Methods: Two-photon (2P) vision is triggered when light from a pulsed light source is focused on the photopigments. SS-OCT device operating at 1.6MHz rate was used to trigger 2P vision and perform OCT imaging. 1.06μm wavelength light was seen by the subjects as green. OCT data were acquired in the fovea and 7° nasally from the fovea over 5°×5°FOV. The focal plane was moved across the retina over ±312μm from the photoreceptor layer in 31 steps. 6 data sets were taken at each. The same defocus steps were implemented in a random order in the 2P psychophysics experiment. A 5° horizontal line was scanned over the retina. For each defocus the subjects were matching the brightness of a green LCD screen placed in the eye fixation path to the apparent brightness of the OCT line providing a relative measure of the 2P perception intensity. 186 trials were completed. 4 normal subjects were tested. The accommodation was blocked with Tropicamide. The study was approved by the Bioethics Committee of NCU and was adhering to the Declaration of Helsinki.

Results: The effect of defocus on the OCT images was analyzed in C-scans by calculating speckle contrast. With increasing beam defocus from the selected retinal depth, the contrast was deteriorating. Maximum contrast was occurring at different retinal depths as the focal plane was moving across the retina. 2P vision deteriorated as the beam was defocused from the layer containing photopigments. The focal plane position at which the 2P vision was strongest correlates with the maximum contrast of the inner/outer photoreceptor segments junction (IS/OS).

Conclusions: 2P vision can be used to determine in which retinal layer in the OCT images the visual photopigments are located. We were able to determine that the strongest 2P perception correlates with the maximum contrast of the IS/OS layer, demonstrating in in vivo experiment that the light-sensitive band is indeed identified in OCT images as the photoreceptors layer.

TITLE: Localized refractive changes induced by a new asymmetric intracorneal ring segment: a 3D Finite-element simulation

SESSION TITLE: New improvements in imaging and development of biomarkers

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Kling, ITET, Eidgenossische Technische Hochschule Zurich, Zurich, Zürich, SWITZERLAND|S. Kling, ARTORG, Universitat Bern, Bern, Bern, SWITZERLAND|G. García de Oteyza, 1Clínica Oftalmológica García de Oteyza, SPAIN|J. Álvarez de Toledo, R.I. Barraquer, 3Centro de Oftalmología Barraquer, SPAIN|

Commercial Relationships Disclosure: Sabine Kling: Commercial Relationship(s);Code F (Financial Support):Mediphacos; Heidelberg Engineering | Gonzalo García de Oteyza: Commercial Relationship: Code N (No Commercial Relationship) | Juan Álvarez de Toledo: Commercial Relationship: Code N (No Commercial Relationship) | Rafael Barraquer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To report the localized changes induced by an asymmetric intracorneal ring segment (ICRS) with varying base width and ring thickness in a finite-element simulation.

Methods: A 3D finite element model (FEM) was developed to simulate both a healthy and a keratoconic cornea. After creating a tunnel at 70% depth of corneal thickness, the displacements corresponding to the insertion of an ICRS of 160° arc length were enforced. Different ICRS designs were studied: (i) an asymmetric ICRS with increasing thickness (150 to 300 mm) and base width (600 to 800 mm) from one end to the other, and (ii) a symmetric ICRS with constant thickness (150, 225 or 300mm) and base width (600, 700, or 800mm) at all angular positions. The deformed geometry was assessed in terms of global curvature, sagittal curvature and optical aberrations; induced strains were assessed qualitatively.

Results: The asymmetric ICRS simulated implantation did correct vertical coma (-12.09 vs -8.34 mm), primary spherical aberration (12.98 vs 12.64 mm) and defocus (8.80 vs 8.29 mm) better than the simulated implantation of symmetric ICRS. Global curvature changes were dominated by ICRS thickness and less influenced by ICRS symmetry. Sagittal curvature showed a pattern of locally restricted flattening interior to the ring and local steepening on the opposite half of the cornea, which was more pronounced in the healthy than in the keratoconic cornea.

Conclusions: This study positions the asymmetric ICRS implantation as the most powerful vertical coma corrector. Correcting optical aberrations by ring design has the potential to prevent poor and disappointing results of ICRS surgery in asymmetric keratoconic phenotypes.

ABSTRACT BODY:

Purpose: Infliximab and biosimilar infliximab-dyyb are widely used for steroid sparing treatment of non-infectious uveitis. The purpose of this study is to report on the safety and efficacy of high-dose infliximab (INX) and biosimilar infliximab-dyyb (INXB), and immunogenicity of INXB, in the treatment of non-infectious uveitis.

Methods: A retrospective review of all patients with non-infectious uveitis treated with INX and/or INXB from 2016 to 2021 was conducted. Data collected included patient demographics, best corrected visual acuity (BCVA), INX/INXB dosage information and any adverse effects, additional immunosuppression medication, and clinical evidence of uveitis flare or quiescence. An active flare was defined as a two-step increase in the level of inflammation, and quiescence was defined as <1/2+ cell in the anterior chamber, no vitreous haze and no active posterior segment findings. Positive clinical immunogenicity was defined as an increased number of flares and/or decreased period of quiescence after starting INXB.

Results: A total of 35 patients met the inclusion criteria. The mean age was 42.6±13.6 years and 24 (69%) were female. Sixteen patients (46%) were African American, 13(37%) were Caucasian, and 5(14%) were Hispanic. Intermediate uveitis (8/35) was the most common diagnosis, followed by scleritis (7/35), anterior uveitis (7/35), and pan-uveitis (5/35). Seven patients had retinal vasculitis and 11 had a co-existing rheumatologic diagnosis (including 4 Bechet's, 3 sarcoidosis, and 2 rheumatoid arthritis). Eight patients received INXB; 4 patients were switched from INX to INXB due to insurance coverage, and 4 were started de-novo. The highest dosages of INX and INXB were 10mg/kg and 12.5mg/kg every 4 weeks, respectively. There were no significant adverse effects associated with high dose INX or INXB, and no significant uveitis flares in the 4 patients that were switched from INX to INXB.

Conclusions: The findings of this retrospective study provide insight into the safety and effectiveness of high-dose INX and INXB in the treatment of non-infectious uveitis. Biosimilar infliximab-dyyb was well-tolerated, safe, and appeared to be of similar clinical effectiveness to originator infliximab, and thus may be a potential cost-effective alternative.

ABSTRACT BODY:

Purpose: Evaluate the efficacy of AGN-190584 in extending depth of focus over the course of 30 days.

Methods: Analysis was pooled from identical phase 3 studies GEMINI 1 and GEMINI 2. Participants (N=750) were randomized to receive AGN-190584 or vehicle once daily, bilaterally for 30 days. Depth of focus was measured in diopters (D) using a phoropter in the dominant and non-dominant eyes at hours 0 and 1 post instillation on Days 1, 3, 7, 14, and 30.

Results: Mean depth of focus change from baseline in the AGN-190584 group for the dominant eye was 0.448, 0.484, 0.569, 0.663, and 0.726 D on Days 1, 3, 7, 14, and 30 at Hour 1 compared to a mean of 0.118, 0.114, 0.136, 0.178, and 0.191 D in the vehicle control group (Figure 1A). Mean depth of focus change from baseline in the AGN-190584 group for the non-dominant eye was 0.422, 0.462, 0.568, 0.664, and 0.699 D on Days 1, 3, 7, 14, and 30 at Hour 1 compared to a mean of 0.046, 0.119, 0.105, 0.156, and 0.157 D in the vehicle control group (Figure 1B). All data points for both the dominant and non-dominant eye were statistically significant at Hour 1 in favor of the active treatment group (achieving greater depth of focus). Mean letters of improvement in mesopic distance-corrected near visual acuity (DCNVA) at Hour 1 were 8, 8.9, 9.7, 10.6, and 10.8 in the AGN-190584 group on Days 1, 3, 7, 14, and 30 compared to 3, 4.1, 4.5, 5.1, and 5.3 in the Vehicle group (Figure 2). All data points were significantly higher in the AGN-190584 group compared to the Vehicle group with $p<.0001$.

Conclusions: Extended depth of focus was greater in the active treatment group compared to the vehicle control group as early as Day 1 Hour 1. Over the course of the 30 day study, a gradual increase in depth of focus was observed possibly suggesting a neuroadaptation response perhaps similar to what has been observed with Extended Depth of Focus (EDOF) Intraocular Lenses. With increased depth of focus and corresponding improvements in visual acuity from the pinhole effect there may be a learning period in which the visual cortex learns to process and utilize the EDOF. Letters of improvement in mesopic DCNVA at Hour 1 followed a similar upward trend over the 30 day studies.

ABSTRACT BODY:

Purpose: Stargardt macular dystrophy (STGD1) is the most prevalent form of inherited macular dystrophy worldwide and is therefore highly clinically relevant. To date, a variety of gene supplementation approaches have been tested to create a therapy with some reaching clinical trials. Currently, however, no treatment exists. Newer technologies, such as RNA base editors, enable correction of pathogenic G>A and T>C mutation correction. ABCA4 has ~1200 known pathogenic mutations, of which ~63% are transition mutations amenable to this editing technology. Here, we investigated the use of a Cas13-ADAR RNA base editing system to correct an ABCA4 pathogenic stop mutation, c.206 G>A; p.W60*.

Methods: These experiments used a dual luciferase reporter assay comparing expression of Firefly luciferin to constitutively expressed Renilla luciferin. Fragments of the ABCA4 gene containing the desired mutation, c.206 G>A; p.W60* were inserted in-frame between the two luciferase elements with flanking F2A sites. As the insert contains a stop codon in frame, Firefly is not expressed but when mutation correction occurs, Firefly is expressed. The assay involved a triple transfection of HEK293T cells with the Cas13b-ADAR construct, the luciferase reporter plasmid, and the gRNA plasmid, for which 15 guide variants were tested. The output is the ratio of Firefly to Renilla expression.

Results: Initial findings indicate that all 15 guides show activity relative to the mutant plasmid and the non-targeting control (NTC), $p<0.0001$. Three guides showed statistically significant levels of editing, G6, G7, and G12, relative to the mutant plasmid. However, there was no significant difference between guides. When taken as a percentage of the wild-type (WT) plasmid ie no mutation, these guides showed between 28-34% of WT expression. Further, initial transcript analysis using EditR was performed, where 43-61% of transcripts showed the WT ‘G’ instead of an 'A' with guides 6, 7, and 12.

Conclusions: Overall, previous meta-analyses show 63% of pathogenic mutations in ABCA4 are amenable to Cas13b RNA base editing, particularly as there is no PAM-site constraint. This is a first look at RNA base editing targeting a mutation in ABCA4. The findings indicate that RNA base editing shows potential in targeting an ABCA4 sequence, thus indicating a clinical potential for Stargardt disease.

ABSTRACT BODY:

Purpose: To knockout zebrafish rd3 and abca4b genes linked to retinal dystrophies and to study the effects of loss of function on retinal development and visual functions

Methods: Zebrafish rd3 and abca4b gene knockout models were generated by CRISPR-Cas9 based genome editing. The edits in the founder animals (F_0) was confirmed by T7 endonuclease assay followed by Sanger sequencing. Homozygous mutants were generated by interbreeding of heterozygotes. The wild type, $rd3^{-/-}$, $abca4b^{-/-}$ mutant fishes were euthanized at 3, 6 and 12 months of age and their retinal morphology was evaluated by immunohistochemistry. Visual assessment of these animals was performed using different functional test paradigms

Results: We report that the retina of $rd3^{-/-}$ mutants at 3 months have underdeveloped cones, with missing outer limiting membrane and lamination defects in the outer nuclear layer. Both rods and cones degenerate at later time points (6 and 12 months), with major loss in cone subtypes. In $abca4b^{-/-}$ mutants, a marked reduction in the cone nuclear layer and a corresponding increase in the number of rod nuclei suggest significant defects in cone precursor cell differentiation and maturation. The single blue cones are completely absent and the UV cones are underdeveloped with rudimentary inner and outer segments. The double cones develop normally, but undergo degeneration in older animals. In experimental paradigms to assess the feed capture response under normal photopic conditions (n=10), the mutant fishes failed to approach their feed/prey and displayed significantly higher latency than the wild type fishes. This visual behavioral deficit corroborates with the cone photoreceptor-specific developmental anomaly and retinal degeneration in mutant fishes

Conclusions: The zebrafish $rd3^{-/-}$ and $abca4b^{-/-}$ mutants show cone developmental defects and degenerative phenotypes that resemble the human disease. Defects in photoreceptor precursor cell differentiation, maturation and lamination indicates possible role(s) for these genes in the early retinal development

TITLE: High positive predictive value of fluorescein angiography contiguous perinerve retinal vascular leakage pattern for birdshot chorioretinopathy

SESSION TITLE: Clinical Uveitis & Orbital Inflammation: Etiology, Epidemiology & Clinical Assessment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Li, L. Sobrin, Ophthalmology, Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Ashley Li: Commercial Relationship: Code N (No Commercial Relationship) | Lucia Sobrin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Birdshot chorioretinopathy (BSCR) is a posterior uveitis with ovoid yellow-white choroidal lesions. If untreated, patients' vision declines, so early diagnosis is critical. While indocyanine green angiography (ICGA) is used to identify subtle lesions, ICGA is not always available. Fluorescein angiography (FA) is more common and a contiguous, perinerve retinal vascular leakage pattern has been described in BSCR patients. The purpose of this study is to determine the sensitivity and positive predictive value (PPV) of a contiguous, perinerve retinal vascular leakage FA pattern for BSCR diagnosis.

Methods: Mass General Brigham patients with a FA Common Procedural Terminology code and mention of BSCR in the free text of notes were identified. BSCR diagnosis required HLA-A29 positivity and typical lesions on fundus photos and/or ICGA hypofluorescent spots. Chart review was performed to confirm BSCR vs. other uveitis/retinal vasculitis diagnosis and symptom duration. The first FA was analyzed for a contiguous, perinerve pattern of leakage by two readers. A perinerve leakage pattern was defined as leakage primarily around the optic nerve and along the larger arcade vessels (Fig 1). We compared the rates of this FA pattern in BSCR vs. other posterior uveitis/retinal vasculitis patients using the chi-square test and determined the sensitivity and PPV of this FA pattern for BSCR diagnosis. All statistical analyses were performed in STATA.

Results: 54 BSCR patients and 42 patients with other posterior uveitis and/or retinal vasculitis were identified (Table 1). A perinerve FA pattern was more common in BSCR patients vs. patients without BSCR (53.7% vs. 4.76%, $p=3.63 \times 10^{-7}$). The sensitivity and specificity of the FA pattern were 53.7% and 95.2%, respectively. The PPV was 93.5%. BSCR patients with an FA perinerve pattern had a shorter time from symptom onset to FA vs. BSCR patients without the pattern (217 vs. 1510 days, p=.0015, t-test).

Conclusions: An FA contiguous, perinerve retinal vascular leakage pattern is a useful tool to identify potential BSCR for further imaging and serological testing. This pattern is more common when the interval between symptom onset and FA is shorter.

ABSTRACT BODY:

Purpose: A clinical trial of oral metformin for treatment of ABCA4 retinopathy was initiated at National Eye Institute (NEI) (ClinicalTrials.gov: NCT04545736). Power analysis was based on a single site (NEI) with high-resolution Optical Coherence Tomography (OCT) volume scans and equally spaced visits. To aid recruitment, an additional site with lower density volume scans is considered and unequally spaced visits introduced to account for missed visits due to the Coronavirus Disease 2019 pandemic. The aims were to determine the effects of adding a site that uses a mix of low- and high-resolution images and an increased number of natural history visits and spacing between visits on power.

Methods: A longitudinal spline regression is proposed for the primary outcome analysis, comparing growth rate in square-root transformed ellipsoid zone band loss area on OCT between the treatment phase (current study) and pre-treatment phase (natural history study), with a knot at the baseline visit when patients initiate treatment. Data were simulated using the observed mean, variance and inter-eye correlation for baseline values (from the last available pre-treatment visit) and pre-treatment growth rates from available natural history data at NEI; expected improvement in the primary outcome due to treatment; and other salient features of the study. Low-resolution values were derived from the natural history high-resolution images at NEI. The number of pre-treatment visits and spacing between visits were varied keeping other factors constant for a fixed sample size, while accounting for the appropriate resolution values at each site. The resultant power for detecting a treatment effect was estimated based on 2000 simulated datasets.

Results: The power estimated when accounting for a mix of low- and high-resolution values at the second site was the same as that with all high-resolution values at 80%. An increase from 4 to 6 pre-treatment visits increased power by 15% and increasing the spacing between visits from 6 to 12 months increased power by 6% for the study.

Conclusions: Increasing the number of pre-treatment visits and spacing between visits increased power. Derivation of low-resolution values from high-resolution images may be the reason for the high correlation between the two resolutions, which may explain why including a mix of low- and high-resolution values did not decrease power.

ABSTRACT BODY:

Purpose: In addition to cardiometabolic changes, high fat diet (HFD) feeding causes loss of corneal sensitivity loss and impairs corneal wound healing. Diet reversal (DR) strategies effectively mitigate cardiometabolic effects of HFD and corneal sensitivity loss. Their utility for attenuating the impaired corneal wounding that accompanies HFD feeding, however, remains unclear. This study used a diet-induced obesity mouse model to test the hypothesis that in addition to attenuating corneal sensitivity loss, DR also attenuates impaired corneal wound healing induced by HFD.

Methods: 6-week-old C57BL/6 male mice were fed ad libitum, either normal diet (ND) or HFD for 10 weeks. Some of the HFD-fed mice were then switched to ND (DR group), with the rest continuing their respective feeding regimen for an additional 10 weeks. Mice were weighed weekly. Visceral adiposity was measured by epididymal adipose tissue (eAT) weight and adiposity index and fatty liver by liver weight. Corneal sensitivity was measured every 5 weeks using a Cochet-Bonnet aesthesiometer. At 10 and 20 weeks of feeding, a 2-mm diameter corneal epithelial abrasion wound was created, and wound closure monitored for 30h using sodium fluorescein staining. Data were analyzed with ANOVA. Significance was set at $p \leq 0.05$.

Results: Mice fed HFD-only gained ≥110 % more body weight ($p<0.0001$) and had ≥50% more visceral adiposity ($p<0.005$) than mice fed ND-only. Fatty liver was observed in mice fed HFD-only ($p<0.001$). DR markedly reduced body weight, visceral adiposity, and fatty liver. Corneal sensitivity was significantly reduced in mice fed HFD-only, corresponding to an ≥30% increase in pressure required to elicit a blink compared to mice fed ND-only ($p<0.05$). DR halted further progression of corneal sensitivity loss. After 5 and 10 weeks of DR, there was no difference in corneal sensitivity between DR group and age-matched ND group. At both 10 and 20 weeks of feeding, corneal wound closure was delayed (~6h) in mice fed HFD-only ($p<0.002$). DR for 10 weeks returned corneal wound closure to that of age matched fed ND-only.

Conclusions: The results are consistent with the hypothesis that DR attenuates HFD-induced corneal sensitivity loss and impaired corneal wound healing.

TITLE: Interrater reliability of the refractive measurements of plano-protective eyewear using the American National Standard Institute (ANSI) Z87.1 telescope approach

SESSION TITLE: Optics: Accommodation, Lens and Ocular Biometry

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E.B. Alabi, Eye and Face Research, ICS Laboratories, Brunswick, Ohio, UNITED STATES|J. Hovis, Optometry and Vision Science, University of Waterloo, Waterloo, Ontario, CANADA|

Commercial Relationships Disclosure: Emmanuel Alabi: Commercial Relationship(s);Code E (Employment):ICS Laboratories | Jeffery Hovis: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The optical testing requirements of plano-protective eyewear in national/international standards rely on subjective evaluation methods that are negatively impacted by factors such as differences in accommodation, depth of focus, field of view, criteria and resolving power of the telescope-human observer system. These challenges can lead to significant variation in the testing results provided by different test laboratories. This study examined how observer differences could affect the results by evaluating the interrater reliability of refractive measurements of plano-protective eyewear using the ANSI Z87.1 (2020) telescope approach.

Methods: Spherical and astigmatic power measurements were performed by two experienced observers on the left oculars of 52 pairs of military plano-protective eyewear in accordance with the method described in the ANSI Z87.1 standard. The observers were blind to each other's results. Briefly, the objective lens of a calibrated 8x telescope was mounted 35 feet from a combined sunburst-resolution test pattern in a controlled laboratory environment. The data was analyzed using a multiple rater, absolute-agreement, 2-way mixed-effects intraclass correlation (ICC) model for the spherical and astigmatic power measurements. SPSS-V26 was used for all statistical analysis and $p<0.05$ was used to determine statistical significance.

Results: The mean (±SD) refractive powers of the eyewear for raters 1 and 2 were spherical -0.005(±0.019), -0.006(±0.02) and astigmatism 0.031(±0.015), 0.026(±0.016), respectively. There was good reliability between the spherical power measurements, with an ICC of 0.813 and 95% confidence interval from 0.674 to 0.893 ($p<0.001$). The reliability between the astigmatic power measurements was lower. The ICC was 0.531 with a 95% confidence interval from 0.191 to 0.729 ($p<0.005$).

Conclusions: The ANSI Z87.1 telescope approach may provide reliable estimates of spherical power between raters for plano-protectors but less reliable interrater estimates of astigmatic power when using the same telescopic system. Objective refractive power measurement methods may improve this reliability further.

ABSTRACT BODY:

Purpose: Meibomian glands (MGs) are specialized sebaceous glands (SGs) in which meibocytes are constantly replenished through proliferation and differentiation of acinar basal stem cells (SCs). However, specific markers for self-renewing SCs of MG (MGSCs) are poorly defined, and the signals that control their activity are incompletely understood. The Hedgehog (HH)/GLI pathway controls proliferation and differentiation of rat MG epithelial cells in vitro, and GLI2 is highly expressed in acinar basal cells and differentiating meibocytes but is absent from fully differentiated meibocytes in vivo. We hypothesize that MGSCs express similar marker genes as SCs of hair follicle SGs (SGSCs), and that GLI2 regulates MG homeostasis by coordinating proliferation and differentiation of MGSCs.

Methods: To determine whether the hair follicle SGSC markers Lrig1 and Lgr6, and the ubiquitous Wnt target gene Axin2, label self-renewing MGSCs we performed short- and long-term lineage tracing experiments using Lrig1-Cre^{ERT2}, Lgr6-Cre^{ERT2}, and Axin2-Cre^{ERT2} mice carrying the Rosa26^{mTmG} Cre reporter allele. To determine the effects of GLI2-mediated HH signaling on MGSCs we generated transgenic mice with forced expression of activated GLI2 (GLI2ΔN) in MG basal epithelial cells and carried out transcriptional profiling of laser captured MGs from control and GLI2ΔN-expressing mice. RNAscope and immunofluorescence were used to confirm RNA-seq results.

Results: Short-term lineage tracing data showed that Lrig1, Lgr6 and Axin2 label basal cells in MG ducts and acini. Long-term lineage tracing results showed that clones of labeled cells persist through multiple rounds of ductal and acinar renewal and give rise to differentiated progeny, identifying Lrig1+, Lgr6+ and Axin2+ ductal and acinar basal cells as self-renewing SCs. Forced expression of GLI2ΔN enhanced basal proliferation, caused expansion of Lrig1+ SCs, and lead to replacement of lipid-filled meibocytes by proliferative and poorly differentiated acinar cells. Transcriptional profiling of GLI2ΔN-expressing and control MGs revealed that forced GLI2ΔN expression caused greatly increased expression of Lrig1 and Lgr6 and suppressed expression of meibocyte differentiation genes.

Conclusions: (1) Lrig1^{+}, Lgr6^{+} and Axin2^{+} mark self-renewing basal SCs that replenish MG acinar and ductal epithelium in vivo. (2) GLI2-mediated HH signaling promotes proliferation and inhibits differentiation of MGSCs.

ABSTRACT BODY:

Purpose: The key risk factor for glaucoma is increased intraocular pressure (IOP). Glaucoma drainage devices have been developed to reduce IOP and thus stop disease progression, however, the lack of proper IOP control can lead to serious postsurgical complications. To have a better control of the IOP, we are developing an innovative magnetically actuated glaucoma implant with a hydrodynamic resistance that can be adjusted following surgery.

Methods: Our smart implant is comprised of a drainage tube and a housing element in which a magnetic “micro-pencil” valve is integrated (Figure 1A and B). The implant is made from poly(styrene-block-isobutylene-block-styrene), or ‘SIBS’.The magnetic microvalve was fabricated from SIBS containing homogeneously dispersed iron microparticles. “Micro-pencil” valves of this material were fabricated by replica molding using hot embossing, with femtosecond laser-machined fused silica glass molds (Figure 1C). The same technique was used to fabricate the housing element.

Results: Microfluidic experiments involving actuating the magnetic micro-pencil with a moving external magnet were carried out to confirm the valving function. The pressure upstream the implant, which would correspond to the IOP, was measured while the microvalve switched between open/closed states (Figure 2A). A pressure difference up to 10 mmHg was achieved which is sufficient to overcome hypotony, i.e. too low IOP (Figure 2B).

Conclusions: The femtosecond laser machining process has proved to be an effective technique to fabricate the molds for both the microvalve and the glaucoma device. The features in these molds were successfully transferred to a thermoplastic material like SIBS. Microfluidic experiments performed with the novel, magnetically actuated glaucoma implant have shown that, when in the closed state, the microvalve can provide a sufficient hydrodynamic resistance that can help to overcome hypotony.

ABSTRACT BODY:

Purpose: Report non-clinical in vivo expression data and efficacy in the mouse laser-induced choroidal neovascularization (CNV) model after subretinal delivery of GT005, an investigational AAV2 gene therapy expressing recombinant human complement factor I (hCFI).

Methods: HEK-293 cells were transduced with GT005 to confirm expression of hCFI at both the mRNA and protein levels. Expressed CFI protein function was evaluated with a C3b cleavage assay. In rodent expression studies, GT005 was unilaterally, subretinally injected in mice at $2x10^7$-$2x10^8$ GC/eye. 28 days later ocular fluids and tissues were collected for expression analyses including qRT-PCR, ELISA, in situ hybridization and immunohistochemistry. In laser CNV model studies, GT005 or mGT005, which encodes for murine CFI, was subretinally injected in mice at $2x10^7$-$2x10^8$ GC/eye 28 days prior to lasering. Negative control animals received empty vector at $2x10^8$ GC/eye. Positive control mice received 80 ug aflibercept intravitreally after lasering. CNV leakage was assessed 4 and 7 days post-lasering by optical coherence tomography (OCT) and fluorescence angiography (FA). Lesion area was evaluated by staining RPE/choroid flatmounts with FITC-conjugated isolectin-B4 7 days after lasering.

Results: Expression and secretion of functional, processed hCFI was demonstrated in vitro after transduction of HEK-293 cells with GT005, and in vivo after subretinal injection of GT005 to mice. hCFI mRNA and protein were mainly localized in the outer retina and was enriched in the bleb area. In the CNV model, no significant difference was detected in CNV leakage at days 4 and 7 in mice treated with GT005 or a murine version (mGT005) compared to the negative control. However, both showed a dose-dependent effect in reducing CNV lesion size which was statistically significant at the $5x10^7$ and $2x10^8$ GC/eye doses (mGT005: P=0.040 and P=0.011 respectively).

Conclusions: GT005 leads to expression of functional CFI protein in vitro and in vivo in mice, localizing to the target tissues that are affected in dry age-related macular degeneration (AMD). GT005 shows therapeutic efficacy in the mouse CNV model, a model of wet AMD in which complement activation plays a key pathophysiological role. These data support the therapeutic potential of GT005 for the treatment of GA by complement system modulation.

ABSTRACT BODY:

Purpose: Subvisible, non-damaging retinal laser treatments are currently used for several retinal diseases. Due to strong inter- und intraocular variations of light scattering and pigmentation at the fundus the laser-induced temperatures differ widely. In order to overcome these uncertainties we developed an optoacoustic (OA) method allowing to determine and control the temperature rise during treatments. For treatment the currently used green and yellow wavelengths primarily address the retina and the retinal pigment epithelium (RPE) due to the strong melanin absorption in the RPE. The involvement of the choroid in the pathogenesis of chorioretinal diseases has been increasingly recognized, and the choroid is now being discussed as a target for treatment. Since IR wavelength are well suited for a choroidal thermal stimulation, this work attempts a combination of green and IR wavelength to achieve non-damaging stimulation of the retina, RPE and also the choroid with a proper temperature control.

Methods: Porcine RPE/choroid/sclera explants were placed in a cuvette filled with physiological saline solution. The specimen were irradiated via a laser slitlamp by a Q-switched Nd:YLF-laser (1053 nm and 527 nm wavelength) with a repetition rate of 10 kHz and pulse duration of 50 ns for 100 ms on a spot diameter of 200 µm. Acousto-optic modulators were used to modulate the laser pulse energies and clock ratio of the two wavelengths. OA transients induced by each laser pulse were recorded with an ultrasonic transducer embedded in a contact lens for temperature monitoring.

Results: OA transients were detected for every laser pulse of both wavelengths. Their ratios indicated a stronger absorption behind the RPE when combining both wavelengths compared to the 527 nm applied alone. For example, under the same average power of 35 mW, the maximum temperature of the RPE was measured to be 58,4 °C when irradiating with 527 nm and 3,5 µJ pulse energy, compared to 34,9 °C when 527 nm and 1053 nm were combined with 2,5 µJ and 4,5 µJ pulse energy, respectively, at 1:1 clock ratio.

Conclusions: This study is a first step towards a deeper thermal stimulation of the retina, RPE and choroid under proper temperature control. Future work will focus on temperature estimation at the choroid by the IR pulses. Further a feedback controlled irradiation with proper active temperature control will be implemented.

ABSTRACT BODY:

Purpose: Albinism has significant genetic and phenotypic heterogeneity and can be difficult to distinguish from other causes of infantile nystagmus, particularly in a paediatric setting. Children with albinism are at risk of poor visual development and hence require timely diagnosis. We sought to identify clinical parameters specific to albinism, in order to contribute to the growing need for international consensus guidelines for the diagnosis of this complex condition.

Methods: Patients with nystagmus presenting to a paediatric ophthalmology department were screened in centres including Denmark, Korea, Netherlands, United Kingdom and the United States. Patients were stratified according to diagnosis through genetic confirmation. Ophthalmic examination, foveal hypoplasia (FH) and visual evoked potentials (VEP) were recorded. Receiver operating characteristic curves were plotted to assess the diagnostic ability of clinical parameters. Principal component analysis was used to identify unique-most variables. A binary logistic regression model was used to identify a single combined metric.

Results: 249 patients were included, of which 63% had molecular confirmation of albinism. Other diagnoses included FRMD7 (17%), PAX6 (8%), achromatopsia (8%) and congenital stationary night blindness (4%). Parameters with a positive correlation with albinism included fundus hypopigmentation (AUC=0.91), transillumination defect (TID) (AUC=0.91), FH (AUC=0.82) and VEP misrouting (AUC=0.73). Parameters with weak correlation included stereopsis (AUC=0.64), visual acuity (AUC=0.53) and altered head position (AUC=0.43). Regression modelling identified a single metric incorporating FH, TID and VEP with the highest predictive power (AUC=0.96). Removing VEP from the model revealed an AUC of 0.95.

Conclusions: Combining FH and TID may provide sufficient diagnostic power in suspected albinism and dismiss other causes of congenital nystagmus. VEP misrouting may only provide a marginal improvement in diagnostic ability.

TITLE: Acute Posterior Vitreous Detachment
SESSION TITLE: Vitreoretinal surgery/VR Interface/PVR
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: M. Driban, J. Chhablani, Department of Ophthalmology, University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania, UNITED STATES|
Commercial Relationships Disclosure: Matthew Driban: Commercial Relationship: Code N (No Commercial Relationship) | Jay Chhablani: Commercial Relationship(s);Code C (Consultant/Contractor):Salutaris, Novartis, Allergan
ABSTRACT BODY:
Purpose: Posterior vitreous detachment (PVD) is a common ocular condition with myriad risk factors and complications that remain incompletely studied. In this retrospective clinical study, we analyzed the typical presentation of acute PVD, as well as the prevalence of various treatable findings and changes in the same and fellow eye.
Methods: This was a retrospective analysis of medical records from 2,346 patients with acute PVD. Patients with new cases of acute PVD were included in the study. Acute PVD was defined as patients presenting with new symptoms of PVD, including flashes or floaters in one or both eyes, or patients with diagnosis of PVD in their code. Patients with a history of any associated ocular disease, prior PVD, and intraocular injections were excluded. Descriptive statistics were generated on age, sex, contact date, visual acuity, and slit lamp and fundoscopy findings. Multivariate regressions were used to generate odds ratios with 95% confidence intervals (CI) to quantify associations between variables, such as demographics, seasonal presentation, and complications.
Results: A total of 4,692 eyes from 2,346 patients were analyzed. The majority of patients were female (60.5%) with an average age of 62.8-years-old. Mean visual acuity was 20/30 equivalent. Overall, 605 patients (25.8%) had any additional ocular finding on fundus exam, including pigmentation (N=184, 7.8%), lattice degeneration (N=158, 6.7%), tear (N=131, 5.6%), and hole (N=131, 5.2%). Unilateral retinal detachment was present in 26 patients (1.1%) and these patients demonstrated a similar rate (26.9%) of additional ocular findings compared to the entire sample size. Female sex (OR 1.21, 95% CI 1.03-1.43, p = 0.020) was independently associated with presentation during spring or summer.
Conclusions: In this study we describe the risk factors and prevalence of peripheral lesions and complications in acute PVD. We show associations between female sex and presentation during the spring or summer. Additionally, we highlight the incidence of previously unstudied ocular findings in acute PVD, which may be useful in predicting development of other ocular conditions or for identifying patients at risk for future PVD.

ABSTRACT BODY:

Purpose: Stargardt disease STGD1/ABCA4 retinopathy (ABCA4R) is the commonest childhood onset inherited retinal dystrophy and can show marked phenotypic heterogeneity and is associated with a number of phenocopies. The characteristic phenotypic features of STGD1 are macular atrophy, flecks, and peripapillary sparing. In this study we aim to describe the broader phenotype in a cohort of 178 patients with ABCA4R to characterise further the spectrum of phenotypic features.

Methods: Patients with variants in ABCA4 were identified from the Oxford Medical Genetics laboratory database. Patients were only included if they had at least one retinal image, a minimum of 2 variants in ABCA4, or 1 variant with a phenotype consistent with an ABCA4R. Phenotyping included: colour fundus imaging (Optos or Topcon), fundus autofluorescence imaging (FAF), and optical coherence tomography (OCT). FAF imaging was primarily used to describe the phenotypic features in this study.

Results: The cohort included 151 patients with at least 2 ABCA4 variants and 27 monoallelic patients with phenotype consistent with ABCA4R. Typical phenotypes associated with ABCA4R were identified in 136 biallelic and 25 monoallelic patients and included: abnormal foveal AF with a ring of raised AF and minimal flecks; flecks but no macular atrophy; macular atrophy surrounded by a well confined ring of flecks; macular atrophy with minimal flecks; mottled macular AF; macular atrophy with flecks within the posterior pole; well defined lesion of macular atrophy surrounded by a heterogenous background AF; patchy areas of macular atrophy with a heterogenous background AF; and widespread chorioretinal atrophy. Atypical phenotypes were identified in 15 biallelic patients and 2 monoallelic patients and included macular atrophy surrounded by a ring of raised AF, heterogenous AF throughout the retina, cone rod dystrophy, retinitis pigmentosa, panretinal atrophy, punctate inner choroidopathy type appearance, and atypical foveal changes.

Conclusions: We present an ethnically diverse British cohort of 178 patients with a diagnosis of an ABCA4R demonstrating the wide spectrum of phenotypic features including atypical cases. Recognition of these different phenotypes in ABCA4R is key in diagnosis, with genetic confirmation, and will be important in selection of patients for inclusion for future therapeutic intervention.

ABSTRACT BODY:
Purpose: Deep learning can detect and classify age-related macular degeneration (AMD), which are critical to patient monitoring and prognosis. Traditionally deep learning requires vast amounts of labelled data, which are time-consuming and costly to acquire. In this work we leverage self-supervised pretraining of deep-learning models to achieve high accuracy in classifying AMD while using fewer labelled training data.
Methods: Experiments were conducted on a dataset of 57,875 OCT images from the Southampton Eye Unit collected by the PINNACLE consortium. We trained multiple ResNet50 neural networks to classify between healthy eyes and early/intermediate AMD, and between early/intermediate and late AMD. For both tasks we measured the degradation in classification accuracy when limiting the amount of available training labels. We then repeated these experiments but used self-supervised pretraining, which learns from all images in the dataset even in the absence of labels. To this end, we used two different self-supervised pretraining methods: BYOL, which aims to maximize agreement between different views of the same image, and SimCLR which additionally aims to maximize disagreement between two views from different images.
Results: As expected, classification performance degraded as the number of training labels decreased. Without pretraining, classification between early/intermediate AMD and healthy eyes degraded from 0.92 to 0.64 area under curve (AUC) as the number of training labels decreased from 8299 to 20. Self-supervised pretraining restored performance, and furthermore elevated accuracy when all labels were available. Methods pretrained with BYOL/SimCLR decreased from 0.94/0.91 to 0.74/0.68 AUC for 8299 and 20 training labels respectively. Similar trends were observed when classifying between late and early/intermediate AMD.
Conclusions: Self-supervised pretraining significantly boosted the ability of deep learning to classify AMD in OCT images, especially when only small amounts of data were available as is typical in medical imaging. This motivates a

shift in focus towards procuring fewer, higher quality annotations and unlocks the benefits of deep learning for smaller datasets.

ABSTRACT BODY:

Purpose: To evaluate safety and efficacy of topically administered 0.024% latanoprostene bunod ophthalmic solution (Vyzulta™; Bausch & Lomb) in glaucomatous dogs with ADAMTS10-open-angle glaucoma (ADAMTS10-OAG).

Methods: Twenty glaucomatous Beagle dogs with ADAMTS10-OAG, 10 females and 10 males, between the ages of 2.4-4.9 years (median: 2.7 years) were used. In each dog, left or right eye was randomly selected for latanoprostene bunod treatment. Contralateral eyes were treated with generic 0.005% latanoprost ophthalmic solution with well established canine efficacy and safety. Part 1 (n = 15 dogs) consisted of a 4-week study with diurnal intraocular pressure (IOP) and pupil diameter being the main efficacy outcome measures: Following a baseline period (Week 1), dogs were treated once (q24h, Week 2) and twice daily (q12h, Week 3); Week 4 served as washout period. In Part 2 (n=11 dogs), IOPs were monitored for 8 hours following a 1-time drug administration. Safety was assessed by routine ophthalmic examination, gonioscopy and pachymetry. Differences in least square means of quantitative outcome measures were compared between latanoprostene bunod and latanoprost treated eyes by linear Gaussian model.

Results: Mean baseline IOP was 30.0 ± 3.1 mmHg (mean ± SEM). While there were significant decreases in IOPs and pupil diameters for both treatments ($p < 0.0001$), there were no differences in IOP treatment effects between latanoprostene bunod and latanoprost (q24h: 15.1 ± 1.3 mmHg vs. 15.9 ± 1.3 mmHg; q12hr: 13.1 ± 1.1 mmHg vs. 14.1 ± 1.1 mmHg). Furthermore, there was no difference in short-term IOP effect over 8 hours between the 2 drugs. Both latanoprostene bunod and latanoprost administration resulted in mild to moderate conjunctival hyperemia.

Conclusions: Once or twice daily administration of latanoprostene bunod and latanoprost were equally effective in lowering IOP in glaucomatous dogs with no detectable treatment effect resulting from latanoprostene bunod's nitric oxide (NO) donating moiety.

ABSTRACT BODY:

Purpose: Previous evidence suggests serial ‘non-attenders’ to clinic appointments are more likely to be socially disadvantaged, afflicted by poor health, and have higher use of emergency healthcare. This report seeks to quantify and characterise factors associated with non-attendance within a population of patients for face-to-face (F2F) outpatient appointments, pre—and during the COVID-19 pandemic.

Methods: This was a retrospective cohort study of all National Health Service (NHS) patients, aged 18 and over, who were newly referred to Moorfields Eye Hospital NHS Foundation Trust, a tertiary ophthalmic institution consisting of a principal central site, four district hubs and five satellite clinics in London between January 1st 2019 and November 1st 2021. We included patients referred to the adnexal, cataract, general ophthalmology, glaucoma and medical retina services. Only the patient’s first encounter (attendance or non-attendance) with MEH was included.

Results: A total of 70,328 of first appointments were F2F (mean age pre-pandemic: 54 and pandemic: 56 – IQR: 30 for both cohorts). The non-attendance rates for face-to-face pre-pandemic were 9.0% and face-to-face pandemic were 10.5%. Male sex (adjusted odds ratio pre-pandemic: 0.85, 0.80-0.91 and pandemic: 0.89, 0.82-0.97), greater levels of deprivation (adjusted odds ratio pre-pandemic: 0.89, 0.88-0.91 and pandemic: 0.91, 0.90-0.93), incompletion of self-reported ethnicity and a previously cancelled appointment (whether instigated by the hospital or patient) were strongly associated with non-attendance within this mode of care delivery ($p<0.01$).

Conclusions: Overall, male sex and greater socioeconomic deprivation are associated with poorer attendance. More specifically, non-attendance was higher amongst patients with self-reported Black ethnicity and early morning appointment times. Older patients, self-reported Caucasian ethnicity, those with diabetes and later appointment times were associated with higher levels of attendance. Further study is warranted to evaluate whether enhanced surveillance of certain cohorts could improve non-attendance rates in these groups.

TITLE: Bidirectional association of glaucoma and chronic kidney disease: a systematic review and meta-analysis of two million participants

SESSION TITLE: Epidemiology of Glaucoma

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: F. Ng, H. Song, B. Tan, C. Teo, National University Singapore Yong Loo Lin School of Medicine, Singapore, SINGAPORE|

Commercial Relationships Disclosure: Faye Yu Ci Ng: Commercial Relationship: Code N (No Commercial Relationship) | Harris Jun Jie Muhammad Danial Song: Commercial Relationship: Code N (No Commercial Relationship) | Benjamin Kye Jyn Tan: Commercial Relationship: Code N (No Commercial Relationship) | Chong Boon Teo: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Glaucoma and chronic kidney disease (CKD) are both prevalent and debilitating conditions, with pathogenic pathways such as oxidative stress and fluid dysregulation common to both diseases. However, previous studies have yielded conflicting results regarding the association between them. We aim to determine if there is a bidirectional relationship between glaucoma and CKD, thus providing a comprehensive and evidence-based summary of their association.

Methods: We searched PubMed, Embase and Cochrane Library from inception until 15 June 2021. We included observational studies, published as full-length English articles in peer-reviewed journals, reporting on glaucoma and CKD as either exposure or outcome. We pooled odds ratios using random-effect meta-analysis and conducted subgroup meta-analyses and univariate meta regression. We assessed risk of bias using the Newcastle-Ottawa Scale (NOS) and quality of evidence using the GRADE framework. Our article is PROSPERO-registered and adherent to both PRISMA and MOOSE guidelines.

Results: We identified 3 retrospective cohort studies and 12 cross-sectional studies from 2,428 records and included 1,978,254 participants. Risk of bias was low to moderate. Participants with CKD at baseline had higher pooled odds of glaucoma (odds ratio[OR]=1.18, 95% confidence interval[CI]=1.04-1.33, I^2=66%, N=12) compared to participants without CKD. The association remained significant in the subgroups of longitudinal studies, diabetic participants, East Asian studies and primary open-angle glaucoma. In the reverse direction, participants with glaucoma at baseline had over two-fold higher odds of incident CKD compared to participants without glaucoma after 10-15 years of follow-up in longitudinal studies (OR=2.44, 95% CI=1.79-3.33, I^2=74%, N=2). All studies adjusted for age and sex, while most studies adjusted for comorbidities such as diabetes and hypertension. Meta-regression identified ethnicity (East Asians vs Non-East Asians) as a significant effect moderator. Associations were robust to trim-and-fill adjustment for publication bias, single-study influence and cumulative meta-analyses.

Conclusions: Our meta-analysis suggests a bidirectional association between glaucoma and CKD, particularly among East Asians. Further studies are required to elucidate the underlying mechanisms and account for the differential association by ethnicity.

ABSTRACT BODY:

Purpose: Negative dysphotopsia (ND) is a photic phenomenon affecting pseudophakic eyes where a dark crescent or shadow is perceived in the peripheral temporal visual field. Although is it understood that the edge of the intraocular lens (IOL) and the space between the IOL's optic and the posterior iris are involved, the exact etiology remains unclear especially with respect to its clinical manifestation. The purpose of the study was to develop a physical model of the pseudophakic eye and to record ND at the retinal plane in a variety of conditions.

Methods: The eye model had realistic dimensions with a cornea made of PMMA (R=7.73mm, Q= -0.24) an iris at a depth of 3.55mm and an IOL holder with variable distance (0.5 to 1.5mm) from the pupil, simulating a pseudophakic anterior chamber depth (pACD) ranging from 4.05 to 5.05 mm. The eye was filled with distilled water. A board level camera (DFM 72BUC02-ML, Imaging Source, Germany) in a water-tight container with a 200μm glass window was used to record the retinal images. Negative dysphotopsia was investigated for two different types of IOLs (Acrysof SA60AT, Alcon, TX USA and ArtIOL, Art55, Voptica SL, Murcia, Spain), for two different pACD values (4.05 and 5.05 mm) and for two different pupil diameters (3 and 6 mm).

Results: A characteristic crescent appeared on the retina when a point source was positioned at an angle of 75 degrees with respect to the optical axis of the eye. The phenomenon was prominent for a pupil diameter of 6 mm and pACD of 5.05 mm. For 3 mm pupil diameter and for shallower pACD (4.05 mm) the phenomenon was not observed. When imaging an extended uniform field, a dark band having a width of approximately 4 degrees and brightness reduced at 74% of the field brightness appeared at the vicinity of 75 degrees. The crescent was less prominent for the meniscus lens (ArtIOL), presumably due to the smaller gap between the IOL edge and the posterior iris.

Conclusions: A peripheral crescent, corresponding to light that misses the IOL's optic results to the formation of a darker zone, between the light that is focused by the IOL and light that is missing the IOL. ND appeared only for large pupils and deep chambers and was reduced for inverted meniscus IOLs. However in clinical practice where IOL tilt and decentration can occur, ND could be manifested for smaller pupil diameters and pACD.

TITLE: Therapeutics of stem cell secretome in dexamethasone-induced ocular hypertension mice

SESSION TITLE: Aqueous humor dynamics & Trabecular Meshwork

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: Y. Du, A. Kumar, Ophthalmology, University of Pittsburgh, Pittsburgh, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Yiqin Du: Commercial Relationship(s);Code P (Patent):University of Pittsburgh | Ajay Kumar: Commercial Relationship(s);Code P (Patent):University of Pittsburgh

ABSTRACT BODY:

Purpose: Glaucoma is a leading cause of irreversible blindness worldwide. Stem cell-free therapy using stem cell secretome offers great hope for vision restoration. We investigated the protective roles of secretome from trabecular meshwork (TMSC) in dexamethasone (Dex) treated trabecular meshwork (TM) cells and Dex-induced ocular hypertension (OHT) mice.

Methods: Primary human TM cells were treated with 100nM Dex for 5 days and added TMSC secretome to be treated for another 5 days. For Dex-induced OHT, adult C57BL/6 mice were periocularly injected with 20 µl of Dex-acetate (Dex-Ac) at 10 mg/ml weekly for four weeks. Then the mice were periocularly injected with concentrated secretome from TMSC or corneal fibroblasts as well as Dex-Ac weekly for another 4 weeks and waited for 2 weeks before sacrifice. Immunofluorescent staining and qPCR were used to quantify expression levels of glaucoma-associated proteins/genes Myocilin (MYOC) and ANGPTL7. Intraocular pressure (IOP) was measured weekly by I-care tonometer. Statistical analysis was done using one-way ANOVA followed by Tukey posttest. $P<0.05$ was set as statistically significant.

Results: Both TMSC and fibroblasts showed high viability after 48-hr serum starvation and secretome harvesting, indicating good quality of secretome collection. TM cells had increased Myoc expression after Dex treatment, which was prevented and reversed by TMSC secretome. The increased expression of both Myoc and ANGPTL7 in response to Dex was significantly reduced by all three TMSC secretomes. CHI3L1 expression was diminished after Dex, which was preserved after TMSC secretome treatment. In OHT model, periocularly injected TMSC secretome successfully reduced the IOP elevation from week 4 (13.8±1.8 mmHg) after a single dose, as compared to Dex-treated mice (15.8±3.3 mmHg) and maintained to normal range till the end of the experiment at week 8, similar to that of vehicle controls. Fibroblast secretome was not able to reduce IOP (16.2±2 mmHg and 15.3±1.4 mmHg on week 4 and week 8 respectively), that was at similar levels to Dex-treated mice (week 4, 15.8±3.3 mmHg and week 8, 15.2±1 mmHg). Retinal ganglion cell function was preserved as evaluated by pattern electroretinography.

Conclusions: TMSC secretome protected both Dex treated TM cells and OHT mice by periocular injection. It opens an avenue for stem cell-free therapy for glaucoma with minimum invasive procedures.

ABSTRACT BODY:

Purpose: Gene therapy for inherited retinal diseases often fails to halt degeneration, likely due to intervening too late in the course of the disease or by not correcting enough cells. However, it is unclear whether any visual improvement following therapy will be retained by surviving cells for a long period of time. Our goal was to characterize how rod and cone visual transmission is impacted by early (30% rod loss), middle (50% rod loss), and late (70% rod loss) treatment timepoints in a mouse model of Retinitis Pigmentosa up to 6 months following therapy. Retinal function was measured by multielectrode retinal ganglion cell recordings, and useful vision assessed by a vision dependent task: a mouse's ability to track and capture a cricket.

Methods: We measured responses of retinal ganglion cells (RGCs) to artificial and natural visual stimuli under mesopic and photopic conditions using a mouse model of Cngb1-RP. In this model, rod death is a relatively slow process: rods progressively die until all are lost at 6-7 months. Importantly, this model can undergo genetic correction with tamoxifen, allowing us to measure responses from a model of a perfect gene therapy irrespective of inefficiencies in delivery, virus, or dosage. We measured RGC responses in animals at 1 month intervals following early, mid, or late treatment and compared responses to RGC recordings from WT and untreated mice out to 7 months. The cricket hunting behavior task was performed on treated, untreated, and WT mice by placing a mouse in a transparent recording box and introducing a cricket. Time to capture was compared across groups. Histology was also performed to correlate visual function to retinal structure.

Results: Untreated rods are non-functional in this model, however, gene replacement restored rod transmission at all treatment timepoints and persisted. In mid-treatment timepoints, rod responses increased quickly following therapy, reaching maximal information fidelity 2 months after treatment. Cone function also improved in response to gene replacement, but took >3 months. These responses were true for both cricket capture behavior and electrophysiology.

Conclusions: There is a known dependence of cone survival on rod survival: rod disorders such as Retinitis Pigmentosa also lead to eventual cone loss. However, this is the first instance of cone rescue also being dependent on first restoring rod structure and function.

ABSTRACT BODY:

Purpose: With the rising prevalance of myopia, there is increasing need for validated screening tools to identify and monitor refractive error in pediatric populations. We conducted a prospective clinical study to compare the spherical equivalent (SE) refractive error measurements of a newly developed mobile app to manifest refraction (MR) and subjective cycloplegic refraction (SCR) performed in clinic.

Methods: Data was collected from 54 myopic subjects (61.1% female, mean age 11.7 ± 3.22 years). Eyes with astigmatism more than -1.75D were excluded. Refractive error was measured with the app before cycloplegia. Using a selfie camera to measure the viewing distance in real time, the app displayed three distance-compensated Tumbling E letters in 20/25 angular size. The subject's refractive error was estimated based on the far point distance at which they correctly identified the orientation of 2/3 letters. Pearson correlation (R) and Bland-Altman 95% limits of agreement were used to compare app measurements to clinical refraction.

Results: For the 95 eyes enrolled, the SE refractive error range was -0.75D to -6.38D as measured by SCR. 6 eyes with a difference in app measurement and MR more than 1.5x IQR (0.795) were outliers and excluded. The app measurement was highly correlated with MR ($R= 0.93$, $p<0.001$), as well as SCR ($R= 0.93$, $p<0.001$). A paired t-test showed that the app systematically underestimated SE refractive error by -0.306D ($p<0.001$) as compared to MR, and by -0.242D ($p<0.001$) as compared to SCR. The Bland-Altman 95% limits of agreement were [-1.46, 0.846] for the app and MR and [-1.37, 0.887] for the app and SCR. Clinically relevant limits of agreement are ±0.50D and 51.6% of eyes were within 0.50D of difference.

Conclusions: The moderate Bland-Altman agreement suggested that one-time measurement with the app may not be sufficiently accurate for some myopic patients. However, the high correlation and small systematic bias of the app with both MR and SCR may support its potential for screening for the presence of myopia and its relative progression in pediatric populations, if the agreement can be improved, for example, by repeated measurement. The similarities in comparing the app to MR and SCR demonstrated that the app could be used without cycloplegia and therefore operated by non-professionals.

ABSTRACT BODY:

Purpose: To evaluate the safety and efficacy of endoscopic vitrectomy (Endo-Vit) for stage 4 retinopathy of prematurity (ROP)

Methods: Consecutive non-comparative case series of surgery of all UK cases for traction RD in ROP (stage 4) between 2015-2021. Inclusion criteria was stage 4A or 4B ROP. Stage 5 cases were excluded. All cases had primary simultaneous high-resolution 19 gauge endoscopy and microscope-based visualisation, with standard 23 gauge vitrectomy

Results: Included were 99 eyes of 57 patients. Mean gestational age, birth weight and follow-up were 25.9 weeks, 789g and 27.4 months, respectively. RD stage was 4A in 54 eyes, 4B in 34 eyes and 4B/5 in 11 eyes. Prior laser was done in 84%, and intravitreal bevacizumab in 28%. Median number of surgeries was 1. Primary retinal re-attachment was 82% overall, 90% in stage 4A, 85% in stage 4B, and 36% in stage 4B/5. Primary lensectomy was required in 0%. Iatrogenic break occurred in 4 eyes. Postoperative cataract occurred in 4 eyes, all of whom developed 12 months after surgery. Visual acuity data was available in 92%, with overall fix and follow vision in 71%, logMAR 2.0 or better in 52%, and logMAR 1.0 or better in 29%.

Conclusions: Endoscopic visualisation significantly reduces the need for primary lensectomy in complex traction retinal detachment in retinopathy of prematurity, with favourable anatomic outcomes. It is a useful adjunct to microscope-based visualisation.

ABSTRACT BODY:

Purpose: Topically administered therapies remain a standard of care for many ocular diseases. Frequent administration, as well as achieving stable therapeutic levels through the night poses a central challenge for effective maintenance of ocular health. As a result, the need to develop treatments with improved effective durations has gained significant attention. The purpose of this study was to investigate if a limited solubility therapeutic agent like dexamethasone (DEXA) could be efficiently encapsulated in Silica Matrix and demonstrate controlled release with a single 30 µL eye drop for 24 hours.

Methods: Two DEXA sustained release formulations, #09D and #12D) were tested. Dexamethasone was encapsulated in the Silica Matrix through sol-gel chemistry. New Zealand Rabbits were administered once with a single 30µL eyedrop in each eye. Tear samples were collected using a capillary up to 48 hours post dosing, and analyzed for DEXA by LC-MS/MS analysis from pooled left and right eye tear samples. In vitro DEXA and Si dissolutions were studied in sink condition and cumulative release as well as total dissolution and content was analyzed by spectrophotometry and HPLC. Intra ocular pressure (IOP) was monitored with Tonovet+ device.

Results: DEXA was successfully encapsulated in both silica microparticle-silica hydrogel formulations. In vivo pharmacokinetic data demonstrated extended controlled release of DEXA in rabbit tear fluid for 24 hours. Treatment was well tolerated and no changes in IOP were detected.

Conclusions: Efficient encapsulation of low solubility therapeutic agents like DEXA is possible by DelSiTech^{TM} Silica Matrix technology ensuring extended release in-vivo for 24 hours.

TITLE: Combined anti-VEGF injections and thermal laser photocoagulation for peripapillary and extrafoveal choroidal neovascular membranes in age related macular degeneration

SESSION TITLE: Macular diseases/Macular edema/Functional testing/evaluation/Laser

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Will, Ophthalmology, Abington Memorial Hospital, Abington, Pennsylvania, UNITED STATES|A. Will, William Penn Charter School, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Daniel Will: Commercial Relationship: Code N (No Commercial Relationship) | Alexandra Will: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Patients with neovascular AMD often require high treatment burden with first-line management using anti-VEGF injections. Lesions primarily located away from the central macula may be amenable to initial treatment with injections, reducing lesion size, followed by thermal laser destruction to maintain control of the disease with a reduced injection burden.

Methods: A retrospective electronic chart review was conducted on a series of 27 patients who had choroidal neovascularization (CNV) related to wet AMD and were treated initially with anti-VEGF injections and subsequently with thermal laser treatment. Demographics, lesion characteristics, clinical course, and outcomes were recorded. Patients were treated with laser if the lesions were relatively small in size and favorably positioned to minimize short-term and long-term risk of vision loss related to treatment.

Results: Chart review assembled 27 patients who were treated with anti-VEGF injections followed by thermal laser (24 peripapillary, 3 extrafoveal). 74% of patients had ceased injections following laser treatment at patient's last follow-up. Mean age was 80 years old (range 63-94). Average time without treatment following laser was 25.26 months (range 3-53 months): 4 patients had recurrent CNV and 3 developed new CNV during follow-up period. 89% of patients had stable or improved visual acuity. 3 patients had improved vision (gain of 2 lines or more), 20 had stable vision (VA within 1 line +/- of baseline acuity), 3 patients had worsened vision (vision loss of 2 lines or greater: 2 GA, 1 new CNV). No patients had reduced acuity due to laser. 33% (9 patients) had fovea involving disease of the fellow eye with reduced vision or need for anti-VEGF injections.

Conclusions: Carefully selected patients with appropriate lesion size and location may benefit from anti-VEGF treatment followed by thermal laser photocoagulation with a high percentage of patients maintaining vision without need for continued injections. A substantial number of patients can experience recurrent or new CNV and many have significant bilateral disease.

ABSTRACT BODY:

Purpose: The ability to interpret the artificial visual stimulus created by the Argus II retinal prosthesis can vary with the user's perceptual capabilities and the scene captured by the device's camera. Outcomes and proficient use may be improved through the introduction of filters as a rehabilitation tool. A mountable filtering system was developed allowing the user to transform the visual stimulus captured by the camera. This study investigates the feasibility of incorporating a filter as a tool to improve scene and pattern recognition.

Methods: Using CAD software and 3D printer, filter holders and an eyewear mount were developed (Fig. 1). During inpatient rehabilitation sessions, Eschenbach tints (17, 21, 31) were held over the user's camera to determine if visualization was improved. Gel film filters with comparable transmission characteristics (green 45%, plum 19%, grey 25%, clear control 99%) were mounted on holders with tactile marks for ease of identification. Each mount can hold up to 2 filters permitting the user to explore and combine filters. The filter system was deployed remotely to one Argus II user with the usage instructions and testing protocol. Filter comparisons were completed both indoors (lit/darkened room) and outdoors (sunny/overcast). The indoor scene consisted of observing a PC screen with a single white line in various orientations. The outdoor scene consisted of visualizing colored 2.5-inch balls with either grass or asphalt background. Filters were graded on a scale: -2 to +2 with zero indicating no change and the -/+ scores indicating decreases or increases in perception. The user was naïve that one filter was a control (Fig. 2).

Results: Indoor visualizations of the computer screen targets in a darkened room were improved with positive ratings, compared to no filter and the control. Conversely, indoor filter usage with incandescent illumination was rated negatively, compared to no filter. Outdoor usage of filters when identifying targets on various backgrounds did not improve visualization.

Conclusions: A mountable filtering system can be deployed to remote Argus II users, with preliminary data indicating indoor visualization improvements, as a function of room illumination. Additional user testing is required to understand the effects of the spectral characteristics of each filter.

ABSTRACT BODY:

Purpose: We have previously reported that depletion of corneal plasmacytoid dendritic cells (pDCs) leads to a robust loss of corneal innervation. Herein, we demonstrate neurotrophic properties of the pDC secretome by concurrent pDC depletion and topical treatment with pDC-derived supernatant. Furthermore, we characterize functional alterations of corneal nerves by ex vivo electrophysiology.

Methods: For rescue studies, pDCs were sorted from adult C57BL/6J mice and cultured in serum-free media for 3 days, at which point supernatant was collected. Adult BDCA2-DTR mice were used for depletion of pDCs by subconjunctival injections of diphtheria toxin (DT; 30 ng/eye) at day 0 and repeated every 2 days and were compared to non-depleted controls In rescue studies, all BDCA2-DTR animals received DT injections every 2 days and were topically treated with pDC supernatant or serum-free media (control) 3 times/day for one week. Corneas were stained with β_{III}-tubulin, imaged by confocal microscopy, and nerve density quantified using NeuronJ. For electrophysiology studies, recordings were performed ex vivo on enucleated eyes using a glass recording micropipette at the ocular surface in a recording chamber perfused with 34°C physiologic solution. The activity of nerve terminal impulses (NTIs) was recorded at baseline and in response to cooling and warming ramps. Analyses were performed in Spike2 software.

Results: pDC supernatant treatment resulted in a significant increase in central cornea innervation compared to controls (131.49 + 10.49 vs 67.77 + 6.80 mm/mm^2; $p<0.01$). This effect was due to a rescue of the subbasal plexus (100.10 + 8.92 vs 30.34 + 7.40 mm/mm^2; $p<0.001$), as the stromal nerve density did not differ between groups. NTI activity of high-threshold cold receptors (HT-CRs) was altered by pDC depletion. Although background activity and cooling responses did not differ between groups. Interestingly, the cooling threshold, the temperature at which HT-CRs respond, was reduced in the pDC-depleted group (22.53 + 0.54°C vs 27.97 + 0.46°C).

Conclusions: These findings demonstrate that corneal pDCs are crucial for both the function and maintenance of corneal nerves. The structural and functional alterations following pDC depletion, as well as rescue of corneal innervation by pDC supernatant, may have relevant consequences for ocular diseases in which sensory abnormalities predominate.

ABSTRACT BODY:

Purpose: Optical coherence tomography (OCT) is a non-invasive, in-vivo imaging technique that enables the cross-sectional examination of retinal layers. This study evaluates the correlation of retinal layer metrics with glycemic control (HbA1c) and visual acuity, in type 2 diabetics. Moreover, the variation in retinal layer metrics between diabetic and non-diabetic patients has also been studied.

Methods: It is a case control study of 146 patients. Macular cube scan of 512x218 protocol was done to assess central subfield thickness (CST) and average ganglionic cell layer (GCL) - inner plexiform layer(IPL) thickness in an elliptical annulus centered on fovea. Additionally, thickness was measured for inner retina (ILM-OPL) from the internal limiting membrane(ILM) to the proximal boundary of the outer nuclear layer(ONL); outer retina (ONL-RPE) from proximal ONL boundary to the retinal pigment epithelium (RPE); ellipsoid zone(EZ) to RPE(EZ-RPE) and total retina(ILM-RPE) from ILM to RPE at fovea, juxtafoveally at 1 mm nasal and temporal to the fovea. Average retinal nerve fibre layer (RNFL) thickness was evaluated using 200x200 protocol of optic disc cube centered on the optic disc.

Results: Inner retina including average RNFL thickness, average GCL-IPL thickness, foveal ILM-OPL thickness; EZ-RPE and total retina including juxtafoveal temporal and nasal thickness, showed significant reduction in diabetics. Visual acuity showed weak positive correlation with inner retinal layers. Additionally, total retina juxtafoveal nasal parameter had weak positive correlation with BCVA in diabetics. HbA1C showed weak negative correlation with inner retinal layers. Multivariate regression analysis showed increase in RNFL, GCL-IPL, inner retinal ILM-OPL juxtafoveal temporal and total retinal juxtafoveal nasal thickness were significantly associated with decreased visual acuity.

Conclusions: With the advent of OCT, quantitative assessment of different retinal layers, could help us detect signs of retinal neuro-degeneration and impending clinical diabetic retinopathy associated with chronic hyperglycaemia. Furthermore, it would serve as a biomarker to detect pre-clinical DR and initiate appropriate clinical interventions.

ABSTRACT BODY:

Purpose: To evaluate the utility of performing ultra-wide field fluorescein angiography (FA) in patients with anterior uveitis and to investigate the frequency of retinal vascular leakage in patients with anterior uveitis.

Methods: A retrospective chart review was conducted. Inclusion criteria included patients referred with a diagnosis of anterior uveitis who received a FA in the same visit at the time of presentation. Patients were excluded if they had evidence of posterior segment involvement on clinical exam. The FAs were reviewed to evaluate for the petaloid leakage consistent with cystoid macular edema (CME), optic disc leakage, and the presence of retinal vascular leakage (graded on a scale of none present, mild, and moderate/severe). The primary outcome was the presence of retinal vascular leakage on FA at presentation. Secondary outcomes included the presence of CME and optic disc leakage.

Results: A total of 30 patients (60 eyes) met the inclusion criteria (11 males, 19 females; mean age 52.6, range 26-83 years). FA grading revealed no retinal vascular leakage in 32 eyes (53.3%), mild leakage in 19 eyes (31.7%) and moderate to severe leakage in 9 eyes (15.0%). Further, 14 eyes (23.3%) showed petaloid leakage, and 3 eyes (5%) revealed disc leakage. Retinal vascular leakage was bilateral in 12 cases. FA was helpful in changing the presenting diagnosis in 5 patients (16.7%).

Conclusions: Our preliminary data suggests that anterior uveitis may be associated with retinal vascular changes. In some circumstances it may be helpful to obtain a baseline FA in anterior uveitis patients to ensure that the uveitis is appropriately characterized, especially given the treatment and prognostic implications.

ABSTRACT BODY:

Purpose: To perform automated segmentation of corneal nerves and pathological structures in corneal confocal microscopy (CCM) images of the subbasal nerve plexus (SNP) in eyes with ocular surface disorders (OSD).

Methods: A novel, deep learning-based autoencoder was constructed to perform 4-class segmentation on SNP images using adversarial loss and clustering-based post-processing. The SNP autoencoder was trained/tested on 207 SNP images from 43 OSD patients, for which an expert manually segmented 4 tissue classes: background, nerve, foreign body, and neuroma. To remove the deleterious effects of applanation artifacts, an artifact-removal (AR) autoencoder was constructed to perform 3-class segmentation (Fig. 1 A-B). The AR autoencoder was trained on 450 SNP, 450 stroma, and 450 epithelium images from 27 patients, as well as examples generated from an auxiliary classifier generative adversarial network (Fig. 1 C-E).

Results: The training/testing split was performed patient-wise. Performance was quantitatively evaluated for the SNP autoencoder + AR autoencoder combination (Fig. 2) based upon tissue class precision, recall, and F1-score. The precision scores were 99%, 80%, 63%, and 73%; the recall scores were 99%, 73%, 84%, and 88%; the F1 scores were 99%, 77%, 70%, and 77% for the background, nerve, foreign body, and neuroma class, respectively.

Conclusions: It was possible to perform accurate segmentation of the SNP with a relatively high degree of precision and recall even under the constraints of a small dataset. This segmentation algorithm facilitates automatic quantification of the cornea’s nerve density, thickness, and tortuosity, which can be used to stratify OSD patients into subgroups that reflect specific pathophysiological mechanisms to the cornea’s immune response and pain experience.

TITLE: Suprachoroidal Delivery of RGX-314 for Diabetic Retinopathy: The Phase II ALTITUDE™ Study

SESSION TITLE: Diabetic Retinopathy

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: D.S. Dhoot, California Retina Consultants, Santa Barbara, California, UNITED STATES|

Commercial Relationships Disclosure: Dilsher Dhoot: Commercial Relationship(s);Code C (Consultant/Contractor):Genentech, Novartis, Regeneron, Allergan, Alimera Sciences, Eyepoint Pharmaceuticals, Bayer, Apelis

ABSTRACT BODY:

Purpose: Sustained anti-VEGF delivery has been shown to decrease severity of diabetic retinopathy (DR) and reduce vision threatening complications, yet it is associated with a high treatment burden. RGX-314 is designed as a single gene therapy intervention utilizing the NAV AAV8 vector to deliver a soluble anti-VEGF fab transgene to potentially provide continuous anti-VEGF therapy. This study will evaluate RGX-314 for the treatment of DR without center-involved diabetic macular edema (CI-DME) utilizing an in-office, suprachoroidal delivery.

Methods: ALTITUDE is an open-label, controlled dose-escalation trial evaluating the efficacy, safety and tolerability of suprachoroidal delivery of RGX-314 using the SCS Microinjector® in patients with a DR diagnosis of moderately severe or severe nonproliferative DR (NPDR) or mild proliferative DR (PDR). 20 patients in Cohort 1 were randomized to receive RGX-314 at a dose level of $2.5x10^{11}$ genomic copies per eye (GC/eye) versus observational control at a 3:1 ratio. Additional cohorts will include 40 patients randomized to receive RGX-314 at an increased dose level of $5x10^{11}$ GC/eye, in which enrollment is ongoing. Patients do not receive prophylactic immune suppressive corticosteroid therapy before or after receiving RGX-314. The primary outcome is the proportion of eyes with 2-step improvement in DR severity scale score (DRSS) at 48 weeks. Secondary outcomes include safety, and development and intervention of DR-related complications.

Results: As of September 29, 2021, RGX-314 was well tolerated in 15 patients in Cohort 1. One serious adverse event was reported in the fellow eye of a patient treated with RGX-314 and is considered not related to RGX-314. No intraocular inflammation was observed on slit-lamp exam. Common adverse events in the study eye were not considered drug-related and were predominantly mild. 5 of the 15 patients (33%) demonstrated a 2-step or greater improvement in DRSS from baseline at three months, compared to 0 of the 5 patients (0%) in the observational control group. In the 7 patients who had NPDR (DRSS 47-53) at baseline, 3 patients (43%) demonstrated a 2-step or greater improvement.

Conclusions: RGX-314 has the potential to provide sustained clinical outcomes in the treatment of diabetic retinopathy with a one-time treatment administered in-office.

TITLE: Intracranial Pressure and its effects on Intraocular Pressure

SESSION TITLE: Aqueous humor dynamics, IOP, corneal disease, cytokines and growth factors

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Hernandez Isidro, Y.H. Mohamed, C.L. Passaglia, Medical Engineering, University of South Florida, Tampa, Florida, UNITED STATES|

Commercial Relationships Disclosure: Cesar Hernandez Isidro: Commercial Relationship: Code N (No Commercial Relationship) | Youssef Mohamed: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Passaglia: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: There is increasing indication that intracranial pressure (ICP) may play a role in glaucoma since the lamina cribrosa of the optic nerve head is exposed to intraocular pressure (IOP) on one side and ICP on the other. The purpose of this study is to monitor ICP in awake and anesthetized animals to understand its dynamics, and how IOP responds to changes in ICP.

Methods: Experiments were done with adult Brown Norway rats housed in a 12-hr light-dark cycle with access to food and water ad libitum. Continuous recording of ICP in awake rats was done by implanting a fine cannula into the subarachnoid space through a hole in the skull. The cannula was connected to a custom wireless telemetry device attached to a jacket worn on the animal's back. ICP and IOP were concurrently recorded in anesthetized rats. Subarachnoid and ventricular ICP were recorded via a vented screw in the skull and a 25-gauge needle in a cerebral ventricle, respectively. Ventricular pressure was altered by varying the height of a fluid reservoir connected via a three-way stopcock to the needle. IOP was recorded via a 33-gauge needle in the anterior chamber of one eye. Data was analyzed in terms of means and variances. Variance was analyzed in randomly selected 1-hr samples of the ICP record.

Results: ICP was successfully recorded from 3 awake rats for 3 days to 4 weeks, and a diurnal ICP rhythm was observed in every animal. Mean ICP was 5.2 ± 1.8 mmHg during the light phase and 12.3 ± 4.2 mmHg during the dark phase ($p < 0.03$). ICP records of at least an hour in length were recorded from 6 awake rats and 6 anesthetized rats. Average variance of ICP fluctuations was 0.06 ± 0.04 mmHg for awake animals and 4.68 ± 4.49 mmHg for anesthetized animals ($p < 0.03$). IOP was observed to increase by 4.1 ± 4.0 mmHg after ICP elevation of 10 mmHg in 5 anesthetized rats ($p = 0.08$).

Conclusions: Our results show that ICP has a diurnal rhythm in conscious rats, with ICP being significantly higher during the animal's waking hours. We have previously shown that IOP is also higher at night, which implies that translaminar pressure is relatively stable throughout the day. ICP variance in conscious rats can be attributed in large part to animal activity as variance is greatly reduced by anesthesia. Effects of ICP elevation on IOP are reportedly due to changes in ocular blood volume and/or outflow facility and under further investigation.

ABSTRACT BODY:

Purpose: Sequence variants in the RP1 gene account for a significant proportion of autosomal dominant (AD) cases, but are also found in autosomal recessive (AR) RP. No gene therapy has been developed so far for RP1 associated RP that shows a varying degree of severity. We investigated the phenotypic and genotypic differences of a large family with AD RP1 associated RP, and a family with compound recessive variants in RP1.

Methods: Clinical data from comprehensive ophthalmic exams, including multi-modal imaging and full-field ERG, were collected for all patients. Whole exome sequencing was performed for genomic analysis. The full length RP1 gene was cloned into an expression plasmid. Reference RP1 and mutant variants were expressed in cells and analyzed by Western blot and confocal microscopy for localization.

Results: The large Swiss family carrying an already described dominant RP1 variant showed varying degree of disease severity from almost complete loss of central vision at age 50 years to conservation of full central function at a similar age. The RP1 family with a recessive trait revealed two novel, compound heterozygous variants . The patient presented a typical RP phenotype with significant nyctalopia in early adulthood, and advanced visual field constriction. Autofluorescence showed a characteristic hyperautofluorescent perifoveal ring. The OCT confirmed retained photoreceptor layers at the fovea, and loss of the photoreceptor and outer nuclear layer outside of it. The father carrying the recessive frameshift variant did not show any signs of RP both clinically and electrophysiologically. The truncated RP1 from the AR family showed an increased nuclear localization, whereas the truncated protein from the AD family seems to be expressed more similar than the reference RP1 within the cell.

Conclusions: Frameshift variants in exon 4 of RP1 appear to not always be disease causing. The variant in the AD family appears to be quite frequent in patients of Swiss origin, and shows a great intrafamilial phenotypic variability. The variant in the AR family did not cause disease in the heterozygous state, but compound heterozygous state. Localization of expressed RP1 variants seems to differ according to their mode of inheritance. These observations are of utmost important when considering future therapeutic approaches.

ABSTRACT BODY:

Purpose: NV located above the vitreoretinal interface indicates proliferative diabetic retinopathy. However, in OCTA enface images it is often difficult to distinguish whether NVs have penetrated this interface. We developed a widefield SS-OCTA system that highlights NVs over a field of view of up to 90 degrees.

Methods: Our widefield SS-OCTA system scans the retina at an A-scan rate of 1.7 MHz, enabling fields of view of up to 90 degrees while maintaining Nyquist sampling density. The high scan speed keeps the acquisition time at a comfortable 15s. A deep neural network (DNN) is used for 3D denoising of the acquired data. For automated detection of NV we implemented a robust ILM segmentation algorithm. After a graph-cut search and flattening of the retina, 3D smoothing filters and morphological operations on the structural OCT data yield the segmentation of the ILM layer. The standard deviation of voxel gray values in the area above the ILM provides the neovascularization segmentation.

Results: Our prototype SS-OCTA device produced excellent image quality far out into the periphery. With this device, we have so far imaged nearly 100 subjects with diabetic retinopathy at various disease stages. Figure 1 shows a montage of two 18 mm x 18 mm scans of a healthy subject to an ultra-widefield 23 mm x 18 mm SS-OCTA image. The zoom-in in the bottom left corner highlights that even the smallest capillaries around the foveal avascular zone can still be resolved despite the large field of view. An SS-OCTA image of a diabetic patient with proliferative NV, where the automatic NV segmentation result was overlaid in red can be seen in Figure 2. It allows the ophthalmologist to distinguish between proliferative and non-proliferative vascular abnormalities at first glance.

Conclusions: Widefield SS-OCTA in combination with DNN-based image quality improvement techniques and segmentation algorithms enhances and simplifies the diagnosis and disease monitoring of preretinal NV. The occurrence, the corresponding spatial location, and the specific extent of vascular anomalies are accompanying signs of many retinal diseases. In future studies we will therefore aim at demonstrating the benefit of widefield SS-OCTA imaging beyond diabetic retinopathy.

TITLE: Effect of Peripheral Optical Quality in Accommodation Responses of Young Children

SESSION TITLE: Myopia and refractive error development

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: F.A. Vera-Diaz, A. Jnawali, K.L. Kerber, New England College of Optometry, Boston, Massachusetts, UNITED STATES|P.J. Bex, College of Science, Northeastern University, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Fuensanta Vera-Diaz: Commercial Relationship(s);Code C (Consultant/Contractor):Essilor International | Ashutosh Jnawali: Commercial Relationship: Code N (No Commercial Relationship) | Kristen Kerber: Commercial Relationship: Code N (No Commercial Relationship) | Peter Bex: Commercial Relationship(s);Code I (Personal Financial Interest):Adaptive Sensory Technology, LLC

ABSTRACT BODY:

Purpose: The optical quality in the near periphery has been associated with refractive error development. We investigated whether peripheral optical quality in children at High (HR) or Low Risk (LR) for myopia affects their accommodation responses.

Methods: Young children (n=97, 7.58±0.96yrs) with functional emmetropia (SE OD +0.95±0.54D; AXL OD 22.79±0.75mm) were enrolled. Optical quality across the central horizontal ±30° was assessed using a scanning aberrometer. Strehl ratios, Defocus (Z4) and primary Spherical Aberration (SA, Z12) were computed for 4mm diameter pupils. Accommodation responses were assessed with an open-field WAM binocular autorefractor for a central target at 40cm (20° 'dead leaves' that mimic natural images). Linear regression models were used to test if the optical quality measures predicted accommodation responses, for all subjects and also when divided into HR and LR, based on parental myopia and baseline SE.

Results: Peripheral Strehl ratios significantly predicted central accommodation responses for the LR group (temporal retina: R^2=0.31, p=0.04; T25deg: β=-14.04, p=0.04; nasal retina: R^2=0.45, p<0.01; N10deg: β=-4.29, p<0.01), but not for children at HR for myopia. Central accommodation was also predicted by peripheral SA (temporal: R^2=0.335, p=0.05; nasal: R^2=0.48, p<0.01), and central SA (0deg: R^2=0.43, p<0.01). When split into LR and HR groups, only the nasal retina significantly affected accommodation responses for the LR group at N5deg (β=-7.97, p=0.03). Lastly, central accommodation was predicted by peripheral Defocus (nasal: R^2=0.48, p<0.01; temporal: R^2=0.39, p=0.02) and central Defocus (R^2=0.43, p<0.01). When split into HR and LR groups, nasal Defocus predicted accommodation responses only for the HR group (R^2=0.55, p<0.01). No significant differences were found between HR and LR groups in Strehl ratios, Defocus or SA, although a trend for more positive Defocus was found in the HR group and more positive SA (significant for T25deg and T15deg) in the LR group across the periphery.

Conclusions: Peripheral optical quality is associated with central accommodation responses in young children with functional emmetropia. Accommodation responses in children at LR for myopia are affected by their peripheral Strehl ratios and SA, and those at HR for myopia by peripheral Defocus. Peripheral optical quality, particularly in the nasal retina, may have implications in myopia development.

ABSTRACT BODY:

Purpose: Wide angle imaging is an increasingly important area of retinal research as imaging the retinal periphery may aid in diagnosis of various retinopathies. This is currently being done easily with the Optos machine or, with little difficulty, using overlapping 55-degree scans across the fundus with the Heidelberg system. We aimed to determine if we could overlay images from these two imaging modalities to evaluate abnormalities seen on either machine. We evaluated and compared image alignment using mathematical warping of the images for comparison to Artificial Intelligence-assisted alignment as our group previously described with posterior pole imaging.

Methods: A total of 58 eyes were included in the study. Imaging was done on the same day. Single Optos image and 9 images of standard 55-degree fields were captured from multiple views using the Heidelberg machine.

Optos image was designated as a reference (i.e. fixed image) during alignment and each of the 9 Heidelberg images were aligned onto the reference. We assumed that both images were captured over a standard 3D spherical eyeball and the Optos camera has a fixed view with regards to the globe, as specified in DICOM standard. Therefore, we set up 3D keypoint coordinates for the Optos image and then estimated a 3D-to-2D (or vice versa) Direct Linear Transformation (DLT) matrix to warp the Heidelberg image.

Dice metric based on anatomical structures is adopted as the measurement to evaluate alignment quality. Retinal vessel maps were extracted from both images using third party segmentation algorithms. The Dice value was calculated over the vessel maps. Image masks indicating imaging circles are also applied to limit the computation in the overlapping areas between both images.

Results: Twenty-four eyes are currently being studied with a total of 240 images (10 image per eye). Four out of the 24 resulting composite images contain exaggerated patterns due to distortions which cannot be solved by the DLT method and manual labels, which are therefore excluded from the alignment evaluation. The average Dice values for the remaining 20 image pairs is 0.4652.

Conclusions: Ultra-wide angle from different instruments can be co-localized and this may permit better evaluation of abnormalities seen on the two instruments. AI-enhancement of mathematical warping is ongoing and will be presented in the final paper.

ABSTRACT BODY:

Purpose: To test whether oral administration of nicotinamide riboside (NR), a nicotinamide adenine dinucleotide (NAD^+) precursor, protects retina ganglion cells (RGCs) against neurodegeneration in the DBA/2J (D2) mouse model of age-related inherited pigment dispersion glaucoma.

Methods: NR administration in drinking water and food (4000mg/kg of body weight per day) started when DBA/2J mice were 4 months old and continued until 12 months old. Control cohort identically received vehicle water and food with no added NR. Intraocular pressure (IOP) was measured every month until experiment completion. Pattern electroretinography (PERG) was recorded at 4, 6, 9 and 12 months old using a Celeris system (Diagnosys LLC, MA). Retinas were harvested for whole mount immunofluorescence staining with RGC marker Brn3a and imaged by fluorescent confocal microscopy. Retinal NAD^+ levels were enzymatically assayed (Abcam, CA). Iris depigmentation degree was assessed by transillumination pattern assay.

Results: The retina NAD^+ level of NR-treated aged D2 mice was significantly higher than untreated aged mice (220±21.5% vs 108±5.9% of young naïve D2 retina NAD^+ level, N=6-8, $p<0.05$). Brn3a-positive immunofluorescent cell counts were significantly higher in NR-treated aged D2 mice compared with untreated ones (1412±248 cells per field vs 475±378 cells per field, N=20, $p<0.05$). PERG P1 and N2 amplitudes were significantly higher from NR group than vehicle group (P1: 2.89±0.27uV vs 1.37±0.12uV, N=40, $p<0.05$; N2: (-5.85±0.5uV vs -3.11±0.24uV, N=40, $p<0.05$). The degree of iris atrophy in NR group was much less severe compared with vehicle group.(Fig.1)
The IOP in NR group was modestly but significantly lower than vehicle group when DBA/2J mice were 7, 8 and 9 months old; there was no significant difference at other time points.

Conclusions: NR oral supplementation significantly preserved RGC numbers and retina function in aging D2 mice. Interestingly, treatment also prevented iris atrophy, delayed IOP elevation associated with this glaucoma model, and elevated retinal NAD+ levels. NR oral supplementation thus treated several aspects of murine pigment dispersion glaucoma. Given parallels between this model and glaucoma in humans, our data indicate that NR is worth exploring as a therapeutic candidate in treatment of glaucoma.

ABSTRACT BODY:

Purpose: To investigate the safety and effectiveness of the Vitesse hypersonic vitrectomy device for retinal re-attachment surgery in proliferative (diabetic) vitreoretinopathy cases. Vitesse utilizes hypersonic technology to liquefy instead of cut the vitreous, providing an alternative to the traditional pneumatic guillotine cutter.

Methods: Patients with proliferative vitreoretinopathy or proliferative diabetic vitreoretinopathy where hypersonic vitrectomy was used for re-attachment of detached retina were analyzed. Effectiveness of hypersonic vitrectomy was evaluated, both subjectively using a questionnaire, and objectively by means of video documentation of procedures, device settings, and data collection of the patients' medical histories.

Results: In all 16 cases, Vitesse separated the vitreous from the detached retina completely with no iatrogenic tissue damage. Vitreous traction was only documented in one case. A conversion to a guillotine cutter was necessary in none of the cases. In 6 of 16 cases shaving of the vitreous base was performed after early fluid-air exchange with hypersonic vitrectomy as a safe procedure without any complications. No adverse events suspected to be related to hypersonic vitrectomy were documented in the follow-up visits.

Conclusions: The Vitesse device has potential advantages over traditional devices used for vitrectomy including reduced vacuum volumes which limited the amount of turbulence and avoid traction in the eye. Liquefaction directly in front of the probe entrance allows for continuous unrestricted fluid flow. A potential disadvantage of this procedure is a longer duration of procedure time for liquefying the vitreous. Investigation is ongoing to optimize the machine settings and device tip design.

ABSTRACT BODY:

Purpose: The aging of the crystalline lens induces an increase in its rigidity responsible for the loss of accommodation. Research on presbyopia requires the use of a large number of animal lenses that are available without limit in the eyeballs of animals from slaughterhouses. The use of lenses from older animals, which are rarer, seems judicious to understand the physiopathology and to evaluate the effect of new treatments. The measurement of lens deformation at high speed (lens spinning) is one of the methods described to estimate lens rigidity. Objectives: To measure the deformability of the porcine lens as a function of the age of the animal using a new digital lens spinner.

Methods: 65 pairs of porcine globes aged from 6 months to 5 years were obtained from a local slaughterhouse and dissected within 2 h postmortem. We developed an original lens spinner integrating: 1/ a rotating support illuminated by a stroboscopic light synchronized with a CMOS camera; 2/ a software for acquisition and analysis of images in real time. Five parameters were measured on 8 positions of the lens in rotation and averaged. A measurement was performed at 75 rpm inducing no deformation (accommodated state) and then at 1500 rpm (non-accommodated state). The lenses were spun at t0 to estimate the initial comparability between the two lenses of the same animal. They were then stored in culture medium and one of the lenses was heated to 50°C to stiffen it while the other remained at 20°C. A second spin was performed after 6h. A linear mixed-effect model was used for statistical analysis.

Results: The anterior radius of curvature was the most sensitive parameter to deformation. The deformability of the 2 lenses of the same animal were very strongly correlated at t0, regardless of age (R^2=0.94, p<0.0001). Elasticity was inversely correlated with age (R^2=0.82, p<0.0001). Heating induced a stiffening by a factor of 5 compared to the fresh state, the more so the younger the animals were (p<0.0001). Storage at 20°C did not significantly alter elasticity.

Conclusions: Our lens spinner is suitable for the analysis of large series of lenses. The anterior radius of curvature is the least noisy parameter. This parameter is sensitive enough to measure age-related loss of elasticity in pigs. Heating artificially ages the lens and can be used as a model. The lens of aged pigs can serve as a model of presbyopic lens.

ABSTRACT BODY:

Purpose: The Protocol S trial compared ranibizumab with PRP and found that treatment with ranibizumab leads to fewer vitrectomy procedures. The purpose of this study is to characterize the odds of pars plana vitrectomy (PPV) after pan-retinal photocoagulation (PRP) or anti-vascular endothelial growth factor (anti-VEGF) injections in the treatment of proliferative diabetic retinopathy (PDR).

Methods: A retrospective cross-sectional study from January 1, 2012 to December 31, 2017 was conducted using a nationally representative claims-based database, Clinformatics™ Data Mart Database (OptumInsight, Eden Prairie, MN). Newly diagnosed, treatment naïve adults (≥ 18 years old) with PDR as defined by ICD9/10 codes and continuous enrollment for at least two years after diagnosis were included. CPT codes were used to determine PDR therapy and PPV status. Eyes were analyzed separately and were stratified into two groups: eyes receiving only anti-VEGF therapy (anti-VEGF group) and eyes treated with PRP monotherapy (PRP group). Primary outcomes were rates of PPV and median time to PPV for each group.

Results: The cohort consisted of 2368 eyes with PDR. Overall, 52.8% of patients were male with a median age of 65 (54-71). Of these, 1787 eyes were treated with PRP only, and 581 were treated with anti-VEGF only. 3.4% (20/581) and 4.9% (87/1787) of eyes required PPV in the anti-VEGF and PRP groups respectively (p=0.150). Median time to PPV was 114 days and 188 days in the anti-VEGF and PRP groups respectively (p=0.079). Adjusted for gender and age, the odds of vitrectomy were not different between eyes treated with PRP only compared to those treated with anti-VEGF only (odds ratio [OR] 1.14, CI 0.69-1.96, p=0.629).

Conclusions: This study examines eyes with PDR treated with either anti-VEGF monotherapy or PRP monotherapy to determine the likelihood of vitrectomy in a large, nationally representative cohort. Although median time to vitrectomy was longer for anti-VEGF monotherapy compared to PRP monotherapy, both treatment modalities had the same odds of ultimately requiring a vitrectomy. These results suggest that PRP does not increase the odds of vitrectomy compared to anti-VEGF in PDR patients. The implications for clinical practice and patient counseling should be further explored.

ABSTRACT BODY:

Purpose: Neurotrophic keratopathy (NK) is typically considered a disease with reduced corneal sensation and lack of symptoms of discomfort, although we have reported recently that some patients may have concurrent ocular pain, including neuropathic corneal pain (NCP). Our aim was to evaluate the clinical outcomes of patients treated for concurrent NK and NCP.

Methods: A retrospective case series of 19 patients with stage 1 NK and concurrent NCP who were seen at the New England Eye Center (Boston, MA, USA) between August 2016 and November 2021 was conducted. NCP was diagnosed based on clinical examination, proparacaine challenge test, and in vivo corneal confocal microscopy (IVCM) findings. Best-corrected visual acuity (BCVA), ocular surface disease index (OSDI), pain on visual analog scale (VAS), ocular pain assessment survey (OPAS), and corneal fluorescein staining (CFS) by National Eye Institute (NEI) grading system were reviewed retrospectively.

Results: Patients' mean age was 61.9±3.9. NK etiology included chronic dry eye disease (DED) (n=12, 63%), herpes simplex keratitis (n=4, 21%), and post-surgery complications (n=3, 16%). Among the 12 subjects with DED, 8 patients had a positive serology for autoimmune diseases (Sjögren's syndrome, rheumatoid arthritis, and small fiber neuropathy). At baseline, mean BCVA was 20/50, OSDI score was 64.5±5.2, VAS score was 5.7±0.6, pain severity on OPAS for the past two weeks was 5.4±0.4, and mean CFS was 7.8±0.8. All patients were treated with autologous serum tears (100%), 8 (42%) received recombinant human nerve growth factor (cenegermin), and 17 (89%) were prescribed oral medications (nortriptyline, low dose naltrexone, gabapentin). Following treatment (mean 25.3±7.3 months), BCVA increased to 20/30 ($p<0.01$), we observed an improvement in OSDI score (37.1±6.1, $p<0.001$), VAS score (1.7±0.3, $p<0.001$), and OPAS pain severity for the past 2 weeks (2.3±0.4, $p<0.001$), and CFS significantly decreased to 3.1±0.4 ($p<0.001$).

Conclusions: NK patients are typically thought to lack symptoms of discomfort, but they can present with concurrent NCP. Our data outline the importance of addressing both conditions to treat the ocular surface alterations and the ocular pain to improve the patients QoL. Topical growth factors and oral pain modulators can lead to a significant improvement in BCVA, CFS and ocular discomfort scores.

Michael Redmond: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal pigment epithelium (RPE) cell loss or dysfunction caused by a variety of stressors is a factor in the onset of age-related macular degeneration (AMD). Sodium iodate ($NaIO_3$), an oxidizing agent causing selective RPE cell damage, is used in pre-clinical models of RPE damage. $NaIO_3$ damage to RPE mimics features of AMD and geographic atrophy, due to reactive oxygen species (ROS) generation by $NaIO_3$. We have found that fenretinide-induced apoptosis in ARPE-19 cells decreases stearoyl-CoA desaturase (SCD), important in regulating cellular functions by maintaining saturated/unsaturated fatty acid equilibrium. Here, we investigate the effect of the SCD inhibitor sterculic acid (SA) on $NaIO_3$-induced apoptosis in RPE cells.

Methods: Human RPE cells (ARPE-19) grown on tissue culture plates in MEM alpha medium with 1% FBS and antibiotic were differentiated for 4 weeks; media exchange was performed twice a week. Differentiated cells were treated with 5 mM $NaIO_3$ in the presence or absence of 10 mM SA in a serum-free medium for 20 h. The progression of apoptosis was followed by the extracellular release of LDH. Total RNA fractions were used to analyze mRNA and lncRNA expression using cell death pathway finder, inflammatory response, and autoimmunity PCR arrays by real-time RT-PCR.

Results: $NaIO_3$ induced apoptosis in ARPE-19 cells in a dose- and time-dependent manner as indicated by LDH release in the medium. Treatment with 10 mM SA blocked $NaIO_3$-induced apoptosis by ~90%. Of 98 lncRNAs assayed, 12 lncRNAs were upregulated, and 28 were downregulated, while out of 98 mRNAs assayed, 10 mRNAs were upregulated and 48 were downregulated, with a fold change of 2 or more, in cells treated with $NaIO_3$. $NaIO_3$ treatment increased GADD45a mRNA and SLC7A11-AS1 lncRNA expression by ~22- and ~34-fold, respectively. This increase was blocked by SA. Increase in expression, in response to $NaIO_3$ treatment, of HO-1, a stress response protein, and BCL2L11, a regulator of apoptosis via the intrinsic mitochondrial pathway, were also blocked by SA treatment.

Conclusions: Our results show that SA treatment effectively blocked $NaIO_3$-induced apoptosis in human RPE cells. The mode of action of this SCD inhibitor appears to be at the level of ROS generation. Thus, SA may be an effective agent in regulating the response of RPE to oxidative stress.

ABSTRACT BODY:

Purpose: Full-length human IgG1 antibodies antagonize pathological angiogenesis independent of antigen binding, and thus may be a next-generation anti-angiogenic target for retinal disease like age-related macular degeneration and diabetic retinopathy. However, the extent to which sex influences this angioregulatory activity is unknown.

Methods: Laser photocoagulation was performed in male and female C57BL/6J mice, followed by intravitreous injection of a full-length humanized IgG1 antibody. Choroidal neovascular volume (CNV) was measured 7 days later. Male and female derived primary macrophages BL/6J and BALB/c mice and human single donors were analyzed for VEGF-A-induced chemotaxis in the presence or absence of humanized or human IgG1 antibodies, or human IgG2 (negative control).

Results: Human IgG1 induced a significantly greater reduction in CNV in male mice to female mice. In B6 and BALB/c macrophages, IgG1 inhibited Vegf-a induced chemotaxis to greater degree in male than female-derived cells. Similarly, primary human macrophages from male donors were significantly more sensitive to IgG1 inhibition than female donors. IgG2 treatment did not affect chemotaxis of male- or female-derived cells.

Conclusions: The effects of IgG1 antibodies are different between male and female systems with male models being significantly more sensitive to IgG1 than females. Future studies are needed to understand the hormonal and genetic causes of these sexually dimorphic responses. These findings may support sex-specific translational application of antigen-independent antibody activities, which may ultimately result in more personalized anti-angiogenic therapies.

ABSTRACT BODY:

Purpose: Retinal and macular degenerations are conditions with progressive photoreceptor or retinal pigment epithelium (RPE) dysfunction resulting in blindness. Most patients lack effective treatments to preserve vision. Efficient and effective phenotypic screening of randomised compound libraries can uncover first-in-class drugs. Here, using a bespoke drug discovery workflow we identify drugs rescuing vision.

Methods: Phenotypic drug discovery was performed on the atp6v0e1^{UCD6} zebrafish model of impaired vision screening a Chembridge DIVERSet® randomised compound library. 80 compounds were combined into 18 orthogonal drug pools for plate testing. Visual behaviour was analysed at 5 dpf by optokinetic response.

Results: Proof-of-concept assays validated orthogonal drug pooling as appropriate for optokinetic response screening. The orthogonal pooling protocol successfully detected visual rescue of atp6v0e1^{UCD6} in Tubastatin A spiked pools (positive control) with 3-fold visual improvement. Of the 720 compounds screened, 86% of pools did not alter vision and 8% of pools showed overt toxicity. Two hit compounds were identified. UCD-OPGG-2C is a benzenedicarboxylic acid and dimethyl ester with a molecular weight (MW) of 277.28 UCD-OPGG-3E is a cyclohexanecarboxamide with a MW of 265.79. Re-purchased UCD-OPGG-3E elicited a significant ($p< 0.025$), two-fold improvement in vision in atp6v0e1^{UCD6} larvae.

Conclusions: We developed a novel workflow to efficiently detect compounds restoring vision in zebrafish. Future experiments will analyse retinal histology, and ocular safety and efficacy in rodent models. Computational approaches will identify novel structural analogues of UCD-OPGG-2C and UCD-OPGG-3E.

ABSTRACT BODY:

Purpose: RB1 is a tumor suppressor protein that regulates cell cycle and its loss of function results in retinoblastoma. This study aims to generate RB1 null models of human induced pluripotent stem cells (hiPSCs) to understand the effects of loss-of function on retinal development and maturation in vitro.

Methods: Adipose-derived mesenchymal cells from familial retinoblastoma patient, harboring nonsense mutation in exon 18 of RB1 was reprogrammed into iPSCs, using episomal constructs expressing OCT4, SOX2, KLF4 and cMYC ($RB1^{+/-}$ hiPSCs). Isogenic mutant lines were also generated by CRISPR-Cas9 mediated, targeted editing within the exon 18 of human RB1 ($RB1^{-/-}$ hiPSCs). Stably expanding mutant iPSC lines were characterized by RT-PCR, immunofluorescence, western blotting and karyotyping. Healthy control and mutant iPSCs were differentiated into retinal lineage using established protocols.

Results: The patient specific heterozygous $RB1^{+/-}$ and CRISPR-edited homozygous $RB1^{-/-}$ iPSC mutant lines maintained their stemness, pluripotency, genomic integrity and formed embryoid bodies comprising of cell types of all three germ layers. Upon differentiation into retinal lineages, the $RB1^{+/-}$ hiPSCs formed normal eye-fields in 2D cultures at 4 weeks. About 30-40 eye-field primordial clusters (EFPs) were formed per million cells plated for differentiation (n=4) and this was comparable to that of the healthy control hiPSC line. However, the differentiation of $RB1^{-/-}$ hiPSCs resulted in about 25 folds reduction in eye-field numbers per million cells. The eye-field cells of all mutant lines expressed the early neuro-retinal precursor markers such as PAX6, RX, CHX10, MITF, SOX10 and also formed retinal pigmented epithelial patches, which suggested normal retinal lineage commitment. When the EFPs were excised and grown in suspension cultures, the retinal progenitors underwent self-organization and formed well laminated neuro-retinal cups in control and $RB1^{+/-}$ hiPSCs. However, the rare EFPs in $RB1^{-/-}$ hiPSCs formed only atypical retinal clusters with severe lamination and maturation defects.

Conclusions: The iPSC models confirm that either a partial or total loss of RB1 does not affect their stemness, pluripotency or retinal lineage commitment. However, the presence of at least one normal copy of the gene is necessary for proper differentiation, post-mitotic maturation and lamination of neuro-retinal precursors.

ABSTRACT BODY:

Purpose: Keratoconus (KC) is a progressive disorder of the cornea. Increasing evidence indicates that immune disorders play an essential role in KC progression. In addition, the manifestations of KC vary across populations. However, the immune-related etiology and concordant regulatory mechanisms in different populations remain elusive. Here, we comprehensively utilized bioinformatics approaches and experimental methods to explore the potential immunoregulatory mechanism of KC progression among populations.

Methods: Transcriptomics data contains two KC populations was derived from the public dataset GSE151631 (America: N=11; Saudi Arabia: N=15). Taking the intersection of genes across populations and known immunological genes to obtain immune-related differentially expressed genes (IRGs). Protein clustering algorithms were utilized to screen out the hub IRGs, which were further verified in the third populations (China: N=8). The underlying drug targets were predicted by drug-gene interaction analysis. Additionally, the KC-related immunoregulatory competitive endogenous RNAs networks (ceRNA) were constructed and experimentally validated.

Results: Overall, KC-associated common differentially expressed IRGs were obtained. After experimental validation, 15 hub IRGs were credible and not related to populations. Moreover, a total of 9 intersecting drugs targeting three genes, CCR2, CCR5, and F2RL1, were considered as potential druggable molecular targets for KC. Furthermore, upon ceRNA interaction network, we identified several lncRNAs and miRNAs as critical non-coding RNAs regulating the shared IRGs in different populations of KC patients.

Conclusions: The current study facilitated the understanding of KC-related immune processes and provided novel insights into developing new immunotherapies for KC. Moreover, finding commonalities in the onset and progression of KC in different populations would facilitate the generalizability of treatment.

ABSTRACT BODY:

Purpose: To describe the technique, safety profile, and outcomes of performing pars plana vitrectomy (PPV) without intravenous (IV) anesthesia. Benefits of performing PPV without IV anesthesia include increased patient satisfaction due to decreased out-of-pocket costs, no preoperative fasting requirements, and no IV-line placement prior to surgery.

Methods: Retrospective single-surgeon case series of patients who underwent PPV without IV sedation between September 2018 and December 2021. Patients elected to undergo PPV without sedation (N=23) or with oral sedation (N=261) via 0.125 to 0.25 mg sublingual triazolam administered 30 minutes preoperatively. A 5 cc sub-tenon's block with a 1:1 ratio of 0.75% bupivacaine and 2% lidocaine was slowly administered at the initiation of each case. A circulating nurse monitored patient vitals and electrocardiogram tracings without anesthesiologist support. Ocular and systemic adverse events, visual acuity, anatomic outcomes, supplemental block administration, and re-operation rates were examined.

Results: A total of 284 PPVs in 255 patients (68.53 ± 11.11 years old) were performed for a variety of surgical indications including floaters, intraocular lens/cataract surgery complications, retinal detachment, and epiretinal membrane. Patients elected to undergo surgery without IV sedation due to personal preference (N=251), insurance status (N=17), anesthesia risk (N=8), difficulty fasting prior to surgery (N=4), lack of IV access (N=2), anxiety (N=1), and pregnancy (N=1). For eyes with greater than 1 month of follow up (N=223), preoperative VA of 0.62 ± 0.70 LogMAR improved to 0.25 ± 0.38 LogMAR ($P<0.01$) postoperatively. No intraoperative complications, systemic adverse events, need to cease surgery prematurely, or conversion to intravenous sedation occurred. 1.77% of eyes (N=5) required intraoperative supplemental sub-tenon's block administration. Patient satisfaction was not measured; however, 96% of patients who underwent reoperation (N=4) or fellow eye surgery (N=19) requested the same method of anesthesia without IV sedation.

Conclusions: Vitreoretinal surgery with sub-tenon's block and oral sedation or no sedation can be safely performed without the support of an anesthesiologist. Additional trials should be performed to further quantify patient comfort and complication rates.

ABSTRACT BODY:

Purpose: To determine the one-year surgical outcomes of trabecular meshwork microstent placement for eyes with severe glaucoma

Methods: The retrospective cohort study included patients with a diagnosis code of severe stage glaucoma before trabecular meshwork (TM) microstent placement from 1/2014 to 6/ 2021. Patients with at least 6-months follow-up in the post-operative period were included. Demographic and clinical data were collected at the preoperative visit and post-operative visits for up to 1 year. Surgical failures were defined as eyes that required further glaucoma surgeries or progressed to no light perception.

Results: 40 eyes of 36 patients were included. Mean age was 74.9±7.5 years old. 37 (93%) eyes had iStent and 3 (7%) had Hydrus. 23 (58%) eyes had 1 microstent (first generation iStent or Hydrus) placed, 16 (40%) had 2 microstents (iStent inject), and 1 (2%) had 3 stents (iStent infinite). All (100%) microstents were placed in combination with cataract surgery. At the preoperative (pre-op) visit, Humphrey 24-2 visual field (VF) mean deviation was -9.2±8.1 dB (n=12), Octopus 30-2 GTOP VF mean defect was 13.5±8.8 dB (n=26), and mean cup-to-disc ratio was 0.8±0.2. Mean pre-op intraocular pressure (IOP) was 15.9±5.1 mmHg and mean number of pre-op medications was 2.6±1.2. Post-operative (post-op) mean IOP overall ranged from 13.8±3.9 to 16.7±7.2 mmHg and were only different at 3- and 6-month visits ($p<0.05$ for both). Mean number of glaucoma drops at the 6- and 12-month visits of 1.6±1.2 and 1.8±1.5 drops, respectively were also lower than baseline ($p<0.05$ for both). Within 3 months post-op, 1 (2.5%) eye developed IOP less than 5 mmHg without hypotony related complications and 16 (40%) eyes developed elevated IOP: 14 (35%) greater than 20 mmHg and 2 (5%) greater than 30 mmHg. There was no difference in drop regimen at 6- and 12-months comparing the use of 1 versus 2 microstents ($p>0.2$ for both). Within the first post-op month, 3 (7.5%), 18 (45%), and 4 (4.5%) eyes developed microhyphema, mild iritis (1+ cell and/or flare or worse), and corneal edema, respectively. 2 patients required further glaucoma surgery with 1 Xen gel stent and 1 Ahmed tube shunt.

Conclusions: Although not approved by insurance for severe glaucoma, any microstent placement demonstrated a possible benefit of decreasing medication burden for patient for up to 12 months with low surgical risk when combined with cataract surgery.

ABSTRACT BODY:

Purpose: To evaluate the performance of a 10mm corneal diameter threshold definition for microcornea among patients with disorders of ocular development and to explore the utility of inclusion of axial length in classification.

Methods:

This prospective cohort study recruited patients with microphthalmos, microcornea and coloboma who presented to the Srikiran Institute of Ophthalmology in Andhra Pradesh, India between 2014 and 2019. All patients underwent a full clinical examination. Only right eyes were included in the study. Patients were excluded if visual acuity was worse than hand motions or if no corneal diameter measurement was obtained.

Subjects were classified as having microcornea (uC) if their horizontal corneal diameter (measured with a ruler and external photo) was <10mm; otherwise, they were classified as having normal corneas (nlC). Subjects were classified as having coloboma if an optic fissure closure defect was identified in either the anterior or posterior segment. Subjects were defined as having microphthalmos if their axial length was <21mm; these subjects were further classified as having nanophthalmos if no other abnormalities were present.

Patients were divided into uC and nlC groups, then separately classified by the ratio of their corneal diameter and axial length with a cut off of 2.1 defining high axiocorneal symmetry (ACS). Chi squared analysis was performed to assess the proportions of patients with the various abnormalities of development between groups. Logistic regression analysis was run to evaluate associations between each classification system and visual acuity as well as corneal power.

Results: A total of 46 patients met inclusion criteria for the study. The mean corneal diameter was 8.5mm in the uC group (n=26) and 10.5 in the nlC group. The mean axial length was longer in the uC group than the nlC group (22.8mm vs 21.1mm (p=0.04)). The proportion of patients were significantly different in the high and low ACS groups (p<0.001), but there was no difference between the uC and nlC groups. There was a small but significant association between uC classification and visual acuity (p=0.047; adjusted R2=0.064).

Conclusions: Inclusion of axial length in classification of patients with microcornea distinguished patients with coloboma from others in the cohort. The presence of microcornea was associated with decreased visual acuity in this cohort.

ABSTRACT BODY:

Purpose: Assessing the impact of COVID-19 on visual acuity (VA) in eyes treated for Diabetic Macular Edema.

Methods: Anonymized data from 21 UK centers were extracted from Medisoft for eyes receiving treatment with aflibercept and with VA data in the pre-COVID baseline period (01/10/19 to 30/03/20, N=3,248). Comparisons for period 1 (01/04/20 to 30/09/20, N=2,077) – lockdown following RCOphth Medical Retinal Management Plan, period 2 (01/10/20 to 30/03/21, N=1,850) - intermittent lockdown and period 3 (01/04/21 to 30/09/21, N=1,111; 20 centers) - easing of COVID-19 restrictions.

VA change was compared for baseline VA, <7 vs. ≥7 injections before period 1 and for eyes losing ≥5 ETDRS letters in period 1.

Results: The mean change in VA for eyes with a baseline VA of ≤35 letters, was +4.9, +2.5 and +1.7 letters from baseline to period 1, period 1 to 2 and period 2 to 3, respectively. For baseline VA of 36-55 letters, +0.6, +1.7 and -0.2 letters, from baseline to period 1, period 1 to 2 and period 2 to 3, respectively. For baseline VA of 56-75 letters, +1.9, zero and -0.5 letters, from baseline to period 1, period 1 to 2 and period 2 to 3, respectively. For baseline VA of >75 letters, -4.3, -0.5 and zero letters, from baseline to period 1, period 1 to 2 and period 2 to 3, respectively.

For eyes receiving <7 injections before period 1, the mean change in VA was -1.9 letters (N=1,335) from baseline to period 1, +0.5 letters (N=992) from period 1 to 2 and +0.1 letters (N=592) from period 2 to 3. For ≥7 injections before period 1, the mean change in VA was -3.4 letters (N=742) from baseline to period 1, -0.4 letters (N=515) from period 1 to 2 and -1.1 letters (N=303) from period 2 to 3.

For eyes losing ≥5 letters before period 1, the mean change in VA when receiving ≥1 injection in period 2 was +3.9 letters (N=283) from period 1 to 2 and -0.1 letters (N=140) from period 2 to 3. For eyes not retreated in period 2, the

mean change in VA was -2.9 letters (N=162) from period 1 to 2 and zero letters (N=73) from period 2 to 3.
Conclusions: Visual gain between time periods was more likely for lower baseline vision. For eyes with <7 or ≥7 injections before period 1, the mean VA change was a loss in vision in the first period with little change in later periods. For eyes with ≥5 letter loss in period 1, subsequent visual gain was more likely if treatment continued.

ABSTRACT BODY:

Purpose: In recent years different biomaterials have been developed to improve corneal repair, among these, silk fibroin-derived biomaterials. In this study, we evaluated the corneal stroma cells response to silk fibroin-derived membranes (SFMs) following injury.

Methods: A stromal in vitro wound model, previously described by our group (Gallego Muñoz et al., 2017, 2018) was used to evaluate the effect of SFMs on the different processes occurring during stromal repair. Briefly, transparent SFMs were placed on the bottom of Petri dishes, on top of which human corneal stromal cells (HCSCs) were seeded and cultured. When HCSCs reached confluence a linear wound was made. Similar cultures without SFMs were used as control group. Wound closure time and cell organisation were evaluated by microscopy. Proliferation and myofibroblast differentiation were analysed by immunocytochemistry. Hepatocyte growth factor (HGF) secretion was measured by ELISA.

Results: SFMs induced a significantly faster wound closure than control showing complete closure at day 3 (Fig. 1A). HCSCs showed higher organisation on the substrate during the wound closure than in control (Fig. 1B). A peak of proliferation was observed at day 1 in both groups but it was significantly increased in HCSCs seeded on SFMs ($p<0.001$). On day 3, the percentage of proliferation decreased in both groups showing no differences. HGF secretion was significantly increased by SFMs at day 3 compared to control ($p<0.05$). No myofibroblast differentiation was observed in HCSCs seeded on SFMs at any study time compared to a low percentage of myofibroblasts observed in control at day 3.

Conclusions: We showed the positive effects of SFMs during the stromal wound closure. The SFMs could improve the corneal repair process and prevent the development of corneal opacities in view of the promotion of faster wound closure. The faster closure appears to be caused by an earlier proliferation peak in presence of SFMs, but may also indicate SFMs support of the migration process. The absence of myofibroblasts with SFMs may result from a higher HGF secretion, which has been shown to inhibit myofibroblast generation in the corneal stroma.

ABSTRACT BODY:

Purpose: Exosomes are small membrane vesicles that carry functional biomolecules derived from donor cells and can be horizontally transferred to recipient cells.

We aim to analyze whether uveal melanoma -derived exosomes were able to condition liver cells to create a favorable niche for the metastatic colonization and outgrowth of uveal melanoma cells

Methods: We isolated exosomes by differential ultracentrifugation from primary and metastatic UM cell lines with a common genetic background. Secretome was obtained from cells growing in vitro either in 2D or 3D conditions. Exosomes were characterized by electron microscopy; proteomic analysis was performed by LC-MSMS (LTQ-Orbitrap), and exosomal biomarkers by immunoblot. The uptake of exosomes by human liver cells was assessed by immunofluorescence. Human liver stellate cells (LX2) and macrophages (THP1) in co-culture in vitro, were exposed to uveal melanoma-derived exosomes. Transcriptomic and proteomic analyses were studied after the exosomal treatments.

Results: We identified 3241 proteins in exosomes from the isogenic UM cell lines, 895 of which were differentially expressed between invasive and non-invasive UM cells and the identified targets were validated by immunoblot. Interestingly, bioinformatic analysis showed that invasive UM cells display an enrichment in proteins involved in cell migration, invasion and signaling pathways such as WNT, IGF-1R, TGFß and NFkB, as well as specific integrins and focal adhesion proteins.

Moreover, we assessed the uptake of UM-derived exosomes by macrophages (THP1 cells) which contribute to the activation and reprogramming of human hepatic stellate cells (HSCs). HSCs adopt then a proangiogenic phenotype by upregulation of VEGF, IL8 and IL1ß; a pro-inflammatory and pro-fibrotic environment via upregulation of extracellular matrix molecules such as FN1 and FN-EDA and CCN2 and a promigratory phenotype. These changes are at least in part, orchestrated by the induction of ZEB1 and PRRX1 transcription factors.

Conclusions: Our results indicate that uveal melanoma-derived exosomes have a key role in the education of the Human Liver Stellate Cells favoring the development of the pre-metastatic niche in the liver that tilt in favor of metastasis. Furthermore, uveal exosomes can be used as biomarkers of metastatic disease and their cargo reflect the plasticity of uveal melanoma cells and announces possible new therapeutic targets for uveal melanoma.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is a progressive retinal disease and a common cause of blindness in people over age 50. AMD pathology can be detected by optical coherence tomography (OCT) and categorized into advanced and non-advanced AMD based on presence of geographic atrophy and/or neovascularization. Here we propose a stack-based ensemble deep learning method and demonstrate that it can improve non-advanced and advanced AMD detection using retina OCT scans.

Methods: Images from 150 subjects and 278 eyes diagnosed as non-advanced or advanced AMD obtained by Zeiss Cirrus OCT (Carl Zeiss Meditec, Inc., Dublin, CA, USA) were used in this study. Low-quality images were excluded before processing. The cleaned dataset had 767 images labeled as non-advanced and 663 images labeled as advanced AMD. The quality of retina images improved by contrast limited adaptive histogram equalization. Each image was divided into 4 patches without overlap between each other. Two center patches near the fovea were used, resulting in 2860 patch images in total. The processed images were split into 80% for training, 15% for validation, and 5% for testing. Base learners include 3 custom sequential models with 15, 23, and 25 hidden layers trained by stochastic gradient descent (SGD), rmsprop, and Adam optimizers, respectively. The weights calculated from each base model were used as an input feature for a meta model. Figure 1 shows the block diagram of the proposed model.

Results: Classification results for the base and ensemble models are shown in Table 1. Model 3 trained by Adam achieved slightly higher accuracy (87%) than model 1 (85%) and model 2 (84%) using SGD and rmsprop optimizers. By stacking base learners, the ensemble model can improve the accuracy, specificity, sensitivity up to 91%, 92%, 90.9%, respectively, on the test set.

Conclusions: Stack-based ensemble deep learning can improve the detection of non-advanced and advanced AMD.

ABSTRACT BODY:

Purpose: We report on the development of a 400 kHz handheld optical coherence tomography angiography (HH-OCTA) system for imaging of young children and infants in the operating room and the intensive care nursery (ICN). The high speed of the 400 kHz engine allows for rapid capture of 9x9mm OCTA images (750 A-scans/B-scan, 750 B-scans/Volume, 4 repeats per B-scan location, total acquisition time of 7.5 seconds). Images are montaged to produce a composite OCTA image with a nasal temporal field of view comparable to a contact fundus camera.

Methods: We developed a 400 kHz OCT engine based on a VCSEL swept source laser (Thorlabs inc.) and used our previously reported HH-OCTA scanner that has an ergonomic grip optimized for supine imaging. Imaging was performed in 8 normal adult subjects in a supine position, 47 children/infants in clinic or during exams under anesthesia (EUAs) in the operating room, and 9 infants in the ICN. Retcam (Natus Medical, Pleasanton, CA) fluorescein angiography (FA) images were obtained during some EUAs for clinical care. OCTA images were generated in post processing using speckle variance and graph cut based segmentation was used to create projections of the vasculature. OCTA images were montaged in post processing. Optical power was set in accordance with the ANSI Z80.36 standard Light Hazard Protection for Ophthalmic Instruments and all human subjects research was performed under protocols approved by the Duke University institutional review board.

Results: Representative HH-OCTA images from an infant undergoing exam under anesthesia are shown in fig. 1.

Conclusions: We demonstrated a 400 kHz HH-OCT system capable of capturing images at the infant bedside. These depth resolved OCTA images can show important pathological vascular features such as the extraretinal neovascular plaque and intraretinal vascular loops. When compared to a contact fundus camera fluorescein angiography the OCTA images provide superior, depth resolved visualization of the retinal microvasculature.

TITLE: Indications for and effect of nasal and temporal partial tenotomy of the vertical rectus muscles in strabismus

SESSION TITLE: Strabismus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Rostamzad, H.M. van der Meulen-Schot, H.J. Simonsz, S.E. Loudon, Erasmus MC, Rotterdam, Zuid-Holland, NETHERLANDS|

Commercial Relationships Disclosure: Parinaz Rostamzad: Commercial Relationship: Code N (No Commercial Relationship) | Helma van der Meulen-Schot: Commercial Relationship: Code N (No Commercial Relationship) | Huibert Simonsz: Commercial Relationship: Code N (No Commercial Relationship) | Sjoukje Loudon: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Nasal and temporal partial tenotomies of the vertical rectus muscles differentially correct vertical deviation (VD) in adduction, VD in abduction, V- or A-Pattern and ex- or incyclotropia. In an initial analysis of a large case series we defined clinical indications for this operation and differences in effect.

Methods: A retrospective analysis was carried out of patients who were treated between 1996 and 2021 in our clinic. All patients were included who had a nasal or temporal partial tenotomy of the vertical rectus muscles. Patients were excluded if postoperative measurements were missing. The changes in angle of strabismus in VD in adduction, in gaze ahead, VD in abduction, V- or A-pattern and ex- or incyclotropia were calculated by subtracting the measurement three months postoperatively from the pre-operative measurement. The Mann-Whitney U test was used in SPSS (version 27) to detect significant differences between effects.

Results: In total 126 patients were included, 100 of whom were treated by nasal and 26 by temporal partial tenotomy. Twenty-six patients were excluded due to missing postoperative measurements. The median age at operation was 48 years, range 8 - 70 years. Seventeen patients treated by nasal and seven patients by temporal partial tenotomy did not have sufficient binocular vision for a cyclotropia measurement. Sixteen patients had first strabismus surgery, 58 had re-operations, six had traumatic strabismus, 10 had an eye muscle palsy, 17 had vertical nystagmus, and 19 had unicoronal craniosynostosis. The change in angle of strabismus is depicted in the Figure. Effect of surgery was analyzed for inferior and superior rectus together and absolute values were used for change in angle. There was a statistically significant difference between nasal and temporal partial tenotomy for VD in adduction ($Z= 4.215$, $p<0.001$) and for VD in abduction ($Z=-2.365$, $p=0.018$) but not for pattern and cyclotropia.

Conclusions: The significant differences between the change of VD in adduction as compared to that in abduction, show that nasal and temporal partial tenotomies are suited for an isolated small VD in either ad- or abduction. It remains unclear why the change of cyclotropia by temporal partial tenotomies (N=19) was so small.

ABSTRACT BODY:

Purpose: Nicotine can affect cellular metabolic states and is considered as a high-risk factor for various retinal diseases. The aim of this study is to determine, whether nicotine causes a change in the fluorescence lifetime (FLT) of the healthy ocular fundus using fluorescence lifetime imaging ophthalmoscopy (FLIO).

Methods: Twenty eight smokers (≥5 cigarettes/day, >2 years) aged between 20 and 37 years and 26 age-matched nonsmokers without systemic or retinal diseases were investigated. All participants were examined with routine ocular examinations including optical coherence tomography and FLIO (473 nm excitation, detection with the short spectral channel (SSC, 498-560 nm) and the long spectral channel (LSC, 560-720 nm)). FLT was analyzed for the macular areas using the Early Treatment Diabetic Retinopathy Study (ETDRS) grid.

Results: Compared to the non-smoking group, the smoking group showed significantly longer FLT (mean FLT: τ_m) in the SSC's inner ring of the ETDRS grid (Median: 211 ps non-smokers vs. 221 ps smokers), and a shorter τ_m in the LSC's outer nasal (244 ps non-smokers vs. 232 ps smokers) and outer superior (238 ps non-smokers vs. 227 ps smokers) ($p<0.05$). Variance analysis indicated a significant dose-dependent correlation between τ_m in the LSC and the cumulative nicotine dose, while an increased nicotine dose correlates with a shorter τ_m in the outer ring. There was no difference in retinal thickness between both groups and no correlation was found between retinal thickness and τ_m.

Conclusions: The results suggest a significant influence of smoking on the FLT of the ocular fundus, which might indicate metabolic or hemodynamic changes of retinal tissues by nicotine consumption.

ABSTRACT BODY:

Purpose: To identify whether patients with systemic autoimmune diseases without uveitis are at an increased risk for adverse outcomes following phacoemulsification surgery.

Methods: Medical records were reviewed of patients who underwent phacoemulsification cataract extraction with intraocular lens implantation between January 1, 2014, and December 31, 2019, at the University of Colorado Hospital. Exclusion criteria included history of uveitis and cataract surgery combined with another intraocular surgery. Data including sex, race/ethnicity, age, surgery length and cumulative dissipated energy (CDE), pre- and post-operative best-corrected visual acuity (BCVA) and intraocular pressure (IOP), and the presence or absence of post-operative persistent anterior uveitis (PAU) and post-operative cystoid macular edema (CME) were obtained. At our institution, patients with autoimmune diseases without uveitis receive the same post-operative corticosteroid regimen without additional pre-operative corticosteroids as compared to patients without autoimmune diseases.

Results: The charts of 762 eyes from patients with autoimmune diseases were reviewed. The control group of patients without autoimmune diseases comprised 10,201 eyes. Baseline demographics of the two groups were notable for a significantly higher percentage of females (76.4%, $p < 0.0001$) and younger age (68.3, $p=0.013$) within the autoimmune group. There was no statistically significant difference between the two groups with regards to race/ethnicity, surgery length, post-operative BCVA and IOP, and post-operative PAU and CME. For PAU specifically, 3013 eyes that had previously been reviewed for PAU made up the control group. In this control group, 2.4% of eyes developed PAU.

Conclusions: Patients with systemic autoimmune diseases without uveitis do not appear to be at higher risk for adverse outcomes, including persistent anterior uveitis, following phacoemulsification cataract extraction. These findings suggest that patients with autoimmune diseases without uveitis do not require a modified peri-operative corticosteroid regimen.

ABSTRACT BODY:

Purpose: To describe the morphology of the corneal endothelium in healthy Hispanic patients with primary cornea guttata (PCG).

Methods: A retrospective, descriptive, and analytical study of specular microscopies was performed to study the central region of the corneal endothelium in healthy, surgery-naive Hispanic patients with PCG.

Results: 123 eyes from 76 patients with PCG were included for analysis. Mean age was 68.14 ± 10.55 years (range 45-88 years). Mean cell density (MCD) 1853.10±643 cells/mm2, the mean cell area was 596.1±263 µm2, and the mean central corneal thickness was 527.55±47.56 µm. 65% of patients had polymegethism and 80.5% had pleomorphism. 84% of patients had less than 25% total area affected. Females were the majority of PCG patients (64%), with higher rates of polymegethism (58.6%), and pleomorphism (63.6%).

Conclusions:

Hispanic patients with PCG show a lower than average MCD compared to the Hispanic population. A high rate of polymegethism and pleomorphism was observed, particularly in females, where PCG was more frequent.

ABSTRACT BODY:

Purpose: In the last decade there have been vast advancements in artificial intelligence (AI) in ophthalmology. However, reporting in AI literature is highly unstandardized and algorithmic fairness remains challenging to assess. In this preliminary study, we evaluate 59 studies on the development, validation, and trialing of AI tools for referable diabetic retinopathy (RDR) diagnosis, on measures of transparency. To do so, we employ a scoring system using an AI model card, a framework for benchmarked assessment of algorithmic fairness.

Methods: We identified 59 studies on AI algorithms for RDR diagnosis using fundus photos. 17 studies reported on algorithm training and internal validation, 26 studies on external validation, and 16 studies on prospective, clinical validation of RDR algorithms. We apply our model card scoring system to these studies to broadly assess algorithm transparency. Model card scored elements include basic model details (i.e. model version), elements of intended use, input/output definitions and architecture, training and evaluation dataset details (i.e, source, size, demographics), performance measures (AUC, sensitivity (SE) and specificity (SP)), and ethical factors relating to algorithm bias.

Results: Out of a total possible score of 22, clinical validation studies scored an average of 16.7 (range 13- 20), representing a moderate level of transparency. Only 1 clinical validation study defined a clear scope of use and only 3/16 studies reported data on race. While nearly all reported sensitivity and specificity, only 9/16 studies reported AUC and only 4/16 reported imageability. Clinical validation studies were conducted on an average of 1094 patients, ranging from 143-4381 patients. Average AUC, SE and SP was 0.9305, 90.8%, and 85.8% respectively. Similarly, reporting on training and external validation varied widely. 6/43 studies reported race data. Training datasets ranged from 89 to 466,247 images, averaging 52,035 images. Average AUC, SE, and SP was 0.960, 90.9% and 89.46% for training algorithms respectively. Average AUC, SE and SP of externally validated algorithms was 0.942, 92.4%, and 86.17% respectively.

Conclusions: Our results demonstrate a high level of variability in reporting of AI algorithms for RDR, with many clinical validation studies demonstrating moderate or poor levels of transparency. Model cards may help in promoting fairness and standardization of AI reporting.

ABSTRACT BODY:

Purpose: To compare complications of dexamethasone implants (DEX) and intravitreal triamcinolone (IVTA) in eyes with post-vitrectomy macular edema (ME).

Methods: A single-center, retrospective study was conducted at Wills Eye Hospital (Philadelphia, PA, USA). 0.7 mg DEX (Ozurdex; Allergan, Inc., Irvine, CA) and 2mg IVTA (Triesence; Alcon Laboratories, Fort Worth, TX) were injected in an office-based clinical setting. The medical records of patients who underwent DEX or IVTA for post-vitrectomy ME between July 2014 and May 2021 with a minimum follow-up of three months were reviewed. We reviewed the following parameters: age, gender, ophthalmic history, pre-treatment and post-treatment visual acuity, and post-treatment ocular complications.

Results: A total of 125 eyes from 124 patients were included in this study. There were 65 eyes from 65 patients in the DEX group (43% female, mean age 69.7 [±11.5] years) and 60 eyes from 59 patients in the IVTA group (% female, mean age 72.2 [±12.5] years). The total follow-up duration was 2.9 ± 1.7 years, with no significant difference between the two groups (p=0.059). The reasons for prior vitrectomy included rhegmatogenous retinal detachment (RRD), epiretinal membrane, macular hole repair, vitreous hemorrhage, proliferative diabetic retinopathy, retained lens fragments, vitreous opacities, and endophthalmitis. The reasons for DEX and IVTA treatments included post-vitrectomy ME, central retinal vein occlusion, branch retinal vein occlusion, and diabetic ME. The rate of ocular hypotony was significantly higher in the DEX group (9 eyes [14%]) compared with the IVTA group (1 eye [2%]) (p=0.029). The incidence of ocular hypertension was higher in the DEX group (24 eyes [37%]) compared with the IVTA group (12 eyes [20%]) but not statistically significant (p=0.059). There were no between-group differences in the incidence of vitreous hemorrhage (DEX 3 eyes [5%]; IVTA 1 eye [2%]; p=0.669) or RRD (DEX 2 eyes [3%]; IVTA 1 eye [2%]; p=0.944).

Conclusions: The risk of ocular hypotony was significantly higher and the incidence of ocular hypertension was higher after DEX treatment than after IVTA in eyes with a history of vitrectomy. There were no between-group differences in the other complications.

ABSTRACT BODY:

Purpose: Estimating the full 3-D biometry of the crystalline lens is important for understanding its changes with aging, accommodation or myopia development, and for improving intraocular lens calculations. In Martinez-Enriquez IOVS 2016, we proposed a 2-region parametric model (2RM) to estimate the full lens shape ex vivo and in vivo from optical coherence tomography (OCT) images. Martinez-Enriquez BOE 2020 described a novel method for the representation of the full shape of the lens ex vivo (Eigenlenses). Here we demonstrate the use of Eigenlenses to estimate the full shape of the lens in vivo, in comparison with the 2RM method.

Methods: OCT images were obtained on one eye of 17 human subjects (26±2 y/o; unaccommodated; 5 repetitions) using a custom-developed swept source OCT system (200K A-scans/s, axial depth=16 mm, pixel size=8.3 μm). Surface segmentation and distortion correction were performed to obtain 3-D models of the lens within the pupil. From these models, the full shape of the lens represented by 6 Eigenlenses coefficients was estimated using multiple linear regression. The following parameters were quantified: diameter (DIA), volume (VOL), equatorial plane position (EPP) and lens surface area (LSA). Results from the two methods (2RM and Eigenlenses) were compared in terms of repeatability (standard deviation of repeated measurements) and Pearson coefficient (ρ).

Results: The mean values of lens parameters across subjects were DIA=8.86±0.12/8.70±0.25 mm, VOL=140±7/136±9 mm^3, LSA=152±4/150±7 mm^2, and EPP=1.43±0.03/1.56±0.08 mm, for Eigenlenses/2RM, respectively. Repeatability was DIA_SD=0.06/0.11 mm, VOL_SD=2.3/3.3 mm^3, LSA_SD=1.8/3.1 mm^2 and EPP_SD=0.029/0.041 mm for Eigenlenses/2RM, respectively. The correlation between the parameters calculated with both methods were ρDIA=0.89, ρVOL=0.94, ρLSA=0.92 and ρEPP=0.88. R^2 from multiple linear regression between the first two Eigenlenses coefficients, which are related with the size and aspect ratio of the lens, and the DIA and VOL were R^2=0.98 and R^2=0.997 respectively. Using just these two coefficients only reduced the accuracy of DIA by 0.017 mm and VOL by 0.3 mm^3.

Conclusions: 2RM and Eigenlenses are both robust methods to estimate the full lens shape parameters in vivo. However, the Eigenlenses method is more repeatable and efficient, requiring only two coefficients for an accurate estimation of lens volume and diameter.

ABSTRACT BODY:

Purpose: Femtosecond laser technology has been well established for cataract surgery and has also been attempted for animal corneal wound creation model. The femtosecond laser instrument uses a suction cup (a sterile component that is placed on the cornea) that generates a negative pressure which applanates the cornea to prepare it for the laser operation. This cup is designed to suit human eye and is not compatible for any animal model. In this study, we have prototyped a custom suction cup that is suitable for rabbit cornea for the optimization of wound model.

Methods: Femtolaser instrument (LDV Z8,Ziemer Ophthalmology GmbH ,Germany) was used to initially create the corneal wound (5mm diameter, x N NaOH, x seconds) using the standard suction cup. A 3 dimensional scan of the cup was used to extract the dimensions and used as a reference to redesign a modified suction cup based on the rabbit eye dimensions. The redesigned cup was first prototyped using Digital light processing until the validation stage. The final model was additively manufactured using direct metal laser sintering process using titanium.

Results: The standard suction cup suited for humans had an internal diameter of 12 mm,an external diameter of 20mm and a height of 3.5mm that created a pressure of 70mm-Hg to get the right amount of applanation for the surgery. The standard suction cup when used on the rabbit cornea generated a pressure lesser than 50 mm-Hg and hence the right applanation was not achieved for surgery. Four set of iterations was done to achieve the final desired results of the cup before it was printed in titanium. The final dimensions were reported to have an internal diameter of 9.5 mm, outer diameter of 16 mm and a height of 2.7mm and it achieved pressure of 70 mm-Hg.

Conclusions: A femto-laser assisted rabbit cornea wound model was optimized with the redesigned suction cup. The redesigned suction cup helped generate the right corneal applanation required to carry out the laser surgery and provides a reliable component that suits a rabbit cornea.

TITLE: Patient characteristics from a post hoc analysis of nascent geographic atrophy progression following treatment with avacincaptad pegol from the GATHER1 study

SESSION TITLE: AMD and Geographic Atrophy

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: C.J. Danzig, Rand Eye Institute, Deerfield Beach, Florida, UNITED STATES|

Commercial Relationships Disclosure: Carl Danzig: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Avacincaptad pegol is a C5 inhibitor being investigated for the treatment of geographic atrophy (GA). Based on optical coherence tomography (OCT) changes that signify the evolution of the atrophic process, the atrophy can be subdivided as (1) complete retinal pigment epithelium (RPE) and outer retinal atrophy (cRORA), (2) incomplete RPE and outer retinal atrophy (iRORA), and (3) drusen. This post hoc analysis was conducted to better understand the impact of avacincaptad pegol treatment on earlier stages of GA and to investigate patient baseline characteristics that may be associated with progression of disease and response to avacincaptad pegol treatment.

Methods: GATHER1 was a Phase 2/3, randomized, double-masked, sham-controlled clinical trial. A post hoc imaging analysis of GATHER1 OCT data was performed by a masked analysis evaluating regions of OCT volume scans >500µm from the border of GA lesion(s) at baseline and months 6, 12, and 18 for progression of iRORA to cRORA and drusen to iRORA and/or cRORA.

Results: In the avacincaptad pegol 2-mg group, as compared to the sham group over 18 months, a smaller proportion of patients progressed from iRORA to cRORA (20% vs 42%, respectively) and from drusen to iRORA or cRORA (8% vs 27%, respectively). Baseline characteristic evaluation included prior ocular history, prior surgeries/procedures, visual acuity (Early Treatment Diabetic Retinopathy Study [ETDRS] and Snellen equivalent), low luminance ETDRS, fundus autofluorescence imaging assessments, and fluorescein angiogram imaging assessments. These baseline characteristics were assessed to determine which were potentially associated with progression from drusen to iRORA or cRORA, from iRORA to cRORA, and treatment response to avacincaptad pegol.

Conclusions: In this post hoc analysis of the GATHER1 trial, avacincaptad pegol 2 mg was associated with greater numerical reduction compared to sham in the progression of iRORA to cRORA, and in the progression of drusen to iRORA or cRORA over 18 months. Baseline characteristics potentially associated with GA progression and treatment response with avacincaptad pegol are identified.

ABSTRACT BODY:

Purpose: School vision screening programmes play a key role in the early detection of uncorrected refractive error and other ocular conditions in children. The efficacy of vision screening depends on the specific test protocol and criteria used. Here, we used scalar blur values (SBV; representing blur attributed to refractive error; Blendowske, 2015), derived from childhood refractive error data, to simulate the effect of modifying cut-off criteria on the accuracy of visual acuity (VA) in vision screening tests

Methods: Calculations were based on eye examination data from 255 primary and high school students aged 4-18 years in rural Queensland, Australia. Data included uncorrected monocular and binocular logMAR distance and near VA, distance VA with +1.50DS blur, and with cycloplegic autorefraction. The sphero-cylindrical autorefractor results (range of spherical equivalents -3.63D to +8.13D) were converted to SBV and used to classify the presence of refractive error. ROC curves were generated for a range of SBV and screening test performance simulated by calculating the effect of different VA cut-off values. The area under the curve (AUC) provided an overall diagnostic accuracy measure, a conservative 0.9 criterion was applied.

Results: Sensitivity and specificity depended on both VA cut-off values, and the magnitude of refractive error (SBV) considered significant. The 0.9 AUC criterion was achieved for myopes at SBV values of 1.25D and 1.50D for monocular and binocular measures respectively. Applying a cut-off value of 0.3 logMAR with these SBV yielded a sensitivity of 100% and specificity of 85% for myopes tested monocularly. For hyperopes, the same criterion was achieved at SBV values of 3.50D (monocular and binocular). Unlike near VA which did not improve SBV, adding a +1.50 blur test for hyperopes substantially reduced these values: 2.00D (monocular) and 2.25D (binocular).

Conclusions: The SBV approach allows the effect of different screening tests and criteria on sensitivity and specificity to be simulated and quantified. Distance VA measured in isolation was effective at detecting approximately 1D of myopia, compared to 3.5D of hyperopia. The inclusion of a +1.50DS blur test in children with good distance acuity substantially improved hyperopia detection. Using the SBV approach on larger datasets will help determine the most effective test protocol for school vision screening.

TITLE: Comparison of Cataract Surgery Outcomes in Patients with Type 1 versus Type 2 Diabetes

SESSION TITLE: Cataract surgery: techniques and outcomes

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J.L. Xia, J.L. Patnaik, K.L. Christopher, Ophthalmology, Sue Anschutz-Rodgers Eye Center, University of Colorado Anschutz Medical Campus in Aurora, Colorado, Colorado, UNITED STATES|

Commercial Relationships Disclosure: Julia Xia: Commercial Relationship: Code N (No Commercial Relationship) | Jennifer Patnaik: Commercial Relationship: Code N (No Commercial Relationship) | Karen Christopher: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Existing studies on cataract surgery in diabetic patients have either looked at all types of diabetes combined or type 2 diabetes alone. This study aims to report the intraoperative and postoperative outcomes of cataract surgery in patients with type 1 diabetes (T1DM) compared to type 2 diabetes (T2DM). We hypothesize that T1DM eyes have greater prevalence of preexisting diabetic retinopathy, worse postoperative visual outcomes, and higher rates of postoperative cystoid macular edema (CME).

Methods: A retrospective chart review was performed for 8117 patients who underwent cataract surgery at the Sue Anschutz-Rodgers Eye Center, University of Colorado Anschutz Medical Campus from January 2014 to January 2020. Demographic data, ocular history, intraoperative and postoperative outcomes were compared using general logistic regression modeling with estimating equations to account for patients who had two eyes included. SAS version 9.4 software was used for the analyses.

Results: Our patient population was divided into T1DM (n=146), T2DM (n=1849), and patients without diabetes (n=6122). Patients with T1DM were diagnosed with diabetes at a mean age of 23.5 years and underwent cataract surgery after a mean of 29.9 years from diagnosis. Compared to T2DM eyes (n=3115), T1DM eyes (n=233) were more likely to have a history of proliferative retinopathy (63.1% vs 42.4%, $p<0.0001$), retinal detachment (9.0% vs 2.9%, $p<0.0001$), and were more likely to have undergone prior vitrectomy surgery (12.9% vs 4.0%, $p<0.0001$). T1DM eyes had worse postoperative best-corrected visual acuity (BCVA) (logMAR 0.27 vs 0.15, $p=0.0003$) despite having similar preoperative BCVA to T2DM eyes (logMAR 0.52 vs. 0.44, $p=0.092$). T1DM eyes had higher rates of posterior capsule opacification (PCO) requiring YAG capsulotomy compared to T2DM eyes (18.9% vs 9.0%, $p<0.0001$). The rate of postoperative CME was higher in T1DM compared to T2DM eyes but the difference did not reach statistical significance (5.2% vs 2.7%, $p=0.105$).

Conclusions: T1DM eyes have greater prevalence of preoperative diabetic retinopathy and have worse BCVA after cataract surgery compared to T2DM eyes. While there was more postoperative CME development in T1DM compared to T2DM eyes, this difference did not reach statistical significance. Additionally, there were higher rates of PCO requiring YAG capsulotomy in T1DM compared to T2DM eyes.

TITLE: Scleral deformation under air pulse – a finite element study

SESSION TITLE: Refractive Error: Myopia, Hyperopia, vision and models

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. De la Hoz, J.S. Birkenfeld, S. Marcos, Instituto de Optica Daza de Valdes, Madrid, Comunidad de Madrid, SPAIN|S. Marcos, Center for Visual Science, Rochester, New York, UNITED STATES|

Commercial Relationships Disclosure: Andres De la Hoz: Commercial Relationship: Code N (No Commercial Relationship) | Judith Birkenfeld: Commercial Relationship(s);Code P (Patent):WO2021152185A1 | Susana Marcos: Commercial Relationship(s);Code P (Patent):WO2021152185A1

ABSTRACT BODY:

Purpose: The mechanical properties of the sclera are relevant for the understanding of tissue remodelling and potential new treatments of myopia. Air pulse deformation imaging has been used to characterize the mechanical properties of the cornea in vivo, and has shown some potential for use in characterizing the sclera's mechanical properties. In this work, we studied the influence of parameters such as material preoperties, intraocular pressure (IOP), and tissue thickness on scleral deformation, using a parametrized finite element model of the porcine sclera.

Methods: A three-dimensional finite element model of the porcine eye globe was created in ANSYS Mechanical. IOP was incorporated as an internal fluid volume. A one-term Ogden hyperelastic model was used to describe the non-linear elastic behavior of the tissue. A range of values were evaluated for each variable: thickness of .58 to 0.78 mm at site of air pulse loading, IOP of 15 to 30 mmHg, material model μ value of 0.01 to 0.1 MPa. Central displacement, central-peripheral deformation ratio, applanation time, and peak-to-peak distance were calculated from the deformed sclera. A multiple regression was done to quantify the influence of the independent variables.

Results: Unlike results in the cornea, applanation and peak-to-peak distance do not appear to be suitable descriptors of deformation, as higher scleral rigidity produced small values in these parameters. Central displacement was found to be highly correlated to material properties (correlation coefficient R^2=0.90), but thickness (R^2=0.06) and IOP (R^2 =0.02) were poorly correlated. The influence of thickness and IOP was more pronounced for the upper range of deformation values (>1mm central displacement). At the lower range (>0.4mm), deformation is driven primarily by material coefficient.

Conclusions: Porcine scleral deformation is influenced by elastic material properties, IOP, and thickness, with the former being the primary influence in the lower deformation range. Results suggest that air pulse deformation imaging could be used to estimate the elastic mechanical properties of the sclera in vivo.

TITLE: Csk regulates lacrimal gland development by controlling YAP activity

SESSION TITLE: Ocular surface health and conjunctiva

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. hannan, ophthalmology, Columbia University Irving Medical Center, New York, New York, UNITED STATES|

Commercial Relationships Disclosure: abdul hannan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Lacrimal gland (LG) is the tear secreting gland which keeps eyes moistened. Dysfunction of the lacrimal gland can lead to the aqueous-deficient dry eye disease and even corneal damage. In this study, we find that C-terminal Src kinase (Csk) plays a key role in the development of lacrimal gland in a YAP dependent manner.

Methods: Csk was deleted in the lacrimal gland using a LG epithelial specific Cre during embryogenesis. Csk-deleted mouse was sacrificed, and the phenotype of the lacrimal gland was examined at various postnatal stages by fixing the glands with 4% paraformaldehyde followed by immunofluorescence and H&E staining. Primary LG epithelial cells were collected from P1-4 mouse pup and cultured for one week and treated with Csk inhibitor.

Results: We observed that the Csk-ablated lacrimal gland could not differentiate into a functional LG, instead we found dilated acini and ducts with complete loss of suppressive Src phosphorylation (pSRC-527Y) and the presence of active nuclear YAP. By RNA-seq analysis of the FACS-sorted LG epithelial cells, we also observed a significant increase in Yap target genes. Remarkably we could also rescue the dilated phenotype of the LG by homozygous deletion of YAP in the Csk deletion background, which supports our hypothesis that Csk regulates LG development via regulating YAP activity. Hippo pathway is known to regulate YAP by S-127 phosphorylation on its N terminal domain, which results in the inhibition of YAP function and cytoplasmic retainment. On the other hand, phosphorylation of YAP at Y-357 by Src family of kinase leads to the nuclear localization of YAP and enhanced transcriptional activity. WB analysis shows that treatment of LG epithelial cell with Csk inhibitor did not change the phosphorylation pattern of YAP at the S-127 site, but it led to a significant increase of Y-357 phosphorylation, suggesting that Csk regulates Yap activity independent of Hippo signaling.

Conclusions: Our results demonstrate that Csk regulates lacrimal gland morphogenesis by controlling the Yap activity. Deletion of Csk results in the activation of Src kinase which activates YAP by phosphorylating Y-357 and results in the dilation of the lacrimal gland.

ABSTRACT BODY:

Purpose: Metastatic uveal melanoma (MUM) is a poor prognosis cancer wherein approximately 85% of patients diagnosed do not survive beyond one year. There is no standard of care for MUM. Therefore, it is vital to understand and identify novel pharmacological based drugs for MUM. Ergolide, a sesquiterpene lactone isolated from the flowers of Inula species (a medicinal herb), exerts anti-cancer properties. The objective of this study is to: 1) evaluate whether Ergolide reduced MUM cell survival/viability in vitro and in vivo; and 2) understand the Ergolide mechanism of action.

Methods: Clonogenic cell survival assays assessed the ability of uveal melanoma (UM) cells derived from primary (Mel285 and Mel270) and metastatic (OMM2.5) tumours to proliferate following treatment with Ergolide. Cells were treated with 1, 5 or 10 μM Ergolide (N = 3) for 96 hours and additionally cultured for 10 days with fresh media. DiI labelled OMM2.5 cells were transplanted into the perivitelline space of 2 days old zebrafish larvae, treated with 0.5% DMSO or 2.5 μM Ergolide for 3 days and analysed for changes in primary xenograft cell fluorescence. Methods to isolate extracellular vesicles from OMM2.5 cells and UM patient samples are being optimised.

Results: Ergolide treatment resulted in a dose dependent, significant reduction (ranging from 48.5 - 99.9%; $p < 0.02$) in cell colony proliferation across all three UM cell lines. In vivo, in zebrafish OMM2.5 xenograft models, 2.5 μM Ergolide treatment averaged a 56% regression ($p < 0.0001$) of normalized primary xenograft fluorescence compared to vehicle controls.

Conclusions: Our findings suggest that Ergolide is capable of preventing UM/MUM cell survival in vitro; and reduces OMM2.5 primary xenograft fluorescence in vivo that needs to be further explored. Future studies will investigate 1) the mechanism of action of Ergolide in vitro through proteome profiling, and 2) changes to the molecular properties of extracellular vesicles isolated from OMM2.5 cells treated with Ergolide.

ABSTRACT BODY:

Purpose: To compare differences and agreement for ocular parameters and target refractive error in Chinese emmetropic (AL 22-24 mm), hypermetropic (AL <22 mm) and myopic eyes (> 26 mm) obtained by two optical biometric instruments; the CASIA2 AS-OCT (Tomey, Japan) and Pentacam AXL (Oculus, Germany) using two different IOL power calculation formulae.

Methods: In this random population-based cross-sectional study, 174 consecutive subjects aged 50 and over underwent biometric assessment using the CASIA2 and the Pentacam AXL devices. The right eye of each subject was used for analysis. Ocular parameters and target refractive error were compared between devices using a constant IOL SEQ equal to 19.50. Measurements were expressed as mean and standard deviation. Differences between devices, using Barrett UII and SRK/T formulae, and across emmetropes, hypermetropes and myopes were determined using Wilcoxon signed-rank test and Kruskal-Wallis test. The agreement in ocular biometry and IOL power between the 2 devices was evaluated by the Bland-Altman method.

Results: Overall, 174 eyes of 174 subjects were analyzed. Mean age was 60.49 (± 6.58). Based on axial length and refractive error, 134 were emmetropes, 7 were hypermetropes and 33 were myopes. 66.67% of subjects were female. There were no significant differences in measured ocular parameters between devices and across emmetropes, hypermetropes and myopes. For target refractive error, statistically significant differences between devices were noted for all three groups, with the difference being highest using Barrett UII formula and in myopes (0.31 ± 0.22), followed by emmetropes (0.26 ± 0.27), and then hypermetropes (0.25 ± 0.29). For each device, there were no statistically significant differences in target refractive error between the two formulae.

Conclusions: Despite using different imaging principles, parameters obtained by the CASIA2 and Pentacam AXL devices are comparable. There were statistically significant differences in target refractive error between devices, but would be within a clinically acceptable margin of error. Both devices are comparable across a range of axial lengths.

ABSTRACT BODY:

Purpose: The interaction of ICAM-1/LFA-1 is essential for T cell activation and migration. Intravascular ICAM-1 has been shown to be upregulated during corneal inflammation, such as in dry eye disease (DED). The purpose of this study was to assess if LFA-1 antagonist Lifitegrast can reduce $CD4^+$ T cell migration to the cornea by modulating the expression of chemokine receptors during DED

Methods: DED was induced in 6–8 week-old mice by exposure to the controlled environment chamber and subcutaneous injections of scopolamine. Mice were treated with topical Lifitegrast (or normal saline [NS] control) 3 times daily. Fifteen days later, DED severity was assessed with corneal fluorescein score (CFS) and T cells were quantified by flow cytometry (FC) of corneal single cells for the cytokines IFN-γ (Th1) or IL-17A (Th17). Expression of chemokine receptors on T cells from local draining lymph nodes (dLNs) were assessed by qRT-PCR and FC. $CD4^+$ T cells from DED mice treated with Lifitegrast or NS were sorted and adoptively transferred to RAG knockout (KO) mice. Five days later, DED severity was assessed and T cells were quantified in pooled corneas and dLNs by FC

Results: CFS and tear secretion were significantly increased at day 15 in DED mice treated with Lifitegrast, compared to DED mice treated with NS ($p < 0.001$). Lifitegrast treatment resulted in reduction of $CD4^+$ T cell recruitment (Th1) to the cornea by FC($P<0.05$) with reduction of corneal IFN-γ and TNF-α compared to DED mice treated with NS. $CD4^+$ T cells from dLNs showed reduction on the expression of chemokine receptors CXCR3 and CCR4 by FC in DED-Lifitegrast vs. NS-treated controls mice ($p<0.05$). Interestingly, adoptive transfer of $CD4^+$ T cells from DED mice treated with Lifitegrast resulted in significant reduction of CFS and improved tear secretion ($p<0.05$) with reduction of T cells (Th1) recruitment into the cornea (17% vs. 44%) but no changes in the dLN compared to NS-treated controls

Conclusions: Lifitegrast treatment reduces CFS and improves tear secretion in DED mice, and resulted in significant reduction in corneal effector Th1 cell recruitment and reduction in pro-inflammatory cytokines. Lifitegrast treatment may mediate DED by inhibiting corneal T cell migration through the modulation of CXCR3 and CCR4 expression on $CD4^+$ T cells in dLNs

ABSTRACT BODY:

Purpose: The retinal pigment epithelium (RPE) is thought to be functionally different in different regions of the eye, implicating its role in regional retinal diseases like age-related macular degeneration (AMD). Recently, we completed a morphometric map of human RPE and defined five concentric rings containing subpopulations with varying cell sizes. Going from the macula to the periphery, these subpopulations were named P1 to P5. Using this map, this study aims to determine if any subpopulation had a higher prevalence of lesions in non-AMD and AMD eyes and to use changes of cell morphometry to predict the initiation of AMD.

Methods: Flatmounts of 17 non-AMD donor eyes and 5 AMD eyes were stained and analyzed with a machine learning based software created to quantify RPE morphometrics. After identifying micro lesions, 3 RPE-retina flatmounts were optically cleared with BABB and stained for RPE borders and photoreceptors.

Results: RPE cells in the lesioned area exhibited weak phalloidin staining, elongated borders, and a larger area. Analysis of lesion prevalence in each subpopulation indicated that P5 (far-periphery) had significantly more lesioned area than P3 (mid-periphery) in non-AMD eyes (24% vs 7%). AMD eyes showed the same pattern, albeit without statistical significance. To understand RPE morphometric changes with age, we divided the eyes into age groups (<65, 65-79, 80-100, and AMD 80-100). We found that, compared to younger donors, the 80-100 age group of non-AMD eyes had more elongated and less hexagonal cells in P1 (macula). AMD 80-100 data presented with more variability but generally showed worse aspect ratio, hexagonality, and an irregular number of neighbors, indicating abnormalities in the RPE.

Conclusions: The findings show that far peripheral RPE presents with more risk for developing sub-RPE deposits as compared to mid-peripheral RPE in non-AMD donors, highlighting the importance of imaging peripheral retina. Changes in RPE morphometry with age are more evident in the macular region and advances in the resolution of adaptive optics could allow analysis of RPE morphometrics in real time and could be a predictive tool for clinicians.

ABSTRACT BODY:

Purpose: To evaluate and compare the characteristics of the filtering bleb and scleral flap in trabeculectomy, created with a diamond or metal blade, using an anterior segment optical coherence tomography (AS-OCT).

Methods: We enrolled patients after a first trabeculectomy, in which the scleral flap was created using a diamond or metal blade, and continued follow up in our clinic by a glaucoma specialist. An AS-OCT was done at least 6 months post operation and analyzed for bleb height, bleb-wall thickness and para-scleral drainage route in the anterior and posterior parts of the scleral flap. Operative success was defined as IOP reduction of 30% and bellow 18 mmHg, addition of medication was considered as qualified success.

Results: 32 eyes (of 30 patients) were evaluated, 18 in the diamond blade group (DB) and 14 in the metal blade (MB) group. Success rate was 94.44% and 71.43%, respectively. Preoperative IOP was 23.33±7.09 [range 12-38 mmHg] in the DB group and 23.43±4.97 [range 16-36 mmHg] in the MB group. A mean IOP reduction at last follow up was 11.56±7.42 and 10.43±5.35 mmHg, respectively, with a lower medication rate in the DB group: 0.7 vs 1.7.
AS-OCT analysis showed a mean bleb height and bleb wall thickness of 843.33±357.37 and 685.11±259.35μm in the DB group compared to 651.29±284.17 and 519.5±237.61μm in the MB group, respectively, with $p<0.05$ for bleb wall thickness.

Conclusions: Higher success rate, IOP and medication reduction was seen with a diamond blade used for the scleral flap in trabeculectomy. This may be attributed to a thicker bleb wall associated with higher filtration rate.

ABSTRACT BODY:

Purpose: Subretinal injection of AAV5-RPGR gene therapy in participants (pts) with XLRP aims to target as much of the structurally intact retina as possible within the posterior pole. We assessed whether the topographically treated area of the retina (within the bleb) functionally improved over time compared to the untreated surrounding area (outside the bleb), as measured by photopic static perimetry of all tested loci.

Methods: Pts in study MGT009 (multicenter open-label Phase 1/2 trial; NCT03252847) were given 0.3-0.8 mL of AAV5-RPGR subretinally at 1 of 3 doses to the worse-seeing eye in the study dose-escalation phase; maximal coverage of structurally intact retina was achieved with >1 retinotomy, if needed. Location/extent of blebs were documented with intraoperative video. Retinal sensitivity (Octopus 900 full-field static perimetry) was compared within/outside the bleb(s) within 30-degree hill-of-vision (V30) at baseline through 12 mo for 2 intermediate dose pts. To create bleb overlay images, the hill-of-vision surface was superimposed onto the color fundus image; bleb locations were outlined by the surgeon.

Results: Pts 005 and 007 (male; 33 & 27 years of age, respectively) were analyzed. Pt 005 received therapy in a single bleb, while Pt 007 received 4 blebs to allow for maximal coverage. At 12 mo compared with baseline, V30 in total in the treated eye improved in Pt 005 (7.56 dB-sr vs 9.50 dB-sr, +25.7% improvement) and in Pt 007 (9.54 dB-sr vs 10.18 dB-sr, +6.7% improvement). Within the bleb area(s) within V30, improvements were demonstrated in both patients (Pt 005: 1.94 dB-sr vs 2.60 dB-sr, +33.8%; Pt 007: 3.85 dB-sr vs 4.06 dB-sr, +5.4%). Outside the bleb area within V30, hill-of-vision also improved in Pt 005 and Pt 007 (22.9%; +7.5%, respectively). These data are consistent with the expression of a functional RPGR protein.

Conclusions: Increases in baseline-subtracted retinal sensitivity at 12 mo (within/outside the bleb area within V30) indicate improvements in photoreceptor function suggesting local efficacy of AAV5-RPGR gene therapy. The treatment effect may extend beyond the margins of the bleb following surgery owing to subretinal extension before retinal reattachment. Further development of this therapy is warranted.

