediate AMD; N=13 geographic atrophy). Nodular drusen located between RPE- BL and inner collagenous layer of BrM were solid, globular, and homogeneously stained with toluidine blue. They lacked overlying basal laminar deposit (BLamD, between RPE and native BL) and basal mounds (soft drusen material within BLamD). Soft drusen material in any location was granular and light grayish brown. In images acquired with an oil immersion objective, base widths of single (non-confluent) nodular drusen were measured using FIJI. In one eye with non-exudative neovascular AMD, an area of punctate hyperfluorescence in late-phase fluorescein angiography (FA) 11 years before death (PMID 32247535) was mapped in histology.

Results: In 104 images from 43/92 eyes, small lesions included nodular drusen, 53 images; small soft drusen, 8; BLamD / basal mounds, 33; multilayer BLamD / BLinD-drusen, 10. The Figure shows that the range of nodular drusen (N=128) widths was 2.2 to 110 μm (median, 13.0 μm; interquartile range 7.7, 20.0 μm). In the eye with late phase FA, 91 similar-sized nodular drusen were found in an area with small circles of uniform fluorescence.

Conclusions: In two samples, 90% and 95% of nodular drusen (92% total) have base width <30 μm, a size just visible in color fundus photography (CFP; PMID 10365048). Results support reports that CFP reveals depigmentation over drusen and underestimates drusen dimensions, relative to histology and OCT (PMID 32568988, 33411474). The FA appearance is consistent with staining of individual drusen. Whether these deposits resemble cuticular drusen with "starry sky" angiograms needs further research (PMID 7525362, 10365048, 20924263, 28964580). Direct visualization of a sequence from numerous small drusen to soft drusen (PMID 17270675, 25905023) may be possible.

TITLE: Dynamic Prediction Model for Treatment-requiring Retinopathy of Prematurity

SESSION TITLE: Public Health

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: G. Ying, Y. Yu, Ophthalmology, University of Pennsylvania, Philadelphia, Pennsylvania, UNITED STATES|G. Binenbaum, Ophthalmology, The Children's Hospital of Philadelphia, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Gui-Shuang Ying: Commercial Relationship: Code N (No Commercial Relationship) | Yinxi Yu: Commercial Relationship: Code N (No Commercial Relationship) | Gil Binenbaum: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Prior risk models for retinopathy of prematurity (ROP) have been based on risk factors assessed at a single time point, even though risk factors can change over time. We sought to develop and validate a dynamic prediction model for treatment-requiring ROP (TR-ROP) using time-updated risk factors in two large, broad-risk cohort studies of premature infants.

Methods: Secondary analyses were performed using data from the G-ROP-1 study (retrospective, 7483 infants from 29 hospitals, 2006-2012) for model development and data from the G-ROP-2 study (prospective, 3980 infants from 41 hospitals, 2015-2017) for model validation. The outcome was development of TR-ROP (e.g., type 1 or treated ROP). Risk factors considered for the prediction model included birth weight [BW], gestational age [GA], gender, race, oxygen use, Sepsis/NEC, thrombocytopenia, maternal or donor milk feedings, weight gain rate, a time-updating previously validated ROP severity score, and postmenstrual age (PMA). Univariable and multivariable repeated measures logistic regression models were performed to identify predictive risk factors. Area under the ROC curve (AUC) was calculated to evaluate the prediction model performance.

Results: TR-ROP occurred in 524 (7.0%) of G-ROP-1 infants (median GA 28 wks; median BW 1099g) and 256 (6.4%) of G-ROP-2 infants (median GA 28 wks; median BW 1072g). Using G-ROP-1 data, a dynamic prediction model (Table 1) was developed that included BW ($p<0.001$), race ($p<0.001$), week of first enteral feeds during the first 6 weeks of life ($p<0.001$), time-updating thrombocytopenia ($p=0.004$), NEC/sepsis ($p=0.004$), slow weight gain ($p=0.004$), ROP severity score ($p<0.001$), PMA, and interaction term between ROP severity score and PMA ($p<0.001$). This prediction model had an AUC of 0.88, which was significantly higher than a prediction model based on BW and GA only (AUC=0.77, $p<0.0001$). A prediction model that included significant predictors (BW, GA, race, ROP severity score, PMA, and interaction between ROP severity score and PMA) that were available in both the G-ROP-1 and G-ROP-2 datasets had an AUC of 0.86 in G-ROP-1 and 0.87 in G-ROP-2 (Table 2).

Conclusions: Our developed and validated dynamic prediction model that considers time-updating ROP severity score and other traditional and novel risk factors may provide a tool for dynamically identifying high risk premature infants that are likely to develop TR-ROP.

ABSTRACT BODY:

Purpose: Understanding of the ocular manifestations of coronavirus disease 2019 (COVID-19) is continuing to develop. While ocular symptoms, chiefly conjunctivitis, have been reported, retinal pathologies have been suggested as a rarer complication and are hypothesized to derive from a combination of the inflammatory and vasculopathic effects of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection. Using a retrospective, observational case series design, we describe a series of four eyes in three patients with acute macular neuroretinopathy (AMN) and paracentral acute middle maculopathy (PAMM) associated with COVID-19 illness.

Methods: Our practice's electronic medical record (EMR) was retrospectively queried for patients from April 2020 to December 2021 who had been diagnosed with AMN or PAMM and COVID-19 illness. Three patients were identified by this method. Patient demographic information, physical exam, optical coherence tomography (OCT), infrared reflectance (IR), and fluorescein angiography (FA) studies were all used for analysis.

Results: Imaging signs of AMN were revealed in four eyes in three female patients, aged 22, 32, and 64 years old, all with confirmed symptomatic COVID-19 corresponding to the start of visual symptoms. The average onset of visual symptoms from COVID-19 illness was 14 days (range 0–56). 4/4 eyes were symptomatic for scotomata. Average logMAR visual acuity was 0.024 (Snellen 20/21, range 0–0.097). 4/4 eyes demonstrated typical findings of AMN: IR imaging with prominent dark petaloid or ovoid parafoveal lesions and corresponding disruption of the ellipsoid zone on OCT (Fig. 1). FA imaging did not show any abnormal fluorescence pattern. Autofluorescence in 1/4 eyes demonstrated hyperautofluorescence corresponding to the abnormal area on IR imaging (Fig. 2). Two month follow-up showed persistent symptoms of scotomata with unchanged findings on follow-up imaging in 100% of cases.

Conclusions: This series demonstrates that, although rare, SARS-CoV-2 infection may result in microvasculopathic injuries to the retina, namely AMN and PAMM.

ABSTRACT BODY:

Purpose: To assess the prevalence and characteristics of preterm infants with Retinopathy Of Prematurity (ROP) treated outside the recommendation guidelines.

Methods: In this retrospective monocentric cohort, we included all premature babies treated in our department for ROP by photoablative laser or anti-VEGF intravitreal injection. Main outcome was treatment of both eyes for ROP less severe than type 1.

Results: A total of 114 children received treatment for ROP in our department, among them 32 (28.1%) children received treatment for off-label indications. The off-label indications were persistent stage 2 or 3 ROP that showed no evidence of regression after 41 weeks of corrected gestational age (11 children; 34.4%), pre-plus stage (11 children; 34.4%), difficulties in disease staging (7 children; 21.9%), type 2 ROP with plus disease (2 children; 6.2%), and logistical difficulties (1 child, 3.1%). In the off-label treated group, mean gestational age was 25.3±1.4 weeks and mean birth weight was 734±174 grams. Off-label treated children were older (40.6±7.0 weeks vs. 37.4±3.6 weeks; p=0.002) and received less laser impacts (1460±207 vs. 2007±171 impacts; p=0.03). In the group treated inside the guidelines, 10 babies received bilateral treatment with one eye less severe than type 1 ROP.

Conclusions: To resume, in our cohort 28.1% of babies received treatment for ROP less severe than type 1. Main indications for off-label treatment were the persistence of active ROP during follow-up and the presence of pre-plus stage disease. If thisOur data suggests the need to update ROP treatment criteria to reflect real-life practices. Additional studies are required to evaluate long-term impact of a treatment outside the recommended indications and to establish revised treatment guidelines.

ABSTRACT BODY:

Purpose: Fluorescence lifetime imaging ophthalmoscopy (FLIO) allows for unprecedented temporal resolution of the macular fluorescence signal. Current visualization techniques for FLIO rely on hand-adjusted parameters that may not be reproducible. Here we fully-automate the visualization of FLIO data by embedding in a lower dimensional space, merging 1-D autoencoder and classification deep learning networks.

Methods: FLIO images were collected from healthy (n=91), MacTel (n=128) and AMD (n=30) eyes for the short (f1) and long (f2) spectral channels (each with 1024 time bins). The images were patient-split 80/20 into training and validation sets. Labels for vessels were segmented using a threshold on the mean across time. A parafoveal window of 64x64 pixels was extracted from each train subject and each pixel time course (f1 and f2) was truncated to 512 time points and labeled as either: Healthy, MacTel, AMD, or vessel. The f1 and f2 time courses were embedded into two dimensions with parallel autoencoders linked through a 4-class classification head (see Figure 1A). The whole validation images (256x256) were embedded into four dimensions (two each for f1 and f2) and visualized.

Results: We achieved a validation accuracy of 80.0% and correlation coefficients of 0.911 and 0.957 between the true and decoded time courses for f1 and f2, respectively (Fig 1B). The examples of the decoded time courses are more smooth but preserve the shape of the true FLIO time courses (Fig 1C). The example MacTel embeddings show changes in the perifoveal area while the example AMD embeddings show a more widespread alteration throughout the macula (Fig 2).

Conclusions: Utilizing autoencoders linked with a classification head, we created an embedding that is sufficient to recover the original signal (autoencoder) and is designed to be disease specific (classification). This fully-automated approach may enable FLIO to be used as a biomarker in future clinical studies.

ABSTRACT BODY:

Purpose: Treatment for autosomal dominant retinitis pigmentosa (adRP) by gene therapy is challenging, due to genetic heterogeneity. We used innovative NANOBODY® technology to test our hypothesis that nanobodies (Nbs), due to their nano-scale size, would efficiently stabilize P23H mutant RHO and restore rhodopsin homeostasis without cellular toxicity in an in vitro HEK293 cell model of RP. We also characterized the thermodynamics and crystal structure of the Nb-RHO complexes to assess the binding stability and identify the interface between the Nb and its target.

Methods: 29 Nbs were raised against native bovine rod outer segments (ROS). After confirming their binding affinity to native bovine ROS by gel shift assay, selected Nbs were expressed intracellularly in bovine wild type (WT)-RHO cells, or P23H-RHO HEK293 cells. Accumulation of mutant RHO by the Nbs was evaluated by Western blot and UV-visible spectroscopy, relative to controls with non-binding Nb. The stability of the antigen-antibody interactions was analyzed by spectroscopy at different temperatures and pH in light or dark conditions over the period of 11 days. Crystal structures of the Nb-RHO complexes were collected and analyzed along with the results from alanine-scanning mutagenesis in Nb-complementarity-determining regions.

Results: Among the 29 Nbs, 4 Nbs showed a gel shift, indicative of binding to native bovine ROS in a dose-dependent manner. Nb-RHO complexes maintained an equilibrium between ground and active states for 11 days after bleaching in the dark, at 4 ^{o}C or room temperature (RT). Under light conditions, the complexes were still stable at 4 ^{o}C, but gradually bleached and degraded at RT. While P23H-RHO levels were lower compared to WT-RHO by Western blot, intracellular co-expression of Nb in P23H cells significantly increased RHO protein levels ($P<0.05$), relative to the non-binding Nb control. Crystal structure and alanine-scanning results revealed the binding epitopes of Nb to RHO in its extracellular loop II and the N-terminal tail, explaining the action mechanism on mutant P23H stabilization.

Conclusions: Intracellular expression of Nbs rescues the mutant RHO phenotype in an in vitro HEK293 adRP model, suggesting therapeutic potential of the nanobody technology. Since there are few treatment options for RHO-adRP, NANOBODY technology might offer a new treatment option regardless of a patient’s genetic background.

ABSTRACT BODY:

Purpose: Aging is associated with inflammation and oxidative stress. In the eye and lacrimal gland (LG), increasing age is associated with chronic inflammation, a greater infiltration of immune cells, and tissue damage. Heterochronic parabiosis is an experimental method used to identify how soluble serum factors impact aging and disease. We investigated if heterochronic pairing of mice (young to aged) could modulate age-related eye and LG alterations.

Methods: Male and female PepBoy mice 4 months of age were surgically joined to either another PepBoy or a C57BL/6J (B6) mouse aged 18 months. Pairings were either isochronic (young to young or aged to aged) or heterochronic (young to aged), all same-sexed. Mice were evaluated 2 months post-surgery. General appearance and focus score were investigated in H&E-stained LG sections (n=21 male pairs; n=5 female pairs). LGs were analyzed by qPCR for inflammatory and T and B-cell related markers (n=5 male pairs; n= 6 female pairs).

Results: There were significant increases in focal score in aged-aged pairings compared to young-young pairings (Kruskal-Wallis test; $P<0.0001$). In male LGs, there was a significant increase in focal score in both mice in the heterochronic young-aged pairing (2±2 vs 3±2 focus score/4mm^2) compared to the isochronic young-young and young non-parabiotic (0.8±0.7 and 0±0 focus score/4mm^2, respectively, at least $P<0.01$). There were significant increases in mRNA fold expression of Ctss (3-fold), Ciita (MHC II,3-fold), Cd19 (57-fold), Ccl19 (3.67-fold), and Ifng (IFN-γ,7-fold) by age (young-young vs. aged-aged) in aged female pairs. There were significant sex-related changes in mRNA fold in Cxcl13 (13-fold) and Il1b (2-fold) in isochronic pairs (at least $P<0.05$ for all). Interestingly, we found significant fibrosis in 36% of the aged parabiotic male LGs, irrespectively of pairing.

Conclusions: Our results indicate that serum soluble factors from young mice for 8 weeks were not enough to reverse inflammation and infiltrating immune cells in aged tissues. It is possible that a longer duration of parabiosis is needed. This suggests that age-related changes in the LG microenvironmental/architecture participate in perpetuating inflammation. Therapies that aim at improving cellular health may have a stronger impact on improving inflammation and cellular inflammation in LGs than parabiosis.

ABSTRACT BODY:

Purpose: Primary Open Angle Glaucoma (POAG) is the main cause of irreversible blindness worldwide, being described as a neurodegenerative disease of multifactorial etiology. Thus, the identification of genetic and environmental factors is of utmost importance for early diagnosis and to establish an appropriate clinical management. Multiethnic Genome Wide Association Studies (GWAS) identified single nucleotide variants (SNVs) in the FOXC1, ATXN2 and TXNRD2 genes that may be associated with the pathophysiology and endophenotypes of POAG. However, to our knowledge, these variants have not been investigated in admixed populations, such as the Brazilian population. The aim of this case-control study was to investigate the association of the variants rs2745572 (FOXC1), rs7137828 (ATXN2) and rs35934224 (TXNRD2) as risk factors for the development of POAG in a Brazilian cohort from the Southeast.

Methods: This study comprised 506 cases and 501 controls. Variants rs2745572 and rs35934224 were genotyped through Taqman® assay and validated by Sanger sequencing in 10% of the samples. Variant rs7137828 was genotyped exclusively by Sanger sequencing. Genetic association was estimated through Chi-Square and Logistic Regression tests.

Results: The case group was consisted of 50.99% males, while the control group was composed by 43.11% males (p=0.011). There was no statistical difference in age between cases and controls. The primary research outcome has revealed that the variant rs7137828 (ATXN2), was associated with an increased risk for development of POAG in the presence of the T allele (p=0.0025). Through multivariate logistic regression adjusted for gender, the TT genotype was associated with an increased risk for development of POAG compared to the CC genotype (p=0.006; OR=1.717; IC95%=1.169-2.535). There was no significant association of rs2745572 (FOXC1) and rs35934224 (TXNRD2) variants for alleles and genotypes with POAG.

Conclusions: Our data indicate an association of the variant rs7137828 in homozygosity as well as in the presence of the T allele with an increased risk for POAG in a Brazilian cohort. If validated in additional sub-populations from the country, this finding may enable the development of relevant strategies for early diagnosis of glaucoma in the future.

ABSTRACT BODY:

Purpose: To calculate and compare the average interval between Anti-VEGF injections for patients with diabetic retinopathy (DR), retinal vein occlusion (RVO), and wet age-related macular degeneration (wAMD).

Methods: All data was collected by the practice management of Retina Associates of Cleveland, Inc. Data was collected from patients who received Anti-VEGF injections of Aflibercept (AFL), Bevacizumab (BEVA), Brolucizumab-Dbll (BROL), and Ranibizumab (RAN) from July 2020 through July 2021 and includes patient number, injection service dates, injection service ID's, procedure codes, and primary diagnoses. The patients selected were those injected unilaterally and diagnosed with DR, RVO, or wAMD. The number of days between injection service dates were calculated for each patient. The data set was then organized by primary diagnosis and average number of days between Anti-VEGF injection.

Results: From July 2020 through July 2021, 14,911 patients were injected unilaterally. There were 1,313 DR patients with an average interval between injections of 70 days. There were 2,809 RVO patients with an average interval between injections of 54 days. There were 10,789 wAMD patients with an average interval between injections of 55 days. When comparing average interval between Anti-VEGF injections for DR versus RVO, a two-tailed t-test calculates a p-value of $p<0.01$. When comparing average interval between Anti-VEGF injections for DR versus wAMD, a two-tailed t-test calculates a p-value of $p<0.01$. Lastly, when comparing average interval between Anti-VEGF injections for RVO versus wAMD, a two-tailed t-tests calculates a p-value of $p=0.25$.

Conclusions: The results of this study suggest that patients diagnosed with RVO or wAMD have a shorter interval of time between injections when compared to patients diagnosed with DR. There does not appear to be a significant difference in average injection intervals between patients with RVO and wAMD.

ABSTRACT BODY:

Purpose: Inherited corneal dystrophies may cause severe visual impairment. While phototherapeutic keratectomy or corneal transplantations may provide symptomatic relief, the procedures are associated with high infection and recurrence rates. Gene therapies may provide an alternative and a potentially permanent treatment. Adeno-associated viruses (AAVs) have emerged as the vectors of choice for ocular gene therapy thanks to their established safety profile. This study aimed to investigate limbal injections into human cadaveric tissues using 1) trypan blue as a visual guide and 2) two AAV serotypes to test the in situ transduction efficiency of human limbal stem cells (LSCs).

Methods: Human cadaveric corneal tissues were fixed on an artificial anterior chamber (Katena, Parsippany, NJ, USA). Trypan blue (50-µl) was injected into the limbal region using a beveld 34-gauge needle (JBP Nanoneedle, South Korea) and a 1-ml syringe (BD Syringe, Franklin Lakes, NJ, USA). In parallel, 50-µl of AAV serotypes 1 and DJ (10^{11} genome copies(GC)/mL diluted in phosphate-buffered saline) harboring enhanced green fluorescent protein (eGFP) gene were injected into separate human cadaveric corneal tissues using the same injection technique. Tissues injected with AAV-eGFP were cultured for 2 weeks using the “air-lift” method and evaluated for immunohistochemical staining. Expression of eGFP as well as recombinant stem cell marker p63 was analyzed using a confocal microscope.

Results: Histological assessment showed trypan blue staining of the sub-limbal region, confirming that LSCs can be targeted using the injection technique. Immunohistochemical analysis of the corneal tissues injected with AAV serotypes 1 and DJ show that LSCs co-stain p63alpha, eGFP, and DAPI.

Conclusions: The injection technique could successfully target human LSCs in a reproducible manner, and led to effective transduction of LSCs with AAV serotypes 1 and DJ. Thus, we demonstrate that in situ injection of limbal cells may provide a feasible mode for corneal genetic therapy.

TITLE: Comparison of the Recommended ISCEV and a Modified Analysis Protocol for the PhNR Test.

SESSION TITLE: Electroretinography: basic mechanisms and disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W.H. Ridder, Southern California College of Optometry, Marshall B. Ketchum University, Fullerton, California, UNITED STATES|J. Farmer, Diagnosys, LLC, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: William Ridder: Commercial Relationship(s);Code C (Consultant/Contractor):Abbvie;Code C (Consultant/Contractor):Ionis Pharmaceuticals;Code C (Consultant/Contractor):jCyte, Inc. | Jeff Farmer: Commercial Relationship(s);Code E (Employment):Diagnosys, LLC

ABSTRACT BODY:

Purpose: Several studies have reported that glaucoma patients have abnormal Photopic Negative Response (PhNR) results compared to normal subjects. The International Society for Clinical Electrophysiology of Vision (ISCEV) released an extended protocol standard for PhNR in 2018. The purpose of this study was to compare the standard ISCEV PhNR protocol to a similar protocol modified to enhance the performance of the method in detecting glaucomatous damage.

Methods: Thirty-three subjects were enrolled in this study (12 glaucoma, 10 glaucoma suspects, and 11 control subjects). PhNR tests were conducted with a Diagnosys E3 mobile system (Diagnosys LLC, Lowell, MA) with a monocular ColorBurst stimulator. ISCEV PhNR tests utilized all parameters specified by the ISCEV requirement including 1 cd•s/m^2 red flashes on a 10 cd/m^2 blue background, 1 Hz stimulation frequency, bandpass filters of 0.3 to 300 Hz, and an average of at least 50 recordings. Modified ISCEV PhNR tests used the same parameters as the ISCEV tests with exceptions of 2 cd•s/m^2 red flashes at 1 or 4 Hz stimulation frequency, 5 to 45 Hz bandpass filters and novel, objective sweep selection parameters. All subjects were dilated and PhNRs were conducted with Burian-Allen bipolar electrodes. According to ISCEV standards, the PhNR relative to baseline, a-wave and b-wave response amplitudes and PhNR-baseline/b-wave amplitude ratios were measured. Coefficients of variation and 2-sample t-test were used to assess the data from one randomly chosen eye per subject.

Results: The modified analysis protocol for the PhNR-baseline amplitude resulted in a decrease in the average coefficient of variation for all conditions (Average ISCEV protocol CV = -63% and Modified analysis CV = -41%). The modified analysis resulted in the glaucoma suspects being significantly different from the glaucoma subjects (1 and 4 Hz stimuli with ISCEV analysis p values were 0.083 and 0.838, respectively and with the modified analysis were 0.004 and 0.018, respectively).

Conclusions: The modified analysis protocol resulted in a decrease in within group data variability which resulted in a significant difference between the PhNR-baseline data for the glaucoma subjects and glaucoma suspects. Thus, the modified analysis protocol may result in greater test sensitivity making it a better diagnostic tool.

ABSTRACT BODY:

Purpose: To compare binocular distance, intermediate, and near visual acuity and patient reported outcomes of non-diffractive extended depth of focus (ND-EDOF; Alcon Vivity) and neutral aspheric monofocal (Bausch & Lomb enVista) intraocular lenses.

Methods: This was a prospective, single-center, patient and assessor-masked clinical study. Qualified subjects were randomized to receive either the ND-EDOF or monofocal IOL in both eyes, targeted for emmetropia. Post-operatively, subjects underwent examination at regularly scheduled intervals through 3 months. The primary endpoint was the mean logMAR best-distance corrected visual acuity at intermediate (DCIVA; 66 cm) tested in binocular photopic conditions. Secondary endpoints included binocular best-corrected distance (BCDVA; 4 m) and best-distance corrected near (DCNVA; 40 cm) visual acuity. Subjects' outcomes will also be assessed by way of questionnaires evaluating visual disturbances and spectacle dependence.

Results: Fifty-six subjects have been enrolled to date. Thirty (ND-EDOF = 15; monofocal = 15) and 20 (ND-EDOF = 9; monofocal = 11) subjects have completed the one- and three month study visits, respectively. At one month, the binocular BCDVA, DCIVA and DCNVA's were -0.003 ± 0.09, -0.019 ± 0.12, and 0.03 ±0.13 for the ND-EDOF lens and -0.016 ± 0.05 ($p = 0.83$), 0.17 ± 0.12 ($p = 0.0009$), and 0.17 ± 0.14 ($p = 0.0126$) logMAR for the monofocal IOL, respectively. This equates to two lines of improvement compared to the monofocal lens results. Clinically speaking, the ND-EDOF IOL resulted in 93% of patients obtaining 20/25 or better at intermediate and 87% obtaining 20/25 or better at near. This compares with 40% at intermediate and 47% at near for the same thresholds in patients implanted bilaterally with the monofocal.

Conclusions: The ND-EDOF had similar distance vision and provided two lines of improvement for both intermediate and near vision when compared to the monofocal IOL with a neutral aspheric optical profile.

ABSTRACT BODY:
Purpose: Previously we described the longitudinal glaucoma relationship between structure and function using a broken stick analysis approach to identify the location where the rate of change accelerates or decelerates. In that analysis we used each measurement point as an independent point, aggregated all eyes from all visits, and treated longitudinal data as cross-sectional. Using improved statistical methodology, we accounted for repeated measurements and the use of data from both eyes in the longitudinal model. The purpose of this study is to identify the locations of tipping points and rates of change before and after them in structural and functional measurements.
Methods: Subjects with comprehensive ophthalmic examination and 5 or more visits with qualified visual fields (VF; Humphrey Field Analyzer; Zeiss, Dublin, CA) and OCT (Cirrus HD-OCT; Zeiss) with ONH and macular scans were enrolled. Segmented mixed models that account for repeated measurements were utilized to estimate the tipping points and the difference-in-slope. The number of tipping points was determined by identifying the optimal model using Bayesian information criterion.
Results: 216 eyes (164 open angle glaucoma, 45 glaucoma suspect, and 7 healthy eyes) of 145 subjects were analyzed (Table). Retinal nerve fiber layer (RNFL), and ganglion cell inner retinal layer (GCIPL) decreases and cup to disc ratio (CDR) increases since early stages of the disease were measured (Figure). Unlike previous cross-sectional reports, visual field mean deviation (MD) also decreases along with structural parameters since early stages of the disease. RNFL thinning stalls beyond MD<-15.63dB (Figure A) while GCIPL keeps decreasing (B), and CDR slowly increases (C) throughout the functional damage range. Direct comparison between the structural parameters shows that RNFL thinning decelerates in advanced disease compared to both GCIPL and CDR and GCIPL thinning decelerates compared to CDR.
Conclusions: Structural and functional measurements (RNFL, GCIPL, CDR and MD) are useful to evaluate glaucoma change from early stages of the disease. As glaucoma progresses and RNFL reaches its minimal measurable level GCIPL, CDR and MD remain useful to evaluate the disease. The clinical routine for following subjects with glaucoma should account for the ability to measure relevant parameters at various stages of disease.

SUBMITTER (NAME ONLY): Mitchell Sullivan

TITLE: Circumpapillary retinal nerve fiber layer axon density is reduced in experimental glaucoma eyes.

SESSION TITLE: Neurodegeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Sullivan, M. Gondo, N.B. Patel, Optometry, University of Houston, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure: Mitchell Sullivan: Commercial Relationship: Code N (No Commercial Relationship) | Margaret Gondo: Commercial Relationship: Code N (No Commercial Relationship) | Nimesh Patel: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Histological studies show that there is good correspondence between optical coherence tomography (OCT) determined circumpapillary retinal nerve fiber layer (RNFL) thickness and total retrobulbar axon counts. However, these relationships don't include differences in axon size and distribution with circumpapillary location and disease. The purpose of this study was to determine the variability in axon size and density for six circumpapillary regions, in the non-human primate experimental glaucoma model.

Methods: Four animals with unilateral experimental glaucoma were included in this study. Following endpoint OCT imaging, animals were euthanized, and perfusion fixed with 4% paraformaldehyde. The eyes were enucleated and circumpapillary tissue ~600µm from the rim margin, for the temporal, superior-temporal, superior-nasal, nasal, inferior-nasal and inferior-temporal regions, was dissected. This tissue, was then placed in 2% glutaraldehyde/2% paraformaldehyde and processed for serial block face scanning electron microscopy (SBFSEM). 20x20x20µm SBFSEM volumes were obtained from each block at 100nm, and all axons were delineated for three frames (frame 10, 100, and 190) using imageJ.

Results: Endpoint OCT circumpapillary average RNFL thickness for experimental eyes were 49µm, 52µm, 76µm, and 84µm. For control eyes, the temporal sector had the highest axon density (1.9-3.2 axons/μm^2), while the superior-nasal sector had the lowest (0.9-1.3 axons/μm^2). This difference was maintained in eyes with experimental glaucoma. Although the mean axon diameter in eyes with experimental glaucoma (0.34±0.45µm) was less than that of control eyes (0.36±0.43µm, $p<0.01$), axon density in experimental glaucoma was reduced (control eyes 1.67 axons/μm^2, experimental 1.27 axons/μm^2, $p=0.023$).

Conclusions: To estimate retinal ganglion cell content from in vivo OCT RNFL scans, both circumpapillary location and stage of experimental glaucoma need to be considered. Although in vivo OCT measures of the temporal NFL are the thinnest, it has the smallest axons and greatest density. The smaller axon diameters in glaucomatous eyes could reflect a change in axon morphology, or a selective loss of larger axons.

ABSTRACT BODY:

Purpose: The dynamics of mitochondrial genome partitioning in complex tissues such as the retina have implications for how mitochondrial variants cause disease. In this study, we sought to understand how the most common pathogenic mitochondrial variant (m.3243A>G) is distributed across ocular cell types in eyes from patients with mitochondrial encephalopathy, lactic acidosis, and stroke-like episodes (MELAS), and how this distribution relates to gene expression in ocular cells. We hypothesized that in the eyes of MELAS patients with severe retinal atrophy, the photoreceptors and retinal pigment epithelium (RPE) would harbor high levels of m.3243G.

Methods: We profiled the proportion of the m.3243A>G variant in single cells from the retina, RPE, and choroid of a MELAS patient, as well as from a healthy control donor. Chromatin accessibility and heteroplasmy were assessed using the mitochondrial single-cell assay for transposable chromatin by sequencing (mt-scATACseq), which captures both nuclear and mitochondrial DNA reads. The transcriptomes of single cells from the same samples were profiled in parallel using single-cell RNA sequencing (scRNAseq). Data were analyzed using Seurat and Signac in R.

Results: We find that the proportion of the pathogenic m.3243G allele is neither evenly nor randomly distributed among ocular cell types. While all classes of neural retinal cells and the RPE exhibited a high degree of heteroplasmy, endothelial and lymphocyte populations of the choroid are near homoplasmic for the wildtype m.3243A allele. Single cell gene expression analysis reveals that the presence of the m.3243G allele in neural retinal cells deranges expression of pathways involved in energy metabolism and the response to oxidative stress. However, many of the same pathways in choroidal cell classes homoplasmic for the wildtype allele are also dysregulated.

Conclusions: This work illuminates the non-random segregation of a pathogenic mitochondrial variant in the retina and choroid and demonstrates that the m.3243A>G variant causes non-cell autonomous tissue dysfunction in the complex and metabolically linked light sensing tissue of the eye. Expanding our understanding of the mechanisms that underlie the non-random partitioning of m.3243A>G will enhance management of this and potentially other mitochondrial diseases.

Commercial Relationships Disclosure: Timothy Yap: Commercial Relationship: Code N (No Commercial Relationship) | Benjamin Davis: Commercial Relationship: Code N (No Commercial Relationship) | Philip Bloom: Commercial Relationship: Code N (No Commercial Relationship) | Maria Francesca Cordeiro: Commercial Relationship(s);Code S (non-remunerative):Heidelberg | Eduardo Normando: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To improve the detection of disease progression with novel analysis and display of circumpapillary optical coherence tomography (OCT) progression data.
Methods: Glaucoma rose plot analysis (RPA) was developed to automatically analyse and display progression analysis of circumpapillary retinal nerve fibre layer (cRNFL) OCT data. A clustering technique was employed to allow circumferential statistical determination of progressing regions of varying widths, without the use of predefined sectors. Results were presented in the form of an angular histogram for each eye.

RPA was evaluated using data from primary open-angle glaucoma (POAG) or POAG suspect eyes and compared to a gold-standard determined by three clinicians' assessment of OCT series and linear regression plots. Each eye was graded as 'progressing' or 'stable/unaffected'.

Rose plots were assessed using objective and subjective methods to confirm their relevance and practical application. Objectively, the area of red rose petals was compared. Subjectively, rose plots were assessed by three masked assessors as suspicious of progression or not, with time to diagnosis compared against sequential linear regression of global and sectoral cRNFL values.
Results: A total of 743 scans making up registered series from 98 eyes were analysed. The mean ± SD number of visits was 8.5 ± 3.8 μm in the progressing eyes, and 7.1 ± 2.8 μm in the stable or unaffected eyes ($p = 0.06$). Rose plots were able to distinguish progressing eyes from stable or unaffected eyes with area under receiver-operating characteristic curve (AUROC) of 0.968 (95% CI 0.92-1.00) compared to 0.706 (95% CI 0.585 – 0.826) using global cRNFL thickness. Furthermore, agreement on progression status between clinician graders using RPA was greater than when assessing OCT scans and linear regression plots (Fleiss' kappa = 0.86, 95% CI 0.81 – 0.91 compared with 0.66, 95% CI 0.54 – 0.77), with progression detected 8.7 months sooner than traditional linear regression methods ($p<0.0001$).
Conclusions: Glaucoma RPA is a representative and intuitive progression analysis tool that can improve the reproducibility and speed with which progression is detected. As RPA is a statistical (deterministic) technique not dependent on deep learning, this should facilitate rapid clinical translation.

ABSTRACT BODY:

Purpose: New intraocular drugs still need to be tested in in vivo models before becoming approved. Available retina cultures are only of limited value to replace in vivo studies due to a short life time, a small number of samples gained per retina, and mostly they are of animal origin. We aimed to prolong the duration of a retina organotypic culture, to increase the number of samples harvested per retina, and to humanize the system from pig to human retina. The enhanced model offers the analysis of efficiency and toxicity of intraocular drugs while replacing animal experiments according to 3R and being highly transferable to human patients.

Methods: Retinae derived from pig (from a local slaughterhouse 5-8h post-sacrifice) or from human donor eyes (from the Lions Gift of Sight Eyebank 2-5d post-enucleation); both were cultured in serum free Ames' medium supplemented with growth factors (1% N2, 1% B-27) for 14d at 21°C. Retinae were analyzed for viability performing a PI staining, a CytoTox-Glo® and a TUNEL assay. Morphology was assessed in flatmounts by a customized score (0=no damage to 3=severe damage, cell loss) and in cross sections after histological staining, while cell-type-specific degradation and inflammation were evaluated by immunofluorescent staining (rhodopsin, GFAP, Iba-1).

Results: The combination of hypothermia, cell-protective growth factors, optimized tissue processing, and the harvest of 6 mm small punch-samples (12-24 samples/retina) preserved retinal structure for 14d in pig and human cultures as quantified by the modestly increasing score from 0.56 to 1.91 (pig) and 1 to 1.95 (human) (0 vs. 14d); and qualitatively assessed in H&E-stained sections. Viability decreased moderately over time (0 vs. 14d: 20.6 vs. 39.1 mean grey value [PI^+ cells], 2690 vs. 2002 AU [LDH-release]; 2.5 vs. 135 apoptotic cells/section). Immunohistology confirmed presence of photoreceptors up to day 11 and a low activation of Muller and microglia cells in both, pig and human retina.

Conclusions: Summarized, pig and human neural retinas (central & peripheral parts) can be cultured for 14d preserving key cell types and structure. Degradation, cell loss and inflammatory cell activation are modest, allowing efficiency and toxicity analyses. The enhanced model is suitable to evaluate the benefit of new intraocular treatments while using less animals and improving transferability to humans.

ABSTRACT BODY:

Purpose: To compare cone structure and function in patients with autosomal dominant-cone rod dystrophy (AD-CRD) due to genetic mutations in retinal guanylate cyclase (GUCY2D), which encodes a protein that modulates calcium metabolism, and in the homeodomain transcription factor (CRX) that regulates photoreceptor differentiation.

Methods: Refractive error, best corrected visual acuity, short-wavelength autofluorescence fundus photos, and spectral domain optical coherence tomography (SD-OCT) were obtained from all subjects. Confocal and split-detector adaptive optics scanning laser ophthalmoscopy (AOSLO) images were acquired from one patient each with GUCY2D and CRX mutations and stable fixation. Cone spacing was calculated using a density recovery profile method and Z-scores were used to report standard deviation (std dev) from the normal mean at the eccentricity of the measured cones; < 2 was within normal limits. Differences between groups were assessed by Student's t-test (GraphPad PRISM-9 software).

Results: Our cross-sectional study included 14 eyes of 7 AD-CRD patients (3 with GUCY2D and 4 with CRX mutations); the groups were not different in age (GUCY2D mean ± std dev: 51.3 ± 17.8 years, and CRX 41.0 ± 3.8, P = 0.3). Though both groups displayed reduced visual acuity and central scotomas, CRX patients had better visual acuity (P = 0.013) and less myopic refractive error (P = 0.0075) than GUCY2D patients. Fundus autofluorescence revealed retinal pigment epithelial mottling in early stages and bull's eye maculopathy in advanced disease in both groups. SD-OCT revealed outer retinal layer thickness loss with foveal atrophy in all but one GUCY2D patient and ellipsoid zone irregularity in CRX patients. AOSLO images showed no evidence of cone structure at the anatomical fovea for either CRX- or GUCY2D-related AD-CRD. In the eyes with CRX-related AD-CRD, cone spacing Z scores were within normal limits (0.76 ± 0.70; n=3 regions), while in the eyes with GUCY2D-related AD-CRD, Z-scores were abnormal (5.2 ± 5.3; n=10 regions).

Conclusions: AD-CRD differs in disease severity as evidenced by worse visual acuity, greater myopic refractive error and more abnormal cone spacing in GUCY2D patients relative to similarly aged CRX patients. High resolution retinal imaging showed cone loss in all imaged patients and may aid in diagnosis and disease severity monitoring in patients with GUCY2D and CRX-related AD-CRD.

ABSTRACT BODY:

Purpose: While in standard transverse en-face image analysis, optical coherence tomography angiography (OCTA) is averaged over predefined retinal vascular slabs, in axial OCTA analysis, the signal is averaged over the transverse directions, and the resulting axial profiles are subsequently analyzed in depth. Axial profile analysis may provide a more sensitive method for detecting microvasculature changes with disease at different depths even in high-speed OCT acquisitions at lower transverse resolution (preserving the high original OCT resolution axially). In this study, we sought to compare axial profiles in healthy eyes with eyes afflicted with diabetic retinopathy (DR).

Methods: The study cohort includes 17 healthy eyes and 18 eyes with DR. Among the 18 DR eyes, 4 had mild non-proliferative (NP) DR, 9 had moderate NPDR, and 5 had diabetic macular edema (proliferative (P) DR or NPDR). OCTA macular images were captured with the Spectralis OCT2 (Heidelberg Eng.) using a scan pattern size of ~5.8mm x 5.8 mm (20° x 20°; 512 x 512 pixels). Axial signals were quantified from specific retinal layers: NF - nerve fiber, GC - ganglion cell, IP - inner plexiform, IN - inner nuclear, and OP - outer plexiform. Axial signals were quantified within fovea-centered concentric rings with radii 1.5°- 2° (paracentral), 3°- 3.5° (pericentral), and 4.5° - 5° (peripheral).

Results: Fig.1 compares axial profiles in eyes from healthy subjects and DR patients. Fig. 2 compares DR subcategories. Compared to healthy eyes, overall axial signal reduction was observed in DR eyes and DR subcategories. Blunting of axial signal peaks in GCL and in IPL-INL (intermediate capillary plexus) in paracentral ring was observed in DR eyes compared to healthy eyes. Additionally, both intermediate and deep (INL-OPL) peaks were blunted in DR eyes in pericentral and peripheral rings. Significant differences were not observed among eyes with different DR stages.

Conclusions: Axial profile analysis can distinguish normal and DR eyes, providing new insights into disease pathophysiology. The parafoveal OCTA signal was attenuated in DR eyes at multiple flow layers. These observations warrant further investigation with a larger study cohort.

ABSTRACT BODY:

Purpose: IL-27 (IL-27p28/Ebi3) and IL-35 (IL-12p35/Ebi3) are members of the IL-12 family of cytokines that suppress experimental autoimmune uveitis (EAU) and experimental autoimmune encephalomyelitis (EAE), two autoimmune diseases that serve as mouse models of human uveitis and multiple sclerosis (MS), respectively [1,2]. IL-27 is constitutively expressed in the retina and upregulation of IL-27 by microglia cells contributes to suppression of uveitis [3,4]. Because IL-27 and IL-35 share the Ebi3 subunit and are functionally and structurally similar, we generated IL-12p35 (il12a) reporter mice and investigated whether IL-35 is also constitutively expressed in the retina.

Methods: We used CRISPR-Cas9 technology to generate il12a knock-in reporter mice driven by endogenous il12a promoter and yfp-gene cassette (venus-bGH/PA) was inserted into exon 1 of il12a. Founder mice were back-crossed for several generation and mice expressing IL-12p35 and yellow fluorescent protein (YFP) were identified by FACS, qPCRs, Western blotting, FACS, ELISA, immunohistochemistry and confocal microscopy. EAU was induced in control or IL-12p35/YFP reporter mice and disease severity was assessed as previously described [3,4]. The YFP reporter mouse was used to trace IL-12p35-expressing cells during immune response to EAU.

Results: We have shown that retinal cells constitutively express the IL-12p35 subunit and its expression was down-regulated during the onset of EAU. We further show that the IL-12p35-YFP knock-in mice, deficient in p35 expression, developed a more severe EAU in comparison to wild-type controls.

Conclusions: Our results show that p35 or IL-35 are constitutively expressed by retinal cells. Thus, similar to IL-27, IL-35 might also suppress inflammatory responses in the retina and confer protection against prolonged inflammation in the retina during uveitis.

ABSTRACT BODY:

Purpose: Adaptive optics (AO) can be used to visualize autologously-reinjected, indocyanine green (ICG)-loaded erythrocytes (erythrocyte mediated angiography, EMA) in the living human eye. In this study, we introduce an improved approach to longitudinally map erythrocytes in stasis within the choriocapillaris.

Methods: EMA was performed annually for four years in one subject, with images acquired at various timepoints after injection using a Heidelberg Spectralis Scanning Laser Ophthalmoscope (SLO). For three of the visits, AO imaging was performed on the same day as the EMA procedure to obtain higher resolution images of the erythrocytes in stasis. AO enhanced ICG angiography (AO-ICGA) was also performed to map out the choriocapillaris in the foveal region (PMID 30456310). All images were co-registered and locations of cells in stasis identified using both SLO and AO were combined for further analysis.

Results: Erythrocytes in stasis were observed at all visits. Across the four-year follow-up, a total of 54 cells in stasis were identified by SLO and/or AO within the foveal choriocapillaris network mapped using AO-ICGA. Remarkably, 100% of these cells were localized to pixels corresponding to the choriocapillaris vessel lumens, which would be highly unlikely to occur by random chance ($p<0.01$, one-sided binomial test, with the probability of success set at 68% - the overall percentage of pixels that corresponded to choriocapillaris lumens). The observation of cells in stasis within the choriocapillaris (as opposed to retinal capillaries) was further corroborated using AO images acquired over a series of different focal planes throughout the retina (~35 μm step size). Interestingly, when comparing locations at which cells in stasis were observed over the four years, there were positions within the choriocapillaris network at which cells in stasis was observed across multiple visits, suggesting that these may be preferential sites of erythrocyte stasis within the choriocapillaris.

Conclusions: The combination of AO with EMA enables erythrocytes to be mapped to the choriocapillaris network at fine spatial resolution, a first step towards unraveling the peculiarities of how cells flow through the choriocapillaris meshwork. We demonstrate, for the first time, longitudinal assessment of erythrocytes in stasis at the single capillary level.

ABSTRACT BODY:

Purpose: Ophthalmic OCT currently requires patients to position themselves in chin or forehead rests for stabilization with the system operator in close proximity. Robotically aligned OCT (RAOCT) enables remote patient imaging by autonomously aligning itself to a freely seated patient while the imager is physically elsewhere.

Methods: Face and pupil tracking cameras triangulated 3D eye and pupil motion enabling real-time autonomous robotic alignment of a custom 32° FOV retinal SSOCT (1040nm) system (Fig. 1A&C). In conjunction with robotic alignment, we introduced a network layer to the acquisition hardware stack: Zoom© for 2-way A/V communication and NoMachine© for encrypted IP-to-IP, GPU accelerated remote PC and hardware control (Fig. 1B), enabling kilometer-scale distances between imager and patient. The imager instructed patients (where to look, when to blink), began/ended OCT acquisition, and verified image quality. We acquired remote RAOCT retinal volumes from healthy and diseased eyes at the Duke Eye Center on 17 individuals (seated, without chin/forehead rest) under an IRB approved protocol with the imager 10.8 km away at a satellite clinic (Fig. 1D).

Results: Using autonomous robotic alignment, we remotely acquired (10.8 km) OCT and OCTA images in healthy and diseased eyes. Retinal capillaries surrounding the foveal avascular zone are well resolved in a 15° FOV OCTA image (Fig. 2A). In Fig. 2C&D are the thickness map and B-scan from a patient with cystoid macular edema (CME), epiretinal membrane (ERM), and a schisis cavity. Healthy retinas (n=14 eyes) had a mean foveal thickness of 272±1 μm with an intra-subject repeatability of ±1.7 μm; diseased retinas (n=17) had a mean thickness of 308±91 μm and a repeatability of ±1.6 μm.

Conclusions: We demonstrate OCT and OCTA imaging with kilometer-scale distance between imager and patient. This can serve as a foundation for telehealth retinal OCT without physically present technicians or physicians.

ABSTRACT BODY:

Purpose: Pharmacologically-induced mydriasis (PIM) typically lasts 6-24 hours, during which patients may experience ocular discomfort decreased visual performance. Pre-specified sub-group analyses of the MIRA-2 Phase 3 trial assessed the efficacy and safety of 0.75% phentolamine ophthalmic solution (POS) to expedite the reversal of PIM.

Methods: The MIRA-2 trial was a randomized, double-masked, placebo-controlled, multi-center, 1 day Phase 3 clinical trial. Healthy subjects were randomized 1:1 to POS or Placebo (two drops in the study-eye, and one drop in the fellow-eye) one hour after PIM with phenylephrine, tropicamide, or Paremyd (hydroxyamphetamine and tropicamide combination), with 3:1:1 randomization to mydriatic agents, respectively. The primary efficacy endpoint was the percentage of subjects' study eyes returning to ≤ 0.2 mm from baseline pupil diameter (PD) at 90 min post-treatment (with POS vs placebo, compared by logistic regression). Analyses of this efficacy endpoint were stratified by study- vs fellow-eye, by iris color, and by mydriatic agent.

Results: Ninety-four subjects were randomized to POS (mean age 34 years, 62% female) and 91 were randomized to placebo (mean age 33 years, 55% female). More study-eyes treated with two drops of POS had reversal of mydriasis at 90 min compared to placebo (49% vs 7%; $p<0.0001$). This difference between POS and placebo was similar in fellow-eyes which received one drop (48.9% vs 5.5%; $p < 0.0001$). Significant differences were observed both in those with light (56% vs 2%; $p < 0.0001$) and dark (43% vs 11%; $p < 0.0001$) irides at 90 min. Significant differences between POS and placebo were seen with phenylephrine at all time points from 1 to 6 hours, including at 90 min (79% vs 18%; $p < 0.0001$); and in subjects dilated with longer lasting tropicamide or Paremyd at each time point from 2 hours (24% vs 0%; $p < 0.05$) to 6 hours (97% vs 28%; $p < 0.0001$).

Conclusions: Both one and two drops of POS had rapid onset of effect, significantly reducing PD within 90 min or less. POS had benefits across common mydriatic agents and across iris colors, providing a potential treatment to reverse PIM.

ABSTRACT BODY:

Purpose: SARM1 deletion is neuroprotective in many but not all neurodegenerative disease models. Optic neuropathy is a group of optic nerve (ON) diseases with progressive degeneration of ON and retinal ganglion cells (RGCs). Here we tested the neuroprotection potentials of two gene therapy strategies for SARM1 inhibition, antisense oligonucleotide (ASO) and CRISPR-mediated gene knockdown, comparing with germline SARM1 deletion, in three optic neuropathy mouse models.

Methods: Mice intravitreal injection was used for retina local ASO delivery or AAV-mediated RGC-specific CRISPR SARM1 knockdown. After SARM1 inhibition, three optic neuropathy models, traumatic ON crush (ONC), silicone oil-induced ocular hypertension (SOHU) glaucoma, and experimental autoimmune encephalomyelitis (EAE)/optic neuritis, were generated. To evaluate the neuroprotective effects of these SARM1 inhibition strategies, in vivo spectral-domain optical coherence tomography (OCT) imaging and post-mortem retina and ON histological analysis were used to estimate survival retinal ganglion cells (RGC) and axons; Pattern electroretinogram (PERG) recording was used to analyze RGC function in response to a visual stimulus.

Results: This study reveals that retinal local SARM1 ASO delivery and AAV-mediated RGC-specific CRISPR knockdown of SARM1 achieve similar neuroprotective effects as SARM1 straight KO: SARM1 inhibition only protects ON but not RGC soma after traumatic ONC injury, however, it protects both RGC soma and axons in SOHU glaucoma model. And these two gene therapy strategies of SARM1 inhibition have no neuroprotective effect on RGCs and ONs in the EAE/optic neuritis model.