ABSTRACT BODY:

Purpose: The axons of retinal ganglion cells in the optic nerve head (ONH) can be visualized and quantified with 3D-OCT. Thickness as well as cross-sectional surface area have been suggested as possible quantification methods to assess pathological loss of axons in glaucoma. Currently, there is no consensus on a preferred method. This study aimed to estimate the minimal cross-sectional surface area in non-glaucomatous subjects with a custom-made computational algorithm. The cross-sectional surface area, Pigment epithelium central limit - Inner limit of the retina Minimal Area (PIMA), was calculated over the circumference of the ONH as PIMA-2π.

Methods: One eye from each of 40 non-glaucomatous subjects aged 20-69 equally stratified according to age group and gender was estimated for minimal cross-sectional surface area. Image volumes were acquired with 3D-OCT Topcon models OCT2000 and Triton, commonly available at the clinic. Confidence intervals and linear regression were used for statistical evaluation.

Results: A 95% confidence interval for PIMA-2π was estimated to 2.03 ± 0.14 mm^2. In each age group, PIMA-2π was estimated to 2.02 ± 0.36 mm^2, 2.35 ± 0.54 mm^2, 2.13 ± 0.26 mm^2, 1.78 ± 0.30 mm^2 and 1.87 ± 0.23 mm^2 for ages [20;29] [30;39] [40;49] [50;59] [60;69] respectively. The correlation coefficient estimated as a 95% CI for k was $-9.48 \pm 9.07 \times 10^{-3}$ mm^2/year (D.f.= 38).

Conclusions: Presented values of cross-sectional surface area are slightly higher but of the same magnitude as measurements done with Heidelberg Spectralis 3D-OCT in similar studies. This can be attributed to our custom computational algorithm which takes undulations of the cross-sectional area into account. Furthermore, the results imply a loss of retinal ganglion cell axons in non-glaucomatous subjects as measured in cross-sectional surface area. Due to a small sample size and large variation among individuals, definite conclusions cannot be drawn on typical loss in non-glaucomatous subjects.

ABSTRACT BODY:

Purpose: To optimize delivery of erythropoietin (EPO) as a treatment for optic neuropathies and investigate mechanisms of action.

Methods: We generated a mutant form of EPO, EPO-R76E, that has attenuated erythropoietic activity. Purified EPO-R76E was loaded into either PLGA particles or PPS microspheres, which scavenge reactive oxygen species (ROS) and injected into the vitreous of mice one day after elevation of intraocular pressure (IOP) by intracameral injection of microbeads. Levels of EPO-R76E, ROS, and antioxidant proteins were quantified. EPO-R76E activated signaling pathways and NRF2 phosphorylation were quantified. Activation of the antioxidant response element (ARE) was quantified using a reporter construct delivered to ganglion cell layer neurons by AAV. Visual function was assessed by electroretinogram (ERG) and visual evoked potentials (VEP). Optic nerves were assessed histologically.

Results: Treatment with PLGA-EPO-R76E increased phosphorylation of NRF2, activation of the ARE, and levels of antioxidant proteins. This response occurred 1-week earlier than the endogenous NRF2 activation that we previously detected after IOP elevation. In addition, EPO-R76E activated a different signaling pathway to phosphorylate Nrf2. We found that EPO-R76E activates the MAPK pathway to induce phosphorylation of Nrf2, which is a different pathway than used by the endogenous response. This also resulted in a different pattern of antioxidant protein expression than the endogenous response. Both PLGA-EPO-R76E and PPS-EPO-R76E particles preserved the amplitude of the photopic negative response of the ERG (PhNR), the VEP, and reduced axon degeneration. The empty PLGA particles showed increased axon degeneration and decreased visual function compared to glaucomatous controls. In contrast, the empty PPS particles showed improved visual function compared to glaucomatous controls.

Conclusions: EPO-R76E activates the NRF2/ARE pathway through a different signaling pathway than the endogenous antioxidant response to elevated IOP. A single injection of EPO-R76E loaded particles provided neuroprotection for several weeks. The PPS microsphere mediated delivery of EPO-R76E may be safer and more efficacious than PLGA-mediated delivery.

ABSTRACT BODY:

Purpose: The relationship between intraocular pressure (IOP), ocular perfusion pressure (OPP), retinal perfusion and retinal electrophysiologic responses have been explored previously only in animal models. These studies have demonstrated that elevated IOP reduces OPP and when this exceeds the autoregulatory capacity of the retina vasculature, retinal perfusion and electrophysiologic responses are reduced. This study aimed to evaluate these interactions for the first time in the living human eye.

Methods: Three research-consented brain-dead organ donors, designated AOC039, AOC040, and AOC041, underwent ocular examination with biometry, fundoscopy, optical coherence tomography angiograph (OCTA; Spectralis, Heidelberg Engineering), and electroretinography (ERG, Diagnosys LLC). Prior to organ procurement, the anterior chamber was cannulated and IOP was directly measured and stepwise elevated at 10, 30 and 50 mmHg. Both eyes were evaluated in two donors (AOC040 and AOC041), and only the right eye in AOC039 due to time constraints. Systemic blood pressure was monitored continuously during testing by their life-support equipment. Photopic ERG and photopic negative response and OCTA-based perfused retinal capillary density were evaluated as OPP was reduced.

Results: Reductions in retinal capillary density and inner retinal function defined by OCTA and photopic ERG were observed in three human brain-dead donors associated with elevation in IOP and concomitant reduction in OPP (Table 1). Reductions in a-wave, b-wave, and PhNR amplitudes and latencies appeared to be correlated to OPP. There were more appreciable changes in perfusion and functional responses in eyes with lower systemic blood pressure (Figure 1).

Conclusions: In the living human eye, retinal perfusion and inner retinal function is acutely impacted by elevation of IOP, and this impact appears related to systemic BP and OPP. This novel approach will provide a viable model to study the autoregulatory responses to IOP elevation in the living human eye.

ABSTRACT BODY:

Purpose: AMD is one of the leading causes of blindness in the world. We developed and assessed an automated screening tool for AMD using deep learning (DL) on color fundus images. The model is deployable on-the-edge on the target device, a smartphone based portable fundus camera.

Methods: We trained an AI binary classifier in two steps. We used two distinct datasets with macula centered images: 108,251 images (55% referable AMD) from the Age-related Eye Disease Study (AREDS), and 598 images (26% referable AMD) captured on Asian eyes using the target device. The model was trained to indicate the presence of referable AMD (intermediate and advanced AMD). We first trained a base model using AREDS only, with a validation set (A) of 990 images (45% referable AMD). We then finetuned this model using the target device dataset only. The finetuning validation set (B) comprised 334 images (34% referable AMD) and test set comprised 332 images (33% referable AMD), both from target device. The reference standard for AMD diagnosis on the AREDS dataset was fundus image grading by a central reading center. On the target dataset, it was the consensus image grading of two vitreo-retinal specialists

Results: The DL algorithm had sensitivity of 94.7% (95% CI: 88.9% to 98.0%), specificity of 87.7% (95% CI: 82.7% to 91.8%) and AUC of 0.98 (95% CI: 0.95 to 1.00) in detecting referable AMD on the validation set B. On the test set, sensitivity was 86.2% (95% CI: 78.3% to 92.1%), specificity was 88.8% (95% CI: 83.9% to 92.6%) and AUC 0.95 (95% CI: 0.92 to 0.98). The model before finetuning had a validation set (A) sensitivity of 89.7% (95% CI: 86.5% to 92.4%), specificity of 93.6% (95% CI: 91.6% to 95.3%) and AUC of 0.97 (95% CI: 0.96 to 0.98).

Conclusions: The DL algorithm shows promising results, despite the small size of the target device and population dataset. This is made possible by finetuning a model previously trained for the same task on a much larger dataset. The strategy proved helpful despite AREDS being captured by traditional desktop cameras on a different population. This on-the-edge AI deployable on a portable camera has potential to make AMD screening accessible, affordable, and effective.

TITLE: Preliminary Retrospective Validation of a Novel Virtual Reality Visual Field Standard Testing Algorithm, as Compared to Standard Automated Perimetry

SESSION TITLE: Visual Fields and Psychophysics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Munshi, K. Da Silva, E. Savatovsky, E. Bitrian, A.L. Grajewski, T.C. Chang, Ophthalmology, University of Miami, Coral Gables, Florida, UNITED STATES|

Commercial Relationships Disclosure: Hounsh Munshi: Commercial Relationship: Code N (No Commercial Relationship) | Kirsten Da Silva: Commercial Relationship: Code N (No Commercial Relationship) | Eleonore Savatovsky: Commercial Relationship: Code N (No Commercial Relationship) | Elena Bitrian: Commercial Relationship: Code N (No Commercial Relationship) | Alana Grajewski: Commercial Relationship(s);Code O (Owner):Virtual Vision;Code P (Patent):Virtual Vision | Ta Chang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Visual field testing is a pillar of glaucoma diagnosis and management, though it requires an in-person patient visit, a designated space, and a skilled technician to administer the test. This study aims to compare a portable VRVF device utilizing a novel algorithm based on relevant physiological retinal nerve bundles to the SITA Standard algorithm used in Standard Automated Perimetry (SAP).

Methods: A retrospective chart review of glaucoma patients seen at a tertiary care clinic between March and July 2021 was conducted. Eligible patients had a VRVF (24-2, Size III) using the VRVF Standard algorithm, and at least 2 previous SAPs (24-2, Size III) using SITA Standard, taken within 4 years of the most recent visit, with good reliability (<30% false positives, false negatives, and fixation losses) on both VRVF and SAP. The mean light sensitivity threshold values from the first eye tested for each patient were compared between the 2 algorithms using an intraclass correlation analysis (ICC) and a Bland-Altman plot.

Results: From the 40 patients identified, 10 were excluded due to poor reliability, or inconsistent stimulus size or testing strategy. Of the remaining 30 patients, an ICC of 0.89 (95 % CI = 0.79 – 0.95; $p < 0.0001$) was calculated from the respective mean sensitivities of the VRVF Standard and the SITA Standard algorithms. A Bland-Altman plot revealed a mean difference of 0.27±3.36, with upper and lower limits of agreement of 6.87 and -6.33, respectively.

Conclusions: ICC showed excellent agreement between VRVF Standard and SITA Standard algorithms, suggesting that this novel algorithm is a promising tool in perimetric testing in glaucoma patients. Although the Bland-Altman plot showed wide limits of agreement, the data was normally distributed around a low mean difference, reflecting the accepted variability of visual field testing. VRVF Standard detects mean sensitivities with significant correlation to SAP SITA Standard and may accurately be used as an alternative to SAP for visual field testing in glaucoma patients.

ABSTRACT BODY:

Purpose: Ranibizumab is a well-established treatment for diabetic patients with macular edema. However, very little is known about the effect of ranibizumab on regulation of VEGF (vascular endothelial cell growth factor) family members by pro- and anti-inflammatory signaling pathways, which was the aim of this study.

Methods: Diabetic patients (n=10) aged 18 years with central diabetic macular edema, BCVA >24 and <78, and central macular thickness (CMT) greater than 250 mm were enrolled in this study (ML39638). Following a full eye exam, imaging, and an aqueous tab, patients received ranibizumab (0.3mg/0.05mL) injections at day one and weeks four and eight. At week 12, a full eye exam, imaging, and a second aqueous tab was obtained prior to the last injection of ranibizumab. Pre- and post-treatment aqueous humor samples were then analyzed using Milliplex MAP magnetic bead assays.

Results: As expected, ranibizumab lowered levels of VEGF-A, decreased CMT (central macular thickness), and improved VA (visual acuity). Ranibizumab – induced changes in levels of VEGF-A and VEGF-C strongly correlated with changes in soluble receptors, sgp130 and sIL-6R, which are associated with IL-6 signaling. In contrast, changes in VEGF-D correlated with sIL-1R1 and sIL-1R2, soluble receptors participating in IL-1 signaling. Changes in CMT and VA did not correlate with changes in levels of VEGF family members. However, following ranibizumab treatment for 3 months, post-treatment values of CMT correlated with post-treatment levels of VEGF-C. Post-treatment VA values correlated with a wide variety of potential biomarkers linked to inflammation.

Conclusions: Ranibizumab treatment affected production of individual VEGF family members and altered specific pro-inflammatory signaling pathways that are seemingly linked to these differing VEGFs. Thus, new drug development focusing on targeting specific VEGF family members or, alternatively, the pro-inflammatory pathways connected to these family members could improve treatment of patients with diabetic macular edema and/or allow for a more personalized treatment approach.

ABSTRACT BODY:

Purpose: Improving the temporal signal-to-noise ratio (tSNR) of functional magnetic resonance imaging (fMRI) data helps identify task-relevant signals. 'NOise Reduction with Distribution Corrected' (NORDIC) principal component analysis (PMID: 34462435) suppresses thermal noise, showing benefits when analyzing block-based or event-related fMRI designs across visual and auditory modalities. However, it is not known if the more precise spatiotemporal signals required for retinotopic mapping are preserved. Here, we evaluate the effects of NORDIC pre-processing on tSNR as well as retinotopic cluster sizes and cortical organization at equivalent R-thresholds.

Methods: Healthy sighted subjects (n=7) had T1-weighted anatomical and T2*-weighted functional scans (voxel size=2x2x3.24mm^3, repetition time=2000ms, echo time=26ms) over bilateral visual cortices using a 3-Tesla MRI scanner. Subjects were visually presented checkerboard rings (expanding, or contracting) or wedges (rotating clockwise, or counterclockwise). Each image was shown for 2000ms, across 16 positions, with 8 repetitions, and 4 runs, taking 17 min 4 s overall (Fig. 1a). tSNR (mean of 'voxel mean÷SD') was measured on the fMRI data with or without NORDIC pre-processing, and retinotopy was computed using population receptive field mapping (pRF) with BrainVoyager.

Results: With NORDIC pre-processing, the retinotopic maps appeared to show similar cortical delineation points to standard pre-processing without NORDIC, however, NORDIC also expanded brain activation areas at the same correlation threshold of R>0.2 (Fig. 1b). Quantitatively, functional volume tSNR was significantly increased by NORDIC pre-processing [$t(6)=7.784$, $p=.000237$, $d=3.75$] (Fig. 2a). Similarly, the largest cluster sizes (LCS) of activated brain regions surviving at R>0.2 correlation thresholds increased in both hemispheres with NORDIC pre-processing [$t(13)=5.960$, $p=.000047$, $d=1.59$] (Fig. 2b-d). A regression analysis revealed that LCS increased alongside tSNR [$F(1,12)=11.95$, $p=.0048$, $r^2= 0.4989$] (Fig. 2e).

Conclusions: We show that NORDIC pre-processing increases tSNR and cluster sizes while preserving their retinotopy. This suggests NORDIC retains the spatiotemporal precision in fMRI data required for pRF and improves the detection of activated brain areas. Overall, NORDIC may serve as an important pre-processing technique for topographical mapping in fMRI.

ABSTRACT BODY:

Purpose: Accurate segmentation of retinal layers offers a wealth of information to clinicians and scientists in terms of diagnostic and predictive biomarkers. Disruption of certain retinal layers is key to determining visual outcomes for patients with nAMD. Accurate quantification of such features remains a time-consuming task for retinal specialists and is challenging to automate. This work proposes an effective DL solution to segment the external limiting membrane (ELM) and ellipsoid zone (EZ) with and without disruptions on OCT scans in eyes with nAMD.

Methods: Our dataset contains OCT images acquired with Cirrus HD-OCT (Carl Zeiss Meditec) from patients enrolled in the HARBOR clinical trial (NCT00891735). Manual annotations denoting ELM, EZ, retinal pigment epithelium (RPE), and Bruch's membrane (BM) as layer boundary elevation maps were performed on a subset of the dataset (989 B-scans from 170 patients).

A DL model with UNet architecture is trained on 90% of the dataset using generalized Dice loss. Schematic of the end-to-end pipeline is shown in Figure 1. Performance is validated on the test set (10% of dataset) with (1) Chamfer distance (CD) for measuring distance in layer boundary between the ground truth and segmented result, (2) layer Dice coefficients of retinal layers using argmax of the segmented output, and (3) 1-dimensional (1D) disruption Dice coefficients for measuring overlap of the linearized layer disruption area between the ground truth and segmentation results. An example of how 1D disruption Dice score is calculated on a single B-scan is shown in Figure 2. Results are reported in mean ± SD.

Results: Evaluated on the test set, model performances to segment ELM and EZ, respectively, are as follows: CD, 17.67 ± 13.22, 13.00 ± 9.35; layer Dice coefficient, 0.56 ± 0.16, 0.60 ± 0.15; 1D disruption Dice coefficient, 0.62 ± 0.38, 0.62 ± 0.37.

Conclusions: Our proposed end-to-end DL solution segments disruptions in the ELM and EZ with reasonable accuracy. This provides clinicians and scientists with an automated tool to quickly generate layer disruption features, which may benefit patient management. The proposed 1D disruption Dice score presents a metric designed to capture the model’s ability to accurately predict retinal layers with disruption.

TITLE: Three Year Outcomes from the PALADIN Phase IV Study: Distribution of Intraocular Pressure Outcomes by Patient Subgroup

SESSION TITLE: Diabetic macular Edema

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Dyer, Alimera Sciences Inc, Alpharetta, Georgia, UNITED STATES|

Commercial Relationships Disclosure: David Dyer: Commercial Relationship(s);Code E (Employment):Alimera Sciences

ABSTRACT BODY:

Purpose: As a class effect, corticosteroids can increase intraocular pressure in some patients, but few studies have looked at long term outcomes due to the short lifespan of most treatment options. However, the 0.19 mg fluocinolone acetonide (FAc) implant US FDA label mandated steroid challenge is designed to mitigate the risk of uncontrolled IOP. Here, we report the IOP outcomes of the PALADIN phase IV study, including mean IOP and time to IOP elevation, in the 36 months post-FAc treatment to determine the impact of the 0.19 mg FAc implant on IOP and functional outcomes within this population.

Methods: Full analysis population includes 202 eyes from 159 patients enrolled with CI-DME that received FAc and were followed for up to 36 months. Eyes were followed at day 1, day 7, month 2, and quarterly from month 3 up to month 36. IOP and best corrected visual acuity (BCVA) were reported at each visit and used to determine outcomes post-FAc.

Results: In the full population, most eyes had a mean IOP of ≤ 25 mmHg in the 36 months post-FAc which was similar to that of pre-FAc baseline values (96.6%=post-FAc; 99.0%=baseline). A breakdown of the population showed subtle changes in the frequency distribution that was not dramatically affected over the 36 months post-FAc. For those eyes that experienced an IOP elevation > 25 mmHg, > 30 mmHg, or were prescribed IOP lowering medications, median time to these events were 9.1, 13.7, and 11.8 months respectively. To determine which eyes may be more susceptible to IOP events post-FAc, subgroups were created and the incidence of IOP events were compared to the full population. Eyes with the no additional treatment post-FAc and baseline BCVA ≤ 20/40 were all associated with less incidence of IOP events compared to the full population. Finally, BCVA was not significantly impacted in the eyes experiencing an IOP elevation >30 mmHg or requiring IOP lowering therapy.

Conclusions: In the 36 months post-FAc, the IOP distribution was marginally affected with over 96% of eyes showing a mean IOP ≤ 25 mmHg at any study visit. In eyes who had an IOP elevation > 30 mmHg or required IOP lowering therapy, these events did not affect long term vision when compared to baseline. Finally, a lower incidence of IOP events post-FAc were noted in the eyes with better vision and fewer additional treatments.

TITLE: Epidemiology Of Herpes Zoster Ophthalmicus in context of the SARS-CoV2 (COVID) pandemic

SESSION TITLE: Antimicrobial Resistance, Epidemiology and New Antimicrobials

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Soifer, A.A. Jammal, H.M. Mousa, A.J. Snyder, V.L. Perez, Duke University Department of Ophthalmology, Durham, North Carolina, UNITED STATES|

Commercial Relationships Disclosure: Matias Soifer: Commercial Relationship: Code N (No Commercial Relationship) | Alessandro Jammal: Commercial Relationship: Code N (No Commercial Relationship) | Hazem Mousa: Commercial Relationship: Code N (No Commercial Relationship) | Alexander Snyder: Commercial Relationship: Code N (No Commercial Relationship) | Victor Perez: Commercial Relationship(s);Code S (non-remunerative):Alcon;Code C (Consultant/Contractor):Dompe;Code C (Consultant/Contractor):Eyegate;Code C (Consultant/Contractor):kala;Code C (Consultant/Contractor):novartis;Code C (Consultant/Contractor):trefoil;Code C (Consultant/Contractor):oculis

ABSTRACT BODY:

Purpose: The incidence of herpes zoster ophthalmicus (HZO) may be increasing, however the impact of the SARS-CoV2 pandemic (COVID) on HZO epidemiology is unclear. This study seeks to determine the variation in the incidence of HZO over the past 6 years with a special focus on its correlation with overall systemic herpes zoster (SHZ) incidence and HZO monthly and seasonal changes before and after the onset of COVID.

Methods: This is a hospital-based epidemiology study of patients attending Duke University Hospital System (DUHS) between 01/2016 and 10/2021 via Duke Enterprise Data Unified Content Explorer (DEDUCE) data with corresponding ICD codes for HZO and SHZ diagnosis. The analysis calculated monthly incidence of novel consults of HZO and SHZ with emphasis on demographics, seasonal variation, and the changes in rates with the COVID pandemic (estimated to impact DUHS population starting in 03/2020).

Results: 24896 patients presented with SHZ at DUHS in the study period, of whom 2921 (11.7%) suffered from HZO. The mean age at the incident episode of HZO was 62.8±15.6 years. Most patients were white (78%), female (63.5%), above 50 years old (79.5%) and non-smokers (61.5%). Over the study period SHZ experienced an overall decline in its incidence, however HZO incident cases have been slightly increasing with a mean of 37/month in 2016, 47/month in 2019, and 50/month in 2021. The ratio of monthly incidence HZO/SHZ demonstrates a steady increase from an annual 9% in 2016 to 13.4% in 2019 and 15.5% in 2021. Interestingly, HZO annual peak incidence steadily emerged in the months of November and February throughout all the years. Since COVID onset, the mean monthly incidence of SHZ decreased significantly (373.1 +/- 35 vs 312.1 ± 28, $p<0.0001$). However, the mean monthly incidence of HZO exhibited a statistically significant increase (39.5 ± 10 vs 46.7 ± 16; $p=0.025$). Likewise, the trendlines of HZO/SHZ exhibited a significant increase since COVID (10.6% ± 4.6 to 15.1% ± 2.7; $p<0.0001$).

Conclusions: These study findings point that HZO incidence may be increasing, despite an overall lower SHZ incidence, which may suggest a distinct mechanism for HZO appearance despite vaccination efforts. A specific seasonal variation with winter peaks was observed, which should guide physicians towards early recognition of HZO. COVID, directly or indirectly, may have accelerated the already increasing HZO incidence.

TITLE: Comparative Localized Corneal Biomechanical Changes Following Laser Vision Correction Using Brillouin Microscopy

SESSION TITLE: Corneal Imaging and Corneal Nerves

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.B. Randleman, Ophthalmology, Cleveland Clinic, Cleveland, Ohio, UNITED STATES|

Commercial Relationships Disclosure: James Randleman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To identify and compare focal in vivo changes in corneal biomechanical properties after PRK, LASIK, and SMILE using Brillouin microscopy.

Methods: Ongoing prospective, cross-sectional study comparing Brillouin scan data from patients with normal corneas as determined by routine clinical evaluation before and after undergoing PRK, LASIK, or SMILE. The primary endpoint was regional change in Brillouin longitudinal modulus after surgery.

Results: All eyes having PRK, LASIK, and SMILE showed relatively uniform Brillouin modulus preoperatively across the central 6mm of their corneas. All normal corneas had slightly lower Brillouin modulus centrally of 20-50MHz. Following laser vision correction by all three methods, central longitudinal modulus decreased by 30-50 MHz, while there were no significant changes in peripheral modulus. There were no significant differences between procedure centrally or peripherally.

Conclusions: Brillouin microscopy was able to successfully identify a focal reduction in corneal stiffness for all three laser vision correction procedures and thereby provide novel highly specific localized corneal biomechanical data in vivo.

ABSTRACT BODY:

Purpose: Under-five mortality (U5M) rate is disproportionately high in Sub-Saharan Africa. Prior studies have revealed an association between childhood blindness and U5M. Employing CHAMPS procedures which includes postmortem minimally invasive tissue sampling and testing, we studied the feasibility for eyes to provide supportive diagnostic information for determining etiologies of U5M.

Methods: Prospective assessment of the feasibility of photography and tissue sampling of postmortem eyes for identifying disease patterns correlating with ophthalmic disease and causes of U5M. Randomly selected cases of stillbirth and under-5 death from Kenya were enrolled. External, anterior, and posterior segment images were obtained with a portable camera, graded by 2 independent ophthalmologists, and adjudicated by a third ophthalmologist. Intra-class correlation coefficients (ICC) were calculated to determine the inter-rater reliability (IRR) of the grading scheme. Conjunctival specimens were obtained for impression cytology and molecular PCR detection of pathogens.

Results: Of 71 subjects (142 eyes) that underwent ophthalmic photography and standardized grading, external photos predominantly showed periorbital edema (16%), skin mottling (14%), ecchymosis (13%), and periorbital erythema (11%). Anterior segment findings were predominantly conjunctival injection (30%), corneal opacity (23%), and conjunctival icterus (16%). Posterior segment findings were predominantly macular whitening (51%), retinal fold (34%), and optic nerve pallor (9%). The ICC for posterior segment findings was 0.68, indicating moderate IRR. The ICC for external and anterior segment findings were < 0.50, indicating poor IRR for both measures.

Of 50 subjects (100 eyes) in which impression cytology was performed, goblet cells (78%), mucin spots (24%) and squamous metaplasia (5%) were observed. Other findings were acute inflammatory cells (4%), viral inclusions (4%), bacteria morphologies (7%), and fungal elements (3%).

Conclusions: In the postmortem assessment of causes of U5M, an ophthalmic surveillance protocol was implemented and feasible with moderate IRR for posterior segment findings on photography and gradable impression cytology specimens in most eyes assessed. Further studies of these diagnostics in relation to time-of-death may provide further

insight into whether ocular findings may contribute to causes of U5M.

ABSTRACT BODY:

Purpose: To report the characteristics of inflammatory findings in patients with USH2A-associated retinal degeneration.

Methods: We retrospectively identified 75 subjects (M=38/F=37, age 4-84) with confirmed disease-causing USH2A gene mutations, all of whom had a complete eye exam, including visual acuity (VA), visual fields (VFs), full field electroretinograms, macular (n=75) and optic nerve (n=40) spectral domain optical coherence tomography (SD-OCT), fluorescein angiography (FA) (n=31), and CLIA-certified testing (n=35) for circulating auto-antibodies (AAbs) against retinal and/or retrobulbar optic nerve (ON) antigens by immunoblot, Western blot, and retinal immunohistochemistry (IHC).

Results: Of the 62 tested eyes with FA, 38 eyes had leakage of optic nerve head, vascular arcades, macula, or a combination thereof. The nerve fiber layer (NFL) was thickened on SD-OCT, most often sectorally, in 49 of 80 eyes, and correlated well with FA leakage, helping explain disproportionate VA losses compared to foveal SD-OCT findings. Cystoid macular edema (CME) was seen by SD-OCT in 47 of 150 eyes. Anti-retinal AAbs were found in 32 of the 35 tested patients [most often against carbonic anhydrase II (16/35) and enolase (15/35)]. AAbs recognizing anti-ON antigens were found in 28 of 34 tested patients. Retinal IHC showed positive staining in 28 of 34 cases, labeling predominantly photoreceptors (26/34) and less frequently ganglion cells (GC=11/34) and NFL (8/34). Altogether, 66.7% (50/75) of patients exhibited clinical signs of inflammation, which correlated directly with the presence of circulating AAbs in 25 of them. These patients received intravitreal and/or sub-Tenon steroid injections, with both subjective and measurable increase in vision (VA, VF, or both), associated with improved OCT and FA characteristics in most cases.

Conclusions: Secondary autoimmunity (affecting optic nerve, NFL, and/or GC) and clinical inflammation involving retina and/or optic disc appear to be common yet underdiagnosed features of USH2A-associated retinal degeneration. Clinical inflammatory manifestations that can be readily detected with macular OCT, disc OCT, and FA affected 2/3 of the patients. Clinical suspicion can be further confirmed by AAb/IHC testing. Identification of these complications is clinically and prognostically important, as meaningful vision improvements can be achieved with treatment.

ABSTRACT BODY:

Purpose: To describe the progression of flecks temporal to the fovea in young patients with ABCA4-related Stargardt disease.

Methods: From a total of 44 patients, aged 4.7–19 (median 11. 9) years at first visit, having confirmed biallelic pathogenic variants in ABCA4 and serial autofluorescent (AF) Optos imaging, we selected green laser (532 nm) optomap images of 10 eyes from 5 patients to demonstrate the progression of ABCA4-related Stargardt's (STDG1) by genotype. We selected these patients because their genotypes could be sorted according to the putative residual functionality of the combined alleles based on biochemical characterizations available in the literature. We analyzed the AF images using ImageJ. In the analyses, we set the distance between the center of the fovea and the center of the optic nerve, in each respective image, to unity. We then produced a rectangular region of interest (ROI) of size 1×1.5, with the long sides parallel to the fovea-ONH segment and the nasal short side centered on the fovea (such that the ROI extended into temporal macula). We then used the thresholding tool to identify and quantify (%) bright flecks within the ROI for each image. (Fig. 1A.)

Results: We observed the rise and fall in %AF within the ROI with the age of patient, consistent with the disease progression model described in Cideciyan, et al. (2004). Furthermore, severe genotypes, such as double null, peaked earlier in life than did the milder genotypes (e.g., two semi-functional alleles).

Conclusions: The %AF in the temporal macula is a strong indicator of the stage of STDG1 disease progression in young patients. Both the timing and the peak values of %AF within the ROI are indicative of the severity of the genotype; more severe genotypes produce higher %AF at earlier ages.

ABSTRACT BODY:

Purpose: Disruption of the actomyosin networks in the chicken lens has been shown to affect lenticular biomechanics. This study compares methods of analyzing and quantifying myosin distributions.

Methods: Lenses from 7-day old white leghorn (Gallus gallus domesticus) chickens were labelled for myosin. Nearest neighbour distances (NNDs) for myosin centroids at the posterior surface were determined using three methods on the same image: 1) ImageJ: manual using the Elliptical tool, 2) ImageJ: automatic using the Analyze Particle tool, 3) MATLAB: automatic using custom-coded software. For analyses using ImageJ, the NND plugin was used. First, the Elliptical tool (manual) on ImageJ was used to determine XY centres of ellipses superimposed on the image by the user. Three ellipses were superimposed on each centroid to account for user error. For the automated ImageJ method, the image was converted to a binary format using the program's Make Binary function. The Fill Holes and Eraser tools in ImageJ were used to correct centroids altered by the thresholding process before determining the myosin centres using the Analyze Particles tool. For analysis in MATLAB, the image was opened and the custom-coded script was run to obtain the myosin centres and NNDs. Corrections were made using MATLAB's Brush tool. The three methods of calculating NNDs from the same 135 centroids were compared (repeated measures ANOVA).

Results: The Analyze Particles tool detected the fewest centroids (135) compared to the Elliptical (166) and MATLAB methods (163). Although the elliptical tool allowed for greater detection, the ellipses do not always fit properly, possibly leading to inaccurate NND values. The MATLAB program uses adaptive thresholding to consider variations in illumination, allowing it to detect more centroids with fewer detection errors than the Analyze Particles tool. Ranges and mean NNDs (±SD) for the same 135 centroids are listed in Table 1; no significant differences were found between the three methods (P=0.2754).

Conclusions: The custom MATLAB program is the choice method for mapping out the proten network using confocal images. It is automated, reducing user error compared to the manual elliptical tool. It also recognized more centroids than the ImageJ "Analyze Particles" feature with fewer errors. Future work involves actin detection to measure actin-myosin distances.

ABSTRACT BODY:

Purpose: Choroideremia is an X-linked inherited retinal degeneration, characterised by loss of the retinal pigment epithelium (RPE) followed by photoreceptor cell death. Fundus autofluorescence (FAF) imaging reveals three distinct RPE patterns in the early stages: smooth, mottled and atrophic appearances (Figure 1). It is not known how structural RPE patterns on FAF relate to retinal function as measured by microperimetry (MP).

Methods: A retrospective review of patients with choroideremia, who had smooth and mottled regions on FAF imaging in both eyes, was performed. These were selected from patients recruited for clinical trial NCT02407678. The smooth and mottled regions on FAF images at baseline were delineated and superimposed on to the MP plots (MAIA, 10-2 grid with 68 points) ensuring alignment of retinal vessels. Eight age and gender-matched controls were used to determine expected normal sensitivity values for each point on the MP plots. These were then used to calculate mean sensitivities for the zones corresponding to smooth and mottled regions in the participants. Mean changes from expected normal values in smooth and mottled regions were compared with a paired t-test.

Results: 30 patients fulfilled the inclusion criteria for the clinical trial (mean age 32.2±8.8 years). Of these, eight had distinct smooth and mottled regions in both eyes (mean age 32.3±9.8 years). The mean MP sensitivities for the smooth and mottled regions were 26.5±3.2 dB and 21.0±4.1 dB, respectively. The mean change from expected values was significantly higher in the mottled compared to the smooth regions (4.6 dB loss versus 1.7 dB loss; 95% confidence interval 1.2 to 4.5; p=0.002). In areas of RPE loss, there was no detectable sensitivity.

Conclusions: This study identifies a correlation between retinal function on MP and structure on FAF imaging in patients with choroideremia. The smooth region is more likely to contain intact ellipsoid zone and preserved photoreceptor anatomy (Stevanovic et al, 2020). There are therefore three RPE patterns seen on FAF imaging in choroideremia: i) an early stage with smooth reflectance which correlates to normal retinal anatomy and similar to normal function; ii) an intermediate ‘mottled’ stage associated with measurably impaired photoreceptor function; and iii) the late stage in which RPE loss is complete and function as assessed with MP is absent.

ABSTRACT BODY:

Purpose: To report on safety of AGTC-401 and AGTC-402, two gene therapies designed to compensate for the most often mutated genes, CNGB3 and CNGA3, in ACHM, a form of autosomal recessive congenital severe cone photoreceptor dysfunction.

Methods: A macular subretinal injection (≤300 µL) of AGTC-401 (CNGB3, n=31) or AGTC-402 (CNGA3, n=24) was performed in a study eye of 55 subjects, 5-69 years old (37 adults, 18 children). Subjects were sequentially assigned to 1 of 5 (CNGA3) or 6 (CNGB3) dose groups spanning from $4.0e^{10}$ to $3.2e^{12}$vg/ml. Safety results were evaluated by reported ocular and non-ocular adverse events (AEs), functional and microanatomical imaging-based outcome measures, and chemistry parameters.

Results: Across both trials, 3 drug-related serious adverse event (SAE) cases were seen in children at the highest dose level [$3.2e^{12}$vg/mL, CNGA3 (N=2) and CNGB3 (N=1)], which was assessed to be a dose-limiting toxicity (DLT) dose level in children. Uveitis and posterior segment changes were seen clinically and by imaging studies in 3 children, one of whom also developed subretinal fluid in the untreated fellow eye. No DLTs were observed at any dose level in adults.

At dose levels below the DLT in adults and children, both drugs had a favorable safety profile and none of the 3 SAEs were deemed drug-related [macular hole related to subretinal surgery (n=1); steroid-induced elevated IOP resolved after glaucoma surgery (n=2)]. Most AEs were Grade 1 or 2 (except one Grade-3 anterior chamber inflammation). All intraocular inflammatory AEs were controlled with oral, intravenous and/or topical steroids. Steroid-related IOP elevations were seen in 24 subjects (47.1%), and were non-serious and controlled with IOP-lowering agents in 22 (91.7%). Immunological T-cell and antibody tests to AAV and genes CNGA3 or CNGB3 were not associated with safety findings.

Conclusions: AGTC-401/AGTC-402 gene therapy to potentially treat ACHM was safe and well-tolerated in children up to and including second highest dose ($1.1e^{12}$vg/mL), and in adults up to and including the highest dose ($3.2e^{12}$ vg/mL), which was assessed to be a DLT level in children due to intraocular inflammation that responded to adjusted steroid regimens. Imaging studies were very important in characterizing the SAEs.

ABSTRACT BODY:

Purpose: To examine the innervation of central corneal subbasal nerve plexus in patients with fibromyalgia and compare to normal values of healthy patients.

Methods: A prospective, observational study was conducted analyzing 15 right eyes of 15 patients with fibromyalgia (12 women and 3 males) aged 49.83 ± 12,55 years (range 34 to 70 years). Nineteen eyes of 19 healthy patients (12 women and 7 males) aged 40.26 ± 10.86 years (range 23 to 54 years) was selected as control group. Subjects underwent microscopy confocal in vivo (IVMC) with the Rodstock cornea Module attached to Heildelberg's HRT3. At least 3 images of each eye were selected and the following subbasal central nervous plexus parameters were measured with ACC Metrics software: corneal nerve fiber density (CNFD), corneal nerve branch density (CNBD), corneal nerve fiber length (CNFL), corneal nerve fiber total branch density (CTBD), corneal nerve fiber area (CNFA), corneal nerve fiber width (CNFW), corneal nerve fractal dimension (CNFrD). Data analysis was performed with SPSS® software for Windows 22.0 (SPSS ® Inc, Chicago, IL.). The normality of the sample was checked with the Saphiro Wilk test and the results were compared to the T test or the Man-Whitney U test based on the distribution of the data. The differences were considered statistically significant for $P<0.05$

Results: The mean and standard deviation were CNFD: (13.407 ± 2.027 fibers/mm2) vs (23.353 ± 1.778 fibers/mm2) ($p<0.05$); CNFL: (10.108 ± 1.016 mm/mm2) vs (13.850 ± 0.768 mm/mm2) ($p<0.05$); CNFrD: (1.440 ± 0.174) vs (1.475 ± 0.007) ($p<0.05$). These values were significantly reduced in patients with fibromyalgia compared to control group.

Conclusions: Patients with fibromyalgia show a significant decrease CNFD and CNFL. CNFrD may be a diagnostically able parameter in fibromyalgia patients as has already been observed in peripheral neuropathies.

TITLE: Gliosis in RPE65-associated inherited retinal degeneration

SESSION TITLE: RPE/choroid pathology: oxidative stress, inflammation and neovascularization

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Makhlouf, W. Su, S. Sun, H. Lin, B. Tian, Ophthalmology, University of Massachusetts Chan Medical School, Worcester, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Abed Makhlouf: Commercial Relationship: Code N (No Commercial Relationship) | Wenqi Su: Commercial Relationship: Code N (No Commercial Relationship) | Shuo Sun: Commercial Relationship: Code N (No Commercial Relationship) | Haijiang Lin: Commercial Relationship: Code N (No Commercial Relationship) | Bo Tian: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal gliosis, characterized by increased numbers and morphology change of glial cells in the retina has been associated with retinal degeneration. As inherited retinal degeneration, RPE65 gene mutation associated Leber Congenital Amaurosis (LCA) leads to early onset blindness. Nevertheless, the role of gliosis has not been clearly elucidated in this disease. We seek to determine the development of reactive gliosis during the retinal degeneration in RPE65 mutant LCA disease model. In addition, the potential role of gene replacement therapy on the retinal gliosis in this retinal degenerative model was also evaluated.

Methods: The rd12 mice, the naturally occurring animal model of LCA with the homozygous point mutation (C>T) in the RPE65 gene served as the disease model. Rd12 mice were treated by delivering the wild type copy of hRPE65 cDNA vectorized by AAV2 into subretinal space at 14 days of age. The untreated control group of rd12 mice was injected with formulation buffer. One month post injection, the retina tissue from treated rd12 mice, untreated rd12 mice and the wild type of C57BL/6 mice at the same age were harvested and immune-stained with antibodies against Glial fibrillary acidic protein (GFAP) to assess the activation of astrocytes and Müller cells.

Results: The GFAP-positive Müller cell end-feet were observed at the ganglion cell layer in untreated rd12 mouse from 1.5 months of age and gradually increased along with age until 5 months. In contrast, density of Müller cell end-feet in the AAV2.hRPE65 treated rd12 mouse showed significantly less by quantification. In addition, astrocyte activation was also evaluated by the number of astrocyte quantitation, exhibiting a significant higher density in untreated rd12 mice than treated counterpart. To be noted, the density of both astrocytes and Müller cell end-feet are significantly higher in treated rd12 than that in wild type C57BL/6 mice.

Conclusions: In the rd12 mouse, the degenerated photoreceptors and RPE cells elicits activation of astrocytes and Müller cell, associated with reactive gliosis. The therapy of gene replacement alleviates gliosis observed in rd12 mice. Here, we present an evaluation of reactive gliosis in LCA model. An expanded understanding of the features of gliosis in other inherited retinal degeneration or retinal injury will advance the therapeutic strategies to prevent the formation of the glial scar during the development of retinal degeneration.

ABSTRACT BODY:
Purpose: To compare the photoreceptors' (PRs) manifestations in three hereditary optic neuropathies affected by primary mitochondrial dysfunction and discuss whether the retinal ganglion cells (RGCs) or the PRs are preferentially affected.
Methods: A retrospective analysis of patients with genetically-confirmed diagnoses of optic neuropathies associated with mitochondrial dysfunction was performed. This cohort included Leber's hereditary optic neuropathy (LHON), autosomal dominant optic atrophy type 1 (OPA1), and optic atrophy type 13 (OPA13). Patient chart evaluation included clinical characteristics, best-corrected visual acuity (BCVA), fundus photography, spectral domain-optical coherence tomography (SD-OCT), electroretinogram (ERG), and visual evoked potential (VEP) data.
Results: A total of 7 patients with LHON, 6 with OPA1 and 1 with OPA13 were included from a tertiary medical center. Thirteen of 14 individuals were male. The average BCVA at diagnosis was 20/285 and 20/500 in the right and left eyes, respectively. Five out of 7 patients with LHON, and 3 out of 6 patients with OPA1 also showed a mild amplitude reduction or delayed latency on light-adapted ERG and 30Hz flicker responses; however, SD-OCT imaging did not show correlated PR abnormalities. Notably, a 7-year follow up of a patient with OPA13 revealed degeneration of RGCs prior to the degeneration of PRs. Follow-up data also demonstrated continuous loss of cone outer segment tips on SD-OCT imaging.
Conclusions: RGCs are, in general, affected by mitochondrial dysfunction, whereas variable PR dysfunction exists in patients with LHON and OPA1, especially with respect to the cone responses. Involvement of PRs are particularly evident in OPA13 after RGC degenerations.

ABSTRACT BODY:

Purpose: To analyse the expression of human host cell specific attachment, entry and anti-viral response genes to SARS-CoV-2 in various layers of human eyes. To investigate if such host factors may be modulated by eye drops for prophylaxis.

Methods: Donor eyes from healthy controls(n=5), COVID-19 infected(n=5) and COVID-19 recovered(n=2) were studied by immunofluorescence or dissected and analysed for gene expression. Expression of ACE2, TMPRSS2, CTSL, MxA, type-1, 2 and 3 IFNs(interferons) were assessed. Ocular surface impression cytology(IC) and nasal swabs from controls(n=12) before and after trehalose eye drops; and IC from dry eye disease(DED) patients(n=7) and controls(n=8) obtained during pre-pandemic period was used to for gene expression analysis.

Results: Gene expression and immunofluorescence revealed significantly higher distribution of ACE2, TMPRSS2, CTSL and antiviral interferon in ocular surface layers compared to retinal and other layers. Increased ocular surface expression of ACE2 and TMPRSS2; along with decreased expression of type-1 IFNs(IFNalpha) was observed in COVID-19 infected eyes compared to healthy donors and COVID-19 recovered eyes. Similar host factor expression profile was observed from IC of pre-pandemic DED patients. Prophylactic use of trehalose eye drops significantly enhanced Type-1 IFN while reducing ACE2 in ocular surface and nasolacrimal ducts of volunteers which may possibly halt the entry & transmission of COVID-19 through ocular portals.

Conclusions: Consistent expression of ACE2, TMPRSS2 and CTSL were observed in ocular surface tissues highlighting potential for SARS-CoV-2 adhesion & transmission. Pharmacological induction of IFNα-mediated antiviral MxA can possibly protect the ocular surface and nasolacrimal duct from respiratory viral infections.

TITLE: Can tear fluids' microRNAs predict molecular changes associated with age-related macular degeneration (AMD) at an early stage?

SESSION TITLE: AMD - Biochemical and molecular disease mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Wijesinghe, J. Xi, J.Z. Cui, J.A. Matsubara, Ophthalmology & Visual Sciences, The University of British Columbia Faculty of Medicine, Vancouver, British Columbia, CANADA|

Commercial Relationships Disclosure: Printha Wijesinghe: Commercial Relationship: Code N (No Commercial Relationship) | Jeanne Xi: Commercial Relationship: Code N (No Commercial Relationship) | Jing Cui: Commercial Relationship: Code N (No Commercial Relationship) | Joanne Matsubara: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: MicroRNAs (miRNAs) are small, non-coding RNAs which comprise a large family of post-transcriptional regulators of gene expression. Several miRNAs (miR-146a, -125b, and -34a) have been associated in the pathogenesis of age-related macular degeneration (AMD). Here, we tested 10 selected candidate miRNAs in tear fluids, eye tissues and 5 different brain regions (neocortex-hippocampus, olfactory bulb, striatum-thalamus-hypothalamus, brainstem, and cerebellum) of a transgenic AMD mouse model and its matched control to see the miRNA expression levels and their direction of regulation over time.

Methods: High-fat diet apolipoprotein E knockout ($ApoE^{-/-}$) and wildtype (WT, C57BL/6J) female mice (n=16, 4 per group) were studied at young, 3-4 months and old, 9-10 months. Expression level of mature miRNAs -101a-3p, -125b-5p, -140-3p, -146a-5p, -15a-5p, 34a-5p, -342-3p, -374c-5p, -302c-3p and -653-5p were determined using TaqMan advanced miRNA assays. Cycle threshold (Ct) values normalized to Cel-miR-39-3p were compared between young $ApoE^{-/-}$ vs. WT and between old $ApoE^{-/-}$ vs. WT mice separately for tear fluids, eye tissues and brain regions. A statistically significant (2-tailed Welch's t-test at a Bonferroni corrected $P < 0.01$) intergroup >2-fold difference was used to determine the differentially expressed miRNAs.

Results: 8 miRNAs were detected at Ct <35.0. miR-146a, a proinflammatory marker was significantly upregulated in the tears of both young (7.8-fold) and old (5.8-fold) $ApoE^{-/-}$ mice compared to its age-matched WT control. miRNAs -34a, -15a and -342 were also significantly upregulated in the tears of old $ApoE^{-/-}$ mice. Between young $ApoE^{-/-}$ vs. WT eyes, miR-374c (2.7-fold), and between old $ApoE^{-/-}$ vs. WT eyes, miR-146a (6.5-fold), -125b (4.1-fold) and -374c (3.6-fold) were significantly upregulated. Regarding different brain regions, all tested miRNAs were significantly downregulated or insignificant in young $ApoE^{-/-}$ mice. In contrast, most of the tested miRNAs were significantly upregulated in old $ApoE^{-/-}$ mice. Notably, miR-146a was upregulated by 62.4, 41, and 32.7 folds in neocortex-hippocampus, olfactory bulb and brainstem, respectively.

Conclusions: Our study has demonstrated the translational potential of tear fluids' miRNAs in a transgenic early stage AMD model and with changes over time. Detailed interpretation and significance of the results will be discussed.

ABSTRACT BODY:

Purpose: CECs cultured in a two-step approach proliferate and retain hexagonality and molecular markers over a vitrified collagen membrane (VCM) produced in a customizable method. In this work, we aimed to analyze the CECs/VCM construct obtained from transplanted corneas of old White New Zealand rabbits

Methods: Five 18 month-old White New Zealand rabbits were used in accordance with ARVO guidelines and the approval of the Institutional Committee. CECs/VCM constructs of 8mm2 with a 30% cell confluence were produced to determine the ability of CECs to proliferate in vivo. Five male New Zealand rabbits 20 months-old were used. Under general and topical anesthesia a paracentesis was made and an anterior chamber maintainer was introduced, descemethorexis was performed and transplantation of the CECs/VCM constructs was done in 5 eyes. Three eyes were transplanted using only VCM. The transplanted eyes were photo-documented daily for 90 days. The corneas were excised and analyzed for ATPase-1 and ZO-1 molecular markers and CECs confluency evaluation by confocal microscopy and light microscopy

Results: Transplanted corneas with CECs/VCM construct showed transparency beginning in the periphery of the engineered tissue after 3 weeks, albeit central corneal opacity remained. Confocal microscopy showed hexagonal CECs positive to ATPase and ZO-1 mainly in the periphery of VCM and fibrosis was observed with light microscopy in the central cornea, which correlates with the central opacity. Eyes transplanted with VCM showed total corneal opacity, edema and neovascularization after 7 days of transplantation that persisted throughout the follow-up. Confocal microscopy showed no CECs over the VCM, and light microscopy showed fibrosis

Conclusions: Thirty percent confluent CECs/VMC construct partially restore corneal transparency in a preclinical model. However, the fibrotic process might be faster than the healing rate of CECs with 30% confluence, thus preventing full corneal transparency restoration. Increasing cell confluence could potentially be necessary to improve corneal healing.

TITLE: Characterization of transient and sustained intraocular pressure fluctuations in rats

SESSION TITLE: IOP and laser therapy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C.M. Nicou, C.L. Passaglia, Medical Engineering, University of South Florida, Tampa, Florida, UNITED STATES|

Commercial Relationships Disclosure: Christina Nicou: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Passaglia: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Although elevated intraocular pressure (IOP) is a major risk factor for glaucoma, little is known about IOP dynamics on different time scales. Most researchers use tonometry to estimate IOP, which gives only pressure snapshots and was shown to induce a stress response in rats. This study sought to characterize the duration, magnitude, and mechanical energy associated with transient and sustained IOP fluctuations in rats.

Methods: Brown-Norway rats underwent an anterior segment cannulation to record IOP from a wireless backpack pressure transducer. Animals were housed in normal light/dark cycle and IOP was sampled at 0.25 Hz for weeks to months. IOP data was mean filtered and analyzed with a peak detection algorithm in MATLAB to characterize transient IOP fluctuations. Sustained IOP fluctuations were determined by interpolating the local minima between peaks. The IOP-related mechanical energy that the eye experiences over time was found by multiplying the area under the transient or sustained curves by the average eye conductance. IOP data was mean-normalized and subjected to a 1-hr statistical analysis to determine daily IOP trends.

Results: Continuous IOP data collected for 246 days in total across 37 animals were analyzed. Based on autocorrelation analysis, transient events were defined as peaks occurring at least 2 minutes apart with a 1 mmHg minimum prominence. There were approximately 219 transients per day that lasted seconds to minutes with magnitudes up to 60 mmHg. The IOP-related mechanical energy associated with transient events was 77 ± 34 mJ/day as compared to 312 ± 345 mJ/day for slow sustained fluctuations in mean IOP. Much of the sustained energy is attributed to the circadian IOP rhythm. The mechanical energy of mean IOP alone was 3455 ± 2303 mJ/day. Distributions of IOP fluctuations failed normality tests and were better described by a dual Gaussian model with standard deviations of 1.9 and 15.3 mmHg, which presumably corresponds to transient and sustained components.

Conclusions: Our results suggest that transient and sustained IOP fluctuations comprise about 10% of the total IOP-related mechanical energy the eye absorbs daily. This is comparable in total energy impact to a 1 mmHg change in mean IOP. The energy of IOP fluctuations is also concentrated in time and thus has considerably more power, which may have implication for glaucoma.

ABSTRACT BODY:

Purpose: Second Harmonic Generation (SHG) can be used to generate confocal images of the collagen architecture of ocular tissue through the depth of said tissue. Typically, SHG images of collagen are collected with a near infrared (IR) source, but the use of longer IR wavelengths is appealing due to deeper penetration and lower potential for photodamage. However, it is unknown if collagen can efficiently create SHG signal using deeper IR wavelengths. To compare how well collagen can convert deeper IR wavelengths, the magnitude of the nonlinear susceptibility ($|X_2|$) of collagen was measured.

Methods: A sample of porcine cornea (n=1) and sclera (n=1, posterior temporal) was optically cleared with Murray's Clear (2:1 Benzyl Benzoate, Benzyl Alcohol) and placed in a custom built SHG microscope. The laser source was a super-continuum SCHx (Fyla, 18 fs, 80 MHz, 925-1175 nm, 37 mW at sample). Images (160×160 μm, 400×400 pxls, 25 μs dwell time) of collagen fibers were taken at 3 μm steps through the sample. Photons were collected in the forward scattering direction with a 10 μm bandpass filter. Once measurement of the image stack completed, the 10 μm bandpass filter was replaced with another 10 μm bandpass filter and the scan repeated. A total of 12 image stacks of the same tissue volume were taken (emission range 465-585 nm). The total number of photons was counted for each image by summing up the value of the pixels. The number of SHG photons generated was compared to the number of excitation photons and $|X_2|$ was computed.

Results: The values of $|X_2|$ (units of $(eV \times cm^5/photons \times s)^{0.5}$) in the wavelength range of 930-1170 nm ranged from $4.87 \pm 0.37 \times 10^{-16}$ to $7.90 \pm 3.27 \times 10^{-18}$ in the cornea and from $3.01 \pm 0.23 \times 10^{-15}$ to $7.30 \pm 0.43 \times 10^{-17}$ in the sclera. In the cornea and the sclera, the largest $|X_2|$ was located in the 930-950 nm range and the smallest was located in the 1054-1074 nm range.

Conclusions: Collagen was able to generate SHG from 930-1170 nm light. The amount of SHG collected was higher in sclera than in cornea, which in turn indicated a higher $|X_2|$ value. Included in the calculation of $|X_2|$ was the concentration of collagen, which is higher in sclera than in cornea and may explain differences in calculated $|X_2|$. Values of $|X_2|$ measured here are from healthy corneas, but irregularities of $|X_2|$ measurements could be used to determine irregularities in collagen formation and be a biomarker of ocular diseases.

TITLE: Impact of Neural Crest Derived Foxc2 on the Schlemm's Canal Examined with visible-light Optical Coherence Tomography

SESSION TITLE: Multidisciplinary Ophthalmic Imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R. Fang, L. Beckmann, H. Zhang, Biomedical Engineering, Northwestern University, Evanston, Illinois, UNITED STATES|P. Norden, T. Kume, Feinberg Cardiovascular Research Institute, Northwestern University Feinberg School of Medicine, Chicago, Illinois, UNITED STATES|

ABSTRACT BODY:

Purpose: Glaucoma, a leading cause of blindness, is associated with increased aqueous outflow resistance. Aqueous outflow primarily occurs through the conventional outflow pathway, which includes the trabecular meshwork and Schlemm's Canal (SC). We investigated the role that neural crest (NC)-derived Foxc2 has on the structural development of SC in vivo.

Methods: $Foxc2^{fl/fl}$ and NC-$Foxc2^{-/-}$ (NC-Foxc2-KO) mice were generated. A TonoLab rebound tonometer measured the intraocular pressure (IOP) of mice under deep anesthesia to establish the baseline IOP level. An anterior segment visible-light optical coherence tomography (vis-OCT) system was used to visualize the SC. Only NC-$Foxc2^{-/-}$ with a mild phenotype, having a visually intact anterior segment under a surgical microscope, were imaged. The anterior chamber was cannulated, and the IOP was adjusted to -10 mmHg, -5 mmHg, 0 mmHg, +5 mmHg, and +10 mmHg relative to the baseline IOP. At each IOP level, the SC volume in a 1.5mm by 1.8mm field of view in the nasal quadrant was measured. Additionally, the average SC height and width were found by fitting an ellipse to the segmented SC for each cross-sectional B-scan image (Fig. 1A-B).

Results: Both $Foxc2^{fl/fl}$ and NC-$Foxc2^{-/-}$ mice had an inverse relationship between IOP and SC volume and height. The SC volume was between 34 and 42% smaller in NC-$Foxc2^{-/-}$ relative to $Foxc2^{fl/fl}$ mice at IOP levels from -10 to +5 mmHg relative to baseline (Fig. 1C). No statistically significant difference in SC volume was found at +10 mmHg. The SC height was between 20 and 23% smaller in NC-$Foxc2^{-/-}$ relative to $Foxc2^{fl/fl}$ mice at IOP levels from -10 to 0 mmHg relative to baseline. The SC width was 17 to 18% smaller in NC-$Foxc2^{-/-}$ relative to $Foxc2^{fl/fl}$ mice at IOP levels of 0 to +5 mmHg relative to baseline.

Conclusions: The decreased SC volume in NC-$Foxc2^{-/-}$ mice relative to $Foxc2^{fl/fl}$ mice suggests that NC-specific deletion of Foxc2 influences the structure of SC and conventional outflow pathway. As SC height is less in NC-$Foxc2^{-/-}$ mice at -10 and -5 mmHg, Foxc2 has a crucial influence on the proper development of the aqueous outflow pathway and trabecular meshwork.

Commercial Relationships Disclosure: Isaac Chay: Commercial Relationship: Code N (No Commercial Relationship) | Colin Tan: Commercial Relationship(s);Code R (Recipient):Roche

ABSTRACT BODY:

Purpose: To evaluate the size and characteristics of the foveal avascular zone (FAZ) in the superficial and deep capillary plexus in normal, healthy adults using optical coherence tomography angiography (OCTA).

Methods: In a prospective cohort study of 170 eyes, healthy volunteers underwent OCTA scans. The FAZ from 3mm x 3mm scans was independently graded using the ImageJ software. Circularity represents the degree of resemblance of the area to a perfect circle (a value of 1.0 denotes a perfect circle).

Results: The mean age of participants was 22.7 years (21 – 30, SD± 1.5), with mean spherical equivalent of -4.3 D. Mean superficial FAZ area was 0.25 mm^2 (0.04 mm^2 – 0.48 mm^2) while mean deep FAZ area was 0.38 mm^2 (0.12 mm^2 – 0.66 mm^2). The deep FAZ was significantly larger than the superficial FAZ ($p<0.001$). When the left and right eyes were compared, the superficial and deep FAZ sizes correlated strongly (correlation coefficients of 0.94 and 0.89, respectively), with mean differences between eyes of 0.001 mm^2 ($p=0.720$) and 0.005 mm^2 ($p=0.408$), respectively. The mean circularity index was 0.81 (range 0.54 to 0.95) for the superficial FAZ, and 0.89 (range 0.76 to 0.97) for the deep FAZ. The mean Feret's (maximum) diameter was 0.65 mm for the superficial FAZ and 0.78 mm for the deep FAZ ($p<0.001$), at Feret's angle of 92.3^o for the superficial FAZ and 78.4^o for the deep FAZ.

Conclusions: Both the superficial and deep FAZ size varies significantly among healthy young adults. There is strong correlation between the areas of the superficial and deep FAZ, and between the contralateral eyes. Deep FAZ area and Feret's diameter are significantly larger than the superficial FAZ.

ABSTRACT BODY:

Purpose: Mutations in Myocilin (MYOC) are responsible for the most common genetic cause of glaucoma, accounting for 8-10% of autosomal dominant familial Juvenile Open Angle Glaucoma cases, as well as 2-3% of POAG cases. MYOC toxic gain of function mutant proteins aggregate intracellularly, leading to trabecular meshwork (TM) stress, elevated IOP, and glaucoma. In this study, we tested the hypothesis that silencing expression of disease-causing MYOC variants could lead to decreased TM stress and lowered IOP.

Methods: First, we made humanized MYOC mice to screen different siRNA duplexes in vivo. Next, we developed humanized MYOC.Y437H mice over-expressing human mutant MYOC using a CRISPRa approach (SAM-MYOC mice). We also validated the model using IOP lowering drugs (timolol and Rhopressa). We then tested several lead MYOC siRNA duplexes in the SAM-MYOC model to assess the IOP lowering efficacy. In addition, we also used ex vivo human eye perfusion culture model to screen this lead siRNA duplexes

Results: First, we found the several best siRNAs duplexes to lower both MYOC mRNA and protein. To develop animal model, out of several CRISPR guides delivered via AAV or Lentivirus in mouse eye, one guide led to significant upregulation (15-20-fold) of mutant MYOC and high IOP (5-6 mmHg from baseline). We showed that both timolol and Rhopressa lowered IOP in these mice, further validating the model. Next, 5 weeks after virally inducing high IOP in SAM-MYOC, we injected either control or MYOC siRNA intravitreally. While the control siRNA had no effect on IOP, in the MYOC siRNA group IOP was lowered to baseline within a week and this effect persisted for more than 5.5 months, when IOP elevated again gradually. Second, we used the ex vivo human eye perfusion culture system to explore the efficacy of MYOC siRNA to knockdown MYOC mRNA and protein in the TM and MYOC protein levels in the perfusate. Over 90% knockdown of both RNA and protein was achieved.

Conclusions: These results suggest that siRNA based knockdown of MYOC is a feasible therapeutic approach to treat human MYOC based glaucoma.

ABSTRACT BODY:

Purpose: ANGPTL7 is a secreted glycoprotein initially discovered in the cornea. There is evidence that ANGPTL7 levels are elevated in aqueous humor of glaucoma patients and it is highly upregulated upon steroid treatment of trabecular meshwork (TM) cells. We have also shown that in our scRNA-seq data, it is one of the most highly expressed genes in TM. We conducted whole exome sequencing of several large cohorts of individuals and demonstrated an association of the ANGPTL7 gene with both lowered IOP and a reduced risk of glaucoma. Both common and rare variants were identified. To further investigate the relationship of ANGPTL7 to IOP, a series of experiments were performed.

Methods: IOP measurements in wild-type and KO mice using a rebound tonometer (Tonolab). Intravitreal and intracameral injections of several agents.

Results: First, we injected ANGPTL7 protein into the eyes of mice and monitored IOP. Either intravitreal or intracameral injection led to elevated IOP that persisted for more than a 4 days. Next, we made an ANGPTL7 knockout (KO) mouse. There was a gene-dose dependent decrease in IOP, with Het mice exhibiting IOP significantly lower than wt and in homozygous KOs the pressure was further decreased (about 2-3 mm difference between wt and full KO). Ocular anatomy was normal. These results suggest, but do not prove, that ANGPTL7 is involved in the normal physiological maintenance of IOP. To further test this notion, we used an RNAi based approach to test whether a distinct means of acute gene silencing, in an adult animal, will lower IOP. We identified several siRNA duplexes that decreased ANGPTL7 expression, and those that showed >50% mRNA KD also lowered IOP (comparably to the KO). We have also shown that siRNA against ANGPTL7 normalizes IOP in several rodent models of ocular hypertension.

Conclusions: These data strongly indicate that ANGPTL7 contributes to the normal physiological regulation of IOP and that pathological over-expression could lead to potentially damaging elevations in IOP. ANGPTL7 thus is a promising new glaucoma therapeutic target.

TITLE: Development of long-acting PAS-nomacopan for treatment of GA and other retinal diseases
SESSION TITLE: AMD and diabetic retinopathy
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: W. Weston-Davies, Medical Affairs, Akari Therapeutics PLC, New York, New York, UNITED STATES|
Commercial Relationships Disclosure: Wynne Weston-Davies: Commercial Relationship(s);Code E (Employment):Akari Therapeutics Plc;Code I (Personal Financial Interest):Akari Therapeutics Plc;Code P (Patent):Akari Therapeutics Plc
ABSTRACT BODY:
Purpose: Studies indicate that complement inhibitors slow the progression of geographic atrophy (GA) but may promote choroidal neovascularisation (CNV).[i] [ii] Treatments that slow the progression of GA whilst inhibiting CNV are needed.
Long-acting 68kda PASylated-nomacopan (PAS-nomacopan) inhibits complement C5 and leukotriene B4 (LTB_4), a potent leukotactic agent that increases retinal VEGF. The addition of a PAS polypeptide tail to nomacopan increases the effective MW to 580kda which may permit a dosing interval of up to 3 months. Inhibition of LTB4 may decrease the risk of CNV seen with avicincaptad and pegcetacoplan.
Here we report 1.) the effect of IVT administered PAS-nomacopan in a mouse model of laser-induced CNV, 2.) the pharmacokinetics (PK) of IVT administered PAS-nomacopan in rabbits.

[i] Liao DS, et al. Ophthalmology. 2020 Feb;127(2)

[ii] Jaffe GJ et al. Ophthalmology. 2021 Apr;128(4)
Methods: For the CNV study, 5 groups of C57BL/6 mice received single or repeat 3µL doses of saline, PAS-nomacopan (20mg/ml) or aflibercept (40mg/ml). CNV was induced by laser in the right eye on Day 0. Retinal angiography was undertaken on Days 7 and 14. CNV volume was measured on Day 16 from flat mount choroid preparations.
To examine PK, pigmented rabbits received a single IVT dose of 50µL PAS-nomacopan on Day 1 to the right eye. Vitreous (V), retina (R) and choroid (CH) were harvested on Days 3, 7, 14, 21, 28 and 56. PAS-nomacopan concentrations in eye tissue were measured using liquid chromatography mass spec to derive half-life and bioavailability.
Results: Single IVT PAS nomacopan significantly ($p = 0.022$) reduced CNV compared to saline and was as effective as multiple IVT aflibercept ($p = 0.019$). Single IVT PAS-nomacopan showed a trend towards reduced leakage on Day 14 ($p = 0.097$). Surprisingly, multiple IVT PAS-nomacopan did not reduce leakage or CNV.
The V and R half-life of PAS-nomacopan in rabbits was shown to be 5-6 days and the concentration of the drug in R was approximately 30% of the concentration in V indicating that PAS enters R.
Conclusions: VEGF is a key driver of CNV and LTB4 inhibition reduces VEGF and CNV.[1] We have shown that nomacopan inhibits retinal VEGF in a uveitis model.[2] Collectively, these data support ongoing development of PAS-nomacopan as therapy for GA and other retinal diseases.

ABSTRACT BODY:

Purpose: To quantify biomechanical properties on different scleral locations using Optical Coherence Elastography (OCE), and to evaluate the effects of Rose Bengal-Green Light (RGX) crosslinking in scleral stiffening.

Methods: Five freshly enucleated rabbit eyes (24-48h post-mortem) from adult New Zealand white rabbits were measured at four sclera locations (superior/inferior temporal (ST, IT) and nasal (SN, IN)). Elastic waves were induced in the sclera with a small contact probe (diam. 2mm) vibrating at 2 kHz. Wave propagation speeds (WPS) were calculated from images taken with a phase-sensitive swept source optical coherence tomography system in three meridians, vertical (90°), oblique (135°) and horizontal (180°). Intraocular pressure was fixed at 15 mmHg. RGX (523nm, 0.1W/cm2, 400s) was applied on the temporal side of the sclera. OCE measurements were performed before and after RGX. Subsequently, scleral strips were extracted and used for stress-strain measurements (uniaxial stretcher, CellScale, Canada). Young's modulus (YM) was calculated at 8% strain.

Results: WPS in untreated scleral tissue ranged approximately from 5 to 40 m/s. Mean WPS was calculated per each scleral region. Multi-meridional analysis showed differences in WPS across ST: 25m/s (90°), 22m/s (135°), 19m/s (180°); IT: 21m/s (90°), 22m/s (135°), 21m/s (180°); SN: 21m/s (90°),16m/s (135°), 15m/s (180°); and IN: 18m/s (90°), 26m/s (135°), 11m/s (180°). After RGX, WPS increased in IT region (0.7% (90°), 12% (135°). IN region showed the lowest measured WPS (16m/s (135°), 10m/s (180°)). Uniaxial stretching showed that RGX produced 30% increase in stiffness compared with the contralateral untreated sclera. At 8% strain, the estimated YM of RGX-treated tissue were 11.3±7.0MPa(ST), 11.2±4.4MPa(IT), and of untreated tissue were 7.9±6.7MPa(SN), 7.2±4.1MPa(IN), suggesting a vertical WPS to stiffness ratio of 2 and 3 in temporal and nasal regions, respectively.

Conclusions: Wave propagation speed is dependent on scleral location and direction. Both WPS and YM reveal variations of the scleral properties by Rose-Bengal cross-linking, with regional differences in efficiencies. OCE appears as a promising, non-invasive method to quantify the efficacy of scleral stiffening myopia treatments.

ABSTRACT BODY:

Purpose: Moorfields Eye Hospital, London, is a centre of excellence for ophthalmic research, education and patient care. During the COVID-19 pandemic, medical students' clinical education exposure and patients' multidisciplinary care were greatly affected.

Telepresence robots have been suggested as a solution to reduce the impact of COVID-19.

We present the results of a trial used to evaluate the capabilities of a telepresence robot in improving clinical education for undergraduate medical students, and the possibility to deliver multidisciplinary clinical patient care via a telepresence robot.

Methods: In a two-day trial period, the telepresence robot was used in four tasks: 1) to livestream an adnexal surgery to students off-site; 2) autonomously navigating patients from clinic to pharmacy; 3) by a clinician to remotely review patients with an ophthalmologist who was consulting the patient face to face; 4) and to deliver a teaching session to medical students.

Feedback was gathered using a questionnaire and in a group discussion together with clinicians, patients, students, robot specialists and IT specialists.

Results: 15 patients of a wide age range and 5 medical students were surveyed. The vast majority of both groups were unaware of telepresence robots. The mean rating given by both groups was 6/10 (with a range of 1-10/10 and 3-8/10) respectively. The groups praised the innovation, felt it could support clinical pressures, and improve their involvement. However, there were concerns about impersonality and technical limitations, and each offered ideas for improvements. All students felt there was potential to improve medical education using the robot. Qualitative feedback during the group discussion highlighted the importance of adapting the currently available hardware and software to enhance its use in education and patient care.

Conclusions: This trial provided a greater understanding into the practicalities of incorporating a telepresence robot, in its current form, to clinical medical care and education. While there are challenges with the technical specification of the telepresence robot, the proposition of using such a device has drawn positive engagement from students, patients and clinicians thus validating further research.

TITLE: Investigating the effect of dissolved oxygen-assisted corneal cross-linking (CXL) on porcine corneas

SESSION TITLE: Keratoconus and corneal biomechanics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Dar, C. Greene, B. Yang, Engineering, Duquesne University, Pittsburgh, Pennsylvania, UNITED STATES|J.P. Vande Geest, V. Jhanji, Ophthalmology, University of Pittsburgh, Pittsburgh, Pennsylvania, UNITED STATES|J.P. Vande Geest, Bioengineering, University of Pittsburgh, Pittsburgh, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Julianni Dar: Commercial Relationship: Code N (No Commercial Relationship) | Caitlin Greene: Commercial Relationship: Code N (No Commercial Relationship) | Jonathan Vande Geest: Commercial Relationship: Code N (No Commercial Relationship) | Vishal Jhanji: Commercial Relationship: Code N (No Commercial Relationship) | Bin Yang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The overall treatment time of standard CXL takes around 60 to 120 minutes but risks infection and corneal dehydration. There are two types of CXL pathways, with Type-II CXL requiring oxygen. However, the dissolved oxygen in the cornea has limited quantity, thus limiting the effect from Type-II CXL. To reduce the overall treatment time while maintaining efficacy, we propose to improve the Type-II CXL contribution by introducing dissolved oxygen during the treatment. In this study, we assess the enhancement of the cornea's mechanical properties with oxygen-assisted CXL (O2CXL).

Methods: 12 Porcine eyes were obtained from a slaughterhouse 6-hour postmortem and divided into two groups: standard CXL and O2CXL groups. Riboflavin solution at a concentration of 0.146% was used. The corneal portion of the whole globe was submerged in the riboflavin solution for 30 minutes before the treatment. The riboflavin solution used for O2CXL was saturated with oxygen for 20 minutes prior to cornea staining, and oxygen supply was maintained during the 30 minutes staining process. Before each CXL treatment, two identical cornea strips were dissected along the short axis. Given the large intra-sample variation of mechanical properties, we chose one strip as a reference (no CXL treatment). The other cornea strip underwent CXL treatment. All corneal strips were treated with 365nm UV light at 3 mW/cm^2 for 30 minutes. Uniaxial tensile testing was performed on both reference and treated corneal strips to assess the biomechanical enhancement. We determined the tangential modulus at 10% strain and calculated enhancement for each group.

Results: At 10% strain, the treated corneal strip with O2CXL (σ_{mean}=1.22±0.43MPa) resulted in an average of 69.1%±29.5% increase in tangential modulus compared to the non-treated samples (σ_{mean}=0.70±0.25MPa). The treated samples with standard CXL (σ_{mean}=1.45±0.13MPa) showed an average improvement of 26.1%±9.03% compared to the non-treated samples (σ_{mean}=1.06±0.19MPa). Overall, O2CXL is 1.6 times more effective than the standard CXL.

Conclusions: O2CXL showed a significant increase in biomechanical enhancement compared to the standard CXL. Such enhancement could be attributed to the supplied oxygen, which prolonged the Type-II CXL, thus improving its stiffening effect. O2CXL should be further investigated to optimize the current CXL procedure, such as reducing the overall treatment time.

TITLE: Comparing educational videos with standard education at the post-op visit

SESSION TITLE: Telehealth

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Moran, S. Groth, Vanderbilt Eye Institute, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure: Cullen Moran: Commercial Relationship: Code N (No Commercial Relationship) | Sylvia Groth: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Patient education is a critical component of post-surgical care. Adequately educating patients after eye surgery can be time consuming, possibly leading to clinic delays and impacting the care of other patients in the clinic. We performed an exploratory study to determine if educational videos are comparable to face-to-face education in terms of time required for the visit and knowledge retained by the patient.

Methods: This prospective study consisted of 46 patients undergoing their first eye surgery, either cataract removal or glaucoma surgery (trabeculectomy or tube shunt) in a single glaucoma specialist's clinic in a tertiary academic medical center. Patients were enrolled on their first post-operative visit. Patients were randomized to undergo standard post-operative patient education or view an educational video of the surgeon explaining precautions, medications, and expectations for the post-operative period. Patients who viewed the video then received an abbreviated version of the standard patient education during their clinic visit with the glaucoma specialist. The time spent face-to-face with the glaucoma specialist was measured for each patient. A survey containing ten surgery-specific knowledge-based questions was given to a subset of patients to assess patient understanding of the post-operative instructions and returned in a pre-stamped and addressed envelope by mail.

Results: Twenty-one patients were randomized to the standard education group and 25 patients were randomized to the video group. The mean age of patients in this study is 66.5 (56% females). Thirty-six patients underwent cataract surgery, 8 tube shunt, and 2 trabeculectomy. The time required for the face-to-face visit with the glaucoma specialist was 5.31 minutes for the video group, compared to 6.10 minutes for the control group ($p = 0.26$). A subset of 33 patients were given the survey and 16 responded. The average score was 8.3 for the standard education group and 8.6 for the video group ($p = 0.75$).

Conclusions: These results demonstrate that educational videos for post-operative patients are comparable to face-to-face patient education both in terms of time required for the visit and patient retention of the information. This study was limited by a small sample size, and further evaluation of these patient education methods is warranted for wider application.

ABSTRACT BODY:

Purpose: Atropine has become standard of care for myopia control in the Netherlands; high dose is recommended for those at risk of high myopia. A risk factor for progression of myopia despite therapy is a young age. In our 3 year follow up study, we evaluated the effect of age on spherical equivalent of refraction (SER) and axial length (AL) change in myopic children receiving atropine 0.5%.

Methods: Children aged 4-16 years with progressive myopia ≥ 1D/year or myopia ≤ -2.5D were prescribed atropine 0.5% at baseline. Children with additional ocular pathology were excluded. Examination including cycloplegic refraction and AL measurement was performed at baseline and follow-up. Outcome measures were AL and SER; annual progression of Al and SER were compared between age groups 4-6, 7-9, and 10-16 years. Differences in progression of AL and SER between age groups were calculated with linear regression adjusted for gender. Correlation of progression rates between first year and second or third year was calculated with the Pearson's correlation.

Results: A total of 116 patients were enrolled in the study (mean age: 9.26 ±2.2 years). At baseline, mean SER was -3.47 ±1.73D; mean AL was 24.92 ±0.90mm. 90 (78%) children continued therapy throughout the 3-year follow-up. Mean AL annual progression was 0.41mm ±0.23 (SER -0.75D ±0.08) for 4-6 year-olds; 0.15mm ±0.12 (-0.22D ±0.35) and for 7-9 year-olds and 0.08 mm ±0.08 (-0.14D±0.23) for 10-16 year-olds. Children aged 4-6 years progressed faster in AL than those aged 7-9 years (P=0.001) or 10-16 years (P<0.001), for SER faster progression was found between 4-6 and 10-16 year old's (P=0.04). Children with higher AL progression in the first year of therapy were also the faster progressors in the second and third year of therapy (r=0.40 and r=0.40 1^{st} vs 3^{rd}). Due to the hyperopic shift of SER in the first year of therapy only the 2^{nd} and 3^{rd} year of therapy was a predictor of response to therapy (r=0.14 and r=0.24 1^{st} vs 3^{rd}).

Conclusions: Despite 0.5% atropine, children younger than 7 years of age for progressive myopia progressed up to three times faster in both SER and AL than older children. The latter also had a more consistent protection by this concentration of atropine during the 3 year regimen. Myopia progression in young children may need more stringent control, such as atropine 1% or combination therapy, in particular since they are at risk for the more extreme values of myopia.

ABSTRACT BODY:

Purpose: Inherited macular dystrophies are a subset of inherited retinal diseases (IRD) that affect central vision over time. Visual impairment can have significant socioeconomic implications. The purpose of our study is to assess the quality of life of patients with inherited macular dystrophy.

Methods: This questionnaire study included 34 patients who were diagnosed with inherited macular dystrophies. The sample population came from the University of Florida Department of Ophthalmology patient base. Each patient was called over the phone to participate the survey. Data on education, employment, and medical care status were collected. Each of their responses were then analyzed collectively with other patients' responses.

Results: A total of 34 patients (13 males, 21 females) with a mean age of 49.9 +/- 18.3 years (range, 21-78 years) were assessed. 47% of our sample population started having visual difficulties under the age of 18. 12% of participants noticed visual impairments at 19-34 years of age. 21% of participants noticed visual impairments at 35-44 years of age and 17% reported visual losses starting at 45-54 years. At the time of data collection, one patient was still attending school. Of those who have finished school, 36% (12 of 33) only have a high school diploma and 64% (21 of 33) have completed college. 6 of the 12 patients who only finished high school education (50%) reported that it was due to visual difficulties. 30% (10 of 33) of those who were out of school were unemployed (6 females, 4 males). Of the patients who were no longer attending school and unemployed, 60% (6 of 10) stated that they did not have a job due to low vision. 33 out of the 34 patients were insured. Of those who were insured, 12% (4/33) were not fully satisfied with their insurance. In addition, 6% of these patients were reported to have financial or visual difficulties, or both reasons, obtaining vision aids and only 32% had disability insurance.

Conclusions: The results of our study show that inherited macular dystrophy may contribute to lower levels of education, employment rate, and limited access to medical care. Further studies and statistical analysis, such as obtaining vision and visual field data as well as comparing our results to normal population, are required to confirm the contributing factors of the quality of life of patients with inherited macular dystrophy.

ABSTRACT BODY:

Purpose: Aging is a significant factor in the development of age-related diseases but how aging disrupts cellular homeostasis to cause age-related retinal disease is unknown. We identified transmembrane protein 135 (Tmem135) as a regulator of retinal aging and its impairment results in age-related disease phenotypes. Notably, the RPE is sensitive to changes of Tmem135 function. Homozygous Tmem135 mutant ($Tmem135^{FUN025/FUN025}$) mice display thickened RPE, and this layer is postulated as the primary site affected by the $Tmem135^{FUN025}$ mutation. Here, we further our studies on Tmem135 in the RPE by performing RNA sequencing on posterior eyecups from $Tmem135^{FUN025/FUN025}$ mice.

Methods: Pooled posterior eyecups from individual 2.5-month-old male and female WT, $Tmem135^{FUN025/+}$, $Tmem135^{FUN025/FUN025}$ mice were collected for RNA sequencing. Analysis was performed using routine methods and focused on genes with more than twofold changes from wild-type (WT) controls. Genes with twofold differences were compared with two transcriptomic datasets of AMD-afflicted RPE/choroid complexes (GSE135092 and GSE29801) to determine common gene expression changes between these mouse models and AMD. Additional eyecups as well as neural retinas were collected from WT and $Tmem135^{FUN025/FUN025}$ mice for lipid measurements and quantitation of lipid synthesis gene expression.

Results: We found significant gene expression changes in $Tmem135^{FUN025/FUN025}$ mouse eyecups relative to WT controls. Many of the significantly-altered genes with greater than twofold differences in the $Tmem135^{FUN025/FUN025}$ mouse eyecups were involved in lipid metabolism. We confirmed these expression changes occur in the eyecup and not in the neural retina. Consistent with these changes, we found increased cholesterol and neutral lipid accumulation in mutant Tmem135 eyecup samples. We found similar changes in genes involved in lipid metabolism between $Tmem135^{FUN025/FUN025}$ eyecups and AMD donor eyes.

Conclusions: Our study suggests that the Tmem135 mutation affects lipid metabolism as similarly observed in human AMD eyes. Thus, Tmem135 mutant mice can serve as a good model for the role of dysregulated lipid metabolism in AMD.

ABSTRACT BODY:

Purpose: To evaluate the results of three different Bowman layer (BL) graft preparation methods: manually (m-BL), femtosecond laser-assisted (fs-BL), and by femtosecond laser followed by excimer laser (fs/ex-BL).
Methods: Descemet membrane-denuded donor corneas (n=41) were used for this study, 2 corneas for m-BL graft, 18 corneas for fs-BL graft and 21 corneas for fs/ex-BL. For fs-BL, the corneas were placed on an artificial anterior chamber and different depth cuts were performed with decreasing increments starting from 30 µm, diameter 9.0 mm. For fs/ex-BL graft preparation, a superficial flap thickness of 80 µm was created by the femtosecond laser (FEMTO LDV Z8, Ziemer). Subsequently, the graft was placed stromal side up and the residual stroma was ablated by the excimer laser (Schwind Amaris 750S) with increasing increments starting from 40 µm. Grafts were analyzed visually and graft thickness regularity was evaluated by histological analysis.
Results: Fs-BL preparation was successful using 30, 20, 15 and 14 µm cuts (success rate: 12 out of 14, 86%). Fs/ex-BL graft preparation was most successful after an 80 µm cut by femtosecond laser with subsequent 60 µm ablation by excimer laser (success rate: 15 out of 21, 71%). Immediately after the femtosecond laser flap, stripes were visible on the treated surface of the flap which were sometimes still visible after excimer laser ablation. Fs/ex-BL grafts were more transparent and less visible in fluid compared to fs-BL or m-BL.
Fs-BL grafts prepared at 14 µm depth were smoother and seem to resemble the thickness of m-BL grafts based on histological analysis. Compared to fs-BL and fs/ex-BL grafts, m-BL grafts showed long fibers protruding from the graft. Macroscopically, laser prepared grafts resembled manually prepared grafts.
Conclusions: It is feasible to prepare thin, regular BL grafts by femtosecond and by femtosecond followed by excimer laser and these grafts were smoother than m-BL grafts. Fs and fs/ex-BL preparation may therefore be an alternative to manual BL graft preparation.

ABSTRACT BODY:

Purpose: Cell therapy is a promising treatment for retinal pigment epithelium (RPE)-associated eye diseases. Herein, microsecond laser irradiation targeting RPE cells was used for large-area RPE removal followed by subretinal injection of human induced pluripotent stem cell derived RPE (hiPS-RPE).

Methods: 19 immunosuppressed pigmented rabbits (Chinchilla bastard hybrid) underwent a large area RPE removal using an infrared reflectance (IR) confocal scanning laser ophthalmoscope (cSLO) with spectral-domain optical coherence tomography (SD-OCT) system (Heidelberg Engineering) extended with a prototype laser (modified Merilas 532 shortpulse ophthalmic laser photocoagulator, Meridian Medical) (wavelength, 532 nm; pulse duration, 8 µs), followed by a 25G vitrectomy. Subsequently, a suspension of hiPS-RPE (1000 cells/ µl) was grafted subretinally into the RPE laser lesion under real-time intraoperative OCT imaging (RESCAN 700, Zeiss) by manual injection via a 25/38G cannula connected to a 100µl Hamilton syringe. 5 rabbits served as a control with hiPS-RPE injected subretinally over healthy RPE. The rabbits were followed with in vivo multimodal retinal imaging at baseline after laser and then for 7 days including fluorescein (FA) and indocyanine angiography (ICGA), aw well as SD-OCT (Spectralis ®, Heidelberg Engineering).

Results: Baseline imaging of RPE laser wounds showed mild late phase FA/ICGA leakage, with normal outer retinal and choroidal reflectivity on OCT, without signs of coagulation. The size of the RPE wounds was typically 10-12mm^2. Real time iOCT showed a directed spread of the bleb retinal detachment (bRD) within the lasered zone, in contrast to a circular spread in controls. Subretinal injection ranged from 5-20µl, with lesser volumes/ larger bRD areas over lasered regions. At 7 days, implanted regions showed FA/ICGA leakage, blockage due to hyperpigmentation was observed mostly at the edges of the lasered zone; OCT showed hyperreflectivity of the outer retina with RPE irregularities. Control implantation sites showed hyperreflectivity in all retinal layers and a variably thickened RPE band suggesting clumping.

Conclusions: Microsecond laser irradiation to the RPE seems to accelerate the subretinal integration of hiPS-RPE, when compared to subretinal injection over intact RPE. Future work will address correlation of multimodal imaging and histology.

TITLE: Probiotics pretreatment attenuates impaired corneal re-epithelialization in diabetic mice through amelioration of T cell immunity and remodulation of the intestinal microbiome

SESSION TITLE: Corneal Cell and Molecular Biology | Corneal Development

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Bu, S. Xu, Y. Chan, A.C. Lo, J. Ho, K.C. Shih, The University of Hong Kong Li Ka Shing Faculty of Medicine, Hong Kong, HONG KONG|

Commercial Relationships Disclosure: Yashan Bu: Commercial Relationship: Code N (No Commercial Relationship) | Sheng Xu: Commercial Relationship: Code N (No Commercial Relationship) | Yau Kei Chan: Commercial Relationship: Code N (No Commercial Relationship) | Amy Lo: Commercial Relationship: Code N (No Commercial Relationship) | Joshua Wing-Kei Ho: Commercial Relationship: Code N (No Commercial Relationship) | Kendrick Shih: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: 1) To compare corneal re-epithelialization rates, ocular surface and systemic T cell immunity after corneal alkali burn injury between probiotics- or vehicle (PBS) -pretreated Akita (diabetic) and wild type (WT) mice.
2) To compare gut microbiota between probiotics- or PBS-pretreated diabetic and WT mice at baseline and 72 hours after corneal alkaline burn injury and to correlate this with the findings of systemic and ocular surface immunity

Methods: Heterozygous $Ins2^{Akita}$ mice were used as a mouse model of Type I diabetes, with WT C57Bl6/J mice serving as controls. Probiotics IRT5 or PBS was administered to the mice by oral gavage continuously for 14 days before the corneal alkaline burn injury. At day 15, alkaline burn was induced on the right eye of mice under general anesthesia. Immediately after injury and on post-injury day 3, the cornea was examined with slit lamp with fluorescein stain under cobalt blue light. T cell profiles on the ocular surface and in the peripheral blood were analyzed by flow cytometry. Intestinal microbiome was characterized by shotgun metagenomics sequencing.

Results: Probiotics pretreatment has restored the delayed corneal wound healing in diabetic mice. In the peripheral blood and on the ocular surface, significantly elevated levels of CD4+ T cells were seen in PBS-pretreated WT mice and probiotics-pretreated WT and diabetic mice, but were not seen in PBS-pretreated diabetic mice. On post-injury day 3, the gut microbiome of diabetic mice had higher alpha diversity in the PBS-pretreated groups but not in the probiotics-pretreated groups. In the probiotics-pretreated diabetic mice, we observed increased Muribaculaceae and Enterococcus faecalis, and reduced Lactobacillus johnsonii and Bacteroides at baseline compared to vehicle pretreated ones. The baseline and post-injury differences in gut microbiome are potentially linked to the altered T cell immunity in diabetic mice, suggesting the immunomodulatory effects of probiotics.

Conclusions: Probiotics pretreatment attenuated the impaired corneal wound healing response after injury in diabetic mice. The ameliorated T cell immunity and remodulated gut microbial composition with probiotics-pretreatment suggest that probiotics is a promising therapeutic agent in the management of diabetic keratopathy.

ABSTRACT BODY:

Purpose: Evaluation of the subjective visual experience through intraocular lenses (IOL) prior to implantation is important both for patient satisfaction and for optimizing the optical design of the IOL. In this work we have designed a compact see-through IOL telescope (Type 2, IOL-T2) that can transfer the scattering as well as other optical properties of the IOL correctly into the pupil plane of the eye.

Methods: The objective of the IOL-T2 consists of a +45 D camera objective and the +20 D IOL in a water cuvette that together have an effective power of +40 D. The intermediate image can then be viewed by a +40 D eyepiece, thus generating a telescope with angular magnification of -1. The eyepiece also serves the purpose to, together with the cornea of the observer, image the IOL into the pupil plane with both the angular and the transverse magnification equal to -1. As a proof of concept, the IOL-T2 was used to evaluate the foveal contrast sensitivity (CS) with and without a glare source for one monofocal and two multifocal IOLs in three subjects. The glare source was located in the 2.5° nasal visual field of the right eye and gave 1 lux at the level of the IOL telescope. The average luminance of the screen was 50 cd/m^2.

Results: The grating resolution CS at 7.5 cycles/degree was reduced with the multifocal IOLs compared to the monofocal design. No statistically significant difference was found between the +2.75 D and the +4.00 D addition. The glare source induced additional decrease in CS, but the reduction varied between individuals and was larger for the monofocal design than the multifocal designs.

Conclusions: The new IOL-T2 has a compact design and transfer all optical properties of the IOL correctly into the pupil plane of the eye. It is thereby a useful tool to compare the subjective (and the objective, see separate abstract) experience through different IOL designs prior to implantation as well as to develop new IOL designs.

TITLE: Charactering Y79 Cells as a Model of Human Photoreceptor Differentiation

SESSION TITLE: Stem cells and organoids

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. John, A. Kantor, M.E. McClements, R.E. MacLaren, K. Xue, Nuffield Department of Clinical Neuroscience, University of Oxford, Oxford, Oxfordshire, UNITED KINGDOM|

Commercial Relationships Disclosure: Molly John: Commercial Relationship: Code N (No Commercial Relationship) | Ariel Kantor: Commercial Relationship: Code N (No Commercial Relationship) | Michelle McClements: Commercial Relationship: Code N (No Commercial Relationship) | Robert MacLaren: Commercial Relationship: Code N (No Commercial Relationship) | Kanmin Xue: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Model systems for the study of human photoreceptor differentiation are limited. These include retinal organoids and a limited number of cell lines which vary in their states of differentiation. Y79 cells are derived from a retinoblastoma in a 2.5-year-old Caucasian female and grow as multicellular clusters in suspension. Here, we aim to determine the pattern of expression of photoreceptor-specific genes in Y79 cells to determine their suitability as a model for studying human cone versus rod fate determination in vitro.

Methods: Y79 cells were cultured in RPMI 1640 medium supplemented with 10% foetal bovine serum, 1% L-glutamine, 1% Pen-Strep in 5% CO_2 at 35C. Cells were harvested at passage number 15 for total RNA extraction. The expression of a panel of cone-specific, rod-specific, and pan-photoreceptor genes were analysed by RT-PCR and RT-qPCR (n=3).

Results: Y79 cells demonstrated consistent (n=3) and clear expression of rod-specific (NR2E3, NRL, PDE6A, GNAT1) and cone-specific (ARR3, GNAT2, GNTG2) genes, as well as the pan-photoreceptor transcription factor, CRX. While rhodopsin expression was absent, cone photopigment expression was limited, with minimal expression of medium- and long-wavelength opsins and no detectable short-wavelength opsin by both RT-PCR and qPCR.

Conclusions: Retinoblastomas are generally thought to arise from post-mitotic cone precursors and that cone-related gene circuitry sensitises the cells to the oncogenic effects of RB1 mutations. Our results show that Y79 cells express M/L-cone-specific markers, but also a range of distinct rod markers, which could indicate their origin from a precursor stage during cone/rod fate divergence or a degree of trans-differentiation during oncogenic transformation. Further studies will evaluate the use of Y79 cells as a model system for studying photoreceptor differentiation.

ABSTRACT BODY:

Purpose: Keratoconus (KC) is a multi-factorial disease with the involvement of genetic and environmental factors. The current study aims to explore the genetic heterogeneity and gene variant identification by high-throughput sequencing.

Methods: Blood samples were collected from 9 KC families(24 KC subjects and 17 healthy first-degree relatives) at Narayana Nethralaya hospital post IEC approval and written informed consent, followed by Whole Exome Sequencing (WES). Variants in protein coding regions with loss of function were identified using SIFT and Polyphen-2. Allele frequency of variants were analysed using gnomAD.

Results: WES revealed variations in the genes involved in regulation of inflammation, a major pathologic driver in KC patients. 485 variants in 57 genes were identified with diverse inheritance patterns. Within these, 28 variants were nonsynonymous with predicted deleterious effects. Further, the variants present in 2 or more families with allele frequency less than $1X10^{-5}$ were identified. Variations in novel genes involved in regulation of inflammatory signalling including ADAMTS18, ANKRD36B/C, CTBP2, FAM104B, KIR2DL1, etc were present in KC subjects. Network analysis revealed their interaction with 138 genes associated with major signalling pathways including inflammation, of which 131 genes showed differential expression in KC epithelium.

Conclusions: Chronic inflammation in KC may be due to mutations in proteins that regulate inflammatory signalling pathways. Our data reveal novel genes including metalloproteinases with possible immunomodulatory roles which may be useful for genomic diagnostics as well as serve as therapeutic targets for KC. Together, our findings provide novel insights into plausible mechanisms underlying the pathogenesis of KC.

ABSTRACT BODY:

Purpose: Botulinum Toxin (BTX) offers the possibility to temporarily release the contracture of the muscle enabling a far greater effect of surgery. We report on a novel application for BTX in 2 patients with esotropia-associated high myopia (EAHM) to increase effectiveness and long-term stability after surgery.

Methods: The first patient had long standing slowly progressive esotropia of 61 degrees with limited abduction in both eyes: 40 degrees abduction in the RE, 35 degrees abduction in the LE. High myopia was present in both eyes: RE S-14, and LE S-13 with an axial length of 30.88mm and 29.34mm, respectively. Visual acuity was 20/20 in both eyes. He was given 2.5 units of BOTOX^{TM} in the Medial Rectus of the LE followed by 8mm resection of the Lateral Rectus of the LE 2 weeks later. A second surgery was conducted 3 months later on the other eye: 2.5 units of BOTOX^{TM} in the Medial Rectus of the RE followed by an 8mm resection of the Lateral Rectus of the RE 2 weeks later. The second patient had an esotropia of 30 degrees. Abduction was limited in both eyes to 30 degrees. She had undergone previous strabismus surgery at the age of 44 years on the RE (5mm recession of the Medial Rectus and 3.5mm resection of the Lateral Rectus). High myopia was present in the RE of S-17 with an axial length of 33.06mm. Myopia in the LE was S-9 with an axial length of 27.19mm. Visual acuity in the RE was poor: counting fingers. Visual acuity in the LE was 20/20. She was given 2.5 units of BOTOX^{TM} in the Medial Rectus of the RE followed by 7.5mm resection of the Lateral Rectus of the RE 2 weeks later. All procedures in both patients were performed under general anesthesia.

Results: In the first patient we found an overall reduction of esotropia of 57 degrees: post-op results after the first surgery showed a remaining esotropia of 27 degrees in primary position. Six months after the second surgery there was a minimal angle of esotropia of 4 degrees with minimal abduction limitation. In the second patient the esotropia had improved with 18 degrees, to a remaining 12 degrees of esotropia with an improved abduction 6 months later.

Conclusions: We found a large reduction in esotropia using BTX as adjuvant to a resection of the rectus muscle in patients with EAHM. So in addition to the reported applications for BTX, it can also have an important role in increasing the success of surgery in patients with high myopia.

ABSTRACT BODY:

Purpose: Comprehensive lipid profiling of the aqueous humor (AH) in patients with pseudoexfoliation glaucoma (PEXG) and primary open angle glaucoma (POAG) compared to controls with the aim of determining lipidome based disease group predictability.

Methods: The AH samples were collected from human donors following tenets of the declaration of Helsinki, under IRB exempted protocols. The following samples were collected 23 non-glaucomatous control, 19 POAG, 9 pseudoexfoliation syndrome but without glaucoma (PEX), and 14 PEXG AH. The samples were subjected to Bligh and Dyer lipid extraction. Untargeted lipidomic analysis was performed with 13 deuterated lipid internal standards for normalization among the lipid classes. Machine learning prediction was performed using three supervised logistic regression binary classification tasks stratified by patients: 1) POAG vs control, 2) PEXG vs control, and 3) PEX vs control vectors. Data are presented as mean peak intensity ± standard deviation.

Results: Lipidomic analysis resulted in the combined identification of 489 lipid species within 26 lipid classes across PEX, PEXG, POAG, and control AH. The mean total lipid content demonstrated lipid content to be highest among control AH (13.54±56.1) compared to the remaining PEX (4.21±10.90), PEXG (9.08±25.97), and POAG (5.66±15.75) samples. Notably, multiple cholesterol esters (ChE), phosphatidylcholines (PC), triglycerides (TG), and ceramides (Cer) were present in higher concentrations for the PEXG AH samples: ChE(16:0), ChE(20:3), ChE(18:1), ChE(18:3), ChE(22:6), ChE(18:2), ChE(20:4), PC(16:0/16:0), PC(16:0/18:2), TG(18:1/18:1/20:4), and Cer(t18:0/24:0). The PC (18:0/18:2), PC (36:2), and PC (34:1e) lipid clases are in low concentrations for PEX AH but highly concentrated in PEXG AH samples. Machine learning prediction yielded accuracy as follows: 1) POAG vs control, with 86% accuracy 2) PEXG vs control, with 71% accuracy and 3) PEX vs control, with 86% accuracy.

Conclusions: Despite the similarity in material deposition, several PC species were found in low concentration in PEX AH samples and found in high concentration in PEXG AH samples, suggesting the composition of the materials are fundamentally different in composition. These differences in lipid composition may help to distinguish them. Machine learning prediction has demonstrated the ability to differentiate all three groups and control, mostly with 86% accuracy.

ABSTRACT BODY:

Purpose: The detection of localized biomechanical alterations in early keratoconus (KC) may open new pathways for diagnosis and customized treatment options. Cross-meridian air-puff deformation Optical Coherence Tomography (OCT) was applied to healthy and early KC subjects. Deformation parameters, cross-meridian symmetry and estimated corneal biomechanical properties were evaluated as potential biomarkers for KC detection.

Methods: Corneal air-puff deformation images from 8 eyes of 8 subclinical/early-stage KC patients (mean age 35yo), and 5 eyes from 3 control (C) subjects (mean age 28yo) were captured along the horizontal (H) and vertical (V) meridian using a novel OCT device (ImTOPScanner, Curatolo, 2020). Custom-built routines were used for image segmentation and quantification at maximum deformation for H and V: 1) Distance between the two peaks of deformed cornea (PD); 2) Asymmetry in Deformation Area (ADefA), i.e. difference between nasal/temporal and superior/inferior deformation area; 3) Deformation Amplitude (DA) Ratios (Vinciguerra, 2016) at distances n=1; 1.5; 2 mm from the corneal apex. Patient-specific eye models were generated using a second-order Ogden material model. Inverse analysis was performed to quantify biomechanical variations. For KC corneas, a custom-built algorithm detected the boundary of the region of pathology, to which distinct material parameters were allocated.

Results: KC corneas showed lower PD (mean PD_{KC}=4.70±0.03 mm) than C corneas (mean PD_{C}=5.13±0.02 mm). In KC corneas $|ADefA_{V}-ADefA_{H}|$ was 0.12±0.15 mm^2, compared to 0.08±0.06 mm^2 in C corneas. The DA ratio was higher in KC than in C corneas for all n (mean increase 0.10±0.04 (H) and 0.14±0.06 (V) for n=1 mm; 0.28±1.11 (H) and 0.44±0.23 (V) for n=1.5 mm; 0.79±0.31 (H) and 1.71±1.17 (V) for n=2 mm). $|DARatio_{V}-DARatio_{H}|$ was higher in KC than in C corneas (2.2, 2.7, and 6.6-fold for n=1; 1.5; 2 mm, respectively). Inverse analysis revealed a tangent modulus at 2% strain of 1.75±0.29 MPa for KC corneas; 1.20±0.37 MPa for KC areas of pathology and 1.43±0.18 MPa for C corneas.

Conclusions: Cross-meridian air-puff corneal deformation OCT reveals differences between healthy and early-stage KC patients. Parameters comparing different deformations in horizontal and vertical meridians seem a well-suited biomarker, independent of intraocular pressure. Results of inverse analysis complement these parameters.

ABSTRACT BODY:

Purpose: To investigate the prevalence of vitreous cortex remnants (VCR) and the utility of VCR removal using a diamond-dusted membrane scrapers (DDMS) on visual and anatomic outcomes after pars plana vitrectomy (PPV) for primary rhegmatogenous retinal detachment (RRD) repair.

Methods: We evaluated the prevalence of VCR in eyes that underwent PPV for primary RRD between July 2014 and February 2021. The presence or absence of VCR on the retinal surface extending from the macula to outside the vascular arcade was identified during PPV using triamcinolone acetonide. The VCR outside the vascular arcade was completely removed using a DDMS under a wide-viewing system. In some cases, the VCR at the fovea was also removed, though not always systematically assessed. Preoperative factors and outcomes were compared between eyes with VCR removed intraoperatively to those without VCR.

Results: VCR was present and removed (VCR+) in 86 (46%) eyes and absent (VCR-) in 101 (54%) eyes. Patients with VCR were significantly older than those without (P=0.006). The preoperative BCVA (logarithm of the minimum angle of resolution) tended to be worse in VCR+ (1.23±0.92 [Snellen equivalent, 20/340]) than in VCR- (1.03±0.89 [20/214]), however, the difference was not statistically significant (P=0.095). There were no between-group differences in postoperative BCVA (VCR+ 0.44±0.54 [20/55]; VCR- 0.42±0.50 [20/53]; P=0.38) or visual improvement (+0.79±0.91, VCR+; +0.61±0.81, VCR-; P=0.31). SSAS was also comparable between the groups (90%, VCR+; 91%, VCR-; P=0.573). The incidence of postoperative PVR (9%, VCR+; 6%, VCR-; P=0.554) and postoperative ERM (28%, VCR+; 29%, VCR-; P=0.97) were comparable between the groups during mean follow-up period of 28.2 months.

Conclusions: Nearly half of the patients with RRD had VCR, which was more likely to occur in older patients. VCR removal resulted in favorable functional and anatomical outcomes comparable to those in eyes without any VCR in patients with RRD.

ABSTRACT BODY:

Purpose: Bright-spot lesions in the tvrm5 mouse model of CTNNA1-associated butterfly-shaped pigment (or pattern) dystrophy consist of raised inclusions in the retinal pigment epithelium (RPE). The purpose is to test the hypothesis that these lesions share features with basal laminar deposits (BLamD) and are confined to a dorsotemporal streak.

Methods: C57BL6/J control and tvrm5 eyes were assessed by color fundus imaging, optical coherence tomography (OCT), light and fluorescence microscopy, and transmission electron microscopy (TEM). To map bright-spot lesions, color fundus and OCT images were aligned and transformed to a uniform geometry using choroidal vessels as landmarks. To assess the full posterior eye, eyecups stained to reveal RPE cell boundaries and nuclei were surveyed by tiled z-stack fluorescence microscopy. Stitched tissue layers and surface models were generated by a custom program (OMorph), fit to a cut-sphere geometry by a new version of a retina-morphing software (Retistruct), and oriented using vessel landmarks.

Results: Bright-spot lesions were detected by noninvasive imaging in homozygous tvrm5 mice at one month of age and in older heterozygous tvrm5 mice. Lesions were distributed reproducibly within a 1 x 0.5 mm dorsotemporal streak ~0.5 mm from the optic nerve head. This distribution was confirmed in eyecups surveys analyzed by Retistruct. Lesions consisted of eosinophilic mounds within the RPE and exhibited internal lamination. TEM of lesions showed debris below a thinned layer of RPE cells, accompanied by vacuolization of neighboring RPE cells and collagen fiber accumulation in underlying choroidal pillars. Bruch's membrane appeared intact below debris, suggesting that the lesions were similar to BLamD.

Conclusions: BLamD-like lesions in tvrm5 mice are confined to a dorsotemporal streak near the optic nerve head. This distribution may define a chorioretinal structure related to the non-primate visual streak and area centralis, which may be relevant for modeling macular disease in mice.

ABSTRACT BODY:

Purpose: To compare species diversity, antifungal susceptibility and mycotoxin profiles of Fusarium isolates recovered from patients subjected to RB-PDAT plus antifungal therapy vs those treated with antifungal therapy alone.

Methods: We used a combination of PCR and DNA sequencing to confirm and classify 25 fusarium isolates (5 PDAT-treated; 20 non-PDAT treated) recovered from patients presenting at BPEI with fungal keratitis between July 2016 and November 2021. Primer specific PCR and DNA sequencing were used to screen for the presence of Fumonisin and Trichothecene mycotoxins. Etests were used to evaluate antifungal susceptibility profiles for amphotericin B and voriconazole in accordance with CLSI standards in 21 isolates.

Results: Isolates: In general, 60% (n=15) of isolates belonged to the Fusarium solani species complex (FSSC), of which Fusarium falciforme (20%, n=5) was the most common species. 36% (n=9) belonged to the Fusarium chlamydosporum species complex (FCSC), and 4% (n=1) to the Fusarium dimerum species complex (FDSC), namely Fusarium delphinoides. Of the five PDAT isolates included, 60% (n=3) belonged to the Fusarium solani species complex; one being Fusarium falciforme. The remaining two isolates belonged to the FCSC and FDSC, respectively.

Mycotoxins: At least one mycotoxin was identified in all isolates. Fumonisin toxins were documented in 44% (n=11) of all isolates and in 60% (n=3) of the PDAT-treated species. Trichothecenes were documented in 68% (n=17) of isolates and in all PDAT-treated species.

Antifungal susceptibility testing: None of the isolates demonstrated in vitro susceptibility to voriconazole and amphotericin B with $MICs_{90}$ of >32 µg/ml (R) at 72 hours, respectively. Mean MICs for voriconazole were similar in the non-PDAT treated group (28.8 µg/mL/R) compared to the PDAT-treated group (27.2 µg/ml/R). Similarly, MICs for amphotericin B in the non-PDAT treated group (14.3 µg/mL/R) showed little variation compared to the PDAT-treated group (14.6 µg/ml/R).

Conclusions: Toxin producing members of the Fusarium solani complex remain the most frequently recovered fusarium species from fungal keratitis in South Florida conferring increased resistance to standard antifungal treatment. Isolates treated with RB-PDAT were more likely to be toxins producers.

TITLE: β1b chain-containing laminins regulate the regenerative response of Müller glia in the zebrafish retina

SESSION TITLE: Animal models of human ocular disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Twist, D. Serjanov, D. Hyde, Biological Sciences, University of Notre Dame, Notre Dame, Indiana, UNITED STATES|

Commercial Relationships Disclosure: James Twist: Commercial Relationship: Code N (No Commercial Relationship) | Dmitri Serjanov: Commercial Relationship: Code N (No Commercial Relationship) | David Hyde: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The role of laminins, which are principal components of the extracellular matrix (ECM), has been well-studied in vertebrate retinal development. However, far less is known about their potential roles in neuronal regeneration, which is similar to development but is not a mere recapitulation. Therefore, we expect that laminins, which are critical for development, are also involved in regeneration. Here, we examine the role of β1b chain-containing laminins (CCLs) in the regenerative response of Müller glia (MG) in the zebrafish retina.

Methods: Tg(gfap:eGFP) zebrafish, which express enhanced green fluorescent protein within the MG, were dark-adapted for two weeks and used for in vivo morpholino-mediated gene knockdown of Lamb1b protein expression in the retina. The fish were then exposed to intense light for up to 96 hours, resulting in photoreceptor death and initiating a regenerative response, which was assessed via immunohistochemistry in retinal cryosections. Cell-fate tracking studies were performed using intraperitoneal injections of EdU (5-Ethynyl-2′-deoxyuridine), a thymidine analogue that is incorporated into proliferating cells. Finally, the role of lamb1b in the expression of other laminins and cell-surface receptors was assessed via qRT-PCR.

Results: Expression of lamb1b is upregulated in the regenerating retina after 48 hours of light damage (4-fold increase) and remains highly expressed throughout the regeneration process. Morpholino-mediated knockdown of Lamb1b expression results in a significant decrease in the number of proliferating MG and neuronal progenitor cells (NPC) during retinal regeneration at 36 (decreased by 60%; $p \leq 0.01$) and 72 hours (decreased by 30%; $p \leq 0.0001$) of light treatment. Lamb1b protein knockdown also results in significantly fewer EdU+ cells within the outer nuclear layer (decreased by 30%; $p \leq 0.01$). Moreover, the expression of other laminin chains and several integrin receptors is downregulated in the lamb1b morphant.

Conclusions: These data illustrate that β1b CCLs regulate the regenerative response in the zebrafish retina. Specifically, MG and NPC proliferation, as well as the expression of other laminins and their receptors, are both disrupted in response to reduced β1b CCL expression. These results suggest that the ECM plays a crucial role in regeneration and begin to uncover the molecular mechanisms of these processes.

ABSTRACT BODY:

Purpose: Studies have shown that changes in αvβ3 integrin expression/activity in TM cells can induce a glaucomatous phenotype. This study was to determine if there were age-dependent differences in αvβ3 integrin expression in human anterior segments and TM cell cultures.

Methods: Immunohistochemistry of paraffin embedded human anterior segments was performed by co-labeling with antibodies against αvβ3 integrin and fibronectin. Images were acquired with a Zeiss Z2 epifluorescence microscope. Image J was used to quantify the levels of αvβ3 integrin and fibronectin in the TM/SC. TM cells were cultured in low glucose DME with 10% FBS. One week post confluency, total RNA was isolated and relative levels of the β3 integrin subunit and TGFβ2 were determined using qPCR. An adenovirus vector expressing either wildtype or constitutively active αvβ3 integrin tagged with mCherry was used to determine if its expression in TM cells affected TGFβ2 expression.

Results: Immunolabeling studies showed that αvβ3 integrin levels varied between age-matched donor eyes while fibronectin levels were more uniform. Both αvβ3 integrin and fibronectin could be found on the trabecular beams, in the juxtacanalicular (JCT) region, and both the inner (IW) and outer wall (OW) of SC. Quantification showed there was more αvβ3 integrin in the OW of SC than the beams or JCT/IW of SC. In contrast, there was more fibronectin in the JCT/IW of SC than the beams or OW of SC. Interestingly, the amount of αvβ3 integrin and fibronectin varied from quadrant to quadrant within the same donor eye indicating expression was segmental. Analysis of mRNA levels of isolated cells from normal donor eyes showed an age-dependent loss in αvβ3 integrin and TGFβ2 expression. In contrast, cells isolated from glaucomatous tissue showed an increase in αvβ3 integrin and TGFβ2 expression compared to age matched controls. TM cells overexpressing a constitutively active αvβ3 integrin also showed increased TGFβ2 mRNA levels.

Conclusions: These studies show that expression of αvβ3 integrin appears to be segmental suggesting it may play a role in regulating segmental outflow and its expression/activity may be age dependent. These studies also support earlier findings and show that expression of αvβ3 integrin correlates with TGFβ2 expression in vitro and suggest that αvβ3 integrin signaling may be a gain of function that contributes to glaucoma.

ABSTRACT BODY:

Purpose: CLN3-Batten disease is a lysosomal storage disorder that leads to retinal degeneration and vision loss. Using induced pluripotent stem cell (iPSC)-based disease modeling studies, we previously showed impairment of a critical retinal pigment epithelium (RPE) cell function, phagocytosis of photoreceptor outer segments (POS) in CLN3-Batten. In this study, our goal was to investigate a direct link between CLN3 mutation and retinal degeneration. Specifically, we introduced a CLN3 mutation (966 bp deletion spanning exons 7 and 8) in an embryonic stem cell line (ESC; H9) and generated a transgenic pig model to study the impact of $CLN3^{\Delta 7/8}$ mutation on POS phagocytosis and retinal homeostasis.

Methods: Isogenic control and mutant ESC lines were generated by CRISPR/Cas9-mediated biallelic deletion of exons 7 and 8. Control and $CLN3^{\Delta 7/8}$ ESC were differentiated to RPE, and parallel cultures were evaluated for morphological and functional characteristics. Yucatan miniswine carrying the orthologous mutation were generated via rAAV-mediated CLN3 editing and somatic cell nuclear transfer; heterozygote offspring were bred to produce homozygote pigs. CLN3-Batten associated retinal phenotypes (reduced RPE lipofuscin, photoreceptor loss) were evaluated by histological analysis of $CLN3^{\Delta 7/8}$ and wild-type (WT) pig eyes at 6-, 36-, and 48-month timepoint. To evaluate POS phagocytosis in ESC-RPE and primary porcine RPE cultures, RPE cells were fed POS (~20 POS/RPE cell) for 2h and rhodopsin (RHO; a POS protein) level was analyzed by Western blotting.

Results: $CLN3^{\Delta 7/8}$ ESC-RPE did not display any disease-associated cellular phenotypes in the absence of POS feeding. However, $CLN3^{\Delta 7/8}$ ESC-RPE showed reduced uptake of POS compared to isogenic control ESC-RPE . Furthermore, compared to POS isolated from WT pigs, POS isolated from $CLN3^{\Delta 7/8}$ pigs was phagocytosed less efficiently by WT primary RPE cells. Consistent with reduced POS phagocytosis, lipofuscin/autofluorescence accumulation was decreased in $CLN3^{\Delta 7/8}$ pig RPE by 36 months, which was followed by significant loss of photoreceptors at 48-month timepoint.

Conclusions: Using in vitro and in vivo models of CLN3-Batten, we show that $CLN3^{\Delta 7/8}$ mutation (that affects ~75% patients) is independently sufficient for promoting both impaired POS phagocytosis and retinal degeneration in CLN3-Batten.

ABSTRACT BODY:

Purpose: Statins are one of the most widely prescribed medications, and may be protective for age-related macular degeneration, but studies are not consistent. Retinal thickness is reduced in early AMD; even before AMD develops protective/deleterious AMD polymorphisms may be associated with thicker/thinner retinas respectively. The purpose of this study was to determine if statin use is associated with retinal thickness in a population-based cohort.

Methods: Participants of European ancestry from the UK Biobank were included for analysis. Quantitative OCT data was obtained using the Topcon 3D OCT-1000 Mk2 machine and data for statin use was self-reported. Following quality control (excluding participants with poor image quality, self-reported eye disease or diabetes, reduced vision), 39035 participants were included, with 6796 cases and 32239 controls. Linear regression analyses, adjusted for age and sex, were performed with retinal thickness measures (RNFL, GCL, GC-IPL, ELM-ISOS, ISOS-RPE, photoreceptor layer, RPE and total retinal thickness) used as the outcome variable.

Results: Significant association (after corrections for multiple testing) was identified between statin use and almost all retinal layers. The strongest association was for the total retinal thickness (β=-1.89, p=2.00x10^{-20}). Inner retinal layers were thinner (GCL β=-0.36, p=9.3x10^{-10}, GC-IPL β=-0.51, p=2.3x10^{-9}, and RNFL β=-0.31, p=2.3x10^{-6}), as were outer retinal layers (ELM-ISOS β=-0.081, p=8.9x10^{-4}, ISOS-RPE β=-0.44, p=5.7x10^{-15}, photoreceptor layer β=-0.32, p=8.7x10^{-17}). Statins were not associated with RPE thickness (β=-0.17, p=0.15). Choroidal thickness was not available.

There was no significant difference in the proportion of participants excluded during quality control between statin users and controls (26% vs 25%), indicating that statin use is unlikely to be associated with other retinal abnormalities.

Conclusions: Statin use is strongly associated with a thinner retinal thickness across multiple retinal layers. Mechanisms underlying this association are unclear. Possibilities include direct effects of the medications or of the underlying conditions for which participants were taking the medications.

ABSTRACT BODY:

Purpose: Histopathology studies described morphological changes of the retinal pigment epithelium (RPE) specific to the onset and progression of retinal diseases in human eyes. However to date, no valuable imaging tool is used in the clinic to image RPE cells. Transscleral Optical Imaging (TOI) uses an oblique illumination of the fundus combined with adaptive optics to provide cell-resolution images of the retinal layers up to the RPE, in vivo. A prospective study was carried out to assess safety and repeatability of TOI technology and characterize healthy RPE cells.

Methods: Eyes of subjects above 18 years presenting normal fundus check were examined with Cellularis®, a novel retinal camera prototype for TOI. For each eye, 6 images of the RPE cells were acquired at different locations of the macula (Fig. 1), one of them being imaged 5 times to evaluate the repeatability of the method. Baseline and follow-up ophthalmic exams were performed before and 1-3 weeks after TOI to assess safety. RPE cell features were extracted with a custom software. Spearman test was used for statistical analyses.

Results: 49 eyes (mean axial length (AL): 24±0.9 mm; mean refractive error: -1±1.7) of 29 subjects (mean age: 37±13.3 years; 19 males) were included. No safety issue was reported during the study. RPE cells were characterized by density of 3663±274 cells/mm^2, cell area of 233±17.1µm^2, intercellular distance of 16±0.6µm and number of neighbor cells around 6, in average. Longer AL significantly correlated with decreased cell density (Spearman's correlation coefficient (R)=-0.757; p<0.001), increased cell area (R=0.667; p<0.001) and increased intercellular distance (R=0.763; p<0.001). Similarly, aging significantly correlated with decreased cell density (R=-0.385; p<0.05), increased cell area (R=0.460; p<0.05) and increased intercellular distance (R=0.391; p<0.05). Interestingly, age also correlated with cell morphological features, showing decreasing circularity (R=-0.611; p<0.001) and increasing elongation (R=0.587; p<0.001) with increasing age. Mean coefficient of variation for repeated images was below 4% for each of the features.

Conclusions: TOI allows safe and repeatable in vivo imaging of human RPE cells, consistent with the literature, paving the way for establishing a full RPE normative database.

ABSTRACT BODY:

Purpose: Structural and vascular changes characterize the disease process in glaucoma; yet the interplay between intraocular pressure (IOP), vascular biomarkers, and retinal and optic nerve structure remains uncertain. Currently, utilization of vascular markers in the management of glaucoma is limited by their translation in clinical applications. Here, we use Transfer Learning (TL) applying outcomes from glaucoma progression data to analyze a prospective cross-sectional study in patients with OAG and healthy controls.

Methods: We applied Fuzzy c-Means (FCM) clustering to a progression dataset (Indianapolis Glaucoma Progression Study (IGPS): n=115) enhanced with hemodynamic variables predicted by a validated mathematical model (Guidoboni et al, IOVS, 2014). The model specifically uses intraocular pressure (IOP-Goldmann), blood pressure (BP-automated) and heart rate (HR-automated) as individualized inputs. The 3 clusters identified via FCM on IGPS are then applied to categorize a cross-sectional dataset (n=45 healthy and 11 OAG) based on the mean arterial pressure (MAP) and IOP measured on each subject. Optical coherence tomography angiography (OCTA) biomarkers were measured and analyzed by (i) distinguishing between healthy and OAG subjects, and then (ii) sectioning each group by the 3 FCM-based clusters.

Results: Data categorized via the FCM-based clusters are shown in Fig. 1. The tables display the OCTA marker medians, 25th, and 75th percentiles. The measurements taken on the inside disc image reveal a 3% decrease from healthy to OAG eyes. When further sectioned, there was an increase in the inside disc image in cluster 1 by 3%, but in cluster 3 there was a 4% decrease. All structural markers were worse in OAG than healthy eyes with or without accounting for the clusters.

Conclusions: While one might assume from conglomerated data that measurements of the inside disc image decrease from healthy to OAG eyes, TL reveals a significant increase in a specific cluster of patients. Differential OAG risk may be highlighted by TL and FCM clustering of OCTA and IOP inputs for a combined hemodynamic and pressure model of risk.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is the leading cause of vision loss in people over the age of 55. Approximately 2.5 million Canadians have AMD with nearly 180,000 experiencing vision loss. Given Canada's aging population, these numbers will continue to increase. This study aims to understand the physical, psychological and practical challenges faced by those with lived AMD experience and to identify areas of need and reform from a medical, health policy and social care perspective.

Methods: This sequential mixed method study comprised an online survey of Canadians living with AMD. Survey data fields included demographic information, self-reported vision, treatment experiences and goals, and disease impact on social functioning. A subset of respondents also participated in a telephone interviews to more deeply explore the burden of their condition.

Results: Between January to June 2020, 337 individuals (mean age = 63.5; male = 47.5%) participated in our survey. Respondents identified having wet (47.1%), dry (37.7%) or wet and dry (12.8%) AMD. Up to 80% of respondents reported that sight loss resulting from AMD affected their ability to do at least one daily activity. Having AMD placed a significant psychological burden on respondents, most notably through anxiety that their condition would worsen (77%). A significant majority of survey participants (75.4%) received injections as treatment for AMD with 46% being satisfied with their treatment. One-fifth of respondents who received injections either felt they were not beneficial or were unsure. Almost one-third of respondents (32.1%) indicated missing at least one injection appointment in the past year, with barriers including the inability to find someone to accompany them to (39.5%), difficulty travelling to (34.6%) or inability to afford (30.9%) the appointment. A large group of respondents also underscored anxiety about the injection (38.2%) as the most difficult part of the appointment.

Conclusions: This study paints a detailed picture of the experiences of the AMD community in Canada, including its support network, the impact of vision loss on respondents' daily activities and emotional wellbeing and their experience with treatment. This data will help better support patient needs and understand barriers to treatment compliance.

ABSTRACT BODY:

Purpose: OCTA is a non-invasive imaging technique for assessment of retino-choroidal vasculature. It allows for the quantitative assessment of retinal microvasculature. This study evaluates macular vessel density (VD), foveal avascular zone (FAZ) area, subfoveal choroidal thickness (SFCT) and retinal layer metrics by optical coherence tomography angiography (OCTA) in COVID-19 recovered patients. Additionally we studied the correlation of OCTA parameters with severity and duration of COVID-19 disease, steroid administration, and vaccination status.

Methods: It is a case-control study of 180 patients. OCTA parameters namely - superficial and deep VD in various sectors - total, superior, inferior, central, inner, superior-inner, inferior-inner, full; superficial and deep FAZ area; SFCT: central subfield thickness (CST) were measured. Additionally, retinal layer metrics, including nerve fiber layer, ganglion cell layer – inner plexiform complex, inner nuclear layer, outer plexiform layer, and outer nuclear layer were compared between cases and controls. A correlation analysis of OCTA parameters was done with severity and duration of disease.

Results: FAZ area (superficial and deep); retinal layer metrics including ganglion cell layer and inner plexiform layer, outer plexiform layer and outer nuclear layer showed significant reduction while there was a significant increase in SFCT in COVID-19 patients. Corticosteroid treatment resulted in significant decrease in VD. A positive correlation was elicited between FAZ area and disease duration; while VD correlated negatively with the duration of disease. Multivariate analysis showed significant relationship between superficial FAZ area, deep FAZ area and SFCT.

Conclusions: OCTA showed alteration in retinal microvasculature and metrics in COVID-19 patients. Choroid being a highly vascular structure was also affected. There was a resultant alteration in FAZ area and SFCT. Moreover, thrombotic phenomenon associated with COVID could alter retinal layer metrics. Additionally, corticosteroids also appear to alter retinal microvasculature. This study could help understand the wide-spread thrombotic phenomenon often associated with COVID infection and predisposition for the same among specific patients.

ABSTRACT BODY:

Purpose: Tissue damage in the center nervous system elicits a robust inflammatory response, which is partly mediated by infiltrating immune cells including macrophages. Macrophages, as professional phagocytes, initially play an important role in cellular debris clearance. Infiltrating macrophages can uptake lipid debris after spinal cord injury. We investigated if a similar mechanism exists in the optic nerve (ON).

Methods: Col1α1-GFP mouse and C57BL/6 mice underwent optic nerve crush. These mice were sacrificed at different time points (7, 14, and 28 days) after ON injury. Optic nerves were stained for immunohistochemistry and immunofluorescence analysis of macrophage and lipid markers.

Results: Our results demonstrate infiltration of foamy macrophages in the ON after ON crush. Lipid droplets are stained with Oil Red O and engulfed by CD11b labeled foamy macrophages. The peak of Oil Red O staining occurs 14 days after ON crush injury. Those foamy macrophages do not co-localize with GFP-labeled Col1α1 fibroblasts.

Conclusions: The experimental results demonstrate that our model can successfully adapt the prior knowledge learned from the axons and dendrites segmentation of RGC images to the segmentation of vascular structures in OCTA images.

ABSTRACT BODY:

Purpose: The vasoactive peptide, endothelin-1 (ET-1) has been shown to be elevated both in the aqueous humor and circulation of primary open angle glaucoma patients as well as in animal models of glaucoma. ET-1 administration in rodents has been shown to produce neurodegeneration of retinal ganglion cells (RGCs) and their axons. However, the precise mechanisms underlying these effects are still not completely known. The purpose of the study was to assess mitophagic changes during ET-1 mediated neurodegeneration of RGCs in culture as well as in the Morrison model of ocular hypertension in rats.

Methods: Primary RGCs isolated from rat pups were treated with either vehicle or ET-1 (100 nM) for 24 h. Mitophagic changes were determined by assessing the extent of co-localization of LC3B (a marker of autophagosomes) and TOM20 (mitochondrial marker). Mitophagy was also evaluated in the cultured RGCs by treating with MitoTracker (a label for mitochondria) and LysoTracker (a label for lysosomes in live cells). To confirm these findings in vivo, intraocular pressure (IOP) elevation was carried out in one eye of retired breeder Brown Norway rats. Two weeks following IOP elevation, retina sections from IOP-elevated eyes and contralateral eyes were analyzed for expression of LC3B and TOM20.

Results: ET-1 treatment of primary RGCs for 24 h produced a decrease in co-localization of LC3B and TOM20. A decreased co-localization of MitoTracker and LysoTracker was also found in primary RGCs treated with ET-1, indicative of decreased mitophagy. IOP elevation for 2 weeks in rats, produced a significant decrease in colocalization of LC3B and TOM20 ($n=4$, $p<0.05$) in retinal ganglion cell layer.

Conclusions: A decreased colocalization of TOM20 with LC3B during ET-1 treatment as well as during IOP elevation could be indicative of ET-1 mediated decrease in mitophagy in RGCs. A decline in mitophagy could be one of the mechanisms by which ET-1 promotes neurodegeneration of RGCs in glaucoma.

ABSTRACT BODY:

Purpose: There is an association between myopia progression and near work that has led to speculation that the larger accommodative lags reported in myopes may be a factor or an effect in progression. We evaluated the impact of contact lenses design and addition on the accommodative behavior in myopes

Methods: A Hartmann-Shack wavefront sensor in an Adaptive Optics (AO) visual simulator was used to measure the wavefront aberrations in 5 myopic subjects (MS, 27±2yrs; spherical error: -2.25±0.3D) while viewing a stimulus changing between 0-6D (ramdomized,1D steps) through multifocal/bifocal corrections, under natural viewing conditions, measurements were repeated 5times for repeatability. The corrections were simulated with a Spatial Light Modulator or a deformable mirror and the accommodative response was calculated using the defocus term, spherical aberration Z (4,0) of the wavefront aberrations.7 conditions were tested: NoLens (NL) and when viewing through aspheric designs of high (2.50D, HA) and medium add (1.75D, MA), bifocal (4mm central zone, 2.5 D) - center distance (CD), center near (CN) and with inducing positive and negative 1µm spherical aberration (PSA, NSA) using deformable mirror were measured.

Results: There was a systematic decrease in pupil diameter with accommodation, the average slope was -0.19/-0.25/-0.15/-0.11/-0.16/-0.11/-0.15mm/D for NL/PSA/NSA/HA/MA/CN/CD. The average slope of change of spherical aberration with accommodative demand (0-6D) shifted to more negative values for NL/PSA/CD -0.02/-0.07/-0.005µm/D whereas the slope of this change reduced for NSA/HA/MD/CN 0.04/0.01/0.02/0.01µm/D. The accommodative lag computed considering only defocus and 4^{th} order spherical aberration showed higher amount of lag with PSA (0.04D) than NL (0.03D) and the least with MA (0.02D), some conditions caused a lead of accommodation NSA(-0.041D).

Conclusions: AO simulators are useful tools to simulate multifocal contact lenses. The performance and interaction of these lenses are driven by individual presence or absence of high-order aberrations which alters the accommodative response. Near additions in some cases can reduce the accommodative lag and convert them to leads.

ABSTRACT BODY:

Purpose: Dual wavelength autofluorescence (dwAF) method to determine macular pigment optical density (MPOD) is based on absorption of blue wavelength by the yellow macular pigment. Studies show association of MPOD with age-related macular degeneration (AMD) stage. MPOD association with the optical coherence tomography (OCT) parameters is yet to be shown. We studied the association between Heidelberg dwAF MPOD values and OCT structural parameters in AMD.

Methods: Prospective, cross-sectional IRB approved study. Patients with early and intermediate AMD, and controls (> 50 years) underwent dual-wavelength (488 and 514 nm) auto-fluorescence, macula centered 97 line enhanced depth imaging (EDI) OCT (Spectralis, Heidelberg) and color fundus photographs used for Age-related Eye disease study scale staging. The MPOD sum of volume (SoV) values were calculated within the 1° radius circle centered on the fovea relative to the 6° plateau. OCTs graded by two independent graders. Linear mixed-effects regression models were used to determine the association of OCT abnormalities - presence of central drusen, drusenoid pigment epithelial detachment (dPED), hyperreflective foci, ellipsoid zone disruption, and reticular drusen with MPOD, accounting for age, AMD presence, intra-ocular lens (IOL) presence, smoking history, and the use of AREDS supplements.

Results: We included 286 eyes of 161 participants; 201(70%) eyes with AMD (19 early and 182 intermediate), and 85 controls (30%). Mean ± SD participant age was 71±9 years, with majority female (58%), non-smokers (57%), and AREDS users (51%). IOL present in 30% of AMD eyes and 8% of control eyes. OCT abnormalities were not observed in any of the control eyes. In AMD eyes, 29% had dPED, 54% had central drusen, 41% had reticular drusen, 28% had hyperreflective foci, and 53% had ellipsoid zone disruption. Higher MPOD values were significantly associated with age ($\beta = 6.38$, 95% CI: 1.24 – 11.52, $p = 0.015$), IOL presence ($\beta = 364.01$, 95% CI: 268.12 – 459.89, $p < 0.001$), and the presence of dPED ($\beta = 83.66$, 95% CI: 4.93 – 162.39, $p = 0.037$).

Conclusions: The significant association between the MPOD SoV in central 1° radius and the presence of dPED after accounting for confounders, has potential use in determining the role of dual wavelength autofluorescence MPOD as a biomarker in AMD.

ABSTRACT BODY:

Purpose: Gram-positive bacteria, especially staphylococci remain the leading cause of bacterial endophthalmitis. The severe vision loss is attributed, in part, to their increasing resistance to antibiotics, leading to treatment failure. Hence, newer antimicrobials are needed to combat multidrug resistant ocular infections. The aim of this study is to identify non-antibiotic drugs/molecules and test their therapeutic efficacy using experimental models of S. aureus (SA) endophthalmitis.

Methods: Temporal transcriptomic analysis was performed using mouse retina infected with SA. The transcriptomic data was used for systems biology analyses to establish gene signature sets and to identify potential candidate drugs using connectivity map (CMAP). The MIC and cytotoxicity of the predicted drugs were determined. In vitro studies were performed on human Muller glia and retinal pigment epithelial cells to check modulation of inflammatory responses challenged with methicillin-sensitive strain (RN6390) and methicillin-resistant strain (USA300). In vivo efficacy of the drugs was evaluated in mouse model of USA300 endophthalmitis. The effect of drug treatment on SA-induced gene expression was performed by RNAseq of BMDMs.

Results: Our systems biology and CMAP analysis predicted three drugs, Dequalinium chloride (DC), Clofilium tosylate (CT) and Glybenclamide (Glb) which counter regulate the infection signatures of SA endophthalmitis. All predicted drugs exhibited anti-inflammatory properties in cells when challenged with sensitive or resistant strains of SA. Moreover, post drug treatment, a reduction in inflammation was also observed in response to LPS stimuli and heat-killed SA in cultured retinal cells. DC and CT were more effective than Glb in all the cell lines. The RNAseq analyses revealed downregulation of inflammatory signatures in MRSA infected BMDMs. In vivo data showed that while all three drugs reduced intraocular inflammation, DC and CT could reduce the bacterial burden as well.

Conclusions: The predicted three drugs were able to suppress inflammatory mediators during ocular SA and MRSA infection in cells. DC and CT were effective in controlling bacterial burden, while all three efficiently suppressed inflammatory responses in MRSA infected mice eyes.

ABSTRACT BODY:

Purpose: Cone dystrophy with supernormal rod response (CDSRR) is a rare autosomal hereditary retinopathy that affects 1 out of every 100,000 people due to mutations in the KCNV2 gene. This gene encodes for the voltage-gated potassium channel Kv8.2, which is a regulatory component of the delayed rectifier potassium channel in the photoreceptors. Several complete gene knock out mouse models reveal molecular mechanism of the disease. We sought to develop a nonsense mutation, Glu-156-to-Ter (E156X), knock in mouse for disease modeling and therapeutic development.

Methods: A targeted c.466 G>T, p.E156X Kcnv2 mutation was achieved through delivery of CRISPR-Cas9 RNP to the mouse zygote. To confirm the single nucleotide substitution, Sanger sequencing and Restriction Fragment Length Polymorphism (RFLP) were performed on genomic DNA isolated from newly generated mice. We used Espion-E3 system at 6 weeks to record full field electroretinography (ERG) to characterize visual outcome. Standard scotopic and photopic (ISCEV) stimulus was used to record responses to compare a-, and b-wave amplitudes and implicit times. For measurement of c-wave we used a 25 $cd.s/m^2$ flash stimulus. Optical Coherence Tomography (OCT) was used to examine retinal structure, and OptoMotor Response (OMR) to measure visual acuity (VA).

Results: Genotyping validated the expected base change in the target codon, GAG to TAG, resulting in the nonsense mutation in the Kcnv2 gene without any off-target alterations. When compared to wild-type (WT) and het ($E156X^{-/+}$) mice, OCT images revealed the absence of EZ layer in the homozygous ($E156X^{+/+}$) mutant retina. At 6 weeks of age, OMR demonstrated no statistical difference in VA between WT, $E156X^{-/+}$, and $E156X^{+/+}$ mice. In comparison to WT mice, full-field ERG in the $E156X^{+/+}$ mice exhibited a reduced and delayed a-wave amplitude with a flattened peak. The $E156X^{+/+}$ mice had a higher b-wave amplitude at lower flash intensities, but their overall response was delayed at all flash intensities. The c-wave amplitude was noticeably reduced.

Conclusions: The supernormal rod response in the $E156X^{+/+}$ mice revealed by increased amplitude b-wave is consistent with Cone dystrophy caused by clinically relevant KCNV2 nonsense mutation. We report a novel CDSRR mouse model for understanding retinal dystrophy progression and possible therapeutic interventions for clinical translation.

ABSTRACT BODY:

Purpose: Trabeculectomy has been established as a safe and effective surgery to control IOP. An important objective of this technique is to adjust the tightness of the scleral flap to establish a balance between fluid under- and over-filtration in order to achieve the target IOP. Intuitive approximations to get trans-operative IOP values is of common practice besides of observing the exit rate of fluid through the scleral flap edges. IC200-tonometry is an accurate instrument to measure IOP in the supine position. The aim of this study is to compare an intuitive manuever to estimate IOP versus IC-200 rebound tonometry during trabeculectomy.

Methods: In non-consecutive cases in which a trabeculectomy was performed, IOP was measured using an empirical manuever consisting in touching the firmess of the cornea with a cannula by both an experienced glaucoma surgeon (S) and an assisting glaucoma fellow (F). IC-200 rebound tonometry (Icare) was also performed by a third person. IOP estimations were done in random order. IOP guessed values (for the intuitive manuever) and the actual IC-200 (IC) IOP values were verbally manifested at the end of each round of measurements. At least four rounds (R1-R4) of measurements were carried out (one before the paracentesis, two more after the scleral flap was sutured and the anterior chamber was filled with BSS, and one more, prior to the conjunctival closure). Mean value comparisons and correlations were used to analyzed the information. P values of ≤ 0.5 were considered statistically significant.

Results: Sixteen eyes of 15 patients (mean age 54.6±7.7 years; 10 male and 5 female) were included in the study. Mean baseline IOP was 29.1±8.9 mm Hg. Mean trans-operative values were not statistically significant among each other (R1-IC, 11.5±7.7, R1-S, 10.0±5.8, R1-F, 13.3±7.4; R2-IC, 3.9±1.8, R2-S, 4.7±3.5, R2-F, 5.8±4.5; R3-IC, 8.3±5.8, R3-S, 9.5±5.2, R3-F, 10.5±5.1; R4-IC, 6.8±4.3, R4-S, 8.8±5.1, R4-F, 9.3±6.2). Correlations were weak in R1 and R2, but good and statistically significant in the other two rounds (R3-S, r=0.54, p=0.027; R3-F, r=0.80, p=0.0002; R4-S, r=0.54, p=0.027; R4-F, r=0.76, p=0.016).

Conclusions: IC-200 rebound tonometry is a feasible technique to be used trans-operatively during trabeculectomy and has potential to be used in a training process in order to improve surgeon’s ability to estimate IOP in the operating room.

ABSTRACT BODY:

Purpose: We have previously reported that matrix metalloproteinase (MMP-3) increases outflow facility in wildtype mice. Here, we aimed to assess the translatability of MMP-3 in non-human primates (NHP) as well as human donor eyes (HDE) ex vivo.

Methods: Outflow facility was measured in vivo using a modified iPerfusion system. NHPs were anaesthetised with isoflurane, further stabilised by controlling body temperature and were monitored via electrocardiogram. Animals were intracamerally cannulated to iPerfusion, where 5 ng/ml recombinant human MMP-3 (rhMMP-3) was perfused into one eye for 1 hour at 5 mmHg above spontaneous IOP. An outflow reading was then taken while accounting for the time-dependent effect on outflow. Aqueous was sampled immediately after perfusion for ELISA analysis of MMP3 levels. To assess outflow in HDE, we designed eye baths and an incubator to extend the capabilities of the iPerfusion system. Anterior segments were mounted to baths, connected to iPerfusion and cultured for up to 2 weeks. Flow rates were stabilised before a baseline measurement was taken. The anterior chamber was then exchanged with 5 ng/ml rhMMP-3 using syringe pumps and another reading taken after 1 hour.

Results: Outflow facility was successfully measured in vivo in NHP eyes, with an average control facility of 0.45 /ul/min/mmHg. On average, outflow facility was significantly increased in non-human primates by 29 % ($P = 0.006$, $n = 15$) after exposure to rhMMP-3, with a moderate dose-response relationship observed ($R^2 = 0.46$, $P = 0.008$). Heart rate and oxygen consumption were also related to facility using iPerfusion. In human donor anterior segments, outflow facility increased by 56 % on average after treatment ($P = 0.14$, $n = 3$ eyes).

Conclusions: Impaired outflow facility is a key driver of glaucoma pathophysiology, resulting in increased IOP and subsequent loss of glaucomatous degeneration. We successfully adapted the iPerfusion system for use with larger model systems. We have shown the translatability of therapeutic MMP-3-mediated increases in outflow in ex vivo mouse models, NHP in vivo, and post-mortem human donor eyes. Using MMP3 to increase conventional outflow holds promise as a potential new treatment for ocular hypertension and open angle glaucoma.

TITLE: Cytoplasmic Hybrids of ARPE-19 Cells and Mitochondria from Patients with Age-related Macular Degeneration Accurately Model Reactive Oxygen Species Hallmarks Found In Vivo

SESSION TITLE: AMD - Biochemical and molecular disease mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Dohl, K. Schneider, S. Atilano, A. Bao, M. Kenney, Pathology and Laboratory Medicine, University of California Irvine, Irvine, California, UNITED STATES|

Commercial Relationships Disclosure: Jacob Dohl: Commercial Relationship: Code N (No Commercial Relationship) | Kevin Schneider: Commercial Relationship: Code N (No Commercial Relationship) | Shari Atilano: Commercial Relationship: Code N (No Commercial Relationship) | Alan Bao: Commercial Relationship: Code N (No Commercial Relationship) | M.Cristina Kenney: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Age-related Macular Degeneration (AMD) is the leading cause of vision impairment among the elderly in the United States, necessitating novel therapies to prevent vision loss; however, AMD research lacks accessible in vivo and in vitro models. Cytoplasmic hybrids (cybrids), generated through fusing mitochondria-rich platelets from AMD patients with mitochondrially-depleted retinal pigment epithelial cells (ARPE-19), provide a novel and accessible in vitro model for AMD research. A major hallmark of AMD is an increase in reactive oxygen species (ROS). We hypothesized the AMD cybrids would show elevated ROS levels as well as downstream effects of ROS, including mitochondrial DNA (mtDNA) damage, and elevated anti-inflammatory protein expression levels.

Methods: Cybrids from age-, sex-, and mtDNA haplogroup-matched patients with dry AMD (AMD, n=6) and without (Ctrl, n=6) were grown under standard culture conditions. ROS levels were determined using DCFDA fluorescence as well as CellROX Deep Red Reagent intensity (ThermoFisher). mtDNA copy number was determined through qPCR using multiplexed Taqman 18S and ND2assays (ThermoFisher), while fragmentation was qualitatively assessed through long extension PCR (LX-PCR). Western blotting was performed using HSP70 and Actin antibodies (Cell Signaling Technology) at a concentration of 1:1000 and 1:5000, respectively. A two tailed Student’s T test was used for statistical analysis between groups.

Results: AMD cybrids showed a 140% increase in ROS levels ($p<0.05$) and a 3-fold increase in mtDNA copy number compared to controls ($p<0.05$). In addition, LX-PCR demonstrated increased levels of fragmentation across the entire mitochondrial genome. Western blotting showed AMD cybrids had a 1.7-fold increase in HSP70, a key chaperonin which is upregulated during cell stress conditions ($p<0.01$).

Conclusions: Taken together, our findings suggest that AMD cybrids exhibit elevated ROS levels, similar to observations found in vivo, which may contribute to increased antioxidant response and damage to the mitochondrial genome. Further investigations are underway to determine if the cybrid model reflects other in vivo hallmarks of AMD.

ABSTRACT BODY:

Purpose: To develop an artificial intelligence (AI) method that can classify real-world optical coherence tomography (OCT) volumes and B-scans into different stages of age-related macular degeneration (AMD).

Methods: We trained a two-stage deep learning network to classify macula centered 3D volumes from Topcon OCT images into 4 different categories, i.e. Normal, Drusen, Atrophy and Neovascularization. A 2D ResNet50 was used to identify the disease categories on B-scans while an ensemble of models (ResNet18/Multilayer Perceptron) that uses the concatenated B-scan-wise output of the last hidden layer of the ResNet50 was used to classify the whole volume. Classification uncertainty estimates were generated with Monte-Carlo drop-out at inference time.

A total of 106,892 2D B-scans from a publicly available Spectralis OCT, Heidelberg Engineering, data set, supplemented with slides of atrophy, were used to pre-train a model in a transfer learning setup in order to ultimately classify Topcon OCT images from a data set consisting of 1,964 B-scans from 215 volumes of 189 eyes. The 3D ensemble model was trained on four binary classification problems with 5-fold cross-validation on a total of 1,575 OCT volumes from 1,418 eyes. Performance is reported as a balanced accuracy (ACC), precision (PREC), recall (REC), and specificity (SPEC).

Results: The Topcon scans were acquired from real world retrospective data sets extracted from the University Hospital Southampton and the Moorfields Eye Hospital as part of the PINNACLE study (75%) and supplemented with an internal data set (25%) from the Medical University of Vienna. The B-scan-level classification on a hold-out test set of 336 B-scans reached the performance of ACC/PREC/REC/SPEC: 0.97/0.97/0.96/0.99. The 3D classification of Topcon volumes achieved good performance on all classes on a hold-out test set out of 629 volumes, with high specificity in all classes (at least ACC/PREC/REC/SPEC 0.95/0.95/0.95/0.99) except for drusen (ACC/PREC/REC/SPEC 0.95/0.95/0.95/0.89).

Conclusions: The proposed approach enables the combination of different kinds of data sets into a domain specialized classifier that can reliably identify biomarkers associated with the relevant stages of AMD. Such automated AI tools can then serve to categorise patients by their disease stage, efficiently facilitating subsequent

large-scale data analysis.

ABSTRACT BODY:

Purpose: To determine the preliminary feasibility of assessing retinal blood flow velocities noninvasively in infants with Retinopathy of Prematurity (ROP) using laser speckle contrast imaging (LSCI) via comparison with intravenous fluorescein angiography (IVFA).

Methods: In this ongoing study, 26 subjects (52 eyes) underwent LSCI using XyCAM RI (Vasoptic Medical, Baltimore, MD) and 6 subjects (6 eyes) received IVFA. Three subjects (3 eyes) aged 3 – 6 months that were diagnosed with ROP received both LCSI and IVFA imaging in quick succession. Perfusion status in 13 arteries and veins of interest was analyzed by determining integrated density and time to peak intensity (TPI) from IVFA data using ImageJ and by computing the mean blood flow velocity index (BFVi) from select vessel segments and in the overall field of view at its peak phase in the cardiac cycle from the LSCI data using the XyCAM software. Time to arterial, laminar, and venous filling was also determined. Arterial-venous transit time (AVTT) and TPI from IVFA was compared to LSCI-based BFVi measurements in subjects with paired imaging data.

Results: Mean peak BFVi for select vessels in subjects who received XyCAM imaging (10 eyes) was 7.2 ± 1.6 (arbitrary units). Mean peak BFVi for overall field of view in subjects who received both imaging modalities was 3.9 ± 1.9. Mean peak BFVi of arteries was significantly different from the peak BFVi of veins ($p < 0.009$). Mean AVTT was 5.4 ± 1.6 seconds and mean TPI was 12.3 ± 0.7 seconds. Among subjects with paired data from IVFA and LSCI, shorter filling times were associated with higher BFVi.

Conclusions: These preliminary findings from a limited cohort of neonates demonstrate the ability to noninvasively assess perfusion using LSCI in a manner that elevated BFVi measurements are associated with faster arterial-venous transit times. Future studies will be needed to establish if noninvasively obtained blood flow information provides insights on ROP severity.

ABSTRACT BODY:

Purpose: To compare the performance of rates of change in 10-2 and 24-2 standard automated perimetry (SAP) in detecting glaucoma progression, using rates of structural loss measured by spectral-domain optical coherence tomography (OCT) as an independent reference standard for progression.

Methods: The study included 291 eyes from 185 glaucoma subjects followed for an average of 1.8±1.0 years. Sixty-nine eyes from 39 healthy subjects followed for 1.5±0.9 years were used as control group to estimate age-related losses over time. Rates of change were estimated using linear mixed models. Receiver operating characteristic (ROC) curve regression analysis was used to compare the performance of rates of change of 10-2 and 24-2 SAP mean deviation (MD) over time in discriminating eyes from the control group versus eyes that had different rates of structural progression as measured by OCT. Areas under the ROC curves (AUC) were estimated at rates of global cpRNFL thinning for pre-defined values of -1.0µm/year (slow progression) and -2.0µm/year (fast progression).

Results: Mean rates of change were -0.14±0.18 dB/year and -0.27±0.23 dB/year for 10-2 SAP MD and 24-2 SAP MD, respectively. Rates of change in 24-2 SAP MD performed significantly better than 10-2 SAP MD to discriminate age-related loss from glaucomatous change, as measured by OCT (AUC = 0.808 versus 0.721, respectively; P = 0.011). For discriminating slow progressors from controls, 10-2 SAP had an AUC of 0.715 (95% CI: 0.622-0.808) versus 0.827 (95% CI: 0.763-0.893) for 24-2. For detecting fast progression, the AUCs were 0.707 (95% CI: 0.578-0.836) versus 0.853 (0.767-0.938), respectively.

Conclusions: SAP testing with the 24-2 pattern of points performed better than the 10-2 for detecting eyes with glaucomatous progression as determined by OCT.

TITLE: Background Adaptation, Stimulus Duration, and the ON and OFF Components of the Full-Field Photopic Flash Rat Electroretinogram

SESSION TITLE: Electroretinography: basic mechanisms and disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.D. Akula, E. Ziska, J. Peralta, R. Manne, J.K. Patel, Ophthalmology, Boston Children's Hospital, Boston, Massachusetts, UNITED STATES|J.D. Akula, Ophthalmology, Harvard Medical School, Boston, Massachusetts, UNITED STATES|E. Ziska, J. Peralta, R. Manne, Northeastern University, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: James Akula: Commercial Relationship: Code N (No Commercial Relationship) | Emma Ziska: Commercial Relationship: Code N (No Commercial Relationship) | Jashwa Peralta: Commercial Relationship: Code N (No Commercial Relationship) | Rithvik Manne: Commercial Relationship: Code N (No Commercial Relationship) | Jagvi Patel: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess the impact of light adaptation on the ON and OFF contributions to the amplitude of the photopic b-wave in the rat.

Methods: Electroretinograms (ERGs) were elicited from Long-Evans rats using 4–512 ms (5 durations) stimuli in the presence of 6–500 cd/m^2 (5 intensities) backgrounds. Stimuli were 3–518,240 cd/m^2. In respective sessions covering each of the 25 combinations of duration and background, nine flashes of increasing Weber contrast (0.5–1,036) were presented. To determine if an "equivalent background" could be measured, photopic b-waves were elicited in the dark, 800 ms after a 262 cd.s/m^2 conditioning flash (CF). The respective depolarizing (ON) and hyperpolarizing (OFF) components of each ERG were estimated by optimizing a sum of sigmoidal curves to the stimulus/response (SR) data at multiple timepoints along the ERG traces (Akula et al., 2019). Finally, b-wave amplitude SR data were fit with the Naka-Rushton (NR) equation to estimate the semisaturating intensity (σ).

Results: The b-wave SR function never displayed the "photopic hill" characteristic of the human response. Although it varied by session, across stimulus duration and background intensity, the respective mean maximal derived ON and OFF response was >200 and <40 μV. At fixed stimulus duration, the Weber contrast at σ was stable across background intensity. The "equivalent background" of the CF, assessed from σ, was ~290 cd/m^2.

Conclusions: First, in contrast to the human photopic ERG OFF response, which is of approximately equal amplitude to the ON, in rat the OFF response is <1/5th as large as the ON. This may have important implications for rat daytime vision and likely explains the lack of a rat "photopic hill" (notably, all human conditions characterized by a lack of photopic hill are believed to cause ON pathway deficits). Second, regardless of stimulus duration, amplitudes of the photopic b-wave and its constituent ON and OFF components are mediated by stimulus contrast rather than intensity. Therefore, accurate absolute calibration of photopic stimuli is of secondary importance to internal (i.e., relative) consistency, mitigating issues such as pupil size and instrumentation differences. Third, the value of the NR σ parameter can be used to determine equivalent background, such as for conditioning flashes, which may be of use in designing certain experiments into cone function.

ABSTRACT BODY:

Purpose: Batten Disease is a neurodegenerative genetic condition that presents with impaired vision in children before symptoms progress into motor loss, neurological deficits, and premature death. Recently, phase 1 human clinical trials at UT Southwestern Medical Center have begun to administer AAV9-CLN7 gene therapy to the intrathecal space of pediatric patients (NCT04737460). This gene therapy approach prolongs motor function and extends lifespan in a preclinical mouse model for human CLN7 Batten Disease (MGI:6388452); however, alternative approaches to directly target the retina are likely needed to rescue vision loss. We tracked the progression of vision loss and the overall ocular phenotype in this CLN7 knockout (KO) mouse model. Establishing how this preclinical model compares to the human condition allows it to be used to test preclinical efficacy and safety of gene therapy to address the visual deficits found in Batten Disease patients.

Methods: Retina function and morphology were analyzed in vivo in wild-type, heterozygous, and homozygous CLN7 KO mice. Scotopic and photopic electroretinography (ERG) recordings were taken at 2, 4, and 6 months of age. Ocular coherence tomography (OCT), infrared (IR) and autofluorescent (AF) imaging were analyzed at 3 and 5 months of age. Histological analysis of the eyes and retinal cells were analyzed throughout the study from 1 to 6 months of age.

Results: Live imaging of the CLN7 KO mouse model confirmed that it mimics the human Batten Disease clinical progression, showing a reduction in both a- and b-wave amplitudes by scotopic and photopic ERG and a thinning of the outer nuclear layer of photoreceptor cells along with their inner and outer segments. Both IR and AF imaging showed the vasculature attenuation and accumulation of autofluorescent puncta in the KO mice over time. Histological analysis detected a significant loss of the inner nuclear layer cells by 6 months of age, indicative of bipolar cell death seen in human patients but not previously detected in this preclinical model system.

Conclusions: Overall, our findings establish the clinical progression of vision loss and ocular disease in the CLN7 KO mouse model through 6 months of age, when the mice present with neurological deficits and premature death. These results establish the baseline for preclinical testing of therapeutic vectors to treat vision loss for Batten Disease using this CLN7 KO mouse model.

Joussen: Commercial Relationship: Code N (No Commercial Relationship) | Alexandre Dubrac: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Central Serous Chorioretinopathy (CSCR) is a pachychoroidal maculopathy that manifests by fluid accumulation between the neurosensory retina and the RPE. CSCR risk gene loci have been identified and there is clinical and experimental evidence that elevated levels of steroid hormones play a pivotal role in CSCR pathogenesis. Here, we investigate risk and steroid receptor gene expression patterns and their distribution across human choroid/RPE cell types. We aim to decipher potential mechanisms, that might explain the characteristic clinical findings in CSCR patients.

Methods: Query of scRNA seq data from human choroid/RPE: 15,300 sc transcriptomes from 14 samples: macula and peripheral from 7 donors. Unbiased clustering, dimensionality reduction and visualization using PCA, UMAP, tSNE. Counts per million (CPM) comparison: Mann-Whitney U test between donors, paired t-tests for comparison between mac. and perip. Correlation analysis: Pearson R with p-value adjustment by Benjamini-Hochberg. $p<0,05$ considered statistically significant.

Results: Three major results: (1) Expression of the CSCR risk genes PTPRB, CFH, CDH5, TNFRSF10A, ADAMTS9, and NR3C2 is precisely located to the choroidal endothelium, and vascular cell types – not to the RPE. (2) AR (androgen receptor) is significantly higher expressed in the macular endothelium compared to the periphery (expression ratio: er=1,736, p=0,0287). No differential expression was detected for GCCR (glucocorticoid rec.; er=1,317; p=0,0858), MCR (mineralocorticoid rec.; er=0,991; p=0,9172), and PGR (progesterone rec.; er=1,455; p=0,4939). (3) AR expression is positively correlated with CSCR risk gene expression, and with genes coding for VEGF signaling molecules. Among 244 significantly correlated genes, the strongest correlation was detected for RUNX1T1 (Pearson R= 0,096; adjusted p=0,003).

Conclusions: Our findings are a molecular hint that CSCR initially manifests in the choroidal vasculature, not in the RPE – and thus, should be understood as a vascular eye disease. Furthermore, this article puts androgen hormones in the center of the scientific attention. By illuminating a link to VEGF signaling - RUNX1T1 is a strong mediator of VEGF-A initated angiogenesis and permeability - we might also be able to propose a potential mechanistic explanation for this androgen hypothesis.

ABSTRACT BODY:

Purpose: An ideal scleral lens fit will result a comfortable wear and minimize ocular complications. A successful scleral lens design starts with understanding the ocular topography of the wearer.

Methods: 997 (517 right eyes and 480 left eyes) EyeFit data from EyePrint Pro was analyzed. Ocular topography information was collected using impression-based technology. Scleral elevation data was exported every 10 degrees radially, starting 0.5mm outside of limbus up to 8mm (0.5mm step), which is roughly 30mm in diameter. Data was analyzed via elevation change measured perpendicular to the average limbal plane. Scleral steepness change was then calculated to evaluate the meridional symmetricity and the distribution of this population data is examined. In addition, the potential for successful interpolation and extrapolation of missing data is also assessed.