Conclusions: Our studies suggest that SARM1 inhibition by local ASO delivery or AAV-mediated CRISPR is a promising neuroprotective gene therapy strategy for traumatic and glaucomatous optic neuropathies, but not for demyelinating optic neuritis.

ABSTRACT BODY:

Purpose: The type of retinal hemorrhage (heme) in central and hemi-retinal vein occlusions (CRVO/HRVO) may serve as a biomarker of visual acuity. Our study investigated association between superficial heme (within nerve fiber layer (NFL)) and deep heme (below the NFL) and visual acuity letter score (VALS) in participants of the Study of COmparative Treatments for REtinal Vein Occlusion 2 (SCORE2). We hypothesized that superficial heme is associated with worse visual acuity VALS both at baseline and at 6 months, following fixed monthly intravitreal anti-VEGF injections.

Methods: 304 eyes with gradable baseline CFP were graded to determine the proportion of superficial and deep heme within a 9 subfield grid (Figure). Field 9 was ungradable in >10% of eyes and not included in the analysis; Field 1 is over the optic nerve and was analyzed for peripapillary superficial heme (PSH) only. The predominant type of heme in each location was categorized as peripapillary superficial heme (PSH) in Field 1 - 5; macular superficial heme (MSH) and macular deep heme (MDH) in Fields 6 - 8. Predominance was assigned based on the highest proportion of heme in each location (superficial vs deep in all fields; PSH vs MSH vs MDH).

Results: Predominantly superficial compared to predominantly deep retinal hemorrhage at baseline was associated with worse VALS at baseline (48.9 vs 53.1; $p = 0.03$) but greater VALS at 6 months (71.1 vs 66.2; $p = 0.029$). When stratified for predominance based on location, there was no significant difference in baseline VALS between MSH, PSH and MDH (47.8, 49.5, and 53.1 respectively; $p < 0.18$). At 6 months, after adjusting for age, gender, race and ethnicity, subjects with MSH had higher VALS (69.8) than those with PSH (65.4) or MDH (65.2, $p = 0.02$). Subjects with MDH and MSH had greater increases in VALS from baseline to 6 months than subjects with PSH (20.7, 23.0, and 13.6 respectively; $p < 0.001$).

Conclusions: Superficial heme at baseline, specifically in the peripapillary location, has a worse VALS outcome in eyes with CRVO/HRVO. This suggests that assessment of type of heme in CRVO/HRVO may be a biomarker of VALS and peripapillary heme may correlate with worse VALS outcomes.

ABSTRACT BODY:

Purpose: Mitochondrial stress impairs the function of photoreceptors and can lead to retinal degeneration and blindness. Microtubules and the cytoplasmic dynein complex are necessary for proper trafficking and localization of cargo, including mitochondria. We have identified Nuclear Distribution Protein C (NUDC), a known regulator of cytoplasmic dynein, to be critical in rod and cone photoreceptor health. We hypothesize that the absence of NUDC causes a dysregulation in dynein movement along microtubules leading to mitochondrial and protein mislocalization, as well as cellular stress and cell death.

Methods: We generated a floxed Nudc mouse and bred it to the rod-specific Opsin-iCre75 mouse to produce $Nudc^{+/-}$ or $Nudc^{-/-}$ in rods. To characterize the effect of NUDC loss on mitochondria in the retina of these mice, we performed a combination of assays including: Optical Coherence Tomography (OCT) to uncover retinal thickness in vivo; Transmission Electron Microscopy (TEM) to investigate the ultrastructure of mitochondria in rods; quantitative RT-PCR (qRT-PCR) to measure changes in transcripts of selected mitochondrial genes; immunohistochemistry (IHC) to reveal localization of key proteins involved in phototransduction, mitochondrial fission/fusion, and unfolded protein response (UPR) pathways; and seahorse assays to assess mitochondrial respiration in freshly dissected ex vivo retinal tissues.

Results: At P21, OCT analysis revealed retinal degeneration progressing through P42. TEM demonstrated an increased number of mitochondria scattered throughout the inner segment in $Nudc^{-/-}$ rods, rather than localized in the ellipsoid as in wild type. qRT-PCR showed no change or decrease in mRNA levels of genes associated with mitochondrial fission, but IHC revealed an upregulation of gliosis via GFAP in Müller glia and rhodopsin mislocalization in photoreceptors in the absence of NUDC. Additionally, altered mitochondrial respiration and mitochondrial reserve capacity were observed with Nudc deletion in P21 rods.

Conclusions: We have demonstrated that, in the absence of NUDC, mitochondria are mislocalized and exhibit compromised function in rod photoreceptors. We detect an upregulation of proteins involved in the UPR and in the inflammatory response concomitant with retinal degeneration, underscoring the importance of microtubule trafficking by NUDC in the overall health of photoreceptors.

ABSTRACT BODY:

Purpose: Exfoliation syndrome (XFS) is a common identifiable cause of secondary open-angle glaucoma[1]. Estimates gathered over a decade ago on the prevalence of glaucoma in Native American populations hover around 6%; however, data is lacking regarding the burden of XFS in this population[2,3]. In 1971, Faulkner et al. estimated the prevalence of XFS in a sample of 50 Navajo Native Americans over the age of 60 as 38%[4]. Given that XFS can cause irreversible blindness secondary to glaucoma, this study aims to identify the current prevalence of XFS among Navajo Nation residents within the Four Corners region of the United States.

Methods: A retrospective chart review was conducted from 2016-2021 for patients aged 18 and older, examined in partnership with the Utah Navajo Health System and the Moran Eye Center. All patients with XFS or XFG diagnosed by slit lamp exam were identified through chart review. Additionally, patient demographic information and ocular/systemic comorbidities were gathered.

Results: Of the 1,152 patient charts available for review, eight patients (11 eyes) were diagnosed with XFS with three patients (4 eyes) demonstrating concomitant XFG. Of the patients with XFS, three had bilateral disease, three were right eye, and two were left eye. Within this XFS population, 50% of the patients identified as male, with a mean age of 73 years. Of patients with XFS, 38%, 50%, and 13% were seen at the Montezuma Creek, Monument Valley and Navajo Mountain sites respectively. Average presenting IOP in XFS eyes was 19.54 mmHg (n=11) and 18 mmHg (n=4) for non-XFS fellow eyes. The overall prevalence of XFS was 0.7% and the overall prevalence of XFG was found to be 0.26%. The rate of XFG among patients with XFS was 37.5%.

Conclusions: Compared to Faulkner's study of the Navajo Nation residents in 1971, our findings show a considerably lower prevalence of XFS at 0.7%. We present the largest population-based study to date of XFS and XFG among this population. The discrepancy of our findings compared to Faulkner's could be due to variation in diagnostic and inclusion criteria, clinician-dependent factors, and perhaps most critically, differences in study populations. The difference could indicate unique genetic and epigenetic factors within a single ethnic group that spans a large geographic area of the American Southwest, which has not been investigated to date.

ABSTRACT BODY:

Purpose: A recent pilot study demonstrated that foot reflexology can temporarily lower intraocular pressure (IOP) in ocular hypertension (OHTN) patients, however this study lacked a control and a more robust study is necessary to confirm its effect. We performed a prospective randomized controlled clinical trial to see if a shoe insert could be designed to both duplicate the effects seen by foot reflexology in OHTN patients and lengthen the treatment effect beyond the 90-120 minute treatment effect suggested by the original pilot data. We also performed a pilot study to see if foot reflexology could lower IOP in primary open angle glaucoma (POAG) patients.

Methods: This is a pilot study in POAG patients undergoing selective laser trabeculoplasty and a prospective therapeutic trial in OHTN patients recruited from the Temple Ophthalmology clinic. OHTN patients underwent a one-month medication washout. POAG patients performed a 5-minute foot massage on a massage board. OHTN patients performed a 5-minute foot massage with 3D-printed shoe inserts (study insert) or sham inserts. IOP was checked by a masked investigator pre-massage and 5-, 30-, 60-, 90- and 120-minutes post-massage. On two separate days, OHTN patients wore either study inserts or sham inserts for the full day. IOP was measured at 8 AM before wearing the inserts and again at 4 PM.

Results: For the 18 POAG patients, IOP significantly decreased after 5-minute foot massage by 1.9 mmHg (10.1%, p=0.02) and 3.1 mmHg (18.0%, p=0.01) in the right and left eyes compared to baseline. For the 12 OHTN patients, the 5-minute study insert massage significantly decreased IOP by 2.7 mmHg (12.3%, p=0.003) and 2.2 mmHg (10.2%, p=0.004) in the right and left eyes. The sham insert massage significantly decreased IOP by 1.9 mmHg (7.9%, p=0.03) in the right eye. The difference between the study inserts and sham inserts was not significant. During the all-day trial, IOP decreased 1.6 mmHg (7.1%) and 2.3 mmHg (10.3%) for the right and left eyes. Neither was significantly different from the sham.

Conclusions: 5-minute foot reflexology temporarily lowers IOP in some POAG and OHTN patients. The study insert did not lower IOP in OHTN patients more than the sham. Perhaps a different application of foot reflexology or a different version of the insert would be more effective and remains a topic for future research.

TITLE: Evaluating scleral vessel density changes before and after ab interno trabeculotomy using IOL Master 500 : a case series

SESSION TITLE: Data science, machine learning, and AI

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K.Y. Lin, Gavin Herbert Eye Institute, Irvine, California, UNITED STATES|M. Chang, University of California Irvine School of Medicine, Irvine, California, UNITED STATES|

Commercial Relationships Disclosure: Melissa Chang: Commercial Relationship: Code N (No Commercial Relationship) | Ken Lin: Commercial Relationship(s);Code C (Consultant/Contractor):Zeiss, Johnson and Johnson

ABSTRACT BODY:

Purpose: This case series demonstrates a proof of concept using automated machine learning to quantify the change in limbal episcleral vessel morphology in glaucoma patients who undergo trabeculotomy ab interno (Trabectome). Currently there are no reliable noninvasive methods to quantify changes in anatomy after minimally invasive glaucoma surgeries (MIGS). Intraocular pressure (IOP) and gonioscopy remain the two parameters that surgeons can assess for MIGS efficacy. One type of MIGS, Trabectome, is thought to decrease IOP by decreasing aqueous humor outflow resistance. Sclera images may offer a methodology for assessing changes seen noninvasively as a result of Trabectome.

Methods: This study retrospectively analyzed 3 eyes from 2 patients who underwent combined Trabectome with phacoemulsification cataract surgery by 1 surgeon in a hospital setting. Images were taken immediately before and 1 month after the procedure using the Zeiss IOLMaster 500. The open-source image processing package Fiji (ImageJ mirror) was used to load images that were cropped to rectangles of the sclera-only nasal region. The Fiji plug-in Trainable Weka Segmentation was used with 4 reference patients' images from a different dataset to train a model to identify scleral vessels from sclera. The trained model was then applied to study images to calculate the % area of scleral vessels. 3 rectangles of each patient's eye were cropped from the nasal region to optimize either width, height, or most salient vessels, and averages and standard deviations were calculated using Microsoft Excel 2021.

Results: The first patient's right eye had an average % area of scleral vessels compared to white sclera of 9.10±0.27% pre-procedure, and 8.72±0.30% post-procedure. The second patient's right eye had an average % area of 13.75±0.83% pre-procedure compared to 7.18±0.72% post, and left eye average of 12.77±1.21% pre-procedure compared to 11.05±0.65% post. All three eyes had greater than 30% IOP reduction after Trabectome.

Conclusions: Overall there was a decrease in visible sclera vessel area across all three patients who underwent the Trabectome surgery. This presumably is due to less blood and more aqueous in these episcleral vessels following Trabectome. The images captured noninvasively with the IOLMaster 500 along with the machine learning model may be useful adjunctive tools to assess surgical outcomes following MIGS.

ABSTRACT BODY:

Purpose: To quantitatively investigate the microstructural properties of the optic nerve (ON) in vivo using diffusion tensor imaging (DTI) in patient with unilateral optic atrophy (OA) and to determine the association between the ON diffusion properties and retinal nerve fiber layer (RNFL) thickness of optic nerve head (ONH).

Methods: Diffusion magnetic resonance imaging (MRI) was scanned from 6 patients with unilateral OA (OA group) and 11 control subjects (control group). ONs were tracked and a central tract was extracted from optic nerve head to orbital apex along the ON length. To obtain quantitative values of ON microstructure from tensor derived-metrics, fractional anisotropy (FA; a measure of diffusion directions), mean diffusivity (MD; a measure of averaged diffusivity), axial diffusivity (AD; a measure of diffusion in the major axes), and radial diffusivity (RD; a measure of diffusion in radial axes) were computed in the atrohpic (affected) and non-affected ONs of patients with unilateral OA and both ONs of controls. In control group, the averaged measurements of both ONs in each subject were used for statistical analysis. RNFL thickness was measured using optical coherent tomography and the correlation between the tensor measures and RNFL thickness was also analyzed.

Results: FA of atrophic ON was lower than that of non-affected and control ONs (Atrophic[A], 0.136 ± 0.059; Non-affected[N], 0.384 ± 0.048; Control[C], 0.389 ± 0.053). MD and RD of atrophic ONs were higher than those of non-affected and control ONs (MD, A, 0.988 ± 0.247; N, 0.658 ± 0.058; C, 0.687 ± 0.079; RD, A, 0.920 ± 0.247; N, 0.510 ± 0.054; C, 0.532 ± 0.078). However, AD of atrophic ON did not show significant differences to that of non-affected and control ONs (A, 1.123 ± 0.252; N, 0.955± 0.080; C, 0.998 ± 0.094; A vs N, P = 0.152; A vs C, P = 0.155). All DTI measures of atrophic ON except for AD showed a significant correlation with RNFL thickness of ONH; FA showed the strongest correlation, followed by RD and MD (FA, R^2 = 0.936, P < 0.001; RD, R^2 = 0.795, P < 0.001; MD, R^2 = 0.655, P = 0.001; AD, R^2 = 0.183, P = 0.073).

Conclusions: We quantitatively analyzed the optic nerve using DTI and identified differences in DTI measures between atrophic and normal ONs. Additionally, the significant correlation between DTI measures and RNFL thickness suggests the applicability of DTI as a clinical tool to evaluate the optic nerve.

ABSTRACT BODY:

Purpose: Mitochondria distribution in retinal ganglion cells (RGC) is crucial for homeostasis and neurotransmission. Here, we tested the hypotheses that: i) mitochondrial axonal transport deficits contribute to energetic imbalance and RGC damage in glaucoma, and ii) supplementation of the adaptor protein Disc1 (Disrupted in Schizophrenia 1) restores mitochondrial mobility, prevents energy decline, and rescues RGC function

Methods: Ocular hypertension (OHT) was induced by intracameral injection of magnetic microbeads in Thy1-CFP-MitoS mice. RGC-specific Disc1 levels were increased using recombinant adeno-asociated virus (AAV.Disc1). Two-photon laser scanning microscopy was used to i) record mitochondrial movement along RGC axons followed by kymograph analysis, and ii) measure axonal ATP levels using the sensor Ateam. Mitochondrial volume in single RGC axons was quantified using confocal microscopy and Imaris software. RGC density was quantified in RBPMS-stained retinas using a stereological approach. RGC function was assessed by measuring light-evoked positive scotopic threshold responses (pSTR) and using the optomotor reflex assay for visual acuity.

Results: Live imaging of mitochondrial mobility along RGC axons showed a reduction of anterograde transport in glaucomatous eyes (OHT-2 weeks: 40% decrease, t-test $p<0.001$, n=14/grp). Transport deficits were accompanied by a decrease in mitochondrial volume in RGC axons, both in the retina and the myelination transition zone (~50% reduction vs. sham, t-test $p<0.001$, n=16/grp). Intravitreal administration of AAV.Disc1 fully restored mitochondrial mobility and volume in RGC axons subjected to OHT (ANOVA $p<0.01$, n=10/grp). Remarkably, enhanced mitochondrial transport restored axonal ATP levels preventing energetic decline (ANOVA $p<0.05$, n=4/grp) and promoted robust RGC survival (ANOVA $p<0.001$, n=10/grp). Furthermore, AAV.Disc1 prevented loss of light-evoked pSTR responses (ANOVA $p<0.01$, n=12/grp) and improved visual acuity relative to sham animals (ANOVA $p<0.01$, n=8/grp).

Conclusions: Glaucomatous damage disrupts mitochondrial anterograde transport along RGC axons leading to mitochondria depletion and energy decline. Disc1 adaptor supplementation improved mitochondrial anterograde transport, replenished axonal mitochondria, rescued energy homeostasis, and restored light-evoked responses and visual acuity in glaucoma.

ABSTRACT BODY:

Purpose: Chromatic pupillometry is increasingly used for assessing human retinal function through measurements of pupil responses to different colored light stimuli. The discovery of intrinsically photosensitive retinal ganglion cells (ipRGCs) adds a new dimension to the detection and monitoring of retinal and optic nerve disorders, including open-angle glaucoma (OAG) through pupillometry. However, the detection of pre-perimetric glaucomatous deficits still remains a challenge. We hypothesize that early damage in OAG risk could be reflected in affected flickering pupil responses.

Methods: All participants underwent ophthalmological assessments and were classified in healthy controls (HG) and OAG risk patients (GR). The GR group was characterized with high intraocular pressure and/or a family history of OAG with no pre-existing OAG; assessed by OCT and ERG. Pupillary recordings were obtained using a lab-made photostimulator-pupillometer system with monochromatic stimuli of blue (468 nm), green (516 nm), and red (632 nm). Flickering sinusoidal stimuli of 1Hz frequency and 10s duration were presented in an integrating sphere-like dome with a Lambertian inner surface at two modulation levels: 100% and 70%. Each participant was monocularly tested and was light-adapted to the mean chromaticity during 60 s., previous to the stimulus onset. In the frequency domain, amplitude (mm) and phase (degrees) parameters were assessed. In the temporal domain (% initial diameter), initial constriction, and post pulse plateau parameters were evaluated.

Results: The amplitude was significantly reduced ($p<0.05$) in GR group for green (100%), red (100%), and red (70%). The phase was significantly reduced ($p<0.05$) in the GR group for blue (100%), green (100%), red (100%), blue (70%), and green (70%). The Initial Constriction was higher ($p<0.01$) in the HC group for blue (100%), green (100%), red (100%), and red (70%) with respect to the GR group. No significant differences were found for the post pulse response parameter.

Conclusions: We found differences in transient pupil responses between healthy control and glaucoma risk groups, especially for high-modulation red and green stimuli. These results suggest that flickering chromatic pupillometry can reveal early changes in patients with potential OAG, not detected by other clinical methods. Furthermore, early signs of OAG might contain detriments in cone afferences to ipRGCs.

TITLE: Evaluating the effect of titaminates in a metal-organic engineered bioactive film on growth of conjunctival epithelial cells

SESSION TITLE: Ocular surface health and conjunctiva

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D.A. Dartt, C. Lee, Schepens Eye Research Institute of Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|S. Murali, O. Nilsen, Chemistry, Universitetet i Oslo, Oslo, NORWAY|D.A. Dartt, C. Lee, Ophthalmology, Harvard Medical School, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Darlene Dartt: Commercial Relationship: Code N (No Commercial Relationship) | Changrim Lee: Commercial Relationship: Code N (No Commercial Relationship) | Srinath Murali: Commercial Relationship: Code N (No Commercial Relationship) | Ola Nilsen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Infections, autoimmune diseases, trauma or chemical/thermal burns can scar the conjunctiva, requiring transplantation. The purpose of this study is to explore the biological potential of a class of bioactive films named titaminates and identify the ideal candidate for use in development of a functional conjunctival equivalent for transplantation to repair the conjunctiva.

Methods: Titaminates were produced by a molecular layer deposition (MLD) technique on a plain glass coverslip using titanium (T) combined with amino acids (X). Four titaminates (TD (aspartic acid), TGD (glycine aspartic acid), TG (glycine), and TC (cysteine)), a zinc variant (ZnC), and unmodified glass coverslip (NT) were tested using six different epithelial cell preparations cultured from human and rat conjunctiva. Each cell preparation was defined by its nativity (primary (p) or first passage (f)), tissue origin (human (Hu) or rat), and cell type (goblet cell (Gob) or mixture of goblet, stratified squamous, and undifferentiated cells (Mix)). For primary cells, an explant was cultured directly on each biofilm. Fold outgrowth was calculated from the cell area and the explant size. First passage cells were prepared by passaging 50,000 primary cells per film. Proliferation capacity was measured using colorimetric redox indicator resazurin.

Results: TG was the optimum bioactive film for supporting primary cell growth. Fold outgrowth of pHuMix on TG was 70-fold, which was substantially higher compared to that of the second-best biofilm TGD at 33-fold, or NT at 7-fold. Fold outgrowth of pHuGob on TG was about 15-fold, which was higher than TGD at 9-fold and NT at 11-fold. TG was also one of the top three for the first passage cells. fHuGob on TG showed the highest proliferation capacity both at 24 and 48 h. The proliferation capacity of fHuMix, fRatGob, and fRatMix on TG was similar to that on TC, TGD, and TD, which were all higher than ZnC and NT. For all first passage cells, the area cultured by cells did not correlate with the proliferation capacity. For proliferation capacity TC> TGD >TG > NT > TD. ZnC was notably inferior in every measurement.

Conclusions: We conclude that titaminates support the construction of a functional conjunctival equivalent when multiple conjunctival cell types are used and that TG is the best performing scaffold used.

ABSTRACT BODY:

Purpose: OC-01 (varenicline solution) nasal spray is a cholinergic agonist that pharmacologically neuro-activates the trigeminal parasympathetic pathway (TPP) to result in increased basal tear production for the treatment of signs & symptoms of dry eye disease. Unilateral activation of the TPP via a single nostril may facilitate bilateral tear production; however, OC-01 was administered to each nostril BID in the ONSET-1 and ONSET-2 clinical trials. Herein, we report bilateral outcomes, and also outcomes by subgroup symptom severity.

Methods: 891 adult subjects with Eye Dryness Score (EDS, range 0-100) were randomized to either OC-01 0.06 mg, 0.03 mg or vehicle control (VC); at baseline, 200 had EDS <40 and 691 had EDS ≥40. The study eye was defined as the eye meeting all inclusion/exclusion criteria at screening. If both eyes qualified, then the eye with the greatest increase in Schirmer's Test Score (STS, mm) upon mechanical stimulation, or (if no difference) the eye with the lower basal STS, was selected. Analysis of covariance (ANCOVA) using a last observation carried forward (LOCF) approach assessed mean changes from baseline in STS at Week 4.

Results: Mean changes from baseline in STS were greater for eyes treated with OC-01 as compared to VC at week 4. Outcomes in the <40 EDS cohort were: 0.06 mg, 11.0 (± 10.0, p<0.01); 0.03 mg, 8.4 (± 10.0, p=0.01); VC, 4.1 (± 6.5). For the ≥40 EDS group, outcomes were similar: 0.06 mg, 9.2 (± 9.0, p<0.01); 0.03 mg, 9.9 (± 9.7, p<0.01); VC, 3.9 (± 7.1).

OC-01 treated subjects also showed statistically significant differences in percent achieving ≥10 mm STS change from baseline as compared to VC at Week 4. Outcomes in the <40 EDS cohort were: 0.06 mg, 37.3% (OR 6.40, p<0.01); 0.03 mg, 30.9% (OR 3.02, p=0.03); VC, 18.5%. For the ≥40 EDS group, outcomes were similar: 0.06 mg, 39.2% (OR 3.10, p<0.01); 0.03 mg, 38.8% (OR 3.17, p<0.01); VC, 17.9%.

Conclusions: Pharmacologic neuro-activation of the TPP via BID administration of OC-01 to each nostril demonstrated consistency in bilateral basal tear production improvements, regardless of baseline EDS severity. OC-01 was generally tolerable under conditions of the study. The most common adverse reaction was sneezing (82%-84%) and, in >5%, cough, throat irritation & nasal irritation.

SUBMITTER (NAME ONLY): Walid Raslan
TITLE: Efficacy and Safety of Subthreshold laser Treatment for Chronic Central Serous Chorioretinopathy
SESSION TITLE: Macular diseases/Macular edema/Functional testing/evaluation/Laser
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: W. Raslan, S. Younis, Ophthalmology - Medical Retina, Western Eye Hospital, London, London, UNITED KINGDOM|
Commercial Relationships Disclosure: Walid Raslan: Commercial Relationship: Code N (No Commercial Relationship) | Saad Younis: Commercial Relationship: Code N (No Commercial Relationship)
ABSTRACT BODY:
Purpose: Chronic central serous chorioretinopathy (CSR) is a disease characterized by focal fluid accumulation underneath the neuroretina. This can cause irreversible vision loss due to progressive and permanent photoreceptor damage and/or RPE atrophy. The complex and multifactorial pathogenesis of CSR, is still uncertain and the effective treatment for CSR is still not fully explored.

Subthreshold laser has been used to treat CSR and has shown some efficacy in CSR patients with subfoveal and extrafoveal leakage sites.
Our research aims to assess the response and safety of subthreshold laser 577-nm (SML) treatment in patients with chronic CSR.
Methods: - We performed a retrospective study of 11 eyes of 11 patients diagnosed with chronic CSR treated with one or two sessions of sub-threshold yellow laser.
- Patients received subthreshold micropulse yellow laser photocoagulation at 5% duty cycle at a reduced energy level from the micropulse laser test burns with Laser exposure time of 20 ms, and the spot diameter was 100 microns.
- Inclusion criteria:
> CSR suffered for a minimum of 6 months
> No previous treatment
> No loss of vision
> Presence of subretinal fluid secondary to chronic CSR when the treatment was performed

- Data collected: age, gender, laterality, duration of the CSR, best-corrected visual acuity (BCVA) pre and post-treatment, central retinal thickness (CRT) pre and post-treatment, retina changes post-treatment.
- Cirrus HD-OCT scan, fundus autofluorescence, and fundus colour photos were used to collect clinical findings.
Results: - Two third of the patients responded to treatment
- The mean CRT measured by OCT pre- treatment changed from 355 +/- 84 µm to 294+/-67 µm post-treatment (P=0.056), showing an 18% average reduction in fluid height
- There was no evidence of retinal pigment epithelium or retinal damage on SD-OCT, FFA, or fundus autofluorescence
- The BCVA changed from 0.57 +/-0.27 LogMAR pre-treatment to 0.46 +/- 0.31 (P=0.11)
Conclusions: - Subthreshold laser photocoagulation is an effective treatment option for chronic CSCR
- There was no evidence of retinal damage after treatment
- The BCVA didn’t improve much, probably because of the chronic nature of the disease in our patients
- We may try this treatment with acute CSCR, in such cases we expect better results
- Future research with larger samples is required

TITLE: Oxidative stress induces Z-DNA binding protein 1-dependent activation of microglia via mtDNA released from retinal pigment epithelial cells.

SESSION TITLE: Cell biology of retinal diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Szczesny, J. Saada, R. McAuley, M. Marcatti, T. Tang, M. Motamedi, The University of Texas Medical Branch at Galveston, Galveston, Texas, UNITED STATES|

Commercial Relationships Disclosure: Bartosz Szczesny: Commercial Relationship: Code N (No Commercial Relationship) | Jamal Saada: Commercial Relationship: Code N (No Commercial Relationship) | Ryan J. McAuley: Commercial Relationship: Code N (No Commercial Relationship) | Michela Marcatti: Commercial Relationship: Code N (No Commercial Relationship) | Tony Zifeng Tang: Commercial Relationship: Code N (No Commercial Relationship) | Massoud Motamedi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Oxidative stress, inflammation, and aberrant activation of microglia in the retina are commonly observed in ocular pathologies. In glaucoma or age-related macular degeneration, the chronic activation of microglia affects retinal ganglion cells and photoreceptors, respectively, contributing to gradual vision loss. However, the molecular mechanisms that cause activation of microglia in the retina are not fully understood.

Methods: We used cultured differetiated ARPE-19 cells, human brain microglia and various cellualr and molecular biologu techniques including: proximity ligation assay, DNA damage analysis, qPCR, RT-qPCR, IP, Nanoparticle Tracking Analysis, ELISA.

Results: Here we show that exposure of retinal pigment epithelial (RPE) cells to chronic low-level oxidative stress induces mitochondrial DNA (mtDNA)-specific damage, and the subsequent translocation of damaged mtDNA to the cytoplasm results in the binding and activation of intracellular DNA receptor Z-DNA binding protein 1 (ZBP1). Activation of the mtDNA/ZBP1 pathway triggers the expression of pro-inflammatory markers in RPE cells. In addition, we show the enhanced release of extracellular vesicles (EVs) containing fragments of mtDNA derived from the apical site of RPE cells induces a pro-inflammatory phenotype of microglia via activation of ZBP1 signaling.

Conclusions: Collectively, our report establishes oxidatively damaged mtDNA as an important signaling molecule with ZBP1 as its intracellular receptor in the development of an inflammatory response in the retina. We propose that this novel mtDNA-mediated autocrine and paracrine mechanism for triggering and maintaining inflammation in the retina may play an important role in ocular pathologies. Therefore, the molecular mechanisms identified in this report are potentially suitable therapeutic targets to ameliorate development of ocular pathologies.

TITLE: Dissecting the role of the Motor Protein MYO1C in Rhodopsin trafficking for Visual Function

SESSION TITLE: Modeling inherited retinal degeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Radhakrishnan, G.P. Lobo, Ophthalmology and Visual Neurosciences, University of Minnesota Twin Cities, Minneapolis, Minnesota, UNITED STATES|

Commercial Relationships Disclosure: Rakesh Radhakrishnan: Commercial Relationship: Code N (No Commercial Relationship) | Glenn Lobo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The proper trafficking of the visual chromophore Rhodopsin, from its site of synthesis the Photoreceptor Inner Segments (IS) to the Outer Segments (OS), represents a critical event for visual function in humans. Mistrafficking or mislocalization of rhodopsin to other photoreceptor compartments due to mutations in Opsin or defects in its transporters, can lead to retinal phenotypes that are observed in Usher Syndrome (USH) and Retinitis Pigmentosa (RP). We recently identified a role for an unconventional motor protein, Myosin 1C (MYO1C), in the transport of Rhodopsin to the OS. The purpose of this study was to explore the mechanistic role for MYO1C in the transport of Rhodopsin, which could have clinical implications for retinal phenotypes in RP and USH.

Methods: Myo1c knockout mice showed mislocalized Rhodopsin in photoreceptors that manifested in a loss of visual function. This suggests a possible interaction between these two proteins. The MYO1C-Rhodopsin putative interaction was predicted by HADDOCK 2.4 docking using available crystal structures of mouse MYO1C and bovine Rhodopsin. MYO1C-Rhodopsin interaction was confirmed using an overexpression system in COS1 and ARPE19 cell lines. Further, the pmCherry MYO1C deletion constructs and GFP Rhodopsin were generated and co-transfected in cell lines for co-localization analysis. The Pearson's correlation was measured and Acceptor Photobleach Förster Resonance Energy Transfer (FRET) was performed to confirm the physical interactions.

Results: The docking analysis of MYO1C and Rhodopsin indicated an interaction at the MYO1C IQ and post IQ domain region with Rhodopsin C'-terminus. In a cell culture system, a positive interaction between MYO1C and Rhodopsin was observed by immunofluorescence and quantified by Pearson's correlation and FRET. The C-terminal domain deletion constructs of MYO1C showed defects in the interaction with rhodopsin, implying a possible MYO1C C-terminus post IQ domain region interaction with Rhodopsin.

Conclusions: The importance of MYO1C C-terminal interaction with Rhodopsin C-terminal was confirmed in vitro. Our analysis has clinical implications for somatic mutations in the Rhodopsin C-terminus domain implicated in RP, possibly due to loss of MYO1C interaction and transport. Thus, it would be interesting to investigate and screen for genetic variants in the C-terminus of Myo1c and Rhodopsin in patients with USH and RP.

ABSTRACT BODY:
Purpose: The SARS-CoV-2 pandemic has been an ongoing area of study in scientific, clinical, and pharmaceutical communities. Although it is known that many in medical fields developed COVID, it is unknown how COVID has involved eyecare professionals. The purpose of this study is to evaluate COVID involvement in eyecare professionals.
Methods: In this cross-sectional study, an anonymous questionnaire survey was distributed among eyecare professionals. Their experiences with COVID exposure, testing, and infection were evaluated.
Results: 92 eyecare professionals answered the survey, consisting of 25 ophthalmologists, 7 ophthalmology residents, 6 optometrists, 48 ophthalmic technicians, and 6 ophthalmology clinic administrative staff. These included 33 men and 56 women; 3 preferred not to disclose their sex. The mean age was 42.0 ± 12.2 years (range, 21-75 years). Of these, 11 (12.0%) have been COVID positive with symptoms, and none were COVID positive without symptoms. The positive rate was 0% in ophthalmologists, ophthalmology residents, and optometrists, 20.8% in ophthalmic technicians, and 16.7% in administrative staff. Of people without COVID (n=81), 15 (18.5%) had been exposed to a COVID-positive individual, 39 (48.1%) had tested negative for COVID, and 27 (33.3%) had not yet been tested for COVID.
Conclusions: Only a small percentage of eyecare professionals have developed symptomatic COVID. The rate of symptomatic COVID was significantly lower in ophthalmologists, ophthalmology residents, and optometrists evaluated in this study compared to the general population. Such low rates may be due to using proper protective measures, including suitable workplace protocols.

ABSTRACT BODY:

Purpose: Damage to axons in the optic nerve head (ONH) likely contributes to vision loss in patients with glaucoma. While the mechanism of axonal injury has not been fully elucidated, vascular factors have long been considered to play a role. Despite efforts to link determinants of ocular blood flow to the development of glaucoma, a simple quantification of the ONH blood supply has not been previously performed. Here, we quantified blood vessels in sections of ONHs obtained from cadaveric donors with and without glaucoma to determine whether deficiencies in ONH vascularity are associated with glaucomatous disease.

Methods: Six ONHs were recovered from four cadaveric donors; of which, one ONH had a history of glaucomatous disease of unknown subtype. The remaining ONHs were obtained from donors with no offered history of ophthalmic disease. All ONHs were sectioned serially (5 μm thick) and stained with an antibody targeting the endothelial cell marker, CD31. 10x images were acquired from each quadrant of the ONHs, and vascularity (i.e., the number of CD31-positive blood vessels) was quantified manually by a blinded observer. Six serial sections per ONH were analyzed. CD31-positive structures were included in our analysis if they exhibited either: 1) a clear and obvious lumen, or 2) 20 μm of uninterrupted staining. The central retinal vessels were excluded from our analysis.

Results: Vascularity within the supero-medial, infero-medial, and infero-lateral quadrants were similar between glaucomatous and non-glaucomatous ONHs. However, the supero-lateral quadrant of the glaucomatous ONH exhibited a consistently lower number of blood vessels ($\mu = 16.0$, SE = 1.7; n = 6 images from 1 eye) compared to the supero-lateral quadrants of non-glaucomatous ONHs ($\mu = 27.8$, SE = 5.3; n = 24 images from 4 eyes).

Conclusions: Our results raise the possibility that glaucomatous ONHs exhibit reduced vascularity. This could reflect either: 1) a lower number of blood vessels entering the nerve parenchyma, 2) a reduction in the amount branching within the vascular bed, and/or 3) vascular remodeling following axonal damage. Further research with increased sample size is needed to confirm our findings.

ABSTRACT BODY:

Purpose: Müller glia, which are astrocyte-like radial cells that play a pivotal role in maintaining retinal homeostasis, are considered to be the main glial cells in the retina. Their expression spans along the retina providing general structural support to retinal neurones and blood vessels. Among several other functions, they prevent aberrant photoreceptors migration into the subretinal space and facilitate glutamate uptake to keep its extracellular concentration below toxic levels.

In lower vertebrates such as fish and amphibians, the injured retina shows a regeneration potential which is believed to stem from Müller glia. Although this regeneration potential is common for all vertebrates, it is, however, absent in mammalian systems for unknown reasons. Although various Müller glia cell lines have been described in the literature including those derived from human and rat, to our knowledge, no non-human primate (NHP) Müller glia cell line is currently available.

Methods: A spontaneously immortalised Müller glia cell line was established from a primary culture of neural retina of a Macaque monkey dissociated using a papain dissociation reagent. The cells were cultured, passaged and eventually immortalised without the presence of growth factors. The cells were examined for expression of Müller glia and other markers by immunocytochemistry and RT-PCR and differentiated with growth factors known to stimulate cells differentiation.

Results: Here we report a spontaneously immortalised Müller glia cell line isolated from rhesus macaque monkeys, grown under normal culture conditions and could be expanded indefinitely without the presence of growth factors. The cell line exhibits normal morphology and expressed Müller glia markers among other stem cell markers when examined with immunocytochemistry and RT-PCR. When cultured in the presence of growth factors that stimulate cell differentiation, they altered their gene expression profile by expressing a combination of retinal neuronal markers

Conclusions: Our observations indicate that the non-human primate retina harbours a population of cells that express both Müller glia and stem cell markers, which can be useful for future cell replacement therapies.

ABSTRACT BODY:

Purpose: Heterozygous mutations in the nuclear encoded gene for the succinate dehydrogenase complex flavoprotein subunit A (SDHA) of the mitochondrial respiratory chain complex II (CII; succinate-ubiquinone oxidoreductase) have been described in a rare syndrome including predominantly adult onset bilateral optic atrophy, progressive neurological impairment, and in some cases cardiomyopathy. They may disturb the electron transfer from succinate to ubiquinone and cause partial CII deficiency. Here, we describe a family featuring optic atrophy with autosomal dominant inheritance as the only symptom in multiple generations, segregating a pathogenic mutation in the SDHA gene, previously described in patients with progressive optic atrophy, ataxia, and myopathy.

Methods: Clinical examinations included visual acuity testing, automated threshold perimetry, OCT-based measurement of peripapillary retinal nerve fiber layer (pRNFL) thickness and macular ganglion cell layer (mGCL) thickness, laboratory tests, cranial MRI, neurological and cardiological examination. Genetic analysis was performed by exome sequencing in the index patient and subsequent confirmation by conventional DNA sequencing in all affected individuals.

Results: Four male patients, two adults and two children aged 7 and 9, from two generations of the same family presented with bilateral optic atrophy, central visual field defects, severely reduced pRNFL thickness (37-48 µm) and moderately reduced mGCL thickness (23-31 µm). Genetic analysis revealed the heterozygous missense mutation NM_004168.4:c.1351C>T p.(Arg451Cys) within the SDHA gene, affecting a highly conserved arginine residue in the FAD/NAD(P)-binding domain of SDHA. No other mutations in known optic atrophy genes were detected in the index patient. Cranial MRI, metabolic laboratory tests, neurological and cardiological examinations were all unremarkable.

Conclusions: Information in this pedigree adds isolated dominant optic atrophy with childhood onset to the phenotype spectrum of heterozygous mutations in SDHA, which are known to cause a syndrome characterized by neurodegeneration with ataxia and late-onset optic atrophy (NDAXOA, OMIM #619259). Although being a rare cause, we advise to include SDHA in gene sequencing panels for dominant optic atrophy.

ABSTRACT BODY:

Purpose: Herpes zoster ophthalmicus (HZO) has been associated with increased rates of composite cardiovascular (CV) events, though the mechanism by which varicella zoster virus (VZV) reactivation induces this risk is unclear. We performed a retrospective study to examine baseline CV risk profiles in HZO patients.

Methods: Patients who presented at our tertiary care academic center for initial HZO management between 1/1/2009 and 12/31/2019 were identified. We excluded those under 18 years of age or with only one recorded clinical encounter. A control cohort of patients presenting during the same timeframe was randomly selected and matched for age, race, and gender. Patient variables were abstracted through manual chart review and Epic SlicerDicer up until initial HZO presentation (pre-diagnosis). Subjects were also tracked for one year past the date of initial HZO presentation (post-diagnosis) for CV event occurrence. Statistics were performed with chi-squared and t-test analyses.

Results: 289 HZO patients were identified during the study period. 43 patients with only one clinical encounter were excluded, leaving a final HZO cohort of 246 patients. Pre-diagnosis HZO patients were more likely than controls to have BMIs in the healthy category (35% vs. 26%; p=0.03) and less likely to fall under the obese category (24.8% vs. 33.3%; p=0.04). No differences in blood pressure values or smoking status were found between cohorts. Hemoglobin A1c (p=0.73) and lipid panel (p=0.13) values also did not differ between cohorts pre-diagnosis. Rates for hypertension medications (46.7% vs. 48.4%; p=0.72), statins (35.4% vs. 37.4%; p=0.64), and aspirin therapy (26.4% vs. 24.4%; p=0.61) were similar between cohorts pre-diagnosis. None of the traditional CV comorbidities or composite CV events (p=0.50) were elevated in HZO patients before their initial diagnosis. Strikingly, rates of composite CV events were also not increased in the year following HZO diagnosis in our cohort (p=0.89).

Conclusions: Although HZO episodes have been associated with increased risk of CV events, the baseline CV disease burden was not elevated in our HZO cohort nor was the 1-year rate of CV events after diagnosis. This suggests that increased HZO-related CV risk, if present, may be driven by productive VZV infection sequelae. An improved understanding of the risk profiles and disease progression of HZO patients may inform novel screening and prevention methods.

ABSTRACT BODY:

Purpose: Fuchs' endothelial corneal dystrophy (FECD) is a genetic disease which leads to eye pain, significant loss of vision and corneal lesions called guttae. Late-onset FECD is characterized by the expanded repeat trinucleotide sequence (CTG)n (n>30-40) in the TCF4 gene. The accumulation of CUG RNA in the nucleus forms cytotoxic RNA foci. Recently, we developed a recombinant variant of DICER, OptiDicer, which can degrade double-strand RNA through RNaseIII activity. In this study, we examined whether OptiDicer can decrease CUG RNA accumulation in corneal endothelial cells from patients with Fuchs' dystrophy.

Methods: F35T cells, Human corneal endothelial cells from an FECD patient with (CTG)n n>1000, were used in this study. pCMV-NLS-OptiDicer (Nuclear localization signal conjugated OptiDicer) was transfected by Lipofectamine-3000 in an Fibronectin coated 8-well chamber slide. As a control, we used D2A-OptiDicer (which has no RNaseIII activity by introducing two alanine scanning mutations in OptiDicer). Two days post transfection, the cells were fixed by 4% PFA, and then subjected to in situ hybridization using Alexa647 conjugated (CAG)8 2O-methyl RNA probes in order to detect CUG RNA accumulation. The images were obtained with an EVOS fluorescence microscope, and the number of CUG RNA accumulation was counted.

Results: The transfection efficiency was estimated as 50%. We did not find significant cell loss by pCMV-NLS-OptiDicer or pCMV-D2A-OptiDicer transfection. Accumulation of CUG RNA was counted in 276 OptiDicer transfected and 222 D2A-OptiDcier transfected F35T cells. The average number of CUG RNA accumulation was 1.9+/-1.4 in OptiDicer-F35T and 2.9+/-1.7 in D2A-OptiDicer control F35T ($p<0.001$), respectively.

Conclusions: We found that OptiDicer significantly decreased CUG-RNA accumulation in late-onset FECD patient derived corneal endothelial cells, although the low transfection efficiency may underestimate OptiDicer effect. Our result suggests OptiDicer can be a potential treatment for long CUG RNA repeat derived FECD. Future studies will explore OptiDicer in other cell lines from FECD patients with other transfection methods.

ABSTRACT BODY:

Purpose: Mutations in collagen type IV alpha 1 (COL4A1) and alpha 2 (COL4A2) cause a multisystem disorder characterized by variable cerebrovascular, ocular, renal, and neuromuscular manifestations. The affected tissues are mainly derived from two distinct embryonic origins: the neural crest cells (NCCs) and the mesoderm germ layer. The periocular mesenchyme (POM) is a transient migratory embryonic tissue of NCCs and paraxial mesoderm derivation. It gives rise to anterior segment structures such as the corneal endothelium and stroma, trabecular meshwork, and ciliary muscle. Morphogenetic defects of these structures can impair aqueous humor outflow, leading to elevated intraocular pressure and glaucoma development. Approximately one-third of patients with COL4A1 and COL4A2 mutations have ocular anterior segment dysgenesis (ASD), including congenital glaucoma resulting from dysgenesis of POM-derived structures. POM terminal differentiation has been the major focus of ASD research, but the cellular mechanisms are still unclear. We hypothesize that Col4a1 mutation may alter POM biology underlying ASD.

Methods: Immunofluorescence and confocal microscopy were performed on control and Col4a1 mutant mouse embryos at embryonic day (E) 9.5 and E10.5 using antibodies against SOX10 to label migratory NCCs, and FOXC1 and PITX2 to label the POM and prospective corneal stroma at E12.5.

Results: SOX10 labeling revealed that Col4a1 mutant and control embryos had similar numbers of migrating cranial NCCs at both E9.5 and E10.5. However, compared to control littermates, cranial NCCs moving towards the eye region in E9.5 mutants showed abnormal migration, forming a less cohesive migratory stream. On the other hand, within the POM of E9.5 and E10.5 Col4a1 mutant embryos, NCCs clustered more closely. POM analysis at E12.5 revealed that $FOXC1^{+}$, but not $PITX2^{+}$, POM cells migrate less cohesively within the prospective corneal stroma of Col4a1 mutant embryos compared to controls.

Conclusions: In agreement with our hypothesis, our results show for the first time that Col4a1 mutations lead to cranial NCC and POM migratory defects without affecting cell numbers. Further examinations are needed to understand both the molecular causes and consequences of the uncovered migratory phenotype. Future work will analyze the mesodermal contribution to ASD in Col4a1 mutants.

ABSTRACT BODY:

Purpose: Microaneurysms (MA) are early clinical signs seen in patients with non-proliferative diabetic retinopathy (NPDR) and proliferative diabetic retinopathy (PDR). They result from capillary wall outpouching, can bleed, and result in vision loss. The advent of optical coherence tomography angiography (OCTA) has allowed for the noninvasive detection of MAs as compared to fluorescein angiography. Herein, we developed an nnU-Net that automatically identifies MAs on OCTA en face images.

Methods: Patients with early, intermediate, and severe NPDR as well as PDR, who were imaged on the ZEISS PLEX Elite 9000 using a field size of 6x6 mm, were retrospectively enrolled from the New England Eye Center. We isolated the automatically segmented superficial and deep capillary layers of the OCTA en face images. Two expert graders independently and manually labeled MA using the EXACT web-based labeling tool. Utilizing the labeled data, we trained a 2D nnU-Net (a self-configuring deep learning tool that utilizes heuristic and data-based rules to choose suitable hyper-parameters) to detect MA. Both the network topology and training process are guided by empiric rules that take into account image dimension, modality, and annotations. Furthermore, we adapted parameters of the nnU-Net to fit the specific needs of MA detection. We evaluated different loss functions and training parameters.

Results: 111 eyes from 60 patients with DR were included for analysis. Preliminary tests on the network utilized the superficial capillary layer labeled by one expert grader. 16 images were held back for testing and the network achieved a per-pixel accuracy score of 99% on the test data. These results are preliminary and do not include all of the data and annotations yet.

Conclusions: Detection of MA in the superficial capillary plexus images from the PLEX Elite system is feasible using annotations generated from both the EXACT labeling tool and nnU-Net and it achieves a per-pixel accuracy score of 99%.

ABSTRACT BODY:

Purpose: To explore novel role and molecular mechanism of a natural anti-inflammatory cytokine interleukin (IL) 37 in preventing corneal epithelial barrier disruption from hyperosmolar stress as occurs in dry eye.

Methods: Primary human corneal epithelial cells (HCECs) were cultured from fresh donor limbal explants. An in vitro dry eye model with hyperosmolar stress was established by switching HCECs from isosmolar (312mOsM) to hyperosmolar medium (350-500 mOsM) alone or with rhIL-37, some cells were treated with TNF-α, for different periods (2-48 hours). The expression of cytokines and cathepsin S, and barrier protein integrity were evaluated by RT-qPCR, ELISA, and immunofluorescent staining with confocal microscopy.

Results: The integrity of epithelial barrier was significantly disrupted in HCECs exposed to hyperosmolar medium, as shown by immunofluorescent images of tight junction (ZO-1, occludin and claudin-1) and adheren junction (E-cadherin) proteins. The opposite responses were observed between TNF-α stimulated and IL-37 suppressed in HCECs exposed to hyperosmolarity. Cathepsin S, encoded by CTSS gene, was found to directly disrupt epithelial barrier. Interestingly, CTSS expression was significantly induced by TNF-α and hyperosmolarity, while exogenous rhIL-37 inhibited TNF-α and CTSS expression at mRNA and protein levels following hyperosmolar stress. rhIL-37 further restored barrier protein integrity, observed in 2D and 3D confocal immunofluorescent images, in HCECs under hyperosmolar stress.

Conclusions: Our findings demonstrate a novel signaling pathway by which the anti-inflammatory cytokine IL-37 suppresses TNF-α and CTSS stimulated corneal epithelial barrier disruption under hyperosmotic stress. This study provides new insight into mechanisms disrupting or preventing corneal barrier in dry eye disease.

ABSTRACT BODY:

Purpose: Evaluate differences in Medicare reimbursements between men and women ophthalmologists between 2013 and 2019.