Results: On average, the eye is steeper at Superior and Temporal, flatter at Inferior and Nasal quadrants (Figure 1). Where Nasal is the flattest quadrant and Temple is the steepest. That means the nasal and temporal sag height differences increases as the chord length increases. As the distance from limbus increases, the range of the population distribution also widens (Table 1, AVG+/- SD). If the slope at adjacent chord length is similar, then a linear extrapolation is possible, but the zone for linear extrapolation is minimal for most eyes. If the slope at adjacent meridian is similar, an interpolation is possible without resulting in localized ridges; however, not all areas can be applied.

Conclusions: Ocular surface is not spherical; the shape becomes more aspheric and asymmetrical as it goes out from the limbus. The ocular shape also deviates from person to person making generalization difficult. A sclera landing zone accounting for the asymmetrical shape of individual eye will have the best outcomes and success.

ABSTRACT BODY:

Purpose: Mutations in the Kizuna (KIZ) gene, that encodes the centrosomal protein Kizuna, have been reported to cause autosomal recessive retinitis pigmentosa (ARRP), including a nonsense mutation (c.226C>T, p.R76*), located in exon 3. There is currently no approved treatment for KIZ-associated disease. Our aim is to characterize the expression pattern of KIZ in patient-derived skin fibroblasts as well as in normal mouse and sheep retinas by a novel method of alternative splicing analysis of RNA using next generation sequencing (NGS).

Methods: Skin biopsies were procured from four controls and three RP patients homozygous for KIZ-c.226C>T. In addition, retinas dissected from normal mice (n=6) and sheep (n=1) were included in the analysis. Primers for RT-PCR and NGS amplifying exons 2 to 5 were designed using Primer3. Following NGS, the aligned BAM files were analyzed using Integrative Genomics Viewer (IGV). In addition, potential exonic splicing enhancer (ESEs) sites were determined in WT and mutant human sequence using ESEFinder 3.0.

Results: RT-PCR and NGS-based analyses of RNA isolated from primary fibroblasts of patients and controls revealed the presence of four different transcripts: (i) the full-length transcript, (ii) skipping of exon 3, (iii) skipping of exon 3 and inclusion of an alternative exon, and (iv) skipping of both exons 3 and 4. Subsequent analysis of the expression pattern in the mouse and sheep retinas identified only two transcripts: (i) the full-length transcript and (ii) skipping of exon 4. The analyses revealed a lower expression level of the full-length transcript in patients compared to control (22% versus 58%). ESE analysis identified a 7 bp long sequence that includes the c.226 position with a higher score for the human WT sequence (4.411) compared to the mutant sequence (2.694).

Conclusions: KIZ- c.226C>T is a relatively frequent cause of ARRP in the Jewish population. Our data indicate that this variant might affect a putative ESE, that results in pronounced skipping of exon 3. Therefore, mutation-specific therapies, such as readthrough therapy and RNA editing, might show lower than expected efficacy since many transcripts do not contain this mutation. The KIZ nonsense variant is one of the few IRD mutations reported to affect an ESE, but we predict that ESE-affecting mutations are more common and need RNA-based analyses to be identified.

TITLE: SARM1 protects the cornea from sensory nerve degeneration and persistent severe inflammation in murine Herpes Stromal Keratitis (HSK)

SESSION TITLE: Ocular surface health and conjunctiva

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: H. Yun, K.L. Carroll, A. St. Leger, Ophthalmology, Eye and Ear Institute, University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Hongmin Yun: Commercial Relationship: Code N (No Commercial Relationship) | Kate Carroll: Commercial Relationship: Code N (No Commercial Relationship) | Anthony St. Leger: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: HSK is a blinding corneal disease caused by herpes simplex virus type 1 (HSV-1) infection, which manifests in both humans and mice as corneal opacity, neovascularization, and hypoesthesia. The replacement of corneal sensory nerves with sympathetic nerves in murine HSK plays a central role in maintaining the severe and persistent inflammation in the cornea. Here, we identify sterile apha and TIR motif containing 1 (SARM1) as a host factor that is critical for maintaining corneal nerve homeostasis after HSV-1 infection. Conventionally, SARM1 is expressed in neurons and is responsible for axonal degradation after insult or injury. In this study, we provide evidence that SARM1 acts intrinsically on immune and neuronal cells to prevent HSK.

Methods: SARM1$^{-/-}$ and litter mate wild-type (WT) mice were infected with HSV-1 KOS strain and were monitored for corneal opacity, neovascularization, and blink reflex. SARM1 gene expression in various tissues was assessed by qPCR. At 7dpi and 14 dpi, immune cell infiltration of the cornea was measured by flow cytometry. To assess the intrinsic effect of SARM1 on monocytes, BM derived myeloid cells were infected with HSV-1 KOS and were assayed for inflammatory factors using flow cytometry and metabolic activity using a Seahorse X_{FP}. Differences in nerve architecture were measured using corneal whole mounts and immunohistochemistry.

Results: SARM1$^{-/-}$ mice developed more severe corneal pathology, lost corneal sensitivity, and showed more disrupted corneal nerves compared to WT controls. After HSV-1 infection, SARM1$^{-/-}$ BM derived monocytes were more metabolically active and expressed more vascular endothelial growth factor (VEGF-A) and iNOS compared to WT BM monocytes. Similarly, monocytes from SARM1$^{-/-}$ corneas expressed more VEGF after HSV-1 infection compared to WT corneas. Finally, superior cervical ganglia, the source of sympathetic nerves, were larger in size in SARM1$^{-/-}$ compared to WT mice.

Conclusions: Together, our data reveal that SARM1 is a host factor responsible for suppressing HSK. Specifically, SARM1 appears to act on immune cells by regulating inflammatory mediators in myeloid cells after HSV-1 infection. Additionally, SARM1 also appears to restrict the growth of sympathetic nerves after infection. Therefore, we conclude that due SARM1 may be key factor in determining susceptibility pathology associated with HSK.

ABSTRACT BODY:

Purpose: Accumulating evidence from both human and animal models of glaucoma implicates the classical complement pathway as an important mediator of neuroinflammation and glaucomatous neurodegeneration. However, the alternative complement pathway mediates amplification of the complement pathway and has recently been implicated in driving inflammation and propagating injury in experimental models of spinal cord injury and brain injury, where specifically inhibiting the alternative pathway significantly reduced the extent of neurodegeneration. Herein we examine whether specifically inhibiting the alternative pathway is neuroprotective in experimental models of glaucoma and optic nerve injury.

Methods: Intracameral injection of magnetic microbeads (control: saline) was used to elevate the intraocular pressure (IOP) in complement factor B knockout mice ($Fb^{-/-}$, deficient in the alternative complement pathway), complement component 3 knockout mice ($C3^{-/-}$, deficient in all three complement pathways), and wild type (WT) mice. The optic nerve was crushed (ONC) approximately 2mm behind the globe with jeweler's forceps for 10 seconds. Visual acuity was measured by optomotor reflex (OMR). RGC density was quantified in retina whole mounts stained with a RGC-specific anti-Brn3a antibody. The nerve fiber layer (NFL) thickness was analyzed by spectral domain coherence tomography.

Results: IOP was increased equally in microbead injected $Fb^{-/-}$, $C3^{-/-}$ and WT mice as compared to saline controls. At day 35 post-microbead injection, visual acuity was significantly reduced in WT mice (0.37 ± 0.03 cyc/deg to 0.29 ± 0.04 cyc/deg, $p<0.001$) while no significant loss was observed in $Fb^{-/-}$ mice (0.39 ± 0.03 cyc/deg to 0.36 ± 0.03 cyc/deg, $p>0.05$) or $C3^{-/-}$ mice (0.35 ± 0.03 cyc/deg to 0.34 ± 0.04 cyc/deg, $p>0.05$). A significant thinning of the NFL and significant reduction in RGC density was also detected in microbead injected WT mice, but not $Fb^{-/-}$ mice. Similar results were observed following ONC, with $Fb^{-/-}$ mice displaying a significant increase in RGC survival at two weeks post ONC when compared to WT mice.

Conclusions: Our data shows that specifically inhibiting the alternative complement pathway is neuroprotective in mouse models of glaucoma and ONC, revealing the importance of the alternative pathway in the pathogenesis of glaucoma and optic nerve injury and introducing a potential new neuroprotective treatment.

ABSTRACT BODY:

Purpose: Congenital Stationary Night Blindness (CSNB) is a heterogeneous inherited group of retinal disorders characterized by a non-progressive photoreceptor degeneration leading to poor vision at night (nyctalopia), decreased visual acuity, myopia and nystagmus. The inherited causes of CSNB include mutations in the Rhodopsin (RHO) gene. Specifically, the substitution of Gly in position 90 of RHO with Asp was associated to the autosomal dominant form of CSNB. We found two new RHO mutations in patients diagnosed with CSNB. Since dominant mutations in RHO cause also Retinitis Pigmentosa (RP) and are characterized by the retention of the protein in the Endoplasmic Reticulum (ER), we evaluated the structural effects of the two new CSNB mutations and assessed the chaperon effect of retinal.

Methods: The structural effects of the new RHO mutations were investigated by equilibrium and steered molecular dynamics (MD) simulations by the CHARMM force field. In vitro analyses were performed in COS7 cells transiently transfected with cDNA of WT or mutant RHO for subcellular localization of mutant RHO and the potential chaperon-like effect of 11-cis-retinal.

Results: The in vitro analysis in COS7 cells highlighted a different behavior of the two CSNB RHO mutants. One mutation caused some retention in the ER of the opsin protein. Administration of 11-cis-retinal reduced the ER retention to the native opsin levels. The second mutant showed a similar distribution in the cellular compartments compared to the wild type protein. Interestingly, when exposed to 11-cis-retinal a marked reduction of membrane localization and increased ER retention were detected. The computational model could predict the effects of the two mutations on ER retention in the presence of 11-cis-retinal. Moreover, MD analysis highlighted a structural communication between mutation sites and the visual arrestin binding regions.

Conclusions: Consistent with in silico analysis, the two new mutations found in CSNB patients showed a different in vitro behavior in their ER-retention. In this respect, the first mutant could fall in the same cluster, cluster 2, of adRP RHO mutants (Behnen et al, iScience 2018). The second mutant appeared to be destabilized by 11-cis-retinal binding. In their opsin state, both mutants could be affected in visual arrestin binding.

ABSTRACT BODY:

Purpose: Psychotic disorders, such as schizophrenia, are associated with increased cardiovascular morbidity and, increasingly, neurovascular impairment. Retinal fractal dimension (FD) is a geometric index of complexity associated with neurovascular pathology. In this study, we sought to evaluate the association between schizophrenia and retinal FD and investigate the effect of other comorbidities on this association.

Methods: A hospital-based retrospective cohort study of 96,995 patients, of which 676 had schizophrenia, was run at a tertiary ophthalmic institution in London, United Kingdom. Retinal FD was extracted from macular-centered color fundus photographs using the Vascular Assessment and Measurement Platform for Images of the Retina. Multivariable linear regression evaluated the association between retinal FD and schizophrenia adjusting for age, sex, hypertension and diabetes mellitus.

Results: Patients with schizophrenia were younger (63.2 +/-12.4 versus 68.3 +/- 12.5 years of age, $p<0.001$) and more likely to be diabetic (73.5% versus 47.3%, $p<0.001$) but there was no significant difference in sex or hypertension distribution. Retinal FD was 1.51 +/- 0.03 for both patients with schizophrenia and without. When stratifying by diabetic status, retinal FD was not different ($p=0.11$) between diabetic patients with schizophrenia and those without. However, retinal FD was significantly reduced ($p=0.004$) in non-diabetic patients with schizophrenia. Adjusting for age, sex, hypertension and diabetes mellitus, schizophrenia remained associated with reduced retinal FD (beta coefficient= -0.0034, 95%CI: -0.0057, -0.0012, $p=0.003$). However the main effect was neutralized when incorporating interaction between DM and schizophrenia (schizophrenia $p=0.41$, interaction $p=0.004$).

Conclusions: Retinal FD is reduced in people with schizophrenia but this association was significant only for non-diabetic individuals. This indicates the compound effect of diabetes and schizophrenia on cerebral vasculature. The strong association between retinal FD and schizophrenia indicated the potential utility of using retinal FD as an economic and accessible marker for neurovascular impairment in non-diabetic patients with schizophrenia.

ABSTRACT BODY:

Purpose: The purpose of this study was to characterize retinal gene expression changes that occur in CRISPR-induced rhodopsin zebrafish mutant, rho^{fl9} which contains a non-sense mutation at codon 347 (pS347*), eliminating the conserved VXPX C-terminal targeting signal. (Zelinka et al., 2018). We previously showed that zebrafish heterozygous for the rho^{fl9}allele display opsin mislocalization, rapid rod degeneration but no secondary effect on cones — a similar phenomenon was observed in XOPS-mCFP transgenic zebrafish (Morris et al., 2011). We predicted that the gene expression profile in rho^{fl9} would reflect dramatic downregulation of rod phototransduction genes but upregulation of genes associated with rod regeneration.

Methods: Total RNA was extracted from retinas of age-matched wild-type and rho^{fl9} adult zebrafish. Gene expression profiles produced from RNAseq were used to determine differentially expressed genes, and pathway analysis was used to identify the relevant biological pathways. Cell proliferation was assessed by EdU labeling.

Results: RNAseq counts yielded 15,401 genes; expression of 1,413 genes was significantly different from wild-type. As expected, these data show decreased expression of rod-associated genes, including many disease-associated genes. As anticipated, increased expression of cell cycle-associated genes was observed, but no changes in genes expressed by cones were observed. Initial pathway analyses indicated that significantly down- and upregulated genes are involved in regulating phototransduction, cell mitosis, and photoreceptor specification. When compared to expression data from XOPS-mCFP zebrafish, the pathway outputs were nearly identical. For both mutants, the top downregulated genes consisted of rod-associated genes, while the top upregulated were involved in cell cycle control and neuronal differentiation. EdU immunolabeling on rho^{fl9} adults confirmed the increase of mitosis of rod progenitor cells, but no Müller glia were labeled.

Conclusions: These data characterize gene expression changes that occur in the rho^{fl9} retina. The similarities found between two distinct rod degeneration models suggest that genetic manipulations leading to rod degeneration evoke a predictable pattern of gene expression consistent with a persistent cycle of rod degeneration, regeneration and degeneration. These tools provide genetic models to better understand persistent rod death and degeneration-induced regeneration.

ABSTRACT BODY:

Purpose: Smartphones are becoming increasingly utilized by older adults with low vision, and an increasing number of visual assistive smartphone apps are available at no or little cost. We explored the effect these apps may have on visual ability for seniors with low vision.

Methods: Seniors naïve to the study apps, with a score >20 on the telephone interview of cognitive status (TICS), aged 55+ (mean 72; SD 10 years) and ETDRS visual acuity (VA) better than 1.3 logMAR (n=33, enrollment ongoing) were randomized to one of three study apps (Supervision+ for magnification; SeeingAI for optical character recognition; Aira for remote visual description). Subjects were provided training upon dispense of a loaner iPhone SE with the study app and again at 2-weeks. App proficiency was evaluated, phone use was monitored via Verizon mobile device management and questionnaires were administered at baseline and 3 months post-intervention: activity inventory (AI), Beck depression inventory (BDI), UCLA loneliness scale, and general self-efficacy scale. We applied the method of successive dichotomizations, a polytomous Rasch model, to estimate person measures from the AI pre- and post-intervention, using calibrated item measures and thresholds. Multiple linear regression was used to determine which factors influenced change in AI person measures.

Results: The majority of subjects were white (70%), college graduates (76%), had macular disease (45%) and were male (56%), with a mean (SD) VA of 0.64 (0.33) logMAR, and CS of 1.01 (0.49) logCS. Mean (SD) baseline AI person measures was 0.07 (1.0) logits, and post-intervention the AI change score was 0.41 (0.67) logits. The majority of subjects (69%) showed improvement in visual ability in each of the AI domains: goals, reading, visual motor, visual information and mobility. Baseline BDI score ($p=0.004$), baseline loneliness score ($p=0.007$), and use of the study phone within the past month ($p=0.03$) were significantly associated with greater AI change scores ($R^2=0.50$). Self-efficacy, TICS, VA, app proficiency, and demographics were not significantly related to AI change scores post-intervention (all $p>0.05$).

Conclusions: Use of visual assistive apps may improve visual ability in seniors with low vision. These results indicate that these interventions should be considered as part of the rehabilitation plan.

ABSTRACT BODY:

Purpose: The molecular characterization of extracellular deposits (drusen, SDD, basal laminar deposit) is crucial for understanding the clinical progression of AMD. Ample evidence supports a role of lipids and associated pathways in forming extracellular deposits, including SDD. Combining powerful analytical tools of Matrix Assisted Laser Desorption Ionization Imaging Mass Spectrometry (MALDI IMS) and liquid chromatography tandem mass spectrometry (LC-MS/MS) provides spatially resolved lipid identifications. The purpose of this study is to localize lipids using imaging mass spectrometry (IMS) and identify them using LC-MS/MS, in human eyes with SDD.

Methods: Fixed retina tissue from two deceased donors (>80 years age) with SDD was sectioned to 12-14 µm thickness and placed on indium-tin-oxide slides for IMS experiments. MALDI matrix was applied by sublimation and images were acquired at 10-15 µm spatial resolution using a Bruker timsTOF Pro instrument. Data were analyzed with FlexImaging and SCiLS software. For nano LC-MS/MS analysis, sections of retina with SDD were manually removed from the slides under a dissecting microscope. Lipids were extracted with MMC (MeOH/MTBE/CHCl3) solvent mixture. In-house packed reverse phase columns (20 cm X 75 µm) were packed with 1.9 µm BEH C18 material. nLC-MS/MS was performed using an EASY-nLC 1000 (Thermo Scientific) coupled to a Q-Exactive HF instrument (Thermo Scientific). LC-MS/MS and MALDI-IMS data were interpreted using MS DIAL-4 and LipostarMSI software.

Results: Five phosphatidic acids (PA (30:0), PA (32:1), PA (32:0), PA (38:6), PA (40:2), 5 phosphatidyl ethanolamines (PE (18:0), PE (40:6), PE (34:1), PE (40:7), PE (38:6), 4 phosphatidylcholines PC(O-32:2), PC (36:3), PC (32:2), PC (40:3), 1 diacylglycerol (DG (38:8) and 1 phosphatidylinositol PI-Cer(38:0) were localized specifically in SDD and tentatively identified using accurate mass measurements from MALDI-IMS in negative ionization mode. Further studies are ongoing to confirm these identities using LC-MS/MS.

Conclusions: Lipid signals were localized to SDD in human retina samples using IMS and are being characterized using LC-MS/MS. Further identifications of lipids in eyes with SDD could help elucidate how lipids are involved in the formation of this extracellular deposit in AMD.

ABSTRACT BODY:

Purpose: Visual performance across the visible spectrum is limited by many factors, including monochromatic & chromatic aberrations,differences in spectral sensitivity across cone types, and post-receptoral processing of spatial & chromatic contrast.We sought to investigate the interplay between these factors using a combination of adaptive optics(AO) psychophysics & computational modeling

Methods: Four cyclopleged subjects were measured in a tumbling ‘E-letter’ visual acuity(VA)4AFC experiment under dynamic AO correction.The visual display consisted of a digital micromirror device (DMD) & two LEDs 427±13nm & 630±16nm(luminance for both=5.7cd/m2).Subjects set subjectively the best focus at each tested wavelength.VA was measured under 4 different stimulus conditions with variations in spatial & chromatic contrast: black ‘E’ on either a blue and red background (BKG); red ‘E’ on blue BKG and blue 'E' on red BKG.These conditions were also simulated using ISETBio(Image Systems Engineering Toolbox for Biology)computational pipeline.The simulations incorporated the effects of the calibrated display,human eye’s optics,absorption by the anterior segment of the eye,macular pigment & cone photoisomerizations.To verify the relative contributions of spatial(L+M modulation) & chromatic(L-M modulation) contrast to the visual task, these were calculated from the resultant cone photoisomerizations

Results: VA improved as expected in all conditions after correcting HOAs.The mean LogMAR VA with AO was -0.20±0.04 & -0.06±0.02 for monochromatic red and blue BKG respectively.The mean VA with AO was -0.17±0.05 & 0.03±0.02 for polychromatic targets(red ‘E’ on blue BKG,and vice-versa respectively).The improvement was typically lower for blue letters (11%) compared to red (16%).Simulations verified that once optical aberrations are removed with AO,VA was better under conditions where both spatial & chromatic contrast were high,i.e.the red letters.Conversely,VA was poorer when either of the contrasts were low, for eg.,the monochromatic blue target where the spatial and the chromatic contrast were high(>95%) & low(<10%) respectively

Conclusions: A combination of AO psychophysics experiments and ISETBio simulations enabled us to understand the factors limiting VA at different wavelengths.Similar experimental & modeling platforms,paired with ideal observer analysis,may give insights on the optical,retinal & neural limitations to spatial & chromatic vision

ABSTRACT BODY:

Purpose: The retina is a visible extension of the brain that may reflect brain neurodegeneration caused by Alzheimer's disease (AD) and natural senescence. The spatial distributions of neurons, glial, and vasculature, which may be afflicted at different stages of a neurodegenerative process, vary in retinal sublayers. Thus, we aimed to characterize and differentiate the spatial and temporal distribution of AD- versus senescence-induced neuronal and vascular changes of the retina based on immunohistochemistry and optical coherence tomography (OCT) studies in the triple transgenic mouse model of AD (3xTg-AD).

Methods: The retina’s superficial (SVP), middle (MVP), and deep (DVP) vascular plexuses were studied in young (2 months old-M) to middle-aged (14M) and old (18-20M) 3xTg-AD and C57bl/6j mice. Amyloid-β (Aβ) and phosphorylated-tau (ptau) deposition were characterized in retinal and brain samples from 4M, 8M, and 12M animals. Retinal sublayer thicknesses were analyzed in annular OCT scans and retinal ganglion cells (RGCs) were quantified in retina flat-mounts in 2M to 12M transgenic and control mice.

Results: Progressive deposition of Aβ and ptau was detected in the retina (4M) before the brain (8M). Vascular attenuation and RGC loss occurred with AD pathology and natural aging; however, RGC loss was more significant in 8M and 12M 3xTg-AD compared to old controls ($p=0.0426$ and $p=0.0002$, respectively). SVP and DVP, but not MVP, attenuation differentiated old 3xTg-AD from old controls ($P<0.05$). The retinal nerve fiber layer (RNFL), but not ganglion cell layer (GCL), thickness decreased (linear regression, $p=0.0002$) as 3xTg-AD mice aged.

Conclusions: In our animal models, the retina manifests AD pathologies before the brain. Various degrees of AD-induced neurovascular coupling dysfunction within the retina layers can be monitored and quantified as biomarkers of AD progression using noninvasive OCT and OCTA approaches. Retinal neurovascular (NV) biomarkers may differentiate AD-neurodegeneration from neurodegeneration caused by natural aging. More specifically, GCL thickening by neuroinflammation and NV dysfunction (trophic changes) may nullify the thinning effect caused by RGC loss (atrophic changes) in AD but not in natural aging. In contrast, the hypocellular RNFL is less affected by the trophic effects of neuroinflammation and NV dysfunction.

ABSTRACT BODY:

Purpose: The pathology of most ocular conditions is driven by a number of known molecular pathways. However, targeted management requires tear-based, rapid, multiplexed diagnostic systems in the clinical setting. We deployed such a system that measures 8 soluble factors in the cornea clinic to stratify patients based on correlations between clinical indices and biomarker levels

Methods: We tested tear samples collected from 621 eyes categorised clinically into controls(n=214), dry eye disease(DED; n=107), Keratoconus(KC; n=125) based on slit lamp examination, ocular surface disease index(OSDI) scoring, dry eye evaluation and ocular surface staining. Tear fluid collected using Schirmer's strips were evaluated for soluble factors on a customised multiplex ELISA platform (Bio-M Pathfinder). Another group of clinically healthy subjects were further stratified into – sub-clinical inflammation (SCI) groups 1(n=95) and 2(n=80) based on the level of biomarkers and correlation to clinical indices.

Results: Patients with DED showed significantly higher OSDI scores, MMP9, IL6, TNFα, IL1β, IL17A and sICAM1 levels with reduced Schirmer's test and TBUT values. KC eyes showed significantly higher MMP9 levels. IL10 and VEGF levels remained unchanged across the conditions. SCI-1 and SCI-2 groups had significantly higher inflammatory markers, significantly reduced Schirmer's and TBUT levels which were not low enough to be clinically classified as DED. Inflammatory biomarker detection was successful in all cases with good reproducibility, high sensitivity and specificity.

Conclusions: Clinical usage of a rapid, biomarker platform is feasible and useful to identify subjects with sub-clinical inflammation, helping stratify subjects for customised treatments and surgery.

ABSTRACT BODY:

Purpose: Intravitreal anti-VEGF injections are approved to treat neovascular age-related macular degeneration (nAMD), yet real world evidence shows patients lose vision over time due to undertreatment. RGX-314 is designed as a single gene therapy intervention utilizing an adeno-associated virus 8 (AAV8) vector, to deliver an anti-VEGF fab transgene, potentially producing continuous anti-VEGF therapy in the eye. Initial data from the AAVIATE trial has provided encouraging evidence of RGX-314 as a potential treatment of nAMD using an in-office, suprachoroidal delivery.

Methods: AAVIATE is an open-label trial that will evaluate the efficacy, safety and tolerability of suprachoroidal delivery of RGX-314 using the SCS Microinjector®. 20 patients in Cohort 1 and 20 patients in Cohort 2 were randomized to receive RGX-314 at a dose level of $2.5x10^{11}$ and $5x10^{11}$ genomic copies per eye (GC/eye), respectively, versus monthly 0.5 mg ranibizumab intravitreal injection at a 3:1 ratio. Cohort 3 is evaluating RGX-314 at the same dose level as Cohort 2 in 20 patients who are neutralizing antibody (NAb) positive. The primary outcome is the mean change in BCVA at 9 months. Secondary outcomes include safety, central retinal thickness (CRT), and additional anti-VEGF injections needed post-RGX-314.

Results: As of November 4, 2021, RGX-314 was well tolerated in 50 patients dosed in Cohorts 1-3. Four serious adverse events were reported in 4 patients, all of which were considered not related to RGX-314. For the total group of Cohorts 1 and 2, all common treatment emergent adverse events (TEAEs) through 6 months in the study eye were mild. Mild intraocular inflammation observed on slit-lamp examination in 7 of 30 patients (23%) was reported at similar incidence across both dose levels, and all cases resolved within days to weeks on topical corticosteroids. Patients dosed with RGX-314 in Cohorts 1 and 2 demonstrated stable BCVA and CRT at 6 months and had a meaningful reduction in anti-VEGF treatment burden (>70%). 4 of 14 patients (29%) and 6 of 15 patients (40%) in Cohorts 1 and 2, respectively, received no anti-VEGF injections over 6 months following RGX-314 administration.

Conclusions: Suprachoroidal RGX-314 has the potential to provide sustained clinical improvements in the treatment of nAMD with a one-time in-office treatment.

ABSTRACT BODY:

Purpose: The purpose of this study is to explore the ability of Cerium-based Metal-organic Frameworks (Ce-MOF) nanoparticles to scavenge ROS and its application prospect in dry eye diseases (DED).

Methods: Three kinds of Ce-MOFs with different particle sizes were prepared by hydrothermal method, which were labeled Ce-MOF 1, Ce-MOF 2 and Ce-MOF 3, respectively. The phase structure, functional groups, morphology, particle size, Zeta potential, element composition and ROS scavenging ability of Ce-MOFs were characterized. Subsequently, the CCK-8 and ocular irritation test were used to determine the cytotoxicity. In H_2O_2-induced ROS model, the ability of cleaning out intracellular ROS in human corneal epithelial cell (HCEC) was tested. Finally, the effect of CeMOF 3 on mouse DED was evaluated by slit lamp observation, corneal epithelial staining.

Results: Three kinds of Ce-MOFs were obtained: 500 nm, 50 nm and 3 nm. The phase structure, functional group and thermal stability in Ce-MOFs show no significant difference. CeMOFs showed the concentration-dependent SOD-like and ROS scavenging activities. The cellular and ocular compatibility were confirmed. In HCECs, Ce-MOF 3 show greater antioxidant capacity which reduced ROS level. In the DED treatment, corneal epithelial defect was significantly reduced by Ce-MOF 3.

Conclusions: We had successfully constructed three kinds Ce-MOFs which own antioxidant enzyme and ROS scavenging activity in vitro. Further, the Ce-MOF 3 not only showed good biocompatibility, it also effectively alleviated DED. The new ultra-small Ce-MOF provides a new method for alleviating dry eye disease.

TITLE: Abl kinases regulate the lens vesicle closure

SESSION TITLE: Lens Biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Wu, Y. Mao, H. yu, X. Zhang, Columbia University Irving Medical Center, New York, New York, UNITED STATES|

Commercial Relationships Disclosure: Hao Wu: Commercial Relationship: Code N (No Commercial Relationship) | Yingyu Mao: Commercial Relationship: Code N (No Commercial Relationship) | honglian yu: Commercial Relationship: Code N (No Commercial Relationship) | Xin Zhang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Incomplete separation of the lens vesicle from the surface ectoderm results in a persistent lens stalk between the lens and cornea, which clinically presents as adhesion between the cornea and the iris and/or lens in Peters anomaly (PA). This study aims to elucidate the Abl-Crk cellular signal network that regulates lens vesicle closure.

Methods: Mouse lines carrying floxed genes of interest were crossed with the lens-specific Le-Cre (Tg/-) to generate conditional knockouts. Embryos carrying expected genes were harvested and sectioned for histochemical analysis. Immunoprecipitation and immunoblotting were carried out using primary mouse embryonic fibroblasts (MEFs) and lens epithelium cells.

Results: Abelson murine leukemia viral oncogene homolog (Abl) and Abl related gene (Arg) mutants (Le-Cre;$Abl^{F/F}$;$Arg^{F/F}$, AblCKO) presented incomplete separation of the lens vesicle from the surface ectoderm as early as embryonic day 10. In vitro, viral expression of Cre recombinase caused $Abl^{F/F}Arg^{F/F}$ lens epithelium cells to scatter, losing their typical hexagon shape and adherens junctions. Heterozygous deletion of Abl substrates Crk adaptor proteins (Crk and its paralog CrkL) in the AblCKO mutants (Le-Cre;$Abl^{F/F}$;$Arg^{F/F}$;$Crk^{F/+}$;$CrkL^{F/+}$) can rescue the lens stalk phenotype in an allele copy-dependent manner, and homozygous deletion of Shp2 was able to rescue the phenotype with partial penetrance. The lens epithelium in AblCKO embryos showed elevated phospho-ERK. But homozygous Abl, Arg, and Erk1/2 quadruple knockout (Le-Cre;$Abl^{F/F}$;$Arg^{F/F}$;$Erk1/2^{F/F}$) embryos still possessed lens stalks. Only homozygous deletion of Rac1 in the AblCKO mutants (Le-Cre;$Abl^{F/F}$;$Arg^{F/F}$;$Rac1^{F/F}$) was able to fully rescue the lens stalk phenotype.

Conclusions: These genetic experimental results suggested that Crk and CrkL, as the direct substrates of Abl, serve as the linkage between Abl and the cell adhesion network. ERK1/2 and Rac1 abolition experiments demonstrated that Rac1, but not ERK, is the downstream effector of Abl in the lens-cornea separation.

ABSTRACT BODY:

Purpose: A recent study [1] has shown that adaptive changes in the pattern electroretinogram (PERG adaptation) are altered in eyes with early manifest glaucoma, indicating reduced autoregulation and energy budget mechanism in affected eyes. The aim of this study was to evaluate PERG adaptation in glaucoma suspect (GS) eyes and to correlate the results with early anatomical changes in retinal ganglion cells (RGCs) and optic nerve fibers (ONF)

Methods: Twenty-one GS patients and 20 age-matched controls were included in the study. PERGs were recorded in response to 7.5 Hz counterphased horizontal bars (field size 50 x 60 °, 90% contrast) presented in 9 packets of 60 events each and alternated with an unmodulated uniform field. Trends of PERG amplitude and phase changes as a function of stimulus packets were measured with vector response analysis and linear regression statistics for amplitude values[1]. Regression coefficients and phase coherence were determined for each measure

Results: PERG adaptation was detected and significant ($p < 0.05$/$p < 0.01$) in all control subjects, with a mean decline as a function of packets of -3 microV/packet. PERG adaptation had a shallower negative slope in glaucoma suspects, compared to controls, with a mean decline of -0.46 microV/packet ($p < 0.01$). Regression coefficients and phase coherence were also reduced in GS patients compared with controls. No significant correlations were found between PERG adaptation parameters and RCG and ONF thickness of patients

Conclusions: In GS patients, the PERG adaptation is abnormal and not correlated with anatomical changes, suggesting that inner retina autoregulation and energy budget mechanisms are altered early,and independently of anatomical damage, in the disease process

ABSTRACT BODY:

Purpose: In the COVID-19 era, tele-retinal technologies are rising to the forefront of contactless ophthalmic care. Point-of-care Optical Coherence Tomography (OCT) and fundus photography remotely analyzed by an off-site retina specialist (tele-R) must be validated for screening retinal disorders. This study assesses the feasibility of tele-R as a screening tool for diabetic retinopathy (DR) in an outpatient clinical setting.

Methods: A retrospective study was conducted on 16 patients (32 eyes, 28 with DR, and 4 controls) presenting to the retina clinic (RC) of an urban academic medical center. Automated OCT-B and 45^0 fundus photographs of the posterior pole were taken using a Topcon Maestro 3D OCT-1 unit, and 3D topographical maps of the macula were generated. Images were transmitted to a remote retina specialist (blinded to patient history and demographics) who assessed severity of DR and diabetic macular edema (DME). Primary outcomes included grading of DR and DME with fundus and OCT-B images, respectively, using the International Clinical Diabetic Retinopathy classification scale. The secondary outcome was identifying the severity grade of DME using the 3D macular map. Concordance was tested between diagnoses obtained from tele-R assessment and in-person examination by the retina specialist (gold standard) using Cohen's Kappa statistic (κ). Eyes that could not be assessed were removed from analysis.

Results: 30 of 32 eyes with sufficient data for analysis were included. The average age was 57.9 (±11.2) years. 37% of patients were male, 69% were Hispanic, and 94% had Type 2 diabetes. The κ±standard error (SE) for DR severity was 0.738±0.099 ($p<0.001$), for DME severity was 0.588±0.122 ($p<0.001$), and for presence of DME was 0.727±0.122 ($p<0.001$). The retina specialist was able to grade the DME severity in only 10/14 (71%) eyes using the 3D macular map alone, but in 93% (13/14) eyes with OCT-B images.

Conclusions: Tele-R is a reliable modality for diagnosis of DR severity; there was substantial agreement on identifying DR severity using tele-R vs in-person examination. There was substantial agreement in discerning DME using tele-R vs in-person while only moderate agreement on determining the severity of DME, which suggests that tele-R may useful in identifying presence of DME but not determining the severity of edema.

ABSTRACT BODY:

Purpose: Uveal melanoma is the most common primary intraocular cancer in adults. Once uveal melanoma metastasizes, median patient survival is less than 18 months. Primary uveal melanomas with high metastatic tendencies differ from their more indolent counterparts in various ways. They are often monosomic for chromosome 3, frequently harbor mutations in the BAP1 gene and exhibit a distinctive gene expression signature. Single cell RNA sequencing of enucleated primary uveal melanoma tumors revealed that uveal melanomas with different metastatic tendencies are not fundamentally distinct disease subtypes, rather individual tumors harbored cells from both prognostic classes. Hence, prognostic tests that classify UM into two major groups lack the resolution to assess the diversity of an inherently heterogeneous tumor. We then asked whether DNA methylation of the different subclones could be employed to estimate the preponderance of aggressive subclones within an individual tumor, as DNA-methylation of a given genomic locus is a binary state.

Methods: Cell Cutlure, single-cell RNA sequencing, Infinium MethylationEPIC array, pharmacologic and genetic modulation of polycomb repressive complex 1 in uveal melanoma cell lines

Results: Using the Infinium MethylationEPIC array we found that uveal melanoma cells with aggressive features, MP38, had a distinctive methylome than their indolent counterparts, 92.1. We had recently demonstrated that loss of Polycomb Repressive Complex 1 induced a transcriptional and morphological transition from an indolent to an aggressive phenotype. We found that inhibition of Polycomb Repressive Complex 1 ligase activity using a small molecule inhibitor, PRT4165, induced global methylation changes in indolent uveal melanoma cells, 92.1, reminiscent of the methylome of aggressive uveal melanoma cells, MP38. We then sought to determine whether utilizing a methylation panel provides useful prognostic information. We identified the top 200 hypermethylated CpG loci in monosomy vs disomy 3 tumors in The Cancer Genome Atlas uveal melanoma cohort. We found that the higher the methylation values, the worse the prognosis.

Conclusions: In summary, our results indicate that high-risk and low-risk uveal melanoma cells can be distinguished by their methylome. This information can readily be translated into an actionable test to provide accurate prognostication.

ABSTRACT BODY:

Purpose: To avoid the need of intraocular injections, several strategies have been investigated to improve the permeation of topical drug delivery to posterior segment of the eye, such as the use of peptides as drug carriers. Kyotorphin (L-Tyr-L-Arg) is a small endogenous neuropeptide, whose derivatives (e.g. $KTPNH_2$) were previously designed to increase membrane permeability. Penetratin (a 16-mer peptide) is a known cell penetrating peptide, which have been suggested as a carrier for drug delivery through many tissues, including the ocular membranes. Herein, the possibility of producing therapeutic contact lenses (CLs), loaded with either $KTPNH_2$, Penetratin or a dexamethasone-$KTPNH_2$ complex (Dex-$KTPNH_2$), was evaluated with the aim of increasing the delivery efficiency of dexamethasone to the back of the eye.

Methods: Hydrogels of HEMA-TRIS-NVP were investigated as potential CL backbone. Autodock software was used to model the molecular interactions between the monomers and the peptide and identify potential functional monomers. After polymerization, hydrogel discs ($N \geq 3$) were loaded by soaking in a peptide solution (1mg/mL). The effect of pre-soaking in a solution of vitamin E in ethanol was investigated to prolong the release time. Drug-release was performed in vitro in sink conditions. The swelling behavior and light transmittance of the hydrogels were tested prior and after loading.

Results: Molecular simulation suggested a strong interaction between acrylic acid (AAc) and the peptides. Therefore, AAc was incorporated in the prepolymer mixture as a functional monomer. The light transmittance of the hydrogels resulted higher than 90% at wavelengths above 500 nm. The peptide uptake and the swelling increased with the addition of AAc for all the tested molecules, while the presence of vitamin E was associated to a lower swelling. The pre-soaking in vitamin E and the presence of the functional monomer prolonged the release time of $KTPNH_2$ up to 8h. Unmodified HEMA-TRIS-NVP hydrogels were able to sustain the release of Penetratin or the Dex-$KTPNH_2$ complex for more than 24 hours (Figure 1).

Conclusions: The obtained results shall contribute for the development of new topical treatment forms, able to provide a therapeutic effect in the back of the eye without need of intraocular injections.

ABSTRACT BODY:

Purpose: Cellular and molecular activities in the RPE-Bruch's membrane (BrM)-choriod complex are essential for maintaining retinal function, and their abnormalities may cause the development of diseases such as age-related macular degeneration. Unlike the live-cell imaging of cell cultures, there has been no method to observe this complex in 3D with high temporal resolution. In this study, we observed response of RPE-BrM-choroid tissue to laser irradiation by high-resolution dynamic optical coherence tomography (dmOCT).

Methods: RPE-BrM-choroid explants were prepared from the freshly enucleated porcine eyes. A 577 nm microsecond pulsed laser (100 µm, 200 ms, 180-220 mW, duty cycle 10%) was used to apply very mild coagulation spots on the RPE. The explants were then maintained at 37°C in 5% CO_2. After 24 hours, the tissue was imaged with FD-OCT with microscopic resolution. Using a wavelength range from 580 nm to 930 nm of a supercontinuum light source, a COMS camera with up to 248 kHz line scan rate, and a 10x/0.3 NA microscope objective, 1.8 µm axial and 1.1 µm lateral resolution were achieved. For the dynamic contrast OCT, B-scans were measured at 108 Hz over 1.39 s and the amplitude of the OCT signal was Fourier transformed. The obtained spectra are displayed in RGB colors depending on the frequency band. The tissues were also assessed with the immunohistochemistry with macrophage markers (CD80, CD206).

Results: B-scan imaging with microscopic FD-OCT allowed clear recognition of individual RPE cells, BrM, and choroidal vessels. The volume scan enabled reconstruction of the en face image with dynamic contrast, showing the fast frequency at the wound edge of the laser spots. In the B-scan time series, a number of fast moving signals with diameters of 5-10 µm were observed in the apical space of the RPE as well as in the choroidal vessels. These migratory cell-like signals were particularly concentrated at laser spots and some of them were observed to move from the choroidal vessel to the apical side of the RPE through the RPE cell gap. Immunohistochemistry confirmed the presence of macrophages in the choroidal vessels.

Conclusions: The high-resolution dmOCT allows 4D-analysis of RPE-BrM-choroid tissue at the cellular level with dynamic contrast information. Time-series of B-scan images is useful to observe the tissue dynamic changes over time and the behavior of migratory cells like macrophages at the RPE and surrounding tissues.

Mulholland: Commercial Relationship: Code N (No Commercial Relationship) | Roger S. Anderson: Commercial Relationship: Code N (No Commercial Relationship) | Julie-Anne Little: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Appropriate detection of, and reaction to, hazards are important components of safe driving, and for drivers with reduced vision, this skill can become compromised. However, the level of blur that significantly impairs hazard perception performance has not been fully determined. This study examined varying levels of optical blur and their effect on response time to hazards during a computer-based Hazard Perception Test (HPT).

Methods: Five healthy drivers aged 24-56 years with a binocular visual acuity <0.00 LogMAR (range: -0.18 to -0.22 LogMAR) undertook 14 computer-based HPT assessments. These high-quality, first-person CGI video clips require viewers to respond to real-world hazards and are used by the UK Driver and Vehicle Licensing Agency to assess hazard perception performance in learner drivers. The HPT tasks were undertaken with participants being optimally corrected for the viewing distance and with optical blur induced using +1.00, +2.00 and +3.00-diopter spherical lenses. Baseline and blur testing were conducted over four visits with blur levels and video clips being randomized to minimize memorization effects. Participants' response time to hazards was collected with a Cedrus RB540 response box. Data were analysed using a two-factor repeated measures ANOVA and post-hoc pairwise comparisons of means with Holm-Bonferroni correction as appropriate.

Results: The mean visual acuity at baseline, and with +1.00, +2.00 and +3.00-diopter spherical lens was -0.20±0.02, 0.04±0.12, 0.47±0.09 and 0.69±0.1.00 LogMAR respectively. Compared to baseline (1.40±0.16s), response time was significantly ($p<0.001$) delayed by the introduction of a +3.00-diopter lens (mean difference: 0.78s, 95% CI:0.30-1.24). The +2.00-diopter and +1.00-diopter blur lenses delayed responses by 0.40±0.20s (95% CI:-0.06-0.85) and 0.14±0.20s (95% CI:-0.34-0.61) respectively, but these differences were not statistically significant (both $p>0.05$). There was no statistically significant interaction effect of optical blur and hazard perception video type on response time ($p=0.99$).

Conclusions: Simulation of optical blur with a +3.00-diopter spherical lens significantly impairs detection of hazards during hazard perception tests. Lower levels of blur, despite being visually compromising to acuity, did not have a significant effect on HPT.

ABSTRACT BODY:

Purpose: The aim of this study was to assess the thickness of the ganglion cell-inner plexiform layer complex (GC-IPL) in autosomal dominant optic atrophy (ADOA) and its nasotemporal thickness profile in relation to healthy individuals.

Methods: The study included 145 participants (74 males, 71 females, mean age 44, SD ± 20 years) with various OPA1 mutations, 63 of their first-degree relatives (24 males, 39 females, mean age 38, SD ± 18 years) and 92 unrelated healthy controls (40 males, 52 females, mean age 42, SD ± 19 years). Retinal structure was assessed using optical coherence tomography (OCT) with automated layer segmentation, ETDRS grid pattern thickness analysis (Heidelberg Spectralis, Heidelberg, Germany) and comparison of thickness profiles between groups (RStudio, mixed model, corrected for age and sex with family and eye as a random effect).

Results: For ADOA subjects, first-degree relatives and unrelated controls, mean GC-IPL thickness 3 mm nasal of the foveal center was 43, 98 and 95 µm respectively, whereas 3 mm temporal of the foveal center it was 44, 93 and 89 µm, showing that on a cohort level the nasotemporal thickness ratio is inverted in ADOA, namely 0.98, compared to 1.05 and 1.07 in subjects without ADOA ($p<0.001$). The thickness 6 mm nasal of the fovea center in the three respective groups was 43, 68 and 67 µm and 6 mm temporal of the fovea and 45, 70 and 66 µm, showing that a difference in pattern of ratio reversal was absent at this eccentricity ($p=0.8$ for ADOA versus first-degree relatives). More than half the participants with ADOA had nasotemporal GC-IPL thickness ratios lower than 1.0, which was found in less than 5 % of unrelated healthy subjects.

Conclusions: Half the participants with ADOA in this study were immediately recognizable in that their perifoveal GC-IPL layer was thicker on the temporal than on the nasal side of the fovea, which did only occur in few unrelated healthy controls and relatives without OPA1 mutations. Recognizing this characteristic will often make it possible to make a spot diagnosis of ADOA by comparing the nasal and temporal perifoveal ETDRS field thicknesses.

ABSTRACT BODY:

Purpose: Retinal Optical Coherence Tomography (OCT) has potential for early detection of neurodegenerative disease (NDD). This requires accurate, automatic segmentation of retinal boundaries despite challenges often pronounced in images from people with NDD, e.g. atrophic layers and indistinct boundaries, media opacity, and movement artefacts. An ideal algorithm would also handle different OCT devices and imaging protocols with diverse resolution, size, artefacts and noise. Our algorithm (NDD-SEG) gives a solution.

Methods: The basic structure is a U-net without pooling and upsampling layers. An initial Retinal Tissue Segmentation Network (RTSN) identifies the retina within the image, even against a noisy background. The Retinal Layer Segmentation Network (RLSN) focuses on fine segmentation of the intra-retinal layers, using the probability map from RTSN cascaded with the original input image. This probability map and texture features are injected into decoder levels of RLSN. The Self-Attention Transformer Block represents higher-level descriptions of the merged data instead of simple concatenation. A new Boundary Preservation Loss (BPL) function is introduced which enables high-precision layer edges to feed into a classification loss function. Together, texture awareness and precision targeting of edges make the network robust to noise.

Results: From 111 OCT volumes from healthy controls and patients with multiple sclerosis (doi:10.1016/j.dib.2018.12.073 and doi:10.1155/2015/259123), 23 are randomly selected for testing and the remainder for training. Reported results are based on two metrics: the mean absolute difference (MAD) for 9 boundaries (in pixels) and Dice's coefficient for 8 layers as distance/similarity between the predicted boundaries/layers and ground truth. The MAD values and Dice scores are presented in Table 1. Size-independence is demonstrated by a < 1% variation in Dice score between segmentation outputs for the original vs. 5 size-distorted images (mean Dice 93.4%). For challenging Parkinson's OCT images (N=44) from an untrained dataset (Newcastle PDD-SRC), NDD-SEG outputs were expert-rated as useable on 54% vs. 1% for a comparator U-net algorithm (Doi:978-3-319-24574-4_28), and more accurate on 100%. See Figure 1 for examples.

Conclusions: Our new method achieves size-independence and robust segmentation even in the presence of image artefacts and pathologies.

ABSTRACT BODY:

Purpose: Familial Uveal Melanomas (FUM), defined as more than one case of uveal melanoma within a family, are rare representing less than 1% of all UM patients. The genetic contribution of UM is still largely unknown. This study was performed to better characterize the clinical phenotype and genetics of FUM.

Methods: Germline genetic variants were assessed by whole exome sequencing, a 30-gene cancer panel sequencing and/or BAP1 sequencing in a cohort of 43 FUM presented or referred to the Department of Ophthalmology, The Ohio State University. Patients with detectable germline pathogenic/likely pathogenic (P/LP) variants in BAP1 were not tested for other candidate genes. A systematic review of reported FUM was performed.

Results: Table 1, summarizes the clinical phenotype and genetics of FUM included in the study. Genetic testing of our cohort detected germline BAP1 P/LP variants in 9/43 (21%). Germline P/LP in three established cancer genes (MLH1, PALB2, SMARCE1) were identified in three other families. P/LP variants in five genes possibly associated with cancer predisposition (MMS19, TP53AIP1, DLEC1, RECQL4 and POLI) were identified in five other FUM. Germline P/LP variant in MBD4 was identified in one UM patient with FUM but the variant was not detected in another UM from the family. Except for BAP1, P/LP alteration in other candidate genes were observed in only one patient each. Out of the 121 FUM families reported in the literature, germline testing for BAP1 was carried out on 81 families and P/LP variants were detected in 19%-23%.

Conclusions: BAP1 is the most important cancer predisposition gene in FUM, detected in 19-23% of families. Germline pathogenic variants in other established or possible cancer predisposition genes are detected in ~21% of FUM. Further assessment of the association of other candidate genes with predisposition to FUM and study of other candidate genes are warranted.

ABSTRACT BODY:

Purpose: Limbal stem cells (LSC) residing in the limbus continually repopulate the corneal epithelium. Limbal stem cell deficiency (LSCD) occurs when these LSC are damaged or missing. Patients with LSCD are unable to regenerate the corneal epithelium, resulting in blindness due to invasion of the conjunctiva and neovascularization. While tissue from the unaffected eye can be used to treat unilateral LSCD, patients with bilateral LSCD as well as those with inflammation and severe pathologies would greatly benefit from an alternative autologous source of stem cells as allogeneic transplants are associated with poor outcomes and require lifelong immunosuppression. We previously demonstrated that human ABCB5+ LSC were capable of restoration of the corneal epithelium in an NSG mouse model of LSCD. We found that ABCB5 is also expressed by skin stem cells and hypothesized that these dermal cells could provide an alternative source of stem cells for corneal regeneration.

Methods: We first tested the ability of human ABCB5+ dermal stem cells (DSC) expanded in vitro and purified by cell sorting to transform into corneal epithelial cells when cultured in corneal differentiation media. Next, we tested the ability of ABCB5+ DSC to regenerate clear corneas when transplanted onto NSG mice with mechanically induced LSCD. We are currently scaling up to a rabbit model of LSCD and using a 3D bioprinter to seed ABCB5+ DSC on a custom-designed contact lens created from eye impression technology.

Results: Human ABCB5+ DSC were induced in vitro to express significant levels of PAX6 and KRT12. Mice transplanted with human ABCB5+ DSC had clearer corneas compared to controls (Fig 1). Using eye impression technology, we created custom contact lenses modified to accommodate bioprinted ABCB5+ DSCs (Fig 2).

Conclusions: Our results support the use of ABCB5+ DSC as an alternative autologous source of stem cells to regenerate the corneal epithelium. Delivery of these cells using 3D bioprinting and custom contact lenses is promising for robust regeneration of the ocular surface.

ABSTRACT BODY:

Purpose: Purpose: The FAM161A-p.Arg523* mutation is the most frequent premature termination codon causing retinitis pigmentosa (RP) in the Israeli Jewish population. Our major aim is to generate and characterize a KI mouse model for this mutation and evaluate its outcome on retinal function and structure.

Methods: Methods: Homozygous knock-in (KI) mice for the p.Arg512* mutation, which corresponds to the human p.Arg523* mutation, were generated by Cyagen Biosciences. Retinal function and structure were examined at the ages of 1 through 21 months (in a 3-months interval) using visual acuity (VA), electroretinography (ERG), optical coherence tomography (OCT), fundus autofluorescence (FAF) imaging, histological and immunohistochemical (IHC) analysis.

Results: Results: Visual acuity analysis showed gradual decrease at the ages 1 to 21 months. Evaluation of retinal function by ERG revealed a progressive decrease in rod and cone amplitudes as compared with WT mice from 1 to 21 months, and a flat response at 21 months. Anatomical structure of the retina, examined by OCT, revealed total loss of outer nuclear layer (ONL) at the age of 21 months, which was first evident at 3 months. Funduscopy examination revealed narrowing of the blood vessels and patchy hyperautofluorescent spots, indicating widespread retinal degeneration. Histological analysis showed progressive loss of photoreceptor nuclei in the ONL but a few nuclei were still evident even in relatively old ages. IHC staining demonstrated reduced and diffused Fam161a expression in the KI comparted to the wildtype retina.

Conclusions: Conclusions: The outcome of the study evidently indicate that the homozygous p.Arg512* mutation has an impact on retinal function and leads to retinal degeneration in the KI mice. Unexpectedly, the rate of photoreceptor loss in the KI model is much slower than in the FAM161A knockout model we previously characterized. In a parallel in vitro study, we provided evidence for the positive significant effect of ataluren on the ability of FAM161A-p.Arg523* patient-derived fibroblasts to grow cilia. Therefore, the KI mouse model can serve as a suitable model to test this therapeutic modality in vivo as well as other modalities such as gene augmentation therapy and RNA editing.

ABSTRACT BODY:

Purpose: The membrane-associated mucins (MAMs) MUC1, MUC4, MUC16, MUC20, MUC21 and MUC22 project from the apical layer of the ocular surface mucosal epithelia and into the tear film (PMID: 33775913; PMID: 31493487). They are thought to provide a barrier against pathogens and other noxious agents, contribute to hydration, and participate in signal transduction and immune suppression. We investigated the specific role of Muc4 at the ocular surface by characterizing Muc4 knockout (KO) mice.

Methods: Muc4 KO mice were compared to their wildtype (WT) littermates. The ocular surface was imaged using the rodent micron IV with slit-lamp attachment, using white or cobalt blue light after staining with fluorescein (detects epithelial cell damage) or rose bengal (detects mucosal barrier disruption). Staining was scored from 0 to 9 using a scoring system modified from van Bijserveld's. Smoothness was scored from 0-4 considering the alteration of a ring light reflection. The ocular surface was also imaged by scanning electron microscopy (SEM). Gene expression was analyzed by qPCR.

Results: Gross examination revealed no conjunctivitis, blepharitis or other inflammatory disease in KO mice. Fluorescein staining revealed no evidence of epithelial cell damage. In contrast, rose bengal staining was distinctly higher in KO mice than in WT littermates ($n=20$; $P < 0.01$), with a punctate pattern indicative of mucosal barrier disruption. SEM revealed more surface epithelial cells with a lower density of microplicae in KO mice ($n=8$; $P < 0.05$). Pax6 expression was decreased, while K10 expression was increased ($P < 0.05$, $P < 0.01$; respectively), indicating keratinization. In contrast, no increase was detected in expression of cornified envelope genes Sprr1b and Sprr2h. Corneal smoothness was reduced in KO mice ($n=18$; $P < 0.05$), suggesting tear film disruption. No compensatory changes due to Muc4 KO were observed in expression of Muc1 or Muc16, or the secreted mucin Muc5ac ($n=11$).

Conclusions: Cell culture studies have provided evidence that deficiency of a single MAM is sufficient to disrupt the mucosal epithelial barrier at the ocular surface and reduce surface microplicae (PMID: 24968021). This is the first in vivo validation of this finding. We also provide the first evidence that loss of Muc4 results in keratinization, but not cornification of the ocular surface, and leads to tear film disruption.

ABSTRACT BODY:

Purpose: Adaptive-optics-based visual simulation is a useful tool in different areas of clinical ophthalmology. However, current commercial instruments are monocular and the most thorough binocular testing can only be performed with bulky laboratory prototypes. In this context, the aim of this work was to develop a compact binocular instrument suitable for clinical environments and able to deal with a wide variety of patients, including those with abnormal eye's optics.

Methods: The new binocular device has been adapted from a commercial monocular version (VAO, Voptica SL, Murcia, Spain). Both eyes' pupils were fit into the Hartmann-Shack (HS) wavefront sensor and liquid crystal on silicon (LCoS) phase modulator, for measurement and manipulation of ocular aberrations. Conversely, the stimulus generator was replaced by two HD screens, one for each eye, for stimulus presentation and psychophysics, including stereo-acuity tests. Additionally, a single intensity modulator was included for generating artificial pupils in both eyes, and a single tunable lens for correction of defocus. A pupil camera monitoring both eyes and a periscopic system allows controlling eye separation and tilt for precise patient's positioning. The whole system is mounted in a relatively compact housing similar to standard ophthalmic equipment. GPU-based processing of the HS images allows for simultaneous measurements in real time for both eyes.

Results: The dynamic range of the device was determined by measuring and inducing aberrations in artificial eyes and in a group of highly-aberrated volunteers, adding trial lenses in some cases to increase ammetropia. By using the tunable lens to roughly compensate for defocus, the instrument successfully copes, both for measuring and correcting, with a range of +/-15D in spherical equivalent, +/-6D in cylinder and at least 1μm in all high-order aberrations over a 4.5-mm diameter pupil. The use of the device was easy both for operators and subjects.

Conclusions: A compact Binocular Visual Adaptive Optics simulator has been developed allowing clinical visual testing under controlled optical conditions in both eyes. The instrument has a high dynamic range much increased with respect to the current commercially available monocular device, and it may be used to better understand the relationship between optics and visual performance in patients with highly aberrated eyes (e.g., keratoconus).

TITLE: The Impact of Pupil Transmission Apodization on Visual Performance at Different Light Levels

SESSION TITLE: Functional imaging and wavefront correction

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Degre Kendrick, G. Yoon, College of Optometry, University of Houston, Houston, Texas, UNITED STATES|M. Chen, J. Buch, P.F. Jubin, Johnson & Johnson Vision, Jacksonville, Florida, UNITED STATES|

Commercial Relationships Disclosure: Chloe Degre Kendrick: Commercial Relationship: Code N (No Commercial Relationship) | Minghan Chen: Commercial Relationship(s);Code E (Employment):Johnson & Johnson Vision | John Buch: Commercial Relationship(s);Code E (Employment):Johnson & Johnson Vision | Philippe Jubin: Commercial Relationship(s);Code E (Employment):Johnson & Johnson Vision | Geunyoung Yoon: Commercial Relationship(s);Code F (Financial Support):Johnson & Johnson Vision

ABSTRACT BODY:

Purpose: A previous study has shown that pupil transmission apodization can significantly improve through-focus visual performance with spherical aberration by decreasing the impact of peripheral wavefront profiles on retinal image quality. However, this improvement may be limited by the loss of retinal illuminance due to the apodization. The goal of this study is to determine the visual performance benefit of pupil transmission apodization at different luminance levels.

Methods: A liquid crystal spatial light modulator (SLM) was used to generate pupil transmission apodization profiles described by the Gaussian-type function, $e^{-\alpha (r/r_0)^2}$, where r_0 is the pupil radius and α is the apodization coefficient. This profile was relayed on the eye pupil through an optical system, while subjects performed high contrast visual acuity (VA) and contrast sensitivity (CS) tasks. A baseline condition and three Gaussian pupil apodization profiles (α=1, 3, 7) were tested at three stimulus luminance levels (2.5, 250, and 1000 cd/m^2). Each of 16 healthy subjects was dilated with phenylephrine, and a 6 mm artificial pupil was used to maintain a constant retinal illuminance throughout each apodization condition. Visual performance was assessed three times for each condition using a 2AFC QUEST paradigm. A Badal optometer was used to optimize subjects' focus prior to vision testing, but other aberrations were left uncorrected.

Results: VA and CS were improved significantly with increasing stimulus luminance for baseline and each apodization condition. For all luminance levels, VA was improved by the medium and high apodization, more than half a line compared to no apodization. Overall, apodization had a greater benefit for CS at higher spatial frequencies. At 4c/deg, visual benefit was only observed with the low apodization at high luminance. For 8 and 16c/deg, medium and high apodization improved CS by a factor of approximately 2 at medium and high luminance levels. However, the high apodization at low light level did not show any improvement at all spatial frequencies due to significant loss in retinal illuminance.

Conclusions: Gaussian-type pupil transmission apodization was found to be beneficial for VA and CS performance especially at medium and high luminance levels tested in this study. The visual benefit was spatial-frequency dependent, with CS at 4 cpd benefitting the least, and CS at 16 cpd benefitting the most.

ABSTRACT BODY:

Purpose: Lid wiper epitheliopathy (LWE) is a critical clinical marker to identify and track abnormal lid/cornea interaction. We proposed an automated grading algorithm using hue and saturation of LWE staining following manual selection of region of interest. Here we determined the repeatability of this semi-automated algorithm.

Methods: 31 images (15 upper and 16 lower eyelids) representative of LWE staining, observed after instillation of 20 microliters combination solution of 2% sodium fluorescein + 1% lissamine green, were analyzed. Images were processed using a custom MATLAB program that semi-automatically identifies the LWE area using hue and saturation values of the manually delineated lid region. LWE height (mm) was calculated as the average extent of staining perpendicular to the lid wiper curve minus the average Marx line height from images without LWE staining. Two independent examiners (E1 & E2) analyzed the images in a random order twice, with analysis sessions separated by more than a week. Bland-Altman analysis and Intraclass Correlation Coefficient (ICC) were performed to compare the results of height, width and area of the LWE staining.

Results: Intra-examiner variability (E1) between analysis runs for height [-0.003 ± 0.011mm; 95% Limits of Agreement (LoA): -0.025 to 0.019], width [0.094 ± 0.478mm; 95% LoA: -0.843 to 1.031] and area [-0.003 ± 0.012mm^2, 95% LoA: - 0.026 to 0.020] were calculated. Intra-examiner variability (E2) between analysis runs results for height [-0.001 ± 0.021mm; 95% LoA: -0.043 to 0.041], width [0.127 ± 0.670mm; 95% LoA: -1.187 to 1.440] and area [0.058 ± 0.291mm^2, 95% LoA: -0.513 to 0.628] were calculated. The inter-examiner (E1 – E2) variability, using the average value of two analysis runs for each examiner, were calculated for height [0.001 ± 0.012mm; LoA: -0.022 to 0.023; ICC 0.999], width [-0.160 ± 0.395mm; LoA: -0.935 to 0.614; ICC 0.996] and area [0.024 ± 0.148mm^2; LoA: -0.265 to 0.314; ICC 0.997].

Conclusions: Inconsistency in subjective grading methods may prevent detection of changes in LWE staining between observers. This novel hue and saturation method results in highly repeatable measures of height, width and area of LWE staining after subjective delineation of the general lid region between examiners.

TITLE: Characterization of VRDN-001, a High Affinity and Potent anti-Insulin-like Growth Factor-1 Receptor (IGF-1R) Inhibitory Antibody for the Treatment of Thyroid Eye Disease (TED)

SESSION TITLE: Thyroid eye disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: V. Bedian, Viridian Therapeutics Inc, Waltham, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Vahe Bedian: Commercial Relationship(s);Code E (Employment):Viridian Therapeutics;Code C (Consultant/Contractor):Dianthus Therapeutics

ABSTRACT BODY:

Purpose: VRDN-001 is an antagonist antibody to IGF-1R under development by Viridian Therapeutics for treatment of patients with TED, a condition driven by Thyroid Stimulating Hormone Receptor (TSHR) agonistic autoantibodies and crosstalk between TSHR and IGF-1R. TED is characterized by recruitment of fibrocytes that express IGF-1R and TSHR into orbital tissues, where they mediate deposition of hyaluronan and expansion of orbital muscle and fat. Blockade of IGF-1R has been shown to improve TED symptoms in randomized clinical trials. To assess its potential for treating TED, we evaluated the binding characteristics of VRDN-001 to IGF-1R and its potency for inhibition of IGF-1R phosphorylation.

Methods: Binding characteristics of VRDN-001 were investigated using surface plasmon resonance where antibodies were immobilized and recombinant IGF-1R extracellular domain (ECD) was used as analyte. Kinetic parameters and equilibrium dissociation constant were derived by global fitting of data. Binding to cell-surface expressed IGF-1R was assessed by flow cytometry. For cell-based potency testing, IGF-1R expressing primary human ocular choroid fibroblasts (HOCF) and A549 lung carcinoma cells were stimulated with IGF-1, and IGF-1R antibodies were evaluated for inhibition of receptor autophosphorylation using a commercial ELISA kit.

Results: VRDN-001 bound IGF-1R ECD with high affinity (equilibrium dissociation constant K_D = 0.57 nM) and exhibited slow dissociation of IGF-1R (off rate $k_d = 5X10^{-5}\ s^{-1}$). These results were consistent with dose-response of binding to cell surface IGF-1R. In IGF-1 stimulated HOCFs and A549 cells, VRDN-001 inhibited IGF-1R phosphorylation in a dose-dependent manner. VRDN-001 IC50 values were ~0.1 nM and greater than 95% inhibition of phosphorylation was observed with VRDN-001 concentrations in the 1-10 nM range (0.15-1.5 µg/mL).

Conclusions: VRDN-001 bound IGF-1R with high affinity and inhibited IGF-1R signaling with high potency. VRDN-001 shut down IGF-1R signaling at concentrations that can be achieved with moderate clinical doses. The in vitro profile of VRDN-001 suggests favorable efficacy and exposure requirements for treatment of TED patients. A phase 1/2 trial for VRDN-001 in healthy volunteers and TED patients is underway (NCT050176639).

ABSTRACT BODY:

Purpose: Zebrafish are widely utilized to investigate retinal regeneration as they can regenerate photoreceptors (PRs) following acute phototoxic damage. This is mediated by Müller glia (MG), which re-enter the cell cycle to produce retinal progenitors. While this acute model has revealed important MG-dependent regenerative pathways, it may not fully reflect the events underlying human retinopathies, which often follow a chronic pathological timeline. To test this hypothesis, we developed a zebrafish model of chronic low light (CLL) exposure and compared morphological and transcriptomic changes in the CLL damaged retina to our acute light damage model.

Methods: Adult albino zebrafish were exposed to 28 days of CLL and eye tissue was collected at 8 time points. Whole right eyes were collected for immunohistochemistry and whole retinas from the left eyes were used for 3'mRNA-seq.

Results: CLL exposure resulted in the truncation of PR outer segments, and reduced numbers of rod PR nuclei by 28 days post light (dpl) (Fig. 1). Unlike the acute model, MG cell-cycle re-entry was not observed in CLL, suggesting that this damage paradigm is not sufficient to trigger MG-mediated regeneration. Additionally, we did not detect any overt signs of MG gliosis, as is seen early in the acute model. However, we did observe a peak of inflammatory markers (i.e. mpeg1.1, apoeb) by 10dpl, much later than seen in the acute model. This corresponded with a gradual accumulation of microglia at the tips of rod outer segments. Transcriptomic comparisons corresponding to PR differentiation in the acute model vs PR degeneration in the CLL model revealed a set of inversely correlated genes likely representing PR development and maintenance. We detected genes known to be involved in human retinal disease (pdca/b, gnat1/2, grk1a/b, rom1b), and genes not yet characterized in zebrafish regenerative retinal biology (kera, pdca/b).

Conclusions: By comparing the molecular and cellular changes associated with acute vs chronic models of PR degeneration, we identified several candidate genes involved in slow PR degeneration and gliosis. These studies serve as a nexus for future experiments aimed at understanding common retinal degenerative diseases.

ABSTRACT BODY:
Purpose: Impaired contrast sensitivity (ICS) may delay drivers' responses to road hazards. Advanced Driver Assistance Systems that provide hazard warnings can mitigate crash risk; however, the benefits may vary with warning design. We tested 3 collision warning systems with different modalities and timing thresholds and evaluated their impact on the responses of drivers with ICS to pedestrian hazards in a simulator.
Methods: To date, 13 subjects with normal vision (NV) (65–86 y, median CS 1.95) and 9 subjects with ICS (63–84 y, median CS 1.35 log units) participated. They completed 6 city drives with 3 warning conditions: auditory (pulse beeps), directional tactile (pulse vibrations on either left or right side), and non-directional tactile (pulse vibrations on both sides). For each condition, they completed one drive with early and one drive with late warnings, triggered when time-to-collision was 3.5s and 2s, respectively. There were 10 pedestrian hazards per drive that crossed the road from the left or right, requiring a braking response by the driver to avoid a collision.
Results: ICS subjects triggered more early warnings (61 vs 54%) and late warnings (20 vs 7%) than NV subjects and had more collisions (3.8 vs 0%). When warnings were triggered (data pooled across groups), early warnings reduced time to fixate hazards (late 1.8 vs early 1.2s, $p=0.02$), reduced brake response times (2.7 vs 1.7s, $p<0.001$) and reduced collision rates (1.5 vs 0.5%). Brake times did not differ between the groups for early warnings; however, ICS subjects took 0.5 s longer to brake than NV subjects with late warnings ($p=0.02$) and still had a 15.4% collision rate. No collisions occurred for ICS subjects with early warnings. For late warnings, non-directional tactile warnings resulted in the lowest collision rates for ICS subjects (6% vs Auditory 20% vs Directional tactile 19%). For early warnings, modality had no effects on fixation and brake times of ICS subjects. Most subjects preferred early warnings (91%) and the directional tactile modality (73%).
Conclusions: With early warnings, both groups were faster to fixate and brake for hazards and had low collision rates. In events with late warnings, ICS subjects were slow to brake resulting in high collision rates. These results suggest that ICS drivers will benefit more from earlier warnings. Warning modality may be important for late warnings.

ABSTRACT BODY:

Purpose: Evaluate the efficacy and safety of tacrolimus for the treatment of pediatric noninfectious uveitis

Methods: Single health system, retrospective review of electronic medical records. A chart review of patients < 18 years old diagnosed with noninfectious uveitis who were intolerant to or failed conventional systemic immunosuppressants seen by Children’s Hospital Colorado Ophthalmology and Rheumatology or University of Colorado Hospital Ophthalmology between January 2014 – January 2021 was completed. The primary outcome was the incidence of improvement in inflammation. Secondary outcomes included incidence of tacrolimus treatment failure and need for dose reduction or discontinuation due to adverse effects. Descriptive statistics were used to analyze the data. This study received IRB approval.

Results: Ten patients (40% female; mean age: 12.9 years) were included. The most common previously failed treatments were methotrexate (n = 10) and biologics (n = 4). Uveitis was secondary to systemic autoimmune diseases in 40% of patients. Tacrolimus was initiated a mean of 3.9 years after onset of uveitis with 9 patients requiring concomitant immunosuppressants. Of the 6 patients with an established goal tacrolimus trough range, 83% reached therapeutic goal at an average of 320.6 ± 205.6 days. Treatment failure requiring alternative therapies occurred in 20% of patients. Laboratory abnormalities were observed in 7 patients; however, dose reduction was only required in 3 patients with no discontinuation of therapy.

Conclusions: In this small cohort of patients who previously failed traditional systemic immunosuppressants, it was effective in reducing inflammation in 80% of patients. Tacrolimus was generally well-tolerated and did not require discontinuation of medication.

ABSTRACT BODY:

Purpose: To denoise visual fields (VFs) in glaucoma by developing a deep autoencoder model.

Methods: We selected reliable SITA Standard 24-2 VFs from a multi-center dataset excluding Massachusetts Eye and Ear (MEE) data. A 2D convolutional autoencoder was developed to denoise VFs using the multi-center dataset for training. The noise is defined as the difference between the original VFs and the reconstructed (denoised) VFs from our deep autoencoder model. Our autoencoder model was tested on the MEE dataset. To demonstrate the effectiveness of our denoising model, we compared the structure-function relationships between linear regression models using 12 clock-hour retinal nerve fiber layer thickness (RNFLT) from reliable optical coherence tomography (OCT, signal strength at least 6) to predict the 52 TDs of the paired (within 3 months) original VFs and the denoised VFs. Model selection based on Bayesian information criteria (BIC) was applied to remove redundant features from the structure-function linear models. Adjusted r-squared and BIC penalized for linear model complexity were used to measure the structure-function relationship strength.

Results: A total of 419,755 of VFs from 204,619 eyes of 116,288 patients (age: 64.17 ± 15.42 years; mean deviation: -4.93 ± 6.10 dB) in the multi-center dataset excluding MEE data were used to train our deep autoencoder. There were 9,456 OCT-VF pairs from 4,609 eyes of 2,962 patients from MEE (age: 61.76 ± 15.53 years; mean deviation: -5.04 ± 7.01 dB) available to test our denoising autoencoder. Two examples of the original VF and denoised VFs are shown in Figure. 1 (a-d), where we observe extreme values (noise) to be mitigated after being denoised by our autoencoder model. The absolute average VF differences between original and denoised VF were greater in the central sector (Figure. 1 [e]). Smaller absolute denoising amount was correlated with worse TD values and the correlations were greater in inferior paracentral region (Figure. 1 [f]). The denoised VFs (Figure. 2) can be better predicted by the 12 clock-hour RNFLTs than the original VF with R-squared and BIC improvements up to 0.02 and 48 (BIC improvement ≥ 6: strong improvement) in both 3,672 left and 5,784 right eyes, and the improvement is relatively more conspicuous in superior hemifield.

Conclusions: Denoising VFs with our deep autoencoder model can improve structure-function correlation in glaucoma.

ABSTRACT BODY:

Purpose: To evaluate whether The National Eye Institute Visual Functioning Questionnaire-25 (NEI VFQ-25) can serve as a generic measure for quality-of-life (QoL) assessment in patients with glaucoma across race and gender.

Methods: This was a cross-sectional study of data sourced from the Duke Glaucoma Registry. Patient level diagnosis of glaucoma was classified by the presence and topographic correspondence of functional and structural damage assessed by spectral-domain optical coherence tomography (SDOCT) and standard automated perimetry (SAP) parameters in the worse eye. The NEI VFQ-25 graded scale was collapsed for all items to have three categories going from extreme and moderate difficulty, slight difficulty, to no difficulty. Only items of visual functioning components were studied. Gender evaluated females and males while race studied African Americans and Caucasians as focal and reference subgroups, respectively. The multiple group analysis and differential item functioning (DIF) of the R package, mirt, were used for item-wise analysis. A five-item anchor selection strategy was employed prior to final DIF detection. Expected score standardized differences (ESSD) were calculated and the effect for each item was classified as small (|ESSD| <0.200), moderate (|ESSD| 0.200 to 0.800), or large (|ESSD| ≥0.800).

Results: 258 glaucoma patients were evaluated in the study of which 82 were self-identified as Black or African American and 176 as White or Caucasian. Gender included 138 females and 120 male subjects. Racial DIF was observed for items pertaining to difficulty reading ordinary newspaper print (p=0.008), going downstairs or curbs in low light (p<0.001), seeing how people react to things the patient says (p=0.026), and picking out and matching ones' own clothes (p=0.044). The respective item-level ESSD values were 0.214, -0.672, 0.290, and -0.190. Gender DIF was observed for items pertaining to difficulty in seeing how people react to things patient says (p = 0.033) and driving in difficult conditions (p=0.011) with low to moderate effect (ESSD of 0.196 and -0.484, respectively).

Conclusions: In assessing QoL in glaucoma patients using the NEI VFQ, racial and gender subgroups demonstrated to have different probabilities of endorsing responses for certain activities of daily living with small to moderate effect sizes for clinical utility.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is the leading cause of blindness in western populations. It is associated with an overactive complement system, and an increase in circulating antibodies against certain epitopes, including elastin has been reported. Aging and AMD is associated with a loss of the elastin layer of Bruch's membrane (BrM; PMID: 15632016), which can be mimicked in the smoke-induced ocular pathology (SIOP) model in mouse. Of relevance, we previously showed that immunization with elastin peptide oxidatively modified by cigarette smoke (ox-elastin), exacerbated structural and functional damage in SIOP (PMID: 32207814). Here we asked whether ox-elastin peptide-based immunotherapy (PIT) ameliorates damage.

Methods: Mice were exposed to cigarette smoke for 6 months. C57BL/6J mice were injected with ox-elastin peptide at two doses via weekly subcutaneous administration, $FcgR^{-/-}$ and uninjected C57BL/6J mice served as controls. Retinal function was assessed by OKR, morphology by electron microscopy, and complement activation, antibody deposition and mechanisms of immunological tolerance were assessed by Western blotting and ELISA.

Results: Elimination of Fcg receptors, preventing antigen/antibody-dependent cytotoxicity, protected against SIOP. Mice receiving PIT with low dose ox-elastin (LD-PIT) exhibited reduced humoral immunity, reduced complement activation and IgG/IgM deposition in the RPE/choroid, and largely a preserved BrM and improved visual function. LD-PIT reduced IFNg and increased IL-4 within RPE/choroid. In contrast, the high dose PIT was not protective.

Conclusions: Our data further support ox-elastin role in ocular damage in SIOP in part via elastin-specific antibodies, and support the corollary that PIT with ox-elastin attenuates ocular pathology. Overall, damage is associated with complement activation, antibody-dependent cell-mediated cytotoxicity, and altered cytokine signature. Finally, peptide-based immunotherapy might be a suitable strategy for the prevention of AMD.

ABSTRACT BODY:

Purpose: Corneal fibrosis can lead to opacity and may ultimately cause partial or complete vision loss. Currently, the only treatment for severe corneal fibrosis is corneal transplantation. Sphingolipids (SPLs) are known to be associated with fibrosis in various tissues and organs, including the cornea. We previously reported that SPLs are tightly related to both, TGF-β signaling and corneal fibrogenesis. The aim of this study was to elucidate the role of SPLs and TGF-β family members, their crosstalk, and downstream signaling in corneal fibrosis using our previously established 3D in vitro model.

Methods: Healthy human corneal fibroblasts (HCFs) were isolated, plated on polycarbonate membranes, and cultured in EMEM+FBS+VitC (control medium) for 4 weeks. Eight treatment combinations were tested using the following groups in control medium: –0.1ng/mL TGF-β1 (β1), 0.1ng/mL TGF-β3 (β3), 1μM sphingosine-1-phosphate (S1P), and 5μM SPHK I_2 (I_2); the combinations (combo) are abbreviated as: (a) β1/S1P, (b) S1P/β1, (c) β1/I_2, (d) I_2 /β1, (e) β3/S1P, (f) S1P/β3, (g) β3/I_2, and (h) I_2/β3. Each combo was administered for 2 weeks with one group then switched to another group for 2 weeks. Cultures without treatment(s) served as controls (Control/VitC-Only). Using Western Blot analysis, the 3D constructs were examined for the expression of fibrotic markers, SPL and TGF-β signaling pathway members.

Results: Our data revealed that stimulation with β1/I_2 caused significant downregulation in the expression of SMA, Collagen 3, LTBPs 1-4, TGF-βRI, TGF-βRII, SMAD4, pSMAD2, pSMAD3, S1PR3, SphK1 and SphK2. The opposite combo treatment, I_2/β1, lead to significant downregulation of SMA, LTBPs 1-3, TGF-βRII, SMAD4, pSMAD2, S1PR3, and SphK2; and significant upregulation of TGF-βRI. Interestingly, both TGF-β1/S1P and S1P/TGF-β1 combo treatments lead to significant upregulation of Collagen 3 and activation of LTBPs, TGF-βRs, and SMADs. Additionally, LTBPs 1-4, SphK1 and 2, and S1PR3 were all activated by the TGF-β/S1P combos and inhibited by the TGF-β/I_2 combos. When comparing both TGF-β/I_2 treatment groups, we observed that β1/I_2 was more effective in reducing fibrosis compared to I_2 /β1.

Conclusions: Conclusively, using our 3D human corneal in vitro model, we have demonstrated that SPHK I_2 treatment with TGF-β1 induced fibrosis, results in reversal of fibrosis regulated by the inhibition of LTBPs, SphKs, and the downstream SMAD pathway.

TITLE: Characterization of cone membrane physiology during secondary cone degeneration in the rd10 model of retinitis pigmentosa

SESSION TITLE: Photoreceptors and the OPL

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: E. Ellis, G. Fain, A. Sampath, Ophthalmology, Jules Stein Eye Institute, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Erika Ellis: Commercial Relationship: Code N (No Commercial Relationship) | Gordon Fain: Commercial Relationship: Code N (No Commercial Relationship) | AP Sampath: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In retinitis pigmentosa, secondary degeneration of cones is one of the most debilitating features of the disease. Currently there is little known about how cone membrane physiology changes during secondary cone degeneration. In this study, we sought to characterize cone membrane physiology throughout secondary cone degeneration.

Methods: Using the rd10 mouse model of retinitis pigmentosa, we performed whole-cell patch-clamp recordings from cones in retinal slices. We measured passive membrane properties, recorded light-evoked responses, and measured isolated conductances using voltage-clamp protocols in combination with specific channel-blocking agents. During patch-clamp recordings, cells were filled with a fluorescent dye and cell morphology was imaged after recordings were completed. Experiments were performed in rd10 animals between 3- and 9-weeks old.

Results: Cones in the rd10 mouse showed significantly altered morphology even at the earliest time point, with no outer segment seen on any cells. In line with this, cone membrane capacitance was significantly lower than normal even at the earliest time point and showed no significant change over 9 weeks, with an average membrane capacitance of 2.2pF (n=44). Even at late time points, small light-evoked responses could be elicited from most cones with a bright flash from a 405nm LED. The cone resting membrane potential showed no significant change during degeneration, with an average resting membrane potential of -50mV (n=34), similar to WT cones. Cones maintained a robust HCN1 conductance at all time points. Preliminary recordings of synaptic calcium currents suggest a decrease in the calcium current with age.

Conclusions: Our results show that degenerating cones maintain a depolarized resting membrane potential, even after the loss of the outer segment. The presence of light-evoked responses, although small and desensitized, suggests that cones can maintain ectopic expression of cyclic-nucleotide-gated channels, which with other conductances still present in the membrane may be responsible for maintaining the cell in a depolarized state. There seems to be little change in the HCN1 conductance, but voltage-gated calcium currents appear to be diminished as degeneration progresses.

ABSTRACT BODY:

Purpose: This study is to design and validate a fully convolutional network (FCN) architecture to compensate for system dispersion in optical coherence tomography (OCT).

Methods: Our proposed FCN method is based on a modified UNet architecture (Fig. 1A) that uses an encoder-decoder pipeline. The input of the deep leaning pipeline can be single or multiple-channel OCT B-scans. Each B-scan was compensated by different second-order dispersion compensation coefficients to optimize different layers sequentially. The output obtained from the network was a fully compensated OCT B-scan where the dispersion was compensated at all depths. A lab-built SD-OCT system with 840 nm central wavelength was used for the experimental imaging. The axial and lateral pixel resolutions were 1.5 μm and 5 μm, respectively. Nine (7 train and 2 test) different OCT volumes with a field of view 3.5 mm x 3.5 mm were acquired from healthy human subjects. The proposed method was trained and tested using 1, 3, 5, 7, and 9 input channel models. Quantitative analysis was performed using peak signal to noise ratio (PSNR) and structural similarity index metric calculated at multiple scales (MS-SSIM).

Results: High quality all depth compensated OCT B-scans were obtained when the proposed model was implemented using 5, 7, and 9 input channels. Output from the 1 and 3 input channel models also demonstrated better resolution retaining more structural information than a raw uncompensated image. High similarity between the output images and the ground truth was observed and the MS-SSIM score for 5, 7, and 9 input channel models were 0.97 ± 0.016, 0.97 ± 0.014, and 0.97 ± 0.014, respectively. High signal strength compared to the background noise was also observed for these models with PSNR values of 29.95 ± 2.52, 29.91 ± 2.13, and 29.64 ± 2.26 dB for 5,7 and 9 input channel models respectively. Fig. 1B illustrates the ground truth (B1), uncompensated (B2), and output B-scan from 5 input channel model (B3).

Conclusions: The proposed FCN can compensate for the dispersion at all depths and thus provides a feasible solution for fully automated dispersion compensation in OCT.

ABSTRACT BODY:

Purpose: Central areolar choroidal dystrophy (CACD) is an inherited retinal disease primarily affecting the macula. The disease is strongly linked to mutations in PRPH2. However, the molecular mechanism underlying PRPH2-associated CACD remains largely unknown. This study aims to unravel the pathological mechanism by which a recurrent PRPH2 missense mutation causes CACD.

Methods: HEK293T cells were transiently transfected with plasmids encoding wildtype or Arg142Trp mutant PRPH2. Western blot analysis was used to determine protein levels. Co-transfections of wildtype and mutant Arg142Trp plasmids, followed by co-immunoprecipitation were performed to study PRPH2 homodimer formation. To study subcellular localization, COS-1 cells were transiently transfected with PRPH2-wildtype or PRPH2-Arg142Trp plasmids. In addition, plasmids were stably transfected into IMCD3 cells. Immunocytochemistry (ICC) was used to determine the localization of PRPH2.

Results: No differences in PRPH2 protein levels between PRPH2-wildtype and PRPH2-Arg142Trp conditions were observed. The PRPH2-Arg142Trp protein can still form homodimers with both wildtype and Arg42Trp proteins. In both COS-1 and IMCD3 cells, the wildtype PRPH2 protein spreads into the cytoplasm and partly localizes to the plasma membrane, while the PRPH2-Arg142Trp mutant protein tends to cluster around the nucleus, partially co-localizing with golgi/ER. Moreover, the mutant protein was found only at the base of the cilium, while wildtype protein was observed along the entire cilium.

Conclusions: Our results show no differences in expression levels between PRPH2-wildtype and PRPH2-Arg142Trp proteins. Furthermore, PRPH2 homodimer formation still occurs under PRPH2-Arg142Trp conditions, ruling out aberrant expression levels and erroneous PRPH2 homodimer formation as mechanism underlying CACD. ICC results indicated a difference in subcellular localization between wildtype and mutant PRPH2, with a potential defect in ciliary localization. Further studies are needed to elucidate the mechanism underlying PRPH2-associated CACD.

ABSTRACT BODY:

Purpose: To examine "AREDS- and AREDS2-based" supplements available for purchase online, with attention to their cost and adherence to the formulation tested in the AREDS2 protocol.

Methods: “AREDS” and “AREDS2” were used as search terms in Amazon and Google Shopping. The top 30 search results, excluding items marked as promoted ads, were recorded for each search, and each product was checked for compliance with the AREDS2 formula, allowing for both low (25mg) and high (80mg) zinc formulations. The price per daily serving was calculated for each product and prices of “compliant” vs. “non-compliant” formulas were compared using Student’s t-tests.

Results: 120 search results were analyzed across Amazon and Google Shopping. 30.8% (37/120) of the products did not adhere to the AREDS2 formula. 14.2% (17/120) were missing at least one of the ingredients in the AREDS2 formula. 5.8% (7/120) followed the AREDS1 formula. 17.5% (21/120) contained a higher dose of at least one ingredient and 13.3% (16/120) contained less of at least one ingredient than in the AREDS2 formula. 15.8% (19/120) contained at least one extra ingredient beyond those in the AREDS2 formula. The products that deviated in any way from the AREDS2 formulation were 26.0 percent more expensive than those that did not ($0.63 vs. $0.50 per day, $p = 0.0027$). Similarly, products that were missing at least one of the ingredients in the AREDS2 formula were 26.9 percent more expensive than those that were not ($0.66 vs. $0.52, $p = 0.012$).

Conclusions: Our analysis demonstrates that many of the AREDS2 supplements found using popular online shopping marketplaces deviate from the formulations recommended by the AREDS2 clinical trials. Several of the formulations had decreased or missing dosages of vitamin C and vitamin E. Further, some included extra ingredients that have not been shown to be beneficial in AMD but were advertised as such, including bilberry extract, fish oil, and alpha-lipoic acid. Moreover, several of the supplements followed the AREDS1 formula, which is no longer recommended as it imposes increased risk of lung cancer for smokers. Importantly, we also found that products that did not follow the AREDS2 formula were more expensive on average to the consumer. Clinicians may wish to be specific in their recommendation of AREDS2 formulations to avoid inaccurate dosing.

ABSTRACT BODY:

Purpose: 85% of US adults have a smartphone with 87 million people using a health or wellness app monthly in 2020.[1] There are 350,000 eHealth apps.[2] Roughly 33M adults in the US have the chief complaint of vision loss. An estimated 93M are at high risk for serious visual impairment[3]. Only half have visited an eye doctor in the past 12 months, due to COVID 19.[3] American adults over the age of 18 fall into the demographic of mobile app users.

Do free apps help our eye patients during this pandemic?

Methods: We used the search terms “vision test” and “eye exam” in the Apple App Store to compile a list of the top 10 free apps. We looked for how many free apps have eye charts that are “recognized” such as Snellen chart, Landolt C, LogMAR chart, Amsler grid & Visual Field. Control: Inclusion criteria: 1) free; 2) English language; 3) ≥50 reviews, ≥4 star rating in the Apple App store. Exclusion criteria: 1) foreign languages 2) paid apps.

Results: Results: Top 10 iOS apps (from most downloads to least) in the Apple App Store seen in Table 1. For all iOS apps, Snellen vision test: 9/10; Landolt C: 1/10; LogMAR chart: 3/10; Amsler grid: 3/10; Visual field 1/10. Only 1 app connected you with a local optometrist or ophthalmologist. Only 3/10 apps had >1K reviews. iOS apps do not provide a number of downloads.

Conclusions: Although many adults have not received an eye exam over the past 12 months, physicians can still connect with their patients through public education with the use of mobile apps. However, current eHealth apps can improve their content for eye patients.

ABSTRACT BODY:

Purpose: To compare peripaillary nerve fiber layer (pRNFL) thickness in pediatric large optic discs with pRNFL in adult large optic discs and pediatric normal sized optic discs.

Methods: 107 large optic discs from 70 children aged 5.7 to 17.7 years (LOD-C group), 107 normal optic discs from 60 children (NOD-C group) and 107 large optic discs from 69 adults (LOD-A group) were included. pRNFL was investigated via Spectralis OCT (Heidelberg Engineering, Heidelberg, Germany). Large optic disc was diagnosed if BMO area measured ≥2.5 mm^2. Large optic discs were matched by BMO area, pediatric optic discs by age. pRNFL thickness profiles (circular scan diameter: 4.1 mm) were compared using t-tests and influence of optic disc size on pRNFL was determined with generalized estimating equation (GEE).

Results: Median age was 12.0, 12.1 and 47.3 years and median BMO area was 2.82, 2.02 and 2.80 mm^2 for LOD-C, NOD-C and LOD-A groups, respectively. Pediatric large optic discs showed a larger mean pRNFL thickness than pediatric normal optic discs (85.4µm vs. 82.4±10.1µm, p=0.031) and maxima of pRNFL thickness profile seemed wider and located more nasally. Adult and pediatric large optic discs did not differ significantly in mean pRNFL thickness (84.8±14.0µm vs. 85.4±10.2µm). In GEE regression analysis, pRNFL thickness was positively correlated with age- and sex-adjusted BMO area (β=4.55, p<0.001) in children.

Conclusions: In children, large optic discs were characterized by a larger mean pRNFL thickness with wider and slightly more nasally located pRNFL thickness maxima compared to normal sized optic discs, measured by OCT. pRNFL profiles of adult and pediatric large optic discs showed a similar shape. pRNFL thickness was linked with BMO area in children.

ABSTRACT BODY:

Purpose: Intravitreal therapy (IVT) with anti-vascular endothelial growth factor (anti-VEGF) is first line treatment for diabetic macular edema (DME). This study describes anti-VEGF IVT frequency and long-term visual outcomes among DME patients in routine clinical practice in the United States.

Methods: A retrospective analysis was performed among treatment-naïve DME patients (no prior IVT in the past 12 months) initiating anti-VEGF IVT from 1/1/2015-12/31/2019 using de-identified electronic medical records (IRIS® Registry). The change in visual acuity (VA) from baseline and anti-VEGF IVT frequency (average number of injections and intervals) were reported for up to 6 years of follow-up. VA outcomes were further stratified by baseline VA and number of injections (0, 1-2, 3-4, 5-7, 8-10, ≥11) for the given year.

Results: At 1 year, 124,684 eyes received a mean (SD) of 3.9 (2.8) anti-VEGF injections with a mean injection interval of 10.0 (7.9) weeks and gained a mean of +3.2 (16.4) letters. Among patients with six years of follow up, at year 6, 1,235 eyes received a mean of 2.9 (2.1) injections with a mean interval of 12.3 (8.2) weeks and gained a mean of +0.5 (19.7) letters from baseline. Median follow-up time was 2.1 years. When stratified by baseline VA, overall change in VA was negative for eyes starting with VA ≥20/25 and <20/25 to 20/40, and positive for eyes starting with VA <20/40 to 20/80, <20/80 to >20/200, and ≤20/200 at the end of follow-up (Figure 1). When stratified by the average number of received injections in each year, change in VA from baseline was +2.8 in those who received 1-2 injections compared to +4.8 in those who received ≥11 injections in the first year. This trend was consistent in subsequent years (Figure 2).

Conclusions: The number of injections decreased and injection intervals increased year over year up to 6 years regardless of baseline VA. Improvements in VA from baseline were greatest in eyes that received 5 or more injections each year. Results are unadjusted.

ABSTRACT BODY:

Purpose: Mutations in LCA5, which encodes lebercilin, account for one of the most severe forms of early-onset blindness, Leber congenital amaurosis (LCA5-LCA). Currently, there are no treatments for this disease. In our previous studies, early delivery of a AAV8-hLCA5 by subretinal injection in knockout mice partially reversed the severe retinal degeneration. In this study we explore the treatment potential of a group of patients with LCA5-LCA and assessed the safety of subretinal delivery of AAV8-hLCA5 in non-human primates (NHPs) in a dose-ranging study.

Methods: Six patients (ages 6-31 years) with LCA5-LCA underwent ophthalmic exams, full-field stimulus testing, and multimodal imaging with fundus autofluorescence and spectral-domain optical coherence tomography over 3- 5 years. In anticipation of Good Laboratory Practices (GLP) studies, we assessed the safety of subretinal injections of two doses (3E10vg and 1E11vg) of AAV8-hLCA5in NHPs. A control animal was injected with excipient. Retinal imaging matching the protocols used in patients was performed prior to euthanasia (d43 post-injection); retina tissue was evaluated for histopathology and LCA5 immunofluorescence.

Results: Visual acuity in the patients ranged from light perception to 20/200 and there was at least ~4 log units of dark-adapted sensitivity loss. Vision declined slightly during the observation period in some patients. Despite the severe retinal dysfunction, patients showed detectable photoreceptors in the pericentral and midperipheral retina. Subretinal delivery of AAV8-hLCA5 at 3E10 or 1E11vg/eye in NHPs was well-tolerated. There were mild injection-related changes in retinal architecture. There were minimal inflammatory cells in the vitreous and mild thinning of the outer nuclear layer in the eye injected with the higher dose (1E11 vg). AAV8-hLCA5 transduces photoreceptors and RPE cells in the exposed area in the NHP retina.

Conclusions: Detectable but severely dysfunctional photoreceptors in the central and midperipheral retina of patients with LCA5-LCA suggest these regions may be targets for gene augmentation. Subretinal delivery of AAV8-hLCA5 was safe at 1E10vg and there was mild inflammation at 1E11vg. The results of this study provide guidance for the doses to be used in a GLP NHP study and ultimately a human clinical trial.

ABSTRACT BODY:

Purpose: Current AAO Preferred Practice Patterns recommend that all patients with diabetes (DM) undergo an annual screening for diabetic retinopathy (DR). However previous screenings at Temple University have revealed only a 15% prevalence of DR. Performing a comprehensive eye exam on a normal patient serves no purpose except to increase healthcare costs, reduce appointment availability, and waste time for both patients and physicians. Since 85% of exams showed no sign of DR, performing comprehensive eye exams on everyone appears to be a waste of resources. We present a DR screening tool based on biometric parameters available to a primary care physician to identify patients at a low risk of DR who can safely have less frequent screening exams. Use of this tool could eliminate unnecessary exams and reduce healthcare costs.

Methods: 1,927 patients with DM underwent DR screening from 2016-2020. A retrospective chart review recorded 29 biometric variables based on clinical suspicion of predicting DR. 896 patients with unreadable fundus photos or missing variables were eliminated. Univariate and multivariate analysis identified predictive variables in the remaining 1,031 patients. Logistic regression with maximum likelihood estimates was used to create a series of models that resulted in a score representing the likelihood an individual patient has DR on exam. Models were plotted on receiver operating characteristic (ROC) curves to determine model accuracy and to identify a threshold value that optimizes the accuracy of a diabetic screening exam.

Results: Of the 1,031 patients, 217 (21%) were found to have DR in at least one eye. Eight models were created using the biometric variables. The leading model was formulated using the variables seen in Table 1. The area under the curve (AUC) was 0.74 (Figure 1). Closest to (0,1) Criteria determined the optimal cutoff value of 0.375 with sensitivity and specificity of 48.8% and 82.1% respectively and an accuracy of 0.76.

Conclusions: Our best model demonstrated moderate sensitivity and high specificity to identify DR using a cutoff value of 0.375. The next step will be to use this model, created with readily available biometric data, to predict DR in a new cohort of patients. If successful, we hope this model can be used by primary care physicians to better identify patients more likely to have DR and reduce the number of unnecessary eye exams.

ABSTRACT BODY:

Purpose: Proteoglycan 4 (PRG4, or lubricin) is a mucin-like glycoprotein present on the ocular surface and in tears. We recently demonstrated ocular surface expression of PRG4 is diminished in a murine dry eye model, and recombinant human PRG4 (rhPRG4) inhibits dry eye inflammation induced chemokine production in human cornea epithelial cells. The ubiquitin like modifier HLA-F Adjacent transcript number 10 (FAT10) is thought to have immune function, and is an important mediator of inflammation with NFκB being a key nodal hub, though its biological role in dry eye remains unexplored. Here, we examined the ability of rhPRG4, to modulate transcriptional and protein expression of the FAT10, as well as NF-κB activation in human corneal epithelial cells.

Methods: Differentiated telomerase-immortalized human corneal epithelial (hTCEpi) cells were cultured in media alone (control) or +TNFα (100ng/ml), ±300μg/ml rhPRG4 (Lubris BioPharma). RNA was collected for RNASeq after 48hr, and cell lysates were collected at 15-60 min for quantitative western blot analysis (N=3).

Results: RNASeq analysis revealed FAT10 was one of the most upregulated genes by TNFα (~8X), and rhPRG4 significantly inhibited this stimulation ($p<0.05$). An increase (~3X) in the proteasomal subunit LMP-2, which is necessary for IκBa degradation and NF-κB activation, stimulated by TNFα was also significantly inhibited by rhPRG4 ($p<0.05$). Quantitative western blotting of hTCEpi cell lysate confirmed both of these findings at the protein level. Finally, immunoblot analysis also indicated reduction of phospho-p65 levels by rhPRG4 followed by TNFa stimulation compared to TNFa alone.

Conclusions: We and others have established rhPRG4's lubricating and anti-inflammatory properties at the ocular surface. rhPRG4 has also been shown to be clinically effective in treating signs and symptoms of dry eye. Here, we demonstrate a novel biological mechanism in which rhPRG4 limits TNFα stimulated NFκB signaling and the production of downstream inflammatory molecules FAT10 and LMP2 in corneal epithelial cells, suggesting a new therapeutic potential for alleviating dry eye inflammation. These findings provide the foundation for further evaluation of rhPRG4's biological mechanism of action on the ocular surface in maintaining homeostasis and effectively treating dry eye disease.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is projected to affect an average of 1.23 million individuals by the 2050. Whilst anti-VEGF treatment for neovascular AMD (nvAMD) is considered the current gold-standard care, this requires regular monitoring and treatment delivery which causes increased capacity challenges. This, along with the current COVID-19 pandemic, have highlighted the need for efficient and safe ways to diagnose and manage nvAMD. The use of artificial intelligence (AI) in medical care has the potential to alleviate some of this projected pressure facing eye clinics. Previous research has shown that AI has comparable sensitivity and specificity to clinicians in identifying ocular disorders from retinal images. The purpose of the current study was to develop and AI model to identify active from inactive nvAMD disease from retinal SD-OCT images.

Methods: Using Google's Vision AutoML software, 1058 Heidelberg SD-OCT images were identified and labelled as either showing nvAMD activity or inactivity. All images were uploaded to Google's cloud storage and automatically assigned two bounding-box labels; 1 label capturing the entire Heidelberg SD-OCT image, including the raster and b-scan, with the second capturing the b-scan only. All labels were automatically allocated to either a train, validate or test group based on an 80:10:10 ratio set by the software.

Results: Of the 1058 images, a total of 2116 labels were assigned, 1012 showing active and 1104 showing inactive nvAMD. Performance of the AI model revealed an area under the precision recall curve (AUPRC) of 0.84 at a threshold of 0.5, specificity of 40.98% and sensitivity of 95.24%. For the active-only images, the specificity was 34.28% with a sensitivity of 97%. For the inactive-only images, the specificity was 51% with a sensitivity of 92.73%.

Conclusions: Utilising Google's AutoML AI software, this model is able to correctly identify active nvAMD from Heidelberg SD-OCT images with a high level of sensitivity and good overall AUPRC.

TITLE: Conditional Knockout of Scavenger Receptor B1 (SR-B1) from RPE Increases Free Cholesterol Accumulation in the RPE of the $Bco2^{-/-}$ Mice

SESSION TITLE: Animal models of human ocular disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Li, F. Chang, A. Ranganathan, N. Giauque, Z. Wan, P.S. Bernstein, Department of Ophthalmology and Visual Sciences, The University of Utah School of Medicine, Salt Lake City, Utah, UNITED STATES|

Commercial Relationships Disclosure: Binxing Li: Commercial Relationship: Code N (No Commercial Relationship) | Fu-Yen Chang: Commercial Relationship: Code N (No Commercial Relationship) | Arunkumar Ranganathan: Commercial Relationship: Code N (No Commercial Relationship) | Nathan Giauque: Commercial Relationship: Code N (No Commercial Relationship) | Zihe Wan: Commercial Relationship: Code N (No Commercial Relationship) | Paul Bernstein: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Free cholesterol can efflux onto lipid-rich HDL2 particles in the bloodstream from scavenger receptor B1 (SR-B1) on the surface of peripheral cells. SR-B1 has been detected in the retinal pigment epithelium (RPE) of humans and mice. In this work, we investigated if RPE SR-B1 can facilitate free cholesterol efflux from the RPE of $Bco2^{-/-}$ mice.

Methods: To specifically delete SR-B1 from the RPE of the $Bco2^{-/-}$ mice, we bred the Best-Cre mice and the floxed SR-B1 mice ($Srb1^{f/f}$) into the $Bco2^{-/-}$ mice and generated the RPE-specific conditional knockout mice of SR-B1 (Best-Cre;$Srb1^{f/f}$;$Bco2^{-/-}$). SR-B1 expression was examined by western blot and Immunohistochemistry (IHC). Next, to detect the accumulation of free cholesterol in the RPE, we stained the retinal sections of 6-month-old Best-Cre;$Srb1^{f/f}$;$Bco2^{-/-}$ mice (Srb1cKO) and Best-Cre;$Bco2^{-/-}$ mice (control) (3 mice/genotype) using filipin, and cholesterol was imaged with a bright-field microscope under excitation of a 365-nm UV light. We also further quantified the contents of free cholesterol in the RPE of these two mice with gas chromatography-mass spectrometry (GC-MS) (3 mice/genotype).

Results: Western blot and IHC data demonstrate that SR-B1 had been successfully deleted from the RPE of $Bco2^{-/-}$ mice. There was no structural difference between the SR-B1 conditional knockout mice (Srb1cKO) and the control mice. Filipin staining revealed more free cholesterol in the RPE of the retinal sections of the Srb1cKO mice. GC-MS data shows that the accumulation of free cholesterol in the RPE of Srb1cKO mice was increased around 30% relative to the control mice.

Conclusions: Our results demonstrate that specific deletion of RPE SR-BI can increase the accumulation of free cholesterol in the RPE. This finding may enhance our understanding of the metabolism of local RPE lipids.

ABSTRACT BODY:

Purpose: Aberrant RNA splicing has emerged as a significant cause of inherited retinal diseases (IRDs). Next generation sequencing of IRD patients living in Ireland and utilisation of in silico splice prediction tools have enabled identification of putative splice-altering variants in IRD-associated genes. The aim of this study was to experimentally validate several of these variants using in vitro splice assays.

Methods: Probands underwent target capture sequencing of exons and canonical/noncanonical splice site regions of 254 IRD-associated genes. Putative splice-altering variants were identified and prioritised for further analysis using in silico splice prediction tools, including SpliceAI and Alamut Visual software. Genomic segments containing the variant of interest or wild-type sequence and flanking exons were amplified, cloned into midigene plasmid vectors and transfected into HEK 293 cells. mRNA was isolated 48 hours post-transfection and transcripts were analysed via RT-PCR, gel electrophoresis and Sanger sequencing.

Results: Midigene splice assays were used to evaluate the consequences of OPA1 c.1681+1G>T (NM_130837.2) and FLVCR1 c.1307+5G>T (NM_014053.3), as well as previously unreported variants in TULP1 (NM_003322.4:c.999+5G>T) and CACNA1F (NM_005183.3: c.2576+4_2576+5delAG). Transfection of a wild-type OPA1 midigene resulted in a single mRNA product of expected length while the mutant construct exclusively produced a shorter fragment in which exon 17 was skipped, leading to a frameshift (p.Ile537Glyfs*10). A wild-type FLVCR1 midigene yielded a full-length transcript and an additional product lacking exon 6. In contrast, the mutant FLVCR1 midigene did not produce any detectable full-length transcript and appeared to increase skipping of exon 6, which causes an in-frame deletion of 37 amino acids. The novel TULP1 and CACNA1F variants tested appeared to induce complex aberrant splicing patterns and work is underway to elucidate the precise nature of these defects.

Conclusions: This study characterised splicing defects resulting from canonical and noncanonical splice site mutations in IRD-associated genes – providing new evidence in support of variant pathogenicity. Functional analysis of such variants is vital for accurate classification of pathogenicity and severity, and increasingly important for enabling access to emerging gene therapies.

ABSTRACT BODY:

Purpose: Here we enumerate hallmarks of corneal fibrosis and ulceration: fibrosis and extracellular deposition (ECM), angiogenesis and inflammation. This study highlights the ophthalmological, clinical and histopathological changes throughout the progression of deep stromal alkali injury in the rabbit cornea.

Methods: Albino New Zealand rabbits were used for the study. Penetrating lamellar keratoplasty was performed on rabbit cornea (n=3) using guarded trephine. 0.75N NaOH was applied followed by irrigating with normal saline. Animals were imaged using the ophthalmological parameters; i) OCT, ii) Slit lamp and iii) Densitometry over the period of 3 weeks. At the end of three weeks animals were sacrificed and eyes were enucleated and further processed for histopathology (H&E, PAS staining) and Immunohistochemistry

Results: The parameters used in clinics for evaluating patients were used to evaluate and grade the scars into nebular, macular and leucomatous. Slit lamp reveled re-epithelization of the wound in first 5-6 days followed by incidences of epithelial defects, inflammation, and opacification. Neovascularization was observed after 14-15 days of alkali burn. OCT: pachymetry wide and raster scans reveled extensive edema and thickening of the central cornea. Densitometry images reveled stable scar formation with the opacity score ≥75, condition of legal blindness. Histology and immunohistochemistry evaluations supported the ophthalmic evaluation results.

Conclusions: The parameters used in clinics for evaluating patients were used to evaluate and grade the scars into nebular, macular and leucomatous. ABSTRACT BODY:

Purpose: Proliferative diabetic retinopathy (PDR) and diabetic macular edema (DME) appear to be two distinctive diseases with unique characteristics, including the response to anti-VEGF treatment. Our previous cross-sectional studies showed that these two phenotypes are not always present concurrently. To determine if PDR and DME have distinctive microvasculature status, ultra-widefield fluorescein angiography (UWF-FA) images of patients with “PDR only” or with “DME only” diagnoses were analyzed.

Methods: A retrospective cohort study, of 18 patients, analyzing the UWF-FA images obtained using Optos California imaging system in patients with PDR only (10 eyes) and DME only (8 eyes). “PDR only” cases included those with preretinal or vitreous hemorrhage without any edema by OCT. The “DME only” cases included only center-involving edema with no concurrent neovascularization or vitreous hemorrhage. Three masked examiners graded the angiograms using the Optos Advance software free-hand tool to demarcate the extent of capillary nonperfusion (areas of hypofluorescence). The outcomes included gradable area, area of capillary nonperfusion, and non-perfusion index (NPI; nonperfused/total gradable area). Statistical analyses were performed with a two-sample t-test for unpaired variables.

Results: Quantification of UWF-FA images revealed that patients with a “PDR only” diagnosis had an average area of nonperfusion measuring 329.6 mm^2 (SD±92.9 mm^2) and those with “DME only” diagnosis had an average area of nonperfusion measuring 193.0 mm^2 (SD±27.8 mm^2). Our analysis revealed that the areas of retinal capillary nonperfusion was significantly higher (1.7 fold) for patients with “PDR only” compared to patients with “DME only” ($p<0.005$). The NPI in “PDR only” cases was significantly higher than that observed in “DME only” cases, 0.43 and 0.26, respectively ($p =0.002$).

Conclusions: Ultra-widefield fluorescein angiography demonstrates significantly increased areas of capillary nonperfusion in cases with a “PDR only” diagnosis compared to “DME only” diagnosed cases. The increased severity of nonperfusion in PDR cases may be related to increased production of VEGF and consequent angiogenesis. These preliminary findings show that PDR and DME may be driven by distinct pathological processes and molecular mediators.

ABSTRACT BODY:

Purpose: Meibomian gland dysfunction (MGD) is the most common cause of dry eye, is linked to screen use and can occur in adolescents. The Standard Patient Evaluation of Eye Dryness (SPEED) questionnaire has predictive value for MGD.The purpose of this study was to evaluate the reproducibility of the SPEED questionnaire for determining symptoms of dryness in middle and high school students.

Methods: The SPEED questionnaire was administered online to middle and high school students living in a suburb of Boston, MA USA in May 2020 and June 2021.

Results: The 2020 survey included 462 respondents (male 177, female 276, non binary 5) mean age 14.38 years (range 11-18). 38 nationalities were self-identified: White 49.94%,Asian 27.57%, all others (mixed <3%). The 2021 survey included 288 respondents (male 70, female 111, non-binary 4, preferred not to answer 1; Mean age 15.86 years(range 10-18). 14 nationalities were self-identified: White 51.1%, Asian 28.1%, African American 4.6%, all others <3%). The mean SPEED score in 2020 was 8.325 (SD 4.67; range 0-28) and the mean SPEED score in 2021 was 10.12 (SD 4.78; range 0-23). Data from the 2021 and 2022 plots were compared using the Spearman correlation test and no significant correlation was found between the two timepoints (rho=0.079).

Conclusions: The SPEED reproducibly revealed an alarmingly high prevalence of dry eye symptoms in middle and high school students. The 2021 scores show higher frequency and severity which may be due to an additional year on screens or the one year average age difference. The use of questionnaires is an inexpensive method for dry eye screening to promote early intervention. School districts should administer validated dry eye symptom questionnaires on an annual basis.

ABSTRACT BODY:

Purpose: The Mediterranean-DASH Intervention for Neurodegenerative Delay (MIND) diet is developed as a strategy to promote healthy cognitive ageing. Adherence to the MIND diet has been associated with reduced incidence of Alzheimer's disease and slowed cognitive decline with aging or after stroke. Since open-angleglaucoma (OAG) is also a neurodegenerative disease, it is of interest to study the effect of the MIND diet on the incidence (i) of OAG. To determine whether this diet has a different effect on iOAG risk than diets designed to improve overall health, we also determined the association between iOAG and the Mediterranean diet and Dutch Dietary Guidelines.

Methods: Participants of the Rotterdam Study, a longitudinal population-based cohort study, were regularly monitored for iOAG. Dietary data were collected at baseline using validated food frequency questionnaires. The association between the diet scores and iOAG was analyzed using multivariate logistic regression analyses, adjusted for body mass index, total energy intake, physical activity and follow-up time. Additional adjustment for intraocular pressure (IOP), smoking and education level was also performed. The association between the diet scores and IOP, the main risk factor of OAG, was assessed using multivariate linear regression analyses.

Results: A total of 1020 participants were included in the analyses, among whom 170 developed iOAG over a mean 10.9-year follow-up period. Controls were age (mean 65.8 years) and gender (54.1% female)-matched. As expected, cases had a significantly higher IOP (16.4 vs. 14.2 mmHg). We found that adherence to the MIND diet was associated with a decreased iOAG risk (11% for each 1-point increase in score; Odds Ratio=0.89; 95% confidence interval 0.80-1.00). This association remained even after adjusting for factors that correlate with a healthy lifestyle. Sensitivity analyses, excluding one component of the total MIND score at a time, showed that the protective effect originated especially from the intake of green leafy vegetables, berries and fish. No associations were observed between the Mediterranean diet score or Dutch Dietary Guidelines score and iOAG. Moreover, none of the diet scores were associated with IOP.

Conclusions: A higher adherence to the MIND diet was associated with a lower incidence of OAG. The mechanism is probably not through the IOP. Thus, the MIND diet may also serve as a beneficial dietary pattern for healthy eyes.

ABSTRACT BODY:

Purpose: Adenosine receptors (AR) A1, A2A, A2B, and A3 are known to have important roles in the modulation of inflammatory and neurodegenerative processes. However, much remains unknown about their choroidal expression and their function in ocular neurodegenerative diseases including age-related macular degeneration (AMD). This study tested the hypothesis that AR are expressed in the human choroid and changes in their expression occur in patients with AMD.

Methods: Human ocular samples were obtained from the Lion Gift of Sight Eye Bank at the University of Minnesota. Donor eyes with wet AMD, dry AMD, and no AMD were selected. Each set of donor samples was stained with ADORA1, ADORA2A, ADORA2B, and ADORA3 specific antibodies. Each sample was also stained with collagen IV antibody to label the vasculature and DAPI to visualize cellular organization. Samples were then incubated with secondary antibodies and fluorescence microscopy was used to compare the presence and intensity of AR expression.

Results: Receptor A1 demonstrated expression within the retina, particularly the inner plexiform layer (IPL) and outer plexiform layer (OPL). There was also evidence of expression within the choroidal vasculature. Receptor A2A demonstrated expression within the retinal and choroidal vasculature, and its expression was modestly decreased in samples from patients with wet and dry AMD. Receptor A2B demonstrated expression throughout the retina in all samples, particularly the ganglion cell layer, OPL, and IPL. Receptor A2B was also expressed in the retinal and choroidal vasculature. Receptor A3 was expressed primarily within the inner nuclear layer and outer nuclear layer of the retina.

Conclusions: Our results provide further evidence that AR are widely expressed throughout the human retina and choroid, and receptors A1, A2A, and A2B appear to be strongly expressed within the choroidal vasculature. Furthermore, our results suggest decreased receptor A2A expression in patients with both wet and dry AMD may contribute to the pathophysiology of AMD. Additional studies with a larger sample size will be required to further evaluate the contribution of changes in A2A expression to AMD pathology.

ABSTRACT BODY:

Purpose: Choroideremia (CHM) is an X-linked inherited retinal degeneration affecting the photoreceptors, retinal pigment epithelium and choriocapillaris. Previous studies have reported local regions of reduced and normal cone density in CHM, but density measurements alone do not fully quantify the cone phenotype. Here, we compare cone inner segment (IS) area and circularity in CHM images to cones in images from normal-sighted controls.

Methods: Nonconfocal split-detection images of the photoreceptor IS mosaic in 13 CHM and 12 normal controls were acquired at 1, 2, and 4° temporal to the fovea using a custom-built, multimodal adaptive optics scanning light ophthalmoscope. Cone centers were manually identified (JIWM) and cone borders segmented (PX). A custom MATLAB script was used to extract perimeter and area for each cone. Cone circularity was calculated as 4π * cone area / cone perimeter^2. Regularities of each metric [defined as mean / standard deviation (stdev)] were calculated for each image. Unbalanced two-way ANOVA and Bonferroni post hoc were used to assess statistical differences between disease states (CHM vs. control) and along retinal eccentricity.

Results: There was an effect of disease [ANOVA; $F(1,65) = 31.88$, $p < 0.001$] and eccentricity [$F(2,65) = 63.23$, $p < 0.001$] on cone area, though there was no significant interaction between disease state and eccentricity [$F(2,65) = 0.02$, $p = 0.981$]. Cones were significantly larger in CHM than control (mean ± stdev: 20.4 ± 8.8 μm^2 vs. 14.5 ± 7.3 μm^2; $p < 0.001$) and larger with eccentricity from the fovea ($p < 0.001$). There was an effect of disease state on cone circularity [$F(1,65) = 4.31$, $p = 0.042$] and circularity regularity [$F(1,65) = 14.72$, $p < 0.001$]. Compared to control, cones in CHM were more circular ($p = 0.042$) and circularity regularity was higher ($p< 0.001$). There was no significant effect of disease state on cone area regularity [$F(1,65) = 1.27$, $p = 0.264$].

Conclusions: Cones are larger and more circular in CHM compared to normal, consistent with the idea that cones expand to form a contiguous mosaic in areas of reduced photoreceptor density. The increase in circularity in CHM was surprising, but one possible explanation may be that the tight packing of normal parafoveal cones result in a lack of intra-cone space and thus adjacent cones' borders abut.

ABSTRACT BODY:

Purpose: Preliminary evidences from the literature, together with our everyday clinical practice and patients reporting, led us to hypothesize that dry eye (DED) symptoms related to some COVID-19 mitigation measures might be a common problem and a relevant issue. We designed this study in order to assess and to monitor DED symptoms' changes from 2019 to 2021, in both DED patients and healthy subjects, and to investigate their relationship with homeworking and facemask wearing.

Methods: We retrospectively reviewed the medical records of patients who, between November and December 2019 (V19), had undergone an eye exam including quantification of Ocular Surface Disease Index (OSDI) score at the Eye Clinic San Giuseppe Hospital, Milan.

Between November and December 2020, we performed a telephone survey (V20) contacting these patients. The survey was repeated between November and December 2021 (V21).

The telephone survey included the OSDI 12-items and a custom-made questionnaire exploring type of job or occupation, home working, screen time, type and average time of face mask-wearing, and recent onset and worsening of DED-related symptoms.

We investigated the difference among V21, V20 and V19 DED symptoms, the rate of subjects with OSDI increase > OSDI minimal clinically important difference (MCID), and associations between DED symptoms, face masks wearing, VDT usage and home working.

Results: Of 120 subjects with V19 OSDI≤12, 43 (36%) and 39 (32%) showed OSDI>12 at V20 and at V21, respectively. OSDI was significantly correlated with duration of face masks use (V20 r= 0.29; P<0.01. V21 r= 0.23; P<0.01) and heavy mask users had a significantly higher OSDI (P<0.05). V20 and V21 OSDI was significantly higher in home-workers (P<0.05) but we did not find a significant correlation between V21 OSDI and referred number of VDT use (r= 0.07; P=0.41).

Of 70 patients with V19 OSDI>12, 18 (26%) and 24 (34%) showed symptoms worsening >MCID at V20 and V21, respectively. The percentage of OSDI worsening >MCID was significantly higher among heavy face masks users (73% vs 12%; P<0.01, Fisher test). The percentage of OSDI worsening >MCID was significantly higher in home workers at V20 but not at V21.

Conclusions: Some COVID-19 mitigation strategies seem to have a significant role in triggering DED symptoms onset or worsening. This issue persisted during the second pandemic year, with weaker correlation to presumed trigger factors.

ABSTRACT BODY:

Purpose: The Intracortical Visual Prosthesis (ICVP) project will implant many (160 – 400) electrodes into a patient's cortex. An accurate phosphene map is needed to present images to ICVP wearers with minimal distortion. As some phosphenes may form closely spaced clusters, this problem becomes significant with absolute mapping methods. Therefore, we created a relative mapping technique presenting pairs of dots for clustered phosphenes.

Methods: Combining the VIVE Pro Eye headset (eye and head tracking) and a Polhemus G4 finger tracker in Unity gaming platform, we tested sighted subjects facing a 36" radius concave sphere cap.

We created a set of 16 randomized dots in the lower left quadrant, representing phosphenes from electrodes in the upper right visual cortex . To limit the number of pairs (which for 160 electrodes would be 12720), we only tested pairs within clusters: Only pairs for which the relative proximity (rp; i.e., pair separation / pair eccentricity) was less than a cut-off value were selected; at rp ≤ 25%, we get 11 pairs (chart 1).

During testing, subjects used the left index finger to indicate the direction between dots in a pair shown in the headset. Subjects performed a practice trial (5 pairs), followed by 3 tests (11 pairs each).

Results: With data sets collected from 23 subjects, we calculate the direction distributions for each pair; as the distance of the dot pair increased, the SD of the distribution decreased, indicating that subjects were able to indicate the direction more precisely. The same relationship was found for relative proximity (box plot size in chart 2). With 5 subjects who were tested twice, we found that subjects improved both accuracy and precision of the direction settings.

Conclusions: The small deviation angles demonstrate that relative direction mapping provides a reliable basis for rearranging phosphenes within local clusters. Limiting pairs to dots within clusters keeps the total number of pairs to be presented to a manageable number compared to the complete combinatorial pairs required for a complete relative mapping. Combined with the absolute mapping techniques we are developing this will allow robust phosphene map construction within a reasonable time frame.

ABSTRACT BODY:

Purpose: Injectable Fluocinolone Acetonide (FA) was approved in 2018 for treatment of non-infectious uveitis (NIU) affecting the posterior segment. We monitored the incidence of rescue events in a year long prospective investigator initiated study (IIS) evaluating imaging outcomes in patients treated with the FA implant.

Methods: A total of 31 adult NIU patients on FA 0.18mg were initially enrolled in an IIS. 27 NIU patients (13 males; 14 females) (17 white; 10 black) (n=32 eyes) were included in this analysis with a baseline visit and at least one month follow-up. Imaging including OCT and wide field fluorescein angiography were performed at study visits. Criteria for treatment rescue involved the use of additional intravitreal (IV) injections or an increase in immunosuppression to treat resilient and/or worsening leakage on imaging. Patients with bilateral eye disease who received systemic rescue treatment for only one worsening eye had their other eye excluded from primary calculations. 32 different sets of eyes were included for the 1 month, 3 month, and 6 month follow-up data, respectively. 26 eyes were included for 9 month follow-up. 19 eyes were included for 12 month follow-up.

Results: 10 of 32 eyes (9/27 pts) required rescue within one year (31%). Five patients required at least two rescues. On average, 11% of eyes required rescue within 6 months and 16% after 6 months. Three patients with bilateral eye disease received systemic rescue treatment for only one worsening eye (one patient at the 6 month, 9 month, and 12-month follow-up, respectively); the other eye for these patients were excluded. Treatments included NSAID eye drops, steroid eye drops, systemic steroids, dexamethasone intravitreal implants, triamcinolone acetonide injections, repeat FA 0.18mg implants, and FA 0.59mg implants.

Conclusions: About one-third of patients on FA 0.18mg will require rescue treatment within one year. The most likely time for rescue will be around six months to one year following initiation of treatment.

ABSTRACT BODY:

Purpose: Usher syndrome (USH) is a leading cause of deafness-blindness and variants in PCDH15 are responsible for USH type 1F (USH1F). Previous studies showeded three alternative spliced cytoplasmic domains (CD1, CD2 and CD3) of PCDH15., however expression and functional data in the murine retina were lacking. Herein, we investigated the spatiotemporal expression pattern of Pcdh15 isoforms in the developing and mature mouse retina. We evaluated the visual function of three mouse lines, lacking one out of three Pcdh15 cytodomains (Pcdh15-CD1, -CD2, -CD3). Finally, we developed and evaluated the impact of dual-AAV based PCDH15 gene delivery in the mouse retina.

Methods: Immunoblotting and immunofluorescent imaging showed using CD1, CD2 and CD3 domain specific antibodies showed the expression and subcellular distribution of protocadherin-15 isoforms. Mice lacking Pcdh15-CD1, -CD2 or -CD3 isoforms were assessed for structure and function was assessed by optical coherence tomography (OCT) and electroretinography (ERG). Two halves of human PCDH15 were packaged in adeno-associated virus (AAV) and subretinal injection were performed in Pcdh15 mutant and control mice followed by serial ERG analysis.

Results: Both protocadherin-15-CD1 and -CD3 isoforms were detected but no expression of CD2 isoform was found. Consistent with immunoblotting, we also observed expression of protocadherin-15-CD1 and -CD3 isoforms in multiple retinal layers, including photoreceptors, at specific ages from P1 to P42. Consistent with expression data we found intact vision in Pcdh15-CD2 knockout mice at 2-months of age. Currently, we are performing ERG analysis and retinal structural analysis of older mice from each of the mutant lines. In parallel, we also packaged two halves of human PCDH15 in AAV-Anc80L65 capsid and performed subretinal injections in. Finally, Pcdh15 null mice injected with dual AAV at P20-P21 or P30, revealed significant improvement of vision.

Conclusions: Our current findings indicate that although retina expresses multiple isoforms of protocadherin-15, but either not all of them require for normal vision or have functional redundancy. Furthermore, dual AAV based PCDH15 vectors mediated gene replacement therapy revealed promising results and significantly restored vision in Pcdh15 mutant mice.

ABSTRACT BODY:

Purpose: CD4$^+$FoxP3$^+$CD25$^+$ regulatory cells (Tregs) are essential for maintaining self-tolerance and their manipulation is of considerable interest as a strategy to prevent allograft rejection. mPTX-35 is an affinity matured mouse IgG1 anti-Human TNFRSF25 antibody, which can expand Tregs by stimulating the TNFRSF25 receptor. This work tested whether mPTX-35 treatment could prolong allogeneic corneal transplants (CT) in mice accompanied by Tregs expansion.

Methods: Balb/c mice were administered different doses (0.5 ug, 5 ug, 50 ug) of mPTX-35 via subconjunctival (SC) injection and compared to an IgG1 (50ug) control. CD4$^+$FoxP3$^+$CD25$^+$ Tregs in conjunctiva and draining LN were analyzed by flow cytometry 6 and 14 days post-treatment. MHC-mismatched CTs were performed from B6 to Balb/c mice, with the following treatment groups: (1) 1-dose-mPTX-35 (single dose, SC, 5ug, day-3), (2) 2-dose-mPTX-35 (2 doses, SC, 5 ug, day 0 & 7). Data is presented using median survival day post-transplant (MST) comparing mPTX-35 treated to IgG1 controls. Corneal opacity of the graft was scored twice per week using a pre-established scale ranging from 0-4; rejection was defined as a recorded score of ≥3 for two consecutive readings.

Results: In the conjunctiva, Tregs/CD4+ frequency was significantly increased in the mPTX-35 treated mice on day 6 post-treatment at doses of 5 ug mPTX-35 (51.4±3.1%, $p<0.0001$) and 50 ug (48.6±2.5%, $p<0.0001$) vs IgG1 control (16.3±1%). Significant increases were also detected on day 14 in all 3 dose groups. Tregs/CD4+ frequency in the draining LN on day 6 was significantly elevated in the 5 ug mPTX-35 (22.7±2.5%, $p=0.0037$) and 50 ug mPTX-35 (19.8±1.6%, $p=0.0048$), but not in the 0.5 ug mPTX-35 (10.6±1.5%, ns) compared to the control (11.3±2.1%). In contrast to the subconjunctiva, no differences were detected on day 14 in the draining LN. Compared to their IgG1 controls, MST was not prolonged in the 1-dose-mPTX-35 group (27.5 d vs 33d, n=6/group), but significantly prolonged in the 2-dose-mPTX-35 group (39 d vs 21 d, $p=0.0224$, n=6/group).

Conclusions: Local ocular delivery of TNFRSF25 specific mPTX-35 prolongs graft survival day in the allogeneic CT setting in mice. We posit recruiting Treg cells to the local conjunctiva and draining LN inhibits rejection responses. mPTX-35 would be a potential candidate to treat CT rejection in clinic.

ABSTRACT BODY:

Purpose: Characterizing immune cells and conditions that govern their recruitment and function in autoimmune diseases of the nervous system or in neurodegenerative processes is an area of active investigation. We sought to analyze the origin of antigen presenting cells associated with the induction of retinal autoimmunity using a system that relies on spontaneous autoimmunity rather than experimentally induced autoimmunity, avoiding uncertainties associated with immunization with adjuvants at remotes sites or adoptive transfer of in-vitro activated T cells.

Methods: We used R161H TCR transgenic mice (Horai, et. al. J Autoimmunity 44:21, provided by Dr. R. Caspi, B10.R3 background), which spontaneously and rapidly develop severe autoimmune retinitis (AR), in conjunction with $CD11c^{DTR/GFP}$ mice (B6/J background) that allow tracking of activated, antigen presenting microglia within the retina (GFP^{hi} cells). $R161H^{+/-}$ x B6/J F_1 mice were used to analyze the influx/expansion of antigen presenting cells and T cells relative to the course of AR. Parabiosis using $R161H^{+/-}$ x B6/J F_1 mice paired with B10.R3 x B6/J F_1 (wild type recipient) mice was done to explore the origin and phenotype of antigen presenting cells crucial for the induction of autoimmunity. Analysis was done by retinal imaging, flow cytometry, and histology.

Results: Onset of AR in $R161H^{+/-}$ x B6/J F_1 mice was delayed relative to B10.R3-$R161H^{+/-}$ mice revealing a distinct prophase of the disease prior to frank autoimmunity that was characterized by expansion of GFP^{hi} cells within the retina prior to any clinical or histological evidence of autoimmunity. Parabiosis between mice carrying the R161H and $CD11c^{DTR/GFP}$ transgenes and wild type recipients showed that recruitment of circulating GFP^{hi}cells to retinas was required for induction of AR. GFP^{hi} cells were found in 19/30 retinas from wild type recipients with 12 of those recipients developing AR. Conversely, none of the 11 recipients devoid of GFP^{hi}cells developed AR ($p = 0.0006$).

Conclusions: Our results here contrast with our previous findings showing that retinal antigen presenting cells expanding in response to either sterile inflammatory injury or neurodegeneration were derived from myeloid cells within the retina or optic nerve thus highlighting a unique facet of retinal autoimmunity.

TITLE: Nonclinical Pharmacokinetics and Pharmacodynamics of Brimochol, a Combination Product for the Treatment of Presbyopia

SESSION TITLE: IOLs and Presbyopia

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: R.S. Verhoeven, Little Creek Research, North Carolina, UNITED STATES|J. Burke, R. Schiffman, Visus Therapeutics, California, UNITED STATES|

Commercial Relationships Disclosure: Rozemarijn Verhoeven: Commercial Relationship(s);Code C (Consultant/Contractor):Visus Therapeutics | James Burke: Commercial Relationship(s);Code E (Employment):Visus Therapeutics;Code P (Patent):Visus Therapeutics | Rhett Schiffman: Commercial Relationship(s);Code E (Employment):Visus Therapeutics;Code P (Patent):Visus Therapeutics

ABSTRACT BODY:

Purpose: Brimochol™ (Visus Therapeutics) is a fixed combination of the cholinergic miotic agent carbachol and the alpha-2 agonist brimonidine that is being developed as a topical ocular product for the treatment of presbyopia. The purpose of these two nonclinical studies was to evaluate ocular distribution and effect on pupil diameter following administration of Brimochol in pigmented rabbits.

Methods: Dutch Belted rabbits (4/group) received a single unilateral administration of 35 µl of Brimochol or carbachol 2.75%, while the contralateral eye received phosphate-buffered saline (PBS). Pupil diameter was measured in conscious animals using a digital pupillometer under scotopic (0 lux), low mesopic (0.3 lux), high mesopic (3 lux), and photopic (669 lux) conditions at baseline and at various time points out to 12 hours postdose. Ophthalmic exams were conducted at 0.25 and 2 hours postdose using the Hackett McDonald scoring system. In a separate study, rabbits received a bilateral administration of Brimochol or carbachol, and concentrations of brimonidine and carbachol were measured in ocular matrices (4 eyes/time point) using liquid chromatography and tandem mass spectrometry.

Results: Brimochol decreased pupil size in all lighting conditions to a greater extent than carbachol alone, and the miotic effect was sustained for up to 12 hours. An improved ocular tolerability profile was observed for Brimochol compared to carbachol alone. The mean maximum concentration (Cmax) for carbachol in the iris ciliary body (ICB) was 32.8 ng/g and the mean area under the curve (AUC) was 223h*ng/g for Brimochol, compared to 17.7 ng/g and 157 h*ng/g, respectively, for carbachol alone, indicating increased exposure to carbachol following Brimochol administration. Time at Cmax (Tmax) was similar between groups.

Conclusions: Brimochol demonstrated effectiveness at reducing pupil size in rabbits for 12 hours and had a greater effect on pupil size than carbachol 2.75% alone. The addition of brimonidine appears to improve the ocular tolerance profile compared to carbachol alone. Perhaps by altering aqueous dynamics, the addition of brimonidine also tends to increase the extent and duration of carbachol exposure in the target tissue.

ABSTRACT BODY:

Purpose: Serum deprivation in cultured human retinal pigment epithelial (RPE) cells has been shown to result in cell responses similar to those seen in age-related macular degeneration (AMD). In this study, we investigated the impact of serum deprivation on mitochondrial respiration of cultured ARPE-19 cells. Furthermore, influence of an uncoupler under serum deprivation conditions was also examined.

Methods: ARPE-19 cells were cultured in Dulbecco's modified Eagle's Medium (DMEM, 4.5 g/L glucose) with either normal (10%) or deprived (1%) fetal calf serum (FCS). Under both conditions, some cells were treated with different concentrations of the uncoupling agent carbonyl cyanide 4-(trifluoromethoxy) phenylhydrazone (FCCP) for 24 hours. Cell viability was assessed by cytotoxicity assay with WST-1 (4-[3-(4-iodophenyl)-2-(4-nitrophenyl)-2H-5-tetrazolio]-1,3-benzene disulfonate). ARPE-19 cells were pre-treated with sublethal doses of FCCP (0.5 µM and 1 µM) for 24 hours before their mitochondrial respiratory function was analyzed by Mitostress Assay with the Seahorse XFe24 Analyzer.

Results: WST-1 assay results showed FCCP at concentrations up to 1 µM did not affect the viability of ARPE-19 cells after 24 hours of exposure under both normal and serum-deprived conditions. Serum deprivation reduced basal and maximal respiration of ARPE-19 cells by 23% and 21%, respectively, compared to normal serum conditions ($p<0.01$). Pre-treatment with 0.5 µM and 1 µM FCCP for 24 hours significantly reduced basal respiration of RPE cells' under serum deprived condition, while maximum respiration and spare capacity were significantly increased after pre-treatment with 1 µM FCCP. Under normal serum condition, pre-treatment of FCCP showed no significant effect on mitochondrial respiratory functions of ARPE-19 cells.

Conclusions: Results indicate that low doses of mitochondrial uncoupling may enhance potential mitochondrial respiratory function of RPE cells under serum deprived conditions, mimicking the phenotypes of RPE cells in AMD. This suggests that mitochondrial uncoupling of RPE cells may be a potential therapeutic target for degenerative retinal disorders, and further studies are needed to clarify this.

ABSTRACT BODY:

Purpose: Retinyl ester hydrolase (REH) cleaves retinyl esters (RE) to produce retinol. REH has not been identified in the RPE previously. The purpose of this project is to investigate the role of patatin-like phospholipase domain containing 2 (PNPLA2) as REH in the visual cycle.

Methods: PNPLA2 mRNA and protein levels were examined in retinal tissues and sections by real-time (RT)-PCR, western blot analysis and immunofluorescence staining. PNPLA2 knockout ($PNPLA2^{-/-}$) mice were used to examine the retinal function and rhodopsin recovery by electroretinography (ERG). Visual chromophore regeneration was determined by photobleaching mice for 30 min at 5k lux light followed by recovering in the dark for 15 and 40 min. Retinoid profiles were analyzed by HPLC. SiRNA-mediated knock-down was used to analyze the REH activity of endogenous PNPLA2 in HEK293A cells.

Results: Western blot analysis and immunofluorescence staining of the WT mouse retinal tissues and sections confirmed PNPLA2 expression in the RPE and retina. ERG analysis revealed a- and b-wave amplitudes were significantly lower in $PNPLA2^{-/-}$ mice, suggesting impaired retinal function. $PNPLA2^{-/-}$ mice showed lower a-wave recovery after photobleach compared with WT mice. More prominent lipid droplet accumulation along the plasma membrane was observed in RPE cells from $PNPLA2^{-/-}$ mice relative to WT mice. Visual chromophore regeneration was slower in $PNPLA2^{-/-}$ mice compared with WT mice. The content of RE was significantly higher in $PNPLA2^{-/-}$ mouse eyes relative to age-matched WT mice at all tested time points, implying that PNPLA2 hydrolyzes RE from the retinosomes in the RPE, releasing all-trans-retinol (atROL). In cultured cells, siRNA-mediated knock-down increased RE levels, confirming REH activity of PNPLA2.

Conclusions: REH activity of PNPLA2 was required to mobilize retinol from lipid bodies in RPE cells and is an essential component of the visual cycle. The absence of PNPLA 2 expression in the RPE led to declined retinal function and impaired visual chromophore regeneration along with a significant amount of lipid accumulation.

ABSTRACT BODY:

Purpose: Electronic cigarettes (e-cigs), battery-powered devices that produce aerosols by heating e-liquid solution, are a popular alternative to smoking. It is well-established that smoking is a major modifiable risk factor for age-related macular degeneration (AMD). Notably, like cigarette smoke, e-cig vapor exposure stimulates pro-inflammatory and angiogenic responses in the mouse retina. Based on these findings, our purpose in this study was to utilize induced pluripotent stem cell (iPSC)-based disease modeling studies and evaluate the direct relevance of e-cig vapor for AMD pathology development.

Methods: Parallel cultures of control iPSC-derived retinal pigment epithelium (RPE) cells grown as polarized monolayer in transwell inserts were supplemented daily with either varied concentrations of freshly prepared e-cig vapor extract (ECVE, 1%, 5% or 10%) or vehicle (cell culture media;untreated) for 14 days and evaluated longitudinally for cell viability (Calcein AM), and epithelial barrier integrity (transepithelial measurements). At the end of the treatment duration (day 14), quantitative real-time PCR and Western blotting was used to assess expression/levels of inflammation-related genes/proteins (e.g., C3, IL-6). Furthermore, rate of phagocytosis of photoreceptor outer segment (POS) post-feeding of POS (~20 POS/RPE cell) for 2h was determined by measuring levels of RHO, a POS-specific protein, by using Western blotting. Lastly, immunocytochemistry was used to evaluate count and area of TIMP3/NileRed/APOE co-localizing sub-RPE deposits on the transwell membrane.

Results: Chronic exposure (14 days) of control RPE to 1%, 5% and 10% ECVE did not adversely impact cell viability and epithelial barrier integrity. In contrast, compared to untreated iPSC-RPE; ECVE-treated iPSC-RPE showed i) reduced uptake of POS, ii) elevated levels of extracellular HMGB1, a prototypic damage associated molecular pattern (DAMP) molecule, iii) increased levels of sPLA2-IIa, a pro-inflammatory enzyme that promotes inflammation by generation of reactive lipids and iv) increased count and area of sub-RPE TIMP3/Nile Red/APOE- positive drusen-like deposits.

Conclusions: Using iPSC-based disease modeling studies, we show that ECVE exposure promotes sterile inflammation and induces several pro-maculopathy changes in RPE cells, including decreased POS phagocytosis and formation of sub-RPE drusen-like deposits.

ABSTRACT BODY:

Purpose: Computer-based color contrast sensitivity (CS) tests diagnose type and severity of hereditary color vision deficiency (CVD) and acquired CVD in various diseases. These tests are predicated on saturation discrimination but provide no information about hue and color naming. Our purpose was to develop a clinically expedient test of cone CS which includes a color naming score (cone contrast naming test; CCNT).

Methods: 26 color vision normals (CVNs, mean age ± SD: 26 ± 5) and 20 hereditary CVDs (CVDs, age 32 ± 12) confirmed by Ishihara, anomaloscope, and cone CS participated after written informed consent. Test distance was 3 ft. in a dark room (Microsoft Surface display). Single letters on a grey background stimulated only L, M or S cones or luminance (Lum). Weber contrast varied from 1%-16% in 2X steps for L, M, Lum; S cones: 8%-128% in 2X steps. On each trial a single letter appeared within a crosshair for 5 sec. Subjects identified the letter and named its color. Letter types (L, M, S, Lum) were presented twice at each of five contrasts and both letter type and contrast were randomized in each session. CS and color naming was based on the number correct using a scale of 100.

Results: CVN CCNT CS correlated with Innova Systems, Inc. cone CS (r^2 = 0.3 $P < .001$) as did CVD CCNT CS (r^2 = 0.8 $P < .001$) validating CCNT CS. Sensitivity of CCNT cone CS for detecting type and severity of hereditary CVD was 100% (mean CVN CS: 84, mean CVD CS: 28, $P < .001$). Specificity in CVDs for confirming normal color vision in the normal cone type was 100% (mean CVN and CVD CS: 84, $P > .89$). Mean CVD CS scores were 6.1 standard deviations below CVD norms ($P < .001$). CVDs showed significant decrements in color naming for the deficient cone, normal cone, and luminance stimulus (mean 39) compared to CVNs (mean 82, $P < .001$). CS alone showed non-repetitive distinct scores in 30% of CVDs and CVNs while a composite score (mean of CS and CN) showed distinct scores in 70% of CVDs ($P < .001$) and in 46% of CVNs ($P < .002$) indicating that the composite score better discriminates between levels of performance in both CVDs and CVNs.

Conclusions: The CCNT combines cone CS with color naming to include both thresholds and color identification in a single, clinically expedient test. The composite score better discriminates levels of color ability important for matching CVDs with occupational needs and identifying the impact of acquired CVD on performance.

Commercial Relationships Disclosure: Timothy A Blenkinsop: Commercial Relationship: Code N (No Commercial Relationship) | Anne Zebitz Eriksen: Commercial Relationship: Code N (No Commercial Relationship) | Rasmus Moller: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The cornea is a highly specialized tissue, that is crucial for vision. Currently, there is a need for in vitro models of the cornea to study infections, wound healing, drug screening, and as sources for transplant cells. Here, we report on the identification of distinct corneal epithelium as well as other important corneal cells through single cell RNA sequencing (scRNAseq) analysis of a 3D eye organoid.

Methods: 3D eye organoids were grown from H9 ESCs, seeding 3000 cells/well in a 96 ultra-low bind u-bottom plate in mTeSR media supplemented with 2.5% Matrigel and 40nM Thiazovivin (THIA) on day 0. Deafferentation was initiated at day 2 by changing to differentiation media (DM): GMEM with 10% knock out serum replacement, 1mM Sodium pyruvate, 1mM non-essential amino acids, 2mM L-glutamate, 1% penicillin-streptomycin solution and 55μM β-mercapto ethanol. Corneal specification was enhanced at day 32-46 by changing to DM:CnT-PR (1:1) supplemented with 10ng/mL keratinocyte growth factor (KGF) and 40nM THIA, before changing to maintenance media; DMEM:F12, 2% B-27 supplement, 10ng/ml KGF and 2μM THIA at day 48. At day 153, one organoid was digested with 2.5mg/mL collagenase II to form a single cell suspension. The single cell suspension was processed for 10x scRNAseq. The data was clustered by guided clustering using the Seurat package in R, and the resulting clusters were annotated using the Enricher online database and expression of specific gene markers.

Results: scRNAseq data revealed clusters that could be annotated as 11 different cell populations, among which were a corneal epithelium population, corneal stroma, and corneal endothelial like cells. The corneal epithelium had a high expression of corneal keratins (KRT12, KRT5, KRT15) as well as expression of mucus (MUC16), E-cadherin (CDH1) and eye filed marker PAX6. The corneal stroma- and corneal endothelium-like cells had high expression of collagen (e.g. COL8A1), hyaluronan acid synthase (HAS2), KERA, mesenchymal, and hematopoietic markers CD44, CD34 and CD133 (PROM1).

Conclusions: We report on the generation of 3D eye organoids from hESCs that mature to form cells from the cornea. These organoids can be used as tools to study infections, wound healing, and pharmacological screening in a cost-effective way with reduced need for animal experiments.

ABSTRACT BODY:

Purpose: To identify plasma metabolites associated with primary open-angle glaucoma (POAG) risk.

Methods: In a case-control study from the Nurses' Health Study (NHS), NHSII and Health Professionals Follow-Up Study (HPFS), 602 incident POAG cases were 1:1 matched to 602 controls. LC-MS/MS metabolomics were measured on plasma samples; 367 metabolites passed quality control analyses. For comparison, in a cross-sectional study in the UK Biobank, 167 NMR metabolites were measured in serum samples from 2238 prevalent glaucoma cases and 44723 controls. Multiple logistic regression was used to identify metabolites associated with POAG in NHS/NHSII/HPFS and glaucoma in UK Biobank. In NHS/NHSII/HPFS, we also used Metabolite Set Enrichment Analysis to identify metabolite classes associated with POAG. All analyses adjusted for established glaucoma risk factors and relevant co-morbidities. False discovery rate (FDR) was used to adjust for multiple comparisons.

Results: Eight metabolite classes were associated (FDR<0.05) with POAG in NHS/NHSII/HPFS: triglycerides (TGs), diglycerides, two lysophospholipids classes [lysophosphatidylcholines and lysophosphatidylethanolamines], and one phospholipid class [phosphatidylethanolamines] were positively associated, while cholesteryl esters, carnitines, and organic acids and derivatives were inversely associated with POAG risk. Interestingly, polyunsaturated TGs with long fatty acyl chains were associated with a lower POAG risk while less unsaturated TGs with shorter fatty acyl chains were positively associated with POAG risk (Figure 1). In the UK Biobank, TGs and phospholipids (from which lysophospholipids are derived through hydrolysis), were positively associated with glaucoma, as found in NHS/NHSII/HPFS. Tyrosine, glucose, and glutamine were positively associated while acetate, 3-hydroxybutyrate, citrate, pyruvate and lactate were inversely associated with glaucoma (FDR<0.2).

Conclusions:

Higher levels of TGs, with potential differences by saturation and fatty acyl chain length, and phospholipids were adversely associated with POAG in both the NHS/NHSII/HPFS and the UK Biobank, suggesting that they play an important and complex role in POAG and may represent new screening and treatment targets.

ABSTRACT BODY:

Purpose: Whilst color fundus photos are used in routine clinical practice to diagnose ophthalmic conditions, a growing body of evidence suggests that ocular imaging contains valuable information regarding systemic clinical features of patients. These features can be identified through a variety of computer vision techniques including deep learning (DL) AI models. Predictions regarding coronary heart disease, chronic kidney disease, hypertension, current smoking status, and gender have been demonstrated in prior studies. In this study, we aim to both construct a DL model that can predict a variety of systemic features from fundus images and determine the optimal method of DL model construction for this specific task.

Methods: Data were collected from a cohort of patients who had routine fundus imaging for diabetic retinopathy screening between March 2020 and March 2021. This data consisted of matched fundus images and clinical data from chart review. A series of DL models were then created and trained based on the DenseNet201 architecture to predict each of the recorded clinical features. In order to ascertain the optimal method of creating these models, two models were created for each clinical feature - one utilizing transfer learning with images from the ImageNet database, and one without transfer learning.

Results: A total of 1277 fundus images were used to train the DL models to predict various systemic clinical features. Area Under the Receiver Operating Characteristics (AUROC) scores were used to compare the performance of each model. We found that models utilizing transfer learning were superior to those that did not (mean AUROC 0.78 vs 0.63, $p < 0.05$). Models using transfer learning were able to predict the following systemic features Age > 70 (AUROC 0.95), Ethnicity (AUROC 0.93), Gender (AUROC 0.85), ARB Medication use (AUROC 0.81), and ACE Medication use (AUROC 0.81).

Conclusions: Fundus images contain valuable information about the systemic characteristics of a patient. A DL model can predict Age, Ethnicity, Gender and ARB/ACE medication usage with a good degree of accuracy. To optimize DL model performance, we recommend that even domain specific models utilize transfer learning techniques to enhance performance.

ABSTRACT BODY:

Purpose: Embryonic amniotes and some adult salamanders can regenerate neural retina from cells of the retinal pigment epithelium (RPE). Injured embryonic chicken RPE can regenerate neural retina if stimulated with FGF2 at embryonic day 4 (E4), but for reasons that are not understood, this ability is lost by embryonic day 5 (E5). We hypothesize that alterations to transcription factor (TF) networks restrict the neural competency of the developing RPE.

Methods: RPE cells from developing E4 and E5 chickens were collected and subjected to gene expression profiling via bulk and single-nuclei RNA-seq, as well as chromatin accessibility profiling via ATAC-seq. In parallel, RPE was collected at both E4 and E5 at several timepoints following retinectomy in the presence or absence of FGF2 treatment. Changes in gene expression and chromatin accessibility were integrated to assess TF DNA-binding activity and differential behavior of downstream targets.

Results: E4 RPE responds to retinectomy and FGF2 by elevating the expression of genes encoding neural retina TFs, such as PAX6, VSX2, and ASCL1, while simultaneously down-regulating RPE markers OTX2 and MITF. In contrast, the E5 RPE can be induced to express neural retina TFs, but also displays enhanced hallmarks of maturity independent of injury or FGF2 treatment, pertaining to pigmentation, retinoic acid synthesis, extracellular matrix deposition, and reduced proliferative status. Accessibility changes across the E4 to E5 window suggest altered activity of the RPE-determining TF OTX2, which has the potential to regulate downstream targets that enhance RPE fate and block neural retina identity.

Conclusions: RPE lineage commitment is accompanied by widespread shifts in the regulation of RPE maturation genes and neural retina-associated TFs. An altered homeobox TF network at E5 promotes RPE fate and blocks neural retina identity, in part through enhanced OTX2 activity. These findings implicate OTX2 activity as a determinant of RPE lineage commitment and assess several indicators of RPE maturity in relation to neural competence.

TITLE: Zeaxanthin Protects Visual Function from A2E Damage

SESSION TITLE: Cell biology of retinal diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Cameron, E.J. Cameron, Optometry, Western University of Health Sciences, Pomona, California, UNITED STATES|

Commercial Relationships Disclosure: D Joshua Cameron: Commercial Relationship: Code N (No Commercial Relationship) | Elizabeth Cameron: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is a devastating eye disease affecting millions of people. One of the compounds that has been shown to contribute to AMD is the vitamin A derivative A2E (N-retinyl-N-retinylidene ethanolamine). Another compound, zeaxanthin, is a carotenoid that naturally accumulates in the retina. Supplements containing zeaxanthin as well as other carotenoids have been shown to improve vision and prevent progression of damage to advanced AMD in some studies. We wanted to see if zeaxanthin alone could protect vision loss associated with A2 in the zebrafish retina.

Methods: Adult zebrafish were maintained using standard conditions. All experiments were approved by our university IACUC. Baseline visual acuity was measured using the optokinetic response as previously described. One eye was injected with 50 μM A2E and the other eye was injected with 0.46 ng/μl zeaxanthin and 50 μM A2E. Visual acuity was assessed at weekly intervals after the injections. Statistical analysis was done using a paired t-test.

Results: Baseline visual acuities were consistent with previously published acuities in adult zebrafish. The average baseline acuity for the right eyes was 49 cycles/degree (c/d) and the left eyes was 47 c/d. A2E caused the visual acuity to slowly decline, whereas zeaxanthin protected the retina from the A2E damage. By the 2^{nd} week post injection, the A2E injected eyes had a nearly 7% decline in the visual acuity on average compared to the original baseline. Zeaxanthin protected the opposite eye. Most eyes even saw an increase in visual acuity relative to baseline.

Conclusions: Zeaxanthin protected visual acuity in zebrafish from A2E damage. Because the zebrafish retina regenerates, longitudinal studies are limited using this testing paradigm, so another model or system may be needed to study the long-term effects of these treatments.

ABSTRACT BODY:

Purpose: The accommodative response of the ciliary muscle (CM) is usually quantified from transscleral OCT images using thickness profiles. This approach does not capture the inward movement and change in length of the CM which is observed in real-time ultrasound images. We present a method to quantify the CM movement from transscleral OCT images acquired dynamically during accommodation.

Methods: A transscleral SD-OCT system operating at 1325 nm (Ruggeri et al, Biomed Opt Exp; 2016) was used to acquire OCT image sequences of the CM through the temporal side of the left eye of 3 young subjects (ages: 22, 25, 26 years) and two pre-presbyopic subjects (age: 45 years) during accommodation. The system is combined with an accommodation target to produce a monocular accommodation step stimulus during imaging. Each recording consisted of a sequence of 160 OCT images acquired over 6.2 seconds. The dynamic response of the CM was recorded in response to step stimuli of 2D and 4D for the young subjects, and 2D for the pre-presbyopic subjects. The system is synchronized with an extended depth SD-OCT system that simultaneously acquires images of the crystalline lens during accommodation (Ruggeri et al, Biomed Opt Exp; 2016). In-house software was used to segment the ciliary muscle and lens boundaries in each image. Procrustes analysis was used to register the sequences of CM images assuming that there is no change in CM volume during accommodation. The movement of the CM centroid and apex were then quantified. Changes in lens thickness were also assessed to confirm that all subjects accommodated.

Results: For a 2D stimuli, the change in lens thickness with accommodation ranges from 0.09 to 0.13 mm in the young subjects, and from 0.07 to 0.09 mm in the pre-prebyopic subjects. For a 4D stimulus, the change in lens thickness ranges from 0.13 to 0.20 mm in the young subjects. Figure A shows the change in contour of the ciliary muscle of a young subject (22 y/o) responding to a 4D stimulus. Figures B-F show the dynamic response of the position of the CM apex (left) and the time course of the change in the CM apex position and lens thickness (right) during accommodation.

Conclusions: We demonstrated the feasibility of quantifying the dynamics of the ciliary muscle movement from transscleral OCT images. The results show that the contraction of the cilary muscle in young and pre-presbyopic subjects is comparable.

ABSTRACT BODY:

Purpose: Recent single cell RNA sequencing studies identified the neurodegeneration-associated microglial phenotype (MGnD/DAM), typically observed surrounding cerebral amyloid plaques in Alzheimer's disease (AD) murine models. Further analyses revealed that the MGnD phenotype expression was regulated by the TREM2/APOE/microRNA-155 (miR-155) signaling pathway. However, this microglial phenotype has never been investigated in any retinal disease, including in the AD-afflicted retina. Mounting evidence demonstrates that the retina mirrors pathological changes that occur in AD brains. Here, we investigated populations of MGnD and their impact on the retinas of double transgenic APP/PS1 mouse models of AD in response to conditional knock-out of microglial miR-155.

Methods: $APP_{SWE}/PS1_{L166P}$, $miR155^{fl/fl}$, and $Cx3cr1Cre^{ERT2}$ mice were crossed to generate an Alzheimer-like mice genotype that can be targeted for conditional knock-out (cKO) of miR-155, specifically in microglia. Mice were sacrificed at 4 and 8 months of age. Retinas or whole eyes were extracted for analyses of retinal flat-mounts, cross-sections, protein homogenates (e.g., MSD, western-blot, mass-spectrometry), and isolated retinal vasculature.

Results: Immunostaining of retinal flat-mounts and cross-sections revealed a substantial population of $clec7a^{+}$ and $galectin\text{-}3^{+}$ MGnD in retinas from APP/PS1 mice. Targeting microglial miR-155 diminished MGnD and upregulated homeostatic microglial marker P2ry12; these findings were associated with anti-inflammatory cytokine profiles. Global proteome analysis by mass spectrometry identified enhanced PI3K-Akt signaling cascades due to microglial miR-155 inhibition. Importantly, such immune intervention protected tight junction integrity and reduced vascular amyloidosis in retinas of APP/PS1 mice.

Conclusions: Targeting neurodegeneration-associated microglia restored the homeostatic retinal-immune milieu in murine models of AD. Our data uncover more complex microglial phenotypes, distinct from the traditional M0, M1 and M2 microglia, and their tight link to the neurovascular unit integrity. The robust protective effects of microglial miR-155 ablation may shed light onto novel innate immune-based treatments for retinal degeneration and AD.

ABSTRACT BODY:

Purpose: Abnormal retinal neovascularization associated with various retinopathies can result in irreversible vision loss. Although the mechanisms involved in the occurrence of retinal neovascularization is still under investigation, increasing evidence suggests that aberrant Wnt signaling activated by reactive oxygen species (ROS), such as hydrogen peroxide (H_2O_2), participates in the pathogenesis of abnormal neovascularization. We utilized novel small molecule Wnt inhibitors to study the role of ROS regulating Wnt activity affecting tight junction formation and transcytosis of human retinal microvascular endothelial cells (HRMECs) in vitro.

Methods: HRMECs were treated with H_2O_2 for 30 minutes, H_2O_2 together with Wnt inhibitors or vehicle. Quantitative PCR (qPCR) analysis of Axin2 was utilized to assess the inhibitory profile of Wnt inhibitors and the activation profile of Wnt signaling upon H_2O_2 stimulation. Transepithelial endothelial Electrical Resistance (TEER) was used to evaluate cell tight junction formation. Transcytosis assay was used to explore whether Wnt signaling regulates transcytosis of HRMEC in vitro.

Results: Application of H_2O_2 to the HRMECs leads to increased Axin2 mRNA expression. In contrast to this, Wnt inhibitors attenuated H_2O_2 mediated Axin2 mRNA expression. Additionally, HRMECs treated with H_2O_2 presented altered tight junction formation and transcytosis that were regulated by Wnt inhibitors.

Conclusions: We found that increased Wnt signaling activity was detected in H_2O_2 treated HRMECs. The abilities of HRMECs to form tight junction and transcytosis affected by H_2O_2 treatment through upregulation of Wnt signaling in vitro. Moreover, these effects were effectively suppressed by small-molecule Wnt inhibitors.

ABSTRACT BODY:

Purpose: Phase 2b/3 study VISTA-1 and Phase 3 study VISTA-2 were designed to identify the optimal dose of mitochondrial reactive oxygen species (mtROS) scavenger Visomitin (SkQ1 ophthalmic solution) in patients diagnosed with dry eye disease (DED) and to identify potential primary endpoints for the pivotal study VISTA-3.

Methods: VISTA-1 and VISTA-2 were multi-center, double-masked, randomized, placebo-controlled studies, each comprising 5 visits over the course of 9 weeks. In VISTA-1, qualified subjects (n=451) were randomized 1:1:1 to receive low or high dose of Visomitin or placebo. In VISTA-2, qualified subjects (n=610) were randomized 1:1 to receive either high dose Visomitin or placebo. In VISTA-1, the co-primary endpoints were change from baseline to Visit 5 (Day 57) in central corneal fluorescein staining (Ora Calibra® Fluorescein Staining Scale) and the change in grittiness (Ora Calibra® 4 Symptom Scale). In VISTA-2, the co-primary endpoints were change from baseline to Day 57 in conjunctival fluorescein staining and in ocular discomfort (Ora Calibra® Ocular Discomfort Scale). Key pre-determined secondary endpoint included the change from baseline to Visit 3 (Day 29) in central corneal fluorescein staining.

Results: The co-primary endpoints of both studies were not met, but in VISTA-2 Visomitin demonstrated statistically significant superiority in the key pre-determined secondary endpoint of change from baseline to Visit 3 (Day 29) in central corneal fluorescein staining ($p<0.05$) relative to vehicle in a large sub-population defined by Schirmer's score. Similar statistically significant improvements in patients treated with Visomitin were observed in the VISTA-1 study. Importantly, in that sub-population both studies demonstrated statistically significant superiority of Visomitin ($p<0.05$) relative to vehicle in clearing of corneal fluorescein staining at Day 29.

Conclusions: Visomitin ophthalmic solution, a drug designed for protecting the ocular surface from oxidative stress at mitochondrial level, demonstrated statistically significant effects on clearing of corneal staining in both VISTA-1 and VISTA-2 studies, which is a highly clinically relevant result. These findings provide support for using clearing of corneal fluorescein staining as the primary endpoint in a forthcoming pivotal study (VISTA-3)."

ABSTRACT BODY:

Purpose: To evaluate the function and therapeutic potential of glutaredoxin (Grx) system, both glutaredoxin 1 (Grx1) and glutaredoxin 2 (Grx2), using Grx1/Grx2 double knockout (DKO) mice and the Grx activators as research models.

Methods: Two-month old Grx1/Grx2 DKO and age-matched wild-type (WT) mice were exposed to 20.6 kJ/m^2 UV radiation for 15 mins to induce cataracts. Mice were euthanized at 4 days post-exposure. The degree of the cataract and lens morphology were evaluated under a dissecting microscope. To further define the crosstalk between the Grx system and nuclear factor erythroid 2-related factor 2 (Nrf2) antioxidant pathway, Nrf2 and its downstream target proteins were examined by using Western blot analysis. Addtionally, we have developed a series of Grx modulators, molecules L1-L4, which are a family of pyridol-containing N-heterocyclic amines. The therapeutic potential of these Grx activators was evaluated using ex-vivo lens organ culture system.

Results: We found that UV radiation caused more severe anterior subcapsular cataract in Grx1/Grx2 DKO than that of WT mice. The opacity of the lenses in DKO mice, appeared to extend deeper into the cortical and even nuclear regions. Lenses of Grx1/Grx2 DKO mice contained significant lower levels of glutathione (GSH) and higher levels of glutathionylated proteins (PSSG), a marker for protein thiol oxidation. Deletion of Grx1 and Grx2 also decreased the expression of antioxidant enzyme transcription factor regulator, Nrf2, and its downstream antioxidant genes, including catalase, superoxide dismutase (SOD), and thioredoxin (Trx). Our ex vivo study showed that L1-L4 dose-dependently protected the lens from H_2O_2-induced opacification.

Conclusions: Grx1 and Grx2 gene deletion impairs Nrf2-dependent antioxidant response, causing elevation of oxidative stress that may increase the lens susceptibility to UV-induced damage. Grx activators can improve the redox homeostasis in the lens and prevent H_2O_2-induced cataract formation.

ABSTRACT BODY:

Purpose: Optic neuropathies are a major cause of irreversible blindness worldwide. While risk factors are known, the molecular progression that ultimately leads to neuronal apoptosis and blindness has yet to be fully elucidated. Recent studies show ephrin signaling as one of the most dysregulated signaling pathways in the pathophysiology of optic neuropathies. In this study, we hypothesize that neuropathic progression is initiated in part by the anachronic reactivation of repulsive ephrin forward signaling within the neural retina.

Methods: We used two optic neuropathic models, DBA/2J (D2J) mice which develop hereditary glaucomatous defects and the optic nerve crush (ONC) model in C57BL/6 (C57) mice. Semi-quantitative immunoblotting was used to assay the activation of several Eph receptors (Ephs) temporally in the D2J mice (2mo – 23mo) and ONC mice (24-, and 48-hr post-injury). Immunofluorescent (IF) staining was used to confirm the localization of activated Ephs within the retina.

Results: Our results show an age-dependent increase in the activation of several Ephs in the retina of D2J mice, with the majority of Ephs present in a hyperphosphorylated state at age 23mo. Interestingly, results show that EphA1, A3, A6, A7, B1, B2, and B6, are significantly phosphorylated as early as 2mo of age ($p=<0.05$). Additionally, several Ephs are activated within 24hrs of ONC with a significantly greater phosphorylation occurring after 48hrs.

IF images determined the localization of Ephs to the RGC layer. IF analysis further showed that D2J retinas exhibit an age-dependent activation of the EphB1 and B2 receptors throughout the inner retina. IF imaging of the ONC mice shows that EphA2, A3, A4, B1, and B2 become phosphorylated after injury (24hr) and that their spatial distribution is predominately in the inner retina.

Conclusions: These results indicate that Ephs activation and repulsive forward signaling may play a role in the neuropathic progression of both hereditary and traumatic optic neuropathy. These results demonstrate that Ephs can be observed as early as 2mo of age in hereditary optic neuropathy and 24hr in traumatic optic neuropathy. Together these studies underscore the need to explore this repulsive pathway in early optic neuropathies and it provides a glimpse of the number of receptors that are present in the retina of mice, and which are engaged in neuropathic states.

ABSTRACT BODY:

Purpose: Our team identified a missense mutation in ITM2B underlying a novel autosomal dominant retinal dystrophy with ganglion cell loss, inner retinal dysfunction and progressive retinal degeneration[1,2] but the function of ITM2B in the retina and physio-pathological mechanisms remains poorly understood. In a previous work, we obtained patient- and control-derived retinal organoids to model the disease recently showed that ITM2B may interact with mitochondrial proteins, implicated in oxidative stress in human retina. This project aims to investigate ITM2B in mitochondrial function and determined if it is altered in the disease.

Methods: Two inducted pluripotent cell lines (iPSC) derived from an affected and unaffected sibling were used. ITM2B mitochondrial immunolocalization in 60 days aged organoids was studied using two mitochondrial markers COX5B and ATP-β. Three sections per conditions were used. Furthermore, IPSC metabolism was analyzed in control and mutant cell lines using a mitostress seahorse assay, using 3 replicates per condition.

Results: ITM2B immuno-localizes with both COX5B and ATB-β mitochondrial markers in retinal organoids sections (figure 1). No difference was noticed between the mutant and the control organoids suggesting that mutant ITM2B does not modify the localization of the protein at this stage. Furthermore, a lower oxygen consumption rate was observed in mutant IPSC compared to control cells (figure 2), which highlight a mitochondrial defect in the mutant cell line, as well as a low capacity to respond to stress.

Conclusions: Our findings suggest a central role of the mitochondria underlying ITM2B pathogenesis in the retina. Further studies on IPSC using biochemical assays, respiratory function using sea-horse and enzyme assays are currently under investigation using as a model fibroblast and iPSC-derived retinal ganglion cells from dissociated mutant organoids and an isogenic control are currently underway and will help determine the function of ITM2B in the retina and elucidate its implications in pathology.

ABSTRACT BODY:

Purpose: Individuals receiving treatment for neovascular age-related macular degeneration (nAMD) can often develop the same pathology in the fellow eye. We describe the changes in volumes of OCT biomarkers for fellow eyes that do not convert to nAMD during treatment by segmenting OCT volume scans using an artificial intelligence (AI) system previously published by De Fauw et al. (2018).

Methods: This study included data from the Moorfields Eye Hospital AMD database for all patients that began treatment for nAMD between June 2012 and June 2017. This included AI-derived segmentation data from Topcon 3D OCT-2000 scans. Only eyes that did not convert by 24 months were used in this analysis. The biomarkers analysed include neurosensory retina (NSR), hyperreflective foci (HRF), retinal pigment epithelium (RPE) and drusen. The median relative change in volume from baseline (month 0) to specified time points of 4, 12, and 24 months was calculated as a percentage.

Results: At baseline our data included a total of 1347 non-converting fellow eyes. The NSR volume remained consistent over the follow-up period, reducing by 0.22% at 4 months and 1.45% by 24 months, relative to baseline. Similarly, RPE volumes reduced by 0.18%, 0.41% and 1.19% from baseline at 4, 12 and 24 months respectively. The volume of HRF changed more considerably, initially increasing by 10.10% and 15.35% at 4 and 12 months respectively, with an overall increase of 51.29% by 24 months. The drusen volume increased by 3.46%, 9.57% and 19.07% at 4, 12 and 24 months, respectively.

Conclusions: The volumes of NSR and RPE tissues in non-converting fellow eyes remained stable over the 24 month follow-up period. In contrast, HRF volume increased considerably, particularly in the second year of follow-up. The drusen volume demonstrated a steady increase over the follow-up period. Longitudinal quantitative analysis of retinal tissue volumes in fellow eyes of patients with nAMD, enabled by AI segmentation, may provide insights into OCT biomarkers that could predict disease progression.

ABSTRACT BODY:

Purpose: We report optical coherence tomography (OCT)-based retinal microanatomical findings at the posterior pole pre- and post-treatment of retinopathy of prematurity (ROP).

Methods: As part of BabySTEPS (STudy of Eye imaging in Preterm infantS), research OCT volumes from pre-and post-treatment of Type 1 ROP were analyzed. We assessed: vascular dilation and tortuosity from en face retinal vessel maps centered on the optic nerve; presence of extraretinal neovascularization (eNV) from en face and B-scans; and presence of macular edema and retinal layer thicknesses at the foveal center from B-scans.

Results: Of 42 eyes (21 infants) treated for ROP, 34 eyes received intravitreal bevacizumab at 33-37 weeks postmenstrual age (PMA) and 8 laser photocoagulation at 34-44 weeks PMA. OCT images were captured a mean±SD of 1±0.9 days pre- and 5±2 days post-treatment. Of 37 eyes with dilated vessels pre-treatment, 29 improved (narrowed) post-treatment and none worsened. Of 35 eyes with tortuous vessels pre-treatment, 22 improved (tortuosity decreased) and none worsened. eNV was visible in the posterior pole in 6 eyes; all improved post-treatment (Fig 1A,B). Macular edema was present in 12 eyes pre-treatment, persisted in 9 post-treatment, and 7 eyes developed macular edema post-treatment (Fig 1C,D). At the foveal center, the photoreceptor layer (mean difference(MD)= +12.08μm, p=.006) and choroid (MD =+34.12μm, p<.001) were thicker post-treatment (matched-pairs analysis).

Conclusions: This is the first comprehensive evaluation of the short-term effects of ROP treatment on retinal microanatomy. We found an increase in photoreceptor layer and choroidal thickness early post-treatment of Type 1 ROP with either bevacizumab or laser. eNV and vascular dilation and tortuosity predictably improved following treatment. In contrast, macular edema, an inner retinal phenomenon not associated with choroidal thickness [Mangalesh et al Ophth Ret 2020], had a variable response to ROP treatment with improvement, persistence or new-onset after treatment.

ABSTRACT BODY:

Purpose: Our goal is to translate our published mouse ocular trauma model to a human relevant species, tree shrews.

Methods: We exposed one eye of an anesthetized tree shrew to repeated bursts of overpressure air (20psi). Sham tree shrews were anesthetized and placed into the air blast chamber but were not exposed to the overpressure air. Two, four, or eight weeks post injury visual function was measured and tissue was collected for histology.

Results: We detected some axon degeneration within the optic nerve at the current parameters that appears to be regional. The level of damage was less than that detected in mice likely due to the greater musculature around the eye of the tree shrew and its load-bearing optic nerve head. We are able to measure ERGs and VEPs in this species.

Conclusions: We are able to induce blast-mediated indirect traumatic optic neuropathy in this human-relevant species. We expect that it will be a useful model for testing various therapeutic interventions.

ABSTRACT BODY:

Purpose: Microbial keratitis is a risk for all users of topical ophthalmic solutions due to microbial proliferation within the formulation upon accidental contamination of the product. Historically, preservatives added to the formulation are included to inhibit the growth of microbes introduced from repeated use. Preservative-free products are viable alternatives for individuals who are sensitive or have reservations about using products containing preservatives. To mitigate microbial growth without the use of preservatives, a multi-dose packaging system must present a physical barrier to contamination throughout the use period. This study evaluates the potential of microbial ingress into PG/HPG nano-emulsion (propylene glycol/hydroxypropyl guar preservative-free lubricant eye drop) presented in the NOVELIA® Multi-Dose package over 30 and 90-day use periods.

Methods: Two methods were evaluated per Note for Guidance on In-Use Stability Testing of Human Medicinal Products (CPMP/QWP/2934/99) to simulate consumer use. First, after four days of dispensing, the tip and air intake were submerged in a high level (10^6 CFU/mL) suspension of Brevendamonas diminuta and the tip actuated to simulate routine use of the product followed by a gross contamination event similar to falling into a heavily contaminated liquid. Following the 30-day simulation, the internal contents of replicate samples were evaluated for sterility per USP<71>. Second, after 90 days of dispensing to simulate routine use of the product, the internal contents of replicate samples at T0 and 6-month stability conditions of 25°/40%RH and 30°/75%RH were evaluated per USP<61>. A passing result of no microbial recovery indicates the packaging system prevented microbial ingress into the bottle while a failing result of microbial recovery indicates ingress into the packaging system.

Results: For all microbial challenge simulations, a passing USP<71> sterility result was obtained following the 30-day use simulations of the NOVELIA package. For all 90-day routine use simulations, no microbial recovery was observed over 6 months of monitored stability.

Conclusions: PG/HPG nano-emulsion when presented in the NOVELIA package with the PureFlow^{TM} 200 nozzle remains contaminate-free for up to 90 days. Users who suffer from dry eye disease now have the option of PG/HPG nano-emulsion preservative-free lubricant eye drops in a unique multi-dose package.

ABSTRACT BODY:

Purpose: Gene augmentation therapy with voretigene neparvovec (VN) has recently been made available for the treatment of patients with RPE65 mutation associated inherited retinal degeneration (RPE65-IRD). In a subset of patients treated with VN, development of atrophy has been previously reported. Here, we identify safety endpoints and imaging modalities that allow assessment of atrophy development following therapy with VN.

Methods: Single center longitudinal analysis of different imaging modalities prior and post treatment with VN in patients treated with VN for RPE65-IRD. Qualitatively analysed imaging modalities included colour fundus photography (CFP, Clarus 700, Zeiss) and confocal scanning laser ophthalmoscopy (Spectralis OCT, Heidelberg Engineering) with 30° and 55° blue light fundus autofluorescence (BAF), 30° and 55° near infrared imaging (IR) as well as spectral-domain optical coherence tomography (SD-OCT) of the macula.

Results: We analysed 18 patients treated with VN (27 eyes treated, 9 fellow eyes untreated). Median age at time of treatment was 28 years (range 7 – 39) and median follow up period was 6 months (range 1-21). Widefield, 55° IR images were available in all patients in good quality and allowed detection of postoperative atrophy development in 7 eyes of 5 patients (26 % of all treated eyes). Acquisition of BAF images was only possible in 3 patients and failed in 15 patients due to low levels of BAF signals. Macular OCT was available in all patients but failed to detect atrophy development sufficiently. Widefield CFP was available and detected atrophy in all patients. However, atrophy development was less obvious in CFP compared with 55° IR and mean time to detect atrophy development with CFP was 4 months (range 1-8) compared to 3.3 months (range 1-8) using 55° IR imaging.

Conclusions: Early detection of atrophy development and progression following VN treatment might be easily missed due to disease specific abnormalities (nystagmus, absent or low levels of BAF, altered retina). Widefield near infrared images appear superior for identification compared with other imaging modalities. Automated detection and quantification of lesion growth based on serial IR images over time is currently explored in order to allow for accurate quantitative analyses.

ABSTRACT BODY:

Purpose: Mitochondrial dysfunction is a hallmark of many human diseases. Our laboratory has previously shown that hyperglycemia, as seen in diabetes, and salt-induced hyperosmolarity, as seen in dry eye disease, lead to mitochondrial dysfunction and metabolic abnormalities in corneal (CECs) and conjunctival epithelial cells. We have further found that the insulin-like binding protein-3 (IGFBP-3) plays a key role in mitigating these responses. This study sought to expand on our prior results and investigate the effects of inflammation on mitochondrial and metabolic homeostasis in CECs.

Methods: Telomerase-immortalized human corneal epithelial cells were cultured in serum-free keratinocyte basal media. To establish an inflammatory environment, cells were treated with 50 ng/mL IL-1β for 24 or 48 hours. Metabolism was measured in real time using a Seahorse metabolic flux analyzer. Oxygen consumption rate (OCR), extracellular acidification rate (ECAR), and other metabolic parameters were quantified using a Seahorse XFp Cell Mito Stress Test kit. Total cell number per well was used for normalization. Protein expression for metabolic, mitochondrial and mitophagy-related proteins was assessed using western blot.

Results: At 24 hours, IL-1β had no effect on basal levels of OCR or ECAR. Maximal and spare respiratory were also unchanged. At 48 hours, IL-1β decreased ECAR (P=0.035), while basal OCR was unchanged. This shifted cells towards a more respiratory phenotype. There was a corresponding decrease in spare respiratory capacity (P=0.023). Interestingly, there was a decrease in non-mitochondrial oxygen consumption at 24 hours in the IL-1β group (P=0.003) which was not evident at 48 hours. There were no changes in ATP-linked respiration at either time point. Consistent with the decrease in non-mitochondrial oxygen consumption, IGFBP-3 also showed a drop in intracellular expression levels at 24 hours. This was associated with an observed increased in BNIP3L/NIX. At 48 hours, IGFBP-3 levels were similar in both treated and control groups, BNIP3L/NIX trended downward, while both mTOR and COVI X were increasing. PINK1 was unchanged.

Conclusions: These data confirm that inflammation triggers changes in metabolic and mitochondrial homeostasis in CECs. Further studies are needed to fully define the ability of CECs to respond and adapt to inflammatory stress.

ABSTRACT BODY:

Purpose: Retinopathy of prematurity (ROP) is the leading cause of blindness in children globally. A key hallmark of ROP is the intricate and underexplored metabolic dysfunction resulting from early hyperglycemia and nutrient/hormone deprivation, which leads to abnormal retinal development. Emerging evidence suggests nutritional interventions may prevent developmental pathology of the retina. However, our knowledge of the metabolic responses occurring during early ROP in premature infants remain very limited. Here we utilized a combination of proteomics and metabolomics to investigate the underlying retinal metabolic shifts in mice with postnatal hyperglycemia-associated retinal vessel growth delay, modeling early ROP.

Methods: Hyperglycemia was induced in neonatal C57BL/6J (WT) pups by intraperitioneal administration of streptozotocin (STZ) on postnatal day (P) 1 to P9. Quantitative mass spectrometry (MS) was utilized to perform proteomic (n=10) and metabolomic (n=12) analyses on pooled retina samples at P10. Bioinformatic analyses were used to determine protein-protein interactions and metabolic overrepresentation enrichment analysis to compare phenotypes. Both male and female mice were used. This work is compliant with ARVO’s Statement for the Use of Animals in Ophthalmic and Vision Research.

Results: In STZ- vs vehicle-control treated WT mice, 63 metabolic enzymes we quantitatively measured and 9 citric acid cycle (TCA) proteins were upregulated (1.2 fold-change [FC]+, $P<0.05$). 147 metabolites were identified with 19 downregulated and 47 upregulated (1.2FC-5FC) resulting from hyperglycemia. Enrichment analysis (Metaboanalyst 5.0) of the differentially expressed metabolites revealed key metabolic pathways including glycolysis/gluconeogenesis ($P<0.003$) and TCA cycle ($P<0.008$), along with purine and pyrimidine metabolism ($P<2.08E-7$, $P<1.47E-4$, respectively) were modulated resulting from postnatal hyperglyemia.

Conclusions: Our data indicate that hyperglycemia induces metabolic shifts in essential pathways necessary for normal retinal development. Further understanding and modulation of these pathways may prevent early ROP.

ABSTRACT BODY:

Purpose: Predicting intraocular penetration after systemic administration is an essential goal in ophthalmic drug discovery. Physicochemical and molecular dynamic properties of xenobiotics are the key elements of bio-intelligence which exist at blood-aqueous barrier. Quantitative structure-property relationship (QSPR) is being used to identify those molecular determinants to define penetration in aqueous humor (AH). Therefore, the proposed study aims to develop QSPR algorithm for penetration of xenobiotics in AH compartment in rabbits.

Methods: New Zealand albino rabbits of either sex weighing (1.5-2 Kg) were divided into five groups (n=12 each) and received intravenous cassette dosage of antifungals (n=8), calcium channel blockers (n=8), beta adrenergic receptor blockers (n=8), statins (n=7) and fluoroquinolones (n=10) at an equimolar dose of 0.1 µM/Kg. Rabbits were sacrificed using carbon dioxide gas followed by AH and blood samples were withdrawn at predetermined time 30, 60 and 120 min post administration. All AH and plasma samples were quantified using validated LC-MS/MS method. Log_{10} aqueous humor-to-plasma (AH/P) ratio were calculated and correlated with molecular descriptors at different time points. Multiple linear regression (MLR) model was derived with best correlated molecular descriptors using Discovery Studio (ver 17.2, Dassault Systemes, BIOVIA).

Results: Differential penetration of xenobiotics in AH compartment was observed. Penetration index (Log_{10} AH/P) was found to be negatively correlated with protein binding ($p<0.0001$), hydrophobicity index ($p=0.022$), and number of double bonds ($p<0.0001$) whereas positively correlated with topological polar surface area ($p=0.001$). MLR algorithm at 60 min generated using parameters viz., protein binding, hydrophobicity index, topological polar surface area and no. of double bonds showed best prediction ($R^2=0.874$, $Q^2=0.823$, RMSE=0.330, n=40, $p<0.001$) as shown in Figure 1.

Conclusions: For the first time, a QSPR algorithm generated based on controlled animal experiment using diverse set of molecules predicted the penetration of drugs in AH. Further the algorithm is under validation using external set to predict the AH penetration in human.

ABSTRACT BODY:

Purpose: Plasma rich in growth factors (PRGF) is a novel autologous ophthalmic therapy that contains a large number of biologically active agents that promote tissue regeneration, healing modulation and anti-inflammatory properties, among others. PRGF can be used in diverse formulations and has been tested in some cases of macular hole improving anatomic and visual outcomes. However, the molecular mechanisms of PRGF in the macular treatment is not fully understood. Here, we showed a preliminary study of modulation response of PRGF in a macular hole in vivo model.

Methods: A retinal break in the macula area were performed in New Zealand rabbits with an ACCURUS® Surgical System. At day 7 eyes were treated by injection of saline or PRGF in the macula hole. Electroretinography (ERG) measurements was performed at month of study. After sacrifice, eyes were collected and the sections were analyzed to IL1b, IL6, IL18, MCP1, proliferation and cell death markers.

Results: PRGF reduced cell death in the area around the damage without proliferation detection. The integrity of the retinal structure was better in PRGF-treated eyes. The glial cell response to damage was maintained and no significant differences were observed with PRGF treatment. There was an inflammatory response at the injury area detected by activation of IL1b, IL6 and MCP1. PRGF treatment reduced the expression of these markers. In addition, a reduction of IL18 was observed with respect to uninjured eyes, suggesting a possible activation of autophagy, as previously described.

Conclusions: The use of PRGF could be used as therapy in the surgical repair of macular holes reducing inflammation and maintaining the functionality of cells.

ABSTRACT BODY:

Purpose: Bacterial endophthalmitis can lead to significant vision loss even after prompt and proper treatment, partially due to the limited time of antibiotics' residence in the vitreous cavity. The purpose of this study was to evaluate the efficacy of a novel drug formulation, which is specifically designed for sustained intraocular release of moxifloxacin, in an experimental model of Escherichia coli (E. coli) – induced endophthalmitis.

Methods: Experimental endophthalmitis was induced in both male and female Sprague-Dawley rats. Animals received an intravitreal injection of approximately 10.000 colony – forming units (CFUs)/eye of the E. coli strain U13, which is susceptible to moxifloxacin. Six hours later, animals received a second intravitreal injection with either free or liposomal moxifloxacin (conventional vs. sustained release delivery respectively). A recently developed novel liposomal formulation of moxifloxacin was used. Clinical scores were evaluated in vivo with slit lamp biomicroscopy and direct ophthalmoscopy and animals were euthanized at 30 hours post treatment, eyes were enucleated and bacterial growth rate was assessed.

Results: An inoculum of 10.000 CFUs/eye of E. coli U13 resulted in conjunctival hyperemia, purulent exudations, iritis and miosed pupils (posterior synechiae) at 30 hours with mild to moderate inflammatory scores and an average bacterial load of 10^5 CFUs/eye. An intravitreal injection of liposomal moxifloxacin (1,6 μg/μl) 6 hours after the bacterial inoculation, resulted in significant reduction of the bacterial load at 30 hours to an average of 200 CFUs/eye.

Conclusions: Escherichia coli – induced endophthalmitis can be achieved in rats and is a highly reproducible model of experimental gram-negative bacterial endophthalmitis. Low inocula of E. coli strain U13 result in mild to moderate progress of the inflammatory signs, thus allowing pharmaceutical intervention. Liposomal moxifloxacin seems as effective as the free antibiotic at early time points. Further experimentation is currently ongoing in order to evaluate the efficacy of the novel moxifloxacin over a longer time frame.

TITLE: Keratocyte-specific ablation of Tgfbr1 gene manifests human keratoconus phenotype in mice

SESSION TITLE: Keratoconus and corneal biomechanics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Y. Wang, Indiana University, Bloomington, Indiana, UNITED STATES|

Commercial Relationships Disclosure: Yen-Chiao Wang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We previously showed that deletion of Transforming Growth Factor beta (TGF-β) signaling pathway via ablation of its type-2 receptor (TbR2) and Smad4 resulted in thin stroma phenotype similar to the human corneal ectasia disease known as keratoglobus. Herein, we tested the role of Tgfbr1 in the same scenario.

Methods: Transforming growth factor-b type 1 receptor (Tgfbr1) was designed to be conditionally knocked out (Tgfbr1kera-cko) from keratocytes. A novel triple transgenic mice: KerartTA;tetO-Cre;TbR1f/f, were administered with doxycycline (Dox) from postnatal day 1 (P1) to various developing stages including postnatal day 21 (P21), P56. Optical coherence tomography (OCT) was performed to examine corneal thickness and radius of curvature. Bulging appearance was measured and compared to the wild-type littermates (WT). We further compare corneal bulging among Tgfbr1Kera-cko, Smad4Kera-cko and Tgfbr2Kera-cko mice.

Results: The OCT scanning appeared a doom-shaped cornea in the WT but an ectasia cornea with hyper-reflectivity of the corneal stroma was observed in Tgfbr1kera-cko. Moreover, overall corneal thickness in Tgfbr1kera-cko becomes ~60% thinner than that of WT at P21. In the hematoxylin and eosin staining, we observed the uneven thinning and missing stroma in Tgfbr1kera-cko. Unlike Tgfbr2Kera-cko or Smad4Kera-cko which revealed 45-50% thinner stroma throughout the entire cornea, more severe phenotypes including the uneven thinning and disappearing stroma were observed in Tgfbr1kera-cko. Moreover, OCT imaging also revealed corneal bulging suggesting ectasia in Tgfbr1kera-cko mice.

Conclusions: The aforementioned corneal phenotypes in this Tgfbr1kera-cko triple transgenic mouse strain resemble keratoconus in human, which suggest that TGF-ß signaling pathway may play an important role in keratoconus pathophysiology and defect of Tgfbr1 may serve as a potential genetic cause of human keratoconus.

TITLE: Age-Related Macular Degeneration Associated Risk Locus Regulates Apoptosis in Retinal Pigmented Epithelium Cells

SESSION TITLE: AMD - Biochemical and molecular disease mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T.J. Kaczynski, M.M. DeAngelis, M. Farkas, Ophthalmology, University at Buffalo, Buffalo, New York, UNITED STATES|T.J. Kaczynski, M.M. DeAngelis, M. Farkas, Research Service, VA Medical Center, Buffalo, New York, UNITED STATES|

Commercial Relationships Disclosure: Tadeusz Kaczynski: Commercial Relationship: Code N (No Commercial Relationship) | Margaret DeAngelis: Commercial Relationship: Code N (No Commercial Relationship) | Michael Farkas: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Genome-wide association studies have identified a myriad of genetic loci and variants linked to age-related macular degeneration (AMD), yet our understanding of how these loci contribute to AMD is lacking. One such locus contains the coding TNFRSF10A and noncoding AC100861.1 genes. Within AC100861.1 lies a SNP whose minor variant is associated with AMD, but the function of the transcribed long noncoding RNA (lncRNA) and the effect of the SNP are not known. Considering that retinal pigmented epithelium (RPE) cell stress is a major AMD risk factor and that TNFRSF10A is involved in death receptor signaling, we investigated AC100861.1 function through the lens of apoptosis to understand how disruption of this locus may contribute to the RPE death associated with AMD.

Methods: TNFRSF10A and AC100861.1 RNA levels were quantified in donor macular RPE samples and cell line isolates via qPCR. Production of TNFRSF10A and AC100861.1 was manipulated within ARPE-19 cells via transfection of siRNAs or expression vectors. The extent of apoptosis was measured through TUNEL staining followed by flow cytometry. Protein levels were measured through western blot analysis. Transcript localization was assessed in ARPE-19 cells through RNA fluorescent in situ hybridization (RNA-FISH).

Results: Expression from TNFRSF10A and AC100861.1 were found to be downregulated in early-stage AMD, yet in more advanced AMD, expression from both genes was upregulated. TUNEL analysis indicated that knockdown of the AC100861.1 reduced susceptibility to apoptosis in ARPE-19 cells in response to cell stress, while AC100861.1 overexpression had the opposite effect. Conversely, knockdown and overexpression of TNFRSF10A elicited minimal changes in the apoptotic susceptibility. Neither knockdown nor overexpression of AC100861.1 affected TNFRSF10A protein levels. RNA-FISH data identified the AC100861.1 transcript as localized to the cytoplasm.

Conclusions: Our findings reveal an altered expression of TNFRSF10A and AC100861.1 in AMD-affected macular RPE, reflecting a dysregulation of this locus in the disease state. AC100861.1 appears to increase susceptibility to apoptosis, although this does not appear to be mediated through an alteration of TNFRSF10A protein levels. Since the AC100861.1 transcript is primarily localized to the cytoplasm it is more likely to influence processes there, yet the mechanism is not yet known.

ABSTRACT BODY:

Purpose: Complex transcriptional gene regulation allows for multifaceted isoform production during retinogenesis. Novel mRNA isoforms transcribed from a single locus can have unlimited potential to code for diverse proteins with different functions. In this study, we explored the CTBP2/RIBEYE gene locus and its unique repertoire of transcripts that are conserved among vertebrates.

Methods: We studied the transcriptional coregulator (CTBP2) and ribbon synapse specific structural protein (RIBEYE) using the developing chicken retina and developing human retinal organoid model systems, as well as in dissected post mortem adult human retina tissue. We performed comprehensive histochemical and multiomics analyses to pinpoint cell and developmental stage-specific expression of CTBP2/RIBEYE isoforms in each of these systems.

Results: We demonstrated that CTBP2 is widely expressed in retinal progenitors beginning in early retinogenesis, but becomes limited to GABAergic amacrine cells in the mature retina. Inversely, RIBEYE is initially epigenetically silenced in progenitors and later expressed in photoreceptor and bipolar cells, where they localize to ribbon synapses. Analysis of previously described ChIP-seq data suggests that differential binding of CRX and OTX2 transcription factors may play a role in isoform-specific expression patterns.

Conclusions: These analyses demonstrate that complex regulation of the multiuse CTBP2/RIBEYE locus is conserved during vertebrate retinal development. Our study also supports a mechanism for epigenetic regulation of this locus by modulating the binding of K50 homeodomain transcription factors.

ABSTRACT BODY:

Purpose: To understand the neural mechanisms underlying contact lens discomfort (CLD). In Phase 1, the effects of 6-month contact lens (CL) wear on corneal sensitivity in neophytes who became symptomatic (NS) for CLD were investigated. In Phase 2, corneal sensitivity changes in these NS subjects when CL wear was first ceased for 3 months (washout) and then restarted for an additional 3-month period (re-challenge) were studied.

Methods: The NS group were classified based on the Contact Lens Dry Eye Questionnaire-8 (CLDEQ-8) scores and comfortable wearing time during Phase 1. A control (C) group of non-CL wearers completed Phase 1 only. Corneal detection thresholds to cooling stimuli (approximately 22°C) were estimated at baseline (BL) by a modified Belmonte esthesiometer at study entry before fitting CLs and repeated at each month over Phase 1 (M1-M6) and during the Phase 2 washout period (WM1-WM3) and re-challenge period (RM1-RM3). Ten NS who completed both phases and 15 C subjects were included in the analysis. Repeated measures ANOVA and post-hoc tests with Bonferroni adjustment were used for data analysis.

Results: Initially, in Phase 1, there was an increase in thresholds (becoming less sensitive) in both groups. The threshold at M4 was significantly different than BL and M1 (both $p \leq 0.041$) for the C group, but the NS group diverged in an opposite direction in M4-6 (Figure 1). In Phase 2, the threshold for the NS subjects increased during the washout period (WM1-WM3) and was significantly higher at WM3 compared to M1, M2 and M4 (all $p \leq 0.046$). Thresholds in Phase 2 tended to decrease (become more sensitive) during the re-challenge period (Figure 2).

Conclusions: Corneal sensitivity in NS wearers tended to increase after an initial reduction and again after restarting CL wear following a washout period. These results demonstrate dynamic sensory responses to CL wear suggesting that altered sensory function may contribute to CLD development in these neophytes.

ABSTRACT BODY:

Purpose: Stereoacuity (stereo) improves monotonically with age during childhood. We investigated vision characteristics that may be associated with stereoacuity in non-strabismic children 3 to 9 years old with uncorrected refractive error.

Methods: Monocular visual acuity (VA, ATS4 Near Acuity Test; logMAR) and stereo (Randot Preschool Stereoacuity Test; arc sec) were assessed. Accommodative accuracy and cycloplegic refraction were measured using the Grand Seiko autorefractor. Accommodative responses were obtained while participants monocularly viewed 20/50 or 20/250 single letters (order counterbalanced) at 33 cm; accuracy was the difference between stimulus and response. Spherical equivalent (SE) measures of accommodation for both letter sizes were averaged for each eye. All sphero-cylindrical measures of cycloplegic autorefraction were converted to Power Vector notation (SE, J0, J45). Cycloplegic SE anisometropia (aniso) was calculated. For analyses, near VA, accommodative accuracy, and cycloplegic refraction from the eye with better near VA (or right eye if equal) were used. Stereo was log transformed for analyses. Associations between log stereo and near VA, interocular difference in near VA (IOD), cycloplegic SE, J0, J45, and SE aniso, and accommodative accuracy were explored using univariate analysis. Variables with significant associations ($p<0.10$) were included in a multivariate regression analysis. We report the log transformed beta-coefficients (β) and 95% confidence interval (CI) for the significant ($P<0.05$) variables from the multivariate analysis.

Results: Poorer log stereo was associated with worse near VA (β = 1.26, 95%CI: 1.02 to 1.50, $P<0.001$), greater IOD (β = 1.01, 95%CI: 0.58 to 1.42, $P<0.001$), greater SE aniso (β = 0.16, 95%CI: 0.08 to 0.25, $P<0.001$), greater J0 (β = 0.18, 95%CI: 0.09 to 0.28, $P<0.001$); and larger accommodative lag (β =0.06, 95%CI: 0.03 to 0.09, $P=0.001$).

Conclusions: Despite stereo improving with age, age itself was not significant after adjustment for other vision characteristics in young children. Of the variables evaluated, worse near VA and greater IOD in near VA had the strongest associations with worse stereo in young children with uncorrected refractive error. Worse stereo was also associated with higher magnitudes of uncorrected astigmatism, anisometropia, and accommodative lag, but to a lesser extent.

ABSTRACT BODY:

Purpose: Stem cells replacement therapy is becoming a promising pursued avenue for vision restoration in people with degenerative diseases of the outer retina. However, the integration and survival of the transplanted cells and the formation of fully functioning synapses remain a challenge. Our aim is to develop an in-vitro experimental paradigm which will allow us to address these issues while working under experimentally controlled conditions and avoiding immune system reactions faced in-vivo

Methods: As a first step, we are utilizing organotypic retinal cultures from transgenic rats expressing the calcium indicator GCaMP6f while monitoring the survival of the retinal ganglion cells (RGCs)using both extracellular recordings (multi electrode arrays), and calcium imaging at various time points.

Results: Our calcium imaging revealed robust spontaneous activity of the RGCs up to 72hrs, albeit decreasing throughout culturing period. We observe a decrease in the percentage of spontaneously active RGCs from 4.26% in acute preparations to 2.09% in 96hrs culture. Concurrently with these experiments, we have successfully established the system for extracellular investigation of RGC electrical properties incorporating flexible light pattern stimulation and multiunit analysis of the light induced responses over 60 channels. We were able to observe various RGCs types e.g., ON, OFF, ON-OFF identified by 1sec flashes applied at 0.2Hz. Moreover, through the well-known white gaussian noise stimulus combined with spike triggered averaging we generated RGCs receptive field maps obtaining the expected results both spatial (160μm FWHM) and temporally.

Conclusions: The experimental paradigm presented here can serve as a useful tool for the investigation of stem cell cells integration with the host retina, a main obstacle towards successful cell replacement based vision restoration approaches.

ABSTRACT BODY:

Purpose: To evaluate the depth of focus induced by a binocular combination of two different models of a new inverted meniscus intraocular lens (IOL), Art40 and Art70 (ArtIOLs, Voptica SL, Murcia, Spain). The two lenses improve the overall off-axis optical quality and induce different amounts of negative spherical aberration.

Methods: Six cataract patients were implanted bilaterally with Art40 and Art70 IOLs to induce low and high values of spherical aberration respectively. The surgery was performed first in the dominant eye with Art40 and a few weeks later in the fellow eye with Art70. As control group, nine patients were bilaterally implanted with a standard monofocal IOL based on aspherical biconvex optics. One month after the last surgery, best-corrected (CDVA) and uncorrected (UDVA) distance visual acuity (LogMAR scale) was measured at 5 m, 66 cm and 40 cm, using trial lenses of -1,5 and -2,5 D and SLOAN charts under photopic lighting conditions.

Results: The monocular CDVA was on average zero in the three groups (eyes implanted with Art40, Art70 models and standard IOLs). In the control group, it decreased rapidly to around 0.25 and 0.43 at intermediate and near distances. In the eyes with Art40, the deterioration was slower to 0.18 and 0.35, while in the eyes with Art70 those values were still better, 0.11 and 0.27. The binocular combination of Art40 and Art70 yielded mean CDVA values of -0.02, 0.01 and 0.12 at far, intermediate and near distances respectively. With the two models of the inverted meniscus lenses, small myopic residual errors were planned (-0.25 and -0.75 D for Art40 and Art70 respectively). As shown in figure, the mean values of binocular UCVA with ArtIOLs were -0.02, 0.01 and 0.06 and in the control group 0.02, 0.17 and 0.39 at 5 m, 66 cm and 40 cm. Inter-subject variability, estimated as standard deviation, ranged between 0.04 and 0.13.

Conclusions: In addition to the optical improvement in the periphery due to the inverted meniscus shape, the binocular combination of the two of ArtIOLs models (Art40 and Art70) improved significantly the useful range of distances. This combination resulted in spectacle independence for the patients without the compromise of halo or disphotopsias.

ABSTRACT BODY:

Purpose: People with vision impairment report low levels of health-related quality of life and lower physical activity. Physical activity is associated with improved physical health, decreased symptoms of depression and anxiety and improved quality of life. This pilot study assessed balance confidence and health related quality of life of people with visual impairment who report participating in regular exercise.

Methods: Subjects with self-reported visual impairment completed the International Physical Activity Questionnaires (IPAQ), Activities-specific Balance Confidence (ABC) Scale and SF-36 Health Surveys. The Mann-Whitney U test was utilized to measure differences between participants who participated in vigorous exercise compared to those who participated in moderate exercise.

Results: Sixteen participants had an average age of 50 years old; 75% were female. Visual impairment was reported as reduced visual acuity worse than 20/70 (81%) and/or reduced visual field (87.5%). In the past 6 months 12.5% reported having a fall. All subjects participated in regular physical activity, with 10 subjects participating in vigorous exercise at least 3 days per week, and 6 subjects participating in moderate exercise, including walking, at least 3 days per week.

There were no significant differences in reports of balance confidence between the group that participated in vigorous exercise than those who participated in moderate exercise. Those who participated in vigorous exercise were more likely to feel calm ($p=0.006$), more energetic ($p=0.0234$), and less worn out ($p=0.030$). The group who participated in moderate exercise reported accomplishing less as a result of emotional problems than the group who participated in vigorous exercise ($p=0.036$).

Conclusions: This pilot study of the impact of exercise on people with visual impairment showed improvements in feelings of emotional well being in people who participated in more vigorous exercise. Participants were already exercising regularly, which likely contributed to high balance confidence regardless of the level of exercise.

ABSTRACT BODY:

Purpose: To describe and analyze the frequency and antimicrobial resistance trends of pathogens that cause keratitis and conjunctivitis in a reference center in Mexico City over a period of 8 years.

Methods: A retrospective and observational study was performed with patients diagnosed with infectious keratitis and conjunctivitis through January 2012 - December 2019. The database of the Ocular Microbiology and Proteomics laboratory was analyzed to identify corneal and conjunctival scrapings obtained in this period. Microbiological data, stains and sensitivity/resistance antibiograms of isolated pathogens were analyzed. Mean and deviation were used for continuous variables; percentages for categorical variables. Difference between proportions of pathogens was compared with chi-squared test; resistance patterns were examined with trend analysis.

Results: From 2337 scrapings, a total of 1770 samples were positive cultures (75.7%). 91.5% of positive cultures had bacterial origin. Gram-positive isolates represented 86.4% (n=1399), Staphylococcus epidermidis was the most common pathogen. Gram-negative isolates embodied 13.6% (n=220) with Pseudomonas aeruginosa as the most common species. Fungi represented 7.3% (n=129) of positive isolates, the most frequent was Fusarium sp. Gram-negative bacilli (GNB) and coagulase-negative Staphylococcus (CNS) showed a positive trend throughout the study evaluated by annual percentage change. A significant increase in Kocuria spproportion was evidenced, representing 7.1% of total positive isolates (P=0.01). Resistance to moxifloxacin in S. epidermidis increased significantly (4.1% to 50.6%) along the 8-year study (P=0.02). Pseudomonas sp had an average sensitivity of 97.4% to ceftazidime through the study period.

Conclusions: Most frequently isolated microorganisms were S. epidermidis and P. aeruginosa in the group of gram-positive and gram-negative bacteria, respectively. An increase in the biodiversity of pathogens previously not involved in ocular infections, such as Kocuria sp, was evidenced. A 12-fold increase in resistance to moxifloxacin was noted as previously reported in gram-positive bacteria.

ABSTRACT BODY:

Purpose:

Children with ROP treated with laser tend to have higher incidence of high myopia compared to individuals treated with intravitreal bevacizumab (IVB); however, the incidence of amblyopia and abnormal binocular vision between these two groups has yet to be established. We examined the progression of refractive error and development of anisometropic amblyopia in children treated for ROP with IVB, laser, or IVB followed by laser treatment.

Methods:

We identified premature infants with ROP treated with IVB at Boston Children’s Hospital from 2011-2020 (n =40). We compared cycloplegic refraction and visual acuity data in these individuals to ROP babies treated with laser during the same time frame (n = 48). A subset of individuals treated with IVB also underwent additional treatment with laser (n = 18). We included cycloplegic refraction and visual acuity from 392 cumulative visits (median 3, range 2-13 per individual) over a median of 3.2 (range 0.5-8.5) years. We used a linear mixed effects model to compare risk factors for amblyopia including anisometropic refractive error, astigmatism, and strabismus between groups to determine differences in amblyopia risk and incidence.

Results:

There was a higher incidence of anisometropic amblyopia, as defined by a >0.1 logMAR difference between eyes, in those treated with both IVB and subsequent laser (P = 0.0243). A secondary analysis accounting for differences in ROP characteristics (zone, stage, and number of clock hours of affected retina) and number of laser spots showed ROP zone had a significant effect on anisometropia, with less anisometropia in individuals with zone 2 ROP. There was no effect on incidence of amblyopia. The number of laser spots used for treatment had no significant effect on anisometropia (P = 0.255) or astigmatism.

Conclusions:

Our data provide evidence that a subset of individuals requiring subsequent laser treatment following IVB therapy are more likely to develop anisometropic amblyopia. There was no effect of ROP zone, stage, and area of affected retina on the development of amblyopia in this sample.

ABSTRACT BODY:

Purpose: In pathological fundus images with maculopathies, the fovea position is usually located using Normative Anatomical Measures (NAM). This simple method relies on two conditions: that images are acquired under standard testing conditions (primary head position and central fixation) and that the optic disk is entirely visible on the image. However, these two conditions are not always met in the case of maculopathies, especially during fixation tasks. Here, we propose a new Vessel-Based Fovea Localization (VBFL) approach.

Methods: The spatial relationship between fovea location and vessel characteristics (density and direction) is learned from 840 annotated healthy fundus images and then used to predict the precise fovea location in new images. We evaluate our method on three different categories of fundus images: healthy (198 images from 21 eyes, each acquired with the combination of five different head positions and two fixation locations), healthy with simulated lesions (3564 images, with lesions ranging from 20 to 400 deg^2) and 89 pathological fundus images collected in AMD patients.

Results: For normal images taken under standard conditions, the NAM method yields a mean fovea localization error of 1.03° of visual angle (95% CI [0.80, 1.33]), which is slightly, but not significantly reduced by 37% with VBFL. For all conditions where the head is tilted to the side, the NAM estimation error is significantly multiplied by 4.42° (95% CI [3.45, 5.64]) while the VBFL method yields no significant increase in error prediction, with an average value of 1.21° (95% CI [0.93, 1.56]), representing a 73% reduction in prediction error compared to the NAM method. With simulated lesions, performance of the VBFL method decreases significantly as lesion size increases, with a mean error ranging from 0.83° at 20 deg^2 up to 2.3° at 400 deg^2. Overall, performance of VBFL remains better than NAM until lesion size reaches 200 deg^2. For pathological images, the error distribution with VBFL is not higher than for healthy data, suggesting that actual AMD lesions do not negatively affect the method's performance.

Conclusions: The vascular structure provides enough information to precisely locate the fovea in fundus images in a way that is robust to head tilt, eccentric fixation location, missing vessels and actual macular lesions.

ABSTRACT BODY:

Purpose: Refractive status and the optical quality of the eye impact visual acuity (VA) in a direct manner. Variability of VA measurements is often not provided, so that the confidence limits of the results are unknown. We examined the means and variability in VA measurements by inducing a positive defocus among normal subjects, similar to the defocus with retinal elevation in exudative eye disease.

Methods: Normally sighted adults (n=44, age = 32 +/- 13.01 yr, 21-71 yr) participated in a visual acuity task with refractive correction and three test conditions with the addition of plus lenses (0.75 D, 1.50 D, and 2.25 D). All subjects had best-corrected visual acuity of at least 20/20 and mean spherical error of 1.35 +/- 2.25 D. All subjects were consented and tested in a manner approved by the Indiana University Institutional Review Board, which adhered to the Declaration of Helsinki. Distance VA was measured and analyzed using a 4 alternative forced-choice task with tumbling E's displayed using custom Matlab software on a monitor calibrated for luminance ($85 cd/m^2$) and distance (11.2 feet), with whole pixel increments for the letter size changes. The E was presented in a 1-up-1-down staircase method starting from MAR of 2 arc min, in logMAR steps, providing VA mean and SD both from staircases data and fits to the psychometric function with a cumulative Gaussian distribution.

Results: As expected the subjects had increasingly reduced VA in conditions with higher plus lenses. Mean VA (76% fitted threshold) for refractive correction, +0.75 D, +1.50 D, and +2.25 D were 0.99 +/- 0.45 MAR, 1.75 +/- 0.9 MAR, 3.51 +/- 1.69 MAR, and 5.91 +/- 2.84 MAR, respectively, (paired t-test, $p<0.00331$ for all with Bonferroni correction). The coefficient of variation of all the sizes after the first reversal and the standard deviation of the fitted curve normalized by mean was significantly different across the test conditions (ANOVA, $F= 16.86$; $df=41$; $P<0.0001$ and F $F=73.27$, $df=41$; $P<0.0001$). The confidence limits of VA increased with higher plus lenses, e.g., a subject with no refractive error had a CI for MAR of 0.60 to 0.78 for 0 D but MAR of 3.39 to 4.15 for +2.25 D.

Conclusions: VA measurements in individuals with poor refractive/optical quality of eye have higher variability, leading to inaccurate assessment of visual function in clinical and research environments.

ABSTRACT BODY:

Purpose: It is known that in many subjects imaged with OCT systems, the cone photoreceptors can be resolved in the peripheral retina without adaptive optics (AO). However, there are no systematic studies investigating what factors influence the visibility of cones in OCT. We analyze how defocusing of the OCT beam influences the visibility of cones in the peripheral macula when imaged with 5 μm lateral imaging resolution.

Methods: Imaging was performed with SS-OCT in 4 healthy subjects. The accommodation was blocked with Tropicamide. Laser operating at 1.6MHz rate with λ = 1.06μm providing 6μm axial resolution was used. 3D data sets were acquired ~6° nasally from the fovea. The FOV was 5°×5°. Light beam diameter of 6.2mm at the cornea was used providing 5μm nominal lateral resolution at the retina. The beam focus was shifted from the photoreceptor layer in 31 steps over ±312 μm depth. 6 data sets were acquired at each defocus. Cones visibility was calculated from the radially averaged power spectrum (RAPS) of the en face images as the height of a Gaussian peak fitted to the RAPS after subtracting non-periodic component fit. The study was approved by the Bioethics Committee of NCU and adhered to the Declaration of Helsinki.

Results: In all imaged subjects, cones were visible in en face images of the inner/outer photoreceptor segments junction (IS/OS) when the beam was focused at that layer. As expected, the visibility of the cones was decreasing with increasing defocus. Focal shift of ~100μm (~1/3 of the thickness of the retina) causes substantial loss in the cones visibility. Cones visibility is shown as a function of defocus in Fig.

Conclusions: Cone photoreceptors of the peripheral macula can be visualized in non-AO OCT imaging with a nominal transverse imaging resolution of ~5μm provided that the device operator pays attention to the proper focusing of the imaging system. The proposed measure of photoreceptors visibility could be used for determining how much the beam size could be decreased to still resolve photoreceptors within the depth of focus reasonable for the device operator and without paralyzing the accommodation and dilating the pupil.

ABSTRACT BODY:

Purpose: Human embryonic stem cell-derived retinal pigment epithelial cells (hESC-RPE) are a promising cell source to treat age-related macular degeneration (AMD). Despite several ongoing clinical studies, a detailed mapping of transient cellular states during in vitro differentiation has not been performed.

Methods: Here we conduct single-cell transcriptomic profiling of a hESC-RPE differentiation protocol that has been developed for clinical use.

Results: Differentiation progressed through a culture diversification recapitulating early embryonic development, in which cells rapidly acquired a rostral embryo patterning signature, before converging towards the RPE lineage. At intermediate steps, we identified and examined the potency of a NCAM1+ retinal progenitor population and showed the ability of the protocol to suppress non-RPE fates. We demonstrated that the method produces a pure RPE pool capable of maturing further after subretinal transplantation in a large-eyed animal model.

Conclusions: Our evaluation of hESC-RPE differentiation supports the development of safe and efficient pluripotent stem cell-based therapies for AMD.

ABSTRACT BODY:

Purpose: Systemic hypertension (HT) is a risk factor for glaucoma, although the precise mechanism remains elusive. Whether or not HT has any effect on intraocular pressure (IOP) as a contributory factor remains controversial. In this preliminary study, we evaluated the cross-sectional changes of blood pressure (BP), IOP changes and functional retinal response in rats with chronic HT.

Methods: Female spontaneously hypertensive rats (SHR) and normotensive Wistar-Kyoto rats (WKY) aged 4 - 15 months were used. Non-invasive systolic BP and IOP measurements were determined under awake condition by the tail-cuff method and rebound tonometry, respectively. At 7 and 15 months of age, functional retinal response in retinal ganglion cells (RGCs) and cone photoreceptors of both SHR and WKY rats were determined by positive scotopic threshold response (pSTR) and photopic a-wave using full-field electroretinogram (ERG).

Results: SHR showed a sustained BP elevation throughout the studied period when compared with age-matched WKY controls. Interestingly, SHR displayed significantly lower IOP than WKY controls at 4 months (9.0 ± 0.1 vs 10.2 ± 0.1 mmHg), 7 months (9.6 ± 0.1 vs 10.3 ± 0.2 mmHg), and 15 months (9.8 ± 0.1 vs 10.8 ± 0.4 mmHg). At 7 months, pSTR reduced by 27% (N=4, $p<0.01$) in SHR (31.9 ± 1.1 μV) as compared to WKY rats (43.9 ± 2.1 μV). Similarly, a 35% reduction of pSTR was observed at 15 months (SHR: 13.5 ± 1.6 μV vs WKY: 20.9 ± 1.3 μV, N=4-6, $p<0.01$). In contrast, photopic a-wave was only found to be reduced in SHR at 15 months, but no difference was observed at 7 months, when compared with WKY controls.

Conclusions: The ERG data suggest that chronic HT leads to a progressive functional loss in RGCs and cone photoreceptors. In addition, impaired retinal responses observed in SHR may be mediated by an IOP-independent mechanism. Further longitudinal studies are warranted to investigate the precise relationship between IOP and the morphological and functional changes in retina over a prolonged period.

ABSTRACT BODY:

Purpose: Mutations in the clarin-1 (CLRN1) gene cause Usher syndrome type 3 (USH3), an autosomal recessive disorder leading to retinal degeneration, progressive hearing loss, and variable vestibular dysfunction. In our recent study, we showed that CLRN1 transcripts in the human retina are specifically expressed by Müller glia, suggesting that USH3 is a Müller glia-driven disease affecting photoreceptors (Xu et al., 2020). Although mouse models of USH3 display profound hearing loss, they maintain normal vision throughout their lifespan. To address this gap in our ability to study USH3 retinal disease, we successfully generated biallelic mutant CLRN1 pigs.

Methods: We generated CLRN1 mutant swine models at the National Swine Research and Resource Center (NSRRC, University of Missouri), using CRISPR/Cas9 genome editing. We designed two guide RNAs to target exon 1 and the downstream intron to disable the main CLRN1 isoform. mRNAs encoding Cas9 nuclease and the two guide RNAs were injected into zygotes, which were then transferred to surrogate females. The genotypes of the resulting piglets were determined by PCR and evaluated for insertions/deletions (INDELs) by Sanger sequencing. Natural history of disease onset and progression in USH3 pigs is ongoing, and includes fundus imaging, full-field ERG and SD-OCT.

Results: From the first round of embryo transfers we generated one male and one female founder pig with biallelic CLRN1 edits. The male has a 308 bp deletion on one allele and a 307 bp deletion with a 4 bp insertion on the other. The female has a 784 bp deletion and a 5 bp deletion. These edits are predicted to result in premature stop codons in the first extracellular loop of CLRN1, similar to the Y63X mutation found in USH3 patients, creating null alleles. We bred the founders, creating F1 offspring (5 males and 6 females) who inherited edited CLRN1 alleles as expected. Dark-adapted (scotopic) ERG analysis performed in the founders shows a decline in rod function at 6 months of age compared to 3 months.

Conclusions: We have successfully generated the first large animal model for USH3 by zygote injection with CRISPR/Cas9 and guide RNAs. The USH3 pig model represents a novel reagent with tremendous potential to answer basic science questions fundamental to our understanding of Müller glia-photoreceptor interactions, and to evaluate the efficacy of gene-therapy approaches to prevent blindness and deafness in USH3 patients.

ABSTRACT BODY:

Purpose: Mutations in the ubiquitous Pre-mRNA Processing Factors (PRPF3, 8, 31) constitute the second cause of autosomic dominant retinitis pigmentosa. The retinal pigment epithelium (RPE), crucial for photoreceptors survival, seems to be affected first in the Prpf3, 8 and 31 mutant mice. Indeed, circadian rhythms of photoreceptor outer segments (POS) phagocytosis and retinal adhesion are deregulated, suggesting a possible RPE circadian clock alteration. Moreover, all 3 models share aging RPE structural defects including cytoplasmic vacuoles, a sign of potential cellular stress.

Methods: RPE/choroid and retinal circadian clock gene and protein levels were studied along the light:dark cycle in Prpf31$^{+/-}$ and WT mice using qRT-PCR, immunoblots and immunohistochemistry. Impact of candidates expression silencing by siRNA on POS phagocytosis was explored in RPE-J cells. Oxidative and endoplasmic reticulum (ER) stresses were evaluated either by immunohistochemistry and qRT-PCR/immunoblots up to 18 months. Mitochondrial activity, glycolysis and fatty acids dependency were analyzed using the Seahorse technology on fresh RPE/choroid punches and on primary cultured peritoneal macrophages. Mice were also analyzed on a full body metabolic platform.

Results: Circadian clock activator complex members are overexpressed when phagocytosis starts earlier in mutant RPE/choroids, while repressors expression increases when the peak is attenuated. Strikingly, we confirmed the direct impact of the circadian clock on in vitro POS phagocytosis by RPE cells. Besides, proteins and lipids oxidation as well as proteasome activation, a sign of ER stress, increase with age. We observed mitochondrial respiratory and energy production defects in young mice associated with CoxIV and ATP synthase overexpression. With age, glycolysis and fatty acids dependency are decreased. In contrast and in accordance with the tissue-specificity of the phagocytic defect, no energetic metabolism failure is detected in the mouse body or in peritoneal macrophages.

Conclusions: Our results suggest a deregulated expression of the circadian clock in Prpf31$^{+/-}$ RPE that directly impacts their phagocytic activity. Ongoing studies explore members of the phagocytic and adhesion machineries. We here confirm the tissue-specificity of the pathogenicity, now pointing out global cellular stress and widespread metabolic deficiencies in Prpf31$^{+/-}$ RPE.

ABSTRACT BODY:

Purpose: Alzheimer's disease is a neurodegenerative disease where there is an accumulation of amyloid-beta plaques and neurofibrillary tangles of Tau protein within the brain. In this study, we aimed to determine if retinal changes preceded and are associated with cognitive decline in the TgF-344-AD transgenic rat model of Alzheimer's disease.

Methods: In TgF344-AD transgenic rats (n=7-12) and wild type littermate controls (Fischer 344 background, n=5-12), the following parameters were assessed at 3, 6, and/or 15 months: retinal function (electroretinography, ERG), retinal structure (spectral-domain optical coherence tomography, SD-OCT), and spatial memory (Barnes maze). At 16 months, rats were euthanized to acquire the brains and retinas, which were analyzed for amyloid precursor protein (APP) via western blot.

Results: Significant delays in ERG oscillatory potential (OP) implicit times were observed in TgF344-AD rats by 6 months ($p<0.001$), and significant delays in both OP and positive scotopic threshold response (STR) were observed at 15 months ($p<0.01$ for both). TgF344-AD rats also showed significant thinning of the inner and outer segments at 6 months ($p<0.01$), as measured by SD-OCT. Significant cognitive deficits (latency) were observed in TgF344-AD rats at 15 months of age ($p<0.01$). The retinas and brains of TgF-344 AD rats showed an increase in levels of APP.

Conclusions: Retinal function and structure changes were exhibited by the TgF344-AD transgenic rat model prior to an age-related cognitive decline. These results suggest that non-invasive retinal biomarkers may be useful in the diagnosis and staging of Alzheimer's disease. Future research will investigate retinal astrocyte number and morphology.

ABSTRACT BODY:

Purpose: To identify candidate systemic metabolic factors which may modulate CNV activity and thereby influence the treatment demand with intravitreal anti-VEGF injections (IAI) in subjects with neovascular AMD.

Methods: Cohort study on 46 patients with neovascular AMD, treated with anti-VEGF injections. The cohort was stratified by treatment need. One group (N=25) received regular IAI at intervals of 6 weeks or less, while still having signs of CNV activity (high frequency group – HF). The second stratum (N=21) included subjects with a treatment interval of 10 weeks or longer and having no signs of CNV activity (low frequency group – LF). Full ophthalmological profiling was performed and EDTA blood samples were collected. Metabolic factors were analyzed using Ultrahigh Performance Liquid Chromatography-Tandem Mass Spectrometry (UPLC-MS/MS). Welch's two sample t-test was performed on natural log-transformed data for statistical analysis. Metabolites reaching a $p<0.05$ were considered for further analysis as potential candidates.

Results: Both strata were well balanced regarding age (HF 78.4±8.14; LF 79.7±7.00 years), gender (HF 40% LF 61.9% female) and BCVA (HF 61.4±15.7; LF 65.0±12.4). Due to the group definition, central retinal thickness differed between HF and LF (HF 352.2±98.0 vs. LF 274.8±45.7µm. 34/899 biochemicals were differently regulated between HF and LF. 24 are up- and 10 are down-regulated in HF. Most of the upregulated metabolites belong to the lipid pathway (54%). Key candidates up-regulated in HF: sarcosine (95% CI HF 1.05-1.25; LF 0.74-1.08; ratio LF/HF 0.79; p=0.0024) and retinol (95% CI HF 1.03-2.06; LF 0.58-1.53; ratio LF/HF 0.68; p=0.0494). Key candidates down-regulated in HF: Glutathione, reduced (GSH) (95% CI HF 0.70-1.09; LF 0.99-1.54; ratio LF/HF 1.42; p=0.0296), 2,3-diphosphoglycerate (2,3-BPG) (95% CI HF 0.80-0.98; LF 0.94-1.10; ratio LF/HF 1.15; p=0.0181) and theanine (95% CI HF 0.28-0.47; LF 0.47-1.25; ratio LF/HF 2.29; p=0.0203).

Conclusions: nAMD subjects with higher and lower treatment need differed in several metabolic factors. Metabolites such as sarcosine and retinol, were elevated in the HF group and have pro-angiogenic potential. GSH, 2,3-BPG and theanine were increased in the LF cohort and may inhibit angiogenesis. In summary, systemic metabolic factors may influence treatment need through modulation of CNV activity.

ABSTRACT BODY:

Purpose: Human color vision is based on the mixing of neural signals from three types of cone photoreceptors that are sensitive to short (S cone), medium (M cone), and long (L cone) wavelengths of light. Although S, M, and L cones differ primarily in differences of photopigment, other structural differences might be detectable by imaging and potentially useful for distinguishing cone spectral types. To test, we extracted morphological features of thousands of cones from AO-OCT images to classify spectral types and validate against functionally classified results.

Methods: Adaptive optics optical coherence tomography (AO-OCT) volume images of 1°×0.8° at 3.8° temporal retina were acquired in three color normal subjects. Cones were first classified using the cone phase optoretinogram [1]. Morphological features of each cone cell were then extracted from the AO-OCT images: inner segment length (ISL), outer segment length (OSL), and reflectance diameters of the inner-segment-outer-segment junction (ISOS) and cone outer segment tip. We tested for statistical differences in morphological features between cone types and assessed whether these differences could identify spectral cone types using machine learning classifiers (K-nearest neighbors, support vector machine (SVM), and multilayer perceptron). Five-fold cross-validation was performed to evaluate classification performance in terms of precision, recall, and F1 scores.

Results: In the three subjects, 1,986 cones were evaluated (1,328 L cones, 542 M cones, and 116 S cones). The only notable difference we found between M and L cones in all three subjects was the longer (0.46μm) OSL of L cones, which was significant ($p<0.05$) in two of the subjects. Compared to M and L cones, S cones had a longer (3.6μm) ISL, shorter (3.8μm) OSL, and larger (0.71μm) ISOS diameter. These differences were significant for all subjects and consistent with histology [2]. While differences were too small to classify M cones from L cones with any classifier, S cones could be classified effectively using all three classifiers with SVM generating the best performance of 81.2±7.2% precision, 71.4±6.3% recall, and an F1 score of 75.7±5.1%.

Conclusions: Differences in S, M, and L cone structures are revealed in AO-OCT images enabling individual S cones to be distinguished from M and L cones.

ABSTRACT BODY:

Purpose: Inhibitor of differentiation 3 (Id3), a transcriptional repressor gene, over-expression effectively inhibited differentiation of corneal fibroblast to myofibroblast in vitro. This study examined the therapeutic potential of targeted AAV5-Id3 gene delivery into stroma to treat corneal fibrosis using an established rabbit model.

Methods: The study was approved by the institutional animal care and use committee and followed ARVO guidelines. Eighteen New Zealand White rabbits were divided into 3 groups. Only one eye of each rabbit was used. Eyes of group-1 (naïve) received vehicle (n=6); group-2 received AAV5-naked following alkali injury, (n-=6); and group-3 received AAV5-Id3 following alkali injury (n=6). Gene vector into stroma was introduced using an optimized reported topical method. Eyes were periodically examined clinically with the slit lamp microscope, stereomicroscope, pachymetry, tonometry, and in vivo confocal microscopy. Fantes and Modified Hackett-McDonald scores were used to record clinical findings. At the end of 4-weeks, rabbits were humanely euthanized, and corneas were collected for histological, immunofluorescence, and qRT-PCR analyses.

Results: Multimodal clinical imaging and ocular eye examinations revealed that AAV5-Id3 gene delivery significantly reduced corneal fibrosis compared to the AAV5-naked group ($p < 0.01$) without significant ocular manifestations. The qRT-PCR data indicated a significant reduction in mRNA levels of profibrotic genes; αSMA, fibronectin, collagen I, and collagen III (1.4-to-3.2-fold; $p<0.01$ or $p<0.001$) in eyes delivered AAV5-Id3 as compared to the AAV5-naked vector group. Histological and immunofluorescence data (H&E, Cd11b, and α-SMA staining) showed noticeably reduced inflammation and pro-fibrotic proteins levels in AAV5-Id3 therapy group compared to the AAV5-naked vector group. Histological and molecular data corresponds well with masked clinical exams.

Conclusions: Targeted AAV5-Id3 gene transfer into stroma effectively reduces corneal fibrosis in vivo in rabbits without gross clinical toxicity.

ABSTRACT BODY:

Purpose: To describe the largest cohort of eyes to undergo simultaneous XEN gel stent +MMC with the addition of Ologen collagen matrix to promote bleb formation and prevent fibrosis.

Methods: Surgical: In addition to ab externo, open-conjunctival XEN + MMC, an Ologen collagen matrix circle was cut in half, with one half positioned below and the other above the XEN stent. Standard post-operative care was followed.
Success Criteria: Success was defined as a >20% drop from preoperative IOP at 12-months without the use of drops, additional procedure (eg. needling), an IOP >21mm Hg at two consecutive visits, or catastrophic events (eg. NLP). Qualified successes were IOPs that met the reduction goal of >20% combined with the use of drops.
Statistics: A linear mixed-effects model was used to estimate change in IOP at each follow-up visit. In this model, age and sex were considered and a patient eye random effect was included for within-eye correlation.

Results: 47 eyes were identified, and 6 were excluded due to insufficient follow up/data or significant compounding factors. After controlling for age and gender, we have strong evidence of a non-zero average change in IOP from baseline and estimate a lower average IOP in all four post-baseline periods (Figure 1 and Table 1). The number of eyes meeting the >20% drop criteria was 82.50% (33/40), 87.80% (36/41), 73.53% (25/34), 70.00% (21/30), and 69.23% (18/26) at 1 month, 3 months, 6 months, 9 months, and 12 months post-operative, respectively. Only one eye required any additional procedures, and no patients had a IOP of >21mm Hg for 2 consecutive clinic visits. No patients had experienced catastrophic events during this time frame.

Conclusions: Some past studies have put the proportion of XEN fibrosis requiring revisions as high as 45%. However, most notably, only 1 eye in this cohort required an additional procedure to control fibrosis. Our numbers also show that the Ologen/XEN gel stent combination resulted in a statistically significant drop in IOP of -7.04 (CI: -9.34, -4.74, $p < 0.001$) from baseline. Thus, the use of Ologen collagen matrix with the XEN gel stent may help prevent bleb fibrosis and the need for revision without affecting XEN efficacy. Further studies with randomization may be required to help determine the true size of this impact in preventing fibrosis and the need for revision.

ABSTRACT BODY:

Purpose: Younger children with myopia benefit most from myopia control treatment(s), which function by slowing myopia progression until eye growth stabilizes. Estimation of myopia prevalence for individuals 5 to 17 years of age in the United States (US) population is of relevance to guide current and future public health responses. Coupling myopia prevalence cross sectional data demographics with the 2020 US Census data offers the opportunity to provide a more up to date estimate of myopia prevalence among children in the US and the subsequent demand on the eye care profession to effectively manage these children.

Methods: The retrospective data set of Kaiser Permanente Southern California pediatric eye exams (Theophanous, 2018) was used to determine the rate of myopia in the 5 to 17 year old age group. This rate was defined as the urban rate of myopia and was then extrapolated to the entire US population, where 80.7% of the US are living in similar urban environments according to the US Census. To estimate the remaining myopia prevalence in rural environments, the myopia odds ratio of 2.61 in urban to rural was applied (Rudnicka, 2016). This gives an estimate of the total myopia prevalence in the US.

Results: The urban myopia prevalence from the Kaiser paper for age 5 to 17 was 41.0%, and the calculated rural prevalence was 15.7%. Extrapolating these myopia prevalence percentage estimations to age-matched US census data, the total number of children with myopia in the US was estimated to be 19,512,708 in 2020 with nationwide myopia prevalence of 36.1%. Holden, 2016 predicted global myopia prevalence of all ages to be 33.9% in the year 2020. Current census data shows Utah, Texas, and Idaho have the largest population proportion of children in this age range; however, the more populous states (California, Texas, Florida, New York, and Illinois) have the greatest number of children, and therefore the greatest numbers of children with myopia.

Conclusions: Estimation of myopia prevalence using the 2020 US Census reveals that 39,025,416 eye exams are required annually across the United States for each child with myopia to be evaluated twice per year. There are approximately 70,000 optometrists and ophthalmologists in the US, and not all provide eye care for children. Each eye care professional would need to provide care to 278 children biannually to meet the current eye care requirements of children with myopia in the US.

Gonzalez-Ramos: Commercial Relationship: Code N (No Commercial Relationship) | Shrilekha Vedhakrishnan: Commercial Relationship: Code N (No Commercial Relationship) | Susana Marcos: Commercial Relationship(s);Code P (Patent):WO2012146811A1 | Eduardo Martinez-Enriquez: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Multifocal contact lenses (MCLs) are designed to provide near vision functionality in presbyopia. They rely on proper deployment of the multifocal power profile on the cornea and on optical interactions between the MCL and eye. Using custom-developed spectral Anterior Segment Optical Coherence Tomography (OCT) we evaluated the contact lens profile on eye, and potential conformity to the cornea.

Methods: OCT images were obtained on one eye of 13 subjects (age: 35.69 ± 13.83 y/o; Spherical error from -4.75D to +2.50D), with naked eyes and with MCLs on eye. All eyes were tested (5 repetitions) with the same MCLs: 1-Day Acuvue® Moist Brand MCL (Johnson & Johnson® Vision Care; -2.00D distance power; 8.4mm base curve; 14.3mm diameter) and three different additions: +1.25D (Low, L), +1.75D (Mid, M) and +2.50D (High, H). The OCT acquisition speed was 25000 A-Scans/s, the axial range was 7mm in depth, and the axial pixel size 3.4μm. Images were processed using custom routines for segmentation, fan distortion correction, 3D model construction, and surface fitting. The radius of curvature of the external surface of the MCLs (RCL) and the anterior surface of the naked cornea (RC) were obtained from spherical fitting within a 3-mm diameter central area (addition area) and within a 3-6 mm peripheral ring.

Results: RC ranged from 7.5 to 8.2 mm across subjects (8.02±0.22mm, on average). The shift in RCL in the periphery (by 0.55 mm on average) was consistent with the flattening produced by the negative MCL base power, and was constant independently of the corneal power of the subject. RC and RCL were correlated ($p<<0.005$) in the periphery for the three MCL additions ($r=0.87$, 0.84 and 0.82 for L, M and H adds, respectively) and also in the addition area ($p<<0.005$, $r=0.85$, 0.82, 0.78, L, M, H, respectively). The average RCL across subjects in the addition area was 8.37±0.31mm (L), 8.32±0.34mm (M) and 8.30±0.28 mm (H), and in the periphery was 8.59±0.30mm (L), 8.54±0.33mm (M) and 8.53±0.28mm (H), consistent with a relative central steepening, particularly for the higher add.

Conclusions: OCT provided with quantification tools allows to study the fitting of MCLs on eye in vivo. We found that, overall, soft MCLs conform to the underlying cornea, both in the central addition area and the periphery. However, the near central add is provided, as expected.

TITLE: Retroprosthetic Membrane Formation Following Glaucoma Procedures with Boston Keratoprosthesis

SESSION TITLE: Surgery & Wound Healing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Gulati, M.S. Cortina, D.P. EDWARD, Illinois Eye and Ear Infirmary, Department of Ophthalmology and Visual Sciences, University of Illinois at Chicago, Chicago, Illinois, UNITED STATES|

Commercial Relationships Disclosure: Shawn Gulati: Commercial Relationship: Code N (No Commercial Relationship) | Maria Cortina: Commercial Relationship: Code N (No Commercial Relationship) | DEEPAK EDWARD: Commercial Relationship(s);Code S (non-remunerative):Genentech;Code C (Consultant/Contractor):Takeda Pharma

ABSTRACT BODY:

Purpose: To assess features of retroprosthetic membranes (RPM) in Boston Keratoprosthesis (KPro) eyes undergoing diode cyclophotocoagulation (CPC) compared to glaucoma drainage implant (GDI).

Methods: We reviewed records for 193 eyes undergoing KPro surgery from 2007 - 2020. We compared prevalence of RPM, preoperative diagnoses, and visual outcomes following CPC vs. GDI.

Results: 36 eyes met inclusion criteria. 1 eye (3%) had primary CPC, 6 eyes (17%) had both GDI and CPC, and 29 eyes (80%) had GDI without CPC. KPro indication was similar in GDI/CPC group: non-inflammatory (61%, n=22), inflammatory (28%, n=10), and chemical injury (11%, n=4). RPM prevalence was 71% (5/7) in CPC vs. 15% (4/27) in primary GDI ($p<0.01$) (OR:4.8). Mean time from procedure to RPM formation was 3.9 years and similar between groups. At last visit, in CPC eyes, mean VA was 1.8 logMAR (5/7) and no light perception in others (2/7). In primary GDI eyes, mean VA was 1.2 logMAR (24/27) and ≤ light perception in others (3/27).

Conclusions: RPM occurrence in KPro following CPC was significantly higher than after GDI with poor VA outcome. Our data has implications for glaucoma intervention selection with KPro.

ABSTRACT BODY:
Purpose: Photoreceptors are the main detectors of light that relay visual information to the brain. Establishing proper photoreceptor connectivity during development is critical for proper transmission of visual information. Within the outer retina, photoreceptors synapse selectively to horizontal cells and bipolars. Cone photoreceptors synapse to the dendrites of horizontal cells and cone bipolars, whereas rods connect to the axon terminal of horizontal cells and to the dendrites of rod bipolars. Although the pattern of connections within the retina has been well-described, the molecular mechanisms that guide their selective wiring during development remains unclear.
Methods: We found a member of the Spectrin family, bII-spectrin to be highly expressed in the developing synaptic layer or OPL where photoreceptors are actively making synaptic connections to their respective partners. Based on the timing and location of expression, we set out to determine if bII-spectrin has a role in photoreceptor connectivity during development. To test our hypothesis, we crossed a floxed allele for bII-spectrin to the Chx10cre transgenic mouse line to conditionally remove bII-spectrin throughout the retina. We refer to this cross as bII-spectrin CKO. Next, we examined bII-spectrin CKO retinas for synaptic defects at various developmental ages.
Results: Our initial findings reveal disruption of bII-spectrin leads to synaptic defects in the adult retina. Specifically, rod terminals retract into the nuclear layer (i.e. ONL) and processes from horizontal cells and the dendrites of rod bipolars misproject into the ONL. Surprisingly, cone terminals do not retract nor do the dendrites of cone bipolars misproject into the ONL. Consistent with these findings, we find selective loss of pre- and post-synaptic protein expression in the rod synaptic layer but not the cone synaptic layer. Our data suggests that loss of bII-spectrin mainly affects the rod pathway and not the cone pathway. Developmental analysis of bII-spectrin CKO animals reveals that these synaptic phenotypes arise at early stages (i.e. P7-9) when rod synapse formation begins in the outer retina.
Conclusions: Our work supports a novel role for bII-spectrin in rod photoreceptor connectivity in the developing retina. Future work will focus on deciphering the cellular and molecular mechanisms of how bII-spectrin mediates synapse formation of the rod pathway and not the cone pathway.

ABSTRACT BODY:

Purpose: To create and assess Deep Learning methods for automated detection of locations and depth of vitreoretinal instruments in retinal surgery videos.

Methods: Surgical videos in vitro were recorded using a custom 3D eye model, vitrectomy instrumentation and an ophthalmic surgery microscope. Videos of instrument manipulation throughout the surgical field and at different instrument depths (far, intermediate and near to the retina) were acquired. Video frames (n=26,460) were extracted, labeled for instrument location and used to train Machine learning (ML) employing Convolutional Neural Networks (CNNs) including ResNet-18. The CNN model used was adapted with two outputs predicting the location and depth of surgical instruments.

Results: The resultant algorithm was validated with high reproducibility. The predictability of the algorithm for detecting locations and depth of vitreoretinal instruments in retinal images achieved a 99% accuracy.

Conclusions: Deep Learning methods achieved remarkable accuracy for detecting locations and depth of vitreoretinal instruments in retinal surgical videos and demonstrates the utility of real-time surgical video analysis to aid in vitrectomy. Despite current advances in vitreoretinal (VR) surgery instrumentation and visualization systems, VR surgery remains challenging for trainees and surgeons. Deep learning is an advanced subfield of artificial intelligence that may aid and improve surgical performance.

TITLE: Effect of hepatocyte growth factor-loaded collagen-PEG gels on corneal wound healing.

SESSION TITLE: Corneal Cell and Molecular Biology | Corneal Development

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Naranjo, G. Fernandes Cunha, D. Myung, Ophthalmology, Stanford Medicine, Stanford, California, UNITED STATES|

Commercial Relationships Disclosure: Andrea Naranjo: Commercial Relationship: Code N (No Commercial Relationship) | Gabriella Maria Fernandes Cunha: Commercial Relationship: Code N (No Commercial Relationship) | David Myung: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Corneal injuries can lead to infection, scarring, and significant vision loss. There continues to be a clinical need for better ways to facilitate rapid and phenotypically normal corneal wound healing after injury or disease. Numerous growth factors, including hepatocyte growth factor (HGF), are secreted by the native cornea following injury to facilitate healing. Recently, exogenous HGF has been shown to enhance corneal wound healing. Hydrogel matrices have also been shown to be a promising approach to providing a substrate that supports corneal healing. Here, we evaluate the sustained release of HGF from a collagen gel crosslinked in situ by a multi-functional PEG crosslinker.

Methods: A corneal epithelial cell (CEC) migration essay was performed comparing a negative control (plain medium) and a positive control (10% FBS) with PEG-collagen gel (8-arm PEG-N-hydroxysuccinimide) with and without HGF as well as free, soluble HGF. The cells were monitored for 24 hours and immunofluorescence was performed on the treated cells to evaluate for the expression of phalloidin, Ki-67, CD44, and ZO-1.

Results: CECs with HGF-loaded PEG-collagen gels were able to migrate faster and close wounds at a faster rate than the negative control, PEG-collagen gels alone without HGF, and free HGF. Immunofluorescence demonstrated no alteration in morphology as a result of the PEG crosslinker or HGF. An increase in proliferation markers was detected in the cells treated with the HGF-loaded PEG-collagen gels.

Conclusions: PEG-collagen hydrogels loaded with HGF improves corneal cell migration over collagen gels and HGF alone, and are a promising approach to enhancing corneal wound healing. Further work is merited to study this therapeutic construct in vivo.

ABSTRACT BODY:

Purpose: Photoreceptor axons terminate in the outer plexiform layer (OPL) of the retina, where they form synapses with the bipolar cells located in the inner nuclear layer (INL). The purpose of this study is to investigate the developmental expression of non-canonical Wnt signaling components in the OPL as potential mediators of circuit assembly in the outer retina.

Methods: Publicly available single-cell RNA sequencing (scRNAseq) data sets (GSE118614 and GSE138002) were analyzed for expression of non-canonical Wnt mediators, ligands, and receptors at various developmental timepoints in mouse and human retina. To validate expression of candidate genes, mouse (P6-P12 and adult, n=3), human fetal retina (human fetal week (HFW) 12-17, n=1) and human retinal organoid (HRO, n=3) sections were prepared using an RNase-free protocol and mRNA transcripts were detected using fluorescence in situ hybridization (FISH). FISH signal was quantified in the ONL and INL areas using the Find Maxima function on ImageJ. ANOVA analysis was performed to determine statistically significant changes between selected timepoints.

Results: Analysis of scRNAseq for 34 selected non-canonical Wnt pathway genes revealed 6 mediators, 3 Frizzled receptors and 4 Wnt ligands expressed in mouse and human retina during early OPL development. In both mouse and human retina, FISH confirmed expression of non-canonical Wnt mediators Dvl1, Celsr3, and Ryk in all nuclear layers, and of Vangl2 in the INL. The Wnt receptors Fzd3 and Fzd5 were expressed in the INL as early as P6 in mouse retina and GW17.4 in human fetal retina. The Wnt ligand Wnt5a was detected in the INL at P10 and showed a significant decrease in adults ($p<0.001$). Mouse Wnt2b co-localized with the amacrine cell marker ChAT. WNT10A expression was human-specific and restricted to the ONL (scRNAseq shows predominant rod expression).

Conclusions: Non-canonical Wnt signaling pathway components are expressed in the developing mouse and human outer retina during synaptic maturation of the OPL. Importantly, we found previously undescribed expression patterns (e.g., mouse Wnt2b in amacrine cells) and human-specific expression (e.g., Wnt10a in the ONL). This provides the basis for further studies to dissect the functional role of non-canonical Wnt genes in outer retinal development.

ABSTRACT BODY:

Purpose: Dry eye disease (DED) is a common ophthalmic condition with many underlying causes that are unified by the destabilization of the tear film. Despite current therapeutics, many patients with DED require additional treatments to provide comfort and reduce irritation. We recently identified a novel nonpolar lipid (NPL) isolated from the Harderian gland of the rabbit, not found in human meibum or tears, that increased tear film break up time (TFBUT) and improved ocular surface health in a rabbit model of DED. The purpose of this study was to determine the effect of this novel NPL on TFBUT in normal Beagle dogs.

Methods: In phase 1, a pilot study was performed to determine the dose of the rabbit NPL that prolonged TFBUT from baseline. Dogs (n = 2) were treated with a single dose of NPL (vehicle, 0.1, 0.5, 1, 3 and 10 mg/mL) in both eyes and TFBUT was measured at 1, 3, 6, 12 and 24 hours (h) post-treatment. In phase 2, dogs (n = 5) received one of three treatments (vehicle, 1 mg/mL or 3 mg/mL NPL) once in both eyes and TFBUT was measured at 6 and 24 h post-treatment. In phase 3, dogs (n = 3) received multiple doses (3 mg/mL NPL) over four days and TFBUT was performed at 6 and 80 h post-treatment. Semi-quantitative preclinical ocular toxicology scoring (SPOTS) was performed to document adverse events.

Results: In phase 1, topical treatment with NPL resulted in a dose-dependent increase in TFBUT in healthy Beagle dogs with the most optimal concentration of 3 mg/mL (mean change from baseline [MCB]: 1 h, +9.6 seconds [s]; 3 h, +8.1 s; 6 h, +3.4 s; 12 h, +3.0 s; 24 h, +7.7 s). In phase 2, topical treatment with NPL resulted in an increase in TFBUT with the 1 mg/mL dose (MCB: 6 h, +3.4 s; 24 h, 2.1 s) yet more pronounced increase in MCB TFBUT with the 3 mg/mL dose (6 h, +4.48 s; 24 h, +3.86 s). In phase 3, there was an increase in TFBUT measured at 6 h post-treatment with NPL (6 h, +3.3 s) that returned to baseline levels at 80 h post-treatment (80 h, +0.1 s). The topical NPL was well-tolerated with no pathologic changes detected using the SPOTS system.

Conclusions: Overall, treatment with a single dose of the NPL was well-tolerated at all doses tested and resulted in an increased TFBUT MCB that was most pronounced with the 3 mg/mL dose. Future studies will be focused on determining the effect of this NPL on stabilizing the tear film in murine and canine models of DED.

TITLE: Crystalline arrangement of S-cones in the central human retina

SESSION TITLE: Fundamental and Applied Psychophysics and Color Vision

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Schleufer, Graduate Program in Neuroscience, University of Washington, Seattle, Washington, UNITED STATES|S. Schleufer, V. Pandiyan, P. Bharadwaj, R. Sabesan, Ophthalmology, University of Washington, Seattle, Washington, UNITED STATES|

Commercial Relationships Disclosure: Sierra Schleufer: Commercial Relationship: Code N (No Commercial Relationship) | Vimal Prabhu Pandiyan: Commercial Relationship(s);Code P (Patent):University of Washington | Palash Bharadwaj: Commercial Relationship: Code N (No Commercial Relationship) | Ramkumar Sabesan: Commercial Relationship(s);Code P (Patent):University of Washington

ABSTRACT BODY:

Purpose: The topography of S-cones in the macula sets neural constraints for coding the short-wavelength spectrum of color vision. We aimed to characterize topography of S-cones in the central human cone mosaic and to what extent it deviates from a random arrangement.

Methods: In 2 subjects, cone sub-types were classified via Adaptive Optics Line-scan OCT and a bleaching stimulus of 660±10 nm. Regions of interest (ROIs) were classified at 1.5, ~4, and 10° eccentricity across the 4 cardinal meridians (12 ROIs each). S-cone spacing was quantified in ROIs containing >= 1000 cones using Density Recovery Profile (DRP). DRP measures the density of S-cones at regular intervals within some radius of other S-cones. These were binned by the average nearest-cone distance per ROI, such that DRP was calculated at 1-cone intervals within 18 arcmin. To compare with random arrangement, 1000 Monte Carlo (MC) simulations of each ROI were generated such that cone locations in the mosaic and number of S-cones were maintained, but positions of S-cones within the mosaic were randomized. Crystalline arrangement is indicated by bins at which the DRP for a true S-cone sub-mosaic is significantly lower than the MC distribution.

Results: Mean and std of total cones classified and quantity S-cones per ROI at each eccentricity were 2374±665, 1211±391, and 700±229 at 1.5°, ~4°, and 10° respectively. Density of S-cones decreased with eccentricity while their percentage increased (density (1/deg.2): [1.5°: 152.9 ± 43.3, ~4°: 74.8±22.3, 10°: 61.1±15.9], percent (%): [1.5°: 5.2±0.5, ~4°: 6.2±1.0, 10°: 8.3±2.0]). DRP was calculated for 14/24 ROIs (8, 5, and 1 ROI(s) at 1.5°, ~4°, 10°, respectively, with bin-widths (arcmin) 1.25±0.16, 1.87±0.17, and 2.25).. A low density of S-cones ($p < 0.05$) was observed in 13/14 ROIs within a 1-cone [1.5°: 8/8, ~4°: 5/5; 10°: 0/1] and 2-cone [1.5°: 7/8, ~4°: 5/5, 10°:1/1] radius. Beyond a 2-cone radius, the DRP was indistinguishable from random but for exceptions in two 1.5° ROIs (at a 6-cone and 12-cone radius respectively).

Conclusions: We find that S-cones are arranged with non-random crystallinity in the central human cone mosaic such that they avoid a 2-cone radius of one another. It is unclear whether this crystallinity changes with eccentricity. This finding departs from previous studies, likely due to their limited sampling, and has important implications for retinal development and color-coding retinal circuits.

Commercial Relationships Disclosure: Alfonso Jimenez-Villar: Commercial Relationship: Code N (No Commercial Relationship) | Bartlomiej Kaluzny: Commercial Relationship: Code N (No Commercial Relationship) | Ireneusz Grulkowski: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To develop a rheological model of the reaction of ocular structures to air-puff stimulation. To determine the relation between Young's modulus and the viscosity modulus according to different IOP values.

Methods: A cross-sectional observational study was performed in 20 healthy eyes from different Caucasian subjects (mean age 27.5 ± 3.5 y.o.; mean spherical equivalent refractive error: -1.1 ± 1.5 D). The reaction of the cornea, crystalline lens and the eyeball to an air jet was recorded by a SS-OCT ocular biometer integrated with an air puff chamber at two different IOP levels. First, in physiological normal IOP conditions and 2 hours after administration of IOP-reducing drops (brimonidine tartrate 0.2%). At the same time, the IOP values were measured with a Goldmann Applanation Tonometer. The displacement of each ocular component was used to design a rheological eye model and to calculate elastic (E) and viscosity (η) moduli from each component after applying an optimization process by a Marquardt-Lavenberg algorithm. Finally, moduli from the cornea were correlated with the IOP measurements.

Results: Fig. 1 demonstrates the rheological model of ocular structures' dynamics during air-puff stimulation. The cornea, crystalline lens and eyeball movement are described by Maxwell and Kelvin submodels to determine the viscoelastic behavior of each component. Moreover, a mass term was included for the lens and for the eye to simulate the lens wobbling and eye retraction. Fig. 2 represents the predicted theoretical deformations based on experimental data. Regarding the mechanical properties of the cornea with the IOP, higher correlation between E and IOP was found although no statistical significance was detected (corneal E: Pearson's R = 0.7097; corneal η: Pearson's R = 0.5869). Additionally, it was observed that η was strongly linearly dependent on the E (Pearson's R = 0.8552).

Conclusions: SS-OCT biometers integrated with air puff subsystems enable to image the dynamics of the cornea, crystalline lens and the whole eye. Therefore, OCT can help to develop rheological eye models which might predict the mechanical behavior of different ocular structures. The determination of the elastic and viscosity moduli from cornea and lens can be used to predict correct IOP values in future studies. In particular, both, E and η from the cornea were linearly dependent on the IOP level.

ABSTRACT BODY:

Purpose: Toll-like receptor (TLR) acting as lipopolysaccharide (LPS) sensor is involved in recognition of and response to endotoxin mediated infections. Their activation contributes to uveitis leading to stimulation of signaling events that include expressions of various cytokines such as TNF-α. The mainstay for the treatment is steroids, which are substrates for P-gp transporters, and on topical application, would be effluxed, leading to insufficient therapeutic levels in aqueous humor (AH). Hence, this study evaluated alternative P-gp sparing molecules that act via similar anti-inflammatory pathways to control inflammation.

Methods: Topical dapsone and nimesulide (0.1%) were formulated aseptically and evaluated in endotoxin-induced uveitis (EIU) Wistar rat model in comparison with topical prednisolone (1%). Rats received 0.1 ml saline containing 200 µg LPS through hindpaw, with three times a day (TID) topical instillation of 10 µl vehicle, nimesulide, dapsone and prednisolone (Table 1) in their respective groups. 30 µl of AH was collected for protein extravasation analysis and TNF-α levels.

Results: Results showed topical nimesulide significantly reduced AH TNF-α levels in EIU (Nimesulide) group (14.07±5.36 ng/ml) as compared to EIU (Vehicle) group (40.6±5.51 ng/ml). It also reduced protein leakage in AH of EIU (Nimesulide) group (8.37±2.87 mg/ml) as compared to control (18.48±2.13 mg/ml). The topical dapsone resulted in a significant decrease in total protein concentration of AH in EIU (Dapsone) group (11.44±0.93 mg/ml) when compared to EIU (Vehicle) group (22.5±2.06 mg/ml). Moreover, 0.1% dapsone topical instillation also decreased TNF-α levels in AH of EIU (Dapsone) group (18.4±2.26 ng/ml) when compared to EIU (Vehicle) group (26.49±3.66 ng/ml). While prednisolone administered (TID) in EIU showed non-significant reduction in total protein as well as TNF-α levels in AH.

Conclusions: For the first time, sterile topical nimesulide and dapsone formulations were developed and were found to be effective in modulating TLR by reducing inflammatory markers (TNF-α) and vascular leakage in AH of rats when compared to prednisolone. Therefore, this study showed that molecules that are P-gp sparing could be a better option for targeting TNF-α pathway for their utility in uveitis.

ABSTRACT BODY:

Purpose: The gene Serpinf1 encodes for Pigment Epithelium-Derived Factor (PEDF), which protects photoreceptors from cell death. The Serpinf1 null mouse exhibits normal retinal function; however, PEDF deficiency increases retinal degeneration susceptibility in the rd10 mouse. CRX is a transcription factor that regulates expression of several photoreceptor specific genes, including opsins and phosphodiesterase. This study aims to explore whether regulation of CRX activation is one mechanism by which PEDF exerts photoreceptor survival.

Methods: Serpinf1$^{-/-}$, Serpinf1$^{+/-}$ and Serpinf1$^{+/+}$ mice at 3 months of age were used. Mouse retinal explant cultures we prepared and treated with recombinant human PEDF. Zaprinast (a PDE inhibitor) was added to induce photoreceptor death. Photoreceptor cell death was determined using PSVue-550, a visible fluorescent probe for phosphatidylserine detection on the surface of cells. Subcellular distribution of CRX, PDE6A and pan-acetylation was detected by immunofluorescence. The transcriptional levels of Crx, Pde6a, Rho, Opn1mw and Opn1sw were assessed using qPCR.

Results: PEDF treatment induced the expression of Crx and its regulated genes Pde6a, Opn1mw and Opn1sw. PEDF also enhanced the CRX immunoreactivity in the nuclei of photoreceptors. In contrast, the nuclear CRX immunoreactivity was suppressed in photoreceptors from retinas of Serpinf1$^{-/-}$ mice deficient of PEDF. PDE6A immunoreactivity also decreased in Serpinf1$^{-/-}$ photoreceptors compared to those from Serpinf1$^{+/+}$ mice. Histone acetylation was detected in discrete photoreceptors in Serpinf1$^{+/+}$ but was undetectable in the Serpinf1$^{-/-}$ retinas. Zaprinast-induced photoreceptor death was more pronounced in Serpinf1$^{-/-}$ retinal explants than in wild type controls. PEDF pre-treatment prior to the zaprinast treatment improved photoreceptor survival and enhanced CRX immunoreactivity in both Serpinf1$^{-/-}$ and Serpinf1$^{+/+}$ retinal explants.

Conclusions: The findings imply that PEDF activated the CRX-associated transcription factor network. They provide a novel insight linking extracellular PEDF to nuclear CRX during photoreceptor survival.

TITLE: LXB_4 regulation of microglia responses in ocular hypertension induced neuropathy

SESSION TITLE: Neurodegeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Maurya, S. Karnam, L. Yang, J.G. Flanagan, K. Gronert, Herbert Wertheim School of Optometry, University of California Berkeley, Berkeley, California, UNITED STATES|

Commercial Relationships Disclosure: Shubham Maurya: Commercial Relationship: Code N (No Commercial Relationship) | Shruthi Karnam: Commercial Relationship: Code N (No Commercial Relationship) | Lily Yang: Commercial Relationship: Code N (No Commercial Relationship) | John Flanagan: Commercial Relationship: Code N (No Commercial Relationship) | Karsten Gronert: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The neuroprotective role of specialized pro-resolving mediators such as lipoxins (LXA_4 and LXB_4) are lost during retinal insult, including ocular hypertension (OHT). Using a silicone oil (SO) based model of OHT induced neuropathy and LXB_4 treatment, we aimed to better understand the novel mechanisms involved in LXB_4 mediated neuroprotection.

Methods: To discover novel targets for LXB_4 homeostatic function, we performed single-cell (SC) transcriptomics of retinal cells after treating the healthy C57BL6/J mice (n=4 retina) with LXB_4 by intraperitoneal (IP) injection and topical eye drops. For inducing OHT, we used the established SO model that causes stable and sustained OHT. To validate and explore novel targets of LXB_4 under OHT conditions, mice (n=3) were treated with LXB_4 by IP and topical eye drops every other day from day 7 to day 28. Gene expression of potential targets was analyzed by qPCR.

Results: LXB_4 treatment-induced changes in transcriptomic profile in a limited number of retinal cell types in healthy mice. Unexpectedly, LXB_4 treatment markedly changed gene expression for a distinct pathway in microglia. These selected genes were C5ar1, Clec4a2, Entpd1, Il6ra, and CD37, which are components of the new microglia 'sensome' paradigm, responsible for regulating the microglia phenotype switch in stress/immune responses. LXB_4 treatment downregulated these sensome genes by ≥2-fold ($p < 0.05$). Further, we analyzed the expression of LXB_4-regulated sensome genes under OHT conditions at 4 and 8 weeks. Notably, expression of the microglia sensome gene Clec4a2 was elevated at 4 weeks by 1.63-fold (n=4, $p<0.05$) and at 8 weeks by 1.84-fold (n=3, $p<0.05$). Consistent with scRNA results from healthy mice, LXB_4 treatment in mice with the OHT reduced Clec4a2 expression compared to sham treatment.

Conclusions: Our data identify a novel cellular target and potential mechanism of action for the neuroprotective LXB_4, namely by regulation of microglial sensome gene Clec4a2. The microglia sensome is an essential mechanism for directing microglia activation, an early event in glaucoma pathogenesis. LXB_4 regulation of the microglia sensome is of interest given the homeostatic and protective actions of lipoxins in rat and mouse models of OHT-induced glaucomatous injury.

TITLE: The RAP study, Report 6: Quantification of exudative biomarkers in neovascular age-related macular degeneration (nAMD) using deep learning, a type-based comparative analysis.

SESSION TITLE: AI and Retina 2

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: B. Haj Najeeb, B. Gerendas, H. Bogunovic, U. Schmidt-Erfurth, Medizinische Universitat Wien, Wien, Wien, AUSTRIA|

Commercial Relationships Disclosure: Bilal Haj Najeeb: Commercial Relationship(s);Code C (Consultant/Contractor):RetInSight | Bianca S Gerendas: Commercial Relationship(s);Code C (Consultant/Contractor):Roche;Code C (Consultant/Contractor):Novartis;Code C (Consultant/Contractor):DXS | Hrvoje Bogunovic: Commercial Relationship(s);Code C (Consultant/Contractor):Apellis | Ursula Schmidt-Erfurth: Commercial Relationship(s);Code C (Consultant/Contractor):Roche;Code C (Consultant/Contractor):Novartis;Code C (Consultant/Contractor):Genentech;Code C (Consultant/Contractor):RetInSight;Code C (Consultant/Contractor):Boehringer

ABSTRACT BODY:

Purpose: To quantify five exudative biomarkers in eyes with treatment-naïve macular neovascularization type 3 (MNV3) using deep learning and compare the outcomes with those of eyes with MNV 1 and MNV2.

Methods: 34528 optical coherence tomography scans of 457 eyes with nAMD consisting of 281 (250 unifocal, 31 multifocal) eyes with MNV3, 55 eyes with MNV2 and 121 (91 non-polypoidal, 30 polypoidal) eyes with MNV1 were included. The volumes of intraretinal (IRF) and subretinal fluid (SRF), pigment epithelial detachments (PED) and hyperreflective foci (HRF) in nanoliters (nl) and retinal thickness (RT) in micrometers (µm) were quantified by validated deep learning algorithms for each (sub)type of MNV.

Results: The analysis of MNV types shows that MNV3 had the highest mean (± standard deviation) of IRF volume in the central 1, 3 and 6mm: 67±61, 216±196, 291±289nl, and greatest mean of RT 418±104, 391±62, 356±49µm, followed by MNV2 with 31±54, 79±145, 105±216nl (IRF), and 380±80, 372±50, 338±39µm (RT), $p<0.05$. Also, MNV3 presented with the biggest mean of HRF volume 5±5, 32±24, 79±69nl, followed by MNV1 3±3, 22±19, 51±52nl, $p<0.05$. MNV3 revealed the lowest mean of SRF volume 15±35, 72±133, 215±382nl, whereas MNV1 showed the greatest mean of SRF volume 28±38, 168±193, 492±583nl, $p<0.05$, and the biggest mean of PED volume 84±94, 495±583, 667±855nl, $p<0.05$.

The analysis of MNV1 subtypes (polypoidal vs. non-polypoidal) shows that the polypoidal subtype had a significantly higher mean of PED volume in all areas, greater mean of RT in the 3 and 6mm areas, and bigger means of SRF and HRF volumes in the 6mm area only. The mean of IRF volume was not significantly different between both subtypes. In addition, the analysis of MNV3 subtypes (multifocal vs. unifocal) shows that the multifocal subtype revealed significantly higher means of IRF and HRF volumes in all areas and a greater mean of RT in the 3mm area only. No significant mean differences of SRF and PED volumes were observed.

Conclusions: Using deep learning to quantify exudative biomarkers in different MNV types provide clinicians with unprecedented quantitative and topographic details. These pathomorphological differences allow a better understanding of the clinical manifestation, natural course and prognosis of each (sub)type of MNV in nAMD.

ABSTRACT BODY:

Purpose: To present the results of in vivo visualization and quantification of Retinal Ganglion Cells (RGCs) in mice using Temporal Speckle Averaging Optical Coherence Tomography (TSA- OCT).

Methods: We used a custom-built mouse retinal Scanning Laser Ophthalmoscopy / Optical Coherence Tomography (SLO/OCT) system to acquire non-invasive serial OCT volumes with corresponding SLO intensity and fluorescence data to provide input for Temporal Speckle Averaging (TSA) OCT volume processing. The TSA-OCT processing allows reduction of the speckle contrast and enhancement of the cellular retinal morphology probed by OCT. To showcase the performance of this technique, two mouse lines with fluorescently labeled RGC (based on RGCs transcription factor Brn3b-mCherry and Isl2-GFP) were used.

Results: TSA-OCT greatly enhanced the image quality of the Retinal Nerve Fiber Layer (RNFL) and enabled RGCs visualization (see Figure). While a single OCT volume doesn't allow visualization of RGC, the application of TSA-OCT opens the possibility of non-invasive probing of RGCs. Use of mice with fluorescently labeled RGCs allowed mapping of RGC position using a fluorescent SLO system, providing direct comparison with RGC somas visualized by TSA-OCT. Additionally fluorescent labeling of the RGC helped with further validation of TSA-OCT imaging by histology providing one-to-one mapping between in vivo and ex vivo images of RGC.

Conclusions: In these studies, we used a novel TSA-OCT to visualize mouse RGCs in vivo. We did not need Adaptive Optics, suggesting that speckle contrast rather than insufficient lateral resolution is a limiting factor in using OCT for non-invasive in vivo [SJK1] evaluation of cellular retinal morphology in mice. Our ability to visualize and follow RGCs in vivo using non-invasive imaging method should allow a reduction in the number of animals needed in future studies. These results open doors for efficient in vivo monitoring of cellular morphology in animal models of glaucoma during disease progression and therapeutic innervation.

ABSTRACT BODY:

Purpose: To analyse the association between retinal fractal dimension (FD) and all-cause dementia in a large ethnically and socioeconomically diverse cohort in London, United Kingdom.

Methods: The AlzEye project is a retrospective cohort study linking ophthalmic imaging of all patients attending Moorfields Eye Hospital aged ≥ 40 years with secondary care Hospital Episodes Statistics Admissions data between January 1st 2008 and March 31st 2018. Dementia diagnoses were coded using the International Classification of Diseases, 10th revision. Retinal fractal dimension was extracted from macular-centered colour fundus photographs using the Vascular Assessment and Measurement Platform for Images of the Retina. Multivariable linear regression was used to examine the association between retinal FD and dementia.

Results: Among 96,995 patients, 4353 had a diagnosis of dementia: 1222 with AD, 885 with VD, 229 with mixed disease and 2017 with unspecified dementia . Compared to those without dementia, patients with dementia were older (79.7 +/- 8.6 vs 67.7+/-12.4), more likely to be women (58.7% vs 50.6%) and more likely to have hypertension (83.3% vs 80.4%, all $p<0.001$). Patients with dementia had reduced retinal FD after adjusting for age, sex, diabetes mellitus and hypertension (beta: -0.0047; 95% CI: -0.005, -0.003; $p<0.001$). No interaction was apparent among covariates.

Conclusions: A strong inverse association was seen between retinal FD and prevalent all-cause dementia after adjustment of known confounders of FD. Subsequent analyses will examine associations between other metrics of retinal morphology, derived from optical coherence tomography and incident disease.

ABSTRACT BODY:

Purpose: Meibomian gland dysfunction (MGD) is a leading cause of evaporative dry eye disease, yet the mechanism driving pathogenesis remains poorly understood. Recent studies in the Allergic Eye Disease (AED) mouse model have demonstrated the role of a Th17 and neutrophil-driven pathway in MGD pathogenesis. However, the manner by which neutrophils cause MGD in these mice is unclear. We addressed this knowledge gap by performing single cell RNA sequencing on cells, primarily leukocytes, from blood, tears, and conjunctiva collected from the AED mouse model, and compared results against tissues collected from naïve mice.

Methods: AED was induced in 9-week-old female C57Bl/6 mice by immunizing against ovalbumin (OVA) in the presence of pertussis toxin and, following a two-week incubation, OVA was applied to the eye, daily, for one week before collecting tissues, as previously described (Reyes NJ, 2018). Blood, conjunctiva, and tear samples from AED (n=9) and naïve (n=6) mice were harvested and prepared as single cell suspensions. FACS sorting was used to isolate cells from tears (live singlets), neutrophils from blood (live singlets, CD45+, Ly6G+), and leukocytes from conjunctiva (live singlets, CD45+). Sorted cells were pooled by treatment group and by tissue before sequencing. Data was analyzed using Seurat 4 with R version 4.1.

Results: The major immune cell (Ptprc) types identified included neutrophils (S100a8, Cd33), eosinophils (Ccr3, Siglecf), macrophages (Aif1), mast cells (Cd200r3), Th2 αβ T cells (Trac, Gata3), Th17 γδ T cells (Trdc, Rorc), dendritic cells (Flt3, Ccr7), and B cells (Ms4a1). We observed that AED mouse ocular tissues had increased neutrophil abundance and unique neutrophil cluster prevalence relative to naïve ocular tissues. Most notably, of the four identified neutrophil clusters, only a single cluster was associated with disease. This unique population was nearly absent in both the conjunctiva of naïve mice and the blood of either AED or naïve mice.

Conclusions: The notable presence of this disease-associated neutrophil cluster in the conjunctiva and tears of AED mice, but not naïve tissues or AED mouse blood, indicates that this phenotype arises as a result of the local ocular inflammatory environment. Further, it suggests that these neutrophils may be involved in MGD pathogenesis in the AED model.

ABSTRACT BODY:

Purpose: Children with brain injury often exhibit cognitive or communicative deficits that impede conventional vision assessment. Ocular abnormalities in such children can often only be assessed with qualitative or low-resolution techniques. We used a novel vision test powered by eye tracking to determine whether spatial asymmetries in eye movements can be reliably quantified in children with brain injury.

Methods: We measured saccade and pursuit eye movements in 69 children with and 14 children without brain injury (age 3 to 18) during an interactive game-like program called the Visual Ladder, in which the user pops randomly placed/moving virtual bubbles by fixating or tracking them. Mean saccade and pursuit distance for each child were binned into various opposing directional categories to analyze normative asymmetries and identify the children who deviated furthest from the line of best fit (>2 SD) in each comparison.

Results: Both healthy and brain-injured children exhibited significantly longer horizontal saccades/pursuits than vertical and longer downward saccades than upward (all $p < .001$; Fig. 1), in agreement with previously established biases. There were no other significant asymmetries. Children with brain injury did not have shorter saccades than healthy children, but did have significantly shorter pursuits ($p < .001$), which may be partially due to more fragmented pursuit detection from increased noise, and a wider spread for both saccades and pursuits. The 23 outliers detected across the six comparisons (red in Fig. 1) comprised 16 different children with brain injury, revealing how brain injury can manifest in distinct eye movement impairments.

Conclusions: Our results demonstrate that the Visual Ladder can detect and quantify eye movement asymmetries in children with brain injury, including non-verbal children, and suggest that eye movements may be largely healthy in many such children. Further analysis will be needed to relate the distinct impairments apparent in our data to particular disease diagnoses and outcomes.

ABSTRACT BODY:

Purpose: To report and analyze the outcomes of Descemet Membrane Endothelial Keratoplasty (DMEK) in eyes with corneal edema and associated ocular morbidities (glaucoma, maculopathy, and eyes after corneal transplants) in comparison to eyes without.

Methods: A retrospective study of seventy-seven (77) DMEK cases was done. Eyes after combined surgeries, vitrectomy, and eyes with anterior chamber intraocular lenses were excluded. The main outcome measures were best-corrected distance visual acuity (BCDVA) and graft survival. Eyes were separated into six groups as follows and analyzed: glaucoma only (GO), glaucoma and maculopathy (GMC), glaucoma and previous corneal transplant (GCT), previous corneal transplant (CT), maculopathy only (MO), and no associated glaucoma, maculopathy or corneal transplant (N).

Results: Overall, median BCDVA improved from 2.0 [0.2, 3] logMAR before surgery to 0.3 [-0.1, 2.0] logMAR 12 months after DMEK ($p<0.001$) with no difference between the groups at 1month, 3 months, 6 months and 12 months follow up times ($p<0.05$). Median BCDVA logMAR from before surgery improved significantly at 12 months in the N group; 1 [0.4, 3] to 0.2 [-0.1, 0.7] ($p<0.001$), CT group; 2 [0.2, 3] to 0.4 [0.1, 2] ($p<0.01$) and the GCT group; 2 [0.7,3] to 0.4 [0.2, 2] ($p<0.05$) but was not significant in the GO group; 1 [0.3, 3] to 0.3 [0.18, 2] ($p>0.05$), the MO group; 0.6 [0.2, 3] to 0.45 [0.1, 8] ($p>0.05$), and the GMC group; 1.0 [0.3,3] to 0.4 [0.1, 0.6] ($p>0.05$). Overall graft survival rate was 77.9% at 12 months. Highest in the N group (89.5%) and lowest in the GCS group (63.3%) ($p=0.71$).

Conclusions: DMEK offers visual rehabilitation in eyes with associated ocular morbidity. The least improvement in visual acuity is seen in patients with associated glaucoma, or maculopathy, or a combination of glaucoma and maculopathy. Eyes with glaucoma after previous corneal transplantation experience a significant improvement in vision at 12 months, but graft survival is 29% lower than in normal eyes.

ABSTRACT BODY:

Purpose: The COVID-19 pandemic led to unprecedented cancellation or alteration of healthcare events and medical conferences around the world. Many ophthalmology conferences transitioned to virtual interfaces, and the impact of this transition on the ophthalmology community is unclear. The authors wish to objectively define the impact of the COVID-19 pandemic on subspecialty ophthalmology conferences.

Methods: This study included data from the following five ophthalmology conferences from 2019, 2020, and 2021, as available: American Glaucoma Society (AGS), American Society of Ophthalmic and Plastic Reconstructive Surgery (ASOPRS), American Society of Cataract and Refractive Surgery (ASCRS), North American Neuro-Ophthalmology Society (NANOS), and Women in Ophthalmology (WIO). Data requested from organizations included the following, as available: Number of total conference attendees, number of attendees stratified by level of training, number of attendees stratified by identified gender, and number of research abstracts or presentations (submitted and/or accepted). This study has been approved by the City University of New York Institutional Review Board.

Results: In our study, 60% of organizations demonstrated an increase in number of attendees when using a virtual interface compared to their in-person events. 80% of organizations demonstrated a marked increase in attendance by trainees on their virtual interfaces. 60% of organizations displayed a decrease in number of submitted abstracts when using a virtual interface. 40% of organizations experienced an increase in number of accepted posters and presentations through a virtual platform.

Conclusions: Virtual conference interfaces have the potential to increase overall attendance and research participation within the ophthalmology community. Organizations should consider a hybrid model that incorporates aspects of both virtual and in-person interfaces to potentially maximize attendance, outreach, dissemination of information, opportunity, and minimize costs.

ABSTRACT BODY:

Purpose: The trabecular meshwork (TM) of the conventional outflow pathway participates in the regulation of outflow resistance, and TM dysfunction is the primary cause of elevated intraocular pressure (IOP) in glaucoma. Specifically, abnormal extracellular matrix (ECM) homeostasis by the TM contributes to outflow dysfunction, leading to a fibrotic/stiffer TM. In contrast, a healthy TM responds to elevated IOPs by remodeling ECM to facilitate increased outflow. We hypothesized that nano-sized extracellular vesicles (EVs) called “exosomes” are key participants in ECM homeostasis.

Methods: Experiments were designed to determine the effect of mechanical stretch and glaucoma on the exosome proteome released from primary human TM cells. TM cells were isolated from glaucomatous (GTM, n=1) and non-glaucomatous (NTM, n=1) donors that were grown to confluence under normal cell culture conditions and then switched to EV-depleted media. NTM cells (n=3) were also subjected to mechanical stretch (20%) for 24 hours. Conditioned cell culture media was collected every 48-72 hours for up to 3 months, or immediately after cell stretch and purified exosomes were isolated using iodixanol buoyant density gradient centrifugation. Fractions (fraction numbers 5-10) were assessed using mass spectrometry, Western blot and nanoparticle tracking analysis (NTA).

Results: Proteomic analysis of exosomes from TM cells showed an abundance of ECM-related proteins, including fibronectin, collagen and the integrin ligand EDIL3, which mediates cell binding and internalization of ECM proteins. Out of the top 20 proteins found across the cell strains, 72% were ECM-related. We validated fibronectin expression by Western blot, and found a 55% decrease in fibronectin binding to exosomes from GTM cells compared to NTM cells. NTM cells subjected to mechanical stretch released exosomes that bind 63% more fibronectin than unstretched controls. NTA demonstrated that the isolated exosomes from GTM cells appear to be larger than those from NTM cells; fractions 5-8: 103±11 vs 123.1±17nm and fractions 9-10: 112±1 vs 149±20nm.

Conclusions: ECM proteins are major components of exosomes released from TM cells. Abundance of these proteins increase with mechanical stretching, suggesting a role in ECM opsonization, degradation and homeostasis. Importantly, our data also suggests that this process may be disrupted in GTM cells due to tissue stiffening or decreased exosome opsonization/binding.

TITLE: Retinal ganglion cell resilience to injury indicated by cytoplasmic [Ca^{2+}] levels

SESSION TITLE: Neuron rescue and regeneration in the retina

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S. McCracken, P. Williams, Department of Visual Sciences, Washington University in St Louis, St Louis, Missouri, UNITED STATES|S. McCracken, DBBS-Neurosciences, Washington University in St Louis, St Louis, Missouri, UNITED STATES|

Commercial Relationships Disclosure: Sean McCracken: Commercial Relationship: Code N (No Commercial Relationship) | Philip Williams: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinal ganglion cells (RGCs) are the sole projection neurons from the retina to the brain, and injury to their axons with an optic nerve crush (ONC) causes significant RGC death over multiple weeks. However, a subset of RGCs survive the injury, and intrinsic characteristics promoting survival remain unclear. Manipulating RGC activity has been shown to increase regeneration after ONC, and as cytoplasmic [Ca^{2+}] levels are influenced by activity, we hypothesized that ground state [Ca^{2+}] levels could predict the survival of RGCs to ONC injury.

Methods: We used two-photon (2p) microscopy to visualize RGCs in-vivo at single-cellular resolution. To label all RGCs, we used an intersectional approach with VGlut2-Cre mice and intravitreal injections of an adeno-associated viral vector (AAV) expressing a Cre-dependent cytoplasmic [Ca^{2+}] biosensor, Twitch-2b. We visualized individual RGCs and quantified their somatic resting [Ca^{2+}] levels in the alive mouse and then performed ONC to assess RGC survival. We also tested two subtypes of RGCs with this paradigm, alpha RGCs (aRGCs; KCNG4-Cre) and intrinsically photosensitive RGCs (ipRGCs; OPN4-Cre).

Results: Baseline [Ca^{2+}] levels varied greatly between RGCs within a single retina (Fig 1). We found that RGCs with high ground state [Ca^{2+}] levels prior to ONC survived 3x better at two weeks post ONC (38 ± 1.2% survival, n=9 retinas, cells(c)=124) than those with low resting [Ca^{2+}] (16 ± .1%, c=136) (p=.018). Cells that survived had significantly higher ground state [Ca^{2+}] levels than those that died (p=4.6E-6). Two subtypes, aRGC and ipRGCs, had much higher ground state [Ca^{2+}] levels compared to all RGCs (p=7.6E-13, p=1.7E-29). Within each subtype, cells with high baseline [Ca^{2+}] had increased survival (aRGC: 63 ± 2%, n=12, c=132; ipRGC: 60 ± 2%, n=9, c=296) compared to those with low [Ca^{2+}] (35 ± 4%, c=63; 47 ± 4%, c=49). Interestingly, for both subtypes, surviving cells had higher baseline [Ca^{2+}] levels than those that died (p=.15, p=1E-4).

Conclusions: Our results for all RGCs and for each subtype, aRGCs and ipRGCs, are consistent with our hypothesis. Thus, we can conclude that high resting cytoplasmic [Ca^{2+}] levels in the RGC soma indicate resilience to axon injury. Future directions include identifying a low resting [Ca^{2+}] level RGC cohort and testing their survival after ONC.

ABSTRACT BODY:

Purpose: Mutations in the guanylate cyclase activator A1A(GUCA1A) gene which encodes guanylate cyclase activating protein, GCAP1, have been associated with both autosomal dominant (AD) cone and cone-rod dystrophies. GCAP1 plays a key role in recovery of photoreceptor to the dark-adapted state after light stimulus and its dysfunction is hypothesized to result in apoptosis of photoreceptors. Here we explore earlier cellular retinal structure changes in GUCA1A-related AD cone dystrophy using adaptive optics scanning light ophthalmoscope (AOSLO).

Methods: An asymptomatic 11 year old subject with a known GUCA1A-mediated AD cone dystrophy mutation(c.464A>G, p.(Glu155Gly)) underwent a comprehensive ophthalmic examination and high resolution imaging. Outer retinal structure was assessed using spectral-domain optical coherence tomography (SD-OCT) and the photoreceptor mosaic was imaged using confocal and split-detector AOSLO. AOSLO images were compared to 2 age-matched controls.

Results: Vision was 20/20 and color vision was normal OU. Clinical exam showed mild pigment mottling in the central maculas OU. SD-OCT showed intact but speckled-appearing ellipsoid band in the perifoveal macula. AOSLO demonstrated a disrupted photoreceptor mosaic with significantly decreased cone density when compared to age matched controls (8000 cells/mm^2 vs 23,400 cells/mm^2 at 4 degrees temporal to fovea). Split-detector AOSLO revealed inner segment photoreceptor structure (Figure 1B-arrow) in areas where no waveguiding cones were visualized (Figure 1A-arrow).

Conclusions: Significant cone photoreceptor degeneration occurs before functional loss in GUCA1A-mediated cone dystrophy. Split-detector AOSLO allows for a more precise assessment of retained photoreceptor structure. This highlights the potential utility of AOSLO to increase understanding of retinal degeneration at early asymptomatic stages and to identify ideal candidates with retained photoreceptor structure who may most benefit from emerging gene therapies.

ABSTRACT BODY:

Purpose: The leading cause of new cases of blindness in adults is diabetes. Diabetic retinopathy (DR) affects about one-third of adults over 40 years old with diabetes. Patients increasingly seek out online patient educational materials to learn about their health. Given that the American Medical Association (AMA) recommends writing at or below a 6th grade reading level for educational materials, we analyzed the readability of websites about DR found by search engine results to evaluate their accessibility.

Methods: The term “Diabetic Retinopathy” was queried in the Google search engine on November 1st, 2021. The first 10 pages (100 results) were screened and websites with patient-oriented information were analyzed (n=71). They were categorized by search result page number and website organization type: private practice, academic, government organization, informational, or commercial. Flesch Reading Ease, Flesch Kincaid Grade Level, Gunning Fog Score, Coleman Liau Index, and SMOG Index were calculated for each website. Statistical analysis was performed using ANOVA and Student’s T-test.

Results: Private practice websites were the most common (45%). Three sites had Flesch Reading Ease scores of 8th & 9th grade “Plain English”; all other sites were rated “Fairly difficult to read” or worse and averaged college-level difficulty. Only two sites met the 6th grade reading level AMA recommendation by Flesch Kincaid Grade Level; the average was grade 10.5. Average grade level estimation by Gunning Fog Score, Coleman Liau Index, and SMOG Index were 11.4, 11.8, and 12.3 respectively. There was no significant difference in readability between search result pages or website category except for search result page 1 having significantly higher Flesch Reading Ease than pages 5, 6, and 7 ($p<0.009$).

Conclusions: The high reading level of almost all websites in this search exceeds the AMA recommendation, creating difficulty in understanding DR for many patients. Websites that met the recommendation were not listed in the first two pages of search results and are thus less likely to be accessed. These factors could exacerbate disparities in eye health in populations that experience DR more frequently, such as Hispanics and African Americans, or patients with lower health literacy. As search results and website contents are ever-changing, focus on readability may enhance the accessibility of information about DR in the future.

ABSTRACT BODY:

Purpose: Retinitis Pigmentosa (RP) is the most common inherited retinal disease and is characterized by progressive photoreceptor degeneration that leads to visual impairment. It remains unknown to what extent the diseased and surviving photoreceptors transduce light and support vision in RP. To address this, we correlated adaptive optics (AO) imaging of cone structure, AO microperimetry with retinally-tracked stimulus delivery, and AO-OCT based optoretinograms (ORGs) in the same RP subjects.

Methods: Three RP subjects (age 25-29) and 3 aged-matched controls were imaged with AO Scanning Laser Ophthalmoscopy (AOSLO) across the four cardinal meridians and the RP transition zone (TZ), which was verified using clinical OCT. Cones were counted in 100 by 100 micrometer regions of interest (ROI) spanning the TZ. Visual sensitivity was assessed by measuring increment thresholds for 543 nm, ½ Goldmann-I stimuli (3 arc-min), that were targeted to predetermined retinal locations via active eye tracking in the AOSLO. ORGs were measured at the same locations with line-field spectral domain AO-OCT to assess cone function. The change in optical path length (ΔOPL) between the cone outer segment tips and inner-outer segment junction reflections in AO-OCT were calculated following a 44% bleach of L/M-cones with 528 nm light stimulus.

Results: Cone density was reduced compared to controls in the majority of ROIs for all three RP subjects ($p<0.05$). Density reduction trended with TZ onset in Subject 1 (S1) and S2, while S3 had patches of reduced density throughout. ΔOPL was reduced in all 3 RP subjects in regions of reduced cone density compared to controls. There was an increased proportion of cones with reduced ΔOPL with increasing eccentricity in all RP subjects ($p<0.05$). Further, we observed a distinct subset (30%) of cones with reduced ΔOPL in a region with otherwise intact OCT outer retinal layers in S3. Interestingly, negative ΔOPLs were observed in the TZ of S1 and S2 (4.9% and 5.2% of cones). Despite significant deficits in cone density and ΔOPL, visual sensitivity to 3 arc-min retinal stimuli targeted to the same areas remained comparable to controls, with the exception of one test site in S1.

Conclusions: Multimodal high-resolution functional imaging enables a complementary picture of disease progression in RP, and shows that deficits in ORG-based measures of retinal function precede the reduction in visual sensitivity.

ABSTRACT BODY:

Purpose: The ideal tradeoff between A-scan rate, acquisition time and image quality for optical coherence tomography (OCT) and OCT-Angiography (OCTA) is currently unknown. The purpose of this study was to compare the image quality and acquisition time between the variable scanning speed SPECTRALIS® SHIFT technology (spectral domain, 20 kHz, 85 kHz, 125 kHz, and 250 kHz) and 100 kHz swept source OCTA.

Methods: We conducted this cross-sectional observational study from August 2021 to November 2021 at Massachusetts Eye and Ear enrolling 20 healthy eyes. After obtaining written informed consent, patients were imaged on the 100 kHz PLEX® Elite 9000 (Carl Zeiss) using 6 mm x 6 mm angiogram centered on fovea, followed by Heidelberg SPECTRALIS® SHIFT technology (OCTA mode, Scout 20 preset at 85 kHz, 125 kHz, and 250 kHz). The latter gives standard 6.4 mm x 6.4 mm angiogram superimposed on the structural en-face images.

Results: The mean acquisition time were 31.1 seconds for 100 kHz PLEX®, 36 seconds for 85 kHz, 33.8 seconds for 125 kHz and 30.5 seconds for 250 kHz SHIFT technology. The OCTA image resolution was similar for the PLEX® 6 mm x 6 mm image at 1024 x 1024 pixels, while 1016 x 1016 pixels for the 6.4 mm x 6.4 mm image from SHIFT technology. The B-scan image quality and details were comparable between the two devices (Figure 1) but there was better delineation of microvasculature on PLEX® OCTA. Subjectively, there was evidence of higher motion artifacts on all layers and scan speed angiograms from SHIFT technology versus PLEX® due to better iris tracking software in the latter. We also noted progressive decrease in signal to noise ratio with increasing speeds for OCTA images acquired via SHIFT technology (Figure 2).

Conclusions: In this preliminary study we noted that higher scanning speed may not necessarily result in better image quality or significantly shorter scanning time. Although the image resolution was comparable, there were visible difference in capillary details, motion artifacts, etc. between the two devices. Future studies on different scan speed angiograms can open doors to their varied clinical application in patient specific pathology and media opacity status.

TITLE: The polycomb repressor complex 2 influences glial reactivity and the formation of Müller glia-derived progenitor cells in the chick retina

SESSION TITLE: Non-neuronal control of retinal neuron regeneration

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: H.M. El-Hodiri, W. Campbell, D. Torres, E.C. Hawthorn, L.E. Kelly, L. Volkov, A.J. Fischer, Neuroscience, The Ohio State University College of Medicine, Columbus, Ohio, UNITED STATES|

Commercial Relationships Disclosure: Heithem El-Hodiri: Commercial Relationship: Code N (No Commercial Relationship) | Warren Campbell: Commercial Relationship: Code N (No Commercial Relationship) | Diego Torres: Commercial Relationship: Code N (No Commercial Relationship) | Evan Hawthorn: Commercial Relationship: Code N (No Commercial Relationship) | Lisa Kelly: Commercial Relationship: Code N (No Commercial Relationship) | Leo Volkov: Commercial Relationship: Code N (No Commercial Relationship) | Andy Fischer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The mammalian retina does not regenerate, while retinas of cold-blooded animals generally have great regenerative capacity. The chick retina falls in between, generating Muller glia-derived progenitor cells (MGPCs) with limited neurogenic capacity. We investigated epigenetic mechanisms underlying MGPC production in the chick retina. We investigated the role of the Polycomb Repressor Complex 2 (PRC2), which catalyzes histone methylation, in damage-induced MGPC production.

Methods: Retinal damage was induced in chicks by intraocular injection of NMDA. PRC2 component activity was inhibited by injection of pharmacological inhibitors into one eye; the other eye (injected with vehicle) served as a control. PRC2 components were inhibited using DZNexp4 (inhibitor of EZH2), Jib04 (inhibitor of JARID2), and EEDi (inhibitor of EED). Eyes were isolated, hemisected, fixed, and processed for immunohistochemistry or single cell RNA or ATAC seq. MGPCs were identified by double labelling for SOX2 and incorporated EdU and counted. Statistical comparisons were performed using Student's t-test.

Results: The PRC2 subunits EZH2, JARID2, and EED displayed increased levels of expression in damaged retinas. Inhibition of EZH2 resulted in decreased MGPC production [control: 121 ± 21.21 MGPCs per retinal section, treated: 12.25 ± 11.40 MGPCs per section, $p < 3.3E-06$ ($n = 8$)]. Similarly, inhibition of JARID2 and EED resulted in significant reductions in MGPCs [66.56 ± 29.64% reduction for JARID2, $p < 1E-07$ ($n = 7$); 51.98 ± 31% reduction for EED, $p < 0.003$ ($n = 15$)]. Analysis of DZNexp4-treated retinas by scRNA-seq revealed changes in differential expression of genes involved in glial and neuronal development and differentiation. Many of these differentially-expressed genes were found to exhibit differential chromatin accessibility by scATAC-seq.

Conclusions: We conclude that the activity of PRC2, in general, and EZH2, in particular, are required for the reprogramming of Müller glia into MGPCs, and that the PRC2 complex and EZH2 normally influence chromatin access to a network of genes associated with glial differentiation.

ABSTRACT BODY:

Purpose: Ultraviolet B (UVB) is a significant risk factor to cause lens epithelium damage; however, the mechanism of lens epithelium repair after UVB irradiation is not fully understood. This study aimed to investigate the mechanism of the lens epithelium-mediated repair process after UVB irradiation.

Methods: C57BL/6J mice were irradiated by various doses of UVB. Lens cataracts were examined at different time points by slit lamp, darkfield microscopy, and phase-contrast microscopy. Lens epithelial cell (LEC) mitotic activation and apoptosis was determined by immunofluorescence staining and LECs' ultrastructure was analyzed by TEM.

Results: UVB irradiation above a dose of 2.87 kJ/m^2 triggered LECs apoptosis and subcapsular cataract formation associated with a ring-shaped structure composed of multilayered and irregularly stacked epithelial cells. LECs around wound edges transitioned to mitotically active cells reflected by increased Ki67 expression and BrdU incorporation. These mitotic active LECs performed wound-healing repair through the epithelialization process and removed apoptotic cells via phagocytosis. However, repairs ceased when lens epithelial cells made direct contact, and scar-like tissue in the center of the anterior capsule remained even by six months after UVB irradiation.

Conclusions: Our present study demonstrates that normally quiescent lens epithelial cells can be reactivated for epithelialization repair in response to UV-induced damage.

ABSTRACT BODY:

Purpose: Thrombospondin1 (TSP1) is a highly potent anti-angiogenic protein that could be a potential therapy for neovascular age-related macular degeneration (nAMD). Proteins and peptides, however, are poor therapeutics because of rapid degradation and clearance. Our group has pioneered a novel platform wherein therapeutic peptides are packaged as high-density brush polymers called protein-like polymers (PLPs). PLPs display active, functional amino acids, are resistant to proteolysis, and have a high molecular weight, improving pharmacokinetics. ABT898 is an 8 mer bioactive TSP1 peptide that binds the CD36 receptor to inhibit angiogenesis. We created a biostable, nontoxic PLP containing the ABT898 peptide, and tested its ability to inhibit choroidal angiogenesis.

Methods: PLP-ABT898 and PLP-Scramble control were synthesized. PLPs were characterized by size exclusion chromatography-multi-angle light scattering to ensure the molecular weight. PLP binding affinity to CD36 was tested using biolayer interferometry and inhibition of fatty acid uptake in CD36-expressing cells. Toxicity was tested using cell viability assays and by intravitreal injection of PLPs followed by hematoxylin and eosin analysis of retinal morphology. PLP effects upon choroidal angiogenesis were measured using the choroidal sprouting assay and the laser-induced choroidal neovascularization (CNV) model in 10-12 week-old male C57BL6/J mice.

Results: PLP-ABT898 bound CD36 with a KD of 12 nM and inhibited fatty acid update with an IC50 of 184 nM. PLP-ABT898 showed mildly reduced viability at 50 mM in ARPE19 cells. PLP-ABT898 intravitreal injection at 40 μM showed no change in retinal or outer nuclear layer thickness compared to PBS or PLP-Scramble control (N=7-10 per group). In the choroidal sprouting assay, PLP-ABT898 inhibited choroidal angiogenesis by 35% at 5 μM, 68% at 10 μM, and 92% at 20 μM (N=15-22, $p<0.001$ for all) compared to PLP-Scramble. PLP-ABT898 reduced laser-induced CNV area by 2.0-fold (N=19-21, $p<0.05$) on fluorescein angiography and 2.8-fold (N=18-20, $p<0.05$) on immunofluorescence analysis.

Conclusions: PLP-ABT898 was nontoxic and effectively inhibited choroidal angiogenesis. PLP-ABT898 is a potential new therapeutic for nAMD. Additionally, PLP technology is translatable to different peptides or combinations of anti-angiogenic peptides for therapeutic targeting of multiple angiogenesis pathways.

TITLE: Spatial cluster analysis reveals how segmental outflow patterns change over time in living mice

SESSION TITLE: Aqueous humor dynamics & Trabecular Meshwork

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: D.R. Overby, T. Baptiste, D. Duffill, E. Reina-Torres, Bioengineering, Imperial College London, London, London, UNITED KINGDOM|

Commercial Relationships Disclosure: Darryl Overby: Commercial Relationship: Code N (No Commercial Relationship) | Tiffany Baptiste: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Duffill: Commercial Relationship: Code N (No Commercial Relationship) | Ester Reina-Torres: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Aqueous humor outflow through the trabecular meshwork (TM) is non-uniform, or segmental, such that some regions of TM experience higher local outflow than others. Our aims were (i) to develop a quantitative approach to analyze segmental outflow patterns using spatial autocorrelation and cluster analysis, and (ii) to apply these techniques to determine how segmental outflow patterns change over time in living mice.

Methods: Fluorescent tracer microspheres (0.2 μm; 10^{8} μl^{-1}) were infused under anesthesia into the anterior chamber of C57BL/6 mice to label segmental outflow patterns in the TM. To visualize the change in segmental outflow patterns over time within individual eyes, each eye was infused twice with a different tracer color separated by a delay of 2, 7 or 14 days (n=10 mice). Mice were culled 48 hrs after the second infusion. Eyes were enucleated and prepared for flat mount imaging. We analyzed the spatial autocorrelation of tracer intensity patterns within the TM using Moran's I, which yields statistically defined clusters of high, intermediate, and low tracer-labelling (Figure).

Results: The global Moran's I statistic indicated significantly more tracer clustering within the TM than expected by chance (0.67±0.08; mean±SD; N=16 eyes; $p<0.01$). High tracer-labelled clusters were estimated to occupy 26±2% of the TM, while low and intermediate clusters were estimated to occupy 34±6% and 40±7% respectively. There was no change in the total extent of each cluster type over time. However, with increasing delay between the two infusions, the patterns of tracer labelling changed significantly, as indicated by a decreasing spatial correlation coefficient (r=0.69 [0.52,0.86] at 2 days vs. 0.06 [-0.17,0.28] at 14 days; mean [95% CI]; $p<0.01$).

Conclusions: Moran's I provides an objective and reproducible method to identify high, intermediate and low tracer-labelled clusters within the TM. Over 2 weeks in young adult mice, segmental outflow patterns redistribute spatially within the TM. However, despite this redistribution, the TM appears to preserve the overall extent of high, intermediate, and low filtration-active clusters. This suggest that dynamic changes in the spatial distribution of segmental outflow are not random but appear to be regulated by active processes within the outflow pathway.

TITLE: The role of the vLGN in non-image-forming visual behaviors and its underlying circuit organization

SESSION TITLE: Retinal ganglion cells and central processing

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: C. Beier, Z. Zhang, M. Thurman, S. Hattar, 1.Section on Light and Circadian Rhythms, National Institute of Mental Health, Bethesda, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Corinne Beier: Commercial Relationship: Code N (No Commercial Relationship) | Ze Zhang: Commercial Relationship: Code N (No Commercial Relationship) | Martina Thurman: Commercial Relationship: Code N (No Commercial Relationship) | Samer Hattar: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The mouse ventral lateral geniculate nucleus (vLGN) receives dense retinal ganglion cell (RGC) innervation but its role in vision remains unclear. We recently showed that the caudal vLGN segregates the visual input of RGCs that drive image-forming vision from the intrinsically photosensitive RGCs (ipRGCs) that drive non-image-forming behaviors. Here, in the context of this newly understood circuit organization, we investigate cell type-specific retina-to-vLGN pathways that drive and modulate non-image-forming behaviors (pupillary light response, circadian photoentrainment, and light-induced sleep).

Methods: Immunohistochemistry of cFos induction was paired with markers for vLGN cell types (Penk and Nos1) following circadian phase shifting light pulses (phase delay, ZT14, or phase advance, ZT22). We mapped afferents of vLGN $Penk^{Cre}$ and $Nos1^{Cre}$ cell types with Cre-dependent helper viruses and monosynaptic G-deleted rabies virus. We used viral chemogenetic strategies to silence (tetanus toxin) or activate (Gq DREADD) vLGN $Penk^{Cre}$ cells to investigate their role in modulating non-image-forming visual behaviors.

Results: cFos induction in the vLGN increases in Penk cells in response to a ZT22 light pulse but not to a ZT14 light pulse compared to dark controls. Light-induced cFos in Nos1 cells is not time-dependent. $Penk^{Cre}$, but not $Nos1^{Cre}$, cells in the vLGN are post-synaptic to ipRGCs. Silencing/activating vLGN $Penk^{Cre}$, but not $Nos1^{Cre}$, cells causes an increase/decrease in pupil constriction during a light step. Preliminary results implicate vLGN $Penk^{Cre}$ cells in phase advancement and sleep; silencing vLGN $Penk^{Cre}$ cells results in deficits to phase advancing light shifts and activating vLGN $Penk^{Cre}$ cells in the late night, but not the early night, induces sleep.

Conclusions: We find that Penk vLGN cells are light-responsive in a circadian time-dependent manner and receive exclusive ipRGC input, which are characteristics thought to be exclusive to the pacemaker, the suprachiasmatic nucleus. In contrast, vLGN Nos1 cells do not share these same features. In agreement with these findings, we show that vLGN Penk cells play a role in modulating non-image-forming visual behaviors. Penk cells modulate the pupillary light response during light steps and play a role in time-dependent visually responsive behaviors: light induced circadian phase advancement and sleep.

ABSTRACT BODY:

Purpose: The mammalian retina contains an autonomous circadian system that regulates various aspects of retinal physiology critical for the processing of visual information and thus optimizing retinal activity with the daily variation in light intensity. The retinal clock can be entrained by light both in vitro and in vivo suggesting that light plays a critical role in the regulation of the retinal clock. Retinal angiogenesis is dependent on the retinal ganglion cells and in mice lacking RGCs, retinal vasculature does not develop thus highlighting the importance of cues that are provided from the underlying neuronal cells. The goal of this study was to test the hypothesis that the light-regulated retinal circadian clock is essential for developmental and pathological angiogenesis.

Methods: To test this hypothesis, we disrupted the light/dark cycle or conditionally deleted the circadian clock genes Bmal1 and Per2 from the retinal progenitor cells (RPCs) and vascular endothelial cells (VECs). Chromatin immunoprecipitation sequencing analysis (ChIP Seq) was used to identify the angiogenic molecular targets of Bmal1 in the neurons. To address the role of the neuronal clock in pathological angiogenesis, oxygen-induced retinopathy (OIR) model was used.

Results: Our results demonstrate that the neuronal clock genes Bmal1 and Per2 are essential regulators of retinal angiogenesis. The clock gene transcripts exhibit circadian rhythmicity in the embryonic retina and this rhythmicity is lost under disrupted light/dark cycles. ChIP analysis indicates that some of the Bmal1 targets within the retinal neurons are angiogenic regulators. Accordingly, deletion of Bmal1 in neuronal cells results in overgrowth of the vasculature while Bmal1 deletion from the endothelial cells causes reduced proliferation, with reduced vessel density. RNA sequencing data from the endothelial cells suggests that pathways primarily related to the cell cycle are altered by the loss of Bmal1. Furthermore, only the neuronal clock is an important mediator of pathological angiogenesis as loss of Bmal1 and Per2 causes a significant reduction of neovascularization.

Conclusions: The data presented here raise an exciting question about the interrelationship between the circadian clock in the neurons and vasculature during retinal angiogenesis. Importantly, a robust circadian clock in the neurons protects the retinal vasculature from oxygen-induced damage.

ABSTRACT BODY:

Purpose: To study the interobserver concordance between two resident doctors and two ophthalmologists specializing in retina regarding the detection of characteristics of diabetic macular edema (DME) in optical coherence tomography (OCT) in naïve patients using the LET classification.

Methods: A retrospective consecutive analysis was carried out of patients evaluated in our service who presented DME for 1 year. OCTs were independently analyzed by two residents, on the one hand, as well as by two retinologists on the other hand, determining the characteristics of DME using the LET classification. The data were evaluated using a concordance analysis for each pair of observers.

Results: A total of 95 eyes of 70 patients were analyzed, 67,1% being male and 32,9% female, with a mean age of 66,13 years +/-11,73 years. In the evaluation of the DME characteristics according to the LET classification, the kappa coefficient of interobserver concordance in the resident doctors was: Location (L) 0,36; Extension (E) 0,46; and Traction (T) 0,52. On the other hand, the values obtained among the retinologists observers were: Location (L) 0,709; Extension (E) 0,664; and Traction (T) 0,264. All the results were statistically significant.

Conclusions: Classification of DME by OCT using the LET classification produces an acceptable degree of agreement between different observers, although there are notable differences when it is done by physicians in training and when it is done by retina specialists in clinical practice.

ABSTRACT BODY:

Purpose: This research evaluates the disease relevance of cannabinoid receptors in UM patient samples and the therapeutic potential of synthetic cannabinoids in uveal melanoma (UM) cell lines. UM is a rare cancer, but the most common intraocular malignancy in adults that arises from melanocytes within the uveal tract. Unfortunately, up to 50% of patients develop liver metastases that rapidly progress to mortality. There are no effective therapies available for metastatic UM.

Methods: Cannabinoid receptor gene expression in 80 primary UM samples within The Cancer Genome Atlas was analysed for association with disease-free and overall survival. Gene set variation analysis enriched for molecular functions and biological pathways linked to high or low cannabinoid receptor expression. In vitro assays utilised Mel285 and OMM2.5 human UM cell lines derived from a tumour of the eye and a liver metastasis, respectively. Cell viability was examined at 96 hours after treatment with the synthetic cannabinoid HU210 by measuring metabolic activity. Colony formation assays assessed long-term UM cell proliferation. Multiplex ELISA determined the secreted levels of 10 inflammatory factors at 4 and 24 hours after treatment with HU210 in the OMM2.5 cell line. Western Blot analysed expression of CB_1.

Results: Kaplan-Meier survival curves demonstrate a significant corelation between high CB_1 expression and disease-free survival in UM patients. The CB_1/CB_2 agonist HU210 results in a dose-dependent reduction in Mel 285 and OMM2.5 cell viability with 20 μM HU210 reducing cell viability by around 80%, $p < 0.0001$ whereas 150 μM of the more selective CB_2 agonist JWH133 was required to significantly reduced viability by 80%, $p=0.0001$ in both UM cell lines. 10 μM rimonabant hydrochloride and 10 μM SR144528, CB_1 and CB_2 selective antagonists, respectively, were the maximum tolerated concentrations not affecting cell viability. 20 μM HU210 results in a reduction of long-term proliferation of clones in both UM cell lines. Western blot analysis confirmed expression of CB_1 in Mel285, Mel290, OMM2.5 cells.

Conclusions: Significant corelations between high CB_1 expression and disease-free survival in UM patients was identified. HU210 reduces viability and clone proliferation of UM cell lines and modulated inflammatory pathways. Future directions will evaluate the key receptor mediating HU210 effects using antagonists and investigate the mechanism of action.

ABSTRACT BODY:

Purpose: Thus far, our studies using Confetti and the K5-H2B-GFP transgenic mice suggest that there are two stem/progenitor cell populations that independently give rise to the ductal and meibum synthesizing meibocyte populations within the meibomian gland. The purpose of this study was to use single cell RNA sequencing analysis of mouse meibomian glands to further identify/characterize these different cell lineages.

Methods: The tarsal plates from the upper and lower eyelids of 6, 6-month-old, male C57Bl/6 mice divided into two groups were collected and single cells isolated. Cells were then submitted to the UCI Genomics High Throughput Facility and raw sequencing data demultiplexed and processed using Cellranger (10× Genomics version 3.1.0). Preliminary analysis and visualization of the data were performed using R version 4.0.5 and Seurat version 4.0.5. For all datasets, cells with <200 and >6000 genes, and >5% mitochondrial genes detected were removed. We performed integrated analysis of the 2 datasets using SCTransform normalization separately for each dataset, selected 2000 informative features, and performed integration using the FindIntegrationAnchors function. Cells were visualized using UMAP (Uniform Manifold Approximation and Projection). Pseudotemporal ordering of meibocytes and determination of pseudotime dependent transcription factors was performed using Monocle version 2.18.0.

Results: A total of 7259 cells from two different samples were analyzed and 19560 genes detected across all cells. UMAP analysis identified 5 distinct cell clusters, including 1) a Krt 6a positive ductal epithelial cluster, 2) a Krt6a and AWAT2 negative and PPARg positive undifferentiated meibocyte cluster, 3) a AWAT2 positive differentiated meibocyte cluster, 4) a Krt6a and Ki67 positive ductal epithelial progenitor cluster and 5) a Krt6a negative and Ki67 positive meibocyte progenitor cell cluster. Trajectory analysis also identified transcription factors unique to these two different meibomian gland cell lineages.

Conclusions: Our findings support the hypothesis that there are two separate progenitor cell populations that give rise separately to ductal epithelial cells and meibum synthesizing meibocytes. Understanding the regulatory mechanisms that control these separate pathways is needed to establish appropriate cell culture models to evaluate mechanisms that regulate meibum synthesis.

TITLE: Maintaining the integrity of the inner segment of rod photoreceptor neurons for intensive immunolabeling and superresolution microscopy

SESSION TITLE: Photoreceptor Biology, Protection and Degeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M.A. Robichaux, K.N. Haggerty, Ophthalmology, West Virginia University, Morgantown, West Virginia, UNITED STATES|M.A. Robichaux, S.C. Lyons, Biochemistry, West Virginia University, Morgantown, West Virginia, UNITED STATES|

Commercial Relationships Disclosure: Michael Robichaux: Commercial Relationship: Code N (No Commercial Relationship) | Kristen Haggerty: Commercial Relationship: Code N (No Commercial Relationship) | Shanon Lyons: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The inner segment (IS) region of rod photoreceptor neurons is a hub for the synthesis and trafficking of visual proteins. These protein “cargoes” are delivered to the basal body (BB) at the apical edge of the IS region prior to their incorporation into the rod outer segment cilium. The study of the localization and dynamics of IS trafficking processes in single rods with superresolution microscopy techniques requires optimized preparation methods with minimal tissue fixation for thorough antibody penetration and immunolabeling. During such rigorous immunolabeling procedures, the IS membrane is susceptible to membrane extraction. The goal of this project was to develop a new methodology for intensive immunolabeling of mouse rods that both preserves the morphology of the IS and is compatible with superresolution imaging.

Methods: We lightly fixed mouse retinas with paraformaldehyde (PFA) before a 3-day primary antibody incubation period in a blocking solution containing saponin, a mild detergent. Primary antibodies used targeted syntaxin-3 and Na,K ATPase (ATP1B2), which are IS membrane markers, and phosducin, a cytoplasmic chaperone protein. After a secondary antibody incubation period, we tested different “post” fixation solutions prior to dehydrating the retinas for resin embedding. We imaged ultra-thin retinal sections with structured illumination microscopy (SIM), stochastic optical reconstruction microscopy (STORM) and conventional transmission electron microscopy (TEM).

Results: We determined that a post-fix solution of 2% PFA and 0.1% glutaraldehyde (w/v) preserved the IS membrane of most rods in immunolabeled retinas as determined by TEM ultrastructure and the SIM/STORM immunolocalization of syntaxin-3 and ATP1B2. We also used STORM to determine that significantly more cytoplasmic phosducin was preserved in the IS of retinas treated with our optimized post-fix solution compared to just PFA alone.

Conclusions: Our optimization of mouse retinal immunolabeling conditions enables future superresolution localization studies focused on the IS. Specifically, by preserving the IS membrane and cytoplasm, we can more accurately test dynamics of visual protein cargoes with trafficking organelles in the IS and the BB region in future studies.

Commercial Relationships Disclosure: Un Chul Park: Commercial Relationship: Code N (No Commercial Relationship) | Zeljka Smit-McBride: Commercial Relationship: Code N (No Commercial Relationship) | Ning Sun: Commercial Relationship: Code N (No Commercial Relationship) | Ping Zhou: Commercial Relationship: Code N (No Commercial Relationship) | Johnathon Anderson: Commercial Relationship: Code N (No Commercial Relationship) | Jan Nolta: Commercial Relationship: Code N (No Commercial Relationship) | Paul Sieving: Commercial Relationship: Code N (No Commercial Relationship) | Susanna Park: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Human bone marrow (BM) contains CD34+ stem cells and mesenchymal stem cells (MSCs) that are being explored for tissue regeneration and revascularization. CD34+ cells, which include endothelial progenitor cells, are known to promote angiogenesis which may be impaired by the diabetic state. MSCs, which have paracrine effects via exosomes, reverse the impaired migration of diabetic CD34+ cells in vivo to enhance angiogenesis. This study used an in vitro tube formation assay (angiogenesis assay) to evaluate the angiogenic potential of human CD34+ cells and exosomes from MSCs, alone and in combination, to determine whether the exosomes can enhance the angiogenic potential of CD34+ cells.

Methods: CD34+ cells were harvested from the mononuclear cell fraction of BM of a healthy or diabetic human donor. Exosomes were harvested from MSCs from a healthy BM donor cultured under hypoxic conditions. Tubule formation assay was conducted using HUVEC treated with PBS control, healthy CD34+ cells (50k cells), diabetic CD34+ cells (50k cells), or exosomes (0, 1, 10, and 100 μg) alone or in combination with CD34+ cells. Angiogenesis assay was imaged with ImageXpress Micro system and analyzed using built-in MetaXpress software for angiogenesis.

Results: Healthy CD34+ cells significantly increased HUVECs' tube length, area, and thickness compared to PBS ($p \leq 0.007$). Diabetic CD34+ cells significantly increased tube area compared to PBS ($p = 0.050$), although no significant effect on tube length or thickness was noted. In addition, a significant increase in the number of tube segments, nodes, and branching points was observed in HUVEC treated with either healthy or diabetic CD34+ cells compared to PBS ($p \leq 0.003$). Exosomes (100 ug only) significantly increased tube length, area, and the number of tube segments ($p \leq 0.033$), but its combination with healthy or diabetic CD34+ cells had no additional effect .

Conclusions: Human CD34+ cells from a healthy or diabetic donor both showed an angiogenic effect on HUVEC in vitro, but the angiogenic effect was less robust for diabetic CD34+ cells. Exosomes also had an angiogenic effect in vitro, significant only at the highest dose tested. No additional angiogenic effects were observed when exosomes were added to either healthy or diabetic CD34+ cells. Further studies are ongoing to evaluate the effects of higher doses of exosomes on angiogenesis of CD34+ cells.

TITLE: Occludin interaction with dynein required for occludin centrosomal localization and VEGF-induced cell proliferation

SESSION TITLE: Vascular Biology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: X. Liu, L. Gao, M. Merlino, D.A. Antonetti, Ophthalmology and Visual Sciences, University of Michigan, Ann Arbor, Michigan, UNITED STATES|

Commercial Relationships Disclosure: Xuwen Liu: Commercial Relationship: Code N (No Commercial Relationship) | Lu Gao: Commercial Relationship: Code N (No Commercial Relationship) | Madeline Merlino: Commercial Relationship: Code N (No Commercial Relationship) | David Antonetti: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Previous studies suggest that occludin phosphorylation on Ser490 contributes to both VEGF-induced vascular permeability and angiogenesis in cell culture and in transgenic animals. Tight junction, transmembrane protein occludin localizes to centrosomes in a distinct vesicle compartment, required for VEGF-induced endothelial cell proliferation and neovascularization. Dynein motor is solely responsible for minus end trafficking of proteins and vesicles in cells. We hypothesized that dynein trafficks occludin to centrosomes and identified regions of occludin required to bind the dynein light intermedia chain 2 (LIC2).

Methods: Co-immunoprecipitation (Co-IP) studies were performed in bovine retinal endothelial cells (BREC) and human osteosarcoma U2OS cells that have well-characterized centrosomes. A series of occludin mutants were generated to test centrosomal localization in U2OS cells by immunofluorescence (IF) confocal microscopy and VEGF-induced proliferation in BREC.

Results: Accumulation of dynein and pS490 occludin on microtubules was observed in BREC treated with dynein inhibitor dynapyrazole A suggesting a requirement for dynein in trafficking. Co-IP and Western blotting from U2OS cells and BREC revealed that occludin and dynein interact. Mutational analysis of occludin revealed that the occludin coiled-coil domain and specifically the Ser490 phosphorylation site was required for centrosomal localization and VEGF-induced BREC proliferation. The occludin coiled-coil contained homology to the LIC2 binding adapter BICD, CC1 domain and additional mutational analysis and co-IP studies revealed an interaction site between the occludin coiled-coil and the dynein LIC2 with Ser471 contributing an essential role to binding while Ser490 was not required for this interaction but was required for centrosomal localization. Mutation of 7 amino acids in the occludin coiled-coil with homology to the CC1 domain completely blocked LIC2 binding.

Conclusions: These results reveal a novel role for occludin interaction with dynein LIC2 and begin to provide an explanation for the role of occludin in both VEGF-induced vascular permeability and angiogenesis and suggest occludin may serve to link cargo to dynein.

ABSTRACT BODY:

Purpose: Macrophages (MF) play critical roles in innate immunity but are increasingly appreciated for their roles in the maintenance of tissue physiology, particularly with respect to their interactions with nerves. Certain MF populations, including microglia in the central nervous system as well as nerve associated MF (NAM) of the sciatic nerve in the peripheral nervous system, are dependent on IL-34, the alternate ligand for colony stimulating factor 1 receptor (CSF1R), signaling through which sustains these populations locally. However, the presence of these IL-34 dependent NAM populations in the cornea and their function remains unknown. Here we leverage the unique properties of the cornea, which is imbued with the densest sensory innervation in the periphery of the body and possesses a rich network of NAMs, to investigate the functional significance of IL-34 in corneal NAM populations.

Methods: Corneas from wild type (WT) and Il34 deficient ($Il34^{LacZ/LacZ}$) age matched adult mice were dissected and stained for a combination of F480, CD206, or Iba1 and Tuj1 to label MFs and nerves, respectively. Whole mount corneas were visualized using confocal microscopy and z-stacks of the central cornea were acquired. MF counts and nerve volume were calculated by rendering the signal from z-stacks as a surface using Imaris image analysis software. Additionally, corneal mechanosensation was evaluated in WT and Il34 deficient animals using Cochet-Bonnet esthesiometry.

Results: Il34 deficient animals, as compared to WT, yielded significantly reduced MF counts in the central cornea. The central cornea showed a decreased trend in nerve volume when comparing WT to Il34 deficient mice. Moreover, Il34 deficient mice had significantly reduced corneal mechanosensation compared to WT mice.

Conclusions: Collectively, our results suggest that corneal MFs are maintained in part through IL-34 signaling, and that a reduced number of corneal NAMs is correlated with decreased corneal mechanosensation.

ABSTRACT BODY:

Purpose:

We have previously used Immuno Tomography (IT) to identify label retaining stem cell populations in the cornea and meibomian gland. While this method provides the unique ability to quantify stem cell populations comprised of 1-4 cells, the number of antigens that can be sequentially used to characterize these unique cells is limited by the antigen stability after antibody stripping and re-probing. To address this deficiency, we have evaluated the capability of imaging mass cytometry (IMC) to generate multiplexed images using metal-conjugated antibodies to label IT plastic sections and generate 3-dimensional IMC data sets (3D-IMC).