Methods: The Centers for Medicare and Medicaid Services Physician and Other Supplier Public Use File was used to determine total reimbursements and number of charges submitted by MD or DO ophthalmologists between 2013 and 2019. Reimbursements were standardized to account for geographic differences in Medicare reimbursement per service. Billing codes were grouped into service categories including outpatient office visits and eye examinations, diagnostic testing, laser and surgery. Data from the American Community Survey (ACS) were used to determine zip-code-level socioeconomic characteristics (unemployment, poverty, income, and education) for the location of each physician's practice. A multivariable linear regression model was used to evaluate differences in annual reimbursements by gender, accounting for calendar year, years of experience, total number of services, ACS zip-code data, and proportion of procedural services.

Results: Among 20,730 ophthalmologists who received Medicare reimbursements between 2013 and 2019, 15,722 (75.8%) were men. The most common billing codes submitted were for outpatient visits and eye examinations (17.7 million charges/year), diagnostic imaging of the retina (5.9 million charges/year), intra-vitreal injection (3.1 million charges) and removal of cataract with insertion of lens (2.3 million charges). Compared to men, women ophthalmologists received lower median annual reimbursements ($95,042.73, IQR 29,548.99-206,034.7 for women vs. $199,044.10, IQR 77,230.51-397,937.60 for men, $p<0.001$, Figure 1) and billed for a lower annual number of services (1,232, IQR 432-2484 vs. 2,302, IQR 988-4,252, respectively $p<0.001$). After adjustment for covariates, women ophthalmologists received $20,239.80 less in reimbursements than men (95% confidence interval -18,732.28 to -21,747.32, $p <0.001$). The greatest disparity in reimbursements was seen in vitreoretinal surgery, with women ophthalmologists earning 0.27 cents for each dollar earned by men (Figure 2).

Conclusions: Women ophthalmologists received less reimbursements from Medicare than men over time and across all categories of billing codes. Disparities in reimbursement persisted after controlling for physician and practice characteristics.

ABSTRACT BODY:

Purpose: Although the optic nerve, like other mature CNS pathways, cannot regenerate when injured, this failure can be partially reversed by inducing sterile inflammation in the eye. Previous work from our lab showed that this phenomenon is mediated in large part by oncomodulin (Ocm), a 12 kDa Ca++-binding protein that is secreted by myeloid cells. Ocm also induces outgrowth from dorsal ganglion neurons (DRGs) and may play a role in the conditioning lesion effect, whereby injury to a peripheral nerve enhances the ability of DRG neurons to extend central and peripheral axons into spinal cord and sciatic nerve respectively. So we aim to identify the Ocm receptor (Ocm-R) and explore its role in CNS and PNS regeneration.

Methods: Biotinylation by antibody recognition (BAR) followed by mass spectrometry were used to identify Ocm-R candidates. Co-immunoprecipitation and Biacore studies were used to reveal the direct interaction between Ocm and Ocm-R. Ocm-R expression in RGCs and DRG neurons were manipulated by CRISPR-Cas9 and aav2/9-short hairpin RNA (shRNA) targeting Ocm-R respectively. Ocm-R expression in cell line was overexpressed by plasmid transfection.

Results: We now report the isolation of a likely Ocm receptor (Ocm-R). Knock-down of Ocm-R in RGCs leads to the loss of Ocm binding to RGCs and a substantial loss of inflammation-induced regeneration after optic nerve injury without affecting regeneration induced by other means (pten deletion in RGCs). Conversely, ectopic expression of Ocm-R in cells with low baseline expression results in high Ocm binding. Moreover, Ocm-R knockdown reduces conditioning lesion induced DRGs neurons' central and peripheral axon regeneration.

Conclusions: Oncomodulin and its receptor enable the conditioning lesion induced CNS and PNS regeneration.

TITLE: Telemedicine for Diabetic Retinopathy Screening in Low- and Middle-Income Countries: A Systematic Review and Bibliometric Analysis

SESSION TITLE: Diabetic retinopathy epidemiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Halim, Barts Health NHS Trust, London, England, UNITED KINGDOM|J. Xie, V. Chaudhary, McMaster University, Hamilton, Ontario, CANADA|S. Sivaprasad, NIHR Moorfields Biomedical Research Centre, London, England, UNITED KINGDOM|

Commercial Relationships Disclosure: Jonathan Halim: Commercial Relationship: Code N (No Commercial Relationship) | Jim Xie: Commercial Relationship: Code N (No Commercial Relationship) | Varun Chaudhary: Commercial Relationship: Code N (No Commercial Relationship) | Sobha Sivaprasad: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Populations of low- and middle-income countries (LMICs) have poorer access to eye care due to fewer ophthalmologists per capita. Telemedicine enables remote diabetic retinopathy screening and widely improves access. This study aims to evaluate the current role of telemedicine for diabetic retinopathy screening in LMICs.

Methods: A systematic search of PubMed, Embase, Web of Science, and Cochrane Central was undertaken. Studies were included if they involved the use of telemedicine, as defined by the American Association of Telemedicine (ATA), for diabetic retinopathy screening among populations in LMICs. The outcomes reflected the quality of telemedicine according to ATA categories, screening personnel, location, and system used.

Results: Of 301 studies retrieved, 38 were included, involving a total of 206,725 individuals, and comprising 34 cross-sectional studies, 3 randomised controlled trials, and 1 cohort study. The publication year ranged from 2007-2021. The studies were from Bangladesh, Brazil, Cameroon, China, Costa Rica, India, Iran, Kenya, Lebanon, Mexico, Nepal, Peru, Zambia, and Zimbabwe. ATA Category 2 and 3 clinical validation for screening were attained in 61% (n = 23) and 18% (n = 7) of the studies, with the remaining 21% (n = 8) being ATA Category 1. The majority of studies (n = 20) appointed either technicians or nurses as image acquisition personnel, while image graders largely involved ophthalmologists (n = 35). The most common location of screening were hospitals (n = 18), followed by health centres (n = 11), mobile clinics (n = 10), and primary care clinics (n = 9). A median of 2 pictures (range = 1-7) were taken in each study, the majority being non-stereo (n = 31). Nineteen studies used non-mydriatic imaging, 14 utilised mydriasis, and 4 performed dilation as needed. Whilst 55% (n = 21) of the studies involved opportunistic screening programmes, 45% (n = 17) were systematic screening programmes integrated within the healthcare system, and 71% (n = 27) comprised follow-up pathways.

Conclusions: A variety of telemedicine tools have been attempted in LMICs and have successfully screened a large number of individuals. However, more funding and infrastructure are needed for these programmes to be integrated into the healthcare system for systematic population-level screening.

TITLE: Gene knockdown of Col8a2 in mouse corneal endothelium by non-homologous end joint repair using adenovirus-mediated Crispr/Cas9

SESSION TITLE: Animal models of human ocular disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Uehara, X. Zhang, B.K. Ambati, Phil and Penny Knight Campus for Accelerating Scientific Impact, University of Oregon, Eugene, Oregon, UNITED STATES|

Commercial Relationships Disclosure: Hironori Uehara: Commercial Relationship: Code N (No Commercial Relationship) | Xiaohui Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Balamurali Ambati: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Gene knockdown by NHEJ (non-homologous end joint repair) using Crispr/Cas9 can be useful for various eye diseases such as Fuchs' endothelial corneal dystrophy (FECD). In this study, to evaluate Crispr/Cas9 efficacy in corneal endothelium, we examined the indel (insert/deletion) rate in mouse corneal endothelium after adenovirus-mediated Crispr/Cas9 using deep sequencing. Also, we infected adenovirus-Cas9 targeting Col8a2 to human donor corneas and evaluated its safety.

Methods: Adenovirus encoding Cas9 and guide RNA targeting Col8a2 gene (Ad-Cas9-Col8a2gRNA) was injected into anterior chamber in C57BL6/j mice. Mutations of Col8a2 are responsible for early-onset FECD. The genomic DNA (gDNA) was purified from the dissected corneal endothelium. PCR was performed at the gRNA target site. The PCR products were subjected to deep sequencing, and the indel rates were calculated. In human donor corneas, paired corneas were treated with Ad-Cas9-Col8a2gRNA or mock. One week post infection, the corneal endothelial cell density was evaluated by alizarin red staining.

Results: Immunostaining showed that Ad-Cas9-Col8a2gRNA ($6.3x10^6$ vg) significantly decreased 91 ± 33 % of COL8A2 expression in the corneal endothelium compared to the non-injected control corneas ($p<0.01$, N=4). By deep sequencing, the rates of insertion and deletion were 20.0 ± 4.0% and 3.6 ± 0.5% respectively, and the total indel rate was 23.7 ± 4.5%. However, these values may be an underestimate due to inclusion of genomic DNA from stromal cells which were not infected with adenovirus through anterior chamber injection. Therefore, the adjusted indel rate was estimated as 102.5±16.3%. Although this value does not have direct evidence, the immunostaining of COL8A2 in the cornea supports this estimation. In human corneas, we confirmed Cas9 protein expression in corneal endothelium by immunostaining and the indels by PCR/restriction enzyme digestion. We did not find significant difference of corneal endothelial cell density by adenovirus infection (2978 ± 85 cells/mm^2 in mock and 2982 ± 157 cells/mm^2 in Ad-Cas9-Col8a2gRNA).

Conclusions: In this study, we showed the indel rate in mouse corneal endothelium by adenovirus mediated Crispr/Cas9 and safety of this vector in human donor corneas. Our result indicates the gene knockdown by Crispr/Cas9 can be useful for genetic corneal endothelial cell diseases such as FECD.

TITLE: NMNAT2 and NAD^+ are Downregulated in Glaucomatous RGCs and Overexpression of NMNAT2 Rescues Glaucomatous Neurodegeneration

SESSION TITLE: Neuroprotection and neuroregeneration

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: D. Liu, F. Fang, P. Zhuang, X. Feng, P. Liu, H. Huang, L. Li, W. Chen, L. Liu, Y. Sun, Y. Hu, Ophthalmology, Stanford University School of Medicine, Palo Alto, California, UNITED STATES|H. Jiang, J. Ye, Radiation Oncology, Stanford University School of Medicine, Palo Alto, California, UNITED STATES|F. Fang, Ophthalmology, Central South University, Changsha, Hunan, CHINA|

ABSTRACT BODY:

Purpose: Emerging evidence suggests that redox factor NAD^+ decline is a hallmark of aging and neurodegenerative diseases. This study tested the hypothesis that modulating glaucomatous RGC intrinsic NMNAT2 levels which is the key enzyme in the NAD^+ biosynthetic process, is a promising gene therapy for glaucomatous neurodegeneration.

Methods: We first profiled the translatomes of RGCs in naïve and silicone oil-induced ocular hypertension (SOHU)/glaucoma mice by RiboTag mRNA sequencing. NMNATs mRNA levels were then validated in SOHU glaucomatous RGCs by in situ hybridization. NAD^+ levels in retina and optic nerve were acquired by LC/MS based NAD^+. RGCs soma and axon survival were evaluated by in vivo optical coherence tomography (OCT) imaging and post-mortem retina wholemounts and ON sections histological analysis. Visual function were evaluated by the pattern electroretinogram (PERG) and optokinetic tracking response (OKR) test.

Results: Deep sequencing of translating mRNAs isolated from RGC ribosomes reveals that all three isoforms of NMNATs can be detected in RGCs but NMNAT2 is the most abundant isoform, which is significantly decreased in glaucomatous RGCs ($p < 0.0001$). In ON crush neuropathy model, AAV2 mediated RGC-specific overexpression of NMNAT2Δex6 promotes RGC soma and axon survival, comparable with cytNMNAT1 in axonal protection while marginally better in soma protection ($p < 0.05$). In SOHU glaucoma model, RGC-specific overexpression of NMNAT2Δex6 promotes dramatic survival of both RGC somata and axons possibly by significantly restoring NAD^+ levels in glaucomatous retinas ($p < 0.05$) and ONs ($p < 0.01$). In terms of visual function, the peak-to-trough (P1-N2) amplitude ratio of the SOHU eyes to contralateral eyes in PERG increased significantly after NMNAT2 overexpression in RGCs ($p < 0.0001$) and also significantly preserves visual acuity of the glaucomatous eyes in OKR test ($p < 0.0001$).

Conclusions: Taking advantage of our recently developed SOHU mouse glaucoma model and RGC-specific AAV promoter, mSncg, we found decreased NMNAT2 expression in glaucomatous RGCs, which may lead to NAD^+ decline in RGCs and ONs. We further demonstrated that modulating RGC intrinsic levels of NMNAT2 by an AAV2-mSncg vector represents a potent gene therapy strategy for protecting both RGC somata and axons in traumatic ON injury and SOHU glaucoma model.

ABSTRACT BODY:

Purpose: Little is known about the mechanisms by which serotonin (5HT) functions in the retina. Using publicly available RNA sequencing data, we have identified 5HT receptor 1b (Htr1b) as a likely mediator of 5HT in retinal ganglion cells (RGCs). In this study, we investigate the expression and function of Htr1b in the retina and RGCs.

Methods: 8-week wild-type mice were used to determine gene (Htr1b) expression. RNAscope in situ hybridization (ISH) was performed on retinal cryosections and imaged using confocal microscopy.

Whole field flash electroretinograms (ERGs) were used to record scotopic and photopic amplitudes in 22 mice (8 $Htr1b^{-/-}$; 8 $Htr1b^{+/-}$; 6 WT). Positive scotopic threshold response (pSTR), b-wave, and a-wave amplitudes were recorded. Visual behavior was evaluated in $Htr1b^{-/-}$ mice and controls by assessing the scotopic and photopic optokinetic response. Gratings of variable spatial frequency or contrast were presented to evaluate spatial frequency threshold and contrast sensitivity threshold, respectively. We performed retinal histology and in vivo SD-OCT imaging on 8-week $Htr1b^{-/-}$ animals to quantify retinal layer thickness. Retinal layers (GCL, IPL, INL, OPL, and ONL) were measured as a percentage of total retinal thickness and compared to age and sex-matched wild-type controls.RGC numbers were determined from whole-mount retinas which were prepared and visualized with confocal microscopy. RBPMS-positive cells were counted semi-automatically using an ImageJ extension. Total cell density was normalized to image size.

Results: ISH showed that Htr1b RNA is primarily restricted to the GCL layer. $Htr1b^{-/-}$ mice showed reduced ERG amplitudes and OKR thresholds compared to control mice. The pSTR slope (amplitude/light intensity) was reduced by 40% (P=0.0035). With OKR testing, scotopic contrast sensitivity thresholds were diminished by 10%-15% (P=0.0334). Histology, SD-OCT imaging, and RGC counts showed no observable alterations in the retinal morphology of $Htr1b^{-/-}$ mice.

Conclusions: Our results show that loss of Htr1b function results in abnormal retinal physiology and visual function despite overtly normal retinal structure and RGC counts. Collectively, these experiments suggest that Htr1b plays an important and previously unrecognized role in 5HT action in the retina. More research is needed to understand 5HT action and its potential impact on retinal disease.

ABSTRACT BODY:

Purpose: Intraocular lens (IOL) power calculations for cataract surgery remain an imperfect science with known shortcomings in eyes with extreme biometric measurements. The purpose of this study was to investigate whether an augmented intelligence (AI)-based clinical decision aid integrated into the electronic medical record (EMR) improved prediction accuracy of the SRK/T formula in eyes undergoing cataract surgery.

Methods: This was a retrospective consecutive case series compared SRK/T and AI-modified SRK/T predictions on eyes in which monofocal IOLs were implanted in adult subjects. The testing dataset included 116 eyes of 79 patents, implanted with an MX60E IOL. Exclusion criteria included corneal or intraocular opacities of any kind other than cataract, history of other intraocular surgery, post-operative refraction recorded outside study period (21-90 days following surgery), or post-operative best-corrected vision worse than 20/30. A tool was built into the EMR that analyzes biometric data and makes recommendations from the peer-reviewed literature on how to adjust refractive targets for eyes with short or long axial lengths (AI-AL), flat or steep keratometries (AL-K), or shallow or deep anterior chamber depths (AI-ACD). Primary endpoints included standard deviation (SD) of the prediction error (PE) for both SRK/T and AI-modified SRK/T predictions. Secondary endpoints include mean absolute prediction error (MAE), and proportion of eyes with post-operative spherical equivalent (SE) within 0.25 and 0.50 diopters (D) of predicted.

Results: SRK/T + AI-K improved upon the original SRK/T formula based upon several metrics. The SDs of the signed PEs were 0.657 and 0.623 D for the SRK/T and SRK/T + AI-K, respectively. MAEs for the same were 0.455 and 0.420 D, respectively ($p < 0.0003$). The proportion of eyes with post-operative SE within 0.25 and 0.50 D of predicted were 39.7% and 69.8% vs. 44.0% and 72.4%, respectively ($p < 0.0002$ for both). Other adjustments of the SRK/T formula based on AL and ACD did not result in meaningful improvements.

Conclusions: An AI-based clinical decision aid integrated into an EMR may help to refine prediction accuracy of SRK/T. Further validation is needed in more eyes and consideration of multiple biometry measurements simultaneously.

ABSTRACT BODY:

Purpose: The dry form of age-related macular degeneration (AMD), one of the leading causes of blindness in the elderly, has now been established as a multifactorial disease. Cellular metabolic alterations and chronic inflammation have been identified as two major pathological factors that contribute to the progression of dry AMD. In this study we evaluated the crosstalk between metabolic changes and inflammation induction in a mouse model that shows a dry AMD-like phenotype with the intent to target specific molecules in a pathway that would rescue both the metabolic insult and inflammation, thereby halting the progression of the disease.

Methods: RNAseq analysis was performed on RPE cells from cultured wild type RPE explants overexpressing βA1-, βA3- or βA3/A1-crystallin via adenoviral RFP constructs. To compare the metabolic gene profile/intermediates in the RPE cells at the early and advanced stages of disease progression in a mouse model, scRNAseq (cells from the sub-retinal space) and metabolomics/lipidomics (RPE cells) analyses were performed on 3, 10 and 15 month old Cryba1-floxed and cKO mice; data were confirmed with western blotting. βA3 KO and Cryba1 cKO mice were fed a high fat diet (HFD) to induce metabolic stress and resulting changes in signaling mediators and histopathology assessed.

Results: Metabolomics studies revealed a significant increase in the levels of intermediates known to induce mTORC1 signaling, like aspartate and betaine, in cKO RPE relative to controls. Lipidomic profiling showed elevated fatty acids (FAs) in cKO RPE, owing to the activation of the mTORC1-dependent FA synthesis pathway. We identified IL-17 signaling pathway activation as the link between these metabolic changes and chronic inflammation induction in the RPE of our mouse model during disease progression. Further, HFD treatment in our mouse models exacerbated the alterations in IL-17 levels and FA synthesis, and induced lipid droplet accumulation in the RPE cells.

Conclusions: We have now established the onset of IL-17 mediated inflammatory signaling as the link between cellular metabolic alterations and chronic inflammation in a mouse model of dry AMD. It is known that IL-17 is upregulated in the RPE of human AMD patients. Hence, targeting IL-17 and/or molecules of this signaling pathway could be an avenue for future therapeutic interventions to delay the progression of dry AMD.

TITLE: Retinal bipolar cells make inhibitory synapses onto amacrine cells

SESSION TITLE: Retinal and central processing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Jo, S. Deniz, J. Xu, S.H. DeVries, Y. Zhu, Ophthalmology, Northwestern University Feinberg School of Medicine, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Andrew Jo: Commercial Relationship: Code N (No Commercial Relationship) | Sercan Deniz: Commercial Relationship: Code N (No Commercial Relationship) | Jian Xu: Commercial Relationship: Code N (No Commercial Relationship) | Steven DeVries: Commercial Relationship: Code N (No Commercial Relationship) | Yongling Zhu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Amacrine cells (ACs) are the least understood cell class in the retina due to the lack of genetic access and limited accessibility for patch-clamp recording. In this study, we combined mouse genetics, genetic profiling, functional imaging, and electrophysiology recording to discover new AC types and analyze their functional properties.

Methods: We use Cre/tTA intersectional genetics to identify new AC types, followed by analyzing their genetic profiles with single cell RNA sequencing (scRNA-seq), and then characterize their functional properties and circuit roles with GCaMP and iGluSnFr imaging, combined with electrophysiology recording.

Results: With Slc32a1-iCreER/Scg2-tTA intersectional strategy, we identified a new narrow-field AC subtype in the mouse retina, named Scg2-AC2. To our surprise, Scg2-AC2 showed light responses unexpected from morphological features. Scg2-AC2 stratified in the ON layer, but was activated by light decrement (OFF) in the surround and inhibited by light increment (ON) in the center. The ON center inhibition was created by sign-inverting mGluR8 activated by glutamate released from ON bipolar cells. The OFF surround activation was mediated by a wide-filed AC that received excitation from sustained OFF bipolar cells in the OFF sublamina and then made gap junction connections with Scg2-AC2 and activated it in the dark.

Conclusions: This study discovered a new AC type inhibited by bipolar cells via glutamate transmission. The structure and function correlation of Scg2-AC2 positions its potential role in “crossover inhibition” between ON and OFF channels by carrying OFF inhibition to the ON channel to enhance light sensitivity of RGCs in the dark.

TITLE: Identification of Choroidal Vascular Abnormalities in Patients with Hereditary Hemorrhagic Telangiectasia (HHT)

SESSION TITLE: Imaging of posterior segment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Luong, O. Houghton, Mayo Clinic School of Medicine - Scottsdale Campus, Scottsdale, Arizona, UNITED STATES|

Commercial Relationships Disclosure: Hanna Luong: Commercial Relationship: Code N (No Commercial Relationship) | Odette Houghton: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Reported rates of ocular involvement in HHT and recommendations regarding ophthalmic surveillance are variable. Our study sought to evaluate the prevalence of ocular imaging in patients with HHT at a large academic medical institution, characterize the choroidal vascular changes on indocyanine green angiography (ICGA) and optical coherence tomography (OCT), and present the first images of ocular HHT with ultra-widefield ICGA and enhanced-depth imaging (EDI) OCT.

Methods: Retrospective review of patients with HHT who were seen in the ophthalmology clinic at any of the Mayo Clinic sites (MN, AZ, and FL) between October 22, 2011 to October 22, 2021.

Results: Of the 71 patients with HHT identified, 7 individuals had appropriate imaging defined as radial or raster spectral-domain OCT scans and/or ICGA. 4 patients were female and 3 were male. 57% of patients, which included all male patients with imaging, had enlarged choroidal vessels detected on OCT (Image 1) and/or ICGA (Image 2). 43% of patients had both choroidal and retinal vascular changes, which consisted of pre-capillary vascular loop, capillary drop out/ischemia with telangiectasia and microaneurysms, and tortuosity of the retinal veins. The mean age for individuals with and without choroidal findings was 67 ± 11 years and 45 ± 24 years, respectively. Patients with choroidal changes included the endoglin gene mutation and displayed symptoms of gastrointestinal arteriovenous malformations (AVM) and facial and mucocutaneous telangiectasias. In contrast, one patient without choroidal changes had the activin A receptor type-like kinase 1 gene mutation and no signs or symptoms of HHT. A similar proportion of those with and without choroidal abnormalities had epistaxis and pulmonary AVMs.

Conclusions: To our knowledge, this study is the first to illustrate choroidal vascular changes in HHT with ultra-widefield ICGA and EDI OCT. The small number of patients suggests a low incidence of choroidal vascular abnormalities. Those with choroidal vascular abnormalities appear to have corroborating retinal vascular changes as well as a greater number and severity of systemic symptoms than patients without choroidal findings.

ABSTRACT BODY:

Purpose: Multiple studies suggested that alterations in the cellular ability to maintain healthy proteome contribute to vision loss. The majority of proteins in any cells are degraded by Ubiquitin-Protein System (UPS), a complex cellular network that includes hundreds of proteins working in concert with chaperone and autophagy systems. A potentially efficient strategy to manipulate such complex cellular system is to target transcriptional factor(s) or pathways controlling the expression levels of its key components. Previous studies established transcriptional factor Nfe2l1 (Nuclear factor erythroid-2-like 1) as an activator of proteasomal gene expression in response to lethal concentrations of proteasomal inhibitors in cancer cells lines. Other studies suggested that Nfe2l1 instead regulates genes related to redox and anti-inflammatory response, cell regeneration and protection from cholesterol toxicity. Here, we used mouse genetics to define regulatory gene networks of Nfe2l1 in the retina.

Methods: To understand the role of Nfe2l1, we studied retinal phenotypes of mice overexpressing or lacking Nfe2l1. Levels of proteasomes and other proteins were assessed using RNA-seq, qRT-PCR and WB. The proteasomal activity was measured using fluorogenic peptidase assay. Health, function, and structural changes of the retina were evaluated with OCT, ERG, morphometric and microscopic analysis.

Results: Nfe2l1 overexpression increases levels and activity of proteasomes in the retina without affecting retinal morphology or function. Whole retina knockout of Nfe2l1 reduces the pool of proteasomes and their activity. This leads to progressive thinning of the retina, loss of photoreceptors and other retinal neurons with particularly pronounced loss of ganglion and horizontal cells. Transcriptional studies uncovered that in addition to proteasomal subunits, Nfe2l1 regulates critical autophagy genes, ubiquitin ligases, deubiquitinating enzymes and chaperones.

Conclusions: Nfe2l1 is a powerful master regulator of proteostasis in the retina and controls expression of proteasomal components, wide range of proteins involved in the degradation of ubiquitinated proteins, chaperones and autophagy. The basal activity of Nfe2l1 sets proteolytic capacity of retinal neurons and plays an important role in retinal health. These findings warrant further studies of Nfe2l1 in the retina and support exploring an enhancement of this pathway with therapeutic goals.

TITLE: Comparison of axial length measurement in eyes with chorioretinal diseases using spectral-domain optical coherence tomography-based device and partial coherence interferometry

SESSION TITLE: Optics: Accommodation, Lens and Ocular Biometry

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Oh, Y. Kim, C. Yun, S. Ahn, Department of Ophthalmology, Korea University College of Medicine and School of Medicine, Seoul, Foreign, KOREA (THE REPUBLIC OF)|

Commercial Relationships Disclosure: Jaeryung Oh: Commercial Relationship: Code N (No Commercial Relationship) | Young Ho Kim: Commercial Relationship: Code N (No Commercial Relationship) | Cheolmin Yun: Commercial Relationship: Code N (No Commercial Relationship) | So Min Ahn: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Only a few studies have evaluated the reliability and comparability of axial length measurement using various ocular biometry devices in eyes with chorioretinal diseases. Partial coherence interferometry has been most widely used to measure the axial length of the eye, but devices using various principles have recently been developed. We compared the axial length measurement between partial coherence interferometry and spectral-domain optical coherence tomography (SD-OCT)-based devices.

Methods: This instrument validation and comparative study, which was conducted prospectively and retrospectively, included patients with various chorioretinal diseases and healthy subjects. All patients underwent axial length measurement using a recently introduced SD-OCT-based device (HOCT-1F; Huvitz Co., Ltd., Anyang-si, South Korea) and a partial coherence interferometry (IOLMaster, version 5.4, Carl Zeiss Meditec). We compared the axial lengths measured by two devices and evaluated their agreement using the intraclass coefficient (ICC) and the Bland-Altman plots with 95% limits of agreement (LOA).

Results: A total of 151 eyes of 87 patients were included, and the mean age was 63.3 ± 10.0 years. Of 151 eyes, 22 were healthy controls and 129 had chorioretinal diseases. The mean axial length measured by OCT-based device and partial coherence interferometry was 23.72 ± 0.88 mm and 23.63 ± 0.91 mm, respectively. The mean difference in axial length between the two devices was significant both in healthy controls ($P = 0.0048$) and in eyes with chorioretinal diseases ($P < 0.001$). However, the axial length measured by two devices showed excellent agreement both in healthy controls (ICC = 0.992) and in eyes with chorioretinal disease (ICC = 0.991). In Bland-Altman analysis, the mean difference of axial length in healthy controls and in eyes with chorioretinal disease was 0.099 ± 0.144 (95% LOA, -0.183–0.381) and 0.088 ± 0.168 mm (95% LOA, -0.241–0.146), respectively.

Conclusions: The new SD-OCT-based device showed a good agreement with partial coherence interferometry. Axial length measured by SD-OCT-based devices are compatible, but some correction factor is required.

ABSTRACT BODY:

Purpose: Hyaluronan (HA), an integral component of the limbal stem cell niche (LSCN), has been shown to be instrumental in maintaining limbal stem cells (LESCs) in vivo. Here, we investigated whether human LESCs also express HA in vitro. HA is known to assist LESCs in vivo, therefore, we also investigated whether this endogenous matrix supports ex vivoexpansion of LESCs and whether the addition of exogenous HA can further support LESCs.

Methods: Primary human LESCs (hLESCs) were isolated from donor human corneas and a mouse corneal epithelial progenitor (TKE2) cell line was obtained. The HA extracellular matrix was identified in vitro through immunocytochemistry, flow cytometry, and a red blood exclusion assay. LESCs were cultured onto HA coated petri dishes or in the presence of HA through media supplementation. Cell viability, proliferation, cell size, colony formation capacity (CFC), and putative stem cell marker expression were investigated.

Results: Both hLESCs and TKE2 cells present a HA rich ECM in vitro which is essential for maintaining viable LESCs. Providing exogenous HA as supplemented media increased LESC proliferation, CFC, and putative LESC marker expression.

Conclusions: Exogenous and endogenous HA preserve the LESC phenotype supporting ex vivo expansion. The presence of HA in the ECM creates a specialized niche for LESCs both in vitro and ex vivo, therefore, supplementing hLESCs with HA can become an accessible and affordable option for clinical applications.

ABSTRACT BODY:

Purpose: Leber congenital amaurosis (LCA) is the most common cause of inherited retinal degeneration in children. LCA patients with RPE65 mutations show accelerated cone photoreceptor dysfunction and death, resulting in early visual impairment. It is therefore crucial to develop a robust therapy that not only compensates for lost RPE65 function, but also protects photoreceptors from further degeneration. Here, we sought to answer whether base editing could rescue cone photoreceptor's survival and function.

Methods: We first screened for a combination of evolved ABE variants and sgRNAs to enhance the on-target correction rate and reduce bystander base editing. Then, we packaged the selected ABE variant and sgRNA into a lentivirus and subretinally delivered it to rd12 or rd12Gnat1$^{-/-}$ mice at 3-weeks-old. We assessed the DNA correction, RPE65 rescue, survival of S-opsin- and M-opsin-positive cones (S-cones and M-cones), and localization of S-opsins and M-opsins on retinal wholemount and cross-section staining. Furthermore, we evaluated cone function in treated rd12Gnat1$^{-/-}$ mice with electroretinography and visual cortex recordings. Lastly, we used single-cell RNA-sequencing to examine the impact of base editing on cone photoreceptors.

Results: Subretinal delivery of ABE and sgRNA corrected up to 40% of Rpe65 transcripts and preserved significantly higher numbers of S-opsin- and M-opsin-positive cones compared to the age-matched control group. The retinal cross-sections of the treated mice revealed correct localization of S-opsins and M-opsins in the cone outer segments. The photopic ERG waveforms from S- or M-cones from the treated rd12Gnat1$^{-/-}$ mice exhibited a prominent b-wave, whereas untreated eyes did not respond. Long-term protection of cone photoreceptors and function was also evident in older mice at 6 months of age. Furthermore, single-cell RNA-seq of the treated retinas revealed rescue of the gene expressions associated with cone phototransduction and survival.

Conclusions: Our results show that base editing can rescue the function and survival of cone photoreceptors, which has been a major challenge in the treatment of inherited blindness. These findings provide a foundation for a potential one-time treatment for LCA that confers long-lasting retinal protection, and warrant development of base editing for clinical application.

ABSTRACT BODY:

Purpose: Repetitive intravitreal injections of drug or intravitreal injections of sustained-release corticosteroid implants (Ozurdex, Retisert, and Iluvien) are the current standard of care for the chronic diseases. However, these methods involve complications due to the high initial dose at the time of injection, known as burst release.
In this study, we have developed a size-exclusive nanoporous biodegradable poly lactic glycolic acid (PLGA) capsule for dosage-controllable drug delivery implants to avoid the burst release and control the dose only when needed.
Methods: We have developed a biodegradable PLGA implant enclosing light-activated liposomal drug (methotrexate). The PLGA implant has nano-sized pores where methotrexate (MTX) was released through when activated by laser, leaving the liposomal drug in the capsule. We have optimized the porosity and the pore size for MTX release kinetics, and tested the stability and the safety for 6 months in vivo rabbit eyes. We also irradiated near infrared laser (NIR, 1064 nm) through the lens of rabbit eyes to release MTX and fluorescence dye for visualization. The MTX release by laser was quantified based on in vivo imaging.
Results: We created a pore size less than 5 nm to selectively release drug molecules only upon laser irradiation leaving the liposomal drug inside the capsule ($p<0.05$). We observed the nanopore size increased during degradation over 6 months in physiological conditions via scanning electron microscopy.
Shrinkage of the implant structure, observed on Day 180, was attributed to the degradation process. No adverse event due to the implant was observed on the retina via fundus, ultrasound exam and histology, during the 6 months. The implant did not seem to interfere with vision of the rabbits, based on their behavior. The location and position of the implant was not significantly changed.
Lastly, the dose released in vivo by laser followed the first-order kinetics and daily/weekly dose was clinically relevant (~50 ug per week).
Conclusions: We successfully showed effective drug release from a nanoporous PLGA implant using pulsed NIR laser irradiation both in vitro and in vivo. The drug delivery system was safe and stable against leakage for 6 months. The light-activated drug delivery system that we developed will provide tightly-controlled release without burst release. Thus, the drug delivery system could be potentially used for long-term posterior eye disease treatment.

ABSTRACT BODY:

Purpose: In blinding diseases of the retina, loss of visual function may occur long before structural changes are observed. The emerging field of optoretinography (ORG) promises non-invasive, objective assessment of functional, stimulus-evoked responses in the retina. Here we present a novel ORG approach to facilitate and accelerate ORG applications in the clinical setting.

Methods: The swept-source optical coherence tomography (SS-OCT) system uses a source centered at 1060 nm with a 100 kHz A-scan rate and 100 nm bandwidth (Fig. 1). The beam is scanned horizontally over the retina to acquire a series of B-scans. The stimulus source is a fiber-coupled light emitting diode at 555 nm, configured to deliver 30 ms flash. The system was configured to acquire 250 A-scans over each 2.5° scan, resulting in a B-scan rate of 400 Hz and sampling density of ~333 mm^{-1} the retina. Prior to imaging, the subjects were dark-adapted for five minutes. The stimulus flash was delivered after the first 0.25 s of OCT acquisition. A time window of five B-scans (t = 10 ms) was used to do a linear fit of the complex signal over time at each pixel. The angle of the fit to the complex signal reveals local tissue velocity, which was recorded as a function of time relative to the stimulus onset.

Results: The results shown in Fig. 2 used a stimulus power of 42 μW, isomerizing 66% of photopigment in the predominant L- and M-cones in a 1.2° circular region. All three subjects showed reproducible differential velocities (between IS/OS and COST) consistent with the previously reported stimulus-evoked contraction (< 10 ms) and elongation (10-50 ms) phases of the outer segment ORG response.

Conclusions: The results are consistent with previous ORG responses acquired from photoreceptor's outer segments using adaptive optics OCT (AO-OCT). Including time for dark adaptation, imaging, and processing, functional responses can be measured and visualized within ten minutes providing a feasible clinical pipeline for larger scale ORG studies.

ABSTRACT BODY:

Purpose: To establish a natural and reproducible branch retinal artery occlusion (BRAO) mouse model by using intravital confocal retinal microscopy and to analyze pathophysiologic changes of the retinal microglia in Ischemic-Reperfusion (IR) injury after BRAO modeling.

Methods: Rose bengal (75mg/kg) was injected to 7 weeks-old transgenic mice (CX3CR1-GFP, for microglial visualization). 561nm laser was projected to a specified single vessel to induce photo-thrombosis for 27 seconds by custom-built video-rate confocal microscopy. Thrombosis was recorded in real time and intravital retinal images were longitudinally acquired for 7 days. Immunohistochemistry, fluorescence associated cell sorting (FACS) analysis and RT-qPCR were performed to observe IR injury related reactions of retinal microglia.

Results: Establishment of reproducible BRAO modeling was archived. Blocked perfusion in the targeted artery by embolism occlusion and the formation of ischemic area were reliably observed in all BRAO induced model. Dynamic alteration in the molecular profiles of immune cell infiltrated to the ischemic lesion were prominently activated at 3 days after BRAO modeling. Especially, Nox2 RNA expression, CD86 expression and microglial morphology changes were peaked at that time. The time point is co-related with the reperfusion with thrombus self-resolution. At day 7 with restored reperfusion in large vessel, CX3CR1 signal was slightly decreased but the number of CX3CR1+ microglia were significantly increased around ischemic area. These microglia were focally recruited from optic disc through nerve fibers and large veins. And most of the CX3CR1-GFP (+) cells had no CCR2 expression.

Conclusions: Our study successfully demonstrated a reproducible BRAO modeling with technical advantages of precise control of the time points and selection of a specific single target vessel. The role of retinal microglia in IR injury after BRAO could be analyzed. It will be a useful experimental tool to investigate the pathophysiology of BRAO.

ABSTRACT BODY:

Purpose: To investigate which participant and neighborhood characteristics are associated with not showing up for a free glaucoma screening appointment.

Methods: Participant demographics were extracted from the University of Michigan electronic health record and distance between residence and clinic site was calculated using a geographical information system. Neighborhood level characteristics obtained from the United States Census included median household income (HHI), percent of households whose rent burden is 30% or more of their income, percent of household income spent on energy costs, percent of households without vehicles, and area deprivation index (ADI). Demographic and neighborhood characteristics were summarized and compared between participants who attended their screening visits (shows) and those who did not (no-shows). Logistic regression was used to model the probability of no-show for each neighborhood characteristic and distance while adjusting for age, sex, ethnicity, and race.

Results: 1431 participants were scheduled for screening appointments between July 2020 to November 2021. Participants were on average 54.1 years old (SD=14.5), 60% female, 51% Black, 37% White, 9% Latinx, and lived an average of 7.7 miles from each clinic (SD=8.1). Participants lived in neighborhoods with an average median HHI of $49,200 (SD=30,200), where an average of 46.8% of households were rent burdened (SD=23.9%), 5.0% (SD=2.7%) were energy burdened, 11.7% (SD=6.0%) had no vehicle, and the mean ADI was 6.8 (SD=3.2, 1-10 scale where 10 is the most deprived). The no-show rate was 23% (n=330/1431). After adjusting for demographics, a 1% increase in energy burden (odds ratio, OR=1.08, p=0.003), households without a vehicle (OR=1.02, p=0.197), a 5% increase in rent burden (OR=1.04, p=0.023), and a 1-point increase in ADI (OR=1.08, p=0.002) were associated with higher odds of no-show. A 10-mile increase in distance to clinic (OR=0.85, p=0.135) and a $10k increase in median HHI (OR=0.90, p<0.001) were associated with lower odds of no-show.

Conclusions: Higher neighborhood levels of poverty were associated with higher odds of no-showing to a free glaucoma screening appointment, after adjusting for age, sex, race, and ethnicity. Providing communities with high poverty rates additional holistic support to attend free eye care services will help enable early detection and treatment for glaucoma.

ABSTRACT BODY:

Purpose: To evaluate the relationship between COVID-19 case volume and ophthalmic procedural volume during the pandemic.
Methods: A retrospective cohort study using TriNetX (Cambridge, MA, USA), a federated electronic health records research network comprising multiple large health organizations in the United States. Monthly Current Procedural Terminology (CPT)-specific volumes per HCO were clustered chronologically to calculate average volumes into three-month seasons to calculate average volumes. Seasonal averages from a combination of 2018 and 2019 data were used to provide a baseline comparison to pre-pandemic procedural volume. An aggregate of the total pandemic period (March 2020 - August 2021) was compared to the corresponding figures in pre-pandemic timeframes.
Results: 670,541 unique ophthalmic procedures from among 573 HCOs between March 2018 and August 2021 were included. Intravitreal injections was the most prevalent procedure with 320,106 occurrences. Phacoemulsification cataract surgery was the second most prevalent (N = 176,095) procedure with 144,816 uncomplicated (82.2%) and 31,279 complicated (17.8%). Intravitreal injections had the highest mean seasonal volume per HCO for each of the five COVID-19 pandemic seasons. From March 2020 – August 2021, a mean pandemic volume of 266.7 (SD = 15) was observed, a 5% decrease ($p<0.05$) in procedures compared to pre-pandemic mean of 280.8 (SD = 26.1).

During the five COVID-19 pandemic seasons, the seasonal mean volume almost always differed from pre-pandemic comparisons. Spring 2020 exhibited the sharpest seasonal decrease in procedural volume (88%). Spring 2021 had the largest count of significant increase in procedure volume (18%). Aggregate mean volume per HCO showed significant decreases for 11 out of 17 procedures in the 12-month March 2020-February 2021 timeframe and significant decreases for 10/17 procedures over the 18-month March 2020-August 2021 timeframe. A relative inverse relationship between COVID-19 case volume and ophthalmic procedure volume was observed.
Conclusions: This study highlights the relative inverse relationship between COVID-19 cases and ophthalmic procedure volume in the US. Reduction in procedural volume may result in delayed care with potential for vision loss. Awareness and understanding of these trends could help ophthalmologists prepare should a similar cycle occur in the setting of the omicron and future variants.

ABSTRACT BODY:

Purpose: The use of tocilizumab (TCZ), an interleukin-6 inhibitor, to treat non-infectious uveitis (NIU), one of the leading causes of preventable blindness worldwide, has generated considerable controversy. Therefore, we performed a systematic review and meta-analysis (MA) of existing literature to determine the efficacy and safety of TCZ in NIU treatment.

Methods: A comprehensive online search was conducted using PubMed, Web of Science, Embase, Scopus databases and reference lists of pertinent studies for pre-post clinical trials published through October 2021. Overall, 2614 records were identified, of which 991 were duplicates. Subsequently, unrelated studies were excluded by title and abstract screening (n=1594) and full-text assessment (n=21). Ultimately, 5 of the 8 relevant studies included in the systematic review were eligible for inclusion in the MA. We recorded all reported adverse events (AE) and considered the mean difference in best-corrected visual acuity (BCVA) before and after TCZ treatment as the visual outcome. Weighted mean difference (WMD) with 95% confidence interval (CI) was employed as pooled estimation of intervention efficacy using random-effects MA. Heterogeneity was assessed using Cochran's Q test and quantified with the I^2 statistic. Sensitivity analysis was performed to evaluate the robustness of the MA findings using Stata version 14 software.

Results: Pooled data of 46 patients (77 eyes) of the 5 included trials were meta-analyzed. In these studies, which had a mean follow-up of 14.58 months, 8 mg/kg TCZ was administered monthly to treat refractory uveitis-related macular edema, cystoid macular edema and juvenile idiopathic arthritis. TCZ AEs requiring dose lowering/discontinuation were reported in 2 cases (mild neutropenia and community-acquired pneumonia). Between-study heterogeneity was low (I^2 =18.7%,p=0.29) and mean LogMAR BCVA significantly improved after TCZ therapy (WMD=-0.26 (CI=-0.41to-0.10))(Fig1). Our MA supports a statistically significant improvement in BCVA, indicating a robustness of the finding.

Conclusions: TCZ has statistically been demonstrated to be effective in NIU management with almost negligible AEs. This finding may provide clinicians with sufficient information to consider TCZ as a possible therapeutic option for eligible NIU patients.

ABSTRACT BODY:

Purpose: Head scanning may be critical for safe walking, especially for patients with homonymous field defects (HFDs). The study investigated differences in head scanning behaviors between left and right HFD.

Methods: 13 patients (7 Left HFD, 6 Right HFD) walked along two urban routes (each about 0.5 miles long) containing among them 7 different street crossing locations without pedestrian signal, while wearing a mobile gaze (eye + head) tracking system that also captured synchronized scene videos. Time points corresponding to street crossing instances (including approach and crossing phases) were manually identified in the scene videos. Large horizontal head scans (> 20°) relative to torso were counted. Based on the direction of crossing traffic (Left, Right, or Both) at each intersection, scanning behavior was classified as either safe – at least one scan towards the direction of traffic, or unsafe – lack of scanning towards the traffic direction. For crossings with 2-way traffic, scanning in both directions were required to be considered as a safe scan. The proportion of crossings with unsafe scanning was compared between Right & Left HFD patients using a Poisson regression model.

Results: A total of 197 non-signalized crossing instances totaling 55 minutes were annotated, yielding 350 head scans (average of 1.78 scans/crossing). The majority (66%) of crossing instances had one-way traffic (29% from Left and 37% from Right). The proportions of crossing instances with traffic from the left side, right side, and both sides were 30%, 40%, 30%, respectively for Left HFD group, and were 28%, 34% and 38% for Right HFD group, respectively. The proportions of traffic direction experienced was not significantly different between the two patient groups (χ^2 = 1.4, p = 0.5). However, the proportion of crossing instances with unsafe scanning in Right HFD patients (0.74) was 62% higher than Left HFD patients (0.46), which was statistically significant (β = 1.62, 95% CI: 1.12 - 2.34, p = 0.01).

Conclusions: In this study, where direct measurement of head scanning was performed during real-world walking scenarios, Right HFD patients had more instances of unsafe scanning behavior compared to Left HFD patients when crossing non-signalized intersections.

TITLE: Role of macrophage sub-populations in ocular HSV-1 infection.

SESSION TITLE: Pathobiology of Microbial Infections

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: U. Jaggi, H. Matundan, H. Ghiasi, Surgery, Cedars-Sinai Medical Center, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Ujjaldeep Jaggi: Commercial Relationship: Code N (No Commercial Relationship) | Harry Matundan: Commercial Relationship: Code N (No Commercial Relationship) | Homayon Ghiasi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To understand the mechanism of macrophage subtypes on ocular HSV-1 infection, we previously demonstrated that altering macrophage polarization from resting stage (M0) towards M2 leads to reduction in both primary and latent infection in comparison to induction of M1 in ocularly infected mice. Based on these observations, we implemented studies using $M1^{-/-}$, $M2^{-/-}$, transgenic mice lacking autophagy in their M1 or M2 and compared them to wild type (WT) mice.

Methods: We constructed two different transgenic mice by blocking autophagy in M1 macrophages with γ34.5 gene expressed under the control of NOS2 promoter (M1) or ARG1 promoter (M2). Both male and female $M1^{-/-}$, $M2^{-/-}$, transgenic mice lacking autophagy in the M1, transgenic mice lacking autophagy in the M2 and WT control mice were ocularly infected with $2X10^5$ PFU/eye of virulent HSV-1 strain McKrae or avirulent strain KOS with or without corneal scarification. Mice were evaluated for severity of eye disease, viral titers in the eye and latency-reactivation. Bone marrow experiments were conducted to validate the phenotype of mice and in-vitro viral titers. Detailed screening of various genes, cytokines and chemokines were analyzed by nanostring and Luminex.

Results: Increased viral titers ($P<0.05$) and mortality was recorded for $M1^{-/-}$ mice as compared to WT group and $M2^{-/-}$ mice. Viral titers, corneal scarring and mortality were restored on adoptive transfer of M1 macrophages to $M1^{-/-}$ mice with no impact on latency-reactivation. $M2^{-/-}$ mice showed delayed reactivation ($P<0.001$) compared with WT mice. Loss of M1 macrophages in $M1^{-/-}$ mice resulted in enhanced inflammatory response as validated by nanostring and Luminex analysis as compared to other mice groups. We have also shown that blocking autophagy in M1 macrophages increased viral titers and eye disease ($P<0.05$) in ocularly infected mice compared with mice lacking autophagy in their M2 macrophages or WT mice.

Conclusions: Our studies elucidate the importance of M1 macrophages in controlling the virus replication in the eyes of infected mice, preventing mortality and eye disease. We also found the importance of autophagy in protection from virus replication and eye disease in transgenic mice lacking autophagy in their M1 but not their M2 macrophages. Therefore, our data conclude the importance of M1 but not M2 macrophages in protection against ocular HSV-1 infection.

ABSTRACT BODY:

Purpose: Social media has become an increasingly utilized tool in academic medicine and in ophthalmology, especially as COVID-19 pandemic restrictions limit in-person interactions. We performed a cross-sectional study of publicly available accounts on the social media platform Instagram to describe the use of Instagram by academic ophthalmology residency programs in the United States over time and analyzed the impact of the COVID-19 pandemic on ophthalmology's social media presence.

Methods: Accredited ophthalmology residency programs as of November 2021 were identified using the Accreditation Council for Graduate Medical Education (ACGME) database and were reviewed to identify programs with an affiliated publicly available Instagram account. For each account, the number of posts, followers, and followed accounts were calculated, as well as the year of creation. For the top six ophthalmology Instagram accounts, as determined by number of followers, each post after 2018 was classified into one of six categories (Award/Publication, Department Highlight, Flyer/Holiday, Informal/Candid Group Photo, Medical, or Miscellaneous), and the number of likes and comments was calculated with assistance of a Python script. A two-tailed independent t-test was utilized to analyze user engagement by likes and comments before and after January 2020.

Results: Of the 124 ophthalmology residency programs, 78 (62.9%) were identified as having an affiliated Instagram account, 60 accounts (48.4%) were created during the years 2020 or 2021, and 62 (50.0%) accounts focused specifically on promoting the residency training program. Of the top six accounts with the most followers, post categories that received the most engagement were "Medical" and "Informal/Candid Group Photo" while those that received the least engagement were "Flyer/Holiday" and "Miscellaneous." User engagement on posts as measured by likes and comments increased across multiple post categories after January 2020.

Conclusions: Social media presence of ophthalmology residency programs on Instagram increased substantially in 2020 and 2021. As a result of the COVID-19 pandemic restricting in-person interactions, residency programs have used alternative platforms to reach applicants. Given the increasing use of such applications, social media will likely continue to become an important aspect of professional engagement in ophthalmology.

ABSTRACT BODY:

Purpose: Retinal degenerative disorders, including age-related macular degeneration and retinitis pigmentosa (RP), are characterized by the irreversible loss of photoreceptor cells and retinal pigment epithelial (RPE) cells; however, the long-term effect of implanting both human induced pluripotent stem cell (hiPSC)-derived RPE and photoreceptor for retinal regeneration has not yet been investigated. In this study, we evaluated the long-term effects of hiPSC-derived RPE and photoreceptor cell transplantation in Pde6b knockout rats to study RP.

Methods: We differentiated skin fibroblast-derived hiPSC into RPE and photoreceptor cells and verified in vitro. Pde6b knockout rats were generated by using CRISPR-Cpf1 technology. After, differentiated hiPSCs were injected into the subretinal space of the right eyes of rats before the appearance of signs of retinal degeneration at 2–3 weeks of age. Ten months after transplantation, we evaluated the cells using fundus photography, optical coherence tomography, and histological evaluation.

Results: Following transplantation of hiPSC-derived retinal cells no abnormal cell proliferation was observed. A relatively large number of transplanted cells persisted during the first 4 months; subsequently, the number of these cells decreased gradually. Notably, immunohistochemical analysis revealed that the hiPSC-derived retinal cells showed characteristics of both RPE cells and photoreceptors of human origin after transplantation. Functional analysis of vision by scotopic electroretinogram revealed significant preservation of vision after transplantation.

Conclusions: Our study suggests that the transplantation of hiPSC- derived retinal cells, including RPE cells and photoreceptors, has a potential therapeutic effect against irreversible retinal degenerative diseases.

ABSTRACT BODY:

Purpose: To introduce a novel method to measure retinal displacement in 3D using ultra-widefield fundus autofluorescence (UWF-FAF) imaging.

Methods: Images were acquired from patients presenting with primary macula-off RRD treated with pneumatic retinopexy (PnR) or pars plana vitrectomy (PPV). A coordinate grid was applied at the OD center of each UWF-FAF image. Two masked graders selected corresponding points on the retinal vasculature and retinal vessel printings (RVPs) within Zone 1, a circular region centered on the fovea with a radius extending to the center of the optic disk (Figure 1). 2D UWF-FAF images were projected to a 3D projection using OD and fovea coordinates. Vertical, horizontal, and diagonal arc distances between corresponding vessel and RVP pairs were calculated (Figure 2). Vector displacements of the RVP to vessel were calculated and averaged within Zone 1.

Results: 170 retinal vessel-RVP pairs were identified from 54 UWF-FAFs. Mean retinal displacement in Zone 1 was 0.36±0.38 mm with an absolute mean angle of displacement of 94.93±41.48° and directionality of displacement of 191.84±97.39°. Mean Zone 1 displacements were 0.44±0.42 mm and 0.21±0.27 mm in PPV (n=34) and PnR (n=19) eyes respectively, and was significantly greater in PPV eyes than PnR eyes (p=0.041). Between groups no significant difference in mean angle of displacement or directionality was found.

Conclusions: We present a novel method of quantitatively assessing displacement of retinal tissue that considers retinal curvature, via retinal vessels and RVPs on UWF-FAF.

ABSTRACT BODY:

Purpose: Uveal Melanoma (UM) is an aggressive ocular cancer that leads to metastatic death in ≈50% of patients. UM can be divided into two prognostic groups based on molecular landscape: class 1 UM, associated with EIF1AX or SF3B1 variants and low metastatic risk, and class 2 UM with loss-of-function mutations in BAP1 [breast cancer type 1 (BRCA1)–associated protein 1]. BAP1 is known primarily as a tumor suppressor gene implicated in renal cell carcinoma as well as class 2 UM, and recently has been associated with the process of normal eye development. Related to this latter role, BAP1 normally interacts with HDAC1 (histone deacetylase subunit 1), a critical component of the NuRD (nucleosome remodeling and deacetylase) complex, which normally mediates embryonic lineage commitment and cell differentiation through DNA histone deacetylation and chromatin remodeling. Preliminary data from our laboratory strongly suggests that absence of BAP1 disrupts the normal association between HDAC1 and two NuRD complex proteins, CHD3 and CHD4 (Chromodomain Helicase DNA binding protein 3 and 4), DNA-binding proteins with helicase and nucleosome remodeling activities. Here, we further explore the impact of the BAP1-NuRD complex interaction by directly abrogating CHD3 and 4 and comparing downstream expression of biomarkers associated with BAP1 loss.

Methods: We remodeled HEK293 cells and normal melanocytes by siRNA knockdown of CHD3 and CHD4. We used Western blotting and densitometry to quantitate expression of HDAC4 (histone deacetylase subunit 4), a molecular signature of BAP1 loss, in these CHD3/CHD4 knockdown cells.

Results: Western blotting confirmed selective, efficient knockdown of CHD3 and CHD4. Western blots of HEK293 cells with CHD3 or CHD4 knockdown documented increased HDAC4 expression in both conditions compared to cells treated with an siRNA scramble as control. Experiments in progress include assessment of other molecular signatures of BAP1 loss, including the pluripotency marker NANOG, after siRNA knockdown of CHD3 and CHD4 in melanocytes.

Conclusions: These data support the potential involvement of BAP1 in recruitment of NuRD complex components and imply that differences in BAP1 expression may mediate transcriptional events involved in normal and abnormal eye development, via NuRD (Figure). Insights from this research may also be relevant to HDAC inhibitor therapy, previously suggested as promising treatment options for class 2 UM.

Commercial Relationships Disclosure: Jila Noorikolouri: Commercial Relationship: Code N (No Commercial Relationship) | Christian Leal: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: .To report two cases of central serous chorioretinopathy (CSCR) associated with ocular tuberculosis (TB) and improvement following the standard anti-TB treatment

Methods: The first case was a 61 years-old native of India male who presented with recurrent iridocyclitis and episcleritis of the left eye. Fundus exam and macula Optical Coherence Tomography (OCT) revealed subretinal fluid (SRF) and pigmentary changes in the right eye suggestive for CSCR. The normal CXR and the positive quantiferon gold test indicated presumed ocular TB.

The second case was a 47-year-old Mexican male who presented with occlusive retinal vasculitis of unclear etiology and chronic CSCR in both eyes and positive quantiferon gold test.

Both patients subsequently started anti-TB treatment with a two-month course of moxifloxacin 400mg, rifampin 600mg, isoniazid 300mg, pyrazinamide 1500mg, and vitamin B6 50mg daily. Pyrazinamide was discontinued in the first patient after a week of pruritic rash. Both patients ultimately remained on rifampin 600mg, isoniazid 300mg, and B6 50mg daily for a planned treatment course of 9 months.

Results: First patients showed resolution of SRF in 2 months with no recurrence of either the fluid in the right eye and iridocyclitis and episcleritis of the left eye at subsequent follow-up visits, by the end of 7 months ant-TB treatment.

In the second case, the SRF resolved completely in the right eye in 3 months and the left eye in 5 months without recurrence by the end of ani-TB treatment.

Conclusions: Ocular TB may present as CSCR and improve with the standard anti- TB treatment. Large long-term clinical observations are required to confirm this association and response to the treatment.

ABSTRACT BODY:

Purpose: To examine the effect of falls on gait in glaucoma patients and to examine if falls lead to gait changes reflective of more cautious walking.

Methods: The GAITRite Electronic Walkway (CIR Systems Inc) was used to characterize participants' baseline gait and to record subsequent changes during three follow-up visits. Study visits were performed once a year. Gait parameters examined included stride length, stride length coefficient of variation (CV), stride velocity, stride velocity CV, base of support, base of support CV and cadence. Participants were classified into fallers and non-fallers based on the prospective falls data collection during the first year of the study. Assessment of longitudinal gait changes for each gait parameter in relation to faller status was evaluated using generalized estimating equation (GEE) models to account for within-individual clustering. Models controlled for age, race, gender, integrated visual field sensitivities, polypharmacy, and comorbidities.

Results: The 240 participants had a mean age of 71 years (SD = 7.6); about half of the participants were male and one-third were Black. Stratified analyses by fall status showed that over the course of the study stride length became shorter in both non-fallers and fallers (β = -0.08 z-score unit/year, β = -0.09 z-score unit/year, respectively, $p<0.001$ for all), while stride velocity slowed only among fallers (β = -0.08 z-score unit/year, $p=0.003$) and variability in stride velocity decreased only among non-fallers (β = -0.07 z-score unit/year, $p=0.009$). Base of support, cadence, base of support CV and stride length CV remained unchanged over the study period for both groups ($p>0.05$ for all). No differences in the longitudinal change in gait parameters over time were noted for fallers as compared to non-fallers ($p>0.05$ for all).

Conclusions: Among glaucoma patients, both faller and non-fallers seemed to have adopted a more cautious gait over time, though fallers did not appear to change their gait significantly more than non-fallers. Further studies with longer observation time are needed to evaluate this relationship.

TITLE: Hybrid rod-cone anatomical characteristics revealed in the ultrastructural features and synaptic architecture of the functionally plastic pure-rod retina

SESSION TITLE: Photoreceptors and the OPL

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: L. Magana Hernandez, E. Alvarez, D. Umbertus, J. Robles, E. Rose, D. Brown, I. Anastassov, San Francisco State University, San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure: Laura Magana Hernandez: Commercial Relationship: Code N (No Commercial Relationship) | Emma Alvarez: Commercial Relationship: Code N (No Commercial Relationship) | David Umbertus: Commercial Relationship: Code N (No Commercial Relationship) | Julio Robles: Commercial Relationship: Code N (No Commercial Relationship) | Erin Rose: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Brown: Commercial Relationship: Code N (No Commercial Relationship) | Ivan Anastassov: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Our research is aimed at understanding how the pure-rod retina of the elasmobranch Little skate (L. erinacea) can perform rod and cone functions with a monotypic population of photoreceptors. The skate retina allows us to describe the properties of rod circuitry within the context of a functional, evolutionarily optimized visual system, where all downstream components co-evolved to process signals from a single cell type. Here, we reveal the ultrastructural characteristics of a hybrid rod, its postsynaptic partners, and the wiring in the OPL of a pure-rod retina.

Methods: SB-3DEM was performed on individual retinal samples of the little skate. The datasets analyzed are from a region of interest (ROI) in the OPL and from a full cross-section of the skate retina. The ROI dataset XYZ dimensions are 27.6µm x 27.6µm x 21.5µm with a voxel size of 4.5nm x 4.5nm x 70nm. The full cross-section dataset dimensions are 88µm x 304µm x 21.8 µm with a voxel size of 10nm x 10nm x 70nm. 3D reconstructions and measurements were done with Reconstruct and Amira3D software.

Results: ~12-14 anatomically distinct invaginating processes diverge from rod terminals. These are presumed to belong to ON bipolar and horizontal cells. Additionally, ~3-4 processes made basal contacts outside of the invagination and are presumed to belong to OFF bipolar cells. However, it is also possible that there is a switched basal and invaginating identity for ON and OFF bipolar cells, respectively (as seen in some amphibians). The skate rod does not have an axonated terminal and exhibits ~4-6 telodendria (~2-18 µm), which can be traced to neighboring rods, or unidentified postsynaptic processes. Putative synaptic contacts along telodendria are presumed based on local neurotransmitter vesicle clusters along the length of telodendria.

Conclusions: Skate rod terminal morphology suggests a hybrid rod-cone anatomy. The lack of cones in skates may explain why rods are able to light-adapt and process visual information typically in the domain of cones. To fulfill the function of cones, while also retaining rod capabilities, the rod may need to make extra contacts with neighboring rods and other retinal neurons. We hypothesize that the anatomical hallmarks we see in our data suggest that skate rods have a hybrid rod-cone architecture, which also extends to the downstream circuitry.

ABSTRACT BODY:

Purpose: To report the short-term efficacy of switch therapy to brolucizumab in Japanese patients with neovascular age-related macular degeneration (nAMD) recalcitrant to aflibercept or ranibizumab therapy.

Methods: Design: Prospective case series.

Participants: Fifteen eyes of 15 patients with nAMD unable to extend treatment intervals beyond 8 weeks under aflibercept or ranibizumab therapy were enrolled.

Patients were switched to brolucizumab therapy, and the treatment intervals were reassessed based on the recurrence of fluids under the treat and extend protocol.

The best-corrected visual acuity converted to logarithm of the minimum angle of resolution (logMAR) unit, central foveal retinal thickness (CRT), height of subretinal retinal fluid (SRF) at the central fovea, maximum height of pigment epithelial detachment (PED), and the presence or absence of SRF and IRF were compared at baseline (after the last injection before switch therapy) and after the second intravitreal injection of brolucizumab (IVBr).

Results: The CRT(P=0.006), height of SRF (P=0.012) and maximum height of PED(P=0.001) improved significantly from baseline after the second IVBr. The visual acuity did not significantly improved from the baseline after the second IVBr (P=0.799). The proportions of eyes with SRF changed from 80% to 27% ($P = 0.012$, χ^2: 6.40)and the proportions of eyes with IRF changed from 6.7% to 13.3% ($P = 0.318$, χ^2: 1.00). There were three cases of intraocular inflammation without vision loss after the second IVBr.

Conclusions: The switch therapy to brolucizumab resulted in early anatomical response for Japanese patients with nAMD recalcitrant to aflibercept or ranibizumab therapy.

ABSTRACT BODY:

Purpose: Extended wear of color correcting lenses (CCLs, www.enchroma.com) improves suprathreshold color perception in hereditary color vision deficiency (CVD) even when CCLs are removed (Werner et al. 2020, doi.org/10.1016/j.cub.2020.05.054). We reported similar results at threshold and suprathreshold levels including cone visual-evoked potentials (VEPs, Rabin et al. 2022, doi:10.1038/s41433-021-01924-0). Our purpose was to further assess VEPs as a metric of CCL efficacy.

Methods: 13 CVDs (9 deuteranomalous, 4 protanomalous, age 32±14,13-66; CVD confirmed by Ishihara, anomaloscope, cone CS) provided informed consent to participate in our initial before-after design. Each subject was given a CCL appropriate for their CVD and tested without and with CCLs at baseline and 11-14 days after wearing CCLs (2.5±1.8 avg. hrs./day). Average cone specific pattern-onset VEPs (Rabin et al. 2016, doi:10.1167/tvst.5.3.8, 1 deg. checks specific to CVD and normal cones) were recorded to 75 pattern onsets without and with CCLs. Data normality allowed for ANOVA and t-tests (Bonferroni correction for multiple comparisons).

Results: In CVDs immediate wear of CCLs yielded robust VEPs with increased amplitudes ($F=8.8$, $P<.005$) and decreased VEP latencies ($F=7.2$, $P<.01$) in response to the deficient cone stimulus compared to measures without wearing CCLs. Yet immediate use of CCLs had no effect on amplitude ($F=0.2$, $P>.68$) or latency ($F=0.6$, $P>0.43$) in response to the stimulus for the CVDs' normal cone type indicating cone selectivity of this effect. Baseline mean VEP amplitudes for the CVD cone type without CCLs (3.6 μV) was significantly less than mean amplitude with CCLs (6.4 μV, $P<.002$). Baseline latency without CCLs (119.9 msec) was greater than with CCLs (90.8 msec, $P<.02$). After 12 days of CCL wear, 67% of CVDs showed increased VEP amplitude without wearing CCLs (mean increase 2.7 μV) and 75% showed decreased VEP latency (mean decrease 38.3 msec), but changes were not significant when compared to baseline measures without CCLs ($P>0.38$).

Conclusions: Cone VEPs provide an objective metric of color with use of CCLs. While immediate impact of CCLs on VEPs improved amplitude 2X and decreased latency 30 msec., long term effects occurred in some but not all CVDs, likely due wearing time variations, non-optimal matching of available CCLs to patient needs, and CVD severity. Future studies will include improved CCLs and control measures to address these issues.

ABSTRACT BODY:

Purpose: Several back of the eye diseases are mediated through multiple complex pathways with cross-talk. Having the ability to bind multiple targets with a single molecule may prove especially beneficial, bringing gains in efficacy of treatment. The purpose of this study is to characterize a novel bispecific platform (surrobody) for use in back of the eye disease. This study describes the structure of the novel platform and characterizes its Chemistry, Manufacturing, and Controls(CMC) characteristics through use of Size Exclusion Chromatography (SEC), its pharmacokinetic half-life (PK) in cynomolgus monkeys, and its thermostability after 12 months of storage at various temperatures.

Methods: All experiments were performed in accordance with the ARVO statement for Use of Animals in Ophthalmic and Vision Research. Three cynomolgus monkeys were administered an intravenous dose of Bispecific surrobody (10 mg/kg). Serum was tested over a 28 day period, with PK values then calculated. SEC was used to characterize the product after HEK293F transfection which showed high expression. Thermostability was assessed by holding Bispecific Surrobodies at room temperature, -80°C , and 4°C for 12 months and then assessing half maximal effective concentration via Enzyme Linked Immunosorbent Assay (ELISA).

Results: PK in cynomolgus monkeys was found to be 6.04 days for the Bispecific Surrobody as compared to 10.88 days for the control antibody using ELISA. SEC revealed single peaks indicating high levels of heterodimeric bispecific product formation. ELISA testing revealed no loss of activity of the Bispecific Surrobody with storage between -80°C

and room temperature for 12 months.

Conclusions: This novel bispecific platform has several desirable characteristics for a potential therapeutic agent. Its CMC characteristics show single peaks on SEC indicating high levels of heterodimeric bispecific product. Its full length constant fragment (Fc) affords long half-life as demonstrated in serum of cynomolgus monkeys on par with typical antibody half-life. Additionally, its thermostability at room temperature and ability to withstand a freeze-thaw cycle without losing efficacy points to its durability and potential to do away with cold chain logistics required for current generation therapeutics. Further study of the platform is warranted as the potential to develop into a next generation therapeutic exists.

ABSTRACT BODY:

Purpose: To report on demographic and systemic health related factors associated with follow-up eye care for diabetic patients from safety net primary care clinics in one health system who received a teleophthalmology evaluation.

Methods: A retrospective analysis on prospectively obtained cross sectional data for patients who underwent teleophthalmology evaluation at six urban safety net primary care clinics from 2015-2021 was performed. Demographic factors included age, race, ethnicity, sex, and health insurance. Systemic health factors included BP, smoking status, HbA1c, level of diabetic retinopathy (DR) and distance VA. Patients diagnosed with DR post screening were identified as having vision threatening (VTDR) (presence of diabetic macular edema (hard exudates), severe non-proliferative DR or worse) or non-vision threatening DR (NVTDR). Predictor variables associated with dependent variables at $p<0.20$ were included in single and multivariate logistic regressions at a $p<0.05$ significance level.

Results: Of patients (n=1229) evaluated via teleophthalmology, 702 (57%) scheduled follow up eye care appointments. 396 (56%) patients kept their appointments.

More African Americans (62%) made appointments than whites (49%), or those classified as other races (59%) ($p<0.001$). More Hispanics (62%) made appointments than non-Hispanics (56%) ($p<0.05$). Medicare Advantage (59%) ($p<0.006$), Medicare/Medicaid (62%) ($p<0.02$), and Medicaid managed plan holders (62%) ($p<0.003$) were more likely to make appointments than the uninsured (44%). More patients with VTDR (79%) ($p<0.001$) or NVTDR (66%) ($p<0.05$) made appointments than those without DR (55%).

Older age ($p<0.02$) was associated with keeping appointments. More nonsmokers (61%) ($p<0.03$) kept appointments than smokers (51%). More Medicare insurance plan holders (59%) kept appointments than commercial plan holders (51%) ($p<0.03$). VTDR ($p=0.19$) and NVTDR ($p=0.30$) patients were not more likely to keep appointments than those without DR.

Conclusions: Follow-up to eye care following primary care based vision screening and telehealth evaluation for retinopathy in patients with diabetes remains a challenge. Patients diagnosed with DR were more likely to make but not keep follow up appointments. More support to increase appointment adherence in low income, safety net patients is required, especially if they are younger, smoke, or have commercial insurance.

TITLE: A Novel Approach to Estimating Choroidal Lesion Thickness Using 2D Optomap Images

SESSION TITLE: Posterior Segment Imaging

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: M. Yu, M. Heiferman, E. Korot, P. Mruthyunjaya, Byers Eye Institute, Stanford University, Stanford, California, UNITED STATES|M. Heiferman, University of Illinois at Chicago, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Michael Yu: Commercial Relationship: Code N (No Commercial Relationship) | Michael Heiferman: Commercial Relationship: Code N (No Commercial Relationship) | Edward Korot: Commercial Relationship: Code N (No Commercial Relationship) | Prithvi Mruthyunjaya: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Tumor thickness is a well-established risk factor for transformation of choroidal nevus (CN) into choroidal melanoma (CM) and thus plays an important role in risk stratification of melanocytic choroidal lesions (MCL). Currently, B-scan ultrasonography is the most reliable method for measuring tumor thickness, but its utility in screening may be limited. Herein, we describe a novel technique for rapid extraction of tumor thickness data from 2D ultra-widefield (UWF) dual-wavelength scanning laser ophthalmoscope Optomap images (Optos PLC, Dunfermline, Fife, Scotland, UK).

Methods: A consecutive series of patients seen in the Ocular Oncology Service at the Byers Eye Institute (Stanford University, Palo Alto, CA) with clinically diagnosed MCL underwent complete clinical examination, UWF imaging, and standardized B-scan ultrasonography (Eye Cubed, Ellex Medical, Adelaide, Australia). The UWF images were post-processed to isolate the green-wavelength-only image. Using Image J (National Institutes of Health, Bethesda, MD, USA), average pixel intensities within the lesion and of the adjacent retina were obtained, and the difference between both values calculated (“pixel intensity difference”; average lesion intensity minus average adjacent retina intensity). The pixel intensity difference was then plotted against the reference standard for tumor thickness as measured by standardized B-scan ultrasonography. The significance of the relationship between both variables was assessed by linear regression analysis.

Results: A total of 141 MCL (16 CM and 125 CN) of 141 patients were evaluated. Mean ultrasonographic thickness was 1.2 mm (median: 0.8, range: 0.5-7.3). Mean pixel intensity difference was 6.7 (median: 3.8, range: -20.0 – 55.0). The linear correlation coefficient for tumor thickness to pixel intensity difference was 0.85 ($p<0.001$), indicating a strong positive correlation between tumor thickness and tumor brightness on green-wavelength imaging (Figure 1). Coefficient of determination (R^2) was 0.74. A pixel intensity difference threshold of >10 conferred a 100.0% sensitivity and 97.4% specificity for detection of tumors with thickness >2 mm.

Conclusions: Choroidal tumor thickness can be rapidly and reliably estimated using 2D UWF images. With additional validation, this method could augment future high-throughput screening and risk stratification of MCL with UWF images alone.

ABSTRACT BODY:

Purpose: Ageing is an important risk factor for a variety of human pathologies. Biological age (BA) may better capture ageing-related physiological changes, compared to chronological age (CA). We developed a deep-learning (DL) algorithm to predict BA based on retinal photographs and evaluated the performance of our new ageing marker in the risk stratification of mortality and major morbidity in general populations.

Methods: We first trained a DL algorithm using 129,236 retinal photographs from 40,480 participants in the Korean Health Screening study to predict the probability of age being ≥65 years (“RetiAGE”) and then evaluated the ability of RetiAGE to stratify the risk of mortality and major morbidity among 56,301 participants in the UK Biobank. Cox proportional hazards model was used to estimate the hazard ratios (HRs).

Results: In the UK Biobank, over a 10-year follow up, 2,236 (4.0%) died; of them, 636 [28.4%] were due to cardiovascular diseases (CVDs) and 1,276 [57.1%] due to cancers. Compared to the participants in the RetiAGE first quartile, those in the RetiAGE fourth quartile had a 67% higher risk of 10-year all-cause mortality (HR=1.67 [1.42-1.95]; Figure), a 142% higher risk of CVD mortality (HR=2.42 [1.69-3.48]), and a 60% higher risk of cancer mortality (HR=1.60 [1.31-1.96]), independent of CA and established ageing phenotypic biomarkers. Likewise, compared to the first quartile group, the risk of CVD and cancer events in the fourth quartile group increased by 39% (HR=1.39 [1.14-1.69]) and 18% (HR=1.18 [1.10-1.26]), respectively. The best discrimination ability for RetiAGE alone was found for CVD mortality (c-index=0.70, sensitivity=0.76, specificity=0.55). Furthermore, adding RetiAGE increased the discrimination ability of the model beyond CA and phenotypic biomarkers (increment in c-index between 1 and 2%).

Conclusions: The DL-derived RetiAGE provides a novel, alternative approach to measure ageing.

ABSTRACT BODY:

Purpose: Previously, it has been shown that ocular anatomy may be different in different ethnicities. However, little is known about differences in corneal tomography between Hispanic and non-Hispanic populations. This study aims to compare corneal tomographic parameters as measured by Pentacam between Hispanic and non-Hispanic White populations.

Methods: In this retrospective study, we analyzed Pentacam data from patients who underwent surgery for senile cataract. We included patients 50 years or older who were self-identified as Hispanic White and non-Hispanic White. We excluded patients with corneal or anterior segment surgery or trauma, or any abnormality in these structures. The following parameters were compared between the Hispanic White and non-Hispanic White groups for both anterior and posterior corneal surface: steep keratometry (K1), flat keratometry (K2), mean keratometry (Km), maximum keratometry (Kmax), amount of astigmatism, axis of steep meridian, and type of astigmatism.

Results: This study consisted of 200 patients, including 103 Hispanic White individuals and 97 non-Hispanic White individuals. The mean age was 69.9 ± 7.4 years (range, 50-88 years), and there were 68 men and 132 women. There were no statistically significant differences between Hispanics and non-Hispanics regarding K1, K2, Km, Kmax, amount of astigmatism, and steep axis in both front and back corneal surfaces. There were also no significant differences in type of corneal astigmatism (with-the-rule, against-the-rule, or oblique) in front or back corneal surfaces between these two groups. There were significant differences between right and left eyes in corneal front steep axis (73.8 ± 49.9 deg vs 104.3 ± 49.7 deg, respectively, $P<0.001$) and corneal back steep axis (97.8 ± 22.8 deg vs 82.8 ± 21.7 deg, respectively, $P<0.001$). However, no differences existed in corneal front and back steep axes between Hispanics and non-Hispanics.

Conclusions: There are no significant differences in corneal tomographic parameters, including keratometry and degree and amount of astigmatim in front and back corneal surfaces between Hispanic and non-Hispanic White patients.

ABSTRACT BODY:

Purpose: To investigate adaptation and factors associated with vision satisfaction and willingness to wear (WTW) Miyosmart spectacles.

Methods: Twenty-five myopes aged 18-35 years were recruited. In phase 1, subjects wore single vision (SV) and Miyosmart spectacles bilaterally for 1 hour each. Objective variables assessed were; visual acuity (VA) and contrast sensitivity (CS), in high (HI) and low illumination (LI) on and off-visual axis. Subjective variables included; dynamic vision disruption rating (DVDR), vision ratings (VR) for clarity, ghosting, haloes (on and off-axis), overall visual comfort and VR in various scenarios including; reading, screen use, walking, moving eyes/head and overall vision satisfaction (OVS) (1-10 scale). WTW was indicated as yes/no. Multivariate analysis considered all variables using generalised estimating equations for OVS. Odds ratios (OR) determined variables associated with WTW. In phase 2, subjects wore Miyosmart for 2 days and all subjective VR were given before and after wear. Paired t-tests were used to assess changes.

Results: Phase 1 was completed by 24 subject and phase 2, 21. At a univariate level, all variables other than on-axis VA (high and low contrast in HI and LI) and on-axis CS were significantly correlated with OVS and WTW (all $p<0.05$). WTW was 83% in SV and 8% in Miyosmart. Multivariate analysis indicated higher OVS was associated with higher scores in VR for moving eyes/head (r=0.88), reading (r=0.83), overall visual comfort (r=0.78) and CS off-axis (r=0.63), with a model r2=0.85 (all p£0.01). WTW was associated with higher OVS (OR=3.4), lower DVDR (OR=0.59) and near ghosting (OR=0.1) (all p=0.01). After 2 days of wear, there were significant improvements in VR for distance (0.76±1.45), distance off to side (1.38±2.13), when walking (1.33±2.33), moving eyes/head (1.38±2.27), reading (1.19±2.44), screen use (1.62±3.28), and OVS (1.81±2.04). There was also a significant reduction in ghosting on screens (1.62±1.46) and reading (1.43±3.04) (all $p<0.05$). WTW increased to 38%.

Conclusions: Subjective evaluation of visual tasks that depend on peripheral and dynamic vision have a higher correlation with wearability for the Miyosmart lens in an adult population, with significant adaptation occurring after only 2 days. These findings may assist in evaluating the performance of, as well as predicting adaptation in such lens designs.

ABSTRACT BODY:

Purpose: Maintaining corneal health and transparency are necessary pre-requisites for exquisite vision; a function ascribed to stem cells (SCs) nestled within the limbus. Perturbations to this site or depletion of its SCs, results in limbal stem cell deficiency (LSCD). Whilst characterizing a murine model of this disease, we discovered a rare and unreported phenomenon on the cornea; goblet cell metaplasia (GCM). Our goal was to unravel the mechanism through which it transpires.

Methods: C57BL/6 (n=138) and aged matched K14CreER-Confetti (n=30) mice were used. Partial and total LSCD was induced by mechanical debridement. Suture-induced (n=6) and nu/nu athymic (n=3) mice were employed as acute and chronic models of corneal neovascularization. Mice were clinically evaluated and procured tissue assessed after PAS-staining, immunofluorescence for the presence of keratins (K8, K12, K13, K14), mucins (MUC5AC) and blood vessels (CD31), and cell proliferation (BrdU/EdU).

Results: In mapping the evolution of LSCD, PAS^{+}/$MUC5AC^{+}$ GCs were not detected in the region spanning the bulbar conjunctiva-limbus suggesting they did not migrate from their forniceal cull-de-sac. Rather, they appeared 7 days post-injury, arising from K8 conjunctival precursors which invaded the cornea as part of conjunctivalization. Fluorescence intensity for K12 in the central cornea decreased concomitant with elevated MUC5AC and CD31 compared to controls (15.14 v 37.94, $p<0.0001$; 31.12 v 11.03, $p<0.0001$; 27.38 v 20.23, $p<0.0001$, respectively). GCs strongly correlated with blood vessels ($r=0.95$, $p=0.004$). In Confetti mice, multicolored GC rosettes formed indicating that they have a K14 ancestry. In the absence of limbal damage but amidst an acute or chronic corneal neovascular response, GCs were not detected.

Conclusions: This first report on GCM on the murine cornea dismisses the theory that these cells emigrate as a component of conjunctivalization. While neovascularization encouraged GCM, it was not the principal driver, rather a breach in the limbal barrier was necessary to initiate metaplasia. Whether GCM manifests in corneas of patients with LSCD is yet to be determined, nonetheless it should be investigated to determine whether this type of cell identity change can be suppressed or corrected pharmacologically to prevent sequela such as the formation of vision-obstructing mucous plaques.

TITLE: A Bayesian deep learning model for age-related macular degeneration screening

SESSION TITLE: Imaging of posterior segment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Sun, DZNE, GERMANY|S. Yousefi, Department of Ophthalmology, The University of Tennessee Health Science Center, Memphis, Tennessee, UNITED STATES|S. Yousefi, Department of Genetics, Genomics, and Informatics, The University of Tennessee Health Science Center College of Medicine, Memphis, Tennessee, UNITED STATES|

Commercial Relationships Disclosure: Jian Sun: Commercial Relationship: Code N (No Commercial Relationship) | Siamak Yousefi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To develop a reliable deep learning construct for screening of age-related macular degeneration (AMD) based on fundus photographs.

Methods: We developed a Bayesian convolutional neural net (BCNN) to detect AMD and to quantify the predictive uncertainty based on fundus photographs. We utilized 60,511 fundus photographs from the age-related eye disease study (AREDS) to develop models for detecting four levels of disease severity including healthy, small drusen, large drusen, and late AMD and used the 7448 fundus images in the holdout dataset to independently validate the findings. We further evaluated our models based on 20 images collected from a hospital in Japan. We compared the accuracy of the BCNN model with a conventional deep convolutional neural net (DCNN), which used similar architecture as the BCNN model. We also evaluated the relationship between the accuracy and predictive uncertainty of the BCNN model based on input training data with varying size.

Results: Based on the holdout testing dataset, the AUC of the BCNN model in distinguishing four levels of severity was 0.88 (95%CI: 0.86-0.90), and the quadratic Cohen's kappa was 0.86. The AUC of the DCNN model in distinguishing four levels of severity was 0.85 (95%CI: 0.83-0.87), and the quadratic Cohen's kappa was 0.83. For BCNN model, the predictive uncertainty of correct predictions was significantly lower than that of incorrect predictions.

Conclusions: We developed a BCNN model that was more accurate than classical DCNN model in detecting AMD. The proposed BCNN generates prediction uncertainty in addition to prediction likelihood. A lower predictive uncertainty corresponds to a higher confidence of the model in the provided outcome. This feature is critical for currently black-box CNN models and may assist physicians in making more informed clinical decisions.

TITLE: Assessing the role of social determinants of health in children receiving a vision test using national data from the National Survey of Children's Health

SESSION TITLE: Public Health I

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Shelton, M. Robich, D.A. VanNasdale, College of Optometry, The Ohio State University, Columbus, Ohio, UNITED STATES|

Commercial Relationships Disclosure: Erica Shelton: Commercial Relationship: Code N (No Commercial Relationship) | Matthew Robich: Commercial Relationship: Code N (No Commercial Relationship) | Dean VanNasdale: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To identify how social determinants of health relate with the likelihood of a parent or guardian reporting a child has had a vision test within the last 12 months

Methods: National data from the 2016-2020 National Survey of Children's Health were obtained through the National Survey of Children's Health online database. The analysis looked at age, sex, race, household income status, household education status, insurance status, family resilience, and reported adverse childhood events as indirect measures of social determinants of health. Data for each measure across each year were evaluated using a chi square test, while differences over the five years were analyzed through a multiyear logistic regression.

Results: The odds of reporting a vision test decreased by 10% each year. Age, sex, income status, adverse childhood events, and insurance status demonstrated a significant correlation with reporting a vision test for a child in each of the 5 years analyzed (all $p < 0.05$). Family resilience did not show a significant correlation with reporting a vision test for a child in each of the 5 years analyzed. Males were less likely to have a reported vision test and the likelihood of a reported vision test increased with age. Data from 2016-2018 showed that over 50% of the people who reported being uninsured still reported a vision test, but in 2019 and 2020 less than 50% of those who are uninsured reported a vision test.

Conclusions: Social determinants of health impact children's likelihood of receiving vision care and understanding how these determinants impact this likelihood allows for better policy and programs to achieve visual health equity for children.

ABSTRACT BODY:

Purpose: To measure the phenotypic and genotypic associations between glaucoma and psychiatric disorders.

Methods: A total of 169, 362 participants from the UK Biobank cohort were included in the phenotypic analysis, participants underwent detailed questionnaire and standardized physical examinations between 2006 and 2010 and were followed up until 2021. Multivariable Cox regression models were used to investigate the relationship between glaucoma and incident psychiatric disorders. A total of 674,296 samples of glaucoma cohorts and 449,203 samples of psychiatric disorders cohorts from previous genome-wide association studies were included in the genotypic analysis. The conditional/conjunctional false discovery rate methodology was utilized to estimate the specific overlapping loci between glaucoma and psychiatric disorders. Gene expression analysis in the human brain and aqueous humor outflow pathways was further offered to provide independent experimental evidence. The associations of the identified overlapping loci with phenotypes were further validated among the UK biobank participants.

Results: A total of 5,527 participants had glaucoma at baseline. The multivariable-adjusted hazard ratio (HR) (95%confidence interval [CI]) for glaucoma associated with total four psychiatric disorders was 1.11 (1.03-1.21). Specifically, the presence of glaucoma was significantly associated with increased risk of an incident anxiety disorder (HR, 1.33; 95% CI 1.09-1.62). We identified ten independent genomic variants shared between glaucoma and anxiety disorder and between glaucoma and major depressive disorder, encompassing variants predicted to regulate genes expressed in human aqueous humor outflow pathways and the brain. The independent genomic variants rs7310615, rs9820228, rs9831374, rs7784849, rs2193255, rs72963135, and rs11030381 were validated to correlate with both glaucoma and the traits of psychiatric disorders in the UK biobank.

Conclusions: We found that glaucoma was associated with an increased risk of developing anxiety disorder in the UK longitudinal database. Consistently, we found genetic evidence supporting the shared biological basis of comorbidity between glaucoma and psychiatric disorders. This study adds to the body of literature implicating shared genetic architecture as a potential etiology for relationships between glaucoma and psychiatric disorders, and provides insight on their pathogenesis and novel therapeutic targets.

ABSTRACT BODY:

Purpose: To assess the relation between intraocular pressure, macular retinal nerve fiber layer (mRNFL) thickness, macular ganglion cell inner plexiform layer (mGCIPL) thickness and measured metabolites with emphasis on lipids, lipoproteins and their subclasses, amino acids, and ketone bodies in the UK Biobank.

Methods: We analyzed 167 non-fasting serum metabolites measured by NMR (Nuclear Magnetic Resonance; Nightingale, Finland; version 2020). The sample sizes varied by outcome: 28,780, 10,763, and 10,763 participants, respectively, with data on corneal compensated intraocular pressure (IOPcc), mRNFL, mGCIPL and metabolomics. We used multiple linear regression models adjusting for various covariables (such as age, sex, body mass index, smoking status, diabetes, coronary artery disease, beta blocker use, and statin use) with individual metabolites (probit transformed) as the predictor for each outcome. The reported estimates represent the difference in each outcome variable for each standard deviation increase in the probit-transformed metabolite values. We considered false discovery rates (FDR<0.05) for metabolite classes and number of effective test (NEF<0.05) for individual metabolites as significant after correction for multiple testing.

Results: Overall, associations with mGCIPL were not significant after correction for multiple testing (NEF>0.07). Total branched chain amino acids were associated with lower IOP (-0.17mmHg; 95% confidence interval (CI): -0.12, -022; NEF p-value=4.3E-10) but had null associations with OCT parameters (NEF p-value=1.0). Total concentration of lipoprotein particles was associated with higher IOP (0.11mmHg; 95% CI: 0.05, 0.16; NEF p-value=0.02) and thinner mRNFL (-0.18 microns; 95% CI: -0.27,-0.09; NEF p-value=0.02). Several lipoprotein components (cholesterol, cholesterol esters, phospholipids) carried on LDL and HDL were associated with higher IOP (FDR<0.05) and some were also associated with thinner mRNFL (example: cholesterol esters in small HDL particles: -0.19 microns; 95%CI: -0.28,-0.09; NEF p-value=0.03). Interestingly, cholesterol and cholesterol esters carried on VLDL particles were associated with lower IOP and thicker mRNFL (FDR <0.05 for both).

Conclusions: Higher serum levels of LDL and HDL as well as many of their components were associated with higher IOP and thinner mRNFL in a large population based sample.

ABSTRACT BODY:

Purpose: Numerous studies have raised concerns that clinical trial cohorts are frequently demographically different from the population undergoing treatment post FDA approval. Our study describes the racial and ethnic composition of the cohorts of diabetic macular edema
(DME) clinical trials and compares this to the racial and ethnic composition of patients undergoing treatment for DME from the (Intelligent Research in Sight) IRIS ® Registry.

Methods: This is a retrospective cohort study comparing the racial/ethnicity and gender composition of patients undergoing treatment for DME from the (Intelligent Research in Sight) IRIS ® Registry and participants in Diabetic Retinopathy Clinical Research (DRCR) Retina Network clinical trials and industry sponsored trials that met the following inclusion criteria: conducted in the United States of America, Phase III completed, data reported between Jan 1, 2000, and Jan 1, 2020, and demographic information reported with results.

Results: Twenty-two clinical trials met our inclusion criteria. Seventeen were part of the DRCR and five were industry-sponsored trials. Compared to the enrollment fraction of 4.94% among Whites, lower enrollment fractions were found in Black patients (3.99%, odds ratio [OR] 0.816,
confidence interval [CI] 0.786-0.867, P< 0.001) and in Hispanic patients (2.81%, OR 0.579, CI 0.541-0.620, P<0.001). Men were more likely to enroll in the clinical trials compared to women (enrollment fraction, 4.11% vs 3.64%, respectively, OR 1.22, CI 1.074-1.172, P < 0.001).

Conclusions: DME clinical trials have a higher relative proportion of White and male subjects when compared to the population undergoing treatment for DME. Further efforts should consider measures to encourage clinical trial recruitment that is reflective of the DME population undergoing treatment to ensure generalizability of clinical trial results.

ABSTRACT BODY:

Purpose: Recording mfERG using commercial devices requires the subject's sustained fixation at a specific location, which is not always attainable. We used our custom-built gaze-contingent system (GCS) to test the feasibility of recording mfERG in the presence of normal eye movements.

Methods: ERG responses were recorded in young adults (n=7) with a commercial device (Diagnosys) and also with the GCS under two conditions: Fixed and GC. The stimulus consisted of a central disk (radius = 2.5°) with 5 surrounding concentric rings (inner radii = [2.5°-12.5°], outer radii = [5°-15°], step size = 2.5°), and was presented on an LCD monitor (refresh rate = 75Hz). The m-sequence (m-seq) had 2^{12}-1 states, each lasting 39.9ms (1 stimulus frame, and 2 filler frames), and the m-seq lag between the rings was 256 states.

The GCS consisted of a 1401 DAQ system, and a 1902 amplifier (CED UK), a Bits# stimulus generator (CRS UK) alongside MATLAB and Psychtoolbox for stimulus generation, and an Eyelink eye tracker (2KHz sampling rate, SR Research CA) for monitoring gaze. In Fixed mode, the stimulus and fixation point were centered at the screen, while in GC mode, they were updated based on the gaze location at the beginning of the previous stimulus frame. An unfilled 2×2° square centered on the screen designated the permissible extent of gaze locations. If the gaze moved beyond this area, the edges changed color to warn the subject, and the affected m-seq states were repeated. To remove blink artifacts, all states presented 0.7sec prior until 3sec after a blink detection were re-tested. Computation of the mfERG responses required cross-correlation of the ERG signal and the stimulus luminance time-series. A photodiode at the top-left corner of the screen rendered the m-seq based on the luminance of the central stimulus.

Results: A repeated measure correlation (rmcorr) analysis indicated: 1) A high correlation between the P1 latencies measured with the 2 modes of the GCS ($r = 0.84$, $P < 0.001$), 2) An agreement between the commercial device and the GCS-GC mode in terms of P1 latencies ($r = 0.35$, $P = 0.037$), 3) No significant correlations for N1 latencies.

Conclusions: Our results suggest that making the stimulus GC does not affect P1 timings, and our measurements are not qualitatively different from the commercial devices. Therefore, this approach can be used with unstable fixation and to improve the spatial specificity of the mfERG technique.

ABSTRACT BODY:

Purpose: To present the preliminary results of automated measurements for horizontal corneal diameter (white-to-white distance) by a trained deep learning-based artificial intelligence(AI) model.

Methods: A novel dataset of healthy and ptotic eye images was used to develop a deep learning U-net-based model, which performs automated segmentation of the iris. A total of 100 ptotic eyes from the dataset were used for training, with another 100 ptotic eyes utilized for testing the AI model after adequate training. Iris edges were detected automatically based on the results of AI segmentation, then a circle and its center are simulated and represented mathematically in accordance with partially visible iris edges of ptotic eyes. Therefore, A horizontal corneal diameter, white-to-white distance, was calculated using the radius of the simulated circle for ptotic eyes. The AI predicted white-to-white distance was then compared with an attending physician manual measuring the white-to-white distance on the same 100 testing dataset to provide a comparison.

Results: From the 100 image test results predicted by our trained convolutional neural networks (CNNs) model, the mean of the horizontal corneal diameter in ptotic eyes was 11.99mm (range 10.77mm - 13.61mm, SD 0.514). The results of manual measurement by one attending physician in the same 100 test dataset showed that the mean was 12.21mm (range 11.05mm - 13.43mm, SD 0.486). The manual and AI-predicted measurements were well correlated (Pearson $r = 0.66$, $p < 0.01$).

Conclusions: Using our novel ptotic eye dataset, the CNN-based AI model demonstrated its potential to predict the horizontal corneal diameter (white-to-white distance) for ptotic digital photos. Further training on the AI model and careful validation for accuracy both need to be performed and presented in the future.

ABSTRACT BODY:

Purpose: The purpose of this study was to determine if clinical response to anti-VEGF intravitreal injection therapy correlated to quantitative changes of CNV area and vascularity in OCTA.

Methods: 10 eyes of 10 patients (4 males, 6 females, mean age 75,1 y. o) with CNV were enrolled in the study. The inclusion criteria were presence of CNV confirmed with OCT, OCTA and FA in patients with initially active disease. A comprehensive ophthalmological exam was performed and OCTA was performed with Heidelberg Spectralis or Optovue using high resolution scans during the initial disease activity. The follow-up scan was performed after the successful response, i.e. at the presence of major reduction of sub- or intraretinal fluid or disappearance. CNV area was manually delineated and measured using Image J (area of selection in square milimeters). The CNV vascularity was measured using AngioTool by determining area of the vessels and was determined as a percentage of area occupied by vessels inside the explant area. Paired analysis was performed to compare the parameters at baseline and at the follow-up. The images were overlaid using the opencv(CV2) package in Python to look for morphological changes before and after the treatment.

Results: Analysis of vascularity of the lesion showed a decrease from 34% to 23% (p=0.002). The pre-and post-treatment mean CNV area was 74.26 before versus 66.57 square milimeters after treatment (p=0.1621). The analysis of overlaid images showed that in most cases morphology of the vessels changes with narrowing of the vessels and fewer vessels after the injection.

Conclusions: We found that the CNV vessel percentage area correlates with clinical response to anti-VEGF, and it decreases significantly after the successful treatment. Treatment effect may thus be due to reduced lumen and permeability. The reduction in vascular percentage may be due to reduction in vascular lumen and number of vessels. OCTA thanks to its ability to image the dynamics of neovascular changes may be a useful additional method in determining the optimal intervals of anti-VEGF injection.

ABSTRACT BODY:

Purpose: The phosphorylation of αB-crystallin/CRYAB, one of small heat shock proteins also known as HSPB5, modulates its molecular dynamics and chaperone activity. Hyperglycemia and chronic inflammation play pivotal roles in the pathology of diabetic retinopathy, in which biological alterations of retinal glial cells are one of the key elements. However, αB-crystallin expression changes remain elusive in retinal glia cells under various diabetic stimuli. Here, we show interleukin (IL)-1β, an inflammatory cytokine upregulated in diabetic retinopathy, regulates the phosphorylation and mRNA expression of αB-crystallin in Müller cells.

Methods: Human Müller cells (MIO-M1) were used to evaluate changes in gene and protein expression with real-time quantitative PCR, enzyme linked immunosorbent assay (ELISA) and immunoblot analyses. Retinal tissues, isolated from the Spontaneously Diabetic Torii (SDT) fatty rat, a type 2 diabetic animal model with obesity, were examined by double-staining immunofluorescence.

Results: Real-time PCR and ELISA showed that CRYAB mRNA and αB-crystallin protein expression decreased in 50mM high glucose medium compared with 50mM mannitol. CRYAB transcripts expression was downregulated with 10ng/ml IL-1β (fold change; 24 hours = 0.33, 48h = 0.38, $p < 0.01$). AlphaB-crystallin serine 59 residue was phosphorylated with IL-1β application, which was inhibited following CRYAB siRNA induction in MIO-M1 cells. There was co-localization of glial fibrillary acidic protein (GFAP) with αB-crystallin and phosphorylated αB-crystallin at serine 59 in Müller cells in retinal specimens of SDT fatty rats.

Conclusions: CRYAB mRNA expression and the phosphorylation of αB-crystallin serine 59 residue were modulated by IL-1β in Müller cells under diabetic conditions, suggesting that αB-crystallin contributes to the pathogenesis of diabetic retinopathy.

ABSTRACT BODY:

Purpose: To compare anatomic and visual acuity (VA) outcomes of rhegmatogenous retinal detachment (RRD) repair in pseudophakic eyes with multifocal versus monofocal intraocular lenses (IOLs).

Methods: This was a single-institution, retrospective case-control study evaluating all pseudophakic eyes with multifocal IOLs undergoing primary RRD repair with pars plana vitrectomy (PPV) or PPV with scleral buckle (PPV+SB) from 1/1/13-9/1/21. A 1:1 monofocal IOL control group was matched based on age, gender, macula status, primary surgeon, and timing of surgery. Eyes with baseline PVR were excluded. Outcomes included single surgery anatomic success (SSAS) rate at 90 days after surgery, and VA at baseline and final visit after primary RRD repair.