Methods:

K5-H2B-GFP mice, 56 days after doxycycline chase were sacrificed and eyelid tissue processed for IT. A total of 400 serial, plastic sections, 2 mm thick were then probed using metal tagged antibodies specific for sox9, collagen type I, E-cadherin, Ki67, GFP, aSMA, vimentin and DNA Intercalator. Multiplexed images were then generated using an Imaging Mass Cytometery system (Fluidigm), and 3D reconstructions assembled.

Results:

All 8 metal labeled tags were detected and their images were successfully assembled into 3D-IMC data sets. GFP labeled nuclei were identified within the meibomian glands in comparable numbers to those previously reported for slow cycling, meibomian gland stem cells.

Conclusions: These findings demonstrate that IMC can be used on plastic sections to generate multiplexed, 3D data sets that can be reconstructed to show the spatial localization of meibomian gland stem cells. We propose 3D-IMC might prove valuable in more fully characterizing stem cell populations in different tissues.

TITLE: miRNA 9 regulates endothelial to mesenchymal transition in the retina in diabetes

SESSION TITLE: Molecular events in diabetic retinopathy

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S. Chakrabarti, E. Wang, B. Feng, Western University Schulich School of Medicine & Dentistry, London, Ontario, CANADA|

Commercial Relationships Disclosure: Subrata Chakrabarti: Commercial Relationship: Code N (No Commercial Relationship) | Eric Wang: Commercial Relationship: Code N (No Commercial Relationship) | biao Feng: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Diabetic retinopathy (DR) is a significant cause of visual impairment. Glucose-induced endothelial dysfunction is one of the important early occurrences in DR. Endothelial to mesenchymal transition (EndMT) is a hyperglycemia-inducible, epigenetically regulated process where endothelial cells lose their endothelial characteristics and acquire a mesenchymal phenotype, resulting in dysfunction of the endothelium. microRNA (miR) 9 is a short non-coding RNA that mediates epigenetic regulation, and is significantly inhibited in the retina in DR. We set out to investigate the role of miR-9 in the pathogenesis of EndMT in early DR.

Methods: Human retinal endothelial cells (HRECs) were used to model the behaviour of the retinal endothelium in DR. HRECs were harvested after treatment with normal (5mM) or high (25mM) concentrations of glucose, and RNA and protein expressions of EndMT-related genes were assessed using qPCR and western blot respectively. miR-9 mimic was used to rescue glucose-induced EndMT in HRECs. Mouse models were used to validate the findings in vivo. Diabetes was induced in 8-week-old mice using streptozotocin, age-matched controls were given mock injections. Retinal tissues were harvested after 2 months, and RNA and protein expressions of EndMT-related genes were analyzed using qPCR and ELISA respectively. Specially generated endothelial-specific miR-9 overexpressing mice were used to validate the ability of miR-9 overexpression to prevent EndMT in vivo.

Results: Glucose significantly inhibited miR-9 expression in HRECs. Glucose-induced inhibition of miR-9 in HRECs correlated with the downregulation of endothelial markers and the upregulation of mesenchymal markers. Transfection with miR-9 mimics prevented the aforementioned in HRECs. Similar results were reproduced in animals. EndMT was seen in the retinas of normal diabetic mice, but not in those of miR-9 overexpressing diabetic mice.

Conclusions: These results, taken together, show that miR-9 is an important regulator of EndMT in the retina. We showed that glucose-induced inhibition of miR-9 mediated EndMT, and that miR-9 overexpression prevented EndMT in DR. Thus, miR-9 may represent an avenue for targeted RNA-based gene therapy against EndMT in DR in diabetic patients.

Vila, J. Zarranz-Ventura, Hospital Clinic de Barcelona, Barcelona, Catalunya, SPAIN|

ABSTRACT BODY:

Purpose: To evaluate the diagnostic capacity of Automated Machine Learning (AML) algorithms to classify the degree of diabetic retinopathy (DR) from optical coherence tomography (OCT) and OCT angiography (OCTA) images.

Methods: Cross-sectional study on a pseudonymised dataset of images collected during a previous prospective clinical trial (NCT03422965), corresponding to a cohort of 485 patients with type 1 Diabetes Mellitus and 115 healthy controls. The retinal images were labeled with the corresponding demographic and clinical data collected in the clinical trial. The classification models based on Deep Learning and computer vision algorithms were trained hosted in a cloud-based system, under the Vertex AI platform of Google Cloud Platform, which allows the training of algorithms without the need automated fine-tuning of hyperparameters (AML). The performance was compared for superficial and deep capillary plexuses (SCP and DCP, respectively) on 3x3 mm and 6x6 mm captures, following 3 labeling strategies: No DR vs no DR; No DR vs. Mild DR vs. Referable DR, and No RD vs. Non-Proliferative RD vs. Proliferative RD.

Results: The performance of the classification models was evaluated through precision, sensitivity, specificity and f1-score. Overall, despite having good average precision values (ranging between 0.6 to 0.9 for structural OCT and 0.59 to 0.94 for OCTA), the models trained on structural OCT images had consistently a significative lower power of detection on the greater DR grade on each strategy (ranging from 0% to 33%) compared to 30% to 88% for the models trained on OCTA images. Models performance was consistently superior in those trained using SCP images and was greatest using 3x3 mm scanning protocol.

Conclusions: AML algorithms are able to detect the DR status when trained in OCTA images of DM patients, in particular using OCTA images from the SCP and high definition 3x3mm scan field. Unbalanced datasets may give rise to non-significative good performance metrics if not adequatelly analyzed. These preliminary results raise the interesting hypothesis of using OCTA images to investigate the potential ability of AML algorithms to detect systemic microvascular damage elsewhere in the body, by means of exploring existing relationships between OCTA images and quantitative systemic variables through Oculomics.

TITLE: Duo-Pulse Width Laser Engine for Femtosecond Laser Assisted Cataract Surgery: Benefits in Corneal Incision and Lens Fragmentation

SESSION TITLE: Cataract surgery II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Teuma, R&D, LENSAR Inc, Orlando, Florida, UNITED STATES|

Commercial Relationships Disclosure: E Valas Teuma: Commercial Relationship(s);Code E (Employment):LENSAR, Inc

ABSTRACT BODY:

Purpose: A novel system with an integrated duo-pulse engine (Gen-2 ALLY, LENSAR, Orlando, FL) offers the flexibility of operating with either a short (femtosecond) or long (picosecond) pulse laser. The purpose of this study is to evaluate the efficacy of each option in corneal treatment and lens fragmentation.

Methods: Pairs of human donor eyes were utilized. Two full thickness corneal incisions of 2.5mm width each were performed on the eyes 180° apart with each pulse width. Lens fragmentation patterns were generated in each lens using a mask to cover half the lens volume to limit the laser treatment to the exposed half volume for each pulse width. Evaluation of the corneal incisions and lens fragmentation was performed under the surgical microscope.

Results: Following the short pulse laser treatment, the corneal incisions were consistently easier to open and, in, some cases, gaping. In addition, the intrastromal tunnel was generally free of tissue bridges. With the long pulse laser, the incision was characterized by a residual uncut layer beneath the epithelium that needed to be broken to access the incision. Moreover, the occurrence of an opaque bubble layer (OBL) was more frequent and pronounced with the long pulse laser.

For lens fragmentation, larger surface cleavages were observed in the lens volume treated with the long pulse laser. The size of the cleavage was indicative of the laser's generation of incisional cuts /cracks that expanded beyond the point of photodisruption, including in opaque/hard cataract volumes. However, with the short pulse laser, the fragmentation cuts exhibited discontinuities in the posterior lens volume in some cases, indicative of its challenge to be consistently effective in cutting the fibrous posterior plate.

Conclusions: These preliminary data show that a duo-pulse laser offers unique flexibility to use a short pulse laser that is more effective in construction of corneal incisions with the advantages of minimal OBL occurrence, easier opening and absence of tissue-bridges. The long pulse laser is more effective in lens fragmentation with the cuts continued and extended to the posterior lens including the fibrous posterior plate.

TITLE: Utilizing intra-operative surgical navigation to improve implant positioning in orbital fracture reconstruction

SESSION TITLE: Oculoplastics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Lu, B. Erickson, Ophthalmology, Stanford University School of Medicine, Stanford, California, UNITED STATES|

Commercial Relationships Disclosure: Louisa Lu: Commercial Relationship: Code N (No Commercial Relationship) | Benjamin Erickson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Improper orbital implant placement is the most common cause of revision surgery and complications in orbital fracture repair. Ensuring correct orientation of the posterior aspect of the implant in the orbital apex in complex blowout and more extensive craniofacial fractures (ZMC, LeForte) is particularly critical. Once a cantilevered implant is provisionally anchored to the inferior orbital rim, it can also be challenging to adjust implant angulation. We demonstrate a method of intra-operative navigation utilizing a novel instrument that clamps onto a titanium mesh floor/medial wall implant and registers with a surgical navigation system to facilitate optimal positioning with respect to the orbital apex.

Methods: An orbital floor/medial wall titanium mesh implant was positioned into a novel clamping instrument probe that was subsequently registered by the surgical navigation system, into which a CT maxillofacial scan of a man who suffered left ZMC fracture was imported. The navigable instrument was used to manipulate the implant within the orbital floor of the sterolithographic model skull with real-time feedback of the implant's position within the orbital apex via automatic symmetrical visualization with the radiographic overlay (Figures 1-2).

Results: The navigable instrument successfully aided simulated intra-operative positioning of the implant with continuous verification of the implant's exact position within the orbital apex. This demonstration illustrated that instrument-guided navigation facilitates implant manipulation and real-time visualization of placement, allowing the surgeon to assess for deviations and adjust accordingly for optimal placement.

Conclusions: Intra-operative instrument-guided navigation of orbital implants presents a significant advantage in improving implant positioning in orbital fracture reconstructions. This novel instrument facilitates both manipulation of implant angulation and orientation once provisionally placed as well as guidance to ensure optimal orientation.

ABSTRACT BODY:

Purpose: There are some post-marketing safety case reports of Beovu®, a rare occurrence of intraocular inflammation (IOI) in association with retinal vasculitis and retinal vascular occlusion, published. Data from real-life practice does, however, allow the safety of Beovu®. These findings are presented in the current retrospective case series.

Methods: Monocentric audit involving a pool of 51 patients (58 eyes) with nAMD and treated with Beovu® between April 2020 and April 2021. This data includes only the patients which had 3 or more intravitreal injections of Beovu® and were treated after 3 uploading doses ever 4 weeks further in treat and extend regime. The following parameters were measured in these patients: visual acuity (VA); central retinal thickness (CRT) with Optical coherence tomography (OCT); intraocular inflammation (IOI); and, intraocular pressure (IOP). Values are reported as means throughout.

Results: The mean age of the patients was 76 years and 50 eyes were pseudophakic at baseline. The mean number of the injections Beovu® given was 6. Two eyes experienced (incidence < 4%) their first IOI-related event within 3 months of the first Beovu® injection. The mean (range) number of days from the last injection to the onset of event were 4 (3-5) for IOI, and 10 (10) for vasculitis with retinal vascular occlusion. One of them had only vitreous haze. Another presented with Iritis, both had no retinal vasculitis and retinal vascular occlusion. These Patients were treated immediately after presentation with systemic and topical steroids. The IOI was resolved in a 5-7 days without loss of VA. There was only one case out of 58 eyes (incidence < 2%)of at least visual acuity loss (!15 ETDRS letters) in eye due IOI and vasculitis with retinal artery occlusion. The treatment with Beovu® was stoped in these eyes and was switched to another medication. There were no IOP-related events observed.

Conclusions: Beovu® shows an overall well-tolerated safety and efficacy profile in our real life clinical practice. The incidence of intraocular inflammation (IOI) (iritis and uveitis), is almost similar in our case series as in HAWK and HARRIER Study. Early detection of IOI and immediate treatment with steroids resolves the IOI and shows no loss in VA.

TITLE: Molecular and ocular characterization of R345W EFEMP1 mice reveal new disease-related insights

SESSION TITLE: Pathobiology of AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Hulleman, M. Renwick, S. Daniel, Ophthalmology, The University of Texas Southwestern Medical Center, Dallas, Texas, UNITED STATES|

Commercial Relationships Disclosure: John Hulleman: Commercial Relationship: Code N (No Commercial Relationship) | Marian Renwick: Commercial Relationship: Code N (No Commercial Relationship) | Steffi Daniel: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The R345W mutation in EFEMP1 (a.k.a. fibulin-3, F3) causes a rare macular dystrophy (Malattia Leventinese/Doyne Honeycomb Retinal Dystrophy, ML/DHRD) resembling an early onset form of age-related macular degeneration (AMD). Studies have demonstrated that R345W knockin mice form basal laminar deposits (BLamDs) and they have also implicated complement activation as a key pathway in disease progression. Yet little additional information on these mice exists. Herein, we sought to thoroughly characterize the R345W EFEMP1 knockin mice with respect to any molecular or physiological differences vs. wild-type mice with the hope of identifying and eventually targeting new pathways for disease intervention.

Methods: Homozygous R345W knockin mice on the C57BL/6 background (and their littermate controls) were aged up to 20 months prior to analysis. Anterior physiology was measured by in vivo confocal microscopy, rebound tonometer and slit lamp. In vivo retinal structure was evaluated by OCT (also by blue AF), and TEM, histology, and RPE flat mounts post euthanasia. Retinal function was assessed by ERG (scotopic [a,b,c-wave], photopic [a-, b-wave]). Molecular evaluation was achieved using IHC and qPCR.

Results: No increase in corneal haze or stromal thickness were observed, contrasting our findings in EFEMP1 knockout mice. Slit lamp and IOP assessment were unremarkable in mutant mice. Total retinal thickness (by OCT) was not significantly different between groups (16 mo), while retinal AF was slightly, but significantly increased in mutant mice. Aged R345W mice (16 mo) formed canonical, thick, continuous BLamDs, consistent with previous observations. Histologically, aged R345W mice (16 mo) appeared to be more prone to photoreceptor/RPE disorganization/disruptions including RPE whorls. Yet, remarkably, no differences in any ERG functional readings were detected in R345W mice (up to 20 mo). At the molecular level, we detected significant increases in C3, casp1, Il1b and Nlrp3 (qPCR) in mutant RPE/choroid (18 mo) and increased staining for Nlrp3 and Iba1 in posterior sections (IHC).

Conclusions: The R345W mice develop ultrastructural defects (BLamDs), disrupted photoreceptor/RPE organization and increased retinal autofluorescence. Molecularly, inflammasome activation may be a triggering event in ML/DHRD. Pharmacological or genetic targeting of Nlrp3 or Casp1 may alter the course of this AMD-like disease.

ABSTRACT BODY:

Purpose: The biochemical and histological examination of choroid and the status of its cellular components have been very challenging due to the presence of the retinal pigmented epithelium (RPE) layer between the choroid and retina. Here we developed methods for labeling and visualization of choroidal macrophages, mast cells, and vasculature in pigmented mice.

Methods: Eyes from three albino lines (FVBN, CD-1, and BALB/c) and one pigmented line (C57BL/6J) of mice were collected, fixed for 1 h in 4% paraformaldehyde, washed 3 times in PBS, and kept in cold PBS until dissected. The wholemount of choroid-sclera complex from the albino and pigmented mice were independently stained with anti-Iba1 and anti-podocalyxin to label the choroidal macrophages and vasculature, respectively. Mast cells were labeled with Avidin-conjugated rhodamine. To eliminate the pigment from RPE cells of C57BL/6J eyes, the stained tissues were fixed again before bleaching; 4-5 h in a 55°C water bath using 1% H_2O_2. Tissues were then washed and incubated with secondary antibodies and Avidin-conjugated rhodamine. Choroidal macrophages, mast cells, and the vasculature were visualized using confocal microscopy.

Results: The novel staining methods described here allowed the successful visualization of choroidal macrophages, mast cells, and the vasculature in both albino and pigmented mice. Choroidal macrophages in all mouse lines were denser around the optic nerve compared with the equator and periphery. Choroidal mast cells were relatively dense around the optic nerve of all mouse lines examined. However, their distribution in the equator and the periphery were different. The FVBN, CD-1 and C57BL/6J mice had fewer mast cells in the equator compared to the periphery. BALB/c mice had more mast cells, which were almost uniformly distributed in the equator as compared to the periphery. The total number of choroidal mast cells was highest in BALB/c and FVBN mice. The structure of the choroid in all four lines of mice was roughly comparable, except albino mice showed signs of hypotrophy.

Conclusions: Staining and bleaching of pigmented eyes allowed the visualization of choroidal macrophages, mast cells, and vasculature in the eyes of pigmented mice. These methods should allow the evaluation of choroid and its various cellular components in transgenic and preclinical mouse models of eye diseases.

TITLE: Goniotomy and Direct Viscodilation of the Collector Channels with Cataract Surgery: 5 year results

SESSION TITLE: Surgery & Wound Healing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.E. Gilmore, ophthalmology, The University of Texas Southwestern Medical Center Medical School, Dallas, Texas, UNITED STATES|

Commercial Relationships Disclosure: JANE Gilmore: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The purpose is to evaluate a hybrid MIGS procedure using Goniotomy and Direct Viscodilation of the collector channels with cataract surgery in all levels of glaucoma. This unique technique not only removes the trabecular meshwork but also directly viscodilates the collector channels.

Methods: After cataract surgery, the Dual Blade removed 180° of trabecular meshwork. Viscoelastic was injected into the exposed ostium of the Collector Channels as the perpendicular viscoelastic cannula was held firmly against the outer wall and dragged through the gutted canal. Moderate to severe glaucoma comprised 58% of the 213 eyes followed at least 2 years. 32% had previous glaucoma surgery. 71% were African American. 44% were diabetics. 50% were on an anticoagulant.

Results: Initial IOP was 19.0mmHg(SD+/-7.1)on 1.7 medications. At 3 months the IOP was 15.5mmHg(SD+/-5.0). Throughout the first year the IOP hovered around 16.0mmHg in 316 eyes. IOP then settled to 16.2mmHg (SD+/-5.1) at 3 years(n=120)and 16(SD+/-4.1)at 4years(n=63). Although the IOP was reduced by 15%, the reduction in medications hovered around 70% over 5yrs. All eyes had ≤15mmHg AND no meds in 37% (1yr), 30% (2yr) 37%(3yr), and 32% (4yr). Even the moderate to severe group had ≤15mmHg AND no meds 38% (1yr), 30% (2yr), 36% (3yr), and 32% (4yr). Medications were reduced by 1.5 drops per eye over the course of 5 years. Reduction of drops in this group of 316 eyes resulted in a savings of $240,000 in the first year alone.

Conclusions: The synergy of Goniotomy and Viscodilation markedly reduces drops even in advanced glaucoma with at least 50% of eyes achieving IOP ≤15mmHg, thus improving compliance and reducing the associated financial burden. The Goniotomy-Viscodilation-Cataract technique addresses both trabecular outflow resistance and salvages the collapsed collector channels.

ABSTRACT BODY:

Purpose: There is an unmet need for discovering effective treatments and creating animal models of the most prevalent neurodegenerative form of blindness in the elderly, called age-related macular generation (AMD). We performed extensive ocular characterization of an animal model exhibiting AMD-like pathology, the liver-X-receptor alpha knockout mice ($LXR\alpha^{-/-}$, $Nr1h3^{-/-}$), as a function of age and identified multiple endpoints, which may serve as valuable tools in drug discovery.

Methods: $Nr1h3^{-/-}$ mice were divided into three age groups: group 1 (10-14 month old), group 2 (18-22 month old) and group 3 (24-28 month old), and imaged by Micron IV to obtain fundus and optical coherence tomography (OCT) images (n=5/group). Electroretinograms (ERG) were recorded to measure dark-adapted and rod-saturated responses. Retinal morphology and ultrastructure was assessed (n=5/group). RPE-choroid flatmounts (n=4/group) were stained with phalloidin and probed with an antibody to F4/80 and CD68 to evaluate RPE structure and immune cells. Cytokine levels were measured in retinal and RPE/choroid protein lysates as a function of age (n=4/group).

Results: In vivo, $Nr1h3^{-/-}$ mice exhibited inner and outer retinal hyper-reflective spots and localized deposits by OCT. The frequency of outer retinal hyper reflective spots was higher in group 2 (6/10 eyes) and group 3 (4/10 eyes) cohorts as compared to group 1 (1/10 eyes). Also, a significant decline in scotopic-a (Mean ± SEM, group 1: 183 ± 13 µV, group 2: 103 ± 12 µV, group 3: 47 ± 11 µV, group 1 vs 2: $p<0.05$, group 1 vs 3: $p<0.01$), scotopic-b (group 1: 378 ± 36 µV, group 2: 215 ± 23 µV, group 3: 110 ± 8.15, group 1 vs 2: $p<0.05$, group 1 vs 3: $p<0.05$), and photopic-b (group 1: 92 ± 6 µV, group 2: 60 ± 178 µV, group 3: 32 ± 14 µV, group 1 vs 3: $p<0.05$) wave amplitudes were measured with age. Morphologically, the area of RPE dystrophy quantified from RPE/choroid flatmounts increase significantly with age (group 1: 6.2 ± 0.4%, group 2: 8.4 ± 0.8%, group 3:11.5 ± 0.9%, group 1 vs 2: $p<0.05$, group 1 vs 3: $p<0.01$).

Conclusions: $Nr1h3^{-/-}$ mice exhibit an age-related decline in retinal function and compromised RPE morphology, with the oldest cohort showing the most severe phenotype. End-points evaluated in the study can be employed in preventive (younger age; 4-8 months) and interventional pre-clinical studies (older age;14-18 months), testing potential experimental therapies.

ABSTRACT BODY:

Purpose: Aging and diabetes are associated with retinal vascular disease and vision loss. Vascular remodeling that results in retinal endothelial cell (EC) loss of mural coverage has been implicated in early pathogenesis of diabetic retinopathy (DR). We previously observed specific loss of smooth muscle cell (SMC) coverage along superficial arterioles in aged murine and human retinas. Additionally, global-Cav1 (Caveolin-1) knockout in young mice also reduces SMC coverage, and we previously presented data suggesting that EC-specific Cav1 supports SMC preservation. The purpose of this study is to investigate potential EC-Cav1-dependent EC/SMC pathways important for SMC maintenance. As ECs play a role in SMC nutrient availability and EC/SMC communication, our hypothesis is that EC-Cav1 is important for micorvascular SMC maintenance in the adult retina.

Methods: We used Tie2-Cre recombination of the Cav1-floxed gene (Tie2-Cre/Cav1$^{f/f}$) to generate EC-Cav1 KO mice. GC/MS was used to assess changes in whole retinal metabolites from 13-week old male and female EC-Cav1 KO animals. We used shRNA-mediated Cav1 knockdown in human retinal ECs (hRECs) to assess Cav1-dependent effects on Notch receptor expression via Western blot.

Results: EC-Cav1 KO mice showed an overall reduction in retinal glycolytic and amino acid metabolic intermediates. We also show shRNA-mediated Cav1 knockdown reduces hREC Notch1 and Notch4 protein expression. Future metabolic studies will assess EC-Cav1 KO effects on various metabolic pathways in ECs, SMCs, and whole retina tissue. Ongoing studies regarding EC-Cav1 effects on Notch ligand expression, as well as human retinal vascular SMC (hVSMC) receptor and ligand expression, are currently underway.

Conclusions: Our data suggest that EC-Cav1 has a broad impact on the overall retinal tissue metabolic profile, suggesting that Cav1-dependent functions originating from the relatively small proportion of ECs in the retina may have the capacity to significantly alter whole tissue nutrient handling. Additionally, our data showing EC-Cav1 depletion in cultured ECs reduces Notch receptor expression suggests that EC-Cav1 may play an important role in maintenance of EC/EC and/or EC/SMC communication in adult retinal vasculature.

ABSTRACT BODY:

Purpose: Oculocutaneous albinism type 2 (OCA2) is a rare genetic condition due to recessive mutations in OCA2 gene and results in pigmentation defects of the skin, hair, and eyes. We have previously shown that induced pluripotent stem cells (iPSCs) derived from OCA2 patients successfully recapitulate pigmentation defects when differentiated in vitro into retinal pigment epithelium (RPE). We used CRISPR-Cas9-based homology-dependent repair of a mutant allele in iPSCs derived from an OCA2 patient. The purpose of our study was to create an isogenic pair of iPSCs for studying OCA2 related pigmentation defects in the human RPE.

Methods: All human iPSC work was approved by the NIH Institutional Review Board, protocol # 11-E1-0245 (NCT01432847). iPSCs were derived from OCA2 patients with compound heterozygous mutations. Two sgRNAs were designed, targeting chromosome 15 (NG_009846.1). The donor template used for HDR replaced the mutation c.1211C>T (NM_000275.3) in exon 12. The OCA2_iPSC colonies were transfected using Lipofectamine ™ followed by single-cell cloning in the presence of Puromycin to positively select GFP+ colonies. Selected iPSC clones were transfected with a Cre recombinase-expressing plasmid followed by treatment with Geneticin to select for GFP-negative colonies resulting from recombination and excision of the cassette containing GFP and neomycin. The GFP-negative iPSC colonies were then expanded and analyzed using flow-cytometry to confirm the complete lack of GFP expression. Sanger sequencing was performed on GFP-negative iPSC colonies to confirm correction of the mutation (OCA2-IC_iPSC).

Results: We successfully replaced the c.1211C>T mutation in exon 12 of OCA2 with the wild type sequence as confirmed by Sanger sequencing. The isogenic iPSC pair exhibited normal human karyotype and expression of pluripotency markers like NANOG, OCT4, SOX-2, SSEA4, TRA-1-60, and TRA-1-81. The OCA2-IC_iPSC when differentiated towards RPE exhibited normal pigmentation whereas the OCA2_iPSC derived RPE exhibited partial pigmentation.

Conclusions: Our work establishes proof of principle for CRISPR-mediated gene editing as a strategy for pigment rescue in OCA2. Furthermore, we introduce OCA2 patients and corrected isogenic cell lines as valuable tools for in vitro disease investigation and drug discovery.

ABSTRACT BODY:

Purpose: Paravascular inner retinal defects (PIRD) are a well-known association of myopia and epiretinal membranes (ERM). We aimed to determine if PIRD can also be correlated with the presence and stage of posterior vitreous detachment (PVD) using en face optical coherence tomography (OCT).

Methods: This was a retrospective cross-sectional, observational, single center study. 9x9 mm and 12x12 mm en face optical coherence tomography (OCT) images (Solix Full Range OCT, Optovue) were reviewed from an OCT angiography database from a single medical retina office (DS) at the Stein Eye Institute at UCLA. PIRD were confirmed with analysis of both the en face OCT and the corresponding B scan. PVD was graded according to the corresponding OCT B scan. PIRD were classified as paravascular retinal cysts (without communication to the vitreous cavity) versus paravascular lamellar holes (with communication to the vitreous cavity) and according to the number of PIRD a) one PIRD versus b) 2 or more PIRD.

Results: En face OCT datasets from 1137 patients were reviewed. A total of 272 eyes from 176 patients (15.49%) showed evidence of at least one PIRD in one eye. The mean age of this cohort was 70.5 ±13.5 years and 100 (57%) were female. In eyes with PIRD, grade 0 PVD was noted in 25 eyes (13%), grade 1 PVD in 32 eyes (16%), grade 2 PVD in 15 eyes (8%), grade 3 PVD in 22 eyes (11%), and grade 4 PVD in 178 eyes (71%).

Of the 272 eyes, 153 (56.25%) displayed paravascular retinal cysts and 119 (43.75%) displayed paravascular lamellar holes. Paravascular lamellar holes were observed in 3 eyes (12%) without PVD, 34 eyes (49.3%) with partial PVD (stage 1 to 3), and 82 eyes (46.1%) with complete PVD (p=0.003). Two or more PIRD were found in 9 eyes (36%) without PVD and in 171 eyes (69%) with partial or complete PVD (stage 1 to 4) (p=0.001).

Conclusions: PIRD are a well-known complication of myopia and ERM. This study correlated the presence and grade of PVD with the development of PIRD. PIRD likely develop as a result of chronic vitreoretinal traction, especially in areas of increased traction as occurs along the major retinal vessels. En face OCT is an effective tool to detect PIRD.

ABSTRACT BODY:

Purpose: Vascular endothelial growth factor (VEGF or VEGF-A), a major therapeutic target for blood-retina barrier breakdown (BRB) in diabetic retinopathy (DR) and neovascular age-related macular degeneration (AMD), has been shown to act as a direct functional regulator for peripheral and central nervous system (CNS) neurons. The purpose of this study was to determine whether VEGF is a direct regulator of photoreceptor function and its potential role in altering vision during the progression of DR, AMD, and other hypoxic retinal BRB diseases.

Methods: For this study, we developed a procedure to measure the direct effect of VEGF on photoreceptor function with electroretinography (ERG). Overnight dark-adapted wild-type (WT) mice were injected with recombinant VEGF (rVEGF) intravitreally under long-wavelength illumination. Retinal function in these mice was examined with scotopic and photopic electroretinography ERG immediately after intravitreal rVEGF delivery. Diabetes- or hypoxia-induced alteration of photoreceptor function was examined with Akita diabetic mice or hypoxic mice immediately after injected with rVEGF or vehicle.

Results: In dark-adapted WT mice, rVEGF caused a significant reduction of scotopic ERG a-wave and b-wave amplitudes and photopic ERG b-wave amplitudes in a dose-dependent manner. However, the effect of rVEGF on the alteration of ERG amplitudes was nullified in 5-mo-old Akita diabetic mice in which a higher level of VEGF was present in photoreceptors. A similar result was also observed in 1.5 mo-old hypoxic mice generated by placing the animals with 7% oxygen for 5 days.

Conclusions: Our results suggest that VEGF is a direct functional regulator for photoreceptors and a contributing factor to the loss of photoreceptor function in diabetes and hypoxia (retinal environment in AMD). As VEGF is a major therapeutic target for BRB breakdown in DR, AMD, and other hypoxic retinal BRB diseases, our work provides the mechanistic insights for the therapeutic effects on visual acuity and for the care of anti-VEGF drug treated patients.

ABSTRACT BODY:

Purpose: The Adaptive Optics Scanning Laser Ophthalmoscope (AOSLO) can be used to image photoreceptors, in vivo. Recently, several algorithms for cone characterisation have exploited the specificity of split dector to robustly image cone inner segements. The high packing density of cones within the fovea, impedes split dector efficacity[1]. We present a novel algorithm for automated cone detector in confocal images: the Automatic Adaptive Thresholding and Maxima Search (ATMS).

[1] (Morgan, J. I. W., Vergilio, G. K., Hsu, J., Dubra, A., & Cooper, R. F. (2018). The reliability of cone density measurements in the presence of rods. Translational Vision Science and Technology, 7(3), 1–11. https://doi.org/10.1167/tvst.7.3.21).

Methods: ATMS first detects darker areas by adaptive local filtering. Those correspond to blood vessels where cones cannot be reliably counted, so they are excluded from further analysis. The image is then split into Regions Of Interest (ROIs) and contrast enhancement is performed separately in each ROI, normalizing by brightness and subtracting its the second derivative. This enhances the bright spots corresponding to cones. Based on the local distribution of luminosity in each ROI, the image was then segmented using adaprive thresholding, and the cones are identified via a local maxima search. Finally, the output was refined by adjusting the threshold probability based on Veronoi properties of the cell mosaic. From this output, cell densities were calculated.

Results: Results were validated on 53 images from 10 subjects. Each image was annotated by 2 graders: the overall mean Dice’s coefficient was 0.96 (Precision = 0.97, Recall = 0.95).

Conclusions: This paper presented a novel, fully automated labelling method which is suitable for analysis of central foveal regions (0° to 3°) in confocal images. Our method was integrated with existing tools that operate in more peripherical regions (4° to 10°), thus building a cell density estimation pipeline which works across the full range of retinal eccentricities.

ABSTRACT BODY:

Purpose: Blindness afflicts 39 million people worldwide. Retinal ganglion cells are unable to regenerate, making this condition irreversible in many cases. Whole-eye transplantation (WET) may be a viable treatment option. To further enhance our knowledge of WET, individual cell types response to the transplant must be studied. 661W cone photoreceptor cells, derived from mouse, have been widely used as a model for studying macular degeneration. Here, we characterize the 661W cell line for studying the effect of cold ischemia/warm reperfusion injury that is relevant to WET.

Methods: To understand the phenotype of injury during in-vivo cold ischemia/warm reperfusion injury, 661w cells were subjected to cold storage and rewarming (CS/REW). First, cells were subjected to cold storage (CS) in cold saline solution for 24 h at 4°C. Next, cells were rewarmed (REW) in normal growth media at 37°C for 24 h. Control cells were kept at 37°C. A dose response analysis was performed to determine the optimal concentration of pan-caspase inhibitor (Q-VD-OPh) and necroptosis inhibitor (Necrostatin-1) to completely inhibit aoptosis and necroptosis.

Results: Cell death percentage, measured as Annexin V positive and/or PI positive cells by flow cytometry was significantly increased in the 661w cells subjected to CS/REW compared to control cells (Figure 1). We looked for the expression of key integrators of signaling pathways that mediate apoptosis and necroptosis. 661w cells subjected to CS/REW have activation of apoptosis as determined by increased expression of cleaved caspase-3 and increased TUNEL staining. Moreover 661w cells exposed to CS/REW also showed activation of necroptosis as determined by increased expression of RIP3 and pMLKL. The effect of Q-VD-OPh and Necrostatin-1 on caspase-3 protein expression and pMLKL was dose-dependent. Q-VD-OPh treatment at 50 μM inhibit the apoptosis, whereas Necrostatin-1 treatmnet at 100 μM inhibit the necroptosis.

Conclusions: Our results suggest that the inclusion of cold storage followed by warm reperfusion during WET will likely induce cell death by both apoptosis and pnecroptosis. Apoptotic cell death and necroptosis can be successfully prevented using a pan-caspase I inhibitor and Necrostatin-1. Future studies: We will also study the collective effect of inhibiting apoptosis and necroptosis in 661w cells after CS/REW by using a cocktail of Q-VD-OPh and Necrostatin-1.

ABSTRACT BODY:

Purpose: As an accessible component of the central nervous system, the retina may be a site to objectively detect TBI-related neurodegeneration. We studied whether multiple TBIs alter the structure or the function of retinal ganglion cells in human subjects.

Methods: Adult case subjects with a history of at least two mild or moderate TBIs (n = 25, mean age ± SD = 32.2 ± 11.8 yrs, 52% female) and age- and sex-matched control subjects with no TBI history (n = 25, 32.5 ± 12.0 yrs, 52% female) were prospectively recruited from an optometry clinic. Full-field flash electroretinography recordings of the photopic negative response (PhNR) were made in accordance with the International Society for Clinical Electrophysiology of Vision. As a structural correlate, the thickness of the retinal nerve fiber layer (RNFL) was quantified using scanning laser polarimetry (SLP) and optical coherence tomography (OCT). All measurements were averaged between both eyes of each subject. Comparisons between the two groups were made using paired t-tests (significance threshold $p < 0.05$). Pearson correlation coefficient tests assessed linear relationships between RNFL thicknesses and PhNR parameters.

Results: Case subjects reported 4.1 ± 2.8 TBIs over a range of 0-41 years. The PhNR amplitude was not significantly different ($p = 0.11$) between the case (24.1 ± 5.1 μV) and the control (27.8 ± 9.1 μV) cohorts, and neither was the PhNR peak time (case: 69.9 ± 6.9 ms; control: 70.1 ± 8.9 ms; $p = 0.95$). Likewise, there was no significant difference between the two cohorts for global RNFL thickness measured by OCT (case: 96.6 ± 9.4 μm; control: 94.9 ± 7.0 μm; $p = 0.42$) or by SLP (case: 57.9 ± 5.7 nm; control: 58.2 ± 4.6 nm; $p = 0.80$). Within the case cohort, there were no significant correlations between OCT thickness and PhNR amplitude ($r = -0.15$, $p = 0.52$), OCT thickness and PhNR peak time ($r = -0.29$, $p = 0.19$), SLP thickness and PhNR amplitude ($r = -0.06$, $p = 0.80$), or SLP thickness and PhNR peak time ($r = -0.36$, $p = 0.10$).

Conclusions: There were no differences in PhNR parameters or in RNFL thicknesses between the case and the control cohorts. Previous works have shown that multiple TBIs elicit RNFL thickness changes in athletes, but our results showed no changes in a general population that suffered multiple TBIs. Future work will evaluate the structure and the function of the outer retina after multiple TBIs.

ABSTRACT BODY:

Purpose: To examine the relationship between base curve (BC) and sagittal depth (Sag) of scleral lenses (SL) with various tomography metrics in patients successfully fit with SL.

Methods: A retrospective chart review of patients successfully fit with SL (Zenlens, 16mm and 17mm, Bausch + Lomb SVP, Lancaster, NY and CustomStable, 17.8 and 16.8mm, Valley Contax, Springfield, OR) was performed. 76 eyes of 44 patients were included in the study. The average age was 45.92 ± 12.31. Of the 76 eyes, 74 were fit for irregular corneal conditions and 2 were fit for ocular surface disease. Final prescribed SL parameters, BC and Sag, and scheimpflug tomography (Pentacam HR, Oculus, Germany) metrics, including maximum keratometry (Kmax), mean keratometry (Kmean), flat keratometry (Kflat), steep keratometry (Ksteep), anterior chamber depth (ACD), white-to-white horizontal corneal diameter (WTW), and the inferior-superior (IS) ratio at the 6 mm zone, were obtained. To account for differences in labeled Sag between the SL designs, the lowest lens Sag was subtracted from the other lenses in their respective SL design cohort. The difference in μ was then consistent across SL designs for direct comparison. Statistical analysis for correlation of tomography metrics and final SL parameters was performed (SPSS, IBM Corporation, Armonk, NY).

Results: A positive correlation was found between the final prescribed Sag and ACD (R=0.70, p<.001), Kmax (R=0.61, p<.001), Kmean (R=0.54, p<.001), Kflat (R=0.45, p<.001), Ksteep (R=0.59, p<.001), and IS ratio (R=0.25, P=.03). No correlation was found between Sag and WTW (R=0.08, p=.5). No correlation was found between BC and ACD (R=0.14, p=.24), Kmax (R=0.11, p=.34), Kmean (R=0.12, p=.29), Kflat (R=0.06, p=.61), Ksteep (R= 0.1, p=.39), IS ratio (R=0.18, p=.12), or WTW (R=0.04, p=.73).

Conclusions: Of the tomographic metrics analyzed, ACD was most strongly correlated with SL Sag followed by a correlation with Ksteep and Kmax. Tomographic metrics were not correlated with SL BC, indicating BC is an independent variable. This data suggests ACD may be the best metric to aid in selecting diagnostic SL during the SL fitting process.

ABSTRACT BODY:

Purpose: To explore the resilience of the visual system to the blurring effect induced by defocus oscillations. This is determined by the loss in contrast sensitivity produced by sinusoidal oscillations in defocus with a range of amplitudes and temporal frequencies. The aim is to compare with natural conditions of accommodation microfluctuations.

Methods: Contrast sensitivity at 12 c/deg was measured monocularly in 5 young healthy emmetropic subjects through a tunable lens introducing sinusoidal oscillations of defocus around 0 D at 5, 15, and 25 Hz. Peak-to-peak oscillation amplitude varied from 0.15 D to 3 D. The visual stimulus was a Gabor patch at 3 m and a two-choice forced-choice protocol was used. Target presentations were randomized through temporal frequency, amplitude, and contrast (5 contrast values around and adjustment threshold determined in advance). The tunable lens was attached to an open-view Hartmann-Shack wave-front sensor (V. P. Ghoushchi et al., Biomed. Opt. Express 12, 3282-3295, 2021) measuring in real time, thus allowing a) verification of the subject's accommodative state, and b) confirmation of the amplitude and frequency of defocus oscillations generated by the lens.

Results: The figure illustrates the average contrast threshold as a function of amplitude for all subjects. Although there was some variability between subjects, contrast sensitivity was fairly constant despite the defocus oscillations introduced. Only for the fastest oscillations (25 Hz) and highest amplitude (+/-1.5 D) contrast sensitivity appears to suffer a significant degradation.

Conclusions: Our results show that the visual system is resilient to fluctuations in defocus, at least concerning contrast sensitivity tasks. The fact that contrast sensitivity only appears to fall for fast and large oscillations in defocus, suggests that the eye does not average blur and a short time with the image in or around focus is enough to detect the target. These results may have some implications in myopia control and in visual simulators based on oscillating defocus.

ABSTRACT BODY:

Purpose: Evaluating the efficacy of every 6-or-8-week aflibercept extension regimen in resistant Choroidal Neovascularization (CNV)s requiring monthly treatment.

Methods: This was a retrospective, cross-sectional study. Patients who visited the Retina clinic with a diagnosis of CNV due to AMD requiring escalating regimen and needing monthly aflibercept to control disease were reviewed. There were total of 60 eyes which were included. Subjects received either regular (low) dose aflibercept (A/L- 2 mg) or high dose aflibercept (A/H- 4 mg) injections every 4 weeks initially, until their macular Optical Coherence Tomography (OCT)s were dry, and they were then extended to either every 6-or-8-week injections. The durability of extended intervals was monitored by the reappearance of Intra- or Sub- Retinal Fluid (IRF/SRF) in OCTs which had completely dry macula at the start. Statistical analysis was done using Cox regression model.

Results: Analysis performed using dose regimen as a stratum, after adjusting for age and sex, revealed that the dose regimen (High Vs Regular) prior to extension was a significant predictor with high dose (4 mg) showing a longer time to relapse, $p < 0.04$. There was reduced hazard of recurrence (OR A/H vs. A/L = 0.507, $p= 0.0305$). Also, the longer the duration of monthly aflibercept before extension, the shorter the time to relapse, $p=0.0023$.

Conclusions: Resistant CNV requiring monthly aflibercept therapy could be successfully extended to every 6 - 8 weeks. Eyes which received high dose aflibercept injections as the extension regimen took longer to fail and had less disease relapse than the eyes on regular dose.

ABSTRACT BODY:

Purpose: Persistent activity in the nervous system supports tasks that range from working memory to the encoding of eye position. Within the retina, it is a prominent feature of intrinsically photosensitive retinal ganglion cells (ipRGCs), which are vital for processes that include the regulation of circadian rhythms and sleep. IpRGCs respond directly to light using a receptor called melanopsin. Melanopsin's active state is stable and drives phototransduction for minutes even after illumination ceases. Thus, successive periods of illumination can increment the number of activated melanopsin molecules and the rate of persistent spike firing. Because small currents have large impacts on ipRGCs, the existence of graded persistent firing suggests a mechanism of precise control. We tested the hypothesis that persistent activity is controlled by negative feedback in melanopsin phototransduction.

Methods: We focused on ipRGCs of the M1 type, which are principal regulators of the master circadian clock and exhibit large, melanopsin-driven responses that are amenable to quantitative analysis. We identified these neurons in the ex vivo mouse retina using a fluorescent reporter and isolated their intrinsic responses with antagonists of synaptic transmission. We made patch-clamp electrophysiological recordings in voltage clamp and current clamp to examine the melanopsin-driven photocurrent and voltage change, respectively. We delivered optical stimuli to probe persistent responses and negative feedback. We altered negative feedback by manipulating Ca^{2+}, one of its mediators.

Results: We found that persistent photocurrent drove negative feedback, which was evident in response desensitization. When we suppressed the persistent photocurrent, by delivering light that depopulates melanopsin's active state, sensitivity increased for a subset of M1 ipRGCs. Acute removal of extracellular Ca^{2+}, which reduces negative feedback, increased the persistent photocurrent in a reversible manner.

Conclusions: Collectively, our experiments indicate that persistent activity in M1 ipRGC phototransduction recruits and is subject to negative feedback. The latter is mediated in part by Ca^{2+} influx. The balance of persistent activation and negative feedback varies across cells. In some cells, delivering light to suppress persistent activation produces a net increase in sensitivity, despite negative feedback produced by the light itself.

ABSTRACT BODY:

Purpose: To assess the impact of COVID-19 on eyes treated for neovascular AMD.

Methods: Anonymized data from 21 UK centers were extracted from Medisoft for patients receiving treatment with aflibercept and VA data in the pre-covid baseline (01/10/19 to 31/03/20 n=8,313). Comparisons were made for period 1 (01/04/20 to 30/09/20 n=4,011) - lockdown following RCOphth Medical Retinal Management Plan during COVID-19, period 2 (01/10/20 to 31/03/21 n=4,551) - intermittent lockdown following updated RCOphth COVID-19 guidelines, and period 3 (01/04/21 to 30/09/21 n=2,630) -easing COVID-19 restrictions.

VA change was compared for baseline VA, <7 vs. ≥7 injections before period 1 and for eyes losing ≥5 letter in period 1.

Results: The mean change in VA for eyes with a baseline VA of ≤35 ETDRS letters was +0.7, +0.1 and -1.6 letters, 36-55 letters was -3.0, -1.2 and -1.3 letters, 56-75 letters was -2.1, -1.1 and -1.5, and >75 letters was -4.3, -0.7 and -0.4 letters in periods 1, 2 and 3 respectively.

The median VA change was zero letters for all baseline VA groups and time periods except for the >75 letter group in period 1 (median 2 letter loss).

The mean change in VA from baseline for eyes with <7 injections before period 1, was -2.0, -0.6 and -1.2 letters from 2,083, 2,465 and 1,420 eyes in periods 1, 2 and 3, and ≥7 injections before period 1, was -2.9 from 1,928 eyes in period 1 and -1.3 letters from 2,086 and 1,210 eyes in periods 2 and 3. For both groups and time periods the median VA change was zero letters.

For eyes that lost ≥5 ETDRS letters before period 1 the mean change in VA for eyes receiving no injections was +2.3 letters (n=155) and -3.5 letters (n=107), 1-3 injections was +1.4 letters (n=740) and -1.3 letters (n=340), and >3 injections was +2.3 letters (n=199) and -0.8 letters (n=122) in periods 2 & 3 respectively.

The median VA change was zero letters for all time periods and injection number groups except for >3 injection eyes in period 2 (median 3 letter gain) and no injection eyes in period 3 (median 1 letter loss).

Conclusions: In period 1, a small VA loss was experienced by many eyes dependent on baseline VA. Similar VA changes were present for eyes receiving <7 and ≥7 injections before period 1. For eyes that lost ≥5 ETDRS letters during period 1, many had visual gain with more improvement linked to receiving more injections in period 2, falling back in period 3.

TITLE: VRDN-002, A Second-Generation Insulin Like Growth Factor-1 Receptor (IGF-1R) Inhibitory Antibody for Thyroid Eye Disease: Preclinical Pharmacokinetics and Clinical Promise

SESSION TITLE: Thyroid eye disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Dickinson, Viridian Therapeutics Inc, Waltham, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Brent Dickinson: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: VRDN-002 is a novel anti-IGF-1R monoclonal antibody intended for treatment of Thyroid Eye Disease (TED). It is engineered to incorporate Fc modifications for half-life extension to enable convenient dosing. TED is most prevalent in patients with Graves' Disease and is driven by Thyroid Stimulating Hormone Receptor (TSHR) agonistic autoantibodies and crosstalk between TSHR and IGF-1R. We sought to compare the pharmacokinetic (PK) parameters of VRDN-002 in cynomolgus monkeys to the marketed IGF-1R antibody, teprotumumab, and to estimate potential human exposures for various dosing paradigms.

Methods: VRDN-002 was administered to cynomolgus monkeys by 30 min intravenous (IV) infusion at 2, 10, and 50 mg/kg, and by subcutaneous (SC) injection at 2 and 10 mg/kg. Teprotumumab 10 mg/kg was also administered by 30 min IV infusion. PK samples were collected at 30 min, 2 and 8 hrs, and 1, 3, 7, 10, 14, 21, 28, 35, 42, 49, and 56 days. VRDN-002 and Teprotumumab levels in serum were measured using a human IgG specific ELISA. Data were analyzed using the WinNonlin non-compartmental model. In addition, a semi-mechanistic model incorporating target-mediated drug disposition (TMDD) was constructed based on a population pharmacokinetic model of teprotumumab in TED patients, as well as VRDN-002 and teprotumumab PK in NHPs. The model was used to estimate human PK for VRDN-002.

Results: VRDN-002 PK administered by IV infusion was approximately linear between 10 and 50 mg/kg doses, suggesting TMDD was saturated at these doses. At 10 mg/kg, VRDN-002 half-life and AUC_{inf} were 14 ± 4 days and 2,300 ± 312 µg.day/mL, respectively, vs. 6.4 ± 0.3 days and 779 ± 79 µg.day/mL for teprotumumab. Bioavailability of VRDN-002 administered via SC injection was 62%. Human exposure estimates of VRDN-002 for various dosing regimens were generated from the semi-mechanistic model.

Conclusions: VRDN-002 demonstrated a desirable PK profile in non-human primates, suggesting potential as a novel therapeutic monoclonal antibody for the treatment of TED. The prolonged half-life of VRDN-002 may enable lower frequency of IV infusion and/or low-volume SC injection; each possibility awaits clinical confirmation.

ABSTRACT BODY:

Purpose: Neuropathic pain is caused by an injury to the somatosensorial nervous system and can affect the cornea. Immune-mediated mechanisms have been defined in the pathophysiology and intravenous immunoglobulin (IVIG) has been reported to be an efficient treatment in immune-mediated small fiber neuropathy (SFN) patients. We aimed to evaluate the efficacy of IVIG treatment in patients with neuropathic corneal pain (NCP).

Methods: Medical records of patients who were diagnosed with NCP and SFN based on clinical, in vivo corneal confocal microscopic, and positive skin biopsy findings, and were initiated with IVIG treatment were evaluated. All patients underwent detailed serological evaluation for auto-/dyimmune antibodies (Abs). Demographic features of patients, corneal fluorescein staining (CFS) scores (Oxford scale), ocular pain assessment survey (OPAS) scores, and ocular surface disease index (OSDI) scores were reviewed at baseline and 6-months treatment follow-up.

Results: Fourteen NCP patients who were refractory to topical and systemic therapies were included. The mean age of patients was 43.2±13.3 years. Twelve patients had at least one positive auto-/dysimmne Ab. Two patients had negative results for Ab screening while presenting strong clinical suspicion for potential underlying autoimmunity. Ocular surface staining was not detected in 13 of the patients, 1 had +3 CFS. Four patients discontinued the treatment before 6 months (2 patients after 1month and 2 patients after 3 months) due to side effects (headache (n=2) and systemic Staphylococcal infection (n=1)) or insurance denial (n=1). In the remaining 10 patients, the mean pain intensity score (scale 0-10) in the last 24 hours and in the last 2 weeks improved from 5.4±0.8 to 3.6±0.9 (p=0.004) and from 5.0±0.9 to 3.7±0.9 (p=0.02), respectively. The impact of pain on quality of life reduced significantly in the follow-up visit (from 6.0±2.9 to 4.3±2.9, p=0.03). Overall, patients reported a mean of 32.5% eye pain relief compared to their baseline visit. The mean OSDI score (0-100) did not show significant changes between visits (58.3±25.6 vs 56.2±24.0, p=0.46).

Conclusions: IVIG treatment provides significant pain relief and improves the quality of life in NCP patients. Therefore, in selected cases, IVIG treatment seems to be promising in NCP management, when refractory to other therapies.

ABSTRACT BODY:

Purpose: Fuchs endothelial corneal dystrophy (FECD) is a degenerative disease commonly associated with a CTG repeat expansion (termed CTG18.1) situated within an intron of the transcription factor encoding gene TCF4. CTG18.1 typically comprises <30 repeats in unaffected or non-CTG18.1-mediated FECD individuals, whereas the majority of FECD patients have a repeat length of ≥50 copies. It is unknown why repeat lengths within the 30-49 range are so rarely detected and if expansions within this range induce defined biomarkers of CTG18.1-expansion mediated FECD (e.g. RNA foci). Here we aim to describe FECD patients within our updated FECD cohort with intermediate repeat lengths (30-49) and, when possible, investigate biomarkers of disease within their corneal endothelial cells (CECs).

Methods: Genomic DNA was extracted from blood samples taken from FECD patients in the UK and the Czech Republic (n=930) and genotyped for CTG18.1-repeat length using short tandem repeat PCR and triplet-primed PCR. Concurrently, primary CECs were cultured following Descemet membrane endothelial keratoplasty (DMEK) in select FECD patients. CECs were probed for repeat containing RNA foci via fluorescence in situ hybridization (FISH) and foci distributions were quantified.

Results: Out of 930 FECD patients, 730 were expansion positive with a CTG18.1 repeat length ≥50 while 186 patients had a repeat length <30 (Figure 1). CTG18.1 repeat length displays a bimodal distribution with only 14 patients with a repeat length between 30-49 (mean age = 65; 9/5 female/male ratio). Primary CECs cultured from a FECD patient within this group expressed RNA foci, but with atypical distribution.

Conclusions: Only 1.5% (14/930) of FECD patients in our cohort have an intermediate CTG18.1 repeat genotype. All cases investigated within this group to date display biomarkers of CTG18.1 expansion-mediated disease within their CECs. However, RNA foci distribution appears abnormal when compared to FECD patients with ≥50 repeats. This suggests a CTG18.1 founder allele length of between 30-49 repeats is sufficient for foci formation but can influence the frequency of RNA foci in CECs and their likely downstream pathogenic effects.

ABSTRACT BODY:

Purpose: OCT-A is a relatively new imaging modality allowing noninvasive visualization of macular neovascularization (MNV) in neovascular age-related macular degeneration (nAMD). Grader assessment of MNV area includes annotations on the angiogram using properly segmented OCT-A scans within defined slabs. MNV area is delineated after a comprehensive examination of the cube scan and visualization of flow in areas of retinal pigment epithelial detachment with or without a visible network on the angiogram. To reduce burden on human resources and improve efficiency, we developed an automated, deep learning (DL) algorithm for quantitative assessment of MNV area from OCT-A.

Methods: Training dataset included planimetry annotations of MNV area by multiple graders from 6x6mm OCT-A scans of 44 eyes generating a total of 104 lesion annotations. Screenshots of the annotated angiograms were used for training a U-Net DL model with a ResNet backbone for binary image segmentation. Predictions made by the algorithm were fitted with a binary mask to define borders and area measurements. As the images were of a fixed sized, pixel counts of mask sizes were used to measure predicted masked area. Validation dataset included 28 OCT-A for comparison of grader annotation with DL predictions using area measurements and Dice Similarity Coefficient (DSC).

Results: Mean difference in MNV area between graders was $0mm^2$ (95% CI -1.12 to 1.12). Mean difference in MNV area between the DL algorithm and grader was $0mm^2$ (95% CI -4.07 to 4.07) with an intra-class correlation of 0.731. Mean DSC between DL algorithm and grader was 0.45 +/- 0.26. Examination of OCT-A annotations with DSC < 0.6 (16 images) showed quilting artifacts and absence of MNV network on the angiogram.

Conclusions: There is a moderate correlation between DL quantification of MNV lesions and graders' area measurements using OCTA. It is important to note that the algorithm's decision is limited by the angiogram whereas the grader has access to structural b-scans and flow data. This study shows a very promising trajectory for the use of DL in the quantitative analysis of MNV lesions.

TITLE: Refractive outcomes after primary bevacizumab followed by laser versus primary laser alone for Retinopathy of Prematurity

SESSION TITLE: Retinopathy of prematurity

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Spiller, L. Verkuil, B. Forbes, G. Binenbaum, Ophthalmology, The Children's Hospital of Philadelphia, Philadelphia, Pennsylvania, UNITED STATES|Y. Yu, G. Ying, G. Binenbaum, Scheie Eye Institute, Philadelphia, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Alyssa Spiller: Commercial Relationship: Code N (No Commercial Relationship) | Lana Verkuil: Commercial Relationship: Code N (No Commercial Relationship) | Brian Forbes: Commercial Relationship: Code N (No Commercial Relationship) | Yinxi Yu: Commercial Relationship: Code N (No Commercial Relationship) | Gui-Shuang Ying: Commercial Relationship: Code N (No Commercial Relationship) | Gil Binenbaum: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Children with severe retinopathy of prematurity (ROP) commonly develop myopia or high myopia. One proposed benefit of intravitreal bevacizumab (IVB) over laser is decreased myopia; however, many IVB eyes are later treated with laser. We sought to compare prevalence of myopia and high myopia after primary IVB followed by laser photocoagulation (VEGF/LASER) to primary laser (LASER).

Methods: Retrospective cohort of infants who had VEGF/LASER or LASER for Type 1 ROP and cycloplegic refraction at age 6-30 months. Primary outcomes were prevalence of myopic (minimum -1D) and highly myopic (minimum -5D) spherical equivalent refractive error by eye.

Results: 28 eyes (15 infants) had VEGF/LASER at mean PMA weeks 33.8/45.2), 297 eyes (151 infants) had LASER at PMA 37.7; Refractions were at mean 19 months post-treatment. Two groups were similar in myopia (46.4% VEGF/LASER, 43.8% LASER,p=0.23) and high myopia (14.3% VEGF/LASER, 16.2% LASER eyes,p=0.29). Subgroup analysis for zone I at first treatment also showed no difference (myopia 64.3% VEGF/LASER, 67.9% LASER, p=0.73); high myopia (14.3% VEGF/LASER, 37.5% LASER, p=0.22). Among all eyes, total laser spots was associated with myopia (aOR 1.07 per100 spots increase, 95% CI 1.03-1.12) and high myopia (aOR 1.06, 95% CI 1.01-1.12), but spots did not differ among treatment groups (mean 2044 VEGF/LASER, 1857 LASER, p=0.60).

Conclusions: The prevalence of myopia and high myopia did not differ between VEGF/LASER and LASER. Though more laser spots are associated with higher risk of myopia, spot counts were not lower when laser followed primary IVB.

TITLE: Dysregulation of Neuroprotective Lipoxin Pathways in the Mouse Retina Following Silicon Oil-Induced Ocular Hypertension

SESSION TITLE: Neurodegeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. KARNAM, S. Maurya, E. Ng, L. Yang, E. Wang, K. Gronert, J.G. Flanagan, Herbert Wertheim School of Optometry, University of California Berkeley, Berkeley, California, UNITED STATES|

Commercial Relationships Disclosure: SHRUTHI KARNAM: Commercial Relationship: Code N (No Commercial Relationship) | Shubham Maurya: Commercial Relationship: Code N (No Commercial Relationship) | Elainna Ng: Commercial Relationship: Code N (No Commercial Relationship) | Lily Yang: Commercial Relationship: Code N (No Commercial Relationship) | Eileen Wang: Commercial Relationship: Code N (No Commercial Relationship) | Karsten Gronert: Commercial Relationship: Code N (No Commercial Relationship) | John Flanagan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We recently proposed that lipoxins are synthesized in the inner retina, are downregulated following acute and chronic injury, and that restoring their function is neuroprotective. In this study, we characterize the cell-specific regulation and functional expression of lipoxin pathways in response to ocular hypertension (OHT) induced injury to the retina.

Methods: OHT was induced in the C57BL/6J mice by injection of silicone oil (SO) in the anterior chamber of the eye. In the contralateral eye, sterile PBS was injected and served as the control. Intraocular pressure (IOP) was measured weekly in both eyes and mice were maintained for 10 weeks (n=48). At weeks 4, 8, and 10, mice were euthanized, and the retina from both eyes was harvested for qRT-PCR and HPLC/LC/MS/MS-based lipidomic analysis. For cell-specific gene expression of Alox5, Alox15, and lipoxin receptors (Fpr2 and Fpr3), RNAscope in-situ hybridization was performed. GFAP and RBPMS expression were assessed by immunofluorescence of cryosections.

Results: Lipidomic analysis of 4-week retinas showed changes in the activity of the 15-LOX pathway (15HETE and 17HDHA) in the SO injected group when compared with the PBS injected group and age-matched controls. qRT-PCR analysis revealed a significant up-regulation of Alox15, Fpr1, Fpr2, and Fpr3 genes (>2.5-fold induction) at 4, 8, and 10 weeks and a significant down-regulation of Alox5 gene ($p<0.05$) at 8 weeks after SO injection when compared with the PBS injected eyes. Interestingly, this upregulation of Alox15 (~2-fold, $p<0.05$), Fpr1, Fpr2, and Fpr3 genes were also observed in 8-week IOP-induced Alox5 KO mice. RNAscope data showed that Alox5, Alox15, Fpr2, and Fpr3 were localized in GCL along with INL and ONL of the retina and expressed in the optic nerve. At 10 weeks, loss of RGCs was observed as indicated by the expression of RBPMS, and induced GFAP expression was seen in the SO induced retinal sections (including muller glial activation) when compared with the control.

Conclusions: We demonstrate profound dysregulation of the lipoxin pathway in response to induced OHT, further confirming our earlier findings of a potential and novel mechanism for RGC death. Moreover, the lipoxin pathway is expressed in the optic nerve, which provides evidence that this neuroprotective pathway role extends beyond the retina.

TITLE: Keratoconic eyes have reduced collagen XII in Bowman's layer

SESSION TITLE: Keratoconus and corneal biomechanics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Rigi, H. Son, A.S. Jun, C. Eberhart, U. Soiberman, Wilmer Eye Institute, Johns Hopkins Medicine, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Mohammed Rigi: Commercial Relationship: Code N (No Commercial Relationship) | Hyeck-Soo Son: Commercial Relationship: Code N (No Commercial Relationship) | Albert Jun: Commercial Relationship: Code N (No Commercial Relationship) | Charles Eberhart: Commercial Relationship: Code N (No Commercial Relationship) | Uri Soiberman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Corneal biomechanical failure is the hallmark of keratoconus, a common corneal ectasia, however the cause of this failure remains elusive. Collagen type XII (COL12A1), which localizes to Bowman's layer (BL), is thought to interact with collagen type I and function in stress bearing areas, such as BL. A recent genome-wide association study of keratoconus patients has identified a unique missense mutation in COL12A1. Similarly, proteomic, transcriptomic and immunihistochemical studies of COL12A1 in keratoconus suggest reduced expression at the level of the corneal epithelium and its basement membrane. This study aims to better characterize collagen XII expression in keratoconus corneas compared to non-keratoconus controls.

Methods: Full-thickness corneas obtained from 61 keratoconus cases during keratoplasty and 18 non-keratoconus autopsy were used. Tissue microarrays were constructed from corneal keratoconus and non-keratoconus cases and stained with an antibody to collagen XII alpha 1 (Novus Biologicals, Centennial, CO) at a 1:50 dilution. Four skilled observers (MR, HSS, CGE, USS) analyzed collagen XII stained samples and scores were reached by consensus. Corneal epithelium and stroma were evaluated for extent (in percentages by decile; i.e. 0%, 10%, 20%) and intensity (0-3) of staining, with an overall score obtained by multiplying the two. The epithelial basement membrane (BM) and Bowman's layer were scored for intensity (0-3) of staining alone. A two-tailed Mann-Whitney test was used to compare keratoconus staining scores to controls and a p-value≤0.05 was considered statistically significant.

Results: Median (and interquartile range) staining score in BL was 1 (0.25-1) in controls and 0 (0-0) in keratoconus ($p<0.0001$). Median BM staining score was 2 (1-2.75) in controls and 0 (0-1) in keratoconus ($p<0.0001$). Median epithelial staining score was 1.2 (0.7-2.1) in controls and 0.8 (0.2-1.4) in keratoconus ($p<0.06$). Finally, median stromal staining score was 0.8 (0.75-1.6) in controls and 0.1 (0.1-0.3) in keratoconus ($p<0.0001$).

Conclusions: Collagen type XII expression is reduced in BL, corneal BM and stroma in keratoconus. This loss of expression suggests a role in the pathogenesis of keratoconus, given the putative protective role of collagen XII in stress bearing areas. Further studies are necessary to investigate the mechanisms that lead to collagen type XII dysregulation in keratoconus.

Sander: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Rhodopsin is the class A archetypical G-protein-coupled receptor (GPCR). Despite the progress in biophysical characterization of rhodopsin at different points of the photo-activation process, the first stages of this process are still poorly understood at the structural level. We have developed several llama antibodies (nanobodies, Nbs) as tools to facilitate the structural characterization of rhodopsin, especially in its early activation state, Meta-I.

Methods: Several nanobodies that bind rhodopsin were obtained upon immunization of llamas with bovine rod outer segments. UV-visible spectroscopy was used to characterize the conformational/spectral changes of rhodopsin upon binding of Nbs. Finally, we performed trials for the co-crystallization of several nanobodies with ground state rhodopsin, activated rhodopsin and apo-rhodopsin (opsin).

Results: Here we present the crystal structures of a nanobody (Nb2) in complex with ground-state bovine rhodopsin, as well as Nb2 in complex with opsin. The binding site of Nb2 includes rhodopsin's N-terminus and extracellular loops, ECL2 and ECL3. Whereas rhodopsin's structure in the ground-state rhodopsin/Nb2 complex is virtually identical to that of rhodopsin by itself, Nb2 binding induces a dramatic structural change in opsin, trapping it in a conformation similar to that of ground-state rhodopsin. The crystal lattice is maintained by Nb2/bRho, bRho/bRho and Nb2/Nb2 protein contacts that allow the small conformational changes required by rhodopsin to transition from the ground state to Meta-I. In solution, several of these nanobodies bind to photoactivated, deprotonated rhodopsin (Meta-II), shifting the equilibrium towards a protonated Schiff base state corresponding to the Meta-I conformation.

Conclusions: We have developed several nanobodies that shift the equilibrium of photoactivated rhodopsin towards the elusive Meta-I state. These nanobodies might be a useful tool to facilitate the crystallization of wild type rhodopsin in different conformational states, and/or bound to different ligands. Current efforts include solving the crystal structure of the Meta-I rhodopsin/Nb2 complex.

ABSTRACT BODY:

Purpose: Clinical studies support a role for the stress response protein regulated in DNA damage 1 (REDD1) in diabetes-induced visual dysfunction. REDD1 was recently shown to directly promote inflammatory signaling in myeloid cells. Retinal inflammation is a significant contributor to the development and progression of diabetic retinopathy (DR). Thus, we investigated the role of REDD1 in development of retinal inflammation in diabetes.

Methods: $REDD1^{+/+}$ and $REDD1^{-/-}$ mice were administered streptozotocin to induce diabetes. Retinas were isolated after 16 weeks of diabetes and analyzed for protein and RNA expression by western blot and qPCR, respectively. Macrophages were visualized in retinal sections by immunofluorescence. Activity of the transcription factor nuclear factor-kappa B (NF-κB) was measured by luciferase assay. Similar analyses were performed on wild-type and REDD1 knockout human MIO-M1 retinal cell cultures after exposure to hyperglycemic conditions, inflammatory cytokines, or genetic REDD1 induction.

Results: Enhanced REDD1 expression was observed in the retina of diabetic $REDD1^{+/+}$ mice in association with increased pro-inflammatory gene expression and macrophage infiltration of the inner retina. Compared to diabetic $REDD1^{+/+}$ mice, inflammatory markers and macrophage infiltration were attenuated in the retina of diabetic $REDD1^{-/-}$ mice. In retinal cell cultures, REDD1 deletion prevented hyperglycemia- and TNFα-induced pro-inflammatory gene expression. REDD1 was not sufficient to promote inflammation, but rather sustained activation of NF-κB in cells exposed to either hyperglycemic conditions or TNFα. In REDD1-deficient cells, GSK3β phosphorylation and Nrf2 activation was observed in association with NF-κB suppression. Consistent with prior studies, REDD1 deletion prevented the development of oxidative stress in cells exposed to hyperglycemic conditions, and Nrf2 knockdown prevented the effect. However, Nrf2 knockdown was not sufficient to restore NF-κB signaling in REDD1-deficient cells exposed to hyperglycemic conditions. In contrast, inhibition of GSK3β suppressed NF-κB activation in cells exposed to hyperglycemic conditions.

Conclusions: The findings provide new insight into how diabetes promotes retinal inflammation and support that REDD1 acts independently of Nrf2 to suppress inflammatory signaling via GSK3β-dependent activation of NF-κB.

ABSTRACT BODY:

Purpose: There is a heavy burden to annotate clinical images due to the cost and availability of medical experts. To address this problem, we proposed a hierarchical annotation workflow in which medical experts review aggregated crowdsourced annotations, using dense annotation of optical coherence tomography (OCT) images from age-related macular degeneration (AMD) patients as an example.

Methods: Annotation was performed on a cloud-based platform (Labelbox) which distributed images to remote crowds and medical experts. OCT B-scans with ≥ 9 averages from 20x20° volume scans of AMD patients were randomly selected. Two medical experts annotated 25 representative B-scans with rich pathology. In a training session, 27 labellers read through an annotation guideline and practiced on 15 of the B-scans. B-scans with color-coded agreements and disagreements were presented to the crowd, visualizing their discrepancy to the expert annotations. Performance, compared to the medical experts' annotations, was measured quantitatively by a weighted and adaptively normalized mean intersection over union (IOU) for each of the annotated structures (WANI). The top 10 performers on the remaining 10 OCT B-scans (test session, Fig. 1. Left) were selected for larger batches of annotation work. Additional 897 B-scans were labeled by 5 labellers each. Simultaneous truth and performance level estimation (STAPLE) was applied to aggregate the 5 copies of crowd labels. Medical experts qualitatively reviewed the STAPLE result to identify common mistakes to further train the crowd. The crowd and experts annotated another 8 representative B-scans in a follow-up analysis session (Fig. 1. Right).

Results: STAPLE results show above average IOU in individual anatomic structures, while outperforming all crowd labellers in WANI, though lower than experts. On average, it took experts 13.5 minutes to annotate one B-scan in contrast to 23.8 seconds to review one STAPLE result. Improvements in STAPLE WANI were observed in the follow-up session, as the crowd gained experience and further trained on the feedback from experts.

Conclusions: The proposed hierarchical annotation workflow with crowds and medical experts could reduce the burden on medical experts in extensive clinical annotation tasks.

ABSTRACT BODY:

Purpose: To determine chromatic pupillary light reflex (PLR) parameters in dogs with and without sudden acquired retinal degeneration syndrome (SARDS) over time.

Methods: Five dogs with acute vision loss within the previous 6 months, a normal fundus, and a flat-line electroretinogram (ERG) were diagnosed with SARDS; 5 age-matched sighted dogs with a normal fundus and ERG served as controls. Both groups underwent red (630nm), blue (480nm), and white light stimulation using a chromatic light source (Melan-100®) adapted for video pupillometry. The tests were repeated for the SARDS-affected dogs at 6 months (6m) and 1 year (1y) post-diagnosis. Pupil size was estimated using ImageJ software, and degree, latency, and velocity of pupil constriction were calculated.

Results: SARDS-affected dogs had significantly reduced ($P<0.001$) pupil constriction in response to red (8.6±7.1% at 6m and 5.7±6.3% at 1y) and white (37.2±21.3% at 6m and 32.1±7.5% at 1y) light vs. control dogs [red: 70.9±14.5% ($P<0.001$); white: 62.7±11.7%], but no difference in response to blue light (77.1±6.8% at 6m and 77.3±9.3% at 1y of SARDS-affected dogs vs. 88.5±5.0% of control dogs; $P=0.666$). Pupil constriction latency in response to red (5.8±4.9s at 6m and 9.1±2.2s at 1y) and white light (0.7±0.4s at 6m and 3.2±3.7s at 1y) was significantly longer in SARDS-affected dogs compared to controls [red: 0.5±0.1s, $P<0.001$ and white: 0.4±0.1s, $P=0.17$], but both groups responded similarly to blue light. SARDS-affected dogs >1 year from diagnosis responded more slowly to white light than did controls or those SARDS-affected dogs within 6 months of diagnosis. Velocity of pupil constriction did not significantly differ between affected dogs and controls for blue ($P=0.946$), or white ($P=0.292$) light at any of the time points tested. Velocity of pupil constriction in response to red light (0.00016±0.0002mm/ms) was significantly slower in SARDS-affected dogs at 6-month post-diagnosis compared to age-matched controls (0.0013±0.0005mm/ms; $P=0.006$).

Conclusions: The Melan-100® can be adapted for video capture pupillometry in unsedated dogs. When compared to normal age-matched control dogs, SARDS-affected dogs demonstrated a decreased degree and prolonged latency of pupil constriction in response to both red and white light, and these differences became more pronounced with increased time from diagnosis.

TITLE: Determining the Accuracy of Rates of RNFL Loss Measured by Peripapillary OCT

SESSION TITLE: Data science, machine learning, and AI

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Bradley, J. Yohannan, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|K. Hou, P. Herbert, M. Unberath, Malone Center of Engineering in Healthcare, Johns Hopkins University, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Chris Bradley: Commercial Relationship: Code N (No Commercial Relationship) | Kaihua Hou: Commercial Relationship: Code N (No Commercial Relationship) | Patrick Herbert: Commercial Relationship: Code N (No Commercial Relationship) | Mathias Unberath: Commercial Relationship: Code N (No Commercial Relationship) | Jithin Yohannan: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To describe the rates of retinal nerve fiber layer (RNFL) loss in a large population of glaucoma patients and to understand how the accuracy of detecting certain rates of RNFL loss varies based on the frequency and temporal spacing on OCT exams.

Methods: Measurements of RNFL thickness using Zeiss OCT were obtained at a tertiary glaucoma practice from glaucoma and glaucoma suspect patients who were 18 years or older from April 1st, 2013 to July 30th, 2021. Only eyes with at least 5 measurements of superior and inferior RNFL thickness ≥ 50 m and signal strength (SS) ≥ 6 were included in the analysis.

Linear regression was performed on data from each eye and population level rates of RNFL change were computed. Simulated data were then generated from the regression slopes and residuals. The i th simulated data point from the k th eye had the form $y_{i,k} = \beta_k + \varepsilon_{i,k}$ where $\varepsilon_{i,k}$ was randomly chosen from the residuals of all eyes whose rates of worsening were within 0.25 µm/yr of β_k. For each eye, M data points were generated within time period T under two conditions: in the "evenly spread" condition, simulated data were evenly spread out over time; in the "clustered" condition they were clustered (half and half) at the endpoints. The percentage of cases where the true slope was at or below the observed slope was calculated for different M and T.

Results: 12,150 eyes from 7,392 patients satisfied our inclusion criteria. The mean (SD) time between measurements was 403 (180) days. Figure 1 shows the rates of worsening, SS, and baseline RNFL thickness of our sample. The median, 75th and 90th percentile rates of worsening are –0.39, –1.09, and –2.35 µm/yr; the mean (SD) SS is 8.0 (1.0); and the mean (SD) baseline RNFL thickness is 87.50 (32.08) µm. Figure 2 shows the percentage of cases (y-axis) where an observed rate of worsening (x-axis) came from an eye whose actual rate of worsening was at least as severe as the observed rate. Clustering measurements and expanding the time interval between measurements improved accuracy, with the lowest accuracy in the [–3, –2] µm/yr range.

Conclusions: Our analysis shows that detecting rapid worsening (90th percentile) on OCT at 70% correct requires ~13 measurements clustered at the endpoints of a 2-year period. Current clinical practice is 1-2 OCT scans per year.

ABSTRACT BODY:

Purpose: Synaptic remodeling occurs during aging in both humans and mice, leading to neuronal dysfunction. Age-related alterations in the outer retinal synapses have been investigated as a model system to study age-dependent neuronal and synaptic modifications such as in AMD. The role of REV-ERBα has been reported in synaptic strengthening in mice model of Alzheimer's disease. REV-ERBα, a nuclear receptor and transcription factor, regulates multiple biological processes including circadian rhythm, metabolism and neuronal function. The present study aimed to explore whether REV-ERBα regulates age-related retinal synaptic alterations using REV-ERBα knockout (KO) mice as a model.

Methods: 5- and 11- month-old wild-type (WT) and systemic REV-ERBα KO mice were used. Retinal cross sections were immunostained with rod bipolar cell marker Protein kinase C (PKC-α) and pre-synaptic protein synaptophysin antibody to assess synaptic alterations. The number and length of ectopic rod bipolar cell dendrite sprouts were quantified. REV-ERBα localization was analyzed with REV-ERBα antibody immunostaining in WT retinas and with β-Gal reporter staining in REV-ERBα KO retinas. Expression of REV-ERBα in retinal cells was assessed using an online single cell RNA sequencing (scRNA seq) database. RT-qPCR was performed in WT and REV-ERBα KO retinas to evaluate expression of genes involved in cellular energy homeostasis and axonal growth.

Results: REV-ERBα was localized in both outer and inner nuclear layer with REV-ERBα immunostaining and β-Gal reporter staining. scRNA seq analysis indicated expression of REV-ERBα in both rod photoreceptors and bipolar cells. Compared with WT, aging REV-ERBα KO retinas showed an accelerated retraction of rod axons accompanied with aberrant bipolar cell processes extending into the photoreceptor layer by synaptophysin and PKC-α co-localization. Both the number and length of ectopic rod bipolar cell dendrite sprouts in REV-ERBα KO retinas were significantly increased compared to WT in 5- and 11-months old mice. REV-ERBα KO retinas exhibited significantly decreased expression of multiple genes involved in cellular energy and metabolic regulation.

Conclusions: Our findings suggest that genetic loss of REV-ERBα accelerates age-related synaptic remodeling in the outer retina, possibly through modulating expression of genes controlling cellular energy and metabolism to mediate axonal retraction and dendrite growth.

ABSTRACT BODY:

Purpose: 10% of COVID patients have eye symptoms[1]. Conjunctivitis is the most reported ocular symptom, being reported in 88.8% of all pts with eye symptoms[1].

Literature search for SARS-CoV-2 presence in the conjunctiva of COVID patients with conjunctivitis.
Methods: Review of articles dated 2020-2021 for conjunctival swabs in COVID-19 positive conjunctivitis patients using search terms: “COVID conjunctival swabs,” “COVID conjunctivitis,” and “COVID and eyes”. Search was done on Google Scholar and PubMed. Cases were excluded if patients did not have conjunctivitis or if a positive conjunctival swab was found in a patient with no clinical or lab-confirmed COVID diagnosis.
Results: 27 articles published February 2020-December 2021 were found with 223 conjunctivitis patients. We found that conjunctival swabs tested for SARS-CoV-2 using RT-PCR returned positive 54.4% of the time in COVID-19 patients with conjunctivitis. We also found that 18 patients with no conjunctivitis tested positive on conjunctival swabs.
Conclusions: Further research is needed to study the pathophysiology of SARS-CoV-2 in the eyes and its presence on the ocular surface. As we begin our third year of the pandemic, we expect more case reports and clinical studies on COVID conjunctivitis.

ABSTRACT BODY:

Purpose: Intracellular iron can catalyze Fenton chemistry, causing oxidative stress in iron-loaded tissues. The retina is particularly vulnerable to oxidative assault, and iron accumulation has been implicated in retinal degenerative disease. Thus, it is important to understand retinal iron regulation. In mice, systemic knockout of the multi-copper ferroxidases (MCOs), ceruloplasmin (Cp) and hephaestin (Heph), which facilitate cellular iron export, results in retinal iron accumulation and degeneration. However, the role of MCOs within the neural retina is not clear.

Methods: A neural retina-specific Heph knockout model was generated, using previously developed mRx-Cre and Heph-flox lines, on a background of systemic Cp knockout. qPCR was used to verify Heph KO. Immunohistochemistry for ferritin-L (FtL), ferritin-H (FtH), and transferrin receptor (TfR) were used to determine retinal iron accumulation. Retinal morphology and function were assessed using in vivo retinal photography, optical coherence tomography (OCT), and electroretinography (ERG).

Results: Conditional KO of Heph in the neural retina in mice with systemic Cp KO resulted in age-dependent neural retina iron accumulation in amacrine cells and photoreceptors. Interestingly, retinal ganglion cells became iron depleted. However, unlike the systemic Cp/Heph double knockout model, there was no retinal degeneration or loss of retinal function.

Conclusions: MCOs have a local role in regulating neural retina iron homeostasis, with neural retina-specific deletion of MCOs leading to neural retina iron accumulation. Since neural retina-specific KO of Heph does not cause retinal degeneration, such as that observed in systemic double KO mice, preserved Heph function in either the RPE or systemically mitigates the phenotype in the retina-specific Heph KO.

ABSTRACT BODY:

Purpose: To estimate the incidence and risk factors for cataract in anterior uveitis

Methods: Data were harvested by trained expert reviewers using protocol-driven chart review. Cataract incidence—newly reduced visual acuity worse than 20/40 attributed to cataract or incident cataract surgery—was studied in 4105 eyes of 2645 patients with anterior uveitis.

Results: Cataract developed in 558 eyes (13.6%, 0.043/eye-year). Time-updated risk factors associated with cataract included: older age (over 65 vs. <18 years: adjusted hazard ratio (aHR)=4.79; 95%CI, 2.95- 7.77); higher anterior chamber cell grade (P(trend)=0.0006), prior incisional glaucoma surgery (aHR=1.70; 95%CI, 1.03-2.80), band keratopathy (aHR=2.16; 95%CI, 1.42-3.27), posterior synechiae (aHR=3.43; 95%CI, 2.65-4.43), elevated intraocular pressure (IOP)≥30 vs 6-20 mmHg: aHR=2.27; 95%CI, 1.18-4.37). Higher dose topical corticosteroid use (≥2 drops/day) was associated with 2-to 3-fold higher cataract risk in eyes with anterior chamber cell grades of 0 or 0.5+, but was not associated with higher cataract risk in the presence of ≥grade 1+ anterior chamber cells. Primary (aHR=0.61; 95%CI, 0.32-1.14) and recurrent (aHR=0.72; 95%CI, 0.55-0.94) had lower cataract risk than chronic anterior uveitis.

Conclusions: Cataract complicates a large minority of anterior uveitis cases. Several fixed and modifiable risk factors were identified and a point system developed to guide cataract risk minimization. Topical corticosteroids only were associated with increased cataract risk when anterior chamber cells were absent or minimally present, suggesting their use to treat active inflammation (which itself is cataractogenic) does not cause a net increase in cataract incidence.

ABSTRACT BODY:

Purpose: The primary cilium is a microtubule-based, finger-like projection on the surface of most cells in the human body. This organelle plays an important role in both cellular proliferation and division. In most mammalian cells, primary cilia are dynamically regulated in the cell cycle by disassembly at the G2/M phase and reassembly after cell division. Previous studies have found depleted or defective cilia in multiple types of cancer cells, including pancreatic and renal cancers. Although there is more focus on the crosstalk between cilia and cancer development, studies about primary cilia in uveal melanoma (UM) remain scarce. The goal of this study was to investigate the ciliation of human UM tissue and cell lines.

Methods: In the present study, we assessed primary cilia in UM (n=3 patients) and basal cell carcinoma (BCC, n=2 patients) paraffin tissue sections by employing two classic ciliary antibodies: Arl13b and IFT88. These antibodies detect the ciliary axonemes and basal bodies respectively. Unstained paraffin-based slides were deparaffinized and boiled in 1mM EDTA +0.05% Tween 20 prior to immunostaining. UM cell lines (UM 92-1 and UM 202) were cultured until confluent and then serum starved for 48 hours before staining with ciliary antibodies. Arl13b signal was counted as a cilium if one end of the signal was adjacent to the IFT88 signal. Statistical analysis was performed using Student's t-test. $p < 0.05$ was considered statistically significant.

Results: Quantification of immunofluorescently labeled primary cilia indicated that 45 ± 12% of cells were ciliated in BCC tissue (n=658 cells). The ciliation in UM tissue was 0.8 ± 1.2% (n=651 cells), which was significantly reduced compared to BCC tissue ($p < 0.001$). Quantitative analysis showed that ciliary length is significantly shorter in UM samples compared with BCC samples ($p < 0.001$). In cultured human UM cell lines, we found similar ciliation compared to UM tissue samples.

Conclusions: This is the first report of loss of cilia in UM tissue in contrast to BCC which more often retain their cilia. These data provide insight into ocular tumor diagnosis and potential cilia-based therapeutic strategies against UM.

ABSTRACT BODY:

Purpose: To evaluate the impact of intraretinal fluid (IRF) lability in diabetic macular edema (DME) on anatomic and functional outcomes in the Phase III VISTA Clinical Trial in eyes treated with intravitreal aflibercept injection (IAI).

Methods: A post-hoc higher order image analysis was performed on eyes in the Phase III VISTA DME study. Patients were randomized to receive 2mg IAI injection every 4 weeks (2q4), IAI every 8 weeks following 5 initial monthly doses (2q8), or laser photocoagulation. This analysis focused on the 2q8 group for assessment of fluid lability, defined as a 30% increase in IRF central subfield volume (CSV) above the threshold value at week 16 (i.e., last monthly injection administration) at any timepoint between week 20 and week 52. OCT images were evaluated using a machine learning-augmented platform that extracts retinal fluid features, including volumetric characterization and compartmental retinal features, such as ellipsoid zone (EZ) integrity. Groups were compared for baseline variables and final functional outcomes.

Results: For this assessment, 139 of 148 eyes were included from the 2q8 group. There were 71 eyes (51%) that demonstrated IRF volume lability after Week 16, compared to 68 eyes (49%) that did not. Baseline comparative assessment of the 2 groups did not show a significant difference in mean IRF CSV compared to those without lability (0.15 ± 0.10 mm^3 vs 0.14 ± 0.12 mm^3, respectively; p=0.79) or a difference in BCVA (ETDRS: 58.2 ± 11.2 vs 61.16 ± 10.0, p=0.105). However, eyes with subsequent IRF CSV lability demonstrated greater baseline EZ attenuation [i.e. reduced EZ-RPE central subfield thickness (24.2 ± 16.0 µm vs 30.6 ± 14.8 µm, p=0.017)].

The IRF CSV lability group demonstrated significantly worse mean BCVA at Week 52 (ETDRS: 68.3±13.2 v 73.2±11.09, p=0.027) and Week 100 (68.9±14.1 v 74±11.7, p= 0.035) compared to eyes that had more stable fluid dynamics.

Conclusions: DME eyes with volumetric IRF lability exhibited worse BCVA outcomes compared to those eyes with more stable fluid dynamics. Decreased baseline EZ integrity was more significant in eyes that ultimately developed fluid lability.

ABSTRACT BODY:

Purpose: Glucocorticoid-induced actin cytoskeletal reorganization in the trabecular meshwork (TM) cells is thought to participate in increased resistance to aqueous humor outflow through the trabecular pathway. However, our understanding of the molecular mechanisms regulating actin cytoskeletal organization in TM cells remains incomplete. Here, we report identification of several molecules known to directly regulate actin cytoskeletal crosslinking whose levels are upregulated in dexamethasone (Dex) treated human TM cells.

Methods: To identify proteins, whose levels were dysregulated in response to Dex treatment of human TM cells, we analyzed the cytoskeletome and nuclear protein fractions derived from Dex-treated (0.5 μM for 7 days) and control TM cells using non-label quantitative proteomics analyses. The findings from these proteomics analyses were independently validated by immunoblot and immunofluorescence analyses in different (donor) strains of human TM cells.

Results: Human TM cells treated with Dex consistently revealed a preferential and significant increase in the levels of proteins regulating actin cytoskeletal organization, cell adhesion and fibrogenic activity in both the cytoskeletome and nuclear protein fractions. Proteins including ArgBP2 (SORBS2), CAP/Ponsin (SORBS1), LIMCH1 (LIM and calponin homology domains 1), palladin, septin 11, calponin-3, FAT1, SIPA1L1, Phospholipid phosphatase 3, DIAPH2 and CTGF which are directly involved in actin cytoskeletal organization, cell adhesion, contraction, Rho GTPase activation and fibrogenic activity exhibited significantly increased levels in Dex treated cells. Several of these proteins exhibit colocalization with actin stress fibers and focal adhesions in TM cells.

Conclusions: The unbiased and global proteomics approach we utilized in this study to determine dexamethasone-induced changes in proteins of the cytoskeletal enriched and nuclear protein fractions of human TM cells identified several proteins directly involved in actin cytoskeletal crosslinking and cell adhesive interactions. Collectively, these findings provide not only novel insights into the molecular basis for glucocorticoid-induced actin cytoskeletal organization in TM cells but also identify novel potential therapeutic targets for lowering ocular hypertension in glaucoma.

ABSTRACT BODY:

Purpose: Using Vision App to remotely monitor the habitual usage of the smart device in children to understand the device- eye distance usage and ambience illumination usage.

Methods: Children aged 6 – 13 yrs old were recruited in this study for three months to continuously monitor the working distance (near work) and the face illumination level of the children (ambience light level). The remote monitoring device (Amazon Fire HD 8) was installed with Myopia App (Vision App ©). The App measured the face-device distance (near work) and the illumination level (ambience) in which the children used the devices at home. The subjects were split into two groups; intervention and non-intervention. In the intervention group, the device's screen would turn dark forcing the subject to maintain the distance at least 30 cm from the device, while in the non-intervention group the device just recorded the time, illumination and distance data without any warning. Refraction and axial lengths were measured during the entire period of study (3 months) in two-week frequency.

Results: In the non-intervention group, about 80% of the subjects viewed the devices from the distance < 30 cm, and 87% were working in an ambience light under 100 lux, with an average of only 40 lux. In the intervention group, about 80% of the subjects had a working distance of > 30 cm from the eye, and about 57% were working in an ambience light under 100 lux. The accommodative demand difference between the non-intervention and the intervention group was about 0.75 D. Measurements of axial length over three-month period shows marginal increase in subjects but magnitude varies from subject to subject.

Conclusions: Remote monitoring of the children for three months shows clearly that intervention group's working distance was greater than 30 cm. Vision App intervention might potentially aid in the delay of onset of myopia in children. Ambience light was found to be less than 100 lux for both non-intervention and intervention groups. This long-term study will continue to focus on the measurements of near work and illumination, and its impact on the myopia progression in children.

ABSTRACT BODY:

Purpose: The arginase isoforms (A1 & A2) are involved in the pathogenesis of diabetic retinopathy (DR) through a complex relationship with the endothelial and inducible forms of nitric oxide synthase (eNOS & iNOS), which compete with arginase for L-arginine, their common substrate. While eNOS produces nitric oxide to mediate vasodilation, iNOS is expressed under conditions of stress, mediating immune activation that perpetuates inflammation and oxidative stress. With the type 2 diabetic db/db mouse model, we investigated our hypothesis that administration of A1 will halt DR progression by reducing iNOS activity through depletion of L-arginine, thus limiting oxidative stress and inflammation.

Methods: Pegylated arginase-1 (PEG-A1) or PEG-5000 (control) was given via intraperitoneal injection thrice weekly for two weeks (25 mg/kg/dose) in db/db mice between the ages of 16 and 24 weeks (n=11/group). Visual acuity and contrast sensitivity were assessed via Optokinetic tracking. Whole eyes, retinas, and plasma were collected, and globes sectioned for immunofluorescence (IF). IF was performed for A1, markers of inflammation and oxidative stress including IL-6, 3-nitrotyrosine (3-NT), and 4HNE, and for vascular tight junction protein ZO-1. Retina lysates were used to western blot for inflammasome proteins, oxidative stress products, inflammation, and hypoxia, including A1, A2, iNOS, IL-1β, TNF-α, and 4-HNE. Data was analyzed via unpaired t-tests and values of $p<0.05$ were considered significant.

Results: Untreated db/db mice exhibited impaired visual acuity ($p<0.01$), higher visual contrast sensitivity thresholds ($p<0.05$), marked elevation in retinal A1 ($p<0.001$), iNOS ($p<0.05$), IL-1β ($p<0.05$), and 4HNE ($p<0.01$), and increased retinal albumin extravasation ($p<0.0001$) compared to lean controls. PEG-A1 treatment significantly improved visual acuity ($p<0.01$), visual contrast sensitivity ($p<0.05$), and reduced iNOS ($p<0.01$), 3-NT ($p<0.05$), 4HNE ($p<0.01$), IL-1β ($p<0.01$), and TNF-α expression ($p<0.05$) in db/db mice compared to controls. Additionally, ZO-1 integrity was increased ($p<0.05$) and albumin leakage decreased ($p<0.05$) in retinas of PEG-A1 treated db/db mice.

Conclusions: Systemic PEG-A1 administration in db/db mice resulted in improved visual function, increased blood-retinal-barrier integrity, and reduced inflammation and oxidative stress compared to PEG-5000 controls.

ABSTRACT BODY:

Purpose: Dominant CRX-associated Leber congenital amaurosis (LCA7) is a severe retinal degenerative disease for which no treatments exist. Disease-causing variants in CRX typically result in production of a dominant negative form of the protein which disrupts normal photoreceptor maturation. We used an in vitro human retinal organoid model to evaluate gene editing of mutant CRX as a therapy for LCA7.

Methods: We utilized CRISPR/Cas9 tools to (a) correct the $CRX^{K88Q/+}$ mutation in a patient-derived iPSC line, and (b) eliminate the mutant CRX allele, leaving the wildtype CRX allele intact. Rescue of LCA7 phenotypes was then compared in retinal organoids for both editing methods using brightfield images of the outer segments (OS), immunofluorescence (IF) staining, and qPCR.

Results: Successful editing of patient iPSCs ($CRX^{K88Q/+}$) to generate a corrected ($CRX^{+/+}$) and an allelic knockout ($CRX^{+/-}$) line was confirmed via Sanger sequencing. Retinal organoids were successfully generated for each of the three iPSC lines, and they exhibited comparable retinal tissue thickness and photoreceptor numbers throughout differentiation. Morphologically, all organoids remained identical until 180 days (D180), when differences in OS morphogenesis emerged. The $CRX^{+/+}$ organoids produced longer OS-like projections by D180, compared to CRX $^{K88Q/+}$ organoids, while $CRX^{+/-}$ organoids produced OS of intermediate length. mRNA (n=14 organoids per line) and protein (n=8 organoids per line) levels for early photoreceptor markers were comparable between $CRX^{+/+}$ and CRX $^{+/-}$ lines, revealing a similar level of rescue at the cellular level. Morphological differences became less apparent by D240.

Conclusions: Here, we established that both gene correction ($CRX^{+/+}$) and an allele-specific gene knockout strategy ($CRX^{+/-}$) can rescue LCA7 phenotypes. Although there was a mild delay in OS morphogenesis for the $CRX^{+/-}$ line, this may be advantageous for therapy, since gene correction has lower efficiency compared to targeted mutagenesis. This work will guide future experiments focused on treating photoreceptor cells within growing retinal organoids.

TITLE: Auto-centration on a Femtosecond Laser for Refractive Corneal Lenticule Extraction Treatment

SESSION TITLE: Refractive and non-refractive corneal surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Chen, A.P. Voorhees, Y.S. Yu, H. Fu, Johnson and Johnson Vision, Milpitas, California, UNITED STATES|

Commercial Relationships Disclosure: Li Chen: Commercial Relationship(s);Code E (Employment):Johnson and Johnson Vision | Andrew Voorhees: Commercial Relationship(s);Code E (Employment):Johnson and Johnson Vision | Ying Yu: Commercial Relationship(s);Code E (Employment):Johnson and Johnson Vision | Hong Fu: Commercial Relationship(s);Code E (Employment):Johnson and Johnson Vision

ABSTRACT BODY:

Purpose: To evalutate the performance of auto-centration for corneal lenticule extraction treatment on a femtosecond laser.

Methods: Eye images from 9 human eyes were collected on a new femtosecond laser. Before imaging on the femtosecond laser, 3 peripheral marks were created on the nasal, temporal, and inferior cornea of which the nasal and temporal marks were aligned to the horizontal axis when the subject was at upright position. When the subject was under the femetosecond laser at supine postion, one infrared (IR) image and one visible image were captured nearly simultaneously when the eye was about 40mm away from the patient interface viewing a coaxial fixation target. Pupil center was detected from the IR image and the 3 peripheral marks were detected from the visible image before applanation. Another visible image was captured right after the eye was applanated which detected the peripheral marks. Then a transformation matrix was created with the detected mark positions in the visible images before and after applanation. The pupil center detected in the pre-applanated IR image was transformed by the transformation matrix to the visible image under applanation and used as the lenticule treatment center. The rotation angle calculated from the detected nasal and temporal marks in the visible image under applanation was used to correct cyclotorsion axis for lenticule treatment.

Results: Pupil centers were detected correctly in the IR images captured on the femetosecond laser before applanation. Peripheral marks were detected in the visible images before applanation and after applanation from the 9 eyes. On average, the lenticule treatment was automatically adjusted 421.756±173.337μm (range from 136.641 to 692.903μm) from the applanated image center. The cyclotorsion axis was corrected -3.94±5.28° (range from -11.85 to 4.66°). The corrected lenticule treatment center was offset 230.014±179.147μm (range from 57.673 to 648.079μm) from the pupil center in the visible images under applanation.

Conclusions: Auto-centration improves the accuracy of treatment centration by placing the treatment center on the corneal position corresponding to the pupil center of the eye before applanation.

ABSTRACT BODY:

Purpose: Metabolic assessment in ophthalmic diseases is an important, yet largely unrealized, target due to limitations of imaging and tissue target acquisition. Dual-wavelength photographic retinal oximetry measures have identified possible deficits of oxygen metabolism in glaucoma, yet often they yield non-physiological high values of retinal oxygen saturation in small vessels. This study highlights the possible contribution of single and double pass light transmission to the observed diameter artifacts.

Methods: Retinal photographic oximetry images of healthy subjects (N = 10) were obtained with the Oxymap T1 retinal oximeter (Oxymap Analyzer, Iceland). Saturation, optical density (OD), optical density ratio (ODR), and vessel diameter (D) were obtained from arteriolar and venular segments (>30 pixel length) covering a diameter range of 30-200 μm. A conceptual model of light returned from vessels by single and double pass transmission was developed based on optical properties of blood and retinal reflectance to predict their potential contribution to the diameter artifact.

Results: In Fig. 1A, venular saturation showed a greater dependence on D (slope of -0.18) than arteriolar saturation (slope of -0.03). The artifact was more pronounced in small diameter vessels (slope was -0.22 for D <100 μm and -0.07 for D>100 μm, green). The conceptual model predicted that both single and double pass light paths contribute to the steep decrease in ODR with decreasing diameter (Fig. 1B, black).

Conclusions: The widespread adoption of photographic retinal oximetry is currently limited by a lack of precision in measurements that produce non-physiological artifacts. In this analysis, the diameter artifact is manifested most strongly in venules and is predicted to depend on both double and single pass light transmission. Our data suggests improved understanding of the relationships between vessel saturation and diameter are needed to accurately characterize the error in photographic retinal oximetry.

ABSTRACT BODY:

Purpose: To investigate the relationships between optic nerve cupping and total and regional brain volumes.

Methods: This is a secondary data analysis of women, aged 65 to 79, enrolled in a randomized clinical trial of postmenopausal hormone therapy. Women, aged 65+ without glaucoma in the WHI Sight Examination Study with cup-to-disc ratio (CDR) measurements and MRI-based total and regional brain volumes from the WHI Memory Study were included. Large CDR was defined as 0.6 or greater in either eye. Generalized estimating equation (GEE) models were used to account for intra-brain correlations between within right and left sides. Final analysis was adjusted for demographic, clinical characteristics, and the total brain volume (for regional analyses).

Results: Final analyses included 474 women: the mean age ± SD was 69.2 ± 3.6 years; 92.6% of subjects were white. 34 of 474 (7.2%) women had large CDR. With control for total brain volume, demographic, and clinical characteristics, lateral ventricle volume was 3.00 cc larger for those with large CDR compared to those without large CDR (95% CI: (0.02, 5.98), p-value=0.048) (Table 1). Controlling for demographic and clinical characteristics and excluding total brain volume, frontal lobe volume was 4.77 cc lower for those with large CDR compared to those without (95% CI: (-8.70, -0.85), p-value=0.017), and occipital lobe volume was 1.84 cc lower for those with large CDR compared to those without (95% CI: (-3.36, -0.32), p-value=0.018) (Table 2).

Conclusions: Our analysis suggests that in women aged 65+, large CDR is associated with lower relative total brain volume and absolute regional volume in the frontal and occipital lobes. Enlarged CDR in individuals without glaucoma may represent a sign of aging in the optic nerve and the brain.

ABSTRACT BODY:

Purpose: To investigate thickness changes of the peripapillary tissues during high myopia development in juvenile tree shrews.

Methods: Juvenile tree shrews were randomly assigned to two groups: normal visual experience (n=9) and monocular -10D lens treatment to induce high myopia, where the other eye served as a control (n=12). Lens treatment started at 24 days of visual experience (DVE). Refractive and biometric measurements were obtained daily. Optical coherence tomography (OCT) of optic nerve head was performed weekly (Spectralis, Heidelberg Engineering). A deep learning algorithm was used for auto-segmentation of sclera, choroid-retinal pigment epithelium complex (Ch-RPE), retinal nerve fiber layer (RNFL) and remaining retinal layers (RRL) after nonlinear distortion correction. Thickness values were obtained from 3D reconstructed tissues, and quantified over a 50-μm band starting at 1000 μm from anterior scleral canal opening centroid.

Results: The thickness of all tissues significantly decreased during high myopia development. Using one-way ANOVA with post hoc Tuckey test, relative thickness changes from baseline were significantly different in myopic eyes compared to control and normal eyes at 59 DVE for the sclera (2.6±5.1%, 4.4±6.4% and -9.2±4.9% in normal, control and myopic eyes, respectively; $P<0.05$), Ch-RPE (-3.5±5.3%, -4.01±9.8% and -13.4±8.3% in normal, control and myopic eyes, respectively; $P<0.05$), RRL (-3.3±2.7%, -2.3±2.7% and -6.2±1.9% in normal, control and myopic eyes, respectively; $p<0.05$), and compared to control eyes only for RNFL (-4.9±2.2%, -2.2±3.7%, -5.9±1.8% in normal, control and myopic eyes, respectively; $P<0.05$). In myopic eyes, significant time-thickness interactions were found for all tissues (repeated measures ANOVA, $P<0.001$). Post hoc analysis with Bonferroni adjustment revealed significant thinning from baseline to 31 DVE for all tissues, and from 31 to 38 DVE for RRL only, but not from 38 DVE to any subsequent follow-up while refractive changes were progressing until 59 DVE.

Conclusions: Juvenile high myopia is associated with simultaneous but heterogeneous thinning of peripapillary tissues, with scleral and Ch-RPE thinning were more pronounced than retinal thinning. Peripapillary tissue thinning occurrs early during high myopia development and may contribute to increased risk for glaucoma later in life prompting early screening of myopic eyes.

ABSTRACT BODY:

Purpose: Degenerative conditions affecting the outer retina, such as geographic atrophy (GA) and laser-induced retinal injury, involve death of photoreceptor and retinal pigmented epithelium (RPE) cells leading to vision loss. Models aimed at mimicking these conditions either do not fully reproduce the complete RPE and outer retinal atrophy (cRORA) or involve damage to additional structures of the retina such as inner retinal layers and choroid. To overcome these limitations, we have developed and characterized a novel laser-induced swine model that mimics the anatomical defects of GA and laser injury and provides a preclinical model amenable to cell and gene-based regenerative therapies.

Methods: Optical coherence tomography (OCT) guided micro-focal laser (532nm) beam was applied in 10 Yucatan pigs to induce targeted focal areas of degeneration affecting the RPE and photoreceptors. Laser damage was targeted to the visual streak which contains the highest cone density resembling the human macula. Different laser conditions were tested to define the optimal parameters. Evaluation of structural laser damage was performed weekly by fundus photography, OCT and dye angiography up to one-month post-laser and correlated with functional assessment by multifocal electroretinogram (mfERG). Cellular changes were further evaluated by immunofluorescence analysis.

Results: Optimization of laser parameters using the new laser system achieved focal areas of degeneration affecting both RPE and photoreceptor cells, with no overt abnormal changes in inner retinal layers. Following optimized laser time exposure (120 mW, 88 sec") full ablation of the photoreceptor and RPE layers was achieved at 2 weeks post-laser, while the rest of the retinal layers were preserved and showed no obvious signs of inflammation or remodeling. Importantly, laser injury did not lead to neovascularization, significant choroidal damage, hemorrhage, anomalies of the retinal arterial vasculature, or retinal holes. Furthermore, degeneration of RPE and photoreceptor layers correlated with a decrease in mfERG response.

Conclusions: We have established and characterized a Yucatan minipig model of laser-induced retinal degeneration that mimics the anatomical defects of GA and laser injury. This model provides new opportunities for pre-clinical assessment of regenerative therapies for patients affected by GA and laser-induced retinal trauma.

TITLE: IL-33/ST2L Signaling Regulate Blood-Retinal Barrier Integrity via Affecting Cadherin-Catenin Adherens Junction Complex

SESSION TITLE: Retinopathy of prematurity

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: D. Sharma, S. Bisen, G. Kaur, N.K. Singh, Department of Ophthalmology Visual and Anatomical Sciences, Wayne State University, Detroit, Michigan, UNITED STATES|

Commercial Relationships Disclosure: Deepti Sharma: Commercial Relationship: Code N (No Commercial Relationship) | Shivantika Bisen: Commercial Relationship: Code N (No Commercial Relationship) | Geetika Kaur: Commercial Relationship: Code N (No Commercial Relationship) | Nikhlesh Singh: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Angiogenesis, neovascularization and vascular remodeling are highly dynamic processes, where endothelial cell-cell adhesion within the vessel wall controls a range of physiological processes, such as growth, integrity and barrier function. The cadherin–catenin adhesion complex is a key contributor to blood-retinal barrier (BRB) integrity and dynamic cell movements. However, the pre-eminent role of cadherins and their associated catenins in adherens junction structure and function is not fully understood. Also, the role of IL33/ST2L signaling in regulating BRB integrity is not known.

Methods: Using a murine model of oxygen-induced retinopathy (OIR) and human retinal microvascular endothelial cells (HRMVECs), we are trying to understand the significance of IL-33/ST2L-signaling on endothelial barrier disruption, leading to abnormal angiogenesis and enhanced vascular permeability.

Results: Our in vivo genetic deletion studies revealed that deletion of IL-33 resulted in reduced vascular tufts and vascular leakage. Therefore, in order to understand the molecular mechanism by which IL-33 regulates the BRB integrity, we performed some in vitro studies using HRMVECs. The electric cell-substrate impedance sensing (ECIS) analysis showed that IL-33 (20 ng/ml) induce endothelial barrier disruption in HRMVECs. Likewise, FITC-dextran permeability assay also showed that IL-33 stimulate the endothelial dysfunction in HRMVECs. As we know, tight junctions (TJs) and adherens junctions (AJs) form the adhesion structure and maintain the BRB integrity, therefore we look for the junctional proteins involved in the IL-33/ST2L mediated endothelial dysfunction. Furthermore, we found that IL-33 mediates the phosphorylation of VE-cadherin and a-catenin in HRMVECs. Furthermore, mass-spectroscopy (MS) analysis revealed the phosphorylation of specific Ser^{439} residue of a-catenin upon IL-33 inducement in HRMVECs. Consequently, mutation of a-catenin at Ser^{439} residue restores the BRB integrity disrupted by IL-33. In addition, we have observed that IL-33 induce the generation of reactive oxygen species (ROS), thereby destabilize adherens junctions in HRMVECs.

Conclusions: We conclude that IL-33/ST2L signaling plays a significant role in angiogenesis and neovascularization by regulating endothelial permeability and BRB integrity.

ABSTRACT BODY:

Purpose: Development of mouse models and corresponding grading systems is imperative to studying the pathophysiology of human disease. Ocular graft versus host disease (oGvHD) affects 40-60% of patients after allogeneic hematopoietic stem cell transplant (HSCT) characterized by decreased vision, pain, fibrosis, and severe dry eye disease. We have developed a novel grading scale for murine models of oGvHD and tested it in three oGvHD murine models.

Methods: We evaluated 3 different murine models of oGVHD (N=5/group), including major histocompatability (MHC) mismatched (C57Bl/6 donor and Balbc/J host), haploidentical (C57Bl/6 donor and B6D2F1 host), and MHC matched but minor histocompatibility antigen-mismatched (129 donor and C57Bl/6 host). Mice underwent total body irradiation followed by donor T and B cell depleted bone marrow +/- splenocyte from donor mice injected via tail vein at day 1 post radiation. The control mice did not receive splenocytes. GvHD and oGvHD scoring was performed weekly. The novel grading system consisted of categories such as eyelid changes (erythema and edema), periocular fur loss, corneal clarity (corneal haze and visualization of intraocular structures), and corneal fluorescein staining (punctate keratopathy and ulceration) with a grade of 0 (normal) to 3 or 4 (most severe) in each category. The overall score for oGvHD at each time-point is the individual scores for each category per mouse summed and then averaged within the groups.

Results: The MHC mismatched mice experienced higher oGvHD score as compared to the control at days 8, 14, 22, 28 and 42 were p= <0.0001 at all timepoints. The haploidentical mice oGvHD score as compared to control at days 6, 13, 19 and 26 were p= 0.20, p= 0.47, p= 0.051, and p= 0.01, respectively. In the MHC matched but minor histocompatibility antigen-mismatched mice, the oGvHD score as compared to the control at days 6, 13, 19, and 26 were p= 0.49, p= 0.n09, p= 0.06, and p= 0.69, respectively.

Conclusions: This is the first study to directly compare and evaluate the timing and severity of 3 different murine models of oGVHD. Utilizing our novel grading system, we identified clinically significant differences between the splenocyte treated and control groups in all 3 models of oGVHD, ultimately enabling us to use varying genetic backgrounds and treatment modalities to find novel targets for oGVHD.

ABSTRACT BODY:

Purpose: Intrinsically photosensitive retinal ganglion cells (ipRGCs) of the M1 type are principal regulators of the circadian clock and other non-image visual functions. These cells diversify their intrinsic light responses to encode a broad range of environmental irradiances as a population. Here, we test the hypothesis that this intrinsic, functional diversity combines with circuit influences to produce effective irradiance encoding.

Methods: We recorded electrophysiologically from M1 ipRGCs in the dark-adapted, isolated retinas of adult, transgenic mice. These cells were labeled genetically or retrogradely from their projections in the suprachiasmatic nucleus, the master circadian clock. We used optical stimulation and pharmacological manipulation to characterize the contributions of intrinsic and synaptic drives to cellular activity.

Results: Our experiments indicate that the synaptic input to M1 ipRGCs is highly diverse in both sensitivity and dynamics. The most sensitive response in all M1 ipRGCs examined was synaptic in origin. This synaptic input was required for spike firing of some cells but dispensable for that of many others. This spike firing exhibits features that are advantageous for irradiance encoding. In particular, it encodes the total photon count with fidelity over an orders-of-magnitude variation in time scale. This integrative ability is evident for indivual cells that have varying balances of synaptic and intrinsic drive, and is more precise at the population level.

Conclusions: Synaptic and intrinsic drives vary across M1 ipRGCs to produce population activity that is suitable for representing irradiance. Temporal integration, a hallmark of circadian photoregulation, is already present in the set of cells that carry light information to the clock.

ABSTRACT BODY:

Purpose: Mobile, ramified macrophage-like cells (MLCs) are detectable at the vitreoretinal interface (VRI) by optical coherence tomography (OCT) imaging in humans. Macrophages (Macs) are heterogeneous cells and MLC identity is unknown. MLCs could include microglia (yolk sac-derived retinal Macs), perivascular Macs (long-lived Macs supporting healthy vasculature), or monocyte-derived Macs (inflammatory Macs derived from blood). The goal of this study was to characterize VRI Macs.

Methods: OCT and OCT-angiography were performed on C57BL6/J mice. Confocal immunofluorescence (IF) for CD31 (endothelial cells, EC) and IBA1 (pan-Mac marker) were performed at the retinal surface on wholemounts. OCT-angiography and CD31 staining were used to match IF images and en face OCT slabs. $Cx3cr1^{CreER}$ x $Rosa26^{zsGreen}$ (Mac^{GFP}) mice were used to fate map Macs 1 week and 1 month post-tamoxifen treatment. IF staining of frozen sections was performed using IBA1, CD31, and/or Tmem119 to delineate microglia. $Tmem119^{GFP}$ mice were used to quantitate GFP^{+} microglia and $Mrc1^{+}$ perivascular Macs by multi-parameter flow cytometry.

Results: En face OCT slabs above the VRI revealed cellular structures. These cells were $IBA1^{+}$ and showed either a ramified morphology or were colocalized to EC. Fate mapping in Mac^{GFP} mice showed that VRI Macs were 84% GFP^{+} and plexiform Macs were 98% GFP^{+} at Week 1 ($p<0.05$). At Month 1, VRI and plexiform layer Macs were equally GFP^{+} compared to Week 1 (82% vs 96%, $p<0.05$ between groups). VRI Macs were 72% $Tmem119^{+}$ or 21% $Tmem119^{neg}EC^{adjacent}$ ($p<0.001$). Macs from $Tmem119^{GFP}$ retinas were 90% $GFP^{+}Mrc1^{neg}$ microglia or 10% $GFP^{neg}Mrc1^{+}$ perivascular Macs ($p<0.05$) by flow cytometry.

Conclusions: VRI Macs are an emerging disease biomarker. At steady-state, VRI Macs are ~70% microglia and ~20% perivascular Macs without any monocyte-derived Mac component. These findings are potentially important for diseases like multiple sclerosis and Alzheimer's, where microglia and perivascular Macs have been implicated respectively.

ABSTRACT BODY:

Purpose: Despite optical coherence tomography (OCTA) being available in many ophthalmology units, there is controversy regarding whether it can replace fluorescent angiography (FA) in the diagnosis of wet age-related macular degeneration (wAMD). The main aim of this study is to determine whether the sensitivity and specificity of OCTA combined with Optical Coherence Tomography (OCT) is non-inferior to that of FA combined with OCT for the detection of wAMD.

Methods: This is a non-inferiority, prospective, randomised diagnostic accuracy study. Participants are patients with a suspicion of wAMD who present to an NHS secondary care ophthalmology unit in the UK. They will be randomised to OCT+FA or OCT+OCTA trial arms. Following random allocation using a secure online randomisation system, a clinician will review the OCT with either FA or OCTA first and make an initial diagnosis (wAMD: yes/no). Then the remaining test will be reviewed to further confirm or exclude wAMD. Comparison of the two clinical diagnoses in each arm will provide evidence concerning the added value of OCTA vs FA in patients with an OCT suspicious of wAMD. According to the sample size calculation, allowing for 10% withdrawal of consent, missing data and inconclusive test results, we will aim to recruit 1,067 patients. The non-inferiority of OCTA vs FA will be evaluated with two-sided 95% confidence intervals for the differences in sensitivity and specificity.

Results: The primary outcome of the study will be the difference in sensitivity and specificity between OCT+OCTA and OCT+FA for wAMD detection. Secondary outcomes will include sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of OCTA alone and FFA alone and PPV of OCT for the detection of wAMD. We will also evaluate the intra- and inter-rater variation and perform an economic analysis of the incremental cost per true positive detected and incremental cost per correct diagnosis for wAMD.

Conclusions: This study will provide clinically significant information on the diagnostic suitability of OCTA vs FA for the diagnosis of wAMD and validated criteria for OCTA-based diagnosis of wAMD, which can provide evidence to change the goldstandard imaging guidelines.

ABSTRACT BODY:

Purpose: Evidence suggests that glycated hemoglobin (HbA1c) levels may be systematically underestimating past blood glucose levels among individuals with sickle cell trait (SCT) and those with glucose-6-phosphate dehydrogenase (G6PD) deficiency, leading to an underdiagnosis of diabetes and diabetes control. However, it is unclear how these genotypes may affect the risk of having diabetic retinopathy (DR). The objective of this study is to evaluate the impact of SCT and G6PD deficiency on HbA1c levels and having DR among a sample of African American females.

Methods: The African American Eye Disease Study is a population-based, cross-sectional study of 40+ years old African Americans in Los Angeles, CA. HbA1c and random blood glucose were measured using a DCA 2000 Analyzer and HemoCue B-Glucose System. DR was graded according to ETDRS grading of DR based on photography of 7 standard fields of the fundus of each eye. From 1,789 females, DNAs were extracted. Genotype data were obtained for rs334, encoding the sickle cell mutation, and for rs5030868, encoding the G6PD deficiency mutation. Demographic and clinical data including DR severity were compared statistically between those with and without the rs334 and those with and without G6PD deficiency mutation.

Results: Compared with individuals without SCT (Table 1), individuals with SCT had a higher HbA1c level (6.1 vs. 5.9, $P<0.05$) and prevalence of diabetes (25.5% vs. 18.2%, $P<0.05$), despite similar levels of random glucose ($P=0.42$). The odds of having diabetes in SCT individuals were 1.58 times those of individuals without SCT. The prevalence of DR was lower in SCT individuals (30%) than in individuals without SCT (48%); however, this difference was not statistically significant ($P=0.69$). For G6PD deficiency, the mean HbA1c level was lower in carriers and deficient individuals than normal individuals ($p < 0.001$), despite a similar random glucose level ($P=0.37$). There was no significant difference in the prevalence of diabetes and DR by G6PD genotype ($Ps=0.29$ and 0.64, respectively).

Conclusions: Among older African American females, SCT is associated with a higher HbA1c level and prevalence of diabetes but a lower prevalence of DR. G6PD deficiency is associated with a lower level of HbA1c but did not appear to affect the prevalence of diabetes and DR. Further studies with larger sample sizes are needed to confirm these findings.

TITLE: Characteristics of babies with unstable clinical course screened for retinopathy of prematurity

SESSION TITLE: Retinopathy of prematurity

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Patnaik, J. Stutzman, A.M. Lynch, E. McCourt, Ophthalmology, University of Colorado Health, Aurora, Colorado, UNITED STATES|

Commercial Relationships Disclosure: Jennifer Patnaik: Commercial Relationship: Code N (No Commercial Relationship) | Jenae Stutzman: Commercial Relationship: Code N (No Commercial Relationship) | Anne Lynch: Commercial Relationship: Code N (No Commercial Relationship) | Emily McCourt: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Retinopathy of prematurity (ROP) screening examinations are recommended for infants with a birth weight (BW) of less than 1500 grams and/or a gestational age (GA) of less than 30 weeks and select infants who do not meet these criteria but have an unstable clinical course. We conducted this study to investigate and characterize babies who met the unstable clinical course criteria at one academic institution.

Methods: A retrospective chart review was performed on the medical records of infants screened for ROP at our hospitals between January 2006 and December 2020. Unstable clinical course was defined as babies screened for ROP who did not meet the birthweight or gestational age screening criteria. Chi-square tests were used to compare infants with unstable clinical course to other infants screened for ROP.

Results: Among 2,328 infants screened for ROP, 144 (6.2%) were defined as unstable clinical course. Infants with unstable clinical course were similar to babies meeting the BW and GA criteria in terms of gender, race/ethnicity and singleton/multiple birth. Four of the unstable clinical course babies (2.8%) developed low grade ROP and none developed type 1 or type 2 ROP or needed treatment for ROP. Rates of ROP were much higher among babies meeting the BW and GA criteria in which 6.7% developed type 1, 5.9% type 2, and 22.3% low grade ($p<0.0001$). Two of the four unstable clinical course infants who developed low grade ROP were born at GA 31 weeks (BW 1800 and 2200 grams), and two were born at GA 32 weeks (BW 1510 and 1695 grams).

Conclusions: At our academic institution, infants defined as unstable clinical course and screened for ROP did not develop ROP to the level that required treatment. Further investigations at other institutions are warranted to determine if the unstable clinical course criteria is indeed capturing infants at risk for ROP.

TITLE: Spatial Sequencing in a Model of Early Onset Retinal Degeneration

SESSION TITLE: Modeling inherited retinal degeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K. Huffman, S. Borooah, Department of Ophthalmology at the Shiley Eye Institute, University of California San Diego, La Jolla, California, UNITED STATES|R. Sasik, Center for Computational Biology and Bioinformatics, University of California San Diego, La Jolla, California, UNITED STATES|

Commercial Relationships Disclosure: Kristyn Huffman: Commercial Relationship: Code N (No Commercial Relationship) | Roman Sasik: Commercial Relationship: Code N (No Commercial Relationship) | Shyamanga Borooah: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: RNA sequencing has already identified transcriptional signatures associated with retinal degeneration (RD) in various disease models but provides limited spatial data. In this study, we use spatial sequencing in a well characterized model of early onset degeneration resulting from loss of function of Mouse Frizzled Receptor Protein, to better understand the spatial changes associated with RD.

Methods: Eyes from 10–12-week-old RD6 mice (n=6) and C57BL/6 (WT)(n=7) mice were fresh frozen in OCT. 10 µm sections were placed on 10X Genomics Visium Spatial slides. Spatial gene expression was performed, creating a cDNA library mapped to specific tissue locations (Fig 1).

Gene set enrichment analysis identified pathways involved in RD. Pathway analysis of the differentially expressed genes was carried out using WebGestalt.org with Kyoto Encyclopedia of Genes and Genomes as a mapping database.

Results: Uniform Manifold Approximation and Projection clustering identified distinct expression signatures from the ganglion cell layer(GCL), inner nuclear layer(INL), retinal pigment epithelium (RPE)/choroid/sclera, optic nerve, and ciliary body (Fig, 1) but not the outer nuclear layer(ONL) which was contaminated with expression from other layers. Our findings highlight Clu, C4b, Apoe, and C1qa genes (z-score 3.0, 2.4, 2.3, and 2.2) as potential markers of disease in the RPE.

Gene Set Enrichment analysis between rd6 and WT eyes showed upregulation of glycolysis and carbon metabolism pathways in the GCL and Rap1, Hippo and lysosome pathways in the RPE/Choroid/sclera. The ribosomal pathway was downregulated in these layers. No significant pathways were found in the INL, ciliary body or optic nerve.

Conclusions: Our study demonstrates that spatial sequencing can be used to identify differentially expressed genes in most layers in mouse retina, although further optimization is required for ONL. Analysis of differentially expressed genes highlighted potential disease associated targets.

Overall gene set enrichment showed that Rap1 and Hippo pathways are perturbed in rd6 mice. These pathways have previously been implicated in RD. However, further validation with RNAscope will likely confirm their association in this model and as potential targets for treatment.

ABSTRACT BODY:

Purpose: We have shown Nuclear Distribution Protein C (NUDC) has a critical role in the maintenance of rod photoreceptors by regulating outer segment (OS) disk size, likely through actin regulation. We propose that NUDC influences cytoskeletal elements such as microtubule structure and the trafficking of mitochondria or proteins destined for the OS. Here we expand our understanding of the role of NUDC in photoreceptors by testing the hypothesis that NUDC regulation of the cytoskeleton is critical both in rods and cones.

Methods: We generated a NudC floxed mouse and bred it with the rod-cell specific iCre75 or the cone-cell specific HRGP Cre recombinase mouse to produce $NudC^{+/-}$ or $NudC^{-/-}$ in rod or cone photoreceptors, respectively. Retinal function was analyzed using electroretinography (ERG) at P21 and P42, and retinas were isolated and examined by transmission electron microscopy (TEM), immunohistochemistry (IHC), and Western blotting (WB).

Results: ERG analysis uncovered low a- and b-wave amplitudes in P21 rod $NudC^{-/-}$ ($rNudC^{-/-}$) mice under scotopic conditions. IHC staining of retinal cryosections from $rNudC^{-/-}$ mice demonstrate disorganized microtubules in the inner segment (IS) of rod photoreceptor cells along with rhodopsin mislocalization in the IS, outer nuclear layer and synapse. IHC and WB for GFAP also show an increase in gliosis in the $rNudC^{-/-}$ retinas compared with $rNudC^{+/+}$. WB of $rNudC^{-/-}$ retinal lysates show a decrease in rhodopsin, cofilin, and transducin, an increase in LIS1 and Rab11a while ARR1 levels were unchanged compared with $rNudC^{+/+}$. TEM taken from ultrathin sections of $rNudC^{-/-}$ retina show disorganized disk formation and striking morphological changes in the IS. In mice lacking NUDC in cones ($cNudC^{-/-}$), the scotopic ERG response at P21 displays a normal a-wave and a diminished b-wave that is further reduced at 6 wks. The photopic ERG is decreased at P21 and is absent at P42.

Conclusions: NUDC is critical in rod photoreceptor OS disk formation and in localization of mitochondria and phototransduction proteins. Our data are consistent with the hypothesis that NUDC governs disk dimension through actin regulation, stressing the importance of this protein in the cytoskeleton of photoreceptors in development and during homeostasis. Similar to rods, we have found that NUDC is critical for proper cone cell function.

TITLE: Mechanism of AQP5 trafficking in lens fiber cells

SESSION TITLE: Lens proteins: normal and pathogenic biochemistry

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: K.L. Schey, R.B. Gletten, Biochemistry, Vanderbilt University, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure: Kevin Schey: Commercial Relationship: Code N (No Commercial Relationship) | Romell Gletten: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Aquaporin-5 (AQP5) is the second most abundant aquaporin in ocular lens fiber cells and its localization and thus fiber cell permeability can be regulated. Previously we have shown that in bovine outer cortical lens fiber cells, AQP5 localizes to cytoplasmic spheroidal, tubular structures that co-stain with autophagosomal and mitochondrial markers. The purpose of this work is to define the mechanism that trafficks AQP5 from cytoplasmic structures to the plasma membrane.

Methods: High resolution immunofluorescence (IF) was conducted on cryosections from cultured bovine lenses with zonules intact and treated with or without bafilomycin A1, an autophagosome/lysosome fusion inhibitor. AQP5, autophagosome marker LC3B, and lysosome marker LIMP2 were imaged by confocal microscopy. Quantitation of cytoplasmic and plasma membrane localized AQP5 was carried by image segmentation and assessing fluorescence intensity in subcellular regions using Nikon NIS Elements software. Transmission electron microscopy was also used to characterize subcellular structures and fusion of cytoplasmic structures to plasma membranes.

Results: In the bovine lens outer cortex, AQP5 was entirely localized to cytoplasmic structures that were mitochondrial marker TOMM20-positive. Little overlap between LC3B or LIMP2 signals and these AQP5-containing structures was observed in this region. In the transition region between the outer cortex and inner cortex, AQP5 structures co-stained with autophagosomal marker LC3B and LIMP2 and appeared to fuse with the plasma membrane. In the inner cortex, AQP5 was completely localized to the plasma membrane. LIMP2 was detected in the plasma membrane in the inner cortex as well. Upon treatment with bafilomycin A1, plasma membrane AQP5 signal was reduced in the outer cortex/inner cortex transition region and cytoplasmic AQP5 structures appear to increase in number.

Conclusions: Bovine AQP5 appears to traffic to the plasma membrane in the outer cortex/inner cortex transition region via an unconventional lysosomal trafficking mechanism that involves fusion of autolysosomes with the plasma membrane. Future experiments will focus on defining the signals that regulate AQP5 trafficking.

ABSTRACT BODY:

Purpose: Retinal blood flow, measured by optical coherence tomography angiography (OCTA) may be reduced by systemic disease and local ocular ischaemia, but also in association with retinal neurodegeneration. Traumatic brain injury (TBI) impairs the structure and function of the visual pathway. Retinal ganglion cell (RGC) layer degeneration and retinal perfusion loss can occur after TBI, even in absence of visual symptoms, with neurodegeneration delayed by several weeks. It is not clear whether reductions in retinal blood flow associated with neurodegeneration are caused by changes in retinal function (occurring at the time of injury) or simply reflect retinal structural changes (occurring only after neurodegeneration).

Methods: Retrospective case series. Patients attending for moderate to severe TBI assessment at a tertiary referral centre were included. Clinical examination, OCT, OCTA and Humphrey visual field (HVF) analysis were performed for each patient acutely and at follow-up. Data were extracted using manufacturer's software with blood flow assessed as skeletonized vascular density, large vessel masked flow probability and vessel enhanced perfusion density and compared to corresponding retinal ganglion cell layer (GCL) thicknesses.

Results: Sixteen patients aged 20-65 years were included, 12 males and four females. Patients were examined within nine days of TBI and then after 2-6 months. GCL thinning preceded superficial vascular plexus perfusion loss. The strongest association was GCL thickness and skeletonized vascular density (adjusted R squared 0.86; $p<0.0001$). The degree of GCL thinning and perfusion loss correlated to baseline visual function on HVF.

Conclusions: Reduced retinal perfusion is association traumatic RGC degeneration, mirroring, rather than preceding, structural changes.

ABSTRACT BODY:

Purpose: Sodium iodate causes oxidative stress to the retina and is commonly used by vision scientists to test therapeutics intended to treat disorders like age-related macular degeneration (AMD). An important difference, however, between sodium iodate and AMD is the time it takes to damage the retina. While AMD is a chronic disease that develops over years, sodium iodate damages the retina within a week. Because of this, it is possible that some therapeutics that protect against a slower developing disease such as AMD would be unable to protect against the fast-acting sodium iodate; this may lead to incorrectly discarding these therapies. Decreasing the severity of sodium iodate's damage by dropping the dose is a potential solution to this issue, but this also leads to more variability in the severity of retinal degeneration. To explore this, we hypothesized that a low dose of sodium iodate (20 mg/kg or 25 mg/kg IP) would cause different degeneration severity in males vs. females and old vs. young mice.

Methods: To test our hypothesis, 1% sodium iodate was intraperitoneally injected in male and female mice either 3 months old or 22 months old. Damage was assessed in vivo using confocal scanning laser ophthalmoscope (cSLO) and optical coherence tomography (OCT) 1 and 4 weeks after injection. Image analysis quantified the average thickness of the retina and the total area damaged.

Results: Mice injected with 25 mg/kg sodium iodate had more consistent damage than those injected with 20 mg/kg. Females at the 25 mg/kg dose had less (but still consistent) damage than male mice at the same dose. Older mice had more severe pathology than younger mice.

Conclusions: These results suggest that using 25 mg/kg sodium iodate in 3-month-old female mice may be an effective way to use the sodium iodate model when testing potential therapies for retinal disease such as AMD.

ABSTRACT BODY:

Purpose: Associations between microvascular complications of diabetes mellitus (DM), including diabetic nephropathy (DNeph), neuropathy (DNeu) and retinopathy (DR) have been reported, particularly for proliferative DR (PDR). Less is known specifically about their relationship with diabetic macular edema (DME), despite it being the leading cause of vision loss in patients with DM type-2 (DM2) and DR. The contributions of tobacco exposure to PDR and DME are also controversial. We further explore these associations using manually phenotyped cohorts of patients with progressive DR stages.

Methods: Vanderbilt's deidentified health record database, the Synthetic Derivative, was used to obtain clinical data from cohorts of patients with DM and no DR (N=239), no DME (N=365), DME (N=213), no PDR (N=341), and PDR (N=237). Continuous variables for multivariate logistic regression analysis included: DM duration (days) and Max HbA1c (%, A1c/glycated hemoglobin). Categorical variables included: hypertension, DNeu, DNeph, PDR, and DME (absent vs present), DM type (Type 1 vs Type 2), vital status (living vs deceased), race (black, vs. white, vs. other), and tobacco use (never vs remote {>5yrs from last exam or death} or current {within 5yr}). A two-sided T-test with $p<0.05$ was used for statistical significance.

Results: Max A1c and DM duration were significantly associated with PDR (p=0.029 and p=0.002, respectively) and DME (p=5.96e-05 and p=0.003, respectively). However, vital status, DNeu and DNeph were only significantly associated with PDR (p=0.013, p=0.001, and p=0.001, respectively) but not with DME. DM1 was significantly associated with PDR (p=3.30e-11) as DM2 was with DME (p=0.013). Relative to no tobacco exposure, remote (p=0.007), but NOT current tobacco use was significantly associated with increased odds of DME (Varma 2014), but neither was significantly associated with PDR. White race was significantly associated with a decreased presence of PDR relative to black race (p=0.037) but not to "other" race (p=0.109) and no association was found between race and DME.

Conclusions: Our results suggest that, although DME and PDR both represent progression in DR and are managed similarly, the factors that affect their development and their pathophysiology are likely significantly different. Exploring these differences may lead to the development of more effective therapies for these potentially blinding conditions.

ABSTRACT BODY:

Purpose: Stabilization of hepatic hypoxia inducible factor-1 (HIF-1) by dimethyl oxaloylglycine (DMOG) protects both retina and brain from oxygen induced retinopathy (OIR) and oxygen induced periventricular leukomalacia (OPVL), respectively. We have previously demonstrated that hepatic HIF-1 stabilization upregulates serine/1-carbon metabolism (serine/1CM) and that this pathway is essential to HIF induced protection against OIR. In this study, we measured the metabolism of [U-$^{13}C_3$] serine in liver and brain extracts from mouse pups with and without DMOG induced hepatic HIF-1 stabilization.

Methods: C57BL/6J mouse pups were injected with 0.9% NaCl or DMOG 200 µg/g bodyweight intraperitoneally (IP) on P3, P5, and P7. After the third injection, pups were fasted for 4 hrs then injected IP with 80 µL [U-$^{13}C_3$] serine (10 mg/ml), and 1 hr later, brain and liver samples were dissected and snap-frozen. Metabolites were extracted by methanol/chloroform/water and were assayed using gas chromatography mass spectrometry.

Results: DMOG treatment induced a 2-fold increase in both relative abundance and fractional enrichments of M3 serine and M2 glycine in liver. In brain, DMOG treatment increased the fractional enrichment of M3 serine 2.5-fold with no statistiscally significant increase in relative abundance. Brain glycine increased by 50% whereas fractional enrichment increases of M2 glycine was statistically insignificant in brain. There was a trend toward increased M2 hypotaurine in both brain and liver, but hypotaurine levels were decreased in both tissues under DMOG stimulus. Taurine levels were unchanged in both tissues with and without DMOG treatment. M3 Lactate:pyruvate ratios were stable and close to 1.0 in all conditions.

Conclusions: These data demonstrate that exogenous serine (and hence liver derived serine) is able to cross the blood-brain barrier as would be expected for neutral amino acids via their respective carriers. However, DMOG induced increases in M2 hepatic down-stream metabolites of serine/1CM such as M2 glycine in both brain and liver suggesting that hepatic HIF-1 stabilization provides 1C metabolites for brain via liver derived serine, at least in neonatal mouse pups at P7. Serine is a key component of myelin, necessary to glycosphingolipid synthesis, providing a potential mechanism for how hepatic stabilization of HIF-1 (remote protection) could increase CNS myelination.

ABSTRACT BODY:

Purpose: To evaluate the utility of the European School for Advanced Studies in Ophthalmology classification for diabetic macular edema (DME) assessing the interobserver agreement for the staging using optical coherence tomography (OCT) in naïve patients. Secondly to assess the staging problems that may arise.

Methods: We performed a consecutive retrospective analysis of all DME naïve patients who came to our service for 1 year. Two specialist retinal evaluators analyzed independently the OCT images and determined the DME stage using the European School for Advanced Studies in Ophthalmology (ESASO) classification. An interobserver agreement analysis was performed. In cases where staging could not be performed, we evaluated and categorized the cause for no-staging and an interobserver agreement analysis was also performed.

Results: We analyzed 93 eyes of 65 patients (64.6% male and 35.4% female) with a mean age of 66.2 +/- 12.1 years old. Observer 1 staged 60 out of 93 eyes (64.5%). Observer 2 staged 61 out of 93 eyes (65.6%). The Kappa analysis of intra-observer concordance for the staging was 0.508.

Out of 93 cases, observers 1 and 2 could not stage 33(35.5%) and 34 (34.4%) cases respectively as the OCT features of the DME in these cases did not correspond to any of the options provided in the ESASO classification. These findings were statistically significant (p=0.000)

The causes for no-staging were edema with very low thickness that does not alter the ellipsoid zone (T0C1E0/E1), edema with low thickness that does not alter the ellipsoid zone with disorganization of the inner retinal layers (T1C1/2E0D1), edema with increased thickness without cysts (T1-3C0) and Edema with low thickness and severe cysts (T1C3). The Kappa analysis of intra-observer concordance for causes of no-staging was 0.869.

Conclusions: We may conclude that the EMD OCT ESASO classification constitutes a modern and thorough classification for the DME but in our experience does not englobe the totality of DME cases that you may find in clinical practice.

ABSTRACT BODY:

Purpose: The removal of lens organelles from lens fiber cells is critical for lens clarity. Multiple congenital cataract models show retention of nuclei in the purported organelle free zone, indicating that nuclear breakdown is among essential processes in establishing and maintaining lens clarity. Documentation of processes involved in nuclear envelope breakdown is limited. Identifying the steps of nuclear envelope breakdown in lens denucleation may provide insight into mechanisms of cataract development.

Methods: Nuclear morphology and localization of nuclear Lamins, nuclear pore complexes and inner and outer nuclear membrane proteins were examined during differentiation in chick and mouse lenses using immunofluorescence. Nuclear structure was examined in WT mice using electron microscopy.

Results: Phosphorylation of Lamin is associated with nuclear envelope breakdown. In chick lenses, phosphorylation of Lamin A immediately precedes nuclear condensation. Additionally, after Lamin phosphorylation, nuclear Lamin staining becomes discontinuous in the nuclear membrane. The nuclear pore complex also becomes discontinuous in the nuclear membrane after Lamin phosphorylation and no longer localizes with Lamins. Analysis of nuclear membrane structure by electron microscopy shows nuclear envelope breakdown in areas devoid of nuclear pore complexes.

Conclusions: These data suggest that as in mammalian lenses, phosphorylation of Lamin is an important step in nuclear envelope breakdown during lens fiber cell denucleation in the chick. Furthermore, reorganization of nuclear membrane proteins precedes denucleation.

ABSTRACT BODY:

Purpose: We have previously demonstrated the application and utility of an amplification-free long-read sequencing method to characterize the Fuchs endothelial corneal dystrophy (FECD)-associated intronic TCF4 triplet repeat (termed CTG18.1). Here we aim to improve on our previously published method to characterise CTG18.1 in a FECD patient cohort using a dual cutter CRISPR/Cas9 enrichment approach in combination with PacBio single molecule real-time (SMRT) long-read sequencing.

Methods: An amplification-free method using a dual CRISPR/Cas9 system, in combination with PacBio SMRT long-read sequencing on a Sequel II platform, was applied to target CTG18.1. FECD patient-derived gDNA samples comprising a diverse range of CTG18.1 allele lengths were analysed. A robust data analysis pipeline was devised and applied to effectively filter, align and interrogate CTG18.1 specific reads.

Results: Dual CRISPR/Cas9-guided SMRT sequencing of CTG18.1 provided accurate genotyping information and enabled us to characterise the levels of somatic mosaicism present for all samples analysed. Advantages of this refined protocol, when compared to our previous method, include the enrichment and sequencing of a larger region of genomic DNA flanking CTG18.1 to enhance the likelihood of encompassing informative polymorphic markers to phase CTG18.1 reads. Furthermore, the dual cutter CRISPR/Cas9-guided design, in combination with sequencing on the PacBio Sequel II System, also enabled enhanced multiplexing capacity and reduced genomic DNA input requirements compared with our original protocol.

Conclusions: CRISPR-guided SMRT sequencing provides a powerful approach to accurately interrogate disease-associated tandem repeat expansions at a nucleotide level and detect levels of instability that are often prevalent within somatic tissues. The refined method presented here offers enhanced phasing capabilities, reduction of the amount of DNA required and increased multiplexing capacity compared to previously published methods.

TITLE: Correcting Chromatic Aberrations and Spatial-Spectral Crosstalking in Broadband Line-Scanning SD-OCT

SESSION TITLE: Multidisciplinary Ophthalmic Imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. HAN, K.K. Bizheva, University of Waterloo, Waterloo, Ontario, CANADA|

Commercial Relationships Disclosure: LE HAN: Commercial Relationship: Code N (No Commercial Relationship) | Kostadinka Bizheva: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In broadband Line-scanning SD-OCT, chromatic aberrations and spatial-spectral crosstalking prevent diffraction limit imaging. We demonstrate these two problems can be resolved by dividing the original broadband spectrum into sub-bands, digital refocusing separately, and registering them afterward.

Methods: The LS SD-OCT system is based on a Michelson interferometer that is powered by a supercontinuum laser (SuperK, NKT Photonics, Birkerød, Denmark). A custom band-pass filter was utilized to select a spectral range of 600 nm – 980 nm. The spectrum after digital filtering is centered at 800 nm, and the effective FWMH bandwidth is 160 nm. The interference signal is detected by a 2D CMOS camera (Dimax S4, PCO, Germany) with a detection aera of 1920 * 500 pixels (spectral-spatial) at a 2.95 kHz frame rate. Volumetric (500 A-scans × 500 B-scans × 1920 pixels) images were acquired, with a field of view (FOV) ~ 0.5 mm × 0.8 mm (x × y) and depth scanning range 1.2 mm (z). The 3 micrometer diameter microbeads were imbedded in transparent agar-based gel. Cucumbers were cut into thin slice and covered by cover glasses. The rat cornea was ex-vivo imaged within 2h after sacrifice.

Results: Fig. 1A shows the images of enface microbeads images. From left to right, the image corresponds to the original OCT signal, refocused OCT signal using the full spectrum, and the registered sub-bands method. The line profiles comparison in (B) suggests that both the x- and y- resolution are improved using the proposed method. (C) and (D) show the original and corrected tilted projection images of cucumber seeds. (E) and (F) show the original and corrected enface image of the middle stroma in the rat cornea. Both the keratocytes and nerves are refocused. (G) and (H) show the original and corrected endothelium cells of the rat cornea.

Conclusions: Our proposed method was successfully used to refocus the microbeads, cucumber, and rat cornea LS-OCT images. The chromatic aberrations and spatial-spectral crosstalking in broadband LS SD-OCT have been reduced which makes broadband LS SD-OCT suitable for cellular resolution imaging.

ABSTRACT BODY:

Purpose: Progressive rod-cone degeneration (PRCD) is a photoreceptor-specific protein essential for maintaining photoreceptor outer segment (OS) structure and rhodopsin packaging densities into disc membranes. Previously, we have shown that PRCD undergoing protein palmitoylation at the second amino acid (Cys2) is crucial for protein stability and proper trafficking to photoreceptor OS. PRCD has several predicted structural domains with unknown significance, with one of the mutations being located in the polybasic region (PBR). This mutation, an arginine to cysteine at the 17th position (R17C), is linked with retinitis pigmentosa (RP). The goal of our study is to determine the structural importance of the PBR in PRCD and to characterize the R17C mutated protein.

Methods: Constructs expressing R17C and a double mutant (C2Y/R17C) were cloned in a pCAG-IRES-EGFP vector with an HA-tag and transiently transfected in hRPE1 cells. Protein stability, membrane association, and subcellular localization were determined by western blot and immunocytochemistry. Palmitoylation status was determined via Acyl-RAC and Acyl-PEG exchange. Localization of R17C and C2Y/R17C was also studied in vivo by subretinal injection in the murine retina.

Results: Protein stability of mutant R17C is significantly reduced by 50% compared to WT, despite having strong membrane association and palmitoylation observed by Acyl-RAC. Interestingly, we distinguished palmitoylation at the Cys17 position with the loss of endogenous palmitoylation (C2Y/R17C), which enhances the protein stability compared to the C2Y protein. Subretinal injection followed by electroporation in murine retina shows C2Y, R17C, and C2Y/R17C double mutant proteins are mislocalized to the subcellular compartment. Immunolocalization in the RPE cell line expressing R17C shows similar phenotypes to WT, and C2Y/R17C shows similarities to the C2Y protein.

Conclusions: Despite being palmitoylated twice and demonstrating strong membrane association, the mutation in the PBR (R17C) affects protein stability and trafficking from the IS. Furthermore, palmitoylation within the PBR alone (C2Y/R17C) does not compensate for protein stability or trafficking. Overall, we demonstrate that the PBR domain in PRCD is indispensable for its function and any defects of the area lead to dysregulation of PRCD protein associated with blinding diseases.

ABSTRACT BODY:

Purpose: Peripheral retinal vascularization continues following treatment with bevacizumab (IVB) for type 1 Retinopathy of Prematurity (ROP). However, many eyes have persistent avascular retina (PAR) despite therapy, which may lead to late reactivation, retinal detachment, and blindness. We aimed to identify risk factors for PAR following bevacizumab therapy for type 1 ROP.

Methods: We conducted a retrospective series of 106 eyes from 53 infants with type 1 ROP. 74 eyes from 37 infants received IVB with subsequent laser of PAR at an average of 49.5 weeks postmenstrual age (PMA) 95% CI [45.7, 53.2] (Group 1). 20 eyes from 10 infants were treated with IVB and did not receive subsequent laser (Group 2). Fundus photos were available for 52 eyes of 26 infants in Group 1 and from 14 eyes of 7 infants in Group 2. We compared the patient demographics, timing of treatment, and the fundus photographs at the time of IVB and laser photocoagulation. Length and rate of vascular growth after IVB were measured. In addition, we measured changes in vascular severity score (VSS) following IVB, which provides an objective assessment of disease severity.

Results: The average length of vascular growth following IVB was 100.7 millimeters (mm), 95% CI [86.2, 115.1] over an average of 80.4 days, 95% CI [70.3, 90.4]. Group 2 had higher birthweight (BW) ($p<0.05$), greater extent of retinal vascularization at time of IVB ($p<0.001$), and lower VSS at time of IVB ($p<0.01$) than Group 1. Zone/Stage, gestational age (GA), and post-menstrual age (PMA) at time of IVB did not differ significantly between Group 1 and Group 2. The overall mean VSS decreased significantly following IVB in all Group 1 eyes ($p<0.001$). The amount of VSS change from time of IVB to time of laser was positively correlated with the extent of vascular growth following IVB ($p<0.05$), providing a potential biomarker for PAR.

Conclusions: The presence of PAR requiring laser after IVB was associated with lower BW, more posterior disease, and higher VSS at the time of IVB. In addition, a larger VSS change following IVB was significantly associated with increased vascular growth. VSS may provide a tool for predicting PAR and monitoring for arrest of vascularization.

TITLE: The Effect of Topical Recombinant Human Nerve Growth Factor on Tear Production

SESSION TITLE: Corneal Imaging and Corneal Nerves

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Karakus, X. Dai, X. Zhu, Johns Hopkins Medicine Wilmer Eye Institute, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Sezen Karakus: Commercial Relationship(s);Code C (Consultant/Contractor):Dompe | Xi Dai: Commercial Relationship: Code N (No Commercial Relationship) | Xi Zhu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate the effect of the topical recombinant human nerve growth factor (rhNGF) on tear production in patients with severe, refractory dry eye with neurotrophic features.

Methods: A retrospective chart review was conducted on patients treated with topical rhNGF for severe, refractory dry eye with neurotrophic features, defined as refractory corneal staining with minimal or no ocular discomfort that has failed multiple rounds of conventional treatment. Data regarding patient demographics and ocular/systemic past medical history was extracted from patient charts. Tear production as measured by Schirmer test without topical anesthesia was recorded for the worst eye at baseline and subsequent follow-up visits after treatment. Appropriate statistical tests were applied to identify changes in Schirmer test values before and after treatment and the proportion of patients with an increase in tear production reflected by Schirmer test value.

Results: We included 7 patients meeting criteria for severe, refractory dry eye with neurotrophic features with Schirmer values recorded before and after treatment. After an 8-week course of treatment with rhNGF, the median value of the Schirmer test increased from 9 to 16 mm compared to baseline. A meaningful increase was observed in three patients (more than 7 mm). One patient had Sjogren's syndrome and prior LASIK surgery (Schirmer increased from 7 to 27 mm), and the other two patients had prior LASIK surgery (Schirmer increased from 14 to 29 mm and 9 to 16 mm) as a risk factor to have refractory epithelial keratopathy with neurotrophic features. All tolerated the treatment well, reporting eye pain and eyelid sensitivity from drop application that all resolved after completion of treatment.

Conclusions: Treatment with topical rhNGF has shown promising results in our small case series in increasing tear production in patients with severe, refractory dry eye with neurotrophic features with minimum side effects. Further studies should be pursued to determine longer-term treatment effects as well as optimum treatment dose and duration based on underlying etiology.

ABSTRACT BODY:

Purpose: Photoreceptor arrestin 1 (Arr1) from mammalian species self-associates into dimers and tetramers. We have shown that amphibian Arr1 oligomerization is limited to dimers – higher order oligomers are not detected at the highest experimental concentrations examined, nor projected to form at millimolar, physiological concentrations. We thus examined if the mechanism of amphibian Arr1 dimer formation differed from that of mammalian.

Methods: Recombinant Arr1s from the African clawed frog, Xenopus laevis (xArr1), and the tiger salamander, Ambystoma tigrinum (salArr1), were expressed in E. coli, purified, and subjected to analytical ultracentrifugation (AUC). AUC results were analyzed in SEDFIT, plotted in GUSSI and fitted in MATLAB to determine oligomer formation and dissociation constants. 3D structure of xArr1 was estimated using Modeler in Chimera, using bovine Arr1 crystal (PDB: 1CF1 chain A) as template. Regions of greatest sequence divergence among Arr1s were found using MegAlign. Lysine crosslinking - Mass Spectrometry and Patchdock were used to identify potential dimer interfaces and create 3D models of xArr1 dimers. Small angle x-ray scattering (SAXS) was performed and analyzed using Raw to estimate dimer shape. xArr1 dimer structure was predicted by visualizing SAXS envelopes and comparing to 3D models from Patchdock using Chimera.

Results: Arr1 from X. lavis and A. tigrinim self-associate in a concentration-dependent manner, however, oligomerization of both species was limited to dimers. AUC analysis of recombinant and endogenous bovine Arr1 supports previously published results that are interpreted to show the formation of tetramers at physiological concentrations. SAXS envelopes of xArr1 are consistent with dimer formation, without indication of larger oligomers. Inositol-hexakisphosphate (IP6) inhibits xArr1 self-association, but not as effectively as for mammalian Arr1. Mutations in xArr1 residues analogous to key residues in mammalian Arr1 that are essential for their tetramerization and in which mutations increase the Kd of dimerization tenfold, had no impact on the affinity of xArr1 dimers. Homology modeling and circular dichroism spectra suggest a similar fold for xArr1 and bovine Arr1.

Conclusions: Together, these results suggest that amphibian Arr1s have a similar structure to that of mammals but use a dimerization interface that differs from those found in mammalian Arr1s.

SUBMITTER (NAME ONLY): Brandon Lien

TITLE: Comparison of manual versus semi-automated analysis methods for pterygium surface area determination

SESSION TITLE: Machine Learning and Image Processing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: B. Lien, O.L. Lee, Department of Ophthalmology, University of California Irvine, Irvine, California, UNITED STATES|Y. Shin, Doheny Image Reading Center, Doheny Eye Institute Doheny Image Reading Center, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Brandon Lien: Commercial Relationship: Code N (No Commercial Relationship) | Ye Jin Shin: Commercial Relationship: Code N (No Commercial Relationship) | Olivia Lee: Commercial Relationship(s);Code C (Consultant/Contractor):Cloudbreak Therapeutics

ABSTRACT BODY:

Purpose: To describe and validate methodology to assess the pterygium surface area extending beyond the corneal limbus expressed as a percentage of the corneal surface area. To apply and compare the analysis methodology to color photographs of eyes with pterygia using manual grading versus using computer vision techniques.

Methods: The study included 25 photos of 21 eyes of 19 patients with nasal pterygium. The primary gaze images were taken by a single lens reflex camera system (Canfield Scientific, Inc., Fairfield, NJ), using fixed parameters. In both the manual and semi-automated methods, the corneal limbus was identified and demarcated 360 degrees. The extension of the pterygium head, seen as fibrovascular growth extending past the corneal limbus, was identified and demarcated. The pterygium is expressed as a percentage of its surface area over the corneal surface area. Manual analysis was performed by reading center graders using Image J (NIH, Bethesda, MD). The semi-automated method was created using the Python coding language (Python Software Foundation, Fredericksburg, VA) and the OpenCV library (Intel Corporation, Santa Clara, CA). Each method was independently performed and repeated on all 25 images. Intraclass correlation coefficient (ICC) was calculated for inter- and intra- grading agreement.

Results: All 25 images were analyzed using the methodologies described above. The manual and semi-automated method's mean pterygium surface area covered was 11.61% (± 7.21) and 13.08% (± 19.39) of the corneal surface area, respectively. The t-value was 0.354 and the p-value was 0.362. The manual intragrader ICC for percentage of pterygium to corneal surface area was 0.961. The intragrader ICC for the semi-automated pterygium grading methodology was 0.994. When the semi-automated method was compared to the manual method of grading pterygium, the intergrader ICCs ranged from 0.603 to 0.666.

Conclusions: A methodology for measuring pterygium surface area relative to corneal surface area is described and validated using both manual grading and semi-automated computer vision analysis. The reproducibility of this method is high between manual and semi-automated methods. Both methods may be used for standardized evaluation of pterygia in clinical research and clinical trials. The semi-automated quantification allows for reduction in grading speed, while maintaining good reliability.

ABSTRACT BODY:

Purpose: Ocular surface infection by human adenovirus species D (HAdV-D) causes epidemic keratoconjunctivitis (EKC). The most significant long-term complication of EKC is subepithelial infiltrate (SEI) formation, occurring in about one-third of cases. However, the mechanism of SEI formation after adenoviral infection of the cornea remains uncertain. High-mobility group box protein 1 (HMGB1) is an important late inflammatory mediator; extracellular HMGB1 variably regulates inflammatory responses and leukocyte infiltration. In this study, we aimed to define a potential role for HMGB1 in progression to SEI formation.

Methods: Primary human corneal epithelial (PHCE) cells, hTERT-immortalized human corneal epithelial (THE) cells, and primary human corneal fibroblasts (HCFs) were infected with HAdV-D37 or HAdV-C5 at MOI = 5, and cell supernatants were collected through 48 hours post infection. Mass spectrometry (LC-MS/MS) analysis was performed on cell lysates. Immunoblotting was performed on infected cell supernatants, and on cytoplasmic and nuclear cellular fractions, using acetylated HMGB1 antibody. ELISA for secreted HMGB1 was conducted on cell-free supernatants, and HMGB1 gene expression was studied using real-time qPCR. Confocal microscopy was performed to visualize HMGB1 translocation. Cytokine expression by HCFs treated with recombinant HMGB1 was analyzed using human cytokine protein arrays.

Results: HAdV-D37 infection resulted in HMGB1 translocation from the nucleus to the cytoplasm and then to the extracellular space in THE cells, but not in HCF. HAdV-C5, a virus not associated with EKC, did not induce secretion of HMGB1 from any of the cell types tested. Finally, treatment of HCF with recombinant HMGB1 triggered expression of pro-inflammatory mediators.

Conclusions: Our data suggest that HMGB1 is specifically released by adenovirus infected corneal epithelial cells and also provides insights into possible mechanism of corneal SEI formation in EKC. HMGB1 expressed by adenovirus infected corneal epithelial cells could induce underlying stromal cells to express pro-inflammatory mediators, leading indirectly to the development of SEI. HMGB1 may be a viable therapeutic target for preventing the corneal stromal complications of EKC.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is a devastating disease characterized by the ectopic accumulation of calcified protein-lipid deposits. Understanding the molecular basis for deposit formation is key for developing diagnostic, preventive, and therapeutic approaches. Using biophysical methods with purified proteins and lipids, we characterized the role of vitronectin (Vn) in mediating hydroxyapatite (HAP) mineralization on lipid surfaces. Vn is a calcium-binding protein and a major component of the AMD proteome with a potential role in HAP deposition; Vn is known to interact with the complement system and variants have been identified as AMD risk factors.

Methods: Using mammalian and E. coli expression systems, we purified full-length Vn and a shorter construct encompassing its hemopexin domain (Vn-HX). The purified proteins were labeled with fluorescent tags for microscopy and characterized structurally by NMR and crystallography. Their interactions with lipids and HAP were determined using thermal shift assays. To examine the effects of Vn on deposit formation, HAP mineralization was initiated from chemically-defined solutions of calcium and phosphate ions, and monitored in the presence of lipids by fluorescence techniques with HAP-specific dyes. A two-tailed Student’s t-test was used for statistical analysis.

Results: Vn and Vn-HX bind HAP, with HAP association significantly increasing their melting temperatures by ~6 °C (Vn $p<0.01$; Vn-HX $p<0.01$). Both promoted HAP mineralization on lipid vesicles leading to the formation of concentric lipid-HAP-protein micro-spheres, ranging in size from 3-10 μm and similar to those observed in AMD pathology. Surface coating of Vn and Vn-HX could be visualized with fluorescently labeled proteins. Addition of Vn ($p<0.01$) and Vn-HX ($p<0.01$) significantly increased HAP mineralization measured by fluorescence with the HAP-specific stains Xylenol Orange, OsteoSense and Alizarin Red S.

Conclusions: Our results demonstrate that Vn can strongly interact with HAP using the calcium-binding site in its hemopexin domain. The Vn-dependent, HAP-specific fluorescence enhancement suggests that Vn plays a role in regulating HAP deposition on lipid surfaces. Our in vitro assays identify Vn as a promising target for AMD diagnosis and treatment, and future work will focus on translation to cellular and in vivo models.

ABSTRACT BODY:

Purpose: To evaluate the effect of artificial tears based on an extract of Artemia salina, a brine shrimp containing high concentrations of dinucleotides, in a rabbit dry eye model.

Methods: An experimental, prospective, and randomized study was carried out on 20 New Zealand white rabbits divided into 4 different groups (n = 5, each group): healthy rabbits, dry eye rabbits, dry eye rabbits treated with hypromellose, and dry eye rabbits treated with Artemia salina. The dry eye model was induced by the topical instillation of 0.2% benzalkonium chloride. Measurements of tear film quality and damage and inflammation of the ocular surface were performed before and after the topical instillation of the different treatments for 5 consecutive days.