Results: Seventy-one eyes had multifocal IOLs at primary RRD surgery during the study period and were eligible for analysis. Both the multifocal and control groups included 71 eyes, and mean age was 64.8 ± 8.5 and 64.5 ± 8.8 years, respectively (p=0.85). Primary PPV and PPV+SB was performed on 66 (93%) and 5 (7%) multifocal eyes, respectively, vs. 60 (84.5%) and 11 (15.5%) control eyes (p=0.11). Mean follow-up was 773 ± 588 days in the multifocal group vs. 793 ± 565 days in the control group (p=0.84). Overall SSAS was achieved in 55 (77.5%) multifocal eyes vs. 63 (88.7%) control eyes (p=0.073). Primary PPV and PPV+SB resulted in SSAS in 50 (75.8%) and 5 (100%) multifocal eyes vs. 53 (88.3%) and 10 (90.9%) control eyes (p=0.068, p=1.00, respectively). In surgical failures, the mean number of RRD surgeries was 2.4 ± 0.7 in the multifocal group vs. 2.1 ± 0.4 in the control group (p=0.33). Mean baseline logMAR VA was 0.95 ± 0.89 (20/178) in multifocal eyes vs. 0.95 ± 0.92 (20/178) in control eyes (p=0.84), and at final visit was 0.27 ± 0.34 (20/37) in multifocal eyes vs. 0.28 ± 0.43 (20/38) in control eyes (p=0.83). The most common cause of surgical failure in both groups was post-operative PVR which developed in 8 (53.5%) of multifocal and 5 (71.4%) of control failures (p=0.65).

Conclusions: In pseudophakic RRDs undergoing primary surgical repair, there was a trend towards higher SSAS in eyes with monofocal IOLs, but no statistically significant difference in SSAS or PVR development in eyes with multifocal vs. monofocal IOLs. Visual outcomes were similar in both groups and significantly improved compared to baseline.

ABSTRACT BODY:

Purpose: To develop a simple and easy-to-use glaucoma staging system based on visual fields (VFs) and to evaluate the system using an independent validation dataset.

Methods: We developed an unsupervised k-means algorithm to identify clusters with similar VFs (Fig. 1). We annotated the clusters based on their respective mean deviation (MD). To establish an objective criterion for glaucoma staging, we computed optimal MD thresholds that discriminated clusters with the highest accuracy based on Bayes minimum error principle. We validated the entire pipeline based on an independent validation dataset and evaluated the accuracy of the staging system based on the identified MD thresholds (Fig. 1).

Results: k-means model discovered four clusters with 6784, 4034, 1541, and 872 VFs and average MDs of 0.0 dB (±1.4: SD), -4.8 dB (±1.9), -12.2 dB (±2.9), and -23.0 dB (±3.8), respectively. The supervised Bayes minimum error classifier identified optimal MD thresholds of -2.2 dB, - 8.0 dB, and -17.3 dB for discriminating normal eyes and eyes at the early, moderate, and advanced stages of glaucoma (Fig. 2). Approximately 2.2% of normal eyes and eyes in the early stage of glaucoma had VF loss in at least one of the four central VT test locations. The accuracy of the glaucoma staging system based on the identified MD thresholds with respect to the initial k-means clusters was about 94%.

Conclusions: We used unsupervised and supervised machine learning models to develop an objective glaucoma staging system without expert intervention. We discovered that MDs of approximately -2 dB, - 8 dB, and -17 dB provide the optimal thresholds for staging glaucoma to four severity levels. The proposed staging system is unbiased, easy-to-use, and consistent, thus may be used in glaucoma research and clinical practice to improve glaucoma care.

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) is a leading cause of blindness, and world-wide prevalence is expected to increase. Dopamine treatment protects against early neuronal dysfunction in DR in both animal models and people and acts as an anti-angiogenic in models of acute lung injury, cancer, and irritable bowel syndrome. Whether dopamine functions as an anti-angiogenic to reduce clinically-recognized vascular pathology in DR is unknown. Here, we used a retrospective study of Veterans with diabetes to determine whether taking L-DOPA or dopamine agonists delayed DR onset.

Methods: A retrospective analysis of medical records was used to identify patients diagnosed with diabetes, with or without a history of treatment with levodopa or dopamine agonists. The primary outcome was the time interval between initial diabetes diagnosis and DR diagnosis. Patients with >100 days of dopamine prescriptions during the time period between diagnoses (dopamine group, n=424) were compared against patients with no history of dopamine prescriptions (untreated group, n=9952). Other factors compared across groups were age at diabetes diagnosis, gender, race, tobacco usage, co-morbidities, blood sugar control, and insulin/hypoglycemic usage with unpaired t-tests for continuous variables and Chi-square tests for categorical variables. A multivariate linear model was utilized to assess the relative impact of dopamine treatment and other factors on the time to develop DR in Veterans with diabetes. Statistical assessments were performed using RStudio version 1.4.

Results: Dopamine treatment delayed DR onset in Veterans with diabetes by 1.5 years (6.802 vs. 8.381 years, $p<0.001$). On average, the dopamine group was older (55.01 vs. 57.24, $p<0.001$), with a higher proportion of female patients (female: 6.4% vs. 3.8%, $p<0.001$) and a higher Elixhauser co-morbidity score with van Walraven weighting (5.552 vs. 3.338, $p<0.001$). There was no difference in average HbA_{1c} between groups. The primary dopamine drugs taken included D2-like agonists (77.4%), dopamine precursors (20.7%), and dopamine degradation enzyme inhibitors (1.9%).

Conclusions: Veterans with diabetes who took L-DOPA and dopamine agonists showed delayed onset of vascular pathology associated with DR. This research demonstrates the value of long-term dopamine treatment for DR. Future research will include a prospective study to examine the protective effects of L-DOPA on vascular pathology in DR.

ABSTRACT BODY:

Purpose: To evaluate the in situ spatial mRNA expression of 4 Wnt ligands (WNT2, WNT6, WNT11, WNT16B), 4 Wnt inhibitors (dickkopf WNT Signaling Pathway Inhibitor 1 [DKK1], secreted frizzled-related protein 5 [SFRP5], frizzled-related protein [FRZB], WNT inhibitory factor 1 [WIF1]), and frizzled7 (Fzd7), that have been shown previously upregulated in the limbus by differential gene profiling using q-RT-PCR.

Methods: The V2 fluorescent RNAscope (ACD, Newark, California) was performed on fresh frozen tissue sections from 5 human corneas with less than 8 hours of death to preservation time and intact epithelium. Positive signals were quantified using Imaris software.

Results: All 4 Wnt ligands, 4 Wnt inhibitors, and Fzd7 were preferentially expressed in the basal layer of the cornea and limbus compared to the suprabasal layer ($P<0.05$). When compared with the basal corneal epithelial layer, all 4 Wnt ligands, FRZB, and Fzd7 were preferentially expressed in the basal limbal epithelial layer in a decreasing gradient manner towards the superficial layers ($P<0.05$). No gradients were found for DKK1, WIF1, and SFRP5 expression. All 4 Wnt ligands, 4 Wnt inhibitors, and Fzd7 were also detected in the limbal stroma ($P<0.05$). Fzd7 was preferentially expressed in the basal limbal epithelial layer of the superior limbus compared with other limbal quadrants ($P<0.05$).

Conclusions: Wnt ligands are expressed in a gradient manner towards the superficial layers. Both paracrine and autocrine Wnt signaling pathways are involved in LSCs regulation, suggesting that a fine tuning of Wnt signaling exists to control LSC differentiation and proliferation.

ABSTRACT BODY:

Purpose: The Spectralis OCT3 (Heidelberg Engineering, Heidelberg, Germany) is a new OCT device capable of faster image acquisition at 125,000 Hz, compared to 85,000 Hz of the current Spectralis OCT2. The purpose of this study was to evaluate the repeatability and agreement of optic disc and retinal nerve fiber layer (RNFL) parameters obtained by these 2 devices.

Methods: Normal and glaucoma eyes of adult subjects were recruited. OCT scans were obtained 3 times on the same day with the Spectralis OCT2 and Spectralis OCT3, by the same examiner. Sectoral and global RNFL thickness as well as global minimum rim width (MRW) and Bruch's membrane opening area (BMOa) were measured. Repeatability was assessed by the coefficient of variation (COV) with bootstrapped 95% confidence interval (CI) for each parameter of each device. Bland-Altman plots were constructed to assess interdevice agreement.

Results: Included were 20 eyes from 20 subjects, with mean ± standard deviation (range) of 73.7 ± 18.0 µm (42.3 to 111.7 µm) for global RNFL, 219.0 ± 63.0 µm (86.3 to 358.3 µm) for global MRW, and 2.10 ± 0.5 mm^2 (1.45 to 3.24 mm^2) for BMOa measured by the Spectralis OCT2. Both Spectralis OCT2 and OCT3 showed similarly low COVs [95% CI] for global RNFL thickness (1.1% [0.4% to 1.9%] vs. 0.9% [0.6% to 1.2%], respectively), global MRW (1.0% [0.6% to 1.5] vs. 1.1% [0.8% to 1.4%], respectively), and BMOa (0.7% [0.5% to 0.9%] vs. 0.9% [0.6% to 1.2%], respectively). Bland-Altman 95% limits of agreement were -3.7 to 5.1 µm for RNFL, -5.0 to -3.9 µm for MRW, and -0.06 to 0.07 mm^2 for BMOa, demonstrating good interdevice agreement for all parameters.

Conclusions: We found excellent intravisit repeatability of measurements for both devices. Bland-Altman limits of agreement were low, suggesting that measurements are potentially interchangeable between devices.

ABSTRACT BODY:

Purpose: It has been shown that the internal optics can partially compensate for corneal aberrations to maintain the overall aberration of the entire eye at a lower level. However, optical compensation reported in previous studies was based on cross-sectional data collected from adults with fully developed eyes. Longitudinal evidence from children whose eyes are rapidly developing is still lacking. This study investigated longitudinal interactions of corneal and internal aberrations on the ocular aberrations in myopic children.

Methods: Myopic Chinese children (n = 69, age: 8-10 years) were included. Their ocular and corneal wavefront aberrations were measured using an aberrometer incorporated with a corneal topographer at baseline and after two years. Internal aberration was calculated by directly subtracting the corneal aberration from the ocular aberration. Compensation factor (CF) was calculated, using root mean square error (RMSE), to indicate the effectiveness of internal optics to counterbalance the corneal aberrations: CF = 1 – (ocular aberration RMSE / corneal aberration RMSE). Axial length was measured using a partial coherence interferometer.

Results: Ocular lower-order astigmatism RMSE was significantly increased by 0.21±0.03 μm during myopic eye growth, accompanied by 0.18±0.03 μm increase in corneal lower-order astigmatism (paired t-tests, $P < 0.001$). The CF was dropped from 0.51 to 0.38, suggesting that compensation from the internal optics became less effective. When investigating individual Zernike coefficients, there was a significant increase in negative corneal H/V astigmatism (paired t-test, $P < 0.001$) but no significant change for the compensatory positive internal H/V astigmatism (unpaired t-test, $P = 0.07$), resulting in a more negative ocular H/V astigmatism (paired t-test, $P < 0.001$). While myopia progressed over the two-year follow-up period, H/V astigmatic change was not significantly associated with axial elongation (Pearson’s correlation, $P = 0.26$).

Conclusions: The increased ocular lower-order astigmatism indicates that the internal optics failed to compensate for the increased corneal astigmatism in children during myopic eye growth. Further works are required to understand the associated mechanism underlying the astigmatic changes in children.

ABSTRACT BODY:

Purpose: Visual field (VF) is the gold standard for assessing visual function. Archetypal analysis has been applied to unilateral VF to define specific patterns of loss. However, bilateral VF changes have larger impact on patient function. Therefore, we aim to 1) generate distinct archetypes of bilateral VF loss, and 2) assess the impact of archetypes of bilateral VF loss on patient function.

Methods: To develop archetypes for bilateral VF loss, we assessed 15,663 unique patients with bilateral 24-2 VFs obtained on the same day. Included VFs had false positives <15%, false negative <25% for moderate glaucoma and <50% for severe glaucoma, and fixation losses <10%. We decomposed each bilateral VF into 25 distinct archetypes (i.e. distinct patterns of bilateral VF loss) using elbow plot analysis. To assess the impact of the bilateral VF loss on patient function, we used an independent dataset with 229 patients who had bilateral VF data and had undergone functional testing to generate quality of life (QOL) data on reading speed and composite scores. We performed linear regression with projected archetype coefficients as the independent variable and QOL metrics as the dependent variable and applied Bonferroni correction for multiple testing.

Results: Among the 25 archetypes derived from bilateral VF data, twelve show VF defects in similar spatial locations in two eyes (Figure 1). The most represented archetypes are AT 3 (normal), AT10 (superior peripheral OD), and AT 21 (superior peripheral OS, Figure 2). In the clinical evaluation cohort, AT3 (normal, p = .002), AT5 (bilateral superior and inferior arcuate defects, p = .001), AT7 (diffuse bilateral loss p = .001), and AT11 (inferior bilateral loss, p = .001) are significantly associated composite score, while AT3 (p = .04), AT7 (p = .04), and AT11 (p = .04) are associated with reading speed.

Conclusions: Patients with a greater percentage of bilateral normal archetype tend to have improved QOL and higher reading speed. Whereas, patients with greater amounts of diffuse bilateral depression and inferior VF loss have worse QOL and lower reading speed. Bilateral VF archetypal analysis presents a useful framework to characterize subgroups of glaucoma patients, which can allow clinicians to better understand the impact of glaucoma on individual patients.

ABSTRACT BODY:

Purpose: Glaucoma causes progressive retinal ganglion cell (RGC) death. The mammalian retina lacks regenerative capacity, but RGC replacement and optic nerve regeneration hold potential for restoring vision in glaucoma and other optic neuropathies. Here, we characterize a barrier to donor human stem cell-derived RGC integration following intravitreal transplantation in vivo. We demonstrate that the internal limiting membrane (ILM) impedes the migration of transplanted RGCs into the recipient retina.

Methods: We differentiated RGCs from human embryonic stem cells using established methods. To circumvent the ILM, we intravitreally injected the nonspecific protease Pronase-E (or saline, negative control) in immunodepleted mice of both sexes. We verified that Pronase-E digests the ILM without affecting the survival of endogenous retinal neurons or glia. In complementary experiments, we transplanted human RGCs in Lama1^{nmf223} mice of both sexes, which harbor a point mutation in the Lama-1 gene, and which exhibit developmental ILM defects. Samples sizes included ≥15 mice per group and experiments were replicated at least twice by masked investigators. We assessed donor RGC survival and engraftment using 3D reconstructions of confocal z-stacks.

Results: Donor RGC survival progressively decreased ($p<0.0001$) from 6h to 14d post transplantation and was not altered by proteolytic or transgenic ILM disruption. Overall survival rates were ≤1%, commensurate with prior published work. Migration of surviving donor RGC somas into the recipient RGC layer was ≥5-fold greater after proteolytic($p<0.02$) and transgenic ($p<0.003$) ILM disruption. Intriguingly, surviving RGCs spontaneously grew axons towards the optic nerve head (Figure). Extension of dendrites into the recipient inner plexiform layer (IPL) was observed exclusively following ILM disruption (Figure).

Conclusions: These observations advance our understanding of the barriers to human RGC engraftment and synaptogenesis within the adult mammalian retina, and may provide a target for clinically translating regenerative medicine approaches to optic neuropathy. Ongoing work aims to improve donor RGC survival and to characterize the functional connectivity of donor RGCs within the host retinal neurocircuitry.

ABSTRACT BODY:

Purpose: Numerous diseases detrimentally affect corneal nerves. Corneal nerve dysfunction has been linked to dry eye syndrome onset, neurotrophic keratopathy, and other diseases. The morphology and histology of corneal nerves in health and disease has been extensively studied. However, studies of corneal nerve function have been limited (e.g., electrical recordings of ciliary nerves or calcium reporter dyes in ex vivo corneas). Here, we demonstrate functional imaging of corneal nerves over time, as well as stimulus-response.

Methods: We made a cre-lox mouse line expressing GCaMP6f against the Nestin promoter for expression in corneal nerves. We imaged corneas in vivo (mice under isoflurane) with a custom confocal imaging system and an air objective. We applied drops of KCl solution (0.3 M) and tetracaine (0.5%) to the cornea while imaging.

Results: Fig. 1 shows a demonstration of basal corneal nerve signaling in the same cornea over the course of a month. This demonstrates how functional imaging might be used to study nerve activity changes in response to ocular surgeries or pharmaceutical treatments. Fig. 2 shows a demonstration of in vivo calcium imaging where corneal nerves respond to a stimulus. Repeated stimulus and response characterization is one way that the response of corneal nerves could be characterized over time.

Conclusions: The in vivo demonstration of longitudinal imaging and stimulus-response builds upon previous work to develop a model system to study how corneal nerve responses change over time. This will facilitate better studies and understanding of factors that could slow the development of neuropathies. It may also help in the development and testing of new clinical interventions and therapies.

ABSTRACT BODY:

Purpose: There is limited data on the prevalence and genetic diversity of the herpes simplex virus type 1 (HSV-1) virulence genes in ocular isolates. Phylogenetic and genomic analyses of 9 HSV-1 conjunctival isolates were performed to help better understand genetic variability amongst common virulence genes in ocular herpetic disease.

Methods: Whole genome sequencing of 9 HSV-1 isolates recovered in tissue culture from conjunctival scrapings collected between 2004 and 2015 from patients with viral kerato-conjunctivitis were screened using the PacBio Sequel II platform. A phylogenetic network was generated using a multiple sequence alignment method, combining the 9 viral isolate sequences along with 160 global HSV-1 sequences. Protein sequence analyses of common virulence genes (thymidine kinase [TK], DNA polymerase, and ICP22) were performed.

Results: Of the 9 samples, 8 mapped to the American-European clade, whereas the remaining one, closely aligned with the African clade. Both TK and DNA polymerase protein sequencing analyses revealed multiple single nucleotide polymorphisms (SNPs). The majority of these have been previously described, none however are known to confer antiviral resistance. One novel TK SNP (P300S) was found in two viral isolates and the potential effect of the polymorphism on TK and antiviral resistance has yet to be determined. Two novel DNA polymerase SNPs (T929A and R1001Q) were found, which have yet to be described in the literature. The impact on DNA polymerase and acyclovir susceptibility is also unknown. Analysis of ICP22 protein sequences did not reveal any novel protein coding SNPs, however two isolates contained an A78D change, which may affect nucleotidylation of the ICP22 protein.

Conclusions: Whole genome sequencing along with phylogenetic and genomic analyses are powerful tools for understanding genetic variability amongst ocular conjunctival HSV isolates. Identification of novel and common recurrent polymorphisms may help understand drivers of herpetic pathogenicity and factors that may influence virulence in ocular disease.

ABSTRACT BODY:

Purpose: To test the Columbia University (CU) OCT-based method [1,2] for distinguishing glaucomatous damage from healthy controls by applying it to scans from different OCT instruments.

Methods: OCT glaucoma reports [3] were analyzed from 116 eyes from a prospective, observational, case-control study, included 54 healthy controls (HC), 32 early (EG, 24-2 mean deviation (MD) >-6dB), 12 moderate (MG, MD <-6dB and >-12dB), and 18 advanced glaucoma (AG, MD <-12dB). Eyes were scanned with two commercially available OCT instruments from different manufacturers, A and B. Each instrument uses different technology (swept-source vs. spectral-domain), segmentation algorithms, and normative data. A set of reports was generated for each device. These reports [3] included thickness and probability (p-) maps from both the retinal nerve fiber layer (RNFL) and ganglion cell layer (GCL), as well as a circumpapillary (cp) b-scan image and cpRNFL thickness plot. Four graders, experienced with the CU OCT-based method, categorized each eye as glaucoma (G), not glaucoma (NG), or uncertain (UNC) based upon clearly defined rules (Fig. 1).[1,2] Disagreements were adjudicated. Eyes with grades of UNC were treated as G in calculating specificity and sensitivity, as both grades require additional testing.

Results: For 113 (97%) of the 116 eyes, the grades were identical (Table 1). All 3 disagreements involved an UNC grade for either the A or B report. After combining eyes with UNC and G grades, the specificity for the 54 HC eyes was 98% (A) and 96% (B), while the sensitivity for the 62 G eyes was 100% for both A and B instruments.

Conclusions: The CU OCT-based method showed consistency across instruments from different manufacturers, with different normative groups and different algorithms. The sensitivity and specificity suggested that this method may help physicians distinguish glaucomatous eyes from healthy controls using OCT. 1. Liebmann et al; 2022; 2. Hood et al., PRER, 2022; 3. ABSTRACT BODY:

Purpose: A comprehensive analysis of blinking in essential blepharospasm (EB) rather than assessing the global eyelid movements (anomalous eyelid movements + blinking) frequency is clinically relevant to understand the complexity of this condition and the effect of treatment in blinking parameters. This study focuses on objectively evaluating blinking kinematics of EB patients before and after treatment, as well as comparing those parameters to controls.

Methods: Patients with moderate to severe disease and matching-age controls were enrolled. Patients were followed up before and 15 days after the administration of onabotulinumtoxinA (BTX). A high-speed camera and micro-LED were used to register a 3-minute video of eyelid movements (blinking + anomalous eyelid spasms). Movements correspondent to blinking were isolated and a custom-made software was used to objectively evaluate them. Outcomes were blinking frequency, mean amplitude of blinking and mean maximum velocity of eyelid closing (MVEC) during blinking. T-student tests were used to compare different groups and paired-t tests, to compare measurements before and after treatment in the EB group.

Results: 24 eyes from 12 patients with EB and 13 eyes of 13 control subjects were included in this study. Table 1 summarizes the findings (presented as mean ± standard deviation). Baseline EB blinking frequency was significantly higher ($p<0.0001$) and MVEC during blinking was significantly lower ($p=0.0019$), when compared to control subjects', whereas a significant difference was not observed for blinking amplitude ($p=0.6585$) before treatment. After BTX injections, all parameters significantly reduced when compared to baseline measurements in the EB group ($p=0.032$ for blinking frequency; $p<0.001$ for amplitude and $p<0.001$ for MVEC). Although the blinking frequency significantly reduced after treatment, a significant difference was still observed, when compared to the control group ($p=0.0195$). Blinking amplitude ($p=0.0098$) and maximum velocity ($p<0.0001$) were significantly lower when compared to the control group.

Conclusions: Our results show that all assessed blinking parameters significantly differed from control subjects after treament, likely reflecting alterations due to the disease itself and due to the effect of botulinum toxin in orbicularis oculi muscle.

ABSTRACT BODY:

Purpose: To determine the outcomes of eyes with proliferative diabetic retinopathy (PDR) that were lost to follow up (LTFU) after receiving a combination of panretinal photocoagulation (PRP) and intravitreal anti-VEGF therapy.

Methods: Eyes with PDR receiving combination therapy (PRP + anti-VEGF within 3 months of one another) that were LTFU for greater than 6 months were identified. Clinical data (including visual acuity) was then evaluated at different timepoints.

Results: A total of 250 eyes were eligible for analysis. Eyes were LTFU for a mean total of 305 (SD 142) days. Mean logMAR at the date LTFU was 0.62 (SD 0.56). LogMAR was significantly worse at the return from LTFU visit [0.82 (SD 0.70) $p<0.001$)] and the final visit [0.81 (0.75) $p<0.001$]. On the initial visit 201 (79.8%) of patients had diabetic macular edema (DME), 20 (7.9%) had neovascular glaucoma (NVG) , 22 (8.7%) had tractional retinal detachments (TRD), and 140 (55.6%) had vitreous hemorrhage (VH). On the return visit 197 (78.2%) of patients had DME, 30 (11.9%) had NVG, 26 (10.3%) had TRDs, and 143 (56.7%) had VH. On the final visit 184 (73.0%) of patients had DME, 27 (10.7%) had NVG, 35 (13.9%) had TRDs, and 122 (48.4%) had VH.

Conclusions: There was a significant, albeit a minimal decline in the visual acuity of eyes that received combination therapy and were LTFU. This may have been attributed to worsening DME or increase in the prevalence of anatomic complications.

ABSTRACT BODY:

Purpose: Purpose: There have been several reports of impaired lipid metabolism in age-related macular degeneration (AMD) pathogenesis. Large-scale genome-wide association studies in AMD patients have identified genes, including LIPC (HL), CETP, APOE, and ABCA1, that play a role in the generation, transport, and metabolism of high-density lipoprotein (HDL) particles. Additionally, increased systemic lipid levels have been correlated with increased AMD risk, the exact role of which has not been explored. With the premise of dysregulated lipid metabolism as a risk factor for degenerative retinal disorders, our study aims to explore the age-related effect of systemic loss of two lipases, Hepatic Lipase (HL) and Endothelial Lipase (EL) on retinal ultrastructure and function.

Methods: The HL/EL DKO mice on a C57BL/6J background were aged for up to 14 months. Retinal structure and function were assessed using histology, electroretinography, and spectral-domain optical coherence tomography at 7 and 12 months. To investigate retinal pathology and lipid deposits with aging, histological and ultrastructural analysis were performed at 14 months in comparison to wild-type C57BL/6 mice.

Results: The HL/EL DKO mice showed a significant reduction, with age, in all the three-wave responses (rod-a, b, and cone-b) when compared to controls. Small punctate, hyperreflective foci were observed in the retinas of HL/EL DKO mice at 12 months. There was a significant reduction in the number of S-opsin expressing cones in the DKO mice when compared to the controls. Retinal expression of Glutamine Synthetase (mGS) and cellular retinaldehyde–binding protein (mCRALBP) was also found to be reduced in DKOs. The DKO mice showed a marked accumulation of neutral lipids and unesterified cholesterol droplets in the choroidal and sub-RPE region when stained using Oil Red O and BODIPY suggesting deregulated lipid clearance. Ultrastructural analysis of HL/EL DKO mice also showed multiple lipid droplets below the Bruch's membrane (BrM). Additionally, we observed disrupted and swollen RPE basal infoldings in the DKO mice.

Conclusions: Systemic loss of HL and EL leads to degenerative retinal changes and accumulation of lipids in the RPE/BrM/choroid in aged HL/EL DKO mice, sharing features with AMD pathophysiology. Further studies are warranted to understand the role of dysregulated lipid metabolism in inducing age-related degenerative retinal changes.

TITLE: Explaining Deep Learning Models for Low Vision Prognosis

SESSION TITLE: Assistive Devices, Visual Function Assessment, and Vision Restoration Therapies

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Gui, Stanford University School of Medicine, Stanford, California, UNITED STATES|B. Tseng, W. Hu, S.Y. Wang, Byers Eye Institute, Department of Ophthalmology, Stanford University, Stanford, California, UNITED STATES|

Commercial Relationships Disclosure: Haiwen Gui: Commercial Relationship: Code N (No Commercial Relationship) | Benjamin Tseng: Commercial Relationship: Code N (No Commercial Relationship) | Wendeng Hu: Commercial Relationship: Code N (No Commercial Relationship) | Sophia Wang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Low vision rehabilitation improves quality-of-life for visually impaired patients, but referral rates fall short of national guidelines. Automatically identifying patients with poor visual prognosis from electronic health records (EHR) could allow targeted referrals to low vision services. The purpose of this study was to build, understand, and explain deep learning artificial intelligence models that predict visual prognosis using EHR data.

Methods: We identified 5547 patients with low vision (defined as best documented visual acuity (VA) <20/40) from EHR from 2009-2018, with ≥ 1 year of follow-up. From the EHR, we extracted ophthalmology free-text notes and structured data, such as demographics, billing/procedure codes, medications, and eye exam findings. To predict whether low vision patients would still have low vision a year later, we developed deep learning models that used 1) structured inputs, 2) free-text progress notes represented by standardized clinical concepts extracted using named entity recognition (NER), and 3) a combination of the two. Performance metrics including area under the receiver operating curve (AUROC) and F1 score were evaluated on a held-out test set. We then evaluated models using Local Interpretable Model-Agnostic Explanations to determine which input features were most important to the predictions.

Results: Among the 5547 patients, 40.7% (N=2258) never improved to better than 20/40 over one year of follow-up. Our single-modality model based on structured inputs predicted low vision prognosis with AUROC of 80% and F1 score of 70%. Our model combining NER text and structured inputs achieved an AUROC of 79% and F1 score of 63%. Explainability studies revealed that important features for predicting low vision prognosis included features clinicians also rely upon, such as best visual acuity and the presence or absence of irreversible ophthalmic findings, as shown in Fig1.

Conclusions: Deep learning models often suffer from a lack of transparency. Our explainability analyses provide insight into the medical context surrounding low vision prognosis and are a vital step towards increasing clinicians' trust in these models.

ABSTRACT BODY:

Purpose: Choroidal neovascularization (CNV), an advanced form of age-related-macular-degeneration (AMD), is associated with gradual loss of choroidal integrity. However, the molecular mechanisms of CNV initiation and the loss of choroidal integrity remain unexplored. Signaling molecules that help maintain local immune cell populations and regulate local inflammation are suggested to contribute to CNV. Interferon regulatory factor 5 (IRF5) is a transcription factor known for modulation of inflammation and for promoting macrophage subtype polarization between M1 (proinflammatory) and M2 (proangiogenic). Here, we aim to dissect the function of IRF5 in CNV development by characterizing a IRF5 knockout (IRF5null) mouse model.

Methods: Loss of IRF5 expression in RPE/choroid was verified by qRT-PCR and immunohistochemistry with antibody against IRF5. Ocular structures were evaluated live using optical coherence tomography (OCT) and fluorescein angiography, and histologically using light and confocal microscopy. Immune cell populations were characterized by flow cytometry and immunohistochemistry with lineage specific and activation markers, including CD11b, CD11c, F4/80, CD86, CD206, CD14, MHCII, Ly6c. Retina physiology was studied by electroretinography (ERG).

Results: IRF5 null homozygous eyes displayed an increase in the number of immature macrophages. Phenotypically, IRF5 null mice showed normal gross anatomical structure at birth. By 9 months of age, choroidal /RPE morphological defects include overgrowth of new choroidal vessels that invade sub-RPE/Bruch's membrane, degeneration of RPE overlying CNV, and overt presence of migratory cells, presumably phagocytes, in the subretinal space. These changes were concomitant with a reduction in the response amplitudes in the a- and b- waves of ERG.

Conclusions: Loss of IRF5 is sufficient to induce CNV in the eye and compromise choroid/RPE/retina homeostasis. These findings indicate an important role for the IRF5 in controlling immune regulation in the posterior part of the eye. IRF5 null eyes can serve as a model for studying early events in AMD pathogenesis.

TITLE: Molecular characterization of MAP9 in primary cilia as a modifier of canine RPGRIP1 cone-rod dystrophy

SESSION TITLE: Photoreceptors and disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Takahashi, G.D. Aguirre, K. Miyadera, Department of Clinical Sciences and Advanced Medicine, University of Pennsylvania School of Veterinary Medicine, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Kei Takahashi: Commercial Relationship: Code N (No Commercial Relationship) | Gustavo Aguirre: Commercial Relationship: Code N (No Commercial Relationship) | Keiko Miyadera: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A form of canine cone-rod dystrophy (cord1) has been associated with a homozygous insertion in RPGRIP1 ($RPGRIP1^{ins/ins}$) as the primary disease locus with a homozygous deletion in MAP9 ($MAP9^{del/del}$) as a modifier prompting early disease onset. Both gene products are suggested to play important roles in the photoreceptor connecting cilia. However, the role of MAP9 in primary cilia nor the effect of its modifier variant is not fully understood. We aim to characterize the molecular function of MAP9 in photoreceptor primary cilia.

Methods: MAP9 expression in the connecting cilia was evaluated by immunohistochemistry using $RPGRIP1^{ins/ins}$ canine retinal cryosections with/without the $MAP9^{del/del}$ modifier. The role of MAP9 in cilia was studied in an in vitro primary cilia model. Cultured 661w cells were serum-starved for 48h to induce post-mitotic ciliogenesis. RNA was extracted from $MAP9^{+/+}$ and $MAP9^{del/del}$ canine retinas followed by reverse transcription, and wild type and mutant MAP9 cDNA (MAP9-Wt and MAP9-Mut) were subcloned into expression vectors. 661w cells were transfected with the vectors and then assessed for subcellular localization of MAP9 using immunocytochemistry.

Results: MAP9 was localized at the base of connecting cilia in in $RPGRIP1^{ins/ins}$ canine retinas of all MAP9 genotypes. However, MAP9 expression was decreased in the presence of the $MAP9^{del/del}$ modifier. Cultured 661w cells showed that endogenous MAP9 was localized as two juxtaposing puncta. Upon ciliogenesis, there was cilia extension from one of the two MAP9-positive puncta where MAP9 signals extend into the cilia structure. RPGRIP1 signals were comparable with and without ciliogenesis, forming loose aggregates corresponding to the site of the base of cilia. Overexpressed MAP9 proteins exhibited broad cytoplasmic expression but with increased signals corresponding to the site of RPGRIP1 aggregates. Interestingly, the lengths of primary cilia were significantly increased in cells transfected with MAP9-Wt than those with MAP9-Mut.

Conclusions: Ex vivo and in vitro colocalization suggests that MAP9 interacts directly or indirectly with RPGRIP1 in photoreceptor primary cilia. MAP9 might play an important role in the formation and functional regulation of primary cilia. The MAP9-Mut protein may lack normal MAP9 function resulting in altered cilia characteristics leading to the accelerated disease onset observed in cord1 dogs.

ABSTRACT BODY:

Purpose: Geographic atrophy (GA) impairs visual function and patient quality of life (QoL). However, real-world data (RWD) on correlations between GA progression and functional decline are lacking. To address this gap, we performed a retrospective cohort analysis of patient notes to assess the feasibility of quantifying vision-related QoL (VR-QoL) and patient-reported outcomes (PRO) in GA.

Methods: Documentation of VR-QoL was assessed in a random sample of GA patient notes from the American Academy of Ophthalmology IRIS® Registry (Intelligent Research in Sight), a real-world electronic health record (EHR) dataset. Two cohorts were studied: (1) incident GA cases in 2019 analyzed on the date of diagnosis, and (2) prevalent GA cases first diagnosed in 2016 with notes at Year 3 of follow-up. Notes were searched for keywords associated with visual function, mental health, mobility, and independence. For frequently documented functional outcomes, clinical context was analyzed in 50 relevant notes per word.

Results: The mean age of incident (n=101) and prevalent (n=97) GA patients was 80.6 years (SD=7.5) and 81.9 years (SD=6.3), respectively. 54% of incident and 62% of prevalent patients had subfoveal GA; 27 – 39% had concomitant glaucoma or cataract. The majority of patients were managed by retina specialists. Functional outcomes were rarely documented in patient notes: keywords “reading” and “driving” were found in <10% of records. “Low vision” was mentioned in <3% of notes, while “anxiety / depression” was noted in <2%. “Mobility / independence / disability” were not found. 64% of driving-related notes discussed trouble driving or night driving; 44% of reading-related notes indicated impairment, while 32% discussed reading glasses or aids. 74% of low-vision-related notes recommended a low vision consultation.

Conclusions: VR-QoL and PROs are infrequently documented in the EHR by ophthalmologists. Sparse documentation limits the use of standalone EHR note data for QoL/PRO assessment. Retina specialists often refer GA patients to low vision specialists, who may be more likely to monitor and document changes in VR-QoL. While regulatory agencies have advocated for the use of patient-centered outcomes in clinical trials, real-world assessment of PROs is lacking, necessitating improved tools to collect RWD on patient QoL.

ABSTRACT BODY:

Purpose: Hypoxia-induced oxidative stress is one of the vital factors that activate the pathogenic mechanism of retinal diseases such as diabetic retinopathy and retinopathy of prematurity. Cobalt chloride ($CoCl_2$) is a commonly used hypoxia mimetic agent that induces oxidative stress-mediated apoptosis by generating reactive oxygen species (ROS). Most retinal diseases are irreversible with no effective treatment; therefore protecting the RPE cells from hypoxia stress is an effective therapeutic way to prevent or slow down the progression of retinal diseases. L and Z are potent antioxidants and can be used as an effective therapy for the treatment of hypoxia-induced oxidative stress. In this study, we evaluate the protective effect of L and Z from $CoCl_2$-induced hypoxia stress.

Methods: To determine the anti-hypoxia effect of L and Z, ARPE-19 cells were pretreated with 1, 2, and 5 μM of L and Z for 24 h and then incubated with and without 8mM $CoCl_2$ for 4 h. Cell viability was measured by incubating cells with 0.5 mg/ml MTT solution for 2 h in dark and measured at 550 nm. To determine ROS levels, cells were pretreated with 1, 2, and 5 μM of L and Z for 24 h, and then incubated with 2 μM 5-(and 6)- chloromethyl-dichlorodihydrofluorescein diacetate (CM-H_2DCFDA) reagent. Cells were measured at Ex/Em: 485nm/535nm.

Results: ARPE-19 cells treated with $CoCl_2$ result in reduced cell viability and increased ROS levels compared to the untreated $CoCl_2$. Cells pretreated with L and Z before $CoCl_2$ treatment efficiently attenuate $CoCl_2$ induced cytotoxicity and ROS levels in a dose-dependent manner (1-5 μM). Pretreatment with 5 μM of L significantly increase the cell viability by 1.3 fold and decrease the ROS levels by 1.7 fold. Pretreatment with 5 μM of Z significantly increased the cell viability by 1.5 fold and decreased the ROS levels by 2.2 fold compared to control (without carotenoid treatment).

Conclusions: L and Z protect ARPE-19 cells from $CoCl_2$-induced hypoxia stress and attenuate cytotoxicity and ROS levels. Z had a comparatively better protective effect relative to L. This may be due to their better antioxidant activity, but a further detailed study is warranted. Macular carotenoids alone or in combination with other nutrients can be used in the prevention of hypoxia-related retinal diseases.

ABSTRACT BODY:

Purpose: The development of therapies that target blood-retinal barrier (BRB) disruption is hindered by a lack of reliable in vitro models that recapitulate the biology and pathophysiology of BRB-related diseases. We aimed to engineer a model of the human BRB and to validate the model by inducing changes in permeability and testing agents currently employed in the clinic.

Methods: Scaffolds coated with hyaluronan-based hydrogel were seeded with primary human retinal microvascular endothelial cells (hRMVECs) and allowed to grow for 7 days. Scaffolds were inverted, primary human pericytes (PCs) were added and were grown for an additional 6 days. The cocultures were treated with TNF-α (5 ng/mL) or IL1β (10 ng/mL) for 72 hrs then exposed to bevacizumab (0.25 ng/mL), aflibercept (500 ug/mL), prednisolone (100 nM), dexamethasone (100 nM) and/or VEGF-121 (100 ng/mL for 6 days. Expression of endothelial and pericyte markers was examined by immunofluorescence and barrier function was assessed by measuring transendothelial cell resistance (TEER).

Results: The scaffolds supported the growth of the cocultures into a 3D structure. The endothelium expressed CD31, VE-cadherin, ZO1 and VWF whereas the PCs expressed NG2, PDGFR-β and NGFRP75. The TEER day 11 was 223.9±26.5 $\Omega*cm^2$ (N=9). Compared to monocultures, the constructs displayed enhanced expression of VE-cadherin (***P<.001, N=6), CD31 (**P<.005, N=6), PDGFR-β and NG2. Treatment with TNF-α or IL1β decreased ZO-1 and F-actin labeling and led to disrupted localization of VE-cadherin. Endothelial morphology changed from cobblestone to spindle-shaped, and F-actin was localized to the edges and tips of the cells, suggesting cell motility. Treatment with a combination of VEGF neutralizing agents and steroids rescued VE-cadherin expression and its localization at cell junctions, suggesting restoration of barrier integrity. VEGF neutralization alone led to more cytoplasmic localization of VE-cadherin.

Conclusions: These results demonstrate the feasibility of creating a 3D model of the BRB with key physiological and biological characteristics that will be valuable for screening therapeutics as well as understanding the development and maintenance of the BRB.

ABSTRACT BODY:

Purpose: Endolaser (EL) can cause significant inflammation as well as serous choroidal and retinal detachments. A 2003 study noted improvement in postoperative (PO) inflammation after a single intravitreal injection of dexamethasone (DEX) following pars plana vitrectomy (PPV). However, none of these patients underwent air-fluid exchange (AFE). We aim to determine the safety and efficacy of intraoperative intravitreal injection of DEX after AFE in PPV with EL for diabetic retinopathy (DR).

Methods: A retrospective consecutive study was conducted over a one-year period. 23 eyes (21 patients) met inclusion criteria for the study: subjects 18 years of age or older who intraoperatively received a single intravitreal injection of DEX (0.2 mg) after PPV with AFE and EL for DR complications. Data analysis was performed with SAS 9.4 (SAS Institute Inc, Cary, NC, USA).

Results: The mean logMAR best corrected visual acuity (BCVA) at the pre-operative visit was 1.45 (median=1.30, SD=1.03). Twenty-two (95.7%) eyes had an intraocular pressure (IOP) in the normal range (0- 21) at this visit, and one eye had an IOP of 25. No eyes had significant anterior chamber (AC) inflammation prior to PPV. After AFE, two (8.7%) eyes were left under C_3F_8 gas, one (4.3%) under SF_6 gas, and two (8.7%) under silicone oil (SO). Median improvement in BCVA was noted at the PO one month (-0.7, p=0.0277) and three month (-0.9, p=0.0150) visits. Seventeen (94.4%) eyes had an IOP in the normal range at the three month PO visit; one (5.6%) had an IOP of 22. No eyes demonstrated significant AC inflammation at the PO one and three month visits. Three (13.0%) eyes required an intravitreal injection within six months after PPV. The mean central retinal thickness per optical coherence tomography was 367.61 µm (median=302.0, SD=181.9) at a mean PO period of 153.7 days (median=174.00, SD=64.3). Five (21.7%) eyes exhibited choroidal detachments on PO day one; all of which self-resolved by week one. Three (13.0%) eyes underwent repeat PPV: one for proliferative vitreoretinopathy, one for vitreous hemorrhage, and one for SO removal.

Conclusions: A single intravitreal injection of DEX after PPV with EL and AFE appears to be safe. Further studies comparing groups that receive intravitreal DEX to those that do not are warranted to assess the effectiveness of this intervention in improving PO outcomes.

ABSTRACT BODY:

Purpose: Inherited retinal diseases (IRDs) are a diverse group of diseases that can possibly lead to blindness. Ongoing clinical trials are testing the potential for gene therapy as treatment for certain IRDs. Physicians treating IRD patients should know which patients qualify for these trials. However, one barrier for identifying these patients is the limited scope of ICD codes for IRDs. In this retrospective chart review, we use peripheral and macular IRDs to test the hypothesis that some retinal dystrophies are not well represented in current ICD nomenclature compared to more well-known IRDs like retinitis pigmentosa (RP) and Stargardt disease (STGD).

Methods: This study was conducted with approval of the Vanderbilt University Medical Center Institutional Review Board/Ethics Committee. Manual chart review was performed for 250 patients who were isolated from the Vanderbilt Eye Institute electronic health record based on ICD10 H35.52 (peripheral retinal dystrophies) and for 281 patients who were isolated based on ICD10 H35.50 or H35.53 (macular dystrophies). Phenotypes of peripheral disease that were analyzed include RP, rod-cone dystrophy, and Usher syndrome. Phenotypes of macular disease that were analyzed include STGD, macular pattern dystrophy, vitelliform dystrophy, Sorsby fundus dystrophy (SFD), and cone/cone-rod dystrophy. The proportion of patients whose ICD designation aligned with the diagnosis made by an IRD specialist was then calculated for each phenotype.

Results: In the peripheral disease group, the percentage of accurate diagnoses are as follows: 70.8% for RP, 4.8% for rod-cone dystrophy, and 7.6% for Usher syndrome. In the macular disease group, the percentage of accurate diagnoses are as follows: 14.9% for STGD, 31.3% for macular pattern dystrophy, 1.07% for vitelliform dystrophy, 1.4% for SFD, and 8.9% for cone/cone-rod dystrophy.

Conclusions: Our results reveal low concordance between the clinician’s diagnosis and the ICD codes for peripheral and macular IRDs, even including well-known diseases such as RP, STGD, and macular pattern dystrophy. This suggests that current ICD nomenclature is unable to adequately encompass many IRD phenotypes, making big data analysis challenging for these diseases. More specific ICD10 codes are needed to phenotype these IRD patients to help physicians more readily identify those who qualify for IRD clinical trials.

ABSTRACT BODY:

Purpose: To report the phenomenon of subretinal deposits and discuss its possible causes in 3 young patients treated with voretigene neparvovec-ryzl (VN) for RPE65-mediated retinal dystrophy.

Methods: This is a retrospective interventional case series at a single tertiary referral center.

Results: We report a series of 3 young patients ages 22 months, 2 years, and 5 years old who developed subretinal deposits following subretinal VN treatment for RPE65-mediated retinal dystrophy. All 3 patients underwent bilateral surgery with each eye treated 7-10 days apart. At post-operative week 1, curvilinear subretinal deposits were noted inferior to the original bleb location in all three patients. In the 5-year-old patient, more extensive sheets of subretinal white deposits were observed in the inferior periphery of both eyes with no signs of inflammatory leakage on fluorescein angiography. All three patients experienced improved visual function with treatment, and both the macular and inferior subretinal deposits have improved or resolved over the follow-up period.

Conclusions: We describe subretinal deposits following VN in three young children as a phenomenon not well described in the clinical trials. The appearance and location of the deposits suggest that blebs migrate after air-fluid exchange and that there may be transient subretinal inflammation at the time of treatment. These findings may inform the delivery parameters and safety profile of AAV-based gene therapy in young children, and in general, as the number of retinal gene therapy trials continues to grow.

TITLE: Association of the insertion / deletion polymorphism of the angiotensin converting enzyme gene with the presence and severity of diabetic retinopathy

SESSION TITLE: Genetic variants in human ocular disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K.E. BARRERA, S. ROJAS JUAREZ, Retina, Hospital Fundacion Nuestra Señora de la Luz IAP, Cuauhtémoc, Ciudad de México, MEXICO|H.J. Pérez, Centro de investigación biomédica, Hospital Fundacion Nuestra Señora de la Luz IAP, Cuauhtémoc, Mexico City, MEXICO|

Commercial Relationships Disclosure: KARLA BARRERA: Commercial Relationship: Code N (No Commercial Relationship) | Hector Pérez: Commercial Relationship: Code N (No Commercial Relationship) | SERGIO ROJAS JUAREZ: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The I / D polymorphism of the angiotensin converting enzyme (ACE) gene has been the main gene that predisposes to the development of diabetic retinopathy (DR). Activation of I/D is associated with increased ACE activity in plasma, and this elevated activity accelerates the development of DR; however, the evidence for this association is limited and, to date, no association between severity and polymorphism has been demonstrated. A retrospective, observational and analytical case-control study performed to determine whether the deletion / insertion polymorphism of the gene encoding ACE is related to the presence and severity of DR, and to identify the allele with the highest risk.

Methods: 90 subjects were studied in each group. Study group: subjects with a diagnosis of DR at any stage according to ETDRS. Control group: subjects without: DR, retinal involvement, ocular pathology caused by microvascular etiology, diabetes mellitus or systemic arterial hypertension.

DNA was obtained, ECA gene was identified by amplification of the polymorphic region of the gene, with the PCR technique, using specific oligonucleotides and they were analyzed by electrophoresis. Comparative analysis of allelic and genotypic frequencies was performed with Fisher's exact test and the odds ratio was calculated.

Results: DNA analysis has been performed on 28 control patients and 32 patients with diabetic retinopathy.

27 control subjects and 32 patients with DR were studied. The metabolic measurement results were significantly higher in patients. The most frequent allele in patients was insertion (I), when compared with the deletion allele (D), a 3.22-fold risk of presenting DR was obtained in patients with genotype I/I (p 0.007). Frequency of allele I in patients was 73%, in controls 57% (p = 0.013), OR was 2.04. Regarding severity, genotype I/I its being higher in study group with greater severity according to the ETDRS (p <0.0001).

Conclusions: The I / D polymorphism plays a determining role in the development and progression of DR, however more genetic studies are needed on the ACE polymorphism and its etiopathogenic association with DR. The results obtained in this study carried out in the Mexican population were found to differ from those reported in the bibliography. (DNA study and statistical analysis with final n: 180, will be carried out in the next weeks)

ABSTRACT BODY:

Purpose: The relationship between anemia and idiopathic intracranial hypertension (IIH) continues to be controversial. The goal of the present study was to: 1) Determine the relative prevalence of anemia in IIH patients compared to age and sex-matched controls attending neuro-ophthalmology clinics and 2) To compare the initial and final visual outcomes of IIH patients with and without anemia.

Methods: 123 consecutive IIH patients were recruited from tertiary neuro-ophthalmology clinics and matched by age and sex to 113 non-IIH neuro-ophthalmology controls. Retrospective chart review obtained information on demographics, symptoms and visual function at presentation and final follow-up. Complete blood counts (CBC) were collected within 6 months of diagnosis and 3 months of final follow-up and anemia diagnosis was made based on hemoglobin <120g/L for women and <130g/L for men. Anemia was further classified as mild (hemoglobin >110g/L), moderate (hemoglobin 80-109g/L), and severe (hemoglobin <80g/L). The study protocol was approved by the appropriate institutional research ethics board.