Results: Compared with the dry eye rabbits non treated and treated with hypromellose, the treatment with the artificial tears based on Artemia salina manifested beneficial effects on tears secretion (increased 64.38 ± 18.41%), tear break-up time, corneal staining, density of Goblet cells, height of mucin cloud secreted by Goblet cells, and mRNA levels of IL-1β y MMP9 in conjunctival cells ($P < 0.05$).

Conclusions: The topical instillation of artificial tears based on an extract of Artemia salina was confirmed as a potential secretagogue agent for dry eye treatment, which opened the door for future studies to extrapolate the current findings to dry eye patients.

ABSTRACT BODY:

Purpose: Optical coherence tomography (OCT) provides clinicians with a large number of quantitative parameters that aid in glaucoma diagnosis. The OCT Early Glaucoma Diagnostic Structural Index (EGDSI), was previously proposed and validated in healthy and glaucomatous eyes with no associated disease providing a combined structural index for the detection of early glaucoma[1,2]. In this preliminary, ongoing study, we evaluated the sensitivity and specificity of EGDSI in healthy and in a range of glaucomatous eyes that may include comorbidities.

Methods: Retrospective CIRRUS™ 6000 AngioPlex (ZEISS, Dublin, CA) OCT data were sampled from a glaucoma clinic including 76 eyes of 38 subjects that were clinically diagnosed as healthy, glaucomatous, or having other morbidities (see Table 1). Optic Disc 200x200 and Macular 512x128 cube scans from the first clinical visit were used for analyses. Mean Deviation (MD) from SITA Standard or SITA Fast 24-2 visual field data were collected from non-healthy eyes to gauge severity. Sixteen OCT summary parameters were extracted to calculate EGSDI as previously described. Sensitivity and specificity for EGDSI were calculated using 5% and 1% normative cut-off values determined from the CIRRUS reference database.

Results: For 37 healthy eyes, mean age was 56.3 (standard deviation, SD: 18.4; range: 27.1 to 85.7) years. For 39 eyes with glaucoma or other morbidities, mean age was 65.5 (SD: 13.3; range 30.8 to 85.7) years and mean MD was -5.15 (SD: 8.10; range: -28.79 to 0.35) dB. In the full cohort, sensitivities were 78.8% and 60.6% and specificities were 83.7% and 95.3% at the 5% and 1% cutoffs, respectively (see Table 2). There was an additional false positive (1 of 6) and false negative (1 of 3) due to the additional 9 morbidities.

Conclusions: In this preliminary, ongoing study, EGDSI shows comparable sensitivity to detect glaucoma as previously reported in a range of glaucomatous eyes[3] despite the presence of a limited number of comorbidities, and exhibited additional Type I and II errors. Additional data sampling more comorbidities may help determine their effect on the EGDSI and its clinical utility to aid in detection of glaucoma.

ABSTRACT BODY:

Purpose: Induced pluripotent stem cell (iPSC)-derived retinal progenitor cells are a promising cell type for restoring vision in patients with retinal degeneration. The purpose of this study was to develop a protocol to generate clinical grade CRISPR-corrected photoreceptor precursor cells for autologous retinal cell replacement.

Methods: IPSCs were generated using dermal fibroblasts isolated from an unaffected control and a patient with NR2E3-associated enhanced S-cone syndrome. CRISPR-Cas9-based homology-dependent repair strategies were designed to correct disease causing NR2E3 mutations. CRISPR reagents were delivered using a microfluidic device, which operates using a reagent-free, convective transport mechanism amenable to the delivery of large molecules under cGMP. Retinal organoids were derived using a stepwise 3D differentiation protocol testing different cGMP compliant reagents and oxygen tension (5-20%) in a cGMP compliant Biospherix cell culture isolator. Organoids were characterized via light and confocal microscopy.

Results: CRISPR reagents were delivered to patient iPSCs using a Zephyr microfluidic transfection system (CellFE). Different gap sizes (7, 9, and 10μm) and flow rates (achieved by applying pressure of 50 or 90PSI to each well) were tested and cell survival and cutting efficiency were evaluated. A 9μm gap size and 90 PSI consistently gave the greatest cutting efficiency (~31%) with lowest cell death. While we previously found that iPSC reprogramming efficiency is highest under 5% oxygen tension, retinal organoid production was inefficient at this oxygen level. Increasing oxygen tension to 20% resulted in decreased pluripotency and increased ectoderm gene expression by day 7 of differentiation. By day 30, laminated retinal organoids were abundant in cultures differentiated under 20% oxygen tension, while they were smaller and less consistent when differentiated at 5% oxygen tension. By 150 days of differentiation retinal organoids generated at 20% oxygen tension under cGMP conditions contain abundant rod and cone photoreceptor precursor cells expressing markers such as NRL and cone arrestin respectively.

Conclusions: We have generated a cGMP compliant protocol incorporating microfluidic transfection and varying oxygen tensions to enable efficient generation, CRISPR correction and differentiation of transplantable photoreceptor cells for autologous cell replacement.

ABSTRACT BODY:

Purpose: To describe VF progression in glaucoma patients 1 year after a DH and explore the correlation with DH location and re-bleeding.

Methods: 30 patients with glaucoma and a DH were recruited at Moorfields Eye Hospital and followed for 5 visits over 1 year (0-1-3-6 and 12 months). In all visits patients had two 24-2 and two 10-2 VF (Humphrey Field Analyzer, Carl Zeiss Meditec, Inc., Dublin, CA), except on month 3 (only one of each). The Glaucoma Progression Analysis (GPA) software was used to establish progression at 1 year. Trend (MD and VFI for 24-2, MD for 10-2, overall and per hemifield (HF)) and event analyses were included. Progression on the HF corresponding to the DH was compared with the opposite HF. Progression rates were compared between ‘re-bleeders’ and ‘non re-bleeders’.

Results: 7 were excluded from analysis: 1 required surgery for progression in the study eye, 3 withdrew before 1 year, and 3 did not attend the last visit within the 1-year window due to COVID-related issues.

16 (70%) of DH were located in the inferior hemi-disc.

3 (13%) cases were labelled ’Possible progression’ on event-based analysis.

Mean MD (SD) at baseline were -3.39 (2.87) for 24-2 and -2.81 (4.22) for 10-2. Progression rates (SD) for MD were: -0.35 (1.6) in the superior HF and -0.27 (1.48) in the inferior HF (p=0.86), on 24-2 VF. On 10-2 VF, the rates were -0.93 (1.44) for the superior HF and -0.23 (0.93) for the inferior HF, p=0.06.

Progression rates in the HF corresponding to the DH vs the opposite HF were: -0.37 (1.74) vs -0.25 (1.32), p=0.79, on 24-2 and -0.82 (1.34) vs -0.34 (1.12), p=0.18, on 10-2.

16 (70%) patients re-bled in either eye during follow-up. Progression rates for re-bleeders vs non re-bleeders were: -0.33 (1.17) vs -0.24 (2.09), p=0.89, for 24-2 MD and -0.69 (1.11) vs -0.28 (0.9), p=0.41, for 10-2 MD.

Conclusions: VF progression was fairly slow in our cohort and most patients remained stable on event analysis. There was a trend towards faster progression in the HF corresponding to the DH, but there was no statistically significant difference over this short observation period. Re-bleeding was common but was not associated with faster progression.

ABSTRACT BODY:

Purpose: Retinal segmental periarteritis (Kyrieleis plaques) is a rare condition in which white-yellowish exudates are placed in beaded pattern within the retinal arteries. The aim of the study is to report the adaptive optics (AO) imaging characteristics of arterial vasculitis in Varicella Zoster Virus (VZV) related posterior uveitis and correlate it with other imaging modalities.

Methods: Patients diagnosed with VZV posterior uveitis and evidence of retinal segmental periarteritis underwent multimodal imaging including fluorescein angiography (FA), indocyanine green angiography (ICGA), optical coherence tomography (OCT) and AO.

Results: 3 patients (1 female; median age 78 years) were recruited. In all cases, AO images showed arterial wall involvement, perivascular opacification, and focal lumen irregularities. However, the arterial walls were never disrupted. There was no vein involvement. In one case, glistening whitish spots were evident on the surface of the arterial wall, which corresponded to an intense hyperreflectivity on OCT and late focal hypofluorescence on FA and ICGA. In general, arterial plaques showed late iso/hypofluorescence on FA and ICGA. In all cases, arterial plaques modifications were far more evident on AO than angiographic exams.

Conclusions: AO imaging confirms that nodular periarteritis involves arterial walls, but it remains confined within them. Furthermore, AO seems more sensitive to detect vascular inflammation at microscopic level than traditional imaging. Additional studies will be needed to further explore the diagnostic and prognostic value of these findings.

TITLE: Surfactant Protein A Regulates Actin Polymerization and Function in Retinal Endothelial Cells

SESSION TITLE: Retinal vascular diseases

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F.N. Bhatti, Pediatrics and Ophthalmology, The University of Oklahoma College of Medicine, Oklahoma City, Oklahoma, UNITED STATES|W. Chen, J. Fernandes, Pediatrics, The University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma, UNITED STATES|

Commercial Relationships Disclosure: Faizah Bhatti: Commercial Relationship: Code N (No Commercial Relationship) | Wen Chen: Commercial Relationship: Code N (No Commercial Relationship) | Jolyn Fernandes: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Preterm infants are at risk of aberrant angiogenesis and can develop Retinopathy of Prematurity (ROP), a leading cause of acquired visual impairment. Risk factors for ROP are hyperoxia and inflammation. Surfactant protein A (SP-A) is deficient in preterm infants and we previously showed that deficiency of SP-A in mice is associated with decreased retinal vessel growth in early development and in oxygen-induced retinopathy, with abnormal elongation of retinal endothelial cells (EC's). Actin and cytoskeleton function are critical for EC migration and function. We hypothesize that lack of SP-A impairs retinal EC function via decreased actin polymerization, and cytoskeleton dysregulation.

Methods: Gene expression in SP-A$^{-/-}$ and WT P6 mouse retina tissue was evaluated by RNAseq and protein by mass spectroscopy (MS). Confirmation of targets was done by Cytoskeleton PCR Array. Retina flat mounts were evaluated by IHC with staining for actin and cd31 (EC marker). HRECs were treated with control HEPES (HREC+Con) or human SP-A protein (HREC+SPA). Actin expression and organization was analyzed by IHC. Migration and proliferation assays were assessed in HREC's. Data was analyzed by students t-test or one-way ANOVA, with $p< 0.05$.

Results: We show differential expression of factors mapped to signaling pathways and transcriptional regulation of cytoskeleton-dependent functions, including actin polymerization (actin polymerization complex related proteins Arpc2, Arcp4, and WasL), microtubule formation and cell cycle division (Ktn1 and Map4). HRECs+SP-A had more than twice as much cell migration compared to HRECs+Con ($p< 0.0001$) and increased proliferation ($p< 0.0001$). HRECs+SP-A exhibited elongation of actin filaments and protrusion of filopodia compared to HREC+Con, Actin was more peripherally organized in ECs and tip cells of blood vessels in WT compared to SP-A$^{-/-}$ mice.

Conclusions: Deficiency of SP-A alters expression of genes related to actin filament interactions, organization & biogenesis, microtubules, cell shape and size. Furthermore, HREC's exposed to purified SP-A exhibit morphological changes including elongation of cells and migration of actin to endothelial cell borders with an increase in migration and proliferation. Future studies will determine underlying mechanisms of these observed findings which will allow for development of therapy targeting aberrant vessel growth in ROP.

SUBMITTER (NAME ONLY): ZEESHAN AHMAD

TITLE: Lipid peroxidation and iron accumulation induced ferroptosis in bacterial endophthalmitis

SESSION TITLE: Pathobiology of Microbial Infections

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: Z. AHMAD, S. Singh, X. Walker, R. Wright, A. Kumar, Ophthalmology, Vision and Anatomical Sciences, Wayne State University, Detroit, Michigan, UNITED STATES|

Commercial Relationships Disclosure: ZEESHAN AHMAD: Commercial Relationship: Code N (No Commercial Relationship) | Sukhvinder Singh: Commercial Relationship: Code N (No Commercial Relationship) | Xavier Walker: Commercial Relationship: Code N (No Commercial Relationship) | Robert Wright: Commercial Relationship: Code N (No Commercial Relationship) | Ashok Kumar: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Ferroptosis is a recently discovered non-apoptotic mode of cell death triggered by downregulation of antioxidant enzyme glutathione peroxidase 4 (GPX4). In this study, we sought to determine the role of GPX4 signaling in regulating retinal ferroptosis in bacterial endophthalmitis

Methods: In vivo (C57BL/6 mouse) and in vitro (BMDMs, retinal Muller glia) studies were performed by infecting with S. aureus (SA). Ferroptosis induced cell death and its regulation by GPX4 was assessed by pharmacological inhibition and activation approaches. In mice, disease progression was assessed by both non-invasive (ERG and fundus exam) and invasive (bacterial burden, cytokine levels) methods. Bacterial induced downregulation of GPX4 signaling was assessed by Western blot and immunofluorescence (IFA) whereas qPCR and ELISA assays were used to check the expression of inflammatory mediators in retinal tissue or cell lysates.

Results: Our metabolomics and transcriptomic analysis of S. aureus infected mouse retinal tissues showed a time-dependent increase in mediators of ferroptosis. SA infection was found to increase labial iron pool (LIP) and lipid peroxidation (LPO) in infected mouse retinas and bone marrow derived macrophages (BMDM). This coincided with decreased GPX4 and increased ACSL4 expression. Supplementation of iron quencher, deferiprone (DFP) along with glutathione (GSH) exerted protective effects by reducing SA induced ferroptosis cell death and inflammation both in vivo and in vitro

Conclusions: Our study demonstrate the role of antioxidant signaling GSH-GPX4 in regulating cell death and inflammation in bacterial endophthalmitis. Thus, GPX4 activation and reducing labial iron can be used as new therapeutic approaches to ameliorate bacterial endophthalmitis

TITLE: Histatin Improves Corneal Wound Healing in a Rabbit Model of Surgical Keratectomy

SESSION TITLE: Corneal epithelial biology and repair mechanisms

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J. Burke, R. Schiffman, Visus Therapeutics, California, UNITED STATES|R.S. Verhoeven, Little Creek Research, North Carolina, UNITED STATES|

Commercial Relationships Disclosure: James Burke: Commercial Relationship(s);Code E (Employment):Visus Therapeutics;Code P (Patent):Visus Therapeutics | Rozemarijn Verhoeven: Commercial Relationship(s);Code C (Consultant/Contractor):Visus Therapeutics | Rhett Schiffman: Commercial Relationship(s);Code E (Employment):Visus Therapeutics;Code P (Patent):Visus Therapeutics

ABSTRACT BODY:

Purpose: Histatins are low molecular weight salivary and lacrimal peptides that have diverse wound healing, anti-inflammatory, anti-apoptotic, and antimicrobial properties. Wounds that are exposed to histatins, such as in the mouth, heal faster with less scarification and inflammation. The purpose of this study was to evaluate the effects of topical ocular administration of histatin-1 on corneal wound healing endpoints in a surgical keratectomy model in the rabbit.

Methods: New Zealand White rabbits (8/group) were anesthetized, and a partial keratectomy was performed in the right eye only using an 8 mm corneal vacuum trephine. The trephined section of the cornea was removed, leaving a central corneal defect of 10-25% of stromal depth (~100 µm). Following the procedure, dose administration was initiated. Animals received a 35 µl topical ocular instillation of histatin-1 or saline in the study eye three times daily for 28 days. Endpoints included fluorescein staining, confocal microscopy, and corneal wholemount immunohistochemistry with Tuj1.

Results: The rate of corneal epithelial healing as measured by area of fluorescein staining (Image J Software) was significantly increased by histatin-1 administration on Days 1-3 ($p<0.05$ and $p<0.01$), with time to healing reduced from 5 to 3 days compared to control. Evaluation of confocal microscopy indicated that histatin-1 inhibited loss of both stromal keratocytes and corneal endothelial cells following keratectomy compared to control and restored cells counts to baseline levels by Day 28 while the control eyes remained reduced by ~40% and ~20%, respectively. The surgical keratectomy resulted in a reduction of corneal nerves as a percentage of initial lesion size by as much as 70% on Day 28, as noted during immunohistochemistry. Histatin-1 administration inhibited this loss of corneal nerves by 20%.

Conclusions: These data demonstrate that topical ocular application of histatin-1 reduced time to corneal wound healing after surgical keratectomy in rabbits from 5 to 3 days, reduced keratocyte dropout and recovery of keratocyte density, decreased corneal endothelial cell loss, and augmented recovery of the keratocytes, endothelial cells and nerves in sub-Bowman’s plexus, suggesting broad utility across a range of corneal and ocular surface indications.

SUBMITTER (NAME ONLY): Krista Beach

TITLE: Intraocular pressure in infant Rhesus monkeys: diurnal curves and awake versus sedated measurements

SESSION TITLE: Aqueous humor dynamics, IOP, corneal disease, cytokines and growth factors

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K.M. Beach, L. Hung, L. Lou, L.A. Ostrin, Optometry, University of Houston, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure: Krista Beach: Commercial Relationship: Code N (No Commercial Relationship) | Li-Fang Hung: Commercial Relationship: Code N (No Commercial Relationship) | Linjiang Lou: Commercial Relationship: Code N (No Commercial Relationship) | Lisa Ostrin: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Measurement of intraocular pressure (IOP) in young Rhesus monkeys is important for the study of numerous ocular conditions, including eye growth and myopia. Recent studies show that select ocular hypotensive agents may protect against experimental myopia. In young monkeys, IOP is traditionally measured under anesthesia, which may confound the findings. This study aimed to establish a method for awake IOP measurement in young monkeys, assess the effects of dilation and sedation, and determine diurnal variation.

Methods: Subjects were infant Rhesus monkeys (Macaca mulatta, n = 11) undergoing lens-treatment for a refractive study. IOP was measured with a rebound tonometer (iCare TonoVet). At three weeks of age, awake IOP was measured every two hours from 7:30 am to 5:30 pm to determine potential diurnal variations. Beginning the following day, awake IOP, awake and dilated IOP (tropicamide 0.05%), and sedated (ketamine 20 mg/kg + acepromazine 0.2 mg/kg) and dilated IOP was measured biweekly from ages 3-15 weeks. Intraclass correlation coefficient (ICC) was used to determine intersession repeatability for IOP measurement on 2 consecutive days at 3 weeks of age.

Results: At age 3 weeks, mean (±SEM) awake IOP was 15.4±0.6 and 15.2±0.7 mmHg for right and left eyes, respectively (P=.59). The ICC between sessions was .63[-.5 to .9], with a mean difference of 2.2±0.3 mmHg between days. Diurnal IOP measurement from 7:30 am to 5:30 pm showed no significant variation (P=.67). For all ages, IOP while awake and undilated was 17.2±0.5 mmHg, awake and dilated was 18.5±0.5 mmHg, and sedated and dilated was 11.1±0.9 mmHg. There was a significant effect of age (P=.01) and condition (P<.001), with no interaction between age and condition (P=.46).

Conclusions: Awake IOP measurement is feasible in young Rhesus monkeys with moderate repeatability. There was no significant diurnal fluctuation in IOP between 7:30 am and 5:30 pm. IOP measured under sedation was significantly lower than IOP measured in awake monkeys, while topical administration of tropicamide did not affect IOP. Findings show that ketamine/acepromazine anesthesia affects IOP in young Rhesus monkeys, suggesting that measurement should be performed before sedation.

ABSTRACT BODY:

Purpose: Stargardt disease is the most common inherited macular dystrophy caused by the ABCA4 gene's mutations, with an estimated prevalence of 1/8000–1/10000. With its high phenotypic and genotypic heterogeneity, STGD typically causes severe progressive vision loss in children and young adults, incurring a substantial socioeconomic and psychological burden. The typical course of STGD exhibits progressive acuity loss during the school years, yet quantitative assessment of progression remains limited. Any information about natural progression of early disease is essential for anticipatory guidance, as well as for new therapy development.

Methods: We performed a longitudinal retrospective study on a patients' cohort observed at Medical Retina Service, Boston Children's Hospital. Our study group includes 33 children with genetically confirmed biallelic ABCA4 disease whose ages at presentation range from 3 to 18 yr, and age of symptoms onset falls within 7-10 yr range. Genetic variants in the younger group included many with double nulls mutations. We were primarily focusing on studying the STGD progression measuring retinal thicknesses on OCT. Every included patient had at least two longitudinal observations with OCT scan and visual acuity measurements. OCT scans were manually annotated to measure retinal thickness at the fovea, at 1mm and 3 mm away using Label Studio software. In total, 202 OCT images were used in the analysis. Further processing and statistical analysis were performed in Python using Pandas, Numpy, Scipy, and Sklearn packages.

Results: We observed two different modes of the disease progression in the observed patients: a drastic reduction in retinal thickness in the young age (before 8 yr) and changes with low magnitude in older kids. Reduction in ONL thickness for patients < 8 years old was: -38±5 um/yr at the fovea, -23±3 um/yr at 1mm nasal, and -20±3 um/yr at 1mm temporal retina. In older patients, the progression rate was strikingly lower: -1.3±0.6 um/yr at the fovea, 0.8±0.5 um/yr at 1mm nasal, and 0.3±0.5 um/yr at 1mm temporal retinas. Calculations were performed based on N=20 scans from six young patients and N=180 scans from 29 older kids.

Conclusions: Our findings are indicative of the rapid progression of the disease in patients before 8 years old. Studies on STGD progression and early intervention will require the observation of very young children.

ABSTRACT BODY:

Purpose: Endothelin 1 (Edn1) is a 21-amino acid peptide that potently induces vasoconstriction and plays a key role in retinal neuronal and vascular degeneration in glaucoma and diabetic retinopathy. Yet mechanisms that regulate Edn1 expression in retinal cells remain to be elucidated. Given that Edn1 production is associated with aging or cell senescence, we reasoned that molecules that regulate aging process may be involved in the regulation of Edn1 expression. Sirtuin (Sirt) 1 and Sirt6 are evolutionarily conserved nicotinamide adenine dinucleotide (NAD)-dependent histone deacetylases and share homolog with yeast Sir2 protein that critically regulates lifespan of yeast. This study aims to test whether Sirt1 and Sirt6 can regulate Edn1 expression in retinal neuronal cells.

Methods: Localization of Sirt1 and Sirt6 was determined by immunohistochemistry in mouse retinal sections. Differentiated R28 cells were transfected with siRNA to knockdown Sirt1 or Sirt6, with a non-targeting siRNA as control. Edn1 expression was assessed by quantitative PCR (qPCR).

Results: Sirt6 was abundantly expressed in cells in the ganglion cell layer although weak immunoreactivity of Sirt6 was also noted in the inner nuclear layer and outer nuclear layer of the retina. In contrast, Sirt1 immunoreactivity was universally expressed in all cells. In differentiated R28 cells, Sirt1 siRNA reduced Sirt1 expression by 60.7% and 76.7% at 24 and 48 hours respectively, and raised Edn1 expression by 11.2% and 98.7%. Sirt6 siRNA reduced Sirt6 expression by 59.1% and 72.1% at 24 and 48 hours respectively, and resulted in the elevations of Edn1 by 130.2% and 306.6%.

Conclusions: Although knockdown of either Sirt1 or Sirt6 induced Edn1 expression, Sirt6 siRNA had a much more pronounced effect on Edn1 expression, suggesting that Sirt6 had the primary role in regulating Edn1 expression in retinal neuronal cells. Considering Sirt6 but not Sirt1 was predominantly expressed in retinal ganglion cells (RGCs), our study suggests that Sirt6 may be potentially involved in maintaining RGC health by inhibiting Edn1 expression.

ABSTRACT BODY:

Purpose: Topical nonsteroidal anti-inflammatory drugs (NSAIDs) are often prescribed following ophthalmic surgery to reduce ocular pain and modulate inflammation. Sustained-release drug delivery of NSAIDs may overcome some limitations of topical therapy such as patient self-dosing and nonadherence. Here we evaluate the pharmacokinetics of nepafenac delivered from a biodegradable hydrogel intracanalicular insert in a canine model.

Methods: A hydrogel-based intracanalicular insert containing a low dose of nepafenac was placed bilaterally into the inferior canaliculus of 20 beagle dogs on Day 0. After presence of the insert in the canaliculus was confirmed visually, tear fluid was collected from n=10 eyes with pre-cut 10 mm Schirmer test strips at 2 hours, and 1, 3, 7, 10, 14, 17, 21, 24 and 28 days post-insertion. Aqueous humor (0.1 mL, n=6 eyes) was collected 7, 14, 21, and 28 days post-insertion. Tear fluid and aqueous humor samples were analyzed for nepafenac (prodrug) and amfenac (active metabolite) by liquid chromatography tandem mass spectrometry.

Results: Maximum mean concentration of nepafenac (671 ng/mL) and amfenac (153 ng/mL) in the tear fluid was measured at 2 hours post-insertion indicating rapid dissolution of drug from the insert soon after placement. Mean nepafenac and amfenac levels in tear fluid samples over time showed drug levels gradually tapered over time. Nepafenac and amfenac levels were cleared from the tear fluid by 10-14 days. Both the prodrug and active metabolite were found in the tear fluid in an 85:15 ratio, however, only amfenac was detected in aqueous humor samples. Amfenac concentration in the aqueous humor was highest on Day 7 at 18.3 ng/mL and decreased to 2.6 ng/mL at Day 14. Levels of amfenac in the aqueous humor were 41-fold above the half maximal inhibitory concentration of cyclooxygenase-2 for amfenac (COX-2 IC_{50} = 0.45 ng/mL) indicating potential therapeutic benefit at these concentrations.

Conclusions: A hydrogel-based intracanalicular insert containing nepafenac quickly released drug at therapeutic levels to the ocular surface and continued for 10-14 days. Ocular pharmacokinetic studies of inserts with higher drug doses are needed to further characterize the release profile of nepafenac intracanalicular insert.

ABSTRACT BODY:

Purpose: To investigate the development of 3-dimensional full circumpapillary retinal nerve fiber layer (cpRNFL) in full-term infants and young children without sedation and dilation using handheld spectral-domain optical coherence tomography (HH-SDOCT) and also to establish normative age-adjusted values.

Methods: OCT images collected from 375 eyes from 231 infants and children aged between 1 day and 14.5 years using an HH-SDOCT (Leica Microsystems, Envisu C2300, Wetzlar, Germany) system were analyzed semi-automatically using GDx Nerve Fiber Analyzer protocol. The developmental trajectories against log post-menstrual age (logPMA) for cpRNFL thickness (at 6° from the disc center) in four quadrants and ONH parameters mostly approximated to linear changes and were modelled using linear mixed models. Several parameters showed non-linear changes and were modelled using fractional polynomials.

Results: The thickness of superior, inferior and nasal cpRNFL quadrants did not significantly change between birth and 14.5 years old. The 1st quartile (Q1), median (Q2) and 3rd quartile (Q3) were 100 μm, 110 μm and 120 μm for the superior cpRNFL quadrant; 99 μm, 110 μm and 120 μm for the inferior cpRNFL quadrant; and 60 μm, 68 μm and 75 μm for the nasal cpRNFL quadrant, respectively. In contrast, the temporal cpRNFL quadrant demonstrated a significant decrease between birth and approximately 18 months of age and then remained relatively constant up to the age of 14.5 years (Q1 = 57 μm; Q2 = 62 μm; Q3 = 70 μm over 18 months of age).

Conclusions: We describe, for the first time, the development of the full cpRNFL from birth to 14 years using 3-dimensional HH-SDOCT imaging. Interestingly, the temporal cpRNFL quadrant shows a different developmental trajectory to the superior and inferior cpRNFL quadrants despite all three quadrants comprising of fibres projecting from the macular region. Our findings also provide normative data during these critical early years of visual maturation for use in clinical diagnosis, monitoring ocular development and understanding further ocular abnormalities.

ABSTRACT BODY:

Purpose: In this study we describe the use of custom designed robotics and ISO Class 5 cGMP cell culture atmospheric isolators for the high throughput production of clinical grade patient specific iPSCs and retinal organoids containing transplantable photoreceptor cells.

Methods: Patient derived fibroblast were isolated from 27 individuals, ranging from 6 to 92 years of age, with molecularly confirmed inherited retinal degenerative blindness. Cells were used for iPSC generation using Sendai virus. Oxygen tension was dropped from 20-10% and cultures are subsequently fed daily with E8 media and passaged onto laminin 521 coated 6 well culture plates. Over the next 21 days cultures were fed daily, imaged every 3-5 days, picked, and clonally expanded using the CellX robot. IPSCs were subjected to karyotyping and score card analysis prior to being differentiated using a cGMP compliant 3D differentiation protocol. Differentiated organoids were subjected to immunohistochemistry and single cell RNA sequencing.

Results: Robot generated iPSCs were determined to be pluripotent via score card analysis and no significant difference in the rate of karyotypic abnormalities was detected between iPSCs generated under manual or automated conditions ($P>0.05$). Robot generated iPSCs gave rise to retinal organoids that were indistinguishable from their manually generated counterparts as determined via immunostaining and confocal microscopy using antibodies targeted against NRL, rhodopsin, cone opsin, cone arrestin and recoverin. At 120 days, retinal organoids were dissociated and subjected to single cell RNA sequencing and were compared to cells generated in the Reh laboratory (scRNAseq comparison dataset PMID 32023475). Clustering analysis demonstrated that cells generated on the robotic platform were comparable to those generated under manual conditions in a separate laboratory. Specifically, each of the expected retinal cell types were present in roughly the same proportions between those generated in both groups.

Conclusions: We successfully developed a high throughput robot iPSC generation platform and standard operating procedures for production of high-quality photoreceptor precursor cells that are compatible with current good manufacturing practices. This system will enable clinical grade production of iPSCs for autologous retinal cell replacement.

ABSTRACT BODY:

Purpose: Actin cytoskeletal organization and cell adhesive interactions of the trabecular meshwork (TM) are recognized to influence aqueous humor outflow and intraocular pressure in humans. However, the molecular mechanisms regulating such cellular characteristics of TM cells remain poorly understood. This study describes for the first time the role of septins, conserved GTP-binding cytoskeletal proteins that polymerize into filaments, in the regulation of actin cytoskeletal organization in human TM cells.

Methods: The presence and distribution of septin isoforms in human TM cells were evaluated by mass spectrometry, immunoblot, and immunofluorescence analyses. The septin interactome of human TM cells was determined using SEPT9 antibody and proteomics analyses. Septin levels in dexamethasone and TGF-β2 treated TM cells were evaluated by immunoblotting. The effects of actin cytoskeleton and microtubule depolymerizing agents as well as inhibitors of septin and Rho kinase on septin and actin cytoskeletal organization were studied in TM cells by immunofluorescence.

Results: Proteomics and immunoblot analyses readily identified the presence of various septin isoforms (Septin 2, 7, 9, 10, 11, 8 and 5) in human TM cells. Several of these septins revealed filamentous organization, co-localization with actin and microtubule networks, as well as distribution to the TM cell cortical, nuclear, and membrane regions. Dexamethasone and TGF-β2 treatments significantly increased SEPT9 and 11 levels in TM cells. Analysis of the human TM cell SEPT9 interactome identified regulatory proteins of the Rho GTPase, actin cytoskeleton, and cell adhesion pathways, in addition to the expected presence of several septins. Pharmacological inhibition of septin oligomerization decreased septin filaments and actin stress fibers in TM cells. While treatment with a Rho kinase inhibitor and latrunculin decreased septin filaments, nocodazole led to an increase in septin filament organization in human TM cells.

Conclusions: This study reveals not only the presence of septin cytoskeleton but also its direct role in regulation of actin cytoskeletal organization, cell shape, and adhesion in TM cells. Based on the effects of the septin inhibitor on actin cytoskeletal organization in TM cells, we posit that septins are potential therapeutic targets for lowering intraocular pressure in glaucoma.

Kraft, Optometry and Vision Science, The University of Alabama at Birmingham, Birmingham, Alabama, UNITED STATES|A.M. Levy, Biomedical Engineering, The University of Alabama at Birmingham, Birmingham, Alabama, UNITED STATES|

Commercial Relationships Disclosure: Mustapha El Hamdaoui: Commercial Relationship: Code N (No Commercial Relationship) | Alexander Levy: Commercial Relationship: Code N (No Commercial Relationship) | Aaron Stuber: Commercial Relationship: Code N (No Commercial Relationship) | Christopher Girkin: Commercial Relationship(s);Code F (Financial Support):Heidelberg Engineering provided Spectralis OCT2 at no cost | Timothy Kraft: Commercial Relationship: Code N (No Commercial Relationship) | Brian Samuels: Commercial Relationship(s);Code F (Financial Support):Heidelberg Engineering provided Spectralis OCT2 at no cost | Rafael Grytz: Commercial Relationship(s);Code F (Financial Support):Heidelberg Engineering provided Spectralis OCT2 at no cost

ABSTRACT BODY:

Purpose: To investigate the safety of scleral crosslinking (SXL) using genipin at doses that were effective in slowing myopia progression in juvenile tree shrews as shown in our previously published work (El Hamdaoui et al. Transl Vis Sci Technol 2021;10(5):1).

Methods: Three or five retrobulbar injections of genipin at 0 mM (sham), 10 mM, or 20 mM were performed in one eye every other day. Form deprivation (FD) myopia was induced in the injected eye. Retinal thinning, structural integrity, and function were assessed using optical coherence tomography, histology, and ERG, respectively. Differences between treated and control eyes (Treated – Control) were computed and used to test for significant differences across groups (independent samples t-test). The normal and FD groups served as reference groups and the significance level was set to 0.05.

Results: The peripapillary retinal nerve fiber layer (RNFL) thinned significantly in all genipin treated groups compared to the normal and FD groups. Inducing FD alone and in combination with sham injections caused no RNFL thinning suggesting that the observed RNFL thinning was caused by genipin treatment (Fig. 1A). Thickness of the remaining retinal layers (RRL) was significantly thinner in all injected groups, including the sham group, compared to the normal but not to the FD group suggesting that RRL thinning was primarily caused by axial elongation and not by genipin treatment (Fig. 1B). ERG results showed a significant desensitizing shift of the b-wave semi-saturation constant in the sham group and the second highest genipin dose group (Fig. 1C) and a significant reduction in b-wave maxima in the two highest dose groups (Fig. 1D). Histology analysis revealed noticeable degeneration of photoreceptors and retinal pigment epithelium in the highest genipin dose group (Fig. 2).

Conclusions: SXL using genipin may be a feasible treatment for myopia control. However, our results suggest that repeated retrobulbar injections of genipin above 10mM may not be safe in the tree shrew model of myopia. An adequate and sustained delivery strategy of genipin at lower concentrations will be needed to achieve a safe and effective SXL treatment for myopia control in tree shrew eyes. Caution should be used if the proposed treatment approach is translated to humans.

TITLE: Ora Vanishing Optotypes Reading Test™ in Non-Advanced Age-Related Macular Degeneration: Results Of 1-Year Follow-Up

SESSION TITLE: AMD: Clinical and translational research/AMD therapies (excluding anti-VEGF)

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J.D. Rodriguez, K. Dieter, E. bensinger, G. De Moraes, D.L. Welch, M.B. Abelson, Ora, Inc., Massachusetts, UNITED STATES|G. Wallstrom, SDC, Inc., Arizona, UNITED STATES|

Commercial Relationships Disclosure: John Rodriguez: Commercial Relationship(s);Code E (Employment):Ora, Inc | Kevin Dieter: Commercial Relationship(s);Code E (Employment):Ora, Inc | Ethan bensinger: Commercial Relationship(s);Code E (Employment):Ora, Inc | Gustavo De Moraes: Commercial Relationship(s);Code E (Employment):Ora, Inc | Donna Welch: Commercial Relationship(s);Code E (Employment):Ora, Inc | Garrick Wallstrom: Commercial Relationship(s);Code C (Consultant/Contractor):Ora, Inc | Mark Abelson: Commercial Relationship(s);Code E (Employment):Ora, Inc

ABSTRACT BODY:

Purpose: In a previous study, a reading test based on vanishing optotype characters (Ora Vanishing Optotypes Reading Test™) was used to assess visual function impairment in early AMD patients compared to age-matched controls. The current study aims to investigate the usefulness of this test after one-year follow-up testing of the previously investigated early AMD cohort.

Methods: In the initial study, subjects with non-advanced AMD: N = 11 (grade 1 to 4 on AREDS simplified scale) and normal controls N = 24 (AREDS grade 0) with best visual acuity (VA) 20/25 or better (in both groups) were included. In the one-year follow-up, 9 non-advanced AMD subjects and 16 control subjects were again tested. All testing procedures used in the initial study were repeated in the follow-up. The reading test was administered monocularly with best correction in place. All subjects were asked to read nine passages of pepper words at successively lower contrast levels with a maximum contrast passage as baseline. Reading speed in words per minute (wpm) was recorded for each passage. The primary outcome was reduction of reading speed relative to baseline. Only subjects that participated in both trials were included in the comparison.

Results: At the initial visit, there was no difference in reading speed between groups at maximum contrast [102.0 ± 16.7 wpm (AMD) and 96.2 ± 18.9 wpm (control) ($p = 0.2$)]. These findings were replicated at 1-year follow-up: [97.6 ± 15.2 wpm (AMD) and 95.9 ± 17.2 wpm (control) ($p = 0.8$)]. Although reading speed relative to subject baseline tested lower for the AMD group at reduced contrast levels during the initial visit, this did not achieve significance. However, after one year, reading performance was found to be significantly impaired in AMD subjects compared to controls at 7 out of the 9 tested contrast levels ($p < 0.02$).

Conclusions: Results of the one-year follow-up showed good reproducibility and a potential utility of this technique as a novel functional endpoint in non-advanced AMD clinical trials.

ABSTRACT BODY:

Purpose: Pituitary adenylate cyclase activating polypeptide (PACAP) has been shown to exert potent neuroprotective effects in central nervous system and retina disorders. However, whether PACAP could attenuate retinal neurodegeneration induced by acute ocular hypertension (AOH) and the precise mechanisms remain unknown. In this study, we aim to investigate the effects of PACAP on retinal ganglion cells (RGCs) survival, apoptosis, retinal reactive gliosis and vascular inflammation in mouse model of AOH injury.

Methods: PACAP was injected into the vitreous body immediately after inducing the AOH injury. Hematoxylin & eosin staining and optical coherence tomography were used to evaluate the loss of retina tissue. Electroretinogram was used to evaluate the visual function of retina. TUNEL assay was used to detect the apoptotic cells. Immunofluorescence and western blot were employed to evaluate the protein expression level.

Results: PACAP treatment significantly attenuated the losses of retina thickness and RGCs, and improved the b-wave amplitudes of scotopic electroretinogram after AOH injury. Additionally, PACAP treatment remarkably reduced the number of apoptotic cells in AOH injury, and inhibited the upregulation of Bax, cleaved caspase3 and downregulation of Bcl-xL induced by AOH injury. Moreover, PACAP markedly abrogated retinal reactive gliosis and vascular inflammation, as demonstrated by the downregulation of GFAP, Iba-1, CD68 and CD45 in PACAP-treated mice. Furthermore, upregulated expression of NF-κB and phosphorylated NF-κB induced by AOH injury were attenuated by PACAP treatment.

Conclusions: These results demonstrated that PACAP could attenuate retinal injury by inhibiting the Bax-Caspase3 dependent apoptotic pathway and NF-κB dependent inflammatory pathway.

ABSTRACT BODY:

Purpose: Cell specification is a fundamental process that underlies the formation of tissues and organs. In the retina, photoreceptor specification must coordinate with development of other retinal cells and eyecup formation. Photoreceptors have defined subtypes which differ in spectral sensitivity, morphology, wiring, and gene expression. Transcription factors (TFs) modulate genetic programs to specify each photoreceptor subtype. Seminal work in mice identified key TFs required for the determination of rods (Mears, 2001, Cheng, 2006) and L cones (Ng, 2001, Roberts, 2005) but work in other species has highlighted that photoreceptor fate is complex and our understanding is still incomplete (Oel et al., 2020; Ochi et al., 2004, Alvarez-Delfin, 2009; Duval et al., 2018; Ogawa at al., 2019). The purpose of our research is to identify mechanisms that control photoreceptor fate during development.

Methods: We performed deep transcriptomic profiling (RNAseq) of photoreceptors—by manually collecting pools of the five photoreceptor subtypes of the adult zebrafish retina—to determine which transcription factors are differentially expressed. Then we developed a platform to perform CRISPR-based reverse-genetic screens to identify which transcription factors control photoreceptor fate determination.

Results: We identified Tbx2 as a critical TF for photoreceptor fate determination. In zebrafish, tbx2b is implicated in UV-cone specification (Alvarez-Delfin, 2009): mutations in this gene lead to loss of UV cone progenitors, which are routed to become rods. tbx2 was duplicated in teleosts, and RNAseq revealed that tbx2b is expressed by UV and S cones, and tbx2a is expressed by UV and L cones. TBX2 is highly conserved across vertebrates and is highly expressed by S cones in primate (Peng, 2019) and by UV cones in chicken (Yamagata, 2021). Using FØ-CRISPR screening techniques (Hojishima, 2019), we generated tbx2b mutant zebrafish larvae that recapitulate the known phenotype. Surprisingly, tbx2a mutants display the same phenotype, suggesting that tbx2b and tbx2a act independently and are both required for UV-cone specification. Furthermore, we found that tbx2a acts in L cones to represses M-cone fate (Sandkam et al., 2020) and that tbx2b acts in S cones to also repress M-cone fate.

Conclusions: This early success substantiate these methods as an efficient and flexible platform to study mechanisms of fate determination in photoreceptors.

ABSTRACT BODY:

Purpose: Sphingosine-1-phosphate (S1P) is a bioactive sphingolipid that acts through G protein-coupled S1P receptors (S1PR1-5) to participate in a variety of signaling pathways, but its role in the neural retina has not been studied extensively. We previously showed that S1PR2 is expressed in mouse and rat retinas, primarily in photoreceptors and bipolar cells, and expression is altered by conditions of retinal stress. In this study, we developed S1PR2 knockout (KO) mice on an albino background and performed structural and functional characterizations of their retinas under normal conditions and after intense light-induced retinal degeneration (LIRD) treatment.

Methods: Albino S1PR2 KO and wild-type (WT) littermate mice were raised under similar conditions and underwent retinal assessments at various matched age-points between 3 and 6 months. Retinal function was assessed by electroretinography (ERG), and structural differences by electron microscopy (EM) and optical coherence tomography (OCT). Immunohistochemical (IHC) labeling was used to visualize differences in neuronal and synaptic markers in light- and dark-adapted mice. Mice underwent similar assessments after LIRD (1500 lux for 6 hours) to evaluate their sensitivity to retinal stress.

Results: We found significantly elevated A- and B-wave responses at ERG flash intensities between 4-2000 cd.s/m^2 in S1PR2 KO mice compared to WT at baseline (n = 12 and n = 8, respectively) and after LIRD (n = 10 and n = 11; $P < 0.05$). OCT further showed that KO mice (n = 8) had significantly increased retinal nerve fiber layer (RNFL) (14.8 ± 0.3μm vs 13.3 ± 0.5μm) and outer plexiform layer (OPL) (12.5 ± 0.4μm vs 11.6 ± 0.2μm) thickness compared to WT (n = 10; mean ± SE; $P < 0.05$). EM likewise showed differences in inner neuronal layers and OPL, and reduced synapses between rod terminal and bipolar cells in KO mice. IHC also showed differential labeling of synaptic markers and dendritic arborization of secondary neurons in KO mice compared to WT.

Conclusions: Our findings show that S1PR2 knockout alters murine retinal structural and functional characteristics, suggesting an important role of S1PR2 in the mammalian retina.

ABSTRACT BODY:

Purpose: Preserved topical medications used in the management of glaucoma are associated with ocular surface inflammation. The purpose of this cross-sectional study was to describe the ocular surface microbiome of patients treated with preserved topical ophthalmic medications as compared to that of healthy controls and to determine if microbial community changes were related to measures of ocular surface disease.

Methods: V3-V4 16S rRNA sequencing was conducted on ocular surface swabs collected from both eyes of 17 subjects: 10 patients with asymmetric/unilateral glaucoma using preserved topical glaucoma therapy on only one eye and 7 age-matched, healthy controls with no history of ocular disease or eyedrop use. Air swabs were used as negative controls. Samples were categorized into three groups: patients' glaucomatous eye treated with eyedrops, patients' contralateral eye without eyedrops, and healthy control eyes. Comparisons were made for microbial diversity and composition, with differences in composition tested for association with ocular surface disease measures including tear meniscus height (TMH), tear break-up time (TBUT), and Dry Eye Questionnaire scores (DEQ-5). The Columbia University Institutional Review Board approved this study.

Results: Samples obtained from treated and untreated patient eyes both had greater alpha-diversity (Shannon Diversity; Figure 1A, 1C) and distinct microbial composition (Bray Curtis Distance; Figure 1B, 1D) compared to controls. Patient samples had an increased relative abundance of gram-negative organisms dominated by Akkermansia compared to gram-positive commensals in controls (Figure 2). The microbial composition of patient eyes was associated with decreased TMH and TBUT, while metagenomic predictions based on 16S rRNA data suggested increased synthesis of the inflammatory endotoxin lipopolysaccharide.

Conclusions: The ocular surface microbiome of patients taking unilateral preserved glaucoma drops is characterized by a diverse array of gram-negative bacteria that is significantly different from the predominantly gram-positive microbes detected on healthy control eyes. These compositional differences were associated with decreased tear film measures and distinct inferred protein synthesis pathways, suggesting a potential link between microbial alterations and ocular surface inflammation.

ABSTRACT BODY:

Purpose: Triage of patients with visual complications of Diabetic Retinopathy (DR) in the emergency department (ED), urgent care centers, or primary care offices can be challenging due to limited availability of ophthalmic specialists. In this pilot study, we deployed non-mydriatic automated Ocular Coherence Tomography (OCT) technology (or tele-OCT-B) in conjunction with 3D macular mapping software to assess the ability of non-ophthalmologists to triage posterior pole OCT-B images for Diabetic Macular Edema (DME).

Methods: Macular OCT-B scans of 41 eyes (21 patients with mean age 56.5 years and male to female ratio of 3:4) were captured in an academic retina clinic using Topcon Maestro 3D OCT-1. 3D topographical maps were rendered. A retinal physician assessed each OCT-B image and 3D map for the presence of DME and the severity level as described by the International Clinical DME Severity Scale. The fundus photo images from Topcon OCT camera were reviewed for DR. Two third-year medical students independently reviewed the topographic maps for the presence of DME. Cohen's kappa (κ) was used to test concordance between student and retina specialist (gold standard) for identifying DME. Statistical analysis was performed using IBM SPSS software version 25.

Results: 38/41 eyes were included in the final analysis. Non-ophthalmologist graders had an average sensitivity of 70% (SD 4.71) and specificity of 80% (SD 3.08) in detecting DME (Table 1). Inter-grader concordance between non-ophthalmologists was substantial ($\kappa=0.78$, $p<0.00001$). Between non-ophthalmologists and the retina specialist, average concordance in detecting any DME was $\kappa=0.50$ (SD 0.008). When stratified by clinical DME severity, on average, non-ophthalmologists correctly classified 8/9 (90%) eyes with moderate to severe DME, 1/5 (20%) eyes with mild DME, and 14.5/15 (97%) eyes with no DME.

Conclusions: While concordance between non-ophthalmologists and the retinal specialist was modest for detection of DME, non-ophthalmologists correctly identified most moderate to severe DME cases on OCT-B with high agreement. OCT-B 3D map may be an invaluable tool to use with non-mydriatic fundus camera in the ED or primary care offices in screening diabetic patients for vision threatening DME who need urgent ophthalmic referral, especially during a pandemic.

TITLE: Differences in Cataract Surgery Outcomes by Race and Primary Language Spoken

SESSION TITLE: Public Health II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Singh, S. Bal, T. Ta, A.C. Lorch, Massachusetts Eye and Ear Department of Ophthalmology, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Nakul Singh: Commercial Relationship: Code N (No Commercial Relationship) | Sila Bal: Commercial Relationship: Code N (No Commercial Relationship) | Thong Ta: Commercial Relationship: Code N (No Commercial Relationship) | Alice Lorch: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess differences in cataract surgery outcomes by race and primary language spoken in order to better understand delivery of surgical care to diverse patient populations.

Methods: Massachusetts Eye and Ear surgical outcomes were assessed between January 1, 2020 and December 31, 2020. Patient's self-identified race/ethnicity were extracted from the medical record and collapsed into broader categories of White, Black, Hispanic, Asian, declined/unavailable, and other for race. Cataract surgery outcomes were loss to follow up, final refractive error within 0.5 diopter of target refraction and hyperopic final refractive error. Logistic regression was performed to estimate the odds ratios between categories.

Results: A total of 2,166 patients underwent cataract surgery and were included in the analysis (White=1,605, Asian=118, Black=157, Other = 127, Decline/Unavailable = 129) (English speaking = 1,895, Non-English speaking = 248). There were no differences by race or language in final refractive error within 0.5 diopters of target refraction or hyperopic final refractive error. There were no differences by race or primary language spoken for loss of follow up.

Conclusions: There were no racial or language disparities in cataract surgery outcomes, both in final refractive error or loss to follow up during 2020. Hopefully this represents equitable care delivered to patients, but 2020 was an anomalous year in many ways, which may confound identification of structural inequities.

TITLE: Identifying Eyes at Risk for Glaucoma Surgery with Deep Learning
SESSION TITLE: Data science, machine learning, and AI
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: R. Wang, P. Herbert, K. Hou, C. Bradley, M. Unberath, J. Yohannan, Johns Hopkins University, Baltimore, Maryland, UNITED STATES|
Commercial Relationships Disclosure: Ruolin Wang: Commercial Relationship: Code N (No Commercial Relationship) | Patrick Herbert: Commercial Relationship: Code N (No Commercial Relationship) | Kaihua Hou: Commercial Relationship: Code N (No Commercial Relationship) | Chris Bradley: Commercial Relationship: Code N (No Commercial Relationship) | Mathias Unberath: Commercial Relationship: Code N (No Commercial Relationship) | Jithin Yohannan: Commercial Relationship: Code N (No Commercial Relationship)
ABSTRACT BODY:
Purpose: To develop and evaluate a deep learning model (DLM) to predict eyes at high risk for future incisional glaucoma surgery from observations early in the disease course.
Methods: We used the DLM architecture depicted in Figure 1. A vision transformer (VIT) is used for feature extraction. The input of the transformer consists of 3 channels consisting of spatially aligned VF and OCT data. After VIT-based feature extraction, the latent representation of VF and OCT data is concatenated with the normalized clinical data and fed into a linear classifier predicting the occurrence of glaucoma surgery within the pre-specified time horizon. Data were split at the patient level into 76%, 12%, and 12% for training, validation, and testing, respectively.
Results: DLM performance was evaluated and compared using Area Under the Receiver Operating Characteristic Curve (AUC). Additionally, sensitivity, specificity, and positive predictive value were calculated using an optimal threshold selected using Youden's J index.

Between 1788 and 2893 eyes were included in the analysis depending on the time horizon of interest. In the test set, the DLM achieved an AUC of 0.92 (95% CI: 0.86, 0.98), a sensitivity of 0.74, and a specificity of 0.92 for predicting glaucoma surgery within 2 years from baseline (Table 1). The predictions for other time intervals achieved clinically useful AUC values (>0.8) except for the 5-year time interval with an AUC of 0.78 (95% CI: 0.71, 0.87).
Conclusions: It is possible to identify eyes in need of glaucoma surgery with very high sensitivity and specificity. Implementing such prediction models in the clinical setting may help stratify high and low-risk patients. Future studies will need to assess the performance of such models prospectively in a varied clinical setting.

ABSTRACT BODY:

Purpose: This study investigated the effects of competing imposed optical defocus on gene expression of TGF-βs in chick retinal pigment epithelium (RPE).

Methods: 14-day old White-Leghorn chicks wore monocular Fresnel lenses incorporating various optical power combinations (plano/-10D, +5D/-10D, +10D/-10D, +10D/-5D, +10D/plano) for 15 min, 2 h, 2 d and 4 d. qPCR was used to quantify differential gene expression in chick RPE for TGF-β1, 2, and 3.

Results: Gene expression of TGF-β2 was up-regulated after short periods (2 h or 2 d) with all lenses. Notably, TGF-β2 gene expression was up-regulated 266 ± 43% (+5D/-10D), 321 ± 106% (+10D/-10D), 200 ± 35% (+10D/-5D), and 221 ± 41% (+10D/plano), respectively after 2 h exposure. The plano/-10D lens also induced up-regulation of TGF-β2 gene expression, but only after 2 days. Significant up-regulation of TGF-β3 expression, albeit much smaller in magnitude, was also recorded with the +5D/-10D lens, and only after 2 h.

Conclusions: Expression of TGF-β2 genes in chick RPE is sensitive to imposed competing retinal defocus, i.e., of opposite sign. That TGF-β2 gene expression was consistently up-regulated with inclusion of myopic defocus (positive power) is consistent with previous results with single vision lens treatment. The results also further support the targeting of RPE TGF-β2 for myopia control.

ABSTRACT BODY:

Purpose: Corneal surface elevation can be obtained three-dimensionally with anterior segment Optical Coherence Tomography (OCT). However, its accuracy is subject to fixational eye movements during the acquisition. We developed a model to simulate corneal elevation measurements to study the quality of the reconstruction achieved with different scanning patterns.

Methods: A custom spectral domain OCT (25K A-scans/s) was used to obtain videos (N=10, 22 Hz) of the corneal central meridian in 4 eyes from 2 subjects. The anterior corneal surface in each frame was segmented and fitted by conics. The apex movement was compared with simulations of fixational lateral/axial eye movements from MATLAB Image System Engineering Toolbox for Biology (ISETBIO) fixational eye movement generator with/without saccades. The results were used to simulate 3D-OCT acquisition of a cornea using either a raster or a meridional scan pattern with 300x50 A-scans. The 3-mm central data were fitted by a sphere (radius R) and the residuals fitted with up to 6^{th} order Zernike polynomials (zC). Standard deviations (std) of the fitting parameters of repeated simulated adquisitions for different scan patterns were compared.

Results: The mean amplitude of the cornea movement found experimentally was 119 in the lateral and 142 μm in the axial direction. The mean amplitude of the eye movement generator was 88 and 73 μm with and without microsaccades. Amplitude factors 1.32 and 1.95 were then applied to match lateral and axial movements respectively, which reduced the rms error between simulated and average experimental zC std from 3.7 to 0.9 μm. For raster scan, R std was 0.13 mm and mean zC std was 1.3 μm being highest for astigmatism and coma oriented with the slow scan direction. For meridional scan, R std was 0.01 mm and mean zC std was 2.0 μm being highest for astigmatism and trefoil terms. When all meridians were registered in the center, R std was 0.01 and mean zC std was reduced to 0.3 μm.

Conclusions: Simulations of OCT corneal topography measurements with fixational eye movements predict a high influence of the scanning pattern on the measurement variability, particularly on specific Zernike modes. While eye rotations or scan position inaccuracies were not considered, these simulations can serve to determine the variability with different scan patterns and to evaluate the effectivity of motion correction algorithms.

ABSTRACT BODY:

Purpose: Inherited Retinal Disorders (IRDs) such as Stargardt disease (SD) or Leber congenital amaurosis (LCA) are rare, and sight-threatening with significant unmet needs. In these IRDs, dysfunction or degeneration of photoreceptors leads to loss of light sensitivity. Optogenetics offers a unique opportunity to treat IRDs of varied genetic origins with a universal therapeutic strategy. The purpose of the study is to evaluate the therapeutic efficacy of intravitreally delivered AAV2-carried gene encoding for ambient light-activatable Multi-Characteristic Opsin (MCO) in animal models of SD and LCA.

Methods: To evaluate the therapeutic efficacy, AAV2-MCO (vMCO) was intravitreally delivered in mice models of SD (Abca4tm1Ght/J) and LCA (B6(A)-Rpe65rd12/J). OCT imaging of the retina, behavioral assay (water maze), and ERG were performed longitudinally up to 24 weeks to evaluate the safety and efficacy of the treatment. Immunohistochemistry of the retina sample was also performed to visualize the expression of MCO in the retina (Visualized by mCherry expression).

Results: Our results demonstrated that intravitreal delivery of vMCO to Stargardt and LCA mice arrests further retinal degeneration (measured by retina thickness using OCT) and restores visual function, quantified by electrophysiology of retina (ERG) and visual cortex (VEP). The visually- guided water maze assessment on vMCO-treated mice showed significant improvement (measured by latency to reach platform) as compared to the vehicle-injected control mice group.

Conclusions: vMCO is potentially a restorative treatment that can be used irrespective of the underlying gene mutation. Intravitreal delivery of vMCO in the Stargardt and LCA mice model was effective in restoring vision and arresting further retinal degeneration. While the efficacy of MCO optogenetic monotherapy is now being evaluated in a multicenter trial on advanced Retinitis Pigmentosa patients, clinical evaluation of vMCO for other IRDs will establish it as an outer retinal degenerative disease-agnostic therapy.

Commercial Relationships Disclosure: Yi Hua: Commercial Relationship: Code N (No Commercial Relationship) | Marissa Quinn: Commercial Relationship: Code N (No Commercial Relationship) | Fengting Ji: Commercial Relationship: Code N (No Commercial Relationship) | Samuel Salinas: Commercial Relationship: Code N (No Commercial Relationship) | Rouzbeh Amini: Commercial Relationship: Code N (No Commercial Relationship) | Ian Sigal: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The equatorial sclera is central to overall globe mechanics. However, compared to the front or back of the eye, little is known about equatorial sclera mechanics and its underlying microstructure. Our goal was to quantify equatorial sclera mechanical behavior and collagen fiber architecture, focusing on anisotropy and fiber preferred orientation.

Methods: Five porcine eyes were obtained from a slaughterhouse within 24 h postmortem. Equatorial sclera samples (11 mm × 11 mm) were excised from each of four anatomical quadrants: nasal, superior, temporal, and inferior. Each sample was mounted on a custom-built biaxial mechanical testing system, with the loading axes aligned with the equatorial and meridional directions of the sample. Four submillimeter glass markers were attached to the surface of the sample for optical tracking of tissue deformation (strain). The sample was then loaded under equal-biaxial stress control, with the maximum stress of 120 kPa. Each test consisted of ten loading/unloading cycles, and only data from the tenth cycle was used in our analysis. The sample was immersed in PBS during the test. After testing, the samples were fixed overnight in 10% formalin. Four samples from three eyes were cryosectioned into 30-μm-thick sections. Sections were imaged using polarized light microscopy, and collagen fiber orientations determined using a previously reported technique. Orientation maps were registered and quantified to determine fiber orientation distributions and the preferred orientation of each sample.

Results: The superior and inferior quadrants had the highest anisotropy, with the stiffness along the equatorial direction much larger than that along the meridional direction. The preferred fiber orientation in all four quadrants was in the meridional direction.

Conclusions: A sclera that is softer in the meridional direction may steer the eye to respond to loads by elongating longitudinally, without increasing equatorial diameter. This may reduce optical distortions and insult to the delicate neural and vascular tissues. Surprisingly, the higher equatorial sclera mechanical stiffness did not concur with the preferred meridional collagen fiber orientations. The origin of this discrepancy remains unknown. It is possible that not all fibers are equally stiff. Ongoing efforts are to analyze the collagen architecture of more samples.

Commercial Relationships Disclosure: Eric Weh: Commercial Relationship: Code N (No Commercial Relationship) | Ling Mei: Commercial Relationship: Code N (No Commercial Relationship) | Lisa Walsh: Commercial Relationship: Code N (No Commercial Relationship) | Minzhi Yi: Commercial Relationship: Code N (No Commercial Relationship) | Cheng-mao Lin: Commercial Relationship: Code N (No Commercial Relationship) | Abigail Fahim: Commercial Relationship: Code N (No Commercial Relationship) | Anna Schwendeman: Commercial Relationship: Code N (No Commercial Relationship) | Cagri Besirli: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: AMD is a blinding disorder characterized by the accumulation of lipids beneath the Bruch's membrane (drusen) and the invasion of immune cells into the retina. Activating the Liver X receptor (LXR) pathway can promote efflux of cholesterol from atherosclerotic plaques and inhibit pro-inflammatory cytokine production. Here, we evaluated the delivery of the hydrophobic LXR agonist (T0) complexed within a synthetic HDL (sHDL) molecule via intravitreal treatment (IVT) in a dry AMD animal model.

Methods: Mice or rats were injected with sodium iodate ($NaIO_3$, 40mg/kg) via the femoral vein. Either vehicle (PBS or DMSO) or drug (sHDL, T0, or sHDL-T0) was given via IVT immediately before $NaIO_3$ injection. A subset of animals were treated with vehicle or drug only. Retina and eye cups containing RPE/Choroid were collected for qRT-PCR and Western blotting. In vivo OCT and ex vivo histology were performed to assess retinal thickness and photoreceptor viability. Retinal immune cell invasion was assessed via flow cytometry. Human iPSC-RPE cells grown on trans-well inserts were used to determine cholesterol efflux.

Results: T0-sHDL or T0 alone significantly increased expression of both Abca1 and Abcg1 in retina and RPE/choroid. Cholesterol efflux studies in iPSC-RPE cells showed significant increase in both apical and basolateral directions with basal efflux being 3.5-4.7 fold higher than apical efflux. We saw significant decreases in IL-6, Tnfα, Nlrp3, and Nf-κb expression via qRT-PCR. Flow cytometry showed sHDL-T0 induced a significant decrease in microglia and macrophage activity (CD45, Ly6C, IBA1) in retinas from $NaIO_3$ treated animals. OCT analysis did not show any difference in retinal thickness at 7-days post $NaIO_3$ treatment. We also did not detect any differences between vehicle or drug treated eyes at days 1-5 post $NaIO_3$ administration.

Conclusions: Activating the LXR pathway enhances expression of cholesterol transporters in the retina/RPE while significantly increasing basal transport of cholesterol in human iPSC-RPE cells. We found significant decreases in pro-inflammatory signaling and immune cell activation in the $NaIO_3$ model of dry AMD after T0-sHDL treatment. Severe and rapid degeneration associated with $NaIO_3$ treatment prevented our ability to detect any neuroprotection in animals treated with the LXR agonist.

ABSTRACT BODY:

Purpose: To evaluate the features and the visual outcomes of retinal hemangioblastomas arising in proximity to the optic disc in Von Hippel Lindau Disease (VHL) at the National Institutes of Health Clinical Center

Methods: Retrospective longitudinal analysis of patients with ONRH associated with VHL. Data were collected on the duration of follow-up, visual acuities (VA), characteristics of RH on multimodal imaging including color fundus photography, ultra-widefield photography, optical coherence tomography, and autofluorescence imaging. Ocular and lesion characteristics at last follow up were compared with baseline, and response to any treatment was assessed.

Results: A total of 59 patients (53% females) with VHL first examined between 2003 - 2020 had ONRH in at least 1 eye. Of these, 10 (17%) patients were examined only once and exclude from further analysis. The total cohort's mean (SD) age at baseline was 37 (16) years. Twenty-six (44%) patients had ONRH in the right eye while bilateral ONRH was found in 5 (8%) patients. The presence or absence of ONRH could not be confirmed in 7 prosthetic eyes (1 right and 6 left). The mean (SD) VA at baseline in eyes with ONRH was 62.9 (27.9) letters (Snellen equivalent 20/60) and 80.4 (18.5) letters (20/25) in eyes that did not have ONRH. Patients were followed for a median (Q1, Q3) of 6.05 (2.09, 10.3) years and the mean VA in the eye with ONRH dropped to 52.85 (31.7) letters (Snellen equivalent of 20/100) at the time of last follow-up.

Conclusions: This longitudinal case series demonstrates progressive loss of visual acuity in this subset of VHL-associated retinal hemangioblastomas, for which treatment options are limited. New treatments, such as systemic hypoxia inducible factor (HIF)-2α inhibitors, hold promise for management of these vision-threatening tumors.

ABSTRACT BODY:

Purpose: The Response Evaluation Criteria In Solid Tumors (RECIST) provide radiological standards for solid tumor assessment. However, RECIST is not sufficiently compatible with the evaluation of RB. In May 2021, Berry JL et al. presented a new guideline about response criteria for retinoblastoma (RB-RECIST). We considered the clinical outcomes of RB patients treated with IAC according to the RB-RECIST recommendations.

Methods: A retrospective analysis of all RB patients treated with IAC (melphalan with additional topotecan and/or carboplatin) at Kellogg Eye Center between 2015 and 2021 was performed. Patients who had at least 6 months of follow-up after cessation of first- and/or second-line plus consolidation therapy were included.

Results: 21 eyes of 18 patients (72% females) were analyzed. The eyes were classified according to the International Classification of Retinoblastoma as group B (n=2), C (n=7), D (n=6), or E (n=6). The mean age at IAC was 21 months. Each eye received a mean of 5.6 ± 1.4 IAC sessions (range, 3-9). Consolidation therapy (cryotherapy or transpupillary thermotherapy) was applied in 76%, and intravitreal chemotherapy was injected in 57%. After IAC with a mean follow-up time of 33 months, globe salvage was achieved in 16 eyes(76%). Tumor recurrence (n=1, group C), vitreous hemorrhage (n=1, group D), and neovascular glaucoma (n=3, group E) were the reasons for enucleation. The ocular findings in the last follow-up exam or the exam before enucleation were assessed according to RB-RECIST. Tumor and vitreous seeds regression patterns were demonstrated in Table 1. A complete response(CR) in the tumor was seen 100% in group B, 86% in C, 100% in D, 50% in E. 1 eye(14%) in group C showed progressive disease(PD), and 3 eyes(50%) in group E had a partial response(PR) in the tumor. There was no stable disease(SD). During the study, vitreous seeds were observed in 14 eyes(67%) and subretinal seeds in 12 eyes(57%). CR in vitreous seeds was noted 50% in Group C, 83% in D, 67% in E; CR in subretinal seeding was established 100% in C, 83% in D, 60 % in E (Table 2).

Conclusions: Reporting of outcomes in RB is not standardized. These RB-RECIST guidelines may provide a standardized assessment for tumor response in studies of RB therapy.

ABSTRACT BODY:

Purpose: The goal of this study was to determine prevalence of abnormal corneas in pediatric subjects in the US.

Methods: Children aged 3-18 yrs at a school-based vision clinic were enrolled in an IRB approved, prospective, observational, single center (Illinois Eye Institute at Princeton, Chicago) study. Scheimpflug tomography (Pentacam HR, OCULUS Optikgrate GmbH, Germany) was acquired on each eye during comprehensive exams after obtaining consent. Automated multimetric analysis (Belin/Ambrosio Enhanced Ectasia BAD3, OCULUS Optikgrate GmbH, Germany) was run on each scan and the Final BAD-D (Final D) was derived. There is limited reference to prevalence of keratoconus (KC) as determined by tomography in children, and none in a US based population. The prevalence of KC in the generation 2 Raine Study is 1.2% (1 in 84) using a Final D score >2.6 (derived from Scheimpflug imaging). The BAD3 was designed to separate normal from abnormal corneas using a Final D > 2.69. A Final D of > 2.70 was used to calculate prevalence of abnormal corneas for this study.

The following criteria were used to differentiate normal from abnormal corneas (Table 1): Normal, Final D < 2.00 in both eyes, KC Suspect, Final D = or > 2.00 - < 2.70 in at least one eye, and KC, Final D = or > 2.70 in at least one eye. Statistical analysis was performed with SPSS version 25.0 (IBM Corp., Armonk, NY, USA).

Results: 2212 eyes were screened for this analysis. Subjects > 18 yrs of age or subjects missing data on the Final D measurements were excluded. Among those included, 96.3% (n=2131) were identified as Black or LatinX. (61.9% (n=1369) were Black and 34.4% (n=762) LatinX).

7.7% (n=165) of the total eyes screened, 8.3% (n=114) of the Black and 6.0% (n=46) of the LatinX subjects had a Final D between 2.00 – 2.69 in at least one eye and were assumed KC suspect. 2.3% (n=50) of the total eyes, 2.5% (n=34) of the Black and 1.4% (n=11) of the LatinX population had a Final D = or > 2.70 in at least one eye and were considered keratoconic.

Conclusions: In a primarily Black and LatinX pediatric cohort the prevalence of KC was found to be 2.3% (1 in 50), higher than what has been reported. Patients who are considered keratoconus suspect are important to identify as they require close monitoring. Corneal tomography may be a vital component of pediatric eye exams for early diagnosis and treatment of keratoconus.

ABSTRACT BODY:

Purpose: To evaluate the practice patterns and opinion from international dry eye experts with respect to dry eye disease (DED) diagnosis in clinical practice.
Methods: An online survey was distributed to DED experts all over the world. The use of diagnosis tests was evaluated in categories including: symptoms questionnaires, functional tests, tear film stability, tear volume, tear composition, ocular surface damage, ocular surface inflammation and eyelid assessment. After, the subjective importance of symptoms, tear break up time (TBUT), non-invasive TBUT, Schirmer test, tear meniscus height, osmolarity, metalloproteinase 9 (MMP9), blepharitis assessment and non-contact Meibography was evaluated according to Likert scale (never, rarely, sometime frequently and always).
Results: The survey was sent to 110 experts, and 77 respondents completed the questionnaire (rate of response=70%). The majority of the experts were from North America (27%) and Europe (40%). Sixty-four participants (83%) had more than 15 years of clinical experience in managing DED. A majority of respondents (73%) diagnose DED using clinical signs and symptoms, but not fulfilling the DEWS II criteria. Seventy-six participants (98.7%) use symptoms questionnaires, being OSDI the most popular (83%), followed by DEQ-5 (30%). All participants evaluate damage to ocular surface, and fluorescein staining is the most frequent method used (92%). In addition, all the respondents perform meibomian gland and blepharitis assessment. Moreover, most of the respondents (78%, n= 60) use finger compression to evaluate meibomian gland function, and 84% utilize non-contact meibography. Furthermore, ocular surface inflammation, tear volume and tear film stability are evaluated by 82%, 98.7% and 96% of the experts, respectively. On the other hand, only 69.8% evaluate tear composition, being osmolarity the most common test (66.2%), and functional tests are performed by 70% of the respondents. With respect to the importance of different tests for DED diagnosis, TBUT ($p= 0.002$) and Schirmer's (0.021) were found to be more important to experts from Europe than North America. No differences were found in any other test. (Fisher exact test $p>0.05$).
Conclusions: This survey offers updated and day-to-day clinical practices by DED worldwide experts, including DED diagnosis. The results highlight the importance of symptoms and clinical signs, but not necessarily following a strict criteria.

ABSTRACT BODY:

Purpose: In cases of optic disc edema, it is often difficult for the clinician to assess ophthalmoscopically whether the nerve appearance is due to elevated intracranial pressure (ICP) (i.e. papilledema) or due to some other cause (i.e. pseudopapilledema). The differentiation between true papilledema and pseudopapilledema is critically important because of the different implications each diagnosis carries, including prognosis and management. Optical coherence tomography angiography (OCT-A) has recently gained attention as a promising tool to help in the differentiation between papilledema and pseudopapilledema by revealing differences in the pattern of vasculature around the optic nerve between the two conditions. In this retrospective case control study, we compare OCT-A images of patients with true papilledema and patients with pseudopapilledema to test our hypothesis that vascular density variability around the optic nerve is more homogenous in papilledema than in pseudopapilledema.

Methods: Patients who were underwent an OCT-A scan at Aravind Eye Hospital in Coimbatore, India were eligible for the study. Scans which did not meet a useable quality threshold were excluded. The absolute difference between vessel densities in adjacent quadrants were calculated and averaged for the control, papilledema, and pseudopapilledema groups. One-tailed t-tests of the differences were performed among the respective groups to test the hypothesis.

Results: 32 patients qualified for the study including 28 papilledema scans, and 15 pseudopapilledema scans, and 17 control scans. As shown in Table 1, the average adjacent difference in vessel density was significantly higher in pseudopapilledema scans than in papilledema scans ($p=0.02$) or control scans ($p=0.04$). There was no significant difference between papilledema scans and control scans ($p=0.33$).

Conclusions: OCT-A vessel density variability was greater in pseudopapilledema scans than papilledema and control scans in this study.

ABSTRACT BODY:

Purpose: According to Sheir et al. and Satue et al., some OCT studies demonstrated asymmetrical involvement of the retina in Parkinson's disease (PD).

Satue et al., correlated both macular and RNFL thickness with PD severity using the Hoehn and Yahr scale.

This study aims to compare the thickness of the RNFL between the eyes of patients with PD.

Methods: A prospective cross-sectional observational study was conducted to evaluate the RNFL thickness, global and sectorial (superior, inferior, nasal and temporal quadrants), of both eyes in patients with PD. The study protocol was approved by the Committee of Ethics in Research.

A group of 28 patients with PD, consisting of 16 men (57.14%) and 12 women (42.86%), was evaluated.

The recruitment of patients was carried out at the movement disorders clinic, according to the clinical criteria and Hoehn and Yahr scale.

All patients underwent a comprehensive ophthalmologic examination previously to the OCT exam.

The statistical analyses were performed using the paired t-test. A probability (p) value of ≤0.05 with a two-tailed rejection region was considered statistically significant.

Results: A group of 28 patients with PD, consisting of 16 men (57.14%) and 12 women (42.86%), was evaluated. The mean age of the patients was 63.8±12.1 (median 63; range, 42-88) years - table 1.

The mean RNFL thickness in the right eye of those patients, was 121±23 (median 123) μm at the superior quadrant, 125±25 (median 125) μm at the inferior quadrant, 71±15 (median 69) μm at the temporal quadrant, and 78±21 (median 80) μm at the nasal quadrant; and in the left eye, there was a mean RNFL thickness of 123±21 (median 121) μm at the superior quadrant, 127±23 (median 128) μm at the inferior quadrant, 70±13 (median 71) μm at the temporal quadrant, and 77±13 (median 79) μm at nasal quadrant - table 2.

No statistically significant differences ($p>0.90$) were found when comparing the RNFL thickness, in all quadrants, between right and left eyes.

Three patients in the present study had stage 1.5 on the Hoehn and Yahr scale, while 21 patients had stage 2 and four patients had stage 2.5, meaning that only patients in mild to moderate degrees were evaluated.

Conclusions: The present study demonstrated that in mild to moderate stages of the Hoehn and Yahr scale there are no asymmetry in RNFL thickness between eyes of patients with PD.

ABSTRACT BODY:

Purpose: New therapies for Retinitis Pigmentosa (RP) have led to patients desiring more information about the disease and treatment options. Because patients rely heavily on the internet to acquire health information, this cross sectional study was developed to assess the readability, suitability, and quality of online health information for RP and it's associated treatment options.

Methods: We performed two distinct searches of freely available online information: one pertaining to RP and another pertaining to treatments for RP. To assess available information for RP we used the search term "Retinitis Pigmentosa" and evaluated the top 8 search hits. To assess the online information for RP treatment options, we used the search terms "Retinitis Pigmentosa Treatment", "Retinitis Pigmentosa Cure", and "Retinitis Pigmentosa Gene Therapy." 10 websites were evaluated from these three search terms.

A readability analysis was conducted for all sources using Readable (Added Bytes; Horsham, PA). Five readability algorithms were used to produce an average reading grade level for each source. A suitability analysis was conducted to evaluate whether the sources contained content deemed significant for patient knowledge. To assess the quality of the sources, JAMA website quality benchmarks were used.

Results: The readability assessment of RP webpages showed a mean reading grade level of 11.99 (SD=3.15, 95% CI=10.98-12.99). For the RP Treatment sources, the mean reading grade level was found to be 12.53 (SD=3.08, 95% CI=11.65-13.40). The mean suitability score for RP sites was 21.25 of 32 possible points (SD=4.12, 95% CI: 19.51-22.99). The mean suitability score for RP treatment sites was 5.50 out of 16 possible points (SD=3.69 , 95% CI: 4.12-6.88). The interrater reliability was 0.973 (Chronbach's alpha). For the RP sites, the average quality score was 2.63 out of 4 possible points (SD=0.92, 95% CI=1.86-3.39). For the RP Treatment sites, the average quality score was 2 out of 4 possible points (SD=0.86, 95% CI=1.42-2.58).

Conclusions: Our data suggest that the online information made available to patients regarding RP and RP treatment options exceeds the USDHHS recommended 6th grade reading level and contains gaps in content relevant to patients.

TITLE: Gaze Dependence for Blink Rate Measured with Ora EyeCup Phone

SESSION TITLE: Dry Eye, Clinical

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Chang, E. bensinger, J.D. Rodriguez, M. Dusharm, M.B. Abelson, Ora Inc, Andover, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Alexander Chang: Commercial Relationship(s);Code E (Employment):Ora Inc. | Ethan bensinger: Commercial Relationship(s);Code E (Employment):Ora Inc. | John Rodriguez: Commercial Relationship(s);Code E (Employment):Ora Inc. | Mathew Dusharm: Commercial Relationship(s);Code E (Employment):Ora Inc. | Mark Abelson: Commercial Relationship(s);Code I (Personal Financial Interest):Ora Inc.;Code P (Patent):Ora Inc.

ABSTRACT BODY:

Purpose: The rate of blinks provides important insights into the severity of dry eye disease. Without blinking the tear film over the ocular surface will break up and visual acuity will decay, so understanding blink rate is critical to determining the source of ocular discomfort from dry eye. Here we evaluated blink rate at different gaze positions to help determine what gaze prevents blinks or increases blink rates.

Methods: Videos of 4 subjects were acquired from one eye at 3 different gaze positions: up, straight ahead, and down, with 3 one-minute recordings at each gaze position. Patients were instructed to look up approximately 10 degrees from the front position and down approximately 15 degrees from the front position. Videos were recorded using the Ora EyeCup phone with the flash on in 4k and then blinks were counted from each video.

Results: When averaging the whole group across all views the mean blink rate was 15 (standard deviation (stdev) 7.9) blinks per minute. Upward and front facing gaze both led to a similar number of blinks 16 (stdev 6.1) blinks per minute and 16.25 (stdev 8.2) blinks per minute respectively, while a downward gaze subjects averaged 12.2 blinks per minute. A downward gaze showed only trending significance compared to the front gaze ($p=0.069$) and upward gaze ($p=0.1$).

Conclusions: Gaze is a critical factor in blink rate with a downward gaze leading to a lower average number of blinks. This result is in line with the fact that as our gaze lowers so does the interpalpebral fissure height, leading to less exposure of the ocular surface.

ABSTRACT BODY:

Purpose: Swept-Source Optical Coherence Angiography (SS-OCTA) allows wide-field imaging for visualization of choroidal structures. In patients undergoing verteporfin photodynamic therapy (vPDT) for central serous chorioretinopathy (CSCR), the choroid is the main treatment target. Change in subfoveal choroidal thickness (SCT) on spectral domain OCT (SD-OCT) is an accepted quantitative biomarker for vPDT treatment success. We hypothesized that the punctual nature of this read out may underestimate treatment response. Here we evaluate the effect of vPDT on choroidal volume (CV) with a novel algorithm within the Zeiss Advanced Retinal Imaging (ARI) Network.

Methods: Retrospective case series of chronic CSCR patients with or without secondary MNV undergoing a single half-dose vPDT treatment in one eye. The fellow eye served as control. Inclusion criteria were availability of high signal to noise ratio 12x12mm SS-OCTA (Plex Elite 9000, Zeiss) with minimal artefacts at baseline prior to PDT and at 6-8 weeks (range: 4 -12) follow up in both eyes. CV was calculated using the choroid quantification v1.2 algorithm (ARI Network). Central macular thickness (CMT, ETDRS) and SCT data were extracted from corresponding SD-OCTs (Spectralis, Heidelberg Engineering). Primary outcome parameters were the change in CV and SCT, secondary outcome parameters were CMT and best corrected visual acuity (BCVA).

Results: A total of 16 patients (13 male, 3 female, mean age 53 years) with an average of 53 days between vPDT and follow-up examination were included. In all treated eyes, the mean CV was 49.1 mm^3 prior to PDT, compared to 44.7 mm^3 at follow-up (9.6% reduction) – correspondingly, mean SCT decreased from 426.4 to 381.9 µm (10.4%). In control eyes, mean CV and SCT were similar at vPDT and follow-up examination (45.2 vs. 45.3 mm^3 and 361.6 vs. 366.0 µm, respectively). Mean CMT decreased from 351.4 to 295.4 µm (15.9%) in treated eyes, opposed by a slight increase in mean CMT in reference eyes (314.7 to 343.5 µm). Visual acuity changed from 0.31 to 0.24 logMAR in vPDT eyes.

Conclusions: vPDT treated CSCR eyes showed similar changes in CV using wide-field SS-OCTAand SD-OCT B-scan based SCT, whereas no change was observed in control eyes. Future work will analyze regional characteristics of CV and average CT change, as well as correlation of CV and average CT change with SCT and CMT.

SUBMITTER (NAME ONLY): Per Soderberg

TITLE: Glaucoma detection based on the waist of nerve fiber layer at the optic nerve head, average thickness or cross-sectional area?

SESSION TITLE: Data science, machine learning, and AI

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P.G. Soderberg, Z. Yu, K. Kisonaite, Surgical sciences, Uppsala Universitet, Uppsala, SWEDEN|

Commercial Relationships Disclosure: Per Soderberg: Commercial Relationship: Code N (No Commercial Relationship) | Zhaohua Yu: Commercial Relationship: Code N (No Commercial Relationship) | Konstancija Kisonaite: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The waist of the nerve fiber layer at the optic nerve head (ONH) may be expressed as cross-sectional thickness or surface area averaged over the circumference of the ONH. The purpose of the current work was to establish if there is a difference in efficiency between the two quantities for detection of glaucoma.

Methods: A 3D-volume of the optic nerve head was captured with OCT-2000 or OCT-Triton (Topcon, Japan) in one eye without glaucoma in each of 2 groups of 20 subjects aged [20;69]. Each group had a similar age distribution and a gender ratio of 1/1. The waist of the nerve fiber layer at the optic nerve head (ONH) was segmented fully automatically in the OCT volume.

In one group, minimal cross-sectional area was estimated over the circumference of the ONH (PIMA-2π) and in the other group minimal cross-sectional thickness was estimated over the circumference of the ONH (PIMD-2π). On the assumption that both quantities are normal distributed for subjects, a threshold for glaucoma was defined as the probability, α, to classify an eye as glaucoma although it is normal. 1-α then expresses the specificity for detection of glaucoma. The threshold for glaucoma, defined as a fraction below the expected mean of not glaucomatous eyes, is then directly proportional to the variation coefficient with the inverse of the cumulated normal distribution at 1-α as a proportionality constant. A 95% confidence interval for the difference between thresholds for glaucoma estimated as PIMA-2π and PIMD-2π was estimated by iteration based on the estimated mean and standard deviation for PIMA-2π and PIMD-2π, respectively using the t-distribution with d.f. =19.

Results: The estimated mean and standard devation, respectively, for PIMA-2π was 2.01 mm^2 and 0.54 mm^2 (c.v. = 0.26) and for PIMD-2π 350 and 62 μm (c.v. = 0.18). A 95 % confidence interval for the difference between the fraction of PIMA-2π below the expected mean and the fraction of PIMD-2π below the expected mean at specificity 0.95 was estimated to [-4;31] $x10^{-2}$ rel. (D.f 38).

Conclusions: If the threshold for detection is based on variability among subjects and specificity is set to 0.95, there is no difference in efficiency to detect glaucoma between PIMA-2π and PIMD-2π. The lack of difference is probably due to substantial variability among subjects.

ABSTRACT BODY:

Purpose: The eye lens contains anteriorly localized epithelial cells (anterior epithelium of lens, AEL) and posteriorly localized fiber cells (FCs). Cells in the AEL are further distinguished based on their proliferative indexes, while FCs can be distinguished based on their differentiation stages. Thus far, lens transcriptomics has focused on whole lens tissue samples or entire populations of AEL or FCs, and has provided key insights into lens pathobiology. Now, with recent advances, single-cell RNA-sequencing (scRNA-seq) can inform on cell-specific transcript heterogeneity and lead to new insights into pathological changes in individual cells that may contribute toward cataract. To make this approach practicable for wide applicability, we developed a working protocol for lens scRNA-seq that can be applied to tissue samples subjected to short-term storage, and used it to characterize embryonic and newborn mouse lens

Methods: Mouse lenses were micro-dissected at embryonic day (E) 16.5 and postnatal day (P) 0 followed by dissociation with Collagenase/Dispase and TrypLE to obtain a single-cell suspension, followed by cell viability/counts estimates. The cell suspension was frozen for transport and thawed and further processed prior to scRNA-seq library preparation and automated sequencing. Data was analyzed using 10x Genomics data-analysis and Seurat tools

Results: We established a protocol to enzymatically dissociate E16.5 and P0 lenses to obtain a viable cell suspension that can be frozen and thawed and yet be amenable for making scRNA-seq libraries that can yield high-quality RNA for RNA-seq. 10x Genomics tools were used to assign unique molecular identifiers to the expressed transcripts and identify established lens markers. We detected 21,031 cells with total 17,689 genes for E16.5 and 14,108 cells with 17,986 genes for P0. Based on expression profiling and clustering analysis, several distinct cell populations could be distinguished. In addition to known AEL and FC genes, several novel genes in these distinct cell populations were identified

Conclusions: This high-throughput approach to study the lens at single-cell resolution suggests that AEL and FCs can be distinguished further into subsets based on distinct expression profiles. Applying this new approach to lens knockout mouse models will help identify disease-specific cell populations and expedite gene discovery, and thus may find wide applicability in lens studies

TITLE: GPR143 Signaling Alters Intracellular Trafficking of POS
SESSION TITLE: Photoreceptor Biology, Protection and Degeneration
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: D. Tung, B. Good, A. Figueroa, N. Congrove, B.S. McKay, Ophthalmology and Vision Science, The University of Arizona Department of Ophthalmology and Vision Science, Tucson, Arizona, UNITED STATES|D. Tung, B.S. McKay, Physiology, The University of Arizona Department of Physiology, Tucson, Arizona, UNITED STATES|
Commercial Relationships Disclosure: Dorothy Tung: Commercial Relationship: Code N (No Commercial Relationship) | Brandon Good: Commercial Relationship: Code N (No Commercial Relationship) | Anna Figueroa: Commercial Relationship: Code N (No Commercial Relationship) | Nicole Congrove: Commercial Relationship: Code N (No Commercial Relationship) | Brian McKay: Commercial Relationship: Code N (No Commercial Relationship)
ABSTRACT BODY:
Purpose: Photoreceptors undergo a daily renewal process by shedding the distal 10% of their outer segments (POS), which are phagocytosed and degraded by the retinal pigment epithelium (RPE). Inefficient digestion of POS may lead to buildup of lipids and proteins within the RPE and play a role in retinopathies such as age-related macular degeneration (AMD). L-DOPA, a drug that appears to delay onset of AMD, is the ligand of a receptor in the pigmentation pathway involved in vesicular trafficking, GPR143. Here we test whether GPR143 signaling alters the rate of POS degradation by the RPE.
Methods: We isolated POS from bovine retinas via differential ultracentrifugation and sucrose gradient sedimentation. POS were labelled with a pH sensitive dye that increases fluorescence intensity as pH decreases, such that the POS are only visible in the acidic lysosomal compartment. Primary porcine RPE was challenged with POS for 4 hours to allow endocytosis with and without L-DOPA. We removed the excess POS, then added fresh DMEM with dialyzed FBS ± 1μM L-DOPA. Phase-contrast and fluorescent images were captured every 8 hours for 28 hours. 6 experiments were conducted with multiple replicates in each. The number and area of fluorescent POS were analyzed using ImageJ and statistical analysis was performed using Prism Graph.
Results: 4 hours after POS introduction, the number of fluorescent particles and the area they occupied were similar regardless of L-DOPA treatment. At 12 hours, RPE treated with L-DOPA had significantly fewer fluorescent particles (79.1 ± 4.36% of control, $p<0.001$, $n=58$) that occupied a significantly smaller area (79.5 ± 5.03% of control, $p<0.001$, $n=58$). This trend continued at 20 hours, where RPE treated with L-DOPA had significantly fewer fluorescent particles (78.6 ± 5.09% of control, $p<0.001$, $n=58$) that occupied a significantly smaller area (77.7 ± 5.20% of control, $p<0.001$, $n=58$) than the control.
Conclusions: Our results indicate that L-DOPA had no effect on POS phagocytosis measured at 4 hours. Our data also showed that once the POS were in the lysosomal compartment, L-DOPA had no effect on the rate of degradation past 12 hours. However, the reduced number and area of POS in the RPE after 12 hours suggest L-DOPA had a significant effect between hours 4 and 12, which most likely relates to more efficient endosomal trafficking to the lysosomal compartment. These findings may highlight a mechanism by which L-DOPA protects from AMD.

ABSTRACT BODY:

Purpose: Age-related macular degeneration (AMD) is thought to be caused by atrophy of retinal pigmented epithelial (RPE) cells leading to photoreceptor degeneration, and in advanced disease stages, neovascularization in the choroid. We have developed 3D models of AMD that include cell types found in both choroid and RPE including endothelial cells, pericytes, fibroblasts, RPE, and monocytes. With the goal to make an AMD patient-specific disease model, the purpose of this work is to make a fully isogenic tissue. Here, we aim to derive monocytes from iPSCs and compare them to primary monocytes to advance the development of a fully isogenic 3D AMD model.

Methods: iPSC derived monocytes were generated in vitro by treating attached embryoid bodies with m-CSF and IL-3. Monocytes were repeatedly harvested every 3-4 days over two weeks and were compared to primary monocytes via flow cytometry analysis. Monocytes were stained with CD45 and CD14 to indicate true monocyte phenotype, CD11b for overall macrophages, CD86/CD206 for polarized macrophage subtypes. Monocytes were differentiated into polarized macrophages via solutions with gm-CSF for M1-like or m-CSF for M2-like. Macrophages were analyzed with the same panel of surface markers.

Results: iPSC derived monocytes showed compatible surface marker between experiments, harvests, and cell lines demonstrating reproducibility. Batches of monocytes were then compared to primary monocytes. Primary sources showed >95% CD45 and CD14 co-expression while iPSC monocytes showed CD14 expression at an average 82% from 4 harvests and 85% from 4 different iPSC lines. CD11b expression was observed at 0-4% in both populations indicating monocytes did not undergo spontaneous macrophage differentiation. When differentiated into activated macrophages, both primary and iPSC cells demonstrated M1 or M2 appropriate morphologies with CD86/CD206 protein expression.

Conclusions: Our protocol to generate monocytes from iPSCs confirmed consistency across multiple differentiation batches by surface protein expression. This characterization also shows that our monocytes do not spontaneously differentiate into macrophages. Primary monocytes and iPSC derived monocytes showed similar marker expression, indicating the potential to replace their primary counterpart in our 3D-printed iPSC based AMD model.

ABSTRACT BODY:
Purpose: The viscoelastic properties of the crystalline lens play an important role in vision health. There is strong evidence that the development of presbyopia and cataract in the lens correlates with the age-related changes in lens biomechanical properties. In this work, we used dynamic optical coherence elastography (OCE) to measure the surface wave dispersion in the lens inside the eyeball ex-vivo and to evaluate age-related changes in both the elasticity and viscosity of the rabbit lens.
Methods: Fifteen fresh rabbit eyes (Pel-Freez Biologicals, LLC, Rogers, AR) were separated into two groups: young (from two to three months old, N=5) and mature (over six months old, N=10). The OCE system colmbined a single-element ultrasound transducer (model ISO 304HP; CTS Valpey Corporation, Hopkinton, MA) with a spectral-domain optical coherence tomography system. The ultrasound transducer had a focal length of about 19 mm and a central frequency of 3.5 MHz. Five single-tone acoustic radiation force bursts ranging from 500 Hz to 2500 Hz were focused on the lens surface. A Kelvin-Voigt viscoelastic model and Scholte wave model were used to quantify the lens elastic and viscous shear moduli.
Results: The average dispersion curves (i.e., phase velocity vs. frequency) for the young rabbit group and mature group and their respective fitting to the model are presented in Fig. 1. As seen in Fig. 1, the surface wave in mature lenses demonstrates higher speed in comparison with young lenses in the whole frequency range. Figure 2 shows the estimations of Young's modulus and the shear viscosity coefficient for two age groups calculated based on the theoretical model. The results demonstrated that the young lenses are softer and less viscous than the mature lenses.
Conclusions: In this study, the dispersion of the surface waves in rabbit lenses was measured inside the eyeball. Based on these measurements, the elasticity and viscosity of the lenses were quantified for young and mature rabbits. The results demonstrate an increase in both stiffness and viscosity of the lenses with age. In our future work, we will use dynamic OCE to measure lens biomechanical properties as a function of age in vivo.

ABSTRACT BODY:

Purpose: Glucocorticoids induce ocular hypertension by increasing resistance to aqueous humor outflow through the trabecular pathway however, the molecular basis for this etiology remains poorly understood. Here we report the activation of glypican-4-regulated Wnt5/PCP pathway in dexamethasone (Dex) treated trabecular meshwork cells, which offers a novel insight into glucocorticoid induced cytoskeletal changes in the trabecular meshwork.

Methods: Dex treated (0.5 μM for 7 days) and control cells from three different human TM cell strains were used to prepare nuclear protein and cytoskeletal-enriched fractions. These fractions were then subjected to label free quantitative proteomics analysis. The effects of Dex and TGF-β2 on glypican-4 (GPC4) protein levels were determined by immunoblot and immunofluorescence analysis, while levels of Wnt5A and phospho-JNK were evaluated by immunoblot analysis.

Results: Using a 2-fold change relative to corresponding controls and a significance of $P<0.05$ as criteria, we identified differentially expressed proteins in both the nuclear protein and cytoskeletome fractions of Dex treated cells. The levels of GPC4, a cell surface heparan sulfate proteoglycan, and regulator of Wnt signaling were significantly elevated in both cytoskeletome and nuclear protein fractions of Dex treated TM cells compared to control cells. Both immunoblot and immunofluorescence analyses revealed distribution of GPC4 to the cytosol and nuclear fractions of TM cells. Additionally, significant increases in the levels of GPC4 were noted in the total cell lysates of human TM cells treated with Dex and TGF-β2 relative to control cells. Intriguingly, the cytoskeletome fraction of human TM cells revealed the presence of only Wnt5A, Wnt5B, Wnt9A and WLS, and relatively high levels of DAAM2, Frizzled-7, PTK7, and Scribble, which are key regulators of the Wnt/RhoA/PCP pathway. Moreover, Dex treatment also resulted in increased levels of Wnt5A and JNK phosphorylation (indicators of activation of the Wnt/PCP pathway) in TM cells.

Conclusions: This study identifies the Glypican-4/Wnt5/RhoA induced PCP pathway as one of the predominant upstream signaling pathways regulating actin cytoskeletal reorganization and cell adhesive changes in glucocorticoid treated TM cells, unravelling a new molecular target for management of IOP in glaucoma.

ABSTRACT BODY:

Purpose:

Retinal microvasculature can be viewed and measured using color fundus photographs (CFP) and is predictive of systemic microvascular damage. Integrative Vessel Analysis (IVAN) is a semi-automated vessel measurement software that has been used in multiple epidemiological studies. Good focus and clarity of vessels is essential for reliable measurements. Poor image quality accounts for about 10 – 25% data loss using IVAN. This study represents a deep learning autoencoder approach to images and restoring the structural details required for IVAN.

Methods:

The dataset included de-identified CFP (field 1) with vessel measurements in IVAN from the Carotenoids in Age Related Macular Degeneration Study 2 (CAREDS2), an ancillary study of the Women's Health Initiative. The training data was 511 images with reliable vessel measurements, as established by the IVAN software and approved by a human grader using defined criteria. Training images were intentionally degraded by shrinking their original resolution by a factor of 20 and then bringing back to their original size. A U-net based autoencoder was used to reconstruct the original images in 400x400 segments. The trained network was then applied to 12 images IVAN was originally unable to measure. Outcomes included (1) the percent of ungradable images that were considered gradable after autoencoder enhancement and (2) the mean differences between vessel measurements, and 3) sigma, a reliability index between original and enhanced cohorts, to identify any systematic bias.

Results:

Of the 12 images that were considered unreliable by IVAN, autoencoder could retrieve vessel caliber measures in 9 (75%). Two were ungradable due to intrinsic vascular structure and one continued to have poor focus. In the second dataset of gradable images (n = 10) vessel caliber pre and post autoencoder showed a mean difference of 6.03 microns (p = 0.41) for central retinal artery equivalent (CRAE) and 1.12 (p = 0.90) for central retinal vein equivalent (CRVE). The mean sigma for CRAE and CRVE was 3.26 and 3.83 respectively in the original dataset and 4.13 and 4.76 in the autoencoder datase

Conclusions:

A deep convolutional autoencoder improves the vascular details on retinal images and enables IVAN measurements, reducing data loss due to inferior quality photographs. Vessel diameter is not altered due to autoencoder enhancement and can be reliably used in longitudinal data.

ABSTRACT BODY:

Purpose: Our previous studies have demonstrated the importance of hypoxia in uveal melanoma (UM) growth and have identified that a hypoxia-inducible factor (HIF) inhibitor 64B reduces primary tumor growth and metastasis in an intraocular melanoma mouse model. Here, we further observe the longitudinal growth of UM in a heterotopic UM animal model treated by 64B and identify a potential new mechanism of action.

Methods: The HIF inhibitor 64B was provided by OncoSpherix, Inc. MTT and crystal violet assays were performed to determine cell viability in response to varying concentrations of 64B in cultured human UM cell lines 92.1 and Mel202. Athymic nude mice (Jackson laboratory) implanted with human UM cells 92.1 subcutaneously were divided to the vehicle control and 64B group (10 mice per group). 120 mg/kg 64B by intraperitoneal injection, once per day, started at a tumor size larger than 80 mm^3. Tumor size and mice weight were monitored weekly. Tumor necrosis and liver metastases were quantitated by histology. Immunohistochemistry of Ki67/MIB1 and Yes-associated protein (YAP1) were performed.

Results: Cell viability assays demonstrated that 64B killed 92.1 and Mel202 cells after 3 days of 64B treatment when 64B was at or exceeded the concentration of 2μM. In mouse studies, 64B regressed s.c. 92.1 UM with clear evidence of necrosis and decreased numbers and sizes of liver metastasis compared to the control group. Furthermore, there was a reduction in the percentage of mice that had detectable lung metastasis from 50% in the control group to 20% in mice treated with 64B. The tumor proliferation marker Ki67/MIB1 expression in the 64B groups was significantly less than the control group in the primary tumors, and YAP1 expression associated with hypoxia was suppressed by 64B.

Conclusions: The HIF inhibitor 64B inhibits primary UM growth as well as liver and lung metastasis in a heterotopic mouse model. In addition to the inhibition of HIF function by 64B, the inhibition of the expression of the transcription factor YAP1 might contribute to the antitumor effect of 64B by blocking the ability of YAP1 to promote cancer cell proliferation, chemoresistance, and invasion.

ABSTRACT BODY:

Purpose: To report on the level of and associated demographic and systemic health factors for diabetic retinopathy (DR) and distance visual acuity (VA) as determined in a primary care based teleophthalmology program for an underserved urban population.

Methods: A retrospective review was performed of prospectively collected, cross-sectional data from a teleophthalmology program to evaluate patients with a diagnosis of diabetes who had not had a documented eye exam in the last year. The analysis used data from six urban primary care sites within a single health system between 2015-2021. Demographic factors, including age, race, ethnicity, and sex and systemic health related information, including blood pressure, smoking status, last HbA1c, and health insurance were associated with VA level and presence and level of DR using single and multivariate linear and logistic regressions with significance set at a p-value less than 0.05.

Results: 1,232 patients were evaluated for DR, 166 (13.5%) had DR and, of those, 82 (49.4%) cases were deemed vision threatening (VTDR) due to presence of diabetic macular edema (macular hard exudates) and/or severe non-proliferative DR or worse. No variables were identified as multicollinear with DR or VA outcome for multiple regression analysis. HbA1c greater than 7.0 ($p<0.005$), increased age ($p<0.014$), and African American race ($p<0.005$) were correlated with worse VA. No other variable was significantly associated with VA. A 1.0 unit increase in HbA1c increased the odds for DR by 1.24 ($p<0.005$; 95% CI 1.20, 1.29) times while only patients under dual Medicare/Medicaid insurance appeared to be 1.96 ($p=0.051$; 95% CI 1.00, 3.87) times as likely of having DR than commercial payors, controlling for other variables. VTDR was 2.93 ($p<0.005$; 95% CI 1.89, 4.53) times as likely with elevated HbA1c. Neither age, sex, smoking status, race nor level of blood pressure control appeared to confer a significantly higher odds ratio for DR or VTDR.

Conclusions: HbA1c remains a key variable associated with worsening VA and DR in patients evaluated via teleophthalmology with demographic factors such as age and being a minority as well as having certain health insurances correlating with worse VA and increased risk of DR, respectively. Further research is needed to clarify these relationships and their impacts on long-term health outcomes in a safety-net population with diabetes.

ABSTRACT BODY:

Purpose: To evaluate the test-retest agreement and reliability of the novel active-learning quantitative contrast sensitivity function (qCSF) device.

Methods: Seventy-nine (79) eyes of 57 retina clinic patients with various vitreo-retinal disorders were prospectively tested and subsequently retested on the same day at Massachusetts Eye and Ear using the novel qCSF Manifold Contrast Vision Meter (Adaptive Sensory Technology). Contrast sensitivity outcomes included: area under the log contrast sensitivity function (AULCSF), and contrast thresholds at 1, 1.5, 3, 6, 12, and 18 cycles per degree (cpd). Agreement between test and retest measurements was assessed using Bland Alman (BA) plots. Test-retest reliability was assessed using the intraclass correlation coefficient (ICC).

Results: Bland-Altman plots showed a mean bias of nearly zero for all contrast sensitivity outcomes of the qCSF device. The lower to upper limit of agreement was approximately −0.1 to + 0.1 for AULCSF and −0.1 to + 0.1, −0.075 to + 0.075, −0.13 to + 0.19, −0.25 to + 0.25, −0.7 to + 0.6 and −0.5 to + 0.55 for contrast thresholds at 1, 1.5, 3, 6, 12 and 18 cpd, respectively. ICC demonstrated excellent test-retest reliability (>0.9) for all qCSF outcome metrics, with the exception of the contrast threshold at 18 cpd. The ICC for AULCSF was 0.901 with 95% Confidence Intervals (CI) for ICC population values of 0.85 to 0.936. The ICC for the contrast thresholds at 1, 1.5, 3, 6, 12 and 18 cpd were 0.821 (95% CI for ICC population values: 0.735 to 0.882), 0.924 (95% CI for ICC population values: 0.884 to 0.951), 0.943 (95% CI for ICC population values: 0.912 to 0.963), 0.948 (95% CI for ICC population values: 0.92 to 0.966), 0.949 (95% CI for ICC population values: 0.922 to0.967), and 0.831 (95% CI for ICC population values: 0.707 to 0.906), respectively.

Conclusions: Test-retest agreement and test-retest reliability were excellent for all contrast outcomes derived from the qCSF device, including AULCSF and contrast thresholds at 1 to 18cpd. Incorporating functional outcomes with excellent test-retest agreement and reliability such as the qCSF device in the clinical practice and clinical trials offers the clinicians and researchers good perspectives on whether measured changes in contrast sensitivity can be attributed to the test-retest variability of the device or whether they represent a real change in visual performance.

ABSTRACT BODY:

Purpose: Bone marrow-derived macrophages (BMDM) migrate to the site of choroidal neovascularization (CNV) in age-related macular degeneration (AMD). The exact role of these migratory cells in the pathogenesis of CNV remains largely unknown. Inflammation might play a key regulatory role in the pathogenesis of AMD progression. In vivo molecular imaging of inflammasomes could predict the onset and progression of AMD. We report here the development of a novel optical imaging probe, MI-142, that specifically targets NLRP3 and enables the detection and visualization of NLRP3 inflammasomes in retinal cells and ocular tissues.

Methods: MI-142 was synthesized by conjugating a selective NLRP3 inhibitor (CY-09) to a fluorescent dye for optical imaging of inflammasomes. To verify MI-142's ability to target NLRP3, its inhibitory effects were compared to those of CY-09. Following an established protocol, LPS-primed BMDM's were treated with MI-142 or CY-09 and stimulated with nigericin to induce NLRP3 activation. Cell culture supernatants were assayed for mouse IL-1β and TNF-α using enzyme-linked immunosorbent assay (ELISA). To visualize activated NLRP3, LPS-primed BMDM's were stained with MI-142, stimulated with nigericin, fixed with 4% NBF, and imaged through confocal microscopy. In addition, in vivo imaging of inflammasomes was performed in a mouse model of AMD, laser-induced choroidal neovascularization (LCNV).

Results: In comparison to CY-09, MI-142 showed statistically similar inhibitory effects on NLRP3-mediated production of IL-1β at 1 μM, 5 μM, and 10 μM in a dose-dependent manner. In general, neither MI-142 nor CY-09 significantly affected the production of TNF-α. These results suggest that MI-142 retains the inhibitory abilities of its parent compound that enable it to function effectively as a targeted NLRP3 imaging probe. In an in vitro fluorescence imaging experiment, nigericin-induced BMDM's displayed bright MI-142 dependent fluorescence in the cytosol, while untreated cells showed no remarkable fluorescence. In vivo imaging of inflammasomes was achieved in a mouse LCNV model.

Conclusions: This study showed that our novel imaging probe, MI-142, enables visualization of activated NLRP3 inflammasomes in BMDM's and LCNV. Therefore, we propose that MI-142 may be useful to study the onset, progression, and therapeutic response of AMD.

ABSTRACT BODY:

Purpose: Aging is a major factor in the development and progression of macular disease whether age-related or heritable. The choroid contributes to the homeostasis of the retina, and age-related changes in choroid structure and function are thought to contribute to these diseases. The purpose of this study was to identify the major effects of age on the choroid in wild type (Wt) mice and in mouse models of late onset retinal degeneration (L-ORD) due to mutations in C1qtnf5/Ctrp5.

Methods: The proteomes of the choroids of wild type C57BL6 and Ctrp5^{S163R} mutant mice were determined at 4.5 and 19 mo and at 4.5 and 18 mo, respectively. The choroid/Bruch's membrane was dissected, proteins solubilized and separated on SDS gels. After in-gel trypsin digestion, peptides were separated and peptide masses analyzed using mass spectrometry. MaxQuant software was used for database searching, peptide and protein identification and quantification. Principal component analysis (PCA) was done using SOLO, Eigen Vector. IHC was used to localize specific proteins.

Results: PCA showed strong clustering by age for both genotypes. About 24% of the 3700 proteins identified were significantly altered with age in Wt mice. Specific markers for mast cells, endothelial cells and melanocytes showed statistically significant changes in each cell type with age. The decrease in plasmalemma vesicle-associated protein, the major component in fenestrae, an endothelial substructure, suggested structural changes in the choriocapillaris. Tyrosinase, the rate limiting enzyme in melanin synthesis decreased 3 fold. These age-related changes occurred to the same extent in Wt and mutant mice. Of the 250 proteins of the innate immune system 60 underwent changes with age. The most remarkable changes were the 4 mast cell proteases which were increased over 3-4 fold in Wt and 10-12 fold in Ctrp5^{S163R} mutant mice, the 5 fold increase in the carboxypeptidase A inhibitor, latexin, in mutant mice and cathepsin S which was increased 5 fold in Wt and 15 fold in mutant mice.

Conclusions: Each of the aging changes identified correlate with processes that are reported to be factors in macular disease. Loss of melanin, changes in choriocapillaris function and immune activation with age will negatively impact retinal homeostasis in both genotypes. The excess immune system activation in Ctrp5^{S163R} mutant mice may be a major factor in the pathobiology of L-ORD.

ABSTRACT BODY:

Purpose: The purpose of the current study was to identify new contrast mechanisms that can reveal retinal structures not visible with other methods. Simultaneous multi-channels offset AO-SLO imaging provides isotropic images of retinal microstructures free of directionality artifacts and enables phase imaging in the living eye with enhanced visualization contrast.

Methods: We developed a new detection scheme with an arrangement of light collecting fibers that provides isotropic imaging while retaining all the advantages of offset aperture and split-detector imaging. Four optical fibers are arranged as a compact bundle and all offset images are collected simultaneously with the confocal image. The two orthogonal offset pairs provide the split-detector imaging in orthogonal directions removing the directionality disadvantage of other techniques. Oblique back-illumination has been used in microscopy to reveal phase objects that are not visible in confocal microscopy. Split-detection analysis, sometimes called differential phase contrast, is interpreted as phase derivative. One can reconstruct the phase from orthogonal phase derivatives or directly calculate the phase gradient.

Results: Split-detection analysis is performed using multiple combinations of the four offset images. Two orthogonal split images are generated for orthogonal fiber pairs 1-3 and 2-4 (A and B in Fig. 1). Two additional split images (C and D) are obtained by adding first adjacent fibers (for example 1+2 and 3+4) and then performing subtraction divided by sum of the two sums. Therefore we obtain four split images: horizontal, vertical, and two diagonal (+/-45deg). They highlight structural edges such as blood vessel walls along different directions given the directionality associated with the split direction. The phase (P) and the phase gradient (PG) images are obtained from either one of these two pairs of split images. In addition, the mean of the four split standard deviation images (STD) isotropically highlights the blood flow vasculature. Circled areas in Fig. 1 highlight local microstructures that have no blood flow associated with them (not visible in the STD image). They could potentially be microglia based on their location in the proximity of the blood vessels.

Conclusions: The multi-aperture AO-SLO imaging based on simultaneous acquisition of multiple offset aperture images provides an improved, isotropic image in the inner retina free of single offset-axis directionality artifacts.

ABSTRACT BODY:

Purpose: The German ROP registry collects real-life data on infants treated for retinopathy of prematurity (ROP). This is of particular importance in light of the new treatment option of anti-VEGF for ROP. This abstract compares the re-treatment rates of anti-VEGF versus laser in ROP.

Methods: We analyzed data from 353 infants (692 treated eyes) born between 2011 and 2020. Descriptive statistics were used to analyze the percentage of eyes needing at least one re-treatment. Infants with a need for re-treatment were compared to infants without need for re-treatment regarding demographics (birthweight, gestational age (GA) at birth, postnatal age (PNA) as well as postmenstrual age (PMA) at treatment; t-tests). The interval between initial treatment and re-treatment was compared between different treatment groups (laser, bevacizumab (bvz), ranibizumab (rbz)).

Results: Of the 692 treated eyes 108 eyes (15.6%) needed at least one re-treatment. Re-treatment rates varied between 11.6 and 30.6% during the observation period. Of eyes initially treated with laser (396) 14% were re-treated

compared to 12% of eyes treated with bevacizumab (117) and 24.5% of eyes treated with ranibizumab (159). Laser treated eyes were re-treated after a mean of 22 days, which was significantly shorter than after bvz (mean 53; p=0.0004) or rbz (mean 55; p<0.0001). A second re-treatment was conducted in a total of 28 eyes after a mean of 40 days after the first re-treatment in the laser group, 61 days in the bvz group and 47 days in the rbz group. Infants who needed at least one re-treatment were significantly lighter at birth (614g vs. 709g; p=0.0021), were born with a lower GA (24.8 vs. 25.5 weeks; p=0.0128), had lower PMA at treatment (36.3 vs. 38 weeks; p<0.0001) and lower PNA at treatment (11.5 vs. 12.6 weeks; p=0.0086) compared to infants who did not require re-treatment.

Conclusions: Among the group of infants with treatment requiring ROP, infants with lower GA and birth weight have the highest risk for requiring more than one ROP treatment. Re-treatment rates were higher after initial treatment with rbz and occurred later with rbz or bvz compared to laser. Real life data from registries can help adjusting treatment decisions and follow-up regimens in ROP. Our data collection will be continued as part of the newly established European ROP registry EU-ROP (www.eu-rop.org).

ABSTRACT BODY:

Purpose: To assess targeting, compartmentalization, and durability potential of suprachoroidal injection of small molecules via microneedle in multiple preclinical models and multiple drug candidates.

Methods: Suprachoroidal injection of multiple small molecule drug candidates (tyrosine kinase inhibitor (TKI), complement factor inhibitor, steroid, kallikrein inhibitor) via a proprietary microneedle were performed in multiple preclinical species (rabbit, porcine, monkey and dogs) to evaluate safety and tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and/or bioavailability in posterior segment ocular tissues including the macula region. Multimodal imaging methods were employed ex vivo and in vivo to evaluate delivery efficiency, flow dynamics, and spread of injectate in the suprachoroidal space (SCS).

Results: Suprachoroidal injections via proprietary microneedle customized for each species were successfully employed in multiple animal models and well-tolerated across species and multiple disease models. In total, over 1000 injections have been performed with free needle lengths between 300 and 1100 µm dependent on species-specific ocular anatomy characteristics. Injections into the SCS demonstrated circumferential and posterior spread of injectate immediately following the injection, confirmed in ex vivo porcine models. In multiple in vivo rabbit studies, an opening of the SCS in the posterior segment was observed. Suprachoroidal delivery of small molecule suspensions exhibited compartmentalization of a dose depot into posterior tissues with high drug levels in the chorioretina, including therapeutic drug levels as far as posteriorly to the optic nerve. In contrast, drug levels in the aqueous humor were 3-5 log orders lower, and negligible systemic drug exposure was observed. Ocular PK studies in rabbits and monkeys showed durability of multiple drug candidates. Specifically, one small molecule drug candidate showed sustained presence at 6 months (last time point evaluated). Suprachoroidally injected steroid and TKI drug candidates exhibited PD effects in in vivo porcine models of ocular inflammation and neovascularization, respectively.

Conclusions: Suprachoroidally injected small molecule suspensions consistently exhibit targeting, compartmentalization, and durability in multiple preclinical models.

TITLE: Posterior Fixation Sutures Expand Binocularity in Patients with Persistent Paretic or Restrictive Pathology

SESSION TITLE: Strabismus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S.A. Newman, Ophthalmology, University of Virginia, Charlottesville, Virginia, UNITED STATES|

Commercial Relationships Disclosure: Steven Newman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To obtain binocularity in primary and down reading gaze, weakening (recession) or strengthening (advancement or resection) procedures are often adequate. To maximize the area of binocular single vision, more aggressive weakening procedures may be necessary. The use of posterior fixation sutures functionally limits the excursion of an otherwise normal muscle. When combined with a recession procedure and applied to the contralateral synergist to a paralyzed muscle, or to the contralateral antagonist to a restricted muscle the area of binocularity can be substantially improved.

Methods: This is a retrospective review of 33 patients treated with posterior fixation sutures at the University of Virginia over a 10 year period. Patients were assessed for alignment in primary and down reading gaze, but also for increase in binocularity as measured by binocular single vision fields and for equalization based on Hess screen analysis.

Results: A total of 33 patients were treated with posterior fixation suture procedures. Sixteen patients were treated with medial rectus recession and Faden procedure for long standing stable abduction deficits (most commonly VI nerve dysfunction). Nine patients were treated with lateral rectus recession and posterior fixation sutures for contralateral adduction deficits usually related to III nerve dysfunction. One patient was treated with a contralateral superior rectus recession and Faden procedure for a surgically induced Brown syndrome following a tuck procedure for a IV nerve palsy. Seven patients had inferior rectus recession for problems with down gaze.

Conclusions: Posterior fixation sutures by limiting excursion of the better moving eye are an effective way of expanding binocularity. This is applicable to both paretic and restrictive syndromes. The area of binocularity and alignment can be fine tuned by additional surgery on the worse moving eye following the initial recession and Faden procedure. The use of the Hess screen and binocular single vision fields is instrumental in guiding surgery.

ABSTRACT BODY:

Purpose: Some uveitis specialists eschew further differentiation of non-infectious uveitis, even though specific uveitic syndromes may have consequences for systemic health. Sarcoidosis is a multisystem inflammatory disease that is a regionally common cause of non-infectious ocular inflammation. The objective of this study was to determine the prevalence and manifestations of cardiac sarcoidosis in patients with ocular sarcoidosis.

Methods: This was a retrospective cohort study of patients diagnosed with ocular sarcoidosis as defined by the International Workshop on Ocular Sarcoidosis (IWOS) at the University of Louisville from 2017-2020 and the Medical University of South Carolina from 2005-2020. Medical records were first searched for at least a suspected diagnosis of sarcoidosis, then for ocular manifestations of sarcoidosis, and finally for an electrocardiogram (EKG). Patients lacking any of these three components were excluded. Cardiac past medical histories and EKG findings consistent with a sarcoidosis diagnosis were also obtained, including ventricular arrythmias, heart blocks, and paroxysmal ventricular contractions.

Results: Of the 232 patients with sarcoid uveitis, 20 (8.6%) had known cardiac involvement at the time of ocular diagnosis. Sixteen patients (6.9%) had EKG abnormalities consistent with cardiac sarcoidosis. Eight patients had known histories of cardiac sarcoidosis and three had confounding cardiac histories that explained their EKG findings, leaving five patients (2.2%) with ocular sarcoidosis whose cardiac disease was only identified after a diagnosis of possible, probable, presumed, or definite ocular sarcoidosis had been made. Four patients with relevant EKG findings had this study done within 6 months of their diagnosis of sarcoidosis.

Conclusions: Nearly 10% of patients with ocular sarcoidosis have manifestations of cardiac sarcoidosis, some of whom were diagnosed only after presentation to an ophthalmologist with uveitis. Our results suggest that EKG is a reasonable test to include for patients with signs of ocular sarcoidosis to screen for cardiac issues, which are potentially life-threatening. This work suggests that further differentiation of non-infectious uveitis can have important implications for systemic health. Further research is needed to see if EKG abnormalities can be detected before other cardiac manifestations in this patient population.

TITLE: Comparison of biometry measurements using Anterion and Lenstar biometers

SESSION TITLE: Cataract surgery II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. ALNAHRAWY, M. Niestrata, P. Sousa, Y. Gad El, M. Bizrah, A. Aziz, Western Eye Hospital, London, London, UNITED KINGDOM|S. Bazeer, North Middlesex University Hospital NHS Trust, London, London, UNITED KINGDOM|

Commercial Relationships Disclosure: Ahmed ALNAHRAWY: Commercial Relationship: Code N (No Commercial Relationship) | Magdalena Niestrata: Commercial Relationship: Code N (No Commercial Relationship) | Shehnaz Bazeer: Commercial Relationship: Code N (No Commercial Relationship) | Petra Sousa: Commercial Relationship: Code N (No Commercial Relationship) | Yulia Gad El: Commercial Relationship: Code N (No Commercial Relationship) | Mukhtar Bizrah: Commercial Relationship: Code N (No Commercial Relationship) | Ahmad Aziz: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The purpose was to compare biometry readings between Anterion (Heidelberg Engineering) and Lenstar (Haag-Streit) for patients undergoing cataract surgery and to identify any discrepancies and their significance for surgical planning.

Methods: Biometry measurements were performed on patients in Imperial College London between November'21 and January'22, using Lenstar and Anterion. Measurements of axial length (AL), K1, K2 in diopters (D), anterior chamber depth (ACD), lens thickness and white-to-white (WTW) were compared. The mean differences in measurements were evaluated using standard deviation (SD), 95% confidence intervals (CI) and p values. Statistical analysis was performed using Excel and Python.

Results: A total of 15 patients, 30 eyes, was included. The mean age was 71 (SD 3.2). The majority (10 patients, i.e. 67%) were females and 5 (33%) males. Out of 30 AL measurements, 3 were excluded due to inability to obtain measurement with Anterion in dense cataracts. The mean difference in AL was 0.006mm (SD 0.01mm; CI +/- 0.004) (p=0.039). The mean differences in K1 and K2 were 0.046D (SD 0.388D; CI +/- 0.145) (p=0.049) and 0.256D (SD 0.456; CI +/- 0.170) (p=0.454), respectively. The mean ACD difference was 0.451mm (SD 0.157mm; CI 0.059) (p=0.496). One eye was excluded from the lens thickness analysis due to inability to obtain a measurement with Anterion. The mean lens thickness difference was 0.166mm (SD 0.4195mm; CI 0.1596), statistically very significant (p=0.0001). The mean WTW difference was 0.146mm (SD 1.151mm; CI 0.4299) (p=0.0857).

Conclusions: Both Lenstar and Anterion produce very similar AL readings. Anterion seemed unable to produce measurements in some dense cataracts, which should be further assessed on a larger patient cohort. There was a notable difference in ACD, which may be explained by Lenstar reading being taken from the corneal epithelium to lens epithelium vs Anterion one from corneal endothelium to lens epithelium. There was a statistically very significant difference in lens thickness, however, with a large SD. There was a relatively large difference in white-to-white readings, which may be of relevance in anterior chamber intraocular lense selection. Future studies are needed to assess the differences on a larger patient cohort and in extremes of AL, in short and long eyes, to determine any difference in suitability of the different biometry machines in such circumstances.

ABSTRACT BODY:

Purpose: Filtering blebs from glaucoma drainage devices (GDD) form too posteriorly for direct observation. The purpose of this study was to evaluate magnetic resonance imaging (MRI) features of different GDD and explore clinical correlations.

Methods: Cross-sectional study of ocular, GDD and bleb morphology using a 3-Tesla MRI scanner (Philips Medical Systems, Netherlands) with an 8-channel head coil in consecutive glaucoma patients implanted with one of 4 distinct GDD: Ahmed Glaucoma Valve FP7 (AGV) and Ahmed ClearPath 350mm^2 (ACP; both New World Medical, USA), Baerveldt Glaucoma Implant 350mm^2 (BGI; Abbott Medical Optics, USA) and Paul Glaucoma Implant (PGI; Advanced Ophthalmic Innovations, Singapore). Forty-four patients were recruited but 13 were excluded due to inability to undergo quality MRI. Clinical data was retrieved from patient files. Statistical analysis was performed with Prism 8 (GraphPad Software, San Diego, CA).

Results: A total of 36 eyes from 30 patients aged 57±20 years (mean±SD) were included in this study. Seven eyes had been implanted with the AGV (19%), 8 with ACP (22%), 5 with BGI (14%) and 16 with PGI (44%). Orbital MRI was performed 2,4±2,1 months after GDD implantation. Average total bleb volume was 563±390mm^3, with no significant difference among different GDD (p=0,1223). Bleb volume did not correlate with intraocular pressure (IOP) at any timepoint (pre-operative, time of MRI, last follow-up; p>0,1524, all comparisons), with time from surgery to MRI (p=0,5590) or with axial length (p=0,3398). A double-layered bleb was observed in 94% of eyes (n=34), the layers separated by the GDD endplate. Inferior blebs (between the sclera and the endplate undersurface) were significantly larger with the PGI than with the remaining GDD (380±205 vs. 193±161mm^3; p=0,0043) and also larger with non-valved GDD (BGI, PGI and ACP, collectively) versus the AGV (318±202 vs. 101±64mm^3; p=0,0086). Flattening of the scleral bed underneath the endplate was a common finding in eyes with non-valved GDD (n=15, 52%; absent in all AGV patients) and was associated with larger blebs (observed in 78% of blebs in volume quartile 75-100; p=0,0049).

Conclusions: Double-layered blebs are a common finding with GDD filtering blebs. Bleb morphology seems to be independent of IOP or time from surgery, but dependent on the type of GDD, with non-valved devices (particularly the PGI) forming larger inferior blebs which commonly flatten the underlying sclera.

ABSTRACT BODY:

Purpose: From several studies in occulopression, repeated tonometry or ophthalmodynamometry we have knowledge that the intraocular pressure (IOP) decreases during an artificial IOP increase. This phenomenon is known as the tonographic effect. In healthy eyes an IOP drop of 2–3 mmHg/min was reported. However, there are studies that show a reduced decrease of the IOP drop for instance in glaucoma patients. In this work we determine the tonographic effect in healthy eyes by utilizing a novel pneumatic pressure modulator and validate the modulator technically in order to determine the technical confounding of the tonographic effect.

Methods: For technical validation and in vivo application, a pneumatic intraocular modulator (IOPstim, Imedos Systems GmbH, Jena, Germany) was used. A force sensor (KD34s, ME-Meßsysteme GmbH, Hennigsdorf, Germany) was placed in front of the balloon. Pressure stability was analyzed for 2 minutes. The force values were recorded for five different device target pressures from 50 mmHg to 250 mmHg in steps of 50 mmHg, and this sequence was repeated 10 times. A new balloon was used for each sequence. In the subject study, the IOP of 10 healthy subjects (6 male, 4 female, aged 28.8 ± 6.64 years) was modulated and increased linearly to at least 40 mmHg. At this point, the pressure inside the balloon was kept constant for 2 minutes, with IOP measurements taken every 40 seconds using a rebound tonometer (Icare PRO, Icare Finland Oy, Helsinki, Finland).

Results: The technical setup led to an IOP decrease of 0.7 mmHg within 2 minutes at an operating point of 40 mmHg IOP. In the subject study, the IOP could be increased up to 42.8 ± 3.6 mmHg for all subjects (n = 10), whereby a mean pressure decrease of 4.8 mmHg within 2 minutes was determined, which seems to be caused mainly by physiological processes.

Conclusions: With the new pneumatically based setup, a targeted modulation in terms of level and constancy of the IOP can be realized. Technical validation showed that the purely technical influence on the tonographic effect, i.e. the drop in IOP, carried 0.3 mmHg/min with a total effect of 2.4 mmHg/min. The technical confounding of the tonographic effect is clearly less than the physiological effect itself.

ABSTRACT BODY:

Purpose: Previous studies have shown that pharmacological blockade of vascular endothelial growth factor (VEGF) or VEGF-Receptors (VEGF-Rs) can ameliorate corneal neovascularization and improve allograft survival rates in high-risk keratoplasties. However, repeated injections are required because rejection can occur even years after transplantation. In this study, we aim to determine if a single dose of AAV-mediated anti-VEGF treatment can increase the survival rate of corneal grafts in a model of high-risk keratoplasty.

Methods: The corneal suture paradigm was used to produce a rat model of high-risk keratoplasty. Sutures were placed 14-days prior to keratoplasty. At 5 days prior to keratoplasty, sutures were removed and either an anti-VEGF AAV (5×10^9 genome copies/12µl) or PBS (12µl) was introduced to the cornea via intrastromal injection. CoNV and corneal opacity were assessed post-operatively using slit-lamp microscopy weekly and graft thickness was measured post-operatively using optical coherence tomography (OCT). Corneal graft rejection was defined as moderate stromal opacity with only the pupil margin visible and neovascularization around the peripheral graft. Additionally, intraocular pressure (IOP), as one of ocular safety indicators, was measured once a week. Potential inflammation induced by intrastromal injection of AAV-antiVEGF was also analyzed by measuring the percentage of F4/80+ and CD11b+ cells in the cornea.

Results: We observed a significant reduction in CoNV, corneal opacity, and to a lesser extent, corneal thickness in AAV-treated rats (N=6) compared with the control group (N=6). The survival-rate of the allograft was increased in AAV-anti-VEGF treated animals and the incidence of corneal graft rejection was decreased. IOP remained normal in both groups and no inflammation was noted at 2 weeks post-intrastromal injection at this dosage of AAV ($5x\ 10^9$ genome copies), indicating the treatment of AAV vectored anti-VEGF does not elicit IOP change and inflammation.

Conclusions: Anti-VEGF molecules delivered by AAV vectors are safe and efficacious for the long-term inhibition of corneal neovascularization which increases the survival rate of corneal allografts in high-risk keratoplasty.

ABSTRACT BODY:

Purpose: Many patients with dry eye disease (DED) suffer from episodic flare-ups that require an effective short-term treatment. OTX-DED is a physician-administered, biodegradable, preservative-free, hydrogel-based insert that is placed into the canaliculus and releases dexamethasone to the ocular surface for 2-3 weeks. In this study, we evaluated the efficacy and safety of OTX-DED in subjects with dry eye disease.

Methods: Prospective, randomized, double-masked, vehicle-controlled Phase 2 study at 15 US sites. Adult subjects diagnosed with DED in both eyes for >6 months, eye dryness severity score ≥30 and bulbar conjunctival hyperemia grade ≥2 were randomized 1:1:1 to receive either OTX-DED 0.2 mg, OTX-DED 0.3 mg or hydrogel-vehicle (HV) insert. Subjects (N=166) received the same treatment bilaterally on Day 0 and were followed for 8 weeks. The primary endpoint was photographic assessment of bulbar conjunctival hyperemia in the worst zone on Day 15 evaluated by a central reading center and graded using the Cornea and Contact Lens Research Unit grading scale (0 to 4 scale for each zone [nasal, temporal, frontal]). Adverse events (AEs) were collected.

Results: Both 0.2 mg and 0.3 mg groups met the primary endpoint of a statistically significant difference in conjunctival hyperemia in the worst zone compared to HV on Day 15 (P=0.004 and P=0.028, respectively). Change from baseline in mean conjunctival hyperemia grade in the 0.2 mg, 0.3 mg and HV group was -0.51, -0.43, and -0.21 respectively. Statistically significant differences in conjunctival hyperemia compared to HV were also observed for total, nasal, temporal and frontal zones in the 0.2 mg group and total, nasal, and temporal zones in the 0.3 mg group (all P<0.05). No serious ocular AEs were reported. The most common ocular AEs reported by subjects treated with OTX-DED (both 0.2 and 0.3 mg pooled; n=111) were increased lacrimation (8.1%), and intraocular pressure elevation (3.6%).

Conclusions: OTX-DED 0.2 mg and 0.3 mg dexamethasone intracanalicular insert significantly improved bulbar conjunctival hyperemia compared to hydrogel-vehicle in subjects with dry eye disease. Both insert doses were generally safe and well-tolerated.

ABSTRACT BODY:

Purpose: Photoreceptor cells produce a receptor protein for pigment epithelium-derived factor (PEDF-R), which is encoded by the PNPLA2 gene of the patatin-like phospholipase domain-containing 2 family. PEDF-R is a membrane-linked lipase detected in the inner segments of photoreceptors. We aim to reveal the physiological role of PEDF-R in photoreceptors by characterizing CRISPR Pnpla2 knock-out mouse lines.

Methods: CRISPR-derived Pnpla2 knock-out mouse lines were generated in a C57BL/6 and rd8 free background. RT-PCR was performed from dissected retinas. Mice were evaluated for fundoscopy, electroretinography and angiography. Organs of the thorax were harvested and imaged using a LEICA microscope. Plasma was collected for lipid analyses. Eyes were enucleated and processed for histology, immunofluorescence, confocal microscopy, and transmission electron microscopy.

Results: Pnpla2$^{-/-}$ mice had undetectable retinal Pnpla2 expression levels, enlarged whiter hearts, and lower plasma free fatty acids and triglycerides levels than their Pnpla2$^{+/+}$ littermate controls. Their retinal pigment epithelial cells accumulated lipid droplets and their photoreceptors were deformed. Fundi of Pnpla2$^{+/-}$ eyes had white spots. The optic nerve area of Pnpla2$^{-/-}$ and Pnpla2$^{+/-}$ mice had an excess of pigment. The a-wave in Pnpla2$^{-/-}$ and Pnpla2$^{+/-}$ mice, and b-wave in Pnpla2$^{+/-}$ mice were attenuated relative to controls. Retinal rhodopsin and opsin gene expression of Pnpla2$^{-/-}$ and Pnpla2$^{+/-}$ were lower than in controls. The immunofluorescent intensities of rhodopsin and opsin antibodies decreased in Pnpla2$^{+/-}$ and Pnpla2$^{-/-}$ photoreceptors relative to controls. The immunofluorescence of PKCα and synaptophysin antibodies (markers for bipolar cells and ribbon synapse) in the Pnpla2$^{+/-}$ retinas were lower than in controls.

Conclusions: Ablation of Pnpla2 in mice causes malformation of photoreceptors and affects photoreceptor performance, identifying PEDF-R as an important component for photoreceptor structure and function. These findings suggest that the absence of PEDF-R in photoreceptor cells interrupts PEDF neurotrophic action, thereby heightening degeneration in the mice.

TITLE: Longer-Term Outcomes of Trans-scleral Sutured Intraocular Lens Implantation in Children

SESSION TITLE: Pediatric ophthalmology and imaging

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. OBrien, L. Tychsen, Washington University in St Louis School of Medicine, St Louis, Missouri, UNITED STATES|

Commercial Relationships Disclosure: Marisa OBrien: Commercial Relationship: Code N (No Commercial Relationship) | Lawrence Tychsen: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To report longer-term safety and efficacy outcomes after implantation of trans-scleral sutured posterior chamber intraocular lenses (TSS-IOLs) in children lacking capsular support. Comparison was made between children with ectopia lentis, congenital cataract, or traumatic cataract as well those implanted using 9-0 vs. 10-0 Prolene sutures.

Methods: Outcomes were collated retrospectively for 48 children (61 eyes) implanted with TSS-IOLs. All of the children had a history of lensectomy-vitrectomy with primary or secondary extensive or complete capsulectomy. Main outcome variables were final corrected distance visual acuity (CDVA) and occurrence of IOL-related adverse events (AE). The cause of the initial lenticular abnormality was ectopia lentis in 10 children (19 eyes), congenital cataract in 13 children (16 eyes), and traumatic cataract in 16 children (16 eyes). Mean follow-up for the 3 groups was 10.7, 10.6, and 7.5 years respectively. 39 eyes were implanted using 10-0 Prolene and 9 eyes using 9-0 Prolene.

Results: CDVA (mean 0.4 ± 0.3 logMAR) at last follow-up was best for those with ectopia lentis; mean age at initial surgery 7.8 yrs. CDVA (mean 1.25 ± 0.9) was worst for those with congenital cataract-related deprivation amblyopia; mean age at initial surgery 2.1 ± 0.4 months. The major AE encountered was suture breakage and TSS-IOL dislocation, which occurred in 68% of children with ectopia lentis, 23% with traumatic cataract, and 19% with congenital cataract. The IOL dislocation rate for eyes implanted using the thinner 10-0 Prolene suture was 37%, compared to 0% using the thicker 9-0 Prolene suture.

Conclusions: The TSS-IOL remains a useful option for correction of aphakia in pediatric eyes lacking capsular support. The major determinants of outcome success are lack of deprivation amblyopia (older age at first surgery) and use of thicker, breakage-resistant suture.

ABSTRACT BODY:

Purpose: Previously, we showed that the loss of angiotensin converting enzyme 2 (ACE2) results in disturbed gut-retina axis and contributes to developing diabetic retinopathy (DR). However, the mechanisms responsible for causing DR phenotype are poorly understood. Here, we examined the impact of maintained levels of enteral ACE2 on gut barrier defects, glucose homeostasis, and the development of DR in type 1 diabetic (T1D) mice.

Methods: Two approaches were employed to maintain enteral ACE2 levels in the Akita mice. 1) overexpression of human Ace2 in Akita mice (Vil-Cre.Ace2KI-Akita) by genetic manipulation, and 2) oral administration of an engineered probiotic (Lactobacillus paracasei; LP) which expressed and secreted humanized ACE2 into the intestinal lumen. After nine months of T1D, enteral and retinal endpoints were assessed, including expression of local RAS components, gut barrier integrity, visual function, and histological features of DR.

Results: Despite the presence of nine months of diabetes, Vil-Cre.Ace2KI-Akita and LP-ACE2-Akita mice exhibit sustained intestinal Ang 1-7 levels, preserved junctional proteins (ZO-1, p120-catenin, β-catenin), and maintained gut barrier integrity as demonstrated by lower levels of gut microbial products in the systemic circulation. Increased ACE2 activity leads to Ang-II degradation, resulting in higher Ang1-7 levels. Ang1-7, through activation of the Mas receptor, increases intestinal glucose transporters (SGLT1 and GLUT2). Furthermore, enteral ACE2 forms a heterodimer with the tryptophan transporter B^0AT1, as observed by IHC, which increased incretin (GLP-1 and GIP) secretion. These act in combination to control glucose homeostasis, which, within the retina, reduced acellular capillaries in Vil-Cre.Ace2KI-Akita ($p<0.001$) and LP-ACE2 treated Akita mice ($p<0.0001$) compared with untreated diabetic mice. Sustained enteral ACE2 expression also significantly improved retinal electrical response and visual acuity as measured by ERG (scotopic a wave, $p<0.003$; scotopic b wave, $p<0.01$; photopic a wave, ns; photopic b wave, $p<0.002$) and OKN ($p<0.0001$), respectively.

Conclusions: Taken together, our study demonstrates that sustained enteral ACE2 expression in T1D prevents DR by maintaining intestinal barrier integrity and improving glucose homeostasis.

ABSTRACT BODY:

Purpose: Extracellular Vesicles (EVs) are a heterogeneous group of lipid bilayer membrane structures released by all cells. EVs contain specific sets of lipids, proteins, DNA and RNA and are being recognized as key players in cell signaling, homeostasis, and the pathology of various diseases. Most EVs studies have been accomplished by using cell supernatants or different body fluids, but the number of studies on tissue derived EVs is still limited. To characterize and gain insight on the role of EVs derived from the retina and RPE tissue, it is important to establish practical and efficient protocols for their isolation. Here we describe a step-by-step procedure of a novel, optimized and efficient method to isolate EVs directly from both human retina and RPE tissues.

Methods: Our protocol includes enzymatic treatment of dissociated postmortem retina and RPE tissues followed by differential ultracentrifugation and density separation. The isolated EVs were characterized by transmission electron microscopy (TEM), Nanosight (NTA) and Exoview analysis. In addition, western blot against well-known EV specific markers and non-EV markers was used to determine the quality and purity of EV preparations. Furthermore, we analyzed the proteomic cargo of retina- and RPE tissue-derived EVs and validated the proteins found by western.

Results: EVs trapped within the retina and the RPE were successfully isolated while maintaining the integrity of the vesicles and their cargo. The presence of EVs during each isolation step was confirmed via NTA with additional Exoview analysis after final recovery. Characteristic clear rounded membrane vesicles within a size range of 30–170 nm was observed by TEM. The physical characteristics of the vesicle preparations (ultrastructural morphology and size), and their biochemical composition (presence of Syntenin, CD63, and absence of GM130) confirmed that they fulfill the criteria for EVs. Furthermore, proteomic profiling of tissue-derived EV cargo revealed that EVs were enriched in proteins involved in biological processes associated with retina physiology.

Conclusions: This study represents the first human retina and RPE EV isolation protocol to date. This method will enable researchers to gain insight on EV populations in the eye, explore their role in cell-to-cell communication and, provide a novel approach for elucidating mechanisms behind ocular pathogenic conditions.

ABSTRACT BODY:

Purpose: Accumulating evidence shows that extracellular vesicles (EVs) produced by mesenchymal stem/stromal cells (MSCs) exert their therapeutic effects in several disease models. Previously, we also demonstrated that MSC-derived EVs (MSC-EVs) prevent onset of autoimmune disease in murine models including experimental autoimmune uveoretinitis (EAU). In addition, we found that 3D microcarrier culture conditions increased the expression levels of immunomodulators in MSC-EVs such as TGF-β1, let-7b and TSG-6, enhancing the immunomodulatory function of MSC-EVs. Building on these findings, we herein further investigated if MSC-EVs produced under 3D microcarrier culture conditions (3D MSC-EVs) can be used to treat autoimmune uveitis after the onset of the disease.

Methods: To examine the therapeutic potency of MSC-EVs in the management of EAU after disease onset, MSC-EVs were systemically treated in EAU mice on day 14 after immunization and the severity of EAU in mice was assessed on day 28. To examine if MSC-EVs can directly suppress the infiltration of retina-specific autoreactive T cells, an adoptive transfer model of EAU was induced in mice with or without MSC-EV treatment and the disease progress was evaluated in recipient mice. Also, an in vitro chemotaxis assay was used to demonstrate the inhibitory effect of MSC-EVs on T cell migration.

Results: We found that the treatment of 3D MSC-EVs on day 14 after EAU induction effectively suppressed the disease progress in EAU mice compared to those from control monolayer cultures. Also, 3D MSC-EVs were more effective in preventing the development of EAU in an adoptive transfer model of EAU. Consistent with the findings, MSC-EVs effectively suppressed the migration of retinal reactive T cells under an in vitro chemotaxis setting.

Conclusions: Our results suggest that MSC-EVs directly inhibit the infiltration of retinal reactive T cells toward the eyes, thereby halting the disease progress in EUA mice. The data strongly support the therapeutic potency of MSC-EVs for the treatment of autoimmune uveitis.

Commercial Relationships Disclosure: Geetika Kaur: Commercial Relationship: Code N (No Commercial Relationship) | Shivantika Bisen: Commercial Relationship: Code N (No Commercial Relationship) | Deepti Sharma: Commercial Relationship: Code N (No Commercial Relationship) | Nikhlesh Singh: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Pathological retinal neovascularization is a clinical manifestation of various proliferative retinopathies, including retinopathy of prematurity (ROP), diabetic retinopathy, and the wet form of macular degeneration. Over the last decade, numerous studies have reported an increased infiltration of hematopoietic stem cells (HSCs), macrophage/microglia in patients with intraocular angiogenic diseases.

Methods: Using a murine model of oxygen-induced retinopathy (OIR) and human retinal microvascular endothelial cells (HRMVECs), we are trying to understand the significance of IL-33/Hypoxic induced VCAM1 expression in retinal neovascularization.

Results: Here, using a murine model of oxygen-induced retinopathy, we found that NFkB and VCAM1 levels were highly up regulated in retina when new vessels were developing in the retina. Genetic deletion of IL-33 resulted in reduced NFkB activation and VCAM1 levels in hypoxic retina, resulting in reduced neovascularization. These findings suggest a role for IL-33-NFkB-VCAM1 signaling in pathological neovascularization. Our results demonstrate that IL-33 induce tube formation in human retinal microvascular endothelial cells and depletion of VCAM1 levels significantly blocked it. Protein profiler analysis showed that IL-33 regulates VCAM1 dependent IL-8 expression in HRMVECs. In order, to understand how IL-33 induced VCAM1 regulates the expression of IL-8, we did sequence analysis of IL-8 promoter and observed that IL-8 promoter has AP1 binding site. We observed that IL-33 induced the expression of Fra1 and JunB significantly in HRMVECs. Cloning and site directed mutagenesis of IL-8 promoter revealed that the AP1 binds to IL-8 promoter in response to IL-33 and regulate the expression of IL-8 in HRMVECs. Consequently, down regulation of VCAM1 levels significantly reduced IL-33 induced Fra1 and JunB expression as well as IL-8 expression.

Conclusions: These results strongly suggest that IL-33/ST2L-NFkB-VCAM1-AP1 regulates IL-8 expression, playing a key role in retinal neovascularization and thus represents a new pharmacological target for the treatment of diseases where excessive neovascularization is the underlying pathology.

ABSTRACT BODY:

Purpose: Oxidative damage and inflammatory activation of retinal pigment epithelial cells (RPE) are key contributors to age-related macular degeneration (AMD) pathogenesis. Metabolic reprogramming and oxidative stress are known to drive immune cell activation. However, the existence of such interplay between inflammation and metabolism in RPE remains elusive. This study examines the effects of tumor necrosis factor-α (TNFα), a pro-inflammatory cytokine involved in AMD, on RPE metabolism and investigates the metabolic drug, dimethyl fumarate, as a new regulator of RPE immunometabolism.

Methods: Matured primary human RPE cells were treated with TNFα (10 ng/ml) and/or pre-treated with dimethyl fumarate (DMFu, 80 μM) for 2 hours. Glycolytic and oxidative (OXPHOS) metabolic profiles were determined by Seahorse XFe96. Gene expression of metabolic markers was assessed using qPCR. IL-6 secretion was quantified by ELISA. Cellular ATP content was measured by bioluminescence. Reactive oxygen species (ROS) was measured using a fluorometric mitochondrial superoxide detection kit. Ultrastructural features of mitochondria were imaged by transmission electron microscopy (TEM).

Results: TNFα-induced upregulation of IL-6 secretion ($p<0.0001$, $n=6$) in RPE was accompanied by increased basal and maximal OXPHOS on Seahorse Mito Stress Test ($p<0.0001$, $n=10$). TNFα increased ATP production, mitochondrial ROS production ($p<0.0001$, $n=8$) and gene expression of the mitochondrial antioxidant SOD2 ($p<0.0001$, $n=6$). TEM revealed defects in mitochondrial morphology with engorged mitochondria and loss of cristae integrity with TNFα. DMFu suppressed TNFα-induced IL-6 secretion ($p<0.0001$, $n=6$) and maintained mitochondrial OXPHOS and ATP production at control levels ($p>0.05$, $n=6$). DMFu increased PFKFB3 gene expression ($p<0.0001$, $n=6$) and correspondingly, restored TNFα-induced suppression of glycolysis to control levels ($p>0.05$, $n=6$).

Conclusions: The pro-inflammatory effects of TNFα on RPE are accompanied by defects in mitochondrial morphology and a profound metabolic shift promoting OXPHOS and ROS accumulation. Treatment with the fumaric acid precursor, DMFu, efficiently blocks TNFα-induced pro-inflammatory activation and bioenergetic reprograming of RPE. These results reveal a critical interplay between inflammation and metabolic dysfunction in RPE, identifying DMFu as a potent immunoregulatory drug against AMD progression.

TITLE: Isolating the mechanisms of photoreceptor protection elicited by a ketogenic & low protein diet.

SESSION TITLE: Photoreceptor Biology, Protection and Degeneration

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W. Tschetter, D. Wafai, I. Fries, M. Six, R.C. Ryals, Ophthalmology, Oregon Health & Science University, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure: Wayne Tschetter: Commercial Relationship: Code N (No Commercial Relationship) | Dahlia Wafai: Commercial Relationship: Code N (No Commercial Relationship) | Ian Fries: Commercial Relationship: Code N (No Commercial Relationship) | Makayla Six: Commercial Relationship: Code N (No Commercial Relationship) | Renee Ryals: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: We previously showed that a ketogenic & low protein (KLP) diet slows photoreceptor degeneration in early weaned rd10 mice but the neuroprotective mechanism remains unclear. We performed a proteomics analysis to determine which proteins the KLP diet modulate in the retina as a way to isolate targets that slow retinal degeneration.

Methods: C57BL6 mice were early weaned and placed on the KLP diet starting at P15. After 30 days of continuous diet administration, ERGs were recorded, serum albumin was measured and retinas were harvested for tandem mass tag (TMT) mass spectrometry to compare differentially expressed proteins. To investigate the effect of dietary protein restriction, a separate group of rd10 mice were early weaned and placed on a low protein diet containing 8% protein. At P23, P30, P40 and P50 weight and blood b-hydroxybutyrate levels were recorded and retinal thickness was measured with optical coherence tomography (OCT). At P30 and P50, serum albumin levels were measured.

Results: TMT analysis quantified a total of 6247 proteins. Of these, 58 proteins were differentially expressed in the retina due to the KLP diet. Only one of these plays a role in phototransduction (SWOPN1). Of interest was an upregulation of antioxidant (GST, APOA4), lipid metabolism (SCP2) and DNA repair (XRCC4) proteins and a downregulation of markers for neuronal damage (GFAP, NFMP). Mice on the low protein diet weighed an average of 30% less than those on standard chow (SC), but blood albumin concentrations were not significantly different from the SC group (~1300pg/mL). Photoreceptor layer thickness decreased from 60.4uM at P23 to 18.3uM at P50, mimicking the rate of degeneration in the SC group.

Conclusions: We previously published that the KLP diet reduces phototransduction, which may serve as the protective mechanism of the KLP diet. However, our data show that these changes are not due to a significant change in phototransduction protein expression but rather activation and suppression of key proteins for neuroprotective pathways. The low protein diet results further support the hypothesis that reduced phototransduction and serum albumin are required to elicit photoreceptor protection in the rd10 mice. These data generate novel therapeutic targets for inherited retinal degeneration.

ABSTRACT BODY:

Purpose: Macrophages are key pathogenic cells in neovascular age-related macular degeneration. However, macrophages are heterogeneous cells whose function depends upon their microenvironment and/or origin. Choroidal macrophages are derived from blood monocytes, and classical monocyte-derived macrophages (MDMs) are necessary for laser-induced choroidal neovascularization (CNV). We hypothesized that a subtype of classical MDMs stimulates angiogenesis during laser-induced CNV.

Methods: Female wildtype (WT) and $Ccr2^{-/-}$ mice underwent no treatment or laser injury. On Day 3, eyes were harvested, digested into single cell suspensions, and $CD45^{+}$ cells were isolated by fluorescence-activated cell sorting for single cell RNA-sequencing. Cell Ranger was used for genome alignment and empty droplet exclusion. The data were loaded into Seurat v3 for quality control metrics and cell clustering. Hypergeometric distribution analysis determined which genotype and treatment contributed to each cluster. Differential expression (DE) analysis was performed between each macrophage cluster and all other clusters. GOrilla gene ontology analysis was used to determine the function of each macrophage cluster.

Results: We sequenced 34,215 cells with an average 36,890 reads per cell. We identified 12 total macrophage clusters, including 6 microglia subtypes and 6 macrophage subsets. DE and GO analysis found that only one cluster was enriched for positive regulation of angiogenesis (6.3-fold, $q<0.05$). DE genes contributing to positive regulation of angiogenesis included Vegfa (vascular endothelial growth factor), Anxa1/2/4/5 (annexins), Il1b (interleukin-1 beta), Fn1 (fibronectin), Mmp12/14 (metalloproteinases), and Spp1 (osteopontin). This $Spp1^{+}$ cluster was specifically derived from the WT + laser group. In addition, $Spp1^{+}$ MDMs were enriched for glycolysis and lipid catabolism GO terms, two processes implicated in macrophage-driven angiogenesis. Finally, $Spp1^{+}$ MDMs specifically express the CD11c receptor.

Conclusions: $Spp1^{+}$ MDMs express a transcriptome including VEGF and cytokine signaling, matrix metalloproteinases that degrade basement membranes, annexins to increase endothelial sprouting, and fibronectin for scaffolding that stimulates angiogenesis by multiple pathways. $Spp1^{+}$ MDMs express specific cell surface markers like CD11c, which can be used for therapeutic ablation.

ABSTRACT BODY:

Purpose: Retinoblastoma (RB) is the most common intraocular eye cancer in children. Although intra-arterial chemotherapy is effective, there is a strong propensity for therapeutic escape in retinoblastoma and limited second-line treatment options. Characterizing RB cancer progression is essential for discovering novel targeted therapies. Here, we developed different techniques for characterizing RB in vitro and generated a new chemoresistant retinoblastoma cell line.

Methods: A naïve retinoblastoma cell line (RB028) and a treated retinoblastoma cell line (RB006) were transduced with a constitutively expressing GFP system as a surrogate readout of viability using the Incucyte Imaging System. The sensitivity of the GFP signal in retinoblastoma cell lines was validated using DMSO. This system was then used to generate kill curves with clinically relevant chemotherapy agents (carboplatin, melphalan, and topotecan). RB028 was treated with repeated sublethal dosages of 1uM melphalan and 1uM carboplatin and was monitored for the development of chemoresistance after recovery. We characterized the recovered cell lines' invasiveness and clonogenicity in Cultrex and in HyStem matrices.

Results: GFP signals in both RB006 and RB028 were quenched within 4 hours of 50% DMSO treatment and were sufficiently sensitive for generating a cost-effective viability assay. Baseline corrected AUCs of kill curve assays for RB006 is higher than RB028 for carboplatin (1-10uM) and for melphalan (5-20uM), highlighting the preservation of clinically-relevant chemoresistance mechanisms in RB cells using our culturing system. Treated naïve RB028 recovered within two weeks for carboplatin and within three weeks for melphalan. RB028 was treated up to four times with carboplatin (RB028-4XC). Compared with Naïve RB028, RB028-4XC had higher baseline-corrected AUCs for carboplatin (10-40uM) and demonstrated a greater propensity for remaining viable as small clusters in preliminary characterization assays.

Conclusions: We generated a new carboplatin chemoresistant retinoblastoma cell line useful for downstream molecular analysis of chemotherapy resistance mechanisms. Though further in vitro characterization is still necessary, preliminary findings reveal traits associated with more clinically aggressive phenotype.

TITLE: Differences in Serious Difficulty Seeing and Utilization of Eye Exams by Sexual Orientation (2016-2020)

SESSION TITLE: Public Health II

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: K.D. Frick, Carey Business School, Johns Hopkins University, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Kevin Frick: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Challenges with access to some types of health care that result in health differences have been documented for individuals with sexual orientation other than straight. There is little evidence as to whether these occur in eye care and translate into vision impairment.

Methods: Data from the Behavioral Risk Factor Surveillance System (BRFSS) from 2016-2019 and the National Health Interview Survey (NHIS) from 2016-2020 were used. Both surveys employ complex sampling. Analyses accounting for study design were conducted using R. In both studies sexual orientation was coded to compare those who responded straight with lesbian or gay, bisexual, or other. Only BRFSS data from Virginia and Wisconsin were used; these states included the sexual orientation and diabetes modules (including the eye exam question) each year. Respondents were asked "Are you blind or do you have serious difficulty seeing, even with glasses?" Individuals who reported diabetes were grouped into having had an eye exam in the past year and having had one longer ago or never. For vision, in the NHIS, respondents were grouped into those who indicated no trouble or a little trouble seeing even when wearing glasses and those who indicated a lot of trouble or cannot see even with glasses. Accounting for survey design, the association between sexual orientation and outcomes of interest was assessed using chi-squared tests.

Results: In Virginia (Wisconsin), among individuals indicating straight sexual orientation the prevalence of receiving an eye exam in the past year ranged from 72.2-73.8% (71.0-79.7%); these ranged from 11.5% less likely to 23.1% more likely (14.4% less likely to 8.3% more likely) than those of other sexual orientations. In Virginia (Wisconsin) among individuals indicating a straight sexual orientation, prevalence of serious difficulty seeing ranged from 3.9-4.4% (2.3-3.1%), with differences ranging from 0.1% more to 2.7% less (1.4% to 3.2% less) than those of other sexual orientation. In the NHIS, the prevalence of a lot of trouble seeing for those who indicated straight sexual orientation ranged from 1.2-1.7% and the prevalence ranged from 0.1-1.0% less than that for individuals of other sexual orientation. No p-value was ≤0.05.

Conclusions: There is no association between sexual orientation and use of timely eye exams among those with diabetes or the prevalence of serious difficulty seeing.

TITLE: Compensatory phagocytic function and Müller glia reactivity in the absence of microglia

SESSION TITLE: Novel animal models and neuroprotection in the retina

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: W. Thiel, Z.I. Blume, D. Mitchell, Biological Sciences, University of Idaho, Moscow, Idaho, UNITED STATES|

Commercial Relationships Disclosure: Whitney Thiel: Commercial Relationship: Code N (No Commercial Relationship) | Zachary Blume: Commercial Relationship: Code N (No Commercial Relationship) | Diana Mitchell: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Models of microglia deficiency are used to probe their functions in the retina. In these microglia-deficient tissues, phagocytosis may be compensated by other glial cell types. We found Müller glia (MG) increase phagocytic load in microglia deficient retinas (Mitchell et al. IOVS 2021). We further use a microglia-deficient genetic zebrafish mutant to investigate MG phagocytic activity and determine downstream effects on MG. We hypothesized increased phagocytic load leads to MG reactivity.

Methods: Developing whole eyes and retinal cryosections from microglia-deficient and sufficient siblings were analyzed. We used confocal microscopy to visualize apoptotic cells (TUNEL), MG, and lysosomes (LAMP1). We visualized apoptotic cell engulfment in live, transient transgenic zebrafish expressing TP1:mcherry-CAAX stained with acridine orange and 3D image rendering (n=4). To see if phagocytosis induced apoptosis in MG, we correlated phagocytosis to MG cell death using cleaved caspase 3 staining (n=8-20/group). To examine MG reactivity, we measured gfap transcripts in individual pairs of eyes by qPCR (n=10-20/group), and GFAP intensity from stained retinal cryosections (n=3-4). To inhibit MG phagocytosis, we used L-SOP treatment (n=8-20/group). We used a transgenic reporter to quantify reactive MG (gfap:nGFP, Bernardos et al., 2007; n=5-8). To examine possible cell cycle re-entry by post-mitotic MG, we used EdU immersion and quantified EdU+MG (n=8-9/group). We also examined id2a and ascl1a transcripts in eyes using qPCR (n=5-9 & n=9-19/group, respectively).

Results: MG increase their phagocytic load to engulf dying cells in the absence of microglia, from ~15% in wt to ~50% TUNEL+ cell engulfment in mutants ($p<0.0001$). LAMP1 staining of MG increased in the absence of microglia. Correlation analysis of engulfment to MG cell death is ongoing. Increased expression of gfap in microglia-deficient eyes ($p=0.01$) was detected but lost after L-SOP treatment. In the absence of microglia, we found increased gfap:nGFP+ MG compared to wt siblings ($p=0.007$). We detected no increased incorporation of EdU by MG in the absence of microglia, or differences in expression of id2a or ascl1a.

Conclusions: MG compensate phagocytic function in the absence of microglia, leading to signs of MG reactivity. However, increased MG phagocytic activity alone does not trigger cell cycle re-entry of differentiated MG in the absence of tissue damage.