Results: More IIH patients than controls met criteria for anemia (22.8%, 28/123 versus 10.6%, 12/113, p=0.01), with an odds ratio of 2.48 (95% CI 1.19-5.16). IIH patients had a significantly lower mean hemoglobin than controls (127.6g/L ± 18.0 versus 133.0g/L ± 11.8, p<0.01) and 17.9% (5/28) of anemic IIH patients had severe anemia compared to zero in the control group. When comparing the 28 IIH patients with anemia to the 95 IIH patients without anemia, there were no differences between groups in terms of sex, age, body mass index (BMI) or symptomatology. IIH patients with anemia were more likely to have mild-to-moderate visual acuity impairment (logMAR 0.3-1; 14.3%, 8/56 eyes versus 3.7%, 7/190 eyes, p=0.01) and worse Humphrey mean deviation (-5.7dB + 8.1 versus -3.4dB + 4.2, p=0.048) compared to non-anemia IIH patients at presentation. At final follow-up, there was no difference in visual acuity, but Humphrey mean deviation continued to be worse among anemic IIH patients (-5.6dB + 6.4 versus 3.2dB + 5.7, p=0.045).

Conclusions: Anemia is more prevalent among IIH patients compared to neuro-ophthalmology controls and may influence the initial and final visual function in IIH patients. As a CBC is a widely available test, we suggest that this test be obtained in all patients with new papilledema.

ABSTRACT BODY:
Purpose: To study retinal mouse metabolic states ex-vivo using novel tissue preparation and fluorescent lifetime imaging microscopy (FLIM).
Methods: Wild type C57BL/6J mice were included in the study. Following euthanasia and enucleation, corneas were removed, and eyecups were fixed overnight in a 4% Paraformaldehyde (PFA) solution. The next day, eyecups were embedded in polyacrylamide, and 200 µm thick retinal sections were made using a vibratome. Images were taken using the Leica SP8 DIVE FALCON for multiphoton FLIM measurements of metabolic states and tissue structure, using the phasor approach to FLIM analysis. Tissue excitation was performed with 740 nm light from our ultrafast tunable laser at ~500 µW power. FLIM was collected simultaneously on two hybrid detectors from ~425-475 nm for NADH and ~530-650 nm for FAD, retinoids and hemoglobin.
Results: The percentage of bound NADH was ~50% in the retinal pigment epithelium, ~55% in the photoreceptor layer and 60-70% in the inner retina, indicating higher glycolysis in the outer retina and higher oxidative phosphorylation in the inner retina. This finding in fixed tissues, recapitulated previous findings of live-tissue metabolic FLIM NADH measurements. Additionally, our study showed that the hemoglobin signal in the vasculature has a distinct FLIM profile allowing visibility of retinal capillaries on 3-dimensional images as they penetrate the retina and form capillary plexus at different layers. This novel tissue preparation, imaging, and analysis pipeline enable the reconstruction of metabolic states of tissue layers, cells, stroma, and vasculature in 3 dimensions, without the need for staining techniques.
Conclusions: FLIM of retinal sections in mice showed a predominance of glycolysis in the outer retina and oxidative phosphorylation in the inner retina. With additional autofluorescence excitation and emission strategies, FLIM could be used to define the structure and metabolism of healthy versus diseased retinas.

ABSTRACT BODY:

Purpose: To investigate the relationship between severity grading and visual function in patients with Fuchs endothelial corneal dystrophy (FECD).

Methods: This prospective study included 49 eyes of 27 patients with FECD and 10 eyes of 10 normal subjects in the outpatient clinic in the Department of Ophthalmology at Osaka University Hospital. Subjects with cataract N3 or more, and after keratoplasty were excluded. We determined modified Krachmer grade for each subject, and evaluated corrected distance visual acuity (CDVA), contrast sensitivity (AULCSF), and central corneal thickness (CCT). We analyzed the association between the severity grading evaluated using modified Krachmer grade or CCT and visual function shown as CDVA or AULCSF.

Results: For FECD patients, the average age was 63.1±11.3 years. 22 female and 5 male patients were included. The average CDVA, AULCSF and CCT of the patients were 0.02±0.16 (logMAR), 0.98±0.27, 580±47μm, respectively. There were significant differences in CDVA and AULCSF between modified Krachmer grades ($p = 0.0002$, $p < 0.0001$, respectively). Especially, the differences between grade 0 and 3, 4, or 5 were significant by Steel-Dwass analysis (CDVA: $p = 0.03$, $p = 0.003$, $p = 0.02$, AULCSF: $p = 0.004$, $p = 0.0006$, $p = 0.04$, respectively). There were also significant differences in CDVA and AULCSF between CCT grades ($p < 0.0001$, both). Particularly, the differences between normal eyes and CCT of <550 μm, or between 550-599 μm and ≥ 600 μm were significant by Steel-Dwass analysis (CDVA: $p = 0.002$, $p = 0.002$, AULCSF: $p = 0.03$, $p = 0.0004$, respectively).

Conclusions: It was suggested that the visual function was significantly impaired in FECD patients with modified Krachmer grade 3 or worse. This threshold can be considered for surgical indication of endothelial keratoplasty in terms of visual function. However, CCT might not be suitable for an indicator of surgical intervention because visual function was significantly affected even in patients with normal CCT.

ABSTRACT BODY:

Purpose: We previously reported that stimulation efficiency of retinal prosthesis decreases during suprachoroidal-translationally applied trains of stimulus pulses at the frequency of 20 Hz [Y. Nakano, et al. IOVS 2020;61:2210]. To understand the underlying mechanism that led to the decrease, we have investigated how inter-pulse interval (IPI) affects electrical stimulation efficiency in acute animal experiments.

Methods: Field potentials were recorded from the right superior colliculus of healthy adult rats (Long-Evans, n = 7) anesthetized with urethane. Paired-pulse trans-retinal electrical stimulation (TES) at an IPI of 20-200 ms was focally delivered to the sclera of the left eyeball. Each pulse was cathodic-first biphasic, with no gap term (Fig. 1). The amplitudes of evoked potentials (EPs) to the second TES pulse were compared with those to the first one.

Results: The second EPs were significantly suppressed ($p < 0.05$, paired t-test) by 35% of the first EPs at 60 ms and 80% at 100 ms, of IPI. The relative amplitude of the second EP to the first, recovered at 200 ms, is shown in Fig. 2.

Conclusions: In this study, the length of IPI affected the EP of the second pulse. In the future, we will investigate the IPI that can minimize the decrease in EP after the second pulse, during continuous stimulation.

ABSTRACT BODY:

Purpose: Study if baseline relative peripheral refraction (RPR) profile influences myopia progression in Chinese myopic children wearing Defocus Incorporated Multiple Segments (DIMS) compared to single vision (SV) spectacle lenses.

Methods: Data from a 2-year randomized controlled trial were analyzed retrospectively. Peripheral refraction at 10°, 20°, and 30° nasal (10N, 20N, 30N) and temporal (T) retina were measured for the DIMS and SV group. Subjects were subdivided into two subgroups according to baseline RPR: myopic RPR (RPR ≤ 0 D) and hyperopic RPR (RPR > 0 D) subgroup. Myopia progression and axial elongation over 2 years were compared further between myopic RPR and hyperopic RPR subgroup within the SV and DIMS group.

Results: 79 subjects and 81 subjects in the DIMS and SV group were investigated respectively. The comparison between myopic RPR and hyperopic RPR at 10N and 20N was presented as other positions did not show statistically significant results. In the SV group, no statistically significant differences were noted in myopia progression (mean difference: -0.26±0.14 D, p=0.06) and axial elongation (mean difference:0.04±0.05 mm, p=0.48) between the myopic RPR (n=27) and hyperopic RPR (n=54) 10N subgroups. There was also no significant difference in myopia progression (mean difference: -0.25±0.20 D, p=0.19) and axial elongation (mean difference: 0.08±0.08 mm, p=0.27) between myopic RPR (n=11) and hyperopic RPR (n=70) subgroups at 20N. However, in the DIMS group, children with myopic RPR at 10N (n=27) showed significantly more myopia progression (mean difference: -0.36±0.14 D, p=0.009) and more axial elongation (mean difference: 0.16±0.05 mm, p=0.001) than the children with hyperopic RPR at 10N (n=52). And myopic RPR at the 20N subgroup (n=12) showed significantly more myopia progression (mean difference: -0.40±0.16 D, p=0.01) and more axial elongation (mean difference: 0.15±0.07 mm, p=0.02) than the hyperopic RPR at 20N subgroup (n=67).

Conclusions: The baseline RPR profile showed no influence in myopia progression of the SV lens wearers. DIMS lens wearers showed better efficacy in myopia control in children with relatively more baseline hyperopic RPR than children with relatively baseline myopic RPR. This suggests that using customized peripheral myopic defocus based on individual baseline RPR may help to improve myopia control effects.

ABSTRACT BODY:

Purpose: The onset and progression of aortic aneurysms are asymptomatic, which eventually becomes a life-threatening event when the vessel wall is dissected or ruptured. The screening and diagnosing of aneurysms are expensive and sometimes invasive. Retinal vascular features (RVFs) are measured easily and non-invasively, they reflect the systemic vascular properties as well as the clinical risk factors for aneurysms, hence they can be the potential biomarkers for aortic aneurysms and dissections. In this study, we used the genetic information of aneurysms as the genotypes and RVFs as phenotypes and conducted a phenome-wide association study (PheWAS), in order to identify novel imaging biomarkers which can assist the early diagnosis of aortic aneurysms.

Methods: The study was conducted within the UK Biobank participants. Digital retinal fundus images from the right eyes were used. A machine learning method was used to extract the RVFs, which resulted in 91 quantitative features. Genetic risk scores (GRS) for abdominal, thoracic and intracranial aneurysms were generated by PLINK and SNPs representing 4 different Marfan genes (FBN1, COL16A1, LOC728241 and LOC441376) were extracted. The R package 'PheWAS' was used and age, sex, blood pressure and BMI were adjusted as covariates.

Results: A total number of 50380 participants were included. In the PheWAS, after Bonferroni correction, 6 RVFs which represent the vessel caliber, complexity or tortuosity were associated with abdominal aneurysm, and 'artery_calibre' and 'number_of_vascular_tree' (ntree_a) were associated with thoracic (β=0.06, P=4.41e-05) and intracranial (β=-0.09, P=9.92e-05) aneurysms respectively. The 'ntree_a' was shared between abdominal and intracranial aneurysms. For Marfan genes, 'mean_artery_curve_angle' (CurveAngle) was common for all 4 genes (FBN1:β=-0.09, P=4.30e-10; COL16A1:β=-0.07, P=4.28e-08; LOC728241:β=-0.05, P=1.26e-04; LOC441376:β=0.07, P=1.75e-05), and 'ntree_a' was shared by 3 genes (FBN1:β=-1.52, P=3.53e-14; COL16A1:β=-0.04, P=2.71e-04; LOC728241:β=-0.04, P=4.27e-04) (Figure 1). Among the overall traits, 'ntree_a' and 'CurveAngle' were the most common RVFs (Figure 2).

Conclusions: The PheWAS identified several RVFs that are associated with different types of aneurysms. Among them, 'ntree_a' and 'CurveAngle' are most commonly identified by different aneurysms, suggesting they are potential vascular biomarkers for aneurysms.

ABSTRACT BODY:

Purpose: The effect of coronavirus disease 2019 (COVID-19) on ophthalmic surgical case numbers in Australia and globally remains poorly characterised. Increased incidence of COVID-19 in Australia between March and April 2020 led to a national lockdown and elective surgery restrictions. The aim of this population-based study was to quantify the early impact of COVID-19 on ophthalmic surgery in Australia, comparing surgical service rates in 2019 and 2020.

Methods: Retrospective analysis of the number of ophthalmic surgical services in 2019 and 2020 in all Australian States and Territories, as recorded by Medicare (Australian Government-funded universal health insurance scheme subsidising healthcare costs for Australian residents). Monthly surgical service rates were calculated and Poisson regression was used to compare the change in service rates between months.

Results: Between March and April 2020, surgical service rates decreased for: cataract surgery (by 71%, 95% CI: 70-72%), cataract surgery with minimally invasive glaucoma surgical device insertion (by 71%, 95% CI: 65-75%), pterygium removal (by 67%, 95% CI: 60-72%), corneal transplantation (by 31%, 95% CI: 9-48%), and collagen crosslinking for corneal ectasias (by 35%, 95% CI: 18-48%). Comparatively, service rates for these surgeries did not differ or decreased less between March and April 2019. Interestingly, glaucoma filtration surgery rates decreased between March and April in 2020 (by 44%, 95% CI: 29-56%) and also in 2019 (by 45%, 95% CI: 31-55%), whilst retinal detachment surgery rates were unchanged between these months in 2020 (crude decrease 9%, 95% CI: -28 to 16%) and 2019 (crude decrease 11%, 95% CI: -26 to 9%).

Conclusions: Despite relatively low rates of COVID-19 community transmission in Australia in 2020, ophthalmic surgical service rates decreased during months in lockdown and with restrictions, largely for non-time-critical conditions. These data may have health planning implications as the pandemic continues, with future lockdowns and restrictions possible, especially as COVID-19 variants emerge.

ABSTRACT BODY:

Purpose: Chronic non-infectious uveitis (NIU) can result in nerve damage and vision loss. Most patients are treated using corticosteroids, which can lead to serious side effects. Intravitreal (ITV) administration of biologic TNFα inhibitors can substantially reduce the need for steroids. However, these products were not designed or validated for ITV use, and off-label ITV treatment with existing TNFα inhibitors is not recommended. Valitor is developing an anti-TNFα biologic specifically designed for ITV administration with a projected treatment frequency of only 2-3 times per year as a steroid-sparing treatment for chronic NIU.

Methods: We synthesized multivalent protein (MVP) conjugates comprising multiple copies (i.e. valency) of anti-TNFα antibodies bound to soluble hyaluronic acid biopolymers. We determined MVP binding affinity to TNFα using biolayer interferometry and cell bioassays. We assessed the ITV half-life of MVPs by delivering 50 µL of fluorescently-tagged MVP to rabbit eyes and measuring the amount of drug remaining in the eye after over time. We also evaluated the efficacy of anti-TNFα MVPs in a rat model of experimental autoimmune uveitis (EAU). Ocular inflammation was induced in rats by injecting 50 µg of interphotoreceptor retinoid-binding protein in 200 µL of complete Freund's adjuvant. At early stages of disease onset (6 and 8 days after induction), we delivered either 12.6 µg anti-TNFαMVPs, 40 µg of dexamethasone (dex), or vehicle control via 5 µL ITV injection. We assessed inflammation by ocular examination and ocular tissue histopathology.

Results: Based on binding affinity measurements, we found that MVP potency increased directly with valency, and at high valency, the potency of MVPs were substantially (~100X) greater than the unconjugated protein controls. The ITV half-life of the MVPs was also to 6-8 times longer than unconjugated therapeutics. EAU inflammation in rats treated with anti-TNFα MVPs was similar to those treated with dex, and both treatments reduced inflammation compared to the vehicle control.

Conclusions: The MVP platform appears capable of increasing the potency and ITV durability of anti-TNFα inhibitors. By generating a sustained anti-inflammatory response with minimal systemic exposure, we expect our anti-TNFα MVP conjugates will enable a better overall safety profile compared other current treatment strategies for chronic NIU.

ABSTRACT BODY:

Purpose: To compare epithelial thickness in patients who developed ocular Graft Versus Host Disease (definite oGVHD) after hematopoietic stem cell transplantation (HSCT), and those who did not (none oGHVD).

Methods: In this retrospective chart review, patients with GVHD who underwent corneal epithelial thickness mapping at the Illinois Eye and Ear Infirmary between July 1, 2021 and October 15, 2021 were identified. Records were reviewed for corneal epithelial thickness data measured by optical coherence tomography (Optovue Avanti), Schirmer 1 test without anesthetic, corneal and conjunctival staining, and ocular surface disease index (OSDI) scores. Mean ± SD values of each corneal epithelial thickness variable (central 2mm, superior epithelial thickness 2-7mm, inferior epithelial thickness 2-7mm, standard deviation) were calculated for the definite and none oGHVD groups. Correlations of epithelial thickness and standard deviation to the signs and symptoms of dry eye were calculated.

Results: There were 136 definite oGVHD eyes and 40 none oGVHD eyes. The mean (± SD) central, superior, and inferior corneal epithelial thicknesses were 50.90 (± 6.60) um, 46.08 (± 7.21) um, and 52.15 (± 6.81) um in the definite oGHVD group, and 51.96 (± 4.01) um, 48.6 (± 4.71) um, and 53.36 (± 4.72) um in the none oGVHD group. The superior corneal epithelium was thinner in definite oGVHD eyes compared to none oGVHD eyes ($p = 0.048$), while there was no statistical difference in central or inferior epithelium. The variability of epithelial thickness (measured as standard deviation) was higher in definite oGVHD eyes (4.64 ± 2.23) compared to none oGVHD eyes (2.90 ± 1.08; $p < 0.0001$). OSDI scores were higher for patients with definite oGVHD (28.29 ± 23.79) compared to those without oGVHD (14.12 ± 17.21; $p = 0.001$). OSDI scores negatively correlated with superior epithelial thickness (Pearson coefficient = -0.207, $p = 0.007$) and positively correlated with epithelial thickness variability (Pearson coefficient = 0.228, $p = 0.003$).

Conclusions: In this series, eyes with definite oGHVD exhibited thinner superior corneal epithelial thicknesses and higher variability in epithelial thickness compared to eyes without oGVHD. Corneal epithelial mapping may be an objective and efficient method of diagnosing ocular GVHD.

ABSTRACT BODY:

Purpose: There is no recent evidence on progression rates of Primary Angle Closure (PAC) to Primary Angle Closure Glaucoma (PACG). We aimed to study the 5-year progression rates of treated PAC to PACG or acute primary angle closure (APAC).

Methods: A retrospective cohort study of 79 PAC subjects was performed. PAC was defined as iridotrabecular contact of 180 degrees or more, in the presence of raised intraocular pressure or peripheral anterior synechiae, without evidence of glaucomatous optic neuropathy. Data on intraocular pressure (IOP), gonioscopy, treatment instituted and time of progression to PACG or APAC were analyzed. In subjects with bilateral PAC, one eye per subject was randomly chosen for analysis.

Results: Of the 79 PAC subjects, 58 (73.4%) subjects were female and all subjects were of Chinese descent. All eyes were treated - 76 underwent initial laser peripheral iridotomy (LPI) and 3 underwent lens extraction as a primary procedure. During the follow-up period, 30 were started on IOP-lowering medications, and another 21 underwent cataract extraction. 14 of the eyes that underwent cataract extraction required medications. None of the eyes developed APAC. Only 4 eyes progressed to PACG over 5 years of follow-up, 3 of which remained phakic at time of progression.

Conclusions: These results suggest that the risk of progression of treated PAC to PACG is low. Our findings reveal lower rates of 5-year progression compared to previously published data. We found that cataract extraction reduces the likelihood of requiring glaucoma medications at 5 years.

ABSTRACT BODY:

Purpose: A number of vision restoration therapies aim to restore light sensitivity to retinal ganglion cells (RGCs) following extended periods of blindness. In rodent models of retinal degeneration, physiological changes in RGCs after photoreceptor (PR) loss have been reported but this has not been investigated in primates. By expressing both a calcium indicator (GCaMP6s) and an optogenetic actuator (ChrimsonR) in foveal RGCs of a macaque, we use in vivo imaging to assess changes in RGCs in the weeks and years following PR loss.

Methods: AAV2-CAG-GCaMP6s and AAV2-CAG-ChrimsonR-tdTomato were co-injected into the vitreous. Cones were ablated with a Mai-Tai pulsed laser (0.8 x 0.7o, 106 ms, 120-150mW, 730 nm) delivered through an adaptive optics scanning light ophthalmoscope (AOSLO). GCaMP fluorescence from 218 RGCs in two eccentricity matched regions of the fovea was collected using AOSLO and tracked over 10 weeks. In the first location (long-term deafferented) PR input was removed 2 years prior to recording, while in the second location (short-term deafferented) PR input was removed 1 week prior to recording. A 0.5 s, optogenetic stimulus (1 mW, 640 nm) was delivered to the RGCs, the GCaMP fluorescence was recorded for 90 s, and the decay fitted with an exponential model.

Results: Optogenetic responses in RGCs persisted for over 2 years following PR ablation. The mean time to peak calcium response did not differ significantly between the long-term (1.43±0.17s SD) and the short-term (1.45±0.30s SD) deafferented RGCs (unpaired t-test, $p=0.05$, $n=654$). The mean decay constant of the calcium response decreased 2.1 fold (2.5±0.5 s to 1.2±0.2 s SD) in the 8 weeks post PR ablation ($p<0.001$, paired t-test, $n=109$), with 87% of the decrease occurring within the first 5 weeks. The decay constant did not decrease further from week 8-10.

Conclusions: By expressing both an optogenetic actuator and a calcium indicator in foveal RGCs, we tracked the development of altered RGC physiology in vivo in the weeks and years following PR loss. The presence of optogenetic responses 2 years after PR loss and the stability of the rise time are promising for vision restoration therapies targeting RGCs, however, the 2.1 fold reduction of the calcium response decay constant suggests that restored activity may be impacted by changes in the inner retina weeks after PR loss.

SUBMITTER (NAME ONLY): Susana Chung

TITLE: Local analysis reveals lower light sensitivity and thicker retinal layers of the amblyopic eyes near the fovea

SESSION TITLE: Pediatric Ophthalmology - Pathophysiology and Imaging Modalities and Oculoplastics

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S.T. Chung, B.Z. Li, D.M. Levi, University of California Berkeley, Berkeley, California, UNITED STATES|R. Li, Nova Southeastern University, Fort Lauderdale, Florida, UNITED STATES|Q. Lei, Wichita State University, Wichita, Kansas, UNITED STATES|

Commercial Relationships Disclosure: Susana Chung: Commercial Relationship: Code N (No Commercial Relationship) | Roger Li: Commercial Relationship: Code N (No Commercial Relationship) | Betty Li: Commercial Relationship: Code N (No Commercial Relationship) | Quan Lei: Commercial Relationship: Code N (No Commercial Relationship) | Dennis Levi: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Visual deficits associated with amblyopia are often attributed to a cortical origin, with little contribution from the retina. Yet, controversial results have been reported in relation to whether the retinal structures and functions differ between the two eyes in amblyopia. The goals of this study were to compare light sensitivity and thickness of various retinal layers in local retinal regions, and to evaluate the correlations between sensitivity and layer thicknesses, between the amblyopic (AE) and the fellow (FE) eyes of observers with amblyopia.

Methods: Sixteen observers with amblyopia (age: 14 to 72 years, 7 with strabismic amblyopia and 9 with anisometropic amblyopia) participated in this study. Light sensitivity was measured at 37 retinal locations within the central 10° of the visual field for each eye of the observers using a MAIA microperimeter. The 37 locations included the center of the fixation location, and eccentricities at 1°, 3° and 5° along 12 meridians from fixation. Retinal structures were imaged using a Spectralis OCT, with 97 B-scans covering the central 20° of the visual field. En-face retinal images obtained using MAIA and Spectralis for the same eye were co-registered using custom-written software and thickness of the various retinal layers were extracted at each of the 37 retinal locations.

Results: Results were analyzed using linear mixed-effects models (observer as a random effect). Neither light sensitivity nor retinal layer thicknesses depended on the type of amblyopia. Sensitivity was 0.58 dB [SE 0.11] lower in the AE than in the FE. The difference in sensitivity between the two eyes was largest for retinal locations at 1° from fixation. Retinal layers were generally thicker in the AE than in the FE. Layer thickness was significantly correlated with light sensitivity across the central 10° (accounting for repeated measurements) for 6 of the 8 layers for FE, but only 2 of the 8 layers for AE.

Conclusions: Analyzing the function and structures of the retina for local regions, rather than pooling over much larger regions as in previous studies, revealed lower sensitivity and thicker retinal layers of the AE near the fovea, compared with the FE. Additionally, the AE showed an absence of correlations between sensitivity and layer thicknesses that were observed in the FE. These findings suggest that the retina may play a role in limiting vision in the AE.

ABSTRACT BODY:

Purpose: To examine the effects of foveal thickness (FT) fluctuation (FTF) of visual and morphologic outcomes in anti-vascular endothelial growth factor (VEGF) treatments with pro re nata regimen for Branch retinal vein occlusion (BRVO)- macular edema (ME).

Methods: We conducted a retrospective, observational case series (2012-2021) at a multi-center retinal practice among 309 treatment-naïve patients (309 eyes) with BRVO. FT was assessed via optical coherence tomography (OCT) at each study visit. We evaluated the logarithm of the minimal angle of resolution best corrected visual acuity (logMAR BCVA) and the defect length of the foveal ellipsoid zone (EZ) band measured via OCT.

Results: At baseline, the mean logMAR BCVA was 0.30±0.30 and the mean FT was 503±162 μm. The number of anti-VEGF injections for BRVO-ME was 5.8±4.6 during the mean follow-up period (50.6±22.2 months). At the final examination, the mean logMAR BCVA and FT values were significantly improved compared with the baseline. Multiple regression analyses showed that age, baseline logMAR BCVA, and FTF were significantly associated with the final logMAR BCVA (β=0.20, 0.35, and 0.30, respectively). FTF (divided into Groups 0-3 in ascending order of FTF) was significantly associated with the logMAR BCVA and the defect length of the foveal EZ band at the final examination. The defect lengths of the foveal EZ band were longitudinally shortened in Groups 0-1 and were slightly prolonged in Groups 2-3. The logMAR BCVA maintained improvements in Groups 0-1, and worsened slightly in Groups 2-3.

Conclusions: FTF was significantly associated with visual acuity and foveal photoreceptor status. Thus, we conclude that morphologic and functional prognoses of eyes with BRVO may be improved by identifying the characteristics of eyes with a larger FTF and consequently controlling the FTF more strictly.

ABSTRACT BODY:

Purpose: Visual dysfunction in age-related macular degeneration (AMD) is associated with the degeneration of retinal pigmental epithelial cells (RPEs). Several ongoing clinical trials are testing cell replacement therapy as means to halt AMD progression, using human pluripotent stem cell (hPSC)-derived RPEs. Although grafted cells pre-transplantation are routinely characterized, it is unknown how these cells respond transcriptionally post-transplantation. In this study, we dissected the single cell transcriptomic changes in hPSC-RPEs after transplantation.

Methods: Two sources of hPSCs, embryonic (ESCs) and induced (iPSCs), were differentiated to generate RPEs, which were characterized at the mRNA, protein, and functional level to confirm their resemblance to native counterparts. 1-month-old hPSC-RPEs were then either grown further for a month in vitro or subretinally implanted into immunocompetent Dutch Belted rabbits and followed-up for an additional month. At 2 months, both in vitro and in vivo transplanted cells were harvested for single cell RNA sequencing (scRNA-seq).

Results: The in vitro 1-month-old hPSC-RPE cells expressed RPE signature markers, secreted cytokines in a polarized fashion, and demonstrated barrier function and phagocytosis. These 1-month-old cells were successfully xenografted subretinally into immunocompetent hosts and displayed maintenance of overlying retinal structure, and retinal function. There was absence of adverse reactions against both sources of RPEs. ScRNA-seq of in vitro RPEs from both sources revealed a similar heterogenous population consisting of a spectrum of varying maturity states, from progenitor to late RPE. Profiling of RPE after subretinal transplantation unravelled robust in vivo maturation towards late RPE state.

Conclusions: In this work, we generated high quality, functional RPEs from two different hPSC sources. Subretinal transplantation of these cells into an immunocompetent host did not elicit an adverse reaction, highlighting hPSCs as a promising cell source to treat AMD. Furthermore, scRNA-seq performed on subretinally transplanted hPSC-RPEs uncovered the favorable maturation of a heterogenous in vitro RPE population towards a homogenous adult state. Overall, our findings provide a high-resolution perspective on a stem cell-based product intended for future clinical use.

ABSTRACT BODY:

Purpose: We previously reported an RNA-Seq dataset of corneal endothelium derived from healthy subjects (Tokuda Y, et al. Sci Data, 2020). The purpose of this present study was to elucidate the genetic alternations and potential signaling pathways related to the pathophysiology of Fuchs endothelial corneal dystrophy (FECD) by utilizing an RNA-Seq of corneal endothelium obtained from the patients with FECD.

Methods: Corneal endothelial cells were isolated from patients with FECD (n=10) and healthy controls (n=7). RNA-Seq libraries were generated using the SMARTer® Stranded Total RNA-Seq Kit v2, and then sequenced by using a paired-end 100-bp read protocol. Genes were considered as differentially expressed genes (DEGs) with adjusted P-value (< 0.05) and Log_2 Fold Change (≥ 1.0 or ≤ -1.0). Variation or similarity of gene expression was then confirmed by principal component analysis (PCA). For enrichment analysis, gene ontology (GO), Reactome, and KEGG pathways were investigated by use of R software.

Results: Among a total of 24,636 genes detected by RNA-Seq, 2,366 genes were identified as DEGs in FECD (1,092 upregulated and 1,274 downregulated genes). PCA revealed the presence of two visual groups composed of control and FECD, respectively. For downstream analysis, 1,706 DEGs (696 upregulated and 1,010 downregulated genes) were extracted by confirming gene annotations. GO analysis indicated enrichment of extracellular structure organization, extracellular matrix (ECM) organization, response to oxidative stress, and apoptotic signaling pathway. Consistently, Reactome pathway analysis indicated the dysregulation of ECM related pathways. KEGG pathway analysis demonstrated the involvement of the phosphatidylinositol 3-kinase (PI3K)/Akt and mitogen-activated protein kinase (MAPK) signaling pathways.

Conclusions: The current study presented additional evidence that ECM dysregulation and oxidative stress are involved in the pathophysiology of FECD, and that the PI3K/Akt and MAPK signaling pathways might be interesting targets for elucidating the pathophysiology as well as drug discovery, though future in vitro and in vivo FECD-model "wet experiments" will be necessary.

TITLE: A natural history study of functional and structural outcome measures in PRPH2-associated retinal dystrophy

SESSION TITLE: Genetic variants in human ocular disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R.C. Heath Jeffery, J.A. Thompson, I. Constable, I. McAllister, T.L. McLaren, J.N. De Roach, T.M. Lamey, F.K. Chen, Lions Eye Institute, Nedlands, Western Australia, AUSTRALIA|

Commercial Relationships Disclosure: Rachael Heath Jeffery: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Thompson: Commercial Relationship: Code N (No Commercial Relationship) | Ian Constable: Commercial Relationship: Code N (No Commercial Relationship) | Ian McAllister: Commercial Relationship: Code N (No Commercial Relationship) | Terri McLaren: Commercial Relationship: Code N (No Commercial Relationship) | John De Roach: Commercial Relationship: Code N (No Commercial Relationship) | Tina Lamey: Commercial Relationship: Code N (No Commercial Relationship) | Fred Chen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Progression rates of PRPH2-associated retinal dystrophy have not been described. We used structural and functional outcome measures to establish disease progression rates in best-corrected visual acuity (BCVA), total lesion size (TLS), dark autofluorescence (DAF) area, total macular volume (TMV) and mean macular sensitivity (MMS).

Methods: In this retrospective case series, patients with confirmed heterozygous pathogenic PRPH2 variants, 6 monthly serial BCVA, ultra-widefield (UWF) fundus autofluorescence (FAF), optical coherence tomography and MAIA microperimetry with at least 1 year of follow up were included. Linear regression was performed for each eye of each subject to determine the rate of change. Changes in TMV and MMS were compared to a cohort of normal controls.

Results: A total of 12 patients (mean baseline age=55, F:M=4:8) from 10 unrelated families were followed for a mean (SD, range) of 4.7 (2.1, 1.0-8.5) years. The overall mean (SD) BCVA decline was 0.91 (1.86, OD) and 2.93 (5.34, OS) letters/year with no significant interocular difference (p=0.28). Mean (SD) effective radius expansion rates in TLS and DAF were 0.16 (0.13) and 0.10 (0.08) mm/year and 0.15 (0.14) and 0.11 (0.05) mm/year in OD and OS respectively. Mean (SD) TMV decline was 0.079 (0.053, OD) and 0.071 (0.047, OS) mm^3/year with no significant interocular difference (p=0.25). Healthy controls (N=42, mean age=51) showed a mean decline of 0.006 mm^3/year. Overall MMS change was +0.38 (OD) and -0.72 (OS) dB/year. Four patients showed a bilateral MSS decline of 1.90 (OD) and 1.31 (OS) dB/year. Five patients showed a bilateral MSS increase of 0.61 (OD) and 0.49 (OS) dB/year attributed to learning effects. Healthy controls (N=41, mean age=51) showed a mean (SD) MSS decline of 0.02 dB/year.

Conclusions: Patients with PRPH2-associated retinal dystrophy showed slow expansion rates in UWF-FAF derived TLS and DAF area. OCT-derived TMV may serve as an important quantitative outcome measure for future therapeutic clinical trials. Functional outcome measures however warrant further investigation given their large variability and significant learning effects.

ABSTRACT BODY:

Purpose: Although changes in the ocular surface microenvironment are known to occur during aging, it remains unclear whether cellular senescence at the ocular surface contributes to age-related phenotypes. Here, conjunctival tissue samples obtained from elderly subjects (aged 65 years or older) and irradiated primary conjunctival epithelial cells (CjECs) were used to determine the potential role of ocular senescent cells.

Methods: Our study involved 10 conjunctival tissue samples obtained from 10 healthy elderly subjects [4 males and 6 females; mean age: 68.5 years (range: 65-81 years)], and primary CjECs obtained from human donor eyes that were cultured and X-irradiated at 10 Gy. Tissue samples and irradiated CjECs were examined using immunostaining or western blotting for $p16^{INK4a}$ expression (an important marker of cellular senescence) and for the senescence-associated beta-galactosidase (SA-βgal). We also investigated the expression of protein zonula occuludens-1 (ZO-1) in the epithelial barrier, and barrier function of the irradiated CjECs was evaluated via transepithelial electrical resistance (TEER). Student's t-test was used for statistical analysis.

Results: Expression of $p16^{INK4a}$ was observed in 6 (60%) of the 10 conjunctival tissue samples, with an average positive rate of 12.3% in each sample, while no $p16^{INK4a}$ expressing cells was detected in the other 4 tissue samples, and this expression was not sex-dependent. ZO-1 expression was reduced in tissue samples showing $p16^{INK4a}$-positivity but was retained in tissue samples where $p16^{INK4a}$ was undetectable. In irradiated CjECs, there was a significant increase in $p16^{INK4a}$ expression and SA-βgal activity (and a decrease in ZO-1 expression) both at RNA and protein levels compared to control cells ($P<0.05$). Moreover, compared with non-irradiated CjECs, TEER was significantly reduced in irradiated CjECs ($P<0.05$).

Conclusions: We report here the presence of senescent cells in the conjunctival epithelium of elderly subjects, the acquisition of senescent phenotypes in CjECs induced to senescence upon irradiation, and the contribution of ocular senescent cells in the decrease of epithelial barrier function.

ABSTRACT BODY:

Purpose: Diabetic eyes with predominantly peripheral lesions (PPL) have been suggested to be at higher risk for progression to proliferative diabetic retinopathy (PDR). Retinal nonperfusion is known to increase with increasing severity of diabetic retinopathy. We sought to evaluate the relationship between macula vessel density metrics on optical coherence tomography angiography (OCTA) with lesion distribution in eyes with DR.

Methods: Patients with DR presenting to three tertiary care centers (Aravind Eye Hospital (326 eyes), LV Prasad Eye Institute (86 eyes), Sankara Nethralaya (86 eyes)) who underwent both Optos ultrawidefield (UWF) pseudocolor imaging and macular OCTA (Cirrus Angioplex, 6x6 mm) were included in this retrospective analysis. The distribution of DR lesions was assessed by comparing each of the peripheral ETDRS extended fields (3-7) against their corresponding ETDRS field. An eye was determined to have predominantly peripheral lesions (PPL) if any peripheral field had a greater severity or extent of lesions compared to its corresponding central ETDRS field; otherwise, it was classified as predominantly central lesions (PCL). After correction for segmentation errors, en face OCTA images from the superficial and deep capillary plexuses (SCP and DCP) were exported and analyzed using Image J. Perfusion density (PD) and vessel length density (VLD) were calculated following binarization (PD) and skeletonization (VLD). PD and VLD of the SCP and DCP were compared between eyes with PPL and PCL DR lesion distribution.

Results: Total of 404 eyes were included in this study (62.1% PCL and 37.9% PPL). There was no significant difference, however in mean SCP PD (30.45 in PPL eyes and 30.95 in PCL eyes; p=0.415) or in DCP PD (34.13 in PPL and 34.22 in PCL; p=0.480). There was also no significant difference in SCP VLD (11.53 in PPL and 11.73 in PCL; p=0.394) or DCP VLD (14.49 in PPL and 14.47 in PCL; p=0.307).

Conclusions: Though predominantly peripheral lesions are thought to be associated with a higher risk of progression, eyes with PPL do not have worse macular perfusion. OCTA analysis of the retinal periphery will be necessary to determine whether eyes with PPL have more severe peripheral nonperfusion.

ABSTRACT BODY:

Purpose: Among elderly people in developed countries age-related macular degeneration (AMD) is the leading cause of progressive vision loss. Hallmark features of AMD are an accumulation of drusen in the Bruch's membrane and dysfunction of retinal pigment epithelial (RPE) cells. Oxidative stress is an important factor contributing to the damaged RPE cells. Multiple studies provide evidence that melanin is an important antioxidant factor which leads to reduction of the reactive oxygen species (ROS). Melatonin also has anti-inflammatory, antitumor, and antiangiogenic properties.

Evaluate melatonin protection in Non-AMD cybrids and in AMD cybrids.

Methods: AMD patients and age-matched non-AMD individuals provided platelets that were combined with mitochondria-deficient (Rho0) ARPE-19 cells. The resultant Cybrid cell lines have identical nuclei but mitochondria from different individuals. Cybrids were cultured in 96-well plates (10,000 cells/well) and treated with Melatonin 200 μM for 24 hours. Ethanol was used as vehicle-control. ROS levels and cellular metabolism were measured by the H2DCFDA and MTT assays, respectively. After adding 100 μl H2DCFDA solution/well, plates were read via the fluorescent plate reader with the excitation (EX, 492nm) and emission (EM, 520nm) wavelengths. For cell metabolism, 10 μl of MTT assay reagent was added per well and plates were incubated in 37°C for 3 hours. After adding 100 μl/well of DMSO, plates were analyzed (signal at 570 nm and reference at 630 nm) with the absorbance plate reader. – Statistics were calculated using Student T-test.

Results: ROS levels of non-AMD and AMD cybrids with melatonin declined to 90.50 ± 3.79 ($P < 0.0001$, n=4) and 84.50 ± 1.55 ($P < 0.0001$, n=4) versus Ethanol groups (100.8 ± 0.478, n=4) and (99.75 ± 1.75, n=4), respectively. MTT Assay levels of non-AMD and AMD cybrids with Melatonin improved to 129 ± 2.97 ($P < 0.0001$, n=4) and 132.3 ± 2.78 ($P < 0.0001$, n=4) versus Ethanol groups (100.8 ±0.478, n=4) and (99.75 ±1.75, n=4), respectively.

Conclusions: Non-AMD cybrids and AMD cybrids treated with melatonin had significantly increased cellular metabolism and lower levels of ROS, demonstrating that melatonin could protect cells against oxidative stress.

ABSTRACT BODY:

Purpose: To determine demographics and visual acuity for patients with newly diagnosed central serous chorioretinopathy (CSCR) as captured in the IRIS Registry.

Methods: We identified patients with a new diagnosis of CSCR between 2017 and 2018 in the IRIS Registry. We investigated patient characteristics (age, sex, and race/ethnicity) associated with CSCR, and visual acuity (VA) at time of first diagnosis and routine follow-up visits. We processed multivariate regressions to analyze the odds of developing CSCR relative to all patients in the IRIS Registry database.

Results: 28,323 patients were newly diagnosed with CSCR between 2017 and 2018 in the IRIS Registry. The majority of patients with new CSCR were male (68.54%), and the decade with the most CSCR diagnoses was 51-60 years (23.68%). Mean VA at time of diagnosis was 0.29 logMAR (about 20/40) which decreased only slightly to 0.33 logMAR 1 year following diagnosis. Compared to patients in the IRIS Registry without CSCR, patients with CSCR were more likely to be of Asian (Odds ratio (OR) 1.65, $p < 0.001$) or Hispanic descent (OR 1.5, $p < 0.001$) using White as a reference, and were more likely to have Commercial (OR 1.12, $p < 0.001$) or Military (OR 1.29, $p < 0.001$) insurance compared to Medicare, Medicaid (using no insurance as a reference).

Conclusions: According to the IRIS Registry, patients with newly diagnosed CSCR were most commonly middle-aged male, of Asian or Hispanic descent, and with commercial or military insurance. Initial VA at diagnosis was 20/40, and this was relatively stable 1 year following diagnosis.

ABSTRACT BODY:

Purpose: Ultrasound is a commonly available tool to assess the properties of the posterior eye, allowing us to characterize morphological changes. Here, the present study investigates the use of curvature in a simple algorithm to achieve automated (clinician-free) staphyloma detection, as well as pinpoint the location of staphyloma apexes—locations known to be prone to pathologic change.

Methods: 46 individuals (emmetropic, highly myopic (HM) or pathologic myopia) were enrolled in this study (axial length (AxL) range: 22.3-39.3mm) yielded 130 images in total. 10 MHz US B-scan images were acquired while subjects fixated in primary gaze. Eyes were clinically classified into two groups – a non-staphyloma group (composed of eyes that were either emmetropic or HM without staphyloma) and a staphyloma group. On each US image, an intensity-based segmentation algorithm automatically tracked the posterior eyewall. Local curvature (K) of the posterior eyewall and distance (L) of the posterior eyewall to the US transducer were calculated. The location of the staphyloma apex was also automatically estimated. The area under the receiver operator characteristic (AUROC) curve was used to evaluate the diagnostic ability of eight local statistics derived from K, L and AxL. The performance of binary classification (i.e. presence or absence of staphyloma) was assessed at an optimal cut-off point and compared with the performance of junior clinicians.

Results: A fully-automated algorithm was able to detect the posterior eyewall and quantify the non-uniformity of the posterior eye shape with a good classification performance of AUROC > 0.70 for most parameters derived from local curvature (K). The best classifier (the combination of AxL, standard deviation of K, and the standard deviation of L) yielded a diagnostic validation performance of 0.897, which was comparable to the diagnostic performance of junior clinicians. Our method localized the staphyloma apex with an average error of 1.35+/-1.34 mm.

Conclusions: Our fully-automated method enables staphyloma detection with performance comparable to that of junior clinicians. Combined with real-time data acquisition capabilities of US, this method has the potential to be employed as a screening tool for clinician-free in-vivo staphyloma detection.

ABSTRACT BODY:

Purpose: To analyse anterior segment optical coherence tomography (AS-OCT) imaging of the filtering bleb after trabeculectomy with amniotic membrane transplantation (AMT) and evaluate intrableb structural parameters associated with intraocular pressure (IOP) control.

Methods: Ninety-six patients with primary open-angle glaucoma who underwent fornix-based trabeculectomy with AMT (AMT group; 85 eyes, 69 patients) or without AMT (control group; 31 eyes, 27 patients) were included. Intrableb structural parameters including bleb height, bleb wall thickness, striping layer thickness, bleb wall reflectivity, fluid-filled space area/height/score, and microcyst formation were evaluated on horizontal and vertical AS-OCT scans at least one year after trabeculectomy. Surgical success was defined as an IOP ≤ 18 mmHg and IOP reduction ≥ 20% without medication. Logistic regression analyses were performed to determine intrableb parameters associated with IOP control.

Results: Patients with successful IOP control had greater bleb height, bleb wall and striping layer thickness, lower bleb wall reflectivity, and more frequent microcyst formation (all ps ≤ 0.023) in both groups. In the AMT group, the patients with successful IOP control had greater fluid-filled space area and score (all ps ≤ 0.043). Multivariate logistic regression analysis showed that lower bleb wall reflectivity alone was associated with successful IOP control in the control group [odds ratio (OR) = 0.812, p = 0.017]. Greater fluid-filled space score (OR = 8.016, p = 0.027), lower bleb wall reflectivity (OR = 0.913, p = 0.003), and microcyst formation (OR = 16.202, p = 0.041) were associated with successful IOP control in the AMT group.

Conclusions: Hyporeflective bleb wall was associated with successful IOP control after trabeculectomy regardless of AMT. However, the extent of the fluid-filled space was associated with successful IOP control only after trabeculectomy with AMT.

ABSTRACT BODY:

Purpose: To evaluate a deep learning model (DLM) for detecting glaucoma based upon OCT probability maps by applying it to eyes from a university-based clinical practice. We asked if the DLM diagnosis accurately reflects the diagnosis made by OCT experts using a full OCT report, and if it had the potential to aid in the clinical diagnosis.

Methods: The model: A DLM [1] was previously trained and validated on OCT retinal nerve fiber layer probability maps (RNFL p-maps) (Fig. 1A) from good quality scans of patients without obvious co-morbidities or extreme refractive errors. The real-world data: OCT scans were obtained from 99 eyes from 59 patients visiting a university-based, glaucoma practice. 4 eyes with unreadable scans were excluded. Unlike the eyes used to train the DLM, the 95 eyes were older (55 eyes, aged 70 to 98 years), with a range of disease severity, and various co-morbidities (e.g., ERM, AMD, high myopia). The analysis: The DLM output ranges from 0% (H: healthy) to 100% (G: optic neuropathy consistent with glaucoma). Eyes were categorized as H (≤5%), G (≥95%), or UNC (uncertain), and compared to the grading of a Hood report (Fig. 1B) by 4 OCT experts (OCT-E), who rated each eye H, G, or UNC. G and UNC judgments were combined, as both require follow-up. To assess the potential value of the DLM, a glaucoma expert made a clinical decision (CD) of H, G, or UNC (suspect) twice for each eye, first (CD1) based upon past chart notes, visual fields, and OCT scans, except for the recent Hood report, and again (CD2) to see if the OCT Hood report with the DLM output and heatmap (Fig. 1B, 1C) would alter CD1.

Results: The DLM decision agreed with the OCT-E decision in 95% of the eyes; all 5 disagreements involved an UNC judgment. Of the 9 eyes with a CD1 of UNC (suspect), CD2 changed to G in 3 and H in 3, in agreement with the DLM. Of the 7 eyes with a CD1 of H, but a DLM grade of G, CD2 changed to “probably G” in 4 (e.g., Fig. 1B) and UNC in 2. Of the 6 eyes with a CD1 of G, but a DLM grade of H, CD2 changed to H in 1, and in 4 eyes, the CD2 noted that other factors such as ERMs or retinal disease probably contributed.

Conclusions: The DLM output based upon the RNFL p-map showed excellent agreement with the OCT-E decisions based upon the complete OCT report (Fig. 1B). A post-hoc analysis suggested that the DLM has the potential to aid in clinical diagnosis. [1] Thakoor et al., IEEE TBME, 2021.

ABSTRACT BODY:

Purpose:

To report the final study results from the IRISS study with a focus on outcomes in patients with diabetic macular edema (DME).

Methods:

The IRISS study is a European 5-year post-authorisation registry study conducted in a total of a total of 556 patients (N=695 eyes) and studied for up to five-and-a-half years after being treated with the fluocinolone acetonide (ILUVIEN) implant.

Safety assessments included the occurrence of intra-ocular pressure (IOP) events and their management, and effectiveness included changes in best-recorded visual acuity (VA) with a focus on outcomes based on median duration of DME.

Results:

From the 695 eyes that were included, the majority (96.7%) had diabetic macular edema (DME) and had a mean follow-up of 37.8 months (up to a maximum of 65.0 months).

The focus here is therefore on the IOP outcomes and changes in VA reported in the DME population.

In patients with DME, 35.1% of eyes required IOP-lowering medication with a mean of 13.3±11.6 months (mean±SD) to the first IOP-lowering medication.

5.5% of eyes required IOP-lowering procedures (4.3% surgery and 1.2% non-penetrating) were required to control pressure with a mean of 25.9±10.6 months to the first procedure (surgery or non-penetrating).

A rise in pressure of ≥10 mm Hg and of >30 mm Hg was observed in 15.3% and 14.7% eyes, respectively.

Mean VA increased from a baseline of 52.3 letters to 57.5 letters at Month 36, with consistent improvements observed between months 12 and 36.

Subgroup analysis, based on median DME duration, showed improved VA changes in patients where the median duration was less than the median.

Conclusions: This study confirms the favourable long-term benefit-to-risk profile of the fluocinolone acetonide implant with additional benefits observed in patients with DME that were treated earlier.

ABSTRACT BODY:

Purpose: To investigate the cellular receptors and molecular mechanisms of herpes simplex virus type 1 (HSV-1) entry into corneal nerves.

Methods: Immunofluorescence was performed to determine the distribution and expression of HSV-1 entry receptors in corneal nerves of healthy mice, including nectin-1, herpes virus entry medium (HVEM), non-muscle myosin heavy chain IIA (NMHC-IIA), NMHC-IIB, and myelin-associated glycoprotein (MAG). Quantitative real-time Polymerase Chain Reaction (qPCR) were used to further analyze the expression of HSV-1 receptors in trigeminal ganglion (TG) from healthy and Herpes Simplex Keratitis (HSK) mice. Enzymatic digestion and density gradient centrifugation was used to isolate TG to single TG neurons. Antibody antagonism and siRNA techniques were employed to investigate the functional receptors mediating HSV-1 entry into cultured TG neurons from mice in vitro. Subconjunctival injection of specific antibodies was then performed to further explore the roles of functional receptors in vivo.