ABSTRACT BODY:

Purpose: Retinal degenerative diseases, such as retinitis pigmentosa (RP), have complex genetic causes but are characterized by the loss of the photoreceptor neurons. For the majority of these diseases, treatment is unavailable. Previously, we found that cellular metabolic pathways were disrupted in the neural retina at RP disease onset in an autosomal recessive (ar) preclinical mouse model, and that replenishing TCA cycle intermediates provided resilience to the photoreceptors against cell death and delayed vision loss in both the arRP and an autosomal dominant (ad) RP preclinical model. Investigation into the duration of photoreceptor resilience and the mechanism underlying the supplementation effect will provide insight into potential treatment targets for patients with RP disease, regardless of the causal genetic mutation.

Methods: The $Rho^{P23H/+}$ adRP preclinical mouse model was treated orally with single TCA cycle intermediates (alpha-ketoglutarate, succinate, and citrate) and followed via live imaging and histological analysis through 7 months of age. Additionally, as cells with high metabolic demand and mitochondrial dysfunction have been shown to favor reductive carboxylation to increase lipid metabolism, we profiled hundreds of individual lipids via mass spectrometry analysis from neural retinas of wild-type, arRP, and arRP mice treated with TCA cycle intermediates (alpha-ketoglutarate and citrate).

Results: We found that replenishment of TCA cycle intermediates in the adRP preclinical mouse model was able to prolong visual function and provide resilience to the photoreceptor neurons against cell death through at least 7 months of age. Furthermore, we detected an altered lipid profile in the neural retinas of mice with RP disease compared to healthy controls, and that supplementation with TCA cycle intermediates restored many of the lipid pathways in the neural retina to levels seen in wild-type controls.

Conclusions: Enhancement of TCA cycle activity toward altering lipid metabolism provides resilience to the photoreceptor cells against cell death and prolongs visual function in preclinical models of RP, regardless of the causal genetic mutation. Understanding this balance of photoreceptor cell metabolism and its dysregulation during disease can lead to more effective clinical treatments for patients with RP and other forms of retinal degenerative disease.

ABSTRACT BODY:

Purpose: The purpose of this study is to develop a novel culture system capable of providing tightly controlled uniaxial flow to cells cultured on the bottom of a transwell insert to replicate the mechanical stresses applied to choroidal endothelial cells in vivo. In addition to providing a platform capable of elucidating the connection between applied fluidic shear with the molecular and morphological maturity of endothelial cells, by placing patient-matched iPSC-derived retinal pigment epithelium (RPE) and fully differentiated iPSC-derived neural retina on top of the transwell, this system will constitute an in vitro model of the outer human retina.

Methods: Our disposable, single use transwell perfusion system was printed using an Object30 Prime 3D printer (Stratasys). After printing the device, cells from a human choroidal endothelial cell line were seeded on transwell inserts, after which the culture system was assembled by placing the transwell inserts into the device, which in turn was placed in a six well plate. A peristaltic pump was then used to provide controlled fluid flow across the seeded endothelial cells. After the conclusion of a perfusion experiment, the transwell membrane can be recovered from the system, allowing observation of cell morphology via microscopy as well as analysis of the molecular characteristics of the perfused cells.

Results: As per Figure 1, the perfusion device was designed with rectangular flow channels to induce uniaxial flow. Cells perfused using this system remained viable for 72 hours post-perfusion (417µl/hour) and remained attached to the surface of the transwell insert following removal from the perfusion device. Now that we have established that the system can apply controllable fluidic shear stress for days while keeping perfused cells viable, we will proceed to investigate the effect of increasing rates of shear stress on the morphological, molecular, and functional maturity of choroidal endothelial cells with and without RPE plated above.

Conclusions: We have used modern rapid-prototyping techniques to develop a perfusion system capable of testing the effect of fluidic shear on the phenotype and behavior of choroidal endothelial cells in vitro. Further, we believe that this system can be extended to serve as an in vitro model of the entire retina and used to determine the causes of and evaluate treatments for inherited blindness.

ABSTRACT BODY:

Purpose: Despite increasing numbers of women entering the field of ophthalmology, many subspecialties still lack gender parity among their society membership, and significant disparities persist among leadership positions and in the upper ranks of academia. We aim to evaluate male and female representation as members, awardees, executive committee members, and presidents of the American Association for Pediatric Ophthalmology and Strabismus (AAPOS) to understand recent trends in gender diversity within pediatric ophthalmology.

Methods: A retrospective, longitudinal study using publicly available data from AAPOS online archives and member directories from 2000 – 2020. Primary outcomes included percentage of women as new members, award winners, and leadership positions (executive committee, president). Secondary outcomes included total membership and the proportional representation of men and women, calculated by dividing the number of men and women at a given benchmark by the total number of men and women in the organization.

Results: Over the past two decades, AAPOS achieved total membership parity with 52.0% women and 48.0% men, $p=0.087$ (Figure 1). Furthermore, AAPOS demonstrated significant growth in the representation of women as new members (50.1% to 59.8%, $p=0.001$) and in the percent of female award winners between the two decades (23.1% to 39.9%, $p=0.005$), but no significant difference in the percent of female executive committee members or presidents (Table 1). Moreover, the proportion of women who won awards by 2020 was significantly less than that of male awardees (8.6% vs. 19.3%, $p<0.001$), and the proportion of female executive committee members was less than that of men holding such roles (7.7% vs. 15.4%, $p=0.004$). There was no significant difference between the proportion of men and women as presidents (0.6% vs. 1.6%, $p=0.070$) (Figure 1).

Conclusions: AAPOS has demonstrated significant growth in female membership and award recognition over the last 20 years; however, gaps still exist between men and women as award winners and executive committee members. This phenomenon demonstrates that the “wait and watch” approach to diversity is not sufficient to achieve gender parity at all levels of an organization. Targeted interventions such as addressing implicit bias, amending promotion criteria to recognize more varied achievements, and diverse nomination slates are needed to close this gender gap.

ABSTRACT BODY:

Purpose: To evaluate the visual field (VF) measurement repeatability using a portable VF quantification tool for both monocular and simultaneous binocular measurements.

Methods: In a previous work, we designed and implemented a virtual reality head mounted display (VRHMD) to measure VF. The measurement covered the central 80 degrees diameter area, in both monocular and binocular testing modes. In this study, we examined the repeatability of our devices VF measurements by repeating the VF test two times in two different groups of patients. The first group included 10 patients (10 eyes) with known monocular VF losses. We compared the VRHMD VF monocular testing outcomes with the standard of care: standard automated perimetric (SAP), which we used as the reference measurement. In the second group, another 10 patients (20 eyes) with binocular glaucomatous and neurological VF losses, participants were VF tested binocularly (simultaneous VF measurement for the two eyes). Binocular test outcomes were compared with the integrated monocular SAP tests for both eyes of the participants. We compared the VRHMD VF and SAP VF reproducibility tests qualitatively using paired VF images, and quantitatively with Intraclass correlation coefficient statistical metric.

Results: The VRHMD VF outcomes were qualitatively comparable to their matching references in the monocular and binocular groups of patients, as visual results show. The VRHMD VF quantitative repeatability metric for repeated testing with the ICC metric was found to be significant in the two groups (0.83 for the first test monocular group, 0.73 for the second binocular testing group) indicating excellent agreement for VRHMD monocular measurements and good agreement for the binocular measurements, respectively.

Conclusions: Monocular and binocular VRHMD VF measurements were found to be repeatable and statistically reproducible.

TITLE: Effect of Low Dose Atropine Eye Drops on Ocular Structure and Function

SESSION TITLE: Myopia: Clinical Interventions and Diagnostics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Liang, A. Jnawali, S. Curtin, F.A. Vera-Diaz, New England College of Optometry, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Courtney Liang: Commercial Relationship: Code N (No Commercial Relationship) | Ashutosh Jnawali: Commercial Relationship: Code N (No Commercial Relationship) | Sarah Curtin: Commercial Relationship: Code N (No Commercial Relationship) | Fuensanta Vera-Diaz: Commercial Relationship(s);Code C (Consultant/Contractor):Essilor International

ABSTRACT BODY:

Purpose: Myopia is associated with abnormal scleral constitution and remodeling. We investigated the effect of low dose atropine eye drops on scleral thickness and pressure to evaluate ocular rigidity, and other visual parameters in emmetropes and myopes.

Methods: Young adults (N=19, 24.4±1.2yrs) with emmetropia (SE +0.4±0.3D) or myopia (SE -2.4±1.7D) were enrolled. Lenstar LS900 was used to measure axial length (AXL), corneal thickness (CCT), anterior chamber depth (ACD) and lens thickness (LT); Spectralis SD-OCT anterior segment module to evaluate anterior scleral thickness, and wide-field posterior module to evaluate retinal and choroidal thickness. IOP was measured with GAT and iCare in the central cornea and with iCare at four scleral locations: 4mm nasal, 4mm temporal, 5mm superior and 5mm inferior from the limbus. Other tests included pupil sizes under dim, bright and near conditions, dynamic retinoscopy (MEM) and contrast sensitivity (CS, Rubin). Subjects used 1 drop of 0.05% atropine in each eye every night for 7 days. All measurements were taken: twice during Visit-1 (before and 30mins after instillation of atropine), and once during Visit-2 (1 week later, at a similar time: ±2 hours).

Results: Pupils became significantly larger after instillation of atropine (Dim: 1.5±0.7mm, Near: 2.1±0.7mm, Bright: 2.2±0.8mm, $p<0.01$ all). Accommodation lags increased (0.4±0.7D, $p=0.05$) and CS decreased (-0.2±0.3LogCS,$p=0.02$) in Visit-2. Corneal IOP decreased (1.6±2.7mmHg, $p=0.02$), but scleral IOPs significantly increased at 5mm superior (7.2±2.7mmHg, $p=0.04$) and 4mm temporal (3.6±2.7mmHg, $p=0.04$) in Visit-2. ACD was deeper in Visit-2 (0.1±0.1mm, $p=0.02$), and a trend was noted for longer AXL, thicker CCT and thinner LT. Those subjects for whom temporal sclera thickened with atropine, tended to also have higher IOPs temporally ($R=0.4$, $p=0.06$). No significant effect of atropine on retinal or choroid thickness was noted for any eccentricity.

Conclusions: Although short-term use of 0.05% atropine eye drops significantly increased pupil sizes, more variability was noted on accommodation and other visual parameters. Corneal IOP significantly decreased after 1 week use of atropine, whereas superior and temporal scleral IOP increased. Higher IOP in anterior sclera and trend for thickening in the same area with atropine use may be associated with the mechanism of atropine in myopia management.

ABSTRACT BODY:

Purpose: Various vision-related ailments including age-related macular degeneration (AMD) and central serous chorioretinopathy (CSCR) are caused due to the dysfunctions manifested in the highly vascular choroid layer of the posterior segment of the eye. Accurate detection of choroidal structural changes plays a crucial role in disease diagnosis. Optical Coherence Tomography (OCT) imaging enabled clinicians to visualize choroid layer. Consequently, many methods have been developed to assist clinicians in diagnosis. However, the performance of these algorithms is largely constrained by the quality of the OCT scan. This study aims to achieve automated quality assessment of choroidal features (CQA) in OCT scans. We examine deep learning architectures to discriminate between good and bad quality OCT scans and also generate corresponding visual explanations via Grad-CAM.

Methods: A retrospective dataset of 1094 healthy and 3080 diseased OCT B-scans taken from Heidelberg Retina Angiography (HRA) Spectralis OCT machine was used in this experiment. The images were graded subjectively into two classes `good' and `bad' by a trained expert (K. Ozimba) based on various parameters including visibility of the choroid, the contrast between choroidal luminal (vessel) and stromal regions, contrast between the choroid and sclera, especially at choroid sclera interface. Inspired by the efficacy of deep learning features in image quality assessment, we employed variants of two ubiquitous architectures: residual networks (ResNets) and EfficientNet. We evaluated the model performance via stratified 5-fold cross-validation and demonstrated the model's discriminative ability through visual explanations generated by Grad-CAM.

Results: The average accuracy over 5-folds was found to be 97.69%, 96.99%, and 97.92%, respectively, for ResNet18, EfficientNet B0, and EfficientNet B3. Grad-CAM-generated visual explanations on representative images also demonstrate the superiority of EfficientNet B3 over the other models.

Conclusions: We have demonstrated the efficacy of transfer learning in CQA-OCT images by deploying and comparing the performance of state-of-the-art deep learning models, namely, ResNet18 and EfficientNet (B0 & B3). Further, we have also provided explainable visual feedback using Grad-CAM that corroborates closely with clinicians.

ABSTRACT BODY:

Purpose: Caffeine is a readily available and regularly used neurostimulant with effects on systemic vasculature. There is limited data on the effects on retinal vasculature with some reports indicating vessel constriction. We aim to evaluate if caffeine alters the macular vascular density of the superficial capillary plexus (SCP) on optical coherence tomography angiography (OCTA).

Methods: This IRB-approved study prospectively recruited healthy, low caffeine users who consumed, on average, less than 136 mg of caffeine daily. We analyzed 22 eyes from 11 individuals between the ages of 18 and 40, with no preexisting ocular conditions. Baseline 3x3mm and 6x6mm OCTA scans centered on the fovea as well as 6x6mm scans centered on the optic nerve head (ONH) were obtained. Participants were then given a 200mg caffeine pill. Scans were repeated at 60 and 120 minutes after caffeine administration. All images were analyzed with the Advanced Retina Imaging (ARI) network software (Carl Zeiss Meditec, Dublin, CA) superficial perfusion density algorithm for vascular density (VD) defined as the total area of perfused vasculature in a region of measurement. Ordinary one-way ANOVA of each group was performed using GraphPad Prism Version 9.3.0.

Results: Mean age was 24.6 +/- 4.6 years and 82.2% were females. For the 3x3 mm scans, the VD was 31.55%, 31.57%, and 32.06% at baseline, 60, and 120 minutes respectively (p=0.9993 and p=0.7933). For the 6x6 mm scans, the VD was 38.16%, 39.09%, and 39.04% at baseline, 60, and 120 minutes respectively (p=0.7300 and p=0.7546). For the ONH scans, the VD was 41.06%, 39.74%, and 41.44% at baseline, 60, and 120 minutes respectively (p=0.5649 and p=0.9498).

Conclusions: Our results indicate no change in the SCP vessel density after 200 mg caffeine. Larger placebo-controlled studies are needed to confirm this finding.

Galang: Commercial Relationship: Code N (No Commercial Relationship) | Fritz Gerald Kalaw: Commercial Relationship: Code N (No Commercial Relationship) | Anna Heinke: Commercial Relationship: Code N (No Commercial Relationship) | Dirk-Uwe Bartsch: Commercial Relationship: Code N (No Commercial Relationship) | Lingyun Cheng: Commercial Relationship: Code N (No Commercial Relationship) | William Freeman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Controversy exists regarding the therapeutic use of concomitant intravitreal steroids with anti-VEGF (inhibitory vascular endothelial growth factor) in choroidal neovascularization (CNV) resistant to mainstay treatment. We performed a retrospective observational clinical study in a consecutive cohort of patients' eyes with persistent CNV anatomically unresponsive to aggressive high-dose high-frequency (HDHF) monotherapy (i.e.: monthly 4 mg aflibercept). We evaluated anatomic and visual changes proceeding a simultaneous intervention in a long-cohort designed to study the therapeutic safety and efficacy of adjuvant steroids with anti-VEGF in resistant chronic Wet-Age Related Macular Degeneration (Wet-AMD).

Methods: A total of 12 eyes with unresponsive CNV despite treatment with alternating anti-VEGF agents (mean: 43.75±SD23.08) was studied. Resistance was considered persistent retinal fluid following HDHF treatment. Combination consisted in the simultaneous administration of anti-VEGF and steroids followed by 2 weeks of prophylactic topical antiglaucoma medication (Timolol 0.5%/Dorzolamide 2%). Slit-lamp, Visual Acuity (BCVA), Intraocular-pressure (IOP), and Optical Coherence Tomography (Heidelberg Spectralis HRA+Spectral Domain (Heidelberg Engineering, Heidelberg, Germany)) measurements of central retinal thickness (CRT) were recorded every 4 weeks for 4 consecutive months. Baseline predictors relating treatment efficacy were evaluated. Outcomes included changes in BCVA, IOP, and reduction in CRT.

Results: Initial analysis showed no safety data complications. Anatomic outcomes were statistically significant evincing a reduction in CRT ($p<0.0001$) compared to baseline; paired analysis showed an average CRT reduction of 50.90 µm ($p<0.05$) at 1 month, 76.5 µm ($p=0.0336$) at 2 months, and 86.33 µm ($p=0.0340$) at month 3. Association between CNV types and CRT reduction was significant (least-square means: type 1=-81.77, type 2=42.49, RAP/type 3=137.71, $p=0.022$).

Conclusions: We found combination of steroids and anti-VEGF produces clear anatomic improvement in recalcitrant CNV. Although other studies evidenced visual and anatomic changes consequent of combination, these were not in chronic monotherapy resistant eyes. In such eyes, we found overall disease improvement. Therefore, combination therapy may be useful in treating resistant Wet-AMD.

TITLE: Predicting future falls for glaucoma patients based on retrospectively vs. prospectively-collected fall and near fall data from prior years

SESSION TITLE: Mobility, Reading and Driving with Vision Impairment

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Kakani, G. Xiao, A. Mihailovic, P.Y. Ramulu, Wilmer Eye Institute/Glaucoma, Johns Hopkins University, Baltimore, Maryland, UNITED STATES|

Commercial Relationships Disclosure: Tejasvi Kakani: Commercial Relationship: Code N (No Commercial Relationship) | Grace Xiao: Commercial Relationship: Code N (No Commercial Relationship) | Aleksandra Mihailovic: Commercial Relationship: Code N (No Commercial Relationship) | Pradeep Ramulu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To investigate the association between prospectively recorded and retrospectively self-reported fall data with the likelihood of subsequent falls in a cohort of glaucoma patients.

Methods: Participants recorded falls and near falls prospectively daily over a 2-year period. In addition, at the baseline visit participants were asked if they experienced a fall in the year prior to study baseline. Based on these data participants had their faller/near faller status classified for every study year. Logistic regressions were applied to assess whether self-reported falls or prospectively-evaluated falls/near falls over the prior year were associated with falls in the subsequent year. Models controlled for age, gender, race, degree of visual filed (VF) loss, comorbidities and polypharmacy. Models also included interaction between the VF severity and faller/near faller status in the prior year to examine if prediction of a fall in the subsequent year differed by the level of VF severity.

Results: 244 glaucoma patients were included in this study. Average participant age was 71 years (SD=7.6), about half were female and third were Black. Self-report of a fall in the year preceding the study baseline did not predict falls in the first study year. Those who fell in the first year of the study were 2.4 times (Odds Ratio (OR)=2.41, p=0.003) more likely to report a fall in the second year as compared to those who did not fall in the first study year. In addition, near falls in the first year of the study were associated with higher odds of falls in both the first (concurrent) study year (OR=3.49, p<0.001) and the subsequent second year (OR=3.14, p<0.001). However, individuals with more severe VF loss were not disproportionately more likely to fall in subsequent years if they experienced fall or near falls in prior years.

Conclusions: Prospectively recorded falls and near falls for glaucoma patients are predictive of falls in subsequent years, while self-reported falls based on memory do not predict falls in the subsequent years. This highlights the importance of prospective collection of fall data to accurately judge the association of visual impairment and/or fall prevention strategies with fall rates.

TITLE: Immunohistochemical analysis of RPE cell viability atop drusen in enucleation and evisceration specimens

SESSION TITLE: RPE/choroid pathology: oxidative stress, inflammation and neovascularization

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Youhnovska, A.A. Goyeneche, E.B. Nassrallah, S. Bergeron, A.S. Dias, M.N. Burnier, MUHC – McGill University Ocular Pathology & Translational Research Laboratory, McGill University Faculty of Medicine and Health Sciences, Montreal, Quebec, CANADA|

Commercial Relationships Disclosure: Emma Youhnovska: Commercial Relationship: Code N (No Commercial Relationship) | Alicia Goyeneche: Commercial Relationship: Code N (No Commercial Relationship) | Emmanuel Issa Nassrallah: Commercial Relationship: Code N (No Commercial Relationship) | Sabrina Bergeron: Commercial Relationship: Code N (No Commercial Relationship) | Anelise Dias: Commercial Relationship: Code N (No Commercial Relationship) | Miguel Burnier: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Drusen are lipoproteinaceous deposits found between the retinal pigmented epithelium (RPE) and Bruch's membrane. Soft drusen are amorphous, granular, large (>125) and are associated with age-related macular degeneration leading to vision loss. As drusen grow, they disrupt the RPE by pushing against the cells. The aim of this study is to evaluate RPE viability atop drusen in histopathological sections obtained from enucleated and eviscerated eyes.

Methods: A total of 158 eyes were obtained from the MUHC-McGill University Ocular Pathology and Translational Laboratory, Montreal, Canada (2013-2019); 79 were enucleated (50%) and 79 eviscerated (50%). The eyes were embedded in paraffin and histopathological sections were obtained. Initial studies were done to identify the eyes with drusen. These were stained using an immunohistochemical panel aimed at RPE identification and viability assessment. The panel includes HMB-45, MelanA (melanocyte markers) and Cytokeratin 8/18 (CK8/18) (epithelial cell marker) for RPE identification. It also includes the polyclonal cytoplasmic stain Ki-67 (Cell proliferation marker), and monoclonal intranuclear stains p53 (cell damage marker), p21 (cell cycle arrest marker), caspase-3 (apoptosis marker), and lipofuscin for viability. Histopathological analysis was done in scanned sections (Zeiss AxioScan.Z1) in eyes with drusen. RPE atop the drusen were compared to normal RPE cells surrounding it.

Results: Histopathological analysis was performed. The prevalence of drusen was comparable in enucleated (45.6%) and eviscerated (48.1%) eyes and increased with age. Of the 158 eyes, 53 (33.7%) were found to have soft drusen of which we studied 20 (10 enucleated; 10 eviscerated). The cells atop the drusen expressed positivity for CK 8/18 and HMB-45 but were negative for MelanA. Similar results were observed in the undisturbed RPE. As for viability, the intranuclear and cytoplasmic stain positivity reflected the degree of damage to the RPE above the drusen in concordance with the presence of lipofuscin.

Conclusions: The histopathological study of drusen and RPE is possible in enucleation and evisceration patient samples. Our immunohistochemical panel identified the cells overlying drusen as RPE cells. Damage to the RPE overlying drusen was quantified and qualified by intranuclear and cytoplasmic stain positivity and compared to the state of the undisturbed RPE.

ABSTRACT BODY:

Purpose: It has been reported that the rate of asymptomatic magnetic resonance imaging (MRI) optic nerve enhancement is as high as 51% in neuromyelitis optica; however, this has yet to be investigated in patients with myelin oligodendrocyte glycoprotein antibody associated disease (MOGAD). We performed a multicenter retrospective study to determine the frequency of asymptomatic optic nerve enhancement in MOGAD patients.

Methods: This was a multicenter retrospective study of MRI's of patients with MOGAD. Study inclusion included positive serum MOG-IgG by a cell-based assay, MOGAD phenotype, and availability of post contrast orbital MRI sequences. The MRI studies were reviewed by a blinded, expert neuroradiologist. Medical records were reviewed for demographic information, details of ON attacks, and outcomes. Scans performed within 30 days of ON attack were classified as attack scans. Images obtained prior to ON attack or at time of non-ON attack were classified as inter-attack scans.

Results: 172 MRIs and 102 sequences (21 unique patients, 48% female) met study inclusion. Inter-attack MRIs represented 59% (60/102) of sequences (median 105 days post ON, range 35-1897). Of the inter-attack scans, 22% (13/60) of scans or 6 unique patients, showed optic nerve enhancement. This enhancement was located at prior sites of ON in 71% (10/13) of scans. Three patients showed enhancement without obvious clinical symptoms of ON, but two had ADEM without an eye examination at that time of the MRI, and one had a preceding MRI without enhancement, but did have a prior MRI with enhancement in that area. Long term visual outcomes were not significantly different between patients with asymptomatic enhancement and those without, with most patients in both groups improving to 20/20.

Conclusions: Asymptomatic optic nerve enhancement occurred in 22% of inter-attack MRIs, the majority in patients with evidence of prior optic neuritis and occurring at prior sites of ON attack. New asymptomatic optic nerve enhancement in areas without prior optic neuritis was rare. These findings are important for understanding the natural history of MOGAD, the interpretation of symptoms or response to treatment, and the adjudication of attacks in upcoming MOGAD clinical trials.

TITLE: Special spectacle lenses for driving and their spectral effects

SESSION TITLE: Fundamental and Applied Psychophysics and Color Vision

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Hartwig, Hartwig Research Center, Heikendorf, GERMANY|A. Hartwig, Aston University, Birmingham, Birmingham, UNITED KINGDOM|

Commercial Relationships Disclosure: Andreas Hartwig: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Spectacle lenses for improvement of vision during night time driving have been introduced to the market a few years ago. The main purpose of those lenses is to reduce glare. Three options to achieve a reduction of glare are currently used: spectral manipulation especially of shorter wavelengths, purpose-adapted anti reflexion coatings or a combination of the afore mentioned approaches.

To enhance the knowledge, how driving lenses achieve their purpose, the spectral irradiance was compared.

Methods: Four spectacle lenses for driving (refractive power of 0 D, refractive index 1.6) were evaluated (DriveSave, Zeiss, Germany; EnRoute PRO, Hoya, Japan; Formula Drive, Optovision, Germany and Streetlife, Essilor, France). A plano standard lens (refractive index 1.6) was measured as control. The spectral irradiance, within the wavelength range of 380 to 780 nm (step size = 5 nm), was measured using the Mavospec Base spectrometer (Gossen, Germany). The measurements were performed for three different conditions: a filament bulb, a white LED (peak at 455 nm) and a blue LED (peak at 410 nm) in a dark environment.

Results: From the spectrograms it is visible that manufacturers use different approaches to reduce glare whilst driving.

For the filament bulb condition, no significant change of the spectral irradiance was observed for the DriveSave and Streetlife lenses. The EnRoute and Formluar Drive lenses appear as edge filters and start transmittance from 420 nm onwards. The standard lens appears similar, but transmittance starts at 410 nm.

For the white LED condition, no significant change of the spectral irradiance was observed throughout all lenses, except a reduction of the blue peak by about 5 mW/m^2 for the DriveSafe, EnRoute and Formula Drive lenses.

For the blue LED condition, the blue peak was reduced by 82 mW/m^2 by the Streetlife lens. The DriveSafe and standard lenses reduce the peak by 276 mW/m^2 and 455 mW/m^2, respectively. The EnRoute and Formula Drive lenses, however, nearly eliminate the blue peak (2,24 mW/m^2 and 7,95 mW/m^2, respectively).

Conclusions: From the spectrograms of different lenses under different illumination conditions it is evident that various approaches are used to reduce glare whilst driving. As different approaches exist, it is important during patient consultations to test various lenses for driving and allow the patient to choose the lenses, which shows the best effect for each individual.

TITLE: Disheveled interacts with claudin-5 and contributes to norrin-induced BRB restoration.

SESSION TITLE: Biochemistry and Molecular Biology of the Retina/RPE

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Diaz Coranguez, D.A. Antonetti, Ophthalmology and Visual Sciences, University of Michigan, Ann Arbor, Michigan, UNITED STATES|

Commercial Relationships Disclosure: Monica Diaz Coranguez: Commercial Relationship: Code N (No Commercial Relationship) | David Antonetti: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Previous studies reveal that norrin reverses VEGF-induced permeability in a β-catenin dependent pathway. Here, we explored the contribution of disheveled-1 (Dvl1) in norrin-induced blood-retinal barrier (BRB) restoration. We hypothesized that Dvl1 promotes tight junction (TJ) stabilization through both canonical and non-canonical signaling pathways.

Methods: BRB properties in primary bovine retinal endothelial cells (BREC) were determined by measurements of transendothelial electrical resistence (TEER) or solute flux of 70kDa RITC-dextran. The knockdown of Dvl1 using siRNAs was confirmed by qRT-PCR and Axin2 mRNA content was used as a measure of β-catenin signaling activity. Dvl1 localization at the TJ was observed by immunofluorescence confocal microscopy and the interaction between Dvl1 and claudin-5 or ZO-1, was analyzed by co-immunoprecipitation assays in BREC or in HEK293 cells co-transfected with Dvl1 mutants and claudin-5 or ZO-1.

Results: Analysis of BRB properties in BREC demonstrated that norrin was able to completely restore TEER after VEGF. The knockdown of Dvl1 using siRNAs specifically reduced basal barrier properties and ablated norrin-induced barrier restoration, despite increased b-catenin signaling in knockdown samples. Similar results were found in flux assays of a 70 kDa RITC-dextran molecule, suggesting that Dvl1 is required for norrin-induced BRB restoration. Dvl immunofluorescence staining showed co-localization of Dvl1 with ZO-1 and claudin-5 at the TJ complex. Dvl1 and TJ proteins interaction analysis by co-immunoprecipitation of endogenous protein in BREC, demonstrated that Dvl1 interacts with both claudin-5 and ZO-1 and this interaction was most abundant in the presence of VEGF/norrin co-stimulation. Studies in HEK293 cells co-transfected with Dvl1 mutants and claudin-5 or ZO-1, reveal a requirement of the Dvl1 PDZ domain for this interaction. Transfection of the C-terminal fragment of Dvl1, containing the PDZ binding motif but not the DIX, PDZ or DEP domains, blocked Dvl1/claudin-5 interaction, increased basal permeability and prevented norrin-induced BRB restoration.

Conclusions: Together, these results demonstrate that norrin signals though Dvl1 to stimulate barrier properties and suggest a non-canonical signaling role of Dvl1 in regulation of barrier properties through direct binding to claudin-5 and ZO-1.

TITLE: Elovl4b Ablation in Zebrafish Leads to Loss of Ocular C30 to C34 Very-Long-Chain Polyunsaturated Fatty Acids

SESSION TITLE: Retinal metabolism and physiology

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: U. Nwagbo, P.S. Bernstein, Pharmacology & Toxicology, University of Utah Health, Salt Lake City, Utah, UNITED STATES|U. Nwagbo, P.S. Bernstein, Ophthalmology, University of Utah Health, Salt Lake City, Utah, UNITED STATES|

Commercial Relationships Disclosure: Uzoamaka Nwagbo: Commercial Relationship: Code N (No Commercial Relationship) | Paul Bernstein: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Very-long-chain polyunsaturated fatty acids (VLC-PUFAs) are a distinct class of lipids with chain lengths greater than 24 carbons found in the retina and a few other tissues in vertebrates. ELOVL4 is a member of the ELOVL elongase family responsible for the rate-limiting step of VLC-PUFA biosynthesis. Patients with autosomal dominant Stargardt-3 disease, a juvenile form of macular degeneration, have genetic mutations in ELOVL4 leading to the formation of a non-catalytically active protein and loss of retinal VLC-PUFAs. Interestingly, low retinal VLC-PUFAs are also characteristic of age-related macular degeneration. Moreover, retinas isolated from patients with age-related macular degeneration are reported to have low omega-3 (n-3) to omega-6 (n-6) fatty acid ratios compared to healthy controls.

The retinal pathology caused by VLC-PUFA depletion has historically been difficult to study because homozygous Elovl4 mutations cause skin and neurological disorders in humans and neonatal lethality in mice. Mice with homozygous Elovl4 mutations are susceptible to catastrophic drying from losing their protective skin barrier. Thus, we created and examined a zebrafish model of Elovl4 deficiency and haploinsufficiency.

Methods: We created a deletion mutation in exon 2 of the Elovl4b gene using CRISPR-Cas9. F0 mosaic mutant zebrafish were screened and outcrossed with wild-type fish over two generations to generate a stable line. At ~4 months post-fertilization, their eyes were isolated, total fatty acids extracted, and the quantity of n-3 and n-6 VLC-PUFAs was determined through gas chromatography and mass spectrometry.

Results: We found that homozygous Elovl4b mutant zebrafish eyes had no detectable C30 to C34 VLC-PUFAs in their eyes, in contrast to age-matched wild-type controls. Heterozygous fish with one functional copy of Elovl4b had intermediate lipid profiles.

Conclusions: Our data indicate that the loss of Elovl4b in zebrafish alters ocular biochemistry in a way that is comparable to macular degeneration. We expect diminished ERG amplitudes and visual function in the homozygous and heterozygous fish and altered retinal histology. We plan to correct such abnormalities by feeding synthetic VLC-PUFAs.

TITLE: Disability Glare Quantified Rapidly with AIM (Angular Indication Measurement) Glare Acuity

SESSION TITLE: Visual Function: perception, adaptation, spatial, visual acuity and binocular vision

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: J. Skerswetat, A. Boruta, P.J. Bex, Psychology, Northeastern University, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Jan Skerswetat: Commercial Relationship(s);Code I (Personal Financial Interest):PerZeption Inc.;Code P (Patent):Northeastern University, Boston | Anna Boruta: Commercial Relationship: Code N (No Commercial Relationship) | Peter Bex: Commercial Relationship(s);Code I (Personal Financial Interest):PerZeption Inc.;Code P (Patent):Northeastern University, Boston

ABSTRACT BODY:

Purpose: Disability glare is a consequence of straylight that causes discomfort and an objective perceptual deficit. The novel computer-based AIM Glare Acuity method was used to measure subjective and objective performance under standard and simulated straylight conditions.

Methods: AIM Acuity(Figure 1) entailed a sequence of 2 trials, each containing a 4*4 grid of 6° cells displayed on a 32” 4K monitor, using a gray background(3.4 cd/m2). Each cell contained a dark Landolt-type C surrounded by either a 0.1° thin dark(0.2 cd/m2; Baseline), 1° thick dark(Mask control), or 1° thick light(195 cd/m2; Glare) ring. Each C was randomly rotated and varied in size, spanning easy to difficult sizes. An adaptive algorithm updated the sizes in the 2nd trial based on the participant’s responses during trial 1. Participants indicated the location of each C’s gap via mouse click on the surrounding ring. The angle between the true and reported C orientation as a function of stimulus size that was fit with a cumulative gaussian function, from which ETDRS-equivalent acuity was also calculated(Figure 1). After each trial, participants indicated their subjective glare experience via continuous sliders, ranging from “No glare” to “Strong glare”. After 5 min dark adaptation, 18 normally-sighted participants(18 years median age) performed the task using their dominant eye without(control) or with a Bangerter 0.3 filter(simulated straylight condition) at 60cm distance. ANOVAs and planned comparisons determined effects between conditions.

Results: AIM Glare Acuity took 39sec(SD=17sec) to complete. Visual acuity was significantly lower with Glare rings for both control and simulated straylight conditions, but with a much stronger effect for the latter(Figure 2). No significant differences were found between Baseline and Mask dark rings for any condition. Subjective experiences of glare were significantly higher in glare than control ring conditions.

Conclusions: Visual acuity and subjective discomfort reports were significantly impaired by AIM Glare rings and the effects were amplified by stimulated straylight. Dark mask control rings did not affect acuity or discomfort, suggesting that performance was impaired by disability glare rather than contrast masking. AIM Glare Acuity may therefore be suitable to investigate disability glare in <40 sec in clinical populations, e.g. patients pre-/post- refractive or cataract surgery.

ABSTRACT BODY:

Purpose: ABCA4/Stargardt disease is the most prevalent Mendelian eye disorder, with over 1,500 causal variants reported in the ABCA4 locus. The vast clinical variability, ranging from early onset fast progressing cone-rod dystrophy to late-onset macular disease, is mostly explained by extensive heterogeneity in the ABCA4 locus, including several cis-modifier alleles. While comprehensively studied, the penetrance of several causal variants and variant combinations is still not completely understood. We hypothesized that variants in unlinked loci influence the ABCA4 disease penetrance and tested if variation in the PRPH2 gene – known to most often clinically phenocopy ABCA4 disease – may play a modifying role.

Methods: We performed exome sequencing in 622 confirmed and well characterized Stargardt/ABCA4 disease patients and compared variation in the PRPH2 gene to cohorts of ethnically matched controls and between genetically determined subgroups of ABCA4 disease.

Results: The frequent haplotype in the 3' end of PRPH2, including common variants c.910G>C (p.Glu304Gln), c.929A>G (p.Lys310Arg) and c.1013G>A (p.Gly338Asp), and tagged by the p.Asp338 variant with MAF=0.21 in the general population, was significantly increased in the patient cohort, MAF 0.25, p=0.0014. Significant differences were also observed between ABCA4 disease subgroups. In the late-onset subgroup, defined by the hypomorphic p.Asn1868Ile variant, the allele frequency for the PRPH2 p.Asp338 variant was 0.16 vs 0.26 in the remaining cohort, p=0.0065. Known functional data allows suggesting a mechanism by which the PRPH2 haplotype influences the ABCA4 disease penetrance. These associations were replicated in an independent cohort of 408 patients. The association was highly statistically significant in the combined cohorts of 1030 cases, p=4.00E-05 for all patients and p=0.00014 for the hypomorph subgroup.

Conclusions: We suggest that the common haplotype in PRPH2 gene plays substantial trans-modifying role in ABCA4 disease overall, and specifically in the disease subgroup defined by the hypomorphic p.Asn1868Ile allele.

TITLE: The application of collagen matrix to reverse hypotony following trabeculectomy with mitomycin C
SESSION TITLE: Surgery & Wound Healing
SESSION TYPE: Poster Session
AUTHORS/INSTITUTIONS: J. Safran, Thomas Jefferson University, Philadelphia, Pennsylvania, UNITED STATES|J. Wong, D. Lee, Wills Eye Hospital, Philadelphia, Pennsylvania, UNITED STATES|
Commercial Relationships Disclosure: Jordan Safran: Commercial Relationship: Code N (No Commercial Relationship) | Jae-Chiang Wong: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Lee: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To assess the role of collagen matrix in reversing ocular hypotony following trabeculectomy.
Methods: This retrospective cohort study included patients who required surgical revision due to hypotony following trabeculectomy from January 2019 to October 2021. Patients with at least 3 months of follow-up post-surgery were included. Demographic and clinical data were collected at the pre-operative and post-operative visits for up to 6 months. Post-operative complications were recorded at each visit.

Surgical Technique: The conjunctiva was horizontally incised approximately 8-mm posterior to the limbus. Conjunctiva and tenon were dissected anteriorly to the limbus. The collagen matrix was placed overlying the prior trabeculectomy site. The incision was closed using an 8-0 Vicryl suture in a running fashion. All surgeries were performed by a single surgeon (DL).
Results: Of the 18 patients identified, 11 eyes of 11 patients met inclusion criteria. Mean patient age was 71.3±7.5 years and mean follow-up duration was 110.8±78.6 days (range 22-247). Eight (73%) eyes had hypotony associated with an over-filtering bleb and three (27%) were associated with cystic bleb leaks. Four (36%) eyes had prior bleb revisions which included bleb needling (2) which led to over-filtration and conjunctival advancement (1) and thermocautery (1) for cystic bleb leak. 12x1mm implants were used in five (45%) eyes and 6x2mm implants were used in six (55%) eyes. Mean IOP at the pre-operative visit, and 1-day, 1-week, 1-month, 3-month, and 6-month postoperative visits were 3.3±2.1 (n=11), 6.6±4.7 (n=11), 7.8±3.2 (n=11), 8.5±4.0 (n=10), 7.6±2.5 (n=7), 11.0±6.5 (n=4) mmHg, respectively ($p<0.05$ at all time points). All three bleb leak patients were noted to be seidel negative by postoperative week 1. One patient required lamellar keratoplasty for persistent corneal edema, but no additional glaucoma surgeries or medications were indicated during the follow-up period.
Conclusions: Our initial experience with collagen matrix shows promise as an effective method of reversing hypotony while maintaining therapeutic IOP levels. Additionally, it was also effective in reversing leaks associated with thin-walled cystic blebs without the need for additional tissue manipulation. No surgical failures were recorded. Our findings are consistent with previously published literature.

ABSTRACT BODY:

Purpose: Variants in RPGR are associated with severe forms of retinitis pigmentosa (RP) and usually found within the purine rich exon ORF15. Pathogenic variants can also be found in non-canonical splice sites (NCSS), but may be classified as VUS (variant of unknown significance) by ACMG (American College of Medical Genetics) guidelines. We investigated the effect of an NCCS variant 9 nucleotides in front of RPGR exon 12 on splicing by mini-gene assay and whole-blood RNA analysis.

Methods: Clinical diagnosis was established by comprehensive ophthalmic exam and multi-modal imaging of the patient and his mother.

Patient DNA was analyzed by whole exome sequencing. Segregation analysis was performed by Sanger sequencing. Effects of a potential splice variant was analyzed by cDNA derived from a mini-gene assay and a whole-blood sample from the patient and his mother.

Results: A rare NCSS variant was found in a patient with X-linked retinitis pigmentosa (RP) in front of RPGR exon 12, which was predicted to create a novel splice acceptor site 8 nucleotides upstream of exon 12.

Sanger sequencing confirmed the carrier status of the patient’s mother, who showed a tapetal-like fundus reflex as assessed by multi-modal imaging.

Analysis of cDNA form a mini gene assay, designed to study this variant, confirmed the predicted novel acceptor site. This specific acceptor site was not active in the control mini-gene construct which contained the reference sequence. The novel acceptor site was confirmed by the analysis of cDNA generated from a whole blood samples of the proband and his mother, who is a confirmed carrier of the variant.

Conclusions: Care has to be taken by the interpretation of non-canonical splice site variants by ACMG guidelines, as they could be pathogenic. Only a functional assay can classify NCSS as likely pathogenic. It has been suggested that contribution of NCSS variants is underestimated by 35%-40%.

If no blood sample for RNA extraction is available, a mini-gene experiment/approach may be a reliable and a fast assay to characterize NCSS variants in RPGR.

We have shown that NCSS variants can contribute to the diagnostic yield in (RPGR) X-linked RP. These variants should be analyzed on transcript level in order to identify a splicing effect but also for designing therapeutic approaches in the future.

ABSTRACT BODY:

Purpose: In humans, the long and middle wavelength-sensing cone opsins (LWS/MWS) are encoded in a tandemly replicated array. Zebrafish possess a tandemly replicated long wavelength-sensitive (lws) array; the zebrafish lws genes and human LWS and MWS genes share a common ancestor. The differential regulation of human LWS vs. MWS is viewed as a stochastic mechanism, while there is evidence for trans-regulatory mechanisms in zebrafish. Our lab demonstrated thyroid hormone (TH) promotes lws1 at the expense of lws2 (Mackin et al., 2019, PNAS). The present work aims to identify additional transcriptional differences in the LWS1 vs. LWS2 cone populations, toward elucidating the genetic mechanisms underlying the differential regulation of LWS cone opsin expression.

Methods: We isolated GFP+ (LWS1) cones and RFP+ (LWS2) cones from adult male lws:PAC(H) zebrafish using established FACS methods (Sun et al., 2018, Exp Eye Res). Bulk RNA-Seq was used to identify differentially expressed (DE) transcripts of interest in these two cone populations. A separate, single cell RNA-Seq dataset was used to complement this DE list with transcripts enriched in lws1- or lws2-expressing cones. Larval zebrafish were treated with TH, and qPCR and multiplex in situ hybridization (HCR) of DE transcripts were performed.

Results: Based on a false discovery rate (FDR)<0.05, ~130 transcripts were enriched in LWS1 cones (~1.6 % of LWS1 transcriptome), and ~93 transcripts were enriched in LWS2 cones (1.2% of LWS2 transcriptome), suggesting that these cone types are highly similar yet with a subset of distinct transcripts. Among the DE transcripts were those encoding phototransduction components [gngt2b], nuclear receptors [nr2f2], extracellular proteins [si:busm1-57f23.1], transcription factors [vax2], and regulators of circadian rhythm [cry1ba, aanat2]. qPCR and HCR data show some transcripts are DE in control vs TH-treated larvae, including gngt2b (qPCR: $p<0.05$, $n=6$). For some transcripts such as si-busm1, HCR was able to detect expression domain changes in the eye upon TH treatment.

Conclusions: This study identified several transcripts that were DE in LWS1 vs. LWS2 cones, which have been presumed identical aside from opsin expression. Some of those DE transcripts are regulated by TH. This dataset provides foundations to investigate the mechanism by which lws1 and lws2 are differentially regulated, including candidates for functional testing.

ABSTRACT BODY:

Purpose: Tremendous advances have been made in human pluripotent stem cell (PSC)-derived retinal cell transplantation in mammalian model species, but evolutionary divergence in synaptic proteins may limit what can be learned from xenogeneic transplants. Allografts with species-specific PSC-derived retinal cells from pigs, a popular large animal pre-clinical model, can provide valuable anatomic, functional, and safety data for future cell replacement trials. We optimized the timeline of our established human retinal organoid (RO) differentiation protocol to align with porcine development and generated a retinal differentiation protocol that produces an abundance of porcine induced pluripotent stem cell (piPSC)-derived ROs containing a high percentage of photoreceptors.

Methods: To generate piPSC-ROs, we shortened the timing of our human PSC-RO protocol (Capowski et al., Development 2019) to better align with pig gestation. Embryoid bodies (EBs) were weaned into Neural Induction Media (NIM) over 24 hours for pig cultures vs. 4 days for human cultures, then treated with NIM + BMP4 for retinal specification and plating on Matrigel on d2 for pig vs. d6-7 for human. Pig cultures were switched to Retinal Differentiation Medium (RDM) with daily feeding on d5 (vs. d16 for human) until manual lifting of 3D ROs on d11-13 (vs. d25-30 for human). ROs were maintained with twice-weekly feeding of 3D-RDM. Differentiation of ROs was assessed by brightfield microscopy for morphology and structural organization and immunocytochemistry (ICC) for cell type-specific protein expression and localization.

Results: Light microscopic images demonstrated the phase-bright outer rim characteristic of ROs. ICC of piPSC-ROs revealed highly organized outer laminae with an abundant photoreceptor population evidenced by RECOVERIN+ and CRX+ cells, including both rods (NRL+ and RHODOPSIN+) and cones (RP-1+). As expected, piPSC-ROs contained additional retinal cell types such as CRALBP+ muller glia and G0alpha+ bipolar cells.

Conclusions: We present a robust and reproducible protocol for generating retinal organoids from pig iPSCs in a manner that parallels production of human PSC-derived ROs and photoreceptors. We anticipate that piPSC-ROs will provide a highly useful, conspecific donor cell source for assessing the potential for synaptic connectivity and functional responses to photoreceptor transplantation in pig preclinical models.

TITLE: Conjunctival Goblet Cells Stimulated with an Allergic Mediator Secrete Extracellular Vesicles that Exhibit Autocrine Secretagogue Activity

SESSION TITLE: Ocular surface health and conjunctiva

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Lee, D.A. Dartt, Schepens Eye Research Institute, Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|C. Lee, D.A. Dartt, Department of Ophthalmology, Harvard Medical School, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Changrim Lee: Commercial Relationship: Code N (No Commercial Relationship) | Darlene Dartt: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Goblet cell functions especially secretion of mucins are relatively well studied owing to their protective role on the ocular surface; however, little attention is given to the other secretory products, such as extracellular vesicles (EVs). The purpose of this study is to examine the function of goblet cell secreted EVs, especially their secretagogue activity, and test whether EVs produced by vehicle (health) or inflammatory stimuli (disease) will cause distinct actions on recipient goblet cells.

Methods: Serum starved primary human conjunctival goblet cells (HCGCs) grown from conjunctiva explants were incubated for 4 h either with the allergic mediator histamine (His, 10^{-5} M) to induce inflammation or HBSS (non-treated control) to indicate normal cells. EVs isolated from collected media using Total Exosome Isolation Reagent (Invitrogen) were denoted as EVs-His and EVs-NT, respectively. To examine secretagogue activity, first passage cells (trypsinized and passaged primary cells) were treated with EVs diluted to 1, 10, 100, 1000 ng/mL) for 4 h in HBSS. The amount of secreted high molecular weight proteins (HMWP) in the cell culture supernatants was measured using an enzyme-linked lectin assay (ELLA).

Results: HCGCs stimulated with His secreted 4-fold higher amount of total EV proteins into the media compared to that of the untreated cells, which confirmed that the primary cells are effectively stimulated with His. For secretagogue activity of EVs, addition of 10 ng/mL EVs-His to HCGCs induced secretion of HMWP by 4.8-fold. The same concentration of EVs-NT caused a 1.6-fold increase. For both EV-His and EV-NT, an increase of 1.0~1.9-fold was observed at the other four concentrations; however, all lower than the activity seen at 10 ng/mL. Fold-change of secretion in His treated (positive cntl) and untreated cells (negative cntl) was 2.2 and 1.0, respectively.

Conclusions: We conclude that HCGCs EVs have differential secretagogue activity when stimulated with inflammatory mediator compared to under control (healthy). EVs have an indispensable role in regulating goblet cell secretion at the extracellular level, which warrants in-depth investigation into their molecular properties and mechanism of action.

ABSTRACT BODY:

Purpose: To develop a de novo patient-reported outcome (PRO) questionnaire for assessing the impact of treatment with anti-vascular endothelial growth factors (VEGFs) versus panretinal photocoagulation (PRP) on patients' experience of living with proliferative diabetic retinopathy (PDR).

Methods: A review of literature and online resources was conducted to develop a conceptual model of the PDR patient experience and to identify existing PROs used in PDR and other ophthalmic conditions. Concept-to-item mapping of the identified PROs was conducted to identify items relevant to the patient disease and treatment experiences. This formed the initial PRO instrument, which was further refined using insights gained from adult patients treated with aflibercept and/or PRP. Two rounds of in-depth, semi-structured interviews were conducted to elicit patients' feedback on living with PDR and treatment experiences and to assess their ability to interpret the PRO content and its relevance to their experience.

Results: Forty patients treated with aflibercept (n=23) and/or PRP (n=34) for PDR were interviewed during Round 1 and of these, 30 were later interviewed in Round 2. An initial list of 72 items with conceptual coverage across symptoms and impact domains was drafted based from existing instruments relevant for PDR. Patients' feedback led to refinement of instructions, items, and response options to improve clarity and comprehension, remove overlap, and increase relevance. A new scale was added to enable assessment of concepts proximal to experience of PRP or anti-VEGF treatment. The revised PRO measure and preliminary conceptual framework includes 85 items across four scales: Daily activities (54), Emotional impact (5), Vision problems (15), and Treatment experience (11).

Conclusions: A robust and comprehensive PRO instrument was developed to evaluate the effects experienced by patients who are treated for their PDR. A validation study in a larger sample is warranted to confirm scoring, item reduction opportunities, and psychometric properties.

TITLE: Quality of vision improvements with decentered multifocal optics in scleral contact lenses

SESSION TITLE: Contact lens

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: G. Mikaelian, R&D, NIDEK Inc, San Jose, California, UNITED STATES|P. Caroline, College of Optometry, Pacific University College of Health Professions, Forest Grove, Oregon, UNITED STATES|

Commercial Relationships Disclosure: Gary Mikaelian: Commercial Relationship(s);Code E (Employment):NIDEK Inc., Hedgefog Research Inc. | Patrick Caroline: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Decentered contact lens optics can potentially reduce the quality of vision by introduction of unwanted low and higher order aberrations. It is well known that scleral lenses commonly decenter inferiorly and temporarily. Yet, many of the commercially available scleral lenses center the optics at the geometrical center of the lens, which is rarely aligned with the visual axis. A number of scleral lens designs now allow for the offset in the optic zone alignment. In most cases this feature can be used to align the lens optics with respect to the visual axis. However, in some patients with small pupils and large angle kappa (the distance between the visual axis and pupillary axis), the effect of the multifocal design may be diminished due to the misalignment between the pupil and the “add zone” on the lens. The purpose of this study is to evaluate the use of a conventional optometric instrumentation, which provides angle alpha and angle kappa measurement in order to predict which patients may benefit from a decentered multifocal lens design and provide the eyecare practitioner with the tools to quantitatively define the amount of decentration needed for a specific patient.

Methods: Both eyes of three normal eye subjects were measured with the NIDEK OPD Scan III. The subjects LDist and RMS were recorded. Both eyes were fitted with standard scleral lenses and OPD Scan III measurement was performed over the scleral lens. The LDist determines the amount and location of the decentered optics. A custom scleral lens (with displaced optics) was ordered. The custom scleral lenses were placed on the subjects’ eyes and allowed to equilibrate for 30 minutes. OPD Scan III measurement was performed over the lenses and the LDist and RMS was recorded.

Results: Preliminary results demonstrate that the RMS values of the wavefront and quality of vision are both dependent on the optics alignment with respect to the visual axis.

Conclusions: Multifocal scleral contact lenses are a promising modality for presbyopia management. There is a clear need in being able to address the reduction in the quality of vision due to the lens decentration on the eye. This study provides insights on how optometric instrumentation may be used to determine which patients may benefit from multifocal scleral lenses with off-centered optics and provide a pathway for automating the decision of the amount of decentration for a particular patient.

ABSTRACT BODY:

Purpose: Optical coherence tomography (OCT) provides useful assessment of retinal health, but OCT image analysis is often qualitative. Machine learning segmentation methods have been shown to be effective in quantifying changes seen in OCT images. However, there are no automatic segmentation tools for preclinical porcine models. We propose a novel computational pipeline using supervised deep learning methods to automatically segment porcine retinal layers in OCT B-scans in a laser-induced model for retinal injury.

Methods: B-scans were acquired in Yucatan pigs using the Spectralis (Heidelberg, Germany) spectral domain OCT and were exported with a corresponding infrared reflectance fundus image that specifies the scan location. B-scans and fundus images were manually segmented by an experienced observer using LabelMe, a Python based annotation tool (Wada, 2018). The healthy and laser-treated datasets consist of 12 B-scans (6 eyes, 3 pigs) and 12 B-scans (7 eyes, 4 pigs), respectively.

Our proposed pipeline is primarily composed of three U-Net semantic convolutional neural networks. The first U-Net was trained to segment 7 retinal layers under healthy conditions. Due to the destructive effects of the laser in the retinal outer segments, a separate set of models (trained with a laser-treated dataset) is required to accurately segment damaged regions. To automatically identify regions of laser ablation within the OCT, a second U-Net is tasked to perform binary segmentation on the fundus image. Image processing techniques utilize relationships between the two image types, outputting predicted boundaries of lasered regions on B-scans. Using this B-scan input, a third U-Net is trained to segment damaged retinal layers.

Results: Model outputs were compared to manual segmentation and were evaluated using mean dice coefficient (MDC), a measure of similarity between two samples. The first U-Net displayed an average MDC of 0.916 (SD=0.062) and the second U-Net presented an MDC of 0.995. Subsequent computations predict boundaries of the laser ablated regions with a mean absolute pixel error of 7.50 (SD=7.33).

Conclusions: Initial results suggest potential of this framework to be used as an effective evaluative tool for researchers using porcine models for retinal degeneration. Future work includes retraining models with larger datasets and developing algorithms for layer quantification by varied metrics.

ABSTRACT BODY:

Purpose: To determine the characteristics of saccadic eye movements of patients with retinitis pigmentosa (RP) and to what extent they help improve peripheral visual stimuli detection.

Methods: Study included 6 patients with RP (median age 40, 19-56; 3 male) and 8 healthy controls (median age 37, 28-55; 1 male). The median of best-corrected visual acuity (BCVA) on the better eye was 0.8 (0.5-1.0) in patients with RP and 1.0 in controls. Patients with RP had a concentrically narrowed visual field between 10-35° radius measured by II/4 isopter on Goldmann perimetry. Participants underwent visual field examination (IC test) using the HP Omnicept Reverb G2 virtual reality headset with eye-tracking sensors. The test consisted of 24 static and 23 moving targets (size Goldmann V, duration 1.5 s), presented in a repeatable random sequence at 10°, 20°, and 30° distances from the central fixation point. Each participant performed the test twice, first (IC-fixed) with central fixation, and second (IC-mobile) with free eye movements. The number of saccades, average speed, amplitude number, and the average duration were determined using the accompanying IC software (Fusion) and compared between patients with RP and healthy participants. Macro-saccades were defined as the eye movements reaching at least 50°/s with the amplitude at least 1.2°.

Results: All healthy participants detected 100% of stimuli on IC-fixed and median 100% (94-100%) on IC-mobile, while RP patients detected median 30% (0-98%) stimuli on IC-fixed and 84% (11-100%) on IC-mobile ($p=0.18$). On the IC-mobile test, the RP patients had a significantly higher number of macro-saccades than controls (median 547 vs 250; $p<0.01$), which were also significantly faster (median speed 1187 °/s vs 951 °/s, $p< 0.05$), and of larger amplitude (median 9.9° vs 7.9°, $p<0.05$); whereas their duration did not differ significantly (73 ms vs 58 ms, $p=0.11$).

Conclusions: Patients with RP increased the likelihood of peripheral stimuli detection with saccadic eye movements. Interestingly, while the number, speed, and amplitude of their macro-saccades during scanning were higher than in controls, the duration of saccades was relatively similar. VR with biometry is a novel modality that can be used to measure visual function and adaptive mechanisms in patients with visual loss.

ABSTRACT BODY:

Purpose: Pericyte dropout is an early pathologic hallmark of diabetic retinopathy (DR) and may contribute to vascular instability and disease progression. Aqueous humor (AH) and vitreous humor (VH) biomarkers reflecting pericyte status within the retina may therefore be prognostic for progression to more severe, vision-threatening forms of DR, including proliferative DR (PDR) and diabetic macular edema (DME) and may help guide treatment decisions. In this study, putative pericyte-selective markers were evaluated in AH, VH, and plasma for their ability to reflect DR severity.

Methods: AH, VH, and plasma specimens (n=181) were collected during ocular surgery or injection procedures from the study population (n=98) spanning nondiabetic, diabetes mellitus without DR (DM), non-proliferative DR without DME (NPDR), PDR without DME, and DME patients. 24 patients from the total study population had matched VH, AH and plasma. Concentrations of Regulator of G-protein signaling 5 (RGS5), Pigment epithelium-derived factor (PEDF), and Pyruvate dehydrogenase kinase isozyme 4 (PDK4) were measured in samples via enzyme-linked immunosorbent assay. Kruskal-Wallis ANOVA test was used to compare biomarker levels across cohorts, Dunn's multiple comparison test was used for pairwise comparison to DM population, and a Spearman correlation evaluated the relationship between matrices.

Results: In VH, RGS5 was significantly increased in PDR and DME cohorts relative to DM (p=0.0019, p=0.0253 respectively), PEDF was significantly increased in PDR and DME cohorts (p=0.0004, p=0.0157 respectively), and PDK4 was significantly increased in the PDR cohort (p=0.0271). RGS5, PEDF, and PDK4 demonstrated significant correlation between matched AH and VH samples (r=0.8798 p=<0.0001, r=0.6650 p=0.0005, and r=0.5774 p=0.002 respectively). AH had similar significant elevations in advanced disease cohorts over DM for RGS5 and PDK4. None of the markers showed statistically significant elevations over the DM population in plasma across the DR cohorts.

Conclusions: These preliminary results demonstrate that multiple pericyte-selective biomarkers change with disease severity in diabetic retinopathy. This change with disease progression supports further investigation into their utility as prognostic biomarkers.

ABSTRACT BODY:

Purpose: Mutations in RHODOPSIN (RHO) accounts for ~25-30% of autosomal dominant retinitis pigmentosa (adRP). No pharmacological treatments are available for RP. Many RHO mutants are structurally unstable and trigger dominant negative effects including disrupted proteostasis and rod cell death, which cause vision loss. We hypothesize that small molecule chaperones can stabilize the native folding and homeostasis RHO, which in turn will rescue rods in RHO-associated adRP. We previously discovered non-retinoid chaperones of RHO (such as YC-001). The purpose of this study is to test this hypothesis using in vitro, ex vivo and in vivo models and to develop new drug candidates for RP treatment.

Methods: We used high content imaging to profile the chaperone activities of two non-retinal chaperones towards 27 RP-causing human RHO mutants by quantifying cell-surface level of these RHO mutants in NIH3T3 cells. AutodockVina was used for docking calculation of chaperones. Two chaperone molecules were treated to the $Rho^{P23H/+}$ knock-in mouse retinal explants to evaluate their chaperon activities to RHO. Intravitreal injections of two compounds were performed to $Rho^{P23H/+}$ knock-in mice and efficacies were evaluated by OCT, ERG, and retinal histology.

Results: The in vitro high-content imaging assay showed that YC-001 and the other chaperone molecule rescued the transport of 9 and 11 mutants, respectively, in NIH3T3 cells. Docking calculations indicate that YC-001 binds in the β-ionone ring pocket with ΔG=-7.9 kCal/mol while the other chaperone molecule fills in a larger space of chromophore pocket with ΔG=-5.5 kCal/mol. Further, YC-001 treatment led to improved RHO homeostasis in the $Rho^{P23H/+}$ retinal explants. Interestingly, YC-001 also reduces the number of residential macrophages (microglia) in the retinal explants. Finally, single, or double intravitreal injections of chaperones microparticles increased photoreceptor function and ONL thickness in $Rho^{P23H/+}$ mice.

Conclusions: We showed that the YC-001 and the other non retinal chaperones increased RHO transport, improved RHO homeostasis and protected photoreceptors in $Rho^{P23H/+}$ adRP mouse model. Collectively, here we provide a strong proof-of-principle that non-retinoid chaperones are promising drug candidates in treating RHO-associated RP.

ABSTRACT BODY:

Purpose: Retinal cysts or fluid spaces accumulated between different layers of eye are key signatures of diseases like age-related macular degeneration (AMD) and macular edema (ME). Accordingly, for accurate screening and disease management, clinicians seek to quantify these lesions using ubiquitous optical coherence tomography (OCT) scans. However, manual delineation is tedious and may induce errors. In response, attempts were made towards automated quantification based on imag processing and machine learning approaches. However, the detection accuracy is still sub-optimal and has scope for improvement. Against this backdrop, we attempt to build a robust fluid segmentation tool leveraging a pre-trained encoder-decoder architecture with residual network (ResNet) at the encoder that was proven to be effective in other segmentation tasks by preserving features across layers.

Methods: This is a retrospective study consisting of 3175 OCT scans (1048 with fluid/cysts and 2127 without any lesions) taken from wide-field swept-source optical coherence tomography (OCT) device (Carl Zeiss Plex Elite 9000) with a resolution of 12mm×3mm. The presence of fluid was detected based on our previously validated XGBoost algorithm. We employed ResUNet deep-learning architecture which uses residual network at the encoder (see Fig. 1). Masks required to train the model were obtained by manually labeling fluid regions by a trained expert using the ImageJ tool. Dataset is randomly partitioned into training and testing (unseen) sets with a split-ratio of 90:10. Finally, the OCT scans were resized to (256, 256) and the model was trained using Dice coefficient as loss function (epochs: 80, batch size: 16).

Results: The proposed method achieves an averaged Dice score of 91.47% against ground truth segmentations and outperforms the existing UNet based approaches as well. Fig. 2 depicts representative test OCT images with both manual as well as algorithmic segmentation and also provides volumetric quantification of cysts in 3D volume for a subject.

Conclusions: The proposed approach achieves segmentation accuracy close to trained optometrists. Next, we are working towards extending this to identify different types of fluids and also perform voxel-level segmentation that enables volumetric quantification of retinal cysts.

ABSTRACT BODY:

Purpose: Astrocytes are the major glia cell type within the optic nerve head (ONH). During glaucoma pathogenesis, elevated intraocular pressure (IOP) deforms the ONH and activates astrocytes relevant to their mechanosensing mechanisms. In this study, we performed RNA sequencing (RNA-seq) to investigate the mechanisms underlying astrocyte activation.

Methods: Primary mouse ONH astrocytes were derived from C57BL/6J mice and subjected to mechanical stretch of 12% strain for 24 hours using a FlexCell Tension System. Total RNA was extracted from astrocytes and RNA-seq libraries were prepared and sequenced on an Illumina Miseq2000. RNA-seq analysis was performed to identify significant differentially expressed genes, which were further investigated in pathway enrichment analysis. The Egl1 mouse strain was obtained from the Jackson Laboratory and intraocular pressure (IOP) was measured non-invasively using the TonoLab tonometer. Immunofluorescent staining was performed to validate the gene of interest in the ONH of glaucomatous mice.

Results: RNA-seq identified 2197 significantly up-regulated and 2092 significantly down-regulated genes (FDR<0.05) in mechanically stretched ONH astrocytes. Based on gene ontology enrichment results, identified genes are associated with a variety of cellular components (pigment granule, preribosome, et al.), biological processes (ATP hydrolysis coupled cation transmembrane transport, protein folding, et al.) and molecular functions (structural constituent of cytoskeleton, tRNA binding, et al.). Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway analysis show that differentially regulated genes are involved in phagosome, carbon metabolism, and Aminoacyl-tRNA biosynthesis, et al. There was an increased expression of Iba1 in the ONH of glaucomatous mice.

Conclusions: Mechanical stretch regulates the expression levels of genes that may be responsible for ONH astrocyte activation during the pathogenesis of glaucoma. This study provides new insights into mechanisms of astrocyte activation induced by mechanical stimulation. These new insights will lead to novel therapeutic targets for glaucoma.

ABSTRACT BODY:

Purpose: Mutations in the MERTK gene cause autosomal recessive rod-cone degeneration that results in impaired outer segment phagocytosis followed by photoreceptor death. We measured the area of cone coverage and cone density in patients with MERTK-related rod-cone degeneration using adaptive optics scanning laser ophthalmoscopy (AOSLO), a non-invasive method to visualize cones with high resolution.

Methods: Seven eyes of four patients with MERTK-related rod-cone degeneration were studied with visual acuity, optical coherence tomography (OCT), fundus autofluorescence (FAF), OCT angiography (OCTA) and AOSLO. AOSLO images were obtained from six eyes with stable fixation. Twelve-month follow up images were taken in four eyes of two patients and density was calculated at one region in each eye at baseline and at month twelve. The area of cone coverage was measured by tracing the visible and contiguous cones in and around the fovea using ImageJ. Cone density was measured in one region near the fovea by a single grader. AOSLO cone spacing was converted to Z-scores, or standard deviations from the normal mean. We analyzed choriocapillaris flow deficit percent (CC FD%) from 6x6mm OCTA scans in the better eye of each patient. CC FD% was the ratio of area with FD, defined as greater than one standard deviation below mean values from a normal database. Average CC FD% was compared between subjects and controls.

Results: Visual acuity ranged from 0.5 to bare hand motion. At twelve months, the area with visible and contiguous cone mosaics decreased from 3.7 deg^2 ± 1.9 to 1.0 deg^2 ± 0.52 (mean ± std dev). Mean cone density near the fovea decreased from 1391.7 cones/deg^2 to 922.2 cones/deg^2 and spacing increased from 1.7 arcmin to 2.1 arcmin. Cone spacing Z-scores were abnormal (23.2 ± 9.7). For three of four patients, the CC FD% was within normal limits (9.9 ± 3.8). The patient with the most advanced disease showed abnormally increased mean CC FD % (21.7 ± 12.9).

Conclusions: Cones persist at the fovea but the area with contiguous cones decreases over time in MERTK-related rod-cone degeneration. Cone density is reduced below normal and decreases over time. Choriocapillaris flow is preserved even in regions with increased cone spacing until advanced stages of rod-cone degeneration. AOSLO and OCTA may provide sensitive measures of disease progression over one year in patients with MERTK-related rod-cone degeneration.

TITLE: Changes in Buccal Fat Pad Volume in Thyroid-Eye Disease: An Imaging Study

SESSION TITLE: New improvements in imaging and development of biomarkers

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. Osias, M. Cale, P. saffari, S. Diniz, D. Rootman, Orbital and Ophthalmic Plastic Surgery, Jules Stein Eye Institute, Los Angeles, California, UNITED STATES|

Commercial Relationships Disclosure: Ethan Osias: Commercial Relationship: Code N (No Commercial Relationship) | Mario Cale: Commercial Relationship: Code N (No Commercial Relationship) | persiana saffari: Commercial Relationship: Code N (No Commercial Relationship) | Stefania Diniz: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Rootman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Thyroid Eye Disease (TED) is currently considered primarily a disease of the orbit; however, there is a growing body of evidence to suggest that periorbital facial tissue, such as the buccal fat pad (BFP) can also be affected. In some cases, surgeons remove buccal fat during orbital decompression in order to improve cosmesis. We performed this retrospective cohort study in order to determine whether TED is associated with changes in BFP volume.

Methods: Computed Topography (CT) scans and charts of adult patients with and without TED were collected from a database of patients who were seen at Stein Eye Institute. Inclusion criteria for the TED group included presence of TED and availability of adequate scans. The control group consisted of patients presenting for non-thyroid related reasons, who had CT scans done for other orbital pathologies. Exclusion criteria included history of orbitofacial trauma or facial surgery, poor quality scans, scans with a slice interval greater than 2mm, or scans without clear buccal fat pad limits. The collected patients were compiled in a spreadsheet in random order, and three independent, blinded observers then measured buccal fat pad volume, proptosis, and maximal skull width using Horos, a free, open-source medical image viewing software. The primary outcome was buccal fat pad volume, measured in cubic centimeters.

Results: A total of 69 scans were included in our study, 29 TED patients and 40 controls. Our analysis consisted of an analysis of covariance that included TED diagnosis, age, and proptosis as covariates. The difference in BFP volume between TED patients and controls was 0.317cc (p-value = 0.374). In our study, TED was not associated with a statistically significant change in BFP when controlling for relevant patient factors like age and proptosis.

Conclusions: We found that TED did not significantly impact BFP volume. These findings suggest that there may not be a compelling reason to extract buccal fat from these patients during orbital decompression surgery. However further analysis is needed to assess the impact of other factors such as sex and presence of comorbidities on the buccal fat pat volume in TED.

ABSTRACT BODY:

Purpose: Traditional, non-adaptive methods for estimating detection threshold of electrically-evoked phosphenes have not permitted a systematic characterization of stimulation parameters. Instead, the Bayesian adaptive method can accurately estimate thresholds with fewer trials, making it ideal for studies with human subjects. In this study, we implemented the Bayesian method to gain a better understanding of how stimulation parameters influence the thresholds of phosphenes evoked by epiretinal electrodes. Our results will be used to develop advanced stimulation paradigms that increase resolution and minimize perceptual adaptation of visual feedback provided by epiretinal prostheses.

Methods: Three people with Argus II devices participated in this study. 12 electrodes for subject S1 and 6 electrodes for S2 and S3 were selected. Each electrode's threshold was estimated using a Bayesian adaptive method in a yes/no experiment, in which subjects reported if they observed a phosphene after hearing an auditory cue. Using the collected responses, the next stimuli were presented at the amplitude level that maximized the entropy for the threshold and the slope of the Weibull psychometric function. The process continued until the thresholds of all selected electrodes stabilized (the differences between 3 consecutive estimations were smaller than 3 μA) or exceeded 30 trials. Thresholds were estimated for pulse train frequencies of 6, 20, and 60 Hz, each tested with 2 and 4 pulses within a train. We also estimated the thresholds of pulse trains with a fixed train duration of 250 ms at 6, 20, and 60 Hz.

Results: A paired Wilcoxon sum rank test for all pairs of estimated thresholds with different pulse parameters within-subjects showed no significant differences ($p>0.05$) for two out of three subjects. For S2, the estimated threshold at 60 Hz was unexpectedly greater than the threshold at 20 Hz with 250 ms pulse trains ($p=0.02$), with root mean square differences of 128 μA.

Conclusions: We investigated the effect of pulse train duration and frequency on estimated detection thresholds using Argus II electrodes. We interpret the results as showing effects of sensory adaptation at high frequencies, causing the thresholds to not decrease as expected. We, therefore, conclude that higher pulse frequencies do not necessarily enable a broader dynamic range of stimulation parameters for Argus II users.

ABSTRACT BODY:

Purpose: The retinal pigment epithelium (RPE) is a polarized tissue that has important functions like supporting photoreceptors of the eye, transporting nutrients and secreting growth factors and cytokines. Our lab studied the surface proteome of RPE by cell surface capturing technology which revealed the presence of ABCA4 on the surface of RPE. We focused on the role of the ABCA4 protein as mutations in ABCA4 gene have been associated with various retinal degenerative diseases including the Stargardt disease. To specifically understand the function of ABCA4 protein in RPE, we developed an in-vitro Stargardt disease model using ABCA4$^{-/-}$ induced pluripotent stem cells (iPSC)-derived RPE and Stargardt patient iRPE.

Methods: We used CRISPR/Cas9 technology to generate iPSCs with a knockout of the ABCA4 gene targeting exon 1 of the ABCA4 gene. Resultant targeted clones were screened and two independent clones (C1 and C2) that resulted in out-of-frame deletions on both alleles were selected. For the Stargardt patient, fibroblasts were isolated from skin biopsy which were reprogrammed to form iPSCs. ABCA4$^{-/-}$ iPSCs and Stargardt patient iPSCs were differentiated to form Stargardt iRPE. ABCA4 knockout was confirmed by qRT-PCR, dd PCR, immunostaining and Sanger sequencing. Cells were evaluated for RPE-specific morphology by Scanning Electron Microscopy (SEM) and Transmission Electron Microscopy (TEM) and functions such as electrophysiological response.

Results: Stargardt iRPE and the corresponding isogenic control iPSCs displayed normal karyotype and expressed similar levels of developmental and mature RPE markers. Immunostaining of iRPE monolayers for maturity markers RPE65 and EZRIN further confirmed qRT-PCR observation. TEM of iRPE monolayers showed normal polarized RPE features like abundant apical processes and tight junctions between neighboring cells in Stargardt iRPE. SEM also suggested the formation of normal and fully confluent apical processes in Stargardt iRPE compared to isogenic Control iRPE. In addition, Stargardt-iRPE showed similar electrophysiological response compared to the Control iRPE.

Conclusions: We generated an in vitro Stargardt disease model using ABCA4$^{-/-}$ and Stargardt patient iRPE. We found that the genetic profile, cell morphology and structural features of patient and ABCA4$^{-/-}$ iRPE behaved like Control iRPE suggesting there are no developmental defects in RPE due to ABCA4 loss of function.

ABSTRACT BODY:

Purpose: MKIs have been shown to inhibit vascular leakage clinically in the treatment of wAMD, RVO and DME. The approved anti-VEGFs are effective; however, their short duration a creates burden on the practice and patient. Our goal is to develop a long-acting intravitreal biodegradable implant that would be effective in managing the disease for ~6-12 months. We investigated the tolerability and efficacy of MKI biodegradable intravitreal implant, to inhibit retinal vascular leakage in the DL-AAA Dutch-Belted rabbit model.

Methods: Several biodegradable implant formulations were developed and tested in-vitro for drug release kinetics. The lead formulation was selected based on in-vitro release data to be tested in the rabbit model. DL-AAA rabbits were induced 8 weeks prior to study start. Seven DL-AAA female rabbits received 1 GLC-009 implant OD and 1 placebo implant OS, and 3 received 2 GLC-009 implants OU. Eyes were monitored using fluorescein angiography (FA), aide Angle (55°) IR imaging, and slit lamp ophthalmic exams including McDonald-Shadduck scoring at Days 1, 8 and monthly thereafter for 12 months. To assess tolerability, 3 naïve female Dutch Belted rabbits received 1 GLC-009 implant OD and sham injection OS, and 3 rabbits received 2 GLC-009 implants OD and 2 placebo implants OS. Plasma was collected to monitor systemic drug exposure.

Results: Administration of 1 and 2 GLC-009 implants showed significant inhibition of retinal vascular leakage compared to placebo on FAs beginning at Day 8 and continuing for 12 months. Both 1 and 2 GLC-009 implants provided maximal inhibition of vascular leakage. Observations consistent with intravitreal injections were observed and fully resolved. Systemic exposure was minimal, with values near or below the lower limit of quantitation. Initial signs of implant biodegradation were observed beginning on Day 210.

Conclusions: An MKI biodegradable intravitreal implant, was well tolerated in naïve DB rabbit eyes and significantly inhibited retinal vascular leakage in the DL-AAA rabbit model for 12 months. If confirmed clinically, such MKI long lasting implant could offer a long duration therapeutic alternative in the treatment of wAMD, RVO and DME.

ABSTRACT BODY:

Purpose: Fuchs endothelial corneal dystrophy (FECD) is a degenerative disease of the corneal endothelium (CE) with multiple and poorly understood etiologies. Hallmarks of FECD are corneal endothelial cell (CEnC) loss and endothelial guttata. Previously, we have reported that loss of antioxidant enzyme NQO1, which is transcriptionally regulated by Nrf2, and upregulation of estrogen metabolizing enzyme CYP1B1 contribute to increased susceptibility of CEnCs to ultraviolet-A (UVA) light, a physiologic stressor of CE. The purpose of this study is to test the protective effect of a naturally occurring Nrf2 agonist and CYP1B1 inhibitor, berberine, against CEnC loss after UVA exposure in vivo.

Methods: 10-week-old C57BL/6 female mice corneas were irradiated with UVA light (500 J/cm^2). Post-irradiation, 2 cohorts of mice (N=5 each) were intraperitoneally injected with 10 mg/kg berberine or vehicle once a week up to 1 month. CEnCs were imaged before and at 1 week, 2 weeks, and 1-month post-UVA using Heidelberg Retinal Imaging Rostock Corneal Module (HRT-RCM). Cell counting was performed using ImageJ and statistical analyses of computed cell density were performed using a one-way analysis of variance (ANOVA) and post-hoc Tukey's HSD.

Results: At 1-week post-UVA, the vehicle-treated group showed a 25.3±2.7% decrease (1760±23 vs. 2362±42 cells/mm^2 at baseline; $p<0.001$), while the berberine-treated group showed only a 12.7±1.4% decrease (1970±28 vs. 2263±64 cells/mm^2 at baseline; $p<0.001$) in CEnC density, thus exhibiting 49% protection with drug compared to no treatment ($p<0.01$). At 2 weeks, the vehicle-treated group showed a 37.5±2.7% decrease (1474±49 vs. 2362±42 cells/mm^2 at baseline; $p<0.001$), whereas the berberine-treated group showed only a 19.4±1.4% decrease (1822±27 vs. 2263±64 cells/mm^2 at baseline; $p<0.001$) in CEnC density, indicating a continued 48% protection with drug compared to no treatment ($p<0.001$) at this time-point.

Conclusions: We demonstrate that treatment with berberine can rescue UVA-mediated CEnC loss at an early time-point in FECD. This study provides a potential line of treatment to rescue a deficient antioxidant system in FECD. Further investigation into the long term effect is warranted.

ABSTRACT BODY:

Purpose: Greater volatility of retinal thickness during anti-VEGF therapy has been associated with poorer visual acuity outcomes in eyes with neovascular age-related macular degeneration (nAMD). This post hoc analysis of the HAWK study examined whether specific exudative compartmental volatility (e.g., intraretinal fluid [IRF], subretinal fluid [SRF], and subretinal hyperreflective material [SHRM]) was associated with visual outcomes.

Methods: The HAWK study was a randomized phase 3 study in patients with nAMD (NCT02307682). Six hundred fifty-two eyes in the brolucizumab 6 mg and aflibercept 2 mg arms were included in the post hoc analysis. IRF, SRF, and SHRM volume was measured using a machine-learning enhanced feature-extraction platform with manual correction, as needed. For each eye, the standard deviation (SD) of the volume of each exudative compartment (IRF, SRF, and SHRM) was calculated from Week 12 to Week 56 (i.e., following the initial loading phase and representing the visit-to-visit variability). For each exudative compartment, eyes with SDs ≤25th percentile and ≥75th percentile were considered to have low and high volatility, respectively. The effect of volatility on mean change in best corrected visual acuity (BCVA) was examined from Week 12 at Week 56.

Results: Eyes with high SRF volatility demonstrated significantly worse visual outcomes compared to eyes with low SRF volatility (n=163, mean change=-2.18 letters vs n=314, mean change=+1.35 letters, respectively; P=0.0044). Similarly, eyes with high IRF volatility (n=163, mean change=-2.63 letters; P<0.0001) and eyes with low IRF volatility (n=367, mean change=+2.30 letters) had significant differences in change in visual acuity. Finally, there was also a significant difference in change in BCVA between eyes with high SHRM volatility (n=163, mean change=-2.47 letters; P=0.0001) and eyes with low SHRM volatility (n=166, mean change=+1.97 letters).

Conclusions: High volatility of each exudative parameter, including SRF, was associated with poorer visual outcomes. This suggests that identifying exudative fluctuation and potentially stabilizing that volatility may be important in maximizing visual acuity outcomes.

ABSTRACT BODY:

Purpose: Patients with active uveitis with retinal vascular leakage (RL) on ultra-widefield fluorescein angiography (UWFA) may have normal foveal contour on spectral domain optical coherence tomography (OCT). In this study, we evaluate changes in fluorescein leakage on UWFA and changes in retinal thickness measures on OCT to determine the layers of retinal fluid accumulation on OCT in patients with uveitis.

Methods: This is a retrospective IRB approved study. Patients were imaged with UWFA and OCT on the same day at baseline and follow-up visit. Patients included all had active uveitis with significant RL on UWFA and normal foveal contour with absence of macular edema on OCT scans at baseline and significant improvement of RL on UWFA post-treatment. OCT analysis software with manual expert reader-correction was used to segment the ILM, ONL, EZ, RPE, and Bruch's membrane. Segmentation metrics for retinal volume (RV) and mean central subfield thickness (CST) on OCT were obtained. UWFA metrics of leakage area using 3, 6, 9-disc diameter areas centered on the macula were quantified using a fully automated customized software.

Results: A total of 27 eyes from 21 patients (14 females, 7 males) were included in the study. At baseline, the average total RL on UWFA was 8.5%. After treatment, the average total RL decreased to 5.1%. The most significant improvement in RL on UWFA was seen within 3-disc diameters centered on the macula with an average change of 96% pre- and post-treatment. At baseline on OCT, the average total, outer (EZ-RPE), middle (ONL-EZ), and inner (ILM-ONL) RV was 11, 1, 3, and 7 mm^3. On follow-up after treatment, the average total, outer, middle, and inner RV was 10, 1, 3, and 6 mm^3.The average total, outer, middle, and inner CST at baseline was 290, 38, 126, and 127 µm. After treatment, the average total, outer, middle, and inner CST was 267, 37, 110, 120 µm. The most significant decrease in average CST occurred within the middle retinal layer.

Conclusions: In uveitis patients with active RL and normal retinal contour, reduction in leakage leads to decrease in retinal thickness on OCT. The majority of improvement occurs in the middle retinal layer (ONL-EZ). Despite "normal" retinal contour, eyes with active RL have retinal edema. Normal retinal contour and thickness on OCT does not rule out active RL.

ABSTRACT BODY:

Purpose: Heterochromatic epigenetic modifications such as DNA and histone methylation have previously been shown to restrict the potential of neural stem cells, but it has remained unclear how these processes are controlled. Using retina as a model system, our lab identified that transcription factor Casz1 interacts with Mi2/NuRD chromatin remodelling complex to regulate the potential of retinal progenitor cells (RPCs) during development. We hypothesize that the Mi2/NuRD complex regulates RPC potential by restricting the epigenome. Our objective is to determine whether and how the Mi2/NuRD complex regulates RPC potential.

Methods: We focused on the key Mi2/NuRD subunit Chd4, which imparts the nucleosome remodelling enzymatic activity exhibited by the complex. We obtained a floxed Chd4 allele, that was cross-bred with a retina-specific Chx10-Cre allele to excise an essential region of the Chd4 gene specifically in the developing retina. We first performed phenotypic analysis to identify the role of Chd4 during retinal development and follwed up with "omic" studies to identify the mechanisms that might regulate RPC potential.

Results: Phenotypic analysis of adult retinas showed that conditional knock-out (cKO) of Chd4 lead to an atypical retinal architecture, where the retinal layers were highly distorted as compared to control. Using cell-specific markers we ascertained that Chd4 cKO lead to a skewed generation of different retinal cell-fates, where early cell types such as retinal ganglion cells were overproduced at the expense of late-born cell-fates such as rod photoreceptors. To determine how Chd4 affects gene expression, we performed single-cell RNA-seq on control and cKO RPCs. While our analysis of this dataset is still preliminary, we have been able to identify many genes that are differentially expressed in cKO RPCs and are currently in the process of validating these data. Furthermore, we performed ATAC-seq on control and cKO P0 RPCs to determine how Chd4 regulates gene accessibility to modulate RPC potential. Through the preliminary analysis, we observed that Chd4 cKO lead to an increase in genomic accessibility.

Conclusions: In future work, we propose to perform a systematic review of the "omic" datasets we have obtained in order to identify how the Mi2/NuRD complex regulates RPC potential.

ABSTRACT BODY:

Purpose: Nuclear factor activated in T cells (NFAT) has been known to regulate the expression of a wide variety of inflammatory cytokines. The NFAT family of proteins possess five different isoforms (NFAT1-5). NFAT1-4 isoforms are dephosphorylated and activated by calcineurin. Activated NFAT proteins translocate to the nucleus and enhance the expression of several inflammatory cytokines including interferon gamma (IFNγ), interleukin (IL)-2, IL-4, and IL-17, granulocyte-macrophage colony-stimulating factor (GM- CSF). We investigated the involvement of NFAT proteins on lipopolysaccharide (LPS)-mediated expression of inflammatory cytokines in the retinal pigment epithelial cells (RPE).

Methods: We treated ARPE-19 cells with NFAT inhibitor, MAGPHPVIVITGPHEE (VIVIT), for 4-6 hrs followed by 10 μM LPS for 24 hrs to analyze whether NFAT is involved in the regulation of LPS-induced expression of inflammatory cytokines in the RPE. Human cytokine antibody array was used to examine several cytokines expression in the cells treated with LPS and LPS in combination with the NFAT inhibitor, VIVIT. Quantitative real time PCR (qRT-PCR) analysis was performed to evaluate the expression of LPS-induced cytokines in the RPE.

Results: In ARPE-19 cells treated with 10 μM LPS, human cytokine antibody array showed an induction in the expression of several cytokines including IL-6, IL-8, IL-7, Monocyte Chemoattractant Protein-1 (MCP-1), GM-CSF, growth-related oncogene (GRO) and growth-related oncogene alpha (GRO alpha). The cytokine array revealed that LPS-induced expression of IL-6, IL-8 and growth-related oncogene alpha (GRO alpha) was decreased in the presence of 10 and 20 μM of the NFAT inhibitor, VIVIT. qRT-PCR analysis showed an induction in the expression of IL-7, CCL3, GM-CSF, and MCP-1 upon LPS treatment and LPS-induced expression of MCP-1 and GM- CSF was decreased in the presence of the NFAT inhibitor, VIVIT. qRT-PCR analysis also revealed that the expression of tumour necrosis factor alpha (TNF- α) was decreased upon treatment with LPS and VIVIT.

Conclusions: These results suggest NFAT proteins play an important role in regulation of inflammatory cytokine expression in the RPE. Furthermore, these studies suggest that suppression of NFAT activity by a peptide inhibitor can inhibit inflammatory cytokine expression

ABSTRACT BODY:

Purpose: Zebrafish retinal pigment epithelium (RPE) are able to regenerate after genetic ablation and our previous work has identified several critical regulators of RPE regeneration, including Wnt signaling, mTOR signaling, and immune response factors. Despite these advances, our understanding of the mechanisms driving intrinsic RPE regeneration remains limited. To address this, we conducted a rapid in vivo functional screen of candidate regenerative loci to determine a requirement for RPE regeneration.

Methods: Target genes were selected based on upregulation in regenerating RPE identified from bulk RNA-sequencing data generated from FACS-sorted $eGFP^{+}$ RPE cells. Synthetic guide RNAs (gRNAs) targeting three non-overlapping regions of each candidate gene were generated. Each gRNA was injected, followed by headloop (HL) PCR to confirm mutagenesis efficacy. Having validated each gRNA set, one-cell stage embryos derived from rpe65a:nfsB-eGFP transgenic crosses were then injected with the three synthetic gRNAs-cas9 protein complex (RNP) per gene. Control embryos were injected with a set of scrambled RNPs. At 5 days post-fertilization (dpf), RNP injected larvae carrying the rpe65a:nfsB-eGFP transgene were exposed to 10mM metronidazole (MTZ) for 24 hours to ablate the RPE. At 4 days post-injury (dpi), genotyping of individual embryos was performed to confirm mutagenesis. RPE-specific immunostaining with ZPR2 was performed on ablated RNP injected and control larvae at 4dpi. RPE pigment recovery between injected and control groups was quantified using a MATLAB-based script to assess effects on RPE regeneration.

Results: Mutagenesis rates were high for gRNAs, supporting the efficacy of this approach. Preliminary MATLAB-based quantification data showed significant pigment recovery differences ($p<0.05$) between il11a and scrambled RNP injected groups, as well as between ptgs2a and scrambled RNP injected groups.

Conclusions: il11a and ptgs2a are putative pro-regeneration genes required for RPE regeneration and screening of additional candidate regenerative loci are underway.

ABSTRACT BODY:

Purpose:

Physiology-enhanced data analytics provide a platform to quantify the contributions of various risk factors to primary open angle glaucoma (POAG) pathogenesis, a requirement for personalized disease management. Here, physiology-enhanced data analytics is used to estimate intraocular pressure (IOP) and its relationship to vascular resistance in the retinal venules and central retinal vein (CRV) in participants of the Thessaloniki Eye Study (TES).

Methods:

TES involved 3136 eyes including 98 POAG eyes and 423 eyes suspected of POAG. Structural and vascular assessments were conducted via Heidelberg Retinal Tomography (HRT) and Flowmetry (HRF). IOP and systolic and diastolic blood pressures (SBP, DBP) were used as individualized input data for a validated mathematical model (Guidoboni et al 2014), providing hemodynamic outputs based on fundamental mechanisms of vascular physiology. The enhanced dataset is made by the combination of collected and simulated data.

Results:

OAG eyes had higher IOP and lower DBP compared to healthy eyes and POAG suspects. Diastolic CRV resistance was significantly higher (5-fold) in POAG eyes compared to healthy eyes. In glaucoma suspects compared to healthy, median CRV resistance was similar, while the 75^{th} percentile was much higher (Table 1). The differences in the venous resistances are also accompanied by significant differences in structural and vascular biomarkers (Table 1).

Conclusions:

Hemodynamic alterations in the venous circulation may influence the relationship between IOP and glaucoma and alter risk. In addition, increased vascular resistances of the retinal veins are indicative of higher susceptibility to vessel collapse in patients with POAG.

ABSTRACT BODY:

Purpose: Cream-based formulations applied to the eyelid offer a novel approach for the delivery of pharmaceutically active compounds for the treatment of ocular disorders. We performed studies to investigate the tolerability and toxicity of a pilocarpine ophthalmic topical cream applied to the eyelids of Hanford minipigs.

Methods: Male Hanford minipigs (N=16; 3-5/group) were administered sterile Pilocarpine Ophthalmic Topical Cream (low, mid and high dose) or its vehicle (Pilocarpine Ophthalmic Topical Cream, 0%) to the upper eyelids of both eyes for 28 days with a 14-day recovery period. Parameters evaluated included viability, clinical signs, dermal and ocular irritation, ophthalmic examinations, intraocular pressure (IOP), pupillometry, body weight, food consumption, toxicokinetics, clinical pathology (hematology, coagulation and serum chemistry), organ weights, macroscopic and ocular and systemic microscopic observations.

Results: There were no vehicle- or drug-related effects on mortality, clinical signs, eyelid dermal and ocular irritation scores, ophthalmic examinations, IOP, pupil size, body weights, clinical pathology, organ weights, or macroscopic observations. There were no vehicle- or drug-related microscopic findings in ocular tissues and extraocular tissues including eyelids and lacrimal glands. Toxicokinetic evaluation at a local dose 2.1 times higher than the highest planned clinical dose showed lower systemic exposures than those observed following a single dose of 10 mg pilocarpine hydrochloride tablets in human. Pilocarpine concentrations in target tissues, including main and accessory lacrimal glands and ciliary body, were at levels deemed likely to be effective.

Conclusions: A novel sterile Pilocarpine Ophthalmic Topical Cream was well tolerated with low systemic exposures after application to the eyelids. Concentrations achieved in the target tissues support the eyelid route of administration. Therefore, local and systemic safety concerns of Pilocarpine Ophthalmic Topical Cream are low and support the evaluation of the efficacy and safety in the Phase 2 clinical trials for the indications of dry eye disease and presbyopia.

ABSTRACT BODY:

Purpose: To study anatomical and vascular changes in the superficial capillary (SCP) and deep capillary (DCP) plexuses in the retina, as well as changes in the choriocapillaris (CC) and foveal avascular zone (FAZ) using optical coherence tomography angiography (OCTA) (DRI-Triton SS-OCT) in type 1 diabetic (DM1) patients without diabetic retinopathy (DR).

Methods: We performed a single-center cross-sectional descriptive study including 40 eyes of well-controlled DM1 patients who had been diagnosed at least 10 years prior, and 72 eyes of 72 healthy subjects. All participants underwent a full ophthalmic examination including OCTA using Deep Range Imaging (DRI)-Triton swept source (SS)-OCT.

Results: Mean age was 41.70±11.48 and 42.78±13.70 years in DM1 group and in the control group respectively. There were no differences in VA, EE, AL nor IOP. Statistical differences were found in all areas of the SCP, with lower values in DM1 patients. There were differences in all quadrants except the central zone in the DCP. In the CC there were only significant blood flow changes in the central area. We did not find significant differences in the FAZ in neither of the plexuses, but the horizontal FAZ SCP diameter was found significantly different. The anatomical evaluation frequently showed abnormalities such as microaneurysms in both plexuses, FAZ modifications and areas with lack of blood perfusion.

Conclusions: DM1 patients without DR present microvascular abnormalities with lack of retinal and CC blood perfusion, as well as anatomical changes in retinal blood vessels.

TITLE: Accuracy of Laser-Generated Partial Thickness Corneal Incisions Using an Integrated Femtosecond Laser Phacoemulsification System

SESSION TITLE: Refractive and non-refractive corneal surgeries

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: T. Govindarajan, E. Teuma, LENSAR Inc, Orlando, Florida, UNITED STATES|

Commercial Relationships Disclosure: Tina Govindarajan: Commercial Relationship(s);Code E (Employment):LENSAR | E Valas Teuma: Commercial Relationship(s);Code E (Employment):LENSAR

ABSTRACT BODY:

Purpose: Corneal incisions created during cataract surgery include full thickness incisions (FTIs) used to access the anterior chamber and partial thickness incisions (PTIs) used to correct corneal astigmatism. Laser-generated corneal incisions demonstrate increased accuracy, predictability and reproducibility compared to standard, manual incisions. This study assessed the accuracy of partial thickness corneal incisions constructed in the porcine eye model by an integrated femtosecond laser phacoemulsification system (ALLY System, LENSAR, Orlando, FL).

Methods: Paired corneal PTIs, 180° apart, were generated on 36 porcine eyes at 3 incision depth modes and 3 arc lengths (30°, 60°, and 90°). The 3 incision depth modes were Fixed Depth, Fixed Residual Stroma and Percentage Depth. Incision depths were measured with a Fourier Domain OCT system. Incision arc lengths captured from the laser system and from a laboratory microscope were analyzed using a MATLAB algorithm.

Results: For Fixed Depth PTIs, the mean achieved depths were 407µm ± 30µm and 628µm ± 30µm for intended depths of 400µm and 600µm, respectively. In the Fixed Residual Stroma group, the mean achieved residuals were 181µm ± 23µm and 276µm ± 33µm for intended residual depths of 150µm and 250µm, respectively. For the Fixed Percentage Depths group, the mean achieved percentages were 75% ± 4% and 86% ± 4% for intended percentage depths of 75% and 85%, respectively. Arc lengths measured from microscope images for intended arc lengths of 30°, 60° and 90°, were 30.20° ± 0.44°, 60.32° ± 0.56° and 89.56° ± 0.28°. Similarly, arc lengths measured from laser system images were 30.38° ± 0.54°, 60.19° ± 0.61° and 89.55° ± 0.34°, for intended corresponding arc lengths of 30°, 60° and 90°.

Conclusions: The LENSAR ALLY System constructs accurate, predictable, and reproducible PTIs at selected parameters and incision modes. Additionally, incision arc length measurements are consistent between images acquired by the laser system during the procedure and images acquired via microscopy after laser treatment. The consistency and regularity associated with the PTIs created using the ALLY system may help minimize the incidence of undesirable refractive surprises, thus providing an advantage compared to manual PTIs.

ABSTRACT BODY:

Purpose: To develop a fully-automated, end-to-end system that can capture and predict changes in retinal layer thickness from OCT scans.

Methods: We used 1308 OCT images (496 x 768 resolution) collected from 118 patients with AMD that progressed over time. Each patient dataset contained a consecutive sequence of OCT images obtained from multiple follow-up visits over at least two years (mean follow-up time 11.08 years ± 8.53). The region between the retinal pigment epithelium (RPE) and outer plexiform layer (OPL) was initially segmented by experts, and its thickness was presented by averaging the number of pixels between the two layers over the horizontal axis. Then, a Convolutional-Neural Network (CNN) was trained to capture the thicknesses from the longitudinal OCT scans, formulating thicknesses time-series for each patient. At last, a long-short term memory (LSTM) model was trained to process the time series and predict the thickness change in the future.

Results: OCT sequences in the dataset are split by 8:2 ratio to constitute training and testing dataset. In the test set, images obtained from t=0 to t=T-1 were used to evaluate the performance of the CNN, while t=T was left for evaluating the LSTM. The CNN achieved 13.0% mean absolute error (MAE) between the predicted thicknesses and the measurements extracted from segmentations. The LSTM achieved 21.46% MAE in predicting the RPE-OPL layer thickness at t=T, using the thickness time-series (t=0 toT-1) extrapolated by the CNN.

Conclusions: Our learning-based approach can facilitate predictions of retinal layer thickness changes directly from the OCT scans that could be used to predict AMD progression or response to treatment.

ABSTRACT BODY:

Purpose: Vascular adhesion molecules on endothelial cells (ECs) are key players in immune cell recruitment during inflammation. We have recently shown that limbal vessels are in close proximity with sensory nerves and that ciliary nerve axotomy results in upregulation of adhesion molecules on the vascular endothelium. The purpose of this study is to dissect the molecular mechanism involved in the neuronal modulation of vascular adhesion molecules by trigeminal ganglia (TG) sensory neuron.

Methods: $CD31^{+}CD45^{-}Lyve\text{-}1^{-}$ blood ECs and $CD31^{+}CD45^{-}Lyve\text{-}1^{+}$ lymphatic ECs were sorted by flow cytometry (FC) from normal corneal limbus and assessed for the expression of neuropeptide receptors (NP-Rs): NK1R, VIP-R1, VIP-R2, CRLR by qRT-PCR. TG sensory neurons were obtained from C57BL/6 mice pups and HUVECs were purchased from ATCC. Co-cultures were performed by seeding TG neurons in a transwell plate with HUVECs in presence of recombinant TNF-α. The antagonist for NP-Rs for VIP, SP and CGRP were used to block neuropeptides. HUVECs were then assessed for adhesion molecule expression by qRT-PCR or FC

Results: Sorted limbal blood ECs showed high expression levels of NK1R, VIP-R1, VIP-R2 and CRLR compared to lymphatic ECs (800-, 7400-, 6200- and 69-fold change respectively ($P<0.05$). mRNA Expression of adhesion molecules (MadCAM-1, and E-selectin) on HUVECs was reduced with TG neuron in presence of recombinant TNF-α by 94% and 90% respectively ($P<0.05$). qRT-PCR showed that MadCAM-1 and E-selectin inhibition by TG neurons was reversed in the presence of SP and VIP antagonists ($P<0.05$). Similarly, FC histograms confirmed the reversal of the inhibitory effect of TG neurons on MadCAM-1 by using VIP and SP antagonists. Additionally, E-selectin inhibition by TG neurons was reversed by VIP and CGRP antagonists ($P<0.05$) by qRT-PCR.

Conclusions: Corneal limbal blood ECs show high levels of NP-Rs expression, suggesting the potential role of NPs on regulating their functions. We observed that the expression of adhesion molecules was inhibited in co-cultures with TG neurons. Moreover, this inhibitory effect could be reversed blocking NPs, demonstrating a selective NP effect on regulating the expression of adhesion molecules. Collectively, these findings suggest that TG sensory neurons regulates the expression of adhesion molecules on ECs through NPs during inflammation.

ABSTRACT BODY:

Purpose: Being a part of the central nervous system, retinal and optic nerve injuries caused by trauma or diseases often lead to progressive degeneration of retinal ganglion cells (RGCs) and permanent vision loss that cannot be restored. The purpose of this study is to develop a biocompatible polyelectrolyte scaffold that supports RGC survival and directs axon growth to promote optic nerve regeneration.

Methods: Retinal explants or primary RGCs were isolated from postnatal day 0-3 C57BL/6 mouse pups and cultured in the presence or absence of glutamate blockers targeting ionotropic or metabotropic glutamate receptors, respectively. Cultures were treated with or without electrical stimulation (ES) at 20 Hz, 50 μA for 15 min or plated on top of polyelectrolyte scaffolds that were fabricated by electrospinning and incubated for 1-5 days. The rate of cell survival, neurite outgrowth, neurite lengths, and angles of neurite extensions were quantified by immunocytochemistry. Statistical significance was calculated using Student's t-test or one-way analysis of variance (ANOVA), and a value of $p < 0.05$ was considered statistically significant.

Results: We found ES significantly promoted the number and lengths of RGC neurites. This effect of ES was largely diminished in the presence of glutamate receptor blockers targeting ionotropic N-methyl-D-aspartate (NMDA), α-amino-3-hydroxy-5-methyl-4-isoxazole propionic acid (AMPA)/kainate receptors, or metabotropic receptors. Glutamate-conjugated polyelectrolyte biomimetic isotropic or aligned electrospun scaffolds were thus generated, featuring similar 3D fibrous structures and physical properties, to mimic continuous glutamate stimulation. The glutamate-containing polyelectrolyte scaffolds supported RGCs survival and promoted robust growth of long neurites in both retinal explants and dissociated cell cultures ($p<0.01$). The aligned scaffolds also drove directed nerve elongations along the direction of the fibers, guiding neurites growing towards the same orientation.

Conclusions: ES enhances RGCs growing long neurites through glutamate signaling. By constructing a glutamate-rich polymer scaffold, it presents a permissive biomaterial that drives robust and directed axon growth in primary cultured RGCs as well as retinal explants. Such polyelectrolyte scaffolds can be beneficial for future nerve repair and regeneration.

TITLE: Comparison of multiple batches of human iPSC-derived retinal organoids produced at large scale

SESSION TITLE: Stem cells and organoids

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Gandara, W. Atkin, H. Steward, M. Kay, G. Buchanan, L. Armstrong, V. Chichagova, Newcells Biotech, UNITED KINGDOM|L. Armstrong, Newcastle University, Newcastle upon Tyne, Tyne and Wear, UNITED KINGDOM|

Commercial Relationships Disclosure: Carolina Gandara: Commercial Relationship: Code N (No Commercial Relationship) | William Atkin: Commercial Relationship: Code N (No Commercial Relationship) | Hannah Steward: Commercial Relationship: Code N (No Commercial Relationship) | Madalaine Kay: Commercial Relationship: Code N (No Commercial Relationship) | George Buchanan: Commercial Relationship: Code N (No Commercial Relationship) | Lyle Armstrong: Commercial Relationship: Code N (No Commercial Relationship) | Valeria Chichagova: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Due to well-known limitations of current retinal models, an in vitro 3D model of the human retina that is reproducible and accurately predicts in vivo outcomes is highly desirable. In this study, we have compared the gene and protein expression profile in several batches of human iPSC-derived retinal organoids (ROs) to understand the level of variability found in ROs produced at large scale.

Methods: Gene expression of 20 known retinal genes and representative markers of key cell types were quantified every 30 days by real-time PCR and immunofluorescence, respectively. RNA and 10 µm-cryosections were extracted from pools of ROs selected at random at different stages of differentiation and maturation from at least 4 biological replicates. iPSCs were used as a baseline control for relative quantification of gene expression. Quantification of Z-stack sum projections for marker expression was done using Fiji. One-way ANOVA and Turkey's multiple comparison test of gene and protein expression data was performed.

Results: Expression of photoreceptors (PRs), bipolar cells, müller glia, retinal ganglion cells (RGCs), horizontal cells (HCs), amacrine (AC) and retinal pigmented epithelium cells was increased in all ROs compared to iPSCs. The expression of different cell types fluctuates across RO development, which resembles in vivo development. Interestingly, the expression of RGC markers (MATH5 and BRN3) peaked at day 60, whereas cone (OPN1SW, OPN1MW and OPN1LW) and rod (RHO) PR genes are expressed from day 120 achieving highest expression at day 210 in culture. In terms of cell populations, RCVRN was observed on average in 20% of the cells in day 150 ROs. This average was consistent across different batches of ROs ($p>0.05$). This expression level plateaus at day 210 with nearly 30% RCVRN positive cells present in several ROs.

Conclusions: We have analysed the gene and protein expression profile of several batches of human iPSC-derived ROs across different stages of development. We observed that some key retinal cell types, such as PR, HC and AC, appear at consistent levels between batches. This data set provides crucial information for pre-clinical studies in ROs with application in drug discovery, disease modelling and gene therapy.

TITLE: Changes in Optic Nerve Glia Induced by Astrocyte-specific Deletion of STAT3

SESSION TITLE: Neuron/Glia Interactions in Retinal Health and Disease

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: P.F. Cullen, D. Sun, Massachusetts Eye and Ear, Boston, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Paul Cullen: Commercial Relationship: Code N (No Commercial Relationship) | Daniel Sun: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The optic nerve head, where retinal ganglion cell axons emerge from the eye, is a region dominated by astrocytes and a site of early glaucomatous damage, yet much remains unknown about the reactive changes these glia undergo during disease progression and how reactivity influences neuronal survival and the preservation of vision. Although astrocyte reactivity is heterogeneous, many conserved elements are mediated through the transcriptional activator STAT3, and our group has previously shown that astrocyte-specific deletion (KO) of this gene worsens progression in a murine model of ocular hypertension. Here we present additional evidence of changes induced by this targeted deletion, both in astrocytes themselves as well as microglia, in order to better understand the protective roles mediated by this key pathway.

Methods: Optic nerves were isolated from mice with astrocyte-specific STAT3 KO - both constitutive & tamoxifen-induced – and investigated with immunostaining techniques to assess changes in protein expression and morphology in both astrocytes and microglia; as well as astrocyte density.

Results: Astrocyte specific KO of STAT3 was accompanied by diminished expression of cytoskeletal elements – including GFAP & Nestin – in both constitutive and induced animals, with the greatest changes colocalizing with a region of altered astrocyte morphology and reduced density (mean density 10.5 [SD +/- 3.7] per 10,000 μm^2 in KO, 17.2 [SD +/- 3.1] per 10,000 μm^2 in controls, N=3) in the constitutive knock outs. Additional markers seen in control astrocytes, such as Cxcl10 and ApoE, were entirely absent in STAT3 KO astrocytes. Finally, major changes in microglial morphology were observed in the optic nerves of KO animals, including realignment of cellular processes parallel to axonal orientation.

Conclusions: Astrocyte specific deletion of STAT3 results in major changes to astrocytes of the optic nerve – in terms of marker expression, morphology, and overall numbers – as well as resident microglia. That many of these changes are also found in tamoxifen induced knock outs suggests that astrocytic STAT3 is required for normal interactions of these glial cell types in the adult animal, rather than resulting from developmental changes induced by constitutive deletion.

ABSTRACT BODY:

Purpose: Since the advent of induced pluripotent stem cell (iPSC) technology over a decade ago, scientists have harnessed it to develop differentiation processes that can be applied to clinical therapeutics for better patient outcomes. To that end, we have developed a protocol to differentiate iPSCs into fully polarized and functional retinal pigment epithelium (RPE) cells in a way that recapitulates endogenous biological development of RPE. Verifying that our protocol mirrors natural differentiation is a vital step towards developing next-generation therapeutics for diseases that affect RPE.

Methods: iPSC lines were acquired from Allen Institute with GFP tags for TUBA1B and F-ACTIN. Dual SMAD inhibition was used to generate neuroectoderm which was then directed towards RPE progenitors. Inhibition of the FGF and TGF pathways with addition of activin-A then induced the RPE progenitors into committed RPE cells. This differentiation was staged on iBidi chamber slides and lines were fixed at critical stages of differentiation and maturation. The fixed lines were then stained with antibodies for marker proteins critical for development and imaged for fluorescence analysis.

Results: TRA-1-81 and SOX2, proteins expressed most in pluripotent stem cells, decreased during the differentiation process, confirming the cells' transformation from a pluripotent to a non-pluripotent state. Randomly organized intracellular actin filaments in differentiating cells rearranged into polygonal shapes to provide the hexagonal architecture characteristic of mature RPE cells. Cilia, another sign of RPE maturity, was observed with the TUBA1B GFP tag during the start of RPE maturation. MITF expression increased during differentiation, marking RPE lineage. Concomitantly, expression of TYRP1, needed for melanosome formation also increased. Absorbance of light by the cells also increased with maturation, suggesting increasing pigmentation. Additionally, PAX6, OTX2 and RPE65, which are marker proteins for RPE, increase with time.

Conclusions: Our differentiation protocol is successful in developing RPE cells from human-derived iPSC lines. These cells recapitulate the hallmark features and expression patterns characteristic of human RPE cells. This study has provided a more robust understanding of RPE differentiation process and advances us towards a biologically capable clinical therapeutic for RPE disease.

ABSTRACT BODY:

Purpose: To evaluate the refractive results of the modified surgical implantation technique of intraocular acrylic posterior chamber lenses (IOL) with intrascleral fixation Carlevale IOL (FIL SSF, Soleko, Italy).

Methods: 71 patients (72 eyes) were included in this non-randomized retrospective study. Carlevale IOL implantation with intrascleral fixation was performed in all cases. In 29 patients (29 eyes) the standard implantation technique with scleral flaps was preformed (group 1), while in 42 patients (43 eyes) a modified "scleral pocket" technique was used (group2). Standard examinations were carried out after 1, 4, 8 weeks and after 12 months. The modified technique consisted of the formation of 2.5 x 2.5 mm "scleral pockets" of ½ the scleral depth, in the meridian of 3 and 9 o'clock with an opening away from the limbus. Next, sclerotomies were performed with a 23G trocar inside the pockets 1.5 mm from the limbus. Then, Carlevale IOL was implanted through a sclero-corneal tunnel, followed by fixation in the intrascleral space of the "scleral pockets". Postoperative mean refractive error was analyzed in both groups.

Results: The mean follow-up time was 11.8 months (1-30 months). The mean age of the 71 patients (72 eyes) was 75.7 years (28-95 years). The mean refractive error in group 1 was 0.47 (-2.39 - +3.11), while in group 2 it was 0.021 (-2.64 - +1.98). The minimum dioptric power of the implanted Carlevale IOL was +9.0 D, the maximum +25.5 D. The mean axial length was 23.76 mm (21.55-25.92 mm). The complications of the early postoperative period included fluctuations in intraocular pressure (IOP): 11 patients with a history of glaucoma developed an intraocular hypertension (30 to 45 mmHg) and 1 patient developed a transient hypotension. Mild corneal edema was observed in 30 patients. There were no complications associated with Carlevale IOL implantation within 12 months follow-up period.

Conclusions: The new technique makes it possible to minimize the manipulation on the sclera by simplifying access to the sclera, reducing operating time and postoperative rehabilitation through more reliable sealing of sclerotomies. In all cases the correct and centered position of the IOL was achieved. The IOP fluctuation remains one of the most common complications in the postoperative period.

ABSTRACT BODY:

Purpose:

Na+/K+-ATPase plays a major role in the electrochemical equilibrium across the ciliary epithelium (CE). Clinical data demonstrate reducing pump activity through Na+/K+-ATPase inhibitors such as nitric oxide-donating prostaglandin may help reduce intraocular pressure (IOP), an established risk factor for glaucoma. In this investigation we estimate optimal levels of Na+/K+-ATPase inhibitors using a mathematical model of the impact of Na+/K+-ATPase activity regulation on aqueous humor production (AHP).

Methods:

AHP is described by the iterative solution of the coupled interaction between electrodiffusion of Na+, Cl- and K+ and AH fluid motion through a compartment scheme of the CE including ciliary capillary (CC), stroma, pigmented (PE) and nonpigmented (NPE) cells, lateral intercellular spaces (LIS) and posterior and anterior chambers connected to the episcleral vein (EV) through an outflow facility conductance. A gap junction separates PE and NPE and a tight junction separates the two LIS. Ion transport is modeled by passive membrane transporters and active Na+/K+-ATPase pump. Cell electroneutrality is enforced by a fixed intracellular negative charge. Simulations are performed under short circuit conditions and hydrostatic pressures of 25 and 8 mmHg in CC and EV.

Results:

Fig. 1 shows the predicted AH volumetric flow rate Q_{AH} (VFR) as a function of the adimensional ratio $\gamma = [ATP]/Ksat$, [ATP] being the intracellular ATP concentration and Ksat=1μM the half-saturation constant, for several values of the maximum activation pump flux density Jmax. Results indicate that for sufficiently high Jmax, there exists a (different) range of γ for which Q_{AH} decreases with respect to the reference value 2.5 μL/min. Fig. 2 shows the percent variation ΔQ_{AH} with respect to baseline conditions (γ=0, '*') as a function of Jmax, for several values of γ. Results indicate that maximum Na+/K+-ATPase impact on VFR reduction is of 8%.

Conclusions:

Model predictions suggest that a marked inhibition of ATPase activity ($\gamma << 1$) does not significantly reduce AHP. Conversely, modeling demonstrates that allowing an intermediate level of pump activity (for [ATP]=5Ksat) maximizes AHP reduction. These results demonstrate potential ability of mathematical virtual laboratories to assist clinicians in optimizing IOP lowering medications.

Commercial Relationships Disclosure: Carlos Mendez Mangana: Commercial Relationship: Code N (No Commercial Relationship) | Anton Barraquer Kargacin: Commercial Relationship: Code N (No Commercial Relationship) | Jorge Fernandez-Engroba: Commercial Relationship: Code N (No Commercial Relationship) | Pedro Taña: Commercial Relationship: Code N (No Commercial Relationship) | Gil Santolaria: Commercial Relationship: Code N (No Commercial Relationship) | Maximiliano Olivera: Commercial Relationship: Code N (No Commercial Relationship) | Rafael Barraquer: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The overall aim of the study is to explore the capability of detection using algorithms trained in Automated Deep Learning (AutoML) of graft failure from a proprietary dataset of post-keratoplasty patients from a case series published in the literature.

Methods: Observational cross-sectional study, for which Automated Deep Learning algorithms were trained following the success/failure labeling strategy based on clinical notes, on a cohort corresponding to 220 images of post-keratoplasty anterior pole eyes. Once the image quality criteria were analyzed and the dataset was pseudo-anonymized, it was transferred to the Google Cloud platform, where using the Vertex AI- AutoML API, cloud and edge-based algorithms were trained, following expert recommendations on dataset splitting (80% training, 10% test, 10% validation).

Results: The metrics obtained in the cloud-based and edge models have been similar, but we chose to analyze the edge model as it is an exportable model, lighter and cheaper to train. The initial results of the model presented an average accuracy of 0.995, with a Specificity of 95.8% and a Sensitivity of 95.8%. For the label "Graft Failure" the algorithm presented a Specificity of 92.3% and a Sensitivity of 100%. Other metrics such as F1-score, AUC, confusion matrix and activation map development were contemplated.

Conclusions: The initial results of our study indicate that it is possible to train algorithms in an automated fashion for the detection of Graft Failure in patients undergoing penetrating keratoplasty surgery. These algorithms, especially the edge type, are very lightweight tools and easily integrated into mobile or desktop applications, potentially allowing every corneal transplant patient to have access to the best knowledge to enable the correct and timely diagnosis and treatment of this condition.

The metrics obtained in our training process are very good, but since it is a relatively small dataset, it is possible that we have some tendency to overfitting.

The use of Automated Machine Learning opens the possibility of working in the field of artificial intelligence by computer vision to professionals with little experience of programming and is a growing field.

In the next stages of our research line we will seek to expand the working dataset, train algorithms in a traditional way using the Tensorflow library and open ourselves to collaborations to increase the impact of our work.

ABSTRACT BODY:

Purpose: Recent advances in the analysis of large-scale 512-electrode array recordings have revealed 10+ novel retinal ganglion cell (RGC) and amacrine cell types in the primate retina. To better understand the function of these cell types and the way they vary across retinas and experimental conditions, we are developing methods to automatically identify both the known and novel cell types in a large archival dataset.

Methods: We analyzed 182 ex vivo recordings (89k cells) from peripheral macaque retina. The spatial, temporal, and spectral properties of each cell's visual response were parameterized from the spike triggered average obtained with random checkerboard visual stimuli (Fig. 1A). To classify novel cell types with atypically sparse spiking and inhomogeneous receptive fields (RFs), we used a multi-stage process, iteratively identifying known and then novel types. We compensated for the variation of light response properties across the visual field and across retinas by using the parameters of known RGC types as benchmarks.

Results: The automated classification methods reliably identified the ON & OFF parasol and ON & OFF midget RGC types, achieving 0.96±0.06 accuracy (mean±SD), with 49% of experiments reaching >0.98 accuracy (≈1 error/type/recording) relative to manual supervised labels. Normalizing for spatial and temporal variability using ON & OFF parasol RGCs increased classification accuracy from 0.70±0.13 (Fig. 1B) by reducing across-dataset parameter variance (Fig. 1C). Measures of RF properties, such as the RF solidity (fill fraction of convex hull), enabled classification of a novel type with 0.92±0.12 accuracy in 8 recordings (6k cells; Fig. 1D).

Conclusions: Automated classification applied to a large primate retina dataset, using iterative analysis and variability normalization, provides a broad, objective overview of the functional properties of numerous known and novel cell types.

ABSTRACT BODY:

Purpose: Macrophages exhibit a spectrum of phenotypes with differential biological functions including phagocytic, proinflammatory or wound healing, profibrotic. Cornea and conjunctiva contain a significant resident macrophage population. Injury to the cornea and systemic diseases such as graft-versus-host disease can cause ocular surface fibrosis and myofibroblast formation. The present study was designed to investigate whether macrophage polarization can modulate profibrotic signaling in corneal and conjunctival fibroblasts.

Methods: Bone marrow-derived macrophages (M0) were cultured from femur and tibia bone marrow cells of BALB/c mice in the presence of macrophage colony stimulating factor (m-CSF). Macrophage polarization was induced by adding LPS + IFN-γ (M1 spectrum) or IL-4 (M2 spectrum). Flow cytometry was used to characterize the macrophage subtypes by staining for CD11b, F4/80 (Pan markers), CD86 (M1) and CD206 (M2) markers. Cultured murine corneal and conjunctival fibroblasts were exposed to M0, M1 or M2 macrophage supernatants. Immunostaining and real-time PCR were performed to quantify alpha-smooth muscle actin (α-SMA) as a marker for transdifferentiation of the fibroblast to myofibroblasts. The cDNA of supernatant exposed fibroblasts was used to quantify gene expression changes in profibrotic cytokines (TGF-β1, PDGF, CTGF), renin angiotensin system (RAS) components (angiotensin converting enzyme (ACE) and angiotensinogen), and the macrophage proliferation cytokine (m-CSF) using real-time PCR.

Results: Supernatants from M0 and M2 macrophages caused a 2- to 4-fold increase in expression of α-SMA in corneal and conjunctival fibroblasts. Further, > 60% fibroblasts exposed to supernatant of M0 and M2 macrophages showed α-SMA staining. Supernatant from all the three macrophage phenotypes significantly increased the expression of cytokines (TGF-β1 and PDGF), RAS components (ACE and angiotensinogen), and m-CSF and the changes were phenotype specific. Supernatant of M1 macrophages had more prominent effect on RAS components whereas cytokine expression was increased more robustly by supernatant of M0 and M2 macrophage subtypes.

Conclusions: Polarized macrophages cause transdifferentiation of corneal/conjunctival fibroblasts to myofibroblasts and increase the expression of profibrotic mediators in the fibroblasts in a phenotype-specific manner.

ABSTRACT BODY:

Purpose: Publication outcomes for retina conference presentations are not well-described. The objective of this study was to characterize publication outcomes and predictors of publication for publicly available retina abstracts presented at global ophthalmology conferences.

Methods: We included all publicly available, English-language retina abstracts from 2016 meeting archives for conferences in World Health Organization (WHO) regions. We searched PubMed, Medline, and Google Scholar from January 1, 2014 to May 1, 2021 to identify whether each abstract was published within five years. Descriptive statistics, χ^2 tests, and t-tests were used to compare abstracts by conference and publication. Univariate and multivariate logistic regression were used to identify predictors of publication.

Results: Among the 11 included conferences, 900 retina abstracts were presented; 60% (539/900) were published in a peer-reviewed journal within five years. Author affiliation with an academic institution [OR=1.93, 95% CI=1.00–3.71] and positive results [OR=1.85, 95% CI=1.10–3.12] were significant predictors of publication in multivariate analysis.

Conclusions: This study provides a comprehensive evaluation of publication outcomes from retina abstracts. Author affiliation with an academic institution and reporting positive results predicted publication.

ABSTRACT BODY:

Purpose: To investigate structure-function associations between CS and vascular metrics on WF SS OCTA across stages of non proliferative diabetic retinopathy (NPDR) and proliferative diabetic retinopathy (PDR), in the absence of diabetic macular edema (DME).

Methods: This prospective observational study included 95 eyes of 78 patients, including 20 mild NPDR eyes, 12 moderate/severe NPDR, 22 PDR, 14 diabetic eyes without DR (DMnoDR), and 27 control eyes. LogMAR Visual Acuity (VA) was measured. CS was measured with the active learning quantitative CS function (qCSF) Manifold Contrast Vision Meter (Adaptive Sensory Technology) and outcomes included Area under the Log CSF (AULCSF) and contrast sensitivity (CS) thresholds at 1-18 cycles per degree (cpd). All eyes were imaged using WF SS OCTA (Plex Elite 9000, Carl Zeiss Meditec). The ARI Network (Zeiss Portal v5.4) delivered vascular metrics, including vessel density (VD) and vessel skeletonized density (VSD) in the superficial and deep capillary plexus (SCP, DCP) on 6x6 mm images. Mixed-effects multivariate regression models were used to evaluate associations between CS functional outcomes and WF SS OCTA structural outcomes across DR stages.

Results: Controlling for age and lens status in the whole cohort, VD in the SCP was significantly associated with LogMAR VA (β= -0.02, P<0.001), AULCSF (β= 0.03, P<0.001), and CS thresholds at 1cpd (β= 0.02, P=0.004), 1.5cpd

(β= 0.02, P=0.005), 3cpd (β= 0.03, P=0.009), 6cpd (β= 0.04, P=0.002), 12cpd (β= 0.04, P= 0.002) and 18cpd (β= 0.01, P= 0.044).VSD in the SCP was associated with LogMAR (β= -1.19, P= 0.010), AULCSF (β= 1.18, P= 0.010), and CS at 1cpd (β= 1.00, P=0.008), 1.5cpd (β= 0.91, P=0.016), 3cpd (β= 0.89, P= 0.039), 6cpd (β= 1.5, P= 0.011) and 12cpd (β= 1.44, P= 0.008); VD in the DCP was associated with LogMAR (β= -0.01, P=0.008), AULCSF (β= 0.01, P= 0.066) and 12cpd (β=0.18, P=0.013) and VSD in the DCP with LogMAR (β= -0.49, P=0.013), AULCSF (β= 0.47, P= 0.099), 12cpd (β=0.82, P=0.021).

Conclusions: We present novel structure-function associations across stages of DR without DME, leveraging WF SS OCTA imaging and CS metrics. The progressive decline in the OCTA vascular metrics across DR stages seems to be associated with equally large changes in contrast sensitivity metrics as in VA.

TITLE: Impact of Micropulse Laser Trabeculoplasty: A 2-Year Retrospective Analysis

SESSION TITLE: IOP and laser therapy

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Morcos, J. Klenda, P. Fortin, A. Pansick, C. Draper, Ophthalmology, Nassau University Medical Center, East Meadow, New York, UNITED STATES|

Commercial Relationships Disclosure: Marcelle Morcos: Commercial Relationship: Code N (No Commercial Relationship) | Jack Klenda: Commercial Relationship: Code N (No Commercial Relationship) | Patricia Fortin: Commercial Relationship: Code N (No Commercial Relationship) | Andrew Pansick: Commercial Relationship: Code N (No Commercial Relationship) | Christian Draper: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To evaluate change in intraocular pressure (IOP) after micropulse laser trabeculoplasty (MLT).

Methods: A retrospective cohort study was conducted at an ophthalmology clinic at a public hospital in New York. 71 eyes with open-angle glaucoma and no history of incisional surgery treated with MLT were followed. An Iridex IQ 532 laser with MicroPulse technology at 532 nm was used to treat 360° of the trabecular meshwork. Follow-up IOP measurements were obtained at two years. Number of topical glaucoma medications before and after MLT were recorded. Paired t-tests compared baseline to follow-up.

Results: Significant IOP reduction occurred at 2-year follow-up ($p=0.001$) from pre- ($M=18.19$, $SD=4.30$) to post-MLT ($M=15.86$, $SD=3.65$). Stratifying by baseline IOP showed significant IOP reduction for IOP>19,(<p=0.001): pre- ($M=22.39$, $SD=2.99$), post-MLT ($M=17.29$, $SD=4.09$). No significant change occurred for baseline IOP<19 ($p=0.44$). No significant change of number of medications occurred ($p=0.57$).

Conclusions: MLT appears to be a long-lasting beneficial adjunct therapy in patients with uncontrolled IOP on topical medications. Prospective randomized controlled studies would further document the utility of this treatment modality.

ABSTRACT BODY:

Purpose: We previously demonstrated that systemic treatment with nicotinamide riboside (NR), a nicotinamide adenine dinucleotide (NAD^+) precursor, elevated retinal NAD^+ levels and protected retinal ganglion cells (RGCs) in a young mouse model of optic nerve crush (ONC). Because NAD^+ levels decline in age and disease, we now compare neuroprotective effects of systemic NR treatment on young and aged mice subjected to ONC.

Methods: Young (3-6 months old) and aged (18-24 months old) C57BL/6J mice were intraperitoneally (i.p.) injected with NR (1000mg/kg) for 5 consecutive days. PBS was injected as vehicle. Two weeks later, unilateral ONC was conducted. Pattern electroretinography (PERG) was conducted 3 days after ONC. In separate cohorts, young and aged mice were injected with NR or PBS; no crush surgery was conducted. Retinas were harvested for whole-mount immunofluorescence staining with RGC marker Brn3a or NAD^+ concentration measurement (Fig.1)

Results: Systemic NR treatment significantly elevated retinal NAD^+ concentrations in both young(young-PBS+no crush vs young-NR+no crush:100±3vs193±10, $p<0.05$, n=10) and aged C57BL/6J mice(aged-PBS+no crush vs aged-NR+no crush:106±6vs192±10, $p<0.05$, n=10) , and also in eyes of young mice following ONC(young-naïve vs young-NR+ONC 100±3 vs. 142±9, $p<0.01$, n=6), but not in aged mice following ONC(aged-naïve vs aged-NR+ONC:110.2±5 vs 122.6±8, $p>0.05$, n=6). In both young and aged mice, PERG responses and numbers of Brn3a-positive cells from crushed retina were diminished compared with non-crushed(Table.2). NR treatment significantly preserved Brn3a-positive RGC numbers in both young and aged mice following ONC(young-PBS+ONC vs young-NR+ONC:1120±72vs1389±72 cells/field, $p<0.05$, n=7-9; aged-PBS+ONC vs aged-NR+ONC:1004±34vs1193±49 cells/field, $p<0.05$, n=7-8) and preserved PERG responses in young(young-PBS+ONC vs young-NR+ONC: P1:5.43±0.7vs8.91±0.8μV, $p<0.01$; N2:-8.02±0.9vs -12.2± 1.0μV, $p<0.01$, n=15) but not in aged mice following ONC(aged-PBS+ONC vs aged-NR+ONC:P1:2.42±0.4vs3.70±0.5μV; N2:-4.15±0.5 vs -6.03± 0.7μV, $p>0.05$, n=14).

Conclusions: NR treatment significantly protected against ONC-induced RGC death in both young and aged mice and significantly protected against ONC-induced RGC dysfunction in young but not in aged mice. It may be that ONC in aged mice partially suppresses NR-induced elevation of NAD^+, preserving RGC survival but not RGC function.

ABSTRACT BODY:

Purpose: Extracellular matrices (ECMs) are an important source of developmental and homeostatic molecular cues. Although much is known regarding the molecular mechanisms of retinal regeneration, our understanding of the ECM's role in this context remains unclear. This study investigates the role of the ECM molecule nephronectin (Npnt) in regulating Müller glia (MG) and neural progenitor cell (NPC) proliferation and retinal neuron survival in the light-damaged adult zebrafish retina.

Methods: We used in vivo morpholino-mediated gene knockdown to repress Npnt expression in the adult zebrafish dorsal retina. Anti-PCNA immunolabeling of Tg(gfap:egfp) zebrafish retinal sections was used to visualize proliferating MG and NPCs. TUNEL labeling was used to assess cell death. qRT-PCR was used to examine expression of target genes. Protein expression levels and subcellular distribution were assessed using protein immunoblotting of samples enriched for either cytosolic or nuclear proteins from dorsal retinas.

Results: Npnt is present in the adult zebrafish retina and exhibits increased expression 48h after intense light treatment. Knockdown of Npnt results in decreased NPC proliferation and GDNF expression, leading to a significant increase in the death of inner retinal neurons. Protein immunoblotting revealed a novel pattern on Npnt processing and translocation. Under normal conditions, Npnt is observed as a 60 kDa protein, with a portion being cleaved into 20 and 40 kDa fragments. Upon light damage, the entire population is cleaved into the two fragments. Furthermore, our data suggest that one of these fragments is translocated into the nucleus, suggesting that it may directly regulate expression of target. Indeed, Npnt knockdown results in decreased expression of integrins α3b, α4, α11a, and β1, as well as ECM components, such as laminins α1 and α5. Knockdown of these genes also results in decreased MG and NPC proliferation.

Conclusions: These findings demonstrate that the ECM provides regulatory cues guiding zebrafish retinal regeneration. Npnt appears to regulate retinal neuron survival and NPC proliferation. Interestingly, our data suggest that upon damage, Npnt is transported into the nucleus, where it may directly regulate expression of several ECM-related genes that govern the regeneration response. These findings suggest a novel role for Npnt, and expand our understanding of the role of the ECM in retinal regeneration.

TITLE: Effects OF CRISPR knockout of the Humanin trimeric CNTFR/gp130/WSX-1 receptor in AMD

SESSION TITLE: Retinal Prostheses and Transplantation

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S.R. Nashine, M. Kenney, Ophthalmology, University of California Irvine, Irvine, California, UNITED STATES|

Commercial Relationships Disclosure: Sonali Nashine: Commercial Relationship: Code N (No Commercial Relationship) | M.Cristina Kenney: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: In the AMD (Age-related Macular Degeneration) RPE transmitochondrial cell lines, the protective effects of Humanin G (HNG) mitochondrial derived peptide are mediated through the extracellular trimeric CNTFR/gp130/WSX-1 receptor. Binding of Humanin to this receptor leads to the activation of downstream signaling factors, phosphorylation of JAK2 and STAT3, and transcription of genes that confer cytoprotection in AMD.

Methods: We created a novel CRISPR-edited triple knock-out (KO) cell pool of the extracellular trimeric CNTFR/gp130/WSX-1 receptor genes in a wet AMD RPE transmitochondrial cybrid cell line by sequential knock-out of these genes and performed Sanger sequencing to confirm the knockout. HNG was exogenously added to AMD RPE transmitochondrial cybrid cells, which had identical nuclei from the mitochondria-deficient ARPE-19 cells but differed in mitochondrial DNA (mtDNA) content which was derived from a clinically characterized AMD patient. Cell viability and apoptotic cell death were compared between AMD wild-type (WT) vs. AMD KO cells using the MTT assay and Caspase- 3/7/ NucLight IncuCyte® live-cell imaging.

Results: Sanger sequencing of the KO cell pool results: (1) CNTFR gene: KO score=88 %; Indel=94 %; (2) gp130 gene: KO score=62 %; Indel=64 %; (3) WSX-1 gene: KO score=94 %; Indel=99 %. These results demonstrate successful CRISPR editing of the trimeric receptor genes. There was decreased ($P = 0.02$) cellular metabolic activity that reflects cell viability in AMD KO untreated cells (0.88 ± 0.03) compared to AMD WT untreated cells (1 ± 0.04). Higher viable cell number (IncuCyte live-cell imaging) was observed in HNG-treated AMD WT cells (1.14 ± 0.02) compared with untreated AMD WT cells (1 ± 0.04, $P = 0.03$). We found significant reduction ($P<0.01$) in cell number in untreated AMD KO vs. untreated AMD WT cells. HNG-induced rescue was reduced significantly in AMD KO cells compared to that in AMD WT cells ($P<0.05$).

Conclusions: The CRISPR-Cas9 knockout (CRISPR-KO) of the CNTFR/gp130/WSX-1 receptor reduces cell survival in AMD KO cybrids in vitro and blunts the protective effects of exogenous HNG, demonstrating the crucial role of this receptor in HNG-mediated cytoprotection.

ABSTRACT BODY:

Purpose: Evidence suggests that cells from the outer retina play an important role in the pathogenesis of diabetic retinopathy (DR), but whether or not the visual cycle activity is subnormal in diabetes, and whether decreasing or not that activity is a therapeutic approach to inhibit DR is controversial. Here we used the Lecithin:retinol acyltransferase (Lrat) knockout mice to investigate the effects of visual cycle inhibition on the development of early DR.

Methods: Diabetes was induced in male C57Bl/6J (WT) and Lrat heterozygous ($Lrat^{+/-}$) and homozygous ($Lrat^{-/-}$) mice using streptozotocin. Retinoid metabolism, and biochemical and physiological abnormalities in the retina were evaluated at 2 months of diabetes using published methods. Vascular histopathology, permeability and retinal thickness were evaluated at 8 months of diabetes. Non-retinal effects of inhibition of the visual cycle were examined in leukocytes ex vivo at 2- and 8-months of diabetes.

Results: At 2-months of diabetes visual function assessed by OKT and ERG was not significantly affected by diabetes or $Lrat^{+/-}$ whereas in $Lrat^{-/-}$ was severely attenuated. Rhodopsin levels in WT and $Lrat^{+/-}$ diabetics were similar to corresponding values of 11-cis-retinal as determined by retinoid analyses when compared to WT nondiabetics. $Lrat^{+/-}$ mice differed in their level of all-trans-retinyl esters by 50% less when compared to WT and diabetes had no influence in the total levels. No all-trans-retinyl esters were detected in the $Lrat^{-/-}$ groups. Diabetes-induced increase in retinal superoxide was significantly inhibited in $Lrat^{+/-}$ and $Lrat^{-/-}$ diabetic mice when compared to WT diabetics. At 8-months of diabetes, thickness of the ONL by OCT was similar between WT and $Lrat^{+/-}$ but $Lrat^{-/-}$ showed total loss of photoreceptors. Degeneration of retinal capillaries was significantly inhibited in $Lrat^{+/-}$. Similar trends were apparent in diabetic $Lrat^{-/-}$ mice, but mortality in this group precluded further evaluation. The diabetes-induced increase in retinal vascular permeability was inhibited in the inner plexiform and inner nuclear layers of $Lrat^{+/-}$mice, but not in the outer plexiform layer. The leukocyte-mediated cytotoxicity against retinal endothelial cells at 2- and 8-months of diabetes was inhibited in $Lrat^{+/-}$ and $Lrat^{-/-}$ mice when compared to WT diabetic mice.

Conclusions: $Lrat^{+/-}$ diabetic mice are protected from the development of retinal vascular pathology in early DR.

TITLE: A Low-Cost Alternative for Screening Infectious Trachoma in Resource-Limited Settings

SESSION TITLE: Machine Learning: Segmentation and Classification

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: N. Pondicherry, SOM, University of California San Francisco School of Medicine, San Francisco, California, UNITED STATES|J.D. Keenan, L. Della Santina, T. Lietman, M. Deiner, University of California San Francisco, San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure: Neha Pondicherry: Commercial Relationship: Code N (No Commercial Relationship) | Jeremy Keenan: Commercial Relationship: Code N (No Commercial Relationship) | Luca Della Santina: Commercial Relationship: Code N (No Commercial Relationship) | Thomas Lietman: Commercial Relationship: Code N (No Commercial Relationship) | Michael Deiner: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Trachoma, an eye disease caused by Chlamydia trachomatis, is responsible for severe visual impairment/blindness of 1.9 million people worldwide. To treat this disease, WHO recommends community-wide prevalence surveys with trained health workers - a challenge in many resource-limited countries. One possible solution aims to use deep learning (DL), a subsect of artifical intelligence (AI) machine learning. Researchers from the Proctor Foundation at UCSF have developed a DL algorithm to identify trachoma from conjunctival photographs, but the algorithm has only been trained on photographs from Ethiopia - which limits its diagnostic accuracy in other populations. After further training with conjunctival photographs from the Peruvian Amazon, we hypothesize the overall diagnostic accuracy of the algorithm will improve.

Methods: For the present study, 700 conjunctival photographs were selected from a de-identified photo repository of 0–9-year-old kids from the Peruvian Amazon taken during routine trachoma monitoring. The Peruvian photographs were split into a training set (n=600) and a testing set (n=100), and all 700 photos were manually graded and given follicular annotations based on the WHO simplified grading scale for trachomatous inflammation. To test the sensitivity and specificity, the algorithm provided a grade of trachoma (i.e., presence or absence of TF) for each photograph in the test set, and sensitivity and specificity of the algorithm was calculated twice, both pre- and post-exposure to the Peruvian pictures.

Results: When the existing algorithm (trained only on Ethiopian photographs) was run on the 100-photograph Peruvian test set before training with Peruvian photographs, the overall accuracy was 0.50, with a sensitivity of 4% and specificity of 96%. After the addition of the Peruvian training set, the algorithm’s accuracy for the same Peruvian test set improved to 0.82, with a sensitivity of 88% and specificity of 76%.

Conclusions: Our results are consistent with our hypothesis that with increased amounts of diverse population photos, the AI DL algorithm would consolidate and more accurately diagnose follicular trachoma overall. Using a diverse range of populations to improve machine learning for trachoma screening is important to accommodate for the diversity of populations affected by trachoma globally.

ABSTRACT BODY:

Purpose: The p.Gly863Ala missense variant in ABCA4 is associated with ABCA4-retinopathy (Stargardt disease). It has been previously noted that this variant often occurs in cis with another missense variant, p.Asn1868Ile. The purpose of this study was to assess the co-segregation of these variants in a large population-based cohort (UK Biobank) and a single centre ABCA4-retinopathy patient cohort.

Methods: Whole exome sequencing data was available for 37586 participants of European ancestry in the UK Biobank for the population-based cohort. The haplotypic structure of this ABCA4 region was determined from pairwise linkage disequilibrium calculations. The patient cohort included 96 ABCA4-retinopathy patients carrying p.Gly863Ala variant recruited at Moorfields Eye Hospital.

Results: In the UK Biobank cohort 924 participants carried the p.Gly863Ala variant. Only 265 (29%) of these participants also carried the p.Asn1868Ile variant. Haplotypic analysis identified three haplotypes containing the p.Gly863Ala variant, with the p.Asn1868Ile present on one. ICD10 codes indicated that six participants carrying the p.Gly863Ala variant had been diagnosed with retinal disease that may be ABCA4-retinopathy (degeneration of macula and posterior pole), two of whom were also carrying the p.Asn1868Ile variant. In the patient cohort that had received a diagnosis with p.Gly863Ala as one allele, 63/96 had data available for p.Asn1868Ile genotype and 53/63 (84%) also carried the p.Asn1868Ile variant. Therefore, the odds ratio for ABCA4 retinopathy for carriers of both variants compared to p.Gly863Ala only is 9.8 (95% CI: 5.3-17.9, $p=6.7x10^{-14}$).

Conclusions: There is a significant ($p=6.7x10^{-14}$) association of the p.[Gly863Ala;Asn1868Ile] allele in ABCA4-retinopathy cases compared to the p.Gly863Ala variant alone. Thus, the p.Gly863Ala variant is present on several haplotypes with a haplotype carrying both this variant and the p.Asn1868Ile variant being highly enriched in disease. This suggests that a modifying effect of the haplotype may exist (possibly due to the p.Asn1868Ile variant that has recently been shown to act as a low penetrant pathogenic allele in its own right). Further investigation is needed to determine additional factors that may influence the penetrance of disease in carriers of p.Gly863Ala, such as cis modifiers and the severity of trans alleles.

TITLE: Emmetropization is Associated with a Modified Inflammatory Response in the Eye

SESSION TITLE: Myopia: Mechanism of Emmetropization and Eye Growth

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: J.A. Summers, D. Soriano, E. Martinez, Cell Biology, University of Oklahoma Health Science Center, Oklahoma City, Oklahoma, UNITED STATES|

Commercial Relationships Disclosure: Jody Summers: Commercial Relationship(s);Code C (Consultant/Contractor):Plex Pharmaceuticals;Code F (Financial Support):Plex Pharmaceuticals | Diana Soriano: Commercial Relationship: Code N (No Commercial Relationship) | Elizabeth Martinez: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Visually regulated eye growth (emmetropization) is associated with some choroidal changes consistent with that of inflammation. In response to imposed myopic defocus the choroid thickens, exhibits increased vascular permeability, and increases the synthesis of a number of proteins associated with the acute phase response, including ovotransferrin, apolipoprotein A-1 and interleukin 6 (IL6). This study was undertaken to determine whether treatment with the anti-inflammatory drug, dexamethasone (DEX), could alter the emmetropization process.

Methods: DEX or vehicle was administered daily to chicks during the development of monocular form deprivation myopia during the last 7 days of a 17 day deprivation period (4 mg/kg, IP). On the last day of treatment, occluders were removed and chicks were allowed to experience unrestricted vision for ≈20 hrs ("recovery"). Choroids and sclera were isolated from recovering and fellow control eyes. Gene expression of Il6 was quantified using Taqman™ PCR and normalized to GAPDH. Scleral proteoglycan synthesis (an indicator of eye growth in chicks) was evaluated by CPC-precipitation of $^{35}SO_4$-labelled glycosaminoglycans.

Results: DEX treatment resulted in a significant decrease in choroidal IL6 gene expression in recovering eyes, compared to recovering eyes of vehicle treated chicks (↓85%; p = 0.0029, Mann Whitney Test). No significant differences were detected in IL6 gene expression in choroids from control eyes between DEX and vehicle treated chicks (p = 0.4958, Mann Whitney Test). DEX treatment resulted in a significant decrease in scleral proteoglycan synthesis in control eyes, compared to control eyes of vehicle treated chicks (↓59%, p =0.0001, t-test). Despite the suppression of scleral proteoglycan synthesis observed in control eyes of DEX-treated chicks, DEX treatment resulted in a significant increase in scleral proteoglycan synthesis in recovering eyes relative to fellow controls (↑185%, p= 0.0028, paired t-test). No differences were detected in scleral proteoglycan synthesis between recovering and control eyes of vehicle treated chicks (p=0.1374, paired t-test).

Conclusions: DEX treatment reduced choroidal gene expression of IL6 in recovering eyes, resulting in a disinhibition of scleral proteoglycan synthesis during recovery from induced myopia. These results provide additional support for a role of inflammation in visually regulated eye growth.

ABSTRACT BODY:

Purpose: Individuals with neovascular age-related macular degeneration (nAMD) are at considerable risk of developing the same condition in their fellow eye. We analysed the relationship between volumes of OCT biomarkers at baseline with groups of fellow eyes converting to nAMD during a 2-year follow-up period. Biomarkers were quantified using an artificial intelligence (AI) system (De Fauw et al. 2018).

Methods: Fellow eyes of individuals who started treatment for nAMD between June 2012 and June 2017 in the Moorfields Eye Hospital AMD database were included. AI-derived volumes of neurosensory retina (NSR), retinal pigment epithelium (RPE), drusen and hyperreflective foci (HRF) were compared at baseline (the visit the first eye started treatment) between fellow eyes that did and did not convert within 2 years.

Results: A total of 1578 fellow eye scans at baseline were analysed. Of these, 231 eyes converted to nAMD during the 2 year follow-up period and 1347 eyes did not. At baseline, fellow eyes that converted presented with a mean (standard deviation) volume of 0.107mm3 (0.096) and 0.001mm3 (0.001) of drusen and HRF respectively, and were significantly greater (p-values ≤0.05, Mann-Whitney U test]) than the non-converting group (0.068mm3 of drusen and 0.000mm3 of HRF). Baseline RPE volume in eyes that converted was 0.803mm3 (0.097), which was significantly less than in the non-converters (0.835mm3, p-value ≤0.05). NSR volume was 9.211mm3 (0.727) and 9.260mm3 (0.767) in converting and non-converting groups respectively.

Conclusions: Baseline drusen and HRF volumes appear to be important OCT biomarkers for fellow eye disease progression to nAMD. Automated OCT qualification of retinal structures in fellow eyes may suggest new management protocols with a personalised prediction of AMD progression.

ABSTRACT BODY:

Purpose: Autosomal recessive RP (arRP) can be caused by mutations in the phosphodiesterase 6A (PDE6A) gene. Here, we describe the natural course of disease progression with respect to central retinal function, i.e., visual acuity, contrast sensitivity, and color vision and establish a detailed genotype-phenotype correlation.

Methods: 44 patients (26 females; mean ± SD age 43 ± 13 years) with a confirmed genetic diagnosis of PDE6A-associated arRP underwent comprehensive ophthalmological examination and follow-ups including best corrected visual acuity (BCVA) with ETDRS charts, contrast sensitivity (CS) with Pelli-Robson charts at 3 m and 1 m distance, and color vision testing using Roth 28 Hue and Panel D15 saturated color cups. Mean ± SD duration between baseline and last follow-up was 28 ± 12 months.

Results: The most frequently observed variants were c.998+1G>A/p.?, c.304C>A/p., and c.2053G>A/p. In general, symmetry between right and left eyes was high (r = 0.89). Central retinal function in patients homozygous for variant p.R102S was better when compared to patients homozygous for variant c.998+1G>A/p.?, although the former were older at baseline. Central retinal function was similar in patients homozygous for variant p.R102S and patients heterozygous for variants c.304C>A/p.R102S and c.2053G>A/p.V685M, although the latter were younger at baseline. Annual decline rates in central retinal function were small (0.015 logMAR/year).

Conclusions: We conclude that the severity of the different disease-causing PDE6A mutations in humans with respect to central visual function may be ranked as follows: c.2053G>A/p.V685M in homozygous state (most severe) > c.998+1G>A/p.? in homozygous state > c.304C>A/p.R102S and c.2053G>A/p.V685M in compound-heterozygous state > c.304C>A/p.R102S in homozygous state (mildest). The assessment of treatment efficacy in interventional trials will remain challenging due to small annual decline rates in central retinal function.

ABSTRACT BODY:

Purpose: To present safety and efficacy, clinical and surgical observations regarding a novel intracapsular implant

Methods: Ongoing prospective study of 120 patients with 12 months follow-up. The novel implant (fixOflex, EYE-PCR, Netherlands) is a hydrophilic acrylic ring (9.8mm diameter, 1.7mm thickens) injected through a 2.4mm incision prior to the intraocular lens (IOL) implantation. The optic of the IOL is secured in the ring's retainers. Patients were recruited following randomization at Alexandria El nour Eye Hospital. All patient received the same type of IOL (Tecnis ZCB00, J&J, NJ).

Results: Mean best corrected visual acuity and spherical equivalent was 0.92 ± 0.15 and -0.76 ± 0.86 respectively, 6 months postoperatively.

Mean postoperative anterior chamber depth was 4.26 ± 0.53 mm at six months follow up. Endothelial cell dencity at six months postoperatively was within normal limits (2268±432) after cataract surgery. No anterior chamber reaction or IOP changes were observed. Mean time for ring implantation was 1 min and 9 sec. No serious adverse events were observed. No Posterior Capsule Opacification (PCO) was observed (120 cases 6 months follow-up, 59 patients 1 year follow-up).

Conclusions: FixOflex provides an open capsule space for fast and safe IOL implantation providing postoperative stabilisation. The ring and IOL positioning is easy to control while additional minor manipulations are rarely needed.

ABSTRACT BODY:

Purpose: Terminal sterilization could reduce production time and costs for anti-angiogenic monoclonal antibodies (mAbs) needed for sustained ocular delivery in retinal diseases if they retain molecular integrity and prolonged in vivo bioactivity. After observing up to 12 months of sustained release and bioactivity in previous in vitro and in vivo tests, highly densified poly(lactic-co-glycolic acid) (PLGA) microspheres (Densomeres™) incorporating bevacizumab were tested again following e-Beam terminal sterilization for their integrity and sustained bioactivity using a rabbit corneal injury model.

Methods: Bevacizumab was incorporated into Densomeres that were resuspended in saline for injection through a 28-ga needle. Control Densomeres contained no active drug. Terminally sterilized doses using e-Beam were assessed for molecular integrity by SEC-HPLC and functional bevacizumab bioactivity in vivo. Six adult male New Zealand white rabbits (3 active, 3 control) were anesthetized and a 9-0 silk suture placed in one cornea of each animal to induce neovascular encroachment from the limbus. A single 0.5 mL subconjunctival injection with Densomeres was made at the same meridian. External photographs taken over 60 days to documented neovascularization were scored on a 0-5 scale by trained observers. If sutures came out during follow-up, they were replaced to maintain the neovascularization stimulus.

Results: Bevacizumab extracted from Densomere samples for SEC-HPLC before and after e-Beam sterilization matched the authentic reference bevacizumab [Fig. 1]. For e-Beam sterilized Densomeres, anti-angiogenic bioactivity persisted after the single injection through Day 60. Comparing controls to eyes receiving Densomeres with bevacizumab, the average difference in scores from Day 7 to Day 60 was 3.2 ± 0.5 [Fig. 2]. This difference matched the sustained effects observed for up to 12 months after a single injection using traditional Densomere preparations.

Conclusions: Compared to controls, e-Beam sterilized Densomeres™ containing the mAb bevacizumab exhibited both structural integrity and prolonged anti-VEGF bioactivity in vivo following a single injection in the rabbit corneal neovascularization model.

ABSTRACT BODY:
Purpose: To investigate whether patients with pre-perimetric glaucoma have different eye-hand latency in grasping tasks under crowding. Hypotheses: 1) These patients have longer latencies than controls and 2) crowding affects latency.
Methods: 4 patients from the Glaucoma Clinic (age: 53–75 years) and 3 healthy controls (age: 41–55 years) participated. For patients, their visual fields' mean deviation, average retinal nerve fiber thickness, and vertical cup-to-disc ratio ranged from −0.89 to +3.3 dB, 64 to 94 μm and 0.52 to 0.80 (mean: +0.86 dB; 81 μm; 0.67), respectively. Participants performed an object gasping task with eye and hand movement tracking (EyeLink and Leap). The better eye with at least 20/50 near-distance visual acuity was tracked. A vertical whiteboard was placed with only one white target object (control condition), or the white target surrounded by four colored objects along the azimuth. The crowding objects were set up either 5° (narrow crowding) or 10° apart (wide crowding). The target object was placed at the center or at the ±5° (or ±10°) position. At start of each trial, a board with a fixation target hid the whiteboard. After 3 seconds, this board was removed rapidly by the experimenter. The participant grasped the white target object and moved it to a marked target location as quickly and accurately as possible. Each crowding condition was repeated 12 times to obtain mean eye latency (first reported saccade by EyeLink after revealing the whiteboard) and reach latency (when hand velocity exceeded 10 mm/s). The difference between the two was defined as the eye-hand latency.
Results: Glaucoma subjects had on average (±standard error) +105±89 ms longer eye-hand latency than controls across all conditions. This difference was +116±92, +111±93, and +88±84 ms in control, wide, and narrow conditions, respectively. However, crowding had no effect on latency: the averages were 237±70, 256±41, and 272±35 ms in controls, and 354±65, 366±73, 360±66 ms in glaucoma subjects. Latency did not correlate with age (r=0.09, p=0.85).
Conclusions: Patients with early glaucoma have longer eye-hand latency (i.e., they initiate hand movement slower) than controls in grasping tasks. Crowding appears to have no effect on latency. Further limb kinematic parameters will be investigated.

ABSTRACT BODY:

Purpose: Evaluate the in vitro corneal permeability of Pilocarpine HCl 1.25% with varying pH formulations.

Methods: Cornea permeability was assessed using Lonza Human Corneal Epithelial Cells (HCEC) grown in a 24-well Transwell cell culture insert. The permeability of 5 formulations of Pilocarpine HCl 1.25% topical solution with varying pH levels (pH = 4.3, 5.1, 6.06, 7.16, and 7.96) were examined.

Results: Mean Apparent Permeability (P_{app}) increased as pH increased (0.330, 0.431, 1.19, 0.670, 5.03, 7.02 x 10^{-6} cm/s) with a dramatic increase in pH above 7 (Figure 1). A significant decrease in Transepithelial Electrical Resistance (TEER) values at 120 minutes was observed compared with baseline for all tested formulations except mannitol control. Despite this decrease, limited permeability of the lower pH formulations suggest that the barrier function of the cell layers was not compromised during the study.

Conclusions: The increase in permeability from pH 4.3 to pH 7.96 may be attributed to increasing un-ionized form of pilocarpine (~0.07% un-ionized at pH 4.3 vs. ~87.6% un-ionized at pH 7.96) in the formulation, as permeability across corneal epithelial layers favor un-ionized molecules. Increased permeability could translate into higher levels of pilocarpine in the anterior chamber and greater or longer activation of the iris sphincter and/or ciliary muscle, the target tissues of Pilocarpine HCl 1.25% to induce the pinhole effect and increase depth of focus.

ABSTRACT BODY:

Purpose: To provide nationally-representative epidemiological data on falls and fall-related outcomes among older Americans with ocular disease.

Methods: Cross-sectional analysis of National Health and Aging Trends Study (NHATS) data from 2011 to 2017. Observations were obtained from annual interviews of participants. Ocular disease, falls, and fall-related injuries were identified through International Classification of Diseases (ICD) codes. Diagnoses of ocular disease included age-related macular degeneration (AMD), diabetic eye disease, retinal vascular occlusions, cataract, corneal disease, glaucoma, disorders of refraction and accommodation, and visual disturbance and blindness. Risk factors for falls and fall-related outcomes were identified through multivariable analysis.

Results: A total of 24,479 observations were contributed by 7,423 participants with an average number of 3.3 observations per person. There were 9,900 (40.4%) observations from participants with a diagnosis of ocular disease. Of 7,423 participants, 1,379 (18.6%) had >1 fall in the past year, 1,023 (13.8%) had any fall in the past month, 2,578 (34.7%) reported fear of falling (FoF), 1,047 (14.1%) reported FoF limiting activity, and 1,051 (14.2%) suffered fall-related injuries. Risk factors associated with falls and fall-related outcomes included being older, white, requiring a proxy correspondent, and having a higher body mass index or medical comorbidities. AMD was associated with fall-related injuries (OR 1.33; 95% CI, 1.08-1.63, p=0.007). Diabetic eye disease was associated with >1 fall in the past year (OR 1.62; 95% CI, 1.04-2.51, p=0.031), FoF (OR 1.77; 95% CI, 1.28-2.44, p=0.001), FoF limiting activity (OR 1.82; 95% CI, 1.23-2.67, p=0.002), and fall-related injuries (OR 1.64; 95% CI, 1.11-2.42, p=0.014). Visual disturbance and blindness were associated with >1 fall in the past year (OR 1.91; 95% CI, 1.01-3.64, p=0.048), any fall in the past month (OR 1.97; 95% CI, 1.11-3.49, p=0.020), FoF (OR 2.08; 95% CI, 1.13-3.81, p=0.018), and fall-related injuries (OR 2.95; 95% CI, 1.66-5.25, p<0.001).

Conclusions: Various diagnoses of ocular disease including AMD, diabetic eye disease, and visual disturbance and blindness were associated with falls, FoF, FoF limiting activity, and fall-related outcomes.

SUBMITTER (NAME ONLY): Molly Naylor

TITLE: CNG Channel Trafficking to the Rod Outer Segment is Dependent upon Peripherin-2

SESSION TITLE: Biochemistry and Molecular Biology of the Retina/RPE

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Naylor, J. Martínez-Márquez, J.N. Pearring, University of Michigan, Ann Arbor, Michigan, UNITED STATES|

Commercial Relationships Disclosure: Molly Naylor: Commercial Relationship: Code N (No Commercial Relationship) | Jorge Martínez-Márquez: Commercial Relationship: Code N (No Commercial Relationship) | Jillian Pearring: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The outer segment of rod photoreceptors is composed of two distinct membrane subdomains: discs and plasma membrane. We are interested in understanding how membrane proteins are trafficked to these two subdomains. One resident outer segment plasma membrane protein is the cyclic nucleotide-gated (CNG) channel. It was previously reported that in peripherin-2 knockout (Rds) mice the CNGβ1 subunit is absent from rods, suggesting that CNGβ1 stability or trafficking to the outer segment requires peripherin-2 (Prph2). We recently showed that the CNG channel travels by a conventional pathway through the Golgi, while it is established that Prph2 uses an unconventional pathway bypassing the Golgi. Together, these data suggest that either Prph2 and CNGβ1 interact before segregating into separate pathways or the Prph2/Rom-1 complex known to traffic through the Golgi facilitates CNGβ1 delivery. We investigated both possibilities to understand how Prph2 is engaged in CNG channel delivery to the outer segment.

Methods: Rds, Rom1$^{-/-}$, and C57Bl6J mice were analyzed. DNA constructs were introduced in Rds rods by standard in vivo electroporation. Fixed agarose retinal sections were immunofluorescently stained and imaged by confocal microscopy. Retinal lysates were deglycosylated using PNGase F and EndoH enzymes and analyzed by Western blot

Results: We overexpressed a MYC-tagged CNGβ1 in Rds rods and found it was trapped in internal membranes, but CNGβ1 localization was restored to the outer segment when full-length FLAG-tagged Prph2 was expressed. These data are consistent with a trafficking defect and not protein instability. To determine whether the CNG channel is trafficked with the Prph2/Rom1 complex, we stained Rom1$^{-/-}$ retinas and found the CNG channel was properly localized in the outer segment. This suggests CNGβ1 and Prph2 are engaged before pathway segregation, leading us to investigate which molecular feature of Prph2 is required for CNGβ1 delivery. We expressed Prph2/Rhodopsin chimeras containing either the Prph2 C-terminus or tetraspanin core and show that both Prph2 chimeras are capable of trafficking CNG to the outer segment.

Conclusions: We conclude that Prph2, and not the Prph2/Rom1 complex, is necessary and sufficient for CNGβ1 trafficking to the outer segment. Additionally, we determine that both the Prph2 tetraspanin core and C-terminus can facilitate CNGβ1 outer segment delivery.

TITLE: Optic neuropathy associated with TGFβ dysregulation in mice with a glaucoma-causative mutation of Adamts10

SESSION TITLE: Animal models of human ocular disease

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: H. Wu, R.W. Kuchtey, J. Kuchtey, Vanderbilt University Medical Center, Nashville, Tennessee, UNITED STATES|

Commercial Relationships Disclosure: Hangjing Wu: Commercial Relationship: Code N (No Commercial Relationship) | Rachel Kuchtey: Commercial Relationship: Code N (No Commercial Relationship) | John Kuchtey: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Beagle dogs homozygous for a G661R mutation in ADAMTS10 develop primary open angle glaucoma. ADAMTS10 is a secreted matrix metalloproteinase that interacts with fibrillin-1 and is thought to promote formation of fibrillin microfibrils in the extracellular matrix. Here, we established a mouse model carrying the G661R mutation of Adamts10 (Adamts10$^{G661R/G661R}$) to investigate its ocular phenotypes related to glaucoma and to explore possible functions of ADAMTS10.

Methods: ADAMTS10 and fibrillin-1 expression were examined by immunohistochemistry. Retinal ganglion cell (RGC) function was assessed by positive scotopic threshold response (pSTR) in flash electroretinogram (ERG). Cross-sections of the optic nerves from mice at 3, 6 and 24 months of age were stained with PPD for manual axon quantification using ImageJ. Retinal apoptotic cells at postnatal day 10 were examined by TUNEL assay.

Results: ADAMTS10 immunostaining labeled the retinal nerve fiber layer and RGC axons in the optic nerve where fibrillin-1 was not detected, suggesting fibrillin-independent function for ADAMTS10 in these structures. Adamts10$^{G661R/G661R}$ mice had reduced pSTR amplitude, indicating RGC dysfunction. The reduced RGC function in Adamts10$^{G661R/G661R}$ mice coincided with RGC axon structural changes manifested as smaller optic nerves and fewer optic nerve axons, which may contribute to glaucoma. The reduced number of optic nerve axons for Adamts10$^{G661R/G661R}$ mice occurred early, suggesting developmental deficits. Subsequent experiments found increased apoptosis in the retina of Adamts10$^{G661R/G661R}$ mice during postnatal development, which could result in fewer RGCs produced, accounting for fewer optic nerve axons in adulthood. Consistent with a protective effect of TGFβ signaling against apoptosis during retinal development as shown previously by others, we found increased apoptosis accompanied by decreased TGFβ signaling in the developing retina of Adamts10$^{G661R/G661R}$ mice.

Conclusions: The G661R mutation of Adamts10 causes glaucoma-related phenotypes at early age and decreased TGFβ signaling in the developing retina, implying a role of ADAMTS10 in retinal development via regulation of TGFβ signaling.

ABSTRACT BODY:

Purpose: Rod cone dystrophies typically result in progressive concentric loss of visual field which correlates closely to the photoreceptor degeneration as it progresses from the periphery. A recent study noted that photoreceptors at the edge of the degeneration may regrow outer segment processes following successful gene therapy, resulting in some reversal of field loss (Cehajic-Kapetanovic et al., 2020). Within this zone, photoreceptors exist in the outer nuclear layer but without defined inner or outer segment processes. On imaging with fundus autofluorescence (FAF), this zone of partially degenerate photoreceptors can be identified by a fluorescent ring. We, therefore, explored this ring sign further in order to understand its anatomical relationship to outer retinal degeneration.

Methods: We identified 59 patients who had rod-cone dystrophy and fluorescent rings on FAF retrospectively from our clinical database and categorised the rings according to disease progression. The images were analysed using measurements of horizontal fluorescent ring radius from fovea along with ellipsoid zone (EZ) and external limiting membrane (ELM) line width from spectral domain optical coherence tomography (OCT).

Results: The majority of patients had mutations in RPGR (18) or USH2A (18) and the remainder had identified mutations in RHO (5), RP1 (5), SNRNP200 (4), PRPF8 (2), EYS (2), FLVCR1 (2), RP2 (1) and PRPF31 (1). Three distinct stages of ring were evident: early-stage large irregular ring involving the optic disc,10(17%), mid-stage circumferential fluorescent ring around the fovea, 19(32%), and late-stage pattern of diffuse irregular hyperautofluorescence in the central macula, 30 (51%). A high correlation between internal ring radius to EZ width (r=0.94) and external ring radius to ELM width (r=0.97) in all 29 patients with early-mid stage of disease was evident. Fluorescent ring thickness was also strongly correlated with loss of EZ on OCT (r=0.92) in these patients.

Conclusions: Our results suggest that patients with rod-cone dystrophy may exhibit a pattern of fluorescent rings on FAF. Early and mid-stage rings correlated with inner and outer segment loss and got smaller as the degeneration progressed. This may represent a useful biomarker with which to assess the progression of retinitis pigmentosa and may represent a zone in which reversal of visual field loss is most likely to be seen following gene therapy.

ABSTRACT BODY:

Purpose: Topical ocular antibiotics are often prescribed for antimicrobial prophylaxis following ophthalmic surgery or for the treatment of bacterial conjunctivitis. Sustained-release delivery of antibiotics may overcome some limitations of topical therapy such as reliance on patient self-dosing. Here we evaluate the pharmacokinetics of besifloxacin delivered from a biodegradable hydrogel intracanalicular insert in a canine model.

Methods: A hydrogel besifloxacin intracanalicular insert was placed bilaterally into the inferior canaliculus of 20 beagle dogs on day 0. After presence of the insert in the canaliculus was confirmed visually, tear fluid was collected from n=10 eyes with pre-cut 10 mm Schirmer test strips at 0.5, 1, 2, 4, 8 hours, and 1, 3, 7, 10, 14, 21, 28, 35, and 42 days post-insertion. Tear fluid samples were analyzed for besifloxacin by liquid chromatography tandem mass spectrometry.

Results: Mean besifloxacin levels in tear fluid samples post-insertion are presented in Figure 1. Mean besifloxacin levels in tear fluid samples demonstrated gradual tapering over time and clearance from the tear fluid by 35-42 days. All $AUC_{0\text{-}24}/MIC_{90}$ values were above 100 for 21 days for H. influenzae, S. aureus, S. epidermis, and S. pneumoniae suggesting the insert produced bactericidal levels of besifloxacin for common ocular isolates of conjunctivitis.

Conclusions: A hydrogel-based intracanalicular insert with besifloxacin produced clinically effective drug levels capable of killing the most common isolates of bacterial conjunctivitis for 21 days. A single dose besifloxacin intracanalicular insert may reduce the need for patients to self-administer antimicrobial therapy.

ABSTRACT BODY:

Purpose: Insulin treatment decreases neurodegeneration associated with diabetes. Unfortunately, the risks of hypoglycemia and infection limit the use of systemic insulin as a neuroprotective agent in early diabetic retinopathy. Recent evidence suggests that intranasal delivery of insulin penetrates the brain. Here we examined whether intranasal delivery could serve as a non-invasive route of administration for insulin to the retina and choroid.

Methods: Female Sprague Dawley rats were deprived of food for 12-18 hours and anesthetized with IP ketamine/xylazine. Rats (n = 4) were placed in the supine position on a heating pad (37 degrees Celcius) and one 20ul drop of FITC-insulin (total dose 6 Units/40ul saline) was pipetted into each naris 5 minutes apart. The control group (n = 4) received equivalent doses of saline. One hour after the first drop was intranasally given, rats were sacrificed, enucleated, and the brain was removed. The presence of FITC insulin was examined in cryosections of brain and whole eye, using confocal microscopy. Deposition of FITC-insulin in neural retina and choroid was further characterized by immunohistochemical co-localization studies.

Results: Sixty minutes after intranasal administration of FITC-insulin, fluorescent signal was evident in both ocular and brain tissue. Ocular and brain tissue from the control group was negative for FITC signal. FITC patterning indicated deposition of insulin predominantly in the retinal pigment epithelium and near outer segments of rods and cones. Lower intensity deposition was observed in the choriocapillaris, the inner and outer plexiform layers, and the nerve fiber layer. Brain sections, which served as positive controls, confirmed the deposition of intranasal insulin in the hippocampus, cortex, and hypothalamus.

Conclusions: To the best of our knowledge, this is the first study to demonstrate that intranasal insulin is delivered to the retina and choriocapillaris within one hour of administration. These data suggest that intranasal delivery could be a lower risk alternative for early or supplemental insulin therapy in diabetic retinopathy.

ABSTRACT BODY:

Purpose: The healthy cornea is usually resistant to infection. While the tear film covering the ocular surface contains a multitude of antimicrobial factors, the common corneal pathogen Pseudomonas aeruginosa can survive and replicate in human tear fluid in vitro. RNA-sequencing studies performed in our laboratory have shown numerous alterations to gene expression in P. aeruginosa when exposed to human tear fluid, and many suggest changes to the bacterial outer membrane. Here, we sought to identify P. aeruginosa genes required for survival in tear fluid by characterizing genes whose lack of function resulted in bacterial cell death in tear fluid.

Methods: A Tn-Sequencing experiment was designed, in which a pool of transposon mutants with mutations in non-essential genes, was sequentially passaged in tear fluid for 96 h at 24 h intervals. 701 genes were identified to be conditionally essential for survival in tear fluid. Those genes were overlayed onto the RNA-sequencing dataset containing 331 differentially-expressed genes to identify only those genes that were important for survival in tear fluid and differentially-expressed ($p < 0.05$, Log_2 fold-change > 8). Enrichment analysis was performed to furhter identify groups of similarly acting bacterial genes required for survival in tear fluid.

Results: This approach yielded 75 candidate genes with potential involvement in the mechanisms underlying P. aeruginosasurvival in tear fluid. These conditionally-essential genes were associated with cell wall remodeling (arn operon, 14-fold enrichment), glycerol uptake (glp operon, 30-fold enrichment), dicarboxylate transport (dct operon, 31-fold enrichment), 5 two-component systems that regulate bacterial motility (cheY), cell wall biosynthesis and biofilm formation, and include a novel putative two-component sensor histidine kinase.

Conclusions: These data suggest that P. aeruginosaovercomes the antimicrobial activity of tear fluid by altering the expression of genes involved in the remodeling of the bacterial cell wall, overcoming nutritional limitation via uptake of alternative metabolites, and likely other adaptive responses.Targeting these adaptive changes could facilitate development of novel strategies to manage P. aeruginosa infections at the ocular surface and beyond.

ABSTRACT BODY:

Purpose: Inherited retinal disorders and dry age-related macular degeneration undergo the progressive dysfunction and death of photoreceptors at different rate and locations. However, isolated functional characterization of specific regions of the retina, as for example geographic atrophy lesions or therapeutically treated areas, is often challenged by the lack of spatial targetability, and collateral bleed-through responses of nearby cells. Further, different cell and gene therapy approaches may target discrete regions of the retina and photoreceptor types. Therefore, we developed optical coherence tomography (OCT) guided variable-spot electroretinogram (vsERG) platform to enable spatially resolved and isolated measurement of retina function with minimal response from unintended region(s).

Methods: In the novel Nanoscope Instruments' NS-NEEL OCT guided vsERG platform, the stimulation light path for ERG and OCT are combined such that the tunable lens can deliver stimulation spot sizes ranging from 30 μm to 4 mm. Also, the precise scanning optics enable unrestricted placement of the stimulation spot on the retina. ERG responses from normal and photoreceptor-lacking areas of the rat and pig retina were measured. Different stimulation spot sizes were used with pre-selected wavelengths (455, 530 and 630 nm) at various intensities to determine functional responses from rods and the different types of cones.

Results: VsERG measurement showed reduced ERG response from regions lacking photoreceptors compared to normal retinal regions. Both, cone and rod response (detected with photopic and scotopic stimulation respectively), exhibited lower ERG-signals in the photoreceptor-degenerated retinal regions. In addition, vsERG recording from different types of cones produced unique characteristic responses based on stimulation wavelength (blue, green and red), which decreased concomitantly with decreased size of the stimulated retinal area.

Conclusions: Our results demonstrate that OCT-guided vsERG with selected stimulation wavelengths is suitable for functional evaluation of different types of photoreceptors in normal and diseased retina in a highly defined region with minimal contribution from adjacent areas. OCT guided vsERG based monitoring of physiological function will enable improved characterization of retinal degenerative diseases and evaluation of therapeutic interventions.

ABSTRACT BODY:

Purpose: 1) To evaluate the vitreous flow rate of the 25+® Gauge (GA) and 27+® GA dual cutting, 20,000 cuts per minute (cpm) beveled vitrectomy probes under various system settings; 2) Compare the performance of the 20K beveled probes with previous generation 10K beveled probes.

Methods: The 25+ GA and 27+ GA HYPERVIT® beveled20K vitrectomy probes were driven by the CONSTELLATION® Vision System (Alcon Vision, LLC.) to aspirate porcine vitreous. A precision balance (Mettler Toledo, XS) was used to chart and record mass change during aspiration over 1 min.

Flow rates were evaluated ranging from 2.5K to 20K cpm. Three duty cycles were evaluated for each cut rate: core, 50/50, and shave. Vacuum was kept constant at 650 mmHg. For each probe gauge, 6 probes were used to measure flow rate and each duty cycles' cut rate was tested at least 3 times. Average flow rate was calculated for each setting and statistical analysis was performed using Welch's T-Test with a statistical significance level of $p<0.05$.

Results: At the maximum cut rate for the three duty cycles of core, 50/50, and shave, the 25+®GA probe flow rates were 3.52±0.26, 3.47±0.26, and 3.64±0.15 cc/min, respectively. Corresponding flow rates for the 27+®GA probes were 2.17±0.16, 2.09±0.18, and 2.07±0.22 cc/min, respectively. Statistical analysis indicated significant differences in flow rate for cut rates less than 7.5K cpm compared to the maximum cut rate under same duty cycles and vacuum ($p<0.05$) and no significant difference was shown between each duty cycle ($p<0.05$) for both probe gauges.

When operating at maximum cut rate of 20K cpm at core duty cycle, the 25+®GA and 27+®GA HYPERVIT® beveled achieved flow rates 23.61% and 19.63%, respectively, higher than the previous generation 25GA and 27GA Advanced ULTRAVIT® probe flow rates at maximum cut rate of 10K cpm, ($p<0.05$).

Conclusions: The aspiration flow rate did not significantly change by duty cycle for all cut rates for both 25+®GA and 27+®GA HYPERVIT® beveled 20K vitrectomy probes. In addition, for all probes, aspiration flow rates increased as cut rate increased. In comparison with previous generation Advanced ULTRAVIT® probes, the HYPERVIT® beveled vitrectomy probes achieved higher flow rates.

TITLE: Comparison of a virtual reality-based visual field test to conventional perimetry and OCT

SESSION TITLE: Visual Fields and Psychophysics

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: Z. Chia, A.W. Kong, M.L. Turner, M. Deiner, Y. Ou, Department of Ophthalmology, University of California San Francisco, San Francisco, California, UNITED STATES|B.T. Backus, Vivid Vision, Inc., San Francisco, California, UNITED STATES|

Commercial Relationships Disclosure: Zer Keen Chia: Commercial Relationship: Code N (No Commercial Relationship) | Alan Kong: Commercial Relationship: Code N (No Commercial Relationship) | Marcus Turner: Commercial Relationship: Code N (No Commercial Relationship) | Benjamin Backus: Commercial Relationship(s);Code E (Employment):Vivid Vision, Inc.;Code P (Patent):Vivid Vision, Inc.;Code I (Personal Financial Interest):Vivid Vision, Inc. | Michael Deiner: Commercial Relationship: Code N (No Commercial Relationship) | Yvonne Ou: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To 1) assess the correlation between a new virtual reality visual field test, Vivid Vision Perimetry (VVP-10), and standard automated perimetry (SAP) in a global, sector-, and pointwise manner; 2) assess the structure-function relationship between VVP-10 and OCT; and 3) assess the test-retest variability of VVP-10

Methods: Subjects with glaucomatous visual field defects were remotely trained to take the VVP-10 test and proceeded to take 10 tests over 14 days. VVP-10 response rate (fraction seen) at each point and SAP results including mean deviation (MD) and mean sensitivity (MS) at each point were recorded. Retinal nerve fiber layer thickness (RNFLT) at the optic nerve head was also recorded for each subject. Pearson correlation coefficients and the 95% confidence intervals were calculated for VVP-10 overall fraction seen vs SAP MD. Similar correlation coefficients were calculated for sector- and pointwise comparisons of VVP-10 average fraction seen vs SAP MS and structure-function analyses of RNFLT vs SAP MS and VVP-10 average fraction seen by sector. Test-retest variability was assessed with the intraclass correlation coefficient and a Bland-Altman plot of odd- vs even-numbered tests.

Results: A total of 36 eyes from 19 subjects were included in the study. However, one subject who was unable to take the test properly and reproduce accurate results was identified as an outlier and excluded. The global correlation of VVP-10 overall fraction seen vs SAP MD was 0.90 (95% CI [0.80 – 0.96]). Sector-wise correlations between VVP-10 average fraction seen vs SAP MS ranged from 0.31 – 0.95; pointwise correlations ranged from 0.11 – 0.92. The correlation between RNFLT vs VVP-10 overall fraction seen was 0.49 [0.22 – 0.73] with sector-wise correlations ranging from 0.12 – 0.65. The correlation between RNFLT vs SAP MD was 0.57 [0.36 – 0.76], and sector-wise correlations of RNFLT vs SAP MS ranged from -0.14 – 0.62. The ICC was 0.97 [0.95 – 0.98] and one eye fell outside of the lower level of agreement in the Bland-Altman plot.

Conclusions: Strong concordance exists between VVP-10 and SAP in a global, sector-, and pointwise manner. VVP-10 also demonstrates similar correlation with RNFLT compared to SAP. Finally, VVP-10 exhibits excellent test-retest variability, and its portable nature allows for remote testing and monitoring of glaucomatous field progression.

ABSTRACT BODY:

Purpose: To understand how dexamethasone influences the expression of actin cytoskeletal, contractile, and fibrogenic proteins in trabecular meshwork cells, in this study we focused on identifying the upstream regulators of gene expression in dexamethasone treated cells.

Methods: Human TM cells treated with dexamethasone (Dex, 0.5 μM) for 24 hrs, 5 and 7 days along with their respective controls were extracted for the nuclear protein fraction and analyzed for the differential profile of proteins by non-label quantitative LC-MS-MS proteomics. Distribution and changes in Brg1 levels in TM cells treated with Dex were evaluated by immunofluorescence and immunoblot analyses. Effects of Brg1 inhibition and deficiency on the levels of client proteins in TM cells were determined using a chemical inhibitor (PFI-3) and siRNA of Brg1, respectively.

Results: The protein levels of Brg1/SMARCA4, the catalytic subunit of the SWI/SNF family of chromatin remodeling complex, were significantly increased in the Dex treated TM cell nuclear protein fraction compared to control cells based on mass spec and immunoblot analyses. Brg1, an actin binding nuclear protein was distributed predominantly in the nucleus. Brg1 and several of other components of the SWI/SNF complex were readily detectable in the cytoskeletome fraction of the human TM cells indicating an association between the SWI/SNF chromatin-remodeling complex and nucleoskeletal actin and actin related proteins. Inhibition of Brg1 activity and suppression of Brg1 expression significantly decreased the protein levels of cell adhesion proteins (ArgBP2, CAP/ponsin), contractile protein (CNN3), fibrogenic protein (CTGF) and MICAL2 (regulator of SRF/MRTF-A transcriptional activity) and glypican-4 (regulator of Wnt signaling) in human TM cells.

Conclusions: This study identifies Brg1, a catalytic subunit of the SWI/SNF family chromatin-remodeling complex as one of the upstream regulators of the expression of actin cytoskeletal, contractile and cell adhesion proteins in dexamethasone treated human TM cells. Thus, Brg1 and the SWI/SNF chromatin-remodeling complex may be promising targets to lower intraocular pressure in steroid-induced glaucoma.

ABSTRACT BODY:

Purpose: Current circumpapillary RNFLT norms only adjust for age, gender and ocular magnification. We aim to improve the circumpillary RNFLT norms with retina anatomy.

Methods: From the population-based Leipzig Research Center for Civilization Diseases (LIFE) adult study, we include data with: (a) no retinal pathological findings on fundus images; (b) image quality ≥ 20 dB, average number of B-scans ≥ 50, and no more than 5% missing or unreliable RNFLT measurements among the 768 locations of Spectralis optical coherence tomography (OCT) scans. The retinal anatomy was represented by the 2D inner limiting membrane (ILM) contour map and scanning laser ophthalmoscopy (SLO) fundus photo at the optic nerve head. Feature exaction was performed by principal component analysis followed by uniform manifold approximation and projection. Linear regression was applied to associate the ILM and SLO features with pointwise RNFLTs adjusting for age, gender and ocular magnification. One eye per subject was randomly selected for regression analyses. Model selection based on Bayesian information criteria (BIC) was used to remove redundant features from the linear models. Adjusted r-squared and BIC values penalized for linear model complexity were used to measure the linear models' accuracies.

Results: 7,285 eyes from 7,285 subjects (56.1 ± 12.2 years; 53.3% are female) were included. Figure 1 (a) and (b) shows the R^2 improvement by using ILM and SLO features on top of age, gender and ocular magnification, respectively. Additionally using ILM and SLO features strongly (BIC improvement ≥ 6) improved RNFLT norms at 85.4% and 96.5% of the 768 locations with average R^2 improvement of 0.026 (max: 0.051) and 0.029 (max: 0.065) compared with average R^2 of 0.042 (max: 0.082) using age, gender and ocular magnification alone, respectively. Combining ILM and SLO features (Figure 2) provided more accurate personal norms than using SLO and ILM separately, which was supported by RNFLT norm improvement (BIC improvement ≥ 6) at 79.9% and 93.2% of the 768 locations with average R^2 improvement of 0.017 (max: 0.032) and 0.020 (max: 0.049).

Conclusions: Adjusting for retinal anatomy represented by ILM and SLO imaging features substantially improved personal circumpapillary RNFLT norms. Our new norms may improve the diagnostic accuracy of OCT for glaucoma patients, although further validation is needed in patient population.

TITLE: Use of dexamethasone to mitigate occurence of intraocular inflammation associated with brolucizumab intravitreal injections

SESSION TITLE: Anti-VEGF in AMD

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: L. Mein, M. Singer, Retina, Medical Center Ophthalmology Association, San Antonio, Texas, UNITED STATES|M. Singer, Ophthalmology, The University of Texas Health Science Center at San Antonio, San Antonio, Texas, UNITED STATES|

Commercial Relationships Disclosure: Luke Mein: Commercial Relationship: Code N (No Commercial Relationship) | Michael Singer: Commercial Relationship(s);Code C (Consultant/Contractor):Aerie, Allegro, Allergan, DRCR, Genentech, Icon, Ionis, Kalvista, Kodiak, Novartis, Opthea, Optos, Regeneron, Santen, Senju, Sydnexis, Ribomic, Eyepoint;Code I (Personal Financial Interest):Aviceda, Nanoscope, Inflammasome

ABSTRACT BODY:

Purpose: Brolucizumab has been plagued by a higher percentage of intraocular inflammation (IOI) than other anti-VEGF agents currently being used today. In the HAWK and HARRIER studies, the incidence of IOI was 4.4% overall, with 3.3 % of patients demonstrating retinal vasculitis (RV) and 2.1% of patients demonstrating retinal artery occlusion (RO). In this retrospective study, we hypothesize that with concurrent injection of dexamethasone this rate of inflammatory reaction can be mitigated.

Methods: In this series of nine patients, eleven eyes, dexamethasone 0.4mg/0.1mL was injected at the same visit as brolucizumab 6mg/0.05mL, with the intent of assessing the therapeutic effect of decreasing macular thickness/volume on OCT as well as following the patient for potential pressure spikes or IOI events. Each eye was determined to have an absence of any active IOI prior to brolucizumab injection. Patients were followed via the parameters of visual acuity, IOP, presence of inflammation, and OCT via macular volume (MV) and central subretinal thickness (CST). An OCT RNFL was used to compare the treated eye vs the fellow eye to look for any damage due to IOP spike relative to the fellow eye, as well as absolute damage.

Results: Of the fifty-two brolucizumab/dexamethasone injections performed, there were no reported IOP spikes or instances of white-out after injection. Additionally, there were no reported instances of inflammation after injection. These patients had improved CST and MV results on OCT compared to previous treatments with other anti-VEGF medications. There were no significant changes in OCT RNFL values after injections.

Conclusions: Our results are consistent with the hypothesis that dexamethasone is a potential adjunct treatment with brolucizumab as a possibility to decrease intraocular inflammatory events without side effects relating to pressure spikes or RNFL changes. Further analysis will need to be performed with an increased number of patients and eyes to extrapolate the efficacy of this data due to the initial low frequency of intraocular inflammation.

ABSTRACT BODY:

Purpose: This study aims to 1) understand IOP stability during vitreous removal with 27+Gauge (Ga) dual-cutting, 20K cuts per minute (cpm) beveled vitrectomy probes; 2) understand the operation time of vitreous removal during a vitrectomy.

Methods: 27+® HYPERVIT® beveled 20K cpm vitrectomy probes were driven by a CONSTELLATION® Vision System (Alcon Vision, LLC.) to aspirate porcine vitreous in a hollow acrylic eye model. A digital transducer (OMEGA, PX409-001GUSBH) was connected to the bottom of eye model to detect IOP change during aspiration. For each testing, 4cc of fresh porcine vitreous was filled into the eye model. Six samples were tested under core duty cycle, vacuums of 250mmHg, 450mmHg and at 650mmHg and cut rate of 20,000cpm. Both system IOP compensation enabled and disabled were used with 30mmHg as the initial infusion pressure. Average IOP fluctuation during aspiration, final stable IOP and average operation time of vitreous removal were calculated for each test setting. Statistical analyses were performed on average IOP fluctuation rate using Welch's t- test with $p<0.05$.

Results: Without IOP compensation, the average fluctuation rate for vacuums of 250, 450 and 650 mmHg were -0.018 ± 0.003, -0.049 ± 0.007 and -0.094 ± 0.009 mmHg/s, respectively, demonstrating significant fluctuation rate differences between each vacuum setting ($p<0.05$). With IOP compensation, average IOP fluctuation rates significantly decreased to 0.004 ± 0.003, 0.010 ± 0.007, and 0.011 ± 0.010 mmHg/s for the same vacuums compared with IOP off ($p<0.05$). No significant difference of IOP fluctuation rate was shown between each vacuum setting ($p>0.05$).

Without IOP compensation, the final stable IOP after removing vitreous at vacuums of 250, 450, and 650 mmHg were 23.14 ± 0.50, 16.05 ± 0.79, and 8.49 ± 0. 44 mmHg, respectively. With IOP compensation, IOP maintained at 31.32 ± 0.93, 31.33 ± 1.01, and 31.46 ± 1.09 mmHg for the same vacuums. Corresponding operation times of complete removal of 4cc vitreous were 366s, 289s, and 230s, respectively.

Conclusions: At maximum cut rate, 27+® Ga 20K cpm probe with IOP compensation provides stable IOP and less fluctuation during vitrectomy for different vacuum levels compared to no compensation. IOP compensation is an essential feature for surgeons to efficiently control the fluidics environment during posterior segment procedures.

ABSTRACT BODY:

Purpose: To evaluate the safety and tolerability of intracameral recombinant AAV as a gene therapy vector in nonhuman primates. The anterior segment is an attractive target for genetic intervention due to its accessibility, relative immune privilege, and ease of monitoring through aqueous sampling, and in vivo imaging techniques. We demonstrate that intracameral delivery of AAV9 vector is well tolerated and has a unique transduction profile in the nonhuman primate.

Methods: In an initial experiment, 8 primate eyes were intracamerally injected with 50 ml of 5E11 vg or 9E11 vg (vector genomes) of AAV9-expressing eGFP. In a second experiment, 7 primate eyes were intracamerally injected with 50 ml of 5E12 vg of AAV9 encoding a secreted protein. At 2-week intervals for 4 months, ophthalmic examinations were performed using specular microscopy, pachymetry, tonometry, slit lamp biomicroscopy, anterior segment imaging, and anterior segment OCT. Clinical observations were performed routinely. Serum and aqueous samples were also collected as part of routine examinations. Immunohistochemistry (IHC) was performed on the anterior chamber of the eye at study termination.

Results: Intraocular pressure was maintained within normal ranges at all timepoints following treatment. Corneal thickness, endothelial cell area and cell density measurements were not significantly different at any time point between AAV9 vector and vehicle injected eyes. No significant change in body weight or food consumption was observed. No evidence of increased inflammation was detected compared to contralateral vehicle control eyes. IHC revealed an open iridocorneal angle and no evidence of inflammation or cellular damage. Eyes injected with AAV encoding GFP revealed efficient transduction of the corneal endothelium, and eyes injected with AAV encoding a soluble secreted protein demonstrated high aqueous levels by ELISA.

Conclusions: We have observed sufficient tolerability of the anterior chamber to intracamerally delivered AAV vector in the nonhuman primate. This study did not reveal clinical signs indicative of localised or systemic side effects. Transduction was found unique to the corneal. This pre-clinical data demonstrates the potential of genetic intervention in the corneal endothelium of the anterior chamber to treat corneal diseases or to generate a “protein factory” for the treatment of other anterior segment conditions such as glaucoma.

TITLE: Residual fit error of multifocal contact lenses as a function of increasing Zernike coefficients

SESSION TITLE: Contact lens

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A.N. Nti, D.A. Berntsen, The Ocular Surface Institute, University of Houston College of Optometry, Houston, Texas, UNITED STATES|

Commercial Relationships Disclosure: Augustine Nti: Commercial Relationship: Code N (No Commercial Relationship) | David Berntsen: Commercial Relationship(s);Code C (Consultant/Contractor):Visioneering Technologies;Code F (Financial Support):Bausch + Lomb

ABSTRACT BODY:

Purpose: Complex optical designs such as multifocal lenses are being utilized for myopia control. Zernike polynomials are used to calculate metrics of image quality to predict visual performance. We determined if Zernike polynomials can adequately fit zonally reconstructed wavefront maps of multifocal contact lenses.

Methods: Three center-distance multifocal lenses (Biofinity “D” +2.50 add, Proclear “D” +2.50 add, NaturalVue) were studied. The Biofinity and Proclear lenses have a gradual radial increase in plus power from the lens center, while the NaturalVue Multifocal has an extended depth of focus design. Two lenses of each power ranging from -1.00 to -6.00D in 1D steps were measured for each lens design. Wavefront aberrations of each lens were measured in a wet cell with the SHSOphthalmic aberrometer and used to reconstruct zonal wavefront error maps. The wavefront error maps were then fitted with Zernike polynomials through the 6^{th}, 7^{th}, 10^{th}, 15^{th}, 20^{th}, 25^{th} and 30^{th} radial orders for a 6mm diameter pupil. The accuracy of each Zernike fit was calculated as the root-mean-square (in microns) of the difference between the zonal wavefront error map and the modal wavefront error map reconstructed from each Zernike fit. A repeated-measures ANOVA was used to determine the effect of lens design and Zernike radial order on the residual fit error.

Results: Root-mean-square of the residual fit error wavefront map (RMSFE) depended on both the lens design and radial order of the Zernike fit (lens x order interaction; $p < 0.0001$). RMSFE decreased for all three lenses with increasing radial order. For a 6^{th} order fit, RMSFE was less than 0.1μm for the Biofinity and Proclear lenses and 0.22μm for the NaturalVue. RMSFE reduced to less than 0.05 μm for all three lenses with the 15^{th} order polynomial fit. There was little additional improvement in the RMSFE (< 0.005μm) between the 20^{th} and 30^{th} order fits for both Biofinity and Proclear, but there was an additional 0.014μm reduction in RMSFE for the NaturalVue design. There was no difference in RMSFE between all three lens designs with the 30^{th} order fit.

Conclusions: Zernike fits were able to describe the multifocal optics of the lenses studied, but the number of radial orders needed depended on the complexity of the multifocal lens design, requiring through the 25^{th} radial order for one design.

ABSTRACT BODY:

Purpose: To unlock the full potential of regenerative medicine requires a more complete understanding of the molecular determinants that influence cellular migration, proliferation, identity, and fate. Out of the diverse neuronal subtypes exemplified in the neural retina, the dopaminergic amacrine cells (DACs) have an outsized importance given that they are the primary source of retinal dopamine while making up just one percent of the total amacrine cell population. The focus of our investigation was to identify factors that influence DAC placement, number, and connectivity. Through this screen we uncovered a candidate signaling pathway controlled by the serine-threonine kinase LKB1 that is critical for DAC fate.

Methods: We leveraged Cre recombinase technology to selectively knock out LKB1 from either retina or amacrine cell precursors. In concert with transgenic mice that allow for visualization of DACs by the expression of GFP driven by the promoter for tyrosine hydroxylase we were able to analyze the effects of the absence of LKB1 on the fate of the dopaminergic amacrine cells. Using cross sections and whole flat-mounted retinas we analyzed DACs in the first, second, and third post-natal weeks.

Results: We observed an approximate doubling of DACs early in development that persisted into adulthood. Surprisingly, in addition to the increase of DACs in their endogenous location in the Inner Nuclear Layer (INL) we observed a substantial number of DACs displaced into the ganglion cell layer (GCL). These cells retained expression of the amacrine cell marker Ap2 but projected their neurites to the Inner Plexiform Layer (IPL) from the opposite side from their inner nuclear layer counterparts. We also observed DAC stratification in layer S2 of the IPL in addition to layers S1 and S3 observed in controls. Similar results were observed in mice that had LKB1 selectively deleted from amacrine cell precursors.

Conclusions: These results suggest that LKB1 signaling is required cell intrinsically within amacrine cell precursors to restrict the total population of DACS, migration of DACS to the INL, and stratification of DAC processes to S1 and S3 layers of the IPL. These findings contribute to our understanding of signaling pathways that influence important attributes of DAC fate in murine retina.

ABSTRACT BODY:

Purpose: Gulf War Illness (GWI) is a chronic, multisystem disease diagnosed in Gulf War Era (GWE) veterans associated with manifestations of ocular disease including dry eye symptoms, photophobia and convergence insufficiency. Given the ability to image peripheral and central nerves within the eye and detect ocular surface inflammation, the eye may serve as a biomarker for GWI, assisting with diagnosis and the understanding of disease pathophysiology. In this study, we examine whether individuals presenting with GWI symptoms have differences in ocular imaging and inflammatory cytokine profiles compared to their GWE counterparts.

Methods: This is a prospective case-control study of 94 individuals who served during the GWE. Individuals were split into 2 groups: those with GWI symptoms (cases, identified by Kansas criteria) and those without GWI symptoms (controls). Information on demographics, co-morbidities, and diagnoses of eye diseases were captured. In addition, all individuals underwent optical coherence tomography (OCT) imaging (retinal nerve fiber layer (NFL), ganglion cell layer-inner plexiform layer, and macular maps) and provided a blood sample. Blood was analyzed for inflammatory cytokines using a custom ELISA-based chemiluminescent assay. Statistical analyses were performed using SPSS 28.0. Predictors of GWI symptoms were analyzed using forward stepwise binary logistic regression and receiver operating characteristic (ROC) curves.

Results: The mean patient age was 55±5, 90.3% self-identified as male, 55.9% as white, and 53.8% as Hispanic. After confirming non-collinearity between predictors, the binary logistic analysis model revealed that inferior temporal ganglion cell thickness (odds ratio; OR=0.66, 95% confidence interval; CI=0.49-0.88), superior temporal ganglion cell thickness (OR=1.34, 95% CI=1.03-1.75), temporal NFL thickness (OR=1.08, 95% CI=1.01-1.16), IL1 beta levels (OR=0.86, 95% CI=0.73-1.01), IL2 levels (OR=0.71, 95% CI=0.55-0.91), and IL17 levels (OR=1.03, 95% CI=1.01-1.04) all predicted GWI symptoms. ROC analysis demonstrated an area under the curve of 0.83 (95% CI=0.74-0.93, $p<0.001$) for this model. As determined by Youden's index (top left point on the ROC curve), the best cut-of value for the prediction model was associated with a sensitivity of 90% and a specificity of 65%.

Conclusions: These results elucidate differences in OCT and systemic inflammatory markers in individuals with versus without GWI symptoms.

TITLE: Secreted Ly-6/uPAR Related Protein-1 (SLURP1) Suppresses Canonical TGF-b Signaling in Corneal Epithelial Cells

SESSION TITLE: Corneal epithelial biology and repair mechanisms

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: S. Swamynathan, S.K. Swamynathan, Ophthalmology, University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania, UNITED STATES|

Commercial Relationships Disclosure: Sudha Swamynathan: Commercial Relationship(s);Code P (Patent):University of Pittsburgh, patent number-9731014 | Shivalingappa Swamynathan: Commercial Relationship(s);Code P (Patent):University of Pittsburgh, patent number-9731014

ABSTRACT BODY:

Purpose: Secreted Ly-6/uPAR Related Protein-1 (SLURP1), abundantly expressed by the corneal epithelium (CE) and secreted to the tear film, is an anti-inflammatory protein with anti-tumor properties. TGF-b pathway has diverse roles in tissue homeostasis as well as pathological conditions including epithelial-mesenchymal transition (EMT) during tumor metastasis. Here, we studied the influence of SLURP1 on canonical TGF-b signaling using Slurp1X-/- mouse cornea and human corneal limbal epithelial (HCLE) cells.

Methods: The effect of Slurp1 ablation on TGF-b signaling was studied by comparing TGF-b Receptor 2 (TGFBR2), Smad4, and phospho-Smad2/3 expression in wild type (WT) and Slurp1X-/- mouse corneas by immunoblots and immunofluorescent staining. The effect SLURP1 on TGF-b signaling was analyzed by comparing the TGF-b-induced Smad2/3 phosphorylation and E-cadherin expression in HCLE and HCLE-SLURP1 cells engineered to over-express SLURP1.

Results: Slurp1X-/- mouse corneas displayed elevated expression (127% of WT) and prominent nuclear localization of TGFBR2, coupled with elevated expression of Smad4, and phospho-Smad2/3. Upon stimulation with 5ng/ml TGF-b, HCLE-SLURP1 displayed decreased SMAD2/3 phosphorylation compared with that in HCLE cells. After 1h of TGF-b addition, the phospho-SMAD2/Total SMAD2 ratio was 20% lower in HCLE-SLURP1 compared with HCLE cells. Upon TGF-b treatment, E-cadherin expression decreased to a greater extent in HCLE compared with HCLE-SLURP1 cells. Confluent HCLE-SLURP1 cells retained E-cadherin in their cell membranes more efficiently than HCLE cells at 24h and 48h after TGF-b addition.

Conclusions: Increased expression of TGFBR2, Smad4 and pSmad2/3 indicate higher canonical TGF-b signaling activity in Slurp1X-/- corneas. SLURP1 suppresses canonical TGF-b signaling in HCLE cells and protects E-cadherin from TGF-b induced disintegration, consistent with a role for SLURP1 in protecting the CE cells from TGF-b-induced EMT.

ABSTRACT BODY:

Purpose: Optical coherence tomography (OCT) is the main diagnostic tool to detect and monitor progression of neovascular age related macular degeneration (nAMD). The purpose of this study is to predict anti-VEGF treatment requirements in nAMD using artificial intelligence (AI) based on OCT images for identifying fluid biomarkers in a real-world cohort.

Methods: OCT (Spectralis, Heidelberg Engineering) data of treatment-naïve patients with nAMD from the Fight Retinal Blindness! in Zürich were processed at baseline, and the end of the loading dose (2 months after the first anti-VEGF injection), to predict subsequent one year treatment needs. First, intraretinal (IRF), subretinal fluid (SRF) and pigment epithelial detachment (PED) were segmented using a deep learning convolutional neural network (Vienna Fluid Monitor, RetInSight, Vienna, Austria). Second, a set of quantitative features from the segmented layers and fluid regions were computed across the three central subfields at 1mm, 3mm, and 6mm, to describe retinal pathomorphology both quantitatively and spatially. Finally, using the computed set of features, a predictive model of future treatment requirements was built using machine learning and was evaluated with a ten-fold patient-level cross-validation.

Results: Two hundred and nine eyes from 164 patients were evaluated for a one year period following the loading dose. The treatment intervals ranged from 0 to 13 weeks. 100/209 eyes had lower median (≤7) and 109/209 eyes had an upper median (≥8) number of injections. The model identified the two groups (lower and upper median) based on number of injections with a mean accuracy of 0.74 (CI) area under the curve (AUC). The amount of SRF after the loading dose and at baseline in the central-3mm area were found to be the most important predictive features (Figure 1).

Conclusions: We used AI to predict treatment requirements in nAMD by correlating fluid biomarkers with resulting therapeutical patterns based on OCT images. The potential of a personalized anti-VEGF therapy for minimizing the risk of undertreatment while improving resource management and avoiding overtreatment will have to be evaluated in respect to this current state-of-the-art concept in a prospective manner.

TITLE: Stress accelerates age related changes in mammalian vision

SESSION TITLE: Glaucoma: biochemistry, biomechanics and omics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: Q. Xu, C. Rydz, I. Lee, D. Skowronska-Krawczyk, Physiology & Biophysics, UC Irvine, California, UNITED STATES|

Commercial Relationships Disclosure: Qianlan Xu: Commercial Relationship: Code N (No Commercial Relationship) | Cezary Rydz: Commercial Relationship: Code N (No Commercial Relationship) | Irene Lee: Commercial Relationship: Code N (No Commercial Relationship) | Dorota Skowronska-Krawczyk: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Age and elevated intraocular pressure (IOP) are major risk factors for glaucoma. We aim to learn how aging contributes to loss of vision in response to stress caused by elevated IOP.

Methods: 3 and 18-month-old mice were treated with mild IOP (30mmHg). Phenotype and molecular changes in young and old retina upon IOP stress assessed included: RGC cell body survival by Brn3a immunostaining; Visual path in optic nerve neurofilament by NF68 staining; RGC function measured by pattern electroretinography (PERG); Transcriptomic and epigenomic analyses.

Results: Both RGC counting statistics and PERG assays showed significant decreases in old retina upon 1hr of 30mmHg IOP elevation but barely changed in young ones. Optic nerve analysis showed dramatically reduced NF68 immunoreactivity in aged eye. RNA-Seq analysis with FDR<0.05 and two-fold expression change cutoff revealed 156 activated genes and none repressed upon stress in young retina. In old retina, there were more stress dysregulated genes including 257 up- and 24 down-regulated. And a large portion of the stress-activated genes showed higher fold changes in old versus young retina. Pre-ranked gene set enrichment analysis and heatmaps showed multiple curated aging related pathways such as inflammatory/immune response, senescence and p53 pathways. ATAC-Seq analysis revealed that chromatin accessibility changes played a necessary regulatory role in many susceptible genes against stress like Fgf2 and Bcl3.

Conclusions: RGC/axonal loss and deterioration of vision correlated with age. Transcriptomic response to IOP stress revealed ontology enrichment in pathways associated with aging and senescence and showed higher vulnerability in old versus young retinae. Our data suggests that stress accelerates aging of the visual system. Current glaucoma treatment paradigm limits to lowering eye pressure. Elucidating pathways involved in accelerated aging may lead novel therapeutic targets for glaucoma treatment and prevention in the future.

ABSTRACT BODY:

Purpose: Genetic Leukoencephalopathies (gLEs) are white matter disorders affecting the central nervous system, causing progressive abnormalities in visual and motor systems. A mutation in Vacuolar Protein Sorting 11 (VPS11) has been identified in humans as a causative allele of gLE. Functioning with VPS11, VPS16 forms membrane-tethering complexes that control crucial cellular processes in the endolysosomal pathway. However, the role of VPS16 in gLE is unknown. Here, we are characterizing the behavioral responses of a zebrafish vps16 mutant line as potential model for gLE.

Methods: Immunohistochemistry and TUNEL were used to assess retinal and brain pathology and hypomyelination at 7 days post-fertilization (dpf). Behavioral assays were used at 5 and 7dpf to assess evoked visuomotor responses, short-term memory (habituation), and long-term memory (using various time periods between two habituation stimuli). Appropriate statistical analyses were used to determine differences between wild-type and mutant animals.

Results: Immunohistochemical and TUNEL analysis indicated that vps16 mutant larva showed retinal and brain pathology, including hypomyelination and increased apoptosis. Behavioral analysis showed that mutants could visualize changes in light/dark backgrounds but showed a progressive loss of distance moved and velocity from 5-7dpf. Mutants showed signs of short-term memory (habituation to 10 consecutive tap stimuli) but habituated faster than wild-type siblings. Finally, in response to two sets of multiple taps with 2min, 5min or 30min rest periods in between, both wild-type and mutant larva “remembered” the first habituation response after a 2min rest. After 5min, wild-type animals still “remembered” the first response, but mutant animals did not. Finally, after 30min, neither group “remembered” the first habituation event and responded to the second set as a novel habituation stimulus. Together, these results suggest that loss of Vps16 function has a progressive adverse effect on larval zebrafish visual, motor, and cognitive systems, which is consistent with their hypomyelination phenotype.

Conclusions: Our findings support the use of zebrafish to further characterize behavioral defects associated with gLE and provide the first insights into impaired Vps16 function.

ABSTRACT BODY:

Purpose: To associate between the child behavioral problem as determined by the Conners' parent rating scale (CPRS) to cycloplegic refraction and ocular biometry.

Methods: Children, between the age 6-12 years, visiting the pediatric ophthalmology clinic for suspected ammetropia were recruited to the study. A complete eye exam, cycloplegic refraction and ocular biometry using Lenstar ocular biometry were performed. For each child, CPRS was completed and scored for seven behavioral problems and three attention deficit hyperactivity disorder (ADHD) subtypes. Correlation was performed between CPRS reports to refraction and ocular biometry.

Results: Children with emmetropia (N-21) and hyperopia (N-132) were included. CPRS for ADHD was positive 27.2% of the hyperopic children, as compared to 9.5% among emmetropes. Hyperopic children had significantly high cognitive problems and oppositional behavior that present in 24.6% and 21.5%, respectively. Hyperopic children with positive and negative CPRS for ADHD had similar spherical power of +3.2±2.1 D and +3.7±2.7 D (p=0.52), however the cylinder was significantly higher in the positive CPRS for ADHD (p=0.02).

Conclusions: Conners' parental scoring for ADHD was positive three times more in hyperopes than emmetropes. Astigmatism in a hyperopic child was associated with positive CPRS for ADHD.

ABSTRACT BODY:

Purpose: The retinal pigment epithelium (RPE) plays an essential physiological role between the photoreceptor cell layer and the choroid. This interaction is critical in the maintenance of an internal equilibrium within the retina. Several retinal diseases occur as a consequence of RPE dysfunction. Our team has established a differentiation protocol that is efficient in producing pure populations of fully differentiated, functionally mature RPE cells from human induced pluripotent stem cells (hiPSC). The purpose of this study was to analyze and characterize the population of extracellular vesicles (EVs) released by hiPSC-derived RPE cells. EVs are cell-derived nanoscale particles containing a range of molecular cargo including small RNA with emerging roles as essential mediators of cell-to-cell communication in developmental processes.

Methods: We established a differentiation protocol that is efficient in producing functionally mature RPE cells from hiPSC. To characterize EVs secreted by hiPSC-RPE cells, we analyzed the release rate, concentration, morphology and miRNAs content of EVs obtained from hiPSC-RPE. Transcriptomic analysis of miRNA EV cargo provided a comprehensive analysis of this signaling system, including miRNA cargo-predicted targetome correlated with Gene Ontology pathways.

Results: Characteristic EV morphology and size (30-170 nm) was observed by TEM. The average concentration of released EVs corresponded to 7.76×10^{10} particles/ml (apical) and 5.40×10^{10} particles/ml (basal). Transcriptomic analysis identified a total of 208 high confidence miRNAs; 17 detected only in RPE-EVs (1 only found in apical and 5 only in basal). Target gene prediction of differentially expressed miRNAs was carried out against a retinal and choroid database. To gain functional insight on RPE-EV transcriptomic cargo, we conducted over representation analysis and determined several biological processes enricheded in EV-associated miRNAs, including mechanisms of cell communication, signal transduction, cell growth and maintenance, metabolism, oxidative stress, immune response, inflammation, neurogenesis and phagocytosis.

Conclusions: This study represents the first transcriptomic profile from EVs released by hiPSC-derived RPE. EV content provides a snapshot of the originating cell's phenotype by revealing molecular cargo associated with mechanisms regulating human retinal physiology.

ABSTRACT BODY:

Purpose: Charles Bonnet Syndrome (CBS) is a poorly understood, debilitating phenomenon following vision loss from common diseases such as age-related macular degeneration and currently has no treatment. Individuals with CBS often experience visual hallucinations in the form of images such as people, landscapes, or patterns that do not exist. This experience is the result of an imbalance between the loss of vision and the active visual brain but is often misdiagnosed as dementia or a mental health condition. Psychosocial factors have been suggested to exacerbate CBS visual hallucinations. The ongoing COVID-19 pandemic has resulted in the implementation of public health safety measures including extended periods of total or partial lockdowns to reduce virus transmission. To date, Canadians have undergone several waves of restrictions that may increase the risk of pervasive psychosocial issues from social isolation. The goal of this research is to assess how the social constraints of the current COVID-19 pandemic may affect CBS visual hallucinations.

Methods: We surveyed 39 individuals (M: 69 years, SD: 16 years) with CBS from the CNIB Foundation. Visual hallucinations, anxiety, social isolation, loneliness, and QoL were assessed using: The Specific Psychotic Experiences Questionnaire and modified versions of the Generalized Anxiety Disorder 7 scale, Steptoe Social Isolation Index, DeJong Gierveld Loneliness scale, and the World Health Organization QoL scale, respectively.

Results: 90.6% of patients reported no change (increase: 6.3%; decrease: 3.1%) in average duration and 62.2% reported no change (increase: 21.6%; decrease: 16.2%) in frequency of CBS hallucinations. No significant differences were observed in anxiety ($p= 0.514$); QoL ($p= 0.155$); social isolation ($p= 0.835$); and loneliness ($p= 0.296$) between participants who reported experiencing a change compared no change in hallucinations.

Conclusions: The social constraints of the current COVID-19 pandemic measured through anxiety, social isolation, loneliness, and QoL do not affect visual hallucinations caused by CBS. This is consistent with the notion that CBS hallucinations are associated with an active visual cortex following vision loss.

TITLE: Essential role of ELOVL2 in maintenance of membrane structure in ARPE19 cells

SESSION TITLE: Biochemistry and Molecular Biology of the Retina/RPE

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: F. Gao, Department of Ophthalmology, University of California Irvine, Irvine, California, UNITED STATES|E. Tom, Q. Xu, D. Skowronska-Krawczyk, Dept. of Physiology and Biophysics, University of California Irvine, Irvine, California, UNITED STATES|

Commercial Relationships Disclosure: Fangyuan Gao: Commercial Relationship: Code N (No Commercial Relationship) | Emily Tom: Commercial Relationship: Code N (No Commercial Relationship) | Qianlan Xu: Commercial Relationship: Code N (No Commercial Relationship) | Dorota Skowronska-Krawczyk: Commercial Relationship(s);Code C (Consultant/Contractor):Visgenx, Inc

ABSTRACT BODY:

Purpose: ELOVL2 encodes an enzyme that elongates polyunsaturated fatty acids (LC-PUFAs). It's crucial for synthesis of omega-3 docosahexaenoic acid (DHA) and VLC-PUFAs, all playing critical role in retina biology as integral parts of photoreceptor disk membranes. The RPE cells are important in regulation and delivery of LC-PUFAs to the adjacent photoreceptors. However, the practical role of ELOVL2 in RPE structure and function remain unclear.

Methods: To understand the biological role of ELOVL2 in RPE, we used siRNAs directed against ELOVL2 in ARPE19 cells and investigated the effect of ELOVL2 in ARPE19 cells morphology and biology functions. Fluorescently labeled WGA was used to visualize cell membranes. Mass spectrometry-based lipidomic and proteomic analyses were used to understand the molecular role of ELOVL2 in ARPE19 cells.

Results: WGA staining of normal ARPE19 cells reveals a highly ordered pattern of cells, with cell boundaries strongly stained and sharply demarcated. In ELOVL2 KD ARPE19 cells, the staining becomes more diffuse, stronger in cytoplasm and staining perinuclear regions in the cell. Moreover, the borders of ELOVL2 KD ARPE19 cells are disordered and there are more discontinuities between cells. The quantitative results of the fatty acid composition of membrane lipidsshowed that there was a significant decrease of FA 22:4, 22:5 and 26:4 in ELOVL2 KD ARPE19 cells. Among them, FA22:4 and FA22:5 are substrates of ELOVL2, and FA26:4 are elongation products of FA24:4, which is a product of ELOVL2. Therefore, the lack of ELOVL2 leads to a decline in VLC-PUFA synthesis. Then the molecular mechanisms of the role of ELOVL2 in cell membrane were assessed by proteomics,revealing that among all the 153 significantly changed proteins (out of 2381 proteins in total, (|Fold change|≥1.5, P-Value < 0.05), 48 proteins were identified as membrane proteins (DAVID database), including membrane magnesium transporter 1 (MMGT1, up-regulated, p=0.01), caveolin 2 (CAV2, down-regulated, p=0.02), platelet derived growth factor receptor beta (PDGFRB, down-regulated, p=0.004), et al.

Conclusions: Our data revealed that ELOVL2 depletion disrupted membrane compositions on lipid and protein levels and may further alter the membrane structural and functional properties. These changes of the cell membrane will most probably affect transmembrane transport, transmembrane receptors' activity and other membrane related biological functions.

ABSTRACT BODY:

Purpose: Previous work has demonstrated that an artificial-intelligence (AI) based retinopathy of prematurity (ROP) risk model could provide both early prediction of treatment-requiring (TR) ROP and reduce the overall number of examinations in a US population. However, significant demographic differences exist between US and low and middle income countries (LMIC), which may limit translation of risk models based on demographics to other populations. In this work, we evaluate whether a modified AI-based risk model could perform with high sensitivity despite demographic differences in 3 LMICs.

Methods: Retinal fundus images were collected from 2351 subjects as part of an Indian ROP telemedicine screening program. A VSS was derived from the first exam after 30 weeks postmenstrual age. Using five-fold cross-validation, logistic regression models were trained and validated on 2 variables (gestational age at birth and VSS at first exam) for the eventual outcome of TR-ROP. Sensitivity, specificity, and respective 95% confidence intervals (CIs) were evaluated on test datasets acquired from Indian (n = 762 subjects, 27 TR-ROP), Nepalese (n = 330 subjects, 3 TR-ROP), and Mongolian babies (n = 319 subjects, 53 TR-ROP). All 3 test sets were consecutive population-based cohorts imaged as part of ROP telescreening programs.

Results: For the Indian, Nepalese, and Mongolian test datasets, the model had sensitivity [95% CI] equal to 100.0% [87.2%, 100.0%], 100.0% [29.2%, 100.0%], and 100.0% [93.3%, 100.0%], respectively. Specificity was 63.3% [59.7%, 66.8%], 77.1% [72.27%, 81.6%], and 45.8% [39.7%, 52.1%]. The mean ± standard deviation weeks subjects were identified prior to TR-ROP diagnosis was 2.1 ± 2.5, 0.7 ± 1.2, and 4.7 ± 5.1 weeks. Post-hoc analysis of the Indian dataset determined that, if those who screened negative were to never be screened again, the total number of examinations could be reduced by 45.0%.

Conclusions: We found 100% sensitivity and moderate specificity of a modified AI-based ROP risk model in 3 LMIC populations. There are two potential advantages to implementation of this risk model in ROP telescreening programs: (1) high-risk infants could be identified well before TR-ROP diagnosis, potentially reducing the risk of late treatment, and (2) the number of exams required to effectively screen a population could be significantly reduced.

SUBMITTER (NAME ONLY): Assel Talaspayeva

TITLE: The diagnostic accuracy of wearable binocular high-speed pupillometer in subjects with a different eye pathology and normal subjects.

SESSION TITLE: Retina imaging and pupillometry

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: A. Talaspayeva, M. Harooni, Brooklyn Eye Center, New York, UNITED STATES|

Commercial Relationships Disclosure: Assel Talaspayeva: Commercial Relationship: Code N (No Commercial Relationship) | Mark Harooni: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: To test and identify diagnostic accuracy of a single binocular, lightweight pupillometer device, that measures the pupillary light reflex (PLR) and to determine the asymmetry of the PLR (afferent pupillary defect, APD) among normal subjects and subjects with various eye pathology.

Methods: Data from subjects (N=150) with confirmed various ocular pathology (retinal diseases, optic nerve disease, refractive errors, amblyopia) and healthy subjects age 18 -70 yr were collected.

Patients with cloudy corneas and dense cataracts affecting the measurement of APD were excluded from the study. Visual acuity (Snellen visual acuity chart), autorefraction (Auto-Ref-Keratometer), intraocular pressure (IOP) was measured using Goldman tonometry, slit lamp and fundus examination were obtained. The optic nerve and retina were measured with OCTA (Optovue Inc.).

The pupillary light reflex (PLR) of the right and left eye concurrently was measured and analyzed with binocular wearable pupillometer in all patients. Parameters included relative APD, APD in superior and inferior fields, amplitude, latency, time to max constriction.

Pupillometer images interpretation with a single-page report were exported and analyzed, according to a specified grading protocol.

Results: All subjects were divided into 4 groups.

1.Patients who have asymmetric vision from either retinal or optic nerve disease without any other eye pathology.

2. Patients with significant asymmetric refractive errors without any other eye pathology.

3. Patients with monocular amblyopia without any other eye pathology.

4. Control groups with subjects with normal eye exam and normal pupillography test.

All groups had APD and pupillary abnormal parameters when compared with controls ($p<0.03$) with high sensitivity and specificity.

Conclusions: The binocular pupillometer demonstrated good diagnostic accuracy in its ability to help diagnose afferent and efferent pupillary defects (including relative afferent pupillary defects) in a retinal and optic nerve pathologies, refractive errors and amblyopia. This findings demonstrates that pupillometer is a valuable adjunctive tool to assist in diagnosis and may provide a method for monitoring disease progression.

The device does not require a darkened room and requires minimal patient cooperation which makes test easy and accurate.

ABSTRACT BODY:

Purpose: Delayed retinal vascularization of immature retinas (phase I) is the driving force of late-stage retinopathy of prematurity (ROP), a leading cause of blindness in children. Postnatal hyperglycemia within the first few weeks of life is a significant risk factor for ROP. We aim to examine retinal metabolic responses in mice modeling hyperglycemia-associated phase I ROP.

Methods: Hyperglycemia was induced with intraperitoneal (i.p.) injection of streptozotocin (STZ) in mice from postnatal (P) day 1 to 9. At P10, reteinal vessel growth was delayed. Single-cell suspensions were prepared from mouse retinas by using Worthington papain dissociation system (n=3 mice per group). A retinal cell barcoded library was prepared at the Single Cell Core at Harvard Medical School (HMS), sequenced at Biopolymer Facility at HMS, and aligned to the mouse genome at Harvard Chan Bioinformatics core. The downstream clustering analysis was performed using R package ‘Seurat’ (version 3.2.2), genes and cells were filtered so only cells with more than 300 genes detected or genes expressed in more than 10 cells were kept. The gene enrichment analysis was performed using ‘enrichGO’ function from R package ‘clusterProfiler’ and mouse annotation database ‘EnsDb.Mmusculus.v79’. The p-value was adjusted using Benjamini & Hochberg method with a cutoff of 0.05 on the enrichment tests.

Results: In mice with phase I ROP, there was a robust down-regulation of genes involved in metabolic pathways in rod, cone, bipolar and amacrine cell clusters. The major metabolic pathways involved are generation of precursor metabolites and energy, ATP metabolic process, cellular respiration, and oxidative phosphorylation ($p<0.001$). There was an up-regulation in genes involved in visual development, such as visual perception, eye development, axon development, and synapse organization related gene-ontology terms in rod, cone, bipolar and amacrine cell clusters of phase I ROP retinas. In Müller glia, genes involved in energy production-related pathways were downregulated, while genes involved in gliogenesis, axon development and angiogenesis-related pathways were upregulated.

Conclusions: We found that mice with phase I ROP experienced metabolic stress in retinal neurons and glia. Retinal remodeling may occur as compensatory responses. Modulating metabolic pathways may restore cellular homeostasis and prevent progression to severe ROP in premature infants.

ABSTRACT BODY:

Purpose: The photocurrent is an ion gradient that retinal photoreceptors rely on for conversion of light into electrical impulses. This gradient is largely mediated by Na^+/K^+-ATPase pumps, which are localized in the photoreceptor inner segment, where they exist as a heterodimer (a catalytic α3 and a non-catalytic β2 subunits). Previous studies have shown that the mouse lacking ATP1B2 results in rapid photoreceptor degeneration, but the specific importance of ATP1B2 in cones remains unstudied. The goal of this study is to elucidate the role of ATP1B2 in the overall function and health of cone photoreceptors.

Methods: Using CRISPR/Cas9, our lab generated a floxed Atp1b2 mouse model, which was then crossed with a cone-specific Cre to make a conditional knockout of Atp1b2 in cones. Visual function and retinal thickness were assessed using electroretinography (ERG) and optical coherence tomography. Morphology, protein localization, and protein expression were analyzed by immunohistochemistry and immunoblotting. Na^+ concentrations were analyzed using CoroNa$^+$ Green probes. Ultrastructural analysis was completed using transmission electron microscopy (TEM).

Results: Mice with the conditional deletion of Atp1b2 in cones display progressive cone degeneration and severe loss of cone function compared to control littermates. A significant decrease and mislocalization of cone specific proteins, such as PDE6α', and GNAT2, and accumulation of Na^+ ions were observed in these mice. The ultrastructure of Atp1b2$^{-/-}$ cones at P60 showed a dysmorphic cone outer segment structure with abnormal swelling and holes. No major defects were observed in the cone IS, where the Na^+/K^+-ATPase is primarily localized. Interestingly, despite the normal expression of rod-specific proteins and only minor abnormalities to rod ultrastructure in cone Atpb2$^{-/-}$ retinas, a significant reduction of the scotopic ERG response was recorded in these mice at P60.

Conclusions: Our data demonstrate that ATP1B2 is critical for cone photoreceptor function and survival. Loss of ATP1B2 from cones leads to accumulation of Na^+ ions, which we hypothesize is likely the reason we observed abnormal ultrastructure of the cone OS and cone degeneration. Furthermore, our data suggest that alterations to the Na^+ gradient in cones can also have a harmful effect on other retinal neurons such as rods, contributing to changes in overall retinal function and health.

ABSTRACT BODY:

Purpose: The purpose of this study was to show that subjects with allergic conjunctivitis (AC) or allergic rhinoconjunctivitis (ARC) develop moderate to severe ocular allergic signs and symptoms following 90 minutes of exposure to ragweed or timothy grass pollen in a mobile Allergen BioCube (mABC).

The clinical validation of the mobile Allergen BioCube (mABC) was performed in this study. A stationary version of the ABC was previously validated and used to conduct studies assessing the efficacy of drugs in the treatment of allergic rhinitis.

Methods: Subjects with a self-reported history of ocular allergic symptoms for the last 2 consecutive years during the ragweed or timothy grass seasons who had a positive skin test reaction to ragweed or timothy grass pollen within 24 months of Visit 1 were screened for this study. Subjects were exposed to either ragweed or timothy grass pollen in the mABC for 90 minutes and assessments were made at specified intervals (0, 10, 30, 60, and 90 minutes). A qualifying score was defined as a bilateral score of 2 or greater for both ocular itching and redness using standardized 0-4 severity scales at 90 minutes post-exposure.

Results: All subjects were asymptomatic prior to entering the mABC. All subjects experienced an increase in severity of ocular and nasal symptoms upon pollen exposure. Sixty (60%) percent of patients developed qualifying levels of bilateral ocular itching (mean score 2.7) and redness (mean score 3.1) at 90 minutes post-exposure. These subjects had a clinically (>1) and statistically ($P<0.05$) meaningful increase from baseline in all ocular and nasal allergic parameters at 90 minutes.

Conclusions: The mABC was effective in inducing ocular allergic signs and symptoms in subjects with a history of AC/ARC over a 90-minute exposure period. The mABC will be an important tool for evaluating allergy therapeutics in clinical studies requiring an environmental allergy model across multiple ophthalmology/allergy centers.

TITLE: Role of DNA Methylation in RGC Death during Glaucoma Progression

SESSION TITLE: Neuroprotection

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S. Husain, S. Singh, W. Guzman, Ophthalmology, Medical University of South Carolina, Charleston, South Carolina, UNITED STATES|

Commercial Relationships Disclosure: Shahid Husain: Commercial Relationship: Code N (No Commercial Relationship) | Sudha Singh: Commercial Relationship: Code N (No Commercial Relationship) | Wendy Guzman: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The objective of this study is to determine the role of DNA methylation in RGC death during glaucoma pathology. We administered a selective DNA methylation inhibitor (Decitabine) or delta-opioid receptor agonist (SNC-121) to regulate the DNA methylation and methyltransferases activities in a rat glaucoma model and measured changes in biochemical and functional outcomes.

Methods: We used male and female Brown Norway rats (3-4 months old) to elevate intraocular pressure (IOP) by 2.0 M hypertonic saline injections in limbal veins. The changes in global DNA methylation were measured using the ELISA-based 5-methylcytosine (5mC) DNA Quantification Kit (# P-1030, EpiGenetek, Farmingdale, NY) according to manufacturer instructions. The activity of DNA methyltransferases (DNMTs) were measured by Enzyme Assay Kit from EpiGentek (Cat # P-3139, Farmingdale, NY), and changes in the expression pattern of DNMT-1, -3a, and -3b were determined by RT-PCR, WB, and immunohistochemistry.

Results: A significant RGC neuroprotection was offered by Decitabine and SNC-121 treatment at day 42, post glaucomatous injury as measured by Pattern ERGs. We also find an increase in genome-wide DNA methylation in the retina samples of ocular hypertensive animals at day 42, post glaucomatous injury, which was significantly inhibited with SNC-121 treatment. Additionally, we found an overall increase in the DNA methyltransferases (DNMTs) activity, mRNA, and protein expression of DNMT1, DNMT3a, and DNMT3b in the retina sections of ocular hypertensive animals at day 7 and 42, post glaucomatous injury.

Conclusions: Our novel data demonstrate that mRNA and protein expression of DNA methyltransferases (DNMTs) and global DNA methylation were increased in the retina of ocular hypertensive animals. Based on these findings it appears that Inhibition of DNA methylation may provide RGC neuroprotection in glaucoma.

SUBMITTER (NAME ONLY): Mikiko Nagashima

TITLE: Microglial dynamics during photoreceptor death and regeneration in zebrafish

SESSION TITLE: Retinal and central processing

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Nagashima, P.F. Hitchcock, Department of Ophthalmology and Visual Sciences, University of Michigan, Ann Arbor, Michigan, UNITED STATES|

Commercial Relationships Disclosure: Mikiko Nagashima: Commercial Relationship: Code N (No Commercial Relationship) | Peter Hitchcock: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Microglia are the innate immune cells of the central nervous system and govern injury-induced inflammation by secreting pro- and anti-inflammatory cytokines and chemokines. In mammalian retinas, microglia reside in the retinal parenchyma, nerve fiber/ganglion cell layers and inner and outer plexiform layers. We have identified a novel population of microglia, unique to zebrafish, which reside among the retinal pigment epithelial cells. In this study, we compared the response of subretinal microglia with that of parenchymal microglia following death of photoreceptors. We then assay regeneration of photoreceptors in the csf1ra^{j4e1} mutant, where the number of parenchymal microglia, but not subretinal microglia, is diminished.

Methods: Photolytic lesions were used to selectively kill photoreceptors. The transgenic reporter line, Tg(mpeg:eGFP) and 4C4 antibody were used to visualize microglia. PCNA immunocytochemistry and TUNEL staining was used to assay proliferation and cell death, respectively.

Results: At 1 day post lesion (dpl), the number of microglia in the damaged outer retina increases by two-fold, whereas the number of microglia in the inner plexiform layer decreases significantly. This is accompanied by subretinal microglia descending toward the site of photoreceptor death. At 1 dpl, a small subset of microglia is co-labeled with TUNEL and the number of phagocytic microglia increases by 2 dpl. At 2 dpl, more than half of microglia in the subretinal space become PCNA+. By 14 dpl, the subretinal and parenchymal microglia resume their normal distribution, suggesting resolution of inflammation. In the csf1ra^{j4e1} mutants, the number of parenchymal microglia was significantly reduced, whereas the number of subretinal microglia matched that of wildtype animals. The diminished number of parenchymal microglia in the mutants did not affect the photoreceptor regeneration.

Conclusions: This study establishes the common and distinct responses of microglia populations that reside in retinal parenchyma and subretinal space in response to the selective death of photoreceptors. Activation, migration, and phagocytosis universally occur among microglia, whereas activated microglia proliferate predominantly in the subretinal space. The normal regeneration of photoreceptors in csf1ra^{j4e1} mutants suggests that subretinal microglia are sufficient to trigger the acute inflammation that governs photoreceptor generation.

ABSTRACT BODY:

Purpose: The therapeutic potential of the CRISPR/Cas9 mediated gene editing in ophthalmic diseases is uncertain due to the lack of a comprehensive understanding of the toxicity and immune responses associated with the exogenous expression of Cas9. The purpose of this study is to evaluate for signatures of off-target immune responses and cytotoxicity associated with long-term Cas9 expression in the retina and retinal pigment epithelium (RPE).

Methods: Rosa26-Cas9 knock-in mice (RD8 negative), that constitutively express Cas9, were evaluated using color fundoscopy, spectral-domain optical coherence tomography (SD-OCT), and full-field electroretinography (ERG) across different age groups and compared to age-matched wild-type (WT) controls. RPE integrity was examined using ZO-1 immunofluorescence of RPE/choroid flat-mounts. In vitro evaluation of Cas9 toxicity in RPE cells was performed using MTT and annexin/PI assays. A panel of 84 genes associated with mouse innate and adaptive immunity was screened in neural retina and RPE/choroid of Cas9 and WT mice using Taqman PCR arrays. Statistical tests used included Mann-Whitney U, ANOVA, and Fisher's exact.

Results: Cas9 was expressed abundantly in the retina of Rosa26-Cas9 mice compared to WT mice, and fundus imaging revealed a normal-appearing posterior segment in young and aged (up to 12 months) mice. Full-field ERG responses were largely normal, but significant reduction was observed at the highest flash intensity in both a-wave and b-wave amplitudes of Cas9 mice compared to that of controls (p-value = 0.008). ZO-1 staining reveals intact RPE with regular hexagonal tiling even in the aged mice. Plasmid enforced expression of Cas9 in ARPE-19 cells demonstrated no loss of cell viability. Of the 84 genes tested in RPE/choroid of Cas9 and WT mice, IL6 was significantly upregulated (17.20 fold, p=0.0012) in Cas9 mice.

Conclusions: The Rosa-26 Cas9 knock-in mice appear phenotypically normal even up to 1 year. Mildly reduced full-field bright-flash ERG recordings were observed. Overall, long-term Cas9 expression does not appear to significantly reduce retinal cell viability. The altered expression of IL6 observed in the RPE/choroid of Cas9 mice implies the unexpected consequences and off-targeting events that CRISPR/Cas9 might cause. Further investigations of the mechanism by which IL6 is upregulated are underway and should be fully considered before employing this technology.

ABSTRACT BODY:

Purpose: Familial exudative vitreoretinopathy (FEVR) is a genetic disorder in which the retinal vasculature fails to form fully (hypovascular). We discovered that loss of the T-box transcription factor, Tbx3, in mouse embryonic retinal progenitor cells results in a hypovascular retina. This study aimed to characterize this phenotype and determine how the loss of Tbx3 affects angiogenesis.

Methods: To remove Tbx3, we crossed the validated Tbx3-floxed mice with the optic cup-Cre recombinase driver, BAC-Dkk3-CRE, and confirmed loss of retinal protein by western blot. Cryostat retinal sections and flat mounts were immunostained, imaged, and cells counted using standard techniques. Statistical analysis was performed using Prism v9.3. ImageJ (v1.52q) and Volocity (v6.3) software were used for analysis.

Results: Blood vessels failed to extend to the edge of the P9 Tbx3 conditional knockout (cKO) retina and occupied significantly less of the total retinal surface area than wildtype siblings (WT, 0.489 ± 0.019; cKO, 0.230 ± 0.023). We also observed that the hyaloid artery failed to regress. At P30, we observed fewer branch points, decreased vascular density, and incomplete formation of the superficial plexus in mutant mice compared to controls. The astrocytic lattice was similarly stunted in the mutants, primarily in the dorsal region. Previous studies have shown that melanopsin-positive intrinsically photosensitive retinal ganglion (ipRGCs) and dopaminergic amacrine cells control retinal angiogenesis. At one month of age, we found a significant loss of ipRGCs (~30%) throughout the retina, with an even more substantial loss (~50%) in the dorsal region. In addition, we failed to detect the expression of tyrosine hydroxylase-positive amacrine cells in the Tbx3 cKO retina (3 litters: n=6 WT; n=5 cKO).

Conclusions: The loss of Tbx3 in retinal progenitors inhibits retinal angiogenesis in a pattern consistent with previous mouse models of FEVR. Our working hypothesis is that defects in angiogenesis are caused by a loss of ipRGCs and the absence of dopaminergic amacrine cells. Future studies will determine the molecular mechanism driving this defect in the Tbx3 cKO retina.

ABSTRACT BODY:

Purpose: Nuclear distribution protein C (NUDC) has been shown to regulate actin equilibrium through the stabilization of the F-actin severing protein cofilin1 (CFL1). Previously, we have shown NUDC is crucial for the development and maintenance of rod photoreceptors in X. laevis tadpoles and mice. We hypothesize NUDC modulates F-actin dynamics within photoreceptors through CFL1. Since CFL1 is further regulated by phosphorylation (pCFL1), we hypothesize the phospho-mimetic and phospho-null mutants of CFL1 will alter actin equilibrium within rods, thereby affecting outer segment (OS) disk formation. Here, we investigate the biochemical processes underlying F-actin architecture in the rod OS through transgenic expression of CFL1 mutants and shRNAs against Cfl1 in X. laevis.

Methods: We utilized immunohistochemistry (IHC) on X. laevis, mouse and human retinal sections to uncover the presence and localization of CFL in photoreceptors. We have expressed transgenic wild type CFL1 (CFL1), constitutively active phosphonull CFL1 ($CFL1^{S3A}$), dominant negative phosphomimetic CFL1 ($CFL1^{S3D}$), or shRNAs against Cfl1 in X. laevis tadpoles under the rod opsin promoter. Western dot blots, IHC, and protein proximity ligation assay (PLA) with fluorescent confocal microscopy will be employed to visualize the localization of key proteins within the rod cell at 2 and 4 weeks post-fertilization. We will utilize transmission electron microscopy to image ultrathin sections of 2wk old X. laevis to uncover photoreceptor OS ultrastructure in the presence of endogenous CFL1, its knock-down, or the mutant CFLs.

Results: We found CFL1 and pCFL1 both expressed in the inner segment (IS) of X. laevis, mouse, and human photoreceptors. PLA indicates that CFL1 is in close proximity (< 40nm) to NUDC in the IS and at the base of the OS in rods of mouse and X. laevis. Initial IHC staining shows transgenic overexpression of WT CFL1 in X. laevis does not affect photoreceptor development or maintenance while $CFL1^{S3D}$ produces actin and cytoskeletal disruptions.

Conclusions: We show CFL1 is expressed and colocalizes with NUDC at the base of the rod OS. Additionally, transgenic expression of $CFL1^{S3D}$ results in cytoskeletal dysregulation, supporting our hypothesis that NUDC governs the interactions between CFL1 and F-actin. Further analysis is ongoing. This work is critical for furthering our understanding of the molecular mechanisms behind OS disk regulation and formation.

ABSTRACT BODY:

Purpose: Albeit the introduction of spectral-domain optical coherence tomography (SD-OCT) modified screening facilities of Hydroxychloroquine (HCQ) retinopathy, the investigation of risk factors suggesting an early identification of retinal changes due to the drug is pivotal.

Methods: In a retrospective observational manner a dataset of 27 eyes with clinical hydroxychloroquine toxicity were analyzed and compared to an age-, gender-, ethnicity-matched control group with no toxicity. However, both groups had a significant difference in means of cumulative HCQ dosage in gram. SD-OCT scans (Heidelberg Engineering, Heidelberg Germany) were analyzed and automatic retinal-layer segmentation performed. Subsequently, mean thickness values subdivided in full retina, ganglion cell layer (GCL), outer nuclear layer (ONL), photoreceptor layer, retinal pigment epithelium (RPE) and outer retinal layer (photoreceptor layer + ONL) were calculated and compared. Additionally, layers were categorized in center, middle ring and outer ring according to the ETDRS grid.

Results: The conducted study highlights changes of retinal thickness in patients with clinical toxicity. When comparing full retina layer in the central subfield, results revealed significant difference between eyes with toxicity to control eyes (250.8 ± 26.1 versus 272.1 ± 23.6, p=0.011), while the categorical variable including the percentage of eyes with reduced retinal thickness did not outline any significance (7.4% vs. 0%, p=0.554). However, comparing middle and outer ring of the full retina layer did show significant difference in both calculations (292.3 ± 27 versus 332.8 ± 16.6, p <0.001 respectively 59.3% versus 7.4%, p=0.013 and 265.8 ± 31.6 versus 292.0 ± 14.9 respectively 57.7% versus 0%, p=0.011). Similar results were detected for the middle ring of GCL and ONL. The GCL showed a highly significant difference of retinal thickness in eyes with toxicity compared to control eyes (35.3 ± 15.2 versus 49.6 ± 3.9, p=0.001) which resulted in a GCL thinning of 51.9% in toxicity eyes compared to reference data.

Conclusions: Our data elucidate the impact of the cumulative dosage in regard of retinal changes. We emphasize the importance of OCT imaging as a screening tool to quantify structural changes in the different retinal layers that might help to identify early changes for patients with HCQ retinopathy with no clinical manifestation at an early stage.

ABSTRACT BODY:

Purpose: Cerebral hallmarks of Alzheimer's disease (AD) manifest in the neurosensory retina at early disease stages. However, synaptic loss that tightly predicts cognitive decline has never been described in the AD retina. The ubiquitin-proteasome system (UPS), a major degradation pathway for damaged proteins, has been implicated in AD pathogenesis. A vital component of UPS, ubiquitin hydrolase (UCH-L1), exhibits a neuroprotective role and is required for normal synaptic function. Since low levels of brain UCH-L1 were linked with cerebral Aβ accumulation in AD, we explored its expression in AD patients' retina.

Methods: Using various histological approaches, we assessed synaptic integrity, tauopathy, apoptosis and UCH-L1 levels in post-mortem retinas of patients with confirmed mild cognitive impairment (MCI) due to AD or AD dementia, compared to age- and sex-matched subjects with normal cognition (NC). We visualized and quantified synaptic density by analysis of pre- and post-synaptic markers (e.g., VGlut1, PSD95, Synaptophysin) and determined their spatial and cell layer distribution.

Results: We detected extensive (1.6- to 3-fold) pre- and post-synaptic losses in the IPL and OPL of MCI and AD patients, whereas early synaptic loss was mostly detected in the far peripheral regions. Along with marked synaptic loss, the retinal layers of MCI and AD patients demonstrated 2- to 4-fold decreases in levels of UCH-L1 as compared to NC. Notably, decreased levels of retinal UCH-L1 directly correlated with pre-synaptic loss ($p<0.0001$), especially in the far periphery of AD patients. The pre-synaptic VGluT1 marker also inversely correlated with pTau (e.g., AT8) accumulation, colocalizing at sites of synaptic loss, in the IPL and OPL layers in MCI and AD patients. These changes were accompanied by significant 1.8-4.2-fold increases in apoptotic cell death in the retinas of these patients ($p< 0.05–0.001$).

Conclusions: Our results reveal a substantial retinal synaptic loss at sites of pTau accumulation in prodromal and clinical AD patients. Retinal UCH-L1 expression was significantly deficient in MCI and AD patients, and due to its part in the UPS protein degradation pathway and tight correlation with retinal synaptic loss in AD, this study suggests its importance in retinal synaptic protection against AD-related stress.

TITLE: Capturing Tear Film Stability with the Ocular Protection Index (OPI) acquired with Ora EyeCup Phone

SESSION TITLE: Dry Eye, Clinical

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: E. bensinger, J.D. Rodriguez, M. Marquis, K. Dieter, I. Sinyak, M.B. Abelson, Ora Inc, Andover, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Ethan bensinger: Commercial Relationship(s);Code E (Employment):Ora Inc | John Rodriguez: Commercial Relationship(s);Code E (Employment):Ora Inc | Maurice Marquis: Commercial Relationship(s);Code E (Employment):Ora Inc | Kevin Dieter: Commercial Relationship(s);Code E (Employment):Ora Inc | Igor Sinyak: Commercial Relationship(s);Code E (Employment):Ora Inc | Mark Abelson: Commercial Relationship(s);Code E (Employment):Ora Inc;Code I (Personal Financial Interest):Ora Inc

ABSTRACT BODY:

Purpose: Patients with dry eye disease experience greater tear film instability and more rapid rates of tear film break-up post blinks. The Ora EyeCup Phone is able to measure tear film stability utilizing the Ocular Protection Index (OPI) scale. OPI not only looks at the time for the tear film to break up but also allows the assessment of the break up area.

Methods: We tested 15 patients (12 female; mean age 62 yo) with a reported history of dry eye disease and a tear film break up time less than 5 seconds. Fluorescein was instilled via micropipette in both eyes 3 minutes prior to video recording. The EyeCup was fitted with led lights to activate the fluorescein and a filter was placed in front of the camera. Patients were instructed to hold their gaze on a crosshair positioned straight ahead of the subject while a 1-minute 4k 60 frames per second video on each eye was recorded using the google Pixel 5. Patients were asked to blink normally while the video was acquired to provide a natural interblink interval (IBI) and tear film break up time (TFBUT). Videos were processed using a custom semi-automated algorithm previously described.

Results: Video acquisition with the Ora EyeCup Phone was successful in all patients and took five minutes or less from instruction to successful recording of both eyes. Video quality was similar to videos previously measured using a DSLR camera in a slit lamp exam. In all patients the OPI was below 1, indicating they had an unprotected ocular surface. The average OPI was 0.090 (standard deviation 0.027).

Conclusions: This study demonstrated the feasibility of performing real-time, home-based assessment of tear film stability and ocular surface protection using a novel technology. This proof-of-concept study suggests the usefulness of this technology in clinical trials investigating the effect of different treatment modalities for dry eye disease outside the laboratory setting.

TITLE: Time course of artificial tear efficacy in dry eye disease revealed by inter-blink interval visual acuity decay (IVAD) test

SESSION TITLE: Dry Eye, Clinical

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Shelton, E. Besinger, J.D. Rodriguez, M.B. Abelson, K. Dieter, M. Dusharm, G. Wallstrom, Ora Inc, Andover, Massachusetts, UNITED STATES|

Commercial Relationships Disclosure: Michael Shelton: Commercial Relationship(s);Code E (Employment):Ora Inc | Ethan Besinger: Commercial Relationship(s);Code E (Employment):Ora Inc | John Rodriguez: Commercial Relationship(s);Code E (Employment):Ora Inc | Mark Abelson: Commercial Relationship(s);Code E (Employment):Ora Inc | Kevin Dieter: Commercial Relationship(s);Code E (Employment):Ora Inc | Mathew Dusharm: Commercial Relationship(s);Code E (Employment):Ora Inc | Garrick Wallstrom: Commercial Relationship(s);Code E (Employment):Ora Inc

ABSTRACT BODY:

Purpose: Patients with dry eye disease experience greater tear film instability and more rapid rates of tear film break-up. This faster decay of ocular surface protection can impact visual function, as a smooth, regular tear film is critical to maintaining best corrected visual acuity (BCVA). Using an enhanced version of the inter-blink interval visual acuity decay (IVAD) test (1), we examined the impact of an artificial tear compound (Systane Ultra, Alcon, Inc.) on visual function between blinks.

Methods: We tested 15 patients (12 female; mean age 62 yo) with a reported history of dry eye disease. To examine how visual acuity changed between blinks for these patients, we used an upgraded version of the IVAD test (1). In this test, patients are instructed to blink three times and then hold their eye open. While holding their eye open, patients identify rotated Landolt C images presented at their distance BCVA for each eye, with time to visual acuity decay determined by patients' accuracy at this task at various time points between blinks. We repeated the test for each qualifying eye at 5 time points (prior to the administration of the artificial tear, and again at 5, 15, 45, and 90 minutes post-administration).

Results: Our findings revealed that prior to the administration of the artificial tear, patients maintained BCVA for 12.3±2.3 seconds before experiencing decay. Soon after the drop was administered, time increased by more than 50% at both the +5-minute (18.8±3.3 seconds; $p=0.0008$) and +15-minute (22.1±2.5 seconds; $p=0.0449$) timepoints before returning to baseline (12.9±1.7 and 12.6±2.1 seconds at +45- and +90-minute time points respectively; both $p > 0.85$).

Conclusions: Our new version of a technique to assess visual function in dry eye disease revealed that a commercially available artificial tear can help significantly prolong the duration of BCVA in patients with dry eye disease. This effect is transient across the time course, with a larger effect soon after the drop is administered (+5 and +15 minutes) and returning to baseline by the 45-minute time point. These results add further evidence demonstrating how tear film stability impacts visual function in patients with dry eye disease (1) and support the usefulness of the IVAD test as a novel end point for assessing visual function in new therapies developed for the treatment of dry eye disease.

Commercial Relationships Disclosure: Sree Indrani Motipally: Commercial Relationship: Code N (No Commercial Relationship) | Saravanan Kolandaivelu: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Progressive rod-cone degeneration (PRCD) is an integral membrane protein strongly associated with photoreceptor disc membranes that is crucial for maintaining the structural and functional integrity of photoreceptor outer segments (POS). Previously we showed that the sole cysteine (Cys2) in PRCD is palmitoylated, a post translational lipid modification that is essential for protein stability and trafficking to the OS. However, the precise role of palmitoylation in PRCD remains obscure. The focus of this study is to define how palmitoylation in PRCD supports protein stability and trafficking to the OS using multiple PRCD mice models and cell culture studies.

Methods: We evaluated visual function by electroretinogram (ERG) at various ages in the PRCD-C2Y animals and littermate controls. To investigate the role of palmitoylation, we made plasmid construct changing palmitoylation to myristoylation (PRCD-C2G) and analyzed protein stability and trafficking by western blotting and immunohistochemistry. Furthermore, PRCD aggregation into mitochondrial membranes and proteasomal insufficiency was investigated in various PRCD-C2Y models. Next, mitochondrial function is analyzed in age matched WT, and PRCD mutant retinas using seahorse flux analyzer. Ultrastructure of PRCD-C2Y retina was performed by transmission electron microscopy.

Results: Our ERG and ultrastructure studies in PRCD-C2Y animal models show attenuated visual responses, lamellar disorientation, and vesicular profiles in the photoreceptor OS like canine models. Furthermore, substituting myristoylation (PRCD-C2G) for palmitoylation neither alleviated the protein stability nor restored PRCD trafficking to the OS. Interestingly, mutating C-terminal ubiquitin sites (K50R/K54R) enhanced the stability in PRCD-C2Y mutant protein. Also, our data shows dysregulated mitochondrial metabolism in PRCD-C2Y retina.

Conclusions: Our studies demonstrate that palmitoylation in PRCD is indispensable for PRCD protein stability and trafficking to POS. Substituting myristoylation for palmitoylation does not rescue protein stability or trafficking of PRCD-C2Y mutant. However, mutating ubiquitin signal in palmitoylation deficient PRCD-C2Y led to enhanced protein stability suggesting that both palmitoylation and ubiquitination coordinate to maintain PRCD protein homeostasis.

ABSTRACT BODY:

Purpose: Very recent empirical estimates of Americans living with visual acuity loss or blindness have significantly superseded prior benchmarks. Previously published literature demonstrates a strong association between vision loss and psychiatric disease. This US national database analysis utilizes the latest edition of the NSDUH to characterize the odds of lifetime episode of major depression associated with significant visual impairment or blindness in the United States.

Methods: The latest edition of the National Survey of Drug Use and Health (NSDUH) database was executed for procurement of nationally de-identified cases of major depressive episode (MDE) and significant visual impairment or blindness. Significant visual impairment or blindness (despite refractive correction) is defined using interview-generated responses. Patients with unknown incidence of visual impairment or MDE were excluded. Univariable and multivariable logistic regression yielded odds ratios (ORs) and standard error of mean (SEM) with 95% confidence intervals (95% CI). Statistical significance was achieved at $p<0.05$.

Results: Of 42,179 patients, 7543 (17.9%) experienced a lifetime MDE. Of the lifetime MDE cohort, 481 (6.3%) cases experienced significant vision loss or blindness (Table 1). Of the cohort with no lifetime MDE, 1,338 (3.8%) experienced vision loss/blindness. Univariable logistic regression highlights increased odds of lifetime MDE for patients afflicted with significant visual impairment or blindness (OR=1.695, 95% CI: 1.523-1.887, $p<0.001$) (Table 2). Multivariable analysis adjusting for psychosocial factors and chronic diseases supported this finding (OR=1.561, 95% CI: 1.379-1.767, $p<0.001$).

Conclusions: Within the US national population, significant visual impairment or blindness prognosticates significantly increased odds of lifetime development of major depressive episode. Recent advances in our understanding of the heightened prevalence of vision loss and blindness in America acts as provision for highlighting current associations related to psychiatric disease, including major depressive episode. Clinical decision-making should reconcile efforts to maintain quality of life in ophthalmologic patients with low vision through multidisciplinary approaches.

ABSTRACT BODY:

Purpose: To develop widefield OCT angiography (OCTA) imaging with distortion free, a field-of-view (FOV) of at least 100 degrees, and an ability to quantify retinal flow.

Methods: OCTA images were acquired by a swept-source optical coherence tomography (SS-OCT) with a central wavelength of 1060 nm (PLEX® Elite 9000; ZEISS, Dublin, CA) running at 100 kHz with a 6×6 mm scan pattern. Widefield images were obtained by automatic stitching of the OCTA scans acquired at nine fixation spatial positions guided by the system. A phantom eye was used to develop, validate and test the developed distortion correction method. The en face images of retinal flow were first generated for individual scans, and then distortion was corrected by modeling the beam propagation in the eye. The final widefield image was formed by montaging distortion-corrected spatial scans together through an algorithm based on the Distinctive Image Features from Scale-Invariant Keypoints. Measurements of retinal flow impairment zone, vessel density, vessel skeleton density were compared before and after distortion correction.

Results: Normal eyes (N=5) and eyes with diabetic retinopathy (DR) (N=5) were recruited in this study. Results from phantom eye demonstrated successful correction of distortion during scanning. Clinically, the proposed method was shown capable of successfully achieving a FOV as large as 100 degrees on both normal eyes (Figure 1 A) and eyes with DR (Figure 1 B). The distortion-corrected images demonstrated continuous vessel connections across the whole montaged image. The statistical analyses showed a significant difference ($p<0.05$) in retinal flow impairment zone measurements before and after distortion correction.

Conclusions: Distortion correction is clinically important in the visualization and quantification of the widefield OCTA image with a FOV up to 100 degrees, which provides a more accurate assessment of microvascular involvement in eye diseases, particularly for the diseases that require the inspection of peripheral regions, such as DR.

ABSTRACT BODY:

Purpose: To study corneal astigmatism in BBS. The ciliopathy associated with BBS may contribute to increased proliferation and vertical migration of corneal epithelial basal-layer cells, thus consequent astigmatism.

Methods: We studied the cycloplegic refraction and results of keratometry in 48 patients (96 eyes) with biallelic diagnosis of a form of BBS (BBS1, BBS2, BBS6, BBS7, BBS10, BBS12, or MKS1) seen at Boston Children’s Hospital from February 2011–August 2021.

Results: The mean age of patients was 16.3 (± 8.0) years. The mean best-corrected visual acuity was 20/60, the mean keratometry value at the steepest axis was 48.05 D (±9.50) at 89 degrees, and the mean keratometry value at the flattest axis was 43.46 D (±6.35) at 168 degrees. Average corneal astigmatism was 4.59D (>4D = extreme range), mean spheric refractive error was -2.75 D (±3.88), and mean cylindric refractive error was -2.62 D (±1.39).

Conclusions: Genetically diagnosed BBS patients demonstrated high corneal astigmatism. BBS is a member of the ciliopathy family, and corneal microtubule-based protrusion and corneal development/remodeling dysfunction can be linked. We suggest that these patients should be screened by corneal topographic evaluation and that the primary cilium should be considered a target in disease management.

ABSTRACT BODY:

Purpose: Intravitreal injections of anti-vascular endothelial growth factor (VEGF) has become the gold standard of treatment for wet age-related macular degeneration. However, this treatment is limited by the need for repeated injections due to the rapid clearance and short half-life of anti-VEGFs. Recently, we developed a drug delivery system (DDS) that releases bioactive aflibercept (AFL) for six months. This system showed treatment efficacy in a laser induced choroidal neovascularization (CNV) rodent model. The purpose of this study was to determine the treatment efficacy of AFL-DDS in a laser-induced CNV nonhuman primate model.

Methods: AFL-loaded poly(lactic-co-glycolic acid) microparticles were created using a modified double emulsion technique. Then, microparticles were embedded into a biodegradable, thermoresponsive poly(ethylene glycol)-co-(L-lactic-acid) diacrylate/N-isopropylacrylamide hydrogel to create AFL-DDS. Eight CNV lesions were created by laser photocoagulation (50 µm, 150 ms, 750 mW) in each eye of rhesus macaques. For all animals, OD was treated with AFL-DDS (50 µl, 15 ug) and OS was used as control. At Week 0 (14 days after the laser induction), AFL-DDS treatment was administered. Fluorescein angiography (FA) and spectral domain optical coherence tomography (OCT) was obtained at Weeks 0, 2, and 4. Lesion size was measured using the multi-Otsu thresholding (MOT) analysis and normalized to the measurements at Week 0.

Results: Before the AFL-DDS treatment, FA and OCT confirmed that CNV lesions were fully developed. No complications observed due to the CNV induction or AFL-DDS intravitreal injection. At Week 0, average lesion area was 0.38 ± 0.01 mm^2 for the AFL-DDS treated eyes. Two weeks after AFL-DDS treatment administration, average lesion area was 0.78 ± 0.05 mm^2. When normalized to Week 0, the lesion increased by 136.7 ± 16.6%. By 1-month post-treatment, average lesion size was 0.38 ± 0.01 mm^2. When normalized to the Week 0, an increase of 9.7 ± 3.6% was still observed.

Conclusions: Current results show that AFL-DDS treatment had a positive effect on reducing CNV lesions in a short-term treatment study. Based on the positive effects of AFL-DDS, a longer duration of CNV evaluation will be conducted.

TITLE: Patient Reported Outcome Measures while using a device to objectively measure eye drop adherence

SESSION TITLE: Clinical studies and trials

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: S.L. Mansberger, F.G. Sanchez, J.P. Rees, S.K. Gardiner, V. Klei, J. Duvdevany, M.L. Kobak, R.M. Kinast, Devers Eye Institute, Legacy Health System, Portland, Oregon, UNITED STATES|

Commercial Relationships Disclosure: Steven Mansberger: Commercial Relationship(s);Code C (Consultant/Contractor):Thea;Code C (Consultant/Contractor):Nicox;Code O (Owner):Nicox;Code F (Financial Support):AbbVie;Code O (Owner):Universal Adherence | Facundo Sanchez: Commercial Relationship: Code N (No Commercial Relationship) | Jack Rees: Commercial Relationship: Code N (No Commercial Relationship) | Stuart Gardiner: Commercial Relationship: Code N (No Commercial Relationship) | Viridian Klei: Commercial Relationship: Code N (No Commercial Relationship) | Julie Duvdevany: Commercial Relationship: Code N (No Commercial Relationship) | Max Kobak: Commercial Relationship: Code N (No Commercial Relationship) | Robert Kinast: Commercial Relationship(s);Code O (Owner):Universal Adherence

ABSTRACT BODY:

Purpose: The Devers Drop Device (D3) is a first-generation eye cap monitor (Figure) to objectively measure eye drop adherence and eye drop-taking behavior. It includes local and cloud storage of adherence data, wireless communication, visual and auditory alerts, and a universal fit, which allows it to attach onto any FDA-approved eye drop bottle cap. We were interested in patient reported outcome measures (PROM) using the D3.

Methods: We enrolled research subjects with a diagnosis of glaucoma or glaucoma suspect who own an Android smartphone or iPhone, and use latanoprost eye drops at bedtime. The study included two stages: Stage 1) a 25-day period (±3 days) evaluating baseline patient adherence with the D3 device; and Stage 2) a subsequent 25-day (±3 days) period to determine the effect of the D3 device with no reminder versus a daily alert from the D3 device. At enrollment and at the last visit, we administered a questionnaire and the Glaucoma Treatment Compliance Assessment Tool (GTCAT) to determine attitudes about adherence and satisfaction with the D3. We defined adherence as the proportion of eye drops administered within +/-3 hours of the expected dosing time. We used linear regression to determine the association of adherence with sociodemographic factors, and questionnaire responses.

Results: We enrolled 53 participants with 50 completing Stage 1 (1 patient withdrew, 1 patient had a latanoprost-related adverse event, and 1 device failure). Adherence was 90.2% ± 18% (range 32-100%). Lower adherence was associated with lack of insurance coverage for prescription medications (p=.05), higher total number of eye drop bottles used per day (p=.06), higher number of eye drops per day (p=.10), and 4 GTCAT questions (p<=.14 for each). Ninety-six percent (96%) of the subjects were able to use the device; and 98% reported that the device stayed attached to the cap. However, only 49% were able to connect the device to their home wifi network. We received several recommendations for improvement including decreasing its size and improving its connectivity.

Conclusions: We have developed a D3 prototype for research in glaucoma adherence with good patient satisfaction. Future developments should include a smaller, consumer-ready version that is easy to connect.

ABSTRACT BODY:

Purpose: Black patients are prone to prolonged inflammation after cataract surgery, but there is a lack of data on whether rates of pseudophakic cystoid macular edema (PCME) is higher in black patients compared to white patients. This retrospective study aimed to assess if race is an independent risk factor in the development of post-operative PCME after routine phacoemulsification cataract surgery (PCS).

Methods: A retrospective cohort study was conducted using TrinetX, a federated multicenter database with over 80 million patient records across 57 healthcare organizations. Patients who underwent routine PCS were included. Exclusion criteria included complex PCS, history of macular edema, diabetic retinopathy, iridocyclitis, and/or panuveitis. Primary and secondary outcome measures were the incidence and prevalence of PCME and iridocyclitis, respectively, from post-operative day(d) 1 to 180. The cohort was stratified into black and white groups and underwent 1:1 propensity score matching (PSM) for age, gender, and medical comorbidities to calculate adjusted Risk Ratios (aRR) with 95% confidence intervals. Diabetes mellitus (DM) was analyzed in a subgroup analysis.

Results: The study included 24,324 black and 24,324 white patients after PSM. Over the 1-180d post-operative interval, the black cohort had a significantly higher prevalence and risk (aRR [95%CI]) of PCME (0.7% vs 0.4%, aRR 1.98 [1.53,2.56], p<0.001) and iridocyclitis (1.6% vs 0.3%, aRR 5.35 [4.16,6.89], p<0.001). Incidence of PCME peaked between 45-90d in the black cohort (0.3%) and 1-45d in the white cohort (0.2%). Incidence of PCME was higher in the black cohort vs white cohort in the 45-90d (0.3% vs 0.1%, aRR 2.65 [1.69,4.16], p<0.001) and 91-135d interval (0.2% vs 0.1%, aRR 2.93 [1.6,5.38], p<0.001). Incidence of iridocyclitis was higher in the black cohort in the 1-45d (0.5% vs 0.1%, aRR 3.81 [2.58,5.63], p<0.001), 45-90d (0.5% vs 0.1%, aRR 6.19 [3.76, 10.18], p<0.001), and 91-180d intervals (0.6% vs 0.1%, aRR 7.05 [4.47,11.14], p<0.001). A subgroup analysis excluding DM included 15,523 black and 15,523 white patients; prevalence of PCME over 1-180d was higher in black vs. white patients (0.8% vs 0.4%, aRR 1.98 [1.45,2.7], p<0.001), as was iridocyclitis (1.5% vs 0.3%, RR 5.09 [3.7, 7.0], p<0.001).

Conclusions: In this study, race was shown to be an independent risk factor in developing PCME after routine PCS.

Commercial Relationships Disclosure: Aicha Saadane: Commercial Relationship: Code N (No Commercial Relationship) | Alexander Veenstra: Commercial Relationship: Code N (No Commercial Relationship) | Martine Minns: Commercial Relationship: Code N (No Commercial Relationship) | Yunpeng Du: Commercial Relationship: Code N (No Commercial Relationship) | Emma Lessieur: Commercial Relationship: Code N (No Commercial Relationship) | Timothy Kern: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Accumulating evidence suggests that leukocytes play a critical role in diabetes-induced vascular lesions and other abnormalities that characterize the early stages of diabetic retinopathy (DR). However, it is not clear which subset of leukocytes is involved in this process, here we used $Ccr2^{-/-}$ mice to study the role of $CCR2^{+}$ monocytes in the pathogenesis of the retinopathy.

Methods: Experimental diabetes was induced in wild-type (WT) and $Ccr2^{-/-}$ mice using streptozotocin. After 2 months of diabetes, superoxide levels, expression of inflammatory proteins, leukostasis, leukocyte- and monocyte-mediated cytotoxicity against retinal endothelial cell (EC) death, retinal thickness, and visual function were evaluated using published techniques. Retinal capillary degeneration was determined after 8 months of diabetes. Flow cytometry of peripheral blood for differential expression of CCR2 in monocytes was determined.

Results: In nondiabetic mice, CCR2 was highly expressed on monocytes, and $Ccr2^{-/-}$ mice lack $Ccr2^{+}$ monocytes in the peripheral blood. The diabetes-induced retinal superoxide, expression of pro-inflammatory proteins (iNOS and ICAM-1), leukostasis, and leukocyte-mediated cytotoxicity against retinal EC were inhibited in diabetic Ccr2-deficient mice and in chimeric mice lacking Ccr2 only from myeloid cells. In order to focus on monocytes, these cells were immuno-isolated after 2 months of diabetes, and they significantly increased monocyte-mediated EC cytotoxicity ex vivo. Monocytes from Ccr2-deficient mice caused significantly less EC death. The diabetes-induced retinal capillary degeneration was inhibited in $Ccr2^{-/-}$ mice and in chimeric mice lacking Ccr2 only from myeloid cells.

Conclusions: Ccr2-deletion inhibits the development of retinal vascular lesions (presumably via the population of monocytes that express the Ccr2 protein). Thus, $Ccr2^{+}$ myeloid cells (mainly monocytes) contribute to the pathogenesis of early lesions of DR.

ABSTRACT BODY:

Purpose: We investigated the effects of translocator protein (TSPO) on the functional regulation of retinal pigment epithelium (RPE) using an A2E (N-retinylidene-N-retinylethanolamine) induced cellular stress model, mimicking lipofuscin accumulation in degenerative RPE cells.

Methods: We examined A2E-induced changes of TSPO mRNA level in a human RPE cell line (ARPE19). To figure out the function of TSPO in RPE cells, we treated TSPO siRNA for 24 hours and compared their viabilities and oxidative stress levels with the negative control group. Cellular functions following TSPO ligand treatment were investigated.

Results: Four hours after A2E treatment, A2E-exposed ARPE19 exhibited significant induction of oxidative stress and increase in mRNA of TSPO accompanied with intracellular A2E accumulation. Knock-down of TSPO with siRNA exhibited increased intracellular accumulation of A2E and aggravated oxidative stress without significant changes in cell viability. Treatment with TSPO ligand reduced A2E accumulation and restored oxidative stress response.

Conclusions: Our results support the possibility that restoration of TSPO homeostasis may help overcome A2E-induced cellular stress in ARPE19 cells, serving as a potential therapeutic strategy of AMD.

ABSTRACT BODY:

Purpose: Objective measures of conjunctival redness while inside an environmental chamber has til now not measured. With the use of the Ora EyeCup phone we are able to get objective images of ocular redness and obtain patient self assessed redness and itching.

Methods: During exposure in Ora's Biocube 15 patients were given the Ora EyeCup Phone to take photos at 90 minutes into exposure. Patients were prompted to take photos by the EyeCup Phones custom software at multiple timepoints. Patients took photos of their own eye with the Ora EyeCup attached looking straight head and looking upwards while holding down their lower lid. After photos were taken at each timepoint subjects were sent to a e-diary to assess allergic symptoms including eye redness evaluated while using a mirror. Photos were then evaluated using a custom grading software on the same scale that the patient was given.

Results: The mean patient reported redness was 3.1 on a scale from 0 to 4 with only whole integers. Mean redness from photo grading was 3.25 with the average difference between patient reported redness and photo graded redness was 0.3.

Conclusions: These results indicate that patient self-reported redness was in good agreement with expert graders indicating that these experienced allergy patients are able to correctly assess their symptoms. Patients were successfully able to acquire high quality gradable images alleviating the need for a photo technician in the chamber and illustrating the ease of use for the Ora EyeCup phone.

ABSTRACT BODY:

Purpose: Overcome motion artifact during slow Brillouin acquisition by introducing 3-dimensional tracking. Demonstrate that motion-tracking Brillouin microscopy can distinguish keratoconus, post-LASIK or post-PRK from the control based on the different distribution of Brillouin shifts.

Methods: Optical coherence tomography and pupil tracking were combined with a traditional Brillouin microscope to reduce motion blur caused by patient movement during slow Brillouin scan. Positioning errors were corrected in 3 dimensions by combing axial information from OCT and lateral information from pupil tracking. Tracking accuracy was tested in advance using enucleated porcine eyes. During in-vivo human measurement, 30 axial scans were applied to discrete points on each cornea. An axial scan took 5 seconds with a step size of 15 μm. 2-dimensional interpolation was used to connect the measured discrete points to generate a map of Brillouin shifts of the cornea.

Results: Data from tests on porcine eyes showed that axial positioning errors were within 5 μm along a movement of 1 mm with a step size of 100 μm. Meanwhile, lateral positioning errors were within 3 μm over a 9 mm movement. In-vivo Brillouin results showed that a normal cornea, a subtle keratoconus, a post-LASIK and a post-PRK shared similar Brillouin shifts of around 5.7 GHz at the periphery. The difference mainly existed in the center region. The Brillouin shift at the center was about 5.69 GHz for the normal cornea, 5.67 GHz for the post-LASIK cornea and the post-PRK cornea. For the subtle keratoconus cornea, the Brillouin shift at the cone was about 5.65 GHz.

Conclusions: Patient movement can be tracked precisely by pupil tracking and OCT. Brillouin shifts at different depths can be reaccommodated properly after motion compensation. Maps of Brillouin shifts across the cornea can show weak regions and help keratoconus diagnosis.

TITLE: Automated video assessment of the eyelids

SESSION TITLE: Oculoplastics

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: C. Schulz, H. Clarke, S. Makuloluwe, Eye Department, Portsmouth Hospitals University NHS Trust, Portsmouth, Portsmouth, UNITED KINGDOM|S. Kang, Moorfields Eye Hospital NHS Foundation Trust, London, London, UNITED KINGDOM|

Commercial Relationships Disclosure: Chris Schulz: Commercial Relationship: Code N (No Commercial Relationship) | Holly Clarke: Commercial Relationship: Code N (No Commercial Relationship) | Sarith Makuloluwe: Commercial Relationship: Code N (No Commercial Relationship) | Swan Kang: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Advances in artificial intelligence might allow automated video assessment of the ocular adnexa. This study aimed to develop and test a program to automate assessment of eyelid position (MRD1 & MRD2), blink lagophthalmos (bLag) and average ocular surface area exposure (OSAE) from videos.

Methods: A custom program was designed to analyse each frame from a video of a person's face (fig 1). A neural network was trained to label periocular anatomy using 7101 annotated images with 98.2% accuracy. Using this program, MRD1, MRD2, bLag and OSAE were determined for 77 videos of individuals with acute onset facial nerve palsy (FNP), 33 with ptosis, 33 with thyroid eye disease (TED) and compared with 65 controls. For 31 individuals with FNP, videos were assessed prior to onset of FNP, at onset and at 6 months. Test-retest reliability was evaluated by Bland-Altmann analysis of separate videos taken within 48 hours of each other for both controls (n=34) and FNP (n=33).

Results: Comparison of automated measures in each group is seen in figure 2. MRD1 (mm) was 3.6 in controls, vs 2.2 in ptosis ($p<0.001$), 3.9 in FNP ($p=0.049$) and 4.1 in TED ($p=0.038$). MRD2 (mm) was 5.9 in controls vs 6.4 in TED ($p<0.001$). Median bLag (mm) was 0.0 in controls vs 3.7 in FNP ($p<0.001$). OSAE (mm2) was 13.1 in controls vs 12.2 in ptosis ($p<0.001$), 13.3 in FNP ($p=0.50$) and 13.7 in TED ($p=0.002$). At an individual level, OSAE and bLag increased after the onset of FNP ($p=0.002$ & $p<0.001$, respectively) with a subsequent decrease after 6 months ($p=0.035$ & $p=0.004$, respectively). Regarding test-retest reliability, 95% limits of agreement MRD1, MRD2, bLag and OSAE were 1.1mm, 1.0mm, 3.7mm and 1.6mm^2, respectively.

Conclusions: Automated video assessment of the adnexa is feasible, demonstrating promising validity and reliability. Such technology might facilitate remote clinical assessment and self-monitoring. It might also facilitate the measurement of novel, sensitive and clinically meaningful clinical markers e.g. blink lagophthalmos and ocular surface exposure.

TITLE: Personalized patient interface for optimal alignment with ophthalmic devices for remote monitoring

SESSION TITLE: Telehealth

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: M. Darvishzadeh Varcheie, S.A. Bello, G. Zacks, K. Arianta, J. Straub, Carl Zeiss Meditec, Inc., Dublin, California, UNITED STATES|

Commercial Relationships Disclosure: Mahsa Darvishzadeh Varcheie: Commercial Relationship(s);Code E (Employment):Carl Zeiss Meditec, Inc. | Simon Bello: Commercial Relationship(s);Code E (Employment):Carl Zeiss Meditec, Inc. | Gabrielle Zacks: Commercial Relationship(s);Code E (Employment):Carl Zeiss Meditec, Inc. | Kabir Arianta: Commercial Relationship(s);Code E (Employment):Carl Zeiss Meditec, Inc. | Jochen Straub: Commercial Relationship(s);Code E (Employment):Carl Zeiss Meditec, Inc.

ABSTRACT BODY:

Purpose: Patient alignment is a crucial step to obtain acceptable image quality using ophthalmic devices. Alignment is traditionally done by an ophthalmic technician or by an automated system, which requires operator training and can be expensive to manufacture. In this work, we explore the feasibility of a repeatable and easy-to-use self-alignment solution.

Methods: An iPhone X (Apple, Cupertino, CA) was used to acquire a point cloud of participants' faces, which served as the basis for a 3D printed, personalized patient interface (PPI). The PPI was installed on a low-cost OCT prototype system [Zacks et al. IOVS 2021; 62(8):2135] with self-triggered scan acquisition (ZEISS, Dublin, CA). The PPI creates a comfortable face-rest that restricts the subject's motion while yielding repeatable positioning of the eye in relationship to the system. A fixation target was used to guide the subject's gaze. Initial alignment of the system to the subject's pupil was executed by an experienced technician, after which, the optical system's lateral coordinates, reference arm position and refractive error correction were locked. Subsequently, subjects were asked to self-acquire 3 OCT scans on each eye, retracting from the PPI between images. The system captured 5.78 x 5.78 mm OCT volumes with 512 A-scans/B-scan, 128 B-scans and 2.77 mm of depth. A subject matter expert evaluated the OCT cubes and quality maps [Bello et al. IOVS 2021; 62(8):1881] of all acquired scans to determine the PPI self-alignment success rate. Subjects with a range of ocular pathologies, including age-related macular degeneration were recruited under IRB.

Results: A total of 96 OCT scans from 32 eyes (19 subjects) were self-acquired. In 15 scans misalignment in one or more directions caused image quality to be compromised, resulting in a 0.1562 (0.0901, 0.2445) proportion with 95% confidence. 6 cases out of the 15 failed cases were from 2 eyes whose patients had trouble fixating. The other 30 eyes had at least 1 successful scan. A summary of the results and reasons for self-scan failures are shown in Table 1 and Figure 1.

Conclusions: We introduced a novel approach suitable for self-alignment using a PPI. Results show that good OCT image quality can be obtained using this approach, which could pave the way for personalized ophthalmic imaging and facilitate use cases where expert technicians are not available, such as home monitoring.

SUBMITTER (NAME ONLY): Brett King

TITLE: Investigating the Impact of Blur on Virtual Reality Perimetry

SESSION TITLE: Visual Fields and Psychophysics

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: B. King, W.H. Swanson, Optometry, Indiana University Bloomington, Bloomington, Indiana, UNITED STATES|

Commercial Relationships Disclosure: Brett King: Commercial Relationship(s);Code F (Financial Support):Olleyes, inc. | William Swanson: Commercial Relationship(s);Code F (Financial Support):Olleyes, inc

ABSTRACT BODY:

Purpose: Virtual reality perimetry is an evolving diagnostic option for clinicians, yet there is little known on the effect of blur. As some of the devices utilize existing spectacles for distance correction that may have a bifocal or progressive lens design, this could impact the overall results of the test. Furthermore, from previous reports we would expect to see a modest decline in sensitivity with 3.00 diopters (D) of blur for a Size III stimulus and less effect with a Gaussian Blob. This study was aimed at determining the effect of blur in a virtual reality perimeter.

Methods: A virtual reality (VR) headset driven perimeter (Olleyes, Inc. Summit, NJ) was modified to allow the choice of a Gaussian Blob (SD=0.25°) or a standard Size III stimulus. 12 control subjects aged 21-31 years-old were tested using the Normal Threshold 10-2 pattern with different levels of introduced blur for both stimuli (0.00D, +1.50D, +3.00D, +4.50D). For interleaving, the subjects were divided into four groups with either ascending or descending sequences of blur and either starting with the Size III stimulus or the Gaussian Blob. Mean sensitivities (MS) were calculated and a two-way ANOVA was generated.

Results: The Gaussian Blob had a range in median MS from 32.8 decibels(dB) at 0 blur to 32.0dB at +4.50D. The Size III stimulus had a mean MS range from 32.5dB to 31.5dB. The ANOVA found that the effects of blur and stimulus were statistically significant ($p<0.01$) while there did not appear to be a significant interaction ($p=0.85$).

Conclusions: The effects of blur and stimulus may be statistically significant, but the small effect may not have a clinical significance. The results here are unexpected and differ from what has been reported for bowl-style perimeters. A possible reason for the discrepancy could be a slight blur to the stimulus secondary to diffraction from the internal Fresnel lens in the VR headset. Another plausible cause could be the use of a mesopic background allowing for larger summation area that reduces the impact of blur.

TITLE: Decoupling of accommodation by monocular viewing of a midline target

SESSION TITLE: Eye movements and nystagmus

SESSION TYPE: Poster Session

AUTHORS/INSTITUTIONS: P. Riddell, A. Horwood, School of Psychology and Clinical Language Sciences, University of Reading, Reading, Berkshire, UNITED KINGDOM|A. Chandna, D. Singh, S. Heinen, Smith-Kettlewell Eye Research Institute, San Francisco, California, UNITED STATES|J. Badler, Psychology, Philipps-Universitat Marburg, Marburg, Hessen, GERMANY|

Commercial Relationships Disclosure: Arvind Chandna: Commercial Relationship: Code N (No Commercial Relationship) | Devashish Singh: Commercial Relationship: Code N (No Commercial Relationship) | Stephen Heinen: Commercial Relationship: Code N (No Commercial Relationship) | Jeremy Badler: Commercial Relationship: Code N (No Commercial Relationship) | Patricia Riddell: Commercial Relationship: Code N (No Commercial Relationship) | Anna Horwood: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: Chandna et al. (2021) recently showed that during monocular pursuit of a midline target, the covered eye usually did not execute a normal vergence response. Rather, it tended to make a conjugate eye movement while accommodation showed a symmetric response. Although accommodation, driven by blur and proximity, and through vergence by disparity cues, is normally thought to be yoked, there is some evidence for decoupling; e.g. aniso-accommodation reported in anisometropic amblyopia in children (Toor et al., 2018) and experimentally lens-induced in adults (Marran & Schor, 1998). We investigated whether manipulating cues driving accommodation and vergence in a binocular or monocular midline ocular tracking task can decouple accommodation responses in the two eyes and provide clues to the underlying mechanism.

Methods: The data from an earlier study of midline vergence that did test blur and proximity, along with disparity (Horwood and Riddell, 2008) were re-examined. 22 typical participants (age range 19-25 years) with normal visual acuity and binocular status were included. Subjects were naïve to the task and inexperienced with vision experiments, and instructed to observe a midline target (clown image or Gabor patch) under eight different paradigms. Each of these paradigms involved the manipulation of the target to add or remove cues for blur, proximity or disparity.

Results: In paradigms where there was no disparity cue (i.e., monocular viewing) the covered eye still executed predominantly conjugate rather than vergence movements (Horwood et al., 2001; Chandna et al., 2021). There was also evidence of decoupled accommodation for monocular viewing. The covered eye had a significantly lower accommodation amplitude than the viewing eye ($p < 0.01$; Friedman test, Tukey-Kramer correction). The asymmetric accommodation was not present with binocular viewing even when blur and proximity cues were removed ($p > 0.01$; Friedman test, Tukey-Kramer correction).

Conclusions: The results suggest that the accommodation response is not as strongly yoked as previously believed. Absence of the disparity cue results in asymmetric accommodation and decoupling of the accommodative response as well as the vergence response. This may explain the asymmetric accommodation observed in previous studies as well as that observed in anisometropia, in addition to variability in AC/A ratios in certain types of strabismus.

ABSTRACT BODY:

Purpose: Epithelial to mesenchymal transition (EMT) of the RPE, which can leads to RPE dysfunction and retinal degeneration, has been implicated in diseases such as PVR and AMD. As a possible therapeutic approach to these diseases, we have been pursuing in vitro high content screening (HCS) to identify molecules that inhibit RPE-EMT.

Methods: Based on gene and protein expression studies using human stem cell-derived models of RPE EMT, we found that within 3 hours after EMT induction there are significant increases in SNAI1 and decreases in BEST1 expression. Utilizing CRISPR/Cas9 engineering, we are generating a dual knock-in fluorescent reporter stem cell line for SNAI1(GFP) and BEST1 (tdTomato). Both reporters are preceded by a 2A self-cleaving peptide (P2A) sequence, so the endogenous proteins are expressed without alteration. After differentiating the reporter line to RPE monolayers, RPE-EMT is induced by 1) dissociation followed by re-plating into 1536-well plates or 2) treatment of RPE monolayers in 384-well plates with TGF-β/TNF-α. Twelve hours prior to EMT induction, compound libraries to be screened were dispensed using an acoustic liquid handler. After 72 hours, images were acquired and analyzed to determine the percentage of cells that express the reporter fluorescent proteins, the intensity of the reporters' fluorescence per cell, and other morphological characteristics.

Results: With the BEST1-tdTomato line that we generated, dissociation and TGF-β/TNF-α induced RPE EMT show decreased tdTomato expression at 24-72 hrs. In an initial screen for inhibitors of RPE EMT, 19 hits were identified, and these hits are being characterized in a secondary screen by qPCR to assess their effects on a variety of other EMT and RPE markers. One of the active molecules we identified is BAY 65-1942, an inhibitor of IKKβ. Expression of a core set of down-regulated visual cycle genes was significantly restored by BAY 65-1942 treatment, and elevation of EMT regulators was significantly suppressed.

Conclusions: Our initial screen has identified bioactive compounds that can inhibit EMT in hRPE cells and maintain their "RPE-ness." We hope that this new dual reporter screening system will provide a robust platform for the discovery of novel inhibitors of RPE EMT, and aid in the understanding and treatment of RPE EMT.

ABSTRACT BODY:

Purpose: Mitochondrial dysfunction is linked to retinal degeneration and dysfunction, but basic organization of mitochondria on a cellular and ultrastructural level remains poorly characterized. The mitochondria are critical organelles with roles in energy production, intracellular calcium regulation, and developmental cell death. In this study we complement a basic analysis of mitochondrial organization and ultrastructure with additional comparisons in mutant mouse models.

Methods: Using ImageJ and serial electron micrographs of mouse retina, we performed ultrafine 3D reconstructions of mitochondria in rods and rod bipolar cells (RBCs). We characterized the volume distribution and morphological complexity of individual mitochondria within wild type (WT) retinas. We used One-way ANOVAs with a Tukey Kramer post hoc to compare WT mitochondria with two additional genetic models that both regulate developmental cell death; Bcl2 associated x-protein ($Bax^{-/-}$) and Down Syndrome Cell Adhesion Molecule – Like 1 ($Dscaml1^{-/-}$) mutant mice.

Results: Data show that WT and $Bax^{-/-}$ individual mitochondria have larger volumes than $Dscaml1^{-/-}$ mitochondria ($p=0.00014$) and ($p<10^{-6}$). $Bax^{-/-}$ mitochondria show increased morphological complexity when compared to $Dscaml1^{-/-}$ mitochondria ($p<10^{-7}$), with WT mitochondria being more complex than both $Bax^{-/-}$ and $Dscaml1^{-/-}$ mitochondria ($p<10^{-7}$) and ($p<10^{-6}$).

Conclusions: Our results provide a characterization of normal mitochondria in the RBCs of WT retinas. This information is essential in further understanding of mitochondrial function in developing and degenerating models. The comparison between WT and $Bax^{-/-}$ show that loss of Bax contributes to the morphological complexity of mitochondria. Initial comparison of $Dscaml1^{-/-}$, a gene implicated in retinal developmental and degenerative diseases, shows that mitochondrial morphology and volume relies on Dscaml1 expression. Additional studies focused on proteins that interact with Dscaml1 will need to be completed to determine the possible pathways responsible for mitochondrial differences and how these contribute to disease pathology.

ABSTRACT BODY:

Purpose: To compare 2-field (2F) and 5-field (5F) mydriatic handheld retinal imaging for the assessment of diabetic retinopathy (DR) in a community-based teleophthalmology DR screening program (DRSP)

Methods: Following a validated standard imaging protocol, 5F imaging [macula, disc, superior, inferior and temporal] was acquired using a handheld retinal camera (Aurora, Optomed plc) through dilated pupils. 2F (disc and macula) and 5F images were independently assessed by masked graders using the International DR classification at a centralized reading center. Simple (K) and weighted (Kw) kappa statistics were derived for DR/DME. Sensitivity and specificity for referable DR [refDR (moderate nonproliferative DR (NPDR) or worse or ungradable images] and vision threatening DR [(vtDR) severe NPDR or worse] for 2F compared to 5F imaging were calculated.

Results: Images of 805 eyes from 407 consecutive patients with diabetes from a community-based teleophthalmology DRSP were evaluated. Distribution of DR severity by 2F/5F images (%): no DR 66.0/61.7, mild NPDR 10.7/14.4, moderate NPDR 7.9/8.1, severe NPDR 3.3/5.6, PDR 5.6/4.6, ungradable 6.5/5.6. Table 1 presents the cross-tabulation of DR severity by 2F and 5F with ungradable eyes excluded from the analysis. Exact agreement of DR grading between 2F and 5F photos was 81.7%, within 1-step 97.1%, K 0.64, Kw 0.78. Sensitivity/specificity for 2F compared 5F was refDR 0.80/0.97, vtDR 0.73/0.98. Figure 1 presents a sample comparison of 2F and 5F images. The rate of ungradable images with 2F was 16.1% higher than with 5F (6.5% vs 5.6%).

Conclusions: Mydriatic 2F and 5F handheld imaging have substantial agreement for DR severity grading. Mydriatic 2F handheld imaging achieves the sensitivity and specificity thresholds (0.80/0.95) for refDR (0.80/0.97) but not for vtDR (0.73/0.98) suggesting that lower thresholds for referral must be used when using 2F handheld imaging in a community-based teleophthalmology DRSP. Without the addition of peripheral fields included in 5F handheld imaging, the sensitivity threshold when using vtDR for referrals will not be achieved and would limit its use in DRSP.

ABSTRACT BODY:

Purpose: Retinal pigment epithelial (RPE) cells act as metabolic gatekeepers adjusting the exchange of nutrients between the neural retina and the choroid. They are vulnerable in several retinal diseases including age-related macular degeneration and there is great interest in identifying methods to improve their morphology and function. Nicotinamide adenine dinucleotide (NAD+) is a coenzyme common to most metabolic pathways. Previously an association between NAD+ levels and the development and progression of several age-related diseases has been shown. Herein we investigated the effects of NAD+ on the integrity and function of primary human RPE cells derived from old donors.

Methods: Primary RPE from old donors (n=4; ages 71-93) were treated with nic+MEM or DMEM. Bright-field and confocal microscopy (ZO-1 and phalloidin staining) were used to assess RPE morphology. Gene expression of RPE markers including MERTK, MITF, PEDF, OXTR, TYR, VEGF and others was measured by RT-PCR. Mitochondrial function and glycolysis were measured on XFe24 Extracellular Flux Analyzer. Phagocytosis assay was done using pHrodo Red E. coli BioParticles Conjugates. Data analyzed included a minimum of three biological and experimental replicates. Statistical methods for analysis included two-tailed Student’s t-test and two-way ANOVA

Results: Supplementation with NAD+ promoted a significant improvement in RPE cell morphology and cytoskeletal organization, resulting in a more cuboidal cobblestone pattern with defined ZO-1 borders and organized phalloidin. Nic+MEM resulted in a significant increase in the expression of MERTK, MITF, OXTR, and TYR and a decrease in PEDF and VEGF. RPE-related function of phagocytosis also increased by approximately 2 fold in the presence of nicotinamide. A shift in the two metabolic pathways of glycolysis and oxidative phosphorylation was also observed in the presence of nicotinamide.

Conclusions: In line with previous studies, nicotinamide supplementation improves the morphology and function of RPE cells isolated from aged donor eyes. The metabolic shift promoted by nicotinamide in primary RPE cells indicates a potential strategy for improving the health of aged/diseased cells as seen in AMD. Future studies are focused on evaluating the impact of NAD+ on cells isolated from young donors

ABSTRACT BODY:

Purpose: Bisretinoid lipofuscin accumulates in retina with age. Bisretinoids form due to unchecked reactivity of vitamin A aldehyde and levels are known to reflect visual cycle kinetics; the difference between formation vs. photodegradative loss; and conditions underlying some forms of retinal disease. Otherwise modulators are little known. Here we sought to determine whether dysregulation of vitamin A in an experimental model of obesity associated with a high fat diet (HFD) can lead to increased formation of bisretinoids.

Methods: Black (C57BL/6J) and albino (C57BL/6J^{2cj}) wild type mice (all male) were raised either on a HFD (fat: 60% kcal from fat; from age 6 weeks) or a control diet (CD) (fat: 10% kcal from fat). Retinoids and bisretinoids were quantified by HPLC and UPLC with reference to authentic standards and non-invasive measurement of short wavelength fundus autofluorescence (488 nm; quantitative fundus autofluorescence, qAF) was performed. Rbp4 levels in mouse plasma were measured by ELISA.

Results: In albino C57BL/6J^{c2j} mice fed a HFD from age 6 weeks to 12 months, final body weight was 30% higher than in mice fed a CD. At age 6 months, black C57BL/6J mice fed a HFD weighed 37% more than mice given a CD. In C57BL/6J mice receiving the HFD there was a 2.2-fold increase in plasma all-trans-retinol (vitamin A) at age 14 weeks, a 17% increase in glucose and a 29% increase in retinol-binding protein 4 (Rbp4) relative to CD mice. In the plasma of HFD-fed C57BL/6J^{2cj} mice (age 1 year), Rbp4 and retinol were also elevated relative to the CD. Non-invasive measurement of bisretinoid by qAF revealed a 35% increase in the HFD-fed C57BL/6J^{c2j} mice (1.10.12, meanSD) as compared to CD-fed mice (0.80.1). The levels of A2E in the C57BL/6J^{c2j} HFD-fed mice were more than 2-fold greater than in the mice fed the CD and similar increases in A2GPE and A2DHPPE were also measured (for A2GPE, HFD: 11.42.8; control: 4.72.3). Quantitation of bisretinoids revealed that in 6 month old C57BL/6J mice the bisretinoids A2E, A2-DHP-PE and A2GPE were increased 44%, 36% and 3-fold, respectively. Diet-induced obese C57BL/6J mice at age 3 years also exhibited a 1.9 and 2.5-fold increase in A2E and A2-DHP-PE, respectively, relative to CD mice.

Conclusions: A HFD leading to obesity in mice is associated with elevated plasma RBP4 and retinol, and elevated levels of bisretinoid lipofuscin in retina.

ABSTRACT BODY:

Purpose: Diabetes Mellitus (DM) is a group of metabolic disorders that can cause structural and functional changes in the human cornea, including nerve and stromal defects. Monocarboxylate transporters (MCTs) are a family of proton-linked plasma membrane transporters that carry monocarboxylates (i.e. molecules with one carboxylate group) across plasma membranes. In the context of corneal health and disease, their role, presence, and functions are undetermined and solely focused on the most common MCT isoforms 1 through 4. The aim of this study is to investigate the role of MCTs 1 through -5, -8, and -10, in the context of corneal diabetes.

Methods: Primary stromal corneal fibroblasts were isolated from Healthy (HCFs), as well as Type I (T1DMs), and Type II (T2DMs) diabetic subjects. Mono-cultures: Cells were cultured for three weeks on 6-well transwell plates and stimulated with stable Vitamin C, to promote ECM assembly. Co-cultures: SH-SY5Y neurons were seeded at a density of 12k and 500k on top of the 3D stromal constructs after three weeks, to create the stroma-neuron co-culture, followed by an additional week in culture. Cultures without neurons served as controls. At four-weeks, all constructs were processed for RNA isolation and Real-Time Quantitative Reverse Transcription PCR (qRT- PCR). Furthermore, expression of MCTs was also investigated, using immunofluorescence.

Results: No significant modulation of MCTs was observed for any of the cell types tested at the low cell density of 12k. Co-cultures with 500k neuron cell densities showed upregulation of MCT1, MCT8 and MCT10 in HCFs, T1DMs and T2DMs. The cells were stained with different MCT isoforms for immunofluorescence. Data showed bright red signal within the cytoplasm, indicating the presence of MCTs, but no obvious changes between conditions.

Conclusions: By utilizing two 3D in vitro models, this study reveals the existence and modulation of MCTs in the diabetic cornea. The changes observed, due to neuronal density, suggest that MCTs are potentially critical to neuronal degeneration and pathology seen in diabetic keratopathy/neuropathy. Further studies are needed, in order to fully delineate the role of MCTs in corneal diabetes.

ABSTRACT BODY:

Purpose: Presbyopia is a progressive, age-related visual impairment characterized by the lens's lack of ability to focus on nearby objects. During presbyopia, proteins in the lens become increasingly insoluble and aggregated, contributing to the loss of elasticity and accommodation. This study reports the development of a small molecule that improves protein solubility and elasticity in aged lenses.

Methods: Aggrelyte-2 (S,N-Diacetyl-L-cysteine methyl ester) or the control compound (N-Acetyl-L-cysteine methyl ester, aggrelyte-2C) was incubated (at 500 μM) with a suspension of 5 mg/ mL of water-insoluble protein (WI) of aged human lenses (65-75 years) for 24 or 48 h. The mixture was centrifuged, and the protein concentration in the supernatant was measured, N^{ε}-acetyllysine (AcK) in proteins was measured by western blotting and LC-MS/MS (in enzyme digested samples). The protein thiol content was estimated by a fluorescence method. Human (60-70 years) and mouse lenses (C57BL/6J, 5-8 months) were incubated with aggrelyte-2 at 2.5- or 2-mM concentration for 3 days to determine effects on the elasticity of lenses, using a coverslip method.

Results: Upon incubation of aggrelyte-2 with aged human lens WI, we measured 1.0-1.3 μg/μL of soluble proteins after 24 h and 1.0-1.5 μg/μL after 48 h. Incubation of aggrelyte-2C (that lacked the lysine acetylation capacity), we observed 0.7-0.9 μg/μL of soluble proteins after 24 h and 0.7-1.1 μg/μL after 48 h, which were ~1.35-fold lower efficient than aggrelyte-2. The AcK content in the solubilized proteins increased in the samples incubated with aggrelyte-2 but not with aggrelyte-2C. The LC-MS/MS results revealed AcK levels of 1.5–2.1 nmoles/mg protein in the aggrelyte-2 treated samples, compared to 0.6–0.9 nmoles/mg protein in the samples treated with aggrelyte-2C. Western blotting revealed a significant increase ($p<0.01$) in the αA-crystallin content in the solubilized protein. The protein-thiol content in the WI treated with aggrelyte-2 and aggrelyte-2C increased by 1.93- and 5.07-fold over untreated controls. The elasticity of lenses treated with aggreltyte-2 significantly improved ($p<0.01$ and $p<0.001$ for mouse, and human lenses, respectively) with a concomitant increase in the AcK levels.

Conclusions: Aggrelyte-2 solubilizes WI through acetylation and disulfide reduction and decreases stiffness in aged human lenses. It could be developed as a therapy against presbyopia.

ABSTRACT BODY:

Purpose: During the COVID-19 pandemic, in line with the UK Royal College of Ophthalmologists' (RCOphth) guidelines, anti-VEGF treatment regimens for Neovascular Age Related Macular degeneration (nAMD) were adjusted to 8 weekly Aflibercept injections with no clinic review. New patients and those who mentioned a significant drop of vision during their injection visits had OCT and their management adjusted to 4 weekly injections. This work audits our practice at a tertiary university hospital during the 2020 pandemic.

Methods: Retrospective electronic data was collected from the Medisoft ophthalmology database for patients with nAMD, who received Aflibercept over a 5 month period from 01.03.2020 to 01.08.2020.

Best Corrected Visual Acuity (BCVA), Central Macular Thickness (CRT), and number of injections were collected, and compared with our previously published year one data of 225 treatment naïve eyes of 223 patients with nAMD, treated with 8 weekly Aflibercept with mean BCVA of 61 letters & mean CRT of 235 µm at month 5 of therapy. We also assessed the clinical outcomes of our patients who received 4 weekly Aflibercept injections.

Statistical analysis was done using SPSS version 24.

Results: 1778 eyes of 1427 patients met the inclusion criteria and were included in the study. 1338 patients (93.8%) received 8 weekly injections, their mean BCVA ± SD was 59.7 ± 17.3 with CRT of 239.3 µm ± 67.2 SD at baseline and their latest BCVA ± SD was 59.3 ± 17.4, with CRT of 231.8 µm ± 73.8 SD. More than one third of them 618 (43.3%) received three injections during that period.

89 of our patients (6.2%) received 4 weekly injections during our study period. Their mean BCVA ± SD was 60.5 ± 17.6 with CRT of 276.1 µm ± 96.4 SD at baseline and their latest BCVA ± SD was 62.3 ± 15.1, with CRT of 247.8 µm ± 49.0 SD.

Conclusions: Reassuringly, during the COVID-19 pandemic, patients on a fixed 8 weekly Aflibercept pathway maintained their vision. Their mean BCVA & CRT were comparable to our pre-COVID audit outcomes with a treat and extend protocol. Patients on 4 weekly injections also maintained their vision during the pandemic. RCOphth COVID guidelines allowed AMD patients to receive effective therapy whilst minimizing time in hospitals and permitted ophthalmologists to do other COVID related tasks.

ABSTRACT BODY:

Purpose: To examine factors contributing to maximum reading rate in children with low vision.

Methods: Thirty-one children with vision impairment of ocular origin aged 7 to 16 performed a variety of tasks including best-corrected visual acuity (VA), WISC verbal comprehension and working memory testing, Woodcock Johnson IV Broad Reading Cluster (WJ-BRC) which is derived from Letter-Word Identification, Passage Comprehension and Sentence Reading Fluency subtests, RAN/RAS rapid automatized naming tasks and MNREAD testing using the iPad based test and scoring algorithm. Additionally, visual span profiles (range of letters that can be recognized reliably without moving the eyes) were determined using a trigram task. Data was analyzed first looking at univariate associations. A model predicting reading speed was developed using backward stepwise regression. Significance was set at p=.05, 2-tailed.

Results: Mean participant age was 11.5 ± 2.7 years and mean VA was 0.67 ± 0.2 logMAR (range 0.2-1.02). More girls (55%) than boys (45%) participated. Most participants had nystagmus (81%). The mean maximum reading rate (MRR) was 117 ± 38 words per minute. Visual span size averaged 24.7 ± 9.8 bits (range 7.0 to 39.7). Mean standard score was 93.5 ± 12.1 on the WJ-BRC and 105 ± 9 on the RAN/RAS. Visual span size was significantly correlated with MRR (p=.03; R^2=0.16) and age (p=.002; R^2=0.28) but not with VA (p=.5), automaticity (p=.7) or WJ-BRC (p=.7). MRR was not significantly correlated with any demographic or visual factors; it was also not correlated with the WISC verbal comprehension or working memory indices or the WJ-BRC. In addition to visual span size, MRR is significantly correlated with age (p=.003; R^2=0.27), and automaticity (p=.01; R^2=0.2). The final regression model included VA, automaticity, WJ- BRC, age and visual span size as well interactions between visual span and the other variables. The model explained 80% of the variance in reading speed. (R^2 = 0.80, F (10,20) = 7.97, p = < .0001).

Conclusions: Consistent with the literature, reading speeds vary from child to child, and increase over time as they mature. Although visual acuity alone is not significantly associated with reading speed, it does contribute. The visual span contributes to and interacts with other factors associated with reading speed suggesting a significant role for early visual processing in the development of reading speed.

ABSTRACT BODY:

Purpose: Prompt treatment of amblyopia, the leading cause of vision loss in children, is imperative for preserving vision. One of the primary barriers to successful amblyopia treatment is failure to follow up. Previous research has identified socioeconomic status as a significant risk factor for predicting whether patients are lost to follow up after the initial visit (23% of patients). In this retrospective study, we investigate patient follow up for their prescribed appointments and the potential impact on visual outcomes.

Methods: We performed a retrospective data study on pediatric patients aged 0-9 years who were first diagnosed with amblyopia in 2018 at Oregon Health & Science University. We analyzed each patient's consecutive office visits during 1/1/2018 – 12/31/2019, calculating interocular visual acuity for the subset of patients that had recorded subjective visual acuities with optotypes.

Results: There were 904 patients in our study; they had an average of 4.1 completed (SD: ± 3.8), 2.4 canceled (SD: ± 1.4), and 1.4 no-show appointments (SD: ± 0.7). Out of 904 pediatric patients, there was a 46% decline in returning patients by the 5^{th} visit resulting in 488 remaining patients. For the patients who had subjective visual acuity values, we measured visual improvement with the interocular visual acuity (IVA). The IVA improved from the 1^{st} and 5^{th} visits (mean 1^{st} visit, ± SD, 0.277 ± .344 vs. mean 5^{th} visit, 0.178 ± .282 , P<.001).

Conclusions: The number of returning patients decreased with each subsequent visit, but for those patients who returned for 5 visits, they had a significant improvement in visual acuity. However, close to half of patients did not return for 5 visits and may not have experienced an improvement in vision. Further studies need to investigate the factors that contribute to appointment adherence to promote successful treatment in amblyopia patients.

ABSTRACT BODY:

Purpose: To investigate the impact of patient race on the association between cup-to-disc ratio (CDR) and glaucomatous visual field (VF) loss.

Methods: From all patients from Mass. Eye and Ear glaucoma service, the most recent pairs of reliable Humphrey 24-2 VFs (false positives/negatives ≤ 15%, fixation losses ≤ 20%) and vertical CDR measurements obtained from peripapillary optical coherence tomography volume scans (Cirrus HD-OCT, signal strength ≥ 6) were selected if the patient self-identified as either Asian, Black or White on an electronic medical record questionnaire. Model selection by Bayes Factors (BF), estimated by Bayesian Information Criterion, was performed to identify the association between VF mean deviation (MD) and CDR with age and race as covariates. Additionally, the MD vs. CDR relationship was compared between the separate race groups.

Results: 16,198 eyes of 9,597 patients (56.1% female) were selected. 909 patients identified as Asian, 1,561 as Black and 7,127 as White. There was a significant main effect of race (ANOVA, $p<0.001$) vs. age, MD and CDR. Although White patients where the oldest group, their MD was highest and their CDR lowest among all races (Fig. 1A-C). The Bayesian model comparison identified CDR as the best single parameter model and the model consisting of age, race and CDR as the best overall model for MD (Fig. 1D), with higher age, higher CDR, and Asian and Black race significantly associated with lower MD (each $p<0.001$). CDR and MD are negatively correlated; the correlation strength substantially differs by race (Pearson's r in the entire population: -0.28, Asians: -0.23, Blacks: -0.32, Whites: -0.27, each $p<0.001$). Fig. 2 shows a scatterplot of MD vs. CDR colored by patient race, together with the respective three linear regression fits, which considerably differ between the race groups, with the largest negative slope for Black patients.

Conclusions: Based on the most recent measurements of all patients of a large glaucoma clinic, our results confirm larger CDR to be related to more severe glaucomatous VF loss. The strength of this association considerably varies by patient race, with the strongest relationship observed for Black patients. As CDR is an important clinical parameter to diagnose glaucoma, our results suggest to include patient race when interpreting CDR in the context of glaucoma severity.

ABSTRACT BODY:

Purpose: To describe a method for rapid optical coherence tomography (OCT) image capture and multidimensional visualization of retinopathy of prematurity (ROP) in preterm infants in BabySTEPS2.

Methods: We developed retinal OCT imaging protocols for use with an investigational 400kHz, 1060nm swept-source system with a 700g handheld, noncontact probe in preterm infants at risk for ROP. Two imaging protocols were used at the bedside, the day of clinical ROP screening, without sedation or use of an eyelid speculum: Scan 1 (0.7 sec, 1900 A-scans/B-scan, 128 B-scans per 10x10mm volume, with pairs of adjacent A-scans summed producing 950 A-scans/B-scan) for cross-sectional assessment of retinal layers; and Scan 2 (1.4 sec, 640 A-scans/B-scan and 640 B-scans per 10x10mm isodense volume) for en face retinal vascular assessment. For multidimensional visualization, we developed infant-specific software (DOCTRAP v66.2) to optimize automatic segmentation of OCT volumes from Scan 1 and generate total retina thickness maps. We extracted en face retinal vessel maps from maximum pixel intensity at each A-scan position from Scan 2. With auto-montaging software (i2k Retina; DualAlign, Inc.), we created a single posterior pole vessel map per eye and overlaid corresponding thickness maps for comparison to color fundus photos.

Results: We were able to capture, integrate, and visualize multidimensional data from high-speed investigational bedside OCT imaging of preterm infant retinas. This included: depth-resolved analysis of retinal microanatomy at locations of interest (e.g., at the foveal center and vascular-avascular junction); intensity maps of total retinal layer thicknesses; and retinal vessel maps (Figure 1). These data demonstrated important ROP pathology (e.g., retinal neovascularization and plus disease) and in contrast to color photographs, enabled integrated assessment of the developing preterm retina (e.g., retinal layer thicknesses and presence of macular edema).

Conclusions: This method for multidimensional data analysis will be used by human graders and analyzed by semi-automated software (i.e., ROPtool) in BabySTEPS2, and may be integrated into future artificial intelligence-based ROP screening methods.

TITLE: Pathophysiological consequences of Soat1/SOAT1 inactivation for the ocular surface and Meibomian gland homeostasis

SESSION TITLE: Dry eye regulators: lacrimal gland, meibomian gland, basic mechanisms

SESSION TYPE: Paper Session

AUTHORS/INSTITUTIONS: A. Wilkerson, I.A. Butovich, Ophthalmology, The University of Texas Southwestern Medical Center, Dallas, Texas, UNITED STATES|

Commercial Relationships Disclosure: Amber Wilkerson: Commercial Relationship: Code N (No Commercial Relationship) | Igor Butovich: Commercial Relationship: Code N (No Commercial Relationship)

ABSTRACT BODY:

Purpose: The gene/enzyme pair Soat1/SOAT1 was previously shown to be critical for making cholesteryl esters (CEs) in the mouse Meibomian glands (MGs) as the loss of its function in MGs led to arrest of CE production, accumulation of free cholesterol in meibum, and major changes in its rheological properties. The purpose of this study was to investigate the role of Soat1/SOAT1 in meibogenesis and ocular surface (patho)physiology using Soat1 knockout ($Soat1^{-/-}$) mice as animal models of human MG dysfunction (MGD).

Methods: Age matched male and female $Soat1^{-/-}$ mice and their wild type (WT) littermates were used in this study. Ocular surface (OS) damage was assessed via fluorescein staining using a slit lamp. Freshly harvested tarsal plates (TPs) were used for RNA extraction or processed for histology and histochemistry. TP transcriptomes were analyzed using Clariom D microarrays and RNA expression data was processed in the Expression Console software package and transcriptome analysis console. Mouse TPs and corneas were evaluated by H&E, Oil Red O, and/or LipidTox staining.

Results: Slit lamp examination of $Soat1^{-/-}$ mice demonstrated an increase in fluorescein staining ($P<0.001$) of the OS in comparison with WT mice. After 5 months of age, about half of $Soat1^{-/-}$ mice developed corneal ulcers. Lipid staining of knockout MGs revealed minimal lipid accumulation in the acini with most of the lipid staining within the central ducts compared to the robust staining throughout the acini and central ducts of WT mice. Comparative transcriptomic analysis of $Soat1^{-/-}$ vs. WT mice demonstrated upregulation of about 980 coding genes and downregulation of >1,400 genes ($p<0.05$; $2<$Fold Change<-2). The major significantly upregulated pathways included cholesterol and bile acid metabolism, formation of the cornified envelope, keratinization, inflammation, and apoptosis. Among suppressed pathways were lipid metabolism, muscle contraction, Ca(II) signaling, creatine-phosphate metabolism, signal transduction, immune response, and others.

Conclusions: Inactivation of Soat1/SOAT1 leads to severe changes in the OS physiology, and MG biochemistry and morphology that resemble certain types of human MGD. The transcriptomic data were consistent with the $Soat1^{-/-}$ mouse phenotype and biochemical changes in their meibum. The $Soat1^{-/-}$ mice can be used as a useful model of human MGD.

ABSTRACT BODY:

Purpose: The aim of this study is to evaluate the differences in optic nerve head (ONH), choroidal thickness and individual macular layers measurements in normal and glaucoma eyes in groups divided by the area of their peripapillary atrophy (PPA).

Methods: Subjects with glaucoma presenting typical ONH findings, high intraocular pressure with or without visual field (VF) damage and normal controls were included. Patients underwent 24-2 perimetry (SITA standard;Humphrey Field Analyzer; Zeiss) and Spectral Domain Optical Coherence Tomography (SD-OCT) (Spectralis;Heidelberg Engineering). Manual measurements of the temporal and superior and inferior-temporal PPA area observing the infrared image and the B-scans were manually performed by a trained examiner. Eyes were divided in four groups based on the PPA area. SD-OCT parameters analyzed were average circumpapillary retinal nerve fiber layer (cRNFL), average circumpapillary choroidal thickness (cChoroid), the hypotenuse of the vertical optic nerve head cupping (HVOC) and the individual macular layers obtained automatically from the device. For calculating HVOC we used the length and depth of the optic nerve cupping as the sides of a right triangle. The mean deviation (MD) of the VF was evaluated. Statistical analysis was performed using generalized estimated equations.

Results: 89 eyes (57 subjects) qualified for the study. The mean age was 65.72±12.47 years. The number of eyes was 81 in the glaucoma and 8 in the control group. Four groups were divided by the quartiles of the PPA area: 1: ≤ 0.44 mm^2 (n=24); 2: 0.44-0.69 mm^2 (n=21); 3: 0.69-0.92 mm^2 (n=22) and 4: ≥ 0.92 mm^2 (n=22). The control eyes distribution was: 6 eyes in group 1, 2 in group 2 and none in groups 3 and 4. cRNFL, HVOC and inner macular layers demonstrated overall significant differences between groups (table 1). VF MD, additional macular layers and cChoroid differences weren't significant, except for the outer plexiform layer (OPL) in the outer circle of the grid (table 2).

Conclusions: Eyes with distinct PPA areas demonstrated differences in ONH and macular parameters related to glaucoma. Longitudinal studies evaluating PPA area and the associated change in other structural and functional parameters may provide additional information about the clinical course of glaucomatous eyes with PPA.

ABSTRACT BODY:

Purpose: Plus disease, i.e. retinal vascular dilation and tortuosity in the posterior pole, is usually present in type 1 retinopathy of prematurity (ROP), and typically improves after treatment. However, it is unknown if vessels in certain quadrants respond to treatment quicker. The purpose of this study is to quantitatively compare posterior pole vascular changes between temporal vs. nasal and superior vs. inferior quadrants after treatment.

Methods: This retrospective study used prospectively-collected narrow-field retinal images from infants treated for ROP. We included images acquired in the session just prior to and ≤6 weeks post-treatment. We used ROPtool (a semiautomated vessel analysis program) to trace and analyze ≤2 vessels/quadrant, following the same vessels over time. The following ROPtool indices of vessel characteristics were calculated: dilation index (DI), tortuosity index (TI), and combination dilation/tortuosity indices: sum of adjusted indices (SAI) and tortuosity-weighted plus (TWP). Using the Wilcoxon signed-rank test, ROPtool indices pre- and post-treatment were compared between temporal vs. nasal and superior vs. inferior quadrants.

Results: Fifteen eyes (8 infants) were treated for ROP. Among 80 eligible imaging sessions, 627/640 (98.0%) vessels were traceable by ROPtool. Temporal quadrant values were higher than nasal quadrant values for all ROPtool indices pre-treatment, for DI at weeks 1-5 post-treatment, and for SAI at week 1 post-treatment (Table 1). Post-treatment, the temporal quadrant values decreased faster than nasal quadrants for all indices week 1 post-treatment [median weekly rates: DI (-1.2 vs. -0.6, p=0.02), TI (-1.4 vs. -0.8, p=0.003), SAI (-1.0 vs. -0.5, p=0.01), TWP (-1.0 vs. -0.5, p=0.04)] (Fig 1A, 1C).

There were no statistically significant differences in ROPtool indices between superior and inferior quadrants pre- and ≤6 weeks post-treatment.

Conclusions: Among eyes treated for ROP, temporal vessels were more dilated and tortuous pre-treatment, remained more dilated post-treatment, and had faster regression of dilation and tortuosity than nasal vessels in the first week post-treatment.

ABSTRACT BODY:

Purpose: Bruch's membrane resides in the subretinal tissue and helps to regulate the flow of nutrients and waste between the retinal pigmented epithelial (RPE) and vascular cell layers of the eye. Bruch's membrane plays a key role in the development of subretinal diseases such as Age-Related Macular Degeneration. Age-Related Macular Degeneration, or AMD, is the degradation of the RPE cell layer, leading to progressive vision loss. Bruch's membrane plays an active role in the development of AMD. The thickness, brittleness, and permeability of Bruch's membrane all have a significant impact on the degradation of the RPE cell layer. As the interactions between Bruch's membrane, the RPE layer, and the vascular layer play a pivotal role in AMD, modeling these layers is a key step in researching potential therapies for AMD and other retinal diseases.

An accurate model of Bruch's membrane must be proteinaceous, semi-permeable, and nonporous with similar mechanical properties to in vivo Bruch's membrane while also being able to support both RPE and vascular cell cultures. Many current models of the subretinal tissue utilize inferior models of Bruch's membrane called Transwells, which are porous, nonpermeable, plastic membranes that are much thicker than a healthy Bruch's membrane.

Methods: To create a more accurate model, artificial membranes were synthesized using solubilized hagfish slime proteins. The characteristics of the hagfish membranes were evaluated using mechanical stress testing, permeability assays, and brightfield microscopy. The capacity of the membranes to support ARPE-19 and Human Retinal Microvascular Endothelial Cell cultures was determined using cell staining with brightfield microscopy, fluorescent microscopy, immunocytochemical imaging, and enzyme-linked immunosorbent assays.

Results: The tests demonstrate the potential of these hagfish protein membranes to accurately replicate Bruch's membrane in an in vitro model of the subretinal tissue. When compared to existing models of the subretinal tissue, the hagfish membranes demonstrate more mimetic geometric properties, mechanical properties, and permeability characteristics to those of a natural Bruch's membrane, as well as the ability to support relevant cell cultures.

Conclusions: The verification of this model will create an opportunity for more comprehensive and accelerated initial testing for potential retinal disease therapies.

ABSTRACT BODY:

Purpose: Prior studies suggest that inflammation is associated with glaucoma, and glaucoma is known to damage the ganglion cell complex (GCC), defined as the three innermost retinal layers, including the nerve fiber layer, the ganglion cell layer, and the inner plexiform layer. Here, we study the impact of inflammation on GCC thickness in non-glaucoma subjects.

Methods: From the large population-based LIFE-Adult study (Leipzig Research Centre for Civilization Diseases), we extracted the machine-segmented GCC thickness map from Heidelberg Spectralis macular optical coherence tomography (OCT) scans. Subjects with glaucomatous findings on fundus photos, self-reported glaucoma, or glaucoma medication intake were excluded from data analyses. Inflammatory status was assessed by high-sensitivity C-reactive protein (hsCRP) and interleukin 6 (IL-6). The two inflammatory markers were separately associated with the global, sectoral and pointwise GCC thickness by partial correlations adjusted for age, sex, and scan focus. P values were corrected for multiple comparisons. One eye per subject was selected randomly if both eyes were available.

Results: 7,521 eyes from 7,521 subjects (age: 56.7 ± 12.5 years; 52.0% female) were included. Higher IL-6 (partial correlation [r]: -0.02, $p = 0.01$) but not hs-CRP ($p = 0.79$) was significantly associated with thinner global average GCC. Figure 1 shows the pointwise partial correlations between inflammatory markers and GCC thickness. Higher hs-CRP and IL-6 were particularly associated with thinner GCC thickness in the parafoveal ring-shaped region significantly affecting 20.9% and 20.4% of the scan region, respectively. Figure 2 shows the sectoral partial correlations between the inflammatory markers and GCC thickness using Early Treatment Diabetic Retinopathy Study based sectors. Both hsCRP (each $p \leq 0.049$) and IL-6 (each $p \leq 0.001$) were significantly associated with thinner GCC in the four inner sectors. In addition, hsCRP had significant associations ($p = 0.049$) with thicker GCC in the superior outer sector, and IL-6 had significant associations ($p = 0.02$) with thinner GCC in the nasal outer sector.

Conclusions: Our results suggest that higher levels of inflammatory markers are specifically linked with thinner GCC in the parafoveal ring-shaped region in non-glaucoma subjects, which may help better understand the inflammatory pathway in the pathogenesis of glaucoma.