Results: We observed that Nectin-1, HVEM, NMHC-IIA and NMHC-IIB were expressed in healthy corneal nerves, but MAG not. MAG was only expressed on the myelin sheaths in TG, and was nearly unexpressed in cultured TG neurons. On day 3 post-infection, the expression of nectin-1, HVEM and NMHC-IIB in TG was significantly increased, while NMHC-IIA was decreased. HSV-1 entry was significantly inhibited in Nectin-1 or NMHC-IIB knockdown TG neurons in vitro, but had little inhibitory effect in HVEM or NMHC-IIA knockdown TG neurons. Also, in vivo antibody antagonism of nectin-1 or NMHC-IIB inhibited HSV-1 entry into corneal nerves and reduced virus replication in TG.

Conclusions: Nectin-1, HVEM, NMHC-IIA, and NMHC-IIB were expressed in corneal nerves of healthy mice. However, nectin-1 and NMHC-IIB may play the predominant role in mediating HSV-1 entry.

ABSTRACT BODY:

Purpose: Antimicrobial resistant and atypical infectious keratitis has been effectively treated with experimental Rose Bengal Photodynamic Antimicrobial Therapy (RB-PDAT). RB-PDAT creates antimicrobial singlet oxygen ($^1O_2$) by exciting Rose Bengal (RB) photosensitizer with green light. A proof-of-concept chemistry kinetics model was previously developed (Peterson et al., 2021) to predict $^1O_2$ distribution within the cornea during RB-PDAT for a given set of input parameters (light dose, RB concentration, and application time). Although developed using experimental data, the model had not yet been validated using direct $^1O_2$ dose measurement. Validation and fitting of this model will enable optimization of $^1O_2$ dose by optimizing RB-PDAT treatment parameters.

Methods: 4 groups of 3 donor eyes were treated with different RB concentrations (0.054, 0.12, 0.58, 1.2 mM). Donor eyes were treated with 20% dextran for 24 hours to de-swell the cornea and then treated with RB for 30 min. A $^1O_2$ dosage measurement system previously developed for RB-PDAT (Peterson et al., 2021) was used to measure $^1O_2$ generated during green light stimulation (at 10^7 mW/cm^2) before and after RB treatment. Measured $^1O_2$ signal was normalized and compared with normalized $^1O_2$ level predicted by chemical kinetics model for the corresponding RB concentrations at 6 and 12 mW/cm^2 at 525 nm (irradiances typical for RB-PDAT used to compare because solver is unstable beyond 30 mW/cm^2). All values normalized to respective $^1O_2$ value at 1.2 mM. The model was solved numerically in MATLAB.

Results: Predicted normalized $^1O_2$ values were within a standard deviation of measured $^1O_2$ signal at every RB concentration except at RB concentration of 0, where a non-zero $^1O_2$ signal was observed. Comparing normalized predicted $^1O_2$ signal values with mean normalized measured $^1O_2$ dosimeter signal showed relative error ranging from 9.5% to 80.9% and 10.6% to 62.6% at 6 and 12 mW/cm^2 respectively. Highest error is seen at 0.054 mM for all conditions when excluding 0 mM RB (100% error as model assumes no $^1O_2$ production).

Conclusions: We show a proof-of-concept predictive model for $^1O_2$ dose generated during RB-PDAT, capable of testing a range of experimental parameters which can be used for optimizing RB-PDAT clinical efficacy. While limited due to variability of experimental data, early results demonstrate reasonable correlation between measured and predicted $^1O_2$ levels.

ABSTRACT BODY:

Purpose: The psychosocial impact of childhood glaucoma has not been well described due to the complexity, variability and rarity of the disease. We performed an exploratory qualitative study to report and compare the quality of life issues encountered by children and adults with childhood glaucoma.

Methods: A qualitative research methodology (interpretive phenomenology) was applied and data were collected through semi-structured interviews. Children (aged 8 to 17 years) and adults (aged ≥18 years) were recruited from the Australian and New Zealand Registry of Advanced Glaucoma. NVivo-12 software was used to inductively analyze and code data to identify quality of life themes.

Results: Eighteen children (mean age 12.4 ± 3.1 years; 33% female) and 47 adults (mean age 40.0 ± 15.3 years; 55% female) were interviewed. Eleven quality of life themes were identified. Coping strategies was the most prominent theme in either cohort. Shared adaptive coping strategies included peer support, resilience and having a positive relationship with the ophthalmologist. Maladaptive coping behaviors, including treatment nonadherence and clinical nonattendance, appeared to begin in children aged 13 to 17 years and were most prominent in adults aged <40 years. Adults experienced a more significant threat to emotional well-being than children which included feeling misunderstood due to disease rarity, being self-conscious of the physical manifestations of glaucoma and feeling anxious of possible disease progression. Meanwhile, children were more concerned with inconveniences related to clinic waiting times and pupillary dilatation. The effect of childhood glaucoma on family planning was a novel QoL theme in adults and included worry for their child to inherit the condition. This led to genetic counseling-seeking behaviors. Mobility issues were infrequently experienced by either cohort.

Conclusions: The psychosocial impact of childhood glaucoma extends beyond the clinical environment and is minimized by the use of coping strategies. Our data suggest that older children may require additional social and ophthalmic support as they transition into adulthood whilst genetic counseling and family planning options should be timely discussed. This study supports the development of a childhood glaucoma-specific patient reported outcome measure for assessment of the psychosocial impact of childhood glaucoma.

TITLE: USING THE TEAR FILM IMAGER FOR COVID19 DETECTION – A PILOT STUDY

SESSION TITLE: Ocular surface health and conjunctiva

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: O. GABBAY, G. Kleinmann, Ophthalmology, Edith Wolfson Medical Center, Holon, ISRAEL|O. GABBAY, G. Kleinmann, Tel Aviv University Sackler Faculty of Medicine, Tel Aviv, ISRAEL|

Commercial Relationships Disclosure: OREN GABBAY: Commercial Relationship: Code N (No Commercial Relationship) | Guy Kleinmann: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: A key challenge in limiting the spread of Covid-19 is the absence of a fast non-invasive tool to detect infected individuals in the general population. Using polymerase chain reaction (PCR) testing, it has been demonstrated that SARS-CoV-2 is present in the tear film of patients with ocular symptoms. The presence of virions in or next to the lipid layer of the tear film would theoretically cause a measurable interruption of the normal tear bi-layer structure.

The goal of this pilot study is to test the hypothesis that a specialized version of Tear Film Imager (vTFI) could be used for detection of infected individuals, in a quick, non-invasive manner.

It is important to note that vTFI findings are not specific to SARS-Cov-2, and similar enveloped virions might cause a comparable disturbance.

Methods: In our pilot study, twenty eyes of ten patients that were hospitalized due to Covid-19 infection in a designated quarantine department were compared to twenty eyes of ten healthy control patients. The study was approved by the Wolfson medical center's Institutional Review Board. All participants had a nasopharyngeal PCR swab confirming infection status up to 72 hours prior to examination by vTFI. Any patients with chronic viral infection (i.e. HIV, HBV etc'), corneal abnormalities, or corneal/refractive surgery were excluded to ensure uniformity of the data and focus on virion detection

Results: Using vTFI 16 out of 20 healthy eyes correctly tested negative. 15 out of 20 Covid-positive eyes were correctly identified positive using TFI. In total 70% of the control group were correctly categorized by TFI algorithm as healthy (positive if one eye positive) and 80% of the Covid-infected individuals were positively identified.

Conclusions: Identification of Covid-19 status from the tear film layer using ultra-fast non-invasive vTFI shows promise and a larger sample blinded study should be performed to assess its implementation in an outpatient setting. Being a non-specific test, the use of vTFI is not dependent on special primers and may offer a modality for diagnosing individuals suspected of being infected with other emerging pathogens.

ABSTRACT BODY:

Purpose: Pentosan maculopathy may progress despite discontinuation of the drug exposure. The identification of earlier imaging markers of toxicity may be critical to prevent vision loss. Hence, we compared the choriocapillaris flow deficit (CC FD) from optical coherence angiography (OCT) angiography in eyes of patients treated with high cumulative dosages of pentosan polysulfate sodium (PPS) with no signs of retinal toxicity versus healthy age-matched controls

Methods: Patients treated with PPS for interstitial cystitis with a cumulative dosage of more than 1000 grams underwent multimodal imaging screening to exclude evidence of PPS maculopathy or other retinal abnormalities. All study patients and age-matched healthy controls completed OCT angiography (OCTA) using the Solix device (Solix; Optovue Inc, Fremont, California, USA), with a 3x3 mm volume cube scan centered on the fovea. En face OCTA images at the level of the CC were exported, and CC FDs were computed and compared between groups.

Results: Fifteen patients treated with PPS and fifteen age-matched controls were included. The mean PPS cumulative dose was 1974±666.4 grams over a mean of 17.6 ±6.8 treatment years. All patients had visual acuity of 20/25 or better and normal fundus autofluorescence (FAF), OCT, multicolor, near-infrared reflectance (NIR), and ultra-widefield fundus color and AF images. The CC FD was 32.7±3.6% in the PPS group compared to 28.6±4.3% in the control group (p=0.023).

Conclusions: PPS treated patients show significant CC flow impairment before the development of overt signs of macular toxicity compared to healthy age-matched controls. Thus, the choroid may be the earliest manifestation of ocular toxicity, predating the development of clinically evident RPE injury. The subsequent RPE disruption may be the result of choriocapillaris impairment or primary PPS toxicity. Regardless, assessment of the CC on OCTA may be a useful tool for early detection of toxicity, though further longitudinal studies are required.

TITLE: Trial study on applying focal macular electroretinogram function on the microperimetry system

SESSION TITLE: Electroretinography: basic mechanisms and disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Suzuki, Mechanical Engineering, National Institute of Technology, Numazu College, Numazu, Shizuoka, JAPAN|

Commercial Relationships Disclosure: Naoto Suzuki: Commercial Relationship(s);Code F (Financial Support):Japan Society for the Promotion of Science

ABSTRACT BODY:

Purpose: This study aims to investigate cryptogenic diseases including macular dystrophy. The decline in visual sensitivity of the retina has been measured using microperimetry, the retinal layer causing this decline has been identified using multifocal electroretinogram (ERG). Instead of the multifocal ERG, a focal macular ERG function has been applied on the microperimetry.

Methods: This apparatus is made of illumination and photographic optical systems separated by a mirror with a hole. Additionally, it is made of a microperimetry optical system and an ERG optical system separated by a cold mirror. The apparatus consists of an Edmund infrared camera EO-50231, a lens with a 25-mm focal length, a halogen lamp, an objective lens with a 50-mm focal length, four double convex lenses with a 100-mm focal length, two aperture stops, a mirror, a 45° cold mirror, a 12.1-inch high brightness monitor with 2,000 cd/m2, and an artificial eye. A differential amplifier with gain 10, high-pass filter with a 21.2-Hz cut-off frequency, 50-Hz notch filter, and two non-inverting amplifiers with gains 1001 and 11 have been deployed in this study. Moreover, this study used the National Instruments' I/O device USB-6216, shielded connector block SCB-68A, the Nihon Kohden's plate electrode NE-113A, the Nihon Kohden's electromagnetic shield sheet Y049, and the LabVIEW 2018 software for data retrieval. To conduct the focal macular ERG, a DynaScan's 49-inch ultrahigh brightness liquid crystal display (LCD) with 3,500 cd/m2 has been prepared. The focal macular ERG software was developed using C++ Builder 10.2.

Results: On the ultrahigh brightness LCD, the ERG software could show three sizes of stimulus spot circles: 5°, 10°, and 15° in diameters. Moreover, a function, which could adjust size of the stimulus spot circle, has been added as the diameter was changed from 1° to 15°.The stimulus spot circle could be shown as the circle's center was similar to an examination target's center of the microperimetry. The software showed a flicker stimulation as the frequency was changed from 10 Hz to 100 Hz.

Conclusions: The focal macular ERG function is expected to identify the retinal layer causing visual alterations at specific points throughout the retina. Further work towards preclinical animal testing and clinical evaluation are required.

ABSTRACT BODY:

Purpose: To investigate the clinical significance of intercapillary space spectrum on swept source optical coherence tomography angiography (SS-OCTA) images in diabetic retinopathy (DR).

Methods: We retrospectively reviewed consecutive 96 eyes of 82 patients suffering from DR without macular edema. Automatic image processing of en-face OCTA images provided the quantitative parameters and location of intercapillary spaces within central 2 mm circle The parafoveal areas were divided into 40 sectors according to the distance and octant. We evaluated how the intercapillary spaces are associated with logarithm of the minimum angle of resolution (logMAR) and feasible to diagnose diabetic macular ischemia.

Results: Among several quantitative parameters, total counts of the intercapillary spaces showed most significant correlation to logMAR ($\rho = -0.408$, $P<0.001$). The size thresholding did not improve the statistical association, whereas numbers of the spaces in 2 highly significant sectors showed better associations with logMAR ($\rho = -0.488$, $P<0.001$). Multivariate regression analyses revealed that both the FAZ area ($\beta=0.226$, $P=0.043$), and the number of the intercapillary spaces ($\beta=-0.270$, $P=0.014$) were related to logMAR. The clustering using the FAZ area and the intercapillary spaces revealed two major clusters, one of which might be proposed as diabetic macular ischemia. Subsequent receiver operating characteristic analyses demonstrated that the intercapillary spaces (area under the curve [AUC] = 0.999) rather than the FAZ area (AUC =0.785) discriminated these two clusters.

Conclusions: Both enlarged FAZ and decreased interapillary spaces contribute to visual impairment and propose an objective and quantitative diagnosis of diabetic macular ischemia in DR without macular edema.

ABSTRACT BODY:

Purpose: High-Resolution SPECTRALIS OCT is based on a shorter central wavelength and a larger spectral bandwidth providing an axial resolution of up to 3 µm compared to 7 µm in conventional OCT imaging with an identical lateral resolution. The purpose of this study was to investigate efficacy in retinal morphology accessibility on the photoreceptor (PR) level in intermediate age-related macular degeneration (iAMD).

Methods: Patients with iAMD were imaged using a 6x6mm scan pattern (97 B-scans) for standard SPECTRALIS HRA+OCT and the investigational device SPECTRALIS High-Res OCT, both by Heidelberg Engineering, Germany. PR thickness was measured using a previously trained deep learning algorithm for segmenting PR layer (inner border of the ellipsoid zone to retinal pigment epithelium) and manually corrected if necessary. Overall PR thickness and drusen maps were computed for all patients. PR loss area and thickness were compared between devices and areas using mixed effect models.

Results: Twenty-nine eyes from 23 patients were included. Mean PR loss in the central 1 mm area was higher on the standard OCT with 0.07 mm^2 compared to 0.04 mm^2 on the High-Res OCT (p=0.049). Parafoveal (1-3 mm) PR loss was 0.32 mm^2 and 0.16 mm^2 on the standard OCT and the High-Res OCT, respectively (p=0.032). Perifoveal (3-6 mm) PR loss was 0.08 mm^2 on the standard OCT and 0.05 mm^2 on the High-Res OCT (p=0.029). Mean overall PR thickness was 26.46 µm on the standard OCT compared to 32.23 µm on the High-Res OCT. Mean PR thickness in drusen areas was 26.30 µm and 32.39 µm in non-drusen areas. The PR layer was generally thinner on the standard OCT ($p<0.001$) and in drusen areas ($p<0.001$).

Conclusions: High-Res OCT with superior axial resolution is able to identify the condition of the PR level in iAMD with higher precision. High resolution improves the distinction of retinal layers on OCT imaging promoting the understanding of retinal disease particularly in its early stage. Higher axial resolution might therefore be better suited to investigate disease pathomechanisms, progression to advanced macular atrophy and valid therapeutic targets.

ABSTRACT BODY:

Purpose: Congenital stationary night blindness (CSNB) is a group of genetically and clinically heterogeneous retinal disorders, usually manifesting with infantile nystagmus, reduced visual acuity, variable degree of myopia and poor visual behavior in dim light. The diagnosis is done on the basis of full-field electroretinogram (ffERG) features. Most of the patients are characterized by an electronegative Schubert-Bornschein-type of ffERG, showing either a signal transmission defect from photoreceptor to all bipolar cells (incomplete (ic)CSNB) or selectively affecting rod and cone ON-bipolar cells (complete (c)CSNB). The goal of this study was to identify the gene defect in a family with non-syndromic CSNB with peculiar characteristics.

Methods: Three patients from two unrelated families have been clinically and genetically explored by state-of-the-art methods.

Results: Patients had infantile nystagmus, low stable visual acuity, myopia and night blindness. Two older patients had bilateral lens luxation and underwent lens extraction. All patients presented atrophic peripheral chorioretinal changes. The ffERG revealed an electronegative Schubert-Bornschein appearance, but combining characteristics of incomplete and complete CSNB, affecting rod and cone ON- and OFF-bipolar cells. Whole exome and Sanger sequencing identified in each index case a novel homozygous variant (respectively c.595C>T p.(Arg199Cys) and c.698C>T p.(Pro233Leu)) in VSX2 co-segregating with the phenotype in available family members.

Conclusions: Variants in VSX2 can lead to different phenotypes, either defects of early ocular development (anophthalmia, microphthalmia and coloboma) or peculiar CSNB with lens luxation and chorioretinal changes, described herein. VSX2 is a major regulator of early ocular development and is highly expressed in bipolar cells in adult retina. Further studies are needed to understand the pathogenic mechanisms associated with variants in VSX2 leading to two distinct phenotypes.

ABSTRACT BODY:

Purpose: To study the five common ocular antibiotics susceptibility of multidrug-resistant Staphylococcus isolated from conjunctival sac, cornea, eyelid margin and lacrimal sac in the ocular anterior segment.

Methods: 67 isolates were collected from patients from January 2018 to May 2019 at Henan Eye Hospital and identified by DL-STAPH Staphylococcus. Levofloxacin, tobramycin, clindamycin fusidic acid and cefazolin sodium were purchased from Dalian Meilun Biotechnology Co., Ltd.and Shenzhen China Resources Jiuxin Pharmaceutical Co., Ltd.. Ocular antibiotics susceptibility of multidrug-resistant Staphylococcus was determined by the Minimum Inhibitory Concentration methods according to the guidelines of Clinical and Laboratory Standards Institute.

Results: 35 methicillin-resistant Staphylococcus (MRS), 30 beta-lactamase-producing Staphylococcus (β-Lac) and 2 β-Lac MRS isolates were identified from 67 multidrug-resistant Staphylococcus. MRS isolates accounted for 80.00%,75.00%, 44.19% and 42.86%, and β-Lac isolates accounted for 20.00%, 20.00%, 53.49% and 42.86% in lacrimal sac, cornea, conjunctival sac and eyelid margin respectively. The drug-resistant Staphylococcus epidermidis was the major isolates in eyelid margin (57.14%) and conjunctival sac (46.51%). Meanwhile, the drug-resistant Staphylococcus aureus was the major isolates in lacrimal sac (40.00%) and cornea (33.33%). The susceptibility rates of cefazolin sodium, fusidic acid, levofloxacin, clindamycin and tobramycin against 35 MRS isolates were 74.29%, 68.57%, 34.29%, 34.29% and 31.43% respectively. The susceptibility rates of cefazolin sodium against MRS isolates were 100% in cornea, eyelid margin and lacrimal sac. The susceptibility rates of cefazolin sodium, fusidic acid, levofloxacin, tobramycin and clindamycin against 30 β-Lac isolates were 90.00%, 76.67%, 56.67%, 53.33% and 26.67% respectively. The susceptibility of cefazolin sodium and fusidic acid against β-Lac isolates were higher than MRS isolates.

Conclusions: Our results indicate that cefazolin sodium and fusidic acid may be considered a reliable alternative for the treatment of multidrug-resistant staphylococcus in the ocular surface, especially of β-Lac drug-resistant staphylococcus.

TITLE: Spp1 drives retinal ganglion cell resiliency in glaucomatous neuropathy

SESSION TITLE: Neuron rescue and regeneration in the retina

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: M. Zhao, K. Toma, B. Kinde, Y. Han, X. Duan, University of California San Francisco, San Francisco, California, UNITED STATES|Y. Hu, Stanford University, California, UNITED STATES|

Commercial Relationships Disclosure: Mengya Zhao: Commercial Relationship: Code N (No Commercial Relationship) | Kenichi Toma: Commercial Relationship: Code N (No Commercial Relationship) | Benyam Kinde: Commercial Relationship: Code N (No Commercial Relationship) | Yang Hu: Commercial Relationship: Code N (No Commercial Relationship) | Ying Han: Commercial Relationship: Code N (No Commercial Relationship) | Xin Duan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal ganglion cell (RGC) loss subject to elevated intraocular pressure (IOP) represents the leading cause of irreversible vision loss in glaucoma patients. Understanding how different RGC types respond to sustained IOP elevation can provide insight into key molecular players involved in neuroprotection and shed light on potential therapeutic targets for the treatment of glaucoma.

Methods: Chronic IOP elevation was achieved using the silicone oil-induced ocular hypertension under-detected (SOHU) model. Silicone oil was injected into the anterior chamber of mice 8–10 weeks of age and a saline control into the contralateral eye. The IOP was monitored once weekly for up to 6 weeks after SO injection using the tonometer. AAV-mediated Secreted Phosphoprotein 1 (Spp1) knockdown or overexpression in RGCs occurred at 8 weeks of age. Mice were sacrificed at 1 week and 4 weeks post-SOHU surgery for RGC subtype-specific immunohistochemistry (IHC) analysis. Spp1 expression was also assessed by IHC in post-mortem human retina, as well as an enzyme-linked immunosorbent assay (ELISA) to quantify Spp1 in the aqueous humor (AH) from patients with glaucoma.

Results: αRGCs and intrinsic-photosensitive RGCs (ipRGCs) are uniquely resilient in the context of chronically elevated IOP. The preferential resiliency was, in part, driven by elevated expression of Spp1. Our past work showed that Spp1 promotes optic nerve regrowth in combination with growth factors. Elimination of Spp1 from RGCs using either a Spp1 mutant or AAV-mediated Spp1 knockdown led to a significant decrease of αRGC survival. In contrast, overexpression of Spp1 in Foxp2-positive RGCs (F-RGCs) led to enhanced neuroprotection of this RGC subclass, which is highly susceptible to increased IOP. In post-mortem human retina, we found that Spp1 is also enriched in human RGC subsets, particularly in the central regions of the retina, as potential markers for human parasol RGCs. SPP1 quantification by ELISA from AH of patients with glaucoma showed that Spp1 levels are correlated with the severity of glaucoma.

Conclusions: Our study revealed a novel role for Spp1 in promoting RGC resiliency in mouse models of glaucomatous neuropathy. Spp1 levels correlate with the severity of optic neuropathy in patients with glaucoma. Our data indicated that Spp1 may be a relevant biomarker as well as a therapeutic target for promoting neuroprotection in patients with glaucoma.

TITLE: Temporal analysis in Transcriptomic profile identifies immune markers and modulation of key pathways in Murine Model of Multi-Drug Resistant (MDR) Pseudomonas aeruginosa endophthalmitis

SESSION TITLE: Modulation of ocular surface immunity during health and disease

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J. Joseph Ruben, P. NAIK, M.N. Naik, LV Prasad Eye Institute, Hyderabad, Telangana, INDIA|

Commercial Relationships Disclosure: Joveeta Joseph Ruben: Commercial Relationship: Code N (No Commercial Relationship) | POONAM NAIK: Commercial Relationship: Code N (No Commercial Relationship) | Milind Naik: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Increasing incidences of multidrug-resistant (MDR) P. aeruginosa (PA) causing endophthalmitis threaten our ability to manage this vision threatening condition. Understanding host-pathogen interactions is central for improving clinical outcomes. In this study, temporal dynamics of immune response in mouse model of MDR-PAendophthalmitis was investigated by transcriptome analysis.

Methods: C57BL/6 mice were infected with MDR-PA and susceptible (S-PA) and disease progression and severity was monitored at 6h and 24h post infection (p.i). The extent of retinal damage was assessed by H&E staining. Microarray analysis was performed using SuperPrint G3 Mouse Gene Expression v2 chip and the differential gene expression analysis was performed with limma package in R (v4.0.0.) /Bioconductor (v3.11). A computational pipeline then selected differentially expressed genes at both the time points and clustered them into groups with distinct temporal patterns associated with molecular functions and pathways.

Results: Histological analysis revealed significant difference in retinal architecture and vitreous infiltrates. In comparison to S-PA, MDR-PA revealed altered expression of 923 genes at 6h and 2220 genes at 24h. Further, 23% and 76% of these altered genes and their downstream interacting proteins showed time specific expression (6h and 24h respectively), indicating its association with disease progression. Adhesion proteins like Desmocollin-2,-3, Protocadherin 10, Integrin beta-3, and Cadherin-22 were upregulated during 6h, while growth factors like fgf11, fgf9, and regulator of G protein signalling were downregulated. At 24h. Lipocalin along with TNF receptor-associated factor 1 and GFAP was found to be upregulated at 24h. Histopathological changes and DEG's suggest that the magnitude of upregulation was stronger at 24h. Major clustering of genes at 24h involved in disease progression involved: inflammasome signalling, dysregulated ubiquitination, complement cascade, extracellular matrix remodelling.

Conclusions: The transcriptional differences between the two time points reveal that distinct genes contributes to disease severity and provided novel insights by extending the number of molecular determinants and functional pathways that underpin host associated damage.

ABSTRACT BODY:

Purpose: Cytochrome p450 1B1 (CYP1B1) is a CYP enzyme, found primarily in extrahepatic tissues including the eye, with important roles in tissue development and homeostasis. CYP1B1 metabolizes both exogenous and endogenous molecules including 17β-estradiol and arachidonic acid. We previously showed that CYP1B1 deficiency results in increased oxidative stress mitigating angiogenesis in vivo and in retinal endothelial cells (REC) in vitro. The aim of the current study was to determine the molecular mechanisms by which CYP1B1 modulates ocular redox homeostasis. We propose this is accomplished through the regulation of ocular iron homeostasis.

Methods: REC are major regulator of ocular iron homeostasis and express all the iron regulator proteins. REC isolated from wild-type C57BL/6J and Cyp1b1-deficient ($Cyp1b1^{-/-}$, same background) mice were used for in vitro studies. Expression levels of genes involved in iron homeostasis were assessed by RT-qPCR and Western blot analysis. Intracellular iron levels were determined using fluorescent probes. Lipid peroxide production was examined by immunofluorescence staining. Ferroptosis sensitivity was assessed by incubation of cells with different concentrations of erastin, a ferroptosis inducer, using an MTS assay. For in vivo studies, $Cyp1b1^{-/-}$ mice were intraperitoneally injected with estrogen receptor alpha antagonist methyl-piperidino-pyrazole (MPP) or iron chelator deferoxamine (DFO) during oxygen-induced ischemic retinopathy (OIR).

Results: $Cyp1b1^{-/-}$ REC showed increased levels of bone morphogenetic protein 6 (BMP6), which drove hepcidin expression and decreased ferroportin levels resulting in increased intracellular iron accumulation. The intracellular iron levels in REC were confirmed by Calcein and FerroOrange staining. The increased iron levels in$Cyp1b1^{-/-}$ REC were concomitant with increased levels of lipid peroxidation and enhanced sensitivity to ferroptosis. These changes in $Cyp1b1^{-/-}$ REC and $Cyp1b1^{-/-}$ mice were reversed by incubation with iron chelator DFO or MPP.

Conclusions: Our findings establish that CYP1B1 expression maintains ocular redox homeostasis through estrogen receptor signaling impacting iron homeostasis by modulation of BMP6 levels in the endothelium. Lack of Cyp1b1 results in increased intracellular iron levels, enhanced lipid peroxidation, and oxidative stress.

TITLE: Longterm porcine retinal explants as an alternative to in vivo experimentation

SESSION TITLE: Gene Therapy and Gene Editing for Ocular Disorders

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Weller, B. Müller, K. Stieger, Experimental Ophthalmology, Justus Liebig Universitat Giessen, Giessen, Hessen, GERMANY|

Commercial Relationships Disclosure: Maria Weller: Commercial Relationship: Code N (No Commercial Relationship) | Brigitte Müller: Commercial Relationship: Code N (No Commercial Relationship) | Knut Stieger: Commercial Relationship(s);Code C (Consultant/Contractor):SpliceBio, CoaveTx;Code F (Financial Support):CoaveTx

ABSTRACT BODY:

Purpose: The porcine retina represents an optimal model system for inherited retinal dystrophies due to the anatomical similarities to the human retina, including a cone enriched visual streak. As large animal models require significant infrastructural and financial resources, the organotypic retina culture might pose a good model system to study gene therapeutic approaches prior to in vivo application. However, to this date it appeared to be difficult to reproduce good quality explants that can be kept in culture long enough to enable viral vector mediated genome editing experimentation. Our protocol allows to keep explants in culture for up to 20 days with good morphological preservation.

Methods: Two to four retinal explants per eye were obtained from the visual streak and transferred onto a polycarbonate membrane insert with the photoreceptors facing down. They were cultured for up to 28 days with Neurobasal-A medium containing 100 or 450 mg/dl glucose at 37°C and 5% CO_2. We supplemented the medium with combinations of fetal calf serum, B-27 with or without Insulin and N-2. Explants were analyzed using confocal laser scanning microscopy after immunofluorescent (IF) labeling with antibodies against glial fibrillary acidic protein, glutamine synthetase, protein kinase C alpha, rhodopsin, and short-wave-sensitive opsin 1, all counterstained with 4',6-Diamidino-2-phenylindol (DAPI).

Results: We were able to keep explants in culture up to 20 days with only little degradation as seen after IF at different harvesting time points. Best results were attained using Neurobasal-A medium containing 100 mg/dl glucose, 2x B-27 containing Insulin, 1x N-2, 1x L-Glutamine and 1x antibiotic-antimycotic, and a medium change every 48 hours. Eyes treated with heat for decontamination purposes by the butcher showed significantly less good preservation compared to those obtained without heat treatment. Keeping the eyes in ice cold medium until right before preparation and minimizing transport time gave the best results.

Conclusions: Using a standardized protocol, porcine retinal explants represent an easy to handle intermediate model between in vitro and in vivo experimentation. Using pig eyes from a local butcher renders this model system easily reproducible and contributes to the implementation of the 3R principle by Russell and Burch. This model system is currently tested with standard gene therapy vectors for efficient gene transfer.

TITLE: Performance of AI-based Notal OCT Analyzer (NOA) in retinal fluid volume quantification from repeated self-imaging with Home OCT in eyes with neovascular age-related macular degeneration (nAMD)

SESSION TITLE: Machine Learning and Image Processing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.J. Elman, S. Schechet, Elman Retina Group, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Michael Elman: Commercial Relationship(s);Code F (Financial Support):National Eye Institute;Code F (Financial Support):Apellis Pharmaceuticals;Code F (Financial Support):Alimera Sciences, Inc;Code F (Financial Support):Clover Therapeutics ;Code F (Financial Support):Neurotech Pharmaceuticals;Code F (Financial Support):NGM Biopharmaceuticals, Inc;Code F (Financial Support):Novartis Pharmaceuticals, Inc;Code I (Personal Financial Interest):Notal Vision | Sidney Schechet: Commercial Relationship(s);Code C (Consultant/Contractor):Alimera Sciences

ABSTRACT BODY:

Purpose: To evaluate the performance of NOA in 2 different aspects, precision of fluid volume quantification on consecutive in-clinic self-imaging as well as agreement with reference office OCT scans acquired in the same visit

Methods: The NOA is a deep learning algorithm that analyzes scans of the Notal Vision Home OCT (NVHO). The data is comprised of 242 NVHO volume scans acquired from 47 patients and 88 eyes with nAMD. Repeatability of fluid volume was calculated for all eyes with at least two repeats via coefficient of variance (CV). Retinal fluid agreement with manually annotated Cirrus scans was evaluated on a subset of the data and was estimated globally and spatially. Global agreement estimation was calculated with Pearson correlation coefficient (PCC) and Lin's concordance correlation coefficient (CCC). Spatial agreement was calculated with 2D correlation of the fluid thickness maps and on gridded versions of the original maps. All analysis was performed on eyes with clinically meaningful retinal fluid volume greater than 3 nanoliter

Results: NOA repeatability performance was evaluated on a set of scans from 26 eyes resulting in a CV of 4.1%. NOA agreement with Cirrus was evaluated on a subset of 23 eyes with an expert annotation of retinal fluid in the Cirrus scans. The PCC and CCC of retinal fluid volume between Cirrus and the NVHO with NOA were 0.984 and 0.975 respectively. For spatial agreement, the median (IQR) 2D correlation was 0.869 (0.769-0.940) and the median (IQR) 2D correlation of the maps with grids with densities of 20x20,10x10 was 0.841 (0.720-0.941) and 0.915 (0.757-0.963), respectively

Conclusions: The results validate the performance of the home OCT system comprised of a device and an AI-based algorithm. The low CV allows for accurate retinal fluid quantification with small variation in clinically meaningful amounts of retinal fluid. The high PCC and CCC of fluid volume and spatial correlation confirm that the same pathologies were accurately identified by NOA and the reference office OCT. Overall, the results present further evidence for the ability of the Notal Vision Home OCT to remotely monitor nAMD disease activity

ABSTRACT BODY:

Purpose: In patients with geographic atrophy, planar subretinal photovoltaic implants with 100μm bipolar pixels provided prosthetic acuity up to 20/460, closely matching the pixel size. In rats, similar implants with 75 and 55μm bipolar pixels also demonstrated grating acuity matching the pixel pitch. However, stimulation threshold increases with decreasing size of bipolar pixel in planar implants, and it exceeds the electrode charge injection limit with pixels smaller than 40μm. To overcome this limitation, we developed 3-dimensional honeycomb-shaped electrodes. Retinal cells migrating of the into the honeycomb wells should experience a nearly uniform vertical electric field, resulting in a significantly lower stimulation threshold, independent of the pixel width. Here, we investigate the structural integration of the inner retinal cells with the wells matching the single cell size.

Methods: The 1 mm wide, 30 μm thick implants with 10 μm deep wells were fabricated in silicon, with wells diameter of 6, 8, 10 and 12 μm. Devices were implanted beneath the degenerate rat retina (RCS, p180-300) for 6 weeks, and then examined with confocal imaging of retinal whole mounts. The integration was quantified by counting the DAPI-positive nuclei within the wells. The cells populating the wells and the immune response were assessed on immunolabelled whole mounts with various cellular markers.

Results: The fraction of cell-filled wells increased with the pixel width: from 22% in 6 and 8 μm wells to 70% in 12 μm wells. The 10 μm wells had the best integration, with 60% of its cavities containing single cells, while in the 12 μm implants, more than half of the wells had more than one nucleus. The immune reaction to the implants was as mild as with planar arrays: 6% of the 10 μm wells were populated by IBA1 positive cells (microglia).

Conclusions: Honeycomb-shaped subretinal prostheses with 10 μm wide wells enable individual inner retinal neurons to migrate into the cavities that can contain active electrodes of individual pixels, which should allow single-cell stimulation. Since pixel size of 10 μm geometrically corresponds to visual acuity of about 20/40, this approach may enable highly functional restoration of central vision in patients with advanced age-related macular degeneration.

TITLE: Differential expression of aqueous humor microRNAs in central retinal vein occlusion and its association with matrix metalloproteinases

SESSION TITLE: Retinal vascular diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Shin, E. Hong, H. Yu, H. Cho, Hanyang University, Seongdong-gu, Seoul, KOREA (THE REPUBLIC OF)|

Commercial Relationships Disclosure: YongUn Shin: Commercial Relationship: Code N (No Commercial Relationship) | Eun Hee Hong: Commercial Relationship: Code N (No Commercial Relationship) | Hyo Seon Yu: Commercial Relationship: Code N (No Commercial Relationship) | Heeyoon Cho: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate the differential expression of microRNAs (miRNAs) in aqueous humor of patients with central retinal vein occlusion (CRVO) and its association with aqueous humor matrix metalloproteinase (MMPs) activity.

Methods: A total of 18 subjects, including 10 naïve CRVO patients (CRVO group) and 8 control subjects (control group) who were scheduled for intravitreal injection and cataract surgery, respectively, were included. The aqueous humor samples collected at the beginning of each procedure were analyzed. First, a microarray composed of 84 microRNAs was performed to find differentially expressed miRNAs in the CRVO aqueous humor, which were further analyzed using a bioinformatics tool to identify directly related cytokine/proteins in CRVO. Finally, MMP-2 and -9 were selected and the aqueous humor MMP-2 and -9 activities were detected using gelatin zymography.

Results: Eight miRNAs (hsa-mir-16-5p, hsa-mir-142-3p, hsa-mir-19a-3p, hsa-mir-144-3p, hsa-mir-195-5p, hsa-mir-17-5p, hsa-mir-93-5p, and hsa-mir-20a-5p) were significantly downregulated in CRVO group compared to control group. Bioinformatics showed a direct relationship between down-regulated miRNAs, CRVO disease, and the following proteins: MMP-2, MMP-9, tumor necrosis factor (TNF), transforming growth factor-beta 1 (TGFB1), caspase 3 (CASP3), interleukin-6 (IL6), interferon-gamma (IFNG), and interleukin-1-beta (IL1B). Gelatin zymography analysis showed significantly increased MMP-2 and -9 activities in aqueous humor of the CRVO group compared to that of the control group ($p < 0.01$).

Conclusions: This study was the first to investigate the differentially expressed miRNAs and the activity of associated MMPs in aqueous humor of CRVO patients. MMP-2 and -9 were directly related to down-regulated miRNAs, and their activities have significantly increased in the aqueous humor of CRVO patients. Therefore, the relevant miRNAs and MMPs in aqueous humor could serve as potential biomarkers or therapeutic targets in CRVO.

ABSTRACT BODY:

Purpose: Central serous chorioretinopathy (CSCR) is a rare ocular side-effect of glucocorticoids (GCs). But contrarily to the other GCs-induced side effects, the route of GCs administration influences the risk of CSCR. The nasal, articular, oral and dermal routes favor CSCR but not the high and sustained intraocular GCs. To evaluate potential involvement of the hypothalamic-pituitary-adrenal axis (HPA) brake, we studied the corticosterone ocular levels and the corticoid receptors balance after chronic systemic dexamethasone treatment in rats.

Methods: Lewis rats were untreated (N=7) or received systemic injection of either dexamethasone (N=16) or saline (N=5) daily for 5 days. Baseline levels of corticosterone were measured by Elisa at baseline and at 5 days in the serum and the ocular media and dexamethasone levels were measured at 5 days in the serum and ocular media. The expression level of Nr3c1, Nr3c2, 11-bhsd1 and 2 were measured in the neural retina, retinal pigment epithelium (RPE)/choroid and iris/ciliary body. The expression of mineralocorticoid-induced genes was evaluated in the neural retina: Enac-a, Kir4.1 and Aqp4 and in the RPE/choroid: Shroom 2, Ngal, Mmp9, Omg, Ptx3, Plaur and Fosl-1.

Results: After dexamethasone injection, corticosterone level significantly dropped in serum ($p<0.0001$) and in ocular media ($p<0.002$). After saline injection, serum corticosterone also dropped. In the neural retina, the expression of Nr3c1 encoding GR was down-regulated after treatment with dexamethasone ($p<0.01$) or saline ($p<0.001$), which was also seen for Nr3c2 encoding MR ($p<0.001$) but the Nr3c2/Nr3c1 expression balance did not change significantly. In the RPE/choroid of dexamethasone treated rats, a significant increase in the Nr3c2/Nr3c1 ($p<0.01$) and 11β-hsd2/11β-hsd1 ($p<0.05$) ratio was measured showing hyperactivation of MR pathway. In the retina, Enac-a, Kir4.1, Aqp4 were down-regulated after dexamethasone treatment ($p<0.05$). In RPE/choroid, the expression of Plaur ($p<0.01$) and Fosl-1 ($p<0.05$) was increased and Omg was reduced ($p<0.05$) after dexamethasone treatment, in line with MR overactivation.

Conclusions: The HPA axis brake resulting from systemic chronic dexamethasone causes a significant reduction of systemic and ocular corticosterone and an imbalance of corticoid receptors expression in the RPE/choroid towards overactivation of MR, which could favor the occurrence of CSCR.

ABSTRACT BODY:

Purpose: We previously reported a novel method for visualizing drusen using flood illumination adaptive optics (FIAO) ophthalmoscopy that exploits gaze-dependent contrast variations to detect drusen with high contrast and resolution [Rossi et al. TVST 2021;10(14):19]. Here we expand on that method by comparing gaze-dependent FIAO images to adaptive optics scanning laser ophthalmoscopy (AOSLO) and extend this approach to other maculopathies: pigment epithelial detachment, subretinal drusenoid deposits (SDDs), retinal pigment epithelium (RPE) atrophy, small hard exudates, serous retinal detachment and poppers maculopathy.

Methods: A FIAO fundus camera (rtx1, ImagineEyes, France) was used to acquire a 4°×4° fovea-centered image and then its internal fixation target was moved to obtain 4–8 additional, overlapping images, with gaze displaced by +/- 2° vertically and horizontally (n=182 eyes). Custom software registered images and calculated the standard deviation (SD) of each pixel across areas of overlap. A subset of patients were imaged following the same protocol on AOSLO (PSI, Massachusetts) for multimodal comparison and investigation into gaze dependent imaging (GDI) in scanning technology.

Results: Gaze-varying structures were not detected in controls. GDI is effective if each image is in focus and precisely aligned. With GDI in FIAO, drusen were detected in patients with high contrast and clear structural delineation. While GDI of drusen shows a bright annulus, GDI of pigment epithelial detachment showed an irregular bright annulus; SDDs and RPE atrophy were lower contrast than drusen; small hard exudates showed punctuate gaze-dependent variability, while serous retinal detachment and poppers maculopathy did not show enhanced contrast by GDI. Gaze-dependent AOSLO detected drusen (figure) with differences in contrast between split and confocal modalities.

Conclusions: Gaze-dependent imaging in FIAO and AOSLO images allowed for visualization of microstructural features such as drusen via contrast enhancement. Our method shows individual drusen delineation that furthers our capacity to detect, map, measure, and monitor progression of drusen. Multi-modal comparison is essential to build a correct and complete interpretation of gaze dependent retinal structures, therefore extension of our method to scanning technology is beneficial, despite the difficulties of removing scan related-distortions.

ABSTRACT BODY:

Purpose: Functional changes in the neural retina have been proposed to be associated with multiple sclerosis pathogenesis and progression. The aim of the present study was to assess retinal oxygen extraction and total retinal blood flow in patients with diagnosed relapsing multiple sclerosis (RMS) and history of unilateral optic neuritis (ON).

Methods: A total of 16 RMS patients and 18 healthy control subjects participated in this cross-sectional study. Retinal oxygen extraction was calculated using retinal oxygen saturation values obtained from the oxygen module of the retinal vessel analyzer (RVA, Imedos, Germany) and total retinal blood flow data measured with a custom-built Doppler optical coherence tomography (DOCT) system. Measurements were performed in both eyes of RMS patients (MS+ON eye referring to the eye with history of optic neuritis and MS-ON eye referring to the eye with no history of optic neuritis). One eye from each healthy subject was used as control.

Results: Retinal oxygen extraction was lowest in MS+ON eyes (1.8 ± 0.2 µl O_2/min), higher in MS-ON eyes (2.1 ± 0.5 µl O_2/min) and highest in healthy eyes (2.3 ± 0.6 µl O_2/min; p = 0.031 between groups). Total retinal blood flow was lower in MS+ON eyes (33.2 ± 6.0 µl/min) as compared to MS-ON eyes (38.3 ± 4.6 µl/min) and healthy eyes (37.2 ± 4.7 µl/min; p = 0.010 between groups).

Conclusions: The present study found retinal oxygen extraction to be reduced in eyes of patients with RMS. This reduction seems to be more pronounced in eyes with history of optic neuritis. The role of this reduction in retinal oxygen extraction in the disease process and whether it is a cause or consequence needs to be further investigated.

ABSTRACT BODY:

Purpose: To compare the ability of a Deep Learning Model (DLM) and clinicians to identify Visual Field (VF) worsening among a large cohort of glaucoma patients.

Methods: We conducted a retrospective longitudinal study of glaucoma patients across multiple glaucoma providers with at least seven reliable VFs. The clinicians' decision of the presence of VF worsening in each eye was made at the time of the last VF in the series during routine clinical care. We trained a 2D convolutional Long Short-Term Memory DLM to predict VF worsening from the series of VFs for each eye(Figure 1). The reference standard for defining VF worsening used to train/test the DLM and evaluate clinician performance was defined as worsening in at least 4 out of the 6 trend-based and event-based algorithms: Mean Deviation (MD) slope, Visual Field Index (VFI) slope, Point Linear Regression (PLR) slope, Advanced Glaucoma Intervention Study (AGIS) score, Guided Progression Analysis (GPA), and Collaborative Initial Glaucoma Treatment Study (CIGTS). We split the data into 80%, 10%, and 10% for training, validation, and testing respectively for our DLM. The performance of the DLM and clinician at identifying VF worsening was evaluated in the test set using Area Under the Receiver Operating Characteristic Curve (AUROC).

Results: A total of 8,705 eyes from 5,099 patients were included. Adapting the reference standard criteria of VF worsening, a total of 869 eyes (10%) were found to have worsening VFs over time. The DLM had an AUROC of 0.94 (95% CI: 0.93, 0.99) for detecting VF worsening on the test set. In contrast, the clinician decision had an estimated AUROC of 0.63 (95% CI: 0.56, 0.70) on the test set.

Conclusions: A DLM was trained to identify VF worsening with good classification performance. The performance of the DLM at identifying VF worsening was superior to the performance of clinicians during routine clinical care.

ABSTRACT BODY:

Purpose: We aim to develop privacy-preserving deep-learning (DL) models with federated learning (FL), a technique taking advantage of datasets across multiple “clients” (i.e., different end-users or centers) without centralizing or sharing data, to classify glaucomatous optic neuropathy (GON) from 3D optical coherence tomography (OCT) volumetric scans.

Methods: This is a multi-national study. We collected datasets of OCT scans from 7 eye centers. Each dataset was a “client” and split into training, tuning, and testing sets with a ratio of 7:1:2. We experimented with three kinds of DL architectures to develop 3D FL-Models. Figure 1 illustrates the FL process, which consists of a “central server” and 7 local clients. The central server maintains a “Global Model” and coordinates clients’ updates on their local models. To be specific, each client trained locally on its own training set and then updated the model parameters to the central server after one training epoch. The central server aggregated the updates from each local model to refine the Global Model and then redistributed the updated Global Model to all the clients. Subsequently, each client continued fine-tuning locally with its tuning set based on the updated Global Model. This process repeated back and forth until the Global Model converged which was then tested on each client’s testing set. For performance comparison, we used all data from 7 clients to develop Joint-Models which served as the upper bound and were tested on the same testing sets as FL-Models.

Results: We used 8,436 volumetric scans from 2,192 patients (Table 1). FL-Models developed by three architectures achieved the area under the receiver operating curve (AUROC) values with ranges of 0.784-0.993, 0.805-0.996, and 0.809-0.991 in 7 clients, respectively. Joint-Models achieved AUROC values of 0.775-0.997, 0.807-0.999, and 0.822-0.996, respectively. In each client, the FL-Models had accuracy, sensitivity, and specificity similar to corresponding Joint-Models (Table 2).

Conclusions: The 3D FL-Models showed performance non-inferior to Joint-Models and achieved good generalizability without sharing any patient data among multiple centers. Our results demonstrated that the FL technique can ensure data security and enhance the feasibility of implementing DL-based OCT analysis to identify GON in real-world clinics.

ABSTRACT BODY:

Purpose: In the recent past, vision loss secondary to inherited retinal disease (IRD) was considered ‘incurable.’ Progress in both gene therapy and the molecular characterization of IRDs has led to a rapid increase in the number of gene-specific treatments as well as planned and ongoing interventional clinical trials for ocular disease. Perhaps less apparent is how diagnostic genetic testing, such as with next-generation sequencing (NGS), informs the opportunity for gene-specific treatments and interventional clinical trials for IRD. Here, we assess how NGS-based panel results impact access to targeted treatment and clinical trials in a large cohort of patients with IRD.

Methods: We carried out a retrospective analysis of test results from 18,026 deidentified patients who were tested consecutively with an IRD-related panel at Blueprint Genetics (Table 1). The target regions included coding exons, intronic regions ± 20 bps from the exon-intron boundaries and clinically significant noncoding variants. Copy number analysis was done bioinformatically from the NGS data using 2 different pipelines, including 1 proprietary pipeline developed for the detection of small, exon-level CNVs. Variant interpretation was performed according to American College of Medical Genetics guidelines. Clinical information, demographics, and results were extracted from the internal laboratory database.

Results: The median coverage of all target regions was 99.91% at >20X while the median sequencing depth was 210X. The median age at testing was 46 years. Males made up 48.4% (8,730) of the cohort while females made up 51.1% (9,203). Sex was not specified in 0.5% (93) patients. A molecular diagnosis was made in 9,156 (50.8%) patients while a variant of unknown significance (VUS) favoring pathogenic was identified in an additional 973 (5.4%) patients. A total of 214 genes were involved in the molecular diagnoses of IRD. In particular, diagnoses involving the 14 genes for which therapy or clinical trial is available accounted for 41.7% of the total diagnoses (Table 2).

Conclusions: For every 5 patients who received a molecular diagnosis for their IRD in this cohort, 2 have a diagnosis involving a gene/specific variant that may allow them to access treatment or a clinical trial.

ABSTRACT BODY:

Purpose: To identify factors associated with visual field (VF) progression in glaucoma patients with small and large optic discs.

Methods: We performed a retrospective review of glaucoma patients with small and large optic discs from the UCLA Stein Glaucoma Division from 1993-2019. Disc size was defined by optical coherence tomography (OCT) or Heidelberg Retinal Tomography (HRT) values with disc area ≤1.3 mm^2 (5^{th}%) and ≥2.9 mm^2 (95^{th}%). Patient charts were reviewed for demographics, diabetes, cardiovascular disease, autoimmune disease, glaucoma type, and ocular comorbidities. VF deterioration was measured by the Glaucoma Rate Index (GRI),[1] and eyes were categorized into fast (GRI<-6) or slow (GRI>-6) progressors. Logistic regression models were performed with all covariates as predictors and GRI<-6 as the outcome.

Results: Of 4,505 patients with eligible disc photos, the study population included 331 eyes with small discs (mean GRI=-3.7) and 234 with large discs (mean GRI=-3.8). In small discs, female gender was associated with increased progression (adjusted odds ratio [aOR]=3.14, 95% confidence interval [CI]=1.71,5.99), while other types of glaucoma (versus primary open angle glaucoma) were associated with decreased progression (aOR=0.11, CI=0.02,0.40). In large discs, increased intraocular pressure (IOP) range was associated with increased progression (aOR=1.35, CI=1.12,1.66). Characteristics associated with large discs included vasospastic phenotype[2] (aOR=0.37, CI=0.18,0.7) and certain races/ethnicities (Black: aOR=0.05, CI=0.02,0.12; Hispanic: aOR=0.1, CI=0.04,0.24; Asian: aOR=0.23, CI=0.14,0.38; Other: aOR=0.35, CI=0.21,0.6) (aORs calculated as small versus large). Potential associations between some covariates and progression may have been undetected due to low proportions of affected patients and insufficient statistical power.

Conclusions: Multiple characteristics were associated in glaucoma patients with small and large discs, as well as with their disease progression. Further investigation of discernible glaucoma phenotypes would be beneficial to improve disease prognostication, treatment, and interpretation of complex genetic associations.

ABSTRACT BODY:

Purpose: Primary open-angle glaucoma (POAG) is a complex ocular disease characterized by death of retinal ganglion cells and atrophy of the optic nerve head that, if untreated, leads to blindness. Previous studies have shown that POAG has a genetic etiology component, however, the identification of all the causative genetic factors has proven to be challenging. Investigation of the underlying genetics and cell types involved in POAG can contribute to a better understanding of the disease mechanisms. In our study, we conducted post-GWAS analyses oriented to the investigation of pathway, gene, tissue, and cell types prioritization in a multi-ancestry POAG cohort.

Methods: We used results generated from a large-scale genome-wide association POAG meta-analysis, conducted in subjects sourced from 15 global biobanks participating in the Global Biobank Meta-Initiative (GBMI), a collaboration of global biobanks. A total of 26,848 cases and 1,460,599 controls from six ancestries were analyzed. We evaluated if the genomic loci were implicated in POAG map specific cell types using Linkage Disequilibrium Score Regression (LDSC), and compared results obtained from Data-driven Expression Prioritized Integration for Complex Traits (DEPICT) analyses. GeneMANIA was used to investigate gene interaction. In order to prevent spurious findings, false discovery rate method was used for multiple testing corrections.

Results: The significant results from LDSC pointed to mesenchymal, vascular and adipocytes cell types, showing consistency with the results also obtained in tissue-enrichment analysis from DEPICT. Furthermore, gene-prioritization identified 54 genes that were used to construct interaction networks. Potential hub genes identified were BMP2, CPE, FERMT2, FOXC1, MYBPC3, PARVA, SEMA3C, SIX4, TGFB2, TGFBR3, and TPM1. Nine of these genes have a role in epithelial to mesenchyme-like transition cellular mechanism.

Conclusions: Our findings promote the potential role of the epithelial to mesenchyme-like transition in POAG and contribute to improving the biological mechanisms underlying this condition. Further experimental studies are required to investigate this potential contribution with respect to POAG pathogenesis and to identify novel target genes.

ABSTRACT BODY:

Purpose: Type-2 diabetes (T2D) is associated with increased risk of Alzheimer's disease (AD). Commonly affected pathways centre around the neurovascular unit (NVU). Glial pathology, neurodegeneration and vascular damage are hallmarks of both diabetic retinopathy (DR) and AD. Therefore, retinal pathology may be useful to understand brain changes in T2D and AD. We assessed retinal pathology in mice models of AD and T2D, and a crossed model of AD/T2D to understand the pathogenesis of this important co-morbidity.

Methods: The NVU was assessed in retinal tissue from WT, APP/PS1, db/db and APP/PS1xdb/db mice at 14 and 26 weeks old. Immunohistochemistry staining was carried out to assess gliosis (GFAP), acellular capillaries (Isolectin-B4/Collagen 4), and Müller cell potassium/ water homeostasis (Kir4.1, AQP4). Changes to neuronal populations were assessed by staining for Calbindin (Horizontal cells), Brn3a (Retinal Ganglion cells) and Cone-arrestin (Cone-photoreceptors).

Results: We observed NVU dysfunction in APP/PS1xdb/db retina including significant Müller cell gliosis at 14 weeks ($p<0.05$). Müller cells showed alteration of Kir4.1 and AQP4 localisation in APP/PS1 and db/db retina which was more apparent in APP/PS1xdb/db mice at 26 weeks. APP/PS1 x db/db mice had significantly more acellular capillaries than WT mice at 14 weeks ($p<0.01$). A significant decrease in retinal ganglion cells was observed at 26 weeks in db/db ($p<0.05$) and APP/PS1 x db/db mice ($p<0.05$) compared to WT. Horizontal cells were significantly reduced in APP/PS1 ($p<0.05$) and APP/PS1xdb/db ($p<0.05$) retina at 26 weeks. A significant decrease in the number of Cone arrestin^{+} cells in the APP/PS1xdb/db retina was observed at both 14 ($p<0.001$) and 26 weeks ($p<0.001$) vs WT. The number of DAPI^{+} cells in the outer nuclear layer was significantly reduced in APP/PS1xdb/db mice compared to APP/PS1 ($p<0.001$) and db/db ($p<0.05$) alone.

Conclusions: We observed evidence of NVU dysfunction APP/PS1xdb/db retina, which appeared to be more severe than APP/PS1 or db/db alone. This occurs alongside severe cognitive impairment in this model (1). APP/PS1xdb/db had increased gliosis and dysregulation of water and ion homeostasis together with retinal neurodegeneration features. Further studies are required to characterise the changes of the NVU in the retina and brain during diabetes related neurodegeneration. (1) Infante-Garcia et al. 2016

ABSTRACT BODY:

Purpose: To evaluate the accuracy of an algorithm to estimate Central Subfield Thickness (CST) from OCT volumes for patients with AMD or DME.

Methods: We collected OCT volumes from two groups of patients, respectively including exudative AMD (541) and DME (1’568) patients. We refer to them as the AMD group and DME group. All patients received an anti-VEGF treatment, were treated and monitored between 01/2013 and 06/2021. We found 3’974 OCT volumes for the AMD group and 11’501 OCT volumes for the DME group. The algorithm to be evaluated relies on the CE-marked Discovery® layer segmentation algorithm (RetinAI Medical AG, Switzerland) and computes the average retinal thickness in the central-1mm region from the ETDRS grid. For each OCT volume, the true CST was measured independently by two graders and a third grader in case of disagreement. The annotations were performed by the Bern Photographic Reading Center (Inselspital, Universitätsspital Bern, Universitätsklinik für Augenheilkunde, Bern, Switzerland). After removing the ungradable OCT volumes and considering the 99^{th} percentile of the thicknesses, the AMD group comprises of 3’894 OCT volumes (537 patients) and the DME group of 11'269 OCT volumes (1’526 patients).

Results: We reported a strong correlation between the annotated values of CSTs and the predicted ones from the algorithm (R2=0.96) for both groups. We observed that the algorithm tends to over-estimate the retinal thickness in general, leading however to a small mean absolute error (prediction - annotation), 3.19µm (95% CI, 2.6–3.8µm) and 10.68µm (95% CI, 10.4–11µm) for AMD and DME groups, respectively. Indeed, relatively to the median annotated CSTs (302µm and 310µm), these errors represent 1.06% and 3.44% of the total retinal thickness for AMD and DME cohorts, respectively. We observed that 5.4% (210/3’894) samples are located outside the 95% limits of agreement for AMD and 5.1% (574/11 269) samples are located outside the 95% limits of agreement in DME.

Conclusions: We report very good performances for CST estimation on OCT volumes with AMD and DME. This unveils the potential of such algorithms to support clinical decision making and to envision new strategies to facilitate annotation for clinical trials. To understand the sources of the difference in CST errors between the two groups, we plan to analyze the ETDRS alignment and to consider the presence of fluids and other biomarkers.

ABSTRACT BODY:

Purpose: We investigated efficacy and safety of adalimumab (ADA) treatment for exacerbation or recurrence of Vogt-Koyanagi-Harada (VKH) patients.

Methods: This is a retrospective, multi-centre cohort study. Medical records of 70 VKH patients who received ADA treatment for more than 6 months were retrospectively investigated for best corrected visual acuity (BCVA), aqueous flare counts, subfoveal choroidal thickness (SFCT), indocyanine green angiography (ICGA) score, corticosteroid doses, and presence or absence of immunosuppressors at baseline before the initiation of ADA and 6 months later. Adverse events were recorded.

Results: The mean age of VKH patients was 54.8 ± 15.1 years and male/female ratio was 34/36. SFCT, ICGA scores, and corticosteroids and cyclosporine doses were significantly reduced by ADA treatment for 6 months compared to baseline, while LogMAR visual acuity and flare counts were also improved without being statistically significant. When sub-classified into VKH patients with the presence of sunset glow fundus (SGF) and without SGF, SFCT, ICGA scores, and mean corticosteroid doses were significantly lower after ADA treatment for 6 months, but the difference was not significant for LogMAR visual acuity and flare counts compared to baseline in the group without SGF. In the group with SGF, LogMAR visual acuity, ICGA scores and mean corticosteroid doses were significantly lower, but the difference was not significant for flare counts and SFCT when compared to baseline. Adverse events were observed in 17.1%, in which infection including tuberculosis was at 7.14% and psoriasis was at 2.86%. ADA treatment was continued in 91.4%.

Conclusions: ADA was shown to be effective to achieve remission of VKH disease refractory to conventional immunosuppressive treatments, and was generally well tolerated with few serious adverse events.

ABSTRACT BODY:

Purpose: Telerehabilitation is a new way of providing web-based services to chronic patients who receive rehabilitative care at home with remote supervision by trained staff. It allows to increase the frequency and intensity of care provided to the patient.

The purpose of this study was to evaluate the usability of the EyeFitness telerehabilitation software and patients' adherence to treatment

Methods: 44 visually impaired subjects of various etiologies, 19 males and 22 females, mean age 53 4 years (SD= 19, 5 years, Range= 22-89 years), were enrolled. The home training using the EyeFitness software was conducted for 5 days a week, for a total of 6 weeks. The software was individually configured for each patient, choosing the exercises according to the eye disease, the patient's residual perceptive abilities (visual acuity and contrast sensitivity) and the specific visual skills to be enhanced. Recruitment and monitoring of the progress was conducted from five rehabilitation centers. The Post-Study System Usability Questionnaire (PSSUQ) was administered after the use of the software

Results: Patients had good adherence: one had a poor participation and only two interrupt the training before the end of the program; these were excluded from the analysis.The average overall completion rate for the 41 patients included in the analysis was 97,2% (SD= 5,2), indicating that the average patient completed their prescribed exercises 5 days per week over the course of their enrollment in the program. The PSSUQ indicator showed that patients were satisfied with the EyeFitness software, with an overall average score of 1,85 (SD= 0,96, Range= 1,04 - 2,86). The three sub-scales revealed positive opinions on system quality (mean score 1,45, SD= 0,87, Range= 1,19-2,025), information quality (mean score 1,77, SD= 1,5, Range= 1,25-4,23), and interface quality (mean score 2,01, SD= 1,32, Range= 1,82-2,55). Providers also commented favorably on the experience and found this approach useful in supporting traditional in-person vision rehabilitation

Conclusions:

Preliminary results show that both participants and providers gave positive assessments to the feasibility and acceptability of telerehabilitation sessions. The software could be a viable approach for visually impaired individuals who have difficulty attending traditional rehabilitation programs at the low vision center

ABSTRACT BODY:

Purpose: The blood-retinal barrier (BRB) has two components: inner and outer barrier. The neurovascular unit of the retina plays key roles in the inner BRB. Choroid, the major components of the outer BRB provides oxygen and nourishment to the retina. Retinal and choroidal blood vessels come in different morphologies and have distinct organotypic characteristics that enable them to execute tissue–specific functions. In this study, we investigated endothelial heterogeneity across the distinct vascular beds in the eye.

Methods: We evaluated molecular and functional differences between primary human retinal endothelial cells (HRECs) and human choroidal endothelial cells (HCECs) in terms of angiogenic and vasculogenic properties, permeability, and transcytosis. We performed tube formation assay, cell migration assay, in vitro permeability assay, microfluidic sprouting assay, and transcriptome analysis.

Results: HRECs showed higher proliferation and migration activity than HCECs, but the tube formation ability did not show a significant difference. HCECs displayed earlier sprouting angiogenesis but the overall speed was faster and more stable in HRECs under angiogenic stimuli. HRECs expressed higher adherens junctional proteins than HCECs, but the tight junctional genes and transcytosis related genes were more in HCEC. Angiopoietin-2 was predominantly expressed in HRECs, but VEGF receptors were higher in HCECs. PDGFB was higher in HRECs than HCECs which correlates to the less pericytes coverage in choroidal blood vessels. Our data indicate that HCECs is a quiescent endothelium but can be stimulated under the angiogenic environment, and have a specialized transcriptome for trans-endothelial molecular transport.

Conclusions: Retinal and choroidal blood vessels constitute two distinct BRBs under the endothelial heterogeneity: The outer BRB, size-selective barrier with vascular transcytosis for metabolic support, and the inner BRB, forming tight barriers, composes organotypic vasculature and maintains homeostasis in the eye.

ABSTRACT BODY:

Purpose: The disease progression of retinitis pigmentosa (RP) differs between individuals and between different genetic subtypes. We performed a retrospective clinical study to characterize the natural disease progression in PRPF31-related autosomal dominant retinitis pigmentosa (RP11).

Methods: We identified individuals with RP11 and collected retrospective data from disease onset to present date including genetics, demographic data, Goldmann visual field areas, and visual acuity measures. Visual fields were evaluated as summed squared degrees and best corrected visual acuities were converted to logMAR. We performed linear mixed model regression analysis on the longitudinal data to evaluate the annual disease progression in visual fields, and we used survival analysis to evaluate the age when a person first meets legal blindness criteria.

Results: We included information on 46 subjects with RP11. Our study population represented 17 unique PRPF31 variants. Median age of disease onset was 10 years (range 5-65). Follow-up spanned from 0-36 years with a median of 8 years. Goldmann visual field areas decreased by 9.7% (95% CI 7.4 – 11.9) with Goldmann target IV4e and by 7.5% (95% CI 4.8 – 10.1) with target III4e per year. Best corrected visual acuity tends to decrease with age, however it did not decline to less than 20/200 in any of our cases. Survival analysis showed that half of the RP11 patients had reached legal blindness by the median age of 57 years (95% CI 41-75 years).

Conclusions: In retinitis pigmentosa caused by PRPF31 variants, disease onset is most frequently in early childhood with a variable disease progression depending on onset of symptoms. Visual field area deteriorates faster than best corrected visual acuity, and visual field loss is the main reason for legal blindness in our study population. Visual acuity naturally declines with age, but individuals with RP11 maintain a fair and relatively stable central visual acuity until late state disease in high age. This study characterizes the progression of retinitis pigmentosa caused by PRPF31 variants and can aid conduction of future prospective trials, and to advice and inform RP11 patients in a clinical setting.

ABSTRACT BODY:

Purpose: Transcriptome sequencing enables us to reveal fusion genes associated with carcinogenesis and gene expression patterns relevant to classification of cancers. The aims of this study are to identify fusion genes of eyelid and conjunctival malignant tumors, and to assess the characteristics of eyelid and conjunctival tumors among various cancer types by comprehensive cross-tumor gene expression analysis.

Methods: Twenty-three eyelid sebaceous carcinoma (SeC), three basal cell carcinoma (BCC), and three conjunctival squamous cell carcinoma (SCC) samples obtained at Kyushu University Hospital were included in this study. NovaSeq 6000® (Illumina) was used for RNA-sequencing. For detecting fusion genes and counting mapped reads, Genomon2.6.3 and HTSeq0.12.4 were used, respectively. The read counts were normalized for sequence depth and transcript length to assess gene expression level. We integrated publicly available transcriptomic data from 9,924 samples across 36 cancer types, with our 29 samples of RNA sequencing data for gene expression analysis in pan-cancers. The gene expression levels of 19,853 protein-coding genes were examined for differences among tumor types.

Results: We identified 130 pairs of fusion genes in SeC, 5 pairs in BCC, and 9 pairs in SCC, respectively. The fusion genes identified in multiple cases of the same cancer type included HOXC11-CRNDE fusion gene identified in 4 cases of SeC and TMBIM4-RPL14 fusion gene identified in 2 cases of BCC. In SCC cases, fusion genes detected in multiple cases were not identified. In the gene expression analysis of pan-cancer, eyelid and conjunctival tumors appeared to formed a unique cluster by dimensionality reduction using t-SNE. In addition, eyelid and conjunctival tumors exhibited gene expression patterns similar to those of squamous cell carcinomas of various primary organs.

Conclusions: HOXC11-CRNDE fusion and TMBIM4-RPL14 fusion may be associated with carcinogenesis of eyelid and conjunctival malignant tumors.

ABSTRACT BODY:

Purpose: In many retinal diseases such as retinitis pigmentosa (RP), single gene mutations cause rod photoreceptor death which is later followed by cone death. Traditionally, therapeutic efforts have aimed to reintroduce a normal copy of the mutated gene. However, RP is caused by mutations in dozens of different rod-specific or rod-enriched genes. Thus, there is a strong motivation to develop gene-independent therapies that could be used to treat a wide range of genetic forms of RP. While previous studies have shown the feasibility of this approach by targeting the rod-specific transcription factor Nrl, this disrupts gene expression and cases major changes in rod morphology and physiology. We tested the hypothesis that a more subtle approach, the knockout of Nr2e3 (a rod-specific transcription factor downstream of Nrl) will protect photoreceptors against degeneration in two different models of RP.

Methods: Rods in Nr2e3-deficient (rd7) mice are hybrid cells that ectopically express a subset of cone genes in addition to the normal complement of rod genes. We crossed rd7 mice with rhodopsin knockout ($Rho^{-/-}$) or rod phosphodiesterase (rd10) mutant mice. Retinal function and morphology were analyzed at different ages by in vivo electroretinography and immunohistochemistry. Scotopic and photopic visual acuity and contrast sensitivity were evaluated from optomotor behavior tests. RNA-seq analysis was performed to determine differential gene expression in wild type and rd7 retinas.

Results: ERG recordings revealed that M-cone function was preserved at wild-type levels for up to 6 months in $Rho^{-/-}$;rd7 mice, in contrast to control $Rho^{-/-}$ animals where it deteriorated gradually and was fully absent by 4 months. This result correlated with greatly extended survival of both rods and cones and maintenance of photopic vision in the $Rho^{-/-}$;rd7 mice. A similar degree of rod and cone structural and functional protection was observed in rd10;rd7 mice despite the very rapid retinal degeneration in rd10 mice. RNA-seq analysis showed up-regulation of several cone genes in rd7 retinas which might mediate protection against retinal degeneration.

Conclusions: Knockout of Nr2e3 slows retinal degeneration and ameliorates secondary cone death in two distinct models of RP. The therapeutic mechanism may involve the upregulation of one or more cone-enriched genes in rods.

ABSTRACT BODY:

Purpose: Among contact lens materials, ionic materials have pK_a values which affects the degree of protonation by pH of swelling media. As a result of these degree of protonation, physical properties of contact lens can be altered including diameter, equilibrium water content. In this study, physical properties of contact lenses and state of water in contact lenses were examined depend on the pH.

Methods: The 1-Day ACUVUE MOIST (Johnson& Johnson Inc.) and SofLens (Bausch + Lomb Inc.) were used. PBS buffer solutions at pH from 5.8 to 8.2 were used though out the study. The diameter, equilibrium water content, and the quantity of freezable water (W_f) and non-freezable water (W_{nf}) in the contact lens at each pH condition was measured.

Results: The etafilcon A material contact lens showed decreased diameter, equilibrium water content, and the quantity of W_f with decreasing pH below 7.0. The quantity of W_{nf} tended to decrease with increasing pH. Hilafilcon B did not show specific trend in changes of diameter, equilibrium water content, and W_{nf} and W_f .

Conclusions: The diameter and equilibrium water content of the contact lens have decreased due to dehydration of the contact lens. The composition of W_{nf} and W_f showed conflicting results, which implies that dehydration can significantly change the ratio of water composition. Since the ratio of W_{nf} and W_f of the contact lens may vary, research should be conducted to reveal the correlation between these properties and the state of water in contact lens.

ABSTRACT BODY:

Purpose: The interactions between gonadal steroid hormones and the retina have received limited attention, though it has been suggested that they may play a protective role in retinal diseases. The purpose of this work was to study the repurposing of one drug (dutasteride) for retinitis pigmentosa (RP) treatment. Dutasteride (DUT) is a 5α-reductase inhibitor that have not been associated with increases in serum testosterone levels. Furthermore, modulation or inhibition of 5α-reductase activity increases levels of neuroprotective steroids. We also studied the action mechanisms that provide DUT with a neuroprotective role in RP. To this end, the changes that dutasteride induce on markers of inflammation, and glutathione (GSH) metabolism in the retina of rds mice were studied.

Methods: Animals were treated in accordance with the ARVO statement for the use of animals in ophthalmic and vision research. Rds mice were treated intraperitoneally with DUT on postnatal days 11, 13, 15, 17 and 19 and euthanized on day 21. Hematoxylin-eosin, TUNEL, and rod and cone immunohistochemistry were performed to determine if DUT was able to delay photoreceptor death. Immunohistochemical techniques were used to study changes in retinal microglia (Iba-1) morphology and distribution. Degree of inflammatory cells activation was evaluated by measuring expression of CD68. Possible modifications of other glial cells were also studied with GFAP (glial fibrillar acid protein). Finally, GSH localization was examined, and western blot analysis was performed to determine retinal GSH synthesis and transport.

Results: DUT increased photoreceptor survival in rds mice. An increase in iba-1 positive cells was found in rds retinas and DUT normalized the number, migration and the length and number of branches in these cells ($p<0,01$). DUT decreased in CD68 and GFAP expression (more than 50% of increase in rds retina). Finally, DUT was also able to ameliorate the observed alterations in GSH metabolism in rds retina.

Conclusions: DUT may be used to ameliorate retinal micro and macroglial activation in RP, as well as alterations in the metabolism of the most important intracellular antioxidant.

ABSTRACT BODY:

Purpose: Inherited retinal diseases are clinically and genetically heterogeneous. Amongst these are macular diseases (MDs) characterized by central vision loss. Inherited MDs (iMDs) are relatively rare and generally present at an early age, while age-related MD (AMD) is more prevalent and occurs later in life. The clinical and genetic heterogeneity in MDs makes a clear diagnosis challenging. The use of cost-effective single molecule Molecular Inversion Probes (smMIPs) to sequence ABCA4 in patients with Stargardt disease identified many coding and non-coding variants, but ~57% remained unsolved (Khan et al., 2020; PMID: 32307445). We hypothesized that the missing heritability may be revealed by smMIPs-based sequencing of all MD-associated genes.

Methods: We used 17,394 smMIPs designed by Molecular Loop Biosciences (USA) to sequence the coding regions of 105 iMD and AMD-associated genes, known pseudo-exons, and the mitochondrial genome. DNA libraries of 384 iMD samples previously investigated for variants in ABCA4, were pooled for sequencing on the NovaSeq 6000 platform. Variant filtering prioritized autosomal recessive variants with an allele frequency of ≤0.5% in population databases, and autosomal dominant variants with an allele frequency of ≤0.1%. Variants with a Franklin-ACMG classification of class 3-5 were selected.

Results: Across NovaSeq SP sequencing runs, an average nucleotide coverage of 680× was observed. Sequencing data for 104 iMD probands, who previously were shown not to carry two alleles in ABCA4, have been fully analysed. Across these 104 probands, 132 candidate variants in 40 genes, comprising two CNVs and 130 SNVs or indels, were identified. Of the SNVs or indels, 19 were class 5 variants (pathogenic), 21 class 4 variants (likely pathogenic) and 90 class 3 variants (VUS). Forty probands were considered to be genetically solved by disease causing variants in 24 genes, achieving a diagnostic yield of 38% within this ABCA4-pre-screened cohort.

Conclusions: Utilising smMIPs to target MD-associated genes and loci is a cost-effective approach. Further analysis will identify known and novel variants in iMD-associated genes, which will offer an accurate clinical diagnosis to patients and their families in addition to revealing new genetic associations for MDs.

ABSTRACT BODY:

Purpose: Habitual alcohol consumption is an important modifiable risk factor associated with a multitude of adverse health outcomes, but evidence for the associations with glaucoma and related traits are unclear. We performed a cross-sectional observational study of UK Biobank participants as an understanding of these relationships may have important clinical and public health implications.

Methods: Participants (aged 39–72 years) were categorized according to self-reported drinking behaviors. Quantitative estimates of alcohol intake were derived from touchscreen questionnaires and food composition tables. We included participants with data on intraocular pressure (IOP) (n=109,097), inner retinal OCT measurements (n=46,414) and glaucoma (n=173,734). Ocular parameters were measured as part of a comprehensive eye examination and glaucoma case ascertainment was through a combination of self-report and linked national hospital records. Multivariable linear, logistic and restricted cubic spline regression were used to model associations. All analyses were adjusted for key sociodemographic, medical, anthropometric and lifestyle factors.

Results: Compared to never/infrequent drinkers, regular drinkers had higher IOP (+0.15mmHg; P<0.001) and non-significant trends towards a thinner retinal nerve fiber layer (RNFL), thinner ganglion cell–inner plexiform layer (GC–IPL) and higher odds of glaucoma. Former drinkers had a higher odds of glaucoma (OR 1.44; P=0.006). In regular drinkers, alcohol intake was associated with all outcomes in a dose-dependent manner. Compared to the lowest alcohol intake quintile (median 17g/week), participants in the highest quintile (median 278g/week) had higher IOP (+0.26mmHg; P<0.001), thinner RNFL (-0.41µm; P<0.001), thinner GC–IPL (-0.81µm; P<0.001) and higher odds of glaucoma (OR 1.30; P=0.008) (P_{trend} ≤0.003 for all). There was evidence for non-linearity with an apparent threshold effect at approximately 50g/week for RNFL, GC–IPL and glaucoma. No differential effect by sex or alcoholic beverage type was observed.

Conclusions: Alcohol intake was consistently and adversely associated with glaucoma and related traits, and at levels below current UK and US drinking guidelines. If further studies support a causal relationship, this may inform lifestyle advice for people with or at risk of glaucoma.

ABSTRACT BODY:

Purpose: To provide an automated method of characterizing the presumed vascularity of pigment epithelial detachments (PEDs) in neovascular age-related macular degeneration (nAMD) and to quantify the areas of serous, neovascular, and fibrous tissues within PEDs.

Methods: A retrospective dataset of 28 high-resolution spectral-domain OCT (SD-OCT) B-scans taken from 22 patients with nAMD with presence of fibrovascular PED, were analyzed for this experiment. B-scans were acquired using the Heidelberg Spectralis device with a resolution of 1536x1536 in pixels. Exclusion criteria included drusenoid PEDs. For pre-processing, shadow compensation and linear standardization were applied. PEDs were segmented and then filtered using 2D kernels to create a series of generated images. A PED vascularity index score (PEDVI) was calculated for each pixel within the PED using a function of generated images. Pixels within the PED were classified as serous, neovascular, or fibrous based on PEDVI and respective areas were calculated. Accuracy of segmentation and classification within the PED were graded independently twice by two expert clinicians in masked fashion on a scale of 0-100.

Results: Of the 28 eyes, 15 had serous fluid, 24 had neovascular tissue, and 16 had fibrous tissue within a PED. Inter-observer reproducibilities were 0.99, 0.78, 0.94, and 0.79 for grader 1; 0.95, 0.78, 0.79, and 0.74 for grader 2; intra-observer repeatabilities were 0.90, 0.73, 0.84, and 0.81 for accuracy of segmentation, and classification of serous, neovascular, and fibrous respectively. Mean inter-grader reproducibility and intra-grader repeatability were 0.85 ± 0.10 and 0.82 ± 0.07 respectively. The mean graded scores were 96.88 ± 8.81, 92.67 ± 7.84, 93.44 ± 8.12, and 92.89 ± 8.25 for segmentation, serous, neovascular, and fibrous respectively. Mean total PED area, and when present, mean serous, neovascular, and fibrous areas in mm^2 were 0.26 ± 0.44, 0.218 ± 0.462, 0.108 ± 0.102, and 0.061 ± 0.077 respectively.

Conclusions: PEDVI scores calculated from a kernel-based image processing approach demonstrates potential for quantifying PEDs and approximating relative sizes of serous, neovascular, and fibrous tissue. An automated algorithm for segmentation is underway.

ABSTRACT BODY:

Purpose: To reveal targetability of polo-like kinase 1 (PLK1) with a small molecular inhibitor ON-01910.Na using retinoblastoma, an intraocular malignancy that lacks targeted therapy, as a disease model.

Methods: Transcriptomic analysis on patient retinoblastoma tissues was done to find key pathway and to select key factor of retinoblastoma. Subsequently, antitumor activity of ON-01910.Na, the drug targetting the selected key factor, was investigated in both cellular and animal levels.

Results: Transcriptomic analysis on patient retinoblastoma tissues suggested that cell cycle progression was deregulated and confirmed that PLK1 pathway was upregulated. In the investigation of antitumor activity of ON-01910.Na, a PLK1 inhibitor, it was found that cytotoxicity induced by ON-01910.Na was tumor specific and dose dependent in retinoblastoma cells, while nontumor cells were minimally affected. In three-dimensional culture, ON-01910.Na demonstrated efficient drug penetrability with multilayer cell death. Posttreatment transcriptomic findings revealed that cell cycle arrest and MAPK cascade activation were induced following PLK1 inhibition and eventually resulted in apoptotic cell death. In Balb/c nude mice, a safe threshold of 0.8 nmol intravitreal dosage of ON-01910.Na was established for intraocular safety, which was demonstrated by structural integrity and functional preservation. Furthermore, intraocular and subcutaneous xenograft were significantly reduced with ON-01910.Na treatments.

Conclusions: Local treatment of ON-01910.Na may be a novel, effective modality benefiting patients with PLK1-aberrant retinoblastoma.

ABSTRACT BODY:
Purpose: Anisometropia is a risk factor for atypical binocular development associated with strabismus and amblyopia. The goal of this study was to understand the impact of different degrees of simulated anisometropia on vergence eye movements.
Methods: Participants viewed a cartoon character (2deg wide) displayed dichoptically on a 68x41deg gray background with varying amounts of retinal disparity. Spherical defocus of 1, 2 or 4D was applied to one or both eyes' stimuli using convolution with the Point Spread Function adjusted for the subject's pupil size. Eye movements were recorded with an Eyelink 1000. In condition 1, a step change in disparity (0-8deg) was introduced and displayed for 320ms, followed by a blank screen. Open-loop vergence amplitude was used to estimate the reflex response. In condition 2, retinal disparity varied between ±4deg relative to the screen with quasi-random velocities for 40s. Cross-correlations between stimulus and vergence velocities were computed.
Results: 22 youth and adults (15-51yrs) and 16 typically developing children (4-8yrs) participated in condition 1. With no defocus, open-loop vergence peaked for ±2deg disparity for both groups. Median (IQR) amplitudes were similar at 0.33 (0.19) deg convergence and -0.40 (0.23) deg divergence for adults, and 0.50 (0.51) deg and -0.42 (0.43) deg for children. Bilateral defocus had no effect. However, 4D of unilateral defocus reduced convergence and divergence amplitudes, especially for children (0.28 (0.33) deg and -0.36 (0.30) deg, respectively). Condition 2 was completed by 18 typical youth and adults (16-53yrs). The median (IQR) peak correlation of 0.61 (0.14) with no defocus decreased to 0.33 (0.41) with 4D unilateral defocus, while the decrease was smaller with 4D bilateral defocus (0.57 (0.23)). The median (IQR) latency of 183 (40) ms with no defocus increased to 198 (40) ms and 223 (40) ms with 4D of bilateral and unilateral defocus, respectively.
Conclusions: Our results confirm that unilateral defocus has a more detrimental effect than bilateral defocus on reflex vergence movements especially in children, which emphasizes the importance of similar retinal images for binocular development. For adults, the sustained responses required in condition 2 were especially affected. Although 1D of anisometropia can be associated with amblyopia, 2 to 4D are needed to disrupt this reflex oculomotor system and compromise accurate alignment for this small central stimulus.

ABSTRACT BODY:

Purpose: Retinal prostheses help to restore vision in patients with degenerative retinal diseases, and require safe insertion. To prevent intra-/postoperative complications, e.g. retinal tearing and detachment, we performed an anatomical, histological study to describe safe insertion sites into the eye in mice, rats, and rabbits as well as in vivo experiments to observe the effect of laser- and cryo-ablation on the insertion sites. We pursue a better understanding of the surgical anatomy of the insertion sites and surgical feasibility of the implantation of retinal stimulators.

Methods: Four 15-28 weeks C57BL/6J wild-type(wt) mouse eyes, four 12-16 weeks rd10 mouse eyes, six 28 weeks Brown Norway rat eyes and twelve Chinchilla Bastard rabbit eyes went under histological processing. Three-dimensional (3D) data sets were created with two approaches: One was to create a rotationally symmetric 3D model of the eyeball by rotating a central sagittal section through the corneal apex and posterior retinal pole 360°. The second was that acquired images were subjected to image registration to align multiple scenes into one integrated image. The data was also used to reconstruct the eyes' anatomy in a virtual reality platform.

Laser- and cryo-ablation were performed in six wt mice, six rd10 mice, six Brown Norway rats and six Chinchilla Bastard rabbits. The effect of ablation was examined after 3 weeks by funduscopic effect control and histological processing of the treated areas.

Results: 3D models of mouse, rat and rabbit eyes were successfully established. We observed atrophy of the inner retinal layers as an effect of laser- and cryo-ablation. No retinal detachment occurred in the treated areas.

Conclusions: 3D models of small animal eyes can help to simulate surgical interventions of the implantation procedure of retinal stimulators. Laser- and cryo-ablation of the insertion sites may greatly contribute to a successful implantation procedure. These projects lead to safer implantation of microsystems into the eye.

ABSTRACT BODY:

Purpose: To characterize the two-year progression of capillary closure in different diabetic retinopathy (DR) risk phenotypes in type 2 diabetes (T2D).

Methods: A prospective longitudinal cohort study (CORDIS, NCT03696810) was conducted with 4 visits (baseline, 6-months, one-year and two-year). Demographic and systemic data included age, sex, diabetes duration, lipidic profile and hemoglobin A1c (HbA1c). Ophthalmological examinations including visual acuity (BCVA), color fundus photography (CFP) and optical coherence tomography (OCT and OCTA) identified nonproliferative diabetic retinopathy (NPDR). Phenotype classification was performed, at 6-month visit, based on microaneurysm turnover (MAT, on CFP) and central retinal thickness (CRT, on OCT). Only risk phenotypes B (MAT<6 and increased CRT) and C (MAT≥6 with or without increased CRT) were included. ETDRS grading was performed at the baseline and last visit based on 7-fields CFP.

Results: 133 T2D individuals were included in the study, 81 (60%) eyes classified as phenotype B and 52 (40%) eyes as phenotype C. Of these, 127 completed the two-year follow-up with 24 (19%) developing central-involved macular edema (CIME) and 2 (1.6%) clinically significant macular edema (CSME).

At baseline, eyes with phenotype C showed more capillary closure in the superficial capillary plexus (SCP), deep capillary plexus (DCP) and full retina (FR), p<0,001) and increased FAZ area (p<0,001), indicating more advanced ischemic disease. During the two-year follow-up period, the decrease in skeletonized vessel density indicating capillary closure, occurred mainly in the DCP in both phenotypes. Positive associations with the increased capillary closure were identified with GCL+IPL thinning (representing neurodegeneration) and decreased BCVA.

Conclusions: Significant progression in capillary closure was identified by a decrease in vessel density in the deep capillary plexus occurring in both phenotypes and in the different ETDRS levels. Eyes developing CIME had less decrease in vessel density of the SCP at baseline.

ABSTRACT BODY:

Purpose: This study examined the effect of plasma rich in growth factor treatment (PRGF), on subbasal nervous plexus innervation of patients diagnosed with dry eye disease (DED).

Methods: A prospective, observational study was conducted analyzing 31eyes images of 31 patients with DED (22 women and 9 males) aged 53.4±8.5 years (range 36 to 71 years). Subjects underwent microscopy confocal in vivo (IVMC) before (bf) and after (af) 3 months of treatment with PRFG. At least 3 images of each eye were selected and the following subbasal central nervous plexus parameters were measured with ACC Metrics software: Corneal Nerve Fiber Density (CNFD), Corneal Nerve Branch Density (CNBD), Corneal Nerve Fiber Length (CNFL), Corneal Nerve Fiber Total Branch Density (CTBD), Corneal Nerve Fiber Area (CNFA), Corneal Nerve Fiber Width (CNFW) and Corneal Nerve Fractal Dimension (CNFrD). Data analysis was performed with SPSS® software for Windows 22.0 (SPSS® Inc, Chicago, IL.). The normality of the sample was checked with the Shapiro-Wilk test and the results were compared to the t test or the Wilcoxon test based on the distribution of the data. The differences were considered statistically significant for $P<0.05$

Results: The mean and their standard deviations obtained for the variables analyzed were: CNFDbf: 17,854±1,311 and CNFDaf: 18,590±1,699 fibers/mm2, CNBDbf: 21,847±2,465 and CNBDaf: 24,591±3,310 branches/mm2, CNFLbf: 12,324±0,548 and CNFLaf: 12,828±0,789mm/mm2, CTBDbf: 37,728±3,428 and CTBDaf: 41,187±5,124 branches/mm2, CNFAbf: 0.00598±0.00277 and CNFAaf: 0.00596 ± 0.00332 mm2 by mm2, CNFWbf: 0.0223±0.0030 and CNFWaf: 0.0224±0.0029 mm2 by mm2, CNFrDaf: 1,471±0,006 and CNFrDbf: 1,463±0,02. Differences versus before and after treatment values were not statistically significant in all values analyzed.

Conclusions: Nervous plexus parameters improved after treatment with PRGF, although without being statistically significant. Further studies should include a larger sample.

TITLE: Performance assessment of QobuR-RhCE – a cruelty-free in vitro cornea model

SESSION TITLE: New drugs, mechanisms of action and ocular toxicology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Chacon, N. Vázquez, M. Persinal-Medina, S. Alonso-Alonso, I. Alcalde, J. Merayo-Lloves, A. Meana, Instituto Universitario Fernández-Vega - Fundación de Investigación Oftalmológica - Universidad de Oviedo, Oviedo, SPAIN|

Commercial Relationships Disclosure: Manuel Chacon: Commercial Relationship: Code N (No Commercial Relationship) | Natalia Vázquez: Commercial Relationship: Code N (No Commercial Relationship) | Mairobi Persinal-Medina: Commercial Relationship: Code N (No Commercial Relationship) | Sergio Alonso-Alonso: Commercial Relationship: Code N (No Commercial Relationship) | Ignacio Alcalde: Commercial Relationship: Code N (No Commercial Relationship) | Jesus Merayo-Lloves: Commercial Relationship: Code N (No Commercial Relationship) | Alvaro Meana: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To replace the Draize eye irritation test (OECD Test Guideline 404), several test methods based on reconstructed cornea-like epithelium (RhCE) have been developed and adopted in the OECD TG 492. The objective of this study was to define the essential structural, functional and procedural elements and to stablish the experimental procedures and evaluate the performance assessment of QobuR-RhCE, an in-house cruelty-free RhCE model to be used for the evaluation of eye hazard

Methods: QobuR-RhCE consists in normal human corneal epithelial cells cultured at the air-liquid interface forming a stratified squamous epithelium resembling a native human corneal epithelium

Essential test method components consisting of structural, functional and procedural elements were evaluated and standardized. These components included unique characteristics of the test method (i.e. histology), critical procedural details (i.e. barrier function) and quality control measures

Performance assessment was evaluated in accordance with the revised performance standards for the assessment of proposed similar or modified in vitro reconstructed human cornea-like epithelium and the minimum list of reference chemicals was evaluated on QobuR-RhCE. In addition to standard cell viability evaluation, we describe a secondary endpoint based on Transepithelial Electrical Resistance (TEER) that could be of use to better discriminate between irritants and non-irritants

Accuracy, specificity, sensitivity and within-laboratory reproducibility (WLR) were calculated according to the OECD Performance Standards for the assessment of proposed similar or modified in vitro RhCE test methods for Eye Hazard

Results: As result, the proposed method scored 93.3% sensibility, 60% specificity, 76.7% accuracy and 96.7% WLR, providing a similar performance in comparison to the validated reference methods. The inclusion of TEER as a barrier disruption predictor provided additional information for safety assessment that could be of interest during the evaluation of particular chemical products such as borderline chemical products, colored compounds or direct MTT reducers

Conclusions: The results of this study suggest that QobuR-RhCE test method is capable of fulfilling the performance standards as described in OECD TG 492 for similar in vitro RhCE test methods for eye hazard, suggesting that QobuR-RhCE is a reliable method for predicting eye irritation

ABSTRACT BODY:

Purpose: A new deep-learning based method for automatic eye fundus diagnosis using multispectral images is proposed. The method discriminates between healthy and diseased eyes exploiting the potential of multispectral data. Among other pathologies, those mainly considered were age-related macular degeneration (ARMD), glaucoma and diabetic retinopathy as the leading causes of vision loss affecting the retina.

Methods: We analyzed 68 healthy and 68 diseased eyes from 89 subjects, 63% females and 37% males (19-95 years); only patients with retinal and/or choroidal pathologies were included. For each eye, 15 images from 400 nm to 1300 nm were acquired with a novel multispectral fundus camera. The deep learning network was adapted from that developed by Ly et al. (Ly B. et al. Lect. Notes Comput. Sc., vol. 12738, 2021) for sustained ventricular arrhythmia prediction, which involves a conditional variational autoencoder (CVAE) and a classifier model. The low dimensional features generated by the encoder are the inputs for the classifier and the decoder, which reconstructs the original sequence of 15 spectral images. These features contain information of healthy and diseased structures such as drusen, scars, edemas and neovascularization. The error between the encoder-decoder outputs is used to improve the performance of the network. The dataset was divided in training/validation (80% data) and test (20% data) datasets.

Results: The multispectral images offered very relevant information of healthy (Fig. 1 left) and diseased (Fig. 1 right) eye fundus structures to be used as input data for the proposed algorithm. The CVAE ran for 85 epochs leading to a classification accuracy of 96.43%, a loss of 0.20, a sensitivity of 92.86% and a specificity of 100.00% when discriminating between healthy and diseased fundus of the test dataset.

Conclusions: The proposed CVAE for the automatic classification of healthy and diseased eyes from multispectral eye fundus images produced an excellent outcome, highlighting the power of an encoder-decoder network and the significant information retrieved from multispectral images in the visible and near-infrared beyond 900 nm, a relatively unexplored range. Future work will focus on differentiating among pathologies by means of approaches such as attention maps, which help identifying abnormal structures.

ABSTRACT BODY:

Purpose: Structural variants (SVs) play an important role in the development of inherited retinal diseases (IRDs). Although the identification of SVs has significantly improved with the arrival of whole genome sequencing (WGS), we hypothesize that the involvement of SVs in IRDs is larger than currently anticipated. In this study, we revisited short-read WGS (srWGS) data from an IRD cohort to identify gene-disruptive SVs. Prioritization criteria were re-established to allow optimal detection and interpretation of SVs.

Methods: Optical genome mapping (OGM) was performed to improve SV detection in srWGS-negative cases. OGM identified a pericentric 173 Mb inversion in a monoallelic USH2A case. One breakpoint of this inversion is located within USH2A and disrupts the coding region of the gene. Retrospectively, the variant could be observed in srWGS data but was previously deemed false positive, mainly because of the unexpected large size of the variant. The identification of this extremely large inversion urged us to revisit our srWGS data and reestablish SV quality and filtering criteria. In total srWGS data of 425 IRD cases were screened for disruptive SVs affecting IRD-associated genes.

Results: Reanalysis of srWGS data revealed large inversion events that were overlooked during initial analyses, including a 5.8 Mb USH2Aand 4.1 Mb EYS inversion. The EYS inversion was identified in a case that was previously considered genetically solved, as this individual harbors compound heterozygous EYS variants of which one variant of unknown significance (Pt-12, Fadaie et al., PMID:34795310). The identification of the SV prompted us to revise this genetic diagnosis and emphasizes the need for complete genome analysis including SV detection. Additionally several small homozygous or heterozygous deletions were identified affecting e.g. EYS and PRPF31. The corresponding samples are now considered genetically solved.

Conclusions: Our data confirm a significant contribution of small and large SVs to the mutational landscape of IRDs and thus possibly also of other inherited disorders. The optimized prioritization protocol significantly improved SV identification from srWGS data, as it yielded several pathogenic SVs that were missed during previous analyses. This strongly suggests that more attention should be paid to SV identification and interpretation, and that the current contribution of SVs is still underestimated.

TITLE: Ophthalmic screening of young rhesus and cynomolgus monkeys in China
SESSION TITLE: Animal models of human ocular disease
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: H. He, Z. Jin, Beijing Institute of Ophthalmology, Beijing, Beijing, CHINA|
Commercial Relationships Disclosure: Hailong He: Commercial Relationship: Code N (No Commercial Relationship) | Zi-Bing Jin: Commercial Relationship: Code N (No Commercial Relationship)
ABSTRACT BODY:
Purpose: To examine the ocular refraction parameters of young rhesus and cynomolgus monkeys in the natural growth and development conditions of China.
Methods: In this cross-sectional study, 26 rhesus monkeys and 12 cynomolgus monkeys, aged 2-5 years old, were selected. Spherical equivalent (SE), axial length (AXL), anterior chamber depth (ACD), lens thickness (LT) and vitreous chamber depth (VCD) were measured by automatic computer optometry and A-scan ultrasonography. A fundus camera and OCT were also performed to exclude ocular diseases. T-test was used to compare the continued normal distribution data. Wilcox on Rank-Sum test was used to compare the non-normal distribution data. Spearman's correlation and logistic regression analysis were used to identify the factors associated with AXL. $P<0.05$ was considered statistically significance.
Results: Two rhesus monkeys were excluded for abnormal eye development. For remaining 24 rhesus monkeys, SE was 0.01±1.08 D, AXL was 19.57±0.85 mm, ACD was 3.36±0.77 mm, LT was 4.08±0.74 mm, VCD was 12.11±0.55 mm for right eyes and 0.27±1.22 D, 19.59±0.84 mm, 3.59±1.23 mm, 4.22±0.66 mm, 12.11±0.72 mm for left eyes. For 12 cynomolgus monkeys, SE was -0.52±0.92 D, AXL was 18.24±0.56 mm, ACD was 3.59±0.27 mm, LT was 3.23±0.23 mm, VCD was 11.41±0.78 mm for right eyes and -0.38±1.03 D, 17.98±0.51 mm, 3.57±0.59 mm, 3.22±0.38 mm, 11.12±0.70 mm for left eyes. The SE of 48 rhesus monkeys eyes was 0.14±1.15D and -0.45±0.96 D for 24 cynomolgus monkeys eyes, there was a significant difference between the two groups ($t=2.174$, $P<0.05$). The AXL of 48 rhesus monkey eyes was 19.80±0.95 mm and 18.02±0.99 mm for 24 cynomolgus monkey eyes, there was a significant difference between the two groups ($Z=-5.734$, $P<0.05$). The AXL of 72 rhesus and cynomolgus monkeys' eyes were included. Spearman's correlation showed that ACD, LT, ACD, strain, gender, age and weight were statistically significantly associated with AXL ($R=0.396$, 0.558, 0.717, -0.681, -0.456, -0.421, 0.657, $P<0.05$). The results of logistic regression analysis showed that ACD, LT and VCD were statistically significantly associated with a longer AXL (Beta=0.663, 0.704, 0.669, $P<0.05$).
Conclusions: This study found there was significant difference in SE and AXL between the rhesus and cynomolgus monkeys. ACD, LT and VCD were statistically significantly associated with axial elongation. The ocular parameters could provide a foundation for future research.
